1500.6 (1)	1163.5 (1)

Bond Lengths and Angles C-H = 1.12 ± 0.01 Å C-O = 1.21 ± 0.01 Å ∡ H-C-H = 118 ± 2°

Moments of Inertia $I_A = 2.975 \times 10^{-40}$ g. cm.^{2} $I_B = 2.161 \times 10^{-39}$ g. cm.^{2} $I_C = 2.468 \times 10^{-39}$ g. cm.^{2}

$\sigma = 2$

Heats of Formation

M. Delepine and M. Badoche, Compt. rend. 214, 777 (1942), measured the heat of combustion of a formaldehyde polymer. Their value is revised to $\Delta H_{f\ 298.15} = -25.0$ kcal. mole^{-1} based on the following thermochemical cycle:

I	$C_{(c)} + 1/2O_{2(g)} + H_{2(g)} = \frac{1}{n}(CH_2O)_{n(c)}$	-42.3 kcal.
II	$\frac{1}{n}(CH_2O)_{n(c)} + H_2O = CH_2O(aq)$	2.4
III	$CH_2O(g) = CH_2O(aq)$	14.9

Equation I and II are based upon data listed by Delepine and Badoche. For reaction III Delepine and Badoche obtained 15 kcal. mole^{-1}. Whereas, F. Walker, J. Am. Chem. Soc. 55, 2821 (1933) obtained 14.8 kcal. mole^{-1}. A value of -27.7 kcal. mole^{-1} is obtained from the combustion experiments of H. von Wartenberg and B. Lerner-Steinberg, Z. angew. Chem. 38, 591 (1925). Corrections of -0.6 and 0.1 kcal. mole^{-1} were applied to obtain a heat of reaction at constant pressure and at 298.15°K.

Equilibrium constant determinations of reaction (IV) by R. H. Newton and B. F. Dodge, J. Am. Chem. Soc. 55, 4747 (1933), lead to a $\Delta H^\circ_{f\ 298.15} = -29.0$ kcal. mole^{-1}.

IV $H_{2(g)} + CO_{(g)} = H_2CO_{(g)}$

The value obtained from the measurements of Wartenberg and Lerner-Steinberg is believed to be the most reliable.

Heat Capacities and Entropies

Frequencies were measured by H. H. Blau and H. H. Nielsen, J. Molec. Spect. 1, 124 (1957) in the I. R. Microwave determinations of R. B. Lawrence and M. P. W. Strandberg, Phys. Rev. 83, 363 (1951), and those of G. Erlandson, J. Chem. Phys. 25, 579 (1956) are in essential agreement.

0	2
46205	2

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[3002] (1)
580 (1)
[3184] (2)
1383 (2)

Bond Distance: C-H = 1.079 Å

Bond Angle: H-C-H = 120°

σ = 6

Product of the Moments of Inertia: $I_AI_BI_C = 4.99 \times 10^{-119}\ g^3\ cm^6$

Heat of Formation

W. A. Chupka (1) has measured the photoionization spectrum of methane and from the onset of CH_3^+ production has reported $D_0(CH_3\text{-}H) = 103.244 \pm 0.12$ kcal. This value was corrected for the thermal rotation energy of the fragment ions and is the value adopted here.

V. H. Dibeler et al. (2) had earlier reported $D_0(CH_3\text{-}H) = 101.7 \pm 0.5$ kcal but they did not apply the rotational energy correction, which would bring them closer to Chupka.

The photoionization values are in good agreement with earlier electron impact determinations as summarized by Stevenson (3) who gives $D_0(CH_3\text{-}H) = 101.9 \pm 1$ kcal. Kinetic determinations have been recently reviewed by Kerr (4) and yield $D_0(CH_3\text{-}H) = 102.5 \pm 1$ kcal again in excellent agreement.

Heat Capacity and Entropy

The structure, bond length, angles and electronic levels are those reported by Herzberg (5). A set of vibrational frequencies have been reported by Andrews and Pimentel (6) in an argon matrix, of which only two were observed. Milligan and Jacox (7) observed $\nu_2 = 611\ cm^{-1}$ in an argon matrix and disagreed with Andrews and Pimentel who reported 730 cm^{-1}. Later Tan and Pimentel (8) agreed that the earlier values were for a methyl radical interacting with an alkali halide molecule. This would affect the ν_2 mode strongest, thus, we adopt the remaining in plane frequencies which appear to be of the correct magnitudes. The ν_2 mode is taken from the analysis of Herzberg (5) since this represents the gas phase molecule and is in reasonable agreement with the matrix value of Milligan and Jacox. The uncertainty in the entropy reflects the uncertainties in the vibrational frequencies.

The individual moments of inertia are $I_A = I_B = 2.923 \times 10^{-40}\ g\ cm^2$, $I_C = 5.846 \times 10^{-40}\ g\ cm^2$.

METHYL CHLORIDE (CH_3Cl) (IDEAL GAS) MOL. WT. = 50.492

Point Group C_{3v}

$S^\circ_{298.15}$ = 55.99 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 1

$\Delta H^\circ_{f\ 0}$ = -18.76 ± 0.17 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -20.66 ± 0.17 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
2928 (1)	3047 (2)
1355 (1)	1460 (2)
732 (1)	1020 (2)

Bond Distance: C-H = 1.0959Å C-Cl = 1.7812Å

Bond Angle: H-C-H = 108° H-C-Cl = 110°54'

$\sigma = 3$

Product of the Moments of Inertia: $I_A I_B I_C = 21.460 \times 10^{-117}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was measured using hydrogenation to give methane and hydrogen chloride, by J. R. Lacher, E. Emery, E. Bohmfalk and J. D. Park, J. Phys. Chem. 60, 492 (1956). The value adopted was recalculated using JANAF auxiliary data for methane and HCl.

Heat Capacity and Entropy.

The vibrational frequencies were tabulated by E. K. Plyler and W. S. Benedict, J. Research Natl. Bur. Standards 47, 202 (1951). C. C. Costain, J. Chem. Phys. 29, 864 (1958) has calculated the bond distances and angles based on an isotopic substitution method. From these the individual moments of inertia were calculated to be $I_A = 0.5262 \times 10^{-39}$ g. cm.^{2} and $I_B = I_C = 6.3863 \times 10^{-39}$ g. cm.^{2}

Dec. 31, 1960; Dec. 31, 1963

FLUOROMETHANE (CH_3F) (IDEAL GAS) MOL. WT. = 34.035

Point Group = C_{3v}

$S^\circ_{298.15}$ = 53.25 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 1

$\Delta H^\circ_{f\ 0}$ = -54 ± 8 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -56 ± 7 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
2965 (1)	3006 (2)
1464 (1)	1467 (2)
1049 (1)	1182 (2)

Bond Distances: C-F = 1.391 ± 0.005 Å C-H = 1.095 ± 0.010 Å

Bond Angles: H-C-H = 109.5° ± 2° σ = 3

Product of the Moments of Inertia: $I_AI_BI_C$ = 5.96 X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

Appearance potentials for CH_3^+ from CH_4^* and CH_3F reported by F. P. Lossing, K. V. Ingold, and I. H. S. Henderson, J. Chem. Phys. 22, 1489 (1954), the heats of dissociation of hydrogen (104.20 kcal.) and fluorine (37.72 kcal.), and the heat of formation of Methane (-17.90 kcal.) were used to calculate the heat of formation of gaseous CH_3F. These authors measured an appearance potential for CH_3^+ from CH_3F of 14.6 ± 0.6 e.v., which would give an uncertainty of about ±15 kcal. mole^{-1} in the heat of formation of methyl fluoride. However, a correlation of the heats of formation from the atoms of the methyl fluorides and methyl chlorides indicates that the uncertainty can be reduced to ± 7 kcal. mole^{-1}.

Heat Capacity and Entropy.

Fundamental vibrational frequencies were taken from the summary reported by W. L. Smith and I. M. Mills, J. Mol. Spect. 11, 11 (1963). Moments of inertia from the microwave results of O. R. Gilliam, H. D. Edwards, and W. Gordy, Phys. Rev. 75, 1014 (1949) are: I_A = 5.52 X 10^{-40} g. cm.^{2}, $I_B = I_C$ = 32.854 X 10^{-40} g. cm.^{2}. Bond parameters are the values of L. O. Brockway, C. G. Thornton, and L. S. Bartell, whose electron diffraction results are given in the Annual Review of Physical Chemistry 5, 397 (1954). These values are in close agreement with the microwave parameters reported by Gilliam, Edwards, and Gordy (loc. cit.).

Trifluoromethylsilane (Si(CH$_3$)F$_3$)

(Ideal Gas) Mol. Wt. = 100.125

Bond Lengths and Angles $\angle$ H-C-H = 109° 28' C-H = 1.091 ± 0.002 Å

Moments of Inertia $I_A = I_B = I_C = 5.313 \times 10^{-40}$ g. cm.^{2}

Heat of Formation

F. D. Rossini, J. Research Nat. Bur. Standards 6, 37 (1931) measured the heat of combustion of methane gas. His value at 298.15°K was corrected to the presently accepted molecular weight of water. The heat of formation was calculated using -68.3174 and -94.0540 kcal. mole^{-1} for the heat of formation of $H_2O(l)$ and $CO_2(g)$ respectively.

Heat Capacities and Entropies

D. P. Stevenson and J. A. Ibers, J. Chem. Phys. 33, 762 (1960), calculated the bond distance from an analysis of available spectroscopic data. Vibrational frequencies listed by L. H. Jones and R. S. McDowell, J. Mol. Spect. 3, 632 (1959), are consistent with their results of a force constant calculation.

Rotational Constant: B_0 = 0.1076 cm^{-1}

Heat of Formation

The heat of formation is calculated from ΔHf_{298}(ICN, c) = 39.71 kcal/mol (1) and $\Delta Hs°_{298}$ = 14.29 ± 0.15 kcal/mol. This latter value is obtained from a 2nd and 3rd law analysis of the vapor pressure data of Yost and Stone (2) and Ketelaar and Kruyer (3), which are in good agreement after dropping the lowest point in the first set and the lowest 3 points in the second set.

The heat of formation of the crystal is calculated from ΔHr_{298} = -46.3 ± 0.08 kcal obtained by Lord and Woolf (4) for the reaction ICN(c) + 2 NaOH(56 H_2O) = NaCNO(2800 H_2O) + NaI(2800 H_2O) + $H_2O(\ell)$. The auxiliary data used were ΔHf_{298}(NaOH·56 H_2O) = -112.26 kcal/mol (1, 5); ΔHf_{298}(NaCNO·2800 H_2O) = -92.25 kcal/mol (1, 5) and ΔHf_{298}(NaI·2800 H_2O) = -70.54 kcal/mol (1, 5). The uncertainty in the final value reflects the uncertainty in ΔHf_{298}(NaCNO·2800 H_2O) which was determined by Lord and Woolf to be -93.6 kcal/mol in excess NaOH·56 H_2O.

Heat Capacity and Entropy

The molecular structure, bond distances and angle were determined using microwave spectroscopy by Tyler and Sheridan (6). The infrared spectrum of the gas has been reported by Hemple and Nixon (7) using a 10m folded path cell. The fundamentals have been confirmed by the Raman data of West and Farnsworth (8) on a solution in methanol; and by the infrared data of Freitag and Nixon (9) on solid ICN.

June 30, 1962; Mar. 31, 1966

POTASSIUM CYANIDE (KCN) (CRYSTAL) MOL. WT. = 65.11985

$S^\circ_{298.15}$ = 30.54 ± 0.25 cal. deg.$^{-1}$ mole^{-1}

T_t = 168.3 ± 0.1°K.

T_m = 895 ± 2°K.

$\Delta H^\circ_{f\ 0}$ = -28.28 ± 0.2 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -27.12 ± 0.2 kcal. mole^{-1}

ΔH°_t = 0.279 kcal. mole^{-1}

ΔH°_m = 3.5 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to dimer) = 52 ± 10 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to monomer) = 46 ± 5 kcal. mole^{-1}

Heat of Formation.

The enthalpy change, $\Delta H^\circ_{r\ 298.15}$ = 2.80 ± 0.10 kcal. mole^{-1}, for the reaction KCN(c) → KCN(∞H_2O) was reported by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS 2, National Bureau of Standards, April 1, 1965. Incorporating this data with the heat of formation for K^+(∞ H_2O) and CN^-(∞ H_2O), reported by D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Part 1, Technical Note 270-1, October 1, 1965, National Bureau of Standards, the value of $\Delta H^\circ_{f\ 298.15}$ for KCN(c) was evaluated to be -27.12 ± 0.2 kcal. mole^{-1}.

Heat Capacity and Entropy.

The heat capacity for KCN(c) has been measured with a heat conduction method by C. E. Messer and W. T. Ziegler, J. Am. Chem. Soc. 63, 2703 (1941), 101.6-345.8°K., and adiabatically by H. Suga, T. Matsuo and S. Seki, Bull. Chem. Soc. Japan, 38, 1115 (1965), 14.23-308.5°K. The data of Suga, Matsuo and Seki were adopted after correction for curvature. The anomalous region between 50-105°K. has been treated as second order by inclusion of the enthalpy in the heat capacity. The C_p values above 310°K. were estimated by graphical extrapolation. The value of $S^\circ_{298.15}$ was evaluated based on S°_{15} = 0.193 cal. deg.$^{-1}$ mole^{-1}. This extrapolated value appears more reasonable than the value, S°_{15} = 0.307 cal. deg^{-1}mole^{-1} reported by Suga, Matsuo and Seki.

Transition Data.

T_t was taken from Suga, Matsuo and Seki, loc. cit. ΔH°_t was calculated as the difference between the total enthalpy change, $H^\circ_{173.80}-H^\circ_{159.02}$ = 0.533 kcal. mole^{-1} obtained from C_p values measured by Messer and Ziegler, loc. cit., and the enthalpy change, 0.254 kcal. mole^{-1}, calculated from the arbitrarily smoothed C_p curve. Suga, et al. reported ΔH_t = 0.339 kcal. mole^{-1}; however, their C_p data do not adequately define the total enthalpy change through the transition region. The values of T_t and ΔH°_t reported by Messer and Ziegler, loc. cit., were 168.3 ± 0.4°K. and 0.30 kcal. mole^{-1}, respectively. The lower transition, T = 82.9 ± 0.2°K. and ΔH° = 0.095 ± 0.001 kcal. mole^{-1} reported by Suga, et al., was treated as second order by inclusion of the enthalpy in the heat capacity.

Melting Data.

See KCN(l) table.

Heat of Sublimation.

The difference between $\Delta H^\circ_{f\ 298.15}$ for $(KCN)_2$(g) and 2KCN(c) is $\Delta H^\circ_{s\ 298.15}$ (to dimer) and for KCN(g) and KCN(c) is $\Delta H^\circ_{s\ 298.15}$ (to monomer).

June 30, 1962; Mar. 31, 1966

POTASSIUM CYANIDE (KCN) (LIQUID) MOL. WT. = 65.11985

$S^\circ_{298.15}$ = 32.104 cal. deg.$^{-1}$ mole^{-1}

T_m = 895 ± 2° K.

T_b = [1898]°K.

ΔH_f° 298.15 = -24.891 kcal. mole^{-1}

ΔH_m° = 3.5 kcal. mole^{-1}

ΔH_v° = [37.55] kcal. mole^{-1}

Heat of Formation.

ΔH_f° 298.15(l) was obtained from ΔH_f° 298.15(c) by adding ΔH_m° and the difference between $H^\circ_{895}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

Heat capacity was estimated and assumed constant in the temperature range 298.15-3000°K. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting temperature was reported by W. Truthe, Z. anorg. Chem. 76, 129 (1912). The value of ΔH_m° was taken from K. K. Kelley, U. S. Bur. Mines Bull, 393, 1936, based on phase diagrams of the systems KCN-AgCN, KCN-$Cu_2(CN)_2$, KCN-KCl, KCN-NaCN, and KCN-$Zn(CN)_2$ reported by W. Truthe, loc. cit.

Vaporization Data.

T_b is the temperature at which the free energy change for the reaction KCN(l) = KCN(g) becomes zero. The difference between ΔH_f° for KCN(g) and KCN(l) at T_b is ΔH_v°.

Bond Distance: C-N = 1.16 ± 0.01 Å K-C = [2.294] Å

Bond Angle: K-C-N = 180°

Rotational Constant: B = 0.11891 cm.$^{-1}$

σ = 1

Heat of Formation.

The vapor pressure of KCN(g) at 870°C. was estimated to be 1-10 mm. Hg by D. S. Villars, J. Am. Chem. Soc. 53, 405 (1931). Assuming the vapor pressure at this temperature to be 1 mm. Hg, the heat of vaporization ($\Delta H^\circ_{v\ 298.15}$) for KCN(l) was evaluated as 44 kcal. mole^{-1}. Based on $\Delta H^\circ_{f\ 298.15}$ = -24.89 kcal. mole^{-1} for KCN(l), the value of $\Delta H^\circ_{f\ 298.15}$ for KCN(g) was calculated to be 19 ± 5 kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular structure of KCN(g) has not been determined. It was assumed to be linear by comparison with that for HCN(g). The C-N bond distance was determined by N. Elliott and J. Hastings, Acta Cryst. 14, 1018 (1961) by use of neutron diffraction measurements. The K-C bond distance was taken from G. E. Leroi, Ph. D. Thesis, Harvard University, 1961, which was estimated. The vibrational frequencies, ν_2 and ν_3, were obtained from G. E. Leroi and W. Klemperer, J. Chem. Phys. 35, 774 (1961). The value of ν_1 was calculated by valence force method described by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is 2.3540 X 10^{-38} g. cm.^{2}

Dec. 31, 1961; Mar. 31, 1966

POTASSIUM CARBONATE (K_2CO_3) (CRYSTAL) MOL. WT. = 138.21335

$\Delta H^\circ_{f\ 0}$ = -273.57 ± 0.5 kcal. mole^{-1}

$S^\circ_{298.15}$ = 37.17 ± 0.1 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{298.15}$ = -274.9 ± 0.5 kcal. mole^{-1}

T_m = 1174 ± 1°K.

ΔH°_m = 6.6 ± 0.1 kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained from the heat of solution ΔH°_{∞} = -7.6 ± 0.5 kcal. mole^{-1} and the heats of formation for K^+(aq) and CO_3^{--} (aq), -60.32 and -161.84 kcal. mole^{-1}, respectively. The standard heat of solution, ΔH°_{∞} = -7.6 ± 0.5 kcal. mole^{-1}, was calculated by extrapolation to infinite dilution of the calorimetric data of L. Benjamin, J. Chem. Eng. Data 7, 239-40 (1962), using the methods suggested by J. P. Rupert, H. P. Hopkins, Jr., and C. A. Wulff, J. Phys. Chem. 69, 3059-62 (1965). The equilibrium constant for the hydrolysis CO_3^{--} (∞H_2O) + H_2O(1) → HCO_3^-(∞H_2O) + OH^-(∞H_2O) was taken as K = 2.1 X 10^{-4} based on the selected values of D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties", NBS Technical Note 270-1, October 1, 1965. The resulting extrapolations were not so consistent as those of Rupert et al. (loc. cit.) for Na_2CO_3. The ionic heats of formation were taken from Wagman et al. (loc. cit.). This procecure was adopted even though it may involve an inconsistency between the extrapolations for ΔH°_{∞} and CO_3^{--}(∞H_2O). The alternative evaluation of $\Delta H^\circ_{f\ 298.15}$ for K_2CO_3(~1900 H_2O) from the heats of mixing given by J. A. Muller, Ann. chim. phys. (6), 15, 517 (1888) and M. Berthelot, Ann. chim. phys. (4) 29, 433 (1873) may be subject to significant error if dissolved CO_2 was not excluded from the solutions. Presumably, this path was used by D. D. Wagman, NBS Report 8628, January 1965, in the selection of $\Delta H^\circ_{f\ 298.15}$ = -274.3 kcal. mole^{-1}. This value is 0.6 kcal. mole^{-1} less negative than the value adopted here.

Heat Capacity and Entropy.

The low temperature heat capacity, 14.0-315°K. was measured by F. L. Oetting, unpublished data, Thermal Research Laboratory, Dow Chemical Company, Midland, Michigan, 1963. G. I. Janz, E. Neuenschwander and F. J. Kelly, Trans. Faraday Soc. 59, 841 (1963) measured the heat content by drop calorimetry in the temperature range 630-1250°K., and gave enthalpy and heat capacity equations based on their measurements. The above information was used in a Shomate analysis in order to smooth the enthalpy and calculate heat capacity above 298°K. The values from the low and high temperature sources join smoothly at 298°K. The heat capacity was **graphically extrapolated above the melting point.** The entropy at 14.0°K. was calculated from the extrapolated low temperature C_p data, using the cubic law. The value of $S^\circ_{14.0}$ = 0.109 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

T_m was obtained from A. Reisman, J. Am. Chem. Soc. 80, 3558 (1958) and ΔH°_m was taken from Janz et al. (loc. cit.).

Dec. 31, 1961; Mar. 31, 1966

POTASSIUM CARBONATE (K_2CO_3) (LIQUID) MOL. WT. = 138.21335

$S^\circ_{298.15}$ = 40.719 ± 0.1 cal. deg.$^{-1}$ mole^{-1}

T_m = 1174 ± 1°K.

ΔH_f° 298.15 = -270.22 ± 0.5 kcal. mole^{-1}

ΔH_m° = 6.60 ± 0.1 kcal. mole^{-1}

Heat of Formation.

The ΔH_f° 298.15 was obtained from ΔH_f° 298.15(c) by adding ΔH_m° and the difference between $H^\circ_{T_m} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 800°K. The heat capacity below 800°K. was obtained from the heat capacity of the crystal. Above 800°K. the heat capacity was adopted as 50.0 cal. deg.$^{-1}$ mole^{-1}, based on the enthalpy measurements in the range 1169-1250°K. reported by G. J. Janz, E. Neuenschwander and F. J. Kelly, Trans. Faraday Soc. 59, 841 (1963). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See K_2CO_3(c) table.

Mar. 31, 1966

LITHIUM CARBONATE (Li_2CO_3) (CRYSTAL) MOL. WT. = 73.88735

$S^\circ_{298.15}$ = 21.551 ± 0.05 cal. deg.$^{-1}$ mole^{-1}

T_{t_1} = 623°K.

T_{t_2} = 683 ± 3°K.

T_m = 993 ± 1°K.

$\Delta H^\circ_{f\ 0}$ = -288.69 ± 0.04 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -290.84 ± 0.04 kcal. mole^{-1}

$\Delta H^\circ_{t_1}$ = [0.134] kcal. mole^{-1}

$\Delta H^\circ_{t_2}$ = [0.535] kcal. mole^{-1}

ΔH°_m = 10.70 ± 0.1 kcal. mole^{-1}

Heat of Formation.

The heat of formation was derived from the enthalpy change of the following reactions:

	Reaction	$\Delta H^\circ_{r\ 298.15}$ kcal. mole^{-1}	References
a	$2Li^+(\infty H_2O) + CO_3^{--}(\infty H_2O) = Li_2CO_3(c)$	4.20	(1)
b	$2Li(c) + 2H_2O(l) = 2Li^+(\infty H_2O) + 2\ OH^-(\infty H_2O) + H_2(g)$	-106.310	(2)(3)(4)(5)

Summation of these two reactions gives

$2Li(c) + 2H_2O(l) + CO_3^{--}(\infty H_2O) = Li_2CO_3(c) + 2\ OH^-(\infty H_2O) + H_2(g)$ -102.110

Using ΔH_f° of $H_2O(l)$, $CO_3^{--}(\infty H_2O)$ and $OH^-(\infty H_2O)$ from Ref. 6 yields ΔH_f° Li_2CO_3 = -290.64 kcal. mole^{-1}.

Heat Capacity and Entropy.

The low temperature heat capacity, 16.68-300.20°K., was measured by O. L. I. Brown and W. M. Latimer, J. Am. Chem. Soc. 58, 2228 (1936). G. I. Janz, E. Neuenschwander and F. J. Kelly, Trans. Faraday Soc. 59, 841 (1963) measured the heat content by drop calorimetry in the temperature range 560-1150°K., and gave enthalpy and heat capacity equations based on their measurement. The above information was used in a Shomate analysis in order to smooth the enthalpy and calculate heat capacity. The values from the low and high temperature sources join smoothly at 298°K. The heat capacity was graphically extrapolated above the melting point. The entropy at 16.68°K. was calculated from the extrapolated low temperature C_p data, using the cubic law. The value of $S^\circ_{16.68}$ = 0.053 cal. deg.$^{-1}$ mole^{-1}.

Transition Data.

T_t were taken from A. Reisman, J. Am. Chem. Soc. 80, 3558 (1958). The enthalpies of transition were estimated from the relative areas of the transitions and the heat of fusion of the differential analysis curve reported by Reisman loc. cit.

Melting Data.

T_m was obtained from Reisman loc cit. and ΔH°_m was taken from Janz et. al. (loc. cit.).

LITHIUM CARBONATE (Li_2CO_3) (LIQUID) MOL. WT. = 73.88735

$S^\circ_{298.15} = 30.423 \pm 0.05$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 993.15 \pm 1$°K.

$\Delta H^\circ_{f\ 298.15} = -281.63 \pm 0.04$ kcal. mole^{-1}

$\Delta H^\circ_m = 10.7 \pm 0.1$ kcal. mole^{-1}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ was obtained from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 683.15°K. The heat capacity below 683.15°K. was obtained from the heat capacity of the crystal. Above 683.15°K. the heat capacity was adopted as 44.32 cal. deg.$^{-1}$ mole^{-1}, based on the enthalpy measurements in the range 996-1150°K. reported by G. J. Janz, E. Neuenschwander and F. J. Kelly, Trans. Faraday Soc. 59, 841 (1963). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $Li_2CO_3(c)$ table.

Dec. 31, 1960; Dec. 31, 1966

MAGNESIUM CARBONATE ($MgCO_3$) (CRYSTAL) GFW = 84.32135

$S°_{298.15}$ = 15.74 gibbs/mol

Td = 675°K

$\Delta Hf°_0$ = -263.9 ± 2 kcal/mol

$\Delta Hf°_{298.15}$ = -265.7 ± 2 kcal/mol

Heat of Formation.

The adopted $\Delta Hf°_{298.15}$ = -265.7 ± 2 kcal/mol is the average value derived from the dissociation pressures of $MgCO_3(c)$ in the temperature range 671-782°K measured by Marc and from the $\Delta Hr°_{923}$ = 25.9 ± 0.6 kcal/mol determined by Thomasson using a high temperature differential calorimeter. The decomposition of $MgCO_3$ has been studied in a bomb calorimeter by Roth; this yields $\Delta Hr°_{293}$ = 23.8 kcal/mol when corrected to constant pressure. The value is derived from the small difference between two large heats of combustion,so the uncertainty is probably large. Roth also reported $\Delta Hr°_{363}$ = 26.15 kcal/mol from calorimetric data on the heat of solution in HCl. Berthelot measured the heat of solution of $MgSO_4(aq)$ with $K_2CO_3(aq)$. Analyzing his data we find $\Delta Hf°_{298.15}$ = -268.6 kcal/mol.

Discrepancies are apparent in the wide range of the calorimetric results and in the third law drift of the equilibrium data. Possible sources for the drift include lack of true equilibrium (e.g., excess surface energy for MgO) and uncertainty in the high temperature entropy of $MgCO_3$(see entropy write-up). Non-standard state behavior of the crystal phases may also be a problem in the calorimetric studies. The data of Thomasson and Cunningham, based on a high temperature differential thermal analysis technique, are probably the most reliable of the calorimetric values; however, there are uncertainties in the absolute energy calibration. The first result of Roth may be dismissed as too discrepant and the remaining two calorimetric values are within ± 3 kcal of the selected heat of formation.

Source	Method	Reaction	T, °K	$\Delta Hr°_T$ (kcal/mol)	$\Delta Hr°_{298.15}$ (kcal/mol)	Drift eu	$\Delta Hf°_{298.15}$ kcal/mol
1. Marc	Kp	$MgCO_3(c) = MgO(c) + CO_2(g)$	671-782	—	28.3	4.8 ± 0.9	-266.04
2. Thomasson	Calorimetric	$MgCO_3(c) = MgO(c) + CO_2(g)$	923	25.9	27.7		-265.45
3. Roth	Calorimetric	$MgCO_3(c) = MgO(c) + CO_2(g)$	293	23.8	23.8		-260.35
Roth	Calorimetric	$MgCO_3(c) = MgO(c) + CO_2(g)$	363	26.15	26.10		-263.95
4. Berthelot	Calorimetric	$K_2CO_3\ (\sim .5m) + MgSO_4(\sim .5m) = MgCO_3(c) + K_2SO_4(\sim .5m)$	288	1.05	1.35		-268.6

Heat Capacity and Entropy.

Low temperature heat capacities (56.3 - 291.6°K) were measured by C. T. Anderson, J. Am. Chem. Soc. 56, 849 (1934). The high temperature heat capacities are derived by a Shomate analysis of smoothed enthalpies reported by K. K. Kelley, Bulletin 584, p. 114, U.S. Bureau of Mines, Washington, D.C. 1960. Kelley obtained the smoothed values from unpublished high temperature (400-743°K) enthalpy measurements by C. H. Shomate, Berkeley Thermodynamics Laboratory, Region II, Bureau of Mines, Berkeley, California. The data were joined smoothly at 298°K and extrapolated graphically above 743°K. The entropy was obtained from the heat capacities using $S°_{56.2}$ = 0.57 eu.

Because of the drift in the decomposition pressure data, it is pertinent to assess the uncertainty in the functions. The greatest potential source for error is in the values above room temperature where the increment of entropy is about 20 eu between 298 and 700°K. Unfortunately, no evaluation of the unpublished enthalpies is possible, but an increase of 10% in the entropy increment would reduce the drift to a tolerable level.

Decomposition Data.

Td is calculated as the temperature at which ΔGr° equals zero for $MgCO_3(c) = MgO(c) + CO_2(g)$.

Heat of Formation

The heat of formation of CN has been the subject of considerable uncertainty for many years. J. Berkowitz (1) has reviewed the earlier work and he concludes that ΔHf°_0(CN, g) = 109 kcal/mol. Since this review a considerable body of work has emerged which supports a value near 100 kcal/mol.

Tsang et al. (2) obtained ΔHf°_{298}(CN, g) = 100 ± 4 kcal/mol from shock tube studies of the decomposition of cyanogen.

Dibeler and Liston (3, 4) have studied a series of cyanogen compounds and obtained their heats of dissociation from photoionization threshold measurements. The values below are obtained from the halogen ion threshold measurements using JANAF auxilliary data, except for HCN which is from the CN^+ threshold measurements. The value below is calculated using the ionization potential from CNCl measurements (3).

Davis and Okabe (5) employed a direct photodissociation technique to obtain dissociation energies for many of the same molecules. The method determines the disappearance threshold for fluorescence due to decay of excited molecules CN $B^2\Sigma^+$ - $X^2\Sigma^+$. This corresponds to the energy needed to just break the bond and form excited cyanogen in the $B^2\Sigma^+$ state, whose energy above ground is well known.

Setser and Stedman (6) used metastable excited argon atoms with a maximum electronic energy of 270 kcal/mol to break the bonds in HCN and $(CN)_2$. From the emission spectra of the excited $B^2\Sigma^+$ CN they were able to calculate the highest populated vibrational level and thus a maximum limit to the dissociation energy.

Berkowitz et al. (7) have recently examined the photoionization spectrum of HCN using the H^+ ion threshold. They also determined the threshold for the CN^+ ion which agrees exactly with that of Dibeler and Liston (4) when the latter is corrected for rotational energy contributions (0.7 kcal). Berkowitz et al. (7) suggest that the HCN limit of Setser and Steadman (6) should be ≤105 due to neglect of the significant vibrational population of the first harmonic of the bending mode. However, if the same allowance is made for the C_2N_2 data the limit is only ≤104 and this presumes significant occupation of the third harmonic of the bending mode of C_2N_2.

It is apparent from the data that considerable scatter still exists and several sources of error are probable. HCN and the cyanogen halides all have significant uncertainties in their heats of formation, and the effects of rotational and vibrational contributions at 300°K are uncertain, but could be eliminated by using refrigerated gases. We choose to adopt a median value within the range of almost all determinations of ΔHf°_0(CN, g) = 103.2 ± 2.5 kcal/mol.

Heat Capacity and Entropy

The thermodynamic functions are taken from Johnston et al. (8) calculated based on the direct summation of the energy levels. All the electronic levels and molecular constants listed above are from Carroll (9). Johnston et al. used only the first two excited electronic states but the contribution of the higher levels is negligible.

June 30, 1969

Ground State Configuration $[^3\Pi]$

$\Delta Hf^\circ_0 = 428.6 \pm 3.0$ kcal/mol

$S^\circ_{298.15} = 50.98 \pm 1.5$ gibbs/mol

$\Delta Hf^\circ_{298.15} = 429.4 \pm 3.0$ kcal/mol

Electronic Levels and Degeneracies

ε_i, cm^{-1}	g_i
0	[6]
[1500]	[1]
[6000]	[2]
[8000]	[3]
[15000]	[2]

$\omega_e = [1580]\ cm^{-1}$ $\omega_e x_e = [12.5]\ cm^{-1}$ $\sigma = 1$

$B_e = [1.566]\ cm^{-1}$ $\alpha_e = [0.017]\ cm^{-1}$ $r_e = 1.29$ Å

Heat of Formation

Dibeler and Liston (1) have measured the photoionization thresholds for the processes:

$ClCN + h\nu \rightarrow Cl^+ + CN + e^-$ $\Delta Hr^\circ_0 = 399.44 \pm 0.5$ kcal

$ClCN + h\nu \rightarrow Cl + CN^+ + e^-$ $\Delta Hr^\circ_0 = 426.65 \pm 0.5$ kcal

By subtraction we obtain

$Cl + CN^+ \rightarrow Cl^+ + CN$ $\Delta Hr^\circ_0 = -27.21 \pm 0.7$ kcal

Using JANAF values for Cl, Cl^+ and CN we obtain $\Delta Hf^\circ_0(CN^+) = 430.6 \pm 3.0$ kcal/mol and the ionization potential of CN, g = 327.42 ± 0.7 kcal/mol.

Berkowitz et al. (2) have measured the photoionization thresholds for the processes:

$HCN + h\nu \rightarrow H^+ + CN + e^-$ $\Delta Hr^\circ_0 = 438.18 \pm 0.3$ kcal

$HCN + h\nu \rightarrow H + CN^+$ $\Delta Hr^\circ_0 = 448.09 \pm 0.3$ kcal

By subtraction we obtain

$H + CN^+ \rightarrow H^+ + CN$ $\Delta Hr^\circ_0 = -9.91 \pm 0.4$ kcal

Using JANAF values for H, H^+ and CN we obtain $\Delta Hf^\circ_0(CN^+) = 426.7 \pm 3.0$ kcal/mol, and the ionization potential of CN, g = 323.51 ± 0.4 kcal/mol.

We adopt a median value for $\Delta Hf^\circ_0(CN^+) = 428.6 \pm 3.0$ kcal/mol and 325.4 ± 2 kcal/mol for the ionization potential of CN.

Heat Capacity and Entropy

The molecule has eight valence electrons and thus we expect that its molecular constants should fall between those for C_2 and BN. The ground electronic state is either $^1\Sigma$ or $^3\Pi$ and the two levels are likely to be very close. As a consequence the thermodynamic functions are dominated by the $^3\Pi$ contribution and so we choose this to be the ground state. The other levels are estimated based on the values of Fougere and Nesbet (3) for C_2 and of Verhaegen et al. (4) for BN. The vibrational constants and bond length are estimated between those for the $^3\Pi$ states of BN and C_2. The rotational constants B_e is obtained from the estimated bond length and α_e is calculated from the other constants assuming a Morse potential function. The enthalpy at 0°K is -2.076 kcal/mol.

CYANO UNINEGATIVE ION (CN^-) (IDEAL GAS) GFW = 26.01840

Ground State Configuration $[^1\Sigma^+]$

ΔHf°_0 = 15.2 ± 3 kcal/mol

$S^\circ_{298.15}$ = 46.81 ± 0.5 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 16 ± 3 kcal/mol

Electronic Levels and Degeneracies

ϵ_i, cm^{-1}	g_i
0	[1]
[67000]	[2]

ω_e = [2250] cm^{-1} $\omega_e x_e$ = [13.8] cm^{-1} σ = 1

B_e = [2.116] cm^{-1} α_e = [0.0177] cm^{-1} r_e = [1.11] Å

Heat of Formation

Berkowitz et al. (1) have recently obtained 88 ± 0.5 kcal for the electron affinity of CN from the photoionization thresholds of the reactions $HCN \rightarrow H^+ + CN^-$ and $HCN \rightarrow H^+ + CN + e^-$.

Other values have been reported by Page (2), who reinterpreted his earlier data (3), to yield 73 ± 1 kcal/mol; Bakulina and Ionov (4) in conjunction with the data of Branscomb and Smith (5) reported 78 ± 5 kcal/mol and Inoue (6) who obtained 83 ± 7 kcal/mol.

We adopt the value given by Berkowitz et al. (1) as being the most well defined in terms of both the precision of measurements and the reactions being studied. This leads to $\Delta Hf^\circ_0(CN^-, g)$ = 15.2 ± 3 kcal/mol or $\Delta Hf^\circ_{298}(CN^-, g)$ = 16 ± 3 kcal/mol.

Heat Capacity and Entropy

The electronic structure and molecular constants are estimated by analogy with the isoelectronic species CO and N_2. The uncertainties in the constants are generally small since N_2 and CO are quite similar, thus the entropy has an uncertainty of only 0.5 eu. The enthalpy at 0°K is -2.072 kcal/mol.

Dec. 31, 1960; Mar. 31, 1966

SODIUM CYANIDE (NaCN) (CRYSTAL) MOL. WT. = 49.00765

$S^\circ_{298.15}$ = [28.32 ± 0.5] cal. deg.$^{-1}$ mole^{-1}

T_m = 835° K.

$\Delta H^\circ_{f\ 0}$ = -23.49 ± 0.3 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -21.68 ± 0.3 kcal. mole^{-1}

ΔH°_m = [2.1] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to dimer) = [41.3] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to monomer) = 44.21 kcal. mole^{-1}

Heat of Formation.

The enthalpy change for the reaction NaCN(c) → NaCN(∞ H_2O) was reported to be 0.29 ± 0.20 kcal. mole^{-1} by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS 2, National Bureau of Standards, April 1, 1965. Incorporating this data with the heats of formation for Na^+(∞ H_2O), -57.39, and CN^-(∞ H_2O), 36.0 kcal. mole^{-1}, reported by D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properites," Part 1, Technical Note 270-1, October 1, 1965, National Bureau of Standards, the value of $\Delta H^\circ_{f\ 298.15}$ for NaCN(c) was derived and adopted.

G. Lord and A. A. Woolf, J. Chem. Soc. 2546 (1954), determined the value, $\Delta H^\circ_{f\ 298.15}$(NaCN, c) = -21.4 kcal. mole^{-1}, by solution calorimetry. This value is in agreement with the adopted one.

Heat Capacity and Entropy.

The low temperature heat capacities, 101.6-345.8°K., were reported by C. E. Messer and W. T. Ziegler, J. Am. Chem. Soc. 63, 2703 (1941). The C_p values above 345.8°K. were estimated by graphical extrapolation. $S^\circ_{298.15}$ was derived from low temperature heat capacities, based on S°_{100} = 8.4 cal. deg.$^{-1}$ mole^{-1} which was estimated by comparison with the $S^\circ_{298.15}$ values for NaCl, KCl, and KCN crystals.

Transition Data.

The transition temperatures, T_{t_2} and T_{t_1}, were determined by C. E. Messer and W. T. Ziegler, loc. cit. The corresponding enthalpies of transition were reported to be 0.15 and 0.70 kcal. mole^{-1}, respectively. However, these quantities were incorporated with C_p values used to evaluate $H^\circ-H^\circ_{298.15}$. Therefore ΔH_t°'s are not listed.

Melting Data.

ee NaCN(l) table for details.

Heat Sublimation.

The difference between $\Delta H^\circ_{f\ 298.15}$ for $(NaCN)_2$(g) and 2NaCN(c) is $\Delta H^\circ_{s\ 298.15}$ (to dimer) and for NaCN(g) and NaCN(c) is $\Delta H^\circ_{s\ 298.15}$(to monomer).

Dec. 31, 1960; Mar. 31, 1966

SODIUM CYANIDE (NaCN) (LIQUID) MOL. WT. = 49.00765

$S^\circ_{298.15}$ = [29.996] cal. deg.$^{-1}$ mole^{-1}

T_m = 835° K.

T_b = [1803]°K.

$\Delta H^\circ_{f\ 298.15}$ = [-20.160] kcal. mole^{-1}

ΔH°_m = [2.1] kcal. mole^{-1}

ΔH°_v = [35.39] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}(l)$ was obtained from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_m and the difference between $H^\circ_{835}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated by comparison with those for NaCN(c), KCN(c) and KCN(l). A glass transition temperature is assumed at 600°K. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting temperature was reported by W. Truthe, Z. anorg. Chem. 76, 129 (1912). ΔH°_m was estimated such that the derived third law value for ΔH°_v (NaCN, l) agrees with the second law value. See NaCN(g) table for details.

Vaporization Data.

T_b is the temperature at which the free energy change for the reaction NaCN(l) = NaCN(g) becomes zero. The difference between ΔH°_f for NaCN(g) and NACN(l) at T_b is ΔH°_v.

Heat of Formation.

The vapor pressures of NaCN(l) at temperatures 805-1353°K. were measured by C. K. Ingold, J. Chem. Soc. 123, 885 (1923). According to the investigation reported by R. F. Porter, J. Chem. Phys. 35, 318 (1961), the vapor consists of NaCN and $(NaCN)_2$. Based on his data the dimer/monomer ratios at temperatures 805-1353°C. (1078.2-1626.2°K.) were calculated to be 0.29-0.09. Hence the respective partial pressures for NaCN(g) and $(NaCN)_2(g)$ were derived. By the second and third law methods, the values of $\Delta H_v^\circ{}_{298.15}$ (l → monomer) were evaluated to be 43.43 and 42.69 kcal. mole^{-1}, respectively. The heat of formation ($\Delta H_f^\circ{}_{298.15}$) for NaCN(g) was calculated from $\Delta H_f^\circ{}_{298.15}$ (NaCN, c) and the third law value for ΔH_v°.

Heat Capacity and Entropy.

The molecular structure of NaCN(g) has not been determined. It was assumed to be linear by comparison with that for HCN(g). The C-N bond distance was assumed to be the same as that in KCN(g) and the Na-C bond distance was taken from G. E. Leroi, Ph. D. Dissertation, Harvard University, 1961, which was calculated. The vibrational frequencies, ν_2 and ν_3, were measured by G. E. Leroi and W. Klemperer, J. Chem. Phys. 35, 774 (1961) from infrared absorption spectra. The value of ν_1 was calculated by valence force method described by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is 1.53187 X 10^{-38} g. cm.^{2}

CNN RADICAL (CN_2)   (IDEAL GAS)   GFW = 40.02455

Point Group $C_{\infty v}$ ΔHf°_0 = [139.5 ± 30] kcal/mol

$S^\circ_{298.15}$ = 55.35 gibbs/mol $\Delta Hf^\circ_{298.15}$ = [139.7 ± 30] kcal/mol

Ground State Quantum Weight = 3

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
1241 (1)
393 (2)
2847 (1)

Bond Distance: C-N = [1.15] Å   N-N = [1.25] Å

Bond Angle: C-N-N = 180° σ = 1

Rotational Constant: B_o = [0.450388] cm^{-1}

Heat of Formation.

The heat of formation is calculated from the estimated heat of reaction ΔHr°_0 = 255 ± 30 kcal/mol for CNN(g) → C(g) + 2N(g). Since CNN radical can dissociate to give C + N_2 or CN + N, the molecule must have more energy than either CN or N_2. It is assumed that the extra bond will be quite weak, for this we estimate 30 ± 30 kcal/mol which gives ΔHr°_0 = 255 ± 30 kcal/mol for the first path and ΔHr° = 204 ± 30 kcal/mol for the second. We adopt the former value.

Heat Capacity and Entropy.

D. E. Milligan and M. E. Jacox, J. Chem. Phys. 44, 2850 (1966), have measured three fundamental vibrational frequencies for CNN radical (g) in the infrared and ultraviolet spectra by matrix-isolation, and proposed a linear molecular configuration with a $^3\Sigma$ ground state which has been confirmed by E. Wasserman, L. Barash and W. A. Yager, J. Am. Chem. Soc. 87, 2075 (1965), in the electron paramagnetic resonance observations. Also Milligan and Jacox suggested a "C≡N=N" bond structure, based on the agreement between the C-N and N-N stretching force constants (calculated from observed vibrational frequencies in the CNN radical) and the typical C≡N and N=N stretching force constants. In addition, they estimated the bond distances r_{C-N} = 1.15Å and r_{N-N} = 1.25 Å from the proposed structure. The principal moment of inertia is 6.2148 X 10^{-39} g cm^2.

NCN RADICAL (CN_2) (IDEAL GAS) GFW = 40.02455

Point Group $D_{\infty h}$

ΔHf°_0 = [102.6 ± 25] kcal/mol

$S^\circ_{298.15}$ = 54.194 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [102.8 ± 25] kcal/mol

Ground State Quantum Weight = 3

<u>Vibrational Frequencies and Degeneracies</u>

ω, cm^{-1}
[808](1)
423 (2)
1475 (1)

Bond Distance: C-N = 1.232 Å

Bond Angle: N-C-N = 180°

σ = 2

Rotational Constant: B_o = 0.3968 cm^{-1}

Heat of Formation.

The heat of formation of NCN radical (g), ΔHf°_{298} = 102.8 ± 25 kcal/mol, was calculated from the heat of reaction ΔHr°_{298} = 294 ± 25 kcal/mol for N=C=N → 2N(g) + C(g) which was estimated as twice the C=N bond dissociation energy (147 kcal/mol). The value of C=N bond dissociation energy was derived from the heat of combustion for n-butyl-isobutylidine amine, determined by G. E. Coates and L. E. Sutton, J. Chem. Soc. 1187 (1948).

Heat Capacity and Entropy.

G. Herzberg and D. N. Travis, Can. J. Phys. 42, 1658 (1964), have found NCN radical (g) is a linear symmetric molecule with a $^3\Sigma^-_g$ ground state in the rotational spectra by a flash photolysis technique, and determined the bond distance r_{C-N} = 1.232 Å and rotational constant B_o = 0.3968 cm^{-1} which have been adopted in the tabulation. Also the structure "N=C=N" has been suggested by Herzberg and Travis, based on the bond distance of 1.232 Å, which is in good agreement with the C=N bond length observed in the HNCO, HNCS and CH_3NCS. The principal moment of inertia is 7.0601 X 10^{-39} g cm^2.

D. E. Milligan, M. E. Jacox and A. M. Bass, J. Chem. Phys. 43, 3149 (1965), have found two infrared-active vibrational fundamentals of NCN(g) at 423 and 1475 cm^{-1} in the infrared and ultraviolet spectra by a matrix-isolation method. They also estimated the symmetric stretching frequency (ν_1 = 808 cm^{-1}) by valence force calculation.

E. Wasserman, L. Barash and W. A. Yager, J. Am. Chem. Soc. 87, 2075 (1965), have confirmed the NCN radical(g) is a linear molecule with a triplet ground state by electron paramagnetic resonance.

Dec. 31, 1960; Mar. 31, 1966

SODIUM CARBONATE (Na_2CO_3)   (CRYSTAL)   MOL. WT. = 105.98895

$S^\circ_{298.15}$ = 33.17 ± 0.2 cal. deg.$^{-1}$ mole^{-1}

T_t = 723.15°K.

T_m = 1123.15°K.

$\Delta H^\circ_{f\ 0}$ = -268.79 ± 0.05 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -270.26 ± 0.05 kcal. mole^{-1}

ΔH°_t = 0.165 kcal. mole^{-1}

ΔH°_m = 7.090 kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained from the heat of solution ΔH°_∞ = -6.36 kcal. mole^{-1} and the heats of formation for $Na^+(aq)$ and $CO_2^{--}(aq)$, -57.39 and -161.84 kcal. mole^{-1}, respectively. The heat of solution was taken from J. P. Rupert, H. P. Hopkins, Jr., and C. A. Wulff, J. Phys. Chem. 69, 3059-62 (1965). The ionic heats of formation were taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm "Selected Values of Chemical Thermodynamic Properties" NBS Technical Note 270-1, October 1, 1965.

A value of $\Delta H^\circ_{f\ 298.15}$ = -270.9 kcal. mole^{-1} has been selected by D. D. Wagman, Natl. Bur. Std. Rept. No. 8628, 87, Jan. 1965.

Heat Capacity and Entropy.

The low temperature heat capacities, 54.6-292.1°K., were measured by C. T. Anderson, J. Am. Chem. Soc. 55, 3621 (1933). In the temperature range 473.15-873.15°K. Popov and Galchenko (Source 1) measured the heat capacities (by heat conduction calorimetry) and observed two transformations, one at about 623°K. and the other at about 750°K. Popov and Ginzburg (Source 2) measured enthalpies in the temperature range 480-1350°K. and tabulated their data only in the range 476-872°K. Ginzburg (Source 3) has given heat capacity equations based on the data from Source 1 and 2 and has tabulated thermodynamic functions in the range 500-1500°K. There appear to be inconsistencies among the data, equations and functions. Rolin and Recapet (Source 4) also measured the enthalpy in the temperature range 645-1322°K. Janz, Neuenschwander and Kelly (Source 5) have given an enthalpy equation based on their heat content measured data in the range 707-1127°K. May (Source 6) has tabulated smoothed measured enthalpy values in the range 400-1500°K. All the above information was used in a Shomate analysis in order to smooth the enthalpies and calculate heat capacities. The values from the low and high temperature sources join smoothly at 298°K. The heat capacity was graphically extrapolated above the melting point.

The entropy was calculated at 54.60° using the Debye and Einstein function $D(\frac{138}{T}) + 2E(\frac{266}{T}) + 2D(\frac{737}{T})$ given by Anderson, loc. cit. The value of $S^\circ_{54.6}$ = 3.943 cal. deg.$^{-1}$ mole^{-1}.

Transition Data.

T_t was taken from Ginzburg loc. cit. and ΔH°_t was obtained from the above reported enthalpy measurements by means of Shomate function analysis. The heat of transition at 593.15°K. has been incorporated in the heat capacity.

Melting Data.

T_m was taken from Ginzburg loc. cit. and ΔH°_m was obtained from the above reported enthalpy measurements by means of Shomate function analysis.

Dec. 31, 1960; Mar. 31, 1966

SODIUM CARBONATE (Na_2CO_3) (LIQUID) MOL. WT. = 105.98895

$S^\circ_{298.15}$ = 37.14 ± 0.2 cal. deg.$^{-1}$ mole^{-1}

T_m = 1123.15°K.

$\Delta H^\circ_{f\ 298.15}$ = -265.21 ± 0.05 kcal. mole^{-1}

ΔH°_m = 7.090 kcal. mole^{-1}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ was obtained from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 723.15°K. The heat capacity below 723.15°K. was obtained from the heat capacity of the crystal. Above 723.15°K. the heat capacity was adopted as 45.30 cal. deg.$^{-1}$ mole^{-1}, based on the enthalpy measurements in the range 1127-1210°K. reported by G. J. Janz, E. Neuenschwander and F. J. Kelly, Trans. Faraday Soc. 59, 841 (1963). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $Na_2CO_3(c)$ table.

Dec. 31, 1960; Mar. 31, 1961; Sept. 30, 1965

CARBON MONOXIDE (CO) (IDEAL GAS) MOL. WT. = 28.01055

Ground State Configuration $^1\Sigma^+$

$\Delta H_{f\ 0}^\circ$ = -27.20 ± 0.04 kcal. mole^{-1}

$S^\circ_{298.15}$ = 47.21 ± 0.01 cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ$ = -26.42 ± 0.04 kcal. mole^{-1}

ω_e = 2169.52 cm.$^{-1}$

$\omega_e x_e$ = 13.453 cm.$^{-1}$

σ = 1

B_e = 1.9302 cm.$^{-1}$

α_e = 0.01746 cm.$^{-1}$

r_e = 1.1281 Å

Heat of Formation.

The enthalpy change ($\Delta H_{r\ 298.15}^\circ$) for the reaction: CO(g) + 1/2 O_2(g) = CO_2(g) was reported to be -67.636 ± 0.029 kcal. mole^{-1}, based on molecular weight of CO_2 = 44.010, by F. D. Rossini, J. Research Nat. Bur. Standards 22, 407 (1939). It was recalculated to be -67.638 ± 0.03 kcal. mole^{-1}, using molecular weight of CO_2 = 44.011, for internal consistency. From the value of $\Delta H_{r\ 298.15}^\circ$, the heat of formation ($\Delta H_{f\ 298.15}^\circ$) for CO(g) was derived to be -26.417 ± 0.04 kcal. mole^{-1}, which yields D_0(CO) = 11.09 e.v.

The D_0(CO) value has been proposed to be 6.92 to 11.11 e.v. in the past few decades in order to explain data collected from spectroscopic, flame, shock-wave, detonation, and electron-impact studies. Recent evaluations by L. Brewer and A. Searcy, Ann. Rev. Phys. Chem. 7, 259 (1956); M. A. Fineman and A. W. Petrocelli, J. Chem. Phys. 36, 25 (1962); and C. F. Giese and W. B. Maier II, J. Chem. Phys. 39, 197 (1963) favored the value 11.11 e.v., reported by A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., 1953.

The heat of combustion of CO(g) was also determined by J. H. Awbery and E. Griffiths, Proc. Roy. Soc. (London) [A] 141, 1 (1933), R. W. Fenning and F. T. Cotton, ibid., [A] 141, 17 (1933), and W. A. Roth and H. Banse, Arch. Eisenhutten 6, 43 (1932-33).

Heat Capacity and Entropy.

The functions adopted here were obtained from J. Belzer, L. G. Savedoff and H. L. Johnston, Ohio State University, TR 316-6, May 1, 1953, assuming the thermodynamic functions for the naturally occurring isotopic mixture to be the same as those for $C^{12}O^{16}$(g). The spectroscopic constants employed for calculation were reported by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950. The tabulated functions include the second order corrections to the rigid-rotator and harmonic-oscillator molecular model for vibrational anharmonicity, rotational stretching and rotational-vibrational interaction.

The spectroscopic constants listed above are for the naturally occurring isotopic composition given by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

Thermodynamic properties for CO from 70 to 300°K., with pressures to 300 atmospheres were reported by J. G. Hust and R. B. Stewart, NBS-TN-202, National Bureau of Standards, 1963. Calculations of the vapor pressure and heats of vaporization and sublimation of CO and CO_2 below one atmosphere were reported by J. C. Mullins, B. S. Kirk and W. T. Ziegler, U. S. Atomic Energy Commission NP-13862 (1963).

CARBON OXIDE SULFIDE (COS) (IDEAL GAS) MOL. WT. = 60.077

ΔH°_{f0} = -33.11 ± 0.25 kcal. mole^{-1}

Point Group $C_{\infty v}$

$\Delta H^\circ_{f\ 298.15}$ = -33.08 ± 0.25 kcal. mole^{-1}

$S^\circ_{298.15}$ = 55.323 cal. deg.$^{-1}$ mole^{-1}

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$
859 (1)
524 (2)
2064 (1)

Rotational Constant, B_{000} = 0.20287 cm.$^{-1}$ $\sigma = 1$

Ground State Multiplicity = 1

Spectroscopic constants used in calculating corrections to rigid rotator-harmonic oscillator approximation (cm^{-1}):

$\alpha_1 = 0.0006044$
$\alpha_2 = 0.0003539$
$\alpha_3 = 0.001838$
$g_{22} = 3.2$
$X_{11} = -4.0$
$X_{22} = -0.4$
$X_{33} = -7.0$
$X_{12} = -6.8$
$X_{23} = -11.5$
$X_{13} = -4.5$
$A_{000} = 0$
$C_{000} = 0$
$D_{000} = 4.37 \times 10^{-8}$

Heat of Formation

E. Terres and H. Wesemann, Angew. Chem. 45, 795 (1932), report equilibrium constants from 623° to 873°K for the reaction $CO_2(g) + H_2S(g) \rightleftarrows COS(g) + H_2O(g)$. These yield $\Delta H_{r\ 700}$ = 8.19 ± 0.23 kcal, whence $\Delta H_{f\ 298.15}$ for COS is -33.08 ± 0.25 kcal. mole^{-1}. The same authors report equilibrium constants for the reaction $COS(g) + H_2S(g) \rightleftarrows CS_2(g) + H_2O(g)$, but regard these as less reliable than the others. The resulting value of -26.39 kcal. mole^{-1} for $\Delta H_{f\ 298.15}$ of COS has been disregarded.

Heat Capacity and Entropy

J. S. Gordon (private communication, February 1961) has used the constants listed above to calculate C_p from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The constants have been taken from C. A. Burrus and W. Gordy, Phys. Rev. 93, 897 (1954), H. J. Callomon, D. C. McKean, and H. W. Thompson, Proc. Roy. Soc. (London) A208, 341 (1951), A222, 431 (1954), M. W. P. Strandberg, T. Wentink, and R. L. Kyhl, Phys. Rev. 75, 270 (1949), C. H. Townes, A. N. Holden, and F. R. Merritt, Phys. Rev. 74, 1113 (1948), and T. Wentink, J. Chem. Phys. 30, 105 (1959). The thermodynamic functions below 298.15°K have been calculated for the rigidly rotating harmonic oscillator.

Dec. 31, 1960; Mar. 31, 1961; Sept. 30, 1965

CARBON DIOXIDE (CO_2) (IDEAL GAS) MOL. WT. = 44.00995

Point Group $D_{\infty h}$

$S^\circ_{298.15}$ = 51.07 ± 0.03 cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_0$ = -93.965 ± 0.011 kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -94.054 ± 0.011 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$

1342.86 (1)
667.30 (2)
2349.30 (1)

Bond Distance: C-O = 1.16 Å

Bond Angle: O-C-O = 180°

Rotational Constant: B_o = 0.39038 cm.$^{-1}$

$\sigma = 2$

Heat of Formation.

The enthalpy change ($\Delta H^\circ_{r\ 298.15}$) of the reaction C(c, graphite) + O_2(g) = CO_2(g) has been measured by F. H. Dewey and D. R. Harper, J. Res. Natl. Bur. Std. 21, 457 (1938), R. S. Jessup, ibid. 21, 491 (1938), and E. J. Prosen and F. D. Rossini, ibid., 33, 439 (1944). Based on these data, the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for CO_2(g) was reported to be -94.0518 ± 0.0108 kcal. mole^{-1}, using molecular weight of CO_2 = 44.010, by E. J. Prosen, R. S. Jessup and F. D. Rossini, J. Research Natl. Bur. Standards 33, 447 (1944). This value was recalculated to be -94.054 ± 0.011 kcal. mole^{-1}, based on molecular weight of CO_2 = 44.011, for internal consistency.

Heat Capacity and Entropy.

The functions adopted here were obtained from H. W. Woolley, J. Research Nat. Bur. Standards 52, 289 (1954) who calculated the thermodynamic functions by means of a direct summation for the naturally occurring isotopic composition. The spectroscopic constants used are essentially those selected by T. Wentnik, Jr., J. Chem. Phys. 30, 105 (1959). Slightly different sets of spectroscopic constants were obtained by C. P. Courtoy, Mem. soc. roy. Liege 18, 496 (1957) and V. R. Stull, P. J. Wyatt and G. N. Plass, J. Chem. Phys. 37, 1442 (1962). The high-resolution infrared spectrum of O^{18} - enriched CO_2 was examined in the region 5400-1620 cm.$^{-1}$, using an Ebert grating Spectrometer with spectral slit widths ranging from 0.4 to 0.2 cm.$^{-1}$ by C. V. Berney, Ph. D. Thesis, University of Washington, 1962.

The molecular structure was reported by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc. 1945. The rotational constant, B_o, was obtained from H. W. Woolley, loc. cit. The value of bond distance, r_e, was calculated from B_e which was derived from B_o, using B_e-B_o = 0.0011 cm.$^{-1}$ given in G. Herzberg, loc. cit. The principal moment of inertia is I = 7.1495 X 10^{-39} g. cm.^{2}

Heat capacities of CO_2(g) at high pressures were reported by M. P. Vukalovich, V. V. Altunin and A. N. Gureev, Teploenergetika, 12 (7), 58 (1965); K. Krueger, Ver. Deut. Ingr. Z., 106 (32) 1620 (1964), and M. P. Vukalovich and A. N. Gureev, Teploenergetika, 11 (8), 80 (1964).

Bond Angle: O-C-O = 127° ± 8°

σ = [2]

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.1296] x 10^{-116} g^3 cm^6

Heat of Formation.

The heat of formation, ΔHf°_{298} (CO_2^-,g) = -105.5 ± 27 kcal/mol, is estimated from ΔHr°_{298} = 88.6 ± 10 kcal/mol for $HCO_2^-(g) \rightarrow H(g) + CO_2^-(g)$, using the ΔHf°_{298} (HCO_2^-,g) = -142 ± 17 kcal/mol and ΔHf°_{298} (H,g) = 52.1 kcal/mol. The value of ΔHr°_{298} is assumed to be the same as that for $HCOOH(g) \rightarrow H(g) + COOH(g)$. The values of ΔHf°_{298} (HCOOH,g) and ΔHf°_{298} (H,g), -90.5 and 52.1 kcal/mol, respectively, are from "Selected Values of Chemical Thermodynamic Properties," Natl. Bur. Std. Tech. Note 270-1, Washington, D. C., Oct. 1965, and the value of ΔHf°_{298} (COOH,g), -54 ± 3 kcal/mol, is from S. W. Benson, J. Chem. Ed. 42, 502 (1965). The value of ΔHf°_{298} (HCO_2^-,g) is estimated from an approximate lattice energy calculation for sodium formate. The derived electron affinity of CO_2(g) is 11.5 kcal/mol (0.5 eV) with an estimated uncertainty range of 0-40 kcal/mol.

Heat Capacity and Entropy.

The correlations of A. D. Walsh, J. Chem. Soc. 1953, 2266, predict a bent molecular structure for CO_2^- based on its 17 valence electrons. K. O. Hartman and I. C. Hisatsune, J. Chem. Phys. 44, 1913 (1966), measured the asymmetric C-O stretching frequency and derived the bond angle of 127° ± 8° from the infrared spectrum of matrix-isolated CO_2^-. They also estimated the bond distance C-O and the symmetric stretching and the bending vibrational frequencies by the valence force method. These molecular constants are adopted in the tabulation. The three principal moments of inertia are $I_A = 0.4511 \times 10^{-39}$, $I_B = 6.6491 \times 10^{-39}$ and $I_C = 7.1002 \times 10^{-39}$ g cm^2.

D. W. Ovenall and D. H. Whiffen, Mol. Phys. 4, 135 (1961), have derived a bond angle of 134° which is in good agreement with the value selected. This result was obtained from electron spin resonance for the CO_2^- radical trapped in sodium formate.

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ was calculated from the dissociation energy (D°_0) given by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall (1953). H. Barwald, G. Herzberg, and L. Herzberg, Ann. Physik 20, 569 (1934) reported a $D^\circ_0 = 6.9$ e.v. A. G. Gaydon (loc. cit.) reports that a linear Birge-Sponer extrapolation for $X^2\Sigma(\nu, 0\text{-}9)$ gives a $D^\circ_0 = 6.9$ e.v. and that a linear Birge-Sponer extrapolation of the excited states $A^2\Pi$ and $B^2\Sigma$ favored a similar value. Using the spectral data of H. Barwald et al. (loc. cit.), Gaydon concludes that D°_0 is 6 ± 1 e.v. The uncertainty reported by Gaydon (loc. cit.) ± 1 e.v. corresponds to an uncertainty of ± 23.1 kcal. mole^{-1} for the $\Delta H^\circ_{f\ 298.15}$. The 6.9 e.v. of H. Barwald et al. (loc. cit.) would give a $\Delta H^\circ_{f\ 298.15} = 90.6$ kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular constants were taken from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York (1950).

Heat of Formation.

A. Lagerqvist, H. Westerlund, C. V. Wright and R. F. Barrow, Arkiv for Fysik 14, 387 (1958) examined the UV band system of CS and made a new extrapolation of the ground state vibrational levels to find $D_0^\circ = 7.85$ e.v., which leads to $\Delta H_{f\ 298}^\circ$ CS = 55 ± 5.0 kcal. mole^{-1}. H. Schaffer and H. Wiedemeier, Paper presented at the XVIIIth IUPAC Congress Montreal (1961). have measured $\Delta H_{f\ 298.15}^\circ$ CS(g) by an equilibrium method and found 58 ± 3 kcal. mole^{-1}. E. Gallegos and R. W. Kiser, J. Phys. Chem. 65, 1177 (1961) obtained a value of $\Delta H_{f\ 298.15}^\circ$ CS(g) = 55.0 kcal. mole^{-1} from the heat of formation of CS^+ and the ionization potential of CS. C. J. Fincham and R. A. Bergman, J. Metals, 9, 690 (1957) measured the equilibrium between CS_2 and sulphur containing ores. Combining these with similar experiments for H_2S the heat of formation of CS at 298 is calculated to be 69.0 kcal. mole^{-1}. The gases assumed are CS_2, CS, S, S_2, H_2, H_2S, and HS — because of the complex equilibria and the use of outside data for the H_2S equilibrium, the assumption of $P_{H_2} = 1$ atm. and the uncertainty in HS values, this value was given no weight.

Heat Capacity and Entropy.

A. Lagerqvist, et al., loc. cit., give the vibrational constants. The rotational constants are from the microwave measurements of R. C. Mockler and R. Bird, Phys. Rev. 98, 1837 (1955).

Heat of Formation

W. Good and J. P. McCullough, private communication, September 21, 1960, report $\Delta H_{f\ 298.15}^\circ$ from an analysis of combustion calorimetry data of CS_2.

Heat Capacity and Entropy

Functions at 100° and 200°K were calculated by the RRHO approximation using the fundamental vibrational levels of T. Wentink, Jr., J. Chem. Phys. 29, 188 (1958) calculated from zero order levels reported by B. P. Stoicheff, Can. J. Phys. 36, 218 (1958). $S_{298.15}^\circ$ and C_p from 298.15° to 6000°K taken from J. S. Gordon, private communication, February 7, 1961. In addition to the fundamental levels listed above, Gordon, in his calculation of the functions, used the anharmonic constants derived from high resolution Raman spectra by Stoicheff, and the vibration-rotation interaction constants reported by A. H. Guenther, T. A. Wiggins and D. H. Rank, J. Chem. Phys. 28, 682 (1958).

J. P. McCullough, private communication, February 17, 1961, has correlated and summarized the experimental thermodynamic data for CS_2 by a set of empirical equations. The result for C_p is:

$$C_p\ (\pm 0.2\%) = 6.478 + 1.8931 \times 10^{-2}T - 1.3873 \times 10^{-5}T^2 \text{ cal. deg.}^{-1}\text{ mole}^{-1}\ (325\text{-}502°\text{K.})$$

The experimental values of C_p were then fit within 0.08% by a given set of molecular parameters different from that used by Gordon. However, in the temperature range given above, Gordon's calculation is within the uncertainty indicated by McCullough.

Since no method of calculating anharmonic corrections for polyatomic molecules has been programed, Gordon's values were employed.

$\Delta Hf^\circ_{298.15}$ = -17.1 ± 1.5 kcal/mol

Heat of Formation.

The heat of formation is calculated from ΔHr°_{298} = -591.9 kcal/mol for $SiC(\alpha) + 4F_2(g) \rightarrow SiF_4(g) + CF_4(g)$ based on the tentative value of ΔHf°_{298} = -223± 1 kcal/mol for $CF_4(g)$. Greenberg[1] determined the enthalpy of reaction by fluorine bomb calorimetry. Data of Humphrey[2] obtained by oxygen bomb calorimetry yield a ΔHf° which is over 2 kcal more negative; however, this difference is probably within the uncertainties due to use of large amounts of Ti as a kindling agent and to corrections for incomplete combustion. Decomposition pressure data obtained mass spectrometrically by Drowart[3] are in close agreement with the selected ΔHf°, but Knudsen weight loss data of Grieveson[4] and solubility-activity data of Kirkwood[5] yield values less negative by 2 and 3 kcal, respectively. The results are summarized below.

The data of Drowart show a significant drift while those of Grieveson do not, but the latter should be corrected for $C_2Si(g)$ and $CSi_2(g)$ which are present in amounts of about 4 and 3%, respectively, at 2000°K. Silicon carbide may have a small vaporization coefficient, since rates of free evaporation reported by Voronin[6] and Ghoshtagore[7] yield apparent pressures which are smaller by factors of 1/30 to 1/10000.

Source	Method	Reaction	Range, T°K	No. of Points	ΔHr°_{298} (kcal/mol) 2nd Law	ΔHr°_{298} (kcal/mol) 3rd Law	Drift (eu)	ΔHf°_{298} (kcal/mol)

A) $SiC(\alpha) + 4F_2(g) \rightarrow SiF_4(g) + CF_4(g)$

B) $SiC(\alpha) + 2O_2(g) \rightarrow SiO_2(\text{low-quartz}) + CO_2(g)$

C) $SiC(\alpha) \rightarrow C(\text{graph}) + Si(g)$

D) $SiC(\alpha) \rightarrow C(\text{graph}) + Si(l)$

*Value in parentheses is based on authors' data for $Si(l) \rightarrow Si(g)$ rather than JANAF value.

Heat Capacity and Entropy.

Low temperature heat capacities are from data (54-296°K) of Humphrey[2] and are in good agreement with earlier data (54-295°K) of Kelley[8]. The entropy is obtained from Cp° using S°_{50} = 0.038 eu. Cp° above room temperature is based on enthalpy data of Humphrey[2] [389-1789°K], Walker[9] [373-1073°K] and Magnus[10] [372-1172°K]. Maximum deviations of the data from the selected values are 1.4, 2 and -1.7%, respectively; these occur in the range 370-621°K. Kirillin[11] obtained enthalpy data (1114-2843°K) for SiC mixed with 12% free carbon. When corrected for free carbon but not for 0.73% iron impurity, these data deviate by -1±1.5% from the selected values. Enthalpies (793-1790°K) of Fieldhouse[12] are high by 1-8% while those of Maksimenko[13] were not available for analysis.

Transition Data.

SiC(α), also called hexagonal II or 6H, is one of the more common of many hexagonal forms which arise from various possible stacking sequences of the hexagonal SiC layers[14]. The properties of these phases are so similar that they have not been adequately differentiated thermodynamically. It has frequently been assumed that cubic SiC(β) transforms to alpha at about 2300°K, but this seems unlikely since both phases have been prepared over temperature ranges of 1700-3000°K[14]. Heat of formation and equilibrium data indicate that alpha is less stable up to 2000°K. The adopted functions suggest that this is the case at all temperatures; however, the stability difference is small.

Decomposition Data.

The decomposition temperature is calculated as the value at which the total pressure reaches one atm for vapor consisting of C_2Si(44.3 mol %), Si(32.0%), CSi_2(21.2%), Si_2(1.9%), CSi(0.27%), and Si_3(0.25%). The tables predict decomposition to graphite and pure liquid silicon at about 3280°K; however, Scace[15] observed peritectic decomposition to graphite and solution containing 19 atom percent of carbon at 3103±40°K. In contrast, Dolloff[16] reported the peritectic at 2813±40°K and 27 percent carbon. Badami[17] has shown that decomposition in vacuum at lower temperatures (2400°K) leads to graphite.

SILICON CARBIDE, BETA (SiC) (CRYSTAL) GFW = 40.09715

ΔHf°_0 = -17.3 ± 1.5 kcal/mol

$S^\circ_{298.15}$ = 3.97 ± 0.03 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -17.5 ± 1.5 kcal/mol

Td = [3259] °K

Heat of Formation.

The heat of formation is calculated from ΔHr°_{298} = -591.5 kcal/mol for $SiC(\beta)+4F_2(g) \rightarrow SiF_4(g)+CF_4(g)$, based on the tentative value of ΔHf°_{298} = -223 ± 1 kcal/mol for $CF_4(g)$. Greenberg[1] determined the enthalpy of reaction by fluorine bomb calorimetry. Data of Humphrey[2] obtained by oxygen bomb calorimetry yield a ΔHf° which is over 3 kcal more negative; however, this difference is probably within the uncertainties due to use of large amounts of Ti as a kindling agent and to corrections for incomplete combustion. Decomposition pressure data obtained with the Knudsen weight loss method by Davis[3] are in good agreement with the selected ΔHf°, but similar data of Grieveson[4] and solubility-activity data of Rein[5] and d'Entremont[6] yield values less negative by 1.6 to 2.5 kcal. The results are summarized below. Other equilibrium data[5] relating SiC and SiO_2 are not included, pending the revision of tables for SiO_2.

The data of Davis show a serious drift, while those of Grieveson do not; but the latter should be corrected for $C_2Si(g)$ and $CSi_2(g)$ which are present in amounts of about 4 and 3%, respectively, at 2000°K. Silicon carbide may have a small vaporization coefficient, since rates of free evaporation reported by Voronin[7] and Ghoshtagore[8] yield apparent pressures which are smaller by factors of 1/30 to 1/10000.

A) $SiC(\beta) + 4F_2(g) \rightarrow SiF_4(g) + CF_4(g)$

B) $SiC(\beta) + 2O_2(g) \rightarrow SiO_2(\text{low quartz}) + CO_2(g)$

C) $SiC(\beta) \rightarrow C(\text{graph}) + Si(g)$

D) $SiC(\beta) \rightarrow C(\text{graph}) + Si(l)$

*Value in parentheses is based on author's data for $Si(l) \rightarrow Si(g)$ rather than JANAF value.

Heat Capacity and Entropy.

Low temperature heat capacities are from data (54-296°K) of Humphrey[2]. The entropy is obtained from Cp° using S°_{50} = 0.041 eu. Cp° above room temperature is based on Humphrey's enthalpy data (389-1693°K), which show a maximum deviation of ± 1.2% from the selected functions. Humphrey's sample contained about 1% of α-SiC and about 0.6% of other impurities. Kirillin[9] obtained enthalpy data (1114-2843°K) for SiC mixed with 12% free carbon. When corrected for free carbon but not for 0.73% iron impurity, these data deviate by -1±2% from the selected values.

Transition Data.

SiC(β), also called cubic or 3C, has a structure of the diamond or zinc blende type[10]. The cubic phase differs from the many hexagonal forms only in the order of the stacking sequence of the hexagonal SiC layers. It has frequently been assumed that β transforms into α at about 2300°K, but this seems unlikely, since both phases have been prepared over temperature ranges of 1700-3000°K[10]. Heat of formation and equilibrium data indicate that β is more stable up to 2000°K. The adopted functions suggest that this is the case at all temperatures; however, the stability difference is small.

Decomposition Data.

The decomposition temperature is calculated as the value at which the total pressure reaches one atm for vapor consisting of C_2Si(45.4 mol %), Si(32.1%), CSi_2(20.1%), Si_2(1.8%), CSi(0.28%) and Si_3(0.23%). The tables predict decomposition to graphite and pure liquid silicon at about 3337°K; however, Scace[11] observed peritectic decomposition to graphite and solution containing 19 atom percent of carbon at 3103±40°K. In contrast, Dolloff[12] reported the peritectic at 2813±40°K and 27 percent carbon.

[5000]	[3]	[18000]	[1]

ω_e = [1226] cm^{-1} $\omega_e x_e$ = [5] cm^{-1} σ = 1

B_e = [0.6933] cm^{-1} α_e = [0.006] cm^{-1} r_e = [1.7] Å

Heat of Formation.

Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibrium over the systems SiC-graphite[1] and boron-silicon-graphite[2]. Third law analysis of the partial pressures of Si and SiC yields the results summarized below. The adopted value, ΔHf°_{298} = 172 ± 8, is the mean of the two results and the uncertainty reflects the possible effect of an error of up to 4 eu in the functions. The corresponding dissociation energy is D°_0 = 106.5 ± 8 kcal/mol.

*For the reaction C(graphite) + Si(g) = SiC(g)

Heat Capacity and Entropy.

The ground state is assumed to be $^1\Sigma$, as suggested by Weltner and McLeod[3]. By analogy with C_2, there should be a low-lying $^3\Pi$ excited state; this would dominate the thermodynamic functions at temperatures above 2000°K if the level lies below 5000 cm^{-1}. The $^3\Pi$ level is assumed to lie at 1000 cm^{-1}, intermediate between the value[4] observed for C_2 and that estimated for Si_2 (see JANAF table). Additional excited states, $^3\Sigma$, $^1\Pi$, $^1\Delta$ and $^1\Sigma$, are estimated by comparison with those observed or predicted[5] for C_2. The estimates for the electronic levels are relatively uncertain and probably yield an upper limit for the entropy at temperatures where SiC(g) is significant. A probable lower limit for the electronic contribution may be obtained by increasing the $^3\Pi$ level to 7000 cm^{-1} and omitting the other excited states. This would reduce the entropy by 3.5 and 2.0 eu at 2000 and 4000°K.

The vibrational frequency is that estimated by Weltner[3] from a valence bond calculation using $k = 7.44 \times 10^5$ dyn/cm obtained from C_2Si. The constants $\omega_e x_e$, α_e and r_e are estimated by interpolation between those[6,4] for the $^3\Pi_u$ states of Si_2 and C_2. Use of constants based on the $^3\Pi$ state is consistent with the assumption that this state dominates the electronic partition function at high temperatures. B_e is calculated from r_e.

Bond Distance: C-Si = [1.75] Å

Bond Angle: C-Si-Si = [180°] σ = [2]

Rotational Constant: B_0 = [0.0980] cm^{-1}

Heat of Formation.

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor species over the SiC-graphite[1], SiC-silicon[2] and boron-carbon-silicon[3] systems. Third law analysis of the partial pressures of CSi_2 and Si yields the concordant values 127.4, 127.9 and 128.6 kcal/mol. Two of the drifts are rather large, but they are opposite in sign so that no consistent entropy difference is apparent between the data and the tabulated functions. The drifts may be related to the low condensation coefficient for CSi_2 suggested by Drowart[2]. Rates of free evaporation reported by Voronin[4] yield apparent pressures which are lower by a factor of 1/30, thus confirming the existence of a low evaporation coefficient. The adopted value of ΔHf°_{298} = 128 ± 6 kcal/mol includes allowance for an error in the entropy of up to 3 eu.

A) $C(graph) + 2\,Si(g) = CSi_2(g)$ B) $SiC(\alpha) + Si(l) = CSi_2(g)$

Heat Capacity and Entropy.

Weltner and McLeod[5] observed a band system in absorption at 5300 Å in matrix isolation and assigned this tentatively to the transition $^1\Pi_u \leftarrow X^1\Sigma_g^+$ of CSi_2. This assignment is adopted, although the evidence is not at all conclusive. A $^3\Pi_u$ excited state is assumed to lie at 12000 cm^{-1}, presumably arising from the same molecular orbital configuration as the $^1\Pi_u$ state. A linear, symmetric structure is assumed, as suggested by Weltner. The bond distance is estimated by comparison with Si_2, C_2 and C_3. Vibrational frequencies are estimated from a valence bond calculation using $k_1 = 7.46 \times 10^5$ and $k\delta/l^2 = 0.11 \times 10^5$ dyn/cm. The stretching force constant is taken from C_2Si[5], while the bending force constant is from C_2Si and the $^1\Pi_u$ excited state of C_3[5]. The moment of inertia is 28.56×10^{-39} g cm^2.

Dec. 31, 1960; Dec. 31, 1964; June 30, 1968

TITANIUM CARBIDE (TiC) (CRYSTAL) GFW = 59.91115

$\Delta Hf^\circ_0 = -43.7 \pm 1$ kcal/mol

$S^\circ_{298.15} = 5.79 \pm 0.05$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -44.0 \pm 1$ kcal/mol

$Tm = 3290 \pm 15°K$

$\Delta Hm^\circ = [17]$ kcal/mol

Heat of Formation

The adopted $\Delta Hf^\circ_{298} = -44.0$ kcal/mol is derived from $\Delta Hr^\circ_{298} = -275.72$ kcal/mol for reaction (a) determined by Humphrey (1) who burned TiC(c) in an oxygen bomb calorimeter. The author reported that the combustion product TiO_x was >95 per cent rutile and <5 per cent anatase, the heat of formation is calculated assuming the above distribution. The uncertainty adopted is due mainly to the uncertainty in TiO_2(rutile).

Using atomic absorbtion spectroscopy Vidale (2) determined that the pressure ($\log P_{Ti} = -7.269$) of Ti(g) at 1666°K was equal to the pressure of TiC(c) at 2220°K. Using this data for reaction (b) we obtain a $\Delta Hf^\circ_{298} = -43.02$ kcal/mol. Lowell and Williams (3) measured the $\Delta Hf^\circ_{2028} = -43.3 \pm 4$ kcal/mol of TiC(c) directly using a high temperature calorimeter, which reduces to $\Delta Hf^\circ_{298} = -37.7 \pm 4$ kcal/mol.

Fujishiro and Gokcen (4) determined the equilibrium pressure of Ti(g) in reaction (d) in the temperature range 2383-2593°K. Third law analysis of the data yields a $\Delta Hf^\circ_{298} = -31.6$ kcal/mol. Brantley and Beckman (5) measured equilibrium pressures of CO for reaction (e) in the temperature range 1278 - 1428°K. Third law analysis of the data yields a $\Delta Hf^\circ_{298} = -61.9$ kcal/mol.

Heat Capacity and Entropy

Low temperature heat capacities (55 - 295°K) have been taken from Kelley (6). Naylor (7) measured heat contents from 360 to 1738°K and Levinson (8) from 1274 to 2799°K. High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. Above 2799°K the heat capacity is graphically extrapolated. The entropy is based on $S^\circ_{50} - S^\circ_0 = 0.065$ eu.

Melting Data

See liquid table.

Dec. 31, 1960; Dec. 31, 1964; June 30, 1968

TITANIUM CARBIDE (TiC) (LIQUID) GFW = 59.91115

$S^\circ_{298.15}$ = [11.329] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-25.892 ± 1] kcal/mol

Tm = 3290 ± 15°K

ΔHm° = [17] kcal/mol

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(c) by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2200°K the heat capacity is obtained from that of the crystal, above 2200°K it is assumed constant and estimated as 15 gibbs/mol or 7.5 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The adopted Tm is taken from the phase diagram of the system Ti-C, at the composition 50% Ti and 50% C, reported by E. Rudy and D. P. Harmon, Aerojet-General Corporation, BSPN No. 64-6899-735001, Contract AF-33(6115), April 1, 1965. Earlier reports by E. Friederich and L. Sittig, Z. Anorg. Chem. 144, 171(1925) and C. Agte and K. Moers, Z. Anorg. Chem. 198, 233 (1931), gave a Tm of 3430 ± 100°K and 3410 ± 90°K, respectively. ΔHm° is derived from an estimated ΔSm = 2.5 gibbs/g-atom, as suggested by O. Kubaschewski, E. Ll. Evans and C. B. Alcock, "Metallurgical Thermochemistry," Pergamon Press, New York, 1967.

Mar. 31, 1962; June 30, 1964; Dec. 31, 1964

ZIRCONIUM CARBIDE (ZrC) (CRYSTAL) MOL. WT. = 103.231

$\Delta H^\circ_{f\ 0}$ = -46.8 kcal. mole^{-1}

$S^\circ_{298.15}$ = 7.964 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -47.0 ± 3 kcal. mole^{-1}

T_m = 3805 ± 125°K

ΔH°_m = [19] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ = -47.16 ± 1.5 kcal mole^{-1} was calculated from the standard free energy of formation of -38.9 ± 1.5 kcal. mole^{-1} at 2675°K. reported by B. D. Pollock, J. Phys, Chem. 65, 731 (1961). Using spectrophotometric data reported by G. L. Vidale, Missle and Space Vehicle Department, General Electric R61SD147, August, 1961, we calculated $\Delta H_{f\ 298.15}$ = -46.9 ± 1 kcal. mole^{-1}. These values were averaged with $\Delta H_{f\ 298.15}$ = 47.0 ± 0.6 kcal. mole^{-1} reported by A. D. Mah, U. S. Bureau of Mines RI6518 (1964). The equilibria data reported by C. H. Prescott Jr., J. Am. Chem. Soc. 48, 2534 (1926) and V. S. Kutsev, B. F. Ormont, and V. A. Epel'baum, Doklady Akad, Nauk SSSR 104, 567 (1955) were considered but not used.

Heat Capacity and Entropy.

Heat content data over the range 470.8° to 1,174.4°K. were taken from a preliminary report by R. Mezaki, T. F. Jambois, A. K. Gangopadhyay, and J. L. Margrave, Univ. of Wisconsin, Madison, Wisconsin, "Thermodynamic Properties of Inorganic Substances VIII. The High Temperature Heat Contents of Zirconium Carbide and Tantalum Carbide". These data were smoothed by means of the Shomate plot into low temperature data reported by E. F. Westrum Jr. and G. Feick, J. Chem. Eng. Data, 8, 176 (1963). High temperature data reported by D. S. Neel, C. D. Pears, S. Oglesby Jr., Southern Reasearch Institute, Birmingham, Alabama, Technical Documentary Report No. WADD 60-924, p. 134, February 1962, and R. A. McDonald, F. L. Oetting, and H. Prophet, CPIA Publication No. 44(u), P. 213, February 1964 were then used to obtain the heat capacity above 1174°K.

Melting Data.

Melting points were measured by C. Agte and H. Alterthum, Z. tech. Physik 11, 182 (1930) and E. Friederich and L. Sittig, Z. Anorg. Chem., 144, 169 (1925). The value of 3805 ± 125°K. by Agte and Alterthum was chosen. Friederich and Sittig obtained a measurement of 3300°K. but estimated 3500°K. because of the clouding formation of ZrO_2. Wayne L. Worrell, J. Phys. Chem., 68, 954(1964) quoted a value of 3480°C taken from E. K. Storms, Los Alamos Scientific Lab Report LAMS-2674, (1962). The heat of melting is derived from an estimated ΔS_m = 2.5 cal. deg.$^{-1}$ gm. atom^{-1}.

CZr

ZIRCONIUM CARBIDE (ZrC) (LIQUID) MOL. WT. = 103.231

$S^\circ_{298.15}$ = [12.815] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-28.39] kcal. mole^{-1}

T_m = 3805 ± 125°K.

ΔH°_m = [19] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ (l) was obtained from $\Delta H^\circ_{f\ 298.15}$(c) by adding ΔH°_m and the difference between $\Delta H^\circ_{Tm} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p(l) at and below 2500°K. were assumed to be equal to those of ZrC(c). Above 2500°K. the heat capacity was estimated to be constant. $S^\circ_{298.15}$(l) is calculated based on $S^\circ_{298.15}$(c) and an estimated ΔS°_m = 2.5 cal. deg.$^{-1}$ g. atom^{-1}.

Melting Data.

See ZrC(c) table for details.

Heat of Formation

Messerle and Krauss (1) have reported the dissociation energy as 49300 ± 300 cm^{-1} from the variation of the rotational structure cut-off with vibrational level in the $c^1\Pi_g$ state. This state dissociates into $C(^3P) + C^3(P)$, due to an avoided crossing (2), these dissociation products are those of the ground state. The uncertainty in the determination is generous and thus we adopt D°_0 = 140.95 ± 0.9 kcal or $\Delta Hf^\circ_0(C_2, g)$ = 198.2 ± 0.9 kcal/mol, using $\Delta Hf^\circ_0(C, g)$ = 169.576 kcal/mol (3).

Brewer et al. (4) have reviewed several other earlier determinations which confirm ΔHf°_0 = 195 ± 5 kcal/mol. The extensive mass spectrometric data of Drowart et al. (5) yield a 3rd law ΔHf°_0 = 199.2 ± 1.4 kcal/mol in excellent agreement with the adopted value.

Heat Capacity and Entropy

The observed molecular constants and electronic levels were taken from Ballik and Ramsay (2). The estimated parameters are from the correlation calculations of Fougere and Nesbet (6) and Clementi (7), the electronic levels are T_o values. Not all predicted states were included since the contribution of levels above 40000 cm^{-1} is negligible. The functions were calculated from the partition function $Q = Q_t \sum_i Q^i_r Q^i_v g_i \exp(-c_2\epsilon_i/T)$, the values for Q^i_r and Q^i_v were calculated with first order anharmonic corrections. The functions are similar to those reported by Altman (8) and Clementi (7) but include several additional states.

DIMERIC CARBON UNINEGATIVE ION (C_2^-) (IDEAL GAS) GFW = 24.02285

Ground State Configuration $[^2\Sigma]$

$\Delta Hf^\circ_0 = 106 \pm 20$ kcal/mol

$S^\circ_{298.15} = 46.96 \pm 0.05$ gibbs/mol

$\Delta Hf^\circ_{298.15} = 106 \pm 20$ kcal/mol

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	2
[9000]	[4]
18484	[2]

$\omega_e = 1781.04\ cm^{-1}$ $\omega_e x_e = 11.585\ cm^{-1}$ $\sigma = 2$

$B_e = 1.74685\ cm^{-1}$ $\alpha_e = 0.0167\ cm^{-1}$ $r_e = 1.2682$ Å

Heat of Formation

The electron affinity of C_2 has been obtained by Honig (1) as 4 ± 0.8 ev from the difference in heats of sublimation of neutral C_2 and C_2^- and the work function of graphite. Thus, we have the reaction

$$C_2(g) + e^- \rightarrow C_2^-(g) \qquad \Delta H_o = -92.2 \pm 20 \text{ kcal.}$$

Using $\Delta Hf^\circ_0(C_2, g) = 198.2$ kcal/mol (2), we obtain $\Delta Hf^\circ_0(C_2^-, g) = 106 \pm 20$ kcal/mol, which is adopted.

A value for the heat of formation may be obtained from a linear Birge-Sponer extrapolation of the ground state vibrational levels, which gives 195.8 kcal for the reaction

$$C_2^-(g) \rightarrow C(g) + C^-(g).$$

With auxiliary data (2) this yields $\Delta Hf^\circ_0(C_2^-, g) = 114.5$ kcal/mol, in good agreement with the adopted value.

Heat Capacity and Entropy

The molecular constants and electronic levels are from Herzberg and Lagerqvist (3). The values are not definitely ascribed to C_2^- by Herzberg and Lagerqvist, but there is a good deal of evidence to support this assignment. Recently Milligan and Jacox (4) have shown that matrix isolated bands previously attributed to $C_2(g)$ are enhanced in the presence of a photoelectron source. The matrix spectra correspond to the gas system reported by Herzberg and Lagerqvist (3) and leave little doubt that the species is C_2^-.

The estimated electronic level is assumed to be a $^2\Pi$ state and is obtained from the isoelectronic CN(g) (2).

BERYLLIUM CARBIDE (BeC_2) (IDEAL GAS) MOL. WT. = 33.035

Point Group $[C_{\infty v}]$

$S^\circ_{298.15}$ = [52.2] cal. deg.$^{-1}$ mole^{-1}

Ground State Multiplicity = [1]

$\Delta H^\circ_{f\ 0}$ = [134] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [135] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$

[1580] (1)

[423] (1)

[1947] (1)

Bond Distances: Be-C = [1.407] Å C≡C = [1.2] Å

Bond Angle: Be-C≡C = [180°] σ = 1

Rotational Constant: B_0 = [0.4809] cm.$^{-1}$

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ was estimated as a lower positive limit by National Bureau of Standards Report No. 6645, "Preliminary Report on the Thermodynamic Properties of Light-Element Compounds," January, 1960.

Heat Capacity and Entropy.

The vibrational frequencies, bond angle, configuration and moment of inertia, 5.82×10^{-39} g. cm.^{2}, were estimated by Chupka, Berkowitz, Giese, and Inghram, J. Phys. Chem. 62, 611 (1958). Bond distances were calculated assuming the C-C bond distance was the same as in acetylene.

Dec. 31, 1968

DICHLOROACETYLENE (C_2Cl_2) (IDEAL GAS) GFW = 94.9283

Point Group $D_{\infty h}$

ΔHf°_0 = [49.3 ± 10] kcal/mol

$S^\circ_{298.15}$ = [65 ± 3] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [50.1 ± 10] kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[410] (1)
[2200] (1)
[925] (1)
[380] (2)
[165] (2)

Bond Distances: C-C = 1.195Å C-Cl = 1.64Å

Bond Angle: Cl-C-C = 180°

σ = 2

Rotational Constant: $B_0 = 0.046368\ cm^{-1}$

Heat of Formation

The heat of formation of dichloroacetylene is calculated from the estimated $\Delta Hr^\circ_{298} = -53 \pm 10$ kcal/mol for ClC≡CCl(g) + Cl_2(g) → $Cl_2C{=}CCl_2$(g), using $\Delta Hf^\circ_{298}(C_2Cl_4, g) = -2.9$ kcal/mol (1). The value of ΔHr°_{298} is assumed to be the same as that for the reaction HC≡CH(g) + Cl_2(g) → CHCl=CHCl(g), using ΔHf°_{298}(CHCl=CHCl, g) = 1.2 kcal/mol (2).

Heat Capacity and Entropy

The linear molecular structure and bond distances were determined from electron diffraction studies by Hassel and Viervoll (3). The principal moment of inertia is 6.03668×10^{-38} g cm^2.

All five fundamental vibrational frequencies are calculated by the modified valence force method (4) from estimated force constants which are interpolated from those of C_2I_2 (5), CH≡CF (6), CH≡CCl (6), CH≡CBr (6), and C_2D_2 (4).

Bond Distances: Cl - C = 1.724 Å C - C = 1.327 Å

Bond Angle: Cl - C - Cl = 113.3° $\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C = 3.43114 \times 10^{-112}\ g^3\ cm^6$

Heat of Formation

The heat of combustion (ΔE_{293}) of $C_2Cl_4(\ell)$ has been determined by the "Quartz Wool" method by L. Smith, L. Bjellerup, S. Krook and H. Westermark, Acta Chem. Scand. 7, 65 (1953). The free chlorine produced from combustion was reduced to hydrogen chloride by a quartz spiral moistened with a solution of arsenious acid in the combustion bomb. Based on the reported results, the enthalpy change at 298°K for the reaction $C_2Cl_4(\ell)+O_2(g)+2H_2O(\ell) = 2CO_2(g)+4HCl(600H_2O)$ is evaluated as -198.40 kcal/mol, using recent auxiliary data from U. S. Natl. Bur. Std. Tech. Note 270-1, 1965 and V. B. Parker, U. S. Natl. Bur. Std. NSRDS-NBS 2, 1965, and Cp for $C_2Cl_4(\ell)$ from V. Y. Kurbatov, J. Gen. Chem. USSR(Eng. Transl.) 18, 372 (1948). Employing $\Delta Hf^\circ_{298} = -94.054, -39.823$ and -68.315 kcal/mol for $CO_2(g)$, $HCl(600H_2O)$ and $H_2O(\ell)$, respectively, we calculate the heat of formation for $C_2Cl_4(\ell)$ as -12.367 kcal/mol. Incorporating this value with the value $\Delta Hv^\circ_{298} = 9.4$ kcal/mol obtained from E. Eftring, Ph.D. Thesis, University of Lund, 1938, we derive $\Delta Hf^\circ_{298} = -2.97 \pm 0.7$ kcal/mol for $C_2Cl_4(g)$.

Heat Capacity and Entropy

The molecular structure of $C_2Cl_4(g)$ was investigated by the sector-visual method of electron diffraction by C. H. Ramachandra and R. L. Livingston, Current Sci. 27, 330 (1958). The reported bond distances and angle are in agreement with those measured by I. L. Karle and J. Karle, J. Chem. Phys. 20, 63 (1952), using the sector-microphotometer method, and W. N. Lipscomb, Ph.D. Thesis, California Institute of Technology, 1946. The molecular structure has also been determined by L. O. Brockway, J. Y. Beach and L. Pauling, J. Am. Chem. Soc. 57, 2693 (1935), H. de Laszlo, Nature 135, 474 (1935), and R. W. Dornte, J. Chem. Phys. 1, 566 (1933), by use of electron diffraction. The values reported by Ramachandra and Livingston, loc. cit., are adopted.

The vibrational spectra of tetrachloroethylene have been studied by numerous investigators. The vibrational frequencies assigned by D. E. Mann, N. Acquista and E. K. Plyler, J. Res. Natl. Bur. Std. 52, 67 (1954), are adopted here. These authors also reviewed the results of earlier investigations in detail.

The electronic levels and quantum weights are obtained from G. Herzberg, "Electronic Spectra of Polyatomic Molecules," D. Van Nostrand Co., Inc., New York, 1966.

The three principal moments of inertia are: $I_A = 4.88344 \times 10^{-38}$, $I_B = 6.28884 \times 10^{-38}$ and $I_C = 1.11723 \times 10^{-37}$ g cm^2.

Sept. 30, 1967

HEXACHLOROETHANE (C_2Cl_6) (IDEAL GAS) GFW = 236.7403

Point Group D_{3d}

$S^\circ_{298.15}$ = 95.07 gibbs/mol

Ground State Quantum Weight = 1

ΔHf°_0 = -31.54 ± 2.0 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -32.08 ± 2.0 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
976 (1)	678 (1)	223 (2)
431 (1)	377 (1)	778 (2)
164 (1)	858 (2)	267 (2)
Internal rotation	340 (2)	139 (2)

Bond Distances: Cl-C = 1.74 Å C-C = 1.55 Å

Bond Angles: Cl-C-Cl = 110° Cl-C-C = 109° $\sigma = 6$

Product of the Moments of Inertia: $I_AI_BI_C = 1.2358 \times 10^{-111}$ g^3 cm^6

Heat of Formation

Smith et al. (1) determined the heat of combustion of $C_2Cl_6(c)$ to be ΔE_{293} = -718.7 ± 2 cal/g (uncorrected) by use of the "Quartz Wool" method. The free chlorine produced was reduced to HCl by employing the quartz spiral moistened with a solution of arsenious acid in the combustion bomb. Adopting the reported results and recent auxiliary data (2, 3, 4), we evaluate the values ΔHc°_{298} = -173.525 and ΔHf°_{298} = -48.58 kcal/mol for $C_2Cl_6(c)$. Kirkbride (5) measured the enthalpy changes as -32.0 and 4.7 kcal/mol for the following two reactions by solution calorimetry: $C_2Cl_4(\ell)+Cl_2(g) = C_2Cl_6(aq)$ and $C_2Cl_6(c) = C_2Cl_6(aq)$. Hence we obtain ΔHf°_{298} = -49.07 kcal/mol for $C_2Cl_6(c)$, using ΔHf°_{298} (C_2Cl_4, ℓ) = -12.37 kcal/mol. This value is in reasonable agreement with the adopted value -48.58 kcal/mol.

Hexachloroethane (c) has three modifications, namely triclinic, monoclinic and cubic, with transition temperatures of 318 and 345°K (4). The sublimation pressures over the different phases have been measured by Ivin (8), Lee (7), and Nitta (26). Based on these data, values for ΔHs°_{298} (triclinic) are derived by a modified second law method to be 16.5, 17.1 and 14.8 kcal/mol, respectively. The analysis depends on the Cp and ΔHt° data determined by (4). The order of magnitude of the two ΔHt° values is confirmed by R. A. McDonald, private communication, Thermal Research Laboratory, The Dow Chemical Company, Midland, Michigan. Pressures reported by Nelson (6) are systematically lower than the above data by about 10 per cent; therefore, his data are not used. Third law analysis is not applicable to the pressure data due to lack of S°_{298} (triclinic). Adopting ΔHs°_{298} = 16.5 and ΔHf°_{298} = -48.58 kcal/mol for C_2Cl_6 (triclinic), we obtain ΔHf°_{298} = -32.08 kcal/mol for $C_2Cl_6(g)$.

The equilibrium constant at 776°K for the reaction $C_2Cl_6(g) = C_2Cl_4(g) + Cl_2(g)$ was reported as 0.8 ± 0.1 (atm) by Puyo et al. (9). The corresponding enthalpy change at 298°K is evaluated to be 30.8 kcal/mol by the third law method, yielding $\Delta Hf^\circ_{298}(C_2Cl_6, g)$ = -33.77 kcal/mol which is in fair agreement with the adopted one.

Heat Capacity and Entropy

The molecular structure of C_2Cl_6 has been studied previously by means of infrared and Raman spectroscopy (10), X-ray (11), and electron diffraction (12-18). The molecule was found to be in the staggered position in the vapor and solid states. The bond distances and angles adopted here are those reported by Swick et al. (16).

Incomplete assignments of vibrational frequencies for $C_2Cl_6(g)$ were reported by many investigators (21-24). The adopted frequencies, except the torsional mode ν_4, are obtained from Carney et al. (19). The torsional mode is treated as a hindered internal rotation, and thermodynamic properties are calculated (25) from the barrier height of V_0 = 12.8 kcal/mol which was evaluated by Karle (20) from electron diffraction data. The value of S°_{298} is calculated based on S°_{400} = 105.355 eu which is derived from the free rotor value S°_{400} = 108.121 eu by subtraction of the entropy difference between a free rotor and hindered rotor at 400°K. Internal rotation contributions to Cp at temperatures below 350°K could not be calculated since they are beyond the range of the values tabulated by Pitzer (25). These Cp contributions are estimated by graphical interpolation between internal rotation values above 350°K and the corresponding harmonic oscillator values (ν_4 = 67 cm^{-1}) below 150°K. This calculation presumes that the internal rotation approaches harmonic oscillation as $V/RT \gg 1$.

The three principal moments of inertia are: $I_A = I_C = 1.1367 \times 10^{-37}$ and $I_B = 9.5648 \times 10^{-38}$ g cm^2.

1149 (1)	

Bond Distance: C-F = [1.28] Å C-C = [1.20] Å

Bond Angle: F-C-C = [180°] σ = 2

Rotational Constant: B_0 = [0.1179] cm^{-1}

Heat of Formation

M. Farber, M. A. Greenbaum, M. A. Frisch, H. C. Ko, G. Grenier and E. Graper, Rocket Power Inc., 3rd Quarterly Report, AFRPL-TR-67-147, Contract F04611-67-C-0010, May 1967, have obtained equilibrium-weight-change data over the C-CF_4 system. Our reanalysis of these data assumes that the equilibrium constants for CF_4, CF_3 and CF_2 are those in the JANAF Tables, and that C_2F_2 was the only other C-F species present at equilibrium. This gives maximum possible concentrations of C_2F_2 and places a lower limit on the heat of formation. The $\Delta Hf^\circ_{298}(C_2F_2, g)$ values so obtained range from +10 kcal/mol from data at 2023°K to -10 kcal/mol from data at 2373°K; we adopt a weighted mean of +5±5 kcal/mol. This value still predicts complete dimerization of CF at 1 atmosphere pressure below about 2200°K, but only CF would exist under experimental conditions such as the study by Farber.

Farber et al. also investigated the mass spectrum of the vapor over the C-CF_4 system and did not detect any ion ascribable to C_2F_2. This is additional support for the value adopted.

The C-C bond dissociation energy in C_2F_2 is 113 kcal/mol, using the JANAF CF(g) table (Dec. 31st, 1967). This value is 115 kcal weaker than the bond dissociation energy of acetylene. In order to explain such a large decrease, a crossing of the repulsive approach of two $^2\Pi$ CF molecules with an attractive approach of two $^4\Sigma$ CF molecules may be postulated. This follows the reasoning used by J. P. Simons, Nature 205, 1308 (1965), to explain the bond dissociation energy of C_2F_4.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that for $C_2H_2(g)$. The C-F and C-C bond distances are estimated from those in HC ≡ CF reported by J. K. Tyler and J. Sheridan, Trans. Faraday Soc. 59. 2661, 1936. The assymmetric stretching frequency, ν_3 = 1149 cm^{-1}, was observed by J. Heicklen and V. Knight, J. Phys. Chem. 69, 2484 (1965). The other vibrational frequencies were estimated by comparison with those for $C_2H_2(g)$ and $C_2HF(g)$ reported by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand Company, Inc., New York, 1945, G. R. Hunt and M. K. Wilson, J. Chem. Phys. 34, 1301 (1961), and J. K. Brown and J. K. Tyler, Proc. Chem. Soc. 1961, 13 (1961). The moment of inertia is 2.3735 x 10^{-38} g cm^2.

TRIFLUOROACETONITRILE (CF_3CN) (IDEAL GAS) GFW = 95.0242

C_2F_3N

Point Group C_{3v}

ΔHf°_0 = -117.5 ± 0.7 kcal/mol

$S^\circ_{298.15}$ = 71.32 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -118.4 ± 0.7 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
2271 (1)	1215 (2)
1228 (1)	625 (2)
801 (1)	464 (2)
521 (1)	192 (2)

Bond Distance: C-F = 1.335 Å C-C = 1.461 Å CN = 1.153 Å

Bond Angle: F-C-F = 107.5° F-C-C = 111.38° $\sigma = 3$

Product of the Moments of Inertia: $I_AI_BI_C = 1.18645 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, C_2F_4, and CF_3X (X = H, Cl, Br, I, CN). Details of the input data and adjustment are given in (1). Input included a calorimetric link to $NF_3(g)$ and $CF_4(g)$ plus an equilibrium link to $C_2F_6(g)$ and $C_2N_2(g)$. The calorimetric study (2) gave ΔHr° = -824.4 ± 0.6 kcal/mol at 298.15 K for the reaction $3CF_3CN(g) + 5NF_3(g) \rightarrow 6CF_4(g) + 4N_2(g)$. Equilibrium data (3) in the range 865-925 K give ΔHr° (3rd law) = 10.59 and ΔHr° (2nd law) = 10.59 ± 0.20 kcal/mol at 298.15 K for the reaction $C_2F_6(g) + C_2N_2(g) \rightarrow 2CF_3CN(g)$. The entropy difference, ΔSr° (2nd law) - ΔSr° (3rd law), is 0.0 ± 1.5 gibbs/mol. Deviations between the selected ΔHf° and the two observations are 1.37 and 0.15 kcal/mol, respectively, both considerably less than the overall uncertainties including those in auxiliary values of ΔHf°. Subsequent to the adjustment, Curnutt and Sinke (4) reported ΔHr° = -197.6 ± 0.9 kcal/mol from a calorimetric study of $CF_3CN(g) + 1.25\ O_2(g) + 1.5\ H_2O(\ell) \rightarrow 2\ CO_2(g) + 0.5\ N_2(g) + 3\ HF(120\ H_2O)$. Their result of ΔHf° = -118.4 ± 1.2 kcal/mol is confirmation of the selected value.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Danford and Livingston (5) and from microwave data by Sheridan and Gordy (6) and Thomas et al. (7). These studies are in substantial agreement except for a difference of about 0.04 Å in the C-C bond distance. We adopt the results of Thomas et al. (7) since they are based on data for several isotopic species. Principal moments of inertia are $I_A = 14.626 \times 10^{-39}$ and $I_B = I_C = 28.482 \times 10^{-39}\ g\ cm^2$. Vibrational frequencies are taken from the assignments of Edgell and Potter (8). All values except ν_8 are from infrared spectra of the vapor phase. Raman spectra of the liquid provide ν_8 and confirm the infrared data. Similar assignments have been given by Janz and Wait (9) based on spectra of Wait and Janz (10).

Pace and Bobka (11) used low temperature calorimetric data to derive the entropy of the ideal gas at the normal boiling point of 205.47 K. The experimental value of 65.01 ± 0.2 gibbs/mol is in good agreement with 65.03 gibbs/mol obtained from this table. The largest uncertainty in Cp° and S° probably arises from neglect of anharmonicity and rotational distortion. Uncertainty in the entropy is estimated to vary from 0.1 to 0.5 gibbs/mol over the range 300 to 1000°K. Discussions of the neglect of anharmonicity are given on the tables for $CClF_3(g)$ and $CF_4(g)$.

June 30, 1962; June 30, 1963; Mar. 31, 1964; Sept. 30, 1964; June 30, 1969

TETRAFLUOROETHYLENE (C_2F_4) (IDEAL GAS) GFW = 100.0159

Point Group D_{2h}

ΔHf°_0 = -156.6 ± 0.7 kcal/mol

$S^\circ_{298.15}$ = 71.678 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -157.4 ± 0.7 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
1872 (1)	1340 (1)	1337 (1)
778 (1)	551 (1)	218 (1)
394 (1)	406 (1)	1186 (1)
190 (1)	508 (1)	558 (1)

Bond Distance: C-F = 1.313 Å C-C = 1.313 Å

Bond Angle: F-C-F = 114°

σ = 4

Product of the Moments of Inertia: $I_AI_BI_C = 1.5877 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). In this case, the selected ΔHf° corresponds to the weighted average of three calorimetric studies (2, 3) which may be reduced to the following:

Reference	Reaction	$\Delta Hr^\circ_{298.15}$ kcal/mol	$\Delta Hf^\circ_{298.15}$ kcal/mol
(2)	$C_2F_4(g) + CF_4(g) + C(graphite)$	-65.4 ± 0.5	-157.6 ± 0.6
(2)	$C_2F_4(g) + 2H_2(g) \rightarrow 4HF(50\ H_2O) + 2C(graphite)$	-150.9 ± 1.2	-156.2 ± 1.3
(3)	$C_2F_4(g) + 4Na(c) \rightarrow 4NaF(c) + 2C(graphite)$	-392.9 ± 1.3	-157.2 ± 1.4

Amorphous carbon was formed in all three calorimetric reactions and separate combustions were made to refer the observed product to the standard state of graphite. Other calorimetric studies (4, 5, 6) are omitted because of apparent uncertainties in the reductions to the standard-state reactions.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Karle (7), Broun (8) and Young (9). The resulting structures differ in minor respects, particularly in the exact location of the two carbons. Values from Karle (7) are adopted since they are intermediate between the others. Values from Young (9) and Broun (8) correspond to changes of ± 2.2% in the product of the moments of inertia. Principal moments of inertia for the adopted structure are $I_A = 15.30 \times 10^{-39}$, $I_B = 25.46 \times 10^{-39}$ and $I_C = 40.76 \times 10^{-39}$ g cm^2. Vibrational fundamentals are those selected by Shimanouchi (10) from the data of Mann (11), Monfils (12) and Nielsen (13).

Furukawa (14) reported low-temperature calorimetric data from which the ideal gas entropy may be derived as 64.54 ± 0.09 gibbs/mol at 197.53°K. The calculated entropy from this table is also 64.54 eu. The range in values of $I_AI_BI_C$ corresponds to an entropy change of ±0.022 eu.

Sept. 30, 1965; June 30, 1969

Point Group D_{3d}

ΔHf°_0 = -319.2 ± 1.2 kcal/mol

$S^\circ_{298.15}$ = 79.368 ± 0.2 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -321.2 ± 1.2 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
1228 (1)	1117 (1)	376 (2)
807 (1)	714 (1)	1251 (2)
348 (1)	1243 (2)	523 (2)
Torsion	619 (2)	220 (2)

Bond Distance: C-F = 1.32 Å C-C = 1.56 Å

Bond Angle: C-C-F = 109.5 ± 1.5° σ = 6

Product of the Moments of Inertia: $I_AI_BI_C = 6.007 \times 10^{-113}$ g^3 cm^6

Reduced Moment of Inertia: $I_{red} = 7.32 \times 10^{-39}$ g cm^2

Barrier to Internal Rotation: V = 3.96 kcal/mol

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Data pertinent to C_2F_6 are summarized below. Calorimetric data (7) for the reaction of C_2F_6 with potassium were omitted from the adjustment due to insufficient characterization of the products.

Source	Method	Reaction	ΔHr°_{298} kcal/mol	ΔHf°_{298} kcal/mol
(2)	Calorimetric	$3C_2F_6(g) + 2NF_3(g) \rightarrow 6CF_4(g) + N_2(g)$	-311.6 ± 3.0	-321.3 ± 1.2
(3)	Calorimetric	$3CF_3CN(g) + 5NF_3(g) \rightarrow 6CF_4(g) + 4N_2(g)$	-824.4 ± 0.6	----
(4)	Equilibrium	$2CF_3CN(g) \rightarrow C_2F_6(g) + C_2N_2(g)$	-10.59 ± 0.5	-322.2 ± 1.8
(5)	Equilibrium	$C_2F_6(g) + Br_2(g) \rightarrow 2CBrF_3(g)$	3.30 ± 0.7	-320.9 ± 1.6
(6, 5)	Kinetic	$C_2F_6(g) \rightarrow 2CF_3(g)$	97.6 ± 6	-322.4 ± 6

Heat Capacity and Entropy

The adopted molecular structure was derived from electron-diffraction data by Swick and Karle (8). The vibrational frequencies are from the assignment of Carney et al. (9), who reviewed the extensive spectral data. Shimanouchi (10) has selected the same frequencies. Low-temperature calorimetric data were used by Pace and Aston (11) to derive a value for the entropy of the ideal gas of 69.88 ± 0.20 gibbs/mol at 194.87°K. This value is used to fix the barrier to internal rotation at 3960 cal/mol. Thermodynamic functions are calculated from these parameters, using hindered internal rotation in place of a torsional vibration.

An uncertainty of ±0.2 gibbs/mol in the third-law entropy corresponds to a variation in the barrier to internal rotation of about ±700 cal/mol. This range easily includes the barrier of 4300 cal/mol derived by Karle (12) from analysis of the electron-diffraction data (8). Uncertainty in the entropy of this table should not exceed 0.5 gibbs at 1000°K.

Rotational Constant: B_0 = [1.475]cm^{-1}.

Heat of Formation.

The heat of formation of $C_2H(g)$ is not well established; however, we can place reliable upper and lower limits on the value.

T. L. Cottrell, "The Strengths of Chemical Bonds," 2nd Ed., Academic Press, New York, 1958, gives an upper limit for the C-H bond dissociation energy in acetylene, D(HCC-H) $<$121 kcal. This was obtained from the fact that ultra-violet light of 121 kcal/mol energy causes acetylene to form diacetylene and hydrogen; assuming that this process occurs through the CCH radical, the light energy is equated with D(HCC-H). This value of D(HCC-H) gives an upper limit for ΔHf°_{298}(CCH,g) $<$123 kcal/mol.

A lower limit for D(HCC-H) is obtained from a consideration of the C-H bond dissociation energies in ethylene and ethane, D(C_2H_3-H) = 103 kcal and D(C_2H_5-H) = 98 kcal. The heats of formation of the C_2H_3 and C_2H_5 radicals and their parent compounds are taken from S. W. Benson, J. Chem. Educ. 42, 502 (1965). The vibrational frequency of the C-H stretch increases steadily from ethane to ethylene and acetylene. Similarly we expect the bond strength to increase, and so D(HCC-H) $>$103 kcal; this yields ΔHf°_{298}(CCH,g) $>$105 kcal/mol.

F. H. Coats and R. C. Anderson, J. Am. Chem. Soc. 79, 1340 (1957), obtained several values for ΔHf°_{298}(CCH,g) from mass-spectroscopic measurements; their values range from 110 kcal/mol to 153 kcal/mol, but they chose to adopt 112 ± 3 kcal/mol.

Our adopted value of ΔHf°_{298}(CCH,g), 114 ± 7 kcal/mol, is 2 kcal smaller than that estimated by W. Tsang, S. H. Bauer and M. Cowperthwaite, J. Chem. Phys. 36, 1768 (1962).

Heat Capacity and Entropy.

The molecule is assumed to be linear; the bond lengths are assumed to be the same as in acetylene and were taken from L. E. Sutton, "Interatomic Distances Supplement," Special Publication No. 18, The Chemical Society, London, 1965.

The vibrational frequencies are those estimated by M. N. Plooster and T. B. Reed, J. Chem. Phys. 31, 66 (1959). It should be noted that the values of the free energy function given by Plooster and Reed are incorrect due to the neglect of the electronic contributions.

The electronic levels, $X^2\Sigma$ and $A^2\Pi$, were estimated by analogy with those of CN(g) which is isoelectronic; this assumption holds very well in the parent molecules HCCH and HCN (G. Herzberg, "Electronic Spectra and Electronic Structure of Polyatomic Molecules," D. Van Nostrand Co., New York, 1966). The molecule $C_2H_2^+$, which is also isoelectronic with CCH, is predicted to have a $^2\Pi$ ground state by Herzberg, loc. cit.

Dec. 31, 1968

Point Group $C_{\infty v}$ ΔHf°_0 = [50.9 ± 10] kcal/mol

$S^\circ_{298.15}$ = 57.811 gibbs/mol $\Delta Hf^\circ_{298.15}$ = [51.1 ± 10] kcal/mol

Ground State Quantum Weight = 1

Vibrational Freqencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
3340 (1)	604 (2)
2110 (1)	326 (2)
756 (1)	

Bond Distances: C-C = 1.204Å C-H = 1.055Å C-Cl = 1.637Å

Bond Angles: Cl-C-C = 180° C-C-H = 180° $\sigma = 1$

Rotational Constant: $B_0 = 0.188641\ cm^{-1}$

Heat of Formation

The value of ΔHf°_{298} = 51.1 kcal/mol is calculated from the estimated ΔHr°_{298} = -53 ± 10 kcal/mol for HC≡CCl(g) + Cl_2(g) → CHCl=CCl_2(g), using ΔHf°_{298}(CHCl=CCl_2, g) = -1.86 kcal/mol (1). The value of ΔHr°_{298} is assumed to be the same as that for the reaction HC≡CH(g) + Cl_2(g) → CHCl=CHCl(g), using ΔHf°_{298}(C_2H_2, g) = 54.19 kcal/mol (1) and ΔHf°_{298}(CHCl=CHCl, g) = 1.2 kcal/mol (2).

Heat Capacity and Entropy

The linear molecular structure and bond distances were determined from the microwave spectrometrical studies by Tyler and Sheridan (3). Their results are in good agreement with those of Westenberg, Goldstein and Wilson (4). The principal moment of inertia is 1.48381×10^{-38} g cm^2.

The vibrational frequencies were observed in the infrared spectra by Hunt and Wilson (5), and Richardson and Goldstein (6).

Dec. 31, 1967

MONOFLUOROACETYLENE (C_2HF) (IDEAL GAS) GFW = 44.02867

Point Group $C_{\infty v}$

ΔHf°_0 = [30 ± 15] kcal/mol

$S^\circ_{298.15}$ = 55.33 ± 0.01 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [30 ± 15] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
3360 (1)
2250 (1)
1060 (1)
580 (2)
367 (2)

Bond Distances: C-F = 1.279 Å C-C = 1.198 Å C-H = 1.053 Å

Bond Angles: F-C-C = 180° C-C-H = 180° σ = 1

Rotational Constant: B_0 = 0.323571 cm^{-1}

Heat of Formation

The heat of formation is estimated by assuming that the C-C bond strength is the average of those in C_2F_2(113 kcal) and C_2H_2(229 kcal). Combining the average value (171 kcal) with the heats of formation of CF and CH from the JANAF Tables, yields $\Delta Hf^\circ_{298}(C_2HF, g)$ = 30 ± 15 kcal/mol.

Heat Capacity and Entropy

G. R. Hunt and M. K. Wilson, J. Chem. Phys. 34, 1301 (1961), and J. K. Brown and J. K. Tyler, Proc. Chem. Soc. (London) 1961, 13 (1961), have reported the infrared spectrum and have assigned the fundamental frequencies. The frequencies used in the present table are median values of the two sets and are generally within 5 cm^{-1} of each set.

The molecule has been shown to be linear by J. K. Tyler and J. Sheridan, Trans. Faraday Soc. 59, 2661 (1963), who reported the rotational constant B_0.

The electronic ground state is assumed to be $^1\Sigma$ by analogy with C_2H_2.

$X_{15} = -11.75$ $X_{33} = -25.69$ $X_{55} = -2.27$

Values of α_1 not available.

Heat of Formation

Taken from D. D. Wagman, J. E. Kilpatrick, K. S. Pitzer, and F. D. Rossini, J. Research Natl. Bureau Standards 35, 467 (1945).

Heat Capacity and Entropy

J. S. Gordon (private communication, February, 1961) has used the constants listed above to calculate C_p from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954). The constants are from E. E. Bell and H. H. Nielsen, J. Chem. Phys. 18, 1382 (1950) and H. C. Allen, E. D. Tidwell, and E. K. Plyler, J. Research Natl. Bureau Standards 57, 213 (1956). Heat capacities below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

Heat of Formation.

The heat of combustion of ethylene was measured by F. D. Rossini and J. W. Knowlton, J. Res. Natl. Bur. Std. 19, 249 (1937). From the value, $\Delta H^\circ_{r\ 298.15} = -337.28 \pm 0.07$ kcal. mole^{-1} for the reaction $C_2H_4(g) + 3\ O_2(g) = 2\ CO_2(g) + 2\ H_2O(l)$, the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for $C_2H_4(g)$ was derived to be 12.54 ± 0.07 kcal. mole^{-1}. The values of $\Delta H^\circ_{f\ 298.15}$ for $CO_2(g)$ and $H_2O(l)$ used for calculation were obtained from F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and Irving Jaffe, "Selected Values of Chemical Thermodynamic Properties", Circular of the National Bureau of Standards 500, 1952.

Heat Capacity and Entropy.

The molecular structure, bond distances and angles were obtained from H. C. Allen, Jr. and E. K. Plyler, J. Am. Chem. Soc. 80, 2673 (1958). The vibrational frequencies were taken from W. L. Smith and I. M. Mills, J. Chem. Phys. 40, 2095 (1964). Eight of the twelve frequencies were reported by R. L. Arnett and B. L. Crawford, J. Chem. Phys. 18, 118 (1950); B. L. Crawford, J. E. Lancaster and R. Inskeep, J. Chem. Phys. 21, 678 (1953); B. P. Stoicheff, J. Chem. Phys. 21, 755 (1953); T. Feldman, J. Romanko and H. L. Welsh, Can. J. Phys. 34, 737 (1956); and H. C. Allen and E. K. Plyler, loc. cit. G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., New York, 1945, also reported the vibrational frequencies for ethylene as 3019.3 (1), 1623.3 (1), 1342.4 (1), 825.0 (1), 3272.3 (1), 1050 (1), 949.2 (1), 943 (1), 3105.5 (1), 995 (1), 2989.5 (1) and 1443.5 (1) which are very close to the values adopted. The infrared and Raman spectra of ethylene before 1945 have been summarized by G. Herzberg, loc. cit. The molecular structure of ethylene was also determined by L. S. Bartell and R. A. Bonham, J. Chem. Phys. 27, 1414 (1957). Their results, $r_{C-H} = 1.085$ Å, $r_{C-C} = 1.334$ Å and ∡ H-C-H = 116° are in excellent agreement with the values adopted. The three principal moments of inertia are $I_A = 0.5762 \times 10^{-39}$, $I_B = 2.7999 \times 10^{-39}$ and $I_C = 3.3761 \times 10^{-39}$ g. cm.^{2}

Bond Distance: C-H = 1.0802 Å C-O = 1.4363 Å C-C = 1.4728 Å

Bond Angle: H-C-H = 116° 51' H_2-C-C = 158° 5'

H_2-C-O = 142° 45.6'

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 7.42336 \times 10^{-116}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of combustion of ethylene oxide (g) was determined by A. S. Pell and G. Pilcher, Trans. Faraday Soc. 61, 71 (1965) and R. S. Crog and H. Hunt, J. Phys. Chem. 46, 1162 (1942), as -312.15 ± 0.14 and -312.55 ± 0.20 kcal. mole^{-1}, respectively. The corresponding value of $\Delta H^\circ_{f\ 298.15}$ (C_2H_4O, g) was evaluated to be -12.58 ± 0.15 and -12.19 ± 0.22 kcal. mole^{-1}. The former value is adopted.

Heat Capacity and Entropy.

The vibrational frequencies were taken from R. C. Lord and B. Nolin, J. Chem. Phys. 24, 656 (1956). The infrared and Raman sepctra of ethylene oxide have also been examined by J. W. Linnett, J. Chem Phys. 6, 692 (1938) and H. W. Thompson and W. T. Cave, Trans. Faraday Soc., 47, 946 (1951). The vibrational frequencies assigned were slightly different from the ones reported by R. C. Lord and B. Nolin, loc. cit. As a result of analogies between ethylene oxide and ethylene imine, small changes of R. C. Lord and B. Nolin's assignment have been made by W. J. Potts, Spectrochim. Acta, 21, 511 (1965). The bond distances and angles were obtained from G. L. Cunningham, A. W. Boyd and W. D. Gwinn, J. Chem. Phys. 17, 211 (1949). The investigation of the structure of ethylene oxide by electron diffraction was reported by P. C. Ackermann and J. E. Mayer, J. Chem. Phys. 4, 377 (1936) and M. Igarashi, Bull. Chem. Soc. Japan, 26, 330 (1953). The three principal moments of inertia are: $I_A = 3.8052 \times 10^{-39}$, $I_B = 3.2788 \times 10^{-39}$ and $I_C = 5.9499 \times 10^{-39}$ g. cm.^{2}

The calculated heat capacities (307.2 - 371.2°K.) are in good agreement with the experimentally measured ones reported by G. B. Kistiakowsky and W. W. Rice, J. Chem. Phys. 8, 618 (1940).

POTASSIUM CYANIDE, DIMERIC $((KCN)_2)$ (IDEAL GAS) MOL. WT. = 130.2397

Point Group $[D_{2h}]$

$S^\circ_{298.15}$ = [89.15] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = [-2 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-2 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$	ω, cm.$^{-1}$

[130] (1)	[207] (1)	[2158] (1)

Bond Distance: K-C = [2.75] Å C-N = [1.16] Å

Bond Angle: N-C-K = [140]° C-K-C = [100]° K-C-K = [80]° σ = 4

Product of the Moments of Inertia: $I_AI_BI_C = [2.94818 \times 10^{-112}]$ g.^{3} cm.^{6}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ $((KCN)_2$, g) was calculated based on an estimated heat of dissociation, 40 kcal. mole^{-1} for the reaction $(KCN)_2(g) \rightarrow 2KCN(g)$, which was obtained by comparison with that for $(NaCN)_2(g)$.

Heat Capacity and Entropy.

The molecular structure and bond angles were assumed to be the same as those for KCN(c) reported by J. M. Bijvoet and J. A. Lely, Rec. trav. chim. 59, 908 (1940). The C-N bond distance was assumed to be the same as that for KCN(g), and the K-C bond distance was assumed to be 10% longer than that in KCN(g). The vibrational frequencies were estimated by comparison with those for $K_2F_2(g)$. The last six frequencies were adopted from the bending and asymmetric stretching frequencies for KCN(g). The three principal moments of inertia are: $I_A = 4.05745 \times 10^{-38}$, $I_B = 6.73351 \times 10^{-38}$ and $I_C = 1.079096 \times 10^{-37}$ g. cm.^{2}

Dilithium Dicarbide (Li_2C_2)
(Solid) Mol. Wt. = 37.902

Bond Distance: C-N = 1.245 Å

Bond Angle: C-N-C = 180°

$\sigma = 2$

Rotational Constant: B_0 = 0.4535 cm^{-1}

Heat of Formation.

A. J. Merer and D. N. Travis, Can. J. Phys. 44, 353 (1966), state that the observed bond length in CNC(g) indicates double-bonded CN links. The value of the C = N dissociation energy is derived as 147 kcal from the heat of combustion of n-butyl-isobutylidine amine determined by G. E. Coates and L. E. Sutton, J. Chem. Soc. 1187, (1948). However, due to possible extra binding energy from the unpaired electron, we assume here a slightly higher value of 160 kcal. This yields a ΔHf°_{298}(CNC,g) = 133 kcal/mol. It is also possible to calculate another value by assuming that the ratio of the heat of atomization (ΔHa) of Si_2N to that of C_2N(g) is equal to the ratio of the dissociation energies of SiN(g) and CN(g); by this method ΔHf°_{298}(CNC,g) = 144 kcal/mol.

Heat Capacity and Entropy.

Merer and Travis, loc. cit., have observed the ultraviolet absorption spectrum of the CNC radical. They have assigned the configuration, bond distance, and the electronic levels. In addition, they have derived w_2; the remaining frequencies are estimated by comparison with the $^1\Pi$ state of C_3(g), which has been assigned by W. Weltner and D. J. McLeod, J. Chem. Phys. 40, 1305 (1964), and J. Chem. Phys. 45, 3096 (1966).

CYANOGEN (C_2N_2) (IDEAL GAS) MOL. WT. = 52.038

ΔH°_{f0} = 73.428 kcal. mole^{-1}

Point Group $D_{\infty h}$

$\Delta H^\circ_{f\ 298.15}$ = 73.87 ± 0.43 kcal. mole^{-1}

$S^\circ_{298.15}$ = 57.711 cal. deg.$^{-1}$ mole^{-1}

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$
2328.5 (1)
850.6 (1)
2149 (1)
507.2 (2)
240 (2)

Rotational constant B_0 = 0.15752 ± 0.00015 cm.$^{-1}$ CN distance = 1.157 Å CC distance = 1.380 Å σ = 2

Moment of inertia = 1.776(9) X 10^{-38} g. cm.^{2}

Heat of Formation

J. W. Knowlton and E. J. Prosen, J. Research Natl. Bur. Standards 46, 489 (1951), report $\Delta H^\circ_{298.15}$ = -261.94 ± 0.43 kcal. for the reaction $C_2N_2(g) + 2\ O_2(g) \rightarrow 2\ CO_2(g) + N_2(g)$. When corrected for a change in the atomic weight of carbon, this becomes $\Delta H^\circ_{298.15}$ = -261.95 ± 0.43 kcal., whence $\Delta H^\circ_{f\ 298.15}$ for $C_2N_2(g)$ is found to be 73.87 ± 0.43 kcal. mole^{-1}.

Heat Capacity and Entropy

A Langseth and C. K. Møller, Acta Chem. Scand. 4, 725 (1950), determined the vibrational frequencies by Raman spectroscopy. C. K. Møller and B. P. Stoicheff, Can. J. Phys. 32, 625 (1954), determined B_0 by Raman spectroscopy and calculated the bond lengths listed above. These agree with lengths found from electron-diffraction measurements by Langseth and Møller, loc. cit., (CN distance = 1.15 Å, CC distance = 1.38 Å) and L. Pauling, H. D. Springall, and K. J. Palmer, J. Am. Chem. Soc. 61, 927 (1939) (CN distance = 1.16 ± 0.02 Å, CC distance = 1.37 ± 0.02 Å). From measurements reported by R. A. Ruehrwein and W. F. Giauque, J. Am. Chem. Soc. 61, 2940 (1939), $S^\circ_{298.15}$ is calculated by the third law to be 57.63 cal. deg.$^{-1}$ mole^{-1}, in satisfactory agreement with the value calculated here.

Bond Distance: N-C = [1.16] Å C-Na = [2.19] Å

Bond Angle: C-Na-C = [105]° Na-C-Na = [75]° N-C-Na = [142.5]° $\sigma = [4]$

Product of the Moments of Inertia: $I_AI_BI_C = [4.48269 \times 10^{-113}]$ g.^{3} cm.^{6}

Heat of Formation.

The mass spectra of vapors from samples of NaCN have been observed by R. F. Porter, J. Chem. Phys. 35, 318 (1961), at temperatures around 1000°K. The results indicate that the compound evaporates as NaCN(g) and $Na_2(CN)_2(g)$. A comparison of relative ion currents produced by electron bombardment of NaCN vapors effusing from single - and double-oven-type Knudsen cells, yielded information on the partial pressures of monomer and dimer. Based on the partial pressures for NaCN(g) and $(NaCN)_2(g)$ reported at temperatures, 903-1049°K., the vapor pressures of $(NaCN)_2(g)$ over NaCN(l), 1078.2-1626.2°K., were calculated from the total vapor pressure measurements reported by C. K. Ingold, J. Chem. Soc. 123, 885 (1923). By the second and third law methods, the values of $\Delta H_v^\circ{}_{298.15}(l \rightarrow \text{dimer})$ were evaluated to be 38.89 and 38.21 kcal. mole^{-1}, respectively. Using the third law value, the heat of formation for $(NaCN)_2(g)$ was evaluated.

Heat Capacity and Entropy.

The molecular structure, bond distances and C-Na-C bond angle were estimated by R. F. Porter, loc. cit. The vibrational frequencies were estimated by comparison with those for NaCl(g). The last six frequencies were the bending and asymmetric stretching frequencies for NaCN(g). The three principal moments of inertia are: $I_A = 1.3570 \times 10^{-38}$, $I_B = 5.1090 \times 10^{-38}$ and $I_C = 6.4660 \times 10^{-38}$ g. cm.^{2}

$\sigma = 1$

Heat of Formation.

The adopted heat of formation, $\Delta Hf^\circ_{298.15}$ (C_2O,g) = 68.5 kcal/mol, was calculated from the heat of reaction ΔHr°_{298} = 65.5 kcal/mol for $C_3O_2(g) = C_2O(g) + CO(g)$ using all JANAF functions (dated Sept. 30, 1965). The value of ΔHr° was obtained from the third law calculation of the equilibrium constant (Kp = 3.3 x 10^{-6} atm at 1060°K) which was determined in the studies of decomposition rate of $C_3O_2(g)$ by H. B. Palmer and W. D. Cross, Carbon 3, 475 (1966).

M. E. Jacox, D. E. Milligan, N. G. Moll, and W. E. Thompson, J. Chem. Phys. 43, 3745 (1965), have observed the photo-dissociation of C_2O near 5000Å, which corresponds to a minimum of 57 kcal/mol for $C_2O(g) \rightarrow C(g) + CO(g)$. This yields $\Delta Hf^\circ_{298}(C_2O,g) \leq 87$ kcal/mol, which was not adopted because the irradiation was not monochromatic and thus possibly contained all wavelengths below 5000Å.

Heat Capacity and Entropy.

Jacox et al., loc. cit., have observed three vibrational fundamentals in the infrared spectrum by matrix isolation, and suggested a linear structure with $^3\Sigma$ ground state for the CCO radical (g). They also estimated the bond distances C-C = 1.160 Å and C-O = 1.279 Å based on the structural analogy between the carbon suboxide and the CCO radical. The principal moment of inertia is 6.8525 x 10^{-39} g cm^2. K. D. Bayes, J. Am. Chem. Soc. 85, 1730 (1963), has predicted that the $^1\Delta$ and $^1\Sigma$ states lie respectively 0.5 and 0.8 eV above the ground state. These two electronic states have been included in the tabulation.

Bond Distance: C-C = [1.28] Å C-Si = [1.75] Å

Bond Angle: C-C-Si = 180° σ = 1

Rotational Constant: B_0 = [0.2012] cm^{-1}

Heat of Formation.

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibria over the systems SiC-graphite[1], SiC-silicon[2] and boron-carbon-silicon[3]. Third law analysis of the partial pressures of C_2Si and Si lead to the concordant values 146.7, 149.0 and 146.0 kcal/mol. Although the drifts all suggest that the entropy of C_2Si may be about 3.5 eu less than tabulated, this is of doubtful significance because the uncertainty bands are so large. The low condensation coefficient suggested by Drowart[2] may also be involved. Rates of free evaporation reported by Voronin[4] lead to apparent pressures which are smaller by a factor of 1/30, thus confirming the existence of a low evaporation coefficient. The adopted value of ΔHf°_{298} = 147 ± 7 kcal/mol includes allowance for the unlikely possibility that the entropy may be in error by up to 3.5 eu.

Source	Method	Reaction	Range, T°K	No. of Points	ΔHr°_{298}(kcal/mol) 2nd Law	3rd Law	Drift (eu)	ΔHf°_{298} (kcal/mol)

Drowart (1960)	" "	B	1935-2160	4	188±10	194.8	3.3±4.9	149.0
Verhaegen (1964)	" "	A	2166-2344	5	30±16	38.31	3.9±7.2	146.0

A) 2 C(graph) + Si(g) = $C_2Si(g)$

B) 2SiC(α) = Si(l) + $C_2Si(g)$

Heat Capacity and Entropy.

The known molecular constants are from the assignments of Weltner and McLeod[5]. These authors observed the infrared spectrum, emission spectrum and visible absorption spectrum of C_2Si in matrix isolation. The matrix data allowed more certain assignment of the A-X band system of the gas as observed by Kleman[6] and McKellar[7]. Weltner concluded that this system probably involves transitions between a $^1\Sigma^+$ ground state and a $^1\Pi$ excited state. The two stretching frequencies were observed in the matrix infrared spectrum,whereas the bending mode, 300 cm^{-1}, was derived solely from the analysis of the A-X band system. The analysis presumed a linear unsymmetrical structure for the molecule.

A $^3\Pi$ excited state is assumed to lie 7000 cm^{-1} below the $^1\Pi$ state,which presumably arises from the same molecular orbital configuration. The effect of the estimated level is to increase the entropy by about 0.2 and 1.8 eu at 3000 and 6000°K. Bond distances are estimated by comparison with those in Si_2, C_2 and C_3. The moment of inertia is 13.91 x 10^{-39} g cm^2.

Dec. 31, 1960; Dec. 31, 1969

Point Group $D_{\infty h}$

ΔHf°_0 = 194 ± 4 kcal/mol

$S^\circ_{298.15}$ = 56.7 ± 3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 196 ± 4 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω_i, cm^{-1}
1225 (1)
63.5 (2)
2040 (1)

The contribution of the doubly degenerate bending frequency was approximated by direct summation of the following levels (cm^{-1}): 0, 63.5, 132.7, 207.4, 286.5, 370.5, 458.2, and 650 x n where n = 1 to 76. The contribution to each function due to these levels was doubled to account for the degeneracy.

Bond Distance: C-C = 1.277 Å

Bond Angle: C-C-C = 180°

σ = 2

Rotational Constant: B_0 = 0.4305 cm^{-1}

Heat of Formation

Drowart et al. (1) have measured mass spectrometrically the ion intensity ratio C_3^+/C^+ as a function of temperature from 1800 to 2700°K. We derive from a 2nd law analysis of their data ΔHf_{2200} = 185.2 ± 3.3 kcal, and S_{2200} = 74.9 ± 2.8 eu by calculation of the absolute pressure from the vapor pressure of monatomic carbon and a relative ionization cross-section ratio of 2.3. The entropy uncertainty includes 1.3 eu for uncertainty in the absolute pressure. Several earlier mass-spectrometric determinations (2, 3, 4) are in reasonable agreement. The absolute magnitude of the pressure is also confirmed by the work of Thorn and Winslow (5) who measured the total pressure of all species over graphite as 1.2 to 4.8 x 10^{-7} atm. at 2400°K. Subtracting the JANAF values for C and C_2 we obtain C_3 = 5.4 x 10^{-8} to 2.2 x 10^{-7} atm., which compares with Drowart's value of 3.3 x 10^{-8} to 1.3 x 10^{-7} atm. The 2nd law heat of formation is reported (5) to be ΔH_{2400} = 184.4 but the range is only 80°K. It does, however, confirm the magnitude of the mass-spectrometric values for both heat and entropy. We have adopted a heat of formation within the uncertainty limits of Drowart's measurements which with the adopted functions yields pressures in the 2000-3000°K range consistent with the measurements. We were not able to generate functions which agree exactly with the 2nd law entropies, since even direct summation over only the observed levels of the bending frequency gives an entropy which is already too large.

Heat Capacity and Entropy

The stretching frequencies are from Merer (6), Weltner et al. (7) and Weltner and McLeod (8). The bending frequency and its harmonics are from Gausset et al. (9) and Merer (6). The rotational constant and bond distance are from Gausset et al. (9).

As indicated briefly above, the calculated entropy of C_3 gas is higher than the experimental value even when a summation is performed only over the observed first six levels of the bending frequency. Treatment of the vibration as a harmonic oscillator or as a anharmonic oscillator gives values considerably higher. Strauss and Thiele (10) have also calculated functions based on a quartic potential function which still yields values several units higher than the experiments. In order to reduce the entropy to the approximate range of the measurements we have made the assumption that the potential function is of an unusual form above the sixth vibrational level. We assume that the large amplitude of the bending vibration causes a drastic change in the function, possibly due to the increasing repulsion between end carbons, as the amplitude increases. Thus, we assume a very steeply rising potential above the sixth vibrational level. We have chosen to represent this part of the potential by a harmonic oscillator of 650 cm^{-1}. The choice of 650 cm^{-1} is arbitrary, but is not unreasonable for a bending vibration, and yields functions which approximate the experimental data.

In order to explain the observed spectrum of C_3O_2, a molecule with a bending frequency of 63 cm^{-1}, Smith and Barrett (11) have proposed that potential maxima occur in the bending potential away from linearity. Thus, the adoption of an unusual potential function for C_3 bending may be justifiable. We do not claim that our functions are necessarily correct but only that they include all known facts and satisfy the experimental equilibrium observations. Further investigation of the carbon vapor pressure and of the higher vibrational levels of C_3 is desirable.

Dec. 31, 1960; June 30, 1963; Sept. 30, 1965

TETRALUMINUM TRICARBIDE (Al_4C_3) (CRYSTAL) MOL. WT. = 143.95945

$\Delta H_f^\circ{}_0 = -50.35 \pm 1.6$ kcal. mole^{-1}

$S_{298.15} = 21.26 \pm 0.3$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = -51.55 \pm 1.6$ kcal. mole^{-1}

$T_m = [2500]$°K.

ΔH_m° = Unknown

Heat of Formation.

The $\Delta H_f^\circ{}_{298.15} = -51.55 \pm 1.6$ kcal. mole^{-1} is the average value of $\Delta H_f^\circ{}_{298.15} = -49.7 \pm 1.2$ kcal. mole^{-1} by R. C. King and G. T. Armstrong, National Bureau of Standards Report No. 8504 (1964) and that of $\Delta H_f^\circ{}_{298.15} = -53.4 \pm 2.0$ kcal. mole^{-1} by A. D. Mah, United States Bureau of Mines, Report No. 6415 (1964). Both measured the heat of reaction $Al_4C_3(c) + 6O_2(g) \rightarrow 2Al_2O_3(c,\alpha) + 3CO_2(g)$ and used their $\Delta H_r^\circ{}_{298.15}$ and the $\Delta H_f^\circ{}_{298.15}$ of $Al_2O_3(c)$ and $CO_2(g)$ to calculate the $\Delta H_f^\circ{}_{298.15}$ of $Al_4C_3(c)$. The $\Delta H_r^\circ{}_{298.15}$ measured by King and Armstrong was -1033.3 ± 1.1 kcal. mole^{-1}, the $\Delta H_r^\circ{}_{298.15}$ measured by Mah was -1029.6 ± 1.9 kcal. mole.

Heat Capacity and Entropy.

The low temperature heat capacities, 18-390°K., were measured by W. G. Saba and G. T. Furukawa, National Bureau of Standards Report 7587, July 1, 1962. The high temperature heat capacities, 273-1173°K., were measured by A. C. Victor, W. R. Thurber, and T. B. Douglas, National Bureau of Standards Report 7437, January 1, 1962. These two sets of heat capacity data were joined smoothly and extrapolated to 2000°K. by W. G. Saba and G. T. Furukawa, loc. cit. The values of C_p above 2000°K were estimated by extrapolation graphically. $S^\circ_{298.15}$ was reported by W. G. Saba and G. T. Furukawa, loc. cit., using S°_{20}(extrap.) = 0.013 cal. deg.$^{-1}$ mole^{-1}.

Melting Temperature.

T_m was estimated by O. Ruff and E. Jellinek, Z. anorg. u. allgem. Chem. 97, 312 (1916).

Dimagnesium Tricarbide (Mg_2C_3)

CARBON SUBOXIDE (C_3O_2) (IDEAL GAS) GFW = 68.03225

Point Group $D_{\infty h}$

$\Delta Hf^\circ_0 = -23.14 \pm 0.44$ kcal/mol

$S^\circ_{298.15} = 65.959 \pm 0.2$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -22.38 \pm 0.44$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
2200 (1)	2258 (1)	550 (2)
830 (1)	1573 (1)	63 (2)
	577 (2)	

Bond Distances: C-C = 1.28 Å C-O = 1.16 Å

Bond Angles: C-C-C = 180° O-C-C = 180° σ = 2

Rotational Constant: $B_0 = 0.073206\ cm^{-1}$

Heat of Formation

Kybett et al. (1) have determined the heat of combustion of the liquid form under its own pressure using the sample from the heat capacity determinations (2).

The average of four determinations gave $\Delta Hf^\circ_{298}(\ell) = -28.03 \pm 0.24$ kcal/mol; the authors report -29.03 due to an arithmetic error. The sample was 99.98 mole percent pure. McDougall et al. (2) measured $\Delta Hv^\circ_{230} = 6.421 \pm 0.012$ kcal/mol from which we calculate $\Delta Hv^\circ_{298} = 5.65 \pm 0.2$ kcal/mol. Thus the heat of formation of the gas is found to be -22.38 ± 0.44 kcal/mol.

Heat Capacity and Entropy

There has been considerable controversy as to the configuration of this molecule and the assignment of its vibrational frequencies. However, the evidence seems fairly conclusive for the linearity of the molecule from the work of Lafferty et al. (3) and Miller et al. (4). The rotational constant adopted here is that found by Lafferty et al. (3) and the vibrational frequencies are those reported by Miller et al. (4), except for ν_7 which is taken from Miller et al. (5) and Borgers (7). The low frequency Π_u mode is confirmed by the work of McDougall et al. (2), who measured the low temperature entropy of $C_3O_2(c)$ and (ℓ) and also the heat of vaporization. From a comparison of the entropy calculated statistically and that measured, they conclude $\nu_7 = 63.2\ cm^{-1}$. The values adopted are confirmed by third law analysis of the vapor pressure data of McDougall et al. (5) which indicate a heat of vaporization in fair agreement with their calorimetric value. The drift in the third law analysis indicates that the entropy of the solid is too low or that of the gas is too high by 1 eu. Alternatively as systematic error in the pressure measurements could have caused this deviation.

The bond distances are taken from the electron diffraction experiments of Livingston et al. (6) and are in good accord with the adopted rotational constant.

Bond Angle: C-C-C = [180°]

σ = 2

Rotational Constant: B_0 = [0.17132] cm^{-1}

Heat of Formation

The heat of formation is obtained from the mass-spectrometric results of Drowart et al. (1) who obtained ΔHf°_{2400} = 226 ± 7 kcal/mol. This was obtained from a 2nd law analysis of the ion intensity ratio C_4^+/C^+ over a temperature range of 2200-2700°K. The absolute pressure, obtained from a knowledge of the monatomic carbon vapor pressure and an estimated ionization cross-section ratio of 4.96, yields a 2nd law entropy at 2400°K of 90.5 ± 3 eu. The uncertainty in the ionization cross-section ratio is probably no more than a factor of two which gives an overall entropy uncertainty of ±4.5 eu. The heats of formation at temperatures other than 2400°K depend on the functions adopted, for a discussion of these see below.

Heat Capacity and Entropy

The molecular properties of C_4 are all estimated. We have chosen a set of functions which is consistent with the mass-spectrometric observations of Drowart et al. (1). The thermodynamic functions of C_4 were first estimated by Pitzer and Clementi (2) but the basis for this estimate has completely changed. Originally they were calculated by analogy with C_3, C_3O_2 and CO_2, but the discovery of very low bending frequencies in C_3 and C_3O_2 complicated the picture by raising the calculated entropies significantly. Sandborn (3) has correlated the bending force constants in several related triatomics and has estimated the vibrational frequencies in C_4 and C_5. These vibrational frequencies yield high entropies outside the limits of the second law determination. Since these frequencies are estimates based on a basically triatomic correlation we have chosen to adopt two bending frequencies of 550 cm^{-1} rather than the 200 cm^{-1} and 440 cm^{-1} estimated by Sandborn. In addition we have assumed that the ground state arising from a π^2 term is $^1\Sigma$ and not $^3\Sigma$ as assumed by Pitzer and Clementi. The basis for both these changes is to make the functions conform to the only available measured data. Use of the present table will yield values for the vapor pressure of C_4 in excellent agreement with the measurements in the 2000-3000°K range. Outside this range they provide only a general indication of the variation since they may not correspond to the real situation.

The stretching frequencies are from Sandborn (3) and the bond length is estimated from C_3.

Point Group T_d

Heat of Formation. ΔH_f° 298.15 was estimated.

Heat Capacity and Entropy. C_p and $S^\circ_{298.15}$ were taken from G. Janz, Y. Mikawa, and F. Behnke, private communication, March 16, 1960.

Tetracarbon Dinitride (C_4N_2)

(Ideal Gas) Mol. Wt. = 76.06

Heat of Formation

G. T. Armstrong and S. Marantz, J. Phys. Chem. 64, 1776 (1960), measured the heat of combustion of the liquid for which they obtain a $\Delta H_{f\ 298.15}^\circ$ of 120.6 kcal. mole^{-1} using 94.05 kcal. mole^{-1} for $\Delta H_{f\ 298.15}^\circ$ of $CO_2(g)$. They calculate the $\Delta H_{f\ 298.15}^\circ$ of $C_4N_2(g)$ with a ΔH_{vap} taken from A. J. Saggiomo, J. Org. Chem. 22, 1171 (1957).

Heat Capacities and Entropies

Bond lengths determined by F. A. Miller and R. B. Hannan Jr., J. Chem. Phys. 21, 110 (1953) from X-ray diffraction measurements on the solid. The vibrational frequencies were observed in the infra red and Raman by F. A. Miller, R. B. Hannan Jr., and L. R. Cousins, J. Chem. Phys. 23, 2127 (1955).

Bond Distance: C-C = [1.28] Å

Bond Angle: C-C-C = [180°]

Rotational Constant = B_0 = [0.085662] cm^{-1}

$\sigma = 2$

Heat of Formation

The heat of formation is obtained from the mass-spectrometric results of Drowart et al. (1) who obtained ΔHf°_{2400} = 230 ± 5 kcal/mol. This was obtained from a 2nd law analysis of the ion intensity ratio C_5^+/C^+ over a temperature range of 2200-2700°K. The absolute pressure, obtained from a knowledge of the monatomic carbon vapor pressure and an estimated ionization cross-section ratio of 6.3, yields a 2nd law entropy at 2400°K of 103.7 ± 2 eu. The uncertainty in the ionization cross-section ratio is probably no more than a factor of two which gives an overall entropy uncertainty of ±3.5 eu. The heats of formation at temperatures other than 2400°K depend on the functions adopted, for a discussion of these see below.

Heat Capacity and Entropy

The molecular properties of C_5 are all estimated. We have chosen a set of functions which is consistent with the mass-spectrometric observations of Drowart et al. (1). The thermodynamic functions of C_5 were first estimated by Pitzer and Clementi (2) but the basis for this estimate has completely changed. Originally they were calculated by analogy with C_3, C_3O_2 and CO_2, but the discovery of very low bending frequencies in C_3 and C_3O_2 complicated the picture by raising the calculated entropies significantly. Sandborn (3) has correlated the bending force constants in several related triatomics and has estimated the vibrational frequencies in C_4 and C_5. These vibrational frequencies yield high entropies outside the limits of the second law determination. Since these frequencies are estimates, based on a basically triatomic correlation we have chosen to adopt three doubly degenerate bending frequencies of 550 cm^{-1} in place of the 130 cm^{-1}, 330 cm^{-1} and 520 cm^{-1} frequencies estimated by Sandborn. The basis for this change is to make the functions conform to the only available measured data. Use of the present tables will yield values for the vapor pressure of C_4 in excellent agreement with the measurements in the 2000-3000°K range. Outside this range they provide only a general indication of the variation since they may not correspond to the real situation.

The stretching frequencies are from Sandborn (3) and the bond length is estimated equal to that in C_3.

$S^\circ_{298.15}$ = 9.93 ± 0.06 gibbs/mol

Tt = 721 ± 2°K

ΔHf°_0 = 0 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 0 kcal/mol

ΔHt° = 0.220 ± 0.05 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 42.85 ± 0.3 kcal/mol

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacity data of Griffel et al. (1), 1.8° to 4.2°K, Roberts (2), 1.5° to 20°K, and Clusius and Vaughen (3), 10° to 200°K, were fit with polynomial expressions. Up to 20°K the three sets fit the adopted curve within ±6% with a maximum deviation of 14%. This is considered excellent agreement since the heat capacity is only 0.35 gibbs/mol at 20°K. From 20° to 200°K the data of Clusius were within ±1% of the adopted polynomial. The data of Gunther (4), 22° to 62°K, generally deviated from the adopted curve by 10%. The polynomial fit of the data of Clusius was arranged to be linear in temperature at high temperatures and was extrapolated to 298°K. The data of Eastman et al. (5), 67° to 293°K, were consistently high by 5.8 to 9% over the whole range. The extrapolation of the heat capacity to 6.28 gibbs/mol at 298°K is further justified by comparison with the heat capacity of magnesium, which is almost identical to that of calcium over the whole range, if its temperature scale is multiplied by 0.75.

The heat capacity between 298° and 721°K was obtained by forcing a polynomial of the type $H = aT^2 + bT + c + d/T$ through 298° with a slope of 6.28 and also through a value of H_{721} = 2736 cal, and making a good fit of the adopted low temperature enthalpies. The choice of H_{721} = 2736 cal was made, since Zalesinski and Zulinsky (6), Jauch (7), and Eastman et al. (8) were in essential agreement in the beta-phase at this temperature. The enthalpy of transition was subtracted to give the adopted value. The individual measurements of Jauch (7) were not available, but the value at 720°K could be read from a small plot with reasonable accuracy; Eastman et al. (8) gave only an equation for their data.

There is no question that reliable measurements of the heat capacity and enthalpy are needed in the range 200° to 700°K.

Transition Data

The temperature of transition was that reported by Peterson and Fattore (9) and confirmed by Chiotti et al. (10). Earlier reports on impure specimens ranged from 718° to 737°K and were not considered. The heat of transition was measured by Chiotti et al. (10) using an adiabatic high temperature calorimeter, and is in agreement with that reported by Kubaschewski (11) of 0.24 ± 0.04 kcal from enthalpy data.

Sublimation Data

See Ca(g) for details.

Dec. 31, 1968

ΔHf_0 = unknown

$S^\circ_{298.15}$ = 10.15 gibbs/mol

$\Delta Hf_{298.15}$ = 0.117 ± 0.05 kcal/mol

Tt = 721 ± 2°K

ΔHt° = 0.220 ± 0.05 kcal/mol

Tm = 1112 ± 2°K

ΔHm° = 2.04 ± 0.10 kcal/mol

Heat of Formation

Obtained from that of α-Ca by adding ΔHt and the difference in $H_{721} - H_{298}$ for α- and β-Ca.

Heat Capacity and Entropy

The enthalpy at 721°K was fixed as described on the α-Ca table. The data of Jauch (1), and Zalesinski and Zulinski (2), and Eastman et al. (3) were then fitted by an equation of the form $H = a + bT + cT^2$ where a = -1315, b = 4.014 and c = 0.00265. The values of Jauch, read from a small graph, fit within 1% generally and within 2% maximum deviation; those of Zalesinski and Zulinski fit within 0.7% with the exception of the highest point which differed by 1.8%. The data of Eastman et al. vary from 3.6% high to 0.4% low. The entropy was obtained in a manner analogous to the heat of formation.

Transition Data

See the α-Ca table for details.

Melting Data

The melting point is that reported by Peterson and Fattore (4) and confirmed by Chiotti et al. (5). Earlier reports on less pure specimens ranged from 1083° to 1122°K. The heat of melting was measured by Chiotti et al. (5) using an adiabatic high temperature calorimeter, and is in agreement with that reported by Kubaschewski (6) of 2.07 ± 0.1 kcal/mol from enthalpy data.

Dec. 31, 1968

CALCIUM (Ca) (LIQUID) GFW = 40.08

Ca

$S^\circ_{298.15}$ = 12.105 gibbs/mol

Tm = 1112 ± 2°K

Tb = 1767.4 ± 15°K

$\Delta Hf^\circ_{298.15}$ = 2.606 ± 0.1 kcal/mol

ΔHm° = 2.04 ± 0.10 kcal/mol

ΔHv° = 36.9668 kcal/mol

Heat of Formation

Obtained from that of β-Ca by adding ΔHm° and the difference between $H_{1112} - H_{298}$ for β-Ca and liquid.

Heat Capacity and Entropy

The heat capacity was derived as constant from the enthalpy values of R. Jauch, Diplomarbeit, Techn. Hochschule Stuttgart, 1946, quoted by O. Kubaschewski, Z. Elektrochem. 54, 275 (1950). The entropy was obtained in a manner analogous to the heat of formation.

Melting Data

See the β-Ca table for details.

Vaporization Data

Tb is calculated from the free energy crossovers of the Ca(ℓ) and Ca(g) tables, and ΔHv° is the difference between $\Delta Hf^\circ_{1767.4}$ for liquid and gas.

Heat of Formation

The vapor pressure over solid and liquid calcium has been reported by several authors. The results of our analysis of their data are presented in the following table. By using free energy functions based on the α crystal at 298°K all the data yield $\Delta Hs^\circ_{298.15}$ (Ca, α) which is $\Delta Hf^\circ_{298.15}$ (Ca, g).

				$\Delta Hf^\circ_{298.15}$, kcal/mol		Drift
Investigator	Method	Range°K	Points	2nd Law	3rd Law	eu

* 1 point rejected due to statistical test ** 3 points rejected

With the exception of sets 2, 4 and 10, all the results for the third law value fall in the range 42 - 43 kcal/mol. The drifts are both positive and negative over solid and liquid, indicating the reliability of the functions within the experimental accuracies. The adopted heat of sublimation, 42.85 ± 0.3 kcal/mol, is taken as the weighted average of sets 9, 11 and 12 which have drifts less than 1 eu. Note that sets 8 and 9 are in fact the same data but the values in set 8 were read from a graph and initially contained three extra points.

Heat Capacity and Entropy

The electronic levels and quantum weights were obtained from Moore (13), and were cut off at 45000 cm^{-1}, which is approximately the ionization limit minus kT for the maximum temperature. All of the unobserved terms in the spectrum are estimated to occur between 47000 cm^{-1} and the ionization limit.

Heat of Formation

N. D. Potter (1) investigated mass spectrometrically the gaseous equilibria among Ca, CaCl, and $CaCl_2$. Ion intensities were measured 2.5 eV above the ionization threshold. Using the equilibrium constants $K = I(CaCl^+)^2/I(Ca^+)I(CaCl_2{}^+)$ which we calculated from the reported ion intensities for the reaction $Ca(g) + CaCl_2(g) \rightarrow 2CaCl(g)$ in the temperature range 1252°-1557°K, we obtain ΔHr°_{298} = 15.81 kcal/mol by the third law method. The third law drift is -2.8 ± 3.5 eu. The heat of formation is derived as ΔHf°_{298}(CaCl, g) = -27.0 kcal/mol.

K. F. Zmbov (7) determined by mass spectrometry the heat of the above reaction as 24.4 ± 1.3 kcal/mol with a drift of 12.5 ± 9.4 eu. This yields the heat of formation, ΔHf°_{298}(CaCl, g) = -22.7 kcal/mol.

D. L. Hildenbrand (2) also determined the equilibrium constants for the reaction (a) $Ca(g) + CaCl_2(g) \rightarrow 2CaCl(g)$ and the reaction (b) $Ca(g) + AlCl(g) \rightarrow CaCl(g) + Al(g)$ by mass spectrometry in the temperature range 1219-1353°K. Third law analysis of the reported equilibrium constants gives ΔHr°_{298} = 21.08 kcal/mol and drift = -1.4 ± 1.8 eu for reaction (a); and ΔHr°_{298} = 24.20 kcal/mol and drift = 0.5 ± 1.3 eu for reaction (b). From third law ΔHr°_{298} of (a) and (b), we derived ΔHf°_{298}(CaCl, g) as -24.4 and -23.3 kcal/mol, respectively, using all JANAF functions. Hildenbrand has also derived a corrected D°_0(Ca-Cl) = 95.0 kcal/mol from a linear Birge-Sponer extrapolation of the ground state vibrational levels with correction for its ionicity. This corrected D°_0(Ca-Cl) yields the heat of formation, ΔHf°_{298}(CaCl, g) = -23.9 kcal/mol.

Ryabova and Gurvich (3) reported D°_0(Ca-Cl) = 102 ± 6 kcal/mol from flame spectra studies. This leads to ΔHf°_{298}(CaCl, g) = -30.9 kcal/mol.

D. L. Hildenbrand (6) determined the dissociation energy of $CaCl_2(g)$ by electron impact as D°_0(CaCl-Cl) = 5.04 ± 0.02 eV which, combined with JANAF ΔHf°_{298} of $CaCl_2(g)$ and Cl(g) gives ΔHf°_{298}(CaCl, g) = -23.1 kcal/mol.

A weighted average, ΔHf°_{298}(CaCl, g) = -25 ± 3 kcal/mol, is adopted in the tabulation.

Heat Capacity and Entropy

The vibrational constants (ω_e and $\omega_e x_e$), electronic levels and ground state configuration were taken from Herzberg (4). Morgan and Barrow (5) made rotational analysis of the $C^2\Pi - X^2\Sigma$ system and reported B_o = 0.1516 cm^{-1} and r_e = 2.439 Å for the ground state. The value of α_e is calculated from the Morse potential function. The F and G states were reported by Schutte (8).

June 30, 1970

CALCIUM CHLORIDE ($CaCl_2$) (CRYSTAL) GFW = 110.986

ΔHf_0° = -190.3 ± 0.3 kcal/mol

$S^\circ_{298.15}$ = 25.0 ± 1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -190.2 ± 0.3 kcal/mol

Tm = 1045°K

ΔHm° = 6.822 ± 0.2 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 77.5 ± 2 kcal/mol

Heat of Formation

V. B. Parker (1) has selected the standard heat of formation as -190.2 kcal/mol which is adopted in the tabulation. The heat of formation was derived from two independent paths. The first path involves $\Delta Hf^\circ_{298}(Ca^{++}, \infty H_2O)$ = -129.74 kcal/mol (1), $\Delta Hf^\circ_{298}(Cl^-, \infty H_2O)$ = -39.952 kcal/mol (2) and the heat of solution of $CaCl_2$(c) in water (3, 4, 5, 6, 7). The second path involves the heats of reaction of Ca(c), CaO(c) and $CaCl_2$(c) in aqueous HCl solution (4, 8-20).

Heat Capacity and Entropy

Kelley and Moore (21) measured the low temperature heat capacities in the temperature range from 52.6° to 295.1°K and made an extrapolation to 0°K which yielded an entropy of 4.59 ± 0.4 eu at 50.12°K. We have adopted the measured heat capacities, but made our own extrapolation to 0°K by comparison with the measured heat capacities of $BaCl_2$(c) (22) and $SrCl_2$(c) (23) from 6° to 50°K. The extrapolation gives S°_{50} = 2.45 ± 1 eu, which is used in the table. Moore (24) measured high temperature enthalpy data from 403.7° to 1667°K by drop calorimetry. The low temperature heat capacities and high temperature enthalpy data are smoothly joined at 298°K. The deviations of the observed enthalpies from the adopted values are about 2% near 400-500°K and only a few tenths percent at higher temperatures. Dworkin and Bredig (25) determined drop-calorimetrically $H_{1045}-H_{298}$ = 14.3 kcal/mol, which is in very good agreement with the adopted value of 14.2 kcal/mol.

Melting Data

The adopted melting point 1045°K was determined by T. V. Tokareva (26). Dworkin and Bredig determined the heat of fusion ΔH°_{1045} = 6.78 ± 0.1 kcal/mol by drop calorimetry. Chiotti, Gartner, Stevens and Saito (27) also measured the heat of fusion ΔH°_{1055} = 6.79 ± 0.2 kcal/mol in an adiabatic calorimeter. The adopted heat of fusion, 6.822 kcal/mol, is calculated from the difference between the observed relative enthalpy of the liquid and the adopted value for the crystal at the melting point.

Sublimation Data

The heat of sublimation is calculated from the heats of formation of $CaCl_2$(c) and $CaCl_2$(g).

June 30, 1970

$S^\circ_{298.15}$ = 29.608 ± 1.2 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -185.013 ± 0.5 kcal/mol

Tm = 1045°K

ΔHm° = 6.822 ± 0.2 kcal/mol

Tb = 2208.6°K

ΔHv° = 56.2 kcal/mol

Heat of Formation

The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between H_{1045}-H_{298} for the crystal and the liquid.

Heat Capacity and Entropy

The constant heat capacity above the assumed glass transition at 700°K is derived from high temperature enthalpy data in a drop calorimeter from the melting point up to 1667°K by G. E. Moore, J. Amer. Chem. Soc. 65, 1700 (1943). Below the glass transition point, the heat capacity is assumed to be the same as that of the crystal. A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 67, 697 (1963), reported Cp(ℓ) = 23.6 gibbs/mol from enthalpy measurements in a short temperature range by drop calorimetry.

The entropy $S^\circ_{298.15}$ = 29.608 gibbs/mol is calculated in a manner analogous to that of the heat of formation.

Melting Data

See the crystal table for details.

Vaporization Data

The boiling point is calculated as the temperature at which ΔG = 0 for $CaCl_2(\ell) \rightarrow CaCl_2(g)$. The heat of vaporization is the difference in ΔHf°_{Tb} between liquid and gas.

Calcium Chloride ($CaCl_2$)

CALCIUM CHLORIDE ($CaCl_2$) (IDEAL GAS) GFW = 110.986

$CaCl_2$

Point Group $D_{\infty h}$

ΔHf°_0 = -112.7 ± 1 kcal/mol

$S^\circ_{298.15}$ = 69.3 ± 2 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -112.7 ± 1 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
217 (1)
64 (2)
402 (1)

Bond Distance: Ca-Cl = 2.51 Å

Bond Angle: Cl-Ca-Cl = 180°

σ = 2

Rotational Constant: B_o = 0.0377 cm^{-1}

Heat of Formation

Second and third law analyses of vapor pressure data are given below. The selected third law heat of vaporization is taken from Novikov's measurement (1) as ΔHv°_{298} = 72.30 kcal/mol which is combined with ΔHf°_{298} of the liquid to give $\Delta Hf^\circ_{298}(CaCl_2, g)$ = -112.7 ± 1 kcal/mol.

Third law analyses indicate zero drift for Novikov's data, positive and negative drifts for Hildenbrand's (2) and Bautista's (3) data, respectively. Their heats are in agreement within ±1 kcal. Wartenberg (4) reported there was no boiling at 1819°K at 62 mm Hg pressure, and his value (ΔHv°_{298} = 71.1 ± 0.7 kcal/mol) serves as a guide for the minimum heat of vaporization.

Investigator	Method	Temperature Range, °K	Number of Points	ΔHv°_{298}(kcal/mol) 2nd law	3rd law	Drift e.u
Bautista and Margrave (3)	Langmuir	952-993	7	75.25 (80.34)*	73.39 (78.57)*	-1.7±6.9

Hildenbrand and Potter (2)	Torsion Effusion 0.015 cm^2 Orifice	1111-1281	17	68.71	71.24	2.0±0.2
Hildenbrand and Potter (2)	Torsion Effusion Combined	1111-1281	29	68.91	71.24	2.4±0.3
Dewing (5)	Knudsen Effusion	1069-1225	4	59.37	71.03	10.2±1.6
Wartenberg and Bosse (4)	Boiling Point	1819	1	---	>71.10	---
Novikov and Gavryuchenkov (1)	Boiling Point	1591-1701	5	72.25	72.30	0.0±1.2
Lukashenko and Reutova (10)	Langmuir	973-1023	6	78.0	69.01	-9.0
	Knudsen Effusion	1073-1273	6	61.8	69.78	+8.0

*Value in parentheses is the heat of sublimation.

Heat Capacity and Entropy

The linear structure and vibrational frequencies were determined by D. White and co-workers (6) in the matrix-infrared-spectrometric studies. The linear structure is consistent within experimental error with the electric-quadrupole-deflection studies (7), and electron-diffraction data (8). Hayes (9) has qualitatively rationalized the linear structure through molecular orbital theory.

The bond length was measured by Akishin and Spiridonov (8). The moment of inertia is 74.174 x 10^{-39} g cm^2.

Heat of Formation

Hastie and Margrave (1) have recently reviewed the dissociation energy of CaF and conclude that it is 127.5 ± 2.5 kcal/mol. The analysis below considers basically the same data except that all values are JANAF.

Hildenbrand and Murad (2) in a mass spectrometric determination of the equilibria among BF, BF_3, Ca, CaF and CaF_2 reported equilibrium constants for the reaction

(A) $Ca(g) + CaF_2(g) \rightarrow 2CaF(g)$.

Blue et al. (3) have also examined several equilibria mass-spectrometrically and report equilibrium constants for reaction

(B) $Ca(g) + CaF_2(c) \rightarrow 2CaF(g)$ and reaction

(C) $Ca(g) + AlF(g) \rightarrow Al(g) + CaF(g)$.

Ryabova and Gurvich (4) give a heat of dissociation from flame studies for the reaction

(D) $CaF(g) \rightarrow Ca(g) + F(g)$.

The remaining reactions considered by Hastie and Margrave (1) were not included since they involved subtracting reactions not performed simultaneously, or involve species such as SiF_2 whose heat of formation is dependent on that of CaF and CaF_2.

Reference	Range °K	Reaction	Points	ΔHr°_{298} kcal/mol 2nd law	3rd law	Drift eu	ΔHf°_{298}** kcal/mol
Hildenbrand (2)	1583 - 1734	A	15	11.5 ± 6.8	14.70 ± 1.27	2.2 ± 4.1	-65.5 ± 1.8

Ryobova (4)		D		135 ± 7			-73.3 ± 7
Hildenbrand (5)	1423 - 1443	A	2		32.97		-65.6 ± 3.2

* 1 point rejected due to failure of a statistical test

** Calculated from third law value when available

The auxiliary heats of formation used were, in kcal/mol, AlF, g = -63.4, Al, g = 78, CaF_2, g = -187.5, CaF_2, c = -293.0 and Ca, g = 42.85.

We adopt a median value of $\Delta Hf^\circ_{298.15}$(CaF, g) = -65 ± 2 kcal/mol which corresponds to a heat of dissociation of 126.7 ± 2 kcal/mol.

Heat Capacity and Entropy

Herzberg (6) gives the vibrational constants and electronic levels, Harvey (7) has reported a value for B_0 which corresponds to a bond length of 2.02 Å. The Morse potential function was used to calculate α_e.

Dec. 31, 1968

CALCIUM DIFLUORIDE (CaF_2) (CRYSTAL) GFW = 78.0768

$S^\circ_{298.15}$ = 16.39 ± 0.08 gibbs/mol

Tt = 1424 ± 20°K (α-β)

Tm = 1691 ± 5°K

ΔHf°_0 = -292.3 ± 1.5 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -293.0 ± 1.5 kcal/mol

ΔHt° = 1.14 ± 0.1 kcal/mol

ΔHm° = 7.10 ± 0.1 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 105.5 ± 0.8 kcal/mol

Heat of Formation

Torgeson and Sahama (1) measured the heat of solution of CaO in aqueous 20.1% HF as -54.96 ± 0.02 kcal/mol. Using ΔHf°_{298}(CaO, c) = -151.79 kcal/mol (2), $\Delta Hf^\circ_{298}(H_2O, \ell)$ = -68.317 kcal/mol (3) and $\Delta Hf^\circ_{298}(HF, 4.4H_2O)$ = -76.60 kcal/mol (4), we obtain $\Delta Hf^\circ_{298}(CaF_2, c)$ = -291.6 ± 0.6 kcal/mol.

Smyshlyaev and Edeleva (5) report the solubility product of CaF_2 as 2.7 ± 0.27 x 10^{-11} in dilute HCl, which yields ΔG°_{298} = 14.42 kcal/mol for the reaction $CaF_2(c) \rightarrow Ca^{++}(\infty, aq.) + 2F^-(\infty, aq.)$. Using $\Delta Gf^\circ_{298}(Ca^{++}, \infty\ aq.)$ = -132.30 kcal/mol (2) and $\Delta Gf^\circ_{298}(F^-, \infty\ aq.)$ = -66.95 kcal/mol (4) we obtain $\Delta Gf^\circ_{298}(CaF_2, c)$ = -280.64 ± 0.6 kcal/mol, which using the adopted functions yields $\Delta Hf^\circ_{298}(CaF_2, c)$ = -293.1 ± 0.6 kcal/mol.

Vecher and Vecher (17) have measured the emf of a high temperature solid state cell and report ΔGr°_{1200} = -17.6 ± 0.2 kcal/mol for the reaction $CaO(c) + MgF_2(c) \rightarrow CaF_2(c) + MgO(c)$. This reduces to ΔHr°_{298} = -17.6 kcal/mol which, using JANAF values for MgO and MgF_2 and CaO from reference 2, yields $\Delta Hf^\circ_{298}(CaF_2, c)$ = -294.4 ± 1.3 kcal/mol.

Kohlrauch (18) reported the solubility of CaF_2 and fluorspar, which yield solubility products of 3.6 x 10^{-11} and 2.8 x 10^{-11}. From these we obtain, as above, $\Delta Hf^\circ_{298}(CaF_2, c)$ = -292.9 and -293.1 kcal/mol.

Guntz (19) made measurements on the neutralization of $Ca(OH)_2$(aq) and HF(aq) which yield $\Delta Hf^\circ_{298}(CaF_2, c)$ = -293.1 kcal/mol, according to Parker (2).

A median value of $\Delta Hf^\circ_{298}(CaF_2, c)$ = -293 ± 1.5 kcal/mol is adopted.

Heat Capacity and Entropy

Huffman and Norwood (6) have measured the low temperature heat capacity in the range 3.6° to 30°K, Eucken and Schwers (7) in the range 17° to 86°K and Todd (8) from 54° to 296.5°K. We have fitted a smooth polynomial curve through the data of references 6 and 8 and this yields S°_{298} = 16.38 ± 0.08 eu based on $S^\circ_{3.6}$ = 0.0002 eu. The values of reference 7 deviate considerably at the lowest temperatures but are in reasonable agreement at higher temperatures.

The high temperature enthalpy of calcium fluoride has been reported by Naylor (9) to 1789°K, Krestnikov and Karetnikov (10) to 1273°K, and Lyashenko (11) to 1490°K. All the data are in approximate agreement and the more extensive results of Naylor on a very pure sample are adopted. The heat capacities, below 1424°K were derived from a polynomial fit of the enthalpy data of the form $H = aT^2 + bT + c + d/T + e/T^2$.

Transition Data

The temperature of transition is that reported by Naylor (9), the large uncertainty has been assigned since at 1424°K the enthalpies indicate complete conversion to β-CaF_2, and the next lower point is at 1402°K. Evidence in support of a transition in this region comes from Lyashenko (11) whose plot indicates a break between 1273° and 1413°K. In addition, $SrCl_2$ which has the fluorite structure has a transition near the melting point. The enthalpy of transition is that reported by Naylor (9).

Melting Data

McCreary (12) reports the melting point of a 99.1% pure sample as 1687 ± 5°K. Porter and Brown (13) report 1675 ± 5°K as the melting point of 99.8% pure CaF_2 and Rogers et al. (14) obtained 1684°K as the melting point. The adopted melting point 1691 ± 5°K, for a sample of natural fluorite of high purity, was reported by Naylor (9). The heat of melting, 7100 cals, is that measured by Naylor (9). Three determinations from high temperature phase diagrams give 7250 ± 350 cals (15), 5500 cals (16) and 9800 cals (14).

Sublimation Data

See the CaF_2(g) table for details.

Dec. 31, 1968

CALCIUM DIFLUORIDE (CaF_2) (LIQUID) GFW = 78.0768

$S^\circ_{298.15}$ = 22.125 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = −283.477 ± 1.5 kcal/mol

Tm = 1691 ± 5°K

ΔHm° = 7.10 ± 0.1 kcal/mol

Tb = 2806.5 ± 30°K

ΔHv° = 73.78 ± 0.8 kcal/mol

Heat of Formation

The heat of formation is obtained from that of the crystal by adding the heat of melting and the difference between $H_{1691} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived from the heat content measurements of B. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). The heat capacity is constant in the real liquid range but at 1000°K a glass transition is assumed below which it follows that of the crystal. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the crystal table for details.

Vaporization Data

The boiling point is calculated as the temperature at which ΔG = 0 for the vaporization process. The heat of vaporization is the difference in ΔHf°_{Tb} between liquid and gas.

554 (1)

Bond Distance: Ca-F = 2.1 Å

σ = 2

Bond Angle: F-Ca-F = 135 ± 7°

Product of the Moments of Inertia: $I_AI_BI_C = 1.2836 \times 10^{-114}\ g^3\ cm^6$

Heat of Formation

The heat of formation is obtained from that of the crystal by adding $\Delta Hs^\circ_{298.15}$. The vapor pressure data of five authors was analysed by 2nd and 3rd law methods to give $\Delta Hs^\circ_{298.15}$ as listed below. Note that the drifts are small and both positive and negative confirming the correctness of the functions used.

Ruff and LeBoucher (5)	2086 - 2208	7	106.7 ± 4.8	105.22 ± 0.5	-0.7 ± 2.2
Blue et al (2) *	1242 - 1669	19	104.7 ± 0.5		

* This set was not analysed by the third law since the absolute pressures were adjusted by the authors to match their weight loss values.

A median value of 105.5 ± 0.5 kcal/mol is adopted for the heat of sublimation which yields $\Delta Hf^\circ_{298.15}(CaF_2, g)$ = -187.5 ± 2 kcal/mol.

Heat Capacity and Entropy

The bond length was measured by Akishin and Spiridonov (6), but the diffraction patterns were interpreted as indicating a linear molecule. The vibrational frequencies and bond angle are those reported by Calder (7) using matrix isolation spectroscopy and isotopically enriched materials.

The individual moments are $I_A = 2.092 \times 10^{-39}$, $I_B = 2.3749 \times 10^{-38}$, and $I_C = 2.5840 \times 10^{-38}\ g\ cm^2$.

CALCIUM MONOHYDROXIDE UNIPOSITIVE ION ($CaOH^+$) (IDEAL GAS) GFW = 57.08682

Point Group [$C_{\infty v}$]

ΔHf_0° = 88.5 ± 15 kcal/mol

$S^\circ_{298.15}$ = [55.4 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 87.7 ± 15 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[733] (1)
[320] (2)
[3600] (1)

Bond Distance: Ca-O = [1.82] Å O-H = [0.96] Å

Bond Angle: Ca-O-H = [180°] σ = 1

Rotational Constant: B_0 = [0.3926] cm^{-1}

Heat of Formation

D. E. Jensen (1) determined the heat of reaction ΔHr_0° = 35 ± 10 kcal/mol for $Ca(g) + OH(g) \rightarrow CaOH^+(g) + e^-$ in atmospheric pressure hydrogen-nitrogen-oxygen flames using the microwave cavity resonance method. This value was calculated assuming a bent model for $CaOH^+$; the value is not significantly changed, within the uncertainty, by the change in configuration. Combining ΔHr° with JANAF heats of formation of Ca(g) and OH(g) and electron, we obtain $\Delta Hf^\circ_{298}(CaOH^+, g)$ = 87.7 kcal/mol, which is adopted in the table. This corresponds to an ionization potential of 6.11 eV.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that gaseous NaOH, KOH, CsOH, RbOH are linear (2, 3, 4). This evidence also confirms the prediction of A. D. Walsh (5) that "HAB" molecules with 10 or less valence electrons ($CaOH^+$ has 8 valence electrons) will be linear in their ground state. The molecule of $CaOH^+$ has an isoelectronic structure of KOH.

The bond distances O-H and Ca-O are assumed to be the same as those in $H_2O(g)$ and CaO(g), respectively (6, 7). The moment of inertia is 7.1294 x 10^{-39} g cm^2.

The Ca-O stretching frequency 733 cm^{-1} is estimated from those of CaO(g) (7, 9) and CaF(g) (8). The O-H stretching frequency, 3600 cm^{-1}, is estimated from those of $H_2O(g)$ (6) and $Ca(OH)_2(g)$ (10). The bending vibrational frequency, 320 cm^{-1}, is estimated by comparison with those of NaOH, CsOH, RbOH (2, 4).

The enthalpy change between 0° and 298°K is 2.630 kcal/mol.

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[733] (1)
[320] (2)
[3600] (1)

Bond Distance: Ca-O = [1.82] Å O-H = [0.96] Å

Bond Angle: Ca-O-H = [180°] σ = 1

Rotational Constant: B_o = [0.3926] cm^{-1}

Heat of Formation

Cotton and Jenkins (1) determined the equilibrium constants in the temperature range 1570°K-2030°K for the reaction $Ca(g) + H_2O(g) \rightarrow CaOH(g) + H(g)$ by atomic absorption spectroscopy in a fuel-rich hydrogén-nitrogen-oxygen flame. Using all JANAF functions, third law analyses of the data give ΔHr°_{298} = 13.8 kcal/mol and the drift 1.9 ± 2.9 eu. This leads to the heat of formation, ΔHf°_{298}(CaOH, g) = -53.3 kcal/mol which is adopted in the tabulation. The bond dissociation energy, D°_0(Ca-OH), is 104.6 kcal/mol.

Ryabova and Gurvich (2) reported the bond dissociation energy D°_0(Ca-OH) as 100 kcal/mol. Schofield and Sugden (3) found $D^\circ_0(Ca\text{-}(OH)_2)$ as 217 ± 12 kcal/mol. Using the relation D°_0(M-X)/D°_0(X-M-X) = 0.47 suggested by Kent, McDonald and Margrave (4), we obtain D°_0(Ca-OH) = 102 kcal/mol.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that gaseous NaOH, KOH, CsOH and RbOH are linear (5, 6, 7). This evidence also confirms the prediction of A. D. Walsh (8), that "HAB" molecules with 10 or less valence electrons (CaOH has 9 valence electrons) will be linear in their ground state.

The ground state is assumed to be $^2\Sigma$ by analogy with isoelectronic CaF (9). The electronic levels are estimated from band spectra of CaOH reported by Gaydon (14).

The bond distances O-H and Ca-O are assumed to be the same as those in $H_2O(g)$ and CaO(g), respectively (10, 11). The moment of inertia is 7.1295 x 10^{-39} g cm^2.

The O-H stretching frequency, 3600 cm^{-1}, is estimated from those of $H_2O(g)$ (10) and $Ca(OH)_2(g)$ (12). The bending frequency, 320 cm^{-1}, is estimated by comparison with those of NaOH, CsOH and RbOH (5, 7). The Ca-O stretching frequency, 733 cm^{-1}, is estimated to be the same as that of CaO(g) observed by Hultin and Lagerqvist (11) and Brewer and Hauge (13).

Heat of Formation

Bands in the visible for the $^3\Pi \leftarrow {}^1\Sigma$ transitions have been observed by A. Elliott, Proc. Roy. Soc. 127A, 638 (1930), who also lists the work of former contributors. C. F. Goodeve and B. A. Stephens, Trans. Far. Soc. 32, 1517 (1936) have measured several lines in the same system. These data lead to a convergence limit of 20,831 ± 20 cm.$^{-1}$ From which the dissociation energy is obtained assuming excited and normal Cl atoms as the dissociation products of the A state. The assigned accuracy estimation reflects the uncertain knowledge of the products. The value in parenthesis is a precision measure and would apply if the dissociation products were those assumed. See R. G. Aikin and N. S. Baylis, Trans. Far. Soc. 33, 1333 (1937) for further details on the dissociation products.

Heat Capacity and Entropy

The electronic energy levels are listed by C. E. Moore, Nat. Bur. Stands. Circ. 467, (1949).

Heat of Formation.

The heat of formation was calculated from the equation: $Cl(g) - e^- \rightarrow Cl^+(g)$ with the JANAF auxiliary value for Cl(g); using an I.P. = 1.04991 X 10^5 cm^{-1} (300.206 kcal/mole) obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, loc. cit. The electronic levels above 1 X 10^5 cm^{-1} were omitted because their contribution is negligible below 6000°K. The $H^\circ-H^\circ_{298}$ value at 0°K. is -1.526 kcal./mole.

June 30, 1965

CHLORINE UNINEGATIVE ION (Cl^-) (IDEAL GAS) MOL. WT. = 35.45355

Ground State Configuration $^1S_0$

$\Delta H_f^\circ{}_0 = -54.8 \pm .5$ kcal. mole^{-1}

$S^\circ_{298.15} = 36.628$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = -55.9 \pm .5$ kcal. mole^{-1}

Electronic Levels and Quantum Weight

$\mathcal{E}_1$, cm.$^{-1}$	g_1
0.0	1
93143.8	5
93750.639	3
94553.707	1
95399.870	3

Heat of Formation.

The heat of formation was calculated from the equation: $Cl(g) + e^- \rightarrow Cl^-(g)$ with the JANAF auxiliary values for Cl(g); using the measured electron affinity = 3.613 e.v. (83.316 kcal/mole) obtained from R. S. Berry and C. W. Reimann, J. Chem. Phys. 38, 1540 (1963). Other calculated values for the electron affinity are: 3.70 e.v. reported by B. Edlen, J. Chem. Phys. 33, 98 (1960) and 3.56 e.v. reported by E. Clementi, A. D. McLean, D. L. Raimondi and M. Yoshimine, Phys. Rev. 133, A1274 (1964).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Argon. The electronic levels above 1 X 10^5 cm.$^{-1}$ were omitted because their contribution is negligible below 6000°K. The $H^\circ-H^\circ_{298}$ value at 0°K. is -1.481 kcal/mole.

CESIUM CHLORIDE (CsCl) (CRYSTAL) GFW = 168.358

$\Delta Hf^\circ_0 = -105.88 \pm 0.2$ kcal/mol

$S^\circ_{298.15} = 24.183 \pm 0.005$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -105.84 \pm 0.2$ kcal/mol

$Tt(\alpha \rightarrow \beta) = 743°K$

$\Delta Ht^\circ = 0.90$ kcal/mol

$Tm = 918°K$

$\Delta Hm^\circ = 3.8$ kcal/mol

$\Delta Hs^\circ_{298.15}$(to monomer) = 48.74 kcal/mol

Heat of Formation

The heat of solution (ΔHsoln) of CsCl(c) in water has been measured by Forcrand (1, 2), Haigh (3), Samoilov (4, 6), and Rodnikova (5). Based on their results, Parker (7) derived the corresponding $\Delta Hsoln^\circ_{298.15}(\infty\ H_2O)$ values as 4.30, 4.32, 4.08, 4.25, 4.18 and 4.18 kcal/mol. Borob'ev (8) determined the same quantity and reported $\Delta Hsoln^\circ_{298}(CsCl, \infty\ H_2O) = 4.20 \pm 0.04$ kcal/mol. Using this value, 4.20 kcal/mol, and $\Delta Hf^\circ_{298} = -61.69$ (9) and -39.952 kcal/mol (10) for $Cs^+(\infty\ H_2O)$ and $Cl^-(\infty\ H_2O)$, respectively, we evaluate $\Delta Hf^\circ_{298}(CsCl, c) = -105.84 \pm 0.2$ kcal/mol,which is adopted.

Heat Capacity and Entropy

Taylor (11) measured the low temperature heat capacities, 7.19 - 299.38°K, with an adiabatic calorimeter; the sample purity was >99.95 per cent. Employing these data we derive the value $S^\circ_{298} = 24.183$ eu based on $S^\circ_{7.19} = 0.031$ eu.

The high temperature enthalpies, 385.2 - 904.9°K, were measured by Kaylor (21, 12, 13), using a Bunsen ice calorimeter and a CsCl sample of 99.8 per cent purity. The heat capacities derived from the reported enthalpy data at temperatures 385.2 - 740.5°K appear too low (less than the adopted Cp's systematically by 0.9 gibbs/mol) to join smoothly with the low temperature data at 298°K. The Cp values derived from the measured enthalpy data in the temperature range 760 - 920°K increase rapidly from 14.46 to 16.3 gibbs/mol. In order to rationalize this situation, we adopt the high temperature heat capacities, 298 - 743°K, for CsCl(α) obtained by linear extrapolation of the low temperature data. The Cp values for CsCl(β) are adjusted such that the rate of increase in heat capacities is linear and less rapid than the original one, and the total enthalpy remains essentially unchanged. The discrepancy between the high and low temperature Cp for CsCl(α) may be caused by the incomplete β → α phase conversion involved. In order to resolve this discrepancy, independent enthalpy measurements using a high purity sample with composition well characterized before and after each drop experiment seem necessary.

Transition Data

The temperature of transition (in °K) has been reported by many investigators as 718 (14), 752 (15), 745 (16), 742 (21), 742.5 (12), 743 (20), and 733 (17), using different methods and samples of different purity. The value adopted is 743°K.

The heat of transition (in kcal/mol) was reported to be 1.8 (14), 1.55 (18), 1.4 (19), 0.80 (21), 0.58 (12), 0.90 (13), and 1.1 (17). A median value 0.90 kcal/mol is tentatively adopted.

Melting Data

See CsCl(ℓ) table for details.

Heat of Sublimation

ΔHs°_{298} is calculated as the difference between ΔHf°_{298} for CsCl(g) and CsCl(c).

June 30, 1968

CESIUM CHLORIDE (CsCl) (LIQUID) GFW = 168.358

$S^\circ_{298.15}$ = 24.309 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -103.84 ± 2.0 kcal/mol

Tm = 918°K

ΔHm° = 3.8 ± 1 kcal/mol

Tb = 1597.3°K

ΔHv° = 27.52 kcal/mol of liquid (to equilibrium mixture)

Heat of Formation

$\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{918} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The enthalpies of CsCl(ℓ) at temperatures 923.6 - 1168.0°K were measured with a Bunsen ice calorimeter by Kaylor (1, 2). Dworkin (3) derived the heat capacity of CsCl(ℓ) as 18.5 gibbs/mol from enthalpy data at temperatures 918 - 980°K. This value is adopted since it is in agreement with the enthalpy values reported by Kaylor et al. The heat capacity at temperatures above 1168 and below 923.6°K is assumed to be 18.5 gibbs/mol. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting temperature (in °K) of CsCl(c) has been determined by many investigators as 904 ± 3 (4), 919 (5), 912 (6), 911 (7), 918 (8), 916 (9), and 919 (13). The cause of the discrepancies is probably due to the difference in purity of the samples. The melting temperature adopted is 918°K.

The heat of melting (in kcal/mol) was reported to be 4.84 (14), 4.97 (15), 4.58 (10), 4.96 (11), and 4.79 (2), which were obtained calorimetrically. Using a modification of Kelley's method of obtaining heat of melting from freezing point data on binary systems involving CsCl (16), we derive the value of ΔHm° as 3.6 - 4.0 kcal/mol, based on the following systems: CsCl-NaCl (5), CsCl-CuCl (6), CsCl-AgCl (6), CsCl-LiCl (8), and $CsCl-Cs_3(PO_3)_3$ (12). The heat of melting for CsCl(c) is tentatively adopted as 3.8 kcal/mol. The ΔHm° values obtained calorimetrically are not used due to the uncertainties of the state of the sample before and after the enthalpy measurements.

Vaporization Data

Tb is the temperature at which the calculated total pressures of CsCl(g) and $Cs_2Cl_2(g)$ equal one atmosphere. The vapor composition at Tb is derived as CsCl 80.4 per cent and Cs_2Cl_2 19.6 per cent. The boiling point of CsCl(ℓ) has been determined by several investigators as 1562 (17), 1572 (18), and 1576 (19). The heat required to vaporize one mole of liquid to the above vapor mixture at Tb is ΔHv°.

Heat of Formation

The total pressures of CsCl(g) and Cs_2Cl_2(g) over CsCl(c) and CsCl(ℓ) in the temperature range 605 - 1577°K have been determined by manometric, transpiration and Knudsen effusion methods by many investigators. Based on the reported results, the partial pressures of CsCl(g) and Cs_2Cl_2(g) are calculated using the derived free energy functions for CsCl(c), CsCl(ℓ), CsCl(g) and Cs_2Cl_2(g), and the heats of sublimation and vaporization which are adjusted so that the sum of the calculated partial pressures of CsCl(g) and Cs_2Cl_2(g) approaches the measured total pressures, and the evaluated second and third law ΔHr°_{298} values are in reasonable agreement. The results obtained are presented in the table below. The value of ΔHf°_{298}(CsCl, g) adopted is -57.4 ± 1 kcal/mol.

Gaydon (10) reported D_0(Cs-Cl) = 4.6 ± 0.2eV or 106.08 ± 4.61 kcal/mol. Using this D_0 value and ΔHf°_0 = 18.683 and 28.52 kcal/mol for Cs(g) and Cl(g), we evaluate ΔHf°_{298} = -59.4 ± 4.6 kcal/mol for CsCl(g), which is in fair agreement with the adopted value.

*1 CsCl(c) = CsCl(g); 2 CsCl(ℓ) = CsCl(g); A = Knudsen effusion; B = transpiration; and C = manometric.

**Calculation based on the third law ΔHr°_{298} value.

Heat Capacity and Entropy

Clouser (11) studied the pure rotational spectra of CsCl(g) in the 0.96 - 3 mm range of the microwave region with the molecular-beam spectrometer, and derived the values of B_e, α_e, ω_e, $\omega_e x_e$ and r_e, which are adopted and corrected to the average isotopic species.

The Cs-Cl bond distance was measured as 3.06 ± 0.03 Å by the electron diffraction method by Maxwell (12), which is not used. Similar values of B_e and α_e were reported by Honig (13) and Rice (14), determined from microwave and infrared spectra, respectively. Barrow (15) gave ω_e = 240 cm^{-1}(CsCl^{35}) which is significantly different from the adopted value 214.22 cm^{-1} for CsCl^{35} and the value 209 ± 6 cm^{-1} reported by Rice (14). The moment of inertia is 3.924 x 10^{-38} g cm^2.

COPPER MONOCHLORIDE (CuCl) (CRYSTAL) MOL. WT. = 98.993

$S^\circ_{298.15}$ = 20.8 ± 1.0 cal. deg.$^{-1}$ mole^{-1}

T_m = 703°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -33.0 ± 0.4 kcal. mole^{-1}

ΔH°_m = 2.445 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 54.77 ± 0.5 kcal. mole^{-1} of monomer

$\Delta H^\circ_{s\ 298.15}$ = 37.2 ± 0.2 kcal. mole^{-1} of trimer

Heat of Formation.

There have been three calorimetric determinations of the heat of formation. Thomsen, "Thermochemische Unterschungen", Barth, Leipzig (1882-1886) reported -32.875 kcal. mole^{-1}. Berthelot, Ann. Chim. Phys. 20, 504 (1880) reported -35.6 kcal. mole^{-1} and H. V. Wartenberg and H. Werth, Z. physik. Chem. A 151, 109 (1930) reported -32.1 ± 0.4 kcal. mole^{-1}. In addition, values of the heat of formation have been derived from several sets of equilibrium data. A. A. Noyes and M. Chow, J. Am. Chem. Soc. 40, 739 (1918) from a study of cell potentials derived a ΔH_r = 7.19 kcal. for the reaction $Cu(c) + HCl(\infty aq) \rightarrow CuCl(c) + 1/2\ H_2(g)$ which yields $\Delta H^\circ_{f\ 298}(CuCl)$ = -32.76 kcal. mole^{-1}. Several investigators have studied the reaction $2CuCl(c) + H_2(g) \rightarrow 2Cu(c) + 2HCl(g)$ and its reverse reaction. These include A. B. Bagdasarian, Trans. Am. Electrochem. Soc. 51, 449 (1927) who reported equilibrium constants which result in 2nd and 3rd law heats of reaction of 24.3 and 23.2 kcal. mole^{-1}; A. F. Kapustinsky, J. Am. Chem. Soc. 58, 460 (1936) who obtained similarly 20.1 and 21.8 kcal. mole^{-1}; S. A. Shchukarev and M. A. Oranskaya, Z. Obshchei. Khim. 24, 1926 (1954) obtained 25.4 and 21.5 kcal. mole^{-1} for the 2nd and 3rd law heat of reaction. These yield values for $\Delta H^\circ_{f\ 298}(CuCl)$ ranging from -32.1 to -34.8. M. Watanabe, Bull. Inst. Phys. Chem. Res. 9, 94 (1929) from cell studies reports $\Delta H^\circ_{f\ 298}$ (CuCl) = -34.6 kcal. mole^{-1}. A value of $\Delta H^\circ_{f\ 298}$ can also be obtained from $\Delta H^\circ_f\ (CuCl)_3(g)$, which is fixed independently and known with good precision. Using the 3rd law heat of sublimation of CuCl(c) to trimer determined by D. W. Magee, Doctoral Thesis, Ohio State University (1955) [See trimer table], we obtain $\Delta H^\circ_{f\ 298}$ CuCl(c) = -33.01 ± 0.3 kcal. mole^{-1}. A weighted average of -33.0 ± 0.4 kcal. mole^{-1} was adopted.

Heat Capacity and Entropy.

The entropy of CuCl was obtained from the several pieces of equilibrium data reported above and the adopted $\Delta H^\circ_{f\ 298}$. A weighted average of 20.8 ± 1 cal/(mol-deg) was adopted for S°_{298} CuCl(c). The enthalpy and heat capacity above 298°K. have been reported by A. N. Krestovnikov and G. A. Karetnikov, Jour. Gen. Chem. (USSR) 6, 955 (1936). However these values were not adopted since they do not give reasonable heat capacities and other data by these workers is not in agreement with established values. Heat capacities equal to those of AgCl, as given by K. K. Kelley, U. S. Bureau of Mines Bulletin 584, Washington 1960, were adopted here above 298°K.

Melting Data.

The temperature and heat of melting were those selected by K. K. Kelley, U. S. Bur. Mines Bulletin 393 (1936), from phase studies. The heat of melting was reported by Krestovnikov and Karetnikov loc. cit. as 2.54 kcal. mole^{-1}.

Sublimation Data.

The heat of sublimation was calculated from the adopted heats of formation at 298° for the reaction $x\ CuCl(c) \rightarrow (CuCl)_x(g)$ where x = 1 or 3. See the respective gas tables for details.

Mar. 31, 1966

COPPER MONOCHLORIDE (CuCl) (LIQUID) MOL. WT. = 98.993

$S^\circ_{298.15}$ = 22.4 ± 1 cal. deg.$^{-1}$ mole^{-1}

T_m = 703°K.

T_b = [1485]°K. (to equilibrium mixture)

$\Delta H^\circ_{f\ 298.15}$ = -31.35 ± 0.4 kcal. mole^{-1}

ΔH°_m = 2.445 kcal. mole^{-1}

ΔH°_v = [5.18] kcal. mole^{-1} (to equilibrium mixture)

Heat of Formation.

Calculated from $\Delta H^\circ_{f\ 298}$ of the crystal plus ΔH°_m and the difference between $H_{T_m}-H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated to be constant at 8 cal. deg.$^{-1}$ gm. atom^{-1}. The entropy was calculated in a manner analogous to that of the heat of formation.

Boiling Data.

The boiling point and heat of vaporization were calculated from the respective liquid, monomer and trimer gas tables. The boiling point was taken as the point where the total pressure reached 1 atm. At this point the partial pressures are 0.021 atm. of monomer and 0.979 atm. of trimer.

α_e = 0.0001 cm.$^{-1}$

σ = 1

r_e = 2.050 Å

Heat of Formation.

The heat of formation was obtained from the equilibrium data of L. Brewer and N. L. Lofgren, J. Am. Chem. Soc. 72, 3038 (1950). They studied the reaction $x\ Cu(c) + x\ HCl(g) \rightarrow Cu_xCl_x(g) + x/2\ H_2(g)$ by measuring the amount of CuCl formed when various ratios of $HCl:H_2$ were passed over heated copper. Brewer and Lofgren analysed the data by a least squares fitting technique and deduced partial pressures of monomer and trimer. The monomer pressures were subjected to second and third law analysis and gave $\Delta H_{r\ 298}$ = 46.85 ± 3.2 and 43.83 ± 0.4 kcal. mole^{-1} respectively. The 3rd law value yields $\Delta H^\circ_{f\ 298}$ CuCl(g) = 21.77 ± 0.4 kcal. mole^{-1}, which was adopted.

Heat Capacity and Entropy.

The molecular constants were corrected for normal isotopic abundance of both copper and chlorine and were calculated from the values for $^{65}Cu^{35}Cl$ given by R. K. Asundi, P. R. Rao and J. K. Brody, Nature 192, 444 (1961). The rotational constants were in good agreement with those reported by A. Lagerqvist and V. Lazarova-Girsamov for $Cu^{63}Cl^{35}$, Naturwissenschaften 48, 68 (1961).

r_e = 1.62813 Å

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ = -12.14 kcal. mole^{-1} was calculated from the dissociation energy (D°_0 = 58.99) obtained from the visible band spectra measured by H. Schmitz and H. J. Schumacher, Z. Naturforsch 2a, 359 (1947) and A. L. Wahrhaftig, J. Chem. Phys. 10, 248 (1941). The convergence limit of 21,512 ± 20 cm.$^{-1}$ for the A state leads to the selected D°_0 assuming that the products are Cl($^2P_{1/2}$) and F($^2P_{3/2}$) or to D°_0 = 60.36 assuming Cl($^2P_{3/2}$) and F($^2P_{1/2}$). Calorimetric values bracket the two possibilities but more weight was given to the results of Wicke.

	Method	Reaction	Observation	$\Delta H^\circ_{f\ 298}$ kcal. mole^{-1}
1	Spectroscopic	$ClF = Cl(^2P_{1/2}) + F(^2P_{3/2})$	$D^\circ_0 = 58.99$	-12.14
2	Spectroscopic	$ClF = Cl(^2P_{3/2}) + F(^2P_{1/2})$	$D^\circ_0 = 60.36$	-13.51
3	Calorimetric	$1/2\ Cl_2 + 1/2\ F_2 = ClF$	$\Delta H^\circ_{293} = -11.6 \pm 0.1$	-11.6
4	Explosion method	$1/2\ Cl_2 + 1/2\ F_2 = ClF$	$\Delta H^\circ_0 = -11.7 \pm 0.5$	-11.7
5a	Calorimetric	$NaCl + ClF = NaF + Cl_2$	$\Delta H^\circ_{290} = -24.5 \pm 0.5$	-14.34*
5b	Calorimetric	$NaCl + 0.5\ F_2 = NaF + 0.5\ Cl_2$	$\Delta H^\circ_{290} = -39.5 \pm 0.5$	-15.0**

*Based on $\Delta H^\circ_{f\ 298}$(NaCl(c)) = -98.26 and $\Delta H^\circ_{f\ 298}$(NaF(c)) = -137.1 kcal. mole^{-1}

**Based on the difference between the two calorimetric reactions of reference 5a, 5b.

Heat Capacity and Entropy.

The rotational constants were obtained from the microwave spectrum by D. A. Gilbert, A. Roberts and P. A. Griswold, Phys. Rev. 76, 1723 (1949) and by D. A. Gilbert and A. Roberts Phys. Rev. 77, 742 (1950). The vibrational constants were obtained from the analysis vibration-rotation fine structure in the infrared by A. H. Nielsen and E. A. Jones, J. Chem. Phys. 19, 1117 (1951).

The rotational and vibrational constants were adjusted to Cl^{35} = 75.4% and Cl^{37} = 24.6%.

Dec. 31, 1960; Mar. 31, 1966

MAGNESIUM CHLORIDE FLUORIDE (MgClF) (IDEAL GAS) MOL. WT. = 78.7634

Point Group C_{2v}

$\Delta H_{f\ 0}^\circ$ = [-135.6 ± 5] kcal. mole^{-1}

$S^\circ_{298.15}$ = [62.76] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ$ = [-136.0 ± 5] kcal. mole^{-1}

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[719](1)
[205](1)
[453](1)

Bond Distance: Mg-Cl = [2.18] Å Mg-F = [1.77] Å

Bond Angle: Cl-Mg-F = [170]°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.5643 X 10^{-115}] g.^{3} cm.^{6}

Heat of Formation.

The heat of formation is based on an estimated $\Delta H_{r\ 298}^\circ$ = 0 for the reaction $MgCl_2(g) + MgF_2(g) \rightarrow 2MgClF(g)$, using $\Delta H_{f\ 298.15}^\circ$ = -95.85 and -176.2 kcal. mole^{-1} for $MgCl_2(g)$ and $MgF_2(g)$, respectively.

Heat Capacity and Entropy.

The bond angle is taken to be the value we have adopted for $MgCl_2(g)$. The Mg-Cl and Mg-F bond distances are assumed to be the same as those in $MgCl_2(g)$ and $MgF_2(g)$. The vibration frequencies are the averages of those for $MgCl_2(g)$ and $MgF_2(g)$. The three principal moments of inertia are: I_A = 0.0977 X 10^{-39}, I_B = 39.956 X 10^{-39} and I_C = 40.054 X 10^{-39} g. cm.^{2}

Heat of Formation

C. A. Neugebauer and J. L. Margrave, J. Am. Chem. Soc. 79, 1338 (1957), measured the heat of reaction of perchloryl fluoride and hydrogen.

ClO_3F (g) + $4H_2$ (g) = HF (aq., 0.6M) + HCl (aq., 0.6M) + $3H_2O$ (l)

The necessary, additional thermal data for the calculation of the heat of formation was obtained by them from N. B. S., Circ. 500. V. H. Dibeler, R. M. Reese and D. E. Mann, J. Chem. Phys. 27, 176 (1957) obtain a value of -5.3 ± 4 kcal. mole^{-1} from the observed appearance potential of Cl^+.

Heat Capacities and Entropies

The assignment of D. R. Lide and D. E. Mann, J. Chem. Phys. 25, 1128 (1956), based upon the infra red spectra of the gas is supported by the Raman measurements of F. X. Powell and E. R. Lippincott, J. Chem. Phys. 32, 1883 (1960).

The value of the spectroscopic constant B was obtained by R. P. Madden and W. S. Benedict from a high resolution infra red spectrograph. The Cl-F bond distance was estimated assuming a single covalent bond with no ionic character as evidenced by the low dipole momenent obtained by A. A. Maryott and S. J. Kreidler, J. Chem. Phys. 27, 1221 (1957). Electron spin resonance results are explained by S. Brownstein, Can. J. Chem. 38, 1597 (1960), on the basis of a low dipole moment. The Cl-O distance was estimated to be that found in the Chlorate ion, L. Pauling, "The Nature of the Chemical Bond", 3rd ed. Cornell Univ. Press, Ithaca, 1960. The resulting values of the bond angles and I_C are consistent with the measured I_B and the assumed bond lengths.

A calorimetric entropy of 60.17 cal. deg.$^{-1}$ mole^{-1} at 226.48°K was obtained by J. K. Koehler and W. F. Giauque, J. Am. Chem. Soc. 80, 2659 (1958) for the ideal gas. If the lattice doesn't discriminate between F and O atoms then at 0°K a residual entropy of 2.75 cal. deg.$^{-1}$ mole^{-1} exists and the third law entropy would be 62.92 cal. deg.$^{-1}$ mole^{-1}. This value may be compared with 62.64 obtained statistically. The difference 0.3 cal. deg.$^{-1}$ mole^{-1} is within the range found for other molecules and explained on the basis of some discrimination in the lattice, see Koehler and Giauque, loc. cit. for references.

Bond Distance: P-Cl = 2.01 ± 0.04 Å P-F = 1.51 ± 0.03 Å P-O = 1.55 ± 0.03 Å

Bond Angle: F-P-F = F-P-Cl = 103° $\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C = 4.2790825 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ of $POClF_2$ was estimated to be -228 kcal. mole^{-1} from the $\Delta H^\circ_{f\ 298.15}$ of POF_3 by assuming bond energies of 120 kcal. for D(P-F) and 80 kcal. for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from E. Neale and L. T. D. Williams, J. Chem. Soc., 2485 (1955) Part I and E. Neale, L. T. D. Williams and V. T. Moores, J. Chem. Soc., 422 (1956) Part II.

Essentially the same $\Delta H^\circ_{f\ 298.15}$ may be obtained by assuming a $\Delta H_r = 0$ for the following reaction:

$$POCl_3(g) + POF_3(g) \rightarrow POCl_2F(g) + POF_2Cl(g)$$

Heat Capacity and Entropy.

The molecular constants were determined by L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc., 60, 1836 (1938) and by Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys., 20, 164 (1952). Brockway and Beach used electron diffraction. Q. Williams et al. measured microwave spectra. Brockway and Beach assumed that the F-P-F and F-P-Cl angles were equal in POF_2Cl and $POFCl_2$. An analysis of Brockway and Beach's data by Q. Williams et al., indicates that the angles in POF_2Cl, $POFCl_2$, $POCl_3$, and POF_3 should be 103° rather than the reported 106° ± 3°. The principal moments of inertia calculated from these parameters were $I_A = 3.24319 \times 10^{-38}$ g. cm.^{3}, $I_B = 1.87015 \times 10^{-38}$ g. cm.^{3}, and $I_C = 3.13496$ g. cm.$^3 \times 10^{-38}$.

The Raman spectra and vibrational frequencies for POF_2Cl were reported by M. L. Delwaulle and F. Francois, Compt. Rend. 222, 550 (1946). The frequencies were reassigned by M. L. Delwaulle and F. Francois in J. Chim. Phys. 46, 87 (1949).

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ = -37.97 kcal. mole^{-1} was calculated from $\Delta H^\circ_{r\ 298}$ = 25.83 kcal. mole^{-1} obtained by third law analysis of the equilibrium data of H. Schmitz and H. T. Schumacher, Z. Naturforsch 2a, 362 (1947) for the reaction $ClF_3(g) = ClF(g) + F_2(g)$. Similar values are obtained from the equilibrium data of K. Schäfer and E. Wicke, Z. Elektrochemie 52, 205-209 (1948). Calorimetric values scatter widely, as summarized below; these were given little weight.

Source	Method	Reaction	Observation (kcal. mole^{-1})	3rd Law Drift (e.u.)	ΔHf°_{298} (kcal. mole^{-1})
1a	K_p(523-623°K)	$ClF_3(g) \rightarrow ClF(g) + F_2(g)$	$\Delta H^\circ_{r\ 298} = 25.83$	0.8 ± 0.3	-37.97
2a	K_p(733°K)	$ClF_3(g) \rightarrow ClF(g) + F_2(g)$	$\Delta H^\circ_{r\ 298} = 25.77$	---	-37.91

Heat Capacity and Entropy.

The structural constants were obtained from the microwave study of D. F. Smith, J. Chem. Phys. 21, 609 (1953). The planar distorted "T" structure is similar to that derived from X-ray studies of the solid by R. D. Burbank and F. N. Bensey, J. Chem. Phys. 21, 602 (1953). Fundamental frequencies are taken from the infrared and Raman spectra of H. H. Claassen, B. Weinstock and J. G. Malm, J. Chem. Phys. 28, 285 (1958). These data confirm the "T" structure as opposed to the pyramidal structure used in earlier spectral analyses.

Claassen, et al., loc. cit., calculate thermodynamic functions virtually identical with the JANAF values. These authors also correct the third law entropy reported by J. W. Grisard, H. A. Bernhardt and G. D. Oliver, J. Am. Chem. Soc. 73, 5725 (1951) from measurements of heat capacity (14-285°K.) and vapor pressure (226-303°K.). The entropy at the normal boiling point becomes $S^\circ_{284.91}$ = 67.04 cal. deg.$^{-1}$ mole^{-1} when a non-ideality correction consistent with the dimer-monomer vapor equilibrium is applied. The corresponding statistical entropy, $S^\circ_{284.91}$ = 66.59 cal. deg.$^{-1}$ mole^{-1}, is consistent with the third law value within the probable error in the entropy of the liquid and the entropy of vaporization. The three principal moments of inertia are: $I_A = 6.1114 \times 10^{-39}$, $I_B = 1.81545 \times 10^{-38}$ and $I_C = 2.42659 \times 10^{-38}$ g. cm.^{2}

CHLORINE PENTAFLUORIDE (ClF_5) (IDEAL GAS) GFW = 130.445

Point Group C_{4v}

$S^\circ_{298.15}$ = 74.241 gibbs/mol

Ground State Quantum Weight = [1]

ΔHf°_0 = [-54.9 ± 15] kcal/mol

$\Delta Hf^\circ_{298.15}$ = [-57 ± 15] kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
712 (1)	488 (1)	732 (2)
541 (1)	346 (1)	[440](2)
486 (1)	375 (1)	302 (2)

Bond Distance: $(Cl\text{-}F)_{basal}$ = 1.72 Å $(Cl\text{-}F)_{axial}$ = 1.62 Å

Bond Angle: F-I-F = 90°

σ = 4

Product of Moments of Inertia: $I_AI_BI_C = 2.47289 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation.

The heat of formation was estimated by assuming that the ratio [A.B.E.(ClF) - A.B.E.(ClF_3)]/[A.B.E.(ClF_3) - A.B.E.(ClF_5)] was equal to [A.B.E.(BrF) - A.B.E.(BrF_3)]/[A.B.E.(BrF_3) - A.B.E.(BrF_5)], where A.B.E. represents average bond energy. All values were taken from these tables. A.B.E.(ClF_5) was thus calculated to be 36 kcal/mol which leads to ΔHf° = -57 ± 15 kcal/mol.

Heat Capacity and Entropy.

G. M. Begun, W. H. Fletcher and D. F. Smith, J. Chem. Phys. 42, 2236 (1965), have reported the infrared spectra of the gas and the Raman spectra of the liquid. Their assignments have been adopted here, including one frequency ν_8 obtained from a valence force-field treatment. The values are consistent with those for IF_5(g) and BrF_5(g). D. F. Smith, Science 141, 1039 (1963), had previously reported three infrared bands. The structure of the molecule has not been determined but the spectra can only be interpreted assuming C_{4v} symmetry; this is in accord with IF_5 and BrF_5(g). Begun et al. assumed a square pyramidal structure with the chlorine in the base of the pyramid. There is some evidence that the chlorine may not lie in the basal plane but this would not appreciably affect the calculations. The structure adopted was that given by Begun et al. The individual moments of inertia are $I_A = I_B = 25.7380 \times 10^{-39}\ g\ cm^2$ and $I_C = 37.3298 \times 10^{-39}\ g\ cm^2$.

$\omega_e x_e$ = 1.19 cm.$^{-1}$

α_e = [0.00075] cm.$^{-1}$

σ = 1

r_e = [2.09]

Heat of Formation.

The dissociation energy (D_0°) of FeCl(g) was reported as 3 ± 2 e.v. (69 ± 46 kcal. mole^{-1}) by A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The corresponding $\Delta H^\circ_{f\ 298.15}$ (FeCl, g) was evaluated to be 56 ± 46 kcal. mole^{-1}. By comparing D(Fe-O) = 101 kcal. mole^{-1} in FeO(g) with the coördinate bond energies obtained in organic complexes and iron carbonyl halides of E(Fe-O) = 59.4 and E(Fe-Cl) = 37.3 kcal. mole^{-1}, reported by M. M. Jones, B. J. Yow and W. R. May, Inorg. Chem. 1, 166 (1962), the D(Fe-Cl) in FeCl(g) was estimated as 101 x (37.3/59.4) = 63.3 kcal. mole^{-1}, yielding $\Delta H^\circ_{f\ 298.15}$ (FeCl, g) = 64 kcal. mole^{-1}. The adopted value of $\Delta H^\circ_{f\ 298.15}$ for FeCl(g) is 60 ± 20 kcal. mole^{-1}.

Heat Capacity and Entropy.

The ground state configuration, ω_e and $\omega_e x_e$ (corrected to the average isotopic species) were obtained from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950. The Fe-Cl bond distance was assumed to be the same as that in $FeCl_2$(g). Hence the values of B_e and α_e were calculated. The electronic levels and quantum weights were estimated by comparison with the electronic levels in Fe^+(g) reported by C. E. Moore, "Atomic Energy Levels", Circular of the National Bureau of Standards 467, Vol. II, 1952, using the reasoning suggested by J. T. Hougen, G. E. Leroi and T. C. James, J. Chem. Phys. 34, 1670 (1961). The total 30 for the quantum weight was obtained from the ground multiplet of Fe^+ and was split arbitrarily. The entropy values may be in error by a few entropy units due to the uncertainties in the low lying electronic levels. The principal moment of inertia is 1.5728 x 10^{-38} g. cm.^{2}

Dec. 31, 1960; Mar. 31, 1961; Sept. 30, 1964

HYDROGEN CHLORIDE (HCl) (IDEAL GAS) MOL. WT. = 36.465

Ground State Configuration $^1\Sigma^+$

$S^\circ_{298.15}$ = 44.645 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = -22.019 ± 0.05 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -22.063 ± 0.05 kcal. mole^{-1}

Electronic Levels and Quantum Weights

ϵ_1, cm.$^{-1}$	g_1
0	1

ω_e = 2989.59 cm.$^{-1}$

B_e = 10.5884 cm.$^{-1}$

$\omega_e x_e$ = 52.06 cm.$^{-1}$

α_e = 0.3037 cm.$^{-1}$

σ = 1

r_e = 1.2746 Å

Heat of Formation.

The selected value, Rossini's flow calorimetric measurement (1) of the direct combination of the elements, is essentially the same as that in the revised version (2) of NBS Circular 500. JANAF analyses of the more recent measurements are summarized below, while the earlier measurements have been reviewed by Rossini (1).

Experimenters	Date	Method	$\Delta H^\circ_{f\ 298.15}$ (kcal. mole^{-1})	References
Johnson, Ambrose	1963	Comparison of HCl, H_2SO_4 and SO_2 by solution calorimetry	-22.14 ± 0.12	2,3,4,5,6,7,8,9,10
Lacher, et al.	1949-52	Catalytic combination in flow calorimeter	-22.10 ± 0.12	11,12
Roth, Richter	1934	Direct combination in bomb calorimeter	-21.90 ± 0.05	13
von Wartenberg, Hanisch	1932	Direct combination in flow calorimeter	-21.90 ± 0.01	14
Rossini	1932	Direct combination in flow calorimeter	-22.063 ± 0.012	1
- - -	1922-63	ΔF°_f from e.m.f. and ΔS°_f from statistical mechanics	-22.02 ± 0.03	15,16,17,18,19,20
Lewis	1906	Equilibria for reaction HCl(g) + 1/4 O_2(g) = 1/2 H_2O(g) + 1/2 Cl_2(g)	-22.30 ± 0.44	21

The direct combination values of Roth-Richter (13) and von Wartenberg - Hanisch (14) are 0.7% less negative than that of Rossini; however, all of the other methods favor the more negative value. The Roth - Richter value may be affected by errors in the measurement of the extent of reaction by HCl titration (9,22), since a set of experiments based on determination of the amount of H_2 gave a value of -22.02 kcal. mole^{-1}.

Rossini's value is confirmed by a variety of independent methods. The solution calorimetry (3), though it is related through a complex reaction scheme, is based on species which are now quite well known. E.m.f. measurements (15,16,17,18, 19,20) give $\Delta F^\circ_{f\ 298.15}$ = -22.733; assuming an uncertainty of 1.0 mv. in E°, this leads to $\Delta H^\circ_{f\ 298.15}$ = -22.02 ± 0.03 when combined with the statistical entropies. The equilibria of Lewis (625-692°K) give $\Delta H^\circ_{f\ 298.15}$ = -22.20 ± 0.44 (second law) and -22.30 ± 0.04 (third law).

Heat Capacity and Entropy.

Spectroscopic constants for HCl^{35} and HCl^{37} were selected from the work of E. K. Plyler, E. D. Tidwell, Z. Elektrochem. 64, 717 (1960) and C. Haeusler, P. Barchewitz, Compt. rend. 246, 3040 (1958). The values were adjusted to 75.53% HCl^{35}.

Heat of Formation

I. E. Flis, K. P. Mishchenko, and N. V. Pakhomova, Zhur. Neorg. Khim. 3, 1772, 1781 (1958), report the following heats of reaction:

$ClO^-(aq) + H^+(aq) \rightarrow HOCl(aq)$ $\Delta H_{r\ 298.15} = -5.64 \pm 0.03$ kcal.

$ClO^-(aq) + H_2O_2(aq) \rightarrow Cl^-(aq) + H_2O(l) + O_2(g)$ $\Delta H_{r\ 298.15} = -36.93 \pm 0.05$ kcal.

If the following auxiliary heats of formation are used:

$Cl^-(aq)$ $\Delta H^\circ_{f\ 298.15} = -40.02$ kcal. mole^{-1} (National Bureau of Standards Circ. 500, 1952)

$H_2O(l)$ $\Delta H^\circ_{f\ 298.15} = -68.32$ kcal. mole^{-1} (National Bureau of Standards Circ. 500, 1952)

$H_2O_2(aq)$ $\Delta H^\circ_{f\ 298.15} = -45.70 \pm 0.02$ kcal. mole^{-1} (P. A. Giguère, B. G. Morissette, A. W. Olmos, and O. Knop, Can. J. Chem. 33, 804 (1955), consistent with $\Delta H^\circ_{f\ 298.15}$ of $H_2O_2(g)$ in this compilation)

then $\Delta H_{f\ 298.15}$ for HOCl(aq) is found to be -31.35 kcal. mole^{-1}. From the heats of solution in water of other weak acids, $\Delta H_{solution}$ for HClO is estimated to be -8 ± 3 kcal. mole^{-1}. These heats yield -23 ± 3 kcal. mole^{-1} for $\Delta H^\circ_{f\ 298.15}$ of HOCl(g). By averaging the heats of formation of $H_2O(g)$ and $Cl_2O(g)$, $\Delta H^\circ_{f\ 298.15}$ of HOCl(g) is estimated to be -20 ± 5 kcal. mole^{-1}. The value -22 ± 3 kcal. mole^{-1} is adopted here.

Heat Capacity and Entropy

The frequencies are from K. Hedberg and R. M. Badger, J. Chem. Phys. 19, 508 (1951), and the molecular dimensions from L. V. Gurvich and M. M. Novikov, Optics and Spectroscopy (English translation) 7, 70 (1959).

$\Delta H^\circ_{f\ 0}$ = -74.42 ± 0.20 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -75.18 ± 0.20 kcal. mole^{-1}

$\Delta H^\circ_{t_2}$ = 0.25 kcal. mole^{-1}

$\Delta H^\circ_{t_1}$ = 0.944 kcal. mole^{-1}

Heat of Formation.

The equilibrium pressures for the reaction $NH_4Cl(c) = NH_3(g) + HCl(g)$, at 320-626°K., have been measured by many investigators. A. Smits and W. de Lange, J. Chem. Soc., 2944 (1928), using the densi-tensimeter, determined the vapor pressure of $NH_4Cl(c)$ and the density of the saturated vapor simultaneously. The results obtained indicate that within the range 527-626°K. the saturated vapor completely dissociates into gaseous NH_3 and HCl. Based on this conclusion, the reported vapor pressure data were employed to evaluate the heat of dissociation of $NH_4Cl(c)$ by both the second and third law methods. The results are presented as follows.

Investigator	Temperature, °K.	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	Drift, e.u.
Smith and Calvert (1)	521.6-619.1	43.18 ± 0.08	42.11	-2.0 ± 0.2
Smits and Lange (2)	527.9-625.6	42.16 ± 0.22	42.14	-0.2 ± 0.4
Braune and Knoke (3)	525.4-615.0	42.02 ± 0.06	42.20	0.2 ± 0.1
Rodebush and Michalek (4)	471.3-557.0	42.43 ± 0.09	42.08	-0.3 ± 0.2
Wagner and Neumann (5)	319.0-352.7	43.83 ± 0.38	42.17	-4.9 ± 1.1
Markowitz and Boryta (6)	503.4-611.4	41.27 ± 0.38	42.12	1.3 ± 0.8

(1) A. Smith and R. P. Calvert, J. Am. Chem. Soc. 36, 1363 (1914), using isoteniscope.
(2) A. Smits and W. D. Lange, J. Chem. Soc. 2944 (1928), using densi-tensimeter.

(4) W. H. Rodebush and J. C. Michalek, J. Am. Chem. Soc. 51, 748 (1929), glass diaphragm manometer.
(5) H. Wagner and K. Neumann, Z. phys. Chem. 28, 51 (1961), torsion-effusion method.
(6) M. M. Markowitz and D. A. Boryta, J. Phys. Chem. 66, 1477 (1962), differential thermal analysis.

The value of $\Delta H^\circ_{r\ 298.15}$ adopted is 42.15 ± 0.10 kcal. mole^{-1}, yielding $\Delta H^\circ_{f\ 298.15}$ (NH_4Cl, c) = -75.8 ± 0.20 kcal. mole^{-1}. The corresponding $\Delta H^\circ_{r\ 298.15}$ value evaluated from solution data, selected by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NSRDS-NBS2, National Bureau of Standards, is 42.06 kcal. mole^{-1}.

Heat Capacity and Entropy.

The heat capacities (20.1-523.2°K.) of $NH_4Cl(c)$ have been measured by the following investigators: (1) R. Ewald, Ann. Physik, 44, 1213 (1914), 138-301°K; (2) F. Simon, ibid., 68, 241 (1922), 20.1-290.8°K; (3) H. Klinkhardt, ibid., 84, 167 (1927), 323.2-523.2°K.; (4) F. Simon, C. v. Simon and M. Ruhemann, Z. phys. Chem. 129, 339 (1927), 204.5-275.8°K; (5) W. T. Ziegler and C. E. Messer, J. Am. Chem. Soc., 63, 2694 (1941), 107.2-320.2; (6) R. Extermann and J. Weigle, Helv. Phys. Acta, 15, 455 (1942), 228.2-248.2°K; and (7) M. M. Popov and G. L. Galchenko, J. Gen. Chem., USSR, 21, 2489 (1951), 373.2-523.2°K. These C_p data were plotted and a smooth C_p curve was drawn and adopted. The C_p values above 523°K. were obtained by graphical extrapolation of the previous C_p curve. $S^\circ_{298.15}$ was derived from the adopted low temperature data, based on $S^\circ_{20.1}$ = 0.114 e.u.

Transition Data.

There are two transitions reported in the literature. The low temperature transition data (T_{t_2} and $\Delta H^\circ_{t_2}$) were derived based on the heat capacity (107-320°K.) data reported by W. T. Ziegler and C. E. Messer, loc. cit., in which the other T_{t_2} values given by previous investigators were reviewed. The high temperature transition data (T_{t_1} and $\Delta H^\circ_{t_1}$) were taken from H. Klinkhardt, loc. cit. However, $\Delta H^\circ_{t_1}$ = 1030 and $\Delta H^\circ_{463.5}$ = 1059.1 ± 8.0 cal. mole^{-1} were reported by E. C. Scheffer, Proc. Acad. Sci. Amsterdam, 24, 1513 (1915/16), and M. M. Popov and G. L. Galchenko, loc. cit., respectively. M. M. Markowitz and D. A. Boryta, loc. cit. determined T_{t_1} to be 459.5 ± 0.5°K.

Melting Temperature.

T_m was obtained from H. Rassow, Z. anorg. Chem. 114, 117 (1920), determined under pressure.

Decomposition Temperature.

The value of T_d was calculated as the temperature at which the vapor pressure of the decomposition products (NH_3 and HCl) equals 1 atm. By differential thermal analysis, T_d for $NH_4Cl(c)$ was determined to be 611.4°K. by M. M. Markowitz and D. A. Boryta, loc. cit.

ClH_4NO_4

AMMONIUM PERCHLORATE (NH_4ClO_4) (CRYSTAL) MOL. WT. = 117.497

ΔH_f° 298.15 = -70.69 ± 0.30 kcal. mole^{-1}

$S^\circ_{298.15}$ = 44.02 ± 0.04 cal. deg.$^{-1}$ mole^{-1}

T_t = 513.15°K

ΔH_t° = 2.3 ± 0.2 kcal. mole^{-1}

T_d = [513]°K.

Heat of Formation.

A. A. Gilliland and W. H. Johnson, J. Research Natl. Bur. Standards 65A, 67 (1961), and M. M. Birky and L. G. Hepler, J. Phys. Chem. 64, 686 (1960), have derived the heat of formation for NH_4ClO_4(c) from solution-calorimetric measurements. Their values are -70.74 ± 0.32 and -70.63 kcal. mole^{-1}, respectively. The mean of these is adopted here.

Heat Capacity and Entropy.

B. H. Justice and E. F. Westrum, private communication, April 1961, have measured the heat capacity from 5° to 350°K. The C_p values above 350°K were extrapolated. From the partial molar entropies of NH_4^+(aq) and ClO_4^-(aq) and the entropy of solution, Birky and Hepler, loc. cit., calculated a value of 43.6 cal. deg.$^{-1}$ mole^{-1} for $S^\circ_{298.15}$. The fair agreement of this value with that derived from C_p suggests that there is no residual entropy at 0°K, as there would be if the NH_4^+ ion had a random orientation.

Transition and Decomposition Data.

T_t and ΔH_t° were obtained (under a pressure of NH_3) by M. M. Markowitz, Foote Mineral Company, Exton, Pennsylvania (private communication, September 20, 1962). T_d was estimated from the report by M. M. Markowitz, loc. cit.

Heat of Formation

A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall, London 1953, gives 23 ± 2.3 kcal for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from K. Wieland Zeits. f. Elektrochemie 64, 761 (1960) were weighted according to their natural isotopic abundances. Rotational constants were estimated using equation III, 123 p. 108, G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. Bond length given by G. Herzberg (loc. cit.).

Mar. 31, 1962; Sept. 30, 1963; Sept. 30, 1965

IODINE MONOCHLORIDE (ClI) (CRYSTAL) MOL. WT. = 162.3574

$S^\circ_{298.15}$ = 23.405 cal. mole^{-1} deg.$^{-1}$

T°_m = 300.53°K.

$\Delta H^\circ_{f\ 0}$ = -8.699 ± 0.025 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -8.466 ± 0.025 kcal. mole^{-1}

ΔH°_m = 2.773 ± 0.002 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 12.650 kcal. mole^{-1}

Heat of Formation.

The heat of formation is that adopted by G. V. Calder and W. F. Giauque, J. Phys. Chem. 69, 2443 (1965) from an analysis of the equilibrium data of J. McMorris and D. M. Yost, J. Am. Chem. Soc. 54, 2247 (1932) and C. M. Beeson and D. M. Yost, J. Chem. Phys. 7, 44 (1939). This yielded a heat of formation of ICl(g), from which the heat of formation of ICl(c) was calculated by using the heat of vaporization determined by Calder and Giauque loc. cit.

Heat Capacity and Entropy.

The heat capacity has been measured by Calder and Giauque loc. cit. from 17-322°K. The entropy was calculated based on S_{15} = 0.592 cal. mole^{-1} deg.$^{-1}$ Above 300° the heat capacity data was extrapolated smoothly.

Melting Data.

All data were measured by Calder and Giauque loc. cit.

Mar. 31, 1962; Sept. 30, 1963; Sept. 30, 1965

IODINE MONOCHLORIDE (ClI)   (LIQUID)   MOL. WT. = 162.3574

$S^\circ_{298.15}$ = 32.544 cal. mole^{-1} deg.$^{-1}$ ΔH_f° 298.15 = -5.72 ± 0.03 kcal. mole^{-1}

T_m° = 300.53°K. ΔH_m° = 2.773 ± 0.002 kcal. mole^{-1}

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH_m° and the difference between $H_{300.53}-H_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity from 300.53 to 317.76°K. has been measured by G. V. Calder and W. F. Giauque, J. Phys. Chem. 69, 2443 (1965). Above 318°K. it was extrapolated in a smooth manner. The entropy was obtained in a manner analogous to the heat of formation.

Heat of Formation.

The dissociation energy from spectroscopic measurements of ICl(g) has been summarized by W. H. Evans, T. R. Munson and D. D. Wagman, J. Res. Natl. Bur. Standards, 55, 147 (1955) from which they adopt $D_0^\circ = 49.64$ kcal. mole^{-1}. J. McMorris and D. M. Yost, J. Am. Chem. Soc. 54, 2247 (1932) and C. M. Beeson and D. M. Yost, J. Chem. Phys. 7, 44 (1939) studied the equilibria $NOCl = NO + 1/2\ Cl_2$ and $NO + ICl = NOCl + 1/2\ I_2(g)$ from which the equilibrium constant of $ICl = 1/2\ Cl_2 + 1/2\ I_2(g)$ can be obtained. G. V. Calder and W. F. Giauque, J. Phys. Chem. 69, 2443 (1965) have used 3rd law analysis to obtain $D_0^\circ = 49.578 \pm 0.025$ kcal. mole^{-1}. This value was adopted yielding $\Delta H^\circ_{f\ 298} = 4.184 \pm 0.025$ kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular and vibrational constants were obtained from G. Herzberg "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York 1950. The values were then adjusted for the normal isotopic abundance of chlorine.

$\Delta H_{f\,0}^\circ = -104.30$ kcal. mole^{-1}

$S_{298.15}^\circ = 19.73 \pm 0.04$ cal. deg.$^{-1}$ mole^{-1} $\Delta H_{f\,298.15}^\circ = -104.37 \pm 0.06$ kcal. mole^{-1}

$T_m = 1044$°K. $\Delta H_m^\circ = 6.282$ kcal. mole^{-1}

Heat of Formation.

The heat of formation was calculated from the heat of hydrolysis of K(c), the heats of solution of HCl(g) and KCl(c), and the standard heat of neutralization of a strong acid and strong base. Extensive measurements are available for all these quantities. Values used in the calculation, in addition to the heat of formation for HCl(g), are summarized below.

Source	Reaction	$\Delta H_{r\,298.15}^\circ$ (kcal.)
1,2,3,4	$K(c) + H_2O(l) \rightarrow KOH(\infty H_2O) + 1/2\ H_2(g)$	-46.966 ± 0.05
5,2,6	$HCl(g) \rightarrow HCl(\infty H_2O)$	-17.88 ± 0.015
7	$KCl(\infty H_2O) \rightarrow KCl(c)$	-4.115 ± 0.010
7	$KOH(\infty H_2O) + HCl(\infty H_2O) \rightarrow KCl(\infty H_2O) + H_2O(l)$	-13.345 ± 0.025

Heat Capacity and Entropy.

Low temperature heat capacities were obtained from the data (2.8-275°K.) of W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) A242, 467 (1957). Previous measurements scatter around the selected values and are in good agreement. These include P. G. Strelkov, E. S. Itskevich, V. N. Kostryukov, and G. G. Mirskaya (12-298°K.), Zhur. Fiz. Khim. 28, 645 (1954); K. Clusius, J. Goldman, and A. Perlick (10-273°K.), Z. Naturforsch. 4a, 429 (1949); and J. C. Southard and R. A. Nelson (17-285°K.), J. Am. Chem. Soc. 55, 4865 (1933). For other less extensive data see the review by K. K. Kelley and E. G. King, USBM Bulletin 592, 1961. The entropy is based on the extrapolation $S_{2.8}^\circ = 0.0006$ cal./deg.-mole.

High temperature values are based on enthalpy data (373-1038°K.) from T. B. Douglas, private communication, U. S. Natl. Bur. Std., May 23, 1961. These values join smoothly with the low temperature values and are in excellent agreement with the enthalpy data (673-933°K.) of S. M. Skuratov and S. A. Lapushkin, J. Gen. Chem. (USSR) 21, 2485 (1951) and the adiabatic heat capacities (334-721°K.) of A. Mustajoki, Ann. Acad. Scient. Fennicae, Series A, I, 98, 7 (1951).

Melting Data.

The melting point and heat of melting are from Douglas, loc. cit. Values of $T_m = 1043$° and 1045°K. have been reported by E. Aukrust, B. Bjørge, H. Flood, and T. Forland, Ann. New York Acad. Sci. 79, 830 (1960) and J. W. Johnson and M. A. Bredig, J. Phys. Chem. 62, 604 (1958), respectively. The heat of melting is confirmed by $\Delta H_m^\circ = 6.34$ kcal./mole obtained from enthalpy data by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960) and $\Delta H_m^\circ = 6.4$ and 6.5 kcal./mole based on enthalpy and phase diagram studies of Aukrust et al., loc. cit., respectively.

Dec. 31, 1961; Mar. 31, 1966

POTASSIUM CHLORIDE (KCl) (LIQUID) MOL. WT. = 74.555

$S^\circ_{298.15}$ = 20.71 cal. deg.$^{-1}$ mole^{-1}

T_m = 1044°K.

T_b = 1710°K. (to equilibrium vapor)

T_b = [1750°K.] (to monomer only)

$\Delta H^\circ_{f\ 298.15}$ = -100.81 kcal. mole^{-1}

ΔH°_m = 6.282 kcal. mole^{-1}

ΔH°_v = 29.7 kcal. mole^{-1} (equilibrium vapor)

ΔH°_v = [37.14] kcal. mole^{-1} (monomer)

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH°_m and the difference between $(H^\circ_{1044}-H^\circ_{298})$ for the crystal and liquid.

Heat Capacity and Entropy.

The constant heat capacity, 17.59 cal./deg.-mole, was derived from enthalpy data (1053-1173°K.) of T. B. Douglas, private communication, U. S. Natl. Bur. Std., May 23, 1961. This value was extrapolated above and below the experimental range. A lower value of 16.7 cal./deg.-mole was derived by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1, 1964, from enthalpy data (1050-1110°K.) obtained in a heat of melting study. The entropy of the liquid was obtained in a manner analogous to the heat of formation.

Melting Data.

The melting point and heat of melting are from Douglas, loc. cit. Values of T_m = 1043° and 1045°K. have been reported by E. Aukrust, B. Björge, H. Flood, and T. Forland, Ann. New York Acad. Sci. <u>79</u>, 830 (1960) and J. W. Johnson and M. A. Bredig, J. Phys. Chem. <u>62</u>, 604 (1958), respectively. The heat of melting is confirmed by ΔH°_m = 6.34 kcal./mole obtained from enthalpy data by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. <u>64</u>, 269 (1960) and ΔH°_m = 6.4 and 6.5 kcal./mole based on enthalpy and phase diagram studies of Aukrust et al., loc. cit., respectively.

Vaporization Data.

T_b (to equilibrium vapor) is the temperature resulting in unit total pressure based on the calculated partial pressures of KCl(g) and K_2Cl_2(g). This value may be compared with boiling points of 1688° and 1690°K. observed respectively by O. Ruff and S. Mugdan, Z. anorg. allgem. Chem. <u>117</u>, 147 (1921), and H. von Wartenburg and P. Albrecht, Z. Elektrochem. <u>27</u>, 162 (1921). ΔH°_v (equilibrium vapor) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 22.3 mole percent of dimer. According to the selected functions, the amount of dimer at lower temperatures increases gradually to about 32 mole percent at the melting point then decreases rapidly over the crystal. T_b (to monomer only) is taken as the temperature at which the calculated free energy change is zero for KCl(l) → KCl(g), while ΔH°_v (monomer) is the corresponding heat of reaction.

Data on vapor pressures and dimer-monomer equilibrium are reviewed on the tables for KCl(g) and K_2Cl_2(g), respectively.

Heat of Formation.

The heat of formation was calculated from that of the liquid based on $\Delta H_v^\circ{}_{298.15} = 49.5$ kcal./mole as selected from vapor pressure analyses summarized below. Partial pressures for the monomer were obtained from data of the first four sources by combination of total vapor pressures with PVT data or with transpiration data. Mass spectrometric values (source 5) are based on temperature variation of ion intensity. These same five studies were used in selection of $\Delta H_r^\circ{}_{298.15} = 45.0$ kcal./mole for the dimer-monomer equilibrium (see K_2Cl_2).

The resulting tables were tested by comparison with total pressure data over the range 819-1691°K. Dimer-monomer ratios calculated from the tables were used to convert observed total pressures to the monomer pressures which are analyzed below (sources 6-11). The results are consistent except near the boiling point where the observed pressures (sources 10 and 11) are 6-18 percent larger than those calculated. Knudsen effusion and transpiration studies over the crystal were not analyzed since they are in essential agreement with the torsion effusion data of source 6.

Heat Capacity and Entropy.

Rotational and vibrational constants are based on the microwave studies of P. L. Clouser and W. Gordy, Phys. Rev. 134, A863 (1964). Earlier microwave data of A. Honig, M. Mandel, M. L. Stitch, and C. H. Townes, Phys. Rev. 96, 629 (1954) and electric resonance data of C. A. Lee, B. P. Fabricand, R. O. Carlson, and I. I. Rabi, Phys. Rev. 91, 1395 (1953) are in excellent agreement. Infrared spectra of S. A. Rice and W. Klemperer, J. Chem. Phys. 27, 573 (1957) yield $\omega_e = 281 \pm 6$ cm.$^{-1}$ which is also in good agreement. The constants were adjusted to a natural isotopic composition of 24.47% ^{37}Cl and 6.8% ^{41}K.

POTASSIUM PERCHLORATE ($KClO_4$) (CRYSTAL) MOL. WT. = 138.557

$\Delta H^\circ_{f\ 0}$ = -100.9 kcal. mole^{-1}

$S^\circ_{298.15}$ = 36.1 ± 0.2 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -102.8 ± 1.0 kcal. mole^{-1}

T_t = 572.7°K.

ΔH°_t = 3.29 kcal. mole^{-1}

T_m = 798°K.

ΔH°_m = Unknown

Heat of Formation.

The heat of decomposition of $KClO_4(c)$ to $KCl(c)$ and $O_2(g)$ was measured by W. H. Johnson and A. A. Gilliland, J. Res. Natl. Bur. Std. 65A, 63 (1961), yielding $\Delta H^\circ_{f\ 298.15}$ = -103.22 ± 0.15 kcal. mole^{-1}. K. A. Hofmann and P. H. Marin, Sitzber. preuss. Akad. Wiss. Physik. math. Kl. 448 (1932), burned a mixture of paraffin and potassium perchlorate and obtained $\Delta E_{298.15}$ = -1.73 kcal. mole^{-1} for the constant volume process corresponding to the reaction: $KClO_4(c) = KCl(c) + 2O_2(g)$. Correction of their value for $\Delta(PV)$ gives $\Delta H^\circ_{r\ 298.15}$ = -0.55 kcal. mole^{-1} which agrees reasonably well to the corresponding value, -0.96 ± 0.10 kcal. mole^{-1}, reported by W. H. Johnson and A. A. Gilliland, loc. cit. However, for the same reaction, $\Delta H^\circ_{r\ 298.15}$ = -2.55 ± 0.18 kcal. mole^{-1} was determined by S. M. Skuratov, A. F. Vorob'ev and N. M. Privalova, Russ. J. Inorg. Chem. 7, 343 (1962). They measured this quantity by two different methods which gave concordant results. The value of $\Delta H^\circ_{f\ 298.15}$ reported was -101.9 ± 0.2 kcal. mole^{-1}. The value used here is the average of these four results. M. Berthelot and P. Vieille, Ann. chim. et phys. [5] 27, 225 (1882) determined the difference between the heat of explosion of ammonium picrate and that of an ammonium picrate-potassium perchlorate mixture, and also the difference between the heat of explosion of potassium picrate and that of a potassium picrate-potassium perchlorate mixture. They obtained ΔH°_r = 7.5 kcal. mole^{-1} for the reaction $KClO_4(c) = KCl(c) + 2O_2(g)$. From that the value of $\Delta H^\circ_{f\ 298.15}$ was calculated to be -111.9 kcal. mole^{-1}. This value was not used.

Heat Capacity and Entropy.

The low temperature heat capacities (12.53-298.07°K.) were measured by W. M. Latimer and J. E. Ahlberg, J. Am. Chem. Soc. 52, 549 (1930). The heat capacities above 298°K. were estimated by comparison with those of $NaClO_4(c)$. $S^\circ_{298.15}$ was reported by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592 (1961), based on the low temperature heat capacities measured by W. M. Latimer and J. E. Ahlberg, loc. cit., using $S^\circ_{12.59}$ (extrap.) = 0.14 cal. deg.$^{-1}$ mole^{-1}.

Transition Data.

T_t and ΔH°_t were obtained from the National Bureau of Standards, Circ. 500, "Selected Values of Chemical Thermodynamic Properties," by F. D. Rossini, et al., 1952.

Temperature of Melting.

T_m was taken from Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use," June 1949.

June 30, 1962

LITHIUM CHLORIDE (LiCl) (CRYSTAL) MOL. WT. = 42.397

ΔH_f° 298.15 = -97.578 ± 0.273 kcal mole^{-1}

$S^\circ_{298.15}$ = 14.173 ± 0.015 cal deg^{-1} mole^{-1}

T_m = 883 ± 2°K

ΔH_m = 4.74 ± 0.10 kcal mole^{-1}

Heat of Formation

The heat of formation was obtained as follows:

		ΔH_{298}(kcal mole^{-1})
(1)	$LiOH\cdot 100H_2O + HCl\cdot 100H_2O \rightarrow LiCl\cdot 201H_2O$ T. W. Richards and A. W. Rowe J. Am. Chem. Soc. 44, 684 (1922).	-13.704 ± 0.014
(2)	$Li(c) + 100H_2O(\ell) \rightarrow LiOH\cdot 100H_2O + 1/2\ H_2(g)$ S. R. Gunn and L. G. Green J. Am. Chem. Soc. 80, 4782 (1958).	-53.142 ± .019
(3)	$LiOH\cdot 1000H_2O \rightarrow LiOH\cdot 100H_2O + 900H_2O(\ell)$ T. W. Richards and A. W. Rowe, J. Am. Chem. Soc. 43, 770 (1921).	0.153 ± 0.040
(4)	$1/2\ H_2(g) + 1/2\ Cl_2(g) \rightarrow HCl(g)$ JANAF Tables.	-21.97 ± 0.09
(5)	$HCl(g) + 100H_2O(\ell) \rightarrow HCl\cdot 100H_2O$ C. M. Slansky, J. Am. Chem. Soc. 62, 2430 (1940), and J. M. Sturtevant, J. Am. Chem. Soc. 62, 3265 (1940).	-17.575 ± 0.100
(6)	$LiCl\cdot 201H_2O \rightarrow LiCl(c) + 201H_2O(\ell)$ E. Lange and F. Dürr, Z. phys. Chem. 121, 361 (1926).	8.660 ± 0.010
	(1) + (2) + (3) + (4) + (5) + (6) gives $Li(c) + 1/2\ Cl_2(g) \rightarrow LiCl(c)$	-97.578 ± 0.273

A direct calorimetric determination by H. Siemonsen and U. Siemonsen, Z. Electrochem. 56, 643 (1952) gave -94.8 ± 0.6 kcal mole^{-1}. However, the solution route was thought to be inherently more accurate and was adopted.

Heat Capacity and Entropy

The heat capacity between 15° and 325°K has been measured by D. A. Shirley, J. Am. Chem. Soc. 82, 3841 (1960) and by F. L. Oetting, W. E. Hatton and G. C. Sinke, unpublished work, Thermal Laboratory, Dow Chemical Company. The two sets of data are in substantial agreement and were plotted together and used to evaluate the entropy at 298°. The extrapolation to 0°K was done assuming a T^3 law and yielded S_{15} = 0.019 e.u. Above 298° T. B. Douglas, J. L. Dever and A. W. Harman, quoted in Natl. Bur. Standards Report 6297, have made enthalpy measurements to 1200°K. E. N. Rodigina, K. Z. Gomelski, and V. F. Luginina, Zhur. Neorg. Khim. 4, 975 (1959) also made enthalpy determinations to 1100°K. These two sets of measurements were averaged and joined smoothly to the low temperature values.

Melting and Transition Data

The melting point has been reported as follows: 880°K., Douglas et. al., loc. cit.; 883°K., Rodigina et al., loc. cit.; 883°K., H. M. Haendler, P. S. Bennett, and C. M. Wheeler, J. Electrochem. Soc. 106, 264 (1959); 879°K., H. Flood, O. Fykse and S. Urnes, Z. Electrochem. 59, 364 (1955); 879°K., H. von Wartenberg and H. Schulz, Z. Electrochem. 27, 568 (1921). The highest value of 883°K. was taken as representing the most pure samples. At this temperature the enthalpy equations of Douglas et al. yield a heat of fusion of 4.718 kcal mole^{-1}, those of Rodigina et al., 4.669 kcal mole^{-1}. A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960) report a value of 4.76 ± 0.10 kcal mole^{-1} and quote 4.83 kcal mole^{-1} from a private communication from D. F. Smith. The average value ΔH_m = 4.74 ± 0.10 kcal mole^{-1} was adopted.

A transition at 838°K has been reported by Kislova andd Bergman, Russ. J. Inorg. Chem. 5, 1210 (1960) but is not supported by the enthalpy measurements quoted above.

June 30, 1962

LITHIUM CHLORIDE (LiCl) (LIQUID) MOL. WT. = 42.397

$\Delta H_f^\circ{}_{298.15} = -93.394$ kcal. mole^{-1}

$S^\circ_{298.15} = 18.745$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 883 \pm 2$°K

$\Delta H_m = 4.74 \pm 0.10$ kcal. mole^{-1}

T_b(equilibrium mixture) = 1656°K

T_b(monomeric gas) = 1701°K

Heat of Formation.

Obtained from that of the crystal by adding ΔH_m and $H_{883}-H_{298}$(c) and subtracting $H_{883}-H_{298}$(l).

Heat Capacity and Entropy.

The heat capacity from the melting point to 1100°K and 1200°K has been reported by E. N. Rodigina, K. Z. Gomelski, and V. F. Luginina, Zhur. Neorg. Khim. 4, 975 (1959) and T. B. Douglas, J. L. Dever, and A. W. Harman, quoted in Natl. Bur. of Standards Report 6297. The equation given by the former authors for the enthalpy of the liquid does not agree with their measurements and has been replaced by $H_T-H_{293.15} = 18.000T - 1.5 \times 10^{-3}T^2 - 2279$ cal. mole^{-1}, which fits to ± 0.3%. The two sets of results were averaged and the equations were assumed to hold up to the normal boiling point. The entropy was calculated from that of the crystal in a manner analogous to the heat of formation.

Melting.

See table for crystal.

Boiling.

The equilibrium boiling point was taken from H. von Wartenburg and H. Schultz, Z. Electrochem. 27, 568 (1921) and the boiling point of the monomeric gas is defined as the temperature at which it reaches 1 atm. pressure. This was obtained from the free energy crossover between liquid and monomeric gas. The heat of vaporization to the monomeric gas was found from the tables to be 38.8 kcal. mole^{-1}.

June 30, 1962

LITHIUM CHLORIDE (LiCl) (IDEAL GAS) MOL. WT. = 42.397

$\Delta H_{f0}^\circ = -46.742$ kcal. mole^{-1}

$\Delta H_{f\ 298.15}^\circ = -46.778 \pm 3.0$ kcal. mole^{-1}

Ground State Configuration $^1\Sigma$

$S_{298.15}^\circ = 50.864$ cal. deg.$^{-1}$ mole^{-1}

$\omega_e = 641.1 \pm 3.0$ cm.$^{-1}$

$\omega_e x_e = 4.2 \pm 0.3$ cm.$^{-1}$

$\sigma = 1$

$B_e = 0.7053$ cm.$^{-1}$

$\alpha_e = 0.0067$ cm.$^{-1}$

$r_e = 2.022$ Å

Heat of Formation.

W. Klemperer, W. G. Norris, A. Büchler and A. G. Emslie, J. Chem. Phys. 33, 1534 (1960) quote a private communication from W. H. Evans at the National Bureau of Standards giving $D_0^\circ = 4.85$ e.v., which corresponds to $\Delta H_{f0}^\circ = -45.3 \pm 2.4$ kcal. mole^{-1}. A third law analysis of the vapor pressure data of An. N. Nesmeyanov and L. A. Sazonov, Zhur. Neorg. Khim. 4, 231 (1960) in conjunction with the relative concentration of monomer, dimer, and trimer at 870°K from the work of R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1956) and 27, 981 (1957) leads to a monomer heat of sublimation at 298° of 52.56 kcal. mole^{-1}, this gives $\Delta H_{f\ 298.15}^\circ = -45.02$ kcal. mole^{-1}. These values lead, however, to partial vapor pressures of the monomer which are less than half of the total vapor pressure near the boiling point. From the data of Miller and Kusch loc. cit. it would be expected that the monomer would be the predominant species near the boiling point, a fact also substantiated by the work of C. Beusman, AEC Report ORNL-2323 (1957), on the average molecular weight of the vapor. Thus it was decided to change the heat of sublimation so as to give the correct normal boiling point and vapor pressures in the region 1400-1600°K and to approximate the relative concentrations of monomer, dimer, and trimer as found by Miller and Kusch at 870°K. A monomer heat of sublimation at 298° of 50.8 kcal. mole^{-1} was chosen, which gives $\Delta H_{f\ 298.15}^\circ = -46.778$ kcal. mole^{-1}. The normal boiling point was taken as 1656°K as determined by H. von Wartenburg and H. Schulz, Z. Electrochem 27, 568 (1921) and the boiling point of LiCl(g) was found as 1701°K from the free energy crossover between liquid and gas.

Heat Capacity and Entropy.

The spectroscopic constants were taken from Klemperer et al. loc. cit. The value of α_e was calculated from the value of a_1 given by the Rittner potential function and the equation given by Klemperer et al. The value of r_e was taken from the Natl. Bur. of Standards Report 6297 (1959).

Dec. 31, 1960; June 30, 1963; Mar. 31, 1964

LITHIUM PERCHLORATE ($LiClO_4$) (CRYSTAL) MOL. WT. = 106.397

$\Delta H_{f\ 0}^\circ$ = Unknown

$S_{298.15}^\circ$ = [30 ± 1] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ$ = -91.0 ± 0.7 kcal. mole^{-1}

T_m = 509°K.

ΔH_m° = [7] kcal. mole^{-1}

Heat of Formation.

The heats of reaction (ΔH_r°) involving $LiClO_4(c)$ has been determined by several investigators as follows:

Investigator	Chemical Reaction	$\Delta H_{r\ 298.15}^\circ$, kcal. mole^{-1}	$\Delta H_{f\ 298.15}^\circ$, kcal. mole^{-1}
Gilliland and Johnson(1)	$LiClO_4(c) + KCl(c) \rightarrow LiCl(c) + KClO_4(c)$	-5.86 ± 0.06	-90.34
Markowitz, et al.(2)	$LiOH(225H_2O) + HClO_4(225H_2O) \rightarrow LiClO_4(451H_2O) + H_2O(l)$	-13.54 ± 0.09	-91.7
Birky and Hepler(3)	$LiClO_4(c) \rightarrow Li^+(aq.) + ClO_4^-(aq.)$	-6.31 ± 0.13	-91.11

(1) A. A. Gilliland and W. H. Johnson, J. Res. Natl. Bur. Std. 65A, 67 (1961).

(2) M. M. Markowitz, R. F. Harris and H. Stewart, Jr., J. Phys. Chem. 63, 1325 (1959).

(3) M. M. Birky and L. G. Hepler, J. Phys. Chem. 64, 686 (1960).

The adopted value, $\Delta H_{f\ 298.15}^\circ$ = -91.0 kcal. mole^{-1}, for $LiClO_4(c)$ is the weighted average of the three values listed.

Heat Capacity and Entropy.

Heat capacities and $S_{298.15}^\circ$ were estimated by comparison with those of $KClO_4(c)$.

Melting Data.

T_m was obtained from T. W. Richards and H. H. Willard, J. Am. Chem. Soc., 32, 4 (1910). The value of $\Delta H_{m\ 509}^\circ$ was estimated by comparison with the value, $\Delta H_{m\ 528}^\circ$ = 5.4 kcal. mole^{-1}, for $NaClO_3(c)$ reported by K. K. Kelley, Contribution to the Data on Theoretical Metallurgy, XIII. High-Temperature Heat-Content, Heat-Capacity and Entropy Data for the Elements and Inorganic Compounds, U. S. Bur. Mines Bull. 584 (1960).

Dec. 31, 1960; Mar. 31, 1964

LITHIUM PERCHLORATE ($LiClO_4$) (LIQUID) MOL. WT. = 106.397

$S^\circ_{298.15}$ = [39.245] cal. deg.$^{-1}$ mole^{-1}

T_m = 509°K.

$\Delta H^\circ_{f\ 298.15}$ = [-85.574] cal. deg.$^{-1}$ mole^{-1}

ΔH°_m = [7] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$(l) was obtained from $\Delta H^\circ_{f\ 298.15}$(c) by adding ΔH°_m and the difference between $H^\circ_{370.6}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p for $LiClO_4$(l) was estimated by comparison with that for $NaClO_3$(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting temperature (T_m) was obtained from T. W. Richards and H. H. Willard, J. Am. Chem. Soc., 32, 4 (1910). The value of $\Delta H^\circ_{m\ 509}$ was estimated by comparison with the value, $\Delta H^\circ_{m\ 528}$ = 5.4 kcal. mole^{-1}, for $NaClO_3$(c) reported by K. K. Kelley, Contribution to the Data on Theoretical Metallurgy, XIII. High-Temperature Heat-Content, Heat-Capacity and Entropy Data for the Elements and Inorganic Compounds, U. S. Bur. Mines Bull. 584 (1960).

Dec. 31, 1960; Mar 31, 1966

MAGNESIUM MONOCHLORIDE (MgCl) (IDEAL GAS) MOL. WT. = 59.765

Ground State Configuration $^2\Sigma$

$S^\circ_{298.15}$ = 55.760 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = -10.34 ± 10 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -10.4 ± 10 kcal. mole^{-1}

Electronic Levels and Quantum Weights

ϵ_1, cm.$^{-1}$	g_1
0	2

ω_e = 462.4 cm.$^{-1}$

$\omega_e x_e$ = 2.02 cm.$^{-1}$

σ = 1

B_e = [0.2417] cm.$^{-1}$

α_e = [0.0014] cm.$^{-1}$

r_e = 2.199 Å

Heat of Formation.

The heat of formation is calculated from D_0° = 3.2 e.v. reported by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Co., Inc., New York, 1950. D_0° = 2.7 ± 0.7 e.v. reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", 2nd Edn., Chapman and Hall, London, 1953, yields $\Delta H^\circ_{f\ 298}$ (MgCl, g) = 1.0 ± 16 kcal. mole^{-1}.

Heat Capacity and Entropy.

Spectroscopic constants were reported by Herzberg loc. cit. and adjusted for natural isotopic abundance. The bond length was reported by E. Morgan and R. F. Barrow, Nature 192, 1182, (1961). B_e and α_e were estimated by the method suggested by Herzberg loc. cit. The moment of inertia (I) is 11.578 X 10^{-39} g. cm.^{2}

Magnesium Monochloride Unipositive Ion ($MgCl^+$)

Heat of Formation

The ionization potential of MgCl(g) was reported to be 7.2, 7.5 ± 0.5, and 7 ± 1 eV by Krasnov (1), Hildenbrand (9), and Beckett (2), respectively. The corresponding heats of formation at 298°K for $MgCl^+$(g) are derived as 156, 163, and 151 kcal/mol, using ΔHf°_0(MgCl, g) = -10.34 kcal/mol from the JANAF MgCl(g) table (March 31, 1966). The value of ΔHf°_{298} for $MgCl^+$(g) is tentatively selected as 156 ± 20 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as NaCl(g) which is isoelectronic with $MgCl^+$(g). The six electronic states are obtained from Fougere (3). The corresponding electronic levels are estimated by comparison with the isoelectronic molecules BeS (4), BeO (5, 6), and MgO (5, 7). The bond distance is estimated by the method suggested by Krasnov (8). The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for MgCl(g) and NaCl(g). B_e and α_e are calculated by the method recommended by Herzberg (5). The moment of inertia is 1.159 x 10^{-38} g cm^2. The enthalpy at 0°K is -2.27 kcal/mol.

Bond Distance: N-Cl = 1.95 ± 0.06 Å   N-O = 1.17 ± 0.06 Å

Bond Angle: Cl-N-O = 114 ± 3°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = 2.278778 X 10^{-115} g.^{3} cm.^{6}

Heat of Formation.

The equilibrium constants for the reaction $2NOCl(g) = 2NO(g) + Cl_2(g)$ have been measured in the temperature range from 372° to 491°K. by C. M. Beeson and D. M. Yost, J. Chem. Phys. 7, 44 (1938). Using the reported equilibrium constants, the heat of reaction ($\Delta H^\circ_{r\ 298}$) has been calculated by both the second and the third law methods, as 18.33 ± 0.1 kcal. mole^{-1} and 18.42 ± 0.1 kcal. mole^{-1}, respectively. The third law value is adopted to calculate the heat of formation of nitrosyl chloride (g) as $\Delta H^\circ_{f\ 298}$ = 12.37 ± 0.2 kcal. mole^{-1}.

Heat Capacity and Entropy.

The selected bond distances and angle were obtained from the microwave measurements by J. D. Rogers and D. Williams, J. Chem. Phys. 34, 2195 (1961). J. A. A. Ketelaar and K. J. Palmer, J. Am. Chem. Soc. 59, 2629 (1937), reported the bond distance N-Cl = 1.95 Å and the angle O-N-Cl = 116° by the electron diffraction method. These two are in good agreement. The three principal moments of inertia are I_A = 0.9895 X 10^{-39}, I_B = 14.6885 X 10^{-39} and I_C = 15.6780 X 10^{-39} g. cm.^{2} The selected vibrational frequencies which were obtained from the infrared spectrum by L. Landau and W. H. Fletcher, J. Mol. Spectry. 4, 276 (1960), have been modified to natural isotopic mixture. W. G. Burns and J. J. Bernstein, J. Chem. Phys. 18, 1669 (1950), reported the vibrational frequencies as 1799, 592 and 332 cm.$^{-1}$

J. S. Gordon, J. Chem. Eng. Data 7, 82 (1962), has calculated the thermodynamic functions from 298.15° to 6000°K. by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from Landau and Fletcher, loc. cit., and J. D. Rogers, W. J. Pietenpol and D. Williams, Phys. Rev. 83, 431 (1951). These calculated functions have been adopted in the tabulation. Below 298°K. the rigid-rotator harmonic oscillator method was used to calculate the functions.

Bond Distance: N-Cl = 1.83 Å N-O = 1.21 Å

Bond Angle: O-N-O = 129.5° O-N-Cl = 115.25°

σ = 2

Product of Moments of Inertia: $I_AI_BI_C$ = 2.36698 X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

The selected heat of formation was obtained from the recalculation of the heat of reaction $ClNO_2 + NO = ClNO + NO_2$ which has been measured calorimetrically as -9.27 kcal. mole^{-1} by J. Ray and R. Ogg, Jr., J. Chem. Phys. 31, 168 (1959). Not only the thermal effects of $2NO_2 = N_2O_4$ but also $NO + NO_2 = N_2O_3$ (a minor one) have been considered in calculation. Using all JANAF auxiliary data for ClNO, NO, NO_2, N_2O_3 and N_2O_4, the recalculation gives $\Delta H_f^\circ{}_{298}$ = 2.90 ± 0.4 kcal. mole^{-1} for $NO_2Cl(g)$. For the reaction $ClNO + N_2O_5 = ClNO_2 + 2NO_2$ also measured by Ray and Ogg, loc. cit., the recalculation gives $\Delta H_f^\circ{}_{298}$ (NO_2Cl, g) = 2.56 ± 0.4 kcal. mole^{-1}.

H. Martin and E. Koehlein, Z. physik.Chem. 17, 375 (1958), have determined kinetically the heat of reaction, $\Delta H_r^\circ{}_{273.15}$ = 3.10 kcal. mole^{-1}, for the reaction $NO_2 + NOCl = NO + NO_2Cl$ which gives $\Delta H_f^\circ{}_{298}$ = 1.90 ± 1 kcal. mole^{-1} for $NO_2Cl(g)$. H. Cordes and H. Johnston, J. Am. Chem. Soc., 76, 4264 (1954), have also determined kinetically the $\Delta H_r^\circ{}_0$ = 29.5 kcal. mole^{-1} for the reaction $NO_2Cl = NO_2 + Cl$ which gives $\Delta H_f^\circ{}_{298}$ = 6.3 ± 0.3 kcal. mole^{-1}.

Heat Capacity and Entropy.

The selected bond distances and bond angles were obtained from microwave spectrum studies by L. Clayton, Q. Williams and T. L. Weatherly, J. Chem. Phys. 30, 1328 (1959). D. J. Millen and K. M. Sinnott, J. Chem. Soc. 350 (1958), reported bond distance N-Cl = 1.840 Å, N-O = 1.202 Å and angle ONO = 130° 35' from the microwave measurement. These two are in good agreement.

The selected vibrational frequencies were obtained from infrared and Raman spectrum measurements by R. Ryason and M. K. Wilson, J. Chem. Phys. 22, 2000 (1954). However, the assignment of the fundamental frequencies has been revised by R. E. Dodd, J. A. Rolfe and L. A. Woodward, Trans. Faraday Soc. 52, 145 (1956), and Y. Morino and T. Tanaka, J. Mol. Spectry. 16, 179 (1965). Morino and Tanaka's assignment was adopted. The three principal moments of inertia are I_A = 6.3658 X 10^{-39}, I_B = 16.3609 X 10^{-39} and I_C = 22.7267 X 10^{-39} g. cm.^{2}

Dec. 31, 1960; Sept. 30, 1964

SODIUM CHLORIDE (NaCl) (CRYSTAL) MOL. Wt. = 58.448

$\Delta H_f^\circ{}_0 = -98.16 \pm 0.08$ kcal. mole^{-1}

$S^\circ_{298.15} = 17.24 \pm 0.05$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = -98.26 \pm 0.08$ kcal. mole^{-1}

$T_m = 1073.8 \pm 1.0$°K.

$\Delta H_m^\circ = 6.73 \pm 0.04$ kcal. mole^{-1}

Heat of Formation.

The heat of formation is based on $\Delta H_f^\circ{}_{298.15} = -57.39$ and -39.95 kcal. mole^{-1} for $Na^+(\infty H_2O)$ and $Cl^-(\infty H_2O)$, respectively, and on the heat of solution $\Delta H^\circ_\infty{}_{298.15} = 0.922$ kcal. mole^{-1} for NaCl. These values were reported in a private communication from D. D. Wagman, National Bureau of Standards, June, 1964.

Heat Capacity and Entropy.

The low temperature values are based on the heat capacities (3-266°K) reported by T.H.K. Barron, A. J. Leadbetter, J. A. Morrison, Proc. Roy. Soc. (London) A279 (1376), 62 (1964). The earlier work of K. Clusius, J. Goldman, A. Perlick, Z. Naturforsch. 4a, 424 (1949), results in a slightly higher entropy ($S^\circ_{298.15} = 17.33$ cal. deg.$^{-1}$ mole^{-1}) but a lower heat capacity at room temperature ($C_p^\circ{}_{298.15} = 11.9$ cal. deg.$^{-1}$ mole^{-1}). The high temperature values have been obtained by reanalysis of the enthalpies (672 - 1279°K) of R. Dawson, E. B. Brackett, T. E. Brackett, J. Phys. Chem. 67, 1669 (1963), using the new value for $C_p^\circ{}_{298.15}$. The resulting tables agree within ± 0.1 kcal. with the enthalpies (812 - 1058°K) of W. A. Roth, W. Bertram, Z. Elektrochem. 35, 38 (1929). The enthalpies (540 - 1037°K) of A. Magnus, Physik. Zeitschr. 14, 5 (1913), agree well at the lower temperatures but are about 0.3 kcal. smaller near the melting point.

Melting Data.

The melting temperature was taken from Dawson, Brackett and Brackett, loc. cit., and the heat of melting was obtained by reanalysis of their crystal and liquid enthalpies. Values of $T_m = 1073$°K. and $\Delta H_m^\circ = 6.69 \pm 0.06$ kcal. mole^{-1} were reported by A. S. Dworkin, M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

Heat of Sublimation.

The vapor in equilibrium with NaCl contains both monomeric and polymeric forms (for details see the tables for NaCl gases).

Dec. 31, 1960; Sept. 30, 1964

SODIUM CHLORIDE (NaCl) (LIQUID) MOL. WT. = 58.448

$S^\circ_{298.15}$ = [22.719] cal. deg.$^{-1}$ mole^{-1}

T_m = 1073.8 ± 1.0°K.

ΔH°_f 298.15 = [-92.237] kcal. mole^{-1}

ΔH°_m = 6.73 ± 0.04 kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_f(l)$ was obtained from $\Delta H^\circ_f(c)$ by addition of ΔH°_m and the difference between $(H^\circ_{1073.8} - H^\circ_{298.15})$ for the crystal and liquid.

Heat Capacity and Entropy.

These were obtained by analysis of the enthalpies (1076 - 1279°K) of R. Dawson, E. B. Brackett, T. E. Brackett, J. Phys. Chem. 67, 1669 (1963). The heat capacity was extrapolated to a constant value of 16.0 at the higher temperatures. A glass transition was assumed at 800°K. and below this temperature C_p° was taken equal to that of the crystal.

Melting Data.

The melting temperature was taken from Dawson, Brackett and Brackett, loc. cit., and the heat of melting was obtained by reanalysis of their crystal and liquid enthalpies. Values of T_m = 1073°K. and ΔH°_m = 6.69 ± 0.06 kcal. mole^{-1} were reported by A. S. Dworkin, M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

Heat of Sublimation.

The vapor in equilibrium with NaCl contains both monomeric and polymeric forms (for details see the tables for NaCl gases).

α_e = 0.001598 cm.$^{-1}$

σ = 1

r_e = 2.3606 Å

Heat of Formation.

The heat of formation is based on a heat of sublimation $\Delta H^\circ_{s\ 298.15}$ = 54.9 kcal. mole^{-1} obtained from the more consistent sets of vapor pressure data by correction for the presence of dimer. Observed vapor pressures were converted to monomer pressures by use of dimer-monomer ratios calculated from JANAF free energy functions and $\Delta H^\circ_{r\ 298.15}$ = 48.6 kcal. for the reaction $(NaCl)_2(g) \rightarrow 2NaCl(g)$. Higher polymeric species were neglected. Analyses of the resulting monomer pressures are summarized below.

Source	Temperature Range (°K)	Heat of Sublimation $\Delta H^\circ_{s\ 298.15}$(kcal. mole^{-1})

Heat Capacity and Entropy.

The molecular constants are based on molecular beam studies of the rotational spectra by Clouser and Gordy, Bull. Am. Phys. Soc. 8, 326 (1963) and on microwave studies by Honig, Mandel, Stitch and Townes, Phys. Rev. 96, 629 (1954). The infrared spectra of Rice and Klemperer, J. Chem. Phys. 27, 573 (1957) give a frequency in close agreement (366 cm.$^{-1}$).

June 30, 1963

SODIUM PERCHLORATE ($NaClO_4$) (CRYSTAL) MOL. WT. = 122.448

$\Delta H_{f\ 0}^\circ$ = Unknown

$S_{298.15}^\circ$ = [34] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ = -91.48 \pm 0.22$ kcal. mole^{-1}

T_t = 581°K.

ΔH_t° = [3.34] kcal. mole^{-1}

T_m = 755°K.

ΔH_m° = Unknown

Heat of Formation.

A. A. Gilliland and W. H. Johnson, J. Res. Natl. Bur. Std. 65A, 67 (1961) measured the heat of solution of $NaClO_4(c)$ and gave $\Delta H_{f\ 298.15}^\circ = -91.48 \pm 0.22$ kcal. mole^{-1} for $NaClO_4(c)$. The heat of dilution of $NaClO_4(c)$ was measured by C. E. Vanderzee and J. A. Swanson, J. Phys. Chem. 67, 285 (1963). The data led to $\Delta H_{f\ 298.15}^\circ = -91.464$ kcal. mole^{-1} which agrees very well with the data reported by A. A. Gilliland and W. H. Johnson, loc. cit. The value of $\Delta H_{f\ 298.15}^\circ$ was reported to be -92.18 kcal. mole^{-1} in the National Bureau of Standards Circ. 500, "Selected Values of Chemical Thermodynamic Properties," 1952, based upon the data prior to 1950. A. F. Vorob'ev, et al., Proc. Acad. Sci. USSR, 135, 1439 (1960) measured the heat of decomposition of $NaClO_4(c)$ into $NaCl(c)$ and $O_2(g)$ and gave $\Delta H_{f\ 298.15}^\circ = -90.68 \pm 0.3$ kcal. mole^{-1} for $NaClO_4(c)$. The value reported by A. A. Gilliland and W. H. Johnson, loc. cit. was used.

Heat Capacity and Entropy.

Heat capacities and $S_{298.15}^\circ$ were estimated by comparison with those for $NaClO_3(c)$ and $KClO_4(c)$, respectively.

Transition Data.

T_t was reported in the National Bureau of Standards, Circ. 500, loc. cit. ΔH_t° was estimated from that for $KClO_4(c)$.

Temperature of Melting.

T_m was obtained from Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use," June 1949.

CHLORINE MONOXIDE (ClO) (IDEAL GAS) MOL. WT. = 51.457

$D_0 = 63.33 \pm 0.03$ kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15} = 24.19 \pm 0.05$ kcal. mole^{-1}

Ground State Configuration $^2\Pi_{3/2}$

$S^\circ_{298.15} = 54.145$ cal. deg.$^{-1}$ mole^{-1}

Electronic Level and Multiplicity

ϵ_1, cm.$^{-1}$	g_1
0	4

$\omega_e = 866 \pm 26$ cm.$^{-1}$

$\omega_e x_e = 7.5$ cm.$^{-1}$

$D_e = 2.(2) \times 10^{-6}$ cm.$^{-1}$

$\sigma = 1$

$B_e = 0.643(3)$

$\alpha_e = [0.0069]$ cm.$^{-1}$

$r_e = 1.546$ Å

Heat of Formation

R. A. Durie and D. A. Ramsay, Can. J. Phys. 36, 35 (1958) and G. Herzberg and D. A. Ramsay, Disc. Faraday Soc. 9, 80 (1950) report $D_0 = 22152 \pm 10$ cm.$^{-1}$ and $D_0 = 22141$ cm.$^{-1}$ respectively, and these values have been averaged.

Heat Capacity and Entropy

The spectroscopic constants are for the natural mixture of isotopes and are based on measurements by Durie and Ramsay, loc. cit., and by G. Porter, Disc. Faraday Soc. 9, 60 (1950). α_e has been estimated by the method given by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Company, Inc., New York, 1950, p. 108.

TITANIUM OXIDE CHLORIDE (TiOCl) (IDEAL GAS) MOL. WT. = 99.357

Point Group [$C_{\infty v}$]

$\Delta H^\circ_{f\ 0}$ = [-58.0] kcal. mole^{-1}

$S^\circ_{298.15}$ = [62.992] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-58.4] kcal. mole^{-1}

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[880] (1)
[230] (2)
[490] (1)

Bond Distances: O=Ti = [1.62] Å Ti-F = [2.17] Å

Bond Angles: O=Ti-Cl = [180°]

σ = 1

Rotational Constant: B_0 = [0.09225] cm.$^{-1}$

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was estimated as -58 kcal. mole^{-1} by J. S. Gordon, Astrosystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. $\Delta H^\circ_{f\ 298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. Principal moments were: $I_A = I_C = 30.34 \times 10^{-39}$ g. cm.^{2}

Chlorine Dioxide (ClO_2)

(Ideal Gas) Mol. Wt. = 67.457

Heat of Formation

W. H. Evans, T. R. Munson, and D. D. Wagman, J. Research Natl. Bur. Standards 55, 147 (1955), have evaluated the available data and chosen the above value.

Heat Capacity and Entropy

J. S. Gordon, private communication, February, 1961, has calculated the thermodynamic functions from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from J. B. Coon and E. Ortiz, J. Molec. Spectros. 1, 81 (1957). The functions below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

June 30, 1963; Dec. 31, 1963

PHOSPHORUS MONOCHLORIDE (PCl) (IDEAL GAS) MOL. WT. = 66.432

Ground State Configuration [$^3\Sigma$]

$S^\circ_{298.15}$ = [56.8] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = [34.7] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [35.0] kcal. mole^{-1}

Electronic Levels and Multiplicities

ϵ_i, cm.$^{-1}$	g_i
0	[3]

ω_e = [472] cm.$^{-1}$

$\omega_e x_e$ = [1.89] cm.$^{-1}$

σ = 1

B_e = [0.2443]

α_e = [0.00098]

r_e = [2.04] Å

Heat of Formation.

The selected $\Delta H^\circ_{f\ 298.15}$ was calculated by assuming that the second and third bonds in $PCl_3(g)$ are of equal strength, and that the first bond has a strength 20% greater than the other two. These assumptions were used by C. B. Henderson and R. S. Scheffee, Survey of Thermochemical Data, Atlantic Research Corporation, Alexandria, Virginia, January 1960. The selected $\Delta H^\circ_{f\ 298.15}$ was calculated using these bond strengths and auxiliary data from JANAF Tables.

A $\Delta H^\circ_{f\ 298.15}$, 40 kcal. mole^{-1}, estimated by C. J. O'Brien and J. R. Perrin, The Marquardt Corporation and J. Perrine, Olin Mathieson Chemical Corp., "Estimation of the Heats of Formation of Gaseous Combustion Product Molecules," WSS/CI Paper 59-4, October, 1959, when adjusted to the red V phosphorus reference state becomes [44.2] kcal. mole^{-1}.

A. A. Sandoval, H. C. Moser, and R. W. Kiser, J. Phys. Chem. 67, 124, (1963) have calculated a $\Delta H^\circ_{f\ 298.15}$ for PCl from an appearance potential. They selected the process $PCl_3 \rightarrow Cl^+ + e^- + PCl + Cl$ to explain this potential rather than the process $PCl_3 \rightarrow Cl^+ + e^- + P + Cl_2$. The reason for their selection was a calculated $\Delta H_f^+(Cl)$, 10 kcal. lower than the literature value (See National Bureau of Standards "Selected Values of Chemical Thermodynamic Properties" Circular 500). Use of the JANAF $\Delta H^\circ_{f\ 298.15}$ for PCl_3 eliminates this difference. Therefore, the process of the reported appearance potential would apparently be the second process which does not involve the neutral PCl radical.

Heat Capacity and Entropy.

The molecular constants were estimated by J. S. Gordon, Astrosystems International, Livingston, New Jersey, private communication, April 25, 1963.

June 30, 1962

Lead Monochloride (PbCl) (Ideal Gas)

Mol. Wt. = 242.67

ΔH_f° 298.15 = 3.5 ± 7.2 kcal. mole^{-1}

$S^\circ_{298.15}$ = 62.272 cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^2\Pi$

Electronic Level and Multiplicity

ϵ , cm.$^{-1}$	g_1
0	2
[8266]	2

ω_e = 303.8 cm.$^{-1}$ $\omega_e x_e$ = 0.88 cm.$^{-1}$ σ = 1

B_e = [0.1029] cm.$^{-1}$ α_e = [0.00048] cm.$^{-1}$

Heat of Formation. ΔH_f° 298.15 was calculated from the dissociation energy of PbCl(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e, and $\omega_e x_e$ were given by Herzberg, loc. cit. B_e, α_e, and ϵ were estimated by J. S. Gordon, Astrosystems, Inc., private communication, May, 1962.

Dec. 31, 1960; Sept. 30, 1967

SILICON MONOCHLORIDE (SiCl) (IDEAL GAS) GFW = 63.539

Ground State Configuration $^2\Pi_r$

$\Delta Hf^\circ_0 = 45.2 \pm 15$ kcal/mol

$S^\circ_{298.15} = 56.82$ gibbs/mol

$\Delta Hf^\circ_{298.15} = 45.7 \pm 15$ kcal/mol

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
X $^2\Pi_{1/2}$	0	2
$^2\Pi_{3/2}$	207.2	2
A $^2\Sigma^+$	22993.5	2
B $^2\Sigma^+$	34192	2
B' $^2\Delta_i$	35618	4
C $^2\Pi$	41245	4
D $^2\Pi$	44940	4

$\omega_e = 533.75$ cm^{-1} $\omega_e x_e = 2.27$ cm^{-1} $\sigma = 1$

$B_e = 0.25416$ cm^{-1} $\alpha_e = 0.00161$ cm^{-1} $r_e = 2.058$ Å

Heat of Formation

The adopted value is based on $D^\circ_0 = 90 \pm 15$ kcal/mol which is calculated from $D^\circ_0/D''(\mathrm{LBX}) = 1.01$ and $D''(\mathrm{LBX}) = 89$ kcal/mol. The latter value comes from linear Birge-Sponer extrapolation of ground state vibrational constants obtained by Verma (1) from the B'-X system. The ratio $D^\circ_0/D''(\mathrm{LBX}) = 1.01$ is calculated from an empirical relationship proposed by Hildenbrand (9): $D^\circ_0/D''(\mathrm{LBX}) = 0.365(r_x/r_e) + 0.448$ and $r_x = 14.40/(\mathrm{IP}-\mathrm{EA})$, where IP is the ionization potential of the more electropositive element and EA is the electron affinity of the more electronegative element. A similar calculation using $\omega_e''x_e'' = 2.1$ cm^{-1} obtained from the B-X system (2) would give $D^\circ_0 = 98$ kcal/mol. These values for D°_0 may be compared with average (per bond) heats of atomization of 101 kcal/mol for $SiCl_2$ and 94 kcal/mol for $SiCl_4$.

Gaydon (3) selected $D^\circ_0 = 76 \pm 12$ kcal/mol on the assumption that $D^\circ_0/D''(\mathrm{LBX}) = 0.8$, but Ovcharenko (4) suggested that this was too low by comparison with $D^\circ_0 = 117$ kcal/mol obtained from the B' state. The latter value is calculated from D'(LBX) = 33 kcal/mol and presumes that Si(^{1}D) is the excited atomic product. The B and C states could also correlate to give values fairly consistent with $D^\circ_0 = 117$. This interpretation seems unlikely, however, because it would involve a crossing of the potential curves for the B and B' states. Since the potential curves may be distorted due to the close proximity of the B and B' states, it seems preferable to obtain D°_0 from constants for the ground state.

Heat Capacity and Entropy

Electronic levels of the B and C states are taken from the B-X and C-X systems reported by Ovcharenko et al. (5, 6). The A level is that assigned by Sanii (10) from analysis of the A-X system. The D level is that derived by Herzberg (7) from data of Jevons (8), but it is assigned as $^2\Pi$ as suggested by Verma (1). The B' level is from Verma and is confirmed by the earlier analysis of Ovcharenko (4). All vibrational and rotational constants for the ground state are those obtained by Verma (1) from the B'-X system. Values only slightly different were obtained from the B-X system by Ovcharenko (5, 6). The adopted constants are adjusted to the natural isotopic abundances of Si and Cl.

Heat of Formation

The heat of formation, ΔHf°_{298}, of TiCl (g) is calculated from the dissociation energy, D°_0, which is estimated as 105 kcal/mol. This estimate is obtained from the relation $D(TiCl_4) < D^\circ_0(TiCl) < D(TiCl_3)$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF_2(g) by Zmbov and Margrave (1).

Extrapolations of the vibrational levels reported by Shenyavskaya (2), Rao (3) and Mace and Packer (4) yield values of the dissociation energy which are very low when considered with respect to bond energy relations.

Heat Capacity and Entropy

The vibrational frequency, ω_e, and anharmonic vibrational term, $\omega_e x_e$, were reported by Shenyavskaya et al. (2). The interatomic distance is estimated from Guggenheimer's relation (5). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti^+ (6). α_e is estimated from the Morse potential function.

[15000]	[20]

ω_e = [455.4] cm^{-1}

$\omega_e x_e$ = [1.46] cm^{-1}

σ = 1

B_e = [0.11105] cm^{-1}

α_e = [0.00042] cm^{-1}

r_e = [2.26] Å

Heat of Formation

The heat of formation, ΔHf°_{298}(WCl,g) = 132.3 kcal/mol, is calculated from the bond dissociation energy, D°_{298}(W-Cl) = 100 ± 10 kcal/mol. This estimated D°_{298} is obtained from the average bond dissociation energy for $WCl_x(g) \rightarrow W(g) + xCl(g)$ where x = 2,4,5,6, using all JANAF values.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WCl_6(g). This distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental vibrational frequency ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 456 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D^\circ_0 + 0.5\ \omega_e) = 0.0032$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is 25.20 x 10^{-39} g cm^2.

The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for WF(g). See WF(g) table (March 31, 1967) for details.

Heat of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl, $ZrCl_2$, $ZrCl_3$ and $ZrCl_4$. Ion intensities were measured 2.5 eV above the ionization threshold. Using the reported equilibrium constants for the reaction $ZrCl_3(g) + ZrCl(g) = 2\ ZrCl_2(g)$ in the temperature range 1978-2274°K, second and third law analyses give the heats of reaction at 298°K as -10.36 and -12.83 kcal/mol, respectively. The third law drift is 1.4 ± 2.5 eu. Based on the third law $\Delta Hr°_{298}$ and $\Delta Hf°_{298}(ZrCl_2, g)$ = -44.5 kcal/mol (2), and $\Delta Hf°_{298}(ZrCl_3, g)$ = -125.3 kcal/mol (3), we obtain $\Delta Hf°_{298}(ZrCl, g)$ = 49.1 kcal/mol which is adopted in the tabulation.

Farber et al. (4) also studied mass spectrometrically the reaction $Zr(c) + Cl(g) \rightarrow ZrCl(g)$. They reported a second law heat of reaction, $\Delta Hr°_{298}$ = 8.7 ± 1.4 kcal/mol. Using the equilibrium constants K = I(ZrCl)/I(Cl) which we calculated from their reported ion intensities of run 3 in the temperature range 1667-1896°K, we obtain $\Delta Hr°_{298}$ = 20.3 kcal/mol by the third law method. The third law drift is 6.1 ± 2.4 eu. The heat of formation is derived as $\Delta Hf°_{298}(ZrCl, g)$ = 49.2 kcal/mol.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in $ZrCl_4(g)$. The bond distance is then used with Guggenheimer's relation (5) for polar molecules to calculate the fundamental vibrational frequency ω_e. The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D°_0 + 0.5\,\omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is 22.425×10^{-39} g cm^2.

The ground state configuration is taken from the ground state multiplet of Zr^+ reported by Moore (6). The electronic levels and the quantum weights are estimated to be the same as those of ZrF(g).

Heat of Formation.

The heat of formation (ΔH_f°) for Cl_2(g) is zero at all temperatures, by definition.

Heat Capacity and Entropy.

The functions adopted here were calculated by R. L. Potter, J. Chem. Phys. 31, 1100 (1959) using a direct summation over the energy levels not including those of non-bonding states. The functions are for the naturally occurring isotopic composition.

The absorption spectrum of chlorine has been observed by A. Elliott, Proc. Roy. Soc. A 127, 638 (1930); C. F. Goodeve and B. A. Stephens, Trans. Faraday Soc. 32, 1517 (1936); H. Stammreich, R. Forneris and Y. Tavares, Spectrochim. Acta, 17, 775 (1961); Y. V. Rao and P. Venkateswarlu, J. Mol. Spectr. 9, 173 (1962); and A. E. Douglas, C. K. Moller and B. P. Stoicheff, Can. J. Phys. 41, 1174 (1963). There is disagreement over the vibrational assignments. The listed ground state spectroscopic constants for the naturally occurring isotopic composition are based upon the abundances given by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

The molecular structure of gaseous chlorine was determined by the sector-microphotometer method of electron diffraction by S. Shibata, J. Phys. Chem. 67, 2256 (1963). The value of r_e(Cl-Cl) was found to be 1.986 Å. The other r_e values, 1.983 - 1.989 Å, were reported by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., 1950; W. G. Richards and R. F. Barrow, Proc. Chem. Soc., 297 (1962), and L. S. Bartell and K. Kuchitsu, presented at the International Conference on Magnetism and Crystallography, 1961, quoted by S. Shibata, loc. cit.

Bond Distance: Cs-Cl = [3.18] Å

Bond Angle: Cl-Cs-Cl = [93.2°]

σ = [4]

Product of the Moments of Inertia: $I_A I_B I_C$ = [3.6076 x 10^{-111}] g^3 cm^6

Heat of Formation

Datz (1) studied the molecular association equilibrium in cesium chloride vapors by measuring the temperature dependence of the molecular weight of gaseous CsCl. The molecular weights were determined by measurement of the absolute pressure exerted by a known weight of completely vaporized salt contained in an isothermal fused silica bulb of known volume. The pressure sensing element was a fused silica manometer containing Au(ℓ). Based on the reported results, we derive the equilibrium constants for the reaction $Cs_2Cl_2(g) = 2CsCl(g)$ in the temperature range 1224 - 1418°K. The enthalpy change of this reaction is evaluated by the second and third law method as 39.3 ± 1.1 and 42.9 ± 0.6 kcal/mol, respectively. The drift in the third law value is equivalent to an entropy error of 2.7 ± 0.8 eu. Using the third law ΔHr° and $\Delta Hf°_{298}$(CsCl, g) = -57.4 kcal/mol, we obtain $\Delta Hf°_{298}$ = -157.7 ± 2.5 kcal/mol for $Cs_2Cl_2(g)$, which is adopted.

Schrier (2) determined the vapor pressures of molten cesium chloride at temperatures between 1155 and 1387°K by the boiling point or manometric method. The vapor analysis was performed using the transpiration method. An inert gas, N_2, was passed over the CsCl sample at a given temperature. The salt vapor entrained by the carrier gas was collected, weighed and analyzed. The data obtained were combined with the boiling point measurements to yield the average molecular weight of the vapor. Association into dimer was postulated. The mole fraction in the vapor and the partial pressure of CsCl(g) and $Cs_2Cl_2(g)$ were calculated. The equilibrium constants, 1209 - 1350°K, for dissociation of the Cs_2Cl_2 dimer were derived. Using the reported equilibrium constants, we evaluate the enthalpy change ($\Delta Hr°_{298}$) of the reaction $Cs_2Cl_2(g) = 2CsCl(g)$ to be 34.1 ± 2.9 and 43.2 ± 0.9 kcal/mol by the second and third law methods. Based on the third law $\Delta Hr°_{298}$ value and $\Delta Hf°_{298}$(CsCl, g) = -57.4 kcal/mol, we obtain $\Delta Hf°_{298}$ = -158.0 kcal/mol for $Cs_2Cl_2(g)$, which is in agreement with the adopted value.

Miller and Kusch (3) made an analysis of the velocity distribution of the CsCl molecules which escape through an ideal aperture from an isothermal enclosure. They found that there was no definite evidence that any species other than diatomic molecules were present in the beams in measurable amounts, in other words, the dimerization must be small, e.g. <1.5 per cent. However, according to our calculation the concentration of dimer is 15 - 34 per cent in the temperature range 600 - 900°K, and 33 - 20 per cent at the temperatures 1000 - 1600°K.

Heat Capacity and Entropy

The molecular structure is assumed to be planar, having D_{2h} symmetry. Based on the bond distances of Cs-Cs and Cl-Cl estimated by Berkowitz (4), the Cs-Cl bond distance and Cl-Cs-Cl bond angle are calculated. The vibrational frequencies were calculated by Berkowitz (5), on the basis of the potential function for an ionic model. The three principal moments of inertia are: $I_A = 2.105 \times 10^{-37}$, $I_B = 6.272 \times 10^{-38}$, and $I_C = 2.732 \times 10^{-37}$ g cm^2.

COPPER DICHLORIDE ($CuCl_2$) (CRYSTAL) MOL. WT. = 134.446

$S^\circ_{298.15}$ = 25.833 cal. $deg.^{-1}$ $mole^{-1}$

T_d = [766]°K.

$\Delta H^\circ_{f\ 0}$ = -49.39 ± 1.5 kcal. $mole^{-1}$

$\Delta H^\circ_{f\ 298.15}$ = -49.2 ± 1.5 kcal. $mole^{-1}$

Heat of Formation.

S. A. Shchukarev and M. A. Oranskaya, Zhur. Obshchei Khim. 24, 1926 (1954) have reported equilibrium constants for the dissociation $CuCl_2(c) \rightarrow CuCl(c/l) + 0.5\ Cl_2(g)$, which are in general agreement with earlier reports by F. Ephraim, Ber. 50, 1069 (1917) and D. I. Tarasenkov, A. I. Grigorovich and A. V. Boroslovskaya, Collected Works of the Central State Institute for Non-Ferrous Metallurgy, Part 1, 1, 69 (1929). These data were subjected to third law analysis which revealed a significant trend of 13 ± 0.5 cal. $deg.^{-1}$ mole, indicating that equilibrium conditions were not reached. However an average value of $\Delta H_{r\ 298}$ = 16.5 ± 1.9 kcal. $mole^{-1}$ yields a heat of formation of $CuCl_2(c)$ = -49.5 ± 2.5 kcal. $mole^{-1}$ which is in good agreement with the adopted value taken from Natl. Bureau Std. Circular 500, Washington, 1952.

Heat Capacity and Entropy.

The low temperature heat capacity has been measured from 11-300°K. by J. W. Stout and R. C. Chisholm, J. Chem. Phys. 36, 979 (1962). The integration of this data from S_{10} = 0.111 cal. $deg.^{-1}$ $mole^{-1}$ gave S_{298} = 25.833 cal. $deg.^{-1}$ $mole^{-1}$. The heat capacity above 298° was obtained by smooth extrapolation of the above data, since the heat capacities of A. N. Krestovnikov and G. A. Karetnikov, Journ. Gen. Chem. (USSR) 6, 955 (1936) were not compatible with the low temperature data.

Decomposition Data.

The temperature of decomposition was estimated from the table for $CuCl_2(c)$, $CuCl(l)$ and $Cl_2(g)$ so that the pressure of Cl_2 is 1 atm.

207 (1)	372 (1)	620 (1)
254 (1)	386 (1)	894 (1)
330 (1)	547 (1)	1331 (1)

Bond Distance: P-Cl = 1.99 ± 0.04 Å P-F = 1.50 ± 0.03 Å P-O = 1.54 ± 0.03 Å

Bond Angle: Cl-P-Cl = F-P-Cl = 103° $\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C = 4.70732540 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ of $POFCl_2$ was estimated to be -179 kcal. mole^{-1} from the $\Delta H^\circ_{f\ 298.15}$ of $POCl_3$ by assuming bond energies of 120 kcal. for D(P-F) and 80 kcal. for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from E. Neale and L. T. D. Williams, J. Chem. Soc., 2485 (1955) Part I and E. Neale, L. T. D. Williams, and V. T. Moores, J. Chem. Soc. 422 (1956) Part II.

Essentially the same $\Delta H^\circ_{f\ 298.15}$ may be obtained by assuming a $\Delta H_r = 0$ for the following reaction:

$$POCl_3(g) + POF_3(g) \rightarrow POCl_2F(g) + POF_2Cl(g)$$

Heat Capacity and Entropy.

The molecular constants were determined by L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc. <u>60</u>, 1836 (1938) and by Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys., <u>20</u>, 164 (1952). Brockway and Beach used electron diffraction. Q. Williams et al. measured microwave spectra. Brockway and Beach assumed that the F-P-F and F-P-Cl angles were equal in POF_2Cl and $POFCl_2$. An analysis of their data by Q. Williams et al. indicates that the angles in POF_2Cl, $POFCl_2$, $POCl_3$, and POF_3 should be 103° rather than the reported 106° ± 3°. The principal moments of inertia calculated from these parameters were $I_A = 2.69184 \times 10^{-38}$, $I_B = 3.79516 \times 10^{-38}$, and $I_C = 4.60780 \times 10^{-38}$.

The Raman spectra and vibrational frequencies for $POFCl_2$ were reported by M. L. Delwaulle and F. Francois, Compt. Rend. <u>222</u>, 550 (1946). These frequency assignments are summarized in J. Chim. Phys. <u>46</u>, 87 (1949) by M. L. Delwaulle and F. Francois.

June 30, 1965

IRON DICHLORIDE ($FeCl_2$) (CRYSTAL) MOL. WT. = 126.753

$S^\circ_{298.15}$ = 28.190 cal. deg.$^{-1}$ mole^{-1}

T_m = 950°K.

$\Delta H^\circ_{f\ 0}$ = -82.32 ± 0.12 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -81.70 ± 0.12 kcal. mole^{-1}

ΔH°_m = 10.28 ± 0.05 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 46.2 ± 0.7 kcal. mole^{-1}

Heat of Formation.

The enthalpy change, $\Delta H^\circ_{r\ 298.15}$ = -4.06 ± 0.05 kcal. mole^{-1}, for the reaction $Fe(\alpha) + 2(HCl\cdot 12.731\ H_2O)\ (l) = FeCl_2(c) + H_2(g) + 25.462\ H_2O\ (l)$ was reported by M. F. Koehler and J. P. Coughlin, J. Phys. Chem. 63, 605 (1959). The value of $\Delta H^\circ_{f\ 298.15}(FeCl_2, c)$ was then derived. The enthalpy change, $\Delta H^\circ_{r\ 298.15}$ = -19.5 ± 0.2 kcal. mole^{-1}, for the reaction $FeCl_2(c) = Fe^{++}(aq.) + 2\ Cl^-\ (aq.)$ was determined by J. C. M. Li and N. W. Gregory, J. Am. Chem. Soc. 74, 4670 (1952), yielding $\Delta H^\circ_{f\ 298.15}$ = -81.4 ± 0.2 kcal. mole^{-1} which is in agreement with the adopted value reported by M. F. Koehler and J. P. Coughlin. The equilibrium constants for the reaction $FeCl_2(c) + H_2(g) = Fe\ (c) + 2HCl\ (g)$ were determined by W. Kangro and E. Petersen, Z. Anorg. Chem. 261, 157 (1950). By use of the second and third law methods the enthalpy change ($\Delta H^\circ_{r\ 298.15}$) of this reaction was evaluated as 37.81 ± 0.68 and 38.24 kcal. mole^{-1}, respectively. Based on the third law value for $\Delta H^\circ_{r\ 298.15}$, the value of $\Delta H^\circ_{f\ 298.15}(FeCl_2, c)$ was derived to be -82.37 kcal. mole^{-1} which is in reasonable agreement with the adopted value.

Heat Capacity and Entropy.

The low temperature (53.2-295.0°K.) heat capacities were determined by K. K. Kelley and G. E. Moore, J. Am. Chem. Soc. 65, 1264 (1943). The high temperature (670.5-941.0°K.) heat capacities were measured by G. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943). The two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 941.0°K. were obtained by graphical extrapolation. The C_p values, 60-500°C., were also reported by F. L. Oetting and N. W. Gregory, J. Phys. Chem. 65, 138 (1961) which are in good agreement with those determined by G. E. Moore, loc. cit. $S^\circ_{298.15}$ was derived from the smoothed C_p values, using $S^\circ_{53.2}$ = 4.930 e.u. The $S^\circ_{298.15}$ value was determined by E. F. Westrum, Jr. quoted by L. E. Wilson and N. W. Gregory in J. Phys. Chem. 62, 437 (1958). The entropy at 298° is assumed to include the uncoupling energy of Fe^{++} which is calculated to be 3.2 e.u. which corresponds to R ln 5.

Melting Data.

T_m and ΔH°_m were taken from G. E. Moore, loc. cit.

Heat of Sublimation.

The difference between $\Delta H^\circ_{f\ 298.15}$ for $FeCl_2(g)$ and $FeCl_2(c)$ is $\Delta H^\circ_{s\ 298.15}$. The former was obtained by the second and third law analyses on the equilibrium pressure data as described in $FeCl_2(g)$ table.

IRON DICHLORIDE ($FeCl_2$) (LIQUID) MOL. WT. = 126.753

$S^\circ_{298.15}$ = 33.432 cal. deg.$^{-1}$ mole^{-1}

T_m = 950°K.

T_b = 1347°K.

$\Delta H^\circ_{f\ 298.15}$ = -74.411 ± 0.13 kcal. mole^{-1}

ΔH°_m = 10.28 ± 0.05 kcal. mole^{-1}

ΔH°_v = 29.83 kcal. mole^{-1}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}(FeCl_2,\ l)$ was obtained from $\Delta H^\circ_{f\ 298.15}(FeCl_2,\ c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity (950-1100°K.) for $FeCl_2(l)$ was reported as 24.42 cal. deg.$^{-1}$ mole^{-1} by G. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943). A constant C_p was assumed for all the other temperatures. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH°_m were taken from G. M. Moore, loc. cit.

Vaporization Data.

The boiling point (T_b) is determined as the temperature at which the free energy change (ΔF°_r) for the reaction $FeCl_2(l) = FeCl_2(g)$ approaches zero. The corresponding enthalpy change (ΔH°_r) at T_b is the heat of vaporization (ΔH°_v).

Cl_2Fe

Iron Dichloride ($FeCl_2$)

[135] (2)
492 (1)

Bond Distance: Fe-Cl = [2.09] Å

Bond Angle: Cl-Fe-Cl = [180]°

Rotational Constant: B_0 = [0.05442] cm.$^{-1}$

Heat of Formation.

The equilibrium pressures for the reactions: (1) $FeCl_2(l) = FeCl_2(g)$; (2) $FeCl_2(c) = FeCl_2(g)$; and (3) $Fe(c) + 2HCl(g) = FeCl_2(g) + H_2(g)$ were determined by several investigators. Using the reported data, the corresponding enthalpy changes ($\Delta H_r^\circ{}_{298.15}$) for these reactions were evaluated by both the second and third law methods. Hence the respective $\Delta H_f^\circ{}_{298.15}$ values for $FeCl_2(g)$ were derived, based on the third law values for $\Delta H_r^\circ{}_{298.15}$. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	$\Delta H_f^\circ{}_{298.15}$ kcal. mole^{-1}

The value of $\Delta H_f^\circ{}_{298.15}$ for $FeCl_2(g)$ adopted is -35.5 ± 2.0 kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular structure, bond distance and angle, and two vibrational frequencies (ν_1 and ν_3) were obtained from L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The electronic levels and quantum weights were estimated by comparison with the electronic levels in $Fe^{++}(g)$ reported by C. E. Moore, "Atomic Energy Levels", Circular of the National Bureau of Standards 467, Vol. II, 1952, using the reasoning suggested by J. T. Hougen, G. E. Leroi and T. C. James, J. Chem. Phys. 34, 1670 (1961). The total 25 for the quantum weight was obtained from the ground multiplet of Fe^{++} and was split arbitrarily. The bending frequency (ν_2) was derived such that the calculated free energy functions are consistent with the experimental equilibrium data. In other words, the free energy functions were adjusted by choosing a proper value for ν_2 in order to make the second and third law values of ΔH_r° for the reactions in reasonable agreement. The moment of inertia (I) is 5.1426 x 10^{-38} g. cm.$^{-1}$

MERCURY DICHLORIDE ($HgCl_2$) (Crystal)

Mol. Wt. = 271.524

ΔH_f° 298.15 = -55.000 ± 1.0 kcal. mole^{-1}

$S^\circ_{298.15}$ = [34.535] ± 1.5 cal. deg.$^{-1}$ mole^{-1}

T_m = 550°K

ΔH_m = 4.64 ± 0.05 kcal. mole^{-1}

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," (1952).

Heat Capacity and Entropy. C_p was determined from the heat content data of L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) and R. Ewald, Ann. d. Physik u. Chem. (4) 44, 1213 (1914). Above 550° the curve was smoothly extrapolated. The entropy was estimated by adjusting the value to give the best fit of the melting, sublimation, and vaporization data.

Melting. T_m was taken from National Bureau of Standards Circular 500 (loc. cit.) ΔH_m was given by L. E. Topol and L. D. Ransom (loc. cit.).

Mercury Dichloride ($HgCl_2$)

(Liquid) Mol. Wt. = 271.524

March 31, 1962

Cl_2Hg

MERCURY DICHLORIDE ($HgCl_2$) (Liquid)

Mol. Wt. = 271.524

ΔH_f° 298.15 = -51.404 ± 1.0 kcal. mole^{-1}

$S^\circ_{298.15}$ = [40.721] ± 1.5 cal. deg.$^{-1}$ mole^{-1}

T_m = 550°K

ΔH_m = 4.64 ± 0.05 kcal. mole^{-1}

T_b = 577°K

ΔH_v = 14.079 ± 0.25 kcal. mole^{-1}

Heat of Formation. Calculated from $\Delta H_f^\circ(c)$.

Heat Capacity and Entropy. The heat capacity was estimated to conform with the bromide and iodide, the value given by L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) was discounted. A glass type transition was assumed at 367°K below which the heat capacity was equal to that of the crystal. The entropy was obtained from $S^\circ(c)$, the entropy of fusion and the estimated heat capacity.

Fusion and Vaporization. T_m and T_b were taken from National Bureau of Standards (U.S.) Circular 500 (1952). ΔH_m was given by L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) and ΔH_v was obtained from the data of E. B. R. Prideaux, J. Chem. Soc. (London) 97, 2033 (1910) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952 was combined with the 3rd law heat of sublimation at 298°K from the data of K. Niwa and Z. Shibata, J. Fac. Sci. Hokkaido Imp. Univ. Ser. III, 2, 183 (1938); R. Ruf and W. D. Treadwell, Helv. Chim. Acta 37, 1941 (1954) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The bond length is a weighted average of the values given by H. Braune and S. Knoke Naturwiss. 21, 349 (1933); A. H. Gregg, G. C. Hampson, G. I. Jenkins, P. L. F. Jones and L. E. Sutton Trans. Farad. Soc. 33, 852, 1937; L. R. Maxwell and V. M. Mosley Phys. Rev. 57, 21 (1940) and P. A. Akishin, V. P. Spiridinov and A. N. Khodchenkov, Zhur. Fiz. Khim. 33, 20 (1959).

MERCURY MONOCHLORIDE, DIMERIC (Hg_2Cl_2) (CRYSTAL) MOL. WT. = 472.134

$\Delta H_f^\circ{}_{298.15} = -63.319 \pm 0.05$ kcal mole^{-1} $S^\circ_{298.15} = 46.017$ cal deg^{-1} mole^{-1}

$T_{sub.} = 655$ °K (decomp.)

Heat of Formation

Based on the average free energy of formation, -50.315 kcal mole^{-1}, as measured by R. H. Gerke, J. Am. Chem. Soc. 44, 1684 (1922) and G. J. Hills and D. J. G. Ives, J. Chem. Soc. (London) 318, (1951), and the entropy of formation.

Heat Capacity

The data of F. Pollitzer, Zeits. f. Electrochemie 19, 513 (1913), from 22-199°K was treated by K. K. Kelley, U. S. Bureau of Mines Bulletin 592 (1960). The heat capacities listed by Kelley were raised by 0.06 to match the entropy data of Gerke (loc. cit.). Data above room temperature were obtained by smooth extrapolation.

Entropy

A mean value of the entropy of formation of -46.614 e.u. was adopted from the cell measurements of R. H. Gerke (loc. cit.).

Sublimation

The vapor pressure over mercurous chloride reaches 1 atmosphere at 655°K according to A. Smith and A. W. C. Menzies, J. Am. Chem. Soc. 32, 1541 (1910). At this point the vapor is dissociated into Hg(g) and $HgCl_2$(g).

Heat of Formation.

The heat of formation is calculated from that of KCl(g) using $\Delta H^\circ_{r\ 298}$ = 45.0 kcal./mole for $K_2Cl_2(g) \rightarrow 2KCl(g)$ as selected from data analyses summarized below. The three experimental techniques include PVT measurements (source 1), combination of total vapor pressure and transpiration data (sources 2,3,4), and mass spectrometric studies of the variation of ion intensities with temperature (source 5). The results are reasonably consistent, considering the uncertainties inherent in the problem.

The resulting tables were tested by comparison with other data. Calculated total vapor pressures are in satisfactory agreement with the observed values over the range 820-1500°K.; however, near the boiling point they are lower by 6-18 percent [see KCl(g)]. Knudsen effusion data and transpiration data over KCl(c) have been reviewed by A. C. P. Pugh and R. F. Barrow, Trans. Faraday Soc. 54, 671 (1958). These data suggest negligible dimer formation when combined with the total vapor pressures of Pugh and Barrow but significant dimer formation when combined with the lower (20-30 percent) total pressures of V. Dietz, J. Chem. Phys. 4, 575 (1936). Calculated dimer formation (22 mole percent at 900°K.) agrees with the latter combination but calculated total pressures agree with those of Pugh & Barrow. Velocity distribution studies of R. C. Miller and P. Kusch, J. Chem. Phys. 27, 981 (1957); 25, 860 (1956) suggest about 10 mole percent of dimer at 900°K. Thus, while minor inconsistencies do exist, it is not apparent that they exceed the combined experimental errors.

Heat Capacity and Entropy.

The structure and vibrational frequencies are those calculated from an ionic model by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960); 29, 1386 (1958). The sixth fundamental was arbitrarily lowered from 206 to 100 cm.$^{-1}$ since the resulting entropy increase (1.4 eu at 1300°K.) improved the overall agreement with the equilibrium data. Based on electron diffraction studies of the monomer-dimer vapor, P. A. Akishin and N. G. Rambidi, Zhur. Neorg. Khim. 4, 718 (1959) have derived the bond distance and angle to be 2.81 Å and 98°. Interpretation of the diffraction data, however, is complicated by the presence of only about 30 mole percent of dimer at the temperature of measurement. Adoption of this dimer structure would reduce the entropy by 0.23 eu. Principal moments of inertia for the Berkowitz structure are I_A = 45.31 X 10^{-39}, I_B = 60.13 X 10^{-39}, and I_C = 105.45 X 10^{-39} g. cm.^{2}

Bond Lengths and Angles

Li-Li distance = 2.62 Å

Li-Cl distance = 2.23 Å

ClLiCl angle = 108 ± 4° σ = 4

Moment of Inertia $I_AI_BI_C = 6418 \times 10^{-117}$ g.^{3} cm.^{6}

Heat of Formation. A heat of sublimation at 298° of 52.1 kcal. mole^{-1} was chosen to fit the vapor pressure data and relative concentrations of monomer, dimer and trimer as described in the table for LiCl(g). This value is in reasonable agreement with the value of 53.5 kcal. mole^{-1} from a 3rd law analysis of the vapor pressure data of An. N. Nesmeyanov and L. A. Sazonov, Zhur. Neorg. Khim. 4, 231 (1960) and the relative concentrations of monomer, dimer, and trimer from the work of R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1956). Also a value of 54.1 kcal. mole^{-1} was found by T. A. Milne and H. M. Klein, J. Chem. Phys. 33, 1628 (1960), from mass spectrometer studies.

Heat Capacity and Entropy. W. Klemperer and W. G. Norris, J. Chem. Phys. 34, 1071 (1961), observed two bands in the infra-red spectrum and made tentative assignments. The remaining four frequencies were calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), from a reasonable model. The bond lengths and angles were determined from the electron diffraction experiments of S. H. Bauer, T. Ino and R. F. Porter, J. Chem. Phys. 33, 685 (1960).

Magnesium Dichloride ($MgCl_2$)

Dec. 31, 1960; Dec. 31, 1965

MAGNESIUM DICHLORIDE ($MgCl_2$) (CRYSTAL) MOL. WT. = 95.218

$S^\circ_{298.15} = 21.422$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 987$°K.

$\Delta H^\circ_{f\ 0} = -153.25 \pm 0.11$ kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15} = -153.35 \pm 0.11$ kcal. mole^{-1}

$\Delta H_m = 10.30 \pm 0.05$ kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15} = 57.5 \pm 1.5$ kcal. mole^{-1}

Heat of Formation.

The adopted $\Delta H^\circ_{f\ 298.15} = -153.35 \pm 0.11$ kcal. mole^{-1} is from heat of solution measurements reported by C. H. Shomate and E. H. Huffman, J. Am. Chem. Soc. 65, 1625 (1943). Shomate and Huffmans heat of solution of Mg in 1 M HCl ($\Delta H = -111.322 \pm 0.041$ kcal. mole^{-1}) has been substantiated for calibration purposes by S. R. Gunn and B. B. Cunningham, J. Am. Chem. Soc., 79, 1563 (1957) ($\Delta H = -111.3$ kcal. mole^{-1}) and by E. F. Westrum Jr. and L. Eyring, J. Am. Chem. Soc., 74, 2045 (1952) ($\Delta H = -111.27$ kcal. mole^{-1}). Auxilliary heat of dilution and heat of formation data for HCl were taken from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NSRDS-NBS 2, Nat'l. Bur. Stds., April 1965 and from D. D. Wagman et al., N.B.S. Technical Note 270-1, Oct. 1965.

Heat Capacity and Entropy.

High temperature heat content data by G. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943) were joined by Shomate correlation with low temperature heat capacity data reported by K. K. Kelley and G. E. Moore, J. Am. Chem. Soc. 65, 1264 (1943). C_p(c) above T_m is a linear extrapolation from 700°K. $S^\circ_{298.15}$ is derived from the low temperature data and is based on $S^\circ_{53.6} = 2.006$ cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

$\Delta H_m = 10.30 \pm 0.05$ kcal. mole^{-1} is taken from heat content measurements of Moore loc. cit. $T_m = 987$°K. is from National Bureau of Standards Circular 500, 1952.

Sublimation Data.

The value of $\Delta H^\circ_{s\ 298.15}$ was derived by 2nd and 3rd law analyses of vapor pressure data. See the $MgCl_2(g)$ table for details.

Dec. 31, 1960; Dec. 31, 1965

MAGNESIUM DICHLORIDE ($MgCl_2$) (LIQUID) MOL. WT. = 95.218

$S^\circ_{298.15}$ = 30.949 cal. deg.$^{-1}$ mole^{-1}

T_m = 987°K.

T_b = [1710]°K.

$\Delta H^\circ_{f\ 298.15}$ = -143.779 kcal. mole^{-1}

ΔH°_m = 10.30 ± 0.05 kcal. mole^{-1}

ΔH°_v = [37.34] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}(l)$ was calculated from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m}-H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

A constant $C_p(l)$ = 22.0 cal. deg.$^{-1}$ mole^{-1} over the temperature range 1006-1428°K. is from the high temperature heat content data of G. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943). This constant value was assumed to hold from an assumed glass transition of 660°K. to 3000°K. $C_p(l)$ below 660°K. is taken to be that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See $MgCl_2(c)$ table for details.

Vaporization Data.

T_b is calculated as the temperature at which the free energy change of the reaction $MgCl_2(l) = MgCl_2(g)$ approaches zero. The difference between ΔH°_f for $MgCl_2(l)$ and $MgCl_2(g)$ at T_b is ΔH°_v.

Magnesium Dichloride ($MgCl_2$)

MAGNESIUM DICHLORIDE ($MgCl_2$) (IDEAL GAS) GFW = 95.218

Point Group $D_{\infty h}$

$\Delta Hf°_0$ = -93.82 ± 0.5 kcal/mol

$S°_{298.15}$ = 66.184 ± 0.5 gibbs/mol

$\Delta Hf°_{298.15}$ = -93.80 ± 0.5 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
590 (1)
88 (2)
[273] (1)

Bond Distance: Mg-Cl = 2.18 Å

Bond Angle: Cl-Mg-Cl = 180°

Rotational Constant: B_0 = 0.05003 cm^{-1}

σ = 2

Heat of Formation

Analysis of vapor pressure data on $MgCl_2$ is clouded by conflicting evidence for the amount of dimer in the vapor. Berkowitz and Marquart (1) by mass spectrometer studies found about 2% dimer at 920°K and derived ΔH_D = -39.2 kcal/mol and ΔS_D = -29.9 gibbs/mol. Schrier and Clark (2) from gas transpiration data calculated about 30% dimer in the saturated vapor at 1300°K, with ΔH_D = -32.0 kcal/mol and ΔS_D = -18.8 gibbs/mol. Thermodynamic functions for the gaseous monomer adopted here are clearly not compatible with large amounts of dimer and it is assumed for the present that the mass spectrometer results are correct.

Several vapor pressure studies have been published and third law analyses are given below. Berkowitz and Marquart (1) gave a single point while the remaining publications gave only equations but not individual points. Total pressures calculated from the equations were corrected for dimer.

Source	Method	Temperature Range (°K)	$\Delta Hs°_{298}$(kcal/mol) 3rd law
Berkowitz and Marquart (1)	Mass spectrometer	920	58.10
Schrier and Clark (2)	Boiling Point	1208-1413	59.55-59.68
Hildenbrand et al. (3)	Torsion-effusion	802-985	59.55-59.19
Hildenbrand et al. (4)	Torsion-effusion	800-970	59.53-59.38
Fischer et al. (5)	"Bell" method (total vapor pressures)	1136-1435	59.30-59.56

The selected value for $\Delta Hs°_{298}$ is 59.55 kcal/mol which is combined with $\Delta Hf°_{298}$ of the crystal to give $\Delta Hf°_{298}(g)$ = -93.80 kcal/mol.

Heat Capacity and Entropy

White, Mann, and co-workers (6) by matrix infrared spectroscopy determined the molecule to be linear with the asymmetric stretching frequency at 590 cm^{-1} and the doubly degenerate bending frequency at 88 cm^{-1}. The symmetric stretching frequency was estimated as 273 cm^{-1}. The asymmetric stretching was observed by Buchler and Klemperer (7) at 597 cm^{-1} and by Randall et al. (8) at 598 cm^{-1}, both by infrared spectroscopy of the vapor at high temperature. Electric deflection experiments by Klemperer and co-workers as summarized by Hayes (9) and the electron diffraction data of Akishin and Spiridonov (10) agree with the linear structure within their error limits of about 20°. The Mg-Cl bond length was determined as 2.18 Å by Akishin and Spiridonov (10).

MOLYBDENUM DIOXYDICHLORIDE (MoO_2Cl_2) (IDEAL GAS) GFW = 198.845

Point Group C_{2v}

$S°_{298.15}$ = 80.70 ± 1.30 gibbs/mol

Ground State Quantum Weight = 1

$ΔHf°_0$ = -150.3 ± 3.5 kcal/mol

$ΔHf°_{298.15}$ = -151.3 ± 3.5 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
972 (1)	134 (1)	156 (1)
453 (1)	233 (1)	437 (1)
347 (1)	996 (1)	287 (1)

Bond Distance: Mo-O = 1.75 ± 0.10 Å Mo-Cl = 2.28 ± 0.03 Å

Bond Angle: O-Mo-O = 109.5° Cl-Mo-Cl = 113° σ = 2

O-Mo-O plane perpendicular to Cl-Mo-Cl plane

Product of Moments of Inertia: $I_AI_BI_C = 1.0986 \times 10^{-112}\ g^3\ cm^6$.

Heat of Formation

Graham and Hepler (1) determined calorimetrically ΔHr° = -65.3 ± 0.5 kcal/mol for the reaction:

$$MoO_2Cl_2(c) + 4\ NaOH(\infty\ H_2O) \rightarrow Na_2MoO_4(\infty\ H_2O) + 2\ NaCl(\infty\ H_2O) + 2\ H_2O(\ell).$$

Combining this result with the following heat of formation data; $ΔHf°(Na_2MoO_4, \infty\ H_2O)$ = -353.4 ± 0.4 kcal/mol (2); $ΔHf°(NaCl, \infty\ H_2O)$ = -97.33 ± 0.09 kcal/mol (3); $ΔHf°(NaOH, \infty\ H_2O)$ = -112.46 ± 0.1 kcal/mol (5); $ΔHf°(H_2O, \ell)$ = -68.315 kcal/mol (6); we derive $ΔHf°(MoO_2Cl_2, c)$ = -169.6 ± 1.0 kcal/mol.

Shchukarev et al. (7) measured the heats of solution of $MoO_3(c)$, $MoO_2Cl_2(c)$ and NaCl(c) in NaOH(aq) and derived ΔHr = -45.56 ± 0.5 kcal/mol for the reaction $MoO_2Cl_2(c) + 2NaOH \cdot 77\ H_2O \rightarrow MoO_3(c) + 2NaCl(c) + H_2O(\ell)$. Using JANAF auxiliary data (9) we obtain $ΔHf°_{298}(MoO_2Cl_2, c)$ = -172.86 ± 1.0 kcal/mol.

The two investigations differ only in the heat of solution of $MoO_2Cl_2(c)$, both samples were better than 99.9% pure, and multiple determinations on two different samples were employed in each case. We adopt an average of the two values, -171.2 ± 1.7 kcal/mol for $ΔHf°_{298}(MoO_2Cl_2, c)$. Shchukarev et al. (10) reported an equation for the vapor pressure over the solid from which we have calculated a 2nd law $ΔHs°_{298}$ = 19.9 kcal/mol with an estimated uncertainty of ±2 kcal/mol, a ΔCp correction of -4.1 gibbs/mol was used (11). Thus, our adopted value is $ΔHf°_{298}(MoO_2Cl_2, g)$ = -151.3 ± 3.5 kcal/mol.

Shchukarev et al. (8) report equilibrium constants for the reaction $MoO_2Cl_2(g) + 0.5\ O_2(g) \rightleftarrows MoO_3(c) + Cl_2(g)$. Shchukarev et al. (10) and Hultgren and Brewer (12) reported equilibrium data for the reaction $MoO_3(c) + 2HCl(g) \rightleftarrows MoO_2Cl_2(g) + H_2O(g)$. Second and third law analyses of these equilibrium data give the following results:

Investigator		No. of Points	$ΔHr_{298}$, kcal/mol		Drift, gibbs/mol	$-ΔHf°(MoO_2Cl_2, g)$ kcal/mol *
			2nd law	3rd law		
Shchukarev et al. (8)		7	-15.6	-30.11±2.0	-15.0	148.0 ± 3.0
Shchukarev et al. (10)		Equation	12.1	13.8±1.0	2.95	150.6 ± 1.2
Hultgren and Brewer (12)	Set I	5	27.2	15.2±1.7	-21.37	149.2 ± 2.0
	Set II	5	26.5	15.4±3.2	-21.75	149.4 ± 3.5

*Third law values

These equilibrium data are in agreement with the adopted heat of formation but are suspect because of the significant drifts and because the range of validity of the equation (10) is estimated.

Heat Capacity and Entropy

The molecular structural data are from the compilation of Sutton (13). Infrared data (14, 15, 16) for vapor phase MoO_2Cl_2 have indicated that the molecule possesses a distorted tetrahedral structure by reason of the similarity of its spectra to that of CrO_2Cl_2. Individual moments of inertia are $I_A = 53.397 \times 10^{-39}$, $I_B = 63.898 \times 10^{-39}$, and $I_C = 32.200 \times 10^{-39}\ g\ cm^2$.

The vibrational frequencies 972, 996, 453, and 437 have been observed in the infrared vapor phase spectra of MoO_2Cl_2 by Barraclough and Stals (14). These frequencies were assigned to the symmetric and asymmetric Mo-O and Mo-Cl stretches, respectively. Similar infrared data for these four frequencies have been reported by Iorns and Stafford (15) and Ward and Stafford (16). The rest of the frequencies are from the infrared and Raman studies of crystalline MoO_2Cl_2 by Adams and Churchill (17). Assignments are made by comparison with data reported for $CrO_2Cl_2(\ell)$ by Miller et al. (18).

Product of the Moments of Inertia: $I_AI_BI_C = [6.849 \times 10^{-113}]$ g.^{3} cm.^{6}

Heat of Formation.

An analysis is given below of the more extensive measurements relating to the dimer dissociation, $(NaCl)_2(g) \rightarrow 2NaCl(g)$. The mass spectrometric studies suggest that higher polymeric species may be neglected. Velocity distribution analyses are consistent with this procedure. When reduced to 298.15°K, the observed heats of dissociation of the dimer show a range of more than 7 kcal., reflecting the considerable uncertainty involved in such measurements. A value of $\Delta H^\circ_{r\ 298}$ = 48.6 kcal. was selected for the dissociation; combining this with $\Delta H^\circ_{s\ 298}$ = 54.9 kcal. mole^{-1} for sublimation to the monomer leads to $\Delta H^\circ_{s\ 298}$ = 61.2 kcal. mole^{-1} for sublimation to the dimer.

Heat Capacity and Entropy.

The structure and vibrational frequencies are those calculated from an ionic model by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), 29, 1386 (1958). Electron diffraction studies by Akishin and Rambidi, Z. physik. Chem. (Leipzig) 213, 111 (1960) gave a similar bond angle (108°) and a slightly shorter bond distance (2.50 Å); however, interpertation of the diffraction pattern was complicated by uncertainty in the monomer-dimer ratio for the vapor. Principal moments of inertia for the Berkowitz structure are $I_A = 18.01 \times 10^{-39}$, $I_B = 53.31 \times 10^{-39}$ and $I_C = 71.32 \times 10^{-39}$ g. cm.^{2}

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 1.171535 X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

V. A. Kustodina, K. P. Mishchenko and I. E. Flis, Zh. Prikl. Khim. 35, 1374 (1962) (Source 1) derived the heat of formation of Cl_2O dissolved in CCl_4 from solution calorimetry at 278, 283, 298 and 308°K. The heat of formation in CCl_4 was interpolated to 285°K. D. M. Yost and R. C. Felt, J. Am. Chem. Soc. 56, 68 (1934) (Source 2) measured the partial vapor pressures of Cl_2O above its CCl_4 solution at 273 and 298°K which yield the heat of solution -6.59 kcal. mole^{-1} at 285°K. The $\Delta H^\circ_{f\ 298.15}$ = 21.0 kcal. mole^{-1} was calculated from these two values. J. I. Wallace and C. F. Goodeve, Trans. Faraday Soc. 27, 648 (1931) (Source 3) obtained the heat of explosion of $Cl_2O(g)$: their data give $\Delta H^\circ_{f\ 298.15}$ $Cl_2O(g)$ = 21.4 kcal. mole^{-1} which is in very good agreement with the above. Also P. Günther and K. Wekua, Z. Physik Chem. 154, 193 (1931) (Source 4) measured the heat of explosion; their data give $\Delta H^\circ_{f\ 298.15}$ $Cl_2O(g)$ = 24.7 kcal. mole^{-1}.

Source	Reaction	T, °K	ΔH°_T kcal. mole^{-1}	$\Delta H^\circ_{f\ 298.15}$ kcal. mole^{-1}
1	$Cl_2(g) + 1/2\ O_2(g) \rightarrow Cl_2O(\text{in } CCl_4)$	285	14.38	——
2	$Cl_2O(\text{in } CCl_4) \rightarrow Cl_2O(g)$	285	6.59	21.0
3	$Cl_2O(g) \rightarrow Cl_2(g) + 1/2\ O_2(g)$	298	-21.4	21.4
4	$Cl_2O(g) \rightarrow Cl_2(g) + 1/2\ O_2(g)$	298	-24.7	24.7

Heat Capacity and Entropy.

The vibrational frequencies were obtained from M. M. Rochkind and G. C. Pimentel, J. Chem. Phys. 42, 1361 (1965). The infrared spectrum of $Cl_2O(g)$ has been investigated previously beginning with the work of C. R. Bailey and A. B. D. Cassie, Proc. Roy. Soc. (London) A142, 192 (1933). K. Hedberg, J. Chem. Phys. 19, 509 (1951) proposed stretching frequencies at 688 cm.$^{-1}$ (ν_1) and 969 cm.$^{-1}$ (ν_3) but left the bending frequency unknown. Previous evidence concerning the bending mode (ν_2)* was shown by Hedberg (loc. cit.) to be spurious. Rochkind and Pimentel (loc. cit.) present infrared studies of Cl_2O gas and condensed phases which reveal the bending frequency and require reassignment of the stretching fundamentals. The bond distance and bond angle were obtained from J. D. Dunitz and K. Hedberg, J. Am. Chem. Soc. 72, 3108 (1950).

The three principal moments of inertia are: I_A = 2.022 X 10^{-39}, I_B = 2.30806 X 10^{-38}, and I_C = 2.51026 X 10^{-38} g. cm.^{2}

*G. B. B. M. Sutherland and W. B. Penny, Proc. Roy. Soc. (London) A156, 678 (1936).

Bond Distances: O=Ti = [1.62] Å Ti-Cl = [2.20] Å

Bond Angles: O=Ti-Cl = [120°] σ = 2

Product of Moments of Inertia: $I_AI_BI_C$ = [4.628 X 10^{-113}] g.^{3} cm.^{6}

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was estimated as -130 kcal. mole^{-1} by J. S. Gordon, Astrosystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. $\Delta H^\circ_{f\ 298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. Principal moments were: I_A = 42.72 X 10^{-39} g. cm.^{2}, I_B = 17.88 X 10^{-39} g. cm.^{2}, and I_C = 60.60 X 10^{-39} g. cm.^{2}

TUNGSTEN DIOXYDICHLORIDE (WO_2Cl_2) (CRYSTAL) GFW = 286.7548

Cl_2O_2W

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [48.0] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -186.5 ± 1.4 kcal/mol

Td = 642°K

Heat of Formation.

S. A. Shchukarev, I. V. Vasil'kova and G. I. Novikov[1] measured calorimetrically the heats of reaction (1) and (2) at 298°K as -67.3 ± 0.2 and -13.6 ± 0.11 kcal/mol, respectively. The reactions are given as follows:

(1) $WO_2Cl_2(c) + 4\ NaOH(16.3H_2O) \rightarrow Na_2WO_4(80{,}000\ H_2O) + 2\ NaCl(40{,}000\ H_2O) + 2\ H_2O(l)$

(2) $H_2WO_4(c) + 2\ NaOH(16.3\ H_2O) \rightarrow Na_2WO_4(20{,}000\ H_2O) + 2\ H_2O(l)$.

Based on these data and the heats of dilution for NaOH(aq)[2], NaCl(aq)[2] and Na_2WO_4(aq)[3], we obtain ΔHr°_{298} = 53.77 ± 1.0 kcal/mol for $WO_2Cl_2(c) + 2\ OH^-(\infty H_2O) \rightarrow H_2WO_4(c) + 2\ Cl^-(\infty H_2O)$. This leads to $\Delta Hf^\circ_{298}(WO_2Cl_2,\ c)$ = -186.5 kcal/mol using $\Delta Hf^\circ_{298}(H_2WO_4,\ c)$ = -270.5 ± 0.4 kcal/mol[5].

Heat Capacity and Entropy.

Cp_{300} = 25.0 gibbs/mol is estimated using Kopp's rule. Heat capacities at higher temperature are estimated from those of $WO_2(c)$, $WO_3(c)$, $WCl_6(c)$. The entropy, S°_{298} = 48.0 eu, is calculated from $\Delta S^\circ_{598.6}$ = 32.27 ± 1.3 eu for $WO_2Cl_2(c) \rightarrow WO_2Cl_2(g)$. The value of $\Delta S^\circ_{598.6}$ is obtained from the second law analysis of the vapor pressure data given by S. A. Shchukarev and A. V. Suvorov[4].

Temperature of Decomposition.

Shchukarev and Suvorov[4] found that $WO_2Cl_2(c)$ does not melt but decomposes. The saturated vapor over $WO_2Cl_2(c)$ consists mainly of $WOCl_4(g)$ which will disproportionate to form $WO_2Cl_2(g)$ and $WCl_6(g)$. The estimated Td is derived by interpolation to one atmosphere in the total pressures of $WOCl_4(g)$, $WO_2Cl_2(g)$ reported by Shchukarev and Suvorov[4].

TUNGSTEN DIOXYDICHLORIDE (WO_2Cl_2) (IDEAL GAS) GFW = 286.7548

Point Group [C_{2v}]

$\Delta Hf^\circ_0 = -159.7 \pm 6$ kcal/mol

$S^\circ_{298.15} = [84.6]$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -160.5 \pm 6$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
984 (1)	[400] (1)	[150] (1)
972 (1)	[300] (1)	[100] (1)
[400] (1)	[300] (1)	[100] (1)

Bond Distance : W-Cl = [2.26] Å   W-O = [1.81] Å

Bond Angle: Cl-W-Cl = [113°]   O-W-O = [109.47°]   O-W-Cl = [90°]   σ = [2]

Product of the Moments of Inertia: $I_AI_BI_C = [1.165 \times 10^{-112}]\ g^3\ cm^6$

Heat of Formation.

The adopted heat of formation, $\Delta Hf^\circ_{298}(WO_2Cl_2,g) = -160.5$ kcal/mol, is obtained from $\Delta Hr^\circ_{298} = 26.0$ kcal/mol for $WO_2Cl_2(c) \rightarrow WO_2Cl_2(g)$. The latter is calculated by the third law method from the partial pressures of $WO_2Cl_2(g)$ given by S. A. Shchukarev and A. V. Suvorov[6]. Second law analysis gives $\Delta Hr^\circ_{598.6} = 24.1 \pm 0.8$ kcal/mol ($\Delta Hr^\circ_{298} = 26.0$ kcal/mol). These reported partial vapor pressures of $WO_2Cl_2(g)$ were derived by the optical tensimetric method from total pressures over $WO_2Cl_2(c)$ considering the species $WOCl_4(g)$, $WO_2Cl_2(g)$ and $WCl_6(g)$. Since the decomposition of $WO_2Cl_2(c)$ was very complicated, we tentatively assign 6 kcal/mol uncertainty to the adopted heat of formation.

Shchukarev and Suvorov[6] have also derived a log Kp equation for the disproportionation process, $2\ WOCl_4(g) = WO_2Cl_2(g) + WCl_6(g)$. Third law analysis gives $\Delta Hr^\circ_{298} = 10.3$ kcal/mol for the above process. This leads to ΔHf°_{298} (WO_2Cl_2, g) = -145.7 ± 16 kcal/mol. The second law ΔHr°_{590} is 11.0 kcal/mol ($\Delta Hr^\circ_{298} = 10.1$ kcal/mol). The drift in the third law analysis is 0.3 eu.

Heat Capacity and Entropy.

The molecular configuration is assumed to be a distorted tetrahedron of C_{2v} symmetry, similar to that of $MoO_2Cl_2(g)$[1], and $CrO_2Cl_2(g)$[2]. The bond distances W-O and W-Cl are estimated to be the same as those in $WO_3(g)$ and $WCl_6(g)$, respectively. The bond angles are assumed to be the same as those in $MoO_2Cl_2(g)$[1]. The three principal moments of inertia are $I_A = 6.419 \times 10^{-38}$, $I_B = 5.342 \times 10^{-38}$ and $I_C = 3.397 \times 10^{-38}$ g cm^2.

The vibrational frequencies, 984 cm^{-1} and 972 cm^{-1}, were observed in the infrared spectra by C. G. Barraclough and J. Stals[3]. They tentatively assigned these two as the symmetric and asymmetric W-O stretching frequencies. The rest of the frequencies are estimated by comparison with those observed in the infrared and Raman spectra for $CrO_2Cl_2(g)$[4,5]. They are not listed in point group order.

Lead Dichloride ($PbCl_2$) (Crystal)

Mol. Wt. = 278.12

$\Delta H_f^\circ{}_{298.15} = -86.20 \pm 0.07$ kcal. mole^{-1}

$S^\circ_{298.15} = 32.5 \pm 0.5$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_s^\circ{}_{298.15} = 45.59 \pm 0.70$ kcal. mole^{-1}

$T_m = 768°K$

$\Delta H_m^\circ = 5.70$ kcal. mole^{-1}

Heat of Formation. Recalculated from the data reported by E. J. Salstrom, J. Am. Chem. Soc. 55, 2426 (1933) and A. Wachter, J. Am. Chem. Soc. 54, 2271 (1932).

Heat Capacity, Entropy and Melting Data. C_p (15.8° to 205.5°K.) reported by W. Nernst, Ann. Physik, 36, 395 (1911) and adjusted so that $S^\circ_{298.15}$ is equal to the value reported by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592 (1961). C_p above 298.15°K. obtained from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) and joined smoothly to the low temperature heat capacity curve by graphical extrapolation. T_m and ΔH_m° obtained from M. Blanc and G. Petit, Compt. rend. 248, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of E. D. Eastman and L. H. Duschak, U. S. Bur. Mines Tech. Paper 225 (1919), C. G. Maier, U. S. Bur. Mines Tech. Paper 360, 28 (1925), H. V. Wartenberg and O. Bosse, Z. Elektrochem. 28, 384 (1922), and W. Jahn-Held and K. Jellinek, Z. Elektrochem. 43, 491 (1937), which are in good agreement. Vapor pressure was also measured by F. Völmer, Physik. Z. 30, 590 (1929), J. L. Barton and H. Bloom, J. Phys. Chem. 60, 1413 (1956), B. Greiner and K. Jellinek, Z. physik. Chem. A165, 97 (1933), and K. Niwa, M. Sato and M. Yosiyama, J. Faculty Sci. Hokkaido Imp. Univ. Ser. III, 3, 17 (1940).

Bond Distance: Si-Cl = [2.04] Å

Bond Angle: Cl-Si-Cl = [106°] σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = [5.709 \times 10^{-114}]\ g^3\ cm^6$

Heat of Formation

The adopted value is derived from $\Delta Hr^\circ = 78.5 \pm 2$ kcal/mol at 298.15 K for the reaction $Si(c) + SiCl_4(g) \rightarrow 2\ SiCl_2(g)$. JANAF analyses of equilibrium data for this reaction are summarized below. Three sets of data (1, 2, 6) yield average values of ΔHr° (3rd law) which agree within 0.5 kcal/mol and values of ΔSr° (2nd law) which are in reasonable agreement with the JANAF functions. Two of the equilibrium studies used flow techniques while the third used a static technique. A median value of ΔHr° is adopted. Its uncertainty is estimated by assuming that the JANAF entropy for $SiCl_2(g)$ may be too low by 0.7 gibbs/mol at 1400 K. The adopted value corresponds to ΔH°_0 atom = 203.0 kcal/mol and an average bond energy of 101.5 kcal/mol.

Two other flow studies (3, 4) yield large entropy errors, suggesting that there are temperature-dependent errors in Kp. The reported equilibrium constants are reasonable at the lower temperatures but deviate progressively at the higher temperatures. In contrast, the static study of Ishino (5) gave Kp values which differ by a factor of five from the adopted ones. These data yield a consistent entropy but ΔHr° (3rd law) is lower by 5 kcal/mol.

Source	Date	Method	Input	Range	Entropy Test[a]	ΔHr°_{298}, kcal/mol	
				T, °K	δ, gibbs/mol	2nd Law	3rd Law
Schäfer (1)	1967	Flow	Equation	1273-1473	1.6 ± 1	80.6 ± 1	78.35
Teichmann (2)	1966	Flow	Equation	1223-1573	1.7 ± 0.8	80.8 ± 1.1	78.49

Antipin (4)	1954	Flow	Data	1273-1673	26 ± 3	114 ± 4	75.4
Ishino (5)	1965	Static	Data	1448-1573	-2.1 ± 1.4	70.2 ± 2.1	73.4
Schäfer (6)	1953	Static	Equation	1400-1593	0.6 ± 0.9	79.8 ± 1.4	78.84

[a] δ = ΔSr° (2nd law) - ΔSr° (JANAF functions); where equations are used as input, the uncertainties are those given by the original authors.

Heat Capacity and Entropy

The point group is assumed to be the same as that of CF_2 and SiF_2. The Si-Cl bond length and Cl-Si-Cl bond angle are estimated to be intermediate between those in HSiCl and H_2SiCl_2. Comparisons with CF_2, SiF_2, H_2CF_2 and H_2SiF_2 confirm that the estimated angle is reasonable. Further confirmation of the structure comes from analysis of isotopic splittings in the infrared spectra of matrix-isolated $SiCl_2$. Milligan and Jacox (7) deduced angles of 90 to 120° from alternative assignments for the two stretching vibrations. Observations on argon matrices gave 502 and 513 cm^{-1} for these vibrations, but it was not possible to decide which is the symmetric mode. Principal moments of inertia are $I_A = 31.25 \times 10^{-39}$, $I_B = 5.035 \times 10^{-39}$, and $I_C = 36.29 \times 10^{-39}\ g\ cm^2$.

Milligan and Jacox (7) also observed an unstructured absorption in the ultraviolet spectrum. This is the region in which gas-phase emission studies (8) showed features tentatively ascribed to $SiCl_2$. Vibrational spacings of about 250 and 540 cm^{-1} were associated (8) with the ground state; however, this analysis should be reviewed in the light of the matrix spectra. Meanwhile, we estimate that the bending mode should be similar to that in H_2SiCl_2, probably 190 ± 40 cm^{-1}.

The ground state is assumed to be $^1A_1$ as suggested by Hückel-molecular-orbital calculations (9). Singlet excited states (8, 10) are included near 28000 and 30000 cm^{-1}, but the values are placed in brackets to emphasize the uncertainty in the analysis. Also tentatively adopted is the suggestion by Hastie et al. (10) that the continuous spectrum near 23000 cm^{-1} is due to a triplet excited state.

TITANIUM DICHLORIDE ($TiCl_2$) (CRYSTAL) GFW = 118.806

ΔHf°_0 = -123.0 ± 4.0 kcal/mol

$S^\circ_{298.15}$ = 20.88 ±.1.0 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -123.2 ± 4.0 kcal/mol

Ts = [1581.5]°K

ΔHs° = [59.4] kcal/mol

Heat of Formation

The heat of formation of $TiCl_2(c)$ has been measured calorimetrically. The chosen value of ΔHf°_{298} is the average of two such determinations. Values of ΔHf°_{298} are also calculated from the heats of reaction for the processes (A) $2TiCl_3(c) = TiCl_2(c) + TiCl_4(g)$, (B) $3TiCl_2(c) = 2TiCl_3(g) + Ti(c)$, and (C) $2TiCl_2(c) = TiCl_4(g) + Ti(c)$. These heats of reaction are combined with auxiliary JANAF values for the heats of formation of $TiCl_3(c)$, $TiCl_4(g)$, $TiCl_3(c)$ and Ti(c). The following table summarizes the data used to calculate ΔHf°_{298}.

Source	Reac.	Method	No. Pts.	Range T°K	$\Delta Hr^\circ_{298.15}$ Second Law	$\Delta Hr^\circ_{298.15}$ Third Law	Drift eu	ΔHf°_{298}* kcal/mol

***Two points rejected due to failure of a statistical test.

Heat Capacity and Entropy

The heat capacity of $TiCl_2(c)$ has been measured by Kim and Stout (8) over the range 6° to 300°K. They calculated the adopted value of S°_{298} from their measurements based on S°_6 = 0.017 eu. The heat capacity above 300°K is estimated by graphical extrapolation. The large uncertainty on S°_{298} is due to the possibility of sizeable electronic contributions to the heat capacity below 6°K which would account for the rather low value of S°_{298} reported by Kim and Stout (8).

Heat of Sublimation

The heat of sublimation is calculated from the heats of formation of $TiCl_2(c)$ and $TiCl_2(g)$. The temperature of sublimation is taken as the point at which ΔGr° = 0 for the process $TiCl_2(c) = TiCl_2(g)$. These values are hypothetical since $TiCl_2$ would be decomposed to $TiCl_3(g)$ and $TiCl_4(g)$ below this temperature.

Bond Distance: Ti-Cl = [2.3] Å

Bond Angle: Cl-Ti-Cl = [180°] σ = 2

Rotational Constant: B_0 = [0.0449] cm^{-1}

Heat of Formation

Gross and Levi (1) have measured the equilibrium $2TiCl_3(g) + Ti(c) \rightarrow 3TiCl_2(g)$ at 1723°K and obtain ΔGr°_{1723} = 21.7 kcal/mol from four measurements. This yields $\Delta Hf^\circ_{298}(TiCl_2, g)$ = -56.7 ± 3 kcal/mol. They discuss the measurements of Farber and Darnell (2), on the vapor pressure of $TiCl_2(c)$, and show that the results are probably in error due to disproportionation of $TiCl_3(g)$ on condensation. In the work of Skinner and Ruehrwein (3) on the reaction $2NaCl(g) + Ti(c) = 2Na(g) + TiCl_2(g)$, Gross and Levi indicate that the basic assumption, of conversion to $TiCl_2$ only, is erroneous. In the third law analysis of both these data sets significant drifts are obtained which tends to confirm the above arguments.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2(c)$ reported by Benzinger and Rundle (4). The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to correspond to the inverted states of $NiCl_2(g)$ (5). The linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (6, 7, 8, 9).

Sept. 30, 1962; Dec. 31, 1966

TUNGSTEN DICHLORIDE (WCl_2) (CRYSTAL) GFW = 254.756

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [31.2] gibbs/mol

$\Delta Hf^\circ_{298.15} = -61.5 \pm 3$ kcal/mol

Td = 862°K

Heat of Formation.

The heat of formation, ΔHf°_{298} $(WCl_2,c) = -61.5 \pm 3$ kcal/mol, is derived from the heat of combustion, $\Delta Hc^\circ = -140 \pm 3$ kcal/mol for $WCl_2(c) + 3/2\ O_2(g) \rightarrow WO_3(c) + Cl_2(g)$, reported by S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Baev, Zhur. Neorg. Khim. 5, 1650 (1960). The value of ΔHc° was determined calorimetrically, but no further information about the combustion process was given in the paper.

Heat Capacity and Entropy.

Cp_{298} = 6.2 gibbs/g-atom and Cp_{900} = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. Ll. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 900°, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy, S°_{298} = 31.2 eu, is estimated by the method of W. M. Latimer, "Oxidation Potentials," 2nd Ed., Prentice-Hall, Inc., New York, 1952. S. A. Shchukarev et al., loc. cit., have estimated ΔSr° = -30 eu for $W(c) + Cl_2(g) = WCl_2(c)$ which leads to S°_{298} (WCl_2,c) = 31.1 eu, using JANAF auxiliary data.

Temperature of Decomposition.

The decomposition temperature is obtained by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by S. A. Shchukarev, G. I. Novikov, and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 10, Ser. Fiz. i Khim., No. 2,78 (1959). Decomposition pressure data for Cl:W ratios less than two suggest that the decomposition reaction is not simple.

Tungsten Dichloride (WCl_2)

σ = [2]

Heat of Formation.

The value of $\Delta Hf^\circ_{298}(WCl_2,g)$ = -3 ± 25 kcal/mol is calculated from the heat of formation of the crystal plus the heat of sublimation, ΔHs°_{298} = 58.5 ± 25 kcal/mol. The latter is estimated from the heats of sublimation of $TiCl_2$, $CrCl_2$, $MnCl_2$, $FeCl_2$, $CoCl_2$, $NiCl_2$ given by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The uncertainty covers the difference between the heats of sublimation among the above compounds and also the possible error in transference from the first row transition metal dichlorides to tungsten dichloride.

S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Baev, Zh. Neorg. Khim. 5, 1650 (1960), have also estimated the heat of sublimation as 102 kcal/mol.

Heat Capacity and Entropy.

The molecular configuration of $WCl_2(g)$ is assumed to be linear. The bond distance is estimated to be the same as that in $WCl_6(g)$. The ground state configuration ($^5\Sigma$), the low lying electronic levels and their quantum weights are assumed to be the same as those for $CrCl_2(g)$, observed by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966).

The vibrational frequencies are calculated from a valence force field model. The stretching force constant, K_1, is estimated to be the same as that of $HgCl_2(g)$, 2.7 millidyne/Å. The bending force constant is assumed to be one hundredth of the stretching force constant. The moment of inertia is $I = 6.013 \times 10^{-38}$ g cm^2.

June 30, 1962; Dec. 31, 1969

ZIRCONIUM DICHLORIDE ($ZrCl_2$) (CRYSTAL) GFW = 162.126

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [26.3 ± 3] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-103.0 ± 10] kcal/mol

Tm = [1000]°K

ΔHm° = [6.4 ± 3] kcal/mol

$\Delta Hs^\circ_{298.15}$ = [58.5 ± 10] kcal/mol

Heat of Formation

The value of $\Delta Hf^\circ_{298}(ZrCl_2, c)$ = -103.0 kcal/mol is calculated from the estimated ΔHs°_{298} = 58.5 kcal/mol for $ZrCl_2(c) + ZrCl_2(g)$, using $\Delta Hf^\circ_{298}(ZrCl_2, g)$ = -44.5 kcal/mol (1). The estimated ΔHs°_{298} is obtained as an average of the heats of sublimation at 298°K for $TiCl_2$, VCl_2, $CrCl_2$, $MnCl_2$, $FeCl_2$, $CoCl_2$, $NiCl_2$ given by L. Brewer, G. R. Somayajulu and E. Brackett (2).

Heat Capacity and Entropy

The heat capacities of $ZrCl_2(c)$ are estimated based on the assumption that $Cp(ZrCl_2, c) = 1/2[Cp(ZrCl_4, c) + Cp(Zr, c)]$. The entropy, S°_{298}, is also estimated in a manner similar to that of the heat capacity.

Melting Data

The melting point was estimated to be 1000°K by L. Brewer (3) and the heat of melting was also estimated by A. Glassner (4).

June 30, 1962; Dec. 31, 1969

ZIRCONIUM DICHLORIDE ($ZrCl_2$) (LIQUID) GFW = 162.126

$S°_{298.15}$ = [29.278] gibbs/mol

$\Delta Hf°_{298.15}$ = [-98.372] kcal/mol

Tm = [1000]°K

ΔHm° = [6.4 ± 3] kcal/mol

Tb = [1565.3]°K

ΔHv° = [45.0] kcal/mol

Heat of Formation

The $\Delta Hf°_{298}(ZrCl_2, \ell)$ is calculated from $\Delta Hf°_{298}(ZrCl_2, c)$ by adding ΔHm° and the difference between $H_{1000} - H°_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7.25 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

The melting point was estimated to be 1000°K by L. Brewer (1), and the heat of melting was also estimated by A. Glassner (2).

Vaporization Data

Tb is the temperature at which the Gibbs energy change approaches zero for the process $ZrCl_2(\ell) \rightarrow ZrCl_2(g)$. The difference between ΔHf° for $ZrCl_2(\ell)$ and $ZrCl_2(g)$ at Tb is ΔHv°.

Heat of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl, $ZrCl_2$, $ZrCl_3$ and $ZrCl_4$. Ion intensities were measured 2.5 eV above the ionization threshold. Using the reported equilibrium constants for the reaction $ZrCl_4(g) + ZrCl_2(g) \rightarrow 2ZrCl_3(g)$ in the temperature range 1673-2110°K, second and third law analyses give the heat of reaction at 298°K as -15.8 and +1.7 kcal/mol, respectively. The third law drift is 8.9 ± 3.7 eu. Based on the third law heat of reaction and $\Delta Hf_{298}^\circ(ZrCl_4, g)$ = -207.77 kcal/mol (2) and $\Delta Hf_{298}^\circ(ZrCl_3, g)$ = -125.3 kcal/mol (3), we obtain $\Delta Hf_{298}^\circ(ZrCl_2, g)$ = -44.5 kcal/mol which is adopted in the tabulation.

Farber et al. (4) also studied mass spectrometrically the reaction (a) $Zr(c) + ZrCl_4(g) \rightarrow 2ZrCl_2(g)$ and the reaction (b) $Zr(c) + 2Cl(g) \rightarrow ZrCl_2(g)$. They reported second law heats of reaction as ΔHr_{298}° = 28.8 ± 1.8 kcal/mol for reaction (a); and -141.1 ± 2.2 kcal/mol for reaction (b). Third law analysis of the equilibrium constants which were calculated from their ion intensities of run 3 (the only available values) gives $\Delta Hf_{298}^\circ(ZrCl_2, g)$ = -43.4 kcal/mol. See JANAF $ZrCl_3(g)$ table (3) for details.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that other transition metal dichlorides are linear (5, 6, 7, 8, 9, 10) even though some fluorides are bent (11). The bond distance is assumed to be the same as that of $ZrCl_4(g)$. The electronic levels and quantum weights are estimated to be the same as those of $TiCl_2(g)$ (12).

The vibrational frequencies are calculated from a valence force field model. The stretching force constant is estimated to be 2.5 millidyne/Å and the bending force constant 0.05 millidyne/Å. The moment of inertia is 62.2817×10^{-39} g cm^2.

Bond Distance: Cu-Cl = 2.16 Å

Bond Angle: Cl-Cu-Cl = 150° Cu-Cl-Cu = 90°

σ = 6

Product of the Moments of Inertia: $I_AI_BI_C = 2.02847 \times 10^{-111}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of sublimation was determined by second and third law analysis of the following vapor pressure data. D. W. Magee, Doctoral Thesis, Ohio State University (1955), measured both vapor pressure by torsion effusion and vapor density in the range 533-644°K. and found only trimer present. The 2nd and 3rd law analyses gave $\Delta H^\circ_{s\ 298} = 37.37 \pm 0.04$ and 37.24 ± 0.02 kcal. mole^{-1} with a drift of -0.25 ± 0.07 cal. deg.$^{-1}$ mole^{-1}. R. A. J. Shelton, Trans. Faraday Soc. 57, 2113 (1961) using Knudsen effusion in the range 547-657°K. obtained $\Delta H^\circ_{s\ 298} = 40.35 \pm 1.4$ and 37.42 ± 0.4 kcal. mole^{-1} with a drift of -4.9 cal. deg.$^{-1}$ mole^{-1}. P. I. Fedorov and M. N. Shakhova, Izv. Vysshikh Uchebn. Zavedenii, Khim. i Khim. Tekhnol. 4, 550 (1961), using transport methods obtained vapor pressures over the liquid from 751-1057°K. Using 2nd and 3rd law analysis these gave $\Delta H^\circ_{s\ 298} = 38.6 \pm 1.0$ and 39.27 ± 0.5 kcal. mole^{-1}.

L. Brewer and N. L. Lofgren, J. Am. Chem. Soc. 72, 3038 (1950) obtained equilibrium constants for the reaction $3Cu(c) + 3HCl(g) \rightarrow Cu_3Cl_3(g) + 1.5\ H_2(g)$. Second and third law analysis of these constants gave $\Delta H_{r\ 298} = 3.9 \pm 0.6$ and 4.39 ± 0.3 kcal. mole^{-1} which leads to $\Delta H^\circ_f = -61.8 \pm 0.5$ kcal. mole^{-1}. This was the value adopted since it is dependent only on HCl(g) and does not involve three times the uncertainty of CuCl(c) as do the sublimation experiments, which yield values in good agreement but of larger uncertainty.

Heat Capacity and Entropy.

The structure of the trimer has been investigated by C-H. Wong and V. Schomaker, J. Phys. Chem. 61, 358 (1957). They conclude that the molecule is planar with D_{3h} symmetry and a Cu-Cl bond length of 2.16 Å. They also state that a very large amplitude of the symmetric in-plane bending appears plausible from the diffraction pattern. The infra-red spectrum has been investigated by W. Klemperer, S. A. Rice and R. S. Berry, J. Am. Chem. Soc. 79, 1810 (1957). They observed one strong absorption with a maximum at 350 cm.$^{-1}$; they attribute this to bond stretching motion of type E'. They also suggest that the broad absorption may involve another mode of approximately equal frequency.

In order to estimate the remaining frequencies we assumed that the other infra-red active E' mode would be close to the observed 350 cm.$^{-1}$ and this was estimated as 300 cm.$^{-1}$. The in-plane bending is the third E' mode and since this has a very large amplitude it was estimated as 60 cm.$^{-1}$ By analogy with other D_{3h} rings the A_2' mode was assumed to be in the same region as the E' stretches and was taken to be 250 cm.$^{-1}$ The $2A'_1$ stretches were estimated as 100 and 150 cm.$^{-1}$, while the out of plane A_2'' was taken as 200 cm.$^{-1}$ and the E" as 80 cm.$^{-1}$. These values gave calculated entropies in excellent agreement with the equilibrium data and thus support the estimates.

The individual moments of inertia were $I_A = I_B = 100.472 \times 10^{-39}$ g. cm.^{2}, $I_C = 200.944 \times 10^{-39}$ g. cm.^{2}

Trichlorofluorosilane ($FSiCl_3$)

IRON TRICHLORIDE ($FeCl_3$) (CRYSTAL) MOL. WT. = 162.206

$S^\circ_{298.15} = 34.019$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 577$°K.

$\Delta H^\circ_{f\ 0} = -95.80 \pm 0.20$ kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15} = -95.46 \pm 0.20$ kcal. mole^{-1}

$\Delta H^\circ_m = 10.30$ kcal. mole^{-1}

ΔH°_s (to dimer) = 34.52 kcal. mole^{-1}

Heat of Formation.

The enthalpy change, $\Delta H^\circ_{r\ 298.15} = -24.49 \pm 0.07$ kcal. mole^{-1}, for the reaction Fe( ) + 3(HCl·12.731 H_2O)(l) + 1/2(H_2O_2·12.580 H_2O)(l) = $FeCl_3$(c) + H_2(g) + 45.483 H_2O(l) was determined by M. F. Koehler and J. P. Coughlin, J. Phys. Chem. 63, 605 (1959). This leads to $\Delta H^\circ_{f\ 298.15} = -95.46 \pm 0.20$ kcal. mole^{-1} for $FeCl_3$(c), using $\Delta H^\circ_{f\ 298.15} = -38.9 \pm 0.05$ and -45.68 ± 0.01 kcal mole^{-1} for hydrochloric acid and hydrogen peroxide solution, respectively, obtained from F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine and I. Jaffe, National Bureau of Standards Circular 500, 1952. From $\Delta H^\circ_{r\ 298.15} = -38.0 \pm 0.2$ kcal. mole^{-1} for the reaction $FeCl_3$(c) = Fe^{+++}(aq.) reported by J. C. M. Li and N. W. Gregory, J. Am. Chem. Soc. 74, 4670 (1952), the value of $\Delta H^\circ_{f\ 298.15}$ ($FeCl_3$, c) was calculated as -93.26 ± 0.2 kcal. mole^{-1}. The former $\Delta H^\circ_{f\ 298.15}$ value is adopted.

The equilibrium pressures of the reaction 2 $FeCl_2$(c) + Cl_2(g) = 2$FeCl_3$(c), in the temperature range of 435.7-482.2°K., were measured by H. Schäfer and E. Oehler, Z. anorg. allgem. Chem. 271, 206 (1953). Using the reported partial pressures for Cl_2(g), the enthalpy change ($\Delta H^\circ_{r\ 298.15}$) of the reaction was evaluated as -27.49 ± 0.44 and -27.21 kcal. mole^{-1} by the second and third law methods, respectively. Based on the third law value for $\Delta H^\circ_{r\ 298.15}$, the value of $\Delta H^\circ_{f\ 298.15}$($FeCl_3$, c) was derived to be -95.36 ± 0.12 kcal. mole^{-1} which is in good agreement with the adopted value.

Heat Capacity and Entropy.

The low temperature (51-298.16°K.) heat capacities and high temperature (339.6-560.9°K.) heat content of $FeCl_3$(c) were determined by S. S. Todd and J. P. Coughlin, J. Am. Chem. Soc. 73, 4184 (1951). The low temperature C_p and the derived high temperature C_p were plotted. The two C_p curves were joined smoothly at 298°K. The C_p values above 560.9°K. were obtained by graphical extrapolation. The value of $S^\circ_{298.15}$ was derived from the low temperature data reported by S. S. Todd and J. P. Coughlin, loc. cit., using $S^\circ_{51} = 6.29$ cal. deg.$^{-1}$ mole^{-1}. The value of S°_{51} was selected to make the second and third law values of ΔH°_r, derived from the equilibrium data reported by H. Schäfer and E. Oehler, loc. cit., in good agreement. The difference in S°_{51} between the selected value, 6.29, and the reported value, 4.50 cal. deg.$^{-1}$ mole^{-1}, by S. S. Todd and J. P. Coughlin, loc. cit., is assumed to be the magnetic entropy remaining at 51°K. which was unaccounted for in the report.

Melting Data.

T_m and ΔH°_m were obtained from S. S. Todd and J. P. Coughlin, loc. cit.

Heat of Sublimation.

The difference between $\Delta H^\circ_{f\ 298.15}$ for Fe_2Cl_6(g) and 2$FeCl_3$(c) is the heat of sublimation at 298.15°K. The former is obtained by the second and third law analyses of related equilibrium data. See Fe_2Cl_6(g) table for details.

June 30, 1965

IRON TRICHLORIDE ($FeCl_3$) (LIQUID) MOL. WT. = 162.206

$S^\circ_{298.15}$ = 47.955 cal. deg.$^{-1}$ mole^{-1}

T_m = 577°K.

T_b = 605°K.

$\Delta H^\circ_{f\ 298.15}$ = -86.713 kcal. mole^{-1}

ΔH°_m = 10.30 kcal. mole^{-1}

ΔH°_v(to dimer) = 10.46 kcal. mole^{-1}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}(FeCl_3,\ l)$ was obtained from $\Delta H^\circ_{f\ 298.15}(FeCl_3,\ c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity for $FeCl_3(l)$ was taken from S. S. Todd and J. P. Coughlin, J. Am. Chem. Soc. 73, 4184 (1951) and assumed as constant between 298.15° and 1500°K. The entropy ($S^\circ_{298.15}$) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH°_m were reported by S. S. Todd and J. P. Coughlin, loc. cit.

Vaporization Data.

The boiling point (T_b) is determined as the temperature at which the free energy change (ΔF°_r) of the reaction $2FeCl_3(l) = Fe_2Cl_6(g)$ approaches zero. The corresponding enthalpy change at T_b is the heat of vaporization (ΔH°_v).

Heat of Formation.

The equilibrium pressures for the reaction $Fe_2Cl_6(g) = 2FeCl_3(g)$ were determined by Kangro and Bernstorff[1] and Schäfer[2], respectively. Using their vapor pressure data the corresponding values of $\Delta H^\circ_{r\ 298.15}$ for that reaction were evaluated by both the second and third law methods. Based on the third law values for $\Delta H^\circ_{r\ 298.15}$, the heats of formation ($\Delta H^\circ_{f\ 298.15}$) for $FeCl_3(g)$ were derived. The results obtained are presented as follows.

Investigator	Temperature, °K.	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	$\Delta H^\circ_{f\ 298.15}$, kcal. mole^{-1}
Kangro and Bernstorff[1]	760.2-1014.2	34.99 ± 0.44	35.73	-60.34 ± 0.30
Schäfer[2]	673.2-1073.2	34.81 ± 0.02	34.93	-60.74 ± 0.20

[1] W. Kangro and H. Bernstorff, Z. anorg. allgem. Chem. 263, 316 (1950).

[2] H. Schäfer, Z. anorg. allgem. Chem. 259, 53 (1949).

The adopted value of $\Delta H^\circ_{f\ 298.15}$($FeCl_3$ g) is -60.5 ± 1.2 kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that of $AlCl_3(g)$ due to the similarities in structure between $Fe_2Cl_6(g)$ and $Al_2Cl_6(g)$. The Fe-Cl bond distance was estimated by comparison with those for $Fe_2Cl_6(g)$ reported by E. Z. Zasorin, N. G. Rambidi and P. A. Akishin, Zh. Strukt. Khim., 4, 910 (1963) and O. Hassel and H. Viervoll, Acta Chem. Scand. 1, 149 (1947). Both the ground state quantum weight and vibrational frequencies were estimated so that the second and third law values of $\Delta H^\circ_{r\ 298.15}$, derived from the vapor pressure data, for the reaction $Fe_2Cl_6(g) = 2FeCl_3(g)$ are in reasonable agreement. The three principal moments of inertia are: $I_A = I_B$ = 4.15794 x 10^{-38} and I_C = 8.31588 x 10^{-38} g. cm.^{2}

Trichlorosilane ($HSiCl_3$) (Ideal Gas)

Mol. Wt. = 135.469

ΔH_f° 298.15 = -119.6 kcal. mole⁻¹

$S^\circ_{298.15}$ = 74.924 cal. deg.⁻¹ mole⁻¹

Point Group C_{3v}

Ground State Multiplicity = 1

Vibrational Frequencies and Degeneracies

, cm.⁻¹

2274 (1)	810 (2)
497 (1)	600 (2)
250 (1)	179 (2)

Si-H dist. = 1.48 all angles = [109° 28']

Si-Cl dist. = 2.02 = 3

Product of Moments of Inertia: $I_A I_B I_C = 75.642 \times 10^{-114}$ g.³ cm.⁶

Heat of Formation. ΔH_f° 298.15 was calculated from heats of reaction reported by E. Wolf, Z. Anorg. u. Allgem Chem. 313, 228 (1961) for the equation

$SiHCl_3(g) + 5NaOH(c) \rightleftarrows Na_2SiO_3(c) + 3NaCl(c) + 2H_2O(l)$

Heat Capacity and Entropy. Molecular constants were found in Janz and Mikawa, Bull. Chem. Soc. Japan 34, 1495 (1961). Vibrational frequencies can also be found in Henderson and Scheffee, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data," January, 1960.

Lithium Chloride, Trimeric $(LiCl)_3$ (Ideal Gas)

Mol. Wt. = 127.19
ΔH_f° 298.15 = -240.134 ± 5 kcal. mole^{-1}
$S^\circ_{298.15}$ = [80.223] cal. deg.$^{-1}$ mole^{-1}
Point Group = D_{3h}

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$	
[650]	(6)
[220]	(6)

Bond distances and angles Li-Cl distance = [2.2] Å
LiClLi angle [120°] Plane cyclic structure $\sigma = 6$

Moment of Inertia $I_AI_BI_C = 2.675 \times 10^{-112}$ g.^{3} cm.^{6}

Heat of Formation. The heat of sublimation at 298° was chosen so as to give the correct ratio of monomer, dimer and trimer at 870°K. The value used was 52.6 kcal. mole^{-1} which compares very well with the value 53.6 kcal. mole^{-1} obtained from a third law analysis of the data of An. N. Nesmeyanov and L. A. Sazonov, Zhur. Neorg. Khim. 4, 231 (1960) in conjunction with the relative concentrations of monomer, dimer, and trimer at 870°K from the work of R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1950).

Heat Capacity and Entropy. The postulated structure, bond lengths and frequencies were all taken from D. L. Hildenbrand, A. M. Saul P. R. Basford, S. E. Stephanon, L. Larson and A. Uyehara, Aeronutronic Tenth Quarterly Report on Contract NOrd 17980 Report C-898 (1960).

I_C = 578.7 X 10^{-40} g. cm.^{2}

σ = 3

Heat of Formation.

The $\Delta H_{f\,298.15}^\circ$ for $POCl_3(g)$ was derived from the $\Delta H_{f\,298.15}^\circ$ of $POCl_3(l)$ and the $\Delta H_{v\,298.15}^\circ$. The $\Delta H_{f\,298.15}^\circ$ of the $POCl_3(l)$ was calculated from the heat of hydrolysis observed by T. Charnley and H. A. Skinner, J. Chem. Soc., 450, (1953) for the reaction:

$POCl_3(l) + (n + 3)H_2O(l) \rightarrow [H_3PO_4 + 3HCl]$ in n $H_2O(l)$

The auxiliary thermochemical data, on the heats of formation of water and aqueous solutions of HCl and of H_3PO_4, were taken from the National Bureau of Standards, "Selected Values of Chemical Thermodynamic Properties," Circular 500, and were adjusted for consistency with JANAF Tables. The heat of vaporization was measured and corrected to 298.15°K by J. B. Ott and W. F. Giauque, J. Am. Chem. Soc., 82, 1308 (1960). A correction was made for the change in phosphorus reference state [white (α) → red(V)].

Heat Capacity and Entropy.

The molecular constants are from the microwave spectral data of Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys., 20, 164 (1952). In order to determine the structure Williams et al. (loc. cit.) assumed the P-Cl distance equal to 1.99 Å. This was the smallest value allowed (2.02 ± 0.03 Å) by the electron diffraction work of L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc., 60, 1836 (1938).

Ott and Giauque (loc. cit.) have given the moments of inertia obtained from a weighted average of the isotopic species. $I_A \neq I_B$ due to isotopic loss of symmetry. The $S_{298.15}^\circ$ calculated from calorimetric data by Ott and Giauque (loc. cit.) was 77.75 cal. deg.$^{-1}$ mole^{-1} and the $S_{298.15}^\circ$, calculated from the spectral data was 77.77 cal. deg.$^{-1}$ mole^{-1}.

Dec. 31, 1960; Sept. 30, 1962, June 30, 1970

PHOSPHORUS TRICHLORIDE (PCl_3) (IDEAL GAS) GFW = 137.3328

Point Group C_{3v}

$\Delta Hf^\circ_0 = -64.5 \pm 1.3$ kcal/mol

$S^\circ_{298.15} = 74.47 \pm 0.10$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -64.8 \pm 1.3$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
510 (1)	507 (2)
259 (1)	187 (2)

Bond Distance: P-Cl = 2.039 ± 0.0014 Å

Bond Angle: Cl-P-Cl = 100.27 ± 0.09°

$\sigma = 3$

Product of Moments of Inertia: $I_A I_B I_C = 6.0517 \times 10^{-113}$ g^3 cm^6.

Heat of Formation

Neale and Williams (1) measured the heat of hydrolysis of liquid phosphorus trichloride and reported a $\Delta H_r = -67.5 \pm 0.3$ kcal/mol for the following reaction:

$$PCl_3(\ell) + (X_2 + 3)\ H_2O \rightarrow H_3PO_3(aq) + 3\ HCl(aq)$$

with X_2 in range 4500 to 7500. Combining this result with heat of formation data for aqueous H_3PO_3, -229.4 kcal/mol (2, 5, 16), H_2O (2), and aqueous HCl (2), we derive $\Delta Hf^\circ(PCl_3, \ell) = -76.7$ kcal/mol. Charnley and Skinner (3) made an independent investigation of the hydrolysis of liquid phosphorus trichloride and obtained enthalpy data in very good agreement with Neale and Williams' results. Their results lead to $\Delta Hf(PCl_3, \ell) = -76.5$ kcal/mol when combined with heat of formation data (2, 5, 16).

Neale and Williams (4) also investigated the hydrolysis of liquid phosphorus trichloride in aqueous bromine solution with the formation of phosphoric acid rather than phosphorus acid which results when hydrolysis occurs in water. They reported a $\Delta H_r = -137.9$ kcal/mol for the following reaction:

$$PCl_3(\ell) + Br_2(aq) + (X_2 + 4)H_2O \rightarrow H_3PO_4(aq) + 3HCl(aq) + 2\ HBr(aq)$$

with X_2 in range 3500 to 6300. Combining this result with the following heat of formation data:

$\Delta Hf^\circ(H_3PO_4 \cdot 1\ H_2O) = -306.4 \pm 0.5$ kcal/mol (5)

$\Delta Hf^\circ(Br_2(aq)) = -0.2$ kcal/mol (6)

HCl(aq) and HBr(aq) (2)

along with dilution data for $H_3PO_4(aq)$ (2), we derive $\Delta Hf^\circ_{298}(PCl_3, \ell) = -77.0$ kcal/mol

The heat of formation from white phosphorus of gaseous PCl_3, $\Delta Hf^\circ(PCl_3, g) = -69.0 \pm 1.1$ kcal/mol, is calculated from the heat of formation of the liquid, $\Delta Hf(PCl_3, \ell) = -76.7 \pm 1.0$ kcal/mol, an average value of the three results given above, and the heat of vaporization of PCl_3. The heat of vaporization of the liquid, $\Delta Hv_{298} = 7.7 \pm 0.1$ kcal/mol, is determined from a second law analysis of the combined vapor pressure data of Nisel'son and Seryakov (7) and Regnault (8). The smoothed vapor pressure data of Regnault as reported by Stull (9) were used. Converting to the P(red, V) standard state with a $\Delta H_{trans} = 4.2 \pm 0.2$ kcal/mol (10), we derive $\Delta Hf^\circ_{298}(PCl_3, g) = -64.8 \pm 1.3$ kcal/mol.

An independent value for the heat of formation can be obtained from the work of Duus and Mykytiuk (17) on the reaction $1.5CaF_2 + PCl_3(g) \rightarrow 1.5CaCl_2 + PF_3(g)$. The authors report $\Delta H_{630} = -2.97$ kcal. From a reexamination of their technique we believe that this heat evolution is likely to be too small, perhaps by 100%. The analytical results indicate that the reaction is 99% complete or better; thus, we can use this with JANAF entropies to calculate $\Delta Hr_{298} \leq -3.55$ kcal. Finch et al. (18) have reported $\Delta Hf^\circ(CaF_2, c) - \Delta Hf^\circ(CaCl_2, c) = -100.87 \pm 0.02$ kcal/mol; thus, we obtain $\Delta Hf^\circ_{298}(PCl_3, g) \geq -70.1 \pm 2.0$ kcal/mol from $\Delta Hf^\circ_{298}(PF_3, g) = -224.9 \pm 0.9$ kcal/mol. This value is not adopted because of the lack of calorimeter calibration, but it offers an attractive possibility for further study.

Heat Capacity and Entropy

The molecular structure and bond length given above for PCl_3 are from the electron diffraction studies of Hedberg and Iwasahi (11). The adopted values are in good agreement within experimental error with the following structural data reported by Kisliuk and Townes (12) from microwave studies: $r_{P-Cl} = 2.043 \pm 0.003$ Å, the angle Cl-P-Cl = 100°6' ± 20'. The vibrational frequencies are from the recent infrared and Raman studies of Frankiss and Miller (13) and are in excellent agreement with those of Müller et. al (14) and Davis and Oetjen (15). Individual moments of inertia calculated from the electron diffraction data are: $I_A = I_B = 32.393 \times 10^{-39}$ g cm^3, and $I_C = 57.673 \times 10^{-39}$ g cm^2.

Cl-P-Cl angle = 100.5° ± 1° $I_AI_BI_C$ = 2.0690 X 10^{-112} g.^{3} cm.^{6}

Heat of Formation. ΔH_f° 298 was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corporation, Alexandria, Virginia, "Survey of Thermochemical Data," January 1960. Henderson and Scheffee (loc. cit.) use white(α) phosphorus as a reference state. Their estimated ΔH_f° 298 was adjusted to the Red (V) phosphorus reference state [see white(α) phosphorus sheet.]

Heat Capacity and Entropy. J. S. Ziomek and E. A. Piotrowski, J. Chem. Phys. 34, 1087 (1961) have chosen the most probable values for the wave numbers from the infrared spectral data of G. Cilento, D. A. Ramsey, and R. N. Jones, J. Am. Chem. Soc. 71, 2753 (1949), and the Raman spectral data of A. Simon and G. Schulze, Naturwissenschaften 25, 669 (1937); V. N. Thatte, Nature 138, 468 (1936); H. Gerding and R. Westrick, Rec. trav. chim. 61, 842 (1942); and M. Delwaulle and F. Francois, Compt. Rend. 220, 817 (1945). Ziomek and Piotrowski (loc. cit.) found their normal coordinate treatments gave the listed wave numbers as fundamentals and lent support for the 247 cm.$^{-1}$ band missing from the Raman spectral data. The structure (bond distances and angles) was determined from microwave data by Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys. 20, 164 (1952).

Bond Distance: Si-Cl = [2.02] Å

Bond Angle: Cl-Si-Cl = 110.9° σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = [7.5469 \times 10^{-113}]\ g^3\ cm^6$

Heat of Formation

The adopted value is derived from an average bond energy of ΔH°_0atom/3 = 96 ± 3 kcal/mol. This value is estimated by comparison of average bond energies for MX_n where M = C or Si, X = F or Cl, and n = 2, 3 or 4. These comparisons suggest that the average bond energy for $SiCl_3$ should be bracketed by those for $SiCl_4$ and $SiCl_2$, i.e. 94.3 and 101.5 kcal/mol, respectively. Alternative estimates from linear plots of $\Delta Hf^\circ(SiCl_n)$ versus ΔHf° for SiF_n, CCl_n, and CF_n yield -98, -96, and -86 kcal/mol for ΔHf° of $SiCl_3$ at 298.15°K. These agree with the adopted value of -96 ± 10 kcal/mol, which corresponds to ΔH°_0atom = 288 ± 10 kcal/mol.

Kerr et al. (1) reported relative rates for several reactions of $SiCl_3$, but the authors state that no absolute activation energies are known for reactions of this radical. This precludes derivation of thermochemical values from the kinetic studies. Recently, however, Vurzel et al. (4) reported studies of the decomposition of $SiCl_4$ by adiabatic compression. Rate constants, as reported in Chemical Abstracts, led to an activation energy of 88 ± 5 kcal/mol for $SiCl_4 \rightarrow SiCl_3 + Cl$. The activation energy for recombination should be very close to zero, so ΔHr = 88 ± 5 compared with the adopted result of 86 ± 10 at room temperature. Steele et al. (2) derived an average value of $D(Cl_3Si\text{-}H) = 93 \pm 4$ kcal/mol from an interpretation of electron impact studies on several molecules. Using $\Delta Hf^\circ(Cl_3SiH, g) = -122.6$ kcal/mol (3), we calculate $\Delta Hf^\circ(SiCl_3) = -82$ kcal/mol and estimate the uncertainty as about 10 kcal/mol.

Heat Capacity and Entropy

Jacox and Milligan (5) studied the formation of $SiCl_3$ by photolysis of $HSiCl_3$ trapped in matrices of argon, nitrogen and CO. The two stretching fundamentals were assigned from the infrared spectra. Isotopic splittings were found to be consistent with an angle of 72 ± 5° between the threefold axis and each of the Si-Cl bonds. This yields a bond angle of 110.9° which is similar to that of $HSiCl_3$. Non-planarity of $SiCl_3$ is consistent with the electron-spin-resonance studies of Roncin (6).

We adopt the results of Jacox (5) and estimate the bond length and two bending vibrations by analogy with $HSiCl_3$. Similar analogies are reliable for SiF_3 and CF_3. The ground state quantum weight is taken as two, but excited electronic levels are neglected. Jacox (5) observed unstructured absorptions corresponding to excitation energies of 30000-34500 cm^{-1} and 41000-46000 cm^{-1}. Principal moments of inertia are $I_A = 65.18 \times 10^{-39}$ and $I_B = I_C = 34.03 \times 10^{-39}\ g\ cm^2$.

TITANIUM TRICHLORIDE ($TiCl_3$) (CRYSTAL) GFW = 154.259

ΔHf°_0 = -173.1 ± 1.0 kcal/mol

$S^\circ_{298.15}$ = 33.4 ± 0.3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -172.5 ± 1.0 kcal/mol

Tt = 220.1°K

ΔHt° = 0 kcal/mol

Ts = [1104.1]°K

ΔHs° = [39.71] kcal/mol

Heat of Formation

The heat of formation, ΔHf°_{298}, of $TiCl_3(c)$ has been measured by several investigators. The results of these measurements are as follows.

Investigators	Method	ΔHf°_{298} kcal/mol
Schaffer et al. (1954) (1)	Calorimetric, $TiCl_4 + Hg = TiCl_3 + 1/2Hg_2Cl_2$	-171.9, -172.4
Clifton and MacWood (1956) (2)	Solution calorimetric	-172.4
Johnson et al. (1956) (3)	Calorimetric, $TiCl_4(l) + HI(g) = TiCl_3(c) + HCl(g) + 1/2I_2$	-172.5
Krieve et al. (1956) (4)	Solution calorimetric	-171.3
Krieve and Mason (1956) (5)	Equilibrium, $TiCl_3(c) + HCl(g) = TiCl_4(g) + 1/2H_2(g)$	-172.9
Altman et al. (1956) (6)	Equilibrium, $Ti(c) + 3TiCl_4(l) = 4TiCl_3(c)$	-169.4, -171.0
Head (1960) (7)	Equilibrium, $2TiCl_4(2) + H_2(g) = 2TiCl_3(c) + 2HCl(g)$ $TiCl_4(l) + Hg(l) = 1/2Hg_2Cl_2(c) + TiCl_3(c)$ $TiCl_4(l) + Ag(c) = AgCl(c) + TiCl_3(c)$	-172.3

The chosen value of -172.5 ± 1.0 kcal/mol is that reported by Johnson et al. (3).

Heat Capacity and Entropy

The heat capacity and entropy of $TiCl_3(c)$ has been measured over the temperature range 54° to 1000°K by King et al. (8). The value of S°_{298} is calculated from these data based on S°_{51} = 4.29 eu.

Transition Data

A second order transition at 220.1°K was observed by King et al. (8). The heat capacity at this temperature is in excess of 146.8 gibbs/mol. King et al. measured the value of $H^\circ_{240} - H^\circ_{200}$ as 1.213 kcal/mol.

Heat of Sublimation

The heat of sublimation is calculated from the heats of formation of $TiCl_3(c)$ and $TiCl_3(g)$ at the sublimation temperature. The sublimation temperature is taken as the point at which ΔGr = 0 for the process $TiCl_3(c) = TiCl_3(g)$.

Bond Distance: Ti-Cl = [2.3] Å

Bond Angle: Cl-Ti-Cl = [100°] σ = 3

Products of the Moments of Inertia: $I_AI_BI_C = [1.33 \times 10^{-112}]\ g^3\ cm^6$

Heat of Formation

The heat of formation of $TiCl_3(g)$ is calculated from the heats of reaction for the processes, (A) $3TiCl_4(g) + Ti(c) = 4TiCl_3(g)$ and (B) $TiCl_3(c) = TiCl_3(g)$, combined with auxiliary JANAF heats of formation for $TiCl_4(g)$, $TiCl_3(c)$ and Ti(c). Equilibrium measurements of reaction (A) have been reported by Gross and Levi (1). Vapor pressure measurements for reaction (B) have been reported by Sanderson and MacWood (2) and by Farber and Darnell (3). Second and third law analyses of these data yield the following results.

Source	Reaction	No. Points	Range, T°K	ΔHr°_{298}, kcal/mol Second Law	Third Law	Drift, eu	ΔHf°_{298}*
Gross and Levi (1)	A	3	1223		31.6 ± 2.0		-128.5
Sanderson and MacWood (2)	B	9**	628-823	42.8 ± 1.1	42.8	-0.1 ± 1.5	-129.3
Farber and Darnell	B	8	636-732	45.3 ± 2.1	45.8	0.8 ± 3.1	-126.2

*Calculation based on third law ΔHr°_{298}.

**One point rejected due to failure of statistical test.

The chosen value of ΔHf°_{298} is -128.9 kcal/mol. This value is the average of the first two determinations.

Heat Capacity and Entropy

The interatomic distance is estimated from that of the solid, given as 2.46 Å by Natta et al. (4), and from comparisons of bond distances of crystal and gas phase tetrahalides of titanium. The pyramidal bond angle is estimated assuming $TiCl_3(g)$ similar to the group V trihalides. The principal moments of inertia are $I_A = I_B = 4.28 \times 10^{-38}\ g\ cm^2$ and $I_C = 7.26 \times 10^{-38}\ g\ cm^2$. The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti^{+3} (5).

June 30, 1961; June 30, 1962; June 30, 1964; Dec. 31, 1969

ZIRCONIUM TRICHLORIDE ($ZrCl_3$) (CRYSTAL) GFW = 197.579

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [34.8 ± 3] gibbs/mol

$\Delta Hf_{298.15}$ = [-170.7 ± 15] kcal/mol

Ts = [1045.9]°K

$\Delta Hs^\circ_{298.15}$ = [45.4] kcal/mol

Heat of Formation

Turnbull and Watts (1) determined the equilibrium pressures for the disproportionation of $ZrCl_3(c)$ in the temperature range from 613°K to 723°K by a modified dew point technique. Third law and second law analyses of their vapor pressure-temperature equation give the same heat of reaction ΔHr°_{298} = 30.7 kcal/mol for $2ZrCl_3(c) + ZrCl_2(c) + ZrCl_4(g)$. The adopted value, $\Delta Hf^\circ_{298}(ZrCl_3, c) = -170.7$ kcal/mol, is calculated from the heat of reaction at 298°K, and $\Delta Hf^\circ_{298}(ZrCl_4, g) = -207.77$ kcal/mol (2) and $\Delta Hf^\circ_{298}(ZrCl_2, c) = -103$ kcal/mol (3). The assigned uncertainty, ±15 kcal/mol is mainly due to the uncertainty in the heat of formation of $ZrCl_2(c)$, and also the dew point technique used.

Heat Capacity and Entropy

The heat capacities of $ZrCl_3(c)$ are estimated from the Cp values of $ZrCl_4(c)$ by deduction of one Cl atom Cp contributions which are calculated as 1/4[Cp($ZrCl_4$, c) - Cp(Zr, c)]. The S°_{298} is calculated as 34.85 eu based on the assumption that $S^\circ_{298}(ZrCl_3, c) = S^\circ_{298}(ZrCl_4, c) - 1/4[S^\circ_{298}(ZrCl_4, c) - S^\circ_{298}(Zr, c)]$.

Heat of Sublimation

The heat of sublimation is calculated from the difference in the heats of formation of gas and crystal at 298°K. The sublimation temperature is taken as the point at which ΔGr = 0 for $ZrCl_3(c) = ZrCl_3(g)$.

Bond Distance: Zr-Cl = [2.3] Å

Bond Angle: Cl-Zr-Cl = [100°] σ = [3]

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.53104 x 10^{-112}] g^3 cm^6

Heat of Formation

Potter (1) investigated mass spectrometrically the equilibrium $CaCl(g) + ZrCl_4(g) \rightarrow CaCl_2(g) + ZrCl_3(g)$ in the temperature range 1163-1557°K. Ion intensities were measured 2.5 eV above threshold and they were used in the calculation of equilibrium constants. Using the reported equilibrium constants, the heats of reaction at 298°K are evaluated by the third law and second law methods as -3.69 and -16.67 kcal/mol, respectively. The third law drift is 9.31 ± 1.25 eu. Using the third law ΔHr°_{298} = -3.69 kcal/mol, $\Delta Hf^\circ_{298}(ZrCl_4, g)$ = -207.77 kcal/mol (2), $\Delta Hf^\circ_{298}(CaCl, g)$ = -28.8 kcal/mol (3) and $\Delta Hf^\circ_{298}(CaCl_2, g)$ = -115.0 kcal/mol (4), we obtain $\Delta Hf^\circ_{298}(ZrCl_3, g)$ = -125.3 kcal/mol, which is adopted in the tabulation.

Farber et al. (5) also studied mass spectrometrically the reaction $Zr(c) + 3ZrCl_4(g) \rightarrow 4ZrCl_3(g)$ in the temperature range from 1579°K to 1729°K. They reported a second law heat of reaction as ΔHr°_{298} = 59.2 ± 1.6 kcal/mol. Since the attainment of equilibrium was questionable in their studies, the heat of reaction obtained from the third law method is generally more reliable. Using their reported ion intensities of run 3 (temperature range from 1667°K to 1896°K, five points), we have calculated the equilibrium constants $K_1 = (I_{ZrCl_2})^2/(I_{ZrCl_3})(I_{ZrCl})$ for reaction (1) $ZrCl_3(g) + ZrCl(g) \rightarrow 2ZrCl_2(g)$; and $K_2 = (I_{ZrCl_3})^2/(I_{ZrCl_4})(I_{ZrCl_2})$ for reaction (2) $ZrCl_4(g) + ZrCl_2 \rightarrow 2ZrCl_3(g)$. Third law analyses of the equilibrium constants give ΔHr°_{298} = -11.0 kcal/mol for reaction (1) and its drift 4.1 ± 1.7 eu; and ΔHr°_{298} = 1.4 kcal/mol for reaction (2) and its drift 11.1 ± 1.2 eu. Using the third law heats of reaction, and $\Delta Hf^\circ_{298}(ZrCl, g)$ = 49.1 kcal/mol (6) and $\Delta Hf^\circ_{298}(ZrCl_4, g)$ = -207.77 kcal/mol (2), we obtain $\Delta Hf^\circ_{298}(ZrCl_3, g)$ = -124.9 kcal/mol and $\Delta Hf^\circ_{298}(ZrCl_2, g)$ = -43.4 kcal/mol which are in good agreement with the values adopted.

Heat Capacity and Entropy

The molecular structure is assumed to be a pyramid similar to the group VA trichlorides. The bond distance is assumed to be the same as that of $ZrCl_4(g)$. The three principal moments of inertia are $I_A = I_B$ = 45.9145 x 10^{-39} and I_C = 72.6247 x 10^{-39} g cm^2. The electronic levels are estimated as three times higher than those of $TiCl_3(g)$, based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (7). The quantum weights are assumed to be the same as those of $TiCl_3(g)$.

Vibrational frequencies are calculated from the estimated force constants by the valence force method (8). The force constants are estimated from those of PCl_3, $AsCl_3$ and $SbCl_3$ listed by Herzberg (8).

Bond Distance: Mg-Cl = [2.18] Å, Mg-Cl'(ring) = [2.3] Å

Bond Angles: Cl'-Mg-Cl'(in ring) = [90°], Cl-Mg-Cl' = [135°]

σ = 4

Product of the Moments of Inertia: $I_AI_BI_C = 1.3313 \times 10^{-111}$ g^3 cm^6

Heat of Formation

References relative to the monomer-dimer ratio in magnesium chloride vapor are given in the discussion for monomeric ideal gas. The selected best value for the heat of dimerization at 900°K is -39.2 kcal/mol. Combined with heat of formation data for the monomer and the heat capacity of the dimer, this yields $\Delta Hf^\circ_{298.15} = -228.10$ kcal/mol.

Heat Capacity and Entropy

A planar structure with D_{2h} symmetry was assumed, with the outer Mg-Cl distance the same as in $MgCl_2$ and the ring Mg-Cl distance slightly larger. The ring was taken to be square, and the Cl-Mg-Cl' angle 135°. This structure gives individual moments of inertia of $I_A = 31.12 \times 10^{-39}$ g cm^2, $I_B = 191.86 \times 10^{-39}$ g cm^2 and $I_C = I_A + I_B$.

A reasonable set of frequencies was estimated by comparison with $MgCl_2$ monomer and other dimer molecules. The single observed frequency is from A. Buchler and W. Klemperer, J. Chem. Phys. 29, 121 (1958), who erroneously ascribed it to the bending mode of the monomer. The estimated values were adjusted until the entropy of dimerization at 900°K was -29.9 gibbs/mol, as selected in the discussion for ideal monomeric gas. The calculated thermodynamic properties of monomer and dimer give total vapor pressures in good agreement with experiment and yield a boiling point for magnesium chloride of 1624°K at one atmosphere pressure.

Dec. 31, 1968

Cl_4Mo

MOLYBDENUM TETRACHLORIDE ($MoCl_4$) (CRYSTAL) GFW = 237.752

$\Delta Hf°_0$ = Unknown

$S°_{298.15}$ = [53.5 ± 3] gibbs/mol

$\Delta Hf°_{298.15}$ = -114 ± 2 kcal/mol

Tm = 590°K

$\Delta Hm°$ = [4 ± 2] kcal/mol

Heat of Formation

The adopted $\Delta Hf°_{298}$ = -114 kcal/mol was determined by Shchukarev et al. (1) by solution calorimetry. The authors measured the heat of solution of $MoCl_4$ in the aqueous solvent $FeCl_3$ + HCl and obtained the heat of formation from a comparison with the heat of solution of $MoCl_5$ measured in the same solvent.

The decomposition pressures of $2MoCl_5(c) = 2MoCl_4(c) + Cl_2(g)$ (80 - 150°C) were measured manometrically by Saeki and Matsuzaki (2). From the reported data we evaluate the enthalpy change for the above reaction by third law analysis. Based on $\Delta Hf°_{298}(MoCl_5, c)$ = -126 kcal/mol and the third law $\Delta Hr°_{298}$ = 24.132 kcal/mol, we obtain $\Delta Hf°_{298}(MoCl_4, c)$ = -113.94 kcal/mol, which is in very good agreement with the value reported by Shchukarev et al. (1).

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of $WCl_4(c)$. The estimated $S°_{298}$ = 53.5 eu is based on the assumption that the entropy difference between $MoCl_4(c)$ and $MoCl_5(c)$ is about the same as that between $WCl_4(c)$ and $WCl_5(c)$. The entropy obtained from the second law analysis of the data of Saeki and Matsuzaki (2) agrees with the adopted one within the error of the vapor pressure data.

Melting Data

See liquid table.

Dec. 31, 1968

MOLYBDENUM TETRACHLORIDE ($MoCl_4$) (LIQUID) GFW = 237.752

$S^\circ_{298.15}$ = [58.682] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-110.621 ± 2] kcal/mol

Tm = 590°K

ΔHm° = [4 ± 2] kcal/mol

Tb = [680]°K

ΔHv° = [14.7] kcal/mol

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(c) by adding ΔHm° and the difference between H°_{590} - H°_{298} for crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

Tm is taken from V. Gutmann, "Halogen Chemistry," Vol. 3, Academic Press, New York, 1967. ΔHm° is estimated such that the derived ΔGf° for $MoCl_4(\ell)$ yields a reasonable boiling point which is expected to be between 600 and 700°K from comparisons with related compounds.

Vaporization Data

Tb is the temperature at which the Gibbs energy change (ΔGr°) of the following process $MoCl_4(\ell) = MoCl_4(g)$ approaches zero. The difference between ΔHf° for $MoCl_4(\ell)$ and $MoCl_4(g)$ at Tb is the heat of vaporization.

Heat of Formation

S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin and A. K. Baev, Zh. Neorg. Khim. 5, 1650-4 (1960), derived the value $\Delta Hf^\circ_{298}(MoCl_4, g)$ = -89 kcal/mol from the decomposition pressures of $2MoCl_3(c) = MoCl_2(c) + MoCl_4(g)$, 480-600°C, measured by a transpiration method. However, this ΔHf°_{298} value is adjusted to be -92 ± 3 kcal/mol, in order to obtain a reasonable boiling point (see the $MoCl_4(\ell)$ table).

Heat Capacity and Entropy

Vibrational frequencies and quantum weights are estimated by comparison with those of $WCl_4(g)$. The molecular configuration is assumed to be tetrahedral similar to those of $WCl_4(g)$, $SiCl_4(g)$, $TiCl_4(g)$ and $PbCl_4(g)$. The bond distance is estimated to be the same as that of $MoCl_5(g)$. The three principal moments of inertia are $I_A = I_B = I_C = 80.89 \times 10^{-39}$ g cm^2. The low lying electronic levels are estimated to be 0, 10000, and 30000, all triplets, by comparison with those of $WCl_4(g)$.

Cl_4OW

TUNGSTEN OXYTETRACHLORIDE $(WOCl_4)$ (CRYSTAL) GFW = 341.6614

ΔHf_0° = Unknown

$S^\circ_{298.15}$ = [41.3 ± 4] gibbs/mol $\Delta Hf^\circ_{298.15}$ = -160.4 ± 2 kcal/mol

Tm = 484°K ΔHm° = 10.846 ± 3 kcal/mol

Heat of Formation.

S. A. Shchukarev, I. V. Vasil'kova and G. I. Novikov[1] measured calorimetrically the heats of reaction (1) and (2) at 298°K as -131.5 ± 0.3 and -13.6 ± 0.11 kcal/mol, respectively. The reactions are given as follows:

(1) $WOCl_4(c) + 6\ NaOH(16.3\ H_2O) \rightarrow Na_2WO_4(190{,}000\ H_2O) + 4\ NaCl(50{,}000\ H_2O) + 3\ H_2O(l)$

(2) $H_2WO_4(c) + 2\ NaOH(16.3\ H_2O) \rightarrow Na_2WO_4(20{,}000\ H_2O) + 2\ H_2O(l)$

Based on these data and the heats of dilution for NaOH(aq)[2], and $Na_2WO_4(aq)$[3], we obtain ΔHr°_{298} = -118.0 ± 1.6 kcal/mol for $WOCl_4(c) + 4OH^-(\infty H_2O) \rightarrow H_2WO_4(c) + 4Cl^-(\infty H_2O) + H_2O(l)$. This leads to $\Delta Hr^\circ_{298}(WOCl_4,c)$ = -160.4 ± 2 kcal/mol, using $\Delta Hf^\circ_{298}(H_2WO_4,c)$ = -270.5 ± 0.4 kcal/mol[5].

Heat Capacity and Entropy.

Cp_{300} = 35.0 gibbs/mol is estimated using Kopp's rule. Since the melting point of $WOCl_4(c)$ is approximately 500°K, which is relatively low for oxygen to reach its maximum contribution, we estimate Cp_{500} = 40.0 gibbs/mol based on the values for $WO_2(c)$, $WO_3(c)$ and $WCl_6(c)$.

The entropy, S°_{298} = 41.3 eu, is calculated from ΔS°_{457} = 44.5 eu for $WOCl_4(c) \rightarrow WOCl_4(g)$ obtained from the second law analysis of the vapor pressure equation given by S. A. Shchukarev and A. V. Suvorov[4]. See $WOCl_4(g)$ table (Mar. 31, 1967) for details.

It is surprising that this entropy is smaller than the corresponding value for $WOF_4(c)$. See $WOF_4(c)$ table (Mar. 31, 1967) for details.

Melting Data.

Tm is calculated as the temperature at which the gibbs energies of formation of crystal and liquid are equal. The difference between the heats of formation of crystal and liquid at the melting point is ΔHm°. This ΔHm° is derived from 2nd law analyses of the vapor pressure equation determined by Shchukarev and Suvorov[4]. See $WOCl_4(l,g)$ tables (Mar. 31, 1967) for details.

TUNGSTEN OXYTETRACHLORIDE ($WOCl_4$) (LIQUID) GFW = 341.6614

$S^\circ_{298.15}$ = [60.6 ± 4] gibbs/mol

Tm = 484°K

Tb = 493°K

$\Delta Hf^\circ_{298.15}$ = -150.711 kcal/mol

ΔHm° = 10.846 ± 3 kcal/mol

ΔHv° = 10.5 kcal/mol

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298}(WOCl_4, l)$ = -150.711 kcal/mol, is calculated from that of the gas by subtracting the heat of vaporization ΔHv°_{298} = 13.643 kcal/mol. The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev* and A. V. Surorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives $\Delta Hv^\circ_{501.9}$ = 10.32 kcal/mol (ΔHv°_{298} = 13.643 kcal/mol) and the boiling point Tb = 493°K. *Earlier data reported by Shchukarev et al, Zh. Neorg. Khim. 1, 357 (1956); 3, 2630(1958); and 5, 1650 (1960), have been revised and they are not used here.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. Ll. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958.

The entropy, S°_{298} = 60.6 eu, is calculated from $\Delta S^\circ_{501.9}$ = 20.9 eu for $WOCl_4(l) \rightarrow WOCl_4(g)$ obtained from the second law analysis of the vapor pressure equation given by Shchukarev and Suvorov, loc. cit.

Melting Data.

See $WOCl_4(c)$ table (Mar. 31, 1967) for details.

Vaporization Data.

Tb is calculated as the temperature at which the Gibbs energies of formation of liquid and gas are equal. The difference between the heats of formation of liquid and gas at the boiling point is ΔHv°.

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298}(WOCl_4,g)$ = -137.0 kcal/mol, is calculated from ΔHr°_{298} = 23.4 kcal/mol for $WOCl_4(c) \rightarrow WOCl_4(g)$. The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev* and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives $\Delta Hr^\circ_{457.2}$ = 21.9 kcal/mol (ΔHr°_{298} = 23.4 kcal/mol).

*Earlier data reported by Shchukarev et al., Zh. Neorg. Khim 1, 357 (1956), 3, 2630 (1956), 5, 1650 (1960), have been revised and they are not used here.

Heat Capacity and Entropy.

The molecular configuration is assumed to be a trigonal bipyramid similar to that of $SOF_4(g)$, reported by P. L. Goggin, H. L. Roberts and L. A. Woodward[1]. The bond distances W-O and W-Cl are estimated to be the same as those in $WO_3(g)$ and $WCl_6(g)$, respectively. The three principal moments of inertia are $I_A = 8.260 \times 10^{-38}$, $I_B = 1.052 \times 10^{-37}$ and $I_C = 6.757 \times 10^{-38}$ g cm^2.

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for $SOF_4(g)$[1], $MoOCl_4(g)$[2], $WO_2Cl_2(g)$[3], $CrO_2Cl_2(g)$[4,5], $WO_3(g)$[6], and $WCl_6(g)$[6]. The frequencies are not listed in point group order.

Lead Tetrachloride ($PbCl_4$) (Ideal Gas)

Mol. Wt. = 349.04

ΔH_f° 298.15 = [-75] kcal. mole^{-1}

$S^\circ_{298.15}$ = 91.9 cal. deg.$^{-1}$ mole^{-1}

Point Group T_d

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$
326 (1)
83 (2)
341 (3)
99 (3)

Pb-Cl distance = 2.43 Å   Cl-Pb-Cl angle = 109° 28'

$I_AI_BI_C$ = 7.9660 X 10^{-112} g.^{3} cm.^{6} σ = 12

Heat of Formation. ΔH_f° 298.15 was estimated from the value of ΔH_f° 298.15 for $PbCl_2(g)$, using the relation between ΔH_f° 298.15 for dihalides and that for tetrahalides of titanium and zirconium as reference.

Heat Capacity and Entropy. Vibrational frequencies and molecular constants were obtained from G. Nagarajan, Bull. Soc. Chim. Belg., 71, 119 (1962).

Silicon Tetrachloride ($SiCl_4$)

SILICON TETRACHLORIDE ($SiCl_4$) (IDEAL GAS) GFW = 169.898

Point Group T_d

$S^\circ_{298.15}$ = 79.07 gibbs/mol

Ground State Quantum Weight = 1

ΔHf°_0 = -156.58±0.6 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -157.1±0.6 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
425±1 (1)	620±1 (3)
149±2 (2)	220±4 (3)

Bond Distance: Si-Cl = 2.0173±0.0034 Å

Bond Angle: Cl-Si-Cl = 109° 28'

σ = 12

Product of the Moments of Inertia: $I_AI_BI_C = 2.60708 \times 10^{-112}\ g^3\ cm^6$

Heat of Formation

The adopted value is calculated from ΔHv_{298} = 7.09 kcal/mol (see below) and ΔHf°_{298} = -164.18 kcal/mol for the liquid. The latter is derived from the calorimetric study of Schäfer (1) using ΔHf°_{298} (AgCl, c) = -30.37 kcal/mol (2). Both $SiCl_4(\ell)$ and Si(c) were reacted with AgF+HF(aq) to obtain the overall reaction. Other calorimetric studies (3-7) of $SiCl_4(\ell)$ yield values which differ by up to 7 kcal/mol, but each study appears to involve a final state which is not well known or not well defined. Results are summarized below for the overall experimental reactions. Data of Beezer (3) are combined with those of Good (8) for $[H_2SiF_6, 41HF, 174H_2O]$ by neglecting the unknown heat of dilution between the two calorimetric solutions. Data of Wolfe (4) involve a questionable conversion of Na_2SiO_3(calorimetric sol) → Na_2SiO_3(c). The aqueous hydrolysis reactions (5-7) yield SiO_2(colloidal soln) which appears to be an ill-defined state judging by the variation in the observed heats. ΔHf° for this colloidal solution is taken as -214.4 kcal/mol (2).

Source	Reaction	ΔHr°_{298} kcal/mol	$\Delta Hf^\circ_{298}(SiCl_4, \ell)$ kcal/mol
1. Schäfer (1964)	$SiCl_4(\ell)+4Ag(c) = Si(c)+4AgCl(c)$	42.7±0.4	-164.18
3. Beezer (1964)	$SiCl_4(\ell)+185HF(4.335H_2O) = 4HCl(11H_2O)+[H_2SiF_6, 179HF, 758H_2O]$	-97.0±0.4	-169.9
4. Wolf (1961)	$SiCl_4(\ell)+13NaOH(27.8H_2O) = Na_2SiO_3(c)+4NaCl(c)+3H_2O(\ell)+7NaOH(52.14H_2O)$	-129.3±0.8	-167.3
5. Ring (1966)	$SiCl_4(\ell)+2H_2O(\ell) = 4HCl(500H_2O)+SiO_2$(colloidal soln)	-79.8±0.3	-157.2
6. Andrianov (1953)	$SiCl_4(\ell)+2H_2O(\ell) = 4HCl(600H_2O)+SiO_2$(colloidal soln)	-76.6	-160.4
7. Roth (1928)	$SiCl_4(\ell)+2H_2O(\ell) = 4HCl(aq)+SiO_2$(colloidal soln)	-70.1	-166.9

Heat Capacity and Entropy

The bond distance r_g is from the precise electron diffraction study of Morino (9). Earlier data gave values of 2.00 to 2.02 Å. Vibrational frequencies are from the Raman and infrared spectra of the vapor reported by Morino (10). Infrared data of Smith (11) confirm that ν_3 is about 12 cm^{-1} larger in the vapor than in the liquid. The moments of inertia are $I_A = I_B = I_C = 6.3883 \times 10^{-38}\ g\ cm^2$.

Vaporization Data

Vapor pressure data ranging from 20° below Tm (supercooled liquid) to 10° above Tb are in reasonable agreement as summarized below. The analysis is based on fugacities calculated from vapor pressures by the approximation of Pitzer (19) using Tc = 506°K (20), Pc = 37.1 atm (21) and ω = 0.26. At 298.15°K the calculated f/P is 0.982 compared with 0.984 observed by Wood (22). The analysis also presumes a linear variation of the liquid phase Cp based on 33.3 gibbs/mol at 210°K and 34.2 at 300°K. The latter value is from data of Vold (17) since earlier data (77-294°K) of Latimer (18) appear to have a large positive bias below Tm. The Cp at 210°K assumes Latimer's value to have about 1 percent bias by analogy with his data for $CCl_4(\ell)$.

TITANIUM TETRACHLORIDE ($TiCl_4$) (CRYSTAL) GFW = 189.712

$\Delta Hf°_0 = -195.7 \pm 1.0$ kcal/mol

$S°_{298.15} = 49.93 \pm 0.1$ gibbs/mol

$\Delta Hf°_{298.15} = -194.807 \pm 1.0$ kcal/mol

Tm = 249.05°K

$\Delta Hm° = 2.382$ kcal/mol

Heat of Formation

The heat of formation, $\Delta Hf°_{298}$, of $TiCl_4(c)$ is calculated from the corresponding quantity for $TiCl_4(\ell)$ and the values of $H°_{249.05} - H°_{298.15}$ for both crystal and liquid.

Heat Capacity and Entropy

The heat capacity of $TiCl_4(c)$ has been reported by Latimer (1) and by Furukawa (2). The data from the latter investigation are adopted. These data lead to a value of 44.5 eu for $S°_{249.05}$. This compares with Latimer's value (1) of 43.8 eu for the same quantity. The heat capacity of the solid is extrapolated to a value of 18R at 600°K, based on the known heat capacities of $TiBr_4(c)$ and $TiI_4(c)$. The hypothetical entropy at 298°K is based on the integration of the extrapolated curve and the value at the melting point.

Melting Data

The triple point is reported to be 249.05°K, with a measured heat of fusion of 2.382 kcal/mol, by Furukawa (2). Latimer (1) reported values of 248.0°K and 2.233 kcal/mol for these quantities. The former data are adopted.

ΔHm° = 2.382 kcal/mol

Tb = 409°K

ΔHv° = 8.55 kcal/mol

Heat of Formation

The heat of formation, $\Delta Hf^\circ_{298.15}$, of $TiCl_4(\ell)$ is calculated from that of $TiCl_4(g)$ and the value of $\Delta Hv^\circ_{298.15}$. The value of ΔHv°_{298} is determined from second and third law analyses of fugacity as follows.

				ΔHv°_{298}

* two points rejected due to failure of a statistical test

** three points rejected due to failure of a statistical test

*** selected points from extensive data

Third law analyses of the several vapor pressure sets result in drifts which are proportional to the mean temperatures. Conversion of these data to fugacity eliminates this temperature dependence and the drifts are then scattered randomly about a constant value. This constant value is made to be essentially zero by methods described on the $TiCl_4(g)$ table. The conversion to fugacity was made using Pitzer's method for normal fluids (5). The calculation was carried out using the value of 45.7 atm for the critical pressure, P_c, reported by Minzer (6) and estimated values of 643 ± 15°K for the critical temperature, T_c, and 0.23 ± 0.03 for the acentric constant, ω. Schafer et al. (7) reported a calorimetric determination of ΔHv°_{298}. Their value of 9.9 ± 0.2 kcal/mol was used to check the reliability of their equipment, assuming that the vapor pressure data (3) gave a more accurate determination of ΔHv°_{298}. The adopted value of ΔHv°_{298} is 9.82 ± 0.02 kcal/mol.

Heat Capacity and Entropy

The entropy and heat capacity of $TiCl_4(\ell)$ has been measured by Furukawa (8). His reported values are adopted.

Melting Data

See $TiCl_4(c)$ table for details.

Vaporization Data

The boiling temperature, Tb, is taken as the temperature at which Kp = 1 for the reaction $TiCl_4(\ell) = TiCl_4(g)$. The vapor pressure data are discussed above.

TITANIUM TETRACHLORIDE ($TiCl_4$) (IDEAL GAS) GFW = 189.712

Point Group T_d

$\Delta Hf°_0$ = -182.0 ± 0.9 kcal/mol

$S°_{298}$ = 84.8 ± 0.7 gibbs/mol

$\Delta Hf°_{298.15}$ = -182.4 ± 0.9 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
388 (1)	498.5 (3)
111 (2)	131 (3)

Bond Distance: Ti-Cl = 2.185 Å

Bond Angle: Cl-Ti-Cl = 109° 28'

σ = 12

Product of the Moments of Inertia: $I_A I_B I_C = 4.2092 \times 10^{-112}\ g^3\ cm^6$

Heat of Formation

The heat of formation, $\Delta Hf°_{298}$, of $TiCl_4(g)$ and $TiCl_4(\ell)$ has been measured by several investigators. The results of these measurements are as follows.

Investigators	Method	Reaction	$\Delta Hf°_{298}$, kcal/mol $TiCl_4(\ell)$	 $TiCl_4(g)$
Johnson et al. (1959) (1)	Calorimetric	$Ti(c)+2Cl_2(g) = TiCl_4(g)$	(-192.2)	-182.4±0.7
Farber and Darnell (1955) (2)	Equilibrium	$TiO_2(c)+4HCl(g) = TiCl_4(g)+2H_2O(g)$	(-192.7)	-182.9±0.5
Skinner and Ruehrwein (1955) (3)	Calorimetric	$Ti(c)+xCl_2(g) = [TiCl_4+(x-2)Cl_2]$ soln	-190.3±3.0	(-180.5)
Gross et al.(1957) (4)	Calorimetric	$Ti(c)+xCl_2(\ell) = [TiCl_4+(x-2)Cl_2]$ soln	-191.5±0.3	(-181.7)
Krieve et al. (1956) (5)	Calorimetric	$Ti(c)+xCl_2(g) = [TiCl_4+(x-2)Cl_2]$ soln	-190.0±0.4	(-180.2)
Thomsen (1882) (6)		$TiCl_4(\ell)+2H_2O(\ell) = 4HCl_{(0.002\ m)}+TiO_2(c)$	-194.5	(-184.7)

The chosen value of $\Delta Hf°_{298}$ is that reported by Johnson et al. (1). This investigation has the advantage of being independent of the heat of vaporization of chlorine and any heats of solution in deriving the value of the heat of formation.

Heat Capacity and Entropy

The adopted value for the interatomic distance is that reported by Kimura et al. (7). The tetrahedral structure was established by the Raman work of Bhagavantam (8). The vibrational frequencies determined from the infrared and Raman spectra of $TiCl_4$ by Hawkins and Carpenter (9) are adjusted downward 8 cm^{-1} for ν_2 and ν_4 so that the heats of vaporization determined by both second and third law methods are in agreement. See $TiCl_4(\ell)$ table for details. The principal moments of inertia are: $I_A = I_B = I_C = 74.943 \times 10^{-39}\ g\ cm^2$.

Sept. 30, 1962; Dec. 31, 1966

TUNGSTEN TETRACHLORIDE (WCl_4) (CRYSTAL) GFW = 325.662

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [47.4] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -105.9 ± 15 kcal/mol

Td = [771]°K

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298}(WCl_4,c)$ = -105.9 kcal/mol, is calculated from ΔHr°_{298} = 58.9 kcal/mol for $3WCl_4(c) = WCl_2(c) + 2WCl_5(g)$. The value of ΔHr°_{298} is calculated by the third law method from decomposition pressure data in the temperature range from 354°C to 436°C reported by S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔHr°_{298} = 73.6 ± 7.9 kcal/mol and the third law drift is -24 ± 12 eu,which would correspond to a total entropy discrepancy of -8 ± 4 eu per mole of WCl_4. This entropy discrepancy is probably within the combined uncertainty of the data and the estimated entropies for the three species. S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 10, Ser. Fiz i Khim., No. 2, 78 (1959), have shown that decomposition pressures are essentially independent of the composition in the solid phase until $WCl_4(c)$ is almost completely decomposed to $WCl_2(c)$. This is consistent with the assumption of solid phase activities of unity which we have used in the equilibrium analysis.

Heat Capacity and Entropy.

Cp_{298} = 6.2 gibbs/g-atom and Cp_{700} = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. Ll. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 700°, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy of $WCl_4(c)$, S°_{298} = 47.4 eu, is estimated by the method of W. M. Latimer, "Oxidation Potentials," 2nd Ed., Prentice-Hall, Inc., New York, 1952.

Temperature of Decomposition.

Td is calculated as the temperature at which the gibbs energy change of the reaction $3\ WCl_4(c) = WCl_2(c) + 2\ WCl_5(g)$ approaches zero. We have also derived an approximate value of decomposition temperature, Td = 744°K, by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The difference between the two decomposition temperatures is related to the second law entropy and the adopted entropy.

[110]	(2)	[115]	(3)

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl-W-Cl = [109.47]° σ = [12]

Product of the Moments of Inertia: $I_AI_BI_C$ = [5.154 x 10^{-112}] g^3 cm^6

Heat of Formation.

The heat of formation, ΔHf°_{298} (WCl_4,g) = -80.3 kcal/mol, is calculated from ΔHr° = 37.7 kcal/mol for $WCl_6(g) \rightarrow WCl_4(g) + Cl_2(g)$. The value of ΔHr°_{298} is calculated by the third law method from the equation for log Kp given by S. A. Shchukarev and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). The second law ΔHr°_{298} is 43.6 kcal/mol and the third law drift is -9.6 eu.

Heat Capacity and Entropy.

The molecular configuration is assumed to be tetrahedral similar to those of $SiCl_4$, $TiCl_4$, VCl_4, $GeCl_4$, $ZrCl_4$, $SnCl_4$, $PbCl_4$. The bond distance is estimated to be the same as that in $WCl_6(g)$. The three principal moments of inertia are: $I_A = I_B = I_C = 80.18 \times 10^{-39}$ g cm^2.

All vibrational frequencies are estimated from those of $SiCl_4$, $TiCl_4$, VCl_4, $GeCl_4$, $SnCl_4$ and $PbCl_4$ given by Kazuo Nakamoto, "Infrared Spectra of Inorganic and Coordination Compounds," John Wiley & Sons, Inc., New York, 1963.

If it is considered that the metal atoms are effectively ionized, then the W^{4+} will have 2 d electrons in a field of chloride ions. The electronic splitting would be roughly the inverse of that in $NiCl_2(g)$, as given by D. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966), where Ni has a d^8 configuration. By analogy with the splitting in $NiCl_2$, the low lying electronic levels are estimated to be 10000 cm^{-1} and 30000 cm^{-1}, both triplets.

Dec. 31, 1960; June 30, 1961; Dec. 31, 1963; Dec. 31, 1969

ZIRCONIUM TETRACHLORIDE ($ZrCl_4$) (CRYSTAL) GFW = 233.032

$\Delta Hf^\circ_0 = -234.42 \pm 0.28$ kcal/mol

$S^\circ_{298.15} = 43.36 \pm 0.7$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -234.17 \pm 0.28$ kcal/mol

Tm = 710°K

ΔHm = 12 ± 3 kcal/mol

Ts = 606.8°K

$\Delta Hs^\circ_{298.15} = 26.4 \pm 0.3$ kcal/mol

Heat of Formation

Gal'chenko et al. (1) determined the heat of formation of $ZrCl_4(c)$ by the direct chlorination of the highly pure Zr metal in a bomb calorimeter. Complete chlorination of the metal was accomplished as indicated by the absence of unreacted metal and of lower chlorides. Their value, $\Delta Hf^\circ_{298}(ZrCl_4,\ c) = -234.17 \pm 0.28$ kcal/mol, is adopted in the tabulation.

Gross et al. (2) measured calorimetrically $\Delta Hr^\circ_{298} = -225.89$ kcal/mol for $Zr(c) + 2Cl_2(\ell) \rightarrow ZrCl_4(c)$. Corrections for the difference in heat content between liquid and gaseous chlorine at 25°C and 1 atm led to the value of standard heat of formation, $\Delta Hf^\circ_{298}(ZrCl_4,\ c) = -234.7 \pm 0.4$ kcal/mol, which is in good agreement with the value adopted. Siemonsen and Siemonsen (3) also measured the heat of formation by direct chlorination of the metal in an enameled bomb calorimeter. However, they did not report their detailed experimental procedure, neither the purity of their sample, nor the corrections. The value was given as $\Delta Hf^\circ_{298} = -231.9 \pm 0.5$ kcal/mol.

Heat Capacity and Entropy

Todd (4) measured the low temperature heat capacities from 52.6 to 296.7°K, and made an extrapolation to 0°K which yielded an entropy of 8.12 eu at 51°K. We have adopted the measured heat capacities, but have made our own extrapolation to 0°K, based on the ratio of the measured heat capacities of ZrF_4 (5), TiF_4 (6), and $TiCl_4$ (7) from 6° to 50°K. This extrapolation gives $S^\circ_{50} = 6.758 \pm 0.7$ eu which is used in the table. Coughlin and King (8) measured high temperature enthalpy data from 335.9° to 566.8°K by drop calorimetry. Their data are smoothly joined with Todd's low temperature heat capacities and adopted in the table.

Melting Data

The melting point, 710°K, has been observed by Rahlfs and Fischer (9), Palko et al. (10), Denisova et al. (11, 12).

Palko et al. derived the heat of melting as 9 ± 2.5 kcal/mol from their vapor pressure data. Denisova et al. (11, 12) determined thermographically the heat of melting as 14 ± 3 kcal/mol and also determined the heat of vaporization at 710°K as 10.4 kcal/mol which combined with the heat of sublimation at 710°K (23.8 kcal/mol) gives the heat of melting as 13.4 kcal/mol. A weighted average 12 ± 3 kcal/mol is adopted for the heat of melting.

Heat of Sublimation

Several investigators have measured the vapor pressure of $ZrCl_4(c)$ by the static method. Second and third law analyses for the vapor pressure data are summarized below:

Source	No. of Points	Temperature Range (°K)	ΔHs°_{298} (kcal/mol) 2nd law	3rd law	ΔSs°_{298} (eu)	Drift (eu)
Rahlfs and Fischer (9)	11	535-607	27.516	26.379	46.57	-1.95±0.75
Palko et al. (10)	86*	500-689	26.255	26.435	44.573	0.05±0.24
Denisova et al. (11)	17**	626-708	26.515	26.376	44.91	-0.29±0.51

* 4 points rejected due to failure of a statistical test.

** 1 point rejected due to failure of a statistical test.

The third law value, $\Delta Hs^\circ_{298} = 26.4$ kcal/mol, is adopted in the tabulation.

The sublimation temperature is obtained from the Gibbs free energy crossover between solid and gas. Rahlfs and Fischer (9) reported the sublimation temperature as 604°K.

Since the sublimation temperature is lower than the melting point, the liquid phase is thermodynamically unstable at normal conditions.

ZIRCONIUM TETRACHLORIDE ($ZrCl_4$) (IDEAL GAS) GFW = 233.032

Point Group = T_d $\Delta Hf_0^\circ = -207.46 \pm 0.2$ kcal/mol

$S^\circ_{298.15} = 88.0 \pm 0.2$ gibbs/mol $\Delta Hf^\circ_{298.15} = -207.77 \pm 0.2$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
376 (1)	418 (3)
99 (2)	110 (3)

Bond Distance: Zr-Cl = 2.32 ± 0.02 Å

Bond Angle: Cl-Zr-Cl = 109°28' σ = 12

Product of the Moments of Inertia: $I_AI_BI_C = 6.03177 \times 10^{-112}\ g^3\ cm^6$

Heat of Formation

The heat of formation of gaseous $ZrCl_4$, $\Delta Hf^\circ_{298} = -207.77 \pm 0.2$ kcal/mol, is calculated from the heat of formation of the crystal and the heat of sublimation derived from vapor pressure data. (See JANAF $ZrCl_4$(c) table dated Dec. 31, 1969).

Hildenbrand et al. (1) determined the equilibrium constants by the transpiration method for the reaction:

$$ZrO_2(c) + 4HCl(g) \rightarrow ZrCl_4(g) + 2H_2O(g)$$

Second and third law analyses for their data are given below:

Series	No. of Points	Temp. Range (°K)	ΔHr°_{298}(kcal/mol) 2nd law	ΔHr°_{298}(kcal/mol) 3rd law	Drift (eu)	$\Delta Hf^\circ_{298}(g)$* (kcal/mol)
I	10	1171-1375	28.853	29.321	0.29±0.34	-205.6
II	9	1169-1374	31.397	30.007	-1.08±0.47	-205.0

*Derived from third law ΔHr°_{298} and $\Delta Hf^\circ_{298}(ZrO_2, c) = -262.3$ kcal/mol, $\Delta Hf^\circ_{298}(HCl, g) = -22.063$ kcal/mol and $\Delta Hf^\circ_{298}(H_2O, g) = -57.796$ kcal/mol.

The derived heat of formation is in fair agreement with the value adopted.

Heat Capacity and Entropy

Spiridonov et al. (2) measured the bond distance Zr-Cl = 2.32 ± 0.02 Å in the vapor phase by electron diffraction. The molecule was also found to be a regular tetrahedron. The same bond distance was also reported by Lister and Sutton (3) and Kimura et al. (4). The three principal moments of inertia are $I_A = I_B = I_C = 84.4942 \times 10^{-39}\ g\ cm^2$.

Wilmshurst (5) observed one fundamental vibrational frequency ($\nu_3 = 421\ cm^{-1}$) in the infrared spectrum of $ZrCl_4$ vapor, and made reasonable estimates ($\nu_1 = 388$, $\nu_2 = 102$ and $\nu_4 = 112\ cm^{-1}$) for the three remaining unobserved fundamentals, based on observed overtone and combination bands. Godnev et al. (6) calculated the four fundamental vibrational frequencies (382, 108, 423 and 114 cm^{-1}) from data for related group IV halides through the use of a 5-parameter potential function. Büchler et al. (7) also found in the infrared spectrum the vibrational frequency, $\nu_3 = 423\ cm^{-1}$. Delwaulle and Francois (8) observed the symmetric stretching vibration ν_1 at 383 cm^{-1} from the Raman spectrum of $ZrCl_4$ in PCl_5 and $POCl_3$, both of which form complexes with $ZrCl_4$. Bobovich (9) reported the symmetric stretching vibration ν_1 at 315 cm^{-1} from a partially polarized band in his Raman spectrometric studies.

Pontrelli (10) observed in the Raman spectrum all four fundamental vibrational frequencies (376, 99, 418 and 110 cm^{-1}) which are adopted in the tabulation.

MOLYBDENUM PENTACHLORIDE ($MoCl_5$) (CRYSTAL) GFW = 273.205

ΔHf°_0 = unknown

$S^\circ_{298.15}$ = [57 ± 3] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -126 ± 2 kcal/mol

Tm = 467°K

ΔH°_m = [4.5 ± 1.5] kcal/mol

Heat of Formation

The heat of formation is obtained from S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Baev, Zh. Neorg. Khim. 5, 1650 (1960). The authors derived the $\Delta Hf^\circ_{298}(MoCl_5, c)$ = -126 kcal/mol by measuring the heat of solution of $MoCl_5$ in NaOH(aq), which was compared with the heats of solution of MoO_3 and NaCl measured in the same solvent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of $WCl_5(c)$. S°_{298} is estimated as 57 eu from the vapor pressure data for $MoCl_5(c) + MoCl_5(g)$ measured by S. A. Shchukarev, I. V. Vasil'kova and B. N. Sharupin, J. Gen. Chem. USSR (English Transl.) 26, 2335 (1956).

Melting Data

See liquid table.

Dec. 31, 1968

MOLYBDENUM PENTACHLORIDE ($MoCl_5$) (LIQUID) GFW = 273.205

$S^\circ_{298.15}$ = [65.441] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-121.9205] kcal/mol

Tm = 467°K

ΔHm° = [4.5 ± 1.5] kcal/mol

Tb = 537°K

ΔHv° = [12.0] kcal/mol

Heat of Formation

The heat of formation is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed constant and estimated as 42 gibbs/mol or 7 gibbs/g-atm. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Tm is taken from S. A. Shchukarev, G. I. Novikov, A. V. Suvorov and V. K. Moksimov, Russ. J. Inorg. Chem. (English Transl.) 4, 935 (1959). ΔHm° is estimated by comparison with that of $WCl_5(c)$.

Vaporization Data

Tb is the temperature at which the difference between the Gibbs energy of formation for $MoCl_5(\ell)$ and $MoCl_5(g)$ approaches zero. The difference between $\Delta Hf^\circ_{537}(MoCl_5, \ell)$ and $\Delta Hf^\circ_{537}(MoCl_5, g)$ is ΔHv°.

MOLYBDENUM PENTACHLORIDE ($MoCl_5$) (IDEAL GAS) GFW = 273.205

Point Group D_{3h}

ΔHf°_0 = -106.6 ± 1 kcal/mol

$S^\circ_{298.15}$ = [95 ± 3] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -107.0 ± 1 kcal/mol

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[490] (1)	[350] (2)
[400] (1)	[170] (2)
[410] (1)	[100] (2)
[150] (1)	[190] (2)

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	(2)
[7000]	(2)
[14000]	(2)

Bond Distance: Mo-Cl = 2.27 ± 0.02 Å

Bond Angles: Cl*-Mo-Cl* = 120° Cl*-Mo-Cl** = 90° Cl**-Mo-Cl** = 180° σ = 6

* Equatorial ** Axial

Product of the Moments of Inertia: $I_AI_BI_C = 1.02576 \times 10^{-111}\ g^3\ cm^6$

Heat of Formation

The adopted ΔHf°_{298} = -107.0 kcal/mol is obtained from the vapor pressure data for $MoCl_5(c) = MoCl_5(g)$ measured by Shchukarev et al. (1) and Saeki and Matsuzaki (2).

Source	Method	Reaction	Temperature Range, °K	$\Delta Hr^\circ_{298.15}$, kcal/mol Second law	Third law	Drift e.u.	ΔHf°_{298}* kcal/mol
Shchukarev	Transpiration	$MoCl_5(c) = MoCl_5(g)$	343 - 435	19.04 ± 0.45	19.18	0.3	-106.82
Saeki	Manometric	$MoCl_5(c) = MoCl_5(g)$	298 - 474	16.79 ± 0.06	18.94	5.6	-107.06

* Calculation based on third law ΔHr°_{298}.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of $NbCl_5$ obtained from infrared and Raman spectra by Carlson (3). Structure, bond distance and bond angle are taken from Ewens et al. (4). The three principal moments of inertia are $I_A = I_B = 106.1682 \times 10^{-39}$ and $I_C = 91.0024 \times 10^{-39}\ g\ cm^2$. The electronic levels are estimated to be 0, 7000 and 14000 cm^{-1}, all doublets, by comparison with those of $WCl_5(g)$.

Bond angles: $Cl_{(equatorial)}-P-Cl_{(equatorial)} = 120°$ $Cl_{(axial)}-P-Cl_{(axial)} = 180°$ $Cl_{(axial)}-P-Cl_{(equatorial)} = 90°$

Bond distance: $P-Cl_{(equatorial)} = 2.04$ Å $P-Cl_{(axial)} = 2.19$ Å

Product of moment of inertia: $I_AI_BI_C = 6.3873 \times 10^{-112}$ g.³ cm.⁶ $\sigma = 6$

Heat of Formation.

$\Delta H_f^\circ{}_{298.15}$ was calculated from the $\Delta H_r^\circ{}_{298.15}$ for the reaction: $PCl_3(g) + Cl_2(g) \rightarrow PCl_5(g)$. Third law calculations using experimental equilibrium constants, and free energy functions from JANAF Tables gave a $\Delta H_r{}_{298.15} = -20.884$ kcal. mole⁻¹. This ΔH_r° is the average of (1) $\Delta H_r^\circ{}_{298.15} = -20.766 \pm 0.26$ kcal. mole⁻¹ and (2) $\Delta H_r^\circ{}_{298.15} = -21.001 \pm 0.24$ kcal. mole⁻¹. The first, $\Delta H_r^\circ(1)$, was obtained from eleven experimental equilibrium constants measured by C. Holland, Z. Electrochem 18, 234 (1912) as corrected by W. Nernst, Z. Electrochem. 22, 37 (1916). The second, $\Delta H_r^\circ(2)$, was obtained from thirteen experimental equilibrium constants measured by W. Fischer and O. Jübermann, Z. anorg. u. allgem. Chim. 235, 337 (1938).

For the same reaction, $PCl_3(g) + Cl_2(g) = PCl_5(g)$, a third law calculation by D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941) gave a $\Delta H_0^\circ = -21.320 \pm 0.107$ kcal. mole⁻¹. With a new assignment of fundamental frequencies J. K. Wilmshurst and H. J. Bernstein, J. Chem. Phys. 27, 661 (1957) reported a $\Delta E_0^\circ = -20.525 \pm 0.16$ kcal. mole⁻¹.

The $\Delta H_f^\circ{}_{298.15}$ values corresponding to these heats of reaction are:

$\Delta H_f^\circ{}_{298.15}$	Source
-82.9 kcal. mole⁻¹	D. P. Stevenson and D. M. Yost (loc. cit.).
-82.1 kcal. mole⁻¹	J. K. Wilmshurst and H. J. Bernstein (loc. cit.).
-81.9 kcal. mole⁻¹	Calculated using free energy functions from JANAF Tables.

Heat Capacity and Entropy.

The fundamental vibrational frequencies were assigned by Wilmshurst and Bernstein (loc. cit.) from their infrared and Raman spectral data, except the frequency, 176 cm.⁻¹, which they calculated. Electron diffraction data of M. Rouault, Ann. phys. 14, 78 (1940) and Sargent and Schomaker, (quoted in) J. Chem. Phys. 9, 403 (1941), show the free PCl_5 molecule to be a trigonal bipyramid of D_{3h} symmetry. The bond lengths were calculated from force constants and Badger's rule by Wilmshurst and Bernstein (loc. cit.). Their values are in good agreement with the electron diffraction bond lengths of M. Rouault, (loc. cit.). The calculated moments of inertia are $I_A = I_B = 93.2177 \times 10^{-39}$ g. cm.² and $I_C = 73.5053 \times 10^{-39}$ g. cm.²

Dec. 31, 1962; Dec. 31, 1966

TUNGSTEN PENTACHLORIDE (WCl_5) (CRYSTAL) GFW = 361.115

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [52.0] gibbs/mol

$\Delta Hf^\circ_{298.15} = -122.6 \pm 10$ kcal/mol

Tm = 526°K

$\Delta Hm^\circ = 4.917 \pm 1$ kcal/mol

$\Delta Hs^\circ_{298.15}$ = 24.0 kcal/mol

Heat of Formation.

The heat of formation, ΔHf°_{298} (WCl_5,c) = -122.6 kcal/mol, is calculated from that of the gas less the heat of sublimation, ΔHs°_{298} = 24.0 kcal/mol. The latter is calculated by the third law method from partial pressures of WCl_5(g) derived from the total pressure data* of S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4 Ser. Fiz. i Khim., No. 1, 120 (1959). Dimer pressures, calculated from the same authors' dimer-monomer dissociation data, are subtracted from the total pressures in order to obtain the monomer pressures. Analyses of the monomer pressures over both crystal and liquid give similar results and the average values for ΔHs°_{298} are 20.6 (second law) and 24.0 kcal/mol (third law) with a drift of about 7 eu.

*Earlier data reported by Shchukarev et al., Zhur. Neorg. Khim. 1, 357 (1956); 3, 2630 (1958), have been revised and are not used here.

Heat Capacity and Entropy.

Cp_{298} = 6.2 gibbs/g-atom and Cp_{526} = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. Ll. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 526°, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, S°_{298} = 52 eu, is estimated by comparison with those of WCl_2 (c), WCl_4 (c) and WCl_6 (c).

Melting Data.

The melting point was determined from vapor pressure data by Shchukarev et al., loc. cit. The heat of melting is the difference at the melting point between the second law heats of vaporization and sublimation derived from total vapor pressure data of Shchukarev et al., loc. cit.

Heat of Sublimation.

See the heat of formation of WCl_5(g) for details.

Dec. 31, 1962; Dec. 31, 1966

TUNGSTEN PENTACHLORIDE (WCl_5) (LIQUID) GFW = 361.115

$S^\circ_{298.15}$ = [59.393] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -118.4 kcal/mol

Tm = 526°K

ΔHm° = 4.917 ± 1 kcal/mol

Tb = 561.4°K

ΔHv° = 16.266 kcal/mol

Heat of Formation.

The heat of formation, ΔHf°_{298} (WCl_5,l) = -118.4 kcal/mol, is calculated from that of WCl_5(c) by adding the heat of melting and the difference between $H^\circ_{526} - H^\circ_{298}$ for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom.

The entropy of WCl_5(l), $S^\circ_{298.15}$ = 59.393 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See WCl_5(c) table for details.

Vaporization Data.

The boiling point, 561.4°K, is calculated as the temperature at which the gibbs energy of formation for both WCl_5(l) and WCl_5(g) are equal. The difference in the heats of formation of WCl_5(l) and WCl_5(g) at the boiling point is the heat of vaporization. S. A. Shchukarev, G. I. Novikov and N. V. Andreeva[1] revised their previous data[2] and derived the boiling point as 561.2°K from their vapor pressure measurements.

* Equatorial ** Axial

Product of the Moments of Inertia: $I_AI_BI_C$ = [9.98 x 10^{-112}] g^3 cm^6

Heat of Formation.

The heat of formation, ΔHf°_{298} (WCl_5,g) = -98.6 kcal/mol, is calculated from ΔHr°_{298} = 19.4 kcal/mol for $WCl_6(g) \rightarrow WCl_5(g) + 1/2\ Cl_2(g)$. The value of ΔHr°_{298} is calculated by the third law method from the equation for log Kp given by S. A. Shchukarev and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). The second law ΔHr°_{298} is 24.6 kcal/mol and the third law drift is -8.5 eu.

Heat Capacity and Entropy.

The molecular configuration is assumed to be a trigonal bipyramid similar to that of $MoCl_5$ determined by electron diffraction by R. V. G. Ewens and M. W. Lister, Trans. Faraday Soc. 34, 1358 (1938). The bond distance is estimated to be the same as that in $WCl_6(g)$. The three principal moments of inertia are: $I_A = I_B = 105.23 \times 10^{-39}$ and $I_C = 90.20 \times 10^{-39}$ g cm^2.

All vibrational frequencies are estimated from those of $SbCl_5$, PCl_5, $NbCl_5$ and $TaCl_5$ obtained from infrared and Raman spectra by G. L. Carlson, Spectrochim. Acta 19, 1291 (1963).

If it is considered that the metal atoms are effectively ionized, then the W^{5+} will have a single d electron in a field of chloride ions. The electronic splitting would be roughly the inverse of that in $CuCl_2(g)$ as given by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966), where Cu has a d^9 configuration. By analogy with the splitting in $CuCl_2$, the low lying electronic levels are estimated to be 7000 cm^{-1} and 14000 cm^{-1}, both doublets.

Bond Distance: Fe-Cl = 2.11 ± 0.03 Å Fe-Cl_{bridge} = 2.28 ± 0.03 Å

Bond Angle: Cl-Fe-Cl = 128 ± 3° Cl_{bridge}-Fe-Cl_{bridge} = 92 ± 3° $\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C = 7.35910 \times 10^{-111}$ g.^{3} cm.^{6}

Heat of Formation.

The vaporization of $FeCl_3(c)$ is complex. It involves three possible chemical reactions, i.e. (1) $2FeCl_3(c) = Fe_2Cl_6(g)$; (2) $FeCl_3(c) = FeCl_3(g)$; and (3) $2FeCl_3(c) = 2FeCl_2(c) + Cl_2(g)$. Although these equilibria have been studied previously by many investigators, a review of their reported data reveals inconsistencies and errors. At room temperature the main vapor species present above $FeCl_3(c)$ is $Fe_2Cl_6(g)$, a dimer of $FeCl_3(g)$. As temperature increases, the dimer gradually decomposes into monomers ($FeCl_3$, g). Simultaneously, part of $FeCl_3(c)$ also decomposes into $FeCl_2(c)$ and $Cl_2(g)$. Therefore in order to obtain the partial pressure of $Fe_2Cl_6(g)$, the partial pressures of other vapor species, e.g. $Cl_2(g)$ and $FeCl_3(g)$, must be known and deducted from the observed total pressures. However, only few investigators made such corrections. The total pressures above $FeCl_3(c)$, at 500-600°K., have been determined by Maier[1] and Johnstone et al.[2], respectively. The partial pressures of $Fe_2Cl_6(g)$ were evaluated by the subtraction of the calculated equilibrium pressures of Cl_2 (g), obtained from reaction (3), from the reported total pressures. The partial pressures of $FeCl_3(g)$ were found to be insignificant at these temperatures. Using the partial pressures obtained for $Fe_2Cl_6(g)$, the enthalpy change ($\Delta H^\circ_{r\ 298.15}$) of reaction (1) was derived by both the second and third law methods. Then the value of $\Delta H^\circ_{f\ 298.15}$ (Fe_2Cl_6, g) was calculated. The results are given in the table.

Wilson and Gregory[3] have investigated the vaporization and thermal decomposition equilibria of $FeCl_3(c)$ by gas saturation flow and diaphragm gage techniques. Using the partial pressures for $Fe_2Cl_6(g)$, calculated from an equation, the values of $\Delta H^\circ_{r\ 298.15}$ and $\Delta H^\circ_{f\ 298.15}$ were also evaluated and listed in the table. Based on the total pressures measured by Stirnemann[4] and Sano[5], the equations for the pressures of $Fe_2Cl_6(g)$ and $Cl_2(g)$ in equilibrium with $FeCl_3(c)$ and $FeCl_2(c)$ as a function of temperature were reported by Wilson and Gregory[3]. The corresponding values of $\Delta H^\circ_{r\ 298.15}$ and $\Delta H^\circ_{f\ 298.15}$ were hence calculated. A brief summary and discussion of results of some other previous investigators were also given in the same report.

		$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1}		$\Delta H^\circ_{f\ 298.15}$*
Investigator	Temperature, °K.	Second Law Value	Third Law Value	kcal. mole^{-1}
Maier[1]	489.6-591.5	32.18 ± 0.40	34.67	-156.25 ± 0.50
Johnstone, et al.[2]	505.2-562.2	34.81 ± 0.49	34.50	-156.42 ± 0.50
Wilson and Gregory[3]	463.4-577.2	34.46	34.45	-156.47 ± 0.40
Stirnemann[4]	526.2-574.2	35.04	34.49	-156.43 ± 0.50
Sano[5]	513.2-569.2	30.67	34.76	-156.16 ± 0.50

*Based on the third law values for $\Delta H^\circ_{r\ 298.15}$.

[5] K. Sano, J. Chem. Soc. Japan, 59, 1073 (1938).

The value of $\Delta H^\circ_{f\ 298.15}$ for $Fe_2Cl_6(g)$ is selected as -156.4 ± 2.0 kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular structure, bond distances and angles were obtained from E. Z. Zasorin, N. G. Rambidi and P. A. Akishin, Zh. Strukt. Khim., 4, 910 (1963). The vibrational frequencies were estimated by comparison with those for $Al_2Cl_6(g)$ such that the values of ΔH° derived from the equilibrium data by the second and third law methods are in reasonable agreement. The three principal moments of inertia are: $I_A = 2.79395 \times 10^{-37}$, $I_B = 1.16349 \times 10^{-37}$ and $I_C = 2.26383 \times 10^{-37}$ g. cm.^{2}

MOLYBDENUM HEXACHLORIDE ($MoCl_6$) (CRYSTAL) GFW = 308.658

ΔHf°_0 = unknown

$S^\circ_{298.15}$ = [61.0 ± 4.0] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-125 ± 10] kcal/mol

Ts = [527]°K

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. 10, 576-8 (1965), assumed that the equilibrium $MoCl_6(c) = MoCl_5(g) + 1/2\ Cl_2(g)$ exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, ΔH°_T = 4 kcal/mol and ΔS°_T = 8 eu, of the equilibrium $MoCl_6(c) = MoCl_5(c) + 1/2\ Cl_2(g)$, from which they obtained the $\Delta Hf^\circ_{298}(MoCl_6, c) = -125$ kcal/mol.

Heat Capacity and Entropy

The adopted heat capacity is the same as that of $WCl_6(\alpha, c)$, since the heat capacities of W and Mo are almost the same. The entropy is estimated from that of $MoCl_5(c)$ by the addition of 4 eu due to one extra chlorine atom in the molecule.

Vaporization Data

The sublimation point is calculated from the free energy crossover between crystal and gas. However, it should be noted that $MoCl_6(c)$ is unstable with respect to $MoCl_5(c)$ at all temperatures and thus sublimation could occur only under an atmosphere of Cl_2.

Dec. 31, 1968

MOLYBDENUM HEXACHLORIDE ($MoCl_6$) (IDEAL GAS) GFW = 308.658

Point Group O_h

ΔHf°_0 = [-104.7 ± 20] kcal/mol

$S^\circ_{298.15}$ = [100.3 ± 4] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-105.0 ± 20] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[347] (1)	[144] (3)
[326] (2)	[171] (3)
[390] (3)	[106] (3)

Bond Distance: Mo-Cl = [2.26] Å

Bond Angle: Cl-Mo-Cl = [90°] σ = 24

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.7396 x 10^{-111}] g^3 cm^6

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. 10, 576-82 (1965), assumed that the equilibrium $MoCl_6(c)$ = $MoCl_5(g)$ + 1/2 $Cl_2(g)$ exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, ΔH°_T = 2.5 kcal/mol and ΔS°_T = 10 eu of the equilibrium $MoCl_6(g)$ = $MoCl_5(g)$ + 1/2 $Cl_2(g)$, from which they obtained the ΔHf°_{298}($MoCl_6$, g) = -105 kcal/mol.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of MoF_6 and WF_6, given by K. Nakamoto, "Infrared Spectra of Inorganic and Coordination Compounds," John Wiley and Sons, Inc., New York - London, 1963, and WCl_6 given by J. C. Evans and G. Y. S. Lo, J. Mol. Spectrosc. 26, 147 (1968).

Structure, bond distance and bond angle are estimated to be the same as those of WCl_6. The three principal moments of inertia are $I_A = I_B = I_C$ = 120.2684 x 10^{-39} g cm^2.

Dec. 31, 1962; Dec. 31, 1966

Cl_6W

TUNGSTEN HEXACHLORIDE, ALPHA (α-WCl_6) (CRYSTAL) GFW = 396.568

$S^\circ_{298.15}$ = [57.0] gibbs/mol

Tt ($\alpha_1 \rightarrow \alpha_2$) = 450 ± 10°K

Tt ($\alpha_2 \rightarrow \beta$) = 503° ± 3°K

ΔHf°_0 = Unknown

$\Delta Hf^\circ_{298.15}$ = -141.9 ± 6 kcal/mol

ΔHt° ($\alpha_1 \rightarrow \alpha_2$) = [1.0] kcal/mol

ΔHt° ($\alpha_2 \rightarrow \beta$) = 3.77 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 23.9 kcal/mol

Heat of Formation.

S. A. Shchukarev, I. V. Vasilkova and G. I. Novikov, Zh. Neorg. Khim. 3, 2642 (1958), have measured calorimetrically the heat of solution of WCl_6(c) and also of H_2WO_4(c) in a 12% solution of NaOH as -188.0 ± 0.3 and -13.6 ± 0.11 kcal/mol, respectively. Based on these data and a heat of dilution value for Na_2WO_4 which is essentially zero, we obtain ΔHr°_{298} = -174.4 ± 0.3 kcal/mol for WCl_6(c) + 6NaOH(16.3H_2O) → H_2WO_4(c) + 6NaCl(2200$0H_2O$) + 2H_2O(l). This reaction gives ΔHf°_{298}(WCl_6,c) = -141.9 ± 6 kcal/mol, using a revised ΔHf°_{298}(H_2WO_4,c) = -270.5 kcal/mol, and other auxiliary data from JANAF Tables and from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS2, Natl. Bur. Std., Washington, D.C., April, 1965. The authors have suggested a possible uncertainty of the order of 5 kcal/mol due to the slowness of the dissolution of WCl_6(c).

Heat Capacity and Entropy.

J. R. Welty[1] has measured the enthalpy changes for WCl_6(α,c) in the temperature range from 406° to 502.4°K by drop calorimetry. Few points were measured in the region of the $\alpha_1 \rightarrow \alpha_2$ transition and no attempt was made to investigate the phase present at the conclusion of the drop. Thus, these data appear to be inadequate to define the heat capacities of the α_1 and α_2 phases. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy, S°_{298} = 57.0 eu, is calculated from that of the gas using ΔS°_{298} = 43.155 eu from the vaporization and sublimation data given in the WCl_6(g) table (December 31, 1966).

Transition Data.

Transition temperatures and heats of transition have been reported by the following investigators, and their results are summarized as follows:

		$\alpha_1 \rightarrow \alpha_2$ transition		$\alpha_2 \rightarrow \beta$ transition	
Investigator	Method	Temperature (°K)	ΔHt° (kcal/mol)	Temperature (°K)	ΔHt° (kcal/mol)
Ketelaar[2] et al.	Vapor pressure	441	-	500	3.4
Stevenson[3]	Cooling curve	458	-	503	-
	Vapor pressure	-	-	503	1.9
Welty[1]	Drop calorimetric	-	-	504	3.4
Shchukarev[4] et al.	Vapor pressure	-	-	504	3.4
Dobrotin[5]	Approximate calorimetric	-	-	493 ± 10	5.5

The adopted ΔH°_{450} ($\alpha_1 \rightarrow \alpha_2$) and ΔH°_{503} ($\alpha_2 \rightarrow \beta$) are calculated as 1.0 and 3.77 kcal/mol, respectively, based on the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to α_1 phase as the final state, although no experimental evidence for this is given.

Melting Data.

See WCl_6 (β,c) table (December 31, 1966).

Heat of Sublimation.

See WCl_6(g) table (December 31, 1966) for detailed information about sublimation data.

Dec. 31, 1966

TUNGSTEN HEXACHLORIDE, BETA (β-WCl_6) (CRYSTAL) GFW = 396.568

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [67.066] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-136.921] kcal/mol

$Tt\ (\alpha_2 \rightarrow \beta)$ = 503 ± 3°K

$\Delta Ht\ (\alpha_2 \rightarrow \beta)$ = 3.77 kcal/mol

Tm = 555 ± 2°K

ΔHm° = 1.60 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 18.921 kcal/mol

Heat of Formation.

The heat of formation, ΔHf°_{298} (WCl_6,β,c) = -136.921 kcal/mol, is calculated from that of $WCl_6(\alpha,c)$ by adding the heat of $\alpha_2 \rightarrow \beta$ transition and the difference between $H^\circ_{503} - H^\circ_{298.15}$ for $WCl_6(\alpha,c)$ and $WCl_6(\beta,c)$.

Heat Capacity and Entropy.

J. R. Welty[1] has measured the enthalpy changes for $WCl_6(\beta,c)$ in the temperature range from 508° to 553°K by drop calorimetry. Because of the short temperature range, poor distribution of points, and lack of identification of the phase present at the conclusion of each drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are consistent with the enthalpy data within their probable uncertainty.

The entropy of $WCl_6(\beta,c)$, $S^\circ_{298.15}$ = 67.066 eu, is calculated in a manner analogous to that of the heat of formation.

Transition Data.

See $WCl_6(\alpha,c)$ table (Dec. 31, 1966).

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized as follows:

Investigator	Method	Melting Point (°K)	ΔHm° (kcal/mol)
Ketelaar[2] et al.	Vapor pressure	557	2.3
Stevenson[3]	Cooling curve	555	-
	Vapor pressure	555	1.5
Welty[1]	Drop calorimetric	556	1.6
Shchukarev[4] et al.	Vapor pressure	564	2.0
Dobrotin[5] et al.	Approximate calorimetric	545 ± 12	4.2

The adopted heat of melting, ΔH°_{555} = 1.6 kcal/mol, is calculated from the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to α_1 phase as the final state, although no experimental evidence for this is available.

Heat of Sublimation.

$\Delta Hs^\circ_{298.15}$ is calculated as the difference between $\Delta Hf^\circ_{298.15}$ for $WCl_6(\beta,c)$ and $WCl_6(g)$.

Dec. 31, 1962; Dec. 31, 1966

Cl_6W

TUNGSTEN HEXACHLORIDE (WCl_6) (LIQUID) GFW = 396.568

$S^\circ_{298.15}$ = [68.085] gibbs/mol

Tm = 555 ± 2°K

Tb = 613.6°K

$\Delta Hf^\circ_{298.15}$ = -136.091 kcal/mol

ΔHm° = 1.60 kcal/mol

ΔHv° = 14.319 kcal/mol

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298.15}(WCl_6,l)$ = -136.091 kcal/mol, is calculated from that of $WCl_6(\beta,c)$ by adding the heat of melting and the difference between $H^\circ_{555} - H^\circ_{298.15}$ for $WCl_6(\beta,c)$ and $WCl_6(l)$.

Heat Capacity and Entropy.

J. R. Welty, Ph.D. Thesis, Oregon State University (1962), has measured the enthalpy changes for $WCl_6(l)$ in the temperature range from 560° to 603°K by drop calorimetry. Since the temperature range was very short and no attempt was made to investigate the phase present at the conclusion of the drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy of $WCl_6(l)$, $S^\circ_{298.15}$ = 68.085 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See $WCl_6(\beta,c)$ table dated Dec. 31, 1966.

Vaporization Data.

The boiling point, 613.6°K, is calculated as the temperature at which the gibbs energies of formation for both $WCl_6(l)$ and $WCl_6(g)$ are equal. The difference in the heats of formation of $WCl_6(l)$ and $WCl_6(g)$ at the boiling point is the heat of vaporization.

J. A. A. Ketelaar, G. W. Oosterhout and P. B. Braun, Rec. Trav. Chim. 62, 597 (1943), have determined the boiling point and the heat of vaporization as 609.7°K and 15.24 kcal/mol, respectively, from vapor pressure measurements. S. A. Shchukarev and A. V. Suvorov revised their previous data[2,3] and gave the boiling point and the heat of vaporization as 616.2°K and 14.7 kcal/mol, respectively, from their vapor pressure measurements.

See $WCl_6(g)$ table, dated Dec. 31, 1966, for detailed information about vaporization data.

[340] (2)	[180] (3)
375 (3)	[120] (3)

Bond Distance: W-Cl = 2.26 Å
Bond Angle: Cl-W-Cl = 90° σ = 24
Product of the Moments of Inertia: $I_A I_B I_C = 1.7396 \times 10^{-111}\ g^3\ cm^6$

Heats of Formation.

The heat of formation of WCl$_6$(g), ΔHf°_{298} = -118.0 kcal/mol, is calculated from that of the crystal plus the adopted heat of sublimation, ΔHs°_{298} = 23.9 kcal/mol for $WCl_6(\alpha,c) \rightarrow WCl_6(g)$. The latter was obtained from third law analysis of the vapor pressure data [1,2,3,4], using all JANAF functions (Dec. 31, 1966).

Vernon[4]	α, c	298 - 423	4	16.1 ± 4.1	21.02	10.8 ± 12.8	-120.88

A. A. Vernon[4] has also determined the equilibrium constants in the temperature range from 1360° to 1600°K for the decomposition of WCl$_6$(g) to W(c) and Cl$_2$(g) by reaction of the sample with a hot tungsten filament in a vacuum bulb. Using the reported equilibrium constants, the heat of formation of WCl$_6$(g) at 298°K is calculated by the second and third law method as -131.8 ± 2.9 kcal/mol and -135.2 kcal/mol, respectively. The third law drift is 2.4 ± 1.9 eu. Unfortunately, the reported equilibrium constants may be seriously in error, since atomic chlorine is the main species at the pressure and temperature studied.

* Enthalpy changes are converted to ΔHs°_{298} for $WCl_6(\alpha, c) \rightarrow WCl_6(g)$.

** Vapor pressure equations for the crystal (α,β) and the liquid to gas are given.

*** The third law ΔHs°_{298} is used in calculation.

Cl_6W

Heat Capacity and Entropy.

R. V. G. Ewens and M. W. Lister, Trans. Faraday Soc. 34, 1358 (1938), have determined the octahedral structure for WCl$_6$(g) by electron diffraction and found the bond length to be 2.26A.

The vibrational frequency of ν_3, 375 cm^{-1}, was observed in the infrared spectra by J. C. Evans, The Dow Chemical Company, private communication, Dec. 1, 1966. The values of ν_1, ν_2 and ν_5 (360, 340 and 180 cm^{-1}, respectively) are estimated, based on those of the aqueous ion $PtCl_6^{2-}$ reported by L. A. Woodward and J. A. Creighton, Spectrochim. Acta 17, 594 (1961). The values of ν_4 and ν_6 (140 and 120 cm^{-1}, respectively) are estimated by comparison with those of WF$_6$(g).

The three principal moments of inertia are $I_A = I_B = I_C = 120.2684 \times 10^{-39}$ g cm^2.

Dec. 31, 1966

TUNGSTEN PENTACHLORIDE, DIMERIC (W_2Cl_{10}) (IDEAL GAS) GFW = 722.230

Point Group [D_{2h}]

$S^\circ_{298.15}$ = [170] gibbs/mol

Ground State Quantum Weight = [3]

ΔHf°_0 = -208.7 ± 10 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -207.6 ± 10 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}

[250] (2)		[40] (2)

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl*-W-Cl* = [90]° W-Cl*$_{bridge}$-W = [90]° σ = [4]

Cl**-W-Cl** = [180]° Cl*-W-Cl** = [90]°

*Equatorial **Axial

Product of the Moments of Inertia: $I_AI_BI_C$ = [6.638] x 10^{-110} g^3 cm^6

Heat of Formation.

The heat of formation, ΔHf°_{298} (W_2Cl_{10},g) = -207.6 kcal/mol, is calculated from ΔHr°_{298} = 10.4 kcal/mol for W_2Cl_{10}(g) = 2 WCl_5(g), using all JANAF functions (Dec. 31, 1966). The value of ΔHr°_{298} is obtained from third law analysis of the partial pressures of WCl_5(g) and W_2Cl_{10}(g) derived from PVT data determined by S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔHr°_{298} is 10.4 ± 0.3 kcal/mol.

Heat Capacity and Entropy.

The molecular configuration is estimated by analogy with that of Mo_2Cl_{10} reported by D. Z. Sands and A. Zalkin, Acta Cryst. 12, 723 (1959). Chlorine atoms are placed octahedrally around two tungsten atoms and these two octahedra share one common edge with six chlorine and two tungsten atoms in a plane. The bond length is estimated to be the same as that in WCl_6(g). The three principal moments of inertia are I_A = 210.5 x 10^{-39}, I_B = 576.8 x 10^{-39} and I_C = 546.8 x 10^{-39} g cm^2.

All vibrational frequencies are estimated, based on those of WCl_5, $(AlCl_3)_2$ and Cs_2Cl_2, such that $S^\circ_{607}(W_2Cl_{10},g)$ = 216.65 eu. This entropy is derived from ΔS°_{607} = 19.92 ± 0.5 eu for $W_2Cl_{10}(g)$ = $2WCl_5(g)$, obtained by second law analysis of the data of Shchukarev et al., loc. cit. The frequencies are not in point group order.

COBALT (Co) (CRYSTAL) GFW = 58.9332

ΔHf°_0 = 0 kcal/mol

$S^\circ_{298.15}$ = 7.18 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 0 kcal/mol

Tt = [700°] K

ΔHt° = 0.108 kcal/mol

Tm = 1768°K

ΔHm° = 3.87 ± 0.06 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 101.5 ± 0.5 kcal/mol

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity of Co(c) is adopted from Hultgren et al. (1). Their selected values are based on the data from nineteen investigations. The entropy values are based on S°_1 = 0.0011 eu. The heat capacity has a maximum value of 13.14 gibbs/mol at the Curie point (1394°K).

Transition Data

The exact nature of the α(hcp)-β(fcc) transition is yet to be clearly elucidated. Three investigations (2,3,4) indicate that it is not a simple time- and temperature-dependent phenomenon. Crystalline cobalt exists as pure β-phase above 700°K whereas mixtures of alpha and beta cobalt commonly coexist in varying proportions below this temperature. The values of Tt° and ΔHt° are those selected by Hultgren et al. (1).

Melting Data

The temperature and heat of melting are those selected by Hultgren et al. (1).

Heat of Sublimation

The heat of sublimation is calculated from the data of Edwards et al. (5). See Co(g) table for details.

Sept. 30, 1967

COBALT (Co) (LIQUID) GFW = 58.9332

$S^\circ_{298.15}$ = 9.79 gibbs/mol

Tm = 1768°K

Tb = 3170.29°K

$\Delta Hf^\circ_{298.15}$ = 4.303 ± 0.1 kcal/mol

ΔHm° = 3.87 ± 0.06 kcal/mol

ΔHv° = 89.219 kcal/mol

Heat of Formation

The heat of formation (ΔHf°_{298}) of Co(ℓ) is obtained from that of the crystal by adding ΔHm° and the differences between H_{1768}-H_{298} for crystal and liquid.

Heat Capacity and Entropy

The heat capacity of Co(ℓ) selected by Hultgren et al. (1) is used at temperatures above 1768°K. The heat capacities at temperatures below the melting point are estimated by assuming a glass transition at 1100°K and heat capacities similar to those of the crystal below 1100°K.

Melting Data

See Co(c) table for details.

Vaporization Data

The boiling point is calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K so that the free energy functions calculated by integration of the crystal liquid data and by statistical methods from the gas phase are equal at the boiling point.

Heat of Formation

The heat of formation is the heat of sublimation at 298°K. The adopted value is that reported by Edwards et al. (1). Their value is used because their vapor pressure measurements for Fe (1) and Cu (2) have proved to be very reliable. The results obtained by Vintaikin and Tomash (3) are rejected because their vapor pressure data for Fe (4) resulted in a value for the heat of sublimation which was higher than the accepted value [see JANAF Fe(g) Table for details]. The remaining vapor pressure data are rejected either because the drift was too large or because there were not enough points. Second and third law analyses of the available vapor pressure data gave the following results, with reaction A corresponding to Co(c) = Co(g) and reaction B corresponding to Co(ℓ) = Co(g).

**Calculation based on third law $\Delta Hr°_{298}$.

Heat Capacity and Entropy

The electronic levels are taken from Moore (10). Levels above 25,000 cm^{-1} are averaged. Unobserved levels below 20,000 cm^{-1} are estimated.

Heat of Formation

The heat of formation, ΔHf°_{298}, is calculated from the equation $Co(g) - e^- \rightarrow Co^+(g)$ with the JANAF auxiliary value for Co(g); using an ionization potential of 63438 cm^{-1} (181.377 kcal/mol) obtained from C. E. Moore, "Atomic Energy Levels," Vol. II, U. S. Natl. Bur. Std. Circ. 467, 1949. The value of $H^\circ_0 - H^\circ_{298}$ is -1.504 kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, loc. cit. Levels above 30,000 cm^{-1} are averaged.

June 30, 1970

COBALT DIFLUORIDE (CoF_2) (CRYSTAL) GFW = 96.9300

ΔHf°_0 = -160.2 ± 1.0 kcal/mol

$S^\circ_{298.15}$ = 19.60 ± 0.10 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -160.5 ± 1.0 kcal/mol

Tm = 1400°K

ΔHm° = 14.058 ± 3.0 kcal/mol

ΔHs° = 75.3 ± 3.0 kcal/mol

Heat of Formation

Heus and Egan (1) measured the electromotive force of a solid state galvanic cell which involved the reactions

$Al(c) + 3/2\ CoF_2(c) \rightarrow AlF_3(c) + 3/2\ Co(c)$. E_{873} = 1.611 volts

$Mg(c) + CoF_2(c) \rightarrow MgF_2(c) + Co(c)$. E_{873} = 2.231 volts

Combining these results with auxiliary thermodynamic data (2) for the reactants and products, we derive ΔHf°(CoF_2, c) = -160.2 and -159.5 kcal/mol.

Several equilibrium studies (3, 4, 5) involving CoF_2(c) have been reported in the literature. Second and third law analyses of these equilibrium data are summarized below, auxiliary data for CoO(c) and $CoCl_2$(c) are from (6).

Reference	Chemical Reaction	Temp. Range °K	Points	ΔHr_{298} kcal/mol 2nd law	ΔHr_{298} kcal/mol 3rd law	Drift gibbs/mol	*ΔHf°(CoF_2, c) kcal/mol
(3)	$CoF_2(c) + 2HCl(g) \rightleftarrows CoCl_2(c) + 2HF(g)$	588-805	3	4.1	1.75±0.4	-1.7±0.1	-162.6±2.0
(4)	$CoF_2(c) + H_2(g) \rightleftarrows Co(c) + 2HF(g)$	673-873	3	35.2	31.5±1.0	-4.2±3.5	-161.8±2.0
(5)	$CoF_2(c) + H_2O(g) \rightleftarrows CoO(c) + 2HF(g)$	773-1023	5	30.2	31.1±0.2	0.9±0.3	-160.45±1.0

*Third law values except for the first reaction.

We note that Heus and Egan (1), in the same paper, measured $\Delta Hf^\circ_{298}(AlF_3, c)$ = -360.2 kcal in excellent agreement with the JANAF value (2). Domange (5) also measured similar equilibria for MgF_2 and CaF_2, which were very consistent with the JANAF heats of formation (2). Jellinek and Rudat (4) reported similar equilibria for PbF_2(c), which show excellent consistency with the JANAF heat of formation (2). Thus, it is apparent that these three sets are probably quite reliable, and we adopt $\Delta Hf^\circ_{298.15}(CoF_2, c)$ = -160.5 ± 1 kcal/mol.

Heat Capacity and Entropy

Catalano and Stout (7) measured low temperature heat capacities in the temperature range 10° to 300°K. Heat capacity data above 300°K are calculated from the high temperature (468-1400°K) enthalpy data of Binford et al. (8). Both sets of data were smoothed by computer and joined at 298.15°K.

The value of $S^\circ_{298.15}$ is obtained from the low temperature heat capacity data of Catalano and Stout (7) and is based on S_{10} = 0.013 gibbs/mol.

Melting Data

Tm = 1400°K is from the high temperature enthalpy studies of Binford et al. (8). ΔHm is calculated from their enthalpy data. Premelting of the sample is assumed to be responsible for the rapid rise in the enthalpy near the melting point. This enthalpy is included in ΔHm.

Heat of Sublimation

Kana'an et al. (9) made sublimation studies of CoF_2 using Knudsen and Langmuir techniques over the temperature range 972°-1241°K. Second and third law analyses of these sublimation pressures are summarized below.

Method	Temp. Range °K	No. of Points	ΔHs°_{298} kcal/mol 2nd law	ΔHs°_{298} kcal/mol 3rd law	Drift gibbs/mol
Knudsen	1058-1242	17	75.0	75.1±0.1	0.1±0.2
Langmuir	972-1032	8	72.8	75.5±0.2	2.6±1.4

The selected value is ΔHs°_{298} = 75.3 ± 3.0 kcal/mol.

COBALT DIFLUORIDE (CoF_2) (LIQUID) GFW = 96.9300

$S^\circ_{298.15}$ = 20.61 ± 2.5 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -152.412 ± 4.0 kcal/mol

Tm = 1400°K

ΔHm° = 14.058 ± 3.0 kcal/mol

Tb = [2012]°K

ΔHv° = [48.0] kcal/mol

Heat of Formation

ΔHf°(ℓ) is calculated from ΔHf°(c) by adding the heat of melting and the difference in (H_{1400}-H_{298}) between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of liquid CoF_2 is estimated by comparison with those for $FeCl_2$(ℓ), MgF_2(ℓ), and PbF_2(ℓ) and is assumed constant in the temperature range 298°-3000°K. Binford et al. (1) reported Cp = 30.3 gibbs/mol for liquid CoF_2 at 1444°K. This value is based on only two enthalpy points near the melting point and appears high in comparison with heat capacities for other liquid metal dihalides. Therefore, the value is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the CoF_2(c) table for details.

Vaporization Data

Tb is the temperature at which the Gibbs energy change for the process CoF_2(ℓ) → CoF_2(g) approaches zero. The difference between the heat of formation of the gas and liquid at Tb is ΔHv°.

σ = 2

Heat of Formation

The heat of formation of gaseous CoF_2, ΔHf°_{298} = -88.1 ± 7.0 kcal/mol, is calculated from the heat of formation of the crystal, ΔHf°_{298} = -163.4 ± 4.0 kcal/mol, and the heat of sublimation, ΔHs°_{298} = 75.3 ± 3.0 kcal/mol. The sublimation value is determined from a third law analysis of the vapor pressure data for CoF_2 reported by Kana'an et al. (1). See CoF_2(c) table for details.

Heat Capacity and Entropy

Büchler et al. (2) investigated the deflection of a molecular beam of CoF_2(g) by an electric field and found that within the sensitivity of the apparatus the molecule was nonpolar and consequently possessed a linear structure. Hastie et al. (3) recently investigated the infrared absorption spectra of several transition metal difluorides through the use of matrix isolation techniques. Isotopic shift measurements for matrix isolated NiF_2, ZnF_2, and CuF_2 in neon and argon indicated that these species were slightly bent. Based upon these results, the authors estimated the F-Co-F angle as 165°. This value is adopted here. The bond length was estimated by Brewer et al. (4). Individual moments of inertia are $I_A = 0.1925 \times 10^{-39}$, $I_B = 18.341 \times 10^{-39}$, and $I_C = 18.533 \times 10^{-39}\ g\ cm^2$.

Hastie et al. (3) isolated CoF_2 in neon and argon matrices and observed the ν_3 fundamental at 762 cm^{-1}. They also calculated $\nu_1 = 600\ cm^{-1}$ by a valence force field method and estimated ν_2 as 151 cm^{-1} by applying the variation in the frequencies for the chlorides of Co, Ni, Cu, and Zn to the fluorides. The electronic levels and quantum weights are estimated by comparison with the electronic energy levels for Co^{++}(g) ion (5) and those for $CoCl_2$(g) observed by Hougen et al. (6).

CESIUM (Cs) (CRYSTAL) GFW = 132.905

ΔHf°_0 = 0 kcal/mol

$S^\circ_{298.15}$ = 20.351 ± 0.05 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 0 kcal/mol

Tm = 301.55 ± 0.01°K

ΔHm° = 0.499 ± 0.001 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 18.32 kcal/mol

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacities, 0.19-301.55°K, have been measured by Dauphinee (1), McCollum (2), Martin (3), Lien (4), Filby (5), and Morgan (6). The adopted values are derived based on the Cp data reported by Filby (5) and Lien (4). Lien measured the heat capacities in the temperature range 0.1874 to 1.20°K in the adiabatic demagnetization cryostat and at higher temperatures, 1.2 to 4.09°K, in the liquid-helium temperature cryostat. The Cs sample was obtained from a commercial source of 99.8 per cent purity. Filby determined the Cp values in the temperature ranges 0.4-1.5°K, 3-26°K and 20-320°K, using commercial samples of 99.9 per cent purity. These two sets of measurements are joined smoothly at 4°K. $S^\circ_{298.15}$ is derived from the adopted heat capacities, based on $S^\circ_{0.20}$ = 0.0002 eu.

Dauphinee (1) determined the heat capacities of Cs(c) employing a sample badly contaminated with oxygen. In the temperature range of approximately 100 to 200°K, an anomaly of Cp curve somewhat similar to those found for sodium and potassium was reported. This anomaly was not observed by Filby who used the higher purity cesium sample. The Cp values reported by Dauphinee are lower than the adopted ones by about 0.5 to 1.5 per cent in the temperatures 55 to 220°K; above 270°K his reported heat capacities are unreasonably high. Therefore the data are not adopted for evaluation. McCollum (2) calculated the Debye θ values from the measured low temperature heat capacities and plotted them, since no numerical data were reported these were not used. The low temperature Cp values determined by Martin (3) and Morgan (6) are in good agreement with the adopted ones.

Melting Data

See Cs(ℓ) table for details.

Heat of Sublimation

$\Delta Hs^\circ_{298.15}$ is calculated as the difference between $\Delta Hf^\circ_{298.15}$ for Cs(g) and Cs(c).

June 30, 1968

CESIUM (Cs) (LIQUID) GFW = 132.905

$S^\circ_{298.15}$ = 22.005 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 0.499 kcal/mol

Tm = 301.55 ± 0.01°K

ΔHm° = 0.499 ± 0.001 kcal/mol

Tb = 951.6°K

ΔHv° = 16.198 kcal/mol

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(c) by adding ΔHm° and the difference between $H^\circ_{301.55} - H^\circ_{298}$ for Cs(c) and Cs(ℓ).

Heat Capacity and Entropy

The enthalpies of Cs(ℓ) have been measured by Tepper et al. (1), Achener (2), and Lemmon et al. (3), using drop calorimetry. Lemmon et al. used a cesium sample of 99.994 per cent purity and encapsulated in Nb-1Zr alloy. They found that Cs(ℓ) does not behave as a normal liquid from about 100-300°C. The thermal conductivity measurements of Cs(ℓ) show a change of slope at about 200°C and its electrical resistivity also shows scatter in this region. The heat capacities, 301.55-1435.2°K, derived from the reported enthalpies (corrected for vapor condensation), are consistent with the low temperature heat capacity data on Cs(c) at 298°K and are adopted.

Tepper et al. measured the enthalpies in the temperature range 351.1-1238°K. The reported enthalpy values are considerably higher, over 20 per cent, at the lower end of the measured temperature range than the adopted ones. However, the agreement becomes better at the higher temperature end. Achener determined the enthalpies of Cs(ℓ) at the temperatures 340.1-1175.7°K. Using the reported enthalpies, the average heat capacity is derived to be 9.75 gibbs/mol, which is unreasonably high by comparison with those for the other alkali metals. The above two sets of data are not used for evaluation. The enthalpies of Cs(ℓ), 773-1423°K, were also measured by Shapiro (4 and quoted by 3). The derived constant heat capacity, 7.60 gibbs/mol, is in reasonable agreement with the adopted ones.

Heat capacities of Cs(ℓ), 301.55-373.2°K, were reported by Filby (5), 301.55-320°K, Dauphinee (6), 310-320°K, and Rengade (7), 301.7-373.2°K. The values obtained are consistent with the adopted ones.

$S^\circ_{298.15}$ is derived in a manner analogous to that of the heat of formation.

Melting Data

The melting point and heat of melting have been determined by many investigators. The results reported are presented in the table below. The adopted Tm and ΔHm° are obtained from (5). The two determinations of fraction melted against temperature are in very good agreement with one another and lead to a linear plot of reciprocal fraction melted against temperature thus indicating that the major impurity is solid insoluble. This is confirmed by a graph of excess heat capacity against the reciprocal of $(T_0-T)^2$, where T_0 is the melting point, which indicates an impurity (mainly oxygen) concentration of 0.06 atomic per cent.

Vaporization Data

Tb is the temperature at which the Gibbs energy change (ΔGr°) for the reaction Cs(ℓ) = Cs(g) approaches zero. The difference between ΔHf°(Cs, g) and ΔHf°(Cs, ℓ) at Tb is ΔHv°. Due to the presence of dimer (Cs_2) in the vapor (see Cs(g) and Cs_2(g) tables for details), the real boiling point of Cs(ℓ) is calculated to be 941.3°K at which the vapor mixture contains 0.835 mol of monomer/mol of Cs(ℓ) vaporized, or 9.0 per cent of dimer. The corresponding heat of vaporization is evaluated as 15.26 kcal/mol of vapor mixture.

Heat of Formation

The total pressures of Cs(g) and Cs_2(g) over Cs(c) and Cs(ℓ) in the temperature range 238.6 to 1268.3°K have been measured, using the boiling point method, by Bonilla (4), Tepper (3) and Achener (2); using the static method, by Kröner (10), Scott (7) and Stone (1); and the positive ion method by Taylor (6). Füchtbauer (8) and Hackspill (9) have determined the vapor pressures of Cs(ℓ) by a spectroscopic method and P-V-T relationships, respectively. Based on the reported total pressures, the partial pressures of Cs(g) and Cs_2(g) are evaluated by use of dimer-monomer ratios calculated from JANAF free energy functions and $\Delta Hr°_{298.15}$ = 11.24 kcal/mol for the reaction Cs_2(g) = 2Cs(g). The value of $\Delta Hr°_{298.15}$ is adopted such that the derived monomer partial pressures give consistent second and third law heats of vaporization. The results are presented in the table below.

Stone et al. (1) measured the vapor pressures of Cs(ℓ) at temperatures 920-1682°K and pressures 0.811-33.53 atm in both the saturation and superheat regions, using a static method and a refractory metal apparatus with a diaphragm as a null-point detector. These vapor pressures reported at temperatures 920-1267.3°K and total pressure below 10 atm are used for evaluation and are reasonably represented by a mixture of monomer and dimer ideal gases. The value of $\Delta Hf°_{298}$(Cs, g) is adopted as 18.32±0.5 kcal/mol which is derived based on the vapor pressures reported by Stone et al. The results obtained are in reasonable agreement with the values derived from the other vapor pressure sets.

*Calculation based on the third law $\Delta Hr°_{298}$ and $\Delta Hf°_{298}$ = 0 and 0.499 kcal/mol for Cs(c) and Cs(ℓ), respectively.

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights ($n \leqslant 10$) are obtained from Moore (11). The electronic levels above 25000 cm^{-1} are average values calculated from those given by Moore. The missing electronic levels, where quantum number n = 7, 8, 9 and 10, and the corresponding quantum weights are estimated according to the method recommended by Gurvich (12). The calculated values at 6000°K, e.g. Cp = 19.668 gibbs/mol and S° = 61.990 eu, are not significantly different from the corresponding values, Cp = 19.650 gibbs/mol and S° = 61.871 eu, obtained from using all the electronic levels reported by Moore for calculation without cutting or adding any levels.

CESIUM UNIPOSITIVE ION (Cs^+) (IDEAL GAS) GFW = 132.90445

Ground State Configuration $^1S_0$

ΔHf°_0 = 108.5 ± 1 kcal/mol

$S^\circ_{298.15}$ = 40.565 ± 0.0005 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 108.1 ± 1 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	1

Heat of Formation

The ionization potential of Cs(g) was reported as 3.893 eV or 89.776 kcal/mol by C. E. Moore, U. S. Natl. Bur. Std. Circ. 467, 1958. Based on this data we derived $\Delta Hf^\circ_{298.15}$ = 108.1 ± 1 kcal/mol for $Cs^+(g)$.

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights were reported by Moore, loc. cit. However, the lowest electronic level above ground state is given as 107392.33 cm^{-1} which is so high that the evaluated thermodynamic properties of $Cs^+(g)$ will not be affected if we disregard all of these higher levels for calculation. Therefore we do not use them. The $H^\circ-H^\circ_{298}$ value at 0°K is -1.481 kcal/mol.

CESIUM FLUORIDE (CsF) (CRYSTAL) GFW = 151.9034

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [21.1 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -132.57 ± 0.5 kcal/mol

Tm = 976°K

ΔHm° = 5.19 kcal/mol

$\Delta Hs^\circ_{298.15}$(to monomer) = 47.37 kcal/mol

Heat of Formation

The enthalpy of solution (ΔHsoln) of CsF(c) in water at 298.15°K has been carefully determined with an adiabatic calorimeter by Somsen (1). Based on the reported value, $\Delta Hsoln^\circ_{298}$ = -8.62 ± 0.04 kcal/mol and ΔHf°_{298} = -61.69 (2) and -79.5 kcal/mol (3) for $Cs^+(\infty\ H_2O)$ and $F^-(\infty\ H_2O)$, respectively, the heat of formation for CsF(c) is calculated to be -132.57 kcal/mol which is adopted.

The value, $\Delta Hsoln^\circ_{298}$ = -8.81 ± 0.2 kcal/mol for CsF(c), was reported by Parker (4), which is in agreement with the value measured by Somsen (1).

Heat Capacity and Entropy

The heat capacities of CsF(c) are estimated according to the method of Kristov (5), based on $H^\circ_{976} - H^\circ_{298}$ = 9.4 kcal/mol reported by Dworkin (6). The entropy (S°_{298}) is estimated such that the calculated and observed vapor pressures are in good agreement (see CsF(g) and Cs_2F_2(g) tables for details).

Melting Data

Tm and ΔHm° are obtained from Bredig (7) and Dworkin (8). Bukhalova (9) reported Tm = 958°K,which is not adopted.

Heat of Sublimation

ΔHs°_{298} is calculated as the difference between ΔHf°_{298} for CsF(g) and CsF(c).

June 30, 1968

CESIUM FLUORIDE (CsF) (LIQUID) GFW = 151.9034

$S^\circ_{298.15}$ = [21.534] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -129.983 kcal/mol

Tm = 976°K

ΔHm° = 5.19 kcal/mol

Tb = 1504°K

ΔHv° = 27.6 kcal/mol of liquid

Heat of Formation

$\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{976} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

Dworkin (1) measured the heat capacity of CsF(ℓ) at the melting point to be 17.7 gibbs/mol which is adopted and assumed to be constant in the temperature range 298 - 3000°K. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See CsF(c) for details.

Vaporization Data

Tb is the temperature at which the calculated vapor pressures of CsF(g) and $Cs_2F_2(g)$ equal one atmosphere. The vapor composition at Tm is calculated as CsF 80.3 per cent and Cs_2F_2 19.7 per cent. The heat required to vaporize one mole of liquid to the above vapor mixture at Tm is ΔHv°.

Tb has been observed as 1524 and 1526°K by Wartenberg (1) and Ruff (2), respectively, which are in fair agreement with the calculated one, 1504°K.

α_e = 0.001105 cm^{-1}

σ = 1

r_e = 2.345 Å

Heat of Formation

The vapor pressures of CsF(c) and CsF(ℓ) were measured by the manometric method (A) by Wartenberg (1), Ruff (2) and Cantor (3); the torsion-fiber effusion method (B) by Pugh (4); and the Knudsen effusion method (C) by Scheer (5). Based on the reported total pressures, the corresponding partial pressures of CsF(g) and Cs_2F_2(g) were evaluated using the adjusted heats of vaporization and Gibbs free energy functions such that the calculated and observed total pressures are in reasonable agreement, and the derived enthalpy changes by the second and third law methods are consistent. The results obtained are presented in the table below. The value of ΔHf°_{298}(CsF, g) is adopted as -82.5 ± 0.5 kcal/mol.

The dissociation energy (D_0) of CsF(g) has been reported using the spectroscopic convergence limit as 5.65eV(130.3 kcal/mol) and 5.5eV(126.8 kcal/mol) by Herzberg (6) and Gaydon (9), respectively. Based on the above two D_0 values, and ΔHf°_0 = 18.68 and 18.36 for Cs(g) and F(g), we obtain the corresponding value for ΔHf°_{298}(CsF, g) as -93.86 and -90.39 kcal/mol, which are not adopted.

Investigators	Reaction*	Method	ΔHr°_{298}, kcal/mol Second Law	ΔHr°_{298}, kcal/mol Third Law	Drift eu	ΔHf°_{298}, kcal/mol**
1. Wartenberg (1921)	2	A	45.39±0.15	44.98	-0.28±0.10	-85.00
2. Ruff (1922)	2	A	44.78±1.70	44.94	0.11±1.18	-85.04
3. Cantor (1958)	2	A	44.83	44.89	0.05±0.04	-85.09
4. Pugh (1958)	1	B	48.52±0.03	47.57	-1.18±0.04	-85.00
5. Scheer (1962)	1	C	48.43±0.27	46.61	-2.35±0.35	-85.96

*1 represents the reaction CsF(c) = CsF(g); 2, the reaction CsF(ℓ) = CsF(g).

**Calculation based on the third law ΔHr°_{298}, and ΔHf°_{298} = -132.57 and -129.983 kcal/mol for CsF(c) and CsF(ℓ), respectively.

Heat Capacity and Entropy

The ground state configuration was reported by Herzberg (6). The molecular constants are obtained from Honig (7), who observed the microwave spectra of CsF(g) at temperatures of about 700°C. Based on the J = 1 → 2 transition, the molecular constants are derived. The vibrational frequency (ω_e) has been reported, from different kinds of spectra, in the range 270 - 385 cm^{-1} by many investigators, e.g. radiofrequency, infrared, ultraviolet, microwave, etc. The value of ω_e adopted was reported by Baikov (8), who also reviewed the ω_e values obtained by the earlier investigators.

CESIUM MONOXIDE (CsO) (IDEAL GAS) GFW = 148.9044

Ground State Configuration $[^2\pi]$

ΔHf°_0 = [15.5 ± 10] kcal/mol

$S^\circ_{298.15}$ = [61 ± 1] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [15.0 ± 10] kcal/mol

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	[4]

ω_e = [280] cm^{-1}

$\omega_e x_e$ = [1.0] cm^{-1}

σ = 1

B_e = [0.198] cm^{-1}

α_e = [0.001] cm^{-1}

r_e = [2.40] Å

Heat of Formation

The heat of formation is estimated from three calculated values. The methods of estimation are described as follows. Brewer and Margrave (1) suggested that the ΔHf value for MO(g) from the gaseous ions can be taken as the mean of the corresponding ΔHf values for the the alkali fluoride and chloride with a maximum uncertainty of 10 kcal/mol. Adopting ΔHr°_{298} = -131.1 and -109.6 kcal/mol for the reaction $Cs^+(g) + F^-(g) = CsF(g)$ and $Cs^+(g) + Cl^-(g) = CsCl(g)$, respectively, we obtain ΔHr°_{298} = -120.4 kcal/mol for $Cs^+(g) + O^-(g) = CsO(g)$ which leads to ΔHf°_{298}(CsO, g) = 12.0 kcal/mol. The ΔHf°_{298} values of the above species used for calculation are taken from the respective JANAF Thermochemical Tables.

Based on the assumption that D(Cs-O) = 1/2[D(Cs_2) + D(O_2)], we derive D_{298}(Cs-O) = 65.2 kcal/mol and ΔHf°_{298} = 12.7 kcal/mol for CsO(g).

Adopting the Cs-O bond energy as half of the atomization energy of Cs_2O, we calculate D(Cs-O) = 60 ± 10 kcal/mol and ΔHf°_{298}(CsO, g) = 17 ± 10 kcal/mol.

The heat of formation for CsO(g) is tentatively selected as 15 ± 10 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of the isoelectronic molecule OH(g). ω_e is estimated from those of LiO(g), CsF(g), and CsCl(g). The bond distance is taken from that in CsOH(g) reported by Lide and Kuczkowski (2). $\omega_e x_e$ is estimated by comparison with those of the other alkali oxides. The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ by the method suggested by Herzberg (3). The moment of inertia is 1.413×10^{-38} g cm^2.

CESIUM, DIMERIC (Cs_2) (IDEAL GAS) GFW = 265.810

Ground State Configuration ${}^1\Sigma_g^+$

$S^\circ_{298.15}$ = [67.87] gibbs/mol

ΔHf°_0 = 26.45 ± 1.0 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 25.40 ± 1.0 kcal/mol

Electronic Levels and Quantum Weights

State	ϵ_i, cm^{-1}	g_i
${}^1\Sigma_g^+$	0	1
${}^1\Sigma_\mu^+$	9000	1
${}^1\Pi_\mu$	13043.87	2
$[{}^1\Sigma_\mu^+]$	16066.03	[1]
$[{}^1\Pi_\mu]$	16175.80	[2]

ω_e = 41.99 cm^{-1}

B_e = [0.01263] cm^{-1}

$\omega_e x_e$ = 0.08005 cm^{-1}

α_e = [0.000035] cm^{-1}

σ = 2

r_e = [4.48] Å

Heat of Formation

The vapor pressures of Cs(g) and Cs_2(g) over Cs(ℓ) have been measured by many investigators (see Cs(g) table for details). For internal consistency, the vapor pressures determined at temperatures 980-1684°K and pressures 1.1-7.5 atm by Stone (1) are employed for evaluation. The P-V-T data on cesium reported by Tepper (2) are employed for comparison. Using the reported pressures, the JANAF free energy functions and ΔHr°_{298} = 11.24 kcal/mol for the reaction $Cs_2(g) = 2Cs(g)$, the equilibrium constants for this reaction are evaluated. From the derived equilibrium constants, the enthalpy change of the reaction $Cs_2(g) = 2Cs(g)$ is calculated by the second and third law methods. The results are presented in the table below. The value of $\Delta Hf^\circ_{298}(Cs_2, g)$ is adopted as 25.40 ± 1.0 kcal/mol.

The D_0(Cs-Cs) was reported as 0.45 eV or 10.38 kcal/mol by Gaydon (5) and Herzberg (3), yielding ΔHf°_{298} = 25.93 ± 0.92 kcal/mol for Cs_2(g) which is in agreement with the adopted value, within the experimental uncertainty.

Expt. No.	No. of Points	Temperature, °K	Pressure, atm	ΔHr°_{298}, kcal/mol Second Law	ΔHr°_{298}, kcal/mol Third Law	Drift eu	ΔHf°_{298}* kcal/mol
28 (1)	23	1151-1680	4.7-7.5	12.39±0.10	11.63	-0.55±0.07	25.01
30 (1)	24	980-1684	1.1-2.0	10.90±0.16	11.24	0.25±0.12	25.40
38 (1)	19	1100-1657	3.2-5.2	12.28±0.22	11.22	-0.77±0.16	25.42
1-6, 8, 10 (2)	54	955-1375	1.0-5.4	12.35±0.70	11.47	-0.74±0.58	25.17

*Calculation based on the third law ΔHr°_{298} and ΔHf°_{298}(Cs, g) = 18.32 kcal/mol.

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights, ω_{e_1} and $\omega_e x_e$ are obtained from Herzberg (3). The second electronic level is reported as 8800-11000 cm^{-1} and the value 9000 cm^{-1} is chosen for calculation. The last two electronic states are estimated by comparison with those for K_2(g) given by (3). The bond distance r_e is calculated from ω based on the method suggested by Guggenheimer (4). The values of B_e and α_e are calculated (3). The moment of inertia is 2.2145×10^{-37} g cm^2.

CESIUM FLUORIDE, DIMERIC (Cs_2F_2) (IDEAL GAS) GFW = 303.8068

Point Group [D_{2h}]

ΔHf_0° = -211.55 ± 2.0 kcal/mol

$S^\circ_{298.15}$ = [84 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -212.74 ± 2.0 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[200] (1)	[120] (1)
[110] (1)	[220] (1)
[210] (1)	[230] (1)

Bond Distance: Cs-F = [2.35] Å

Bond Angle: F-Cs-F = [85°] Cs-F-Cs = [95°] σ = [4]

Product of the Moments of Inertia: $I_AI_BI_C$ = [3.126 x 10^{-112}] g^3 cm^6

Heat of Formation

Evidence from the velocity distribution in molecular beams (1) has shown that alkali halide vapors contain significant amounts of polymeric species. Using the same method Eisenstadt (2) determined the molecular composition of CsF vapor in the temperature range 838 - 919°K. Based on the reported equilibrium constants for the reaction $(CsF)_2(g) = 2CsF(g)$, we evaluate the enthalpy change (ΔHr°_{298}) by the second and third law methods to be 40.53 ± 1.75 and 42.34 ± 0.26 kcal/mol, respectively. Employing ΔHf°_{298} = 42.34 and ΔHf°_{298}(CsF, g) = -85.2 kcal/mol, we obtained ΔHf°_{298} = -212.74 kcal/mol for Cs_2F_2(g), which is adopted.

Heat Capacity and Entropy

The Cs_2F_2 molecule is assumed to have a rhombic configuration of symmetry D_{2h} as Cs_2Cl_2(3). The Cs-F bond distance is taken as the same as that in CsF(g). The bond angles and vibrational frequencies are estimated by comparison with those of the other dimeric alkali halides (3, 4). The three principal moments of inertia are: I_A = 1.590 x 10^{-38}, I_B = 1.325 x 10^{-37} and I_C = 1.484 x 10^{-37} g cm^2.

Dec. 31, 1968

DICESIUM MONOXIDE (Cs_2O) (IDEAL GAS) GFW = 281.8094

Point Group C_{2v}

ΔHf°_0 = -20.6 ± 10 kcal/mol

$S^\circ_{298.15}$ = [76 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -22.0 ± 10 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[290] (1)
[130] (1)
[300] (1)

Bond Distance: Cs-O = [2.4] Å

Bond Angle: Cs-O-Cs = [105°]

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.415 x 10^{-112}] g^3cm^6

Heat of Formation

The appearance potentials of CsOH and Cs_2O ions were investigated by Emel'yanov et al. (1), using the electron-impact method with a mass spectrometer fitted with a heated ion source and a Pt effusion chamber. The heat of atomization of Cs_2O was derived as 117 ± 9 kcal/mol. Based on this value we calculate the heat of formation (ΔHf°_{298}) of Cs_2O to be -22 ± 10 kcal/mol, employing ΔHf°_0 = 18.68 and 58.99 kcal/mol for Cs(g) and O(g), respectively. Brewer and Mastick (2) calculated theoretically the stability of gaseous alkali oxides according to ionic models and gave the heats of formation from gaseous atoms for Cs_2O(g) as -24 kcal/mol. The ΔHf°_{298} value is evaluated to be 72.2 kcal/mol which is not adopted.

Heat Capacity and Entropy

The molecular structure of Cs_2O(g) has been determined to be nonlinear by Büchler et al. (3), using electric-deflection method. The Cs-O bond distance is assumed to be the same as that in CsOH(g) reported by Lide and Kuczkowski (4). The bond angle is estimated by comparison with that in the H_2O molecule. Three vibrational frequencies are estimated from those for H_2O(g). The three principal moments of inertia are: $I_A = 5.350 \times 10^{-39}$, $I_B = 1.600 \times 10^{-37}$, and $I_C = 1.6535 \times 10^{-37}$ g cm^2.

COPPER (Cu) (CRYSTAL) AT. WT. = 63.54

$\Delta H^\circ_{f\ 0} = 0$ kcal. mole^{-1}

$S^\circ_{298.15} = 7.913 \pm 0.04$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15} = 0$ kcal. mole^{-1}

$T_m = 1356.6$°K.

$\Delta H^\circ_m = 3.17 \pm 0.15$ kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15} = 81 \pm 0.4$ kcal. mole^{-1}

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The low temperature specific heat of copper has been measured by several workers and generally there is good agreement. The selected values lie close to the determinations of J. A. Kok and W. H. Keesom (1.2-20°K), Physica 3, 1035 (1936); D. L. Martin (20-300°K), Can. J. Phys. 38, 17 (1960); C. B. Satterthwaite, R. S. Craig and W. E. Wallace, J. Am. Chem. Soc. 76, 232 (1954), and S. M. Dockerty, Can. J. Research 9, 84 (1933) and 15A, 59 (1937). Several other workers have reported values of C_p slightly higher than the adopted values especially W. F. Giauque and P. F. Meads, J. Am. Chem. Soc. 63, 1897 (1941), however these measurements were not used for reasons discussed by Martin. The heat capacity above room temperature has been determined directly by several workers, the values of R. E. Pawel and E. E. Stansbury, J. Phys. Chem. Solids 26, 607 (1965) join well with the low temperature data and are adopted. These values lie within 1% of the values adpoted by R. Hultgren, R. L. Orr, P. D. Anderson, and K. K. Kelley "Selected Values of Thermodynamic Properties of Metals and Alloys", John Wiley and Sons, Inc., New York,1963. Several determinations of the solid enthalpy are also in good agreement with selected heat capacity curve. For references to these determinations refer to Hultgren et al. loc. cit.

Melting Data.

The melting point of copper is well established and the recent determination of W. Heyne, Exptl. Tech. Physik. 12, 87 (1964) is adopted. The heat of fusion was obtained from the calculated enthalpy of the solid at the melting point and the liquid enthalpy measurements of F. Wust, A. Meuthen and R. Durrer, Forsch. Geb. Ingenieurw. VDI-Forsch. 204 (1918). The liquid enthalpies of I. B. Fieldhouse, J. C. Hedge, J. I. Lang and T. E. Waterman, ASTIA Doc. No. A. D. 150954 are somewhat higher than the adopted values.

Sublimation Data.

See Cu(g) for details.

Dec. 31, 1965

COPPER (Cu) (LIQUID) AT. WT. = 63.54

$S^\circ_{298.15}$ = 8.663 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 2.224 kcal. mole^{-1}

T°_m = 1356.6°K.

ΔH°_m = 3.17 ± 0.15 kcal. mole^{-1}

T°_b = 2848°K.

ΔH°_v = 72.743 kcal. mole^{-1}

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH°_m and the difference between $H_{1356.6}-H_{298}$ for (c) and (l).

Heat Capacity and Entropy.

The heat capacity was calculated from the enthalpy data of F. Wust, A. Meuthen and R. Durrer, Forsch. Geb. Ingenieurw. VDI-Forsch. 204 (1918). The entropy was obtained in a manner analagous to the heat of formation.

Melting Data.

See crystal table for details.

Vaporization Data.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

The first eight references may be considered to have reasonable drifts and second and third law agreement. The three Langmuir values are grouped closely together at about 80.3 kcal. mole^{-1}. The Knudsen values all lie a little higher averaging 81.4 kcal. mole^{-1}, the single transport determination is at 80.55 kcal. mole^{-1}. If the evaporation coefficient is not unity in the Langmuir experiments then one would observe lower pressures and higher heats of sublimation, thus it appears that the coefficient must be unity and that all techniques are measuring valid heats of sublimation. A value of 81 ± 0.5 kcal. mole^{-1} was chosen weighted toward the more precise Knudsen work of Hersh.

Heat Capacity and Entropy.

The electronic ground state configuration and higher electronic levels were taken from C. E. Moore "Atomic Energy Levels", Natl. Bur. Stds. Circular 467, Washington 1952.

Dec. 31, 1965

COPPER UNIPOSITIVE ION (Cu^+) (IDEAL GAS) AT. WT. = 63.53945

Ground State Configuration $^1S_0$

$S^\circ_{298.15}$ = 38.367 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 258.9 ± 0.5 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 260.668 ± 0.5 kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ_i, cm.$^{-1}$	g_i	ϵ_i, cm.$^{-1}$	g_i
0.0	1	68694.7	39
21928.6	7	72095.4	42
22847.0	5	85388.8	5
23998.3	3	88505.7	9
26264.5	5	95565.7	9

Heat of Formation.

The heat of formation was obtained from the dissociation limit of Cu(g) which was given as 62317.2 cm.$^{-1}$ (or 178.187 kcal. mole^{-1}) by C. E. Moore "Atomic Energy Levels", Nat. Bur. Stds. Circ. 467, Washington 1952. This value applies to 0°K., the enthalpy of Cu, Cu^+ and e^- between 298°K. and zero are all 1.481 kcal. mole^{-1}, thus at 298°K. the dissociation energy is 179.668 kcal. mole^{-1}. The heat of formation was then obtained from the reaction $Cu(g) \rightarrow Cu^+ + e^-$ as $\Delta H^\circ_{f\ 298.15}$ = 260.668 ± 0.5 kcal. mole^{-1}, the uncertainty is that due to Cu(g).

Heat Capacity and Entropy.

The ground state configuration and higher electronic levels were taken from C. E. Moore, loc. cit. Levels above 100,000 cm.$^{-1}$ were not included since they do not affect the thermodynamic function, levels above 30,000 cm.$^{-1}$ were averaged.

June 30, 1966

COPPER MONOFLUORIDE (CuF) (CRYSTAL) GFW = 82.5384

$S^\circ_{298.15}$ = [15.5 ± 0.5] gibbs/mol

Tm = Unknown

ΔHf°_0 = Unknown

$\Delta Hf^\circ_{298.15}$ = [-46 ± 10] kcal/mol

ΔHm° = Unknown

$\Delta Hs^\circ_{298.15}$ = [58] kcal/mol

Heat of Formation.

The heat of formation ($\Delta Hf^\circ_{298.15}$) for CuF(c) is not available from literature at the present time. The lattice energy (U_o) for CuF(c) has been calculated to be 209, 213 and 232 kcal/mol, based on the assumption of ionic bonding in CuF(c), by Pauling, Zachariasen and Ebert and Woitinek, respectively (see T. C. Waddington, Trans. Faraday Soc. 55, 1531 (1959) for details). The corresponding enthalpy change for the reaction CuF(c) = Cu^+(g) + F^-(g) was evaluated as 210.18, 214.18 and 233.18 kcal/mol. Using $\Delta Hf^\circ_{298.15}$ = 260.67 kcal/mol for Cu^+(g) and -62.2 kcal/mol for F^-(g), the values of $\Delta Hf^\circ_{298.15}$ (CuF, c) were calculated to be -11.7, -15.7 and -34.7 kcal/mol. However, based on $\Delta Hf^\circ_{298.15}$(CuF, g) = 12 ± 9 kcal/mol which was measured, the values of $\Delta Hs^\circ_{298.15}$ would be 23.7, 27.7 and 46.7 kcal/mol which seem to be too small. By comparison with those for KF(c) and HgF(c), the value of $\Delta Hs^\circ_{298.15}$ was estimated as 58 kcal/mol. From this $\Delta Hs^\circ_{298.15}$ value and $\Delta Hf^\circ_{298.15}$ (CuF, g), the heat of formation for CuF(c) was derived.

Heat Capacity and Entropy.

The heat capacities, 298.15-1000°K, and $S^\circ_{298.15}$ were estimated by comparison with those for CuCl(c), NaCl(c) and NaF(c). The Cp values above 1000°K were obtained by graphical extrapolation.

Heat of Sublimation.

The value of $\Delta Hs^\circ_{298.15}$ was estimated by comparison with those for KF(c) and HgF(c).

COPPER MONOFLUORIDE (CuF) (IDEAL GAS) GFW = 82.5384

Ground State Configuration $^1\Sigma^+$

$S^\circ_{298.15}$ = 54.11 gibbs/mol

ΔHf°_0 = 12 ± 9 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 12 ± 9 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	1

ω_e = 621.89 cm^{-1} $\omega_e x_e$ = 3.941 cm^{-1} σ = 1

B_e = 0.3794 cm^{-1} α_e = 0.004586 cm^{-1} r_e = 1.743 Å

Heat of Formation.

Based on spectroscopic data, the dissociation energy (D°_0) of CuF (g) was selected as 3.0 ± 1.0 eV by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953. Using $\Delta Hf^\circ_{298.15}$ = 18.36 and 80.71 kcal/mol for F(g) and Cu(g), respectively, the value of $\Delta Hf^\circ_{298.15}$ for CuF (g) was calculated to be 30 ± 23 kcal/mol.

Values of the dissociation energy for CuF(g) have been derived by R. A. Kent, J. D. McDonald, and J. L. Margrave, J. Phys. Chem. 70, 874 (1966), as 3.63 ± 0.2 to 4.1 ± 0.5 eV, based on mass spectrometric studies of CuF_2 sublimation from a Knudsen cell, the appearance potential of CuF^+ ion from CuF_2 in both reducing and nonreducing systems, and a theoretical calculation assuming an ionic model like that used by E. S. Rittner, J. Chem. Phys. 19, 1030 (1951). Until further data are available, a value D (CuF) = 3.8 ± 0.5 eV was recommended. Using this dissociation energy for CuF (g), the heat of formation (298.15°K) for CuF(g) was evaluated to be 12 ± 9 kcal/mol which is adopted here.

Heat Capacity and Entropy.

The values of ground state configuration, ω_e, $\omega_e x_e$, B_e, α_e and r_e were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York, 1950, and corrected to the average isotopic species.

COPPER DIFLUORIDE (CuF_2) (CRYSTAL) GFW = 101.5368

$\Delta Hf°_0$ = Unknown

$S°_{298.15}$ = [16.4] gibbs/mol

$\Delta Hf°_{298.15} = -131.2 \pm 0.8$ kcal/mol

Tm = 1043°K

$\Delta Hm°$ = [9.4] kcal/mol

$\Delta Hs°_{298.15} = 62.5 \pm 0.6$ kcal/mol

Heat of Formation.

The chemical equilibrium for the reaction (1) $CuF_2(c) + H_2(g) = Cu(c) + 2HF(g)$ has been studied by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928). The equilibrium gas phase composition was found to be HF 4.3% and H_2 95.7%, at 423°K. From this data the enthalpy change ($\Delta Hr°_{298.15}$) of the reaction was evaluated. The equilibrium for the reaction (2) $CuF_2(c) + H_2O(g) = CuO(c) + 2HF(g)$ was investigated by L. Domange, Compt. rend. 200, 239 (1935). Based on the equilibrium data reported, the $\Delta Hr°_{298.15}$ value for the reaction was derived. The results obtained are presented as follows.

		$\Delta Hr°_{298.15}$, kcal/mol			
Reaction	Temperature, °K	Second Law Value	Third Law Value	Drift eu	$\Delta Hf°_{298.15}$ kcal/mol
(1)	423	—	22.38	—	-152.0
(2)	473.15-723.15	23.06 ± 1.33	22.15	-1.67 ± 1.96	-131.2

Using the third law values for $\Delta Hr°_{298.15}$, the corresponding $\Delta Hf°_{298.15}$ (CuF_2, c) values were calculated. The adopted heat of formation for $CuF_2(c)$ is -131.2 ± 0.8 kcal/mol.

Heat Capacity and Entropy.

The heat capacities, 298.15-1000°K, and $S°_{298.15}$ were estimated by comparison with those for $CuCl_2(c)$, $CaF_2(c)$ and $CaCl_2(c)$, respectively. The Cp values above 1000°K were obtained by graphical extrapolation.

Melting Data.

Tm was reported by H. M. Haendler, L. H. Towle, E. F. Bennett and W. L. Patterson, Jr., J. Am. Chem. Soc. 76 2178 (1954). Tm for $CuF_2(c)$ in HF(g) or $N_2(g)$ was found to be 950 ± 5°C or 785 ± 10°C, respectively, by H. von Wartenberg, Z. anorg. allgem. Chem. 241, 381 (1939). Heat of melting was estimated by comparison with those for other related compounds.

Heat of Sublimation.

See $CuF_2(g)$ table for details.

COPPER DIFLUORIDE (CuF_2) (LIQUID) GFW = 101.5368

$S^\circ_{298.15}$ = [20.584] gibbs/mol

Tm = 1043°K

Tb = [1722]°K

$\Delta Hf^\circ_{298.15}$ = [-124.30] kcal/mol

ΔHm° = [9.4] kcal/mol

ΔHv° = [43.98] kcal/mol

Heat of Formation.

The heat of formation ($\Delta Hf^\circ_{298.15}$) was obtained from $\Delta Hf^\circ_{298.15}$ (CuF_2, c) by adding ΔHm° and the difference between $H^\circ_{1043}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated based on an assumption that the average heat capacity for $CuF_2(l)$ is 7.5 gibbs/atom. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $CuF_2(c)$ table for details.

Vaporization Data.

Tb is the temperature at which the free energy change for the reaction $CuF_2(l) = CuF_2(g)$ becomes zero. The difference between ΔHf° for liquid and gas at Tb is ΔHv°.

Heat of Formation.

The vapor pressures of $CuF_2(c)$, at temperatures from 897 to 1026°K, have been determined by R. A. Kent, J. D. McDonald and J. L. Margrave, J. Phys. Chem. 70, 874 (1966). Based on these data, the heat of sublimation ($\Delta Hs^\circ_{298.15}$) of $CuF_2(c)$ was derived to be 62.45 ± 0.5 and 62.50 kcal/mol by the second and third law method, respectively. From the values of $\Delta Hs^\circ_{298.15}$ and $\Delta Hf^\circ_{298.15}$ for $CuF_2(c)$, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $CuF_2(g)$ was evaluated.

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The ground state electronic configuration, $^2\Sigma$, was obtained from A. Büchler, J. L. Stauffer and W. Klemperer, Interim Tech. Rept. No. 6, Apr. 30, 1964, Arthur D. Little, Inc., Cambridge, Mass. The other electronic levels and quantum weights were assumed from those for $CuCl_2(g)$ reported by J. T. Hougen, G. E. Leroi and T. C. James, J. Chem. Phys. 34, 1670 (1961). The vibrational frequency, ν_3, was determined by P. H. Kasai, E. B. Whipple and W. Weltner, Jr., J. Chem. Phys. 44, 2581 (1966). The other two frequencies, ν_1 and ν_3, were calculated by Valence Force Treatment described by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand Company, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is I = 1.86649 X 10^{-38} g cm^2.

COPPER DIHYDROXIDE $(Cu(OH)_2)$ (CRYSTAL) GFW = 97.55474

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [25.9] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -107.64 ± 2.0 kcal/mol

Td = 433°K

Heat of Formation.

The enthalpy change (ΔHr°_{433}) for the reaction $Cu(OH)_2(c) = CuO(c) + H_2O(g)$ has been determined by L. V. My, Bull. soc. chim. France, No. 3, 545 (1964). Based on the reported value, ΔHr°_{433} = 12 kcal/mol, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $Cu(OH)_2(c)$ was derived as -107.64 kcal/mol, using $\Delta Hf^\circ_{298.15}$ = -37.250 and -57.798 kcal/mol for CuO(c) and $H_2O(g)$, respectively, which was adopted here.

The free energy change ($\Delta Gr^\circ_{298.15}$) of the reaction $Cu(OH)_2(c) = Cu^{++}(aq) + 2\ OH^-(aq)$ was evaluated to be 26.36 and 26.26 kcal/mol, based on the solubility product for $Cu(OH)_2(c)$ reported by (1) E. S. Ganelina, Zh. prikl. Khim. 37, 1358 (1964) and (2) N. P. Zhuk, Zh. Fiz. Khim. 28, 1523 (1954), respectively. Using values of $S^\circ_{298.15}$ and $\Delta Hf^\circ_{298.15}$ for Cu^{++} (aq) and OH^-(aq) from "Selective Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1, 1965, by D. D. Wagman and co-workers, the corresponding enthalpy change $\Delta Hr^\circ_{298.15}$) and heat of formation ($\Delta Hf^\circ_{298.15}$) for $Cu(OH)_2(c)$ were derived. The results obtained are presented as follows.

Chemical Reaction	$\Delta Hr^\circ_{298.15}$ kcal/mol	$\Delta Hf^\circ_{298.15}$ kcal/mol	Reference
$Cu(OH)_2(c) = Cu^{++}(aq) + 2\ OH^-(aq)$	10.06	-104.61	(1)
$Cu(OH)_2(c) = Cu^{++}(aq) + 2\ OH^-(aq)$	9.97	-104.52	(2)
$CuO(c) + H_2O(l) = Cu(OH)_2(c)$	-1.9	-107.5	(3)
$CuO(c) + H_2O(l) = Cu(OH)_2(c)$	0.3	-105.3	(4)

The heats of solution of CuO(c) and $Cu(OH)_2(c)$ in HNO_3(aq.) have been determined by (3) de Forcrand, Compt. rend. 157, 441 (1913) to be -16.38 and -14.46 kcal/mol, respectively. From these data the enthalpy change for the reaction $CuO(c) + H_2O(l) = Cu(OH)_2(c)$ was derived as -1.9 kcal/mol. For the same reaction, the enthalpy change was reported to be 0.3 kcal/mol by (4) P. Sabatier, Compt. rend. 125, 301 (1897). Based on $\Delta Hf^\circ_{298.15}$ = -37.25 and -68.315 kcal/mol for CuO(c) and $H_2O(l)$, respectively, the heat of formation for $Cu(OH)_2(c)$ was evaluated. The results obtained are presented in the above table.

Heat Capacity and Entropy.

The heat capacities, 298.15-700°K, were estimated by comparison with those for CuO(c), CaO(c) and $Ca(OH)_2(c)$. The Cp values above 700°K were obtained by graphical extrapolation. $S^\circ_{298.15}$ was estimated such that the derived ΔGf° $(Cu(OH)_2, c)$ = ΔGf° (CuO, c) + ΔGf° (H_2O, g) at 433°K.

Decomposition Temperature.

Td is the temperature at which the Gibbs energy change for the reaction $Cu(OH)_2(c) = CuO(c) + H_2O(g)$ equals zero.

Copper Monoxide (CuO)

COPPER MONOXIDE (CuO) (CRYSTAL) GFW = 79.5394

$\Delta Hf^\circ_0 = -36.71$ kcal/mol

$S^\circ_{298.15} = 10.18 \pm 0.1$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -37.25 \pm 0.5$ kcal/mol

Td = 1395°K

Heat of Formation.

The more consistent data relative to the heat of formation are reviewed below. The selected value of -37.25 kcal/mol was derived from $\Delta Hf^\circ_{298} = -40.7$ kcal/mol for $Cu_2O(c)$ and $\Delta Hr^\circ_{298} = 33.80$ kcal/mol for $2CuO(c) = Cu_2O(c) + 0.5\ O_2$. Four different sets of oxygen dissociation pressure measurements yield heats of reaction in close agreement with each other and with the aqueous calorimetry of Thomsen. Thomsen's data may be reduced to the heat of reduction of CuO(c) with H_2 by combining heats of reaction for $CuO + H_2SO_4$, $Fe + H_2SO_4$, and $Fe + CuSO_4(aq)$. Direct calorimetric measurement of the heat of reduction by von Wartenberg and Werth yields $\Delta Hf^\circ_{298} = -38.04 \pm 0.2$ when corrected for incomplete condensation of water. Direct measurement is difficult and this value may correspond to incomplete reduction. The value of -33.02 reported by Wöhler and Jochum, Z. physik. Chem. 167A, 169 (1933), is unreasonable. Equilibrium constants derived from Balesdent and Chiche yield -37.6 kcal/mol by third law analysis, but a serious entropy error is present. This is no doubt due to uncertainties in the activity of Cu in Cu-Au alloys. Other data have been reviewed by Randall, Nielsen and West, Ind. Eng. Chem. 23, 388 (1931).

Heat Capacity and Entropy.

Low temperature values are based on data (15-297°K) from J. Hu and H. L. Johnston, J. Am. Chem. Soc. 75, 2471 (1953). Earlier data from R. W. Millar (71-302°K), J. Am. Chem. Soc. 51, 215 (1929), are in satisfactory agreement, while those of K. Clusius and P. Harteck (30-200°K), Z. physik. Chem. 134, 243 (1928), are higher by several percent. A small anomaly in the heat capacity is observed in the region 210-230°K. Magnetic measurements of M. O'Keefe and F. S. Stone, Phys. Chem. Solids 23, 261 (1962), and neutron diffraction studies of B. N. Brockhouse, Phys. Rev. 94, 781 (1954), suggest that this is a Néel point associated with antiferromagnetism. The entropy was obtained from the heat capacities based on $S^\circ_{15} = 0.016$ eu.

High temperature values are based on specific heats (373-1273°K) obtained from a dynamic method by D. M. Chizhikov and A. S. Khirik, Tr. Inst. Met. im. A. A. Baikova, Akad. Nauk SSSR, No. 12, 79 (1963); cf. Chem. Abs. 59, 5800 b (1963). Enthalpy data (523-1253°K) of Wöhler and Jochum, loc. cit., lead to a value for S°_{1200} lower by about 0.25 eu, but this is inconsistent with the equilibrium data for $2CuO = Cu_2O + 0.5\ O_2$.

Temperature of Decomposition.

T_d is calculated as the temperature at which ΔF equals zero for $2CuO(c) = Cu_2O(c) + 0.5\ O_2(g)$.

Heat of Formation

The heat of formation is calculated from that of the crystal, ΔHs°_{298} = 96.1 kcal/mol, which was obtained by 3rd law analysis of the sublimation pressure at 1273°K reported by Mack et al. (1). They employed a transpiration method and analysed for copper (in minute amounts) by its catalytic effect on the oxidation rate of sodium sulfite. The resulting pressure is only 100 times the predicted pressure of Cu(g) over CuO(c). Three pressures were reported but not used in the range 873-1173°K, since these yield a much smaller value for the heat of vaporization and imply a high dissociation energy.

Some estimates of D°_0 CuO obtained by different methods are given below. These estimates along with a correlation of D°_0 values for MnO, FeO, NiO and ZnO favor D°_0 = 82 ± 10, close to the value adopted.

Method	kcal/mol ΔHs°_{298}	D°_0	ΔHf°_{298}
Mack et al. (1) Transpiration	96.1	80.8	58.9
Arithmetic mean of D°_0 for O_2 and Cu_2		82	57.7
Geometric mean of D°_0 for O_2 and Cu_2		73	66.7
Linear Birge Sponer extrapolation of $A^2\Pi$ state		76±12	63.7±12

Heat Capacity and Entropy

The visible spectrum of CuO has been extensively investigated, but only very recently has significant progress been made in its analysis. Antic-Jovanovic et al. (2) were able to obtain a vibrational analysis of the major band system by use of O^{18} isotope studies. Shirk and Bass (3) recently reported absorption and fluorescence spectra in inert-gas matrices which allows assignment of the ground state and the first two excited states. They have strong evidence for the lower state of the blue system being the ground state and also for the second system, which corresponds to the red-orange system, originating in the upper state of the blue system. Thus, it is probable that the B state is $^2\Sigma$ and the X and A states are both $^2\Pi$ with very similar molecular constants, which serves to confuse the analysis of the spectra. It also appears likely that the 4182Å band analysed by Lagerqvist and Uhler (4) is a $^2\Pi$-$^2\Pi$ transition terminating in the ground state; thus we adopt their rotational constants for the X and C states. The vibrational frequencies and anharmonicities for the A and B states were from Antic-Jovanovic (2), as well as the vibrational interval for the ground state. The anharmonicity for the ground state was chosen so as to provide a reasonable Birge-Sponer extrapolation of the dissociation energy. The values of the α_e were estimated from the Morse potential function relations. The rotational constants were assumed to be nearly constant. The values of the splitting in the electronic levels in the X and A states are from Antic-Jovanovic (2), and are roughly confirmed by Shirk and Bass (3).

The thermodynamic functions were calculated by summing over the individual partition functions for the separate states.

COPPER SULFATE ($CuSO_4$) (CRYSTAL) GFW = 159.6016

$S^\circ_{298.15}$ = 26.11 ± 0.1 gibbs/mol

Td = 1078°K

ΔHf°_0 = -181.66 ± 0.2 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -184.03 ± 0.2 kcal/mol

Heat of Formation.

The heat of solution ($\Delta Hr^\circ_{298.15}$) of CuO(c) in sulfuric acid to form $CuSO_4$(c) has been measured by L. H. Adami and E. G. King, U. S. Bur. Mines RI 6617, 1965. From the reported value, ΔHr° = -5.61 ± 0.09 kcal/mol for the reaction $CuO(c) + H_2SO_4(7.068\ H_2O) = CuSO_4(c) + H_2O(l)$, the heat of formation ($\Delta Hf^\circ_{298.15}$ for $CuSO_4$(c) was evaluated as -184.03 kcal/mol, using $\Delta Hf^\circ_{298.15}$ = -37.25, -209.49 and -68.315 kcal/mol for CuO(c), $H_2SO_4(7.068\ H_2O)$ and $H_2O(l)$, respectively. See $Fe_2(SO_4)_3$(c) table for the sources of the last two $\Delta Hf^\circ_{298.15}$ values.

The equilibrium pressures for the following chemical reactions: (A) $2CuSO_4(c) = CuO\cdot CuSO_4(c) + SO_3(g)$, (B) $3Cu(c) + CuSO_4(c) = 2Cu_2O(c) + SO_2(g)$, and (C) $4CuSO_4(c) + Cu_2O(c) = 3CuO\cdot CuSO_4(c) + SO_2(g)$, were determined by several investigators. For reaction (A), the partial pressures of SO_3(g) at different temperatures were calculated from the measured total pressures exerted by SO_3(g), SO_2(g) and O_2(g) produced by the reaction $SO_3(g) = SO_2(g) + 1/2\ O_2(g)$. From these vapor pressure data, the corresponding enthalpy changes ($\Delta Hr^\circ_{298.15}$) for the three reactions were evaluated by the second and third law methods. The results obtained are presented in the following table. The value of $\Delta Hf^\circ_{298.15}$ ($CuSO_4$, c) adopted was -184.03 ± 0.2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities, 52.67-296.29°K, were obtained from W. W. Weller, U. S. Bur. Mines RI 6669, 1965. The high temperature heat capacities were measured by H. Schottky, Z. phys. Chem. 64, 415 (1908), 282°C; R. Ewald, Ann. Physik., 44, 1213 (1914), 275-373°K; A. N. Krestovnikov and E. J. Feigina, J. Gen. Chem. USSR, 6, 1481 (1936), 288-873°K; and D. M. Chizhikov and A. S. Khirik, Tr. Inst. Met. im. A. A. Baikova, Akad. Nauk SSSR, No. 12 79-84 (1963), 373-1273°K. The heat capacities below 51°K were obtained from J. W. Stout, J. Chem. Phys. 9, 285 (1941). In that paper, the Cp values, 15-58°K, were plotted as function of temperature and the Cp curve shows a maximum at 34.8°K. In an attempt to evaluate the entropy due to the anomalous portion of the curve, a "normal" heat capacity curve was drawn. The entropy above the normal Cp curve is reported to be 0.48 eu, rather than a magnetic entropy of Rln2 = 1.377 eu. Apparently the magnetic entropy increases gradually above 40°K so that it is not feasible to separate the heat capacity due to magnetic effects from that of the crystal lattice.

The Cp values above 298.15°K were extrapolated smoothly by comparison with those for $MnSO_4$(c) (see $FeSO_4$(c) table for details). The adopted Cp values are close to the average of the reported Cp values.

The value of $S^\circ_{298.15}$ was derived using the low temperature Cp data reported by W. W. Weller, loc. cit., based on S°_{51} = 2.851 eu evaluated from Cp data determined by J. W. Stout, loc. cit.

Decomposition Temperature.

Td is the temperature at which the total pressure of the gaseous decomposition products equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for $CuSO_4$(c), determined by T. R. Ingraham, loc. cit.

Heat of Formation.

The heat of formation was calculated from that of Cu(g) using ΔHr_{298}° = 46.0 kcal/mol for $Cu_2(g) \rightarrow 2\ Cu(g)$ obtained by third law analysis of the mass spectrometric data of Ackerman et al. Earlier studies of mass spectra and of the electronic band spectra yield values in reasonable agreement as shown below. The selected ΔHr° corresponds to D_0° = 1.97 eV compared with the linear Birge-Sponer extrapolation of 2.1 eV.

Heat Capacity and Entropy.

Molecular constants, except for $\omega_e x_e$, were taken from the rotational analysis of bands of the B-X system given by D. N. Travis and R. F. Barrow, Proc. Chem. Soc. (London), 44 (1962). The value for $\omega_e x_e$ was obtained from the earlier study of Kleman and Lindquist, loc. cit., who showed by means of the vibrational isotope effect that the emitter was Cu_2. The spectroscopic characters of the ground and excited states are uncertain, but Travis and Barrow indicate that the transition is probably $^1\Sigma^+_u - {}^1\Sigma^+_g$ for the B-X system. Vibrational and rotational constants were adjusted for 30.91% ^{65}Cu.

June 30, 1966

DICOPPER MONOXIDE (Cu_2O) (CRYSTAL) GFW = 143.0794

ΔHf°_0 = -40.31 kcal/mol

$S^\circ_{298.15}$ = 22.21 ± 0.08 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -40.7 ± 0.5 kcal/mol

Tm = 1509°K

ΔHm° = 13.58 ± 2 kcal/mol

Heat of Formation.

Summarized below are the more consistent results for the heat of formation. The selected value of -40.7 kcal/mol is based on data from Thomsen and from Ishakawa and Kimura. More recent equilibrium data yield essentially the same average for ΔHf but the separate values scatter by about ±0.7 kcal/mol and significant entropy errors are apparent.

Thomsen obtained values of -40.80, -40.87 and -41.51 from aqueous calorimetry using three different paths. He favored the first path which may be recalculated by combination of the heats of reaction of $Cu_2O + H_2SO_4$, $Fe + H_2SO_4$ and $Fe + CuSO_4(aq)$ to yield the heat of reduction of Cu_2O with H_2. Direct measurements of the heat of reduction reported by L. Wöhler and N. Jochum, Z. physik. Chem. 167A, 169 (1933), appear to be unreliable since they lead to -43.0 for the heat of formation. The cell data of Ishakawa and Kimura show very little drift and are in excellent agreement with Thomsen.

Heat Capacity and Entropy.

Low temperature values are based on data from L. V. Gregor (2.8-21°K), J. Phys. Chem. 66, 1645 (1962) and from J. Hu and H. L. Johnston (15-300°K), J. Am. Chem. Soc. 73, 4550 (1951). Earlier data by R. W. Millar (76-291°K), J. Am. Chem. Soc. 51, 215 (1929) are in satisfactory agreement. The entropy was obtained from the heat capacities based on $S^\circ_{2.8}$ = 0.0015 eu.

High temperature values were obtained from specific heats (373-1273°K) determined with a dynamic method by D. M. Chizhikov and A. S. Khirik, Tr. Inst. Met. im A. A. Baikova, Akad. Nauk SSSR, No. 12, 79 (1963); cf. Chem. Abs. 59, 79 (1963). Enthalpy data (543-1223°K) from Wöhler and Jochum, loc. cit., yield for S°_{1000} a value about 0.4 eu higher, but this is inconsistent with extensive equilibrium data for $2CuO(c) = Cu_2O(c) + 0.5\ O_2$ [see CuO(c)].

Melting Data.

For details see $Cu_2O(l)$.

Cu_2O

DICOPPER MONOXIDE (Cu_2O) (LIQUID) GFW = 143.0794

$S^\circ_{298.15}$ = 22.901 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -32.029 kcal/mol

Tm = 1509°K

ΔHm° = 13.58 ± 2 kcal/mol

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔHm° and the difference between ($H^\circ_{1509}-H^\circ_{298}$) for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated on the basis of 8 gibbs per g atom, giving a value of 24 gibbs/mol which is essentially the same as that of the crystal at the melting point. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

Tm is the value recommended by S. J. Schneider, NBS Monograph 68, U. S. Govt. Printing Office, Washington, D.C., October, 1963, based on pressure-temperature-composition studies of H. S. Roberts and F. H. Smyth, J. Am. Chem. Soc. 43, 1061 (1921). The heat of melting was selected as 13.58 kcal/mol, corresponding to ΔSm° = 3 eu per g atom. A value of 13.4 kcal/mol has been derived from the Cu_2O-CuCl phase diagram by K. K. Kelley, USBM Bulletin 393, U. S. Govt. Printing Office, Washington, 1936. Another value may be obtained from oxygen dissociation pressures for the system $Cu_2O(l)$-CuO(c) determined by Roberts and Smyth, loc. cit. Equilibrium constants may be obtained for the reaction $2CuO(c) = Cu_2O(l) + 0.5\ O_2$ by assuming the activity of Cu_2O in the melt to be equal to its mole fraction. Based on the mole fractions given by Randall, Nielsen and West, Ind. Eng. Chem. 23, 388 (1931), the equilibrium data yield ΔH°_m = 15.8 ± 0.8 kcal/mol by second law analysis of all points or 12.9 ± 1.6 by omission of 4 points at high pressure and low mole fraction. These results appear to be consistent with the selected value within the approximations involved.

COPPER OXIDE SULFATE ($CuO \cdot CuSO_4$) (CRYSTAL) GFW = 239.141

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [37.6 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -221.7 ± 0.3 kcal/mol

Td = 1138.4°K

Heat of Formation.

The equilibrium pressures for the following reactions: (A) $CuO \cdot CuSO_4(c) = 2CuO(c) + SO_3(g)$ and $SO_3(g) = SO_2(g) + 0.5\ O_2(g)$, and (B) $CuO \cdot CuSO_4(c) + Cu_2O(c) = 4CuO(c) + SO_2(g)$, were determined by (1) W. Reinders and F. Goudriaan, Z. anorg. allgem. Chem. 126, 85 (1923), and (2) T. R. Ingraham, Trans. Met. Soc. AIME, 233, 359 (1965). Using the reported vapor pressures, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

Reference	Reaction	Temperature, °K	$\Delta Hr^\circ_{298.15}$, kcal/mol Second Law Value	Third Law Value	Drift eu	$\Delta Hf^\circ_{298.15}$* kcal/mol
(1)	A**	1013 - 1093	53.03 ± 2.53	52.43	-0.7 ± 2.4	-221.5
(1)	B	917 - 1027	41.72 ± 1.42	42.43	0.5 ± 1.4	-221.7
(2)	A**	969 - 1138	50.92 ± 0.16	52.57	1.5 ± 0.2	-221.7

* Based on the third law value for $\Delta Hr^\circ_{298.15}$.

** Partial pressures were calculated from JANAF Values for the SO_3 - SO_2 equilibrium.

The value of $\Delta Hf^\circ_{298.15}$ ($CuO \cdot CuSO_4$, c) adopted is -221.7 ± 0.3 kcal/mol.

Heat Capacity and Entropy.

The heat capacities were calculated as the sum of those for CuO(c) and $CuSO_4$(c). The value of $S^\circ_{298.15}$ was estimated by comparison with those for CuO(c) and $CuSO_4$(c), and adjusted so that, using the derived free energy functions, the second and third law values for $\Delta Hr^\circ_{298.15}$ agree reasonably.

Decomposition Temperature.

Td is the temperature at which the total pressure of the gaseous decomposition products of reaction (A) equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for $CuO \cdot CuSO_4$(c), determined by T. R. Ingraham, loc. cit.

Heat of Formation.

The dissociation energy (D_o) of fluorine has been discussed by numerous investigators for many years. Until about fifteen years ago, high values of $D_o(F_2)$, about 63 kcal. mole^{-1}, were widely accepted. These values were obtained from extrapolations of the spectroscopic data for the halogens, e.g. D_o = 63.3 kcal. mole^{-1} was reported by H. V. Wartenberg, G. Sprenger and J. Taylor, Z. physik. Chem., Bodenstein-Festband, 61 (1931). However, meanwhile many indirect determinations as well as estimation have been carried out, which yield appreciably lower values. In 1950 the available data were examined critically by M. G. Evans, E. Warhurst and E. Whittle, J. Chem. Soc. 1524 (1950) and shown to support a value, $D_o(F_2)$ = 37 ± 8 kcal. mole^{-1}. The indirect determinations include (1) the thermal conductivity measurements by E. U. Franck and E. Wicke, Z. Elektrochem. 55, 643 (1951); (2) the explosion method by H. Friz. Dissert., Göttingen, 1952; (3) estimation by use of the relations between D_o and the vibrational frequencies by A. Eucken and E. Wicke, Naturwiss., 37, 233 (1950); and (4) spectroscopic data on the dissociation energy of diatomic fluorides. Recently more direct methods have been used to determine $D_o(F_2)$. They gave similar values. The D_o values reported by the previous investigators have been reviewed by L. Haar and C. W. Beckett, National Bureau of Standards Report 1435 (1952), and E. Wicke and H. Friz. Z. Elecktrochem. 57, 9 (1953).

The low bond dissociation energy of $F_2(g)$ has been attributed to the repulsion between the unshared electrons on the bound fluorine atoms by K. S. Pitzer, J. Am. Chem. Soc. 70, 2140 (1948), or to the absence in fluorine of strengthening of the bond by hybridization of the p- or d- orbitals as may take place in the higher halogens by R. S. Mulliken, J. Am. Chem. Soc. 77, 884 (1955). M. G. Brown, Trans. Faraday Soc. 55, 9 (1959) suggests that the observed low D_o value results from the large energy required to promote the F atoms to the valence state from which the bond may be formed.

The equilibrium pressures for the reaction $F_2(g) \rightarrow 2F(g)$ have been measured by several investigators. Using the reported equilibrium constants, the dissociation energy, $D_{298.15}$, was evaluated by both the second and third law methods. The results obtained are presented as follows.

	$D_{298.15}$, kcal. mole^{-1}		
Temperature, °K.	2nd Law Value	3rd Law Value	Reference
759 - 1115	36.91 ± 0.41	37.76	1
810 - 860	56.7 ∓ 18.2	33.1	2
513 - 790	34.4 ∓ 1.8	38.0	3
723 - 820	41.8 ∓ 0.2	—	4

2. P. W. Gilles and J. L. Margrave, J. Chem. Phys. 21, 381 (1953).
3. H. Wise, J. Phys. Chem. 58, 389 (1954).
4. M. Farber, et al. "Study of Rocket Engine Exhaust Products", Thirteenth Quarterly Report, June 1 - Oct. 31, 1964, Maremont Corporation, Pasadena, California.

By use of H_2-F_2 mixture explosion method, $D_o(F_2)$ was reported as 37 ± 2 kcal. mole^{-1} by E. Wicke and H. Friz. loc. cit. K. L. Wray and D. F. Hornig, J. Chem. Phys. 24, 1271 (1956), using shock wave method, obtained D_o = 31.0 ± 4.3 kcal. mole^{-1}. The continuous absorption electronic spectrum of $F_2(g)$ and the Raman displacement for the 0 → 1 vibrational transition have been used by A. L. G. Rees, J. Chem. Phys. 26, 1567 (1957) to compute the potential energy curve for the repulsive $_1\Pi_u$ state dissociating to two normal F(g). This curve is consistent with the value, D_o = 37.1 ± 0.85 kcal. mole^{-1}. The absorption spectrum of $F_2(g)$ has been observed in the vacuum UV region by R. P. Iczkowski and J. L. Margrave, J. Chem. Phys. 30, 403 (1959). From a progression of bands at 874A, the value, D_o = 37.5 ± 2 kcal. mole^{-1} is deduced.

The F_2 dissociation energy is selected as 37.72 ± 0.80 kcal. mole^{-1}, yielding $\Delta H_f^\circ{}_{298.15}(F, g)$ = 18.86 ± 0.40 kcal. mole^{-1}.

Heat Capacity and Entropy.

The ground state configuration, electronic levels and quantum weights were taken from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

FLUORINE UNINEGATIVE ION (F^-)   (IDEAL GAS)   MOL. WT. = 18.99895

Ground State Configuration $^1S_0$

$S^\circ_{298.15}$ = 34.768 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = -61.1 ± .5 kcal/mole

$\Delta H^\circ_{f\ 298.15}$ = -62.2 ± .5 kcal/mole

Electronic Levels and Quantum Weight

$\mathcal{E}_1$, cm.$^{-1}$	g_1
0.00	1

Heat of Formation.

The heat of formation was calculated from the equation: $F(g) + e^- \rightarrow F^-(g)$ with the JANAF auxiliary value for F(g); using the measured electron affinity = 3.448 e.v. (79.511 kcal/mole) obtained from R. S. Berry and C. W. Reimann, J. Chem. Phys. 38, 1540 (1963). Other calculated values for the electron affinity are: 3.37 reported by E. Clementi and A. D. McLean, Phys. Rev. 133, A419 (1964); 3.08 e.v. E. Clementi, A. D. McLean, D. L. Raimondi, and M. Yoshimine, 133, A1274 (1964); 3.50 e.v. B. Edlen, J. Chem. Phys. 33, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Neon. The electronic levels above 1 X 10^5 cm^{-1} were omitted because their contribution is negligible below 6000°K. The $H^\circ-H^\circ_{298}$ value at 0°K. is -1.481 kcal/mole.

Sept. 30, 1965

IRON MONOFLUORIDE (FeF) (IDEAL GAS) MOL. WT. = 74.8454

Ground State Configuration $[^6\Sigma]$

$\Delta H^\circ_{f\ 0}$ = [11.4 ± 5.0] kcal. mole^{-1}

$S^\circ_{298.15}$ = [57.4] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [11.4 ± 5.0] kcal. mole

Electronic Levels and Quantum Weight

ϵ, cm.$^{-1}$	g_1
0	[6]

ω_e = [630.0] cm.$^{-1}$

$\omega_e x_e$ = [2.7] cm.$^{-1}$

σ = 1

B_e = [0.3670] cm.$^{-1}$

α_e = [0.0017] cm.$^{-1}$

r_e = [1.8] Å

Heat of Formation.

The Dissociation energy (D_o) of FeF(g) was estimated as 4.64 ± 0.22 e.v. or 107 ± 5 kcal. mole^{-1} by J. L. Margrave, "Optical Spectra and Molecular Parameters of Light Element Molecules", Progress Report No. 8, Jan. 1 to Mar 31, 1965, William Marsh Rice University, Houston, Texas. From the value of D° (Fe-F) the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for FeF(g) was derived to be 11.4 ± 5.0 kcal. mole^{-1}.

Heat Capacity and Entropy.

The ground state configuration and bond distance (r_e) were estimated by comparison with those for FeCl(g). The value of B_e was calculated using the relationship $B_e = \frac{2.79889 \times 10^{-39}}{I}$ where I = moment of inertia of FeF(g), and α_e was estimated by comparison with those for AlF(g), AlCl(g) and FeCl(g). The value of ω_e was derived from the bond distance, reduced mass and number of valence electrons according to the method given by K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 456 (1946), and the $\omega_e x_e$ was estimated from those for AlF(g), AlCl(g) and FeCl(g). The moment of inertia is 7.6259 X 10^{-39} g. cm.^{2}

Dec. 31, 1960; Mar. 31, 1961; Dec. 31, 1963; Dec. 31, 1968

HYDROGEN FLUORIDE (HF) (IDEAL GAS) GFW = 20.00637

Ground State Configuration $^1\Sigma^+$

ΔHf°_0 = -65.13 ± 0.2 kcal/mol

$S_{298.15}$ = 41.508 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -65.14 ± 0.2 kcal/mol

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	1

ω_e = 4138.32 cm^{-1} $\omega_e x_e$ = 89.88^{-1} σ = 1

B_e = 20.9557 cm^{-1} α_e = 0.798^{-1} r_e = 0.9168 Å

Heat of Formation

The selected value is obtained from a least squares, simultaneous solution (1) for the heats of formation of HF(g), HF(50 H_2O) and five closely related fluorides. Other results, based on 23 selected observations relating the 7 variables, are as follows in kcal/mol: HF(50 H_2O), -76.78 ± 0.1; NaF(c), -137.52 ± 0.2; BF_3(g), -271.42 ± 0.4; CF_4(g), -223.04 ± 0.3; NF_3(g), -31.43 ± 0.3; and C_2F_4(polymer), -198.2 ± 0.7. The ± values are approximate estimates of the overall uncertainty including systematic error. Further details of the simultaneous solution are given in (1).

The values given above require the use of certain auxiliary data; e.g., the value for NaF(c) presumes ΔH°_σsoln = 0.23 ± 0.01 and $\Delta Hf^\circ_{298.15}[Na^+(\infty\ H_2O)]$ = -57.47 ± 0.04 kcal/mol. Use of these auxiliary data leads to $\Delta Hf^\circ_{298.15}$ = -79.82 kcal/mol for HF(∞ H_2O) and F^-(∞ H_2O); however, values for HF(n H_2O) should be obtained from that of HF(50 H_2O) by use of $[\phi_L(n) - \phi_L(50)]$ taken from the tables of Parker (2). This procedure should be reliable except in dilute solutions (n > 1000) where the equilibria $HF \rightarrow H^+ + F^-$ and $HF + F^- \rightarrow HF_2^-$ yield an overall ΔH of about 3 kcal/mol. Parker (2) used thermodynamic data for these equilibria in order to calculate ϕ_L for the dilute solutions, but recent data (3-5) suggest that minor changes in the calculations may be desirable. For this reason the simultaneous solution includes $\phi_L(50)$ = 3184 ± 300 cal/mol (2) as an "observation" rather than as a fixed value. The result of the simultaneous solution is smaller by only 150 cal/mol, suggesting that $\phi_L(50)$ does not contain a major inconsistency.

Heat Capacity and Entropy

The ground state configuration is that deduced from UV spectra by Johns and Barrow (6). The excited state near 85000 cm^{-1} is omitted since its contribution to the thermodynamic functions in negligible. High-resolution studies of the vibration-rotation spectrum were reported by Mann et al. (7) and subsequently confirmed by others (8, 9). The analysis of Webb and Rao (9) is adopted for this table.

HYPOFLUOROUS ACID (HFO) (IDEAL GAS) MOL. WT. = 36.00577

Point Group C_s

$S^\circ_{298.15}$ = [53.954] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = [-30 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-31 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[1500] (1)
[1065] (1)
[3645] (1)

Bond Distance: H-O = [0.98] Å O-F = [1.41] Å

Bond Angle: H-O-F = [104]° $\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.2826 X 10^{-117}] g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for HFO(g) was calculated based on an estimated value for the heat of atomization i.e. ΔH°_r = 161.6 kcal. mole^{-1} for the reaction HFO(g) = H(g) + F(g) + O(g). The ΔH°_r value was assumed to be the sum of the F-O and H-O bond energies which were obtained from the corresponding bond energies in $F_2O(g)$ and $H_2O(g)$ molecules.

Heat Capacity and Entropy.

The H-O and F-O bond distances were assumed to be the same as those in the $H_2O(g)$ and $F_2O(g)$ molecules. The vibrational frequencies and H-O-F bond angle were estimated by comparison with the corresponding values for $H_2O(g)$, $F_2O(g)$ and $Cl_2O(g)$. The three principal moments of inertia are I_A = 0.1332 X 10^{-39}, I_B = 3.0366 X 10^{-39} and I_C = 3.1699 X 10^{-39} g. cm.^{2}

Heat of Formation

A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall, London 1953, gives 32 ± 12 kcals for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. Rotational constants were estimated using equation III, 123 p. 108, G. Herzberg (loc. cit.). Bond length estimated by comparison of the mercurous halides with thalium and cesium halides.

B_e = 0.2799 cm.$^{-1}$

$\omega_e x_e$ = 4 cm.$^{-1}$

α_e = 0.00763 cm.$^{-1}$

r_e = 1.906 Å

σ = 1

Heat of Formation.

R. A. Durie and A. G. Gaydon, J. Phys. Chem. 56, 316 (1952), have obtained the dissociation limit (from the spectra) of IF as 23570 cm.$^{-1}$ The first excited states of F and I are 404 and 7598 cm.$^{-1}$ above the ground state respectively. There are two sets of dissociation products possible: $I(^2P_{1/2}) + F(^2P_{3/2})$ or $I(^2P_{3/2}) + F(^2P_{1/2})$. When corrected to the normal atoms, the observed limit gives $D_0(IF(g))$ 2.87 ± 0.04 e.v. or 66.18 ± 0.9 kcal. mole^{-1} and 1.98 ± 0.04 e.v. or 45.66 ± 0.9 kcal. mole^{-1} for dissociation energy respectively. Durie and Gaydon, loc. cit., favored the lower value. However L. Slutsky and S. H. Bauer, J. Am. Chem. Soc. 76, 270 (1954) have pointed out a numerical error in their calculations, which removes the chief support for the lower value and presented additional evidence favoring the higher value. More weight was given to the higher value which gives $\Delta H^\circ_{f\ 298.15}$ = -22.648 ± 0.9 kcal. mole^{-1} for the reaction 1/2 $I_2(c)$ + 1/2 $F_2(g)$ = IF(g).

Heat Capacity and Entropy.

All molecular constants were obtained from W. H. Evans, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bur. of Standards 55, 147 (1955) except r_e = 1.906 Å was obtained from L. G. Cole and G. W. Elverun Jr., J. Chem. Phys. 20, 1543 (1952) and ground state configuration was estimated by comparison with that for IBr and ICl from G. Herzberg,"Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

Dec. 31, 1961; Dec. 31, 1963; June 30, 1969

POTASSIUM FLUORIDE (KF) (CRYSTAL) GFW = 58.1004

ΔHf°_0 = -135.5 ± 0.1 kcal/mol

$S^\circ_{298.15}$ = 15.905 ± 0.05 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -135.9 ± 0.1 kcal/mol

Tm = 1131°K

ΔHm° = 6.50 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 57.8 kcal/mol (to monomer)

Heat of Formation

The heat of solution of KF(c) in water has been measured by several investigators. Their results have been converted to ΔH°_∞ by Parker (5) and listed in the table below. Using $\Delta H^\circ_\infty = -4.24$, $\Delta Hf^\circ_{298}(K^+, \infty H_2O) = -60.32$ (6), and $\Delta Hf^\circ_{298}(F^-, \infty H_2O) = -79.82$ kcal/mol (7), we obtain $\Delta Hf^\circ_{298} = -135.9 \pm 0.1$ kcal/mol which is adopted.

Investigator	Temperature, °K	Concentration, molality	No. of Determinations	ΔH°_∞, kcal/mol
1. Guntz (1884)	291	0.28	1	-3.95
2. Forcrand (1911)	288	0.50	1	-4.54
3. Lange and Eichler (1927)	298	3.16 - 0.21	8	-4.24±0.4
4. Lange and Martin (1937)	298	0.31	1	-4.01

Heat Capacity and Entropy

The low temperature heat capacities, 16-323°K, were measured by Westrum and Pitzer (8). The high temperature enthalpies, 298-530°K and 291-1187°K, were determined by Westrum and Pitzer (8), and Lyashenko (9), respectively. However, the high temperature Cp values derived from both sets appear to be inconsistent with the low temperature Cp values. The heat capacities derived from the enthalpy data of Westrum and Pitzer are too high (3% at 530°K and less at lower temperatures) to be joined smoothly with their low temperature Cp's. The adopted enthalpy at 530°K is about 1.4% lower than the reported value. The heat capacity derived from the enthalpy data of Lyashenko is 2.5% lower than the adopted one at 900°K. The differences are smaller at lower temperatures. At 900°K, the adopted enthalpy is 1.3% higher than the reported value. The adopted heat capacities in the temperature range, 323-2000°K, are estimated by graphical comparison with other alkali fluorides and chlorides, and joined smoothly with the low temperature data at 298°K.

S°_{298} is derived based on the adopted low temperature heat capacities.

Melting Data

See the KF(ℓ) table.

Heat of Sublimation

The value of ΔHs°_{298} is obtained as the difference between ΔHf°_{298} for KF(c) and KF(g).

Dec. 31, 1961; Dec. 31, 1963; June 30, 1969

POTASSIUM FLUORIDE (KF) (LIQUID) GFW = 58.1004

$S^\circ_{298.15}$ = 16.167 gibbs/mol $\Delta Hf^\circ_{298.15}$ = -132.519 kcal/mol

Tm = 1131°K ΔHm° = 6.50 kcal/mol

Tb = 1790°K ΔHv°(to mixture) = 33.9 kcal/mol of liquid

Heat of Formation

The $\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{1131} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those of the alkali fluorides and chlorides, and is assumed to be constant in the temperature range, 298-3000°K. The Cp value, 16 gibbs/mol, derived from the enthalpy data of Lyashenko (12) appears low and is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Tm has been reported as 1119 (1, 2), 1129 (3, 4), 1131 (5, 6), and 1153°K (7). The value 1131°K is adopted. Kelley (8) evaluated the following freezing-point data of binary systems: KF-AlF$_3$ (9), KF-K$_2$SO$_4$ (10), KF-KCl (11), KF-K$_2$CO$_3$ (13), and KF-K$_3$PO$_4$ (14), and derived the values of ΔHm° (in kcal/mol) as 5.5, 5.55, 6.51, 7.1, and 7.1 respectively. The best value is recommended as 6.50 kcal/mol. Other reported ΔHm° values are 6.70 (7) and 6.75 ± 0.1 kcal/mol (12). The value of heat of melting is tentatively adopted as 6.50 kcal/mol.

Vaporization Data

The boiling point (Tb) is calculated to be the temperature at which the partial pressures of KF(g) and $K_2F_2(g)$ equal one atmosphere. The composition of the gaseous mixture in equilibrium with KF(ℓ) at Tb is calculated as K_2F_2 21.1% and KF 78.9%. The heat required to vaporize one mole of liquid at Tb is evaluated to be 33.9 kcal.

The experimental values for the boiling point are 1778°K (1) and 1771°K (15).

Heat of Formation

The total vapor pressures of KF(g) and K_2F_2(g) over KF(c, ℓ) have been determined by many investigators using the boiling point (1, 2, 5), Knudsen-effusion (3), transpiration (4), and torsion-effusion (6) methods. A method of trial and error is employed to select the appropriate values for ΔHs°_{298}(KF, c) and ΔHv°_{298}(KF, ℓ) such that by use of these two values and ΔHr°_{298} = 50 kcal/mol for the reaction $K_2F_2(g) = 2KF(g)$ and the Gibbs energy functions for KF(c), KF(ℓ), KF(g), and K_2F_2(g), the calculated total pressures of KF(g) and K_2F_2(g) are consistent with the measured ones. Adopting $\Delta Hs^\circ_{298} = 57.8$ and ΔHv°_{298} = 54.42 kcal/mol, we evaluate the partial pressures of KF(g) and K_2F_2(g) from the reported total pressure measurements. Based on the derived partial pressures for KF(g), the enthalpy changes for the processes: A. KF(c) = KF(g), and B. KF(ℓ) = KF(g) are calculated by the second and third law methods. Using the third law ΔHr°_{298} and ΔHf°_{298} = -135.90 and -132.519 kcal/mol for KF(c) and KF(ℓ), respectively, we obtain the ΔHf°_{298} for KF(g). The results are presented in the table below.

The dissociation energy (D_0) of KF(g) has been determined as 117 ± 8 kcal/mol by flame photometry by Page and Sugden (7), and Bulewicz, Phillips, and Sugden (8), yielding ΔHf°_{298}(KF, g) = -77.6 ± 8 kcal/mol. Barrow and Caunt (9) measured the fluctuation bands in the ultraviolet absorption spectra of KF and reported the upper limit for the D_0(KF, g) value to be 121.8 kcal/mol which leads to ΔHf°_{298}(KF, g) = -81.4 kcal/mol as the lower limit. Gaydon (10) reported D_0 = 116.9 ± 4.6 kcal/mol for KF(g). The corresponding value of ΔHf°_{298} is calculated as -77.5 ± 4.6 kcal/mol.

The heat of formation for KF(g) at 298°K is adopted as -78.1 ± 0.5 kcal/mol.

** Only the data point at 1233°K is adopted for evaluation.

Heat Capacity and Entropy

The rotational transition spectrum of KF(g) has been measured in the millimeter- and submillimeter-wave region with a high resolution molecular-beam absorption spectrometer by Veazey and Gordy (15). From the derived potential constants the vibrational constants were calculated. The reported values for ω_e, $\omega_e x_e$, B_e, α_e and r_e are adopted.

Other values of ω_e reported are (in cm^{-1}): 390 ± 39 (11), 405 ± 25 (9), 429 ± 3 (12), and 426 ± 4 (13). The value of $\omega_e x_e$ has been determined as 1.45 cm^{-1} by Barrow and Caunt (9), and 2.4 cm^{-1} by Ritchie and Lew (12) and Baikov and Vasilevskii (13). Using the molecular beam electric resonance method, Green and Lew (14) measured the rotational transitions between the J = 0 and J = 1 states of $K^{39}F$ and reported the following values: B_e = 0.27994 cm^{-1}, α_e = 0.002335 cm^{-1}, and r_e = 2.17144 ± 0.00005 Å which are in excellent agreement with the adopted values. By use of the same method, Grabner and Hughes (11) investigated the rotational Stark spectrum of $K^{39}F$ and reported the K-F bond distance for the zeroth vibrational state as 2.55 ± 0.06 Å.

Dec. 31, 1960; Sept. 30, 1962; Dec. 31, 1963; Dec. 31, 1968

LITHIUM FLUORIDE (LiF) (CRYSTAL) GFW = 25.9374

ΔHf°_0 = -146.84 ± 0.2 kcal/mol

$S^\circ_{298.15}$ = 8.523 ± 0.005 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -147.45 ± 0.2 kcal/mol

Tm = 1121.3 ± 1.0°K

ΔHm° = 6.474 ± 0.005 kcal/mol

$\Delta Hs^\circ_{298.15}$(to monomer) = 66.0 kcal/mol

Heat of Formation

The heats of solution and reaction of LiF(c) in water and hydrochloric acid have been measured by many investigators. The reported ΔHsoln values are listed in the table below. Using $\Delta Hf^\circ_{298}(Li^+, \infty H_2O)$ = -66.56 kcal/mol (8), and $\Delta Hf^\circ_{298}(F^-, \infty H_2O)$ = -79.82 kcal/mol (9), we calculate the corresponding ΔHf°_{298} values for LiF(c). Based on the heat of solution of LiOH(c) in excess HF solution measured by Sinke (7), the value, ΔHf°_{298}(LiF,c) = -146.65 ± 0.5 kcal/mol is derived. The value of ΔHf°_{298} for LiF(c) is adopted as -147.45 ± 0.2 kcal/mol

Investigator	Solvent	Temperature, °K	Concentration (LiF·nH_2O)	ΔHr, kcal/mol	ΔH°_∞, kcal/mol*	ΔHf°_{298}, kcal/mol

*The heat of dilution data of Parker (6) are used to convert ΔHr to ΔH°_∞.

Heat Capacity and Entropy

Clusius, Goldman, and Perlick (10) measured the low temperature heat capacities in the temperature range 19 to 272°K and Clusius and Eichenauer (11) from 10 to 111°K. Below 20°K a number of investigators have reported values of θ_D, and the average value of 729 ± 6 is used here. The high temperature enthalpies from 298°K to the melting point 1121.3°K were measured by Douglas and Dever (12), and Voskresenskaya et al. (13). All these data are taken and smoothed by computer up to 400°K. Above 400°K the Cp values are obtained graphically by drawing a smooth line through the data points.

S°_{298} is derived from the adopted low temperature heat capacities, based on S°_{20} = 0.064 eu.

Melting Data

See the LiF(ℓ) table for details.

Heat of Sublimation

The difference between ΔHf°_{298} for LiF(g) and LiF(c) is ΔHs°_{298}.

Dec. 31, 1960; Sept. 30, 1962; Dec. 31, 1963; Dec. 31, 1968

LITHIUM FLUORIDE (LiF) (LIQUID) GFW = 25.9374

$S^\circ_{298.15}$ = 10.269 gibbs/mol

Tm = 1121.3 ± 1.0°K

Tb = 1990°K

$\Delta Hf^\circ_{298.15}$ = -143.081 kcal/mol

ΔHm° = 6.474 ± 0.005 kcal/mol

ΔHv°(to mixture) = 35.08 kcal/mol

Heat of Formation

The $\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{1121.3} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

T. B. Douglas and J. L. Dever, J. Am. Chem. Soc. 76, 4826 (1954), and N. K. Voskresenskaya, V. A. Sokolov, E. I. Banashek, and N. E. Shmidt, Akad. Nauk SSSR, Izvest. Sekt. Fiz. - Khim. Anal. 27, 233 (1956), have measured the enthalpies of LiF liquid to 1200 and 1400°K, respectively. Using the reported enthalpy data, a constant heat capacity is derived for each set. The adopted Cp for LiF(ℓ) is the mean of the two derived heat capacities, and is extended arbitrarily to the temperatures above Tb and below Tm. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point has been determined by many investigators. See the table below for details. The adopted value, 1121.3 ± 1.0°K, is that reported by Douglas and Dever, loc. cit. The heat of melting is the mean of the ΔHm° values reported by Douglas and Dever, loc. cit., and Voskresenskaya et al., loc. cit.

Vaporization Data

Tb is the temperature at which the partial pressures of LiF(g), Li_2F_2(g), and Li_3F_3(g), in equilibrium with LiF(ℓ), equal one atmosphere. The vapor composition at the boiling point is evaluated as LiF 69%, Li_2F_2 26.6%, and Li_3F_3 4.4%. The heat required to vaporize one mole of liquid to form 0.739 mole of vapor mixture of the above composition at Tb is calculated to be 35.08 kcal.

The value of Tb for LiF(ℓ) has been reported to be 1943 and 1949°K by O. Ruff, G. Schmidt, and S. Mugdan, Z. Anorg. Allgem. Chem. 123, 83 (1922), and H. von Wartenberg and H. Schulz, loc. cit., respectively, which were obtained by extrapolation of their vapor pressure data, measured by the boiling point method.

Heat of Formation

The molecular species produced on vaporization of lithium fluoride have been studied by many investigators during the last ten years. The occurrence of dimer and trimer molecules in addition to the monomer has been established by use of mass spectrometric (4, 7, 8), torsion effusion (3, 6), molecular beam (9, 10), and transpiration (11) methods. To evaluate ΔHv°(LiF,g), we have used a trial and error variation of ΔHs° and ΔHv° for the monomer, dimer and trimer in order to obtain reasonable agreement with the observed total pressures, 997-1939°K, (1, 2, 3, 5, 6). Using, as guidelines, these total pressures and the equilibrium data for dimer and trimer (see these tables), we adopt ΔHs°_{298} = 66.0, 69.57 and 79.73 and ΔHv°_{298} = 61.63, 60.83 and 66.62 kcal/mol for LiF, Li_2F_2 and Li_3F_3, respectively. The adopted value ΔHs°_{1000} = 63.1 kcal/mol is in agreement with the reported values: 64.8 ± 2 (12), 63.6 ± 1 (6) and 63.0 ± 1.5 kcal/mol (8) at 1000°K.

A second and third law analysis of the total pressure data is given below. Monomer pressures for this analysis are obtained by deducing dimer and trimer pressures calculated from JANAF free energy functions and the adopted values of ΔHs°_{298} and ΔHv°_{298}.

The vapor pressure data reported by Eisenstadt et al. (9, 10) are too low and so not consistent with the others and are not used for evaluation. The transpiration data of Sense and Stone (11) and Knudsen-effusion data of Evseev et al. (13) are not considered for analysis because of the complications involved in converting the reported apparent pressures to the real total pressures of the gaseous mixtures containing monomer, dimer and trimer.

Herzberg (14) and Gaydon (15) reported the dissociation energies (D_0) of LiF(g) to be ≤ 6.6 and 5.95 ± 0.3 eV, respectively. Using these D_0 values, we derive ΔHf°_{298}(LiF,g) as -95.9 and -80.9 ± 6.9 kcal/mol. By use of flame-photometric method, Page and Sugden (16) and Bulewicz et al. (17) gave D_0 = 141 and 136 ± 8 kcal/mol, yielding ΔHf°_{298}(LiF,g) = -84.7 and -79.7 ± 8 kcal/mol.

* Data points are calculated from the given vapor pressure equation.

† Process I: LiF(ℓ) = LiF(g); II: LiF(c) = LiF(g); ΔHf°_{298}(LiF,g) values are calculated based on the third law ΔHr°_{298}.

Heat Capacity and Entropy

The infrared spectrum of LiF(g) and microwave spectrum of Li^6F have been observed by Vidale (19), and Wharten and Klemperer (21), respectively. The reported vibrational and rotational constants for Li^7F(g) and Li^6F(g), are adopted and corrected to the average istopic species. Veazey and Gordy (18) measured the rotational transitions of Li^7F with a high resolution molecular-beam absorption spectrometer. By use of the electric resonance method of molecular beam spectroscopy, Braunstein and Trischka (22) observed the transitions between v = 0 and v = 1 vibrational states. The infrared spectrum of LiF(g) have also been measured by Vasilevskii and Baikov (20).

Bond Distance: Li-O = [1.59] Å   F-O = [1.41] Å

Bond Angle: F-O-Li = [104]°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [4.21684 X 10^{-116}] g.³ cm.⁶

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) for LiFO(g) was calculated from $\Delta H^\circ_{r\ 298.15}$ = 139 kcal. mole⁻¹ for the reaction LiFO(g) = Li(g) + F(g) + O(g) where the value of $\Delta H^\circ_{r\ 298.15}$ was estimated to be the sum of the F-O and Li-O bond energies. The values of the F-O and Li-O bond energies were obtained from those in $F_2O(g)$ and $Li_2O(g)$ molecules, respectively.

Heat Capacity and Entropy.

The F-O and Li-O bond distances were assumed to be the same as those in $F_2O(g)$ and $Li_2O(g)$ molecules, respectively. The F-O-Li bond angle and vibrational frequencies were estimated by comparison with the corresponding values for the same oxide molecules. The three principal moments of inertia are: $I_A = 5.1543 \times 10^{-39}$, $I_B = 1.2729 \times 10^{-39}$ and $I_C = 6.4272 \times 10^{-39}$ g. cm.²

Heat of Formation.

The equilibrium constants for the decomposition of MgF(g) into Mg(g), MgF_2(c) and MgF_2(g) were determined by T. C. Ehlert, Ph.D. Thesis, University of Wisconsin, 1963. Using this data, the heats of decomposition are evaluated by both the third and second law methods. The results are presented in the table below. The equilibrium constants for the reaction $AlF_3(g) + 2Mg(g) \rightarrow AlF(g) + 2MgF(g)$ were also reported by T. C. Ehlert, loc. cit. The heat of reaction is calculated by the third and second law methods, respectively. The dissociation energy (D°_0) of MgF(g) was reported to be 3.2 ± 0.7 and 4.2 eu by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953, and G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., 1950, respectively. The corresponding values of $\Delta Hf^\circ_{298.15}$ for MgF(g) are derived. The results are also listed in the table. The value of $\Delta Hf^\circ_{298.15}$ for MgF(g) adopted is the average of the first two $\Delta Hf^\circ_{298.15}$ values.

Investigator	Chemical Reaction	$\Delta Hr^\circ_{298.15}$ kcal/mol Third Law Value	Second Law Value	$\Delta Hf^\circ_{298.15}$ kcal/mol
T. C. Ehlert	$2MgF(g) = Mg(g) + MgF_2(g)$	-34.76 ± 0.74	-70 ± 19	-52.8 ± 1.3*
	$2MgF(g) = Mg(g) + MgF_2(c)$	-126.66 ± 0.80	-92 ± 21	-53.4 ± 1.2*
	$AlF_3(g) + 2Mg(g) = AlF(g) + 2MgF(g)$	18.66 ± 0.40	2.7 ± 3.2	-67.7 ± 1.0*
G. Herzberg	$MgF(g) \rightarrow Mg(g) + F(g)$	D°_0 = 4.2 eV		-42.6
A. G. Gaydon	$MgF(g) \rightarrow Mg(g) + F(g)$	D°_0 = 3.2 ± 0.7 eV		-19.6 ± 16.1

*Based on $\Delta Hr^\circ_{298.15}$ value by the third law method.

Heat Capacity and Entropy.

All the molecular constants are taken from G. Herzberg, loc. cit., except α_e which is estimated.

$\nu_e x_e$ = [12.175]

α_e = [.0120]

σ = 1

r_e = [1.51 Å]

Heat of Formation.

The heat of formation was obtained by taking an average of two estimates of the dissociation energy of NF. The first estimate of 3.15 e.v. (72.4 kcal./mole) was obtained from W. C. Price, T. R. Passmore and D. M. Roessler Discussions Faraday Soc. 35, 201 - 11 (1963). The second estimate of 70.4 kcal./mole was obtained by taking one-half the dissociation energy of NF_2 (g) calculated from JANAF values. The $\Delta H_{f\ 298.15}$ for NF (g) was then calculated with auxiliary JANAF data from a dissociation energy of 71.4 kcal./mole.

Heat Capacity and Entropy.

The ν_e value was obtained from infrared studies of D. E. Milligan and M. E. Jacox, J. Chem. Phys. 40, 2461 (1964). The r_e value was estimated from Guggenheimer's relation for single bonded molecules. [K. M. Guggenheimer, Proc. Phys. Soc. (London), 58, 456 (1946)] The anharmonicity constant x_e was estimated by assuming the separation of the vibrational levels to be a linear function of the vibrational quantum number. The α_e value was then calculated using the Morse potential function; B_e was determined from the bond length. The ground state configuration was assumed to be the same as that in NBr. The prinicpal moment of inertia is 3.05247 x 10^{-39} g. cm.^{2}

NITROSYL FLUORIDE (ONF) (IDEAL GAS) MOL. WT. = 49.01

$\Delta H_{f0}^\circ = -15.1 \pm 0.4$ kcal. mole^{-1}

$\Delta H_{f\ 298.15}^\circ = -15.7 \pm 0.4$ kcal. mole^{-1}

Point Group C_s

$S_{298.15}^\circ = 59.273$ cal. deg.$^{-1}$ mole^{-1}

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$
1844.03 (1)
521 (1)
765.85 (1)

Bond lengths and angles: N-O distance = 1.13 Å N-F distance = 1.52 Å O-N-F angle = 110.2°

Moments of inertia: $I_A = 8.8135 \times 10^{-40}$ g. cm.^{2} $I_B = 70.8354 \times 10^{-40}$ g. cm.^{2} $\sigma = 1$

$I_C = 79.8375 \times 10^{-40}$ g. cm.^{2}

Heat of Formation

For the reaction $2NO(g) + F_2(g) \rightarrow 2ONF(g)$, H. S. Johnston and H. J. Bertin, J. Am. Chem. Soc. 81, 6402 (1959), report $\Delta H_{r\ 298.15}^\circ = -74.8 \pm 0.8$ kcal., determined calorimetrically. This yields -15.7 ± 0.4 kcal. mole^{-1} for $\Delta H_{f\ 298.15}^\circ$.

Heat Capacity and Entropy

C. V. Stephenson and E. A. Jones, J. Chem. Phys. 20, 135 (1952), report the frequencies, obtained from the infrared spectrum, and moments of inertia, obtained from the microwave spectrum.

Bond Angle: O-N-O = 129.5° F-N-O = 115.25°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 6.401696 X 10^{-115} g.^{3} cm.^{6}

Heat of Formation.

The heat of reaction at 25°C for direct synthesis of nitryl fluoride from nitrogen dioxide with fluorine ($NO_2(g) + 1/2\ F_2(g) = NO_2F(g)$) has been measured calorimetrically as -33.9 kcal. mole^{-1} by J. D. Breazeale and R. O. MacLaren, "Thermochemistry of Oxygen-Fluorine Bonding" (Final Tech. Summary Report, Contract No. Nonr 3433(00), ARPA Order No. 184-62) United Technology Corporation, Sunnyvale, Calif., Mar. 1963. The heat of formation, $\Delta H^\circ_{f\ 298}$ = -26.0 kcal. mole^{-1}, for $NO_2F(g)$ was then derived. The values of $\Delta H^\circ_{f\ 298}$ = -20 ± 5 and -19 ± 2 kcal. mole^{-1} were issued in their second and third quarterly tech. reports, and have been quoted in the literature by E. Tschuikow-Roux, J. Phys. Chem. 66, 1636 (1962).

G. Hetherington and P. L. Robinson, Special Publication No. 10, The Chem. Soc., London, 1957 quoted ΔH°_f = 26 kcal. mole^{-1} (presumably it has a minus sign) for $NO_2F(g)$ which was derived from the heat of solution measured by Nichols and Robinson, a private communication to Hetherington and Robinson.

Heat Capacity and Entropy.

D. F. Smith and D. W. Magnuson, Phys. Rev. 87, 226(1952), have measured the moments of inertia from microwave spectrum of $NO_2F(g)$. In order to calculate the bond distances, given as N-F = 1.35 Å and N-O = 1.23 Å, the bond angle O-N-O was assumed to be 125°. The selected bond distances and angle were obtained from L. Clayton, Q. Williams and T. Weatherly, J. Chem. Phys. 30, 1328 (1959). Clayton et al. assumed the bond angle O-N-O in $NO_2F(g)$ should be the same as that in $NO_2Cl(g)$, and then calculated the bond distances N-F and N-O from Smith and Magnuson's data of the moments of inertia.

The selected vibrational frequencies were obtained from the infrared and Raman spectra measurements by R. Dodd, J. Rolfe and L. Woodward, Trans. Faraday Soc. 52, 145 (1956).

The three principal moments of inertia are I_A = 6.3658 X 10^{-39}, I_B = 7.3383 X 10^{-39} and I_C = 13.7041 X 10^{-39} g. cm.^{2}

[450] (1)	

Bond Distance: O=N = 1.29 ± 0.05 Å N-O' = 1.39 ± 0.05 Å O'-F = 1.42 ± 0.05 Å

Bond Angle: O-N-O = 125° ± 5° F-O'-N = 105° ± 5° σ = 1

Angle between NO'F plane and O_2NO' plane = 90°.

Product of the Moments of Inertia: $I_AI_BI_C = 3.88637 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The value, 2.5 ± 0.5 kcal. mole^{-1}, for the heat of formation of FNO_3(g) was obtained from R. Anderson, et al., "Thermochemistry of Oxygen-Fluorine Bonding," UTC 2002-QT4, United Technology Corporation, Sunnyvale, California, March 1, 1961, through February 28, 1962. The value of ΔH_f° reported by O. G. Talakin, et al., Russ. J. Phys. Chem., 36, 561 (1962) was -4.2 ± 0.9 kcal. mole^{-1} at 294°K.

Heat Capacity and Entropy.

Vibrational frequencies were estimated by comparison with those of HNO_3(g) reported by A. Palm and M. Kilpatrick, J. Chem. Phys. 23, 1562 (1955). Bond distances and angles were taken from L. Pauling and L. O. Brockway, J. Am. Chem. Soc. 59, 13 (1937). The three principal moments of inertia are: 8.8598×10^{-39}, 1.8572×10^{-38}, and 2.3618×10^{-38} g. cm.^{2} The possible existence of restricted internal rotation in the molecule was not considered. Thus the values of C_p and S° calculated may be low.

Dec. 31, 1960; Dec. 31, 1963; Dec. 31, 1968

SODIUM FLUORIDE (NaF) (CRYSTAL) GFW = 41.9882

$\Delta Hf^\circ_0 = -136.95 \pm 0.2$ kcal/mol

$S^\circ_{298.15} = 12.24 \pm 0.02$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -137.52 \pm 0.2$ kcal/mol

Tm = 1269 ± 2°K

$\Delta Hm^\circ = 7.97$ kcal/mol

$\Delta Hs^\circ_{298.15} = 68.1$ kcal/mol

Heat of Formation

The heats of solution and reaction of NaF(c) have been determined by many investigators. Incorporating their reported data with auxiliary ΔHf°_{298} values (1, 2), we calculate the corresponding values of ΔHf°_{298}(NaF, c). The results are presented in the table below. The adopted ΔHf°_{298}(NaF, c) is -137.52 ± 0.2 kcal/mol.

Investigator	Reaction*	Temperature, °K	Concentration $NaF \cdot nH_2O$	No. of determination	ΔHr°_{298} kcal/mol	ΔHf°_{298} kcal/mol
1. Guntz (1884)	A	285	400	1	0.13	-137.42
2. Latimer - Jolly (1953)	A	298	1850	2	0.23 ± 0.01	-137.52
3. Hepler et al. (1953)	A	298	1540	1	0.22 ± 0.01	-137.51
4. Davies - Benson (1965)	A	298	222	1	0.24 ± 0.01	-137.53
5. Thomsen (1882)	B	291	—	2	16.24 ± 0.15	-137.38
6. Wartenberg - Fitzner (1926)	C	293	—	1	-39.3 ± 0.1	-137.62
7. Schmitz - Schumaker (1947)	C	291	—	1	-39.5	-137.82
8. Coughlin (1958)	D	298	—	6	-1.40 ± 0.06	-137.58
9. Vórob'yev - Skuratov (1960)	E	298	—	5	-325.5 ± 2.2	-137.13

*A represents NaF(c) = NaF(n H_2O) and $\Delta Hr^\circ_{298} = \Delta H^\circ_\infty$; B, NaOH(200 H_2O) + HF(200 H_2O) = NaF(401 H_2O) + H_2O(NaF·401 H_2O); C, NaCl(c) + 1/2 F_2(g) = NaF(c) + 1/2 Cl_2(g); D, NaCl(c) + HF(5.716 H_2O) = NaF(c) + HCl(12.731 H_2O); E, 4Na(c) + CF4(g) = 4NaF(c) + C (graphite).

Heat Capacity and Entropy

The low temperature heat capacities, 0.05 - 15°K and 54.01 -295.86°K, were measured by Harrison et al. (10) and King (11), respectively. These two sets of data are joined smoothly with the high temperature heat capacities at 298°K which were derived from the enthalpy measurements, 406.1 - 1282.2°K, determined by O'Brien and Kelley (12). The Cp values above 1282.2°K are obtained by linear extrapolation. S°_{298} is calculated using the adopted low temperature heat capacities and $S^\circ_{54} = 0.555$ eu.

Frank (13) commented that the temperature measurements of O'Brien and Kelley (12) seemed to be about 20°K high at 1000° with a smaller error at lower temperatures. A correction for the assumed error in the temperature measurement was used in the previous JANAF table. However, Douglas and Ditmars (14) have questioned this correction, since new enthalpy data for AlF_3 yielded Cp values in better agreement with the original Cp values of O'Brien and Kelley than with the corrected values of Frank. The α → β transition of AlF_3(c) was found in the range 723 - 6°K, while O'Brien and Kelley selected 727°K based on a point at 728.1°K in the β region and a point at 724.9°K in the pretransition region. Frank's correction yields an error of 9° at 727°K, yet the true error appears to be negligible (≤2°) for AlF_3(c). Based on the above reasoning and the comparison of the Cp curve of NaF(c) with those of NaCl(c), LiCl(c), and LiF(c) in the temperature range 300 - 1300°K, we adopt the high temperature enthalpy data of O'Brien and Kelley without any correction.

The low temperature heat capacities in the temperature ranges 81 - 190 and 198 - 273°K were also measured by Koref (15); and high temperature enthalpies at temperatures 288 - 1073 and 290 - 1287°K were reported by Krestovnikov and Karetnikov (16), and Lyashenko (17), respectively. They are not used for evaluation.

Melting Data

See the NaF(ℓ) table for details.

Heat of Sublimation

ΔHs°_{298} is the difference between ΔHf°_{298} for NaF(g) and NaF(c).

Dec. 31, 1960; June 30, 1964; Dec. 31, 1968

SODIUM FLUORIDE (NaF) (LIQUID) GFW = 41.9882

$S^\circ_{298.15}$ = 17.559 gibbs/mol

Tm = 1269 ± 2°K

Tb = 2060°K

$\Delta Hf^\circ_{298.15}$ = -130.545 kcal/mol

ΔH°_m = 7.97 kcal/mol

ΔH°_v(to mixture) = 42.1 kcal/mol of NaF(ℓ)

Heat of Formation

ΔHf°_{298}(ℓ) is obtained from ΔHf°_{298}(c) by adding ΔHm° and the difference between $H^\circ_{1269} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacities of NaF(ℓ) are derived from the enthalpy data, 1287.6 - 1746.5°K, determined by O'Brien and Kelley (1). A glass transition temperature is assumed at 900°K, i.e. the heat capacities below 900°K are taken from those for NaF(c). The Cp values above 1746.5°K are obtained by extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

The value of Tm has been reported as (°K): 1313 (2), 1285 (1), 1270 (3, 4, 5), 1269 (6), 1268 (7, 8, 9), 1267 (10, 11, 12), 1265 (13), 1263 (14), and 1253 (15). We select Tm = 1269°K. The value 1285°K reported by O'Brien and Kelley seems unreasonably high and is not adopted. The cause of this discrepancy is still unresolved (17). The heat of melting is calculated as the difference between the adopted enthalpies for NaF(c) and NaF(ℓ) at 1269°K. Kelley (18) derived ΔHm°_{1265} to be 5.82 - 8.43 kcal/mol, based on 13 sets of molten salts equilibrium data involving NaF. The value ΔHm°_{1285} = 8.03 kcal/mol reported by O'Brien and Kelley is not used.

Vaporization Data

Tb is the temperature at which the partial pressures of NaF(g) and Na_2F_2(g) in equilibrium with NaF(ℓ) equal one atmosphere. The vapor composition at Tb is evaluated as NaF 84.8% and Na_2F_2 15.2%. The heat required to vaporize one mole of liquid to form 0.868 mole of vapor mixture of the above composition at Tb is calculated to be 42.1 kcal/mol.

Ruff et al. (16) measured the vapor pressured of NaF(ℓ) in the temperature range of 1699 - 1974°K and reported Tb = 1978°K.

ω_e = 536.10 ± 0.35 cm^{-1} $\omega_e x_e$ = 3.83 ± 0.14 cm^{-1} σ = 1

B_e = 0.4369 cm^{-1} α_e = 0.00456 cm^{-1} r_e = 1.9260 Å

Heat of Formation

The total pressures of NaF(g) and Na_2F_2(g), in equilibrium with NaF(c, ℓ) at temperatures 1020 - 1974°K, have been determined by many investigators, using manometric (1, 2, 5), torsion-effusion (6, 8), Knudsen-effusion (3, 7), transpiration (4), and molecular-beam velocity-selector (9, 10) methods. In order to evaluate ΔHv°(LiF, g) we have used a trial and error variation of ΔHs° and ΔHv° for the monomer and dimer such that the ΔHr°_{298} values derived by the second and third law methods are in reasonable agreement.

Incorporating ΔHs°_{298} = 68.1 and 72.7, and ΔHv°_{298} = 61.12 and 58.75 kcal/mol for NaF and Na_2F_2, respectively, with JANAF functions for NaF(c), NaF(ℓ), NaF(g) and Na_2F_2(g), we derive the partial pressures of NaF monomer from the reported total pressures. Based on the calculated partial pressures of NaF(g), the corresponding heats of vaporization are evaluated by the second and third law methods. Using the third law ΔHr°_{298} and ΔHf°_{298} = -137.52 and -130.545 kcal/mol for NaF(c) and NaF(ℓ), we obtain values of ΔHf°_{298} for NaF(g). The results are presented in the table below. The ΔHf°_{298}(NaF, g) value adopted is -69.42 kcal/mol.

The vapor pressure data reported by Miller and Kusch (9) and Eisenstadt et al. (10) are not consistent with the other sets and are not used for evaluation.

Gaydon (11) and Herzberg (12) reported D°_0 = 114.2 ± 6.9 (4.95 ± 0.3 eV) and ≤ 122.2 kcal/mol (5.3 eV), respectively. Using JANAF ΔHf°_{298} values for Na(g) and F(g), we obtain ΔHf°_{298}(NaF, g) = -70.5 ± 5.8 and ≥ -78.5 kcal/mol. Employing flame-photometric method, Bulewicz et al. (13) and Page and Sugden (14) derived D°_0 = 121 ± 7 and 119 - 120 kcal/mol for NaF(g), which lead to ΔHf°_{298}(NaF, g) = -77.3 ± 7 and -75 to -76 kcal/mol.

Heat Capacity and Entropy

Veazey and Gordy (15) have measured the rotational transitions of NaF in the millimeter- and sub-millimeter-wave region with a high-resolution molecular-beam absorption spectrometer. The derived values of ω_e, $\omega_e x_e$, B_e, α_e and r_e are adopted here.

Using the molecular beam electric resonance method, Bauer and Lew (16) measured the transition between the J = 0 and J = 1 rotational levels of $Na^{23}F^{19}$ in the three lowest vibrational states. Radio-frequency transitions for $Na^{23}F^{19}$ have been observed by Hollowell et al. (19). Infrared spectra of NaF have been analyzed by Snelson and Pitzer (17), Ritchie and Lew (18), and Baikov and Vasilevskii (20). The molecular constants derived by the above authors are similar to the values adopted, except the value ω_e = 550 cm^{-1} (17) which is different from the value 536.1 cm^{-1} reported by Veazey and Gordy (15).

FLUORINE MONOXIDE (FO) (IDEAL GAS) GFW = 34.998

Ground State Configuration $[^2\Pi]$

$S^\circ_{298.15}$ = 51.77 ± 0.3 gibbs/mol

ΔHf°_0 = [26 ± 10] kcal/mol

$\Delta Hf^\circ_{298.15}$ = [26 ± 10] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	[4]
[29000]	[4]

ω_e = 1056 cm^{-1}

$\omega_e x_e$ = [15] cm^{-1}

σ = 1

B_e = [1.148] cm^{-1}

α_e = [0.020] cm^{-1}

r_e = [1.30] Å

Heat of Formation.

Several values have been proposed for the heat of formation of FO(g). V. H. Dibeler, R. M. Reese and J. L. Franklin, J. Chem. Phys. 27, 1296 (1957), obtained D_0(FO,g) = 24 kcal from electron impact studies. However, theoretical estimates give D_0 values in the range 45 - 56 kcal. W. C. Price, T. R. Passmore and D. M. Roessler, Discussions Faraday Soc. 35, 207 (1963), estimated 52 kcal for D_0(FO,g).

From a consideration of the central bond energies in FNNF and HNNH with that in HOOH, using all JANAF values of 101, 109 and 50 kcal, we predict the bond dissociation energy in FO-OF to be 46 ± 4 kcal, which yields D_0(FO,g) = 51 ± 2 kcal. The average F-O bond dissociation energy in F_2O(g) is 49.8 ± 0.5 kcal. Also, since there is one less antibonding electron in FO than in F_2, we should expect the F-O bond to be greater than that in F_2(38 kcal). Thus a median value of D_0(FO,g) = 51.4 ± 10 kcal is adopted here which leads to ΔHf°_{298}(FO) = 26 kcal/mol.

Heat Capacity and Entropy.

The fundamental frequency is obtained by adding $2\omega_e x_e$ to the value reported by A. Arkell, R. R. Reinhard and L. P. Larson, J. Am. Chem. Soc. 87, 1016 (1965), from matrix isolation studies. The bond length was taken equal to that in the isoelectronic molecule O_2^-(g). The value of $\omega_e x_e$ was obtained from the Morse potential function and the assumed dissociation energy. The rotational constant α_e was also estimated from the above parameters and the Morse potential curve. The $^2\Pi$ ground state is that predicted by molecular orbital theory and the first excited state would also be $^2\Pi$. By analogy with the isoelectronic O_2^-(g) states, the first excited level was estimated at 29000 cm^{-1}.

Sept. 30, 1963

TITANIUM OXIDE FLUORIDE (TiOF) (IDEAL GAS) MOL. WT. = 82.9

Point Group $[C_{\infty v}]$

$S^\circ_{298.15}$ = [59.887] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [2]

$\Delta H^\circ_{f\ 0}$ = [-103.0] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-103.5] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[880] (1)
[300] (2)
[740] (1)

Bond Distances: Ti=O = [1.62] Å Ti-F = [1.74] Å

Bond Angle: O=Ti-F = [180°]

$\sigma = 1$

Rotational Constant: B_0 = [0.1705] cm.$^{-1}$

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was estimated as -103 kcal. mole^{-1} by J. S. Gordon, Astrosystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. $\Delta H^\circ_{f\ 298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. Principal moment was 16.419 X 10^{-39} g. cm.^{2}

Monofluorine Dioxide (FO_2)

(Ideal Gas) GFW = 50.9972

Sept. 30, 1966

MONOFLUORINE DIOXIDE (FO_2) (IDEAL GAS) GFW = 50.9972

Point Group C_s

$S°_{298.15}$ = 61.9 gibbs/mol

Ground State Quantum Weight = 2

$\Delta Hf°_0$ = 3.4 ± 5 kcal/mol

$\Delta Hf°_{298.15}$ = 3.0 ± 5 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	
1495.0	(1)
584.5	(1)
376.0	(1)

Bond Distance: O-O = 1.22 Å O-F = 1.58 Å

Bond Angle: O-O-F = 109.5° $\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C = 7.7504 \times 10^{-116}\ g^3cm^6$

Heat of Formation.

The heat of formation for $FO_2(g)$ is unavailable in the literature. Based on a kinetic study of the thermal decomposition of $F_2O_2(g)$ reported by H. J. Schumacher and P. Frisch, Z. physik. Chem. B24, 332 (1934), the enthalpy change for the reaction $F_2O_2(g) = F(g) + O_2F(g)$ was estimated to be + 17.3 kcal/mol by J. B. Levy and B. K. Wesley, J. Phys. Chem. 69, 408 (1965), assuming that the activation energy for the reverse reaction is negligible. From this data the value of $\Delta Hf°_{298.15}(FO_2,\ g)$ was calculated as + 3.2 kcal/mol, using $\Delta Hf°_{298.15}$ = + 4.73 kcal/mol for $F_2O_2(g)$ determined calorimetrically by A. D. Kirshenbaum, A. V. Grosse and J. G. Aston, J. Am. Chem. Soc. 81, 6398 (1959).

Based on the assumption that the enthalpy change for the reaction $F_2O_2(g) = F(g) + O_2F(g)$ is 16.5 kcal/mol, which is half of the enthalpy change for the reaction $F_2O_2(g) = 2F(g) + O_2(g)$, the heat of formation ($\Delta Hf°_{298.15}$) for $FO_2(g)$ was derived as + 2.4 kcal/mol.

The value of $\Delta Hf°_{298.15}(FO_2,g)$ adopted is 3 ± 5 kcal/mol.

Heat Capacity and Entropy.

The vibrational frequencies for FOO(g) were assumed to be the same as those obtained from matrix isolation by P. N. Noble and G. C. Pimentel, J. Chem. Phys. 44, 3641 (1966). These authors have observed two more frequencies for isotopically substituted FOO and combined them with those observed by R. D. Spratley, J. J. Turner and G. C. Pimentel, J. Chem. Phys. 44, 2063 (1966), and performed a normal coordinate analysis. The results confirm the fact that the bond distances and angles in FOO are essentially the same as those reported for $F_2O_2(g)$ by R. H. Jackson, J. Chem. Soc., 4585 (1962). The same molecular structure for FOO was also deduced from electron spin resonance and electron paramagnetic resonance data reported by R. W. Fessenden and R. H. Schuler, J. Chem. Phys. 44, 434 (1966) and P. H. Kasai and A. D. Kirschenbaum, J. Am. Chem. Soc. 87, 3069 (1965), respectively. Hence this molecular structure was adopted. Two vibrational frequencies, ν_1 and ν_3, for FOO molecule were also observed by A. Arkell, J. Am. Chem. Soc. 87, 4057 (1965).

The three principal moments of inertia are: $I_A = 1.1103 \times 10^{-39}$, $I_B = 7.8182 \times 10^{-39}$ and $I_C = 8.9285 \times 10^{-39}$ g cm^2.

Dec. 31, 1960; Sept. 30, 1962

Phosphorus Monofluoride (PF) (Ideal Gas)

Mol. Wt. = 49.975

$\Delta H_f^\circ{}_{298.16} = -14 \pm 3$ kcal. mole^{-1}

$S^\circ_{298.15} = 53.7$ cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^3\Sigma$

Electronic Level and Multiplicity

ϵ, cm.$^{-1}$	g_1
0	3

$\omega_e = 846.75$ cm.$^{-1}$ $\omega_e x_e = 4.489$ cm.$^{-1}$ $B_e = 0.5665$ cm.$^{-1}$

$\alpha_e = 0.00456$ cm.$^{-1}$ $r_e = 1.590$ Å $\sigma = 1$

Heat of Formation. $\Delta H_f^\circ{}_{298.15}$ was derived from a D_0° calculated with spectroscopic constants reported by A. E. Douglas and M. Frackowiak, Can. J. Phys. 40, 832 (1962). The D_0° value was calculated using the dissociation and spectroscopic relations given by G. Herzberg in "Spectra of Diatomic Molecules", D. van Nostrand Co., N. Y., 2nd Ed. (1950) pages 93 and 100. If the PF molecule dissociates to the ground state atoms, $P(^4S_{3/2}) + F(^2P_{3/2})$, the corresponding $\Delta H_f^\circ{}_{298.15}$ is -15 ± 3 kcal. mole^{-1}. If the dissociation is to the phosphorus ground state and the excited fluorine state, $P(^4S_{3/2}) + F(^2P_{1/2})$, the corresponding $\Delta H_f^\circ{}_{298.15}$ is -14 ± 3 kcal. mole^{-1}. The dissociation to an excited $F(^2P_{1/2})$ atom was assumed to obtain the selected $\Delta H_f^\circ{}_{298.15} = -14 \pm 3$ kcal. mole^{-1}.

The heat of formation was estimated to be -17 kcal. mole^{-1} by J. S. Gordon, "Thermodynamic Data for Combustion Products", January, 1960, Thiokol Chemical Corp. This estimate when changed from white(α) to red(V) phosphorus reference state (-13 kcal. mole^{-1}) agrees within uncertainty limits with the derived $\Delta H_f^\circ{}_{298.15}$ values.

Heat Capacity and Entropy. The molecular constants were reported by Douglas and Frackowiak (loc. cit.). They photographed and analyzed the electronic spectra of PF in the emission spectrum of a discharge through a mixture of PF_3 and He.

PHOSPHORUS SULFIDE FLUORIDE (PSF) (Ideal Gas)

Mol. Wt. = 82.041

ΔH_f° 298.15 = [-37 ± 15] kcal. mole^{-1}

$S^\circ_{298.15}$ = [66.35 ± 3] cal. deg.$^{-1}$ mole^{-1}

Ground State Multiplicity = 1

Vibrational Frequencies and Degeneracies

ω cm.$^{-1}$
[940] (1)
[740] (1)
[400] (1)

Product of the Moments of Inertia: $I_A I_B I_C$ = [7.999 X 10^{-114}] g.^{3} cm.^{6} $\sigma = 1$

Heat of Formation. The ΔH_f° 298.15 was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Virginia, "Survey of Thermochemical Data," January, 1960. This estimated ΔH_f 298.15 was corrected for the change in the reference state of phosphorus from white α to red V.

Heat Capacity and Entropy. The vibrational frequencies were estimated by comparison with the corresponding frequencies of PF(g), PS(g), and PF_2(g). The vibrational levels of PF_2(g) in turn were estimated by J. S. Gordon, Thiokol Corp., Reaction Motors Division, Denville, N. J., "Thermodynamic Data for Combustion Products," January, 1960. The entropy was estimated by C. B. Henderson and R. S. Scheffee (loc. cit.). The product of the moment of inertia was derived from the estimated entropy.

Lead Monofluoride (PbF) (Ideal Gas)

Mol. Wt. = 226.21

ΔH_f° 298.15 = -9.0 ± 9.2 kcal. mole^{-1}

$S^\circ_{298.15}$ = 59.627 cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^2\Pi$

Electronic Levels and Multiplicities

ϵ, cm.$^{-1}$	g_1
0	2
8266	2

ω_e = 507.2 cm.$^{-1}$ $\omega_e x_e$ = 2.30 cm.$^{-1}$ σ = 1

B_e = [0.2397] cm.$^{-1}$ α_e = [0.0017] cm.$^{-1}$

Heat of Formation. ΔH_f° 298.15 was calculated from the dissociation energy of PbF(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ϵ, ω_e, and $\omega_e x_e$ were given by G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York, 1950. B_e and α_e were estimated by J. S. Gordon, Astrosystems, Inc., private communication, May, 1962.

Silicon Monofluoride (SiF)

$\omega_e = 857.2 \pm 0.1$ cm^{-1} $\omega_e x_e = 4.74 \pm 0.03$ cm^{-1} $\sigma = 1$

$B_e = 0.58138$ cm^{-1} $\alpha_e = 0.00490$ cm^{-1} $r_e = 1.6008$ Å

Heat of Formation

Ehlert and Margrave (1) have studied mass-spectrometrically the reaction $Si(g) + SiF_2(g) \rightarrow 2SiF(g)$ by monitoring the intensities of the Si^+, SiF_2^+ and SiF^+ ions in an equilibrium system containing CaF_2 and Si. The ionization cross-sections are assumed to cancel so that equilibrium constants can be obtained directly from the ion intensities. We have analysed the above data using present JANAF functions and obtain $\Delta Hr_{298} = 23.5 \pm 3$ kcal by the third law technique with a drift of -0.8 ± 11 eu, the second law value is 23.9 ± 7 kcal. We adopt the third law value which with JANAF auxiliary data gives $\Delta Hf^\circ_{298}(SiF, g) = -4.6 \pm 3$ kcal/mol.

Johns and Barrow (2) have selected $D^\circ_0(SiF, g) = 125 \pm 10$ kcal/mol, from Birge-Sponer extrapolations of several states, this gives $\Delta Hf^\circ_0 = 0.1 \pm 10$ kcal/mol in good agreement with the adopted value.

Heat Capacity and Entropy

The molecular constants of the various electronic levels have been documented by Johns and Barrow (2), Verma (3), Barrow et al. (4), and Appelblad et al. (5). The approximation involving the use of the ground state constants for all electronic levels is used since it introduces negligible error in this molecule.

$\sigma = 1$

$r_e = [1.95]$ Å

Heat of Formation

The heat of formation, ΔHf°_{298}, of TiF(g) is calculated from the dissociation energy, D_0°. The dissociation energy is estimated as 148 ± 6 kcal/mol using the corresponding quantity for TiF_2(g) and the relation $D(MF)/D(MF_2) = 0.46 \pm 0.02$ which Zmbov and Margrave (1) found held for other mono- and di-fluorides.

Heat Capacity and Entropy

The vibrational frequency, ω_e, and anharmonic vibrational term, $\omega_e x_e$, are estimated from those of the alkali and mercury monohalides. The interatomic distance, r_e, is estimated from those of TiCl(g), TiF_2(g) and TiF_3(g). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti^+ (2).

TUNGSTEN MONOFLUORIDE (WF) (IDEAL GAS) GFW = 202.8484

Ground State Configuration $[^2\Delta]$

$S°_{298.15}$ = [59.9] gibbs/mol

$\Delta Hf°_0$ = [92.4 ± 15] kcal/mol

$\Delta Hf°_{298.15}$ = [92.3 ± 15] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i cm^{-1}	g_i
0	[4]
[5000]	[2]
[15000]	[20]

ω_e = [726.5] cm^{-1} $\omega_e x_e$ = [2.9] cm^{-1} σ = 1

B_e = [0.2923] cm^{-1} α_e = [0.0015] cm^{-1} r_e = [1.83] Å

Heat of Formation.

The heat of formation, $\Delta Hf°_{298}(WF,g)$ = 92.3 kcal/mol, is calculated from the bond dissociation energy $D°_{298}(WF)$ = 130 ± 15 kcal/mol. This value of $D°_{298}$ is estimated to be slightly higher than the average bond dissociation energy of $WF_6(g)$ by analogy with the WCl_x system.

Heat Capacity and Entropy.

The bond distance is estimated to be the same as that in $WF_6(g)$. This distance is then used with Guggenheimer's relation to calculate the fundamental vibrational frequency, ω_e (K. M. Guggenheimer, Proc. Phys. Soc. 58, 456 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D_0 + 0.5\ \omega_e) = 0.0042$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is 9.575×10^{-39} g cm^2.

The ground state configuration, low lying electronic levels and their quantum weights are estimated based on the tentative molecular orbital diagram for TaO given by W. Weltner, Jr., and D. McLeod, Jr., J. Chem. Phys. 42, 882 (1965). Using this scheme, we obtain the ground state configuration as $\pi^4\sigma^2\delta^3$, which yields a $^2\Delta$ ground state. The first excited state is assumed to have $\pi^4\sigma\delta^4$ which yields a $^2\Sigma$ state. Higher levels are considered to be formed by transition to π^* antibonding orbitals, and by analogy with TaO these are assumed to lie in the 15000 cm^{-1} region. The degeneracy of these levels is estimated roughly from the large number of possible configurations.

ZIRCONIUM MONOFLUORIDE (ZrF) (IDEAL GAS) GFW = 110.2184

Ground State Configuration $[{}^4\Sigma]$ $\Delta Hf^\circ_0 = [20.0 \pm 5]$ kcal/mol

$S^\circ_{298.15} = [58 \pm 2]$ gibbs/mol $\Delta Hf^\circ_{298.15} = [19.8 \pm 5]$ kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i	ϵ_i, cm^{-1}	g_i
0	[4]	[18000]	[4]
[3000]	[4]	[24000]	[4]
[6000]	[4]	[30000]	[4]
[12000]	[4]		

$\omega_e = [628.0]\ \text{cm}^{-1}$ $\omega_e x_e = [4.0]\ \text{cm}^{-1}$ $\sigma = 1$

$B_e = [0.29699]\ \text{cm}^{-1}$ $\alpha_e = [0.009]\ \text{cm}^{-1}$ $r_e = [1.90]\ \text{Å}$

Heat of Formation

Based on $[D(ZrF)/D(ZrF_2)] = 0.46$, as indicated by recent work on the fluorides of Groups II and IV elements (1, 2, 3, 4, 5), and $D_0(ZrF_2) = 318.1$ kcal/mol, the $D_0(ZrF)$ is calculated as 146.3 kcal/mol. Using $\Delta Hf^\circ_0(Zr,\ g) = 147.99$, $\Delta Hf^\circ_0(F,\ g) = 18.36$, and $D_0(ZrF,\ g) = 146.3$ kcal/mol, we derive $\Delta Hf^\circ_0(ZrF,\ g) = 20.0$ or $\Delta Hf^\circ_{298}(ZrF,\ g) = 19.8 \pm 5$ kcal/mol which is adopted.

The ΔHf°_{298} for ZrF(g) was evaluated as approximately 16 ± 5 kcal/mol by Murad and Hildenbrand (8), employing different $D(ZrF_2)$ value. Their value is in agreement with the adopted one, within the assigned uncertainty.

Heat Capacity and Entropy

The ground state configuration is taken from the ground state multiplet of Zr^+ (6). The electronic levels are estimated as three times higher than those of TiF(g) and the quantum weights are assumed to be the same. ω_e is taken to be approximately the same as the Zr-F stretching frequency ν_1 for $ZrF_4(g)$. B_e is calculated from the formula $B_e = (2.799076 \times 10^{-39})(I_e)^{-1}$ where $I_e = \mu r_e^2$, μ = reduced mass of ZrF(g), $r_e = 1.90$ Å which is estimated from those of ZrF_4, CF_4, CF and other related gaseous molecules. α_e is derived from B_e, ω_e, and $\omega_e x_e$ (estimated), according to the method suggested by Herzberg (7). The moment of inertia is 9.425×10^{-39} g cm^2.

Sept. 30, 1965

IRON DIFLUORIDE (FeF$_2$) (CRYSTAL) MOL. WT. = 93.8438

$S^\circ_{298.15}$ = 20.79 ± 0.04 cal. deg.$^{-1}$ mole^{-1}

T_m = [1373]°K.

$\Delta H^\circ_{f\ 0}$ = -168.6 ± 10 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -168.7 ± 10 kcal. mole^{-1}

ΔH°_m = [12.4] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 75.6 ± 2.0 kcal. mole^{-1}

Heat of Formation.

The equilibrium pressures for the reaction $FeF_2(c) + H_2(g) = Fe(c) + 2HF(g)$ have been measured by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928) at 773, 873 and 973°K. The enthalpy change ($\Delta H^\circ_{r\ 298.15}$) of the reaction was evaluated by the second and third law methods to be 27.19 and 39.08 kcal. mole^{-1}, respectively. Based on the third law value of $\Delta H^\circ_{r\ 298.15}$, the $\Delta H^\circ_{f\ 298.15}$ (FeF$_2$, c) was calculated to be -168.7 ± 10 kcal. mole^{-1}. The drift in the third law values of $\Delta H^\circ_{r\ 298.15}$ was evaluated to be 13.3 ± 1.8 e.u.

Heat Capacity and Entropy.

The low temperature (11.33 - 307.30°K.) heat capacities were determined by E. Catalano and J. W. Stout, J. Chem. Phys. 23, 1803 (1955). The heat capacities above 307°K. were estimated by comparison with those of FeCl$_2$(c), MgCl$_2$(c) and MgF$_2$(c). The value of $S^\circ_{298.15}$ was obtained from E. Catalano and J. W. Stout, loc. cit., in which a sharp maximum C_p of 17.8 cal. deg.$^{-1}$ mole^{-1} at 78.35°K. was reported. The $S^\circ_{298.15}$ value was based on S°_{15} = 0.039 e.u.

Melting Data.

T_m was estimated as 1100°C based on the data reported by W. Biltz and E. Rahlfs, Z. anorg. allgem. Chem. 166, 363 (1927). The value of ΔH°_m was calculated using ΔS°_m = 9 e.u. which was assumed to be the same as the corresponding value for MgF$_2$(c).

Heat of Sublimation.

The value of $\Delta H^\circ_{s\ 298.15}$ was obtained from J. L. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William Marsh Rice University, Houston, Texas. See FeF$_2$(g) table for details.

Sept. 30, 1965

IRON DIFLUORIDE (FeF_2)   (LIQUID)   MOL. WT. = 93.8438

$S^\circ_{298.15}$ = [21.951] cal. deg.$^{-1}$ mole^{-1}

T_m = [1373]°K.

T_b = [2110]°K.

ΔH°_f 298.15 = [-161.229] kcal. mole^{-1}

ΔH°_m = [12.4] kcal. mole^{-1}

ΔH°_v = [53.64] kcal. mole^{-1}

Heat of Formation.

The value of ΔH°_f 298.15 (FeF_2, l) was obtained from ΔH°_f 298.15 (FeF_2, c) by adding ΔH°_m and the difference between $H^\circ_{T_m} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity for FeF_2(l) was estimated by comparison with those for $FeCl_2$(c), $MgCl_2$(c), MgF_2(c), $CaCl_2$(c) and CaF_2(c). The C_p(FeF_2, l) value was assumed to be constant in the temperature range, 298.15 - 3000°K. The entropy ($S^\circ_{298.15}$) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See the FeF_2(c) table for details.

Vaporization Data.

T_b is calculated as the temperature at which the free energy change of the reaction $FeF_2(l) = FeF_2(g)$ approaches zero. The difference between ΔH°_f for FeF_2(l) and FeF_2(g) at T_b is ΔH°_v.

Heat of Formation.

The rate of sublimation of $FeF_2(c)$ was measured between 965 and 1149°K. by the Knudsen technique employing the high temperature magnetic mass spectrometer by John L. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William March Rice University, Houston, Texas. The only vapor species of importance is $FeF_2(g)$. From the vapor pressure data the third law heat of sublimation ($\Delta H^\circ_{s\ 298.15}$) was reported as 75.6 ± 2.0 kcal. mole^{-1}. The sum of the values of $\Delta H^\circ_{s\ 298.15}$ and $\Delta H^\circ_{f\ 298.15}$ for $FeF_2(c)$ is the $\Delta H^\circ_{f\ 298.15}$ (FeF_2, g).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The Fe-F bond distance was estimated from that in $FeF_2(c)$ reported by W. H. Baur, Acta Cryst. 11, 488 (1958). The vibrational frequencies, ω_1 and ω_3, were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The values of ω_2, electronic levels and quantum weights were estimated by comparison with those for $FeCl_2(g)$. See $FeCl_2(g)$ table for details. The moment of inertia is 2.04404×10^{-39} g. cm.^{2}

June 30, 1962; Dec. 31, 1963

POTASSIUM BIFLUORIDE (KHF_2) (CRYSTAL) MOL. WT. = 78.108

$S^\circ_{298.15}$ = 25.0 ± 0.1 cal. deg. mole^{-1}

T_t = 469.8°K.

T_m = 511.8°K.

$\Delta H^\circ_{f\ 0}$ = -220.74 ± 0.35 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -221.90 ± 0.35 kcal. mole^{-1}

ΔH_t = 2.671 ± 0.01 kcal. mole^{-1}

ΔH_m = 1.582 ± 0.003 kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained from the enthalpy of decomposition measurements of M. L. Davis and E. F. Westrum, J. Phys. Chem. 65, 338 (1961) who gave $\Delta H_{d\ 500}$ = 18.82 ± 0.05 kcal. mole^{-1} and the heats of formation of HF(g) and KF(c) from the JANAF Tables, in conjunction with enthalpies at 500°K. from E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949). A third law analysis of the decomposition vapor pressure by Westrum and Pitzer, loc. cit. did not agree with enthalpy of decomposition measurements, giving $\Delta H_{d\ 298}$ = 21.274 ± 0.2 kcal. mole^{-1} as compared to Davis and Westrum's value at 298°K. of 21.505 ± 0.05 kcal. mole^{-1}. As the liquid vapor pressure data, which were not used, have a large trend in the third law heat of vaporization with temperature it was suspected that the pressure measurements were in error. This is borne out somewhat by a small trend in the values over the solid in the range 480-500°K.

Heat Capacity and Entropy.

Westrum and Pitzer, loc. cit., have measured the heat capacity from 16°K. to the melting point. Their data has been used to calculate the entropy at 298° using a T^3 law extrapolation below 16°K., giving S_{16} = 0.103 e.u.

Melting and Transition Data.

The temperatures of melting and transition and the heats of melting and transition were taken from Davis and Westrum, loc. cit.

June 30, 1962; Dec. 31, 1963

POTASSIUM BIFLUORIDE (KHF_2) (LIQUID) MOL. WT. = 78.108

$S^\circ_{298.15}$ = 32.3 cal. deg. mole^{-1}

ΔH_f° 298.15 = -218.24 ± 0.35 kcal. mole^{-1}

T_m = 511.8°K.

ΔH_m° = 1.582 ± 0.003 kcal. mole^{-1}

$T_{decomp.}$ = [751]°K.

Heat of Formation.

This was calculated from the heat of formation of the crystal, the heat of melting and $H_{511.8}-H_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The entropy was determined from that of the crystal in a manner analogous to the heat of formation. The heat capacity just above the melting point was measured by E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949) and was assumed constant above the melting point. A glass type transition was assumed at 341°K. below which the heat capacity is that of the solid.

Melting.

See table for crystal.

Decomposition.

The temperature of decomposition was estimated from the free energy cross-over and is the point where the HF(g) reaches 1 atm. It should be noted that the vapor pressures over the liquid of Westrum and Pitzer, loc. cit. are apparently in error, being high by roughly 12%. A 3rd law analysis at each vapor pressure point gave an almost constant heat of reaction in the solid region but in the liquid region the value changed abruptly with temperature. The only factors which were variable were the pressure and the liquid heat capacity, a trial change of 20% in the heat capacity produced an almost negligible change in the heat of reaction. Thus the vapor pressures over the liquid appear to be in error and the decomposition point of 702°K. obtained by extrapolating to 1 atmosphere is also in error.

Moments of Inertia: $I_A = 3.40 \times 10^{-39}$ g. cm.^{2} $\sigma = 2$

$I_B = 10.76 \times 10^{-39}$ g. cm.^{2} $I_C = 13.16 \times 10^{-39}$ g. cm.^{2}

Heat of Formation. ΔH_f° 298.15 was estimated in C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

Heat Capacity and Entropy. Vibrational levels and multiplicities were taken from G. Janz and Y. Mikawa, Bull. Chem. Soc. Japan 34, 1495 (1961). Moments of inertia were found in Henderson and Scheffee, op. cit.

Mercury Difluoride (HgF_2)

March 31, 1962

F_2Hg

MERCURY DIFLUORIDE (HgF_2) (Crystal)

Mol. Wt. = 238.61

ΔH°_f 298.15 = [-101.0 ± 10.0] kcal. mole^{-1}

$S^\circ_{298.15}$ = [27.800 ± 2.0] cal. deg.$^{-1}$ mole^{-1}

T_m = 918°K

ΔH_m = [5.5 ± 1.0] kcal. mole^{-1}

Heat of Formation. Estimated by comparison of the mercurous and mercuric halides.

Heat Capacity and Entropy. The heat capacity was assumed to be a linear function of temperature and was estimated to be 7.0 cal. deg.$^{-1}$ per atom at the melting point. The entropy was estimated by comparison with the other mercuric and mercurous halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1960).

Melting. T_m was given by O. Ruff and G. Bahlau, Ber. 51, 1752 (1918). The heat of melting was from L. Brewer, paper 7, National Nuclear Energy Series 4-19B "Thermodynamics" McGraw-Hill (1950).

March 31, 1962

MERCURY DIFLUORIDE (HgF_2) (Liquid)

Mol. Wt. = 238.61

ΔH_f° 298.15 = [-96.772 ± 10.0] kcal. mole^{-1}

$S^\circ_{298.15}$ = [32.083 ± 2.0] cal. deg.$^{-1}$ mole^{-1}

T_m = 918°K

ΔH_m = [5.5 ± 1.0] kcal. mole^{-1}

T_b = 920°K

ΔH_v = [22.0 ± 4.0] kcal. mole^{-1}

Heat of Formation. Calculated from ΔH_f° (crystal).

Heat Capacity and Entropy. C_p was estimated by analogy with mercuric iodide and bromide. A glass type transition was assumed at 613°K below which the heat capacity was that of HgF_2(crystal). The entropy was calculated from S°(crystal) and the estimated ΔH_m and heat capacities of crystal and liquid.

Fusion and Vaporization. T_m was given by O. Ruff and G. Bahlan, Ber. 51, 1752 (1918). T_b, ΔH_m, and ΔH_v were all taken from L. Brewer, paper 7, National Nuclear Energy Series 4-19B "Thermodynamics" McGraw-Hill (1950).

December 31, 1961

MERCURY DIFLUORIDE (HgF_2) (IDEAL GAS) MOL. WT. = 238.61

Point Group $D_{\infty h}$

ΔH_f° 298.15 = [-70.2 ± 10.0] kcal mole⁻¹

$S^\circ_{298.15}$ = 63.545 cal deg⁻¹ mole⁻¹

Vibrational Levels and Multiplicities

ω, cm⁻¹
[600] (1)
[120] (2)
[593] (1)

Hg-F distance = [1.96] Å

Moment of Inertia = [12.118 x 10^{-39}] g cm² $\sigma = 2$

Heat of Formation

Estimated by comparison with the other gaseous mercuric halides and with the crystalline mercurous mercuric fluorides.

Heat Capacity and Entropy

Vibrational constants were estimated by analogy with the other mercuric halides and the mercurous halides. The bond length was estimated by assuming the mercurous bond to be 0.965 of the mercuric bond by analogy with the mercury chlorides.

Mercury Monofluoride, Dimeric (Hg_2F_2)

March 31, 1962

MERCURY MONOFLUORIDE, DIMERIC (Hg_2F_2) (Crystal)

Mol. Wt. = 439.22

ΔH_f° 298.15 = [-116.0 ± 3.0] kcal. mole^{-1}

$S^\circ_{298.15}$ = [38.4 ± 2.0] cal. deg.$^{-1}$ mole^{-1}

T_{sub} = [949]°K (decomp.)

Heat of Formation. A value of ΔF_f° 298.15 was obtained from the cell measurements of G. G. Koerber and T. de Vries, J. Amer. Chem. Soc. 74, 5008 (1952). This was combined with ΔS_f° from the estimated entropy.

Heat Capacity and Entropy. The heat capacity was estimated by comparison with mercurous chloride. The entropy was estimated by comparison with the other mercurous and mercuric halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1960).

Sublimation. Sublimation with decomposition to Hg(g) and $HgF_{2(g)}$ was assumed at 949°K from the free energy change of the reaction.

Potassium Difluoride Uninegative Ion (KF_2^-)

Dec. 31, 1968

POTASSIUM DIFLUORIDE UNINEGATIVE ION (KF_2^-) (IDEAL GAS) GFW = 77.09935

Point Group [$D_{\infty h}$]

ΔHf_0° = -165 ± 10 kcal/mol

$S^\circ_{298.15}$ = [63 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -166 ± 10 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[350] (1)
[130] (2)
[500] (1)

Bond Distance: K-F = [2.17] Å

Bond Angle: F-K-F = [180°]

$\sigma = 2$

Rotational Constant: B_0 = [0.094] cm^{-1}

Heat of Formation

The heat of formation is estimated from three calculated values. The methods of calculation are described as follows. In a manner analogous to $LiF_2^-(g)$, the first reaction considered is $KF(g) + F^-(g) = KF_2^-(g)$ and the ΔHr°_{298} value is evaluated to be between 0 and 1/2(-50) = -25 kcal/mol (see $LiF_2^-(g)$ table for details), yielding $\Delta Hf^\circ_{298}(KF_2^-, g)$ between -140 and -165 kcal/mol. The ΔHf°_{298} values for the other species involved are taken from JANAF Tables.

The second reaction employed for estimation is $K_2F_2(g) = KF_2^-(g) + K^+(g)$. The enthalpy change of this reaction is calculated as ΔHr°_{298} = 1/2(50.0) + 138.8 = 163.8 kcal/mol where the KF_2^- ion is considered to be converted from $K_2F_2(g)$ by breaking one of the two dimer association bonds (ΔHr°_{298} = 50.0 kcal/mol) and one K^+-F^- ionic bond (ΔHr°_{298} = 138.8 kcal/mol). Using ΔHf°_{298} = -206.2 and 122.9 kcal/mol for $K_2F_2(g)$ and $K^+(g)$, we obtain the heat of formation for $KF_2^-(g)$ as -165 kcal/mol.

Based on an assumption that the electron affinity of $KF_2(g)$ is similar to that of F (see $LiF_2^-(g)$ table for details), i.e. ΔHr°_{298} = 83.5 kcal/mol (1) for the reaction $KF_2^-(g) = KF_2(g) + e^-(g)$, we derive $\Delta Hf^\circ_{298}(KF_2^-, g)$ = -167.7 kcal/mol. The ΔHf°_{298} for $KF_2(g)$ is calculated as -84.2 kcal/mol from the value ΔHr°_{298} = 143.3 kcal/mol for the reaction $K_2F_2(g) = KF_2(g) + K(g)$ where the ΔHr°_{298} value is calculated as the sum of two enthalpy changes, i.e. half of the heat of dimer dissociation into two monomers or 1/2(50.0) = 25.0 kcal/mol, and the heat of dissociation of KF(g) or 118.3 kcal/mol.

The value of ΔHf°_{298} for $KF_2^-(g)$ is tentatively adopted as -166 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion given by Walsh (2) that molecules with not more than 16 valency electrons are linear in their ground states. The K-F bond distance is taken to be the same as that of KF(g) reported by Veazey and Gordy (3). The vibrational frequencies are estimated from the vibrational frequency of KF(g) using the method suggested by Herzberg (4). The moment of inertia is 2.971 x 10^{-38} g cm^2. The enthalpy at 0°K is -3.293 kcal/mol.

Bond Distance: K-F = 2.2 Å

Bond Angles: F-K-F = [90°] K-F-K = [90°]

Product of the Moments of Inertia: $I_AI_BI_C = [2.240 \times 10^{-113}]\ g^3\ cm^6$

Heat of Formation

The equilibrium constants (K_c) for the reaction $K_2F_2(g) = 2KF(g)$, in the temperature range 974-1052°K, were determined by Eisenstadt, Rothberg, and Kusch (1). Although the reported absolute values of the vapor pressures of KF(c) are not adopted for evaluation, the reported K_c values are used to calculate the enthalpy change (ΔHr°_{298}) for the above reaction. The second law and third law values of ΔHr°_{298} are derived as 51.0 ± 1.6 and 50.0 kcal/mol, respectively. Based on the third law ΔHr°_{298} and ΔHf°_{298}(KF, g) = -78.1 kcal/mol, we obtain ΔHf°_{298} = -206.2 kcal/mol for $K_2F_2(g)$ which is tentatively adopted.

Heat Capacity and Enthalpy

The molecular structure and K-F bond distance were determined by Akishin and Rambidi (2), using electron diffraction with sector microphotometry. The bond angles are estimated by comparison with other alkali halide dimers. The vibrational frequencies are taken from Berkowitz (3) which were calculated based on an ionic model. The three principal moments of inertia are: $I_A = 3.1423 \times 10^{-38}$, $I_B = 1.5267 \times 10^{-38}$, and $I_C = 4.6690 \times 10^{-38}\ g\ cm^2$.

Bond Angle: F-Li-F = [180°]

σ = [2]

Rotational Constant: B_0 = [0.180] cm^{-1}

Heat of Formation

Due to lack of thermal data, the heat of formation for $LiF_2^-(g)$ is arbitrarily selected from the following three estimated values. For the reaction (1) $LiF(g) + F^-(g) = LiF_2^-(g)$, we expect the enthalpy change would be between 0 to -31 kcal/mol. Comparison with the other molecules like CO_2, BOF, BeF_2, etc. having 16 valence electrons leads us to assume that the isoelectronic molecule LiF_2^- should also be quite stable. This indicates that reaction (1) is favorable or ΔHr°_{298} is negative. However, the $LiF-F^-$ bond strength is expected to be weaker than half of the two ionic bonds between Li^+ and F^- in Li_2F_2 molecule (see Li_2F_2 (g) table for the molecular structure). In other words, the ΔHr°_{298} value of reaction (1) is less negative than half of the heat of dimerization (-62.4 kcal/mol). Incorporating ΔHr°_{298} = 0 and -31 kcal/mol, respectively, for reaction (1), with ΔHf°_{298} = -81.45 and -62.2 kcal/mol for LiF(g) and $F^-(g)$, we derived the corresponding values for $\Delta Hf^\circ_{298}(LiF_2^-, g)$ as -144 and -175 kcal/mol, which are the upper and lower limits.

The electron affinities of Li and F atoms are reported as 0.7 and 3.448 eV, respectively, by Beckett and Cassidy (1). From this data we estimate that the electron affinity of $LiF_2(g)$ should be closer to that of F atom than to that of Li. Assuming ΔHr°_{298} = electron affinity of F atom = 83.5 kcal/mol for the reaction $LiF_2^-(g) = LiF_2(g) + e^-(g)$, we obtain the heat of formation for $LiF_2^-(g)$ as -177.3 kcal/mol. The $\Delta Hf^\circ_{298}(LiF_2, g)$ used for calculation is derived from an estimated ΔHr°_{298} = 169.9 kcal/mol for the decomposition of LiF dimer or $Li_2F_2(g) = LiF_2(g) + Li(g)$ as the sum of two enthalpy changes, namely, half of the heat of dissociation of the dimer and the heat of dissociation of the monomer.

The third estimated value for the heat of formation of $LiF_2^-(g)$ is calculated as follows. Based on the two heats of reaction, i.e. ΔHr°_{298} = 62.4 kcal/mol for $Li_2F_2(g) = LiF(g)$, and ΔHr°_{298} = 183.5 kcal/mol for $LiF(g) = Li^+(g) + F^-(g)$, we assume the enthalpy change of the reaction $Li_2F_2(g) = LiF_2^-(g) + Li^+(g)$ to be 1/2(62.4) + 183.5 = 214.7 kcal/mol. In other words, we consider the $LiF_2^-(g)$ molecule is formed by breaking half of the dimer dissociation bonds and one monomer dissociation bond to produce two ions. Using ΔHf°_{298} = -225.33 and 164.24 kcal/mol for $Li_2F_2(g)$ and $Li^+(g)$, we evaluate $\Delta Hf^\circ_{298}(LiF_2^-, g)$ = -174.9 kcal/mol.

From the above three estimated values, we tentatively choose $\Delta Hf^\circ_{298}(LiF_2^-, g)$ as -170 ± 15 kcal/mol.

Heat Capacity and Entropy

According to A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953), molecules with not more than 16 valence electrons are linear in their ground states. Since $LiF_2^-(g)$ has 16 valence electrons, we assume its molecular structure is linear. The Li-F bond distance is estimated by comparison with that of LiF(g) reported by Wharton et al. (2). The vibrational frequencies are estimated from those of the isoelectronic gaseous molecules, CO_2 and BeF_2. The moment of inertia is 1.555×10^{-38} g cm^2. The enthalpy at 0°K is -2.653 kcal/mol.

Bond Distances: Li-F = 1.68 Å F-F = 2.67 Å

Bond Angles: Li-F-Li = 74.76° F-Li-F = 105.24° σ = 4

Product of the Moments of Inertia: $I_AI_BI_C = 3.6766 \times 10^{-115}\ g^3cm^6$

Heat of Formation

The heat of formation (ΔHf°_{298}) is calculated based on the adopted value ΔHr°_{1000} = 61.4 kcal/mol for the reaction $Li_2F_2(g) = 2LiF(g)$ which is consistent with the literature values listed in the table below. Due to lack of knowledge of the fragmentation patterns, the relative ionization cross sections of the ionic species formed in the mass spectrometer, and the molecular constants of the LiF polymers, the evaluation of equilibrium constants used to calculate ΔHr° involves considerable uncertainty. In order to solve this problem more research work seems necessary.

	Investigator	ΔHr°_{1000}, kcal/mol	Experimental Method
1.	Berkowitz et al. (1962)	61.6 ± 2	mass spectrometry with a double-oven apparatus
2.	Buchler and Stauffer (1966)	61.3 ± 3	mass spectrometry with a two-piece Ni Knudsen cell
3.	Eisenstadt et al. (1958)	61.2	molecular-beam velocity-selector
4.	Hildenbrand et al. (1964)	60.4 ± 3	torsion effusion
5.	Akishin et al. (1959)	59.5 ± 3	mass spectrometry with a double effusion chamber
6.	Porter and Schoonmaker (1958)	65.0 *	mass spectrometry with a Mo Knudsen cell

* derived from reported vapor pressures of LiF(g) and $Li_2F_2(g)$ at 1073°K.

Heat Capacity and Entropy

The molecular structure of $Li_2F_2(g)$ was determined as D_{2h} by Buchler et al. (12), using electric deflection and mass spectrometric detection. Akishin and Rambidi (7) studied the structure of $Li_2F_2(g)$ by electron deflection with sector microphotometry and assigned the bond distances of Li-F and F-F which are adopted. Evidence for a matrix stabilized linear structure of Li_2F_2 has been obtained by extending the spectral measurements for matrix isolated lithium fluoride into the far infrared region by Redington (8) and Abramowitz et al. (9).

Klemperer and Norris (10) observed two infrared-active vibrational frequencies, 640 and 460 cm^{-1}, and assigned them as $\nu_5(B_{2u})$ and $\nu_6(B_{3u})$. The infrared absorption spectra of lithium fluoride monomer and dimer isolated in solid inert gas matrices were investigated by Linevsky (11), Snelson and Pitzer (13), and Schlick and Schnepp (14). Redington (8) obtained infrared spectra of LiF species suspended in solid Ne, O_2, CO, and CH_4 at liquid-helium temperature. The observed solvent shifts for LiF and Li_2F_2 spectra exhibit several regularities. The vibrational frequencies used for calculation are those reported by Snelson (15) who re-examined the spectrum of LiF species over the range 200 - 4000 cm^{-1}, using sample purity of 99.3%. The saturated vapor was isolated at 900°C and the superheated unsaturated vapor at 1200°C. A variety of deposition rates and matrix dilutions was tried. Based on the frequencies assigned to the isotopic species, the vibrational frequencies of the natural isotopic $Li_2F_2(g)$ are calculated. It appears that the vibrational frequencies calculated on the basis of the potential function for an ionic model by Berkowitz (16) are too low.

The three principal moments of inertia are: $I_A = 2.3970 \times 10^{-39}$, $I_B = 1.1244 \times 10^{-38}$ and $I_C = 1.3641 \times 10^{-38}$ g cm^2.

MAGNESIUM DIFLUORIDE (MgF_2)   (CRYSTAL)   MOL. WT. = 62.3088

$S^\circ_{298.15}$ = 13.68 ± 0.07 cal. deg.$^{-1}$ mole^{-1}

T_m = 1536°K.

$\Delta H^\circ_{f\ 0}$ = -267.8 ± 0.3 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -268.7 ± 0.3 kcal. mole^{-1}

ΔH°_m = 13.90 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 95.5 ± 1.5 kcal. mole^{-1}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for MgF_2(c) was obtained from E. Rudzitis and W. N. Hubbard, Argonne National Laboratory, Argonne, Illinois, private communication, dated June 18, 1964. This value was determined by fluorine bomb calorimetry which is considered as comparatively the best method available at the present time. The heats of reaction involving MgF_2(c) were measured by many early investigators. However, the $\Delta H^\circ_{f\ 298.15}$($MgF_2$, c) values derived are in reasonable agreement. The results are presented as follows.

Investigator	Chemical Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1}	$\Delta H^\circ_{f\ 298.15}$, kcal. mole^{-1}
Domange(1)	$MgF_2(c) + H_2O(g) \rightarrow 2HF(g) + MgO(c)$	+51.76 ± 1.2(1)	-267.3 ± 1.3
Wartenberg(2)	$Mg(c) + 2(HF\cdot 80H_2O) \rightarrow MgF_2(c) + H_2(g) + 160H_2O(l)$	-109.5 ± 0.7	-262.1 ± 0.8
Torgeson, et al.(3)	$Mg(OH)_2(c) + 2HF(Sol.) \rightarrow MgF_2(c) + 2H_2O(l)$	-29.09	-266.5 ± 0.8
Gross, et al.(4)	$Mg(c) + PbF_2(c) \rightarrow MgF_2(c) + Pb(c)$	-109.5 ± 1.5	-269.1 ± 1.8

(1) L. Domange, Ann. chim. phys. 7(11)225 (1937). The ΔH°_r value was calculated by the third law method.
(2) H. V. Wartenberg, Z. anorg. allgem. Chem. 249, 100 (1942).
(3) D. R. Torgeson and T. G. Sahama, J. Am. Chem. Soc. 70, 2156 (1948).
(4) P. Gross, C. Hayman and D. L. Levi, Trans. Faraday Soc. 50, 477 (1954).

Heat Capacity and Entropy.

The low temperature heat capacities, 54.22-296.5°K., were measured by S. S. Todd, J. Am. Chem. Soc. 71, 4115 (1949). The high temperature heat capacities, 298-1536°K., were obtained from the heat content measurements determined by B. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). These two sets of data were joined smoothly at 298°K. $S^\circ_{298.15}$ was obtained from C_p data reported by S. S. Todd, loc. cit., using S°_{51} (extrap.) = 0.537 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

T_m and ΔH°_m were taken from B. F. Naylor, loc. cit.

Heat of Sublimation.

The vapor pressure of MgF_2(c) has been measured by seven investigators. Using the reported data, the respective $\Delta H^\circ_{s\ 298.15}$ for MgF_2(c) were calculated (see MgF_2(g) table for detail). The adopted value was selected to be 95.5 ± 1.5 kcal. mole^{-1}.

Dec. 31, 1960; June 30, 1964; Mar. 31, 1966

MAGNESIUM DIFLUORIDE (MgF_2)   (LIQUID)   MOL. WT. = 62.3088

$S^\circ_{298.15}$ = 15.290 cal. deg.$^{-1}$ mole^{-1}

T_m = 1536°K.

T_b = [2499]°K.

$\Delta H^\circ_{f\ 298.15}$ = -259.557 kcal. mole^{-1}

ΔH°_m = 13.90 kcal. mole^{-1}

ΔH°_v = [63.48] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}(l)$ was obtained from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

Heat capacity (1691-1800°K.) was reported by B. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). The same value was used for other temperatures. The entropy was obtained in a manner analogous to that of the heat or formation.

Melting Data.

T_m and ΔH°_m were obtained from B. F. Naylor, Loc. Cit.

Vaporization Data.

T_b was obtained from equilibrium calculation between the species $MgF_2(l)$, $MgF_2(g)$, and $(MgF_2)_2(g)$, i.e., the temperature at which the sum of the partial pressures of $MgF_2(g)$ and $(MgF_2)_2(g)$ equals one atmosphere. From the difference between the heats of formation of $MgF_2(l)$ and $MgF_2(g)$ at the boiling point, the heat of vaporization was calculated. At the boiling point the amount of dimeric species is negligible in comparison with that of the monomeric species.

Bond Distance: Mg-F = 1.77 ± 0.02 Å

Bond Angle: F-Mg-F = 150 ± 5°

Product of the Moments of Inertia: $I_AI_BI_C = 1.80632 \times 10^{-115}$ g.³ cm.⁶

$\sigma = 2$

Heat of Formation.

The vapor pressure of $MgF_2(g)$ over $MgF_2(c)$ and $MgF_2(l)$ has been measured by many investigators using different methods. Based on the reported vapor pressure data, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

Investigator	Temperature, °K.	Method*	$\Delta H^\circ_{s\ 298.15}$, kcal. mole⁻¹ Second Law Value	Third Law Value	Drift cal. deg.⁻¹ mole⁻¹

3 R. R. Hammer, Ph.D. Thesis, University of California, 1961. Also see R. R. Hammer and J. A. Pask, J. Am. Ceram. Soc. 47, 264 (1964).

4 J. Berkowitz and J. R. Marquart, J. Chem. Phys. 37, 1853 (1962). The value, 91.36 kcal. mole⁻¹, was converted from the reported value 86 kcal. mole⁻¹ at 1330°K.

5 M. A. Greenbaum, H. C. Ko, M. Wong and M. Farber, J. Phys. Chem. 68, 965 (1964), whose reported $\Delta H^\circ_{s\ 298.15}$ value was derived using different values of free energy functions for $MgF_2(c)$ and $MgF_2(g)$ from those used here.

6 The first two sets of data were obtained from D. L. Hildenbrand, et al., Philco, Ford Motor Company, "An Experimental Program for Obtaining the Thermodynamic Properites of Propellant Combustion Products", U-1187, Third Quarterly Report, Mar. 15, 1961. The last $\Delta H^\circ_{s\ 298.15}$ value was given by D. L. Hildenbrand, private communication, March 19, 1964. The rest were reported by D. L. Hildenbrand, loc. cit., U-2289, Fifth Quarterly Technical Report, Sept. 15, 1963. These values were summarized by D. L. Hildenbrand, et al., J. Chem. Phys. 40, 2882 (1964).

7 J. W. Green, G. D. Blue, T. C. Ehlert and J. L. Margrave, J. Chem. Phys. 41, 2245 (1964).

When vapor pressure data were determined above melting point, 1536°K., the heat of sublimation was derived from the heat of vaporization obtained incorporating heat of melting. All data were carefully examined and some inconsistent vapor pressure points were discarded. The best value of $\Delta H^\circ_{s\ 298.15}$ for $MgF_2(c)$ was selected as 95.5 ± 1.5 kcal. mole⁻¹. The heat of formation for $MgF_2(g)$ was calculated from the heats of formation and sublimation for $MgF_2(c)$.

Heat Capacity and Entropy.

The molecular structure of $MgF_2(g)$ has been reported to be linear by A. Büchler, J. L. Stauffer and W. Klemperer, Interim Technical Report No. 7, June 30, 1964, A. D. Little, Inc., and bent by M. J. Linevsky, First Quarterly Report, Nov. 1, 1963 - Jan. 31, 1964, General Electric Company. An intensive investigation of the matrix spectrum of $MgF_2(g)$ has been made recently by D. E. Mann and G. V. Calder, National Bureau of Standards Report 8919, July 1, 1965. The final results were presented by D. E. Mann at the ICRPG Working Group on Thermochemistry meeting on Mar. 17, 1966. The vibrational frequencies, bent structure and bond angle were confirmed by use of isotopic substitution, and were adopted here. The Mg-F bond distance was reported by P. A. Akishin, V. P. Spiridonov, G. A. Sobolev and V. A. Naumov, Zh. Fiz. Khim. 31, 461 (1957). The three principal moments of inertia are: $I_A = 5.1660 \times 10^{-40}$, $I_B = 1.8442 \times 10^{-38}$ and $I_C = 1.8959 \times 10^{-38}$ g. cm.²

Heat of Formation.

C. B. Colburn and F. A. Johnson, J. Chem. Phys. 33, 1869 (1960), report the study of the dissociation reaction $N_2F_4(g) = 2NF_2(l)$ by two independent methods: (a) measurement of the pressure variation with temperature at constant volume and (b) a spectrophotometric method based on the temperature dependence of the ultraviolet absorption of the NF_2 radical. The authors give a more detailed account of their data in J. Am. Chem. Soc. 83, 3043 (1961). The contents of these articles indicate that $2NF_2(l)$ should read $2NF_2(g)$ in the above reaction. The first method gave a value of 19.85 kcal. mole^{-1} for the heat of dissociation in the temperature range 373 to 423°K. which corresponds to 19.87 kcal. mole^{-1} at 298°K. From their ΔH and ΔS data, ΔF was calculated and used in a third law evaluation of the heat of dissociation. The ΔH_{298} so calculated showed an increasing trend with increasing temperature; the average value was 22.87 kcal. mole^{-1} which is not in agreement with their value of 19.87 kcal. mole^{-1}. The spectrophotometric value of 21.7 kcal. mole^{-1} at 298°K. was obtained from the integrated Van't Hoff equation.

L. H. Piette, F. A. Johnson, K. A. Booman and C. B. Colburn, J. Chem. Phys. 35, 1481 (1961), studied the temperature dependence of the EPR spectrum of the NF_2 radical. They obtained a second law value of 19.3 kcal. mole^{-1} for the heat of dissociation. This value, however, depends upon the degree of dissociation of N_2F_4 which they calculated from the (dP/dT) measurements of Colburn and Johnson. Any error in the (dP/dT) measurements would manifest itself in like manner here.

H. E. Doorenbos and B. R. Loy, J. Chem. Phys. 39, 2393 (1963), investigated the ESR spectrum of the N_2F_4-NF_2 equilibrium from which they calculated a second law value of 19.8 kcal. mole^{-1} for the heat of dissociation. They report that at 25°C. and 13 atm. N_2F_4 is 0.022% dissociated in the vapor phase. A third law calculation using this datum and the relationship $K_p = (4\alpha^2/1-\alpha^2)P_T$, where α is the degree of dissociation of N_2F_4 and P_T is the total pressure, gave a heat of dissociation of 21.79 kcal. mole^{-1} at 298°K.; this is not in agreement with their second law value.

J. T. Herron and V. H. Dibeler, J. Research Natl. Bur. Standards 65A, 405 (1961), report thermal dissociation data for N_2F_4. From their data they calculate a second law value of 21.5 kcal. mole^{-1} for the heat of dissociation of N_2F_4. A second and third law evaluation of their data was performed in the Dow Thermal Laboratory. It was found that if the k factor, relating their measured ion abundances to partial pressures, was taken as 4.72 X 10^{-8}, a third law value was obtained that showed slight scatter but no temperature dependence. Excluding those points that showed scatter, the third law heat of dissociation at 298°K. was 22.27 kcal. mole^{-1}. A second law plot gave a heat value of 22.23 kcal. mole^{-1} at an average temperature of 400°K. or 22.25 kcal. mole^{-1} at 298°K. Those points that deviated from the chosen straight line in the second law plot showed corresponding deviations in the third law calculation. Those points lying on the second law slope gave a constant third law value.

The heat of dissociation for $N_2F_4(g) = 2NF_2(g)$ was taken to be 22.26 kcal. mole^{-1}. Utilizing the heat of formation of $N_2F_4(g)$ (see N_2F_4 table), the heat of formation of the difluoroamino radical becomes 10.1 ± 2.0 kcal. mole^{-1}. All values for the heat of dissociation fall within the limits of error assigned to the heat of formation of NF_2.

Heat Capacity and Entropy.

See table on tetrafluorohydrazine (N_2F_4) (ideal gas) for writeup.

552 (1)	737 (1)

Bond Distance: N-F = 1.384 Å N-N = 1.214 Å

Bond Angle: F-N-N = 114.5 ± 0.5°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 6.583621 X 10^{-115} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was derived from the heat of reaction $N_2F_2(g) + 8/3\ NH_3(g) = 2NH_4F(c) + 4/3\ N_2(g)$ which was measured calorimetrically by G. T. Armstrong and S. Marantz[1]. There are two isomers, the trans and the active form of difluorodiazine. The heats of formation were determined to be 19.4 and 16.4 kcal. mole^{-1} for the trans and the active isomers respectively. The active form of N_2F_2 has been interpreted here as the cis isomer which will be discussed later. The heat of isomerization has also been reported as 3.0 kcal. mole^{-1} by Armstrong and Marantz. The value, $\Delta H^\circ_{f\ 298}$ (cis N_2F_2, g) = 16.4 kcal. mole^{-1}, is adopted in the tabulation.

A. V. Pankratov et al.[2], have measured the enthalpy of reaction $N_2F_2(g) + 3KI = 2KF + N_2 + KI_3$ in acidic solution (pH = 3), and reported $\Delta H^\circ_{f\ 298}$ (active N_2F_2, g) = 25.3 ± 2.0 kcal. mole^{-1}.

The "heat of isomerization" has been reported as 27.5 ± 5.0 kcal. mole^{-1} by C. B. Colburn et al.[9] The derivation of this value is unknown. The authors observed three values of the equilibrium constant for the isomerization reaction. Third law analysis of their data gives $\Delta H^\circ_{r\ 298}$ = 2.52 ± 0.05 kcal. mole^{-1} for the reaction cis $N_2F_2(g) \rightarrow$ trans $N_2F_2(g)$ which is in good agreement with Armstrong and Sidney's data.

Heat Capacity and Entropy.

Although the infrared spectrum[7,8] of the active form of $N_2F_2(g)$ has been interpreted as favoring the 1,1-difluorodiazine over the cis-configuration[3,4], n.m.r.[5] and microwave[6] studies definitely indicate the latter. The vibrational frequencies[7] previously assigned to the 1,1-difluorodiazine have been adopted here for the cis isomer. The selected bond distances and angle were taken from the isotopic nitrogen microwave studies[6]. The principal moments of inertia were: I_A = 4.2438 X 10^{-39}, I_B = 10.5129 X 10^{-39} and I_C = 14.7567 X 10^{-39} g. cm.^{2}

See the trans $N_2F_2(g)$ table for the comparison of the different physical properties between trans and cis isomers.

1010 (1)	989 (1)
1636 (1)	421 (1)
592 (1)	360 (1)

Bond Distance : N-F = 1.44 Å   N-N = 1.25 Å

Bond Angle: F-N-N = 115°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 432.6784 X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

G. T. Armstrong and S. Marantz, J. Chem. Phys. 38, 169 (1963) have measured calorimetrically the enthalpy of reaction $N_2F_2(g) + 8/3\ NH_3(g) = 2NH_4F(c) + 4/3\ N_2(g)$, and reported $\Delta H^\circ_{f\ 298}$ (trans N_2F_2, g) = 19.4 ± 1.2 kcal. mole^{-1} which is adopted in this tabulation.

Heat Capacity and Entropy.

The bond distances and bond angle were obtained from S. H. Bauer, J. Am. Chem. Soc. 69, 3104 (1947), by electron diffraction. The fundamental vibrational frequencies were obtained from R. H. Sanborn, J. Chem. Phys. 33, 1855 (1960) by infrared spectroscopy. The three principal moments of inertia are $I_A = 0.919 \times 10^{-39}$, $I_B = 21.2433 \times 10^{-39}$ and $I_C = 22.1623 \times 10^{-39}$ g. cm.^{2}

As pointed out by R. Ettinger, F. A. Johnson and C. B. Colburn, J. Chem. Phys. 34, 2187 (1961), the trans N_2F_2 is the less active isomer which is different from the active isomer by its (1) vapor pressure (2) boiling point (3) heat of vaporization (4) critical temperature (5) melting point (6) mass spectral cracking pattern (7) NMR spectrum (8) infrared spectrum (9) heat of isomerization (10) reactivity with mercury and glass.

SODIUM DIFLUORIDE UNINEGATIVE ION (NaF_2^-) (IDEAL GAS) GFW = 60.98715

Point Group [$D_{\infty h}$] ΔHf°_0 = -159 ± 10 kcal/mol

$S^\circ_{298.15}$ = [60 ± 2] gibbs/mol $\Delta Hf^\circ_{298.15}$ = -160 ± 10 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[400] (1)
[170] (2)
[650] (1)

Bond Distance: Na-F = [1.93] Å

Bond Angle: F-Na-F = [180°] σ = [2]

Rotational Constant: B_0 = [0.119] cm^{-1}

Heat of Formation

The heat of formation for $NaF_2^-(g)$ is estimated from three calculated values. The methods of calculation are described as follows. The first reaction we take into consideration is $NaF(g) + F^-(g) = NaF_2^-(g)$. In a manner analogous to $LiF_2^-(g)$ molecule (see $LiF_2^-(g)$ table for details), we assume $NaF_2^-(g)$ is stable and ΔHr°_{298} for the reaction $NaF(g) + F^-(g) = NaF_2^-(g)$ is somewhere between 0 to 1/2(-64) = -32 kcal/mol where the value -56 kcal/mol is the heat of dimerization. Based on ΔHr°_{298} = 0 and -28 kcal/mol, respectively, with JANAF ΔHf°_{298} values for the species involved, we obtain $\Delta Hf^\circ_{298}(NaF_2^-, g)$ = -132 and -164 kcal/mol as the upper and lower limits.

The heat of formation, calculated based on the reaction $NaF_2^-(g) = NaF_2(g) + e^-(g)$, is -165.8 kcal/mol, using ΔHr°_{298} and $\Delta Hf^\circ_{298}(NaF_2, g)$ estimated as 83.5 and -82.3 kcal/mol, respectively. The ΔHr°_{298} value is obtained from an assumption that the enthalpy change for removing an electron from $NaF_2^-(g)$ is comparable to that from $F^-(g)$. Due to the fact that the Na atom has smaller electronegativity (0.9) than that of the F atom (4.0), we expect that there is less possibility that the electron will associate with Na atom in the NaF_2^- molecule. Therefore we adopt the electron affinity of F(g) reported by H. O. Pritchard, Chem. Rev. 52, 529 (1953), or ΔHr°_{298} = 83.5 kcal/mol for the reaction $F^-(g) = F(g) + e^-(g)$ as the ΔHr°_{298} for $NaF_2^-(g) = NaF_2(g) + e^-(g)$. The value of ΔHf°_{298} for $NaF_2(g)$ is calculated using the enthalpy change for the reaction $Na_2F_2(g) = NaF_2(g) + Na(g)$ as 145.8 kcal/mol which is derived from the sum of two enthalpy changes, namely, half of the ΔHr°_{298} value for the dimer dissociation reaction $Na_2F_2(g) = 2NaF(g)$, and the ΔHr°_{298} for the monomer dissociation reaction $NaF(g) = Na(g) + F(g)$.

Employing ΔHr°_{298} = 63.5 kcal/mol for $Na_2F_2(g) = 2NaF(g)$ and 153.0 kcal/mol for $NaF(g) = Na^+(g) + F^-(g)$, we estimate ΔHr°_{298} = 1/2(63.5) + 153.0 = 184.7 kcal/mol for the reaction $Na_2F_2(g) = NaF_2^-(g) + Na^+(g)$, which leads to ΔHf°_{298} = 163.4 kcal/mol for $NaF_2^-(g)$. For all calculations the ΔHf°_{298} values of the chemical species involved are taken from JANAF Thermochemical Tables.

The value of ΔHf°_{298} for $NaF_2^-(g)$ is tentatively adopted as -160 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion by A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953) that molecules with not more than 16 valence electrons are linear in their ground state. The Na-F bond distance is estimated by comparison with that of NaF(g) reported by S. E. Veazey and W. Gordy, Phys. Rev. 138, A1303 (1965). The vibrational frequencies are estimated from those for the isoelectronic molecule $SiO_2(g)$. The moment of inertia is 2.350×10^{-38} g cm^2. The enthalpy at 0°K is -3.117 kcal/mol.

SODIUM FLUORIDE, DIMERIC (Na_2F_2) (IDEAL GAS) GFW = 83.9764

Point Group [D_{2h}]

$\Delta Hf°_0$ = [-200.8 ± 3] kcal/mol

$S°_{298.15}$ = [68.7 ± 4] gibbs/mol

$\Delta Hf°_{298.15}$ = [-202.3 ± 3] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[420] (1)	[200] (1)
[400] (1)	[425] (1)
[350] (1)	[500] (1)

Bond Distance: Na-F = 2.02 Å

Bond Angle: Na-F-Na = [85°] σ = [4]

Product of the Moments of Inertia: $I_AI_BI_C$ = [5.6135×10^{-114}] g^3 cm^6

Heat of Formation

Although the absolute values of the vapor pressure measurements are not used for evaluation, the ratios of the numbers of dimeric and monomeric NaF molecules that effuse from the oven at the temperatures 1115 - 1191°K determined by Eisenstadt, Rothberg, and Kusch (1) by use of the electron-beam velocity-selector method are used. Based on the reported equilibrium data we evaluate the enthalpy change of the reaction (A) $Na_2F_2(g) = 2NaF(g)$ by the second and third law methods. The results are presented in the table below.

Porter and Schoonmaker (2) analyzed the vapor effusing from a Knudsen cell at 1121°K mass spectrometrically and derived the partial pressures of NaF(g) and $Na_2F_2(g)$ at that temperature. Using these reported partial pressures we calculate, by the third law method, the value $\Delta Hr°_{298}$ = 64.1 kcal/mol for reaction (A).

Sidorov et al. (3) studied the NaF - ZrF_4 system by the mass spectrometric method and derived the partial pressures of NaF(g) and $Na_2F_2(g)$ as a function of composition and temperature. Employing the data points reported at 1074 and 1167°K we obtain the third law value $\Delta Hr°_{298}$ = 62.0 ± 1.6 kcal/mol for the same reaction.

The $\Delta Hf°_{298}$ (Na_2F_2, g) is calculated based on the adopted third law value $\Delta Hr°_{298}$ = 63.5 kcal/mol for the reaction Na_2F_2 (g) = 2NaF(g), using $\Delta Hf°_{298}$(NaF, g) = -69.5 kcal/mol. Brewer and Brackett (9) reported $\Delta Hr°_{1000}$ = 56.9 kcal/mol for the above reaction. According to our tables the $\Delta Hr°_{1000}$ value is 62.5 kcal/mol.

	Investigator	Temperature, °K	No. of Points	$\Delta Hr°_{298}$, kcal/mol Second Law	Third Law	Drift eu	$\Delta Hf°_{298}$ kcal/mol
1.	Eisenstadt et al. (1958)	1115 - 1191	6	58.1 ± 2.9	63.5	4.7 ± 2.5	-202.4
2.	Porter and Schoonmaker (1958)	1121	1	—	64.1	—	-203.0
3.	Sidorov et al. (1964)	1074 - 1167	8	—	62.0 ± 1.6	—	-200.9

Heat Capacity and Entropy

The $Na_2F_2(g)$ molecule is assumed to have a rhombic structure with D_{2h} (V_h) symmetry (4, 5). The Na-F bond distance is reported by Akishin and Rambidi (5), who studied the molecular structure of alkali halide vapors by electron diffraction with sector microphotometry. The bond angle is estimated by comparison with those of the other alkali halides. Berkowitz (4, 6) has calculated the vibration frequencies of Na_2F_2 based on an ionic model. By comparison of the calculated frequencies of Li_2F_2 (6) with those of the observed ones (see Li_2F_2(g) table for details) we reestimate the vibrational frequencies for $Na_2F_2(g)$ to be higher than the ones reported by Berkowitz (6). Bauer et al. (7) used a pseudo-electrostatic model, similar to the one suggested by O'Konski and Higuchi (8), to calculate the entropies of dimerization for a number of gaseous alkali halides and estimated the six vibrational frequencies as 477, 318, 291, 477, 291, and 291 cm^{-1}. Bauer et al. calculated $\Delta S°_{1146}$ = -32.5 eu for the reaction $2NaF(g) = Na_2F_2(g)$, in reasonable agreement with the value -33.5 eu which is derived using JANAF $S°_{1146}$ values for NaF(g) and $Na_2F_2(g)$.

The three principal moments of inertia are: $I_A = 1.399 \times 10^{-38}$, $I_B = 1.422 \times 10^{-38}$, and $I_C = 2.821 \times 10^{-38}$ g cm^2.

Heat of Formation

King and Armstrong (1) have established the heat of formation with a series of reactions in a flame calorimeter. They burned F_2O in hydrogen to give HF aqueous, in addition they burned F_2 in hydrogen and O_2 in hydrogen so that the heat of formation, 5.86 kcal/mol, is directly obtainable. This value is in good agreement with the recalculated values (1) from Wartenberg and Klinkott (2), 5.7 ± 2 kcal/mol, and Ruff and Menzel (3), 4.7 ± 2 kcal/mol but differs from that of Bisbee et al. (4), -4.06 ± 2.2 kcal/mol. There were several factors in the experiments of Bisbee that might cause a too negative heat of formation and we choose to adopt the definitive value of 5.86 kcal/mol reported by King and Armstrong.

Heat Capacity and Entropy

The structural parameters are those reported by Pierce et al. (5) for the average ground state molecule from the microwave spectrum. Earlier measurements of Hilton et al. (6) disagree but according to Pierce et al. (7) the line assignments used by Hilton are incorrect. The vibrational frequencies were reported by Jones et al. (8), several other investigators report similar values (9, 10, 11). Nebgen et al. (12) have obtained the anharmonic constants for the three vibrations. Individual moments of inertia are $I_A = 1.4396 \times 10^{-39}$, $I_B = 7.7255 \times 10^{-39}$ and $I_C = 9.1651 \times 10^{-39}$ g cm^2.

Dec. 31, 1960; Sept. 30, 1965

THIONYL DIFLUORIDE (SOF_2) (IDEAL GAS) MOL. WT. = 86.0602

Point Group C_s

$S^\circ_{298.15}$ = 66.965 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = [-134 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-135 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
1308 (1)	393 (1)
801 (1)	721 (1)
526 (1)	326 (1)

Bond Distance: O-S = 1.412 Å S-F = 1.585 Å

Bond Angle: O-S-F = 106° 49' F-S-F = 92° 49'

$\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C = 1.65545 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

From the enthalpy change, $\Delta H^\circ_{r\ 298.15}$ = 131.03 kcal. mole^{-1}, for the reaction $SO_2F_2(g) = SOF_2(g) + O(g)$, the value of $\Delta H^\circ_{f\ 298.15}$ for $SOF_2(g)$ was calculated to be -133.5 kcal. mole^{-1}, using $\Delta H^\circ_{f\ 298.15}$ = -205.0 and 59.56 kcal. mole^{-1} for $SO_2F_2(g)$ and O(g), respectively. The value of $\Delta H^\circ_{r\ 298.15}$ was assumed to be the same as that for the reaction $SO_2(g) = SO(g) + O(g)$ which was calculated based on $\Delta H^\circ_{f\ 298.15}$ = -70.95, 0.52 and 59.56 kcal. mole^{-1} for $SO_2(g)$ SO(g) and O(g), respectively. Using $\Delta H^\circ_{r\ 298.15}$ = 127.86 kcal. mole^{-1} for the reaction $SO_2F_2(g) = SOF_2(g) + O(g)$, the value of $\Delta H^\circ_{f\ 298.15}$ (SOF_2, g) was evaluated as -136.7 kcal. mole^{-1} where the $\Delta H^\circ_{r\ 298.15}$ value was assumed to be the same as the S-O bond energy in $SO_2(g)$. The value of $\Delta H^\circ_{f\ 298.15}$ (SOF_2, g) adopted is -135 ± 10 kcal. mole^{-1}.

Heat Capacity and Entropy.

The bond distances and angles were obtained from R. C. Ferguson, J. Am. Chem. Soc. 76, 850 (1954). The vibrational frequencies were taken from R. J. Gillespie and E. A. Robinson, Can. J. Chem. 39, 2171 (1961). The assignment of these vibrational frequencies was based on the previous measurements of the infrared and Raman spectra reported by J. K. O'Loane and M. K. Wilson, J. Chem. Phys. 23, 1313 (1955), P. Bender and J. M. Wood, J. Chem. Phys., 23, 1316 (1955) and D. M. Yost, Proc. Indian Acad. Sci. 8, 333 (1938). The fundamental assignment reported by J. K. O'Loane and M. K. Wilson, loc. cit., was 1333, 808, 530, (410), 748 and 390 cm.$^{-1}$ The three principal moments of inertia are: $I_A = 1.0034 \times 10^{-38}$, $I_B = 9.7421 \times 10^{-39}$ and $I_C = 1.6935 \times 10^{-38}$ g. cm.^{2}

The heat capacities of thionyl fluoride (SOF_2) have been measured, from 12° to 230°K., by E. L. Pace and B. F. Turnbull, J. Chem. Phys. 43, 1953 (1965), for a sample of 99.976 mole % purity. Incorporating them with the measured ΔH°_m, 1.506 kcal. mole^{-1} at T_m = 143.25°K., and ΔH°_v, 5.091 kcal. mole^{-1} at T_b = 228.84°K., which was derived from the measured vapor pressure of $SOF_2(l)$, the entropy of $SOF_2(g)$ at 228.84°K. was evaluated as 63.56 e.u. This value is in excellent agreement with the corresponding value, 63.522 e.u., calculated using the adopted molecular constants. This indicates the fact that the molecular constants used for the calculation of the tabulated thermodynamic functions are adequate. Hence the new vibrational frequencies suggested by Pace and Turnbull, loc. cit., were not used.

Product of the Moments of Inertia: $I_AI_BI_C$ = 2.56608 X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

$\Delta H^\circ_{298.15}$ was estimated by comparison with those for $SiF_4(g)$ and $SiO_2(g)$.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for $COF_2(g)$ and $TiOF_2(g)$. The vibrational frequencies for $COF_2(g)$ and $TiOF_2(g)$ were obtained from R. J. Lovell, C. V. Stephenson, and E. A. Jones, J. Chem. Phys. 22, 1953 (1954), and J. S. Gordon, private communication, May 12, 1961, respectively. The bond distances of Si-O and Si-F were assumed to be the same as those for SiO(g) and $SiF_4(g)$, respectively. Point group, ground state multiplicity, and bond angles were estimated.

Titanium Oxide Difluoride ($TiOF_2$)

(Ideal Gas) Mol. Wt. = 101.9

Sept. 30, 1963

TITANIUM OXIDE DIFLUORIDE ($TiOF_2$) (IDEAL GAS) MOL. WT. = 101.9

Point Group [C_{2v}]

$S^\circ_{298.15}$ = [68.016] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = [-220] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-221] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

[350] (1)	[452] (1)

Bond Distances: Ti=O = [1.62] Å Ti-F = [1.74] Å

Bond Angle: O=Ti-F = [120°] σ = 2

Product of Moments of Inertia: $I_AI_BI_C$ = [4.34 X 10^{-114}] g.^{3} cm.^{6}

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was estimated as -220 kcal. mole^{-1} by J. S. Gordon, Astrosystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. $\Delta H^\circ_{f\ 298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. The principal moments of inertia are: I_A = 14.3274 X 10^{-39} g. cm.^{2}, I_B = 11.6632 X 10^{-39} g. cm.^{2}, and I_C = 25.9907 X 10^{-39} g. cm.^{2}

Sulfuryl Difluoride (SO_2F_2)

Dec. 31, 1960; Mar. 31, 1963

SULFURYL DIFLUORIDE (SO_2F_2) (IDEAL GAS) MOL. WT. = 102.066

Point Group C_{2v}

$S^\circ_{298.15}$ = 68.883 cal. deg.$^{-1}$ mole^{-1}

Ground State Multiplicity = [1]

$\Delta H^\circ_{f\ 0}$ = -203 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -205 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$	ω, cm.$^{-1}$
1269 (1)	274 (1)	539 (1)
848 (1)	360 (1)	885 (1)
553 (1)	1502 (1)	386 (1)

Bond Distance: S=0 = 1.405 ± 0.003 Å S-F = 1.530 ± 0.003 Å

Bond Angle: 0-S-0 = 123° 58' ± 12' F-S-F = 96° 7' ± 10' σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = 4.4873 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was reported by R. M. Reese, V. H. Dibeler and J. L. Franklin, J. Chem. Phys. 29, 880 (1958). The value was calculated from the appearance potential of the SO_2^+ ion obtained from electron impact studies of SO_2 and SO_2F_2.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from G. R. Hunt, and M. K. Wilson, Spectrochim. Acta, 16, 570 (1960). The bond distances and bond angles were reported by D. R. Lide, Jr., D. E. Mann, and R. M. Fristrom, J. Chem. Phys., 26, 734 (1957). The entropy of sulfuryl fluoride gas has been calculated from the calorimetric data and the third law of thermodynamics to be 62.66 cal. deg.$^{-1}$ mole^{-1} at 217.78°K. by F. J. Bockhoff, R. V. Petrella, and E. L. Pace, J. Chem. Phys. 32, 799 (1960). The discrepancy between entropy value calculated from calorimetric data and that calculated from molecular and spectroscopic data (1 atm., 217.78°K) is attributed to randomness in the solid at 0°K by F. J. Bockhoff and E. L. Pace, J. Chem. Phys. 34, 3502 (1962). The vibrational frequencies reported by W. D. Perkins and M. Kent Wilson, J. Chem. Phys. 20, 1791 (1952) were 1269 (1), 848 (1), 544 (1), [300] (1), [385] (1), 1502 (1), 553 (1), 885 (1), and 539 (1) cm.$^{-1}$ The three principal moments of inertia are: 1.6567×10^{-38}, 1.6567×10^{-38}, and 1.6349×10^{-38} g. cm.^{2}

Phosphorus Difluoride (PF_2) (Ideal Gas)

Mol. Wt. = 68.975

$\Delta H_{f\ 298.15}$ = [-105 ± 15] kcal. mole^{-1}

$S^\circ_{298.15}$ = [62.2 ± 3] cal. deg.$^{-1}$ mole^{-1}

Ground State Multiplicity = 2

Point Group C_{2v}

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$
[376] (1)
[775] (1)
[890] (1)

$I_AI_BI_C$ = [1.9059 x 10^{-115}] g.^{3} cm.^{6} σ = 2

Heat of Formation. $\Delta H^\circ_{f\ 298.15}$ was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Virginia, "Survey of Thermochemical Data," January, 1960. For their estimation they assumed certain bond energies for the dissociation of PF_3(g). Bond one was assumed 20% greater than bond two and three which were assumed to be equal. $\Delta H^\circ_{f\ 298.18}$ was corrected for the change in phosphorus reference state (white α → red V).

Heat Capacity and Entropy. Molecular constants and vibrational levels were estimated by J. S. Gordon, Thiokol Chemical Corp., Reaction Motors Division, Denville, N. J., "Thermodynamic Data for Combustion Products," January, 1960.

$\Delta Hf^\circ_{298.15}$ = -161.8 ± 1.0 kcal/mol

Tt_2 = 613°K

ΔHt_2° = [0.61] kcal/mol

Tt_1 = 725°K

ΔHt_1° = 0.65 kcal/mol

Tm = 1099°K

ΔHm° = 2.98 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 58.5 kcal/mol

Heat of Formation

The heats of formation at 298.15°K derived from the enthalpy changes of different chemical reactions are listed below. The adopted one is the average of the last three $\Delta Hf^\circ_{298.15}$ values, which is also in reasonable agreement with the $\Delta Hf^\circ_{298.15}$ values evaluated from (1) and (5).

Reference	Chemical Reaction	$\Delta Hr^\circ_{298.15}$ kcal/mol	$\Delta Hf^\circ_{298.15}$ kcal/mol
1	$PbF_2(c) + H_2(g) = Pb(\ell) + 2\ HF(g)$	32.0 ± 0.56*	-161.3 ± 0.6
2	$PbF_2(c) + H_2O(g) = PbO(c) + 2\ HF(g)$	29.6 ± 2.1**	-154.5 ± 4.0
3	$Pb(c) + F_2(g) = PbF_2(c)$	-159.7 ± 0.5	-159.7 ± 0.5
4	$PbO(c) + 2\ HF(40\%\ aq) = PbF_2(c) + H_2O(\ell)$	-22.9 ± 0.3	-159.0 ± 0.5
5	$PbF_2(c) + 2\ Na(c) = Pb(c) + 2NaF(aq)$	-112.2 ± 0.2	-162.2 ± 0.4
6	$PbF_2(c) + Mg(c) = Pb(c) + MgF_2(c)$	-109.5 ± 1.5	-159.2 ± 2.0
7	$3/2\ PbF_2(c) + Al(c) = 3/2\ Pb(c) + AlF_3(c)$	-118.5 ± 0.1	-161.5 ± 1.0
8	$3/2\ PbF_2(c) + Al(c) = 3/2\ Pb(c) + AlF_3(c)$	-117.7 ± 0.6	-162.1 ± 1.0
9	$1/2\ PbF_2(c) + 1/3\ Al(c) = 1/2\ Pb(\ell) + 1/3\ AlF_3(c)$	-38.3 ± 0.8	-161.8 ± 1.0

* This is the third law value. The second law value is 32.4 ± 0.9 kcal/mol. The entropy drift is -0.5 ± 1.2 eu.

** This is the third law value. The second law value is 39.6 ± 0.7 kcal/mol. The entropy drift is -10.9 ± 0.8 eu.

Heat Capacity and Entropy

Banashek, Patsukova, and Rassonskaya (10) measured the high temperature enthalpies ($H^\circ - H^\circ_{293.16}$), for $PbF_2(c)$ in the temperature range 670-1165°K. Based on their enthalpy measurements the heat capacity of $PbF_2(\gamma)$ at temperatures 725-1099°K is derived as 24.3 ± 0.2 gibbs/mol by the least square method. The heat capacities below 725°K are estimated using their reported enthalpies at 670-725°K, which are based on a mixture of β and γ, as a guide.

The $S^\circ_{298.15}$ is estimated to be 25 eu by the method suggested by Kubaschewski and Evans (11), and adjusted to 27 eu so that the second and third law $\Delta Hr^\circ_{298.15}$ values derived from the equilibrium data reported by Jellinek and Rudat (1) are in good agreement.

Transition Data

The transition temperatures are obtained from Banashek, Patsukova, and Rassonskaya (10). The β → γ transition at 613°K was reported as either slow or irreversible and the γ → β transition at 725°K was reversible. The polymorphism of $PbF_2(c)$ has been studied by many other investigators. However, the relations between the temperature and the character of polymorphic transformation are not consistent (10).

The enthalpy difference at 725°K for $PbF_2(\gamma)$ and $PbF_2(\beta)$ is ΔHt_1°. The value of ΔHt_2° is estimated such that the generated functions yield reasonable agreement among the derived ΔHf°_{298} values (see the above table).

Melting Data

See $PbF_2(\ell)$ table.

Heat of Sublimation

The difference between $\Delta Hf^\circ_{298.15}$ for $PbF_2(g)$ and $PbF_2(c)$ is $\Delta Hs^\circ_{298.15}$.

Mar. 31, 1962; Dec. 31, 1963; Dec. 31, 1965; June 30, 1969

LEAD DIFLUORIDE (PbF_2) (LIQUID) GFW = 245.1868

$S^\circ_{298.15}$ = [28.647] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -158.722 kcal/mol

Tm = 1099°K

ΔHm° = 2.98 kcal/mol

Heat of Formation

$\Delta Hf^\circ_{298.15}(\ell)$ is obtained from $\Delta Hf^\circ_{298.15}(c)$ by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy

The enthalpies ($H^\circ - H^\circ_{293.16}$) of $PbF_2(\ell)$ in the temperature range 1104-1165°K were determined by Banashek, Patsukova, and Rassonskaya (1). Based on their reported results the heat capacity of $PbF_2(\ell)$ is evaluated to be 24 ± 2 gibbs/mol by the least square method. This Cp value is adopted and extended to 298 and 2500°K, respectively.

The entropy ($S^\circ_{298.15}$) is calculated in a manner analogous to that of the heat of formation.

Melting Data

Tm is taken from Banashek, Patsukova, and Rassonskaya (1). The enthalpy difference at Tm for $PbF_2(\ell)$ and $PbF_2(\gamma)$ is ΔHm°.

Other values of Tm (°K) reported are 1091 (2, 11), 1097 (3, 4, 5) and 1128 (6). Using the freezing point data of binary systems PbF_2-$PbBr_2$ (5), PbF_2-$PbCl_2$ (5, 7), PbF_2-PbI_2 (5, 8), PbF_2-PbO (9), and PbF_2-NaF (10), Kelley (3) evaluated the corresponding values of ΔHm° (kcal/mol) as 1.70, 1.70, 1.96, 3.87, and 2.47. Other reported values of ΔHm° are 3.00 (1) and 4.16 (2) kcal/mol.

Vaporization Data

From mass spectroscopic study on the vapor species in PbF_2, Zmbov, Hastie, and Margrave (4) have shown that molten PbF_2 vaporizes partly as molecular PbF_2. There is considerable disproportionation, and at 715°C the vapor composition is approximately 66% PbF_4, 25% PbF_2, 2% PbF, and 7% Pb (4, 12). Tb has been reported as 1565°K (11) where the vapor is expected to be a mixture of the above species.

Heat of Formation

Vapor pressure data for PbF_2 have previously been interpreted on the assumption that PbF_2 was the only species present in the gas phase (1, 2). Zmbov, Hastie, and Margrave (3) have studied the vapor species over PbF_2(c, ℓ) mass spectrometrically and shown that PbF_2 vaporizes only partly as molecular PbF_2 and there is considerable disproportionation. The vapor composition at 988°K is approximately 66% PbF_4, 25% PbF_2, 2% PbF, and 7% Pb (3, 4). From extrapolation of the ion intensity data from 1043 to 988°K to the temperature region in which Nesmeyanov and Iofa (2) measured the saturated vapor pressures of PbF_2(c), 792-988°K, by Knudsen effusion method, the partial pressure of PbF_2(c), at 988°K was calculated to be 0.0435 ± 0.005 torr. Based on this calculated vapor pressure, the heat of sublimation (ΔHs°_{298}) of PbF_2(c) is derived as 58.50 kcal/mol by the third law method, yielding $\Delta Hf^\circ_{298}(PbF_2, g)$ = -103.3 ± 1 kcal/mol.

Due to lack of data on vapor compositions over PbF_2(c, ℓ) at various temperatures, the total pressure measurements reported by Wartenberg and Bosse (1), using boiling point method, and those of Nesmeyanov and Iofa (2) are not used for evaluation.

Heat Capacity and Entropy

The bond distance was determined by Akishin, Spiridonov and Khodchenkov (5). The bond angle is assumed to be the same as that in PbX_2(g) where X = Cl, Br or I (6). The vibrational frequencies are calculated by valence force method (10) using force constants estimated by comparison with those for PbF (7), CaF (7), CaF_2 (8), MgF (7), and MgF_2 (9). The value of ν_2 is in fair agreement with the value, 145 cm^{-1}, estimated by (4). The three principal moments of inertia are: $I_A = 1.5559 \times 10^{-38}$, $I_B = 1.1040 \times 10^{-38}$, and $I_C = 2.6599 \times 10^{-38}\ g\ cm^2$.

Bond Distance: Si-F = 1.5913 Å

Bond Angle: F-Si-F = 100°59'

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = 3.20372 \times 10^{-115}\ g^3\ cm^6$

Heat of Formation

J. L. Margrave, A. S. Kanaan, and D. C. Pease, J. Phys. Chem. 66, 1200 (1962), have reported some approximate equilibrium constants for the reaction $Si(c) + SiF_4(g) \rightarrow 2SiF_2(g)$. These were calculated from yields of polymerized products and a knowledge of the total system pressure given in U. S. Patent No. 2,840,588 (1958). The data were subjected to third law analysis using the present JANAF functions and yielded $\Delta H_{298} = 92 \pm 10$ kcal/mol, which gives $\Delta Hf^\circ_{298}(SiF_2,\ g) = -147 \pm 5$ kcal/mol.

T. C. Ehlert and J. L. Margrave, J. Chem. Phys. 41, 1066 (1964), have reported equilibrium constants for three reactions determined mass spectrometrically.

A. $CaF_2(c) + Si(g) \rightarrow Ca(g) + SiF_2(g)$

B. $CaF_2(g) + Si(g) \rightarrow Ca(g) + SiF_2(g)$

C. $2CaF(g) + Si(g) \rightarrow 2Ca(g) + SiF_2(g)$

A 2nd and 3rd law analysis of the data is shown below.

Reaction	Range °K	Points	ΔHr°_{298} kcal/mol 2nd law	3rd law	Drift eu	ΔHf°_{298} kcal/mol
A	1395 - 1543	12	80.2 ± 14.1	88.0 ± 3.0	4.6 ± 9.7	-140.1 ± 3
B	1395 - 1543	12	-9.2 ± 14.1	-18.0 ± 3.0	-6.6 + 9.6	-140.7 ± 3
C	1395 - 1543	12	-18.6 ± 7.5	-33.6 ± 1.8	-10.2 ± 5.0	-141 ± 3

We adopt $\Delta Hf^\circ_{298.15}(SiF_2,\ g) = -140.5 \pm 3$ kcal/mol.

Heat Capacity and Entropy

The microwave, ultraviolet and infrared spectra have all been extensively studied (1, 2, 3, 4, 5, 6, 7). We have adopted the vibrational frequencies and molecular structure from V. M. Khanna et al. (1). The electronic levels are from V. M. Khanna et al. (2), with an estimated triplet level by analogy with CF_2.

The individual moments of inertia are $I_A = 2.7482 \times 10^{-39}\ g\ cm^2$, $I_B = 9.5100 \times 10^{-39}\ g\ cm^2$, and $I_C = 12.2582 \times 10^{-39}\ g\ cm^2$.

Heat of Formation

Zmbov and Margrave (1) have reported ion intensities and the corresponding equilibrium constants for the reaction $Ca(g) + TiF_3(g) = CaF(g) + TiF_2(g)$. Second and third law analyses of their data give a second law $\Delta Hr°_{298}$ of 7.0 kcal/mol, a third law $\Delta Hr°_{298}$ of 11.76 kcal/mol and a third law drift of 3.1 ± 3.8 eu. The heat of formation, $\Delta Hf°_{298}$, of $TiF_2(g)$ is calculated from the third law $\Delta Hr°_{298}$, above, and the JANAF heat of formation of $TiF_3(g)$, CaF(g) and Ca(g).

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2$, $TiCl_4$, and TiF_4. The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to be the same as $TiCl_2(g)$. The levels of $TiCl_2(g)$ are estimated by assuming they correspond to the inverted states of $NiCl_2(g)$ (2). The linear configuration is assumed because experimental evidence (3) indicates that other transition metal difluorides, viz. those of Mn, Co, Ni, Cu, and Zn, are linear.

ZIRCONIUM DIFLUORIDE (ZrF_2) (CRYSTAL) GFW = 129.2168

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [18 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-230 ± 15] kcal/mol

Tm = [1175 ± 150]°K

ΔHm° = [9 ± 2] kcal/mol

$\Delta Hs^\circ_{298.15}$ = [96.6] kcal/mol

Heat of Formation

More recent thermal data related to the heat of formation of $ZrF_2(c)$ is unavailable. The adopted $\Delta Hf^\circ_{298}(ZrF_2, c)$ value is taken from (1) which was estimated by Brewer (2).

Heat Capacity and Entropy

The heat capacities in the temperature range 298-2000°K are estimated by comparison with those of $ZrF_4(c)$ and Zr(c). The S°_{298} is calculated as 17.2 and 17.0 eu based on the assumptions that $S(ZrF_2) = 1/2[S(ZrF_4) + S(Zr)]$ and $S(ZrF_2) = S(ZnF_2) - S(Zn) + S(Zr)$. Using the additive entropy constants S°_{298} = 12.1 and 4.7 eu for Zr and F suggested by Kubaschewski and Evans (3), we obtain $S^\circ_{298}(ZrF_2, c) = 12.1 + 2\ (4.7) = 21.5$ eu. Based on S°_{298} = 11.5 and 3.9 eu for Zr^{4+} and F^- recommended by Kelley (4), the value $S^\circ_{298}(ZrF_2, c)$ is derived as 19.3 eu. The entropy at 298°K for $ZrF_2(c)$ is tentatively adopted as 18 ± 2 eu.

Melting Data

Both Tm and ΔHm° are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of $ZrF_4(c)$ which was obtained from experimental measurements (5). Therefore these estimated values are tentatively adopted.

Heat of Sublimation

The difference between ΔHf°_{298} for $ZrF_2(g)$ and $ZrF_2(c)$ is ΔHs°_{298}.

Dec. 31, 1960; June 30, 1961; June 30, 1969

ZIRCONIUM DIFLUORIDE (ZrF_2) (LIQUID) GFW = 129.2168

$S^\circ_{298.15}$ = [24.103] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-222.502] kcal/mol

Tm = [1175 ± 150]°K

ΔHm° = [9 ± 2] kcal/mol

Tb = [2529]°K

ΔHv° = [69.0] kcal/mol

Heat of Formation

The $\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{1175} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated from those of $ZrF_4(\ell)$, $CaF_2(\ell)$, $Zr(\ell)$, and $Ca(\ell)$, and is assumed to be constant in the temperature range 800-3000°K. A glass transition temperature is assumed at 800°K. The Cp values below 800°K are adopted from the $ZrF_2(c)$ table.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Both Tm and ΔHm° are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of $ZrF_4(c)$ which was obtained from experimental measurements (1). Therefore these estimated values are tentatively adopted.

Vaporization Data

Tb is the temperature at which the Gibbs energy change of the process $ZrF_2(\ell) = ZrF_2(g)$ approaches zero. The difference between ΔHf° for $ZrF_2(\ell)$ and $ZrF_2(g)$ at Tb is ΔHv°.

Heat of Formation

Murad and Hildenbrand (1) studied the gaseous equilibria involving ZrF_4, ZrF_3, ZrF_2, Ca, and CaF, mass-spectrometrically. Ion intensities were measured 3 eV above threshold over the temperature range 1665-1747°K, and the equilibrium constants for the reaction 2 Ca(g) + ZrF_4(g) = 2 CaF(g) + ZrF_2(g) were calculated. Using the reported equilibrium constants, the enthalpy changes ($\Delta Hr°_{298}$) of this reaction are evaluated by the second and third law methods to be 15.4 and 50.9 kcal/mol, respectively. The drift in third law values is 20.4 ± 17.6 eu. Based on the third law $\Delta Hr°_{298}$ value and $\Delta Hf°_{298}$ = 42.85 ± 0.3, -65.0 ± 2, and -400.0 ± 0.5 kcal/mol for Ca(g), CaF(g), and ZrF_4(g), respectively, we obtain $\Delta Hf°_{298}$(ZrF_2, g) = -133.4 ± 5 kcal/mol, which is adopted.

Using Gibbs energy functions derived from different molecular constants for the reactants and products, Murad and Hildenbrand (1) derived a third law $\Delta Hr°_{298}$ = 42.6 ± 5 and $\Delta Hf°_{298}$(ZrF_2, g) = -141 ± 5 kcal/mol, which are in fair agreement with the adopted values.

Heat Capacity and Entropy

According to the correlations of Charkin and Dyatkina (2), the ZrF_2(g) molecule has an angular configuration. The F-Zr-F angle is estimated as 125°, which is similar to the value reported by Hastie, Hauge, and Margrave (4) for TiF_2(g). The F-Zr bond distance is estimated from that of ZrF_4(g). The vibrational frequencies are calculated based on the method suggested by Herzberg (3). The value ν_1 is calculated from the vibrational frequency (ν) of ZrF(g) by use of the relation $\nu_1 = \nu\sqrt{\frac{Zr}{Zr+F}}$ where Zr and F are gram atomic weights of zirconium and fluorine. ν_3 is derived from ν_1 using the formula $\nu_3 = \nu_1\sqrt{\frac{Zr+2F}{Zr}}$, and ν_2 is calculated as 0.44 ν_3 where the value 0.44 is estimated by comparison with the ratios of ν_2/ν_3 for other related compounds. Ground state quantum weight is taken to be the same as that of TiF_2(g). The three principal moments of inertia are: $I_A = 1.830 \times 10^{-38}$, $I_B = 3.502 \times 10^{-39}$, and $I_C = 2.180 \times 10^{-38}$ g cm^2. The electronic levels and quantum weights are estimated to be the same as those of TiF_2(g).

Sept. 30, 1965

IRON TRIFLUORIDE (FeF_3) (CRYSTAL) MOL. WT. = 112.8422

$\Delta H^\circ_{f\ 0}$ = Unknown

$S^\circ_{298.15}$ = [23.5 ± 2] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -249 ± 3 kcal. mole^{-1}

T_s = [1200]°K.

$\Delta H^\circ_{s\ 298.15}$ = [52.8] kcal. mole^{-1}

Heat of Formation.

The equilibrium pressures for the reaction $2FeF_3(c) + H_2(g) = 2FeF_2(c) + 2HF(g)$ have been measured at temperatures 623, 723 and 823°K. by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928). Using the reported data, the enthalpy change of the reaction was evaluated as 37.9 and 31.3 kcal. mole^{-1} by the third and second law methods, respectively. The corresponding $\Delta H^\circ_{f\ 298.15}$ (FeF_3, c) values are calculated to be -252.4 and -249.2 kcal. mole^{-1}. The equilibrium constants for the reaction $2FeF_3(c) + 3H_2O(g) = Fe_2O_3(c) + 6HF(g)$ were determined by L. Domange, Ann. Chim., 7, 225 (1937). Based on the third law value of $\Delta H^\circ_{r\ 298.15}$, 62.0 kcal. mole^{-1}, the $\Delta H^\circ_{f\ 298.15}$ (FeF_3, c) was calculated as -237.4 kcal. mole^{-1}. The value of $\Delta H^\circ_{f\ 298.15}$ for $FeF_3(c)$ is selected to be -249 ± 3 kcal. mole^{-1}.

Heat Capacity and Entropy.

The heat capacities of $FeF_3(c)$ at temperatures 100-450°K. were determined by H. Bizette, R. Mainard and J. Picard, Comp. rend. 5508 (1965). The results were presented graphically by plotting C_p vs. T. The C_p curve shows a peak at 367°K. An antiferromagnetic transition at about 394°K. was reported by E. O. Wollan, H. R. Child, W. C. Koehler and M. K. Wilkinson, Phys. Rev. 112, 1132 (1958). The heat capacities above 450°K. and $S^\circ_{298.15}$ were estimated by comparison with those for $FeCl_3(c)$ $AlCl_3(c)$ and $AlF_3(c)$.

Sublimation Data.

The phenomenon that $FeF_3(c)$ sublimes without fusion at temperatures near 1000°C has been observed and reported by Poulenc, Ann. Chim. phys. (7), 2, 1 (1894). Based on this data the value of T_s was estimated. The value of heat of sublimation ($\Delta H^\circ_{s\ 298.15}$) was calculated using an estimated entropy of sublimation, ΔS°_s = 40 e.u. in order to have $\Delta F_r \cong 0$ for the reaction $FeF_3(c) = FeF_3(g)$ at 1200°K.

Sept. 30, 1965

IRON TRIFLUORIDE (FeF_3)   (IDEAL GAS)   MOL. WT. = 112.8422

Point Group $[D_{3h}]$

$S^\circ_{298.15}$ = [72.7] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = [-195.5 ± 5] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-196.2 ± 5] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
[600] (1)	[800] (2)
[250] (1)	[220] (2)

Bond Distance: Fe-F = [1.9] cm.$^{-1}$

Bond Angle: F-Fe-F = [120]°

Product of the Moments of Inertia: $I_AI_BI_C$ = [9.96723 X 10^{-114}] g.^{3} cm.^{6}

σ = [6]

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ (FeF_3, g) was calculated from $\Delta H^\circ_{s\ 298.15}$ and $\Delta H^\circ_{f\ 298.15}$ for FeF_3(c). The value $\Delta H^\circ_{s\ 298.15}$ = 65.5 kcal. mole^{-1} was derived from $\Delta H^\circ_{s\ 1200}$ (see FeF_3(c) table for details).

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were estimated by comparison with those for AlF_3(g). The vibrational frequencies were estimated by comparison with those for AlF_3(g), TiF_3(g) and ZrF_3(g). The three principal moments of inertia are: $I_A = I_B = 1.7081 \times 10^{-38}$ and $I_C = 3.4162 \times 10^{-38}$ g. cm.^{2}

Trifluorosilane ($SiHF_3$)

Dec. 31, 1960; Sept. 30, 1962; Dec. 31, 1963; Dec. 31, 1968

LITHIUM FLUORIDE, TRIMERIC (Li_3F_3) (IDEAL GAS) GFW = 77.8122

Point Group [D_{3h}]

$\Delta Hf°_0$ = -361.02 ± 6.0 kcal/mol

$S°_{298.15}$ = [76 ± 2] gibbs/mol

$\Delta Hf°_{298.15}$ = -362.62 ± 6.0 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
280 (1)	530 (2)
[430] (1)	755 (2)
[640] (1)	245 (2)
[480] (1)	[140] (2)

Bond Distance: Li-F = [1.68] Å

Bond Angles: F-Li-F = [120°] Li-F-Li = [120°] σ = 6

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.2122 x 10^{-113}] g^3cm^6

Heat of Formation

The heat of formation ($\Delta Hf°_{298}$) is derived based on the adopted value $\Delta Hr°_{298}$ = 79.73 kcal/mol for the reaction 3LiF(c) = Li_3F_3(g), using $\Delta Hf°_{298}$(LiF, c) = -147.45 kcal/mol. The $\Delta Hr°_{298}$ value is calculated to be 73.9 kcal/mol at 1000°K, which is consistent with the values $\Delta Hs°_{1000}$ = 73.9 ± 3 and 74.9 ± 1 kcal/mol reported by Büchler and Stauffer (1) and Akishin et al. (2), respectively. Using the adopted $\Delta Hf°_{298}$ values for monomer, dimer, and trimer, we also evaluate the value $\Delta Hr°_{1073}$ = 53.8 kcal/mol for the reaction $Li_3F_3(g) = Li_2F_2(g) + LiF(g)$ which is in agreement with the value 50 < $\Delta Hr°_{1073}$ < 65 kcal/mol reported by Porter and Schoonmaker (3). Rothberg et al. (4) have determined the partial pressures of LiF monomer, dimer, and trimer in the temperature range 980 - 1070°K, using the molecular-beam velocity-selector method (5). However, the total pressures derived from these data are too low in comparison with the other reported vapor pressures. Thus their data are not adopted for evaluation.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of the BeO trimer. The Li-F bond distance is taken from that of the Li_2F_2 molecule determined by Akishin and Rambidi (6). Four vibrational frequencies, A_2'' and three E', are reported by Snelson (7) from analysis of the infrared spectra of LiF using the matrix isolation technique. The reported frequencies are corrected to the average isotopic species. The other four frequencies, E_2'' and three A', are estimated by comparison with those for the isoelectronic molecule Be_3O_3. The three principal moments of inertia are $I_A = I_B$ = 1.823 x 10^{-38} and I_C = 3.646 x 10^{-38} g cm^2.

NITROGEN TRIFLUORIDE (NF_3) (IDEAL GAS) GFW = 71.0019

Point Group C_{3v}

$\Delta Hf^\circ_0 = -30.06 \pm 0.3$ kcal/mol

$S^\circ_{298.15} = 62.30 \pm 0.01$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -31.43 \pm 0.3$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
1032 (1)
642 (1)
906 (2)
492 (2)

Bond Distance: N-F = 1.371 Å

Bond Angle: F-N-F = 102°9'

$\sigma = 3$

Product of the Moments of Inertia: $I_AI_BI_C = 8.855 \times 10^{-115}$ g^3 cm^6

Heat of Formation

The adopted heat of formation was obtained from a simultaneous adjustment of several interrelated pieces of data relating to the heat of formation of HF (see HF, g table 12-31-68). The data which was considered relating directly to NF_3 was as follows.

A. $8\ NF_3(g) + 3\ C_2N_2(g) \rightarrow 6\ CF_4(g) + 7\ N_2(g)$

Walker (1) reported $\Delta Hr^\circ_{298} = -1308.8 \pm 1.3$ kcal/mol.

B. $NF_3(g) + 1.5\ H_2(g) \rightarrow 3HF(50\ H_2O) + 0.5\ N_2(g)$

Sinke (2) reported $\Delta Hr^\circ_{298} = -199.49 \pm 0.22$ kcal/mol for a final state of HF(123 H_2O); the corrected value is -199.40 ± 0.22 kcal/mol.

C. $2\ NF_3(g) + S(c, rh) \rightarrow SF_6(g) + N_2(g)$

Walker (3) reported $\Delta Hr^\circ_{298} = -228.26 \pm 0.25$ kcal/mol.

D. $NF_3(g) \rightarrow 0.5\ N_2(g) + 1.5\ F_2(g)$

Sinke (4) reported $\Delta Hr^\circ_{298} = 31.44 \pm 0.3$ kcal/mol for the above dissociation from experimental explosion of hydrogen in 10 percent and 100 percent excess NF_3.

E. $NF_3(g) + B(c, \beta) \rightarrow BF_3(g) + 0.5\ N_2(g)$

Ludwig and Cooper (5) reported $\Delta Hr^\circ_{298} = -239.46 \pm 1.2$ kcal/mol, 5 percent of the boron remained unreacted and was detected by analysis.

Further details of the simultaneous adjustment are given by Syverud (6).

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Schatz and Levin (7) and are in good agreement with those of Pace and Pierce (8), and Wilson and Polo (9). The adopted values are also in agreement with the Raman studies of Kotov and Tatevskii (10). The bond length and angle were from the microwave studies of Sheridan and Gordy (11), whose values are in substantial agreement with the electron diffraction results of Schomaker and Lu (12).

The individual moments of inertia are $I_A = I_B = 7.854 \times 10^{-39}$ g cm^2 and $I_C = 14.354 \times 10^{-39}$ g cm^2.

Pierce and Pace (13) have obtained the entropy of the gas at 144.15°K from solid heat capacity measurements and the heats of melting and vaporization. Their reported value of 54.50 eu is in good agreement with our calculated value of 54.56 eu.

TRIFLUORAMINE OXIDE (NOF_3) (IDEAL GAS) GFW = 87.0013

Point Group C_{3v}

$\Delta Hf°_0 = -37.0 \pm 5.0$ kcal/mol

$S°_{298.15} = 66.54 \pm 0.05$ gibbs/mol

$\Delta Hf°_{298.15} = -39.0 \pm 5.0$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
1687 (1)	887 (2)
743 (1)	528 (2)
558 (1)	398 (2)

Bond Distance: N-O = [1.15] Å N-F = 1.48 ± 0.1 Å

Bond Angle: ONF = [109° 28'] FNF = [109° 28'] σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = [4.0703 \times 10^{-114}]\ g^3\ cm^6$

Heat of Formation

Bougon et al. (1) determined equilibrium constants for the reaction $NOF(g) + F_2(g) \rightleftarrows NOF_3(g)$ as a function of temperature and total pressure. Second and third law analyses of these equilibrium data are given below:

	No. of Points	Temp. Range °K	$\Delta Hr°_{298}$, kcal/mol 2nd Law	3rd Law	Drift gibbs/mol
Set I	7	533-643	-17.1	-18.7	-2.4±2.1
Set II	1	533.2		-18.2	

Set I contains their equilibrium data as a function of temperature, while Set II is their adopted equilibrium constant, Kp(553.2°K) = 0.015 ± 0.005 $atm.^{-1}$, corresponding to the lowest pressure (103 atm.) that was studied. Estimated corrections for nonideality are small and neglected. Adopting $\Delta Hr°_{298} = -18.7 \pm 1.0$ kcal/mol, we derive $\Delta Hf°(NOF_3, g) = -34.4 \pm 1.4$ kcal/mol with $\Delta Hf°(NOF, g) = -15.7 \pm 0.4$ kcal/mol (2).

Armstrong and King (3) determined $\Delta Hr_{304} = -253.7 \pm 0.6$ kcal/mol for the reaction $NOF_3(g) + 5/2\ H_2(g) + 122\ H_2O(\ell) \rightarrow 1/2\ N_2(g) + [3HF \cdot 123\ H_2O](\ell)$ in a constant pressure flame calorimeter. Combining this result with their earlier enthalpy data for reduction reactions involving $F_2(g)$ and $O_2(g)$ with $H_2(g)$, they obtained $\Delta Hf_{304}(NOF_3, g) = -44.7 \pm 1.5$ kcal/mol.

Very recently, Dibeler and Walker (4) investigated the photoionization of NOF_3 by mass spectrometry. From their ionization threshold data, they determined $\Delta Hf°_0(NOF_3, g) = -69.6 \pm 1.2$ kcal/mol.

The value for the heat of formation of gaseous NOF_3 is tentatively selected as -39.0 ± 5.0 kcal/mol.

Heat Capacity and Entropy

Several recent infrared (5, 6, and 7) and Raman (8) studies of NOF_3 have been reported in the literature. The fundamental vibrational frequencies observed in the infrared spectrum of the molecule by the various investigators are in good agreement, although the assignment of the ν_3 and ν_5 bending modes has varied. Fox et al. (6) assigned ν_3 = 558 cm^{-1} and ν_5 = 528 cm^{-1}, while Curtis et al. (7) reversed the assignments. Very recently, Abramowitz and Levin (8) investigated the Raman spectrum of polycrystalline film of NOF_3 at 78°K and assigned ν_3 = 535 cm^{-1} and ν_5 = 522 cm^{-1} consistent with the infrared work of Fox et al. (6). The fundamental vibrational frequencies and assignments given by Fox et al. (6) are adopted here.

Fox et al. (9) also investigated the nuclear magnetic resonance spectrum of NOF_3 which indicated that the molecule contained three equivalent fluorine atoms. This result, along with the general appearance of the infrared spectrum, clearly establishes that the molecule has C_{3v} symmetry. The N-O bond distance and bond angles are estimated quantities from the work of Curtis et al. (7). These estimated data have been used in calculating the N-F bond distance from the rotational constants given by Curtis et al. (7). Individual moments of inertia calculated from the structural data given above are: $I_A = I_B = 14.86 \times 10^{-39}\ g\ cm^2$, and $I_C = 18.44 \times 10^{-39}\ g\ cm^2$.

Mar. 31, 1963; Dec. 31, 1963; Dec. 31, 1969

PHOSPHORYL FLUORIDE (POF_3)   (IDEAL GAS)   GFW = 103.9684

Point Group C_{3v} $\Delta Hf^\circ_0 = -293.9 \pm 1.9$ kcal/mol

$S^\circ_{298.15} = 68.19 \pm 0.07$ gibbs/mol $\Delta Hf^\circ_{298.15} = -295.6 \pm 1.9$ kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
1417.7 (1)	994 (2)
872.8 (1)	483.2 (2)
473.2 (1)	335.6 (2)

Bond Distance: P-O = 1.45 ± 0.03 Å   P-F = 1.52 ± 0.02 Å

Bond Angle: F-P-F = 102.5° ± 2°   F-P-O = 115.8° ± 2° $\sigma = 3$

Product of Moments of Inertia: $I_AI_BI_C = 5.9019 \times 10^{-114}\ g^3\ cm^6$

Heat of Formation

Ebel and Bretscher (1) measured the enthalpy change for the following reaction:

$$PF_3(g) + 1/2\ O_2(g) \rightarrow POF_3(g)$$

They reported a heat of reaction of -70.6 ± 1 kcal/mol. Combining this result with the heat of formation of PF_3, $\Delta Hf^\circ_{298} = -224.9 \pm 0.9$ kcal/mol (2), we derive, $\Delta Hf^\circ_{298}(POF_3, g) = -295.6 \pm 1.9$ kcal/mol.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Selig and Claassen (3) and are in good agreement with the Raman and infrared studies of Gutowsky and Liehr (4). Several microwave studies (5, 6, 7, 8) of POF_3 have been reported. As pointed out by Williams et al. (7), the rotational constant calculated from their microwave studies leads to a moment of inertia, I_B, which is in disagreement with the moment of inertia calculated from the molecular constants obtained from electron-diffraction studies by Brockway and Beach (9). Since insufficient microwave data were available for an independent determination, Williams et al. (7) sought to find parameters which were consistent with both measurements. Their molecular constants are adopted for this tabulation. Individual moments of inertia are $I_A = I_B = 18.244 \times 10^{-39}\ g\ cm^2$ and $I_C = 17.731 \times 10^{-39}\ g\ cm^2$.

PHOSPHORUS TRIFLUORIDE (PF_3) (IDEAL GAS) GFW = 87.969

Point Group C_{3v}

$\Delta Hf^\circ_0 = -224.0 \pm 0.9$ kcal/mol

$S^\circ_{298.15} = 65.23 \pm 0.03$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -224.9 \pm 0.9$ kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
892 (1)	860 (2)
487 (1)	344 (2)

Bond Distance: P-F = 1.5700 ± 0.0012 Å F····F = 2.3643 ± 0.0028 Å

Bond Angle: F-P-F = 97.8 ± 0.2°

$\sigma = 3$

Product of Moments of Inertia: 2.0621×10^{-114} g^3 cm^6

Heat of Formation

Berthelot (1) measured the heats of hydrolysis of $PF_3(g)$ and $PCl_3(\ell)$. These results can be combined to give, ΔHr = 24.5 kcal/mol, for the reaction

$PF_3(g) + 3KCl{\cdot}157\ H_2O \rightarrow PCl_3(\ell) + 3KF{\cdot}112\ H_2O$.

Combining this result with the following heat of formation data,

$\Delta Hf^\circ_{298}(PCl_3,\ \ell) = -72.2$ kcal/mol (2)

$\Delta Hf^\circ_{298}(KCl{\cdot}157\ H_2O) = -100.0$ kcal/mol (3)

$\Delta Hf^\circ_{298}(KF{\cdot}112\ H_2O) = -138.5$ kcal/mol (3)

we derive, $\Delta Hf^\circ_{298}(PF_3,\ g) = -212.2$ kcal/mol.

Duus and Mykytink (4) reported a heat of reaction of -2.361 kcal/mol (corrected to 25°C) for the following reaction

$PCl_3(g) + 3/2\ CaF_2(c) \rightarrow PF_3(g) + 3/2\ CaCl_2(c)$.

Combining this result with the following heat of formation data,

$\Delta Hf^\circ_{298}(PCl_3,\ g) = -64.4$ kcal/mol (2)

$\Delta Hf^\circ_{298}(CaF_2,\ c) = 293.0 \pm 1.5$ kcal/mol (5)

$\Delta Hf^\circ_{298}(CaCl_2,\ c) = -190.0$ kcal/mol (3)

we derive, $\Delta Hf^\circ_{298}(PF_3,\ g) = -221.9$ kcal/mol.

Recently, Rudzitis et al. (6) measured the heat of combustion of PF_3 in fluorine in a two-chambered bomb calorimeter at 25°C. They reported a heat of combustion of -152.0 ± 0.2 kcal/mol for the reaction

$PF_3(g) + F_2(g) \rightarrow PF_5(g)$.

Combining this result with the heat of formation of PF_5, $\Delta Hf^\circ_{298}(PF_5,\ g) = -376.9 \pm 0.7$ kcal/mol (7), we derive, $\Delta Hf^\circ_{298}(PF_3,\ g) = -224.9 \pm 0.9$ kcal/mol. This result is adopted for this tabulation.

Heat Capacity and Entropy

The vibrational frequencies are those reported by Wilson and Palo (8). Several different values for the P-F bond length and F-P-F bond angle have been reported in the literature. This problem was recently discussed by Morino et al. (9), who also reported new data obtained from electron-diffraction studies. Their results are adopted for this tabulation. Individual moments of inertia calculated according to their structure are: $I_A = I_B = 10.814 \times 10^{-39}$ g cm^2 and $I_C = 17.634 \times 10^{-39}$ g cm^2.

THIOPHOSPHORYL FLUORIDE (PSF_3) (IDEAL GAS) GFW = 120.033

Point Group C_{3v}

ΔHf°_0 = [-236 ± 15] kcal/mol

$S^\circ_{298.15}$ = 71.23 ± 0.05 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-237 ± 15] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
981 (1)	945 (2)
442 (1)	275 (2)
695 (1)	402 (2)

Bond Distance: P-S = 1.87 ± 0.03 Å P-F = 1.53 ± 0.02 Å

Bond Angle: F-P-F = 100.3° ± 2° F-P-S = 117.6° ± 2° $\sigma = 3$

Product of Moments of Inertia: $I_AI_BI_C = 1.7316 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation

The heat of formation of PSF_3 is calculated from the heat of formation of POF_3 and estimated P=O and P=S bond strengths. Mortimer (1) calculated several P=O and P=S bond dissociation energies from heat of reaction data reported in the literature. Some of these data are given below.

Reaction	D(P=O) kcal/mole	D(P=S) kcal/mole
ΔH oxidation PF_3 to POF_3	130.3	
ΔH oxidation $P(OEt)_3$ to $PS(OEt)_3$		81.6
ΔH oxidation PPr_3 to $PSPr_3$		82.6

Mole and McCoubrey (2) reported the following heat of reaction:

$PCl_3(\ell) + S(c) \rightarrow PSCl_3(\ell)$. ΔHr = -5.6 kcal/mol.

Combining this result with heat of vaporization data for PCl_3 (3) and $PSCl_3$ (4), along with the heat of sublimation of S (5), we derive, D(P=S) = 71 kcal/mol. Averaging this result with the two values given above, we obtain $\bar{D}$(P=S) = 78.4 kcal/mol. We assume that this result represents the enthalpy change for reaction

$PSF_3(g) \rightarrow PF_3(g) + S(g)$.

Combining this result with similar data for POF_3, namely D(P=O) = 130.3 kcal/mol and $\Delta Hf^\circ_{298}(POF_3, g) = -295.6 \pm 1.9$ kcal/mol (6), we derive, $\Delta Hf^\circ_{298}(PSF_3, g) = -237 \pm 15$ kcal/mol, from the relationship

$$\Delta Hf^\circ_{298}(PSF_3, g) = \Delta Hf^\circ_{298}(POF_3, g) + \Delta Hf^\circ_{298}(S, g) - \Delta Hf^\circ_{298}(O, g) - D(P{=}O) + D(P{=}S).$$

Heat Capacity and Entropy

Several recent infrared and Raman studies (7, 8, 9, 10) of PSF_3 have been reported. These data are in good agreement, except for the ν_1 fundamental. Dewaulle and Francois (11) assigned this fundamental to the 869 cm^{-1} band observed in their spectra. The recent work indicates that this fundamental should be assigned to the 981 cm^{-1} band. Average values of the vibrational frequencies reported by (8, 9, 10) are adopted for this tabulation. The molecular structure of this molecule was determined by Williams et al. (12) and Hawkins and Cohen (13) from microwave studies. The individual moments of inertia calculated from the constants given by Williams et al. (12) are $I_A = I_B = 3.1527 \times 10^{-38}\ g\ cm^2$ and $I_C = 1.7410 \times 10^{-38}\ g\ cm^2$.

Sept. 30, 1963; Dec. 31, 1969; June 30, 1970

SILICON TRIFLUORIDE (SiF_3) (IDEAL GAS) GFW = 85.0812

Point Group C_{3v}

$\Delta Hf°_0$ = [-262.3 ± 5] kcal/mol

$S°_{298.15}$ = 67.45 ± 0.5 gibbs/mol

$\Delta Hf°_{298.15}$ = [-263 ± 5] kcal/mol

Ground State Quantum Weight = 2

Vibrational Frequencies and Degeneracies

ω_i, cm^{-1}
832 (1)
406 (1)
954 (2)
290 (2)

Bond Distance: Si-F = [1.56] Å

Bond Angle: F-Si-F = [109.47°]

$\sigma = 3$

Product of the Moments of Inertia: $I_AI_BI_C = 2.5135 \times 10^{-114}\ g^3\ cm^6$

Heat of Formation

The heat of formation is estimated from the assumption of a 0.5 kcal heat for the reaction:

$SiF_4(g) + SiF_2(g) \rightarrow 2SiF_3(g)$. ΔH = 0.5 kcal

$\Delta Hf°_{298}(SiF_3,\ g) = -263$ kcal/mol is derived from $\Delta Hf°_{298}(SiF_4,\ g) = -385.98$ kcal/mol and $\Delta Hf°_{298}(SiF_2,\ g) = -140.5$ kcal/mol. The above value is confirmed by the observations of Layne (1), whose total pressure data above the silicon -- magnesium fluoride system agree with those calculated from these tables.

Heat Capacity and Entropy

The bond length is estimated between those of SiF_4 and SiF_2. The vibrational frequencies are from Milligan et al. (2), and the angle is taken to be tetrahedral, since they also reported an angle of approximately 71° between the Si-F bonds and the threefold axis. The spectra of the radical were obtained in inert gas matrices and all the fundamentals were observed. The individual moments of inertia are $I_A = I_C = 11.081 \times 10^{-39}\ g\ cm^2$, $I_B = 20.472 \times 10^{-39}\ g\ cm^2$.

TITANIUM TRIFLUORIDE (TiF_3) (CRYSTAL) GFW = 104.8952

ΔHf°_0 = unknown

$S^\circ_{298.15}$ = [21.0 ± 3.0]

$\Delta Hf^\circ_{298.15}$ = -343.1 ± 10.0 kcal/mol

Ts = 1309.7 °K

ΔHs° = 52.97 kcal/mol

Heat of Formation

Blocher and Hall (1) have reported vapor pressure data for the process $1/2Hg_2F_2 + TiF_3(c) = TiF_4(g) + Hg(\ell)$. Second and third law analyses of their data give a second law ΔHr°_{298} of 23.7 kcal/mol, a third law ΔHr°_{298} of 29.864, and a third law drift of 11.9 ± 1.0 eu. The third law value is combined with the JANAF values for the heat of formation of $Hg_2F_2(c)$ and $TiF_4(g)$ to give a ΔHf°_{298} of -343.1 ± 10.0 kcal/mol. The large uncertainty on ΔHf°_{298} is assigned because Blocher and Hall were not able to identify $TiF_3(c)$ as the reaction product in the above process. They reported that the X-ray pattern of the products contained lines corresponding to $Hg_2F_2(c)$ plus others that did not correspond to $TiF_3(c)$.

Heat Capacity and Entropy

The heat capacity of $TiF_3(c)$ is estimated from the heat capacities of ZrF_4 and TiF_4. The entropy, S°_{298}, is estimated from CrF_3 and from ionic entropy contributions. Both methods give values which are within ±0.5eu of the chosen value of 21 ± 3eu.

Heat of Sublimation

The heat of sublimation is calculated from the vapor pressure data of Zmbov and Margrave (2). See $TiF_3(g)$ table for details. The sublimation temperature is taken as the point at which $\Delta Gr = 0$ for the reaction $TiF_3(c) = TiF_3(g)$.

Bond Distance: Ti-F = [1.9] Å

Bond Angle: F-Ti-F = [100°]

σ = 3

Product of the Moments of Inertia: $I_AI_BI_C$ = [7.45 x 10^{-114} g^3 cm^6

Heat of Formation

The heat of formation of $TiF_3(g)$ is calculated from that of $TiF_3(c)$ and the heat of sublimation determined from the mass spectrometric vapor pressure data of Zmbov and Margrave (1). Their data give nine points over the temperature range 759 - 865°K.

Second and third law analyses of their data give a second law ΔHs°_{298} of 61.2 ± 0.4 kcal/mol and a third law ΔHs°_{298} of 59.0 kcal/mol with an entropy drift of -2.7 ± 0.5 units. The third law value is used to calculate ΔHf°_{298}.

Heat Capacity and Entropy

The interatomic distance is estimated from those of $TiF_4(g)$, and $TiCl_4(g)$, and $TiCl_3(g)$. The pyramidal bond angle is estimated assuming $TiF_3(g)$ similar to the group V trihalides. The principal moments of inertia are $I_A = I_B = 1.68 \times 10^{-38}$ g cm^2 and $I_C = 2.66 \times 10^{-38}$ g cm^2. The vibrational frequencies are estimated from those of PF_3 and AsF_3. The electronic levels are estimated from the levels of Ti^{+3} (2).

ZIRCONIUM TRIFLUORIDE (ZrF_3) (CRYSTAL) GFW = 148.2152

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [21 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-335 ± 20] kcal/mol

$\Delta Hs^\circ_{298.15}$ = [70.1] kcal/mol

Heat of Formation

The heat of formation at 298°K for ZrF_3(c) was reported as -350 kcal/mol (1) which was estimated by Brewer (2). Based on this ΔHf°_{298} value, the crystal lattice energy (U) of ZrF_3(c) is calculated to be 1371 kcal/mol by the Born-Haber cycle method (3). For the evaluation of U from the relation: $\Delta Hf^\circ(ZrF_3, c) = \Sigma I_i + L - 3(E - D/2) - U$, the following values (kcal/mol) are used: ΣI_i(the sum of the successive three ionization potentials of Zr metal) = 1055 (4), L(the enthalpy of sublimation of Zr metal) = 148.3 (5), E(the electron affinity of fluorine) = 79.5 (6), and D(the enthalpy of dissociation of fluorine) = 37.7 (7). The derived value of U(ZrF_3, c) is of the same order of magnitude of the value, U(TiF_3, c) = 1376 kcal/mol, calculated by Cavell and Clark (3) using the same method.

From $\Delta Hf^\circ_{298}(ZrF_3, c)$ = -350 kcal/mol, the derived $\Delta Gf^\circ(ZrF_3, c)$ values indicate that ZrF_3(c) is thermodynamically more stable than the system ZrF_4(c) + Zr(c). For example, in the temperature range 298-1200°K, the Gibbs energy changes for the reaction 3 ZrF_4(c) + Zr(c) = 4 ZrF_3(c) are about -29 ± 1 kcal/mol. However, this product ZrF_3(c) has never been prepared successfully from this reaction in many laboratories (8). In order to make the $\Delta Gf^\circ(ZrF_3, c)$ values consistent with the experimental observations, the heat of formation of ZrF_3(c) is arbitrarily adjusted to be 15 kcal/mol less negative, or $\Delta Hf^\circ_{298}(ZrF_3, c)$ = -335 kcal/mol with uncertainty as high as ±20 kcal/mol. This value is tentatively adopted.

The Gibbs energy changes for the reaction 3 ZrF_4(g) + Zr(c) = 4 ZrF_3(c) are evaluated to be very favorable at temperatures below 900°K, e.g. ΔGr° = -93.9 and -6.7 kcal/mol at 298 and 900°K, respectively. But according to Larsen and Leddy (9), this reaction does not occur in the temperature range 473-973°K, and pressure range 5-15 atm. One possible explanation is that these heterogeneous reactants may require very high activation energy to initiate the reaction. In other words, this reaction is unfavorable at these temperatures probably due to kinetic rather than thermodynamic reasons.

Heat Capacity and Entropy

The heat capacities of ZrF_3(c) are not available in the literature. They are estimated from the Cp values of ZrF_4(c) by deduction of one F atom Cp contributions which are calculated as $1/4(Cp_{ZrF_4(c)} - Cp_{Zr(c)})$. The $S^\circ_{298.15}$ is taken to be $1/2[S^\circ_{298}(ZrF_4, c) + S^\circ_{298}(ZrF_2, c)]$ of which the value $S^\circ_{298}(ZrF_2, c)$ is estimated (see ZrF_2(c) table for details).

Heat of Sublimation

The difference between ΔHf°_{298} for ZrF_3(g) and ZrF_3(c) is ΔHs°_{298}. Actually, ZrF_3(c) is thermodynamically unstable, e.g. the Gibbs energy changes for the reaction 4 ZrF_3(c) = 3 ZrF_4(c) + Zr(c) are about -30 kcal/mol in the temperature range 298-1400°K. In other words, ZrF_3(c) decomposes into ZrF_4(c) + Zr(c) before sublimation occurs.

Heat of Formation

Murad and Hildenbrand (1) studied the gaseous equilibria involving ZrF_4, ZrF_3, ZrF_2, Ca and CaF. These species were generated at high temperatures in a graphite Knudsen cell containing powdered calcium fluoride and elemental zirconium. Ion intensities were measured 3 eV above threshold over the temperature range 1665-1747°K and the equilibrium constants were calculated for the following isomolecular reaction: $Ca(g) + ZrF_4(g) = CaF(g) + ZrF_3(g)$. Based on the reported equilibrium constants, the enthalpy change of this reaction is evaluated by the second and third law methods as -8.0 ± 25 and 28.0 ± 2 kcal/mol, respectively. The third law entropy drift is 20 ± 15 eu. Using the third law value and $\Delta Hf°_{298}$ = 42.85 ± 0.3, -400.0 ± 0.5, and -65.0 ± 2 kcal/mol for Ca(g), ZrF_4(g), and CaF(g) we obtain $\Delta Hf°_{298}(ZrF_3, g)$ = -264.2 ± 5 kcal/mol, which is adopted. Employing slightly different Gibbs energy functions and $\Delta Hf°_{298}$ values for the products and reactants, Murad and Hildenbrand (1) evaluated the third law enthalpy change of the above reaction as 29.4 ± 5 and $\Delta Hf°_{298}(ZrF_3, g)$ = -262 ± 5 kcal/mol, which are in reasonable agreement with the values adopted here.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of $TiF_3(g)$. The Zr-F bond distance is estimated by comparison with those for $ZrF_4(g)$ and $ZrF_2(g)$. The F-Zr-F bond angle is taken to be slightly larger than the F-Ti-F bond angle in the $TiF_3(g)$ molecule. The vibrational frequencies are calculated by the valence force method (2) using force constants transferred from those for the $ZrF_2(g)$ molecule. The three principal moments of inertia are: $I_A = I_B = 1.8280 \times 10^{-38}$, and $I_C = 2.9583 \times 10^{-38}$ g cm^2. The electronic levels are estimated to be three times higher than those of $TiF_3(g)$, based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (3). The quantum weights are assumed to be the same as those of $TiF_3(g)$.

Bond Distance: Mg-F = [1.77] Å

Bond Angle: F-Mg-F' = [135]° Mg-F'-Mg = [90]° F'-Mg-F' = [90]°

$\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C$ = [5.5711 X 10^{-113}] g.^{3} cm.^{6}

Heat of Formation.

The enthalpy change, ΔH_r° = 30 kcal. mole^{-1}, for the reaction $MgF_2(c) + MgF_2(g) = (MgF_2)_2(g)$ was determined by J. Berkowitz and J. R. Marquart, J. Chem. Phys. 8, 1853 (1962). Hence the heat of formation for $(MgF_2)_2(g)$ was calculated.

Heat Capacity and Entropy.

The molecular structure was assumed to be planar. The two Mg atoms are at the two opposite corners of a square. The other two corners of the square are occupied by two F atoms. The two remaining F atoms are situated outside the square on a straight line joining the two Mg atoms. The bond distance between Mg and F atom was estimated to be the same as that in the $MgF_2(g)$ molecule. Vibrational frequencies were estimated by comparison with those for MgF(g) and $(NaF)_2$. The vibrational frequencies for $(NaF)_2$ were calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960). The three principal moments are 9.8896 X 10^{-39}, 7.02735 X 10^{-38}, and 8.01631 X 10^{-38} g. cm.^{2}

MOLYBDENUM OXYTETRAFLUORIDE ($MoOF_4$) (IDEAL GAS) GFW = 187.933

Point Group [C_{4v}] ΔHf°_0 = [-298 ± 30] kcal/mol

$S^\circ_{298.15}$ = [78.99 ± 2.00] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [-300 ± 30] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
1045 (1)	[600] (1)	720 (2)
[300] (1)	[300] (1)	530 (2)
680 (1)	[200] (1)	[150] (2)

Bond Distance: Mo-O = [1.64] Å Mo-F = [1.82] Å

Bond Angle: O-Mo-F = [90°] F-Mo-F = [90°] σ = [4]

Product of Moments of Inertia: $I_AI_BI_C$ = [3.1468×10^{-113}] g^3 cm^6

Heat of Formation

Zmbov et al. (1) investigated the stabilities of some molybdenum and tungsten oxyfluorides by means of mass spectrometry. These studies led to heats of formation for MoO_2F_2(g), WO_2F_2(g), and WOF_4(g) which were used by the authors to develop a correlation among the heats of formation of the oxides, oxyfluorides, and fluorides of Mo and W. ΔHf°_{298} varies almost linearly with the number of oxygen atoms (1) for the series WF_6, WOF_4 and WO_2F_2. Assuming a similar variation for MoF_6, $MoOF_4$ and MoO_2F_2, we estimate ΔHf°($MoOF_4$, g) = -320 kcal/mol.

Heat of formation data (2) for MoF_6(g), MoO(g), MoO_2(g), and MoO_3(g) have been used to derive the following average bond dissociation energies:

$\overline{D}$(Mo-F) = 107 kcal/mol
$\overline{D}$(Mo-O) = 135 kcal/mol

From these data we derive ΔHf°($MoOF_4$, g) = -271 kcal/mol.

The heat of formation for $MoOF_4$ is tentatively selected as 300 ± 30 kcal/mol.

Heat Capacity and Entropy

Blanchard (3) suggested that $MoOF_4$(g) possessed C_{4v} symmetry by reason of the similarity of its infrared spectra with that of $XeOF_4$(g). X-ray diffraction studies of crystalline $MoOF_4$ by Edwards et al. (4, 5) support this view. The structure of the molecule is assumed to be square-pyramidal. The bond lengths are from the crystallographic studies of $MoOF_4$ by Edwards et al. (4, 5). Individual moments of inertia are $I_A = I_B = 27.437 \times 10^{-39}$, $I_C = 41.801 \times 10^{-39}$ g cm^2.

Blanchard (3) reported the following vibrational frequencies and assignments:

$$\nu_1 = 1045,\ \nu_7 = 720,\ \nu_3 = 680, \text{ and } \nu_8 = 530 \text{ cm}^{-1}.$$

Similar frequencies have been reported by Edwards et al. (4) from their study of the infrared spectra of gaseous $MoOF_4$. The rest of the frequencies and assignments are estimated by comparison with data for $XeOF_4$ (6).

Bond Distances: N-N = [1.47 Å] N-F = [1.37 Å]

Bond Angles: F-N-F = [108°] N-N-F = [104°] Dihedral Angle = [65°] σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.1817 X 10^{-113}] gm.^{3} cm.^{6}

Heat of Formation.

G. T. Armstrong, S. Marantz, and C. F. Coyle, National Bureau of Standards Report No. 6584, October, 1959, studied the reaction

$$N_2F_4(g) + 16/3\ NH_3(g) = 4NH_4F(s) + 5/3\ N_2(g).$$

From this reaction, they calculate the heat of formation of N_2F_4 to be -2.0 ± 2.5 kcal. mole^{-1}. The recalculated heat of formation of $NH_4F(s)$ (see NF_2 table) differs from the value quoted in Circular 500 by 0.06 kcal. mole^{-1}. This correction would make the heat of formation of tetrafluorohydrazine more negative by 0.24 kcal. mole^{-1}. In view of the large uncertainty in the heat of formation, however, this correction was not applied.

Heat Capacity and Entropy.

The fundamental frequencies were taken from the vapor phase infrared work of J. R. Durig and R. C. Lord, Spectrochim. Acta 19, 1877 (1963). The principal moments of inertia were calculated from the rotational constants reported by D. R. Lide, Jr. and D. E. Mann, J. Chem. Phys. 31, 1129 (1959). Lide and Mann calculated the bond angles for assumed values of the NN and NF distances.

The principal moments of inertia are: I_A = 1.5051 X 10^{-38} gm. cm.^{2}, I_B = 2.6315 X 10^{-38} gm. cm.^{2}, I_C = 2.9836 X 10^{-38} gm. cm.^{2}.

continued from the table nitrogen difluoride (NF_2) (ideal gas).

Heat Capacity and Entropy.

M. D. Harmony, R. J. Myers, L. J. Schoen, D. R. Lide, Jr., and D. E. Mann, J. Chem. Phys. 35, 1129 (1961), investigated the infrared spectrum of NF_2. They were able to assign the band center at 1074 cm.$^{-1}$ to the symmetric stretching mode ω_1. The absorption in the 930-940 cm.$^{-1}$ region was assigned to ω_3.

M. D. Harmony and R. J. Myers, J. Chem. Phys. 37, 636 (1962), performed matrix isolation experiments on NF_2. They arrived at the assignment ω_1 = 1070 cm.$^{-1}$, ω_2 = 573 cm.$^{-1}$, and ω_3 = 931 cm.$^{-1}$. The stretching frequencies for similar molecules in an N_2 matrix are about 5 cm.$^{-1}$ below the gas phase values. A comparison of the gas phase and matrix values of ω_1 show excellent agreement.

F. A. Johnson and C. B. Colburn, Inorg. Chem. 1, 431 (1962), report infrared studies on NF_2 but they draw no definite conclusions.

The gas phase value for ω_1 and the matrix values for ω_2 and ω_3 were taken to represent the fundamental vibrational frequencies of NF_2.

Harmony, Myers, Schoen, Lide, and Mann estimated the N-F distance as 1.37 Å and used this with their data to calculate an F-N-F angle of 104.2°. Using these data the moments of inertia are: I_A = 7.3728 X 10^{-39} gm. cm.^{2}, I_B = 1.2035 X 10^{-39} gm. cm.^{2}, I_C = 8.5763 X 10^{-39} gm. cm.^{2}.

TUNGSTEN OXYTETRAFLUORIDE (WOF_4) (CRYSTAL) GFW = 275.843

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [42.0 ± 4] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-355.37 ± 6] kcal/mol

Tm = 379°K

ΔHm° = 1.219 ± 2 kcal/mol

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298}(WOF_4,c)$ = -355.37 kcal/mol, is calculated from that of the gas less the heat of sublimation, ΔHs°_{298} = 16.97 kcal/mol. The latter is calculated by the third law method from the vapor pressure equation determined by G. H. Cady and G. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law ΔHs°_{298} is 17.01 kcal/mol.

Heat Capacity and Entropy.

The heat capacities are estimated from those of $WOCl_4(c)$, $WO_3(c)$, $WO_2(c)$, $WCl_6(c)$ and $WF_6(c,l)$.

The entropy, S°_{298} = 42.0 eu, is calculated from ΔS°_{348} = 37.0 eu for $WOF_4(c) \rightarrow WOF_4(g)$, obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

It is surprising that this entropy is larger than the corresponding value for $WOCl_4(c)$ (JANAF $WOCl_4(c)$ table dated Mar. 31, 1967). In both cases the entropies of the condensed phases are derived from the gas phase values using second law analysis of sublimation and vaporization data. The resulting entropy of melting for WOF_4, 3.2 eu, is much smaller than the value 22.4 eu for $WOCl_4$. This extreme difference may be a reflection of the uncertainty inherent in derivation of ΔS°_m as the difference between the values for sublimation and vaporization. If the values of ΔS°_m are correct, they suggest the possibility of an undiscovered solid state transition for WOF_4 similar to that observed for WF_6.

Melting Data.

Tm is calculated as the temperature at which the Gibbs energy of reaction $WOF_4(c) \rightarrow WOF_4(l)$ approaches zero. The difference between the heats of formation for crystal and liquid at the melting point is ΔHm°.

O. Ruff, F. Eisner, and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the melting point as 383°K. Cady and Hargreaves, loc. cit., derived the melting point as 378°K, and the heat of fusion as 2.26 kcal/mol from vapor pressure equations for crystal and liquid. This second law value of ΔHm°, when corrected for ΔCp of vaporization and sublimation, is in good agreement with the value adopted in the tabulation.

June 30. 1962; Mar. 31, 1967

TUNGSTEN OXYTETRAFLUORIDE (WOF_4) (LIQUID) GFW = 275.843

$S^\circ_{298.15}$ = [42.8 ± 4] gibbs/mol

Tm = 379°K

Tb = 460°K

$\Delta Hf^\circ_{298.15}$ = [-354.955] kcal/mol

ΔHm° = 1.219 ± 2 kcal/mol

ΔHv° = 13.4 kcal/mol

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298}(WOF_4,l)$ = -354.955 kcal/mol, is calculated from that of the gas less the heat of vaporization, ΔHv°_{298} = 16.555 kcal/mol. The latter is calculated by the third law method from the vapor pressure equation determined by G. H. Cady and G. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law ΔHv°_{298} is 16.60 kcal/mol.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. Ll. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958.

The entropy, S°_{298} = 42.8 eu, is calculated from ΔS°_{415} = 31.2 eu for $WOF_4(l) \rightarrow WOF_4(g)$, obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

Melting Data.

See $WOF_4(c)$ table (Mar. 31, 1967).

Vaporization Data.

Tb is calculated as the temperature at which the Gibbs energy of reaction $WOF_4(l) \rightarrow WOF_4(g)$ approaches zero. The difference between the heats of formation for liquid and gas at the boiling point is ΔHv°.

O. Ruff, F. Eisner and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the boiling point as 458°K. Cady and Hargreaves, loc. cit., derived the boiling point as 459°K, and the heat of vaporization as 14.23 kcal/mol from the vapor pressure equation for the liquid. This second law value of ΔHv°, when corrected for ΔCp of vaporization, is in good agreement with the value adopted in the tabulation.

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298}(WOF_4,g)$ = -338.4 kcal/mol, is the value determined mass spectrometrically by K. F. Zmbov and J. L. Margrave, Rice Univ., private communication, Mar. 1967, from equilibrium studies of $2TaF_5(g) + WO_3(c) = 2\ TaOF_3(g) + WOF_4(g)$.

Heat Capacity and Entropy.

The molecular configuration is assumed to be a trigonal bipyramid similar to that of $SOF_4(g)$, reported by P. L. Goggin, H. L. Roberts and L. A. Woodward.[1] The bond distances W-O and W-F are estimated to be the same as those in $WO_3(g)$ and $WF_6(g)$, respectively. The three principal moments of inertia are I_A = 3.509 x 10^{-38}, I_B = 3.698 x 10^{-38} and I_C = 2.981 x 10^{-38} g cm^2.

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for $SOF_4(g)^1$, $MoOCl_4(g)^2$, $WO_2Cl_2(g)^3$, $CrO_2Cl_2(g)^{4,5}$, $WO_3(g)^6$ and $WF_6(g)^6$. These frequencies are not in point group order.

Lead Tetrafluoride (PbF_4) (Ideal Gas)

Mol. Wt. = 283.21

$\Delta H_{f\ 298.15}^\circ$ = [-186] kcal. mole^{-1}

$S^\circ_{298.15}$ = 79.7 cal. deg.$^{-1}$ mole^{-1}

Point Group T_d

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$
564 (1)
158 (2)
570 (3)
180 (3)

Pb-F distance = 2.08 Å F-Pb-F angle = 109° 28'

$I_AI_BI_C = 4.8233 \times 10^{-113}$ g.^{3} cm.^{6} $\sigma = 12$

Heat of Formation. $\Delta H_{f\ 208.15}^\circ$ was estimated by comparison with the value of $\Delta H_{f\ 298.15}^\circ$ for $PbF_2(g)$.

Heat Capacity and Entropy. Vibrational frequencies and molecular constants were obtained from G. Nagarajan, Bull. Soc. Chim. Belg., 71, 119 (1962).

Sulfur Tetrafluoride (SF_4)

(Ideal Gas) GFW = 108.058

Heat of Formation

Vaughn and Muetterties (1) reported calorimetric data for the hydrogenation of SF_4. Their experiments produced HF in amounts ranging from 5.8 to 7.5g. Roughly 1.3g should have been present as saturated, real vapor in the bomb volume of 360 ml at the final temperature of the experiment. Although the authors made allowance for this mixture of HF(ℓ) and HF(real vapor), their values appear to be quite unrealistic. More reliable corrections are readily obtained from the recent review by Vanderzee (2) of PVT and calorimetric data for HF liquid and real vapor.

We choose to reduce the data to a standard state of HF(ℓ), starting from the authors' values of the calorimeter heat capacity and the observed temperature rise. Calculated values for the heat evolved are corrected by a) an increase of ~120 cal for conversion of real vapor to liquid, b) a decrease of 113 to 175 cal for oxidation of $H_2S(g)$ to S(c) in the last three experiments, and c) an increase of 22 to 75 cal for adjustment of the reaction to 25°C from the final temperature of the experiment. At 298.15 K we obtain

$$SF_4(g) + 2H_2(g) \rightarrow 4HF(\ell) + S(c), \quad \Delta Hr° = -102.9 \pm 4 \text{ kcal/mol},$$

where the uncertainty is increased by 1.5 kcal/mol for other possible corrections which are neglected due to insufficient information.

The adopted ΔHf°, -186.6 ± 6 kcal/mol, is derived from ΔHr° using ΔHf° = -72.38 ± [0.5] kcal/mol (2, 3) for HF(ℓ). Smith (4) quoted a value of ΔHf° = -176 kcal/mol for SF_4 as determined by Nicholls (5) from hydrolysis studies. We do not have details of the hydrolysis studies, but the result presumably should be adjusted for changes in ΔHf° of aqueous HF.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Levin and Berney (6) and are in good agreement with the frequencies reported by Dodd et al. (7) except for the 353 and 171 cm^{-1} bands. The structural data are from the microwave studies of Tolles and Gwinn (8) and are in good agreement within experimental error with electron-diffraction data reported by Kimura and Bauer (9) and Ewing and Sutton (10). Individual moments of inertia calculated from the rotational constants reported by Tolles and Gwinn (8) are $I_A = 1.2552 \times 10^{-38}\ g\ cm^2$, $I_B = 2.0540 \times 10^{-38}\ g\ cm^2$, and $I_C = 2.6069 \times 10^{-38}\ g\ cm^2$.

Product of the Moments of Inertia: $I_AI_BI_C = 7.93269 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation of $SiF_4(g)$ was measured by direct combination of the elements in a bomb calorimeter by S. S. Wise, J. L. Margrave, H. M. Feder and W. N. Hubbard, J. Phys. Chem. 67, 815 (1963). $\Delta H^\circ_{f\ 298.15}$ was found to be -385.98 ± 0.19 kcal. mole^{-1}. Heats of the reaction between $SiF_4(g)$ and Na(c), 19% HF solution, 0.4% HF solution, a solution of NaF saturated with Na_2SiF_6, and water have been measured by A. F. Vorob'ev, V. P. Kolesov, and S. M. Skuratov, Zh. Neorg. Khim. 5, 1402 (1960). The value of $\Delta H^\circ_{f\ 298.15}$ for $SiF_4(g)$ was reported to be -372.4 ± 0.4 kcal. mole^{-1} which was not used.

Heat Capacity and Entropy.

The vibrational frequencies used were reported by E. A. Jones, J. S. Kirby-Smith, P. J. H. Woltz, and A. H. Nielsen, J. Chem. Phys. 19, 242 (1951). The values of vibrational frequencies were given as 800(1), 285(2), 1000(3), and 431(3) cm.$^{-1}$ for $SiF_4(g)$ by D. M. Yost, E. M. Lassettee, and S. T. Gross, J. Chem. Phys. 4, 325 (1936). The molecular data were obtained from L. Pauling and L. O. Brockway, J. Am. Chem. Soc. 57, 2684 (1935). The three principal moments of inertia are: $I_A = I_B = I_C = 1.99437 \times 10^{-38}$ g. cm.^{2}

Heat of Formation

The heat of formation ($\Delta Hf^\circ_{298.15}$) of TiF_4(c) was measured using a fluorine bomb calorimeter by Greenberg et al. (1). Gross et al. (2) reported a value of -393.4 kcal/mol for ΔHf°_{298}. The latter measurements were not corrected for impurities in the titanium sample, thus the value reported by Greenberg et al. is adopted.

Heat Capacity and Entropy

The heat capacity of TiF_4(c) has been measured over the temperature range 6° to 304°K by Euler and Westrum (3). They obtained the value of S°_{298} based on S°_{10} = 0.11 eu. Heat capacities above 300°K are estimated from those of ZrF_4(c) (4).

Heat of Sublimation

The sublimation point is calculated as the temperature at which ΔGr° = 0 for $TiF_4(c) = TiF_4(g)$. The heat of sublimation is obtained from the data of Hall et al. (5).

Heat of Formation

The heat of formation of $TiF_4(g)$ is calculated from that of the crystal and the heat of sublimation, $\Delta Hs°_{298}$, obtained from vapor pressure measurements. E. H. Hall, J. M. Blocher, Jr., and I. E. Campbell, J. Electrochem. Soc. 105, 275 (1958), have reported extensive vapor pressure data for the reaction $TiF_4(c) = TiF_4(g)$. Second and third law analyses of their data yielded the following results.

Method	No. Pts.	Range, T°K	$\Delta Hr°_{298}$, kcal/mol 2nd Law	$\Delta Hr°_{298}$, kcal/mol 3rd Law	Drift, eu	$\Delta Hf°_{298}$*

*Calculation based on third law $\Delta Hr°_{298}$.

**Four points rejected due to failure of a statistical test.

***Eight points rejected due to failure of a statistical test.

Heat Capacity and Entropy

The interatomic distance is obtained from a correlation of the measured values for $TiCl_4(g)$, $TiBr_4(g)$, $TiCl_6^{-2}$, and TiF_6^{-2}. The principal moments of inertia are $I_A = I_B = I_C$ = 2.724 x 10^{-38} g cm^2.

The vibrational frequencies are estimated by a valence force field treatment of estimated force constants. The force constants are estimated from a correlation with the constants of CF_4, SiF_4, CCl_4, $SiCl_4$, CBr_4, $SiBr_4$, $TiCl_4$ and $TiBr_4$. The resulting frequencies are adjusted so that calculations of $\Delta Hs°_{298}$ by both second and third law methods are in agreement.

F_4Zr

ZIRCONIUM TETRAFLUORIDE (ZrF_4) (CRYSTAL) GFW = 167.2136

$S°_{298.15}$ = 25.024 ± 0.05 gibbs/mol

Tt(α → β) = 723°K

Tm = 1205 ± 2°K

Ts = 1179°K

$\Delta Hf°_0$ = -455.44 ± 0.25 kcal/mol

$\Delta Hf°_{298.15}$ = -456.80 ± 0.25 kcal/mol

ΔHt° = Unavailable

ΔHm° = 15.35 ± 0.10 kcal/mol

ΔHs° = 51.64 kcal/mol

$\Delta Hs°_{298.15}$ = 56.80 kcal/mol

Heat of Formation

The heat of formation of zirconium tetrafluoride was measured by direct combination of the elements in a bomb calorimeter by Greenberg, Settle, Feder, and Hubbard (1). The reported value $\Delta Hf°_{298}(ZrF_4, c)$ = -456.80 ± 0.25 kcal/mol is adopted.

Heat Capacity and Entropy

The low temperature heat capacities in the temperature range 5 to 307°K were determined by adiabatic calorimetry by Westrum (2). Using these low temperature Cp data the value of $S°_{298}$ is derived as 25.024 ± 0.05 eu, based on $S°_{10}$ = 0.0074 eu.

McDonald, Sinke, and Stull (3) measured the high temperature enthalpies of $ZrF_4(c)$ at temperatures 283.9 - 1225.8°K in a copper block drop calorimeter. Smith, Miller, and Taylor (4) used a Bunsen ice calorimeter for the heat-content measurements in the temperature range 273 - 1150°K. These two sets of enthalpy data are not in good agreement. It is possible that the discrepancies are due to the difference in crystal structure of the samples used (see "Transition Data" for more information). In order to join smoothly with the low temperature heat capacities at 298°K, the high temperature heat capacities derived from the enthalpy data of McDonald, Sinke, and Stull (3) are adopted. The Cp values above 1200°K are obtained by smooth extrapolation.

Transition Data

Zirconium tetrafluoride has three crystal structures (α, β and γ) and one amorphous form (5). From a differential thermal analysis of $(NH_4)_3 ZrF_7$ sample, Chrétien and Gaudreau (6) found that $ZrF_4(c)$ has an α and β form with a transition temperature above 678°K. They also determined the densities of α(tetragonal) and β(monoclinic) as 4.25 ± 0.05 and 4.61 ± 0.03 gm/cc, and a transition temperature as Tt(α → β) = 723°K (7). It was observed that the α phase is unstable at all temperatures above 298°K. In reference (5), Gaudreau mentioned the methods of preparation of the four varieties of ZrF_4 and indicated that α-, γ-, and amorphous ZrF_4 transform irreversibly to β-ZrF_4 at 723 - 773°K.

The ZrF_4 sample employed by McDonald, Sinke, and Stull (3) for enthalpy measurement was prepared by disolving hafnium-free zirconium metal in 48% aqueous HF, and the resulting solution was evaporated to dryness. The crystalline product was heated slowly to 773°K in a platinum boat in a slow current of anhydrous HF. X-ray diffraction showed only crystalline ZrF_4. Wet analysis indicated 54.6% Zr (theory 54.55) and 44.9% F (theory 45.45). Due to the above facts we are uncertain whether the sample prepared is a mixture of α and β forms or a pure ZrF_4(β). Smith, Miller, and Taylor (4) obtained their ZrF_4 sample from the Oak Ridge National Laboratories, Oak Ridge, Tenn. Since the method of preparation of the compound is unavailable from the report, we do not know what kind of sample they used for measurement.

Because of the above complicated situation, we emphasize that this $ZrF_4(c)$ table is not strictly a α, β-combined phase table. However, the differences in the calculated functions are probably not significant.

Melting Data

Tm and ΔHm° are taken from McDonald, Sinke, and Stull (3). The values were obtained under conditions greater than one atmosphere.

Sublimation Data

The sublimation temperature (Ts) is calculated as the temperature at which the Gibbs energy change of the process $ZrF_4(c) = ZrF_4(g)$ approaches zero. The difference between $\Delta Hf°_{298}$ for $ZrF_4(g)$ and $ZrF_4(c)$ at 1179 and 298°K is ΔHs° and $\Delta Hs°_{298}$, respectively.

Since ths sublimation temperature is lower than the melting point, the ZrF_4 sublimes before it melts.

ZIRCONIUM TETRAFLUORIDE (ZrF_4) (IDEAL GAS) GFW = 167.2136

Point Group Td

$\Delta Hf°_0$ = -399.0 ± 1.0 kcal/mol

$S°_{298.15}$ = [76.3 ± 1] gibbs/mol

$\Delta Hf°_{298.15}$ = -400.0 ± 1.0 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[630] (1)	668 (3)
[180] (2)	190 (3)

Bond Distance: Zr-F = 1.94 ± 0.02 Å

Bond Angle: F-Zr-F = 109.47°

σ = 12

Product of the Moments of Inertia: $I_AI_BI_C = 3.17347 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation

The vapor pressures of $ZrF_4(c)$ in the temperature range 617-1150°K were determined by many investigators using various methods. Based on the reported vapor pressure data, the corresponding heats of sublimation are evaluated by the second and third law methods. Using the third law $\Delta Hs°_{298}$ and $\Delta Hf°_{298}(ZrF_4, c)$ = -456.8 kcal/mol, the heats of formation at 298°K for $ZrF_4(g)$ are evaluated. The results are presented in the table below. The values of $\Delta Hf°_{298}(ZrF_4, g)$ listed in the last column of this table are in excellent agreement which indicate that the estimated missing vibrational frequencies ν_1 and ν_2 are reasonable. The heat of formation at 298°K for $ZrF_4(g)$ is adopted as -400.0 kcal/mol.

Heat Capacity and Entropy

The molecular structure of $ZrF_4(g)$ has been studied by electron diffraction by Spiridonov (11). The configuration was found to be a regular tetrahedron with interatomic distance Zr-F = 1.94 ± 0.02 Å and F-Zr-F bond angle = 109.47° which are adopted.

Employing the estimated interaction coefficients and interatomic distance Zr-F = 1.85 Å, Godnev, Aleksandrovskaia, and Rigina (12) calculated three vibrational frequencies for $ZrF_4(g)$ as ν_1 = 600 - 725, ν_2 = 150 - 200, and ν_4 = 180 ± 230 cm^{-1}. Büchler, Berkowitz, and Dugre (13) observed the infrared spectra of some group IV halides and assigned ν_3 = 668 and ν_4 = 190 ± 20 cm^{-1} for $ZrF_4(g)$. The frequency ν_3 has also been reported as 670 cm^{-1} (14). The values of ν_3 and ν_4 adopted here are those reported by Büchler, Berkowitz, and Dugre (13). The adopted ν_1 is obtained by correlating the corresponding frequencies of the tetrafluorides of C, Pb, Si, Ti and Ge with their respective interatomic distances. ν_2 is calculated from ν_1, ν_3 and ν_4 using the relationship (15) $\frac{\nu_3\nu_4}{\nu_1\nu_2} = \sqrt{\frac{2}{3}(1+\frac{4F}{Zr})}$ where F and Zr are gram atomic weights of fluorine and zirconium, respectively. The three principal moments of inertia are $I_A = I_B = I_C = 3.166 \times 10^{-38}\ g\ cm^2$.

710 (1)	604 (1)	631 (2)
616 (1)	[257] (1)	372 (2)
318 (1)	276 (1)	190 (2)

Bond Distance: I-F(equatorial) = [1.86] Å I-F(axial) = [1.75] Å

Bond Angle: F-I-F = [90°]

Product of the Moments of Inertia: $I_AI_BI_C$ = [4.10383 x 10^{-113}] g^3 cm^6

σ = 4

Heat of Formation

The adopted value is derived from calorimetric data of Settle et al. (1) for the combustion of iodine in fluorine. Although the combustions gave various mixtures of IF_5 and IF_7, the proportions ranged up to almost pure pentafluoride. Reduction of the data gave ΔHf° = $-210.8_0 \pm 0.3_2$ kcal/mol for $IF_5(\ell)$ at 298.15 K. The result is essentially independent of the heptafluoride.

Comparison values of -208.9 ± [≥1] and -208.8 ± [≥1.7] kcal/mol may be obtained from calorimetric data of Woolf (2) for hydrolysis in water and in aqueous KOH. Uncertainties for these values include large contributions due to auxiliary data (3). In particular, we estimate lower limits of ±0.8 kcal/mol for ΔHf° of $HIO_3(1250\ H_2O)$ and $KIO_3(1250\ H_2O)$ by comparison with recent data (4).

ΔHf° for the ideal gas is derived from that of the liquid by use of ΔHv° = 9.96 kcal/mol at 298.15 K. ΔHv° was derived by Osborne et al. (5) from measurements of vapor pressure and the second virial coefficient.

Heat Capacity and Entropy

There is no published structural determination for gaseous IF_5, but spectral data are consistent with C_{4v} symmetry and a configuration which is approximately a square pyramid. It is uncertain whether the iodine is located above, in, or below the base of the pyramid and whether or not the axial and equatorial I-F distances are equal. We adopt the structure used by Begun et al. (7) in correlation of infrared and Raman spectra of BrF_5, IF_5, ClF_5, and $XeOF_4$ by normal coordinate analysis. In this structure the axial bond length is shorter than the equatorial length and the values are close to those observed experimentally for IF_7. The iodine is presumed to be in the base of the pyramid. Simplified Hückel-molecular-orbital calculations (8) predict that C_{4v} is the most stable symmetry, that the axial bond is shorter, and that the equatorial fluorines are distorted toward the axial fluorine. It is not clear to what extent these predictions depend on the simplified HMO model used in the calculations. Begun et al. (7) note that the normal coordinate calculations are insensitive to changes in the bond angles. Principal moments are $I_A = I_B = 30.66 \times 10^{-39}$ and $I_C = 43.65 \times 10^{-39}$ g cm^2.

Vibrational frequencies are based on the assignments of Begun et al. (7) as modified by the vapor-phase Raman spectra observed by Selig (6). Location of the band center of ν_9 (∿200 cm^{-1}) is difficult, so we substitute the liquid value of 190 cm^{-1}. The Raman-active fundamental ν_5 is not observed for IF_5, or any of the similar molecules, so its value is taken from the calculations (7).

Osborne et al. (5) used calorimetric data at low temperatures to derive S° = 57.96 ± 0.06 gibbs/mol for the liquid at 330 K. Combining this with ΔSv° based on their vapor pressure equation, the authors obtained S° = 83.06 ± 0.20 gibbs/mol for the ideal gas at 330 K. The corresponding value from this table (82.50) is lower by 0.56 gibbs/mol. Part of this difference arises from uncertainties in ν_5, ν_9, and the product of the moments of inertia. We estimate this uncertainty at about 0.5 gibbs/mol. Another source of minor uncertainty is the neglect of anharmonicity in the calculations.

Heat of Formation

Gross, Hayman, and Stuart (1) measured the heat of combustion of α-white phosphorus in fluorine at 25°C. They reported a heat of formation of -381.4 ± 0.8 kcal/mol (based on α-white phosphorus standard state) calculated from their combustion studies. Similar combustion studies were performed by O'Hare and Hubbard (2). They reported a heat of formation of -380.8 ± 0.3 kcal/mol (α-white phosphorus standard state), which is in excellent agreement with the work of Gross et al. (1). An average value of -381.1 ± 0.5 kcal/mol is adopted for this tabulation. Converting to the P(red, V) standard state with a ΔH trans = 4.2 ± 0.2 kcal/mol (3), we derive, $\Delta Hf^\circ_{298}(PF_5, g)$ = -376.9 ± 0.7 kcal/mol.

Heat Capacity and Entropy

The molecular structure and bond lengths given above for PF_5 were recently determined by Hansen and Bartell (4) from electron-diffraction studies. These results indicate that PF_5 has a trigonal bipyramid structure with nonequivalent axial and equatorial bonds. Wyatt et al. (5) determined rotational constants for PF_5 from a study of the infrared vibration-rotation band contour of the ν_4 (575 cm^{-1}) fundamental. Their analysis led to the following P-F bond lengths which are in excellent agreement with the electron-diffraction results: $r_{eq.}$ = 1.534 ± 0.024 Å and r_{ax} = 1.581 ± 0.025 Å. Individual moments of inertia, calculated from the rotational constants given by Wyatt et al. (5) and adopted for this table, are $I_A = 2.230 \times 10^{-38}\ g\ cm^2$ and $I_B = I_C = 2.690 \times 10^{-38}\ g\ cm^2$. The electron diffraction data lead to a product of moments of inertia of $1.604 \times 10^{-113}\ g^3\ cm^6$.

Several recent infrared and Raman studies (6, 7, and 8) have been reported for PF_5. These data are in good agreement except for the ν_7 fundamental. Griffiths et al. (6) originally assigned this fundamental to the 126 cm^{-1} band observed in their infrared spectra. Hoskins (9) later attributed this band to one of the pure rotational lines of hydrogen fluoride, which he felt was present in the sample as an impurity. Further work by Griffiths (10) on the pressure dependence of the infrared spectra of PF_5 indicated that the missing fundamental should be assigned to the weak band at 301 cm^{-1}. Deiters and Holmes (11) recently showed that this band is not a fundamental of PF_5 but a difference band (ν_3-ν_2). Very recently, Levin (8) investigated the Raman spectra of solid phosphorus pentafluoride and assigned the ν_7 fundamental to the 179 cm^{-1} band. Also, Beattie et al. (12) investigated the Raman spectra of PF_5 in the gas phase at 25°C and 125°C and assigned the ν_7 fundamental to 175 cm^{-1} band which is in excellent agreement with Levin's assignment (8). The fundamental vibrational frequencies of Holmes and Lord (7) are adopted along with Levin's assignment (8) of the ν_7 fundamental (179 cm^{-1}).

June 30, 1970

MOLYBDENUM HEXAFLUORIDE (MoF_6) (LIQUID) GFW = 209.930

$S^\circ_{298.15}$ = 62.07 ± 0.06 gibbs/mol

Tm = 290.76°K

Tb = 307.04°K ($\ell \rightarrow$ real gas, P = 1 atm, f = 0.966 atm)

Tb = 308.0°K ($\ell \rightarrow$ ideal gas, P = f = 1 atm)

$\Delta Hf^\circ_{298.15}$ = -379.080 ± 0.3 kcal/mol

ΔHm° = 1.034 ± 0.001 kcal/mol

ΔHv = 6.512 ± 0.04 kcal/mol

ΔHv° = 6.562 kcal/mol

Heat of Formation

The adopted heat of formation, ΔHf°(MoF_6, ℓ) = -379.080 ± 0.3 kcal/mol, is calculated from the heat of formation of the gas, ΔHf°(MoF_6, g) = -372.4 ± 0.2 kcal/mol (1), and the heat of vaporization, ΔHv° = 6.680 ± 0.03 kcal/mol at 298.15°K. The value for the heat of vaporization is obtained from a third law analysis of the vapor pressure data reported by Osborne et al. (2).

Myers and Brady (3) determined calorimetrically ΔHr = -154.7 kcal/mol for the hydrolysis reaction:

$$MoF_6(\ell) + 8\ NaOH\cdot 516\ H_2O \rightarrow \begin{bmatrix} Na_2MoO_4 \\ + \\ 6\ NaF \\ + \\ 4\ H_2O \end{bmatrix} \text{ in soln.}$$

Heats of formation of Na_2MoO_4 and NaF in the final solution were determined from the following two auxiliary heat of reaction measurements:

$$MoO_3(c) + 2\ NaOH\cdot 514\ H_2O \rightarrow Na_2MoO_4\ (\text{in soln.}) + H_2O(\ell) \qquad (1)$$

$$\Delta Hr = -17.6\ \text{kcal/mol}$$

$$NaF(c) + \begin{bmatrix} NaOH\cdot 514\ H_2O \\ + \\ 0.00186\ MoO_3 \end{bmatrix} \rightarrow NaF\ (\text{in soln.}) \qquad (2)$$

$$\Delta Hr = +0.09\ \text{kcal/mol}$$

Combining these results with the following heat of formation data:

ΔHf°(MoO_3, c) = -178.1 ± 0.1 kcal/mol (4)
ΔHf°(NaF, c) = -137.52 ± 0.2 kcal/mol (5)
ΔHf°(NaOH·500 H_2O) = -112.12 kcal/mol (6)

we derive ΔHf(Na_2MoO_4, in soln.) = -351.6 kcal/mol and ΔHf(NaF, in soln.) = -137.4 kcal/mol. These data, when combined with the results for the hydrolysis of MoF_6, lead to ΔHf°(MoF_6, ℓ) = -397.6 kcal/mol. This result is not in agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity measurements for liquid MoF_6 by Osborne et al. (2) are adopted. Outside the observed range Cp was extrapolated linearly with temperature. $S^\circ_{298.15}$ is evaluated from the thermal data of Osborne et al. (2) and the third law of thermodynamics. They reported heat capacity data in the range 5°-350°K with $S_{5°K}$ = 0.024 gibbs/mol.

Melting Data

Melting point and heat of melting data for MoF_6 have been reported by several investigators. These results are summarized below.

Investigator	Method	Melting Point °K	ΔHm° kcal/mol
Osborne et al. (2)	Calorimetric	290.76 ± 0.02	1.034 ± 0.001
Brady et al. (7)	Calorimetric	290.7	1.059 ± 0.010
Cady and Hargreaves (8)	Vapor Pressure	290.55	1.00 ± 0.03*
Ruff and Ascher (9)	Vapor Pressure	290.65	1.31 ± 0.2*

* This value is the difference between the 2nd law heat of sublimation corrected for ΔCp of the process and the adopted heat of vaporization calculated at 290.76°K with ($H_{290.76}-H_{298.15}$) for the vapor and liquid.

The value $\Delta Hm^\circ_{290.76}$ = 1.034 ± 0.001 kcal/mol from Osborne et al. (2) is adopted.

Vaporization Data

Second and third law analyses of various sets of vapor pressure data (2, 8, 9) are summarized below. Corrections for nonideality of the vapor have been calculated from the second virial coefficient equation reported by Osborne et al. (2).

Investigator	Temp. Range °K	No. of Points	Boiling Point °K	ΔHv°_{298} kcal/mol	
				2nd law*	3rd law
Osborne et al. (2)	291.15 - 320.15	21	307.04	6.690	6.680
Cady and Hargreaves (8)	290.55 - 307.15	Equation	307.15	6.74	6.68
Ruff and Ascher (9)	290.65 - 294.85	4	308.15	5.99	6.68

* with ΔCp = -11.77 gibbs/mol

The value ΔHv°_{298} = 6.680 ± 0.03 ($\Delta Hv_{307.04}$ = 6.512 ± 0.04) kcal/mol, determined from the vapor pressure data of Osborne et al. (2), is adopted in the tabulation. The temperature at which ΔGv° = 0 is 308.0°K and the corresponding ΔHv° = 6.562 kcal/mol.

Heat of Formation

Settle et al. (1) measured the heat of formation of gaseous MoF_6 by direct combination of its elements in a nickel bomb calorimeter. Their result was $\Delta Hf^\circ_{298}(MoF_6, g) = -372.4 \pm 0.2$ kcal/mol. This value is adopted in the tabulation.

Heat Capacity and Entropy

Tanner and Duncan (2) investigated the Raman spectra of liquid MoF_6, and their results indicated that the structure of the molecule was a regular octahedron with O_h symmetry rather than an unsymmetrical structure as reported by Braune and Pinnow (3) from electron diffraction studies. The Mo-F bond length is from the electron diffraction studies of Nazarian (4). Individual moments of inertia are $I_A = I_B = I_C = 4.268 \times 10^{-38}$ g cm^2.

Several infrared (5, 6, 7, 8) and Raman (5, 7) studies of MoF_6 have been reported. The vibrational frequencies reported for MoF_6 from these studies are in good agreement except for the infrared and Raman inactive ν_6 vibration. Burke et al. (5) and Hellberg et al. (8) derived $\nu_6 = 234\ cm^{-1}$, while Claassen et al. (7) assigned $\nu_6 = 190\ cm^{-1}$ and Gaunt (6) assigned $\nu_6 = 240\ cm^{-1}$. Weinstock and Goodman (9) recently analyzed the infrared and Raman data for MoF_6 and assigned $\nu_6 = 122\ cm^{-1}$.

Osborne et al. (10) calculated S° = 62.06 ± 0.06 gibbs/mol for liquid MoF_6 at 298.15°K from their low temperature thermal data. Combining this with ΔSv, they obtained S° = 83.75 ± 0.10 gibbs/mol for the ideal gas at 298.15°K. Accepting the assignments of Weinstock and Goodman (9), we calculate $S^\circ_{298.15}$ = 83.76 gibbs/mol, which is in excellent agreement with the thermal results. The other assignments given above for ν_6 all lead to ideal gas entropies that are lower than the thermal results. Therefore, the assignments given by Weinstock and Goodman (9) are adopted here.

ω, cm.$^{-1}$	ω, cm.$^{-1}$
770 (1)	345 (3)
640 (2)	615 (3)
522 (3)	947 (3)

Bond Length = 1.564 Å

Bond Angle: F-S-F = 90°

σ = 24

Product of the Moments of Inertia: $I_AI_BI_C$ = 29,400 X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

P. A. G. O'Hare, J. L. Settle, and W. N. Hubbard, Preprint of Paper XIV on Fluorine Bomb Calorimetry, July, 1965, measured the enthalpy of combustion of rhombic sulfur in fluorine. Their result yields $\Delta H_f^\circ{}_{298}$ = -291.79 ± 0.24 kcal. mole^{-1}. P. Gross, C. Hayman, and D. L. Levi, XVIIth Intern. Congr. Pure and Appl. Chem., Abstr. 1, 90 (1959), reported -289.5 kcal. mole^{-1} also based on direct combination of the elements. O'Hare, Settle, and Hubbard mentioned a private communication from Dr. Gross indicating -289.5 kcal. mole^{-1} may be in error due to oxygen in the fluorine used and preliminary results of a redetermination are in better agreement with -291.79 kcal. mole^{-1}. D. M. Yost and W. H. Claussen, J. Am. Chem. Soc. 55, 887 (1933) determined -262 kcal. mole^{-1}, again by direct reaction of the elements, which now appears too low. The work of O'Hare et al., loc. cit., is adopted.

Heat Capacity and Entropy.

V. C. Ewing and L. E. Sutton, Trans. Faraday Soc. 59, 124 (1963) measured the bond length adopted here by the electron diffraction technique. Earlier less accurate work by the same method by H. Braune and S. Knoke, Z. physik. Chem. B21, 297 (1933) and L. O. Brockway and L. Pauling, Proc. Nat. Acad. Sci. USA 19, 68 (1933) is in agreement within experimental error. T. E. Morsy, Ber. Bunsenges Physik. Chem. 68, 277 (1964) reviewed the literature on Raman and infrared spectra. Frequencies given here differ slightly from his selection because more weight was given to the Raman frequencies of C. W. Gullikson, J. R. Nielsen, and A. T. Stair, Jr., J. Mol. Spectroscopy 1, 151 (1957). Calculated functions by Morsy loc. cit. are in reasonable agreement with the present work.

A. Eucken and E. Schröder, Z. physik. Chem. 41B, 307 (1938) measured low temperature thermal data from which K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592 (1961) calculated S°_{298} = 70.3 ± 0.7 cal. mole^{-1} deg.$^{-1}$ which agrees within experimental error with the spectroscopic result.

The three principal moments of inertia are $I_A = I_B = I_C$ = 3.0863 X 10^{-38} g. cm.^{2}

Tungsten Hexafluoride (WF_6)

Sept. 30, 1962; Dec. 31, 1963; Mar. 31, 1967

TUNGSTEN HEXAFLUORIDE (WF_6) (LIQUID) GFW = 297.8404

$S^\circ_{298.15}$ = 59.564 ± 0.2 gibbs/mol

Tm = 275.2°K

Tb = 290.3°K

$\Delta Hf^\circ_{298.15}$ = -417.87 ± 0.5 kcal/mol

ΔHm° = 0.980 kcal/mol

ΔHv° = 6.465 ± 0.08 kcal/mol

Heat of Formation.

The adopted heat of formation, -417.87 kcal/mol, is calculated from the chosen $\Delta Hv^\circ_{290.3}$ = 6.465 ± 0.08 kcal/mol with $\Delta Hf^\circ_{298}(WF_6,g)$ = -411.5 ± 0.4 kcal/mol using all JANAF functions. The value of $\Delta Hv^\circ_{290.3}$ is obtained by corrected 2nd law analysis of vapor pressure data[6,7,8] which are given in the vaporization section of this table.

O. E. Myers and A. P. Brady[1] measured calorimetrically ΔHr°_{298} = -150.1 kcal/mol for the reaction $WF_6(l) + 8\ NaOH(500H_2O) \rightarrow Na_2WO_4(4900H_2O) + 4H_2O(l) + 6NaF(800\ H_2O)$. V. I. Spitsyn and N. N. Patsukova[2] measured calorimetrically ΔHr°_{298} = -13.8 kcal/mol for the reaction $WO_3(c) + 2\ NaOH(66H_2O) \rightarrow Na_2WO_4(4200H_2O) + H_2O(l)$. Based on these data and auxiliary data for NaOH(aq)[3,9], NaF(aq)[3,10] and $Na_2WO_4(aq)$[4], we obtain ΔHr°_{298} = -136.2 kcal/mol for $WF_6(l) + 6\ NaOH(\infty H_2O) \rightarrow WO_3(c) + 3\ H_2O(l) + 6\ NaF(\infty H_2O)$. This leads to $\Delta Hf^\circ_{298}(WF_6,\ l)$ = -416.9 ± 1 kcal/mol which is in good agreement with the value adopted.

Heat Capacity and Entropy.

The heat capacity, 40.5 gibbs/mol, is obtained from a graph of the Cp versus temperature curve determined calorimetrically by E. F. Westrum, Jr.[5]

The entropy, S°_{298} = 59.564 eu, is calculated from the chosen $\Delta Hv^\circ_{290.3}$ = 6.465 kcal/mol with $S^\circ_{298}(WF_6,g)$ = 81.504 eu using all JANAF functions.

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized below. Ruff and Ascher's value, 2.40 kcal/mol, is too high because they did not know of the existence of a solid-solid transition[5] at 264.7°K with ΔHt° = 2.067 kcal/mol. Westrum's data are adopted in the tabulation.

Investigator	Method	Melting Point (°K)	ΔHm° (kcal/mol)
Westrum[5]	Calorimetric	275.2	0.980
Ruff and Ascher[7]	Vapor pressure	275.4	2.400*
Barber & Cady[8]	Warming curve	275.1	0.500
Cady & Hargreaves[6]	Vapor pressure	275.2	0.420*

*This value is the difference between the 2nd law heats of sublimation and vaporization without correction for ΔCp° for both processes.

Vaporization Data.

Second law analyses of the data[6,7,8], neglecting corrections for nonideality of the vapor, are summarized below. The value of ΔHv°_{298} = 6.37 kcal/mol ($\Delta Hv^\circ_{290.3}$ = 6.465 kcal/mol) is selected in the tabulation.

Investigator	Temp. Range (°K)	No. of Points	Boiling Point (°K)	ΔHv°_{298} * (kcal/mol)	ΔSv°_{298} * (eu)
Ruff and Ascher[7]	273 - 287.5	5	290.7 ± 0.2	6.30 ± 0.12	21.70
Barber and Cady[8]	285 - 324.5	16	290.2 ± 0.05	6.37 ± 0.01	21.94
Cady and Hargreaves[6]	275 - 290	Equation	290.3 ± 0.05	6.12	21.09

*From second law analysis using ΔCp = -12.4 gibbs/mol

Sept. 30, 1962; Dec. 31, 1963; Mar. 31, 1967

TUNGSTEN HEXAFLUORIDE (WF_6) (IDEAL GAS) GFW = 297.8404

Point Group O_h

$S^\circ_{298.15}$ = 81.504 gibbs/mol

Ground State Quantum Weight = 1

$\Delta Hf^\circ_0 = -409.4 \pm 0.4$ kcal/mol

$\Delta Hf^\circ_{298.15} = -411.5 \pm 0.4$ kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
769 (1)	256 (3)
670 (2)	322 (3)
712 (3)	216 (3)

Bond Distance: W-F = 1.83 Å

Bond Angle: F-W-F = 90°

σ = 24

Product of the Moments of Inertia: $I_A I_B I_C = 7.54576 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation.

P. A. G. O'Hare and W. N Hubbard, J. Phys. Chem. 70, 3353 (1966), determined the heat of formation, $\Delta Hf^\circ_{298}(WF_6,g) = -411.5 \pm 0.4$ kcal/mol, by combustion of tungsten in fluorine in a bomb calorimeter. This value is adopted in the tabulation.

Heat Capacity and Entropy.

The molecular configuration and vibrational frequencies were obtained from the infrared and Raman spectroscopic studies by J. Gaunt[1]; T. G. Burke, D. F. Smith and A. H. Nielsen[2]; K. N. Tanner and A. B. F. Duncan[3].

The bond distance was reported by H. H. Claasen[4], based on the preliminary result of V. Schomaker, M. Kimura and B. Weinstock[5] who determined the bond distance by electron diffraction. J. Gaunt[6] derived W-F = 1.89 Å from correlations with other hexafluorides and a valence force constant calculation. The three principal moments of inertia are $I_A = I_B = I_C = 4.22572 \times 10^{-38}$ g cm^2.

Bond Distance: I-F(equatorial) = 1.86 Å I-F(axial) = 1.76 Å

Bond Angle: F(eq)-I-F(ax) = 90° F(eq)-I-F(eq) = 72° $\sigma = 10$

Product of the Moments of Inertia: $I_AI_BI_C = 1.1965 \times 10^{-112}\ g^3\ cm^6$

Heat of Formation

Settle et al. (1) derived ΔHf° = -229.7 ± 0.6 kcal/mol for $IF_7(g)$ at 298.15 K from treatment of their calorimetric data on combustion of iodine in fluorine. The combustion products, consisting of mixtures of IF_5 and IF_7, were expanded, treated to remove excess fluorine, and then hydrolyzed. The solutions were analyzed for iodate and the sum of iodate plus periodate. Since the recovery of iodine was not complete (about 70 to 99%), it was necessary to try various assumptions about the form of the unrecovered iodine. Consistent results were obtained only by assigning the unrecovered iodine to IF_7, the less volatile product. This treatment indicated that IF_7 was formed in yields ranging from about 1 to 70%.

ΔHr° for the reaction $IF_7(g) \rightarrow IF_5(g) + F_2(g)$ may be checked via equilibrium data (2). Using six points read from Fig. 2 of Bernstein and Katz, we obtain ΔHr°(3rd law) = 29.36 ± 0.2 kcal/mol and ΔHr°(2nd law) = 29.53 ± 0.7 kcal/mol, both at 298.15 K. The entropy test, ΔSr°(2nd law) - ΔSr°(JANAF Functions) = 0.3 ± 1.4 gibbs/mol, indicates consistency with the JANAF functions. Combination of ΔHr°(3rd law) with ΔHf° for $IF_5(g)$ yields ΔHf°(IF_7, g) = -230.2 ± 0.6 kcal/mol. In deriving the uncertainty, we assume that ΔHr°(3rd law) is uncertain by ±0.5 kcal/mol due to an estimated uncertainty of about 1.0 gibbs/mol in the JANAF value of ΔSr° at 500 K.

Heat Capacity and Entropy

Recent evidence favors D_{5h} symmetry and a pentagonal bipyramidal structure for the heptafluoride. Claassen et al. (3) review the earlier debate about structures of lower symmetry. They provide convincing evidence of D_{5h} symmetry from the first observation of Raman spectra of the vapor state and re-examination of the infrared spectra. Their data--including five fundamentals in Raman (two polarized), five fundamentals in infrared, no coincidences between Raman and infrared, and one fundamental inactive--are consistent only with D_{5h} symmetry. This is confirmed by Falconer et al. (4) who interpret their electric-deflection experiments as indicating a symmetry-forbidden dipole moment. Extended Hückel-molecular-orbital calculations (5) also predict D_{5h} symmetry. The adopted structural parameters are from our approximate analysis of the electron-diffraction data of Thompson and Bartell (6). The authors gave a radial distribution curve and suggested only a gross (unrefined) structure because of the probable presence of a fluorocarbon impurity in their sample. Principal moments of inertia are $I_A = I_B = 46.83 \times 10^{-39}$ and $I_C = 54.57 \times 10^{-39}\ g\ cm^2$.

Observed vibrational fundamentals are from Claassen et al. (3). The inactive fundamental is estimated from the calculations of Khanna (7).

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The heat capacity below 298°K. was obtained by smoothing graphically the data of G. Duyckaerts, Physica 6, 401 (1939) and W. H. Keesom and B. Kurrelmeyer, Physica, 6, 633 (1939) over the range 1° - 20°K; F. E. Simon and R. C. Swain, Z. Physik. Chem. 28B, 189 (1935) (30-220°K.), A. Eucken and H. Werth, Z. Anorg. Chem. 188, 152 (1930) (17-206°K.) and K. K. Kelley, J. Chem. Phys. 11, 16 (1943) (55-295°K.). This data on integration yielded $S_{298.15}$ = 6.529 starting with S_1° = 0.0003 cal. deg.$^{-1}$ mole^{-1}. The heat capacity and enthalpy data above room temperature are extensive and the heat capacities and enthalpies chosen by R. Hultgren, R. L. Orr, P. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York 1963, were adopted here. These values have a sharp peak in the heat capacity curve at the Curie pernt* and through this region follow closely the work of P. R. Pallister, J. Iron Steel Inst. 161, 87 (1949). This data has recently been corroborated using a pulse heating technique by D. C. Wallace, P. H. Sidles and G. C. Danielson, J. App. Phys. 31, 168 (1960). It should be noted that there is some disagreement between the heat capacities chosen and the enthalpies measured by P. D. Anderson and R. Hultgren, Trans. Met. Soc. AIME, 224, 842 (1962). The measured values lie consistently above the chosen enthalpies in the range 298-900°K. by from 30 to 60 calories, however the chosen values are considered to be the more reliable. The γ-iron heat capacities adopted here have recently been substantially confirmed by W. A. Dench and O. Kubaschewski, J. Iron Steel Inst. (London) 201, 140 (1963).

Transition Data.

The enthalpies of the α - γ transition at 1184°K. and the γ - δ transition at 1665°K. were also taken from Hultgren et al. loc. cit.

Melting Data.

The temperature and heat of melting were those adopted by Hultgren et al. loc. cit.

Heat of Sublimation.

The value adopted is from a critical second and third law analysis of the data of 14 investigators over gamma-iron and liquid iron. See the Fe(g) table for details.

---

*See W. F. Giauque, G. E. Brodale, R. A. Fisher and E. W. Hornung, J. Chem. Phys. 42, 1 (1965) for the definition of "pernt".

Mar. 31, 1965

IRON (Fe) (LIQUID) AT. WT. = 55.85

$S^\circ_{298.15}$ = 8.195 cal. deg.$^{-1}$ mole^{-1}

T_m = 1809°K.

T_b = 3145.4°K.

ΔH°_f 298.15 = 3.138 kcal. mole^{-1}

ΔH°_m = 3.630 kcal. mole^{-1}

ΔH°_v = 83.679 kcal. mole^{-1}

Heat of Formation.

The ΔH°_f 298.15 was obtained from that of the crystal by adding ΔH_m and the difference between $H_{1809} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase was that chosen by R. Hultgren, R. L. Orr, P. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York (1963).

Melting Data.

See Fe(c) for details.

Vaporization Data.

The boiling point was calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K. so that the free energy function calculated by integration of the crystal liquid data or by statistical methods from the gas phase were equal at the boiling point.

Heat of Formation.

The heat of formation is the heat of sublimation at 298°K. which was obtained by second and third law analysis of the following vapor pressure data.

The adopted value of 99.5 kcal. mole^{-1} is based mainly on the work of Refs. 5, 8 and 14, which have the best drift analysis and agreement between second and third law.

Heat Capacities and Entropies.

The electronic levels were taken from C. E. Moore, Natl. Bur. Standards Circ. 467 (1949). Levels above 20,000 cm.$^{-1}$ were averaged.

Iron Dihydroxide $(Fe(OH)_2)$

June 30, 1966

IRON DIHYDROXIDE $(Fe(OH)_2)$ (CRYSTAL) GFW = 89.86174

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [21 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -137.2 ± 0.7 kcal/mol

Tm = Unknown

ΔHm° = Unknown

$\Delta Hs^\circ_{298.15}$ = 58.2 kcal/mol

Heat of Formation.

The heat of combustion of $Fe(OH)_2(c)$, according to the chemical reaction $Fe(OH)_2(c) + 1/4\ O_2(g) = 1/2\ Fe_2O_3(c) + H_2O(l)$, was determined to be -29.8 ± 0.65 kcal/mol by R. Fricke and S. Rihl, Z. anorg. allgem. chem. 251, 414 (1943). From this data the heat of formation ($\Delta Hf^\circ_{298.15}$) was evaluated to be -137.2 ± 0.7 kcal/mol. which was adopted here.

The enthalpy changes for the following three reactions were determined by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886:

Reaction	ΔHr°_{291}, kcal/mol
1. $FeCl_2(c) = FeCl_2\ (400\ H_2O)$	-17.9
2. $FeCl_2(200\ H_2O) + H_2SO_4(200\ H_2O) = FeSO_4(200\ H_2O) + 2\ HCl(100\ H_2O)$	-3.6
3. $FeSO_4(aq.) + 2KOH(aq.) = Fe(OH)_2\ (c) + K_2SO_4(aq.)$	-6.34

Using $\Delta Hf^\circ_{298.15}$ = -81.7 kcal/mol for $FeCl_2(c)$ and those for the other compounds in aqueous solution (assuming aq. = 200 H_2O in Reaction 3) obtained from D.D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, National Bureau of Standards, 1965, the heat of formation (298.15°K) for $Fe(OH)_2(c)$ was derived as -135.8 kcal/mol which agrees reasonably with the adopted value.

Heat Capacity and Entropy.

The heat capacities, 298.15 - 700°K, and $S^\circ_{298.15}$ were estimated by comparison with those for $FeCl_2(c)$, $CaCl_2(c)$ and $Ca(OH)_2(c)$. The Cp values above 700°K were obtained by graphical extrapolation of the Cp curve plotted using the above Cp values.

Heat of Sublimation.

The value of $\Delta Hs^\circ_{298.15}$ was calculated as the difference between $\Delta Hf^\circ_{298.15}$ for $Fe(OH)_2(g)$ and $Fe(OH)_2(c)$.

Bond Distance: Fe-O = [1.8] Å O-H = [0.96] Å

Bond Angle: O-Fe-O = [180]° Fe-O-H = [105]°

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C$ = [9.368 x 10^{-116}] g^3 cm^6

Heat of Formation.

The equilibrium constants, at temperatures between 1300 and 1460°C, for the chemical reaction $Fe(c) + 2H_2O(g) = Fe(OH)_2(g) + H_2(g)$, were determined by G. R. Belton and F. D. Richardson, Trans. Faraday Soc. 58, 1562 (1962). Using these data, the enthalpy change ($\Delta Hr^\circ_{298.15}$) of the reaction is evaluated to be 35.53 ± 3.0 and 36.57 kcal/mol by the second and third law method, respectively. Based on the third law value for $\Delta Hr^\circ_{298.15}$, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $Fe(OH)_2(g)$ is calculated to be -79 ± 0.5 kcal/mol.

Heat Capacity and Entropy.

The molecular structure is assumed to be the same as that for $B(OH)_2(g)$. The Fe-O bond distance is taken from FeO(g). The O-H bond distance and Fe-O-H bond angle are estimated from those for $H_2O(g)$. The vibrational frequencies, and electronic levels and quantum weights are obtained by comparison with those for $B(OH)_2(g)$ and $FeCl_2(g)$, respectively. These values are adjusted to give reasonable second and third law agreements. The three principal moments of inertia are: $I_A = 2.658 \times 10^{-40}$, $I_B = 1.864 \times 10^{-38}$ and $I_C = 1.890 \times 10^{-38}$ g cm^2.

Heat of Formation.

P. Schindler, W. Michaelis and W. Feitknecht, Helv. Chim. Acta, 46, 444 (1963), investigated the solubility of aged $Fe(OH)_3$ precipitates by determining the Fe^{+++} and H^+ ion concentration of solution in contact with the solid phase. The ion concentration was measured by the EMF method at the constant ionic strength 3M $NaClO_4$(solution). The precipitates were investigated by X-ray and electron miscroscope methods. The equilibrium constant was derived as $\log [Fe^{+++}] [H^+]^{-3} = \log K = 3.55 \pm 0.1$ for amorphous inactive hydroxide at 25°C. From these data the quantity log Ks = -39.1 ± 0.2 was evaluated where Ks is the solubility product of $Fe(OH)_3$. The Gibbs energy change ($\Delta Gr^\circ_{298.15}$) of the reaction $Fe(OH)_3(c) = Fe^{+++}(aq) + 3OH^-(aq)$ was calculated to be 53.34 ± 0.27 kcal/mol. Using $S_{298.15}$ = 70.1 and -2.57 gibbs/mol for Fe^{+++}(aq) and OH^-(aq), respectively, and an estimated $S^\circ_{298.15}(Fe(OH)_3, c)$ = 25 gibbs/mol, the enthalpy change ($\Delta Hr^\circ_{298.15}$) of the reaction is calculated to be 22.69 kcal/mol, according to the relationship $\Delta H = \Delta F + T\Delta S$. The entropy values for Fe^{+++} and OH^- ions were obtained from "Selected Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1 by D. D. Wagman and co-workers, 1965, respectively. Based on $\Delta Hf^\circ_{298.15}(Fe^{+++}, aq) = -11.4$ and $\Delta Hf^\circ_{298.15}(OH^-, aq) = -54.97$ kcal/mol, taken from the same sources, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $Fe(OH)_3$(c) was evaluated to be -199 ± 3 kcal/mol, which was adopted here.

The divergent values for solubility product (SP) of $Fe(OH)_3$ found in the literature may be due not only to the various forms of precipitate, but also to the tendency to form colloidal solutions. The SP values for $Fe(OH)_3$ were also reported by Evans and Pryor, J. Chem. Soc. S157 (1949); Kriukor and Awsejewitsch, Z. Elektrochem. 39, 884 (1933); Ruff and Hirsch, Z. Anorg. Chem. 146, 338 (1925); Britton, J. Chem. Soc. 2148 (1925); and Jellinek and Gorden, Z. Phys. Chem. 112, 207 (1924).

The enthalpy changes (ΔHr°_{291}) for the reactions: (1) $FeCl_3(aq) + 3NaOH(aq) = Fe(OH)_3(c) + 3NaCl(aq)$ and (2) $FeCl_3(c) = FeCl_3(aq)$ were determined to be -24.50 and -31.68 kcal/mol, respectively, by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886. Assuming the aqueous solutions all contain 200 mol of H_2O, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $Fe(OH)_3$ was calculated as -196.9 kcal/mol from Reactions (1) and (2). The $\Delta Hf^\circ_{298.15}$ values for NaOH(aq) and NaCl(aq) were obtained from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS-2, National Bureau of Standards, 1965, and JANAF $\Delta Hf^\circ_{298.15}$ values for NaOH(c) and NaCl(c).

Heat Capacity and Entropy.

The heat capacities, 298.15 - 1000°K, were estimated by comparison with those for $B_2O_3(c)$, $Fe_2O_3(c)$ and $B(OH)_3(c)$. The Cp values above 1000°K were obtained by graphical extrapolation. The $S^\circ_{298.15}(Fe(OH)_3, c)$ value was estimated by comparison with that for $B(OH)_3(c)$.

Sept. 30, 1966

IRON DIIODIDE (FeI_2) (CRYSTAL) GFW = 309.6558

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [40 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = −25 ± 4 kcal/mol

Tt = 650°K

ΔHt° = 0.2 kcal/mol

Tm = 860 ± 2°K

ΔHm° = [10.7] kcal/mol

$\Delta Hs^\circ_{298.15}$ (to monomer) = [46] kcal/mol

$\Delta Hs^\circ_{298.15}$ (to dimer) = [52] kcal/mol

Heat of Formation.

The chemical equilibrium of the decomposition of $FeI_2(c)$, 771.15 — 858.15°K, has been studied by W. E. Zaugg and N. W. Gregory, J. Phys. Chem 70, 486 (1966). Using the reported partial pressures for $I_2(g)$, the enthalpy change ($\Delta Hr^\circ_{298.15}$) for the reaction $FeI_2(c) = Fe(c) + I_2(g)$ was evaluated by both the second and third law methods to be 39.79 ± 1.0 and 39.69 ± 0.3 kcal/mol, respectively. Based on the third law $\Delta Hr^\circ_{298.15}$ value, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $FeI_2(c)$ was calculated as -25 kcal/mol which was adopted here.

The enthalpy change for the reaction $FeI_2(c) = Fe^{++}(aq) + 2\ I^-\ (aq)$ was determined to be -19.46 ± 0.03 kcal/mol by P. Paoletti, A. Sabatini and A. Vacca, Trans. Faraday Soc. 61, 2417 (1965), using a solution calorimetric method. Adopting $\Delta Hf^\circ_{298.15}$ = -21.3 and -13.19 kcal/mol for $Fe^{++}(aq)$ and I^- (aq), respectively, the value of $\Delta Hf^\circ_{298.15}$ (FeI_2, c) was derived as -28.22 ± 1 kcal/mol. The value of $\Delta Hf^\circ_{298.15}$ (I^-, aq) was taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Part 1, Technical Note 270-1, National Bureau of Standards, 1965. The value of $\Delta Hf^\circ_{298.15}$ (Fe^{++}, aq) was derived from heats of solution and formation for $FeCl_2(c)$.

The heats of solution of Fe(c), $I_2(c)$ and $FeI_2(c)$ in aqueous Br_2-KBr solution were measured by W. Hieber and A. Woerner, Z. Elektrochem. 40, 287 (1934), using an ice calorimeter. From the results obtained the heat of formation for $FeI_2(c)$ was reported as -30.1 kcal/mol.

Heat Capacity and Entropy.

The heat capacities, 343.15 — 773.15°K, were measured by F. L. Oetting and N. W. Gregory, J. Phys. Chem. 65, 173 (1961). The Cp values at temperatures below 343.15 and above 773.15°K were estimated by graphical extrapolation. The low temperature heat capacities, 11-130°K, were determined by G. Miljutin and E. A. Parfenowa, Phys. Trans. Ukrain, Acad. Sci. 9, 81 (1940). These data appear to be inadequate for the derivation of the entropy at 298.15°K. The value of $S^\circ_{298.15}$ adopted was calculated from the entropy change, $\Delta Sr^\circ_{298.15}$ = 28.7 eu, for the decomposition reaction $FeI_2(c) = Fe(c) + I_2(g)$, obtained by the second law analysis of the equilibrium pressure data reported by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 486 (1966).

Transition Data.

A minor transition in the vicinity of 370°C (360-385°C) has been reported by F. L. Oetting and N. W. Gregory, loc. cit. Subsequent studies by T. J. Wydeven, Ph. D. Thesis, University of Washington, Seattle, Wash., 1964, have shown the magnitude of the transition to be sensitive to trace amounts of impurities, but the nature of the transition has not been clearly established. A magnetic transition at 10°K was reported by H. Bizette, C. Terrier and B. Tsai, Compt. rend. 245, 507 (1957). The ΔHt° value was evaluated from the heat capacity - temperature plot given by F. L. Oetting and N. W. Gregory, loc. cit.

Melting Data.

Tm was reported by W. Fischer and R. Gewehr, Z. anorg. allgem. Chem. 222, 303 (1935). ΔHm° was estimated by comparison with that for $FeBr_2(c)$.

Heat of Sublimation.

$\Delta Hs^\circ_{298.15}$ (to monomer) is calculated as the difference between $\Delta Hf^\circ_{298.15}$ for $FeI_2(g)$ and $FeI_2(c)$. $\Delta Hs^\circ_{298.15}$ (to dimer) was calculated as the difference between those for $Fe_2I_4(g)$ and 2 $FeI_2(c)$.

Sept. 30, 1966

IRON DIIODIDE (FeI_2) (LIQUID) GFW = 309.6558

$S^\circ_{298.15}$ = [46.720] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [16.969] kcal/mol

Tm = 860 ± 2° K ΔHm° = [10.7] kcal/mol

Tb =[1366] °K ΔHv° = [25.0] kcal/mol

Heat of Formation.

The heat of formation ($\Delta Hf^\circ_{298.15}$) was obtained from $\Delta Hf^\circ_{298.15}$ (c) by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was assumed to be constant in the temperature range from 298.15 to 2000°K. The value of Cp was calculated on an assumption that Cp = 9.0 gibbs/g-atom for $FeI_2(l)$. The entropy was obtained in a manner analogous to that of the heat of formation.

Vaporization Data.

Tb is the temperature at which the vapor pressure of $FeI_2(g)$ and $Fe_2I_4(g)$ over $FeI_2(l)$ equals one atmosphere. The value of ΔHv° is derived from the vapor composition and the heats of vaporization of $FeI_2(l)$ to monomer and dimer at Tb.

Rotational Constant: B_o =[0.01124] cm^{-1} σ = 2

Heat of Formation.

The chemical equilibria for the reactions: (A) $FeI_2(c) = FeI_2(g)$, (B) $FeI_2(l) = FeI_2(g)$, and (C) $Fe(c)+2I(g)=FeI_2(g)$, have been studied by several investigators. Based on the equilibrium pressures reported, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented in the table below. Using the third law $\Delta Hr^\circ_{298.15}$ values, the heats of formation for $FeI_2(g)$ were calculated. The adopted value for $\Delta Hf^\circ_{298.15}(FeI_2,g)$ is 21.0 ± 3 kcal/mol. The disagreement between the sets of second and third law $\Delta Hr^\circ_{298.15}$ values listed in the table may be due to the presence of dimer, $Fe_2I_4(g)$, which was not accounted for in deriving the partial pressure of $FeI_2(g)$. The data obtained from Schoonmaker et al. was adjusted for the presence of dimer.

*The vapor pressure data used for evaluation were those adjusted by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 490 (1966).

1. H. Schäfer and W. J. Hones, Z. Anorg. Allgem. Chem. 288, 62 (1956).
2. R. C. Schoonmaker, A. H. Friedman and F. R. Porter, J. Chem. Phys. 31, 1586 (1959).
3. R. J. Sime and N. W. Gregory, J. Phys. Chem. 64, 86 (1960). The vapor pressure equation used for calculation is log P_{mm} = -(9760/T) + 11.82. In the original paper, the term A = 960 should be 9760.
4. W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 490 (1966).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The Fe-I bond distance was estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The vibrational frequencies were estimated so that the derived gibbs energy functions yielded second and third law $\Delta Hr^\circ_{298.15}$ values in reasonable agreements (see the above table). The electronic levels and quantum weights were estimated from those for $FeCl_2(g)$ reported by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The moment of inertia is 2.48844 x 10^{-37} g cm^2.

June 30, 1965

WÜSTITE ($Fe_{0.947}O$) (CRYSTAL) MOL. WT. = 68.88651

$\Delta H_f^\circ{}_0 = -63.85 \pm 0.20$ kcal. mole^{-1}

$S^\circ_{298.15} = 13.764 \pm 0.10$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = -63.64 \pm 0.20$ kcal. mole^{-1}

$T_m = 1650$°K.

$\Delta H_m^\circ = 7.49$ kcal. mole^{-1}

Heat of Formation.

The chemical equilibria in the Fe-C-O and Fe-H-O systems have been studied by many investigators. Using the reported equilibrium constants for the following two reactions (1) $Fe_{0.947}O(c) + CO(g) = 0.947Fe(c) + CO_2(g)$ and (2) $Fe_{0.947}O(c,l) + H_2(g) = 0.947Fe(c) + H_2O(g)$, the corresponding enthalpy changes (ΔH_r°) were evaluated by both the second and third law methods. Based on the third law values for ΔH_r°, the $\Delta H_f^\circ{}_{298.15}$ (Wüstite, c) values were also calculated. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	$\Delta H_f^\circ{}_{298.15}$ kcal. mole^{-1}

[1] E. D. Eastman, J. Am. Chem. Soc. 44, 975 (1922).

[2] E. D. Eastman and R. M. Evans, J. Am. Chem. Soc. 46, 888 (1924). The K_p value at 1273.2°K. for reaction (1) is rejected by a statistical criterion.

[3] P. H. Emmett and J. F. Schultz, J. Am. Chem. Soc. 52, 4268 (1930).

[4] E. V. Britzke, A. F. Kapustinsky and T. I. Schaschkina, Z. anorg. allgem. Chem. 219, 287 (1934). The K_p value at 1123°K. for reaction (3) is rejected by a statistical criterion.

[5] W. E. Jominy and D. W. Murphy, Ind. Eng. Chem. 23, 384 (1931). The K_p values at 1590 and 1645°K. are rejected by a statistical criterion.

[6] J. Chipman and S. Marshall, J. Am. Chem. Soc. 62, 299 (1940).

Britzke et al. also determined the equilibrium pressures for the reaction (3) $1.894\ Fe(c) + O_2(g) = 2Fe_{0.947}O(c)$. The corresponding $\Delta H_f^\circ{}_{298.15}$ for Wüstite was evaluated based on the third law value for $\Delta H_r^\circ{}_{298.15}$. The adopted value of $\Delta H_f^\circ{}_{298.15}$ (Wüstite,c) is the weighted average of the $\Delta H_f^\circ{}_{298.15}$ listed in the above table.

Heat Capacity and Entropy.

The low temperature (54.37-298.16°K.) heat capacities (C_p) were measured by S. S. Todd and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3894 (1951). The high temperature (298-1650°K.) heat capacities were determined by J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3891 (1951). The two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 1650°K. were obtained by graphical extrapolation. The low temperature (70.7-279.8°K.)C_p's were also reported by R. W. Millar, J. Am. Chem. Soc. 51, 215 (1929). $S^\circ_{298.15}$ was derived from the low temperature heat capacities, based on $S^\circ_{52} = 0.696$ cal. deg.$^{-1}$ mole^{-1}. S. S. Todd and K. R. Bonnickson, loc. cit. added 0.41 e.u., the amount calculated for completely random distribution of the vacant Fe spaces in the Wüstite lattice. However, the free energy functions derived from $S^\circ_{52} = 0.696$ e.u. give better agreement between second and third law values for ΔH_r° than those derived from $S^\circ_{52} = 1.11$ e.u. Therefore the value 0.41 e.u. was not added here.

Melting Data.

T_m and ΔH_m° were taken from J. P.Coughlin, E. G. King and K. R. Bonnickson, et al. T_m was reported as 1372°C. (1645°K.) by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 798 (1946) and as 1369°C. (1642°K.) by J. Chipman and S. Marshall, loc. cit.

June 30, 1965

IRON OXIDE (FeO) (CRYSTAL) MOL. WT. = 71.8464

$\Delta H_{f\ 0}^\circ$ = Unknown

$S^\circ_{298.15}$ = [14.52] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ$ = [-65.02] kcal. mole^{-1}

T_m = [1650]°K.

ΔH_m° = [5.75] kcal. mole^{-1}

$\Delta H_{s\ 298.15}^\circ$ = [121.62] kcal. mole^{-1}

Heat of Formation.

The value of $\Delta H_{f\ 298.15}^\circ$ for FeO(c) was derived based on an assumption that at 1650°K., ΔF_f° (FeO, c) = ΔF_f° (FeO, l). From the value $\Delta F_{f\ 1650}^\circ$ (FeO, c) = -39.77 kcal. mole^{-1}, $\Delta H_{f\ 1650}^\circ$ (FeO, c) was calculated to be -63.97 kcal. mole^{-1}, yielding $\Delta H_{f\ 298.15}^\circ$ (FeO, c) = -65.02 kcal. mole^{-1}.

Heat Capacity and Entropy.

The C_p values were estimated assuming C_p (FeO, c) = C_p (Wüstite, c) + 0.053 C_p (Fe, c). The C_p values obtained were plotted. The adopted C_p points were taken from the smoothed C_p curve. $S^\circ_{298.15}$ for FeO(c) was calculated as S° (FeO, c) = S° (Wüstite, c) + 0.053 S° (Fe, c) + ΔS° (mixing) where ΔS° is the entropy of mixing (0.41 cal. deg.$^{-1}$ mole^{-1}).

Melting Data.

T_m is assumed to be the same as that for Wüstite. The difference between $\Delta H_{f\ 1650}^\circ$ for FeO(l) and FeO(c) is ΔH_m°.

Heat of Sublimation.

$\Delta H_{s\ 298.15}^\circ$ is calculated as the difference between $\Delta H_{f\ 298.15}^\circ$ for FeO(g) and FeO(c).

IRON OXIDE (FeO) (LIQUID) MOL. WT. = 71.8464

$S^\circ_{298.15}$ = 18.029 cal. deg.$^{-1}$ mole^{-1}

T_m = [1650]°K.

T_d = [3687]°K.

$\Delta H^\circ_{f\ 298.15}$ = [-59.642] kcal. mole^{-1}

ΔH°_m = [5.75] kcal. mole^{-1}

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) was evaluated based on an assumption that the heat of melting of Wüstite, $\Delta H^\circ_{m\ 1650}$ = 7.49 kcal. mole^{-1}, represents the enthalpy change of the reaction $Fe_{0.947}O(c) = 0.947\ FeO(l) + \frac{0.053}{2} O_2(g)$. In other words, during melting the wüstite releases $O_2(g)$ and converts to FeO(l).

Heat Capacity and Entropy.

The enthalpy changes ($H^\circ_T - H^\circ_{298.15}$, 1650-1800°K.) of liquid iron oxide were determined by J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3891 (1951). The C_p (FeO, l) was derived as 16.3 cal. deg.$^{-1}$ mole^{-1}. This value was adopted as the heat capacity for FeO(l) up to 4000°K. A glass transition temperature was assumed at 1100°K. $S^\circ_{298.15}$ (FeO, l) was calculated based on an assumption that the entropy of melting of Wüstite represents also the entropy change of the reaction, $Fe_{0.947}O\ (c) = 0.947\ FeO\ (l) + \frac{0.053}{2} O_2\ (g)$. From the entropy of melting, $\Delta S^\circ_{m\ 1650}$ = 4.539 e.u., the value $S^\circ_{298.15}$ (FeO, l) = 18.029 e.u. was derived.

Melting Data.

The melting point (T_m) for Wüstite ($Fe_{0.947}O$, c) has been reported by many investigators. However, the composition of the liquid state of Wüstite was not identified. An assumption was made that during melting the reaction $Fe_{0.947}O\ (c) = 0.947\ FeO\ (l) + \frac{0.053}{2} O_2\ (g)$ occurs. Hence the related thermodynamic properties were derived.

Decomposition Temperature.

T_d is the temperature at which ΔF°_f equals zero.

[10000]	[10]
[16000]	[5]

ω_e = 880.0 cm^{-1} $\omega_e x_e$ = 5.0 cm^{-1} σ = 1

B_e = [0.4184] cm^{-1} α_e = [0.00293] cm^{-1} r_e = [1.8] Å

Heat of Formation.

The heat of formation for FeO(g) is not well established at the present time. The values of $\Delta Hf^\circ_{298.15}$ (FeO, g) derived from the following reactions: (1) FeO(g) = Fe(g) + O(g), (2) FeO(g) = Fe(g) + 1/2 O_2(g), and (3) FeO(l) = FeO(g), are not in agreement. There are three D° (Fe-O) values reported for reaction (1). The enthalpy change for reaction (2) was evaluated based on the partial pressure data (P_{FeO}/ P_{Fe}) = 0.2 at 1600°C, measured by Washburn[4], using a mass spectrometric method, U. S. Atomic Energy Commission, UCRL-10991, August 1963, and P_{O_2} = 1.66 x 10^{-6} atm reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 798 (1946). The enthalpy value for reaction (3) was calculated based on the reported value, ΔHv°_{2785} = 96.096 kcal/mol determined by Burtsev, Karasev and Samarin[5]. The results obtained are presented as follows. The value of $\Delta Hf^\circ_{298.15}$ for FeO(g) adopted is 60 ± 5 kcal/mol.

Investigator	Reaction	Method	$\Delta Hr^\circ_{298.15}$ kcal/mol	$\Delta Hf^\circ_{298.15}$ kcal/mol

3. A. Lagerqvist and L. Huldt, Z. Naturforsch. 8A, 493 (1953). D°_0 was derived from atomic spectra of Fe produced by acetylene-air flame method.
4. J.Washburn,UCRL 10991, August 1963,obtained from L. Brewer, private communication, October 18, 1966.
5. V. T. Burtsev, R. A. Karasev and A. M. Samarin, Fiz.-Khim. Osnovy Proizv. Stali, Akad. Nauk SSSR, Inst. Met., Tr. 6-01 [Shestoi] Konf., Moscow, 366 (1961); published in 1964.

Heat Capacity and Entropy.

Since the ground state configuration is due to Fe^{++} in a ligand field, it was assumed to be the same as that of $FeCl_2$(g) reported by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The electronic levels and quantum weights were estimated by comparison with those of $FeCl_2$(g). The values of ω_e and $\omega_e x_e$ were taken from G. Herzberg, loc. cit. The bond distance was calculated according to the method suggested by K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 456 (1946), assuming FeO(g) as a polar molecule. The value of B_e was calculated by use of the relationship: B_e = (2.799076 x 10^{-39}) /I where I is the moment of inertia of FeO(g). The value of α_e was derived from ω_e, $\omega_e x_e$ and B_e by the method suggested by G. Herzberg, loc. cit. The principal moment of inertia is 6.6899 x 10^{-39} g cm^2.

Iron Sulfate ($FeSO_4$)

IRON SULFATE ($FeSO_4$) (CRYSTAL) GFW = 151.9086

ΔHf°_0 = -219.7 ± 2 kcal/mol

$S^\circ_{298.15}$ = 28.91 ± 0.3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -222.0 ± 2 kcal/mol

Td = 944°K

Heat of Formation.

The enthalpy change for the reaction $FeSO_4(c) = FeSO_4\ (110\ H_2O)$ was determined to be -14.9 kcal/mol by R. de Forcrand, Comp. rend. 158, 20 (1914). Using $\Delta Hf^\circ_{298.85}$ = -235.85 kcal/mol for $FeSO_4\ (110\ H_2O)$, the heat of formation (298.15°K) for $FeSO_4(c)$ was calculated as -221 kcal/mol. The value of $\Delta Hf^\circ_{298.15}\ (FeSO_4,c)$ was estimated based on $\Delta Hf^\circ_{298.15}$ = 235.9 kcal/mol for $FeSO_4\ (200\ H_2O)$ which was derived from the enthalpy change for the reaction $FeCl_2(200\ H_2O) + H_2SO_4\ (200\ H_2O) = FeSO_4\ (200\ H_2O) + 2HCl\ (100\ H_2O)$ measured by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882-1886. See the $Fe(OH)_2$ (c) table for details.

The decomposition pressures of $FeSO_4(c)$ at different temperatures were investigated by J. D'Ans and E. Greulich. Using their reported partial pressures for SO_3 (g) and $SO_2(g)$, the enthalpy change for the reaction $2\ FeSO_4\ (c) = Fe_2O_3\ (c) + SO_3(g) + SO_2(g)$ was evaluated by both the second and third law methods. The results obtained are presented in the following table.

Investigator	Temperature, °K	$\Delta Hr^\circ_{298.15}$, kcal/mol Second Law Value	Third Law Value	$\Delta Hf^\circ_{298.15}$ kcal/mol
1. J. D'Ans (1905)	753.15 - 908.15	83.2 ± 4.6	82.7 ± 1.1	- 222.7
2. E. Greulich (1927)	887.15 - 971.15	64.8 ± 8.8	80.1 ± 1.4	- 221.5
3. B. Neumann and G. Heintke (1937)	633.15 - 862.15	72.4 ± 5.4	75.3 ± 0.5	- 219.1

1. J. D'Ans, Dissertation, Darmstadt, 1905. Data quoted by B. Neumann and G. Heintke, loc. cit.
2. E. Greulich, Z. anorg. Chem. 168, 197 (1927). Only the last seven high temperature points were adopted for evaluation.
3. B. Neumann and G. Heintke, Z. Elektrochem. 43, 246 (1937), based on the last 18 high temperature points adopted.

The decomposition pressures assumed for the same reaction have been determined by B. Neumann and G. Heintke. From their data the partial pressures for $SO_3(g)$ and $SO_2(g)$ were evaluated. Using the derived $SO_3(g)$ and $SO_2(g)$ partial pressures, the corresponding enthalpy changes for the reaction were calculated by both the second and third law methods. The results obtained are also listed in the same table.

The value of $\Delta Hf^\circ_{298.15}$ for $FeSO_4(c)$ is selected as -222 ± 2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities, 53.0-294.9°K, were determined by G. E. Moore and K. K. Kelley, J. Am. Chem. Soc., 64, 2949 (1942). Based on $S^\circ_{50.12}$ = 2.10 eu, the value of $S^\circ_{298.15}\ (FeSO_4,\ c)$ was reported to be 25.71 ± 0.2 eu. Using the free energy functions for $FeSO_4(c)$ based on this $S^\circ_{298.15}$ value, to evaluate the vapor pressure data for Reaction (1), the second and third law values of $\Delta Hf^\circ_{298.15}$ were derived as 72.36 ± 7.60 and 86.51 ± 1.26 kcal/mol, respectively. Since the report by Moore and Kelley, loc. cit., did not mention the magnetic entropy contribution, an attempt was made to add 3.20 (= Rln5) eu to $S^\circ_{298.15}\ (FeSO_4,\ c)$ and re-evaluate the decomposition pressure data. The results obtained were better than before (see the paragraph on "Heat of Formation," for details). Therefore the value, $S^\circ_{298.15}$ = 25.71 + 3.2 = 28.91 eu for $FeSO_4(c)$, was adopted. The heat capacities above 294.9°K were estimated by comparison with those for $MnSO_4(c)$. The high temperature heat capacities, 870.3-1082.3°K, were determined by J. C. Southard and C. H. Shomate, J. Am. Chem. Soc. 64, 1770 (1942). The two sets of data were joined smoothly at 298.15°K by use of Shomate-function plot.

Temperature of Decomposition.

Td is the temperature at which the vapor pressure of the gaseous decomposition products equals one atmosphere, which was obtained by graphical interpolation of the decomposition pressure data on $FeSO_4(c)$, reported by E. Greulich, loc. cit.

Heat of Formation.

The chemical equilibrium of the interaction of Fe(c) and I(g) has been studied by a transpiration method by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 490 (1966). Using the reported equilibrium constants in the temperature range from 591 to 751°K, the enthalpy change ($\Delta Hr^\circ_{298.15}$) of the reaction 2Fe(c) + 4 I (g) = Fe_2I_4(g) was evaluated by both the second and third law method to be -85.3 and -103.75 kcal/mol, respectively. The corresponding values of the heat of formation ($\Delta Hf^\circ_{298.15}$) for Fe_2I_4(g) were calculated as +16.9 and -1.6 kcal/mol.

Mass spectrometric and Knudsen effusion techniques have been used to study the vaporization of FeI_2(c) by R. C. Schoonmaker, A. H. Friedman and R. F. Porter, J. Chem. Phys. 31, 1586 (1959). Using the reported vapor pressure, P = 1.21 x 10^{-6} atm. at 714°K for Fe_2I_4(g), the enthalpy change ($\Delta Hr^\circ_{298.15}$) for the reaction 2 FeI_2(c) = Fe_2I_4(g) was evaluated by the third law method as 52.8 kcal/mol, yielding $\Delta Hf^\circ_{298.15}$ = 2.8 kcal/mol for Fe_2I_4(g).

The adopted value of $\Delta Hf^\circ_{298.15}$ for Fe_2I_4(g) is 2.0 ± 5 kcal/mol.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that assumed for Fe_2Br_4(g). The Fe-I bond distance was estimated from that in FeI_2(g) molecule. Four vibrational frequencies (ν_i), i.e. i = 2, 4, 5 and 6, were estimated by comparison with those for K_2I_2(g), calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960). The other frequency values were estimated from those for FeI_2(g). The electronic levels and quantum weights were estimated from those for FeI_2(g). The three principal moments of inertia are: I_A = 1.2442 x 10^{-37}, I_B = 7.7996 x 10^{-37} and I_C = 9.0439 x 10^{-37} g cm^2.

HEMATITE (Fe_2O_3) (CRYSTAL) MOL. WT. = 159.6922

$\Delta H_{f\ 0}^\circ = -195.8 \pm 0.3$ kcal. mole^{-1}

$S^\circ_{298.15} = 20.889$ cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15} = -197.3 \pm 0.3$ kcal. mole^{-1}

$T_d = 1735$°K.

Heat of Formation.

The chemical equilibria for the reaction $4Fe_3O_4(c) + O_2(g) = 6Fe_2O_3(c)$ have been studied by several investigators. From the reported data the corresponding values of $\Delta H^\circ_{r\ 298.15}$ and $\Delta H^\circ_{f\ 298.15}$ (Fe_2O_3, c) were evaluated. The results obtained are given as follows.

		$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1}		$\Delta H^\circ_{f\ 298.15}$*
Investigator	Temperature, °K.	Second Law Value	Third Law Value	kcal. mole^{-1}
Tretyakov and Khomyakov[1]	1373-1728	-106.32 ± 0.19	-111.05	-197.11
Schmahl[2]	1583-1683	-123.95 ± 1.37	-112.94	-197.42
Smiltens[3]	1373-1673	-117.88 ± 0.38	-114.25	-197.64
Darken and Gurry[4]	1723	-110.29	——	-196.98

*Calculation based on the third law values for $\Delta H^\circ_{r\ 298.15}$.

[1] Y.D. Tretyakov and K. G. Khomyakov, Russ. J. Inorg. Chem. 7, 628 (1962).

[2] N. G. Schmahl, Z. Elektrochem. 47, 821 (1941).

[3] J. Smilten, J. Am. Chem. Soc. 79, 4877 (1957).

[4] L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 798 (1946). $\Delta H^\circ_{r\ 298.15}$ was calculated based on $\Delta H^\circ_{r\ 1723}$ = -54.5 kcal. mole^{-1}.

The value of $\Delta H^\circ_{f\ 298.15}$ adopted for $Fe_2O_3(c)$ is the weighted average of the $\Delta H^\circ_{f\ 298.15}$ values listed in the above table.

Heat Capacity and Entropy.
