The low temperature (5.58-345.42°K.) heat capacities were determined by F. Gronvold and E. F. Westrum, Jr., J. Am. Chem. Soc. 81, 1780 (1959). The high temperature (298-1750°K.) C_p values were obtained from J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3891 (1951). The two sets of data were plotted and joined smoothly at 298°K. The C_p values above 1750°K. were obtained by graphical extrapolation. The heat capacities of $Fe_2O_3(c)$ have also been reported by G. G. Brown and C. C. Furnas, Trans. Am. Inst. Chem. Eng. 18, 309 (1926), 0-650°C, and G. S. Parks and K. K. Kelley, J. Phys. Chem. 30, 47 (1926), 88-289°K. $S^\circ_{298.15}$ for $Fe_2O_3(c)$ was derived from the smoothed C_p data, based on $S^\circ_5 = 0.0003$ e.u. J. P. Coughlin, E. G. King and K. R. Bonnickson, loc. cit. measured the heat-content for hematite and found two anomalies, presumably of magnetic nature, at about 950 and 1050°K., respectively. Both appear to involve maxima in the heat-capacity curves rather than isothermal heats of transformation. The complex magnetic properties at low temperatures were discussed by F. Gronvold and E. F. Westrum, Jr., loc. cit. No heat capacity anomaly was observed at the magnetic transition about 250°K. The Curie points of the antiferromagnetic α-Fe_2O_3 were reported by A. Aharoni, E. H. Frei and M. Schieber, Phys. Rev. 127, 439 (1962) and J. Lielmezs and A. C. D. Chaklader, Phys. Rev. Letters, 13, 866 (1965).

Temperature of Decomposition.

T_d is the temperature at which $\Delta F^\circ_r = 0$ for the reaction $6Fe_2O_3(c) = 4Fe_3O_4(c) + O_2(g)$. In other words, $Fe_2O_3(c)$ decomposes into $Fe_3O_4(c)$ and $O_2(g)$ at 1735°K.

DIIRON TRISULFATE ($Fe_2(SO_4)_3$) (CRYSTAL) GFW = 399.8788

$S°_{298.15}$ = [73.5 ± 2] gibbs/mol

Td = 1451°K

$\Delta Hf°_0$ = Unknown

$\Delta Hf°_{298.15}$ = -617.35 ± 0.40 kcal/mol

Heat of Formation.

The enthalpy change ($\Delta Hr°_{298.15}$) for the chemical reaction $Fe_2O_3(c) + 3H_2SO_4(14.855\ H_2O) = Fe_2(SO_4)_3(c) + 3H_2O(l)$ was measured to be 8.54 ± 0.18 kcal/mol by solution calorimetry by R. Barany and L. H. Adami, U. S. Bur. Mines RI 6687, 1965. Using $\Delta Hf°_{298.15}$ = -211.178 kcal/mol for $H_2SO_4(14.855\ H_2O)$ and -68.315 kcal/mol for $H_2O(l)$, obtained from "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, by D. D. Wagman and coworkers, National Bureau of Standards, 1965, and -197.3 kcal/mol for $Fe_2O_3(c)$, the heat of formation ($\Delta Hf°_{298.15}$) for $Fe_2(SO_4)_3(c)$ was evaluated as -617.35 ± 0.40 kcal/mol which was adopted here.

The equilibrium pressures for the decomposition of $Fe_2(SO_4)_3(c)$ have been determined by several investigators at different temperatures. The chemical reactions involved are: (1) $Fe_2(SO_4)_3(c) = Fe_2O_3(c) + 3SO_3(g)$ and (2) $SO_3(g) = SO_2(g) + 0.5\ O_2(g)$. However, the measured pressure of the chemical equilibrium is the total pressure of three partial pressures, namely, P_{SO_3}, P_{SO_2} and P_{O_2}. In order to calculate the enthalpy change of Reaction (1), the partial pressures of $SO_3(g)$ were evaluated from the total vapor pressure data at each temperature. Based on the derived values for P_{SO_3}, the $\Delta Hr°_{298.15}$ value for Reaction (1) was calculated by both the second and third law methods. The results obtained are presented in the following table. The $\Delta Hf°_{298.15}$ ($Fe_2(SO_4)_3$, c) values were derived, using the third law $\Delta Hr°_{298.15}$. These determinations were not given any weight.

6. N. A. Warner and T. R. Ingraham, Can. J. Chem. 38, 2196 (1960).

The decomposition pressures of $Fe_2(SO_4)_3$ (c) have also been investigated by : M. Grünzweig, Ph. D. dissertation, Darmstadt, Germany, 1913, 793-994°K; R. F. Blanks, Ph. D. dissertation, University of Melbourne, Australia, 1961, 845 - 976° K; and T. R. Ingraham, Internal Rept. EMT-63-17, Department of Mines and Technical Surveys. Ottawa, Canada, 1963, 856-995°K. These data together with some of the data mentioned previously were critically reviewed by H. H. Kellogg, Trans. AIME, 230, 1622 (1964).

Heat Capacity and Entropy.

The heat capacities were estimated by comparison with those for $FeSO_4$ (c), assuming their average specific heats, gibbs/g, to be the same. The value of $S°_{298.15}$ was estimated so that the second and third law $\Delta Hr°_{298.15}$ values, derived from decomposition pressure data, are in reasonable agreement.

Temperature of Decomposition.

Td is the temperature at which the total pressure of the gaseous products equals one atmosphere, which was obtained by graphical extrapolation of the decomposition pressure data measured by Warner and Ingraham, loc. cit.

MAGNETITE (Fe_3O_4) (CRYSTAL) MOL. WT. = 231.5386

$\Delta H^\circ_{f\ 0}$ = -266.4 ± 0.2 kcal. $mole^{-1}$

$S^\circ_{298.15}$ = 34.72 cal. $deg.^{-1}$ $mole^{-1}$ $\Delta H^\circ_{f\ 298.15}$ = -267.9 ± 0.2 kcal. $mole^{-1}$

T_m = 1870 ± 2°K. ΔH°_m = 33.0 ± 2.0 kcal. $mole^{-1}$

Heat of Formation.

The equilibrium constants for the following four reactions, i.e. (1) $3Fe(c) + 4H_2O(g) = Fe_3O_4(c) + 4H_2(g)$; (2) $Fe_3O_4(c) + H_2(g) = 3FeO(c) + H_2O(g)$; (3) $Fe_3O_4(c) + CO(g) = 3FeO(c) + CO_2(g)$; and (4) $2Fe_3O_4(c) = 6FeO(c) + O_2(g)$, have been studied by several investigators. Using their reported equilibrium data, the corresponding enthalpy changes ($\Delta H^\circ_{r\ 298.15}$) were evaluated by both the second and third law methods. Based on the third law value for $\Delta H^\circ_{r\ 298.15}$, the respective $\Delta H^\circ_{f\ 298.15}$ values for $Fe_3O_4(c)$ were also derived. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	$\Delta H^\circ_{r\ 298.15}$, kcal. $mole^{-1}$ Second Law Value	Third Law Value	$\Delta H^\circ_{f\ 298.15}$, kcal. $mole^{-1}$

[1] R. Fricke, K. Walter and W. Lohrer, Z. Elektrochem. 47, 487 (1941). The two $\Delta H^\circ_{f\ 298.15}$ values listed are the average values of three separate results derived from three sets of experimental data.

[2] E. D. Eastman, J. Am. Chem. Soc. 44, 975 (1922).

[3] E. D. Eastman and R. M. Evans, J. Am. Chem. Soc. 46, 888 (1924).

[4] P. H. Emmett and J. F. Schultz, J. Am. Chem. Soc. 52, 4268 (1930).

[5] O. N. Salmon, J. Phys. Chem. 65, 550 (1961).

The enthalpy change of the reaction $Fe_{0.947}O(c) + 0.8215\ Fe(c) + 0.6787\ O_2(g) = 0.5895\ Fe_3O_4(c)$ has been determined by G. L. Humphrey, E. G. King and K. K. Kelley, U. S. Bur. Mines RI 4870 (1952). Bases on $\Delta H^\circ_{r\ 298.15}$ = -93.46 kcal. $mole^{-1}$ (average of two separate values derived from two experimental determinations) and $\Delta H^\circ_{f\ 298.15}$ (Wüstite, c) = -63.64 kcal. $mole^{-1}$, the value of $\Delta H^\circ_{f\ 298.15}$ (Fe_3O_4, c) was calculated as -266.5 kcal. $mole^{-1}$. The enthalpy change, $\Delta H^\circ_{r\ 298.15}$ = 4.33 kcal. $mole^{-1}$, for the reaction $3Fe(c) + 4CO_2(g) = Fe_3O_4(c) + 4CO(g)$ was reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 798 (1946). The corresponding $\Delta H^\circ_{f\ 298.15}$ (Fe_3O_4, c) was evaluated as -266.22 kcal. $mole^{-1}$. The adopted value of $\Delta H^\circ_{f\ 298.15}$ for $Fe_3O_4(c)$ is selected as -267.9 ± 0.2 kcal. $mole^{-1}$.

Heat Capacity and Entropy.

The low temperature (60.5-299.7°K.) heat capacities were reported by R. W. Millar, J. Am. Chem. Soc. 51, 215 (1929). The high temperature (298-1800°K.) heat capacities were obtained from J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3891 (1951). These two sets of data were plotted and joined smoothly at 298°K. The C_p values above 1800°K. were obtained by graphical extrapolation. Heat capacities (90-295°K.) for $Fe_3O_4(c)$ were also reported by G. S. Parks and K. K. Kelley, J. Phys. Chem. 30, 47 (1926). $S^\circ_{298.15}$ (Fe_3O_4, c) was derived from the smoothed C_p data mentioned previously, using $S^\circ_{44.7}$ = 0.969 e.u. J. P. Coughlin, E. G. King and K. R. Bonnickson, loc. cit. measured the heat-content for magnetite and found a magnetic anomaly around 880°K., corresponding to a maximum in heat capacity. A maximum heat capacity of 37.1 cal. $deg.^{-1}$ $mole^{-1}$ at 114.15°K. was also reported by R. W. Millar, loc. cit.

Melting Data.

T_m and ΔH°_m were obtained from L. S. Darken and R. W. Gurry, loc. cit.

Heat of Formation.

The heat of formation was calculated from D_0° (H_2) = 36113.0 ± 0.3 cm.$^{-1}$, reported by G. Herzberg and A. Monfils, J. of Molecular Spectroscopy 5, 482 (1960). This value was measured more precisely than the value D_0° (H_2) = 36116 ± 6 cm.$^{-1}$ by H. Beutler, Z. Phys. Chem. B29, 315 (1935).

Heat Capacity and Entropy.

Electronic levels taken from C. E. Moore, Natl. Bur. Standards (U. S.) Circ. 467 (1949).

Proton (H^+)

June 30, 1966

PROTON (H^+) (IDEAL GAS) GFW = 1.00742

$\Delta Hf^\circ_0 = 365.236 \pm 0.01$ kcal/mol

$S^\circ_{298.15} = 26.012$ gibbs/mol

$\Delta Hf^\circ_{298.15} = 367.186 \pm 0.01$ kcal/mol

Heat of Formation.

The heat of formation was calculated from the equation $H(g) \rightarrow H^+(g) + e^-$ with the JANAF auxiliary data for H(g), using an ionization potential = 13.598 eV (313.605 kcal/mol) for H(g) obtained from C. W. Beckett, National Bureau of Standards Report 8628, Jan. 1, 1965.

Heat Capacity and Entropy.

Calculated by assuming the proton to be an ideal monatomic gas. The enthalpy between 298° and 0°K is 1.481 kcal/mol as for all unexcited monatomic gases.

Hydrogen Uninegative Ion (H^-)

(Ideal Gas) At. Wt. = 1.00852

Sept. 30, 1965

HYDROGEN UNINEGATIVE ION (H^-) (IDEAL GAS) AT. WT. = 1.00852

Ground State Configuration $^1S_0$

$S^\circ_{298.15}$ = 26.015 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 34.2 ± 0.5 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 33.2 ± 0.5 kcal. mole^{-1}

Electronic Levels and Quantum Weight

$\mathcal{E}_1$cm.$^{-1}$	g_1
0	1

Heat of Formation.

The heat of formation was calculated from the equation: $H(g) + e^- \rightarrow H^-(g)$ with the JANAF auxiliary value for H(g) (this supplement); using an I.P. = 6.083096 X 10^3 cm^{-1} (.754 e.v. or 17.39 kcal/mole) for $H^-(g)$ obtained from C. L. Pekeris, Phys. Rev. 126, 1470 (1962). The I.P. value for $H^-(g)$ reported by C. W. Scherr and R. E. Knight, Rev. Mod. Phys. 35, 436 (1963) is in agreement with the value of Pekeris.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, U. S. National Bureau of Standards Circular 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Helium. The electronic levels above 1 X 10^5 cm^{-1} were omitted because their contribution is negligible below 6000°K. The $H^\circ-H^\circ_{298}$ value at 0°K. is -1.481 kcal/mole.

September 30, 1961

HYDROGEN IODIDE (HI) (IDEAL GAS) MOL. WT. = 127.918

ΔH°_{f0} = 6.82 ± 0.05 kcal. mole^{-1}

Ground State = $^1\Sigma$

$\Delta H^\circ_{f\ 298}$ = 6.30 kcal. mole^{-1}

S°_{298} = 49.351

ω_e = 2309.06 cm.$^{-1}$

$\omega_e x_e$ = 39.73 cm.$^{-1}$

B_e = 6.512 cm.$^{-1}$

α_e = 0.1715 cm.$^{-1}$

σ = 1

Thermodynamic Functions.

Molecular constants are from M. Cowan and W. Gordy [Phys. Rev. 104, 551 (1956)] and D. R. J. Boyd and H. W. Thompson [Spectrochim. Acta 5, 308 (1952)]. The calculated functions are in reasonable agreement with the compilation of K. K. Kelley [U. S. Bur. Mines Bull. 584 (1960)].

Heat of Formation.

Using the calculated functions derived above and functions for $H_2(g)$ and $I_2(g)$ given in the JANAF tables, equilibrium data from the literature were used to calculate ΔH°_{298} for the reaction

$$H_2\ (g) + I_2\ (g) \rightarrow 2\ HI\ (g)$$

	ΔH°_{298}, kcal. mole^{-1}
Taylor and Crist[1] (667° to 764°K)	-2.375 ± .005
Bodenstein[2] (556° to 781°K)	-2.053 ± .133
Bright and Hagerty[3] (696° and 779°K)	-2.219 ± .070
Rittenberg and Urey[4] (671° and 741°K)	-2.156 ± .072

The data of Taylor and Crist are the most concordant and are given the most weight. Converting to the solid state of iodine, which has been adopted as a JANAF reference state gives the standard heat of formation of hydrogen iodide.

POTASSIUM HYDRIDE (KH) (CRYSTAL) MOL. WT. = 40.108

$S^\circ_{298.15}$ = [12] cal. deg.$^{-1}$ mole^{-1}

T_d = [690]°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15} = -13.819 \pm 0.011$ kcal. mole^{-1}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ was taken from S. R. Gunn and L. G. Green, J. Am. Chem. Soc. 80, 4782 (1958). The corresponding value reported by C. E. Messer, L. G. Fasolino and C. E. Thalmayer, J. Am. Chem. Soc. 77, 4524 (1955) was -15.16 ± 0.6 kcal. mole^{-1}. In this paper the results of the previous investigations were also reviewed.

Heat Capacity and Entropy.

C_p and $S^\circ_{298.15}$ were estimated by comparison with those for NaH(c) and LiH(c).

Temperature of Decomposition.

T_d was assumed to be the temperature at which the value of ΔF°_f changes from negative to positive.

POTASSIUM HYDRIDE (KH) (IDEAL GAS) MOL. WT. = 40.108

Ground State Configuration $^1\Sigma^+$

$\Delta H_{f\ 0}^\circ = 30.0 \pm 3.5$ kcal. mole^{-1}

$S^\circ_{298.15} = 47.304$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ = 29.4 \pm 3.5$ kcal. mole^{-1}

$\omega_e = 985.0$ cm.$^{-1}$

$\omega_e x_e = 14.65$ cm.$^{-1}$

$\sigma = 1$

$B_e = 3.407$ cm.$^{-1}$

$\alpha_e = 0.0673$ cm.$^{-1}$

Heat of Formation.

$\Delta H_{f\ 298.15}^\circ$ was calculated from $D_0^\circ = 1.86 \pm 0.15$ e.v. reported by A. G. Gaydon, "Dissociation Energies," Chapman and Hall, Ltd., 1953.

Heat Capacity and Entropy.

All molecular and spectroscopic constants were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., 1950.

Dec. 31, 1961; Mar. 31, 1962; June 30, 1962; Mar. 31, 1966

POTASSIUM HYDROXIDE (KOH) (CRYSTAL) MOL. WT. = 56.10937

$S^\circ_{298.15}$ = 18.95 cal. deg.$^{-1}$ mole^{-1}
T_t = 522°K
T_m = 673°K.

$\Delta H^\circ_{f\ 0}$ = -100.7 ± 0.1 kcal. mole^{-1}
$\Delta H^\circ_{f\ 298.15}$ = -101.5 ± 0.1 kcal. mole^{-1}
ΔH°_t = 1.515 kcal. mole^{-1}
ΔH°_m = 2.240 kcal. mole^{-1}
$\Delta H^\circ_{s\ 298.15}$ (to monomer) = [46.1] kcal. mole^{-1}
$\Delta H^\circ_{s\ 298.15}$ (to dimer) = [45.6] kcal. mole^{-1}

Heat of Formation.

The standard enthalpy of formation, $\Delta H^\circ_{f\ 298}$ (KOH, c) = -101.5 ± 0.1 kcal. mole^{-1}, was calculated from the heat of solution of KOH(c), the heat of hydrolysis of potassium metal and the appropriate auxiliary data.

N. A. Peshetnikov[1] has measured the heat of solution KOH(c) → KOH(650 H_2O) as -13.665 ± 0.009 kcal. mole^{-1} at 298.15°K. in the solution calorimeter. Using the auxiliary heat of dilution reported by V. B. Parker[2], the selected heat of solution of KOH(c) at infinite dilution is -13.770 kcal. mole^{-1}. The heat of solution KOH(c) → KOH(25 H_2O) has also been measured as -13.80 ± 0.10 kcal. mole^{-1} in the solution calorimeter by W. E. Hatton, D. L. Hildenbrand, G. C. Sinke and D. R. Stull[3]. Both results are in good agreement.

The heat of hydrolysis of potassium metal, $\Delta H^\circ_{r\ 298}$, has been measured in the solution calorimeter by the following investigators.

$K(c) + H_2O(l) \rightarrow KOH(nH_2O) + 1/2\ H_2(g)$ $\Delta H^\circ_{r\ 298}$

Source	Number of Moles of H_2O	$\Delta H^\circ_{r\ 298}$ kcal. mole^{-1}	$\Delta H^\circ_{f\ 298}(KOH(\infty H_2O))$ kcal. mole^{-1}	$\Delta H^\circ_{f\ 298}$(KOH, c) kcal. mole^{-1}
Gunn et al.[4]	1000	-46.877 ± 0.01	-115.281	-101.511
Messer et al.[5]	∞	-47.02 ± 0.15	-115.335	-101.565
Ketchen et al.[6]	∞	-46.894 ± 0.24	-115.209	-101.439

The values of $\Delta H^\circ_{f\ 298}(KOH(\infty H_2O))$ were calculated from the heats of reaction, $\Delta H^\circ_{r\ 298}$, using $\Delta H^\circ_{f\ 298}(H_2O,\ l)$ = -68.315 kcal. mole^{-1} [7]. Combination of the selected heat of solution of KOH(c) at infinite dilution with the heat of formation of KOH(∞H_2O) gives the heat of formation of KOH(c) in the last column of the table. A weighted average of these three measurements was taken for the selected heat of formation of KOH(c).

The earlier investigations have been reviewed by F. R. Bichowsky and F. D. Rossini[8] and C. E. Messer et al.[5], and these earlier reported data are not adopted in the tabulation.

Heat Capacity and Entropy.

The low temperature heat capacities of KOH(c) from 15° to 340°K. have been measured by W. E. Hatton et al.[3] who have also observed a sharp peak in the heat capacity curve in the temperature range from 210° to 230°K. These values of C_p were adopted in the calculation. W. D. Powers and G. C. Blalock[9] have measured the high temperature enthalpy changes of the solid KOH in the α and β phases by the drop method. Their enthalpy data are scattered and not precise enough to accurately define the heat capacities in the α phase. Therefore, the selected heat capacities between 340° and 522°K. were estimated from a graphical extrapolation of the low temperature heat capacity curve, and the tabulated $H^\circ-H^\circ_{298}$ functions are in agreement with their enthalpy measurements within the experimental uncertainty. The heat capacities of KOH(c) in the β phase were obtained from Powers and Blalock[9].

The entropy (S°_{298} = 18.95 cal. deg.$^{-1}$ mole^{-1}) was taken from Hatton et al.[3], based on an extrapolation of S°_{15} = 0.054 cal. deg.$^{-1}$ mole^{-1}.

Transition and Melting Data.

Hatton et al.[3] have found a lambda transition at 227.4°K. in the heat capacity measurement. The adopted heat of α-β transition at 522°K. and heat of melting at 673°K. were obtained from Powers and Blalock[9]. P. S. Seward and K. E. Martin[10] found ΔH°_m = 1.83 kcal. mole^{-1} at 683°K. in phase diagram studies of the system $KOH-K_2CO_3$.

Heat of Sublimation.

See KOH(g) table for details.

Dec. 31, 1961; Mar. 31, 1962; Sep. 30, 1962; Mar. 31, 1966

POTASSIUM HYDROXIDE (KOH) (LIQUID) MOL. WT. = 56.10937

$S^\circ_{298.15}$ = 23.518 cal. deg.$^{-1}$ mole^{-1}

T_m = 673°K.

T_b(monomeric gas) = 1600°K.

ΔH°_f 298.15 = -98.433 kcal. mole^{-1}

ΔH°_m = 2.240 kcal. mole^{-1}

ΔH°_v (to monomer) = 32.0 kcal. mole^{-1}

Heat of Formation.

The heat of formation of KOH(l) at 298°K. was obtained from that of the crystal by adding ΔH°_m and the difference between $H^\circ_{673}-H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase, C_p = 19.86 cal. deg.$^{-1}$ mole^{-1}, was obtained from the enthalpy measurements in the drop calorimeter by W. D. Powers and G. C. Blalock, ORNL-1653, Oak Ridge Nat'l. Lab., Jan. 1954. The constant C_p was extrapolated below the melting point and up to 2500°K.

The entropy, $S^\circ_{298.15}$ = 23.51 cal. deg.$^{-1}$ mole^{-1}, was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See KOH(c) table for details.

Vaporization Data.

The boiling point 1600°K. was calculated as the temperature at which the free energies of formation (ΔF°_f) for both KOH(l) and KOH(g) are equal. The difference in the heats of formation (ΔH°_f) of KOH(l) and KOH(g) at the boiling point is the heat of vaporization. If $K_2(OH)_2(g)$ is also considered as a minor component in the vapor mixture (approximately 2% of total vapor pressure at the boiling point) the calculated boiling point is unchanged as 1600°K. (see KOH(g) table for details).

H. von Wartenberg and P. Albrecht, Z. Elektrochem. **27**, 162 (1921), have studied the vapor pressures of liquid KOH and reported the boiling point as 1597°K.

Heat of Formation.

R. F. Porter and R. C. Schoonmaker, J. Phys. Chem. 62, 234 and 486 (1958), have investigated the potassium hydroxide vapor by the mass-spectrometric method and found that the KOH vaporizes mainly as gaseous dimer in the temperature range from 573° to 723°K. Later, Schoonmaker and Porter, J. Chem. Phys. 31, 830 (1959), found the activity of molten alkali hydroxide had been reduced in the presence of MgO in their sample container. Using the reported partial pressures of KOH(g) and $K_2(OH)_2(g)$ at 641° and 666°K. and JANAF free energy functions, the third law calculations give ΔH°_{298} = -45.4 ± 5 kcal. mole^{-1} for 2KOH(g) → $K_2(OH)_2(g)$, and $\Delta H^\circ_{s\ 298}$ = 45.41 ± 3.5 kcal. mole^{-1} for KOH(c) → KOH(g), and $\Delta H^\circ_{s\ 298}$ = 45.6 ± 5 kcal. mole^{-1} for 2KOH(c) → $K_2(OH)_2(g)$. The uncertainties given were derived by assuming K_p to be good to a factor of 5 as stated by the authors and including an extra factor of 2 as possible error in activity. To this was added an estimate of the uncertainty due to functions used. In order to have good agreement between the calculated total pressures of monomeric and dimeric KOH(g) and the observed vapor pressures measured by H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 162 (1921), the heat of sublimation to monomeric gas was adjusted to $\Delta H^\circ_{s\ 298}$ (to monomer) = 46.08 kcal. mole^{-1}. (The heat of sublimation to dimeric gas was unchanged as $\Delta H^\circ_{s\ 298}$ (to dimer) = 45.64 kcal. mole^{-1}). The calculated boiling point is 1600°K. which is in good agreement with 1597 ± 10°K. reported by Wartenberg and Albrecht. The heats of formation were calculated from the selected heats of sublimation as $\Delta H^\circ_{f\ 298}$(KOH,g) = -55.4 and $\Delta H^\circ_{f\ 298}(K_2(OH)_2,g)$ = -157.4 kcal. mole^{-1}.

Heat Capacity and Entropy.

The bond distance K-O was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance K-F(g) (2.17146 Å) which has been accurately measured by R. K. Ritchie and H. Lew, Can. J. Phys. 42, 43 (1964). The bond distance O-H was estimated from that in $H_2O(g)$. The bent molecular configuration with the bond angle of 110° has been proposed by S. H. Bauer, R. M. Diner and R. F. Porter, J. Chem. Phys. 29, 991 (1958), but a linear model has also been suggested by R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 31, 830 (1959). The bent model has been adopted in the tabulation. The three principal moments of inertia are: I_A = [0.1256] X 10^{-39}, I_B = [9.8070] X 10^{-39} and I_C = [9.9326] X 10^{-39} g. cm.^{2}

The K-O stretching frequency (408 cm.$^{-1}$) was obtained from L. H. Spinar and J. L. Margrave, Spectrochim. Acta 12, 244 (1957) in the infrared spectroscopic studies. The O-H stretching and the bending frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rapid convergence to a constant as a heavier atom is attached.

L. Brewer and D. F. Mastick, J. Am. Chem. Soc. 73, 2045 (1951), have calculated theoretically the bond distances of gaseous alkali oxides (Li-O = 1.52 Å, Na-O = 1.94 Å and K-O = 2.27 Å) which have been quoted by Bauer, Diner and Porter, loc. cit., and many other authors.

$\Delta Hm^\circ = 5.40 \pm 0.10$ kcal/mol

$\Delta Hs^\circ_{298.15} = 55.27$ kcal/mol

Heat of Formation

The heats of solution of Li(c) and LiH(c) in water have been measured by Guntz (1) and Moers (2) using an open Dewar flask calorimeter and by Messer (3) and Gunn (4) using closed bomb calorimetry. Based on the reported values of the enthalpy changes (ΔHr°) for the reaction (A) Li(c) + H_2O(ℓ) = LiOH(aq) + 1/2H_2(g), and (B) LiH(c) + H_2O(ℓ) = LiOH(aq) + H_2(g), the corresponding ΔHf°_{298} for LiH(c) are calculated. The results are presented in the table below.

The decomposition pressures of LiH(c) have been determined by Hurd (5), at temperatures 782 - 926°K. By use of the second and third law methods, the enthalpy changes for the decomposition reaction (C) LiH(c) = Li(ℓ) + 1/2H_2(g) are evaluated as 21.87 ± 0.3 and 22.34 kcal/mol, respectively. Based on the third law ΔHr°_{298} and ΔHf°_{298}(Li, ℓ) = 0.569 kcal/mol, we derive the value ΔHf°_{298}(LiH, c) = -21.77 ± 0.2 kcal/mol, which is in good agreement with the values obtained by calorimetric method. Gunts (1) measured the decomposition pressure at 953°K for the same reaction. The third law ΔHr°_{298} and ΔHf°_{298}(LiH, c) are evaluated as 21.86 and -21.29 kcal/mol, respectively.

Johnson (6) has determined the standard Gibbs energy of formation (ΔGf°) for LiH(c) from emf measurements over the temperature range 675 - 885°K. The cell utilized an Armco iron flag over which H_2 was passed as the cathode and a molten Li anode. LiCl, LiBr and LiI, each saturated with LiH were used as electrolytes. Using the reported emf values at different temperatures (47 data points) for reaction (C), we derive a ΔHf°_{298} = -21.81 kcal/mol for LiH(c).

The ΔHf°_{298}(LiH, c) value reported by Gunn (4) is adopted.

6. Johnson (1966)	-	-	22.38	1.0±0.2	-21.81±0.15

Heat Capacity and Entropy

The low temperature heat capacities are obtained from the data of Kostyukov (7), 3.72 - 295.5°K. The cp data reported by Gunther (8) are consistently lower than the adopted ones in the temperature range 74.0 - 90.5°K but considerably higher at 292.7°K. The high temperature enthalpies have been determined by Fieldhouse (9), 413.2 - 914.3°K, and Vogt (14), 878.15 - 953.15°K. The derived high temperature heat capacities are joined smoothly with the low temperature values and extrapolated smoothly above 953.15°K.

S°_{298} is calculated based on the adopted low temperature heat capacities, using S°_7 = 0.0002 eu.

Melting Data

The value of Tm has been reported as 953 (1), 961 ± 1 (10, 12), 959.6 (11), and 961.8 ± 0.3 (13). The value reported by Messer (13) is adopted. The heat of melting (ΔHm°) has been determined as 5.095 ± 0.46 (13) and 5.237 ± 0.040 kcal/mol (14). The first ΔHm° value was evaluated cryogenically from the lowering of melting point in the systems LiH-Li_2O and LiH-CaH_2. The second value was derived from enthalpy data measured with copper block calorimeter. The adopted ΔHm° value is derived from the enthalpy data of Vogt (14) using the adopted heat capacities for LiH(c) and LiH(ℓ).

Heat of Sublimation

The value of ΔHs°_{298} is calculated as the difference between ΔHf°_{298} for LiH(g) and LiH(c).

Sept. 30, 1962; Sept. 30, 1967

LITHIUM HYDRIDE (LiH) (LIQUID) GFW = 7.94697

$S^\circ_{298.15}$ = 5.314 gibbs/mol

Tm = 961.8 ± 0.3°K

Td = 1223°K

$\Delta Hf^\circ_{298.15}$ = -18.573 kcal/mol

ΔHm° = 5.40 ± 0.10 kcal/mol

Heat of Formation

$\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{961.8} - H^\circ_{298}$ for crystal and liquid.

The decomposition pressures of LiH(ℓ) at different temperatures have been investigated by Hill (1), Perlow (2), Johnson, and Gibb (4). Based on their reported equilibrium pressures, the enthalpy changes for the reaction $LiH(\ell) = Li(\ell) + 1/2H_2(g)$ are evaluated by the second and third law methods. The results are presented in the table below. It should be noted that the measured decomposition pressures are highly sensitive to composition and change extremely rapidly between 99 and 100 percent purity. Therefore we give no weight to the equilibrium data.

Investigator	Temperature, °K	No. of Points	ΔHr°_{298}, kcal/mol Second Law	Third Law	Drift eu	ΔHf°_{298}** kcal/mol
Hill (1938)	973.2	1	—	16.93	—	-16.36
Perlow (1941)	1043-1098	2	20.10	17.69	-2.2	-17.12
Johnson*	1050-1090	-	24.69	18.36	-5.9	-17.79
Gibb (1951)	1073-1173	2	5.66	15.2	+8.5	-14.63

*The vapor pressure values are calculated from an equation quoted by Gibb (3), but derived from the vapor pressures measured by W. C. Johnson, University of Chicago.

**Based on the third law ΔHr°_{298}.

Heat Capacity and Entropy

The enthalpies of LiH(ℓ) in the temperature range 975.15-1075.15°K have been measured by Vogt (5). Using the reported enthalpy values, the heat capacity of LiH(ℓ) is derived as 14.9 gibbs/mol. This Cp value is adopted and extrapolated above and below the measured range.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See LiH(c) table for details.

Decomposition Temperature

Td is calculated as the temperature at which LiH(ℓ) decomposes into Li(ℓ) and $H_2(g)$ where the partial pressure of $H_2(g)$ equals one atmosphere.

Heat of Formation

R. Velasco, Can. J. Phys. 35, 1204 (1957), observed the absorption spectra of LiH(g) in the near ultraviolet with high dispersion and absorbing path lengths up to 16 meters. He found a new band system involving the ground state and a $^1\Pi$ excited state. Rotational and vibrational analyses of this system were carried out and the observed breaking off of the rotational structure of the bands was interpreted as due to predissociation by rotation. With this assumption very accurate dissociation limits of the $B^1\Pi$ state were obtained. From these dissociation limits the dissociation energy (D_0) of the ground state of LiH was found to be 2.4288 ± 0.0002 eV. Based on this D_0 value, we adopt ΔHf°_{298} = 33.61 kcal/mol for LiH(g).

W. Kemperer, J. Chem. Phys. 23, 2452 (1955), observed the infrared spectrum of LiH(g) in emission in the frequency region 1500 to 970 cm^{-1}, using a Perkin-Elmer double-pass monochromator with NaCl optics. Estimating the minimum LiH pressure as 10 mm and assuming the maximum possible Li pressure, he reported K = 0.005 (atm) at 1400°K for the reaction $2Li(g) + H_2(g) = 2LiH(g)$. We calculate the corresponding enthalpy change, ΔHr°_{1400}, to be -9.63 kcal/mol, employing ΔSr°_{1400} = -17.407 eu. Incorporating this ΔHr°_{1400} value with ΔHf°_{1400} = 35.601 kcal/mol for Li(g), we obtain $\Delta Hf^\circ_{298} \leqslant 33.92$ kcal/mol for LiH(g), which is in good agreement with the adopted value.

A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953, derived the value $D_0(LiH)$ = 2.5 ± 0.2 eV from earlier spectroscopic data.

Heat Capacity and Entropy

The third electronic level and quantum weight are obtained from Velasco, loc. cit. All the other constants are taken from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., and corrected to the average isotopic species. The moment of inertia is 3.7193 x 10^{-40} g cm^2.

Dec. 31, 1960; Mar. 31, 1966

LITHIUM HYDROXIDE (LiOH) (CRYSTAL) MOL. WT. = 23.94637

$S^\circ_{298.15}$ = 10.225 cal. deg.$^{-1}$ mole^{-1}

T_m = 744.3°K.

$\Delta H^\circ_{f\ 0}$ = -114.46 ± 0.1 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -115.84 ± 0.1 kcal. mole^{-1}

ΔH°_m = 5.010 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to monomer) = [57.0] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to dimer) = [50.2] kcal. mole^{-1}

Heat of Formation.

The standard enthalpy of formation, $\Delta H^\circ_{f\ 298}$ (LiOH, c) = -115.84 ± 0.1 kcal. mole^{-1}, was calculated from the heat of solution of lithium hydroxide (c), the heat of hydrolysis of lithium metal and the appropriate auxiliary data.

N. A. Peshetnikov[1] has measured the heat of solution LiOH(c) → LiOH(400 H_2O) as -5.479 ± 0.007 kcal. mole^{-1} at 298.15°K. by solution calorimetry. Using the auxiliary heat of dilution reported by V. B. Parker[2], the selected heat of solution of lithium hydroxide (c) at infinite dilution is -5.632 kcal. mole^{-1}.

The heat of hydrolysis of lithium metal, $\Delta H^\circ_{r\ 298}$, has been measured in the solution calorimeter by the following investigators.

$$Li(c) + H_2O(l) \rightarrow LiOH(nH_2O) + 1/2\ H_2(g) \qquad \Delta H^\circ_{r\ 298}$$

Source	Number of moles of H_2O	$\Delta H^\circ_{r\ 298}$ kcal. mole^{-1}	$\Delta H^\circ_{f\ 298}(LiOH(\infty H_2O)$ kcal. mole^{-1}	$\Delta H^\circ_{f\ 298}$(LiOH, c) kcal. mole^{-1}
Gunn et al.[3]	1000	-53.115 ± 0.019	-121.532	-115.900
Messer et al.[4]	∞	-53.075 ± 0.20	-121.390	-115.758

The values of $\Delta H^\circ_{f\ 298}(LiOH(\infty H_2O))$ were calculated from the heats of reaction $\Delta H^\circ_{r\ 298}$, using the $\Delta H^\circ_{f\ 298}(H_2O,\ l)$ = -68.315 kcal. mole^{-1}.[5] Combination of the selected heat of solution of LiOH(c) at infinite dilution with the heat of formation of LiOH(∞H_2O) gives the heat of formation of LiOH(c) in the last column of the table. A weighted average of these measurements was taken for the adopted heat of formation of lithium hydroxide (c).

The earlier calorimetric investigations have been reviewed by F. R. Bichowsky and F. D. Rossini[6], and C. E. Messer et al.[4], and these data are not adopted in the tabulation.

Heat Capacity and Entropy.

The low temperature heat capacities of lithium hydroxide (c) from 15.91° to 302.85°K. have been measured by T. W. Bauer, H. L. Johnston and E. C. Kerr[7]. The high temperature heat capacities which were determined from the enthalpy measurements in the temperature range from 418° to 878°K. by the drop method have been reported by C. H. Shomate and A. J. Cohen[8]. The low temperature and the high temperature heat capacities have been joined smoothly by the Shomate method[9]. The smooth values of heat capacity of LiOH(c) were adopted in the tabulation.

W. D. Powers and G. C. Blalock[10] have also measured the high temperature enthalpy changes of LiOH(c) by the drop method. Their results are in agreement with the tabulated H_T-H_{298} values within the experimental uncertainty.

The entropy (S°_{298} = 10.225 cal. deg.$^{-1}$ mole^{-1}) was obtained from Bauer et al.[7], based on an extrapolation of S°_{16} = 0.028 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

The adopted heat of melting and the melting point were obtained from the enthalpy measurements by Shomate and Cohen[8]. Powers and Blalock[10] also found the heat of melting ΔH°_m = 5.029 kcal. mole^{-1} at 746°K. which is in good agreement with the adopted value.

Dec. 31, 1960; Mar. 31, 1966

LITHIUM HYDROXIDE (LiOH) (LIQUID) MOL. WT. = 23.94637

$S^\circ_{298.15}$ = 11.574 cal. deg.$^{-1}$ mole^{-1}

T_m = 744.3°K.

T_b(monomeric gas) = 1803°K.

$\Delta H^\circ_{f\ 298.15}$ = -113.263 kcal. mole^{-1}

ΔH°_m = 5.010 kcal. mole^{-1}

ΔH°_v(to monomer) = 40.1 kcal. mole^{-1}

Heat of Formation.

The heat of formation of LiOH(l) at 298.15°K. was obtained from that of the crystal by adding ΔH°_m and the difference between $H_{744.3}-H_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The selected heat capacity of the liquid phase, C_p = 20.74 cal. deg.$^{-1}$ mole^{-1}, was obtained from the enthalpy measurements in the drop calorimeter by C. H. Shomate and A. J. Cohen, J. Am. Chem. Soc. 77, 285 (1955).

W. D. Powers and G. C. Blalock, ORNL-1653, Oak Ridge Nat'l. Lab., have also determined the heat capacity of lithium hydroxide (l), C_p = 22.03 cal. deg.$^{-1}$ mole^{-1}, from the enthalpy measurements by the drop method.

The entropy ($S^\circ_{298.15}$ = 11.574 cal. deg.$^{-1}$, mole^{-1}) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See LiOH(c) table for details.

Vaporization Data.

The boiling point was calculated as the temperature at which the free energies of formation (ΔF°_f) for both LiOH(l) and LiOH(g) are equal. The difference in the heats of formation (ΔH°_f) of LiOH(l) and LiOH(g) at the boiling point is the heat of vaporization (ΔH°_v).

Bond Distance: Li-O = [1.60] Å O-H = [0.96] Å

Bond Angle: Li-O-H = [110]°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [0.6156 X 10^{-117}] g.^{3} cm.^{6}

Heat of Formation.

J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have studied the equilibrium of $Li_2O(c) - H_2O(g)$ system by the mass-spectrometric method. Using the reported equilibrium constants in the temperature range from 1100° to 1450°K, the heat of reaction $Li_2O(c) + H_2O(g) \rightarrow 2LiOH(g)$ at 298.15°K. has been calculated by both the second and the third law methods as 86.1 and 83.2 kcal. mole^{-1}, respectively. (The third law drift is -2.2 ± 2.6 e.u.) The third law value was taken for the calculation of the heat of formation of LiOH(g) at 298.15°K.

Heat Capacity and Entropy.

Since the bond distance Li-F(g) (r_e = 1.56389 Å) was accurately measured from the microwave studies by L. Wharton, W. Klemperer, L. P. Gold, R. Strauch, J. J. Gallangh and V. E. Derr, J. Chem. Phys. 38, 1203 (1963), the bond distance Li-O in LiOH(g) was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance Li-F(g). Also the bond distance Li-O(g) was estimated as 1.62 Å from the matrix-isolated infrared spectrum by D. White, K. S. Seshadri, D. F. Dever, D. E. Mann, M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963). These two are in good agreement. The bond distance O-H was estimated from that in $H_2O(g)$. The adopted bent molecular configuration with bond angle of 110° was proposed by S. H. Bauer, R. M. Diner and P. F. Porter, J. Chem. Phys. 29, 991 (1958). The three principal moments of interia are I_A =[0.1237] X 10^{-39}, I_B =[2.1699] X 10^{-39} and I_C =[2.2936] X 10^{-39} g. cm.^{2}

The Li-O stretching frequency was estimated to be the same as that in $Li_2O(g)$ (ν = 987 cm.$^{-1}$, see $Li_2O(g)$ table). The bending and the O-H stretching frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rapid convergence to a constant as a heavier atom is attached.

$\omega_e = 1495.7$ cm^{-1} $\omega_e x_e = 31.5$ cm^{-1} $\sigma = 1$

$B_e = 5.8181$ cm^{-1} $\alpha_e = 0.1668$ cm^{-1} $r_e = 1.73$ Å

Heat of Formation.

The heat of formation is calculated using $D^\circ_0 = 2.0 \pm 0.5$ e.v. derived from a graphical extrapolation of the ν(0-3) energy levels of the $X^2\Sigma^+$ state reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Edition, Chapman and Hall Ltd., London, 1953. G. Herzberg, "Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules," 2nd Edition, D. Van Nostrand Co., Inc., New York, 1950, reported $D^\circ_0 \leq 2.49$ e.v. assuming predissociation of the $C^2\pi$ state of MgH into Mg(^{3}P) and H(^{2}S).

Heat Capacity and Entropy.

The molecular constants and electronic levels are obtained from Herzberg, loc. cit., except for the electronic levels 35400 and 48000 obtained from M. A. Khan, Proc. Phys. Soc. (London) 80, 209 - 21 (1962).

Bond Angle: Mg-O-H = [180°]   σ = 1

Rotational Constant: B_e = 0.47595 cm^{-1}

Heat of Formation

The heat of formation is based on the following estimates. The relation D°_0(M-X)/D°_0(X-M-X) = 0.46 ± 0.03 for several alkaline earth dihalides has been reported by R. A. Kent, J. D. McDonald and J. L. Margrave, J. Phys. Chem. 70, 874 (1966). Assuming that this relation applies to hydroxides, we may estimate D°_0(Mg-OH) = 87 ± 12 kcal/mol. A value of D°_0(Mg-OH) = 105 ± 12 kcal/mol is obtained by comparison with D°_0(Be-OH) ≤ 111 ± 10, D°_0(Ca-OH) = 100 ± 10 and D°_0(Sr-OH) = 95 ± 10 kcal/mol. The value for BeOH is from the JANAF tables, while those for CaOH and SrOH are from flame studies of L. V. Gurvich, private communication, High Temperature Institute, Moscow, 1966. The average value of D°_0(Mg-OH) = 96 kcal/mol is used to calculate the heat of formation.

A value of D°_0(Mg-OH) = 56 ± 5 kcal/mol was derived from intensity measurements on the flame spectrum of magnesium by E. M. Bulewicz and T. M. Sugden, Trans. Faraday Soc. 55, 720 (1959). This appears to be too small.

Heat Capacity and Entropy

The ground state is assumed to be $^2\Sigma$ by analogy with isoelectronic MgF. Ultraviolet emission spectra near 3800 Å were observed for MgOH and MgOD by D. Pesic and A. G. Gaydon, Proc. Phys. Soc. (London) 73, 244 (1959), and L. Brewer and S. Trajmar, J. Chem. Phys. 36, 1585 (1962). Vibrational and rotational analyses were not performed. Assuming that the observed spectra correspond to the transition $A^2\Pi \leftarrow X^2\Sigma$, we estimate the first excited state at 27000 cm^{-1}. The vibrational frequencies ν_1 and ν_3 are estimated from those of H_2O(g) and MgO(g). The ν_2 is tentatively estimated at 1000 cm^{-1}.

A linear structure is assumed by use of the prediction of A. D. Walsh, J. Chem. Soc. 1953, 2288 (1953), for "HAB" molecules with less than 11 valence electrons (MgOH has 9 valence electrons). Confirmation of this prediction is scanty for molecules having "A" as the most electronegative element; however, recent microwave evidence [R. L. Kuczkowski, D. R. Lide, Jr., and L. C. Krishner, J. Chem. Phys. 44, 3131 (1966)] for the linearity of KOH and CsOH confirms the prediction for these molecules having 8 valence electrons. The O-H bond distance is assumed to be the same as that of H_2O(g) and the Mg-O bond distance is estimated from that of MgO(g).

MAGNESIUM MONOHYDROXIDE UNIPOSITIVE ION ($MgOH^+$) (IDEAL GAS) GFW = 41.31882

Point Group [$C_{\infty v}$]

ΔHf°_0 = [144 ± 40] kcal/mol

$S^\circ_{298.15}$ = [51.9 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [143 ± 40] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}

[600] (1)

[900] (2)

[3500] (1)

Bond Distance: Mg-O = [1.8] Å O-H = [0.96] Å

Bond Angle: Mg-O-H = [180°] σ = 1

Rotational Constant: B_0 = [0.4765] cm^{-1}

Heat of Formation

The gaseous molecules NaOH, MgOH and AlOH have 8, 9 and 10 valence electrons, respectively. Due to the similarity in molecular structure, we assume that the ionization potential (IP) of MgOH is approximately the average of IP(NaOH) and IP(AlOH). Adopting IP = 9 and 7.5 eV for NaOH (1) and AlOH (2), respectively, we obtain IP(MgOH) = 8.5 eV. Based on this value and ΔHf°_0(MgOH, g) = -52 ± 20 kcal/mol we derive ΔHf°_{298}($MgOH^+$, g) = 143 ± 40 kcal/mol which is tentatively adopted. The estimated value IP(MgOH) is close to IP(MgF) = 7.8 ± 0.3 eV (1), where MF and MgOH are isoelectronic molecules, and thus confirms the value within its uncertainty.

Heat Capacity and Entropy

Walsh (3) predicted that ABH molecules (H = hydrogen atom) containing 10 or less valence electrons will be linear in their ground state. Since $MgOH^+$ molecule has 8 valence electrons, we assume it to be linear. The vibrational frequencies are estimated by comparison with those for NaOH(g) and MgOH(g). The O-H bond distance is assumed to be the same as that in H_2O(g). The Mg-O bond distance is estimated (4). The moment of inertia is 5.874 x 10^{-39} g cm^2. The ground state quantum weight is assumed to be the same as that of NaOH(g). The enthalpy at 0°K is -2.24 kcal/mol.

Heat of Formation.

The value, $\Delta H^\circ_{f\ 298}$ (NH, g) = 81.0 ± 2.5 kcal. mole^{-1}, was calculated from the selected dissociation energy, D_0 = 83 ± 2 kcal. mole^{-1}, based on the following investigations. J. L. Franklin, V. H. Dibeler, R. M. Reese and M. Krause, J. Am. Chem. Soc. 80, 298 (1958) and R. I. Reed and W. Snedden, J. Chem. Soc. 4132 (1959) have determined the dissociation energy of NH(g) by electron impact as 83 ± 2 kcal. mole^{-1} and 85.3 ± 6 kcal. mole^{-1}, respectively. A. L. Companion and F. O. Ellison, J. Chem. Phys. 32, 1132 (1960), and P. C. H. Jordan and H. C. Lonquet-Higgins, Mol. Phys. 5, 121 (1962) have calculated theoretically the dissociation energy by a semi-empirical method and obtained 83.3 kcal. mole^{-1} and 81.2 kcal. mole^{-1}, respectively. These results are in good agreement. G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., D. Van Nostrand Company, New York, 1950, has estimated the dissociation energy D_0(NH, g) = 3.8 e.v. (87.6 kcal. mole^{-1}) based on the average of two earlier theoretical calculations by R. S. Mulliken, (D_0 = 4.2 e.v.), Rev. Mod. Phys. 4, 1 (1932) and G. King (D_0 = 3.4 e.v.), J. Chem. Phys. 6, 378 (1938). A. G. Gaydon, "Dissociation Energies", 2nd Ed., Champman & Hall Ltd., London, 1953, favored G. Glockler's estimation D_0 = 86.3 kcal. mole^{-1} which was based upon the comparison of force constants and D values of related hydrides (i.e. CH, OH and FH).

Heat Capacity & Entropy.

The rotational constants B_e and α_e were obtained from R. N. Dixon, Can. J. Phys. 37, 1171 (1959). The vibrational constants ω_e and $\omega_e x_e$ were calculated from Dixon's data: B_e = 16.6684 cm.$^{-1}$, D_e = 16.85 X 10^{-4} cm.$^{-1}$ and ω = 3125.6 cm.$^{-1}$ by the relation $D_e = 4\,B_e^3/\omega_e^2$ and $\omega = \omega_e - 2\,\omega_e x_e$.

D. E. Milligan and M. E. Jacox, J. Chem. Phys. 41, 2838 (1964) have observed from the spectrum of NH the vibrational fundamental ω = 3133 ± 2 cm.$^{-1}$ in Ar and N_2 matrices. K. Rosengren and G. C. Pimentel, J. Chem. Phys. 43, 507 (1965) also reported ω = 3122.2 ± 0.6 cm.$^{-1}$ in N_2 matrix and ω = 3131.6 ± 0.4 cm.$^{-1}$ in Ar matrix.

NITROXYL HYDRIDE (HNO) (IDEAL GAS) MOL. WT. = 31.016

Point Group C_s

$S^\circ_{298.15}$ = 52.729 cal. deg.$^{-1}$ mole^{-1}

Ground State Multiplicity = [1]

$\Delta H^\circ_{f\ 0}$ = 24.5 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 23.8 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	
2854.17	(1)
1570	(1)
1110	(1)

Bond Distance: H-N = 1.020 ± 0.02 Å N=O = 1.239 ± 0.005 Å

Bond Angle: H-N=O = 114° 25' ± 2°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = 5.939 X 10^{-118} g.^{3} cm.^{6}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ for HNO(g) was calculated from D(H-NO) = 48.6 kcal. mole^{-1} at 0°K. reported by M. J. Y. Clement and D. A. Ramsay, Can. J. Phys. 39, 205 (1961).

Heat Capacity and Entropy.

Vibrational frequencies were assigned by J. L. Bancroft, J. M. Hollas and D. A. Ramsay, Can. J. Phys. 40, 322 (1962) and H. Brown and G. Pimentel, J. Chem. Phys. 29, 883 (1958). Bond distances and bond angles were taken from J. L. Bancroft, J. M. Hollas, and D. A. Ramsay, loc. cit. The molecular constants given by F. W. Dalby, Can. J. Phys. 36, 1336 (1958) were: r(N=O) = 1.211$_6$ Å; r(N-H) = 1.0628 Å, and ∡ HNO = 108.5$_8$°. The three principal moments of inertia are: 1.262 X 10^{-40}, 2.1067 X 10^{-39}, and 2.2330 X 10^{-39} g. cm.^{2}

Nitrous Acid, Cis-(HNO_2)

NITROUS ACID, CIS-(HNO_2) (IDEAL GAS) MOL. WT. = 47.016

Point Group C_s

$S^\circ_{298.15}$ = 59.586 cal. deg.$^{-1}$ mole^{-1}

Ground State Multiplicity = [1]

$\Delta H^\circ_{f\ 0}$ = -16.85 ± 0.32 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -18.34 ± 0.32 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
3462 (1)	855 (1)
1639 (1)	525 (1)
1330 (1)	638 (1)

Bond Distance: O=N = 1.20 Å N-O' = 1.46 Å O'-H = 0.98 Å

Bond Angle: O-N-O' = 114° N-O'-H = 103° σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = 5.50704 \times 10^{-116}$ g.^{3} cm.^{6}

Heat of Formation.

P. G. Ashmore and B. J. Tyler, J. Chem. Soc. 1017 (1961) reported $\Delta H^\circ_{r\ 298.15} = -9.06 \pm 0.32$ kcal. mole^{-1} for the reaction: $NO(g) + NO_2(g) + H_2O(g) \rightleftarrows 2HNO_2(g)$, yielding $\Delta H^\circ_{f\ 298.15} = -18.57 \pm 0.20$ kcal. mole^{-1} for $HNO_2(g)$. L. H. Jones, R. M. Badger and G. E. Moore, J. Chem. Phys., 19, 1599 (1951) estimated the difference in energy of cis- and trans-$HNO_2(g)$ to be 506 ± 250 cal. mole^{-1}. Hence the value of $\Delta H^\circ_{f\ 298.15}$ for cis-$HNO_2(g)$ was calculated.

The heat of reaction and the equilibrium constants for the formation of $HNO_2(g)$ have been calculated by M. M. Karavaev and G. A. Skvortsov, Russ. J. Phys. Chem. 36, 566 (1962). The value of $\Delta H^\circ_{f\ 298.15}$ reported is -18.8 kcal. mole^{-1}. However, based on the heat of formation of liquid HNO_2, P. G. Ashmore and B. P. Levitt, Trans. Faraday Soc., 53, 945 (1957) give $\Delta H^\circ_f = -13.7$ kcal. mole^{-1}. The corresponding value reported by W. A. Rosser and H. Wise, J. Chem. Phys., 26, 571 (1957) is -20.0 kcal. mole^{-1}, based on the experimental data of L. G. Wayne and D. M. Yost, J. Chem. Phys. 19, 41 (1951), and the entropy of the equilibrium mixture of the trans- and cis-$HNO_2(g)$ calculated by L. H. Jones, R. M. Badger and G. E. Moore, loc. cit.

Heat Capacity and Entropy.

Vibrational frequencies, bond distances, and bond angles were obtained from L. D'or and P. Tarte, Bull. Soc. Roy. Sci., Lg. 478 (1951) and L. H. Jones, R. M. Badger and G. E. Moore, loc. cit. The three principal moments of inertia are: 1.0277×10^{-39}, 6.8242×10^{-39}, and 7.8520×10^{-39} g. cm.^{2}

Bond Distance: O=N = 1.20 Å N-O' = 1.46 Å O'-H = 0.98 Å

Bond Angle: O-N-O' = 118° N-O'-H = 105° σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = 4.91847 \times 10^{-116}$ g.^{3} cm.^{6}

Heat of Formation.

P. G. Ashmore and B. J. Tyler, J. Chem. Soc. 1017 (1961) reported $\Delta H^\circ_{r\ 298.15} = -9.06 \pm 0.32$ kcal. mole^{-1} for the reaction: $NO(g) + NO_2(g) + H_2O(g) \rightleftarrows 2HNO_2(g)$, yielding $\Delta H^\circ_{f\ 298.15} = -18.57 \pm 0.20$ kcal. mole^{-1} for $HNO_2(g)$. L. H. Jones, R. M. Badger and G. E. Moore, J. Chem. Phys., 19, 1599 (1951) estimated the difference in energy of cis- and trans- $HNO_2(g)$ to be 506 ± 250 cal. mole^{-1}. Hence the value of $\Delta H^\circ_{f\ 298.15}$ for trans-$HNO_2(g)$ was calculated.

The heat of reaction and the equilibrium constants for the formation of $HNO_2(g)$ have been calculated by M. M. Karavaev and G. A. Skvortsov, Russ. J. Phys. Chem. 36, 566 (1962). The value of $\Delta H^\circ_{f\ 298.15}$ reported is -18.8 kcal. mole^{-1}. However, based on the heat of formation of liquid HNO_2, P. G. Ashmore and B. P. Levitt, Trans. Faraday Soc., 53, 945 (1957) give $\Delta H^\circ_f = -13.7$ kcal. mole^{-1}. The corresponding value reported by W. A. Rosser and H. Wise, J. Chem. Phys., 26, 571 (1957) is -20.0 kcal. mole^{-1}, based on the experimental data of L. G. Wayne and D. M. Yost, J. Chem. Phys. 19, 41 (1951), and the entropy of the equilibrium mixture of the trans- and cis-$HNO_2(g)$ calculated by L. H. Jones, R. M. Badger and G. E. Moore, loc. cit.

Heat Capacity and Entropy.

Vibrational frequencies, bond distances, and bond angles were taken from L. H. Jones, R. M. Badger, and G. E. Moore, loc. cit. The values of vibrational frequencies were in good agreement to those reported by L. D'or and P. Tarte, Bull. Soc. Roy. Sci., Lg. 478 (1951). The three principal moments of inertia are: 7.860×10^{-40}, 7.5268×10^{-39}, and 8.3129×10^{-39} g. cm.^{2}

Bond Distance: O=N = 1.206 ± 0.005 Å N-O' = 1.405 ± 0.005 Å O'-H = [0.96] Å

Bond Angle: O-N-O = 130° ± 20' N-O'-H = 102° ± 30' $\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C = 6.08612 \times 10^{-115}$ g.^{3} cm.^{6}

Heat of Formation.

$\Delta H_{f\,298.15}^\circ$ was taken from National Bureau of Standards Report 7437, January 1, 1962. Equilibria involving HNO_3 were measured by E. J. Jones, J. Am. Chem. Soc. 65, 2274 (1943), G. Feick, J. Am. Chem. Soc. 76, 5858 (1954) and H. E. Abel, H. Schmid and M. Stein-Wien, Z. Elektrochem. 36, 692 (1930), yielding $\Delta H_f^\circ = -32.06, -32.02$, and -32.09 kcal. mole^{-1}, respectively. G. Becker and W. A. Roth, Z. Elektrochem. 40, 836 (1934) and J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882-1886, measured the heat of neutralization of HNO_3(aq.) with NH_3, combining these values with the data for NH_4NO_3 yields $\Delta H_f^\circ = -32.27$ and -32.07 kcal. M. Berthelot, "Sur la Force des Matieres Explosives," 3rd. ed., Paris, 1883, measured the heat of reaction of N_2O_4(g) and Cl_2(g), obtaining $\Delta H_f^\circ = -32.10$ kcal. mole^{-1}. The value of $\Delta H_{f\,298.15}^\circ$ reported by W. R. Forsythe and W. F. Giauque, J. Am. Chem. Soc. 64, 48 (1942) was -31.994 kcal. mole^{-1}. The value adopted is the weighed average of these six values.

Heat Capacity and Entropy.

Vibrational frequencies were obtained from A. Palm and M. Kilpatrick, J. Chem. Phys. 23, 1562 (1955). Bond distances and bond angles were taken from D. J. Millen and J. R. Morton, J. Chem. Soc., 1523 (1960). The basic parameters of HNO_3(g) reported by P. A. Akishin, L. V. Vilkov and V. Y. Rosolovskii, Zhur. Strukt. Khim. 1, 1 (1960) were: r(N=O) = 1.22 ± 0.01 Å; r(N-O) = 1.40 ± 0.01 Å; and ∡ O-N-O = 135° ± 2.5°. Forsythe and Giauque, loc. cit. have calculated the absolute entropy of pure nitric acid (g) from calorimetric data. The value obtained was $S^\circ_{298.1} = 63.62$ cal. deg.$^{-1}$ mole^{-1}. The entropy of nitric acid vapor at 298.1°K. has also been computed by H. Cohn, C. K. Ingold, and H. G. Poole, J. Chem. Soc. 4272 (1952) to be 63.70 cal. deg.$^{-1}$ mole^{-1}. The three principal moments of inertia are: 6.4299×10^{-39}, 7.0314×10^{-39}, and 1.3461×10^{-38} g. cm.^{2}

March 31, 1963

SODIUM HYDRIDE (NaH) (CRYSTAL) MOL. WT. = 23.999

$\Delta H^\circ_{f\ 0} = -12.43 \pm 0.02$ kcal. mole^{-1}

$S^\circ_{298.15} = 9.564$ cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15} = -13.49 \pm 0.02$ kcal. mole^{-1}

$T_d = [700]$°K.

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ was obtained from S. R. Gunn and L. G. Green, J. Am. Chem. Soc. 80, 4782 (1958). The value of $\Delta H^\circ_{f\ 298.15}$ reported by C. E. Messer, L. G. Fasolino and C. E. Thalmayer, J. Am. Chem. Soc. 77, 4524 (1955) was -13.60 ± 0.27 kcal. mole^{-1} which is in excellent agreement with the value given by S. R. Gunn and L. G. Green, loc. cit. The results of the previous investigations were also reviewed by C. E. Messer, et al., loc. cit.

Heat Capacity and Entropy.

C_p below 350°K were measured by E. F. Westrum, et al., University of Michigan, Ann Arbor, Michigan, private communication, May 19, 1960. C_p above 350°K were estimated by comparison with those for LiH(c). C_p, 59.94 ~ 91.84°K., were also measured by E. V. Sayre and J. J. Beaver, J. Chem. Phys. 18, 584 (1950). S° at 100°, 200°, and 298.15° were taken from E. F. Westrum, et al., loc. cit., using S°_{10}(extrap.) = 0.008 cal. deg.$^{-1}$ mole^{-1}.

Temperature of Decomposition.

T_d was estimated from the value of ΔF°_f in the table. The value of T_d given by D. M. Banus, J. J. McSharry and E. A. Sullivan, J. Am. Chem. Soc. 77, 2007 (1955) was 940°K. It was assumed that NaH would behave similarly to LiH and that decomposition pressures would be purity dependent, and this would produce apparently high T_d's.

Dec. 31, 1960; Mar. 31, 1966

SODIUM HYDROXIDE (NaOH) (CRYSTAL) MOL. WT. = 39.99717

$S^\circ_{298.15}$ = 15.400 cal. deg.$^{-1}$ mole^{-1}

T_t = 565.95°K.

T_m = 592.25°K.

$\Delta H^\circ_{f\ 0}$ = -100.82 ± 0.1 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -101.90 ± 0.1 kcal. mole^{-1}

ΔH°_t = 1.519 kcal. mole^{-1}

ΔH°_m = 1.519 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to monomer) = [51.5] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$(to dimer) = [49.0] kcal. mole^{-1}

Heat of Formation.

The standard enthalpy of formation, $\Delta H^\circ_{f\ 298}$ (NaOH, c) = -101.90 ± 0.1 kcal. mole^{-1}, was calculated from the heat of solution of sodium hydroxide (c) and the heat of sodium metal hydrolysis and the appropriate auxiliary data.

N. A. Peshetnikov[1] has measured the heat of solution NaOH(c) → NaOH(400 H_2O) as -10.445 ± 0.015 kcal. mole^{-1} at 298.15°K. by solution calorimetry. Using the auxiliary heat of dilution reported by V. B. Parker[2], the selected heat of solution of sodium hydroxide (c) at infinite dilution is -10.555 kcal. mole^{-1}. Also L. E. Murch and W. F. Giauque[11] measured calorimetrically the heat of solution of solid samples of NaOH-nH_2O in the range from n = 0.1 to 1.0. When extrapolated to n = 0 and infinite dilution[2], this result yields the heat of solution of NaOH(c) at infinite dilution, $\Delta H^\circ_{s\ 298}$ = -10.636 kcal. mole^{-1}, which is in good agreement with the value selected.

The heat of sodium metal hydrolysis, $\Delta H^\circ_{r\ 298}$, has been measured in the solution calorimeter by the following investigators. $Na(c) + H_2O(l) \rightarrow NaOH(nH_2O) + 1/2\ H_2(g)$ $\Delta H^\circ_{r\ 298}$

Source	Number of Moles of H_2O	$\Delta H^\circ_{r\ 298}$ kcal. mole^{-1}	$\Delta H^\circ_{f\ 298}(NaOH(\infty H_2O))$ kcal. mole^{-1}	$\Delta H^\circ_{f\ 298}$(NaOH, c) kcal. mole^{-1}
Gunn et al.[3]	1000	-44.047 ± 0.006	-112.446	-101.899
Messer et al.[4]	∞	-44.215 ± 0.20	-112.530	-101.975
Ketchen et al.[5]	∞	-44.054 ± 0.20	-112.369	-101.814

The values of $\Delta H^\circ_{f\ 298}(NaOH\cdot\infty H_2O)$ were calculated from the heats of reaction $\Delta H^\circ_{r\ 298}$, using the $\Delta H^\circ_{f\ 298}$ (H_2O, l) = -68.315 kcal. mole^{-1}.[6] Combination of the selected heat of solution of NaOH(c) at infinite dilution with the heat of formation of NaOH(∞H_2O) gives the heat of formation of NaOH(c) in the last column of the table. A weighted average of these three measurements has been taken for the selected heat of formation of sodium hydroxide (c).

The earlier investigations have been reviewed by F. R. Bichowsky and F. D. Rossini[9], and C. E. Messer et al.[4], and these earlier reported data are not adopted in the tabulation.

Heat Capacity and Entropy.

L. E. Murch and W. F. Giauque[11] have measured low temperature heat capacities of NaOH·0.04014 H_2O and NaOH·0.97776 H_2O from 15° to 320°K. and calculated the values of C_p for the pure phase of NaOH(c). T. B. Douglas and J. L. Dever[9] have measured the enthalpy changes from 273° to 973°K. in the drop calorimeter and derived the heat capacities. The low temperature and the high temperature heat capacities were joined smoothly by Murch and Giauque, and the smooth values were adopted in the tabulation. Low temperature heat capacities from 60° to 300°K. have also been measured by J. C. R. Kelly and P. E. Snyder[7], whose data are in good agreement with those reported by Murch and Giauque. M. M. Popov and D. M. Ginzburg[10] have determined the heat capacities of NaOH(c) in the temperature range from 298° to 577°K. from the enthalpy measurements by drop calorimetry. The reported H_{500}-H_{298} = 3.112 kcal. mole^{-1} is in good agreement with the tabulated value.

Transition and Melting Data.

The adopted heat of transition and the transition temperature, and the adopted heat of melting and the melting point were obtained from Douglas and Dever.[8] Popov and Ginzburg[10] reported the heat of transition ΔH°_{tr} = 1.930 kcal. mole^{-1} at 576.8°K. and the heat of melting ΔH°_m = 1.629 kcal. mole^{-1} at 595.16°K.

Heat of Sublimation.

See NaOH(g) table for details.

Dec. 31, 1960; Mar. 31, 1966

SODIUM HYDROXIDE (NaOH) (LIQUID) MOL. WT. = 39.99717

$S^\circ_{298.15}$ = 17.727 cal. deg.$^{-1}$ mole^{-1}

T_m = 592.25°K.

T_b(monomeric gas) = 1662.7°K.

ΔH°_f 298.15 = -99.998 kcal. mole^{-1}

ΔH°_m = 1.519 kcal. mole^{-1}

ΔH°_v(to monomer) = 37.9 kcal. mole^{-1}

Heat of Formation.

The heat of formation of NaOH(l) at 298°K. was obtained from that of the crystal by adding ΔH°_m and the difference between $H^\circ_{592.25} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The selected heat capacities in the temperature range from 592.3° to 1000°K. were obtained from the enthalpy measurements of sodium hydroxide (l) in the drop calorimeter by T. B. Douglas and J. L. Dever[1]. The heat capacities below the melting point and above 1000°K. were extrapolated from the selected heat capacity curve.

Douglas and Dever[1] have also compared their heat capacity values with those from W. D. Powers and G. C. Blalock[2] who have applied the same drop method to determine the heat capacities of NaOH(l). Both results are in reasonable agreement. M. M. Popov and G. M. Ginzburg[3] applying the same technique obtained different values of heat capacity. The smoothed enthalpy data reported by Ginzburg[4] are 200 to 500 cal. mole^{-1} smaller than the tabulated values at the temperature range from 700° to 1000°K.

The entropy (S°_{298} = 17.65 cal. deg.$^{-1}$ mole^{-1}) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See NaOH(c) table for details.

Vaporization Data.

The boiling point 1662.7°K. was calculated as the temperature at which the free energies of formation (ΔF°_f) for both NaOH(l) and NaOH(g) are equal. The difference in the heats of formation (ΔH°_f) of NaOH(l) and NaOH(g) at the boiling point is the heat of vaporization. If $Na_2(OH)_2(g)$ is also considered as a minor component in the vapor mixture (approximately 6% of total vapor pressure at the boiling point) the calculated boiling point is 1653°K. (see NaOH(g) table for details).

H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 162 (1921), have studied the vapor pressures of liquid NaOH and reported the boiling point as 1661°K.

Bond Distance: Na-O = [1.97] Å O-H = [0.96] Å

Bond Angle: Na-O-H = [110°]

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [5.3062] X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 28, 454 (1958), have found in their mass-spectrometric studies that the NaOH(l) vaporizes mainly as gaseous dimer in the temperature range from 573° to 723°K. They have also calculated by the slope method the heat of dimerization, $\Delta H^\circ_{d\ 660}$ = -54 ± 5 kcal. mole^{-1}, for 2NaOH(g) = $Na_2(OH)_2$(g) and the heat of sublimation, $\Delta H^\circ_{s\ 298}$ = 46.3 ± 3 kcal. mole^{-1}, for NaOH(c) = NaOH(g). **The second law values were determined using ion intensity ratios, however, a third law calculation using a single data point converted by the authors to absolute pressure (J. Phys. Chem. 62, 486 (1958)) yields $\Delta H^\circ_{d\ 298}$ = -51.8 kcal. mole^{-1},** $\Delta H^\circ_{s\ 298}$(to monomer) = 49.5 kcal. mole^{-1} and $\Delta H^\circ_{s\ 298}$ (to dimer) = 41.1 kcal. mole^{-1} which are in agreement within the limit of uncertainty. Later, Porter and Schoonmaker, J. Chem. Phys. 31, 830 (1959), found the activity of molten alkali hydroxide had been reduced in the presence of MgO in their sample container, and the uncertainty in the heat of sublimation might be ±5 kcal. mole^{-1}, but the heat of dimerization should not be seriously affected because it was calculated from slopes of both species. In order to have good agreement between the calculated total pressures of monomer and dimer of sodium hydroxide (g) and the observed vapor pressures by H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 162 (1921), the heat of dimerization and the heat of sublimation have been so chosen as $\Delta H^\circ_{d\ 298}$ = -54 kcal. mole^{-1} and $\Delta H^\circ_{s\ 298}$ (to monomer) = 51.5 kcal. mole^{-1}, respectively, which are still within the limit of Porter and Schoonmaker's data. The calculated boiling point is 1653°K. which is in good agreement with 1661 ± 20°K. reported by Wartenberg and Albrecht, loc. cit. The heats of formation were calculated from the selected heat of dimerization and heat of sublimation as $\Delta H^\circ_{f\ 298}$ (NaOH, g) = -50.4 kcal. mole^{-1} and $\Delta H^\circ_{f\ 298}$($Na_2(OH)_2$, g) = -154.8 kcal. mole^{-1}.

Heat Capacity and Entropy.

The bent molecular configuration with the bond angle of 110° was proposed by S. H. Bauer, R. M. Diner and P. F. Porter, J. Chem. Phys. 29, 991 (1958). The bond distance O-H was estimated from that in H_2O(g). The bond distance Na-O was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance Na-F(g) (1.92595 Å) which has been accurately measured by R. K. Bauer and H. Lew, Can. J. Phys. 41, 1461 (1963). The Na-O stretching frequency was obtained from L. H. Spinar and J. L. Margrave, Spectrochim. Acta 12, 244 (1958), in the infrared spectroscopic studies. The O-H stretching and the bending frequencies were estimated by compairson with H-OH, D-OH and T-OH which indicate rigid convergence to a constant as a heavier atom is attached. The three principal moments of inertia are I_A = [0.1252] X 10^{-39}, I_B = [6.449] X 10^{-39} and I_C = [6.5742] X 10^{-39} g. cm.^{2}

Heat of Formation.

P. Gray, Trans. Farad. Soc. 55, 408 (1959) has summarized the determinations of the heat of formation of OH and concludes that the short extrapolation by Barrow, Arkiv. Fysik, 11, 281 (1956) of the $B(^2\Sigma^+) \rightarrow A(^2\Sigma^+)$ system gives the most reliable result. The value of D_0 = 101.33 kcal. mole⁻¹ was adopted and leads to a heat of formation of 9.432 kcal. mole⁻¹. A recent determination of the dissociation energy from measurements of the concentration of the radicals in water oxygen mixtures by A. P. Purmal and A. V. Frost, Vestn. Mosk. Univ., Ser. II Khim. 16, 25 (1961) gives $\Delta E_D(OH)$ = 102.8 ± 0.8 kcal. mole⁻¹ in good agreement with the adopted value. Also V. A. Medvedev, V. V. Korobov and V. F. Baibuz, Zhur. Fiz. Khim. 33, 58 (1959) reported a heat of dissociation of 102.2 ± 1 kcal. mole⁻¹ from dissociation of water in a spherical bomb.

Heat Capacity and Entropy.

The molecular constants were all given by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. New York, 1950. This calculation gives values in excellent agreement with L. Haar, A. S. Friedman and C. W. Beckett, National Bureau of Standards Monograph No. 20, May 1961. The agreement with the higher order correction calculations of H. L. Johnston, J. Belzer and L. Savedoff, TR 316-5, Ohio State University, available as ATI 139 967, is good between 298 and 4000°K. This earlier work uses different constants and also a different value of the ground state splitting constant, but at 6000°K. the entropy difference is still less than 0.25%.

Heat of Formation.

The ionization potential of hydroxyl has been determined by M. M. Mann, A. Hustrulid and J. T. Tate, Phys. Rev. 58, 340 (1940) from electron impact data on water vapor, as 13.6 e.v. S. N. Foner and R. L. Hudson, J. Chem. Phys. 25, 602 (1956) have measured the appearance potential of OH^+ from OH as 13.18 ± 0.1 e.v. (303.96 kcal.). This value was the one adopted to obtain the heat of formation of $OH^+(g)$ from that of OH(g) at 0°K.

Heat Capacity and Entropy.

The molecular constants, with the exception of $\omega_e x_e$, were all given by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. New York, 1950. The value of $\omega_e x_e$ was estimated by analogy with OH(g) and other diatomic hydrides.

The value of H_T-H_{298} at 0°K. is -2.06 kcal. mole^{-1}.

Heat of Formation.

L. M. Branscomb, Joint Institute for Laboratory Astrophysics Report No. 62, Feb. 1st, 1966 has deduced an electron affinity of OH of 1.83 ± 0.04 e.v. (42.2 ± 0.9 kcal.) from the photodetachment spectrum of $OH^-(g)$. The vibrational state was deduced to be the ground state since no other absorption sequences could be detected by a thorough search. F. M. Page, Faraday Soc. Discussions 19, 87 (1955) has reviewed the methods and results of earlier determinations of the electron affinity of OH(g) and concludes that it is 65 ± 1 kcal. However he does state that it is not generally known whether the flame systems chiefly investigated are in thermodynamic equilibrium. In a later paper F. M. Page and T. M. Sugden, Trans. Faraday Soc. 53, 1092 (1957) conclude that much higher concentrations of radicals are obtained in flames than predicted thermodynamically. However for certain systems at lower temperatures they estimate only a factor of 3 increase in concentration and thus calculate the electron affinity as 61 kcal. mole^{-1}. The value reported by Branscomb, loc. cit. is adopted here.

Heat Capacity and Entropy.

Branscomb loc. cit. has used his photodetachment spectra to obtain values of ω_e, B_e and r_e for $OH^-(g)$ which are remarkably similar to those for OH(g). The values of $\omega_e x_e$ and α_e were estimated by comparison with OH(g) and other hydrides. The ground state configuration was assumed to be that of HF(g) with which it is isoelectronic.

The value of H_T-H_{298} at 0°K. is -2.057 kcal. mole^{-1}.

Product of the Moments of Inertia: $I_AI_BI_C$ = [0.6424] X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

S. N. Foner and R. L. Hudson, J. Chem. Phys. 36, 2681 (1962) have determined the ionization potential of HO_2 and the appearance potential of HO_2^+ from H_2O_2. Using the ΔH_f° of $H_2O_2(g)$ determined by P. A. Giguere and I. D. Liu, J. Am. Chem. Soc. 77, 6477 (1955), they calculate $\Delta H^\circ_{f\ 0}$ HO_2 = 5.7 ± 2 kcal. mole^{-1}.

Heat Capacity and Entropy.

The point group must be C_1 as the two oxygen atoms have been shown to be non-equivalent, from the increased number of infra-red bands obtained when using O_2^{16} enriched with 28% of O_2^{18}, by D. E. Milligan and M. E. Jacox, J. Chem. Phys. 38, 2027 (1963). They also reported the three frequencies given above in the infra-red spectrum of the matrix isolated HO_2 radical. The bond lengths were taken equal to those estimated by M. E. Boyd, J. Chem. Phys. 37, 1317 (1962), the angle was that recommended by Milligan and Jacox, loc. cit. Boyd's conclusion that the lowest energy configuration should be an isosceles triangle could not be accepted in view of the nonequivalence of the oxygen atoms. The electronic ground state was taken as 2A" as predicted by A. D. Walsh, J. Chem. Soc. London, 2288 (1953).

PHOSPHORUS MONOHYDRIDE (PH)   (IDEAL GAS)   GFW = 31.98177

Ground State Configuration $^3\Sigma^-$ ΔHf°_0 = 60.4 ± 8 kcal/mol

$S^\circ_{298.15}$ = 46.9 gibbs/mol $\Delta Hf^\circ_{298.15}$ = 60.6 ± 8 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i	ϵ_i, cm^{-1}	g_i
0	3	29560	6
[7650]	2	[38110]	2
[15150]	1	[57490]	1

ω_e = 2380 cm^{-1} $\omega_e x_e$ = [55] cm^{-1} σ = 1

B_e = 8.412 cm^{-1} α_e = [0.28] cm^{-1} r_e = 1.43 Å

Heat of Formation

Jordan (1) estimated the dissociation energy (D_0) of PH(g) as 70.44 kcal/mol using a semiempirical theoretical method. The corresponding value for the heat of formation ($\Delta Hf^\circ_{298.15}$) is 60.6 ± 8 kcal/mol.

Heat Capacity and Entropy

Jordan (1) predicted five electronic levels ($X^3\Sigma$, $A^1\Delta$, $B^1\Sigma$, $D^1\Pi$, $E^1\Sigma$) based on the reported value (2) of 29560 cm^{-1} for the $C^3\Pi$ level (this level is designated $A^3\Pi$ by Herzberg (2)). Several qualitative spectroscopic investigations of PH(g) have been reported and are in general accord with the predictions of Jordan (1). Ishaq and Pearse (3) reported the values of the rotational constant B_e and the fundamental vibrational frequency ω_e. The value of α_e is calculated from the Morse potential function. The bond distance is calculated from B_e. The value of the anharmonic vibrational term $\omega_e x_e$ is estimated from the relation $\omega_e x_e = \omega_e^2/(4D_0 + 2\omega_e)$.

Lead Monohydride (PbH) (Ideal Gas)

Mol. Wt. = 208.22

$\Delta H_f^\circ{}_{298.15} = 56.5 \pm 4.6$ kcal. mole^{-1}

$S_{298.15}^\circ = 52.737$ cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^2\Pi_{1/2}$

Electronic Levels and Multiplicities

ϵ, cm.$^{-1}$	g_1
0	2
[8000]	2

$\omega_e = 1564.1$ cm.$^{-1}$ $\omega_e x_e = 29.75$ cm.$^{-1}$

$B_e = 4.971$ cm.$^{-1}$ $\alpha_e = 0.144$ cm.$^{-1}$

$\sigma = 1$

Heat of Formation. $\Delta H_f^\circ{}_{298.15}$ was calculated from the dissociation energy of PbH(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration and spectroscopic data were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York (1950). Electronic levels and multiplicity were estimated by comparison with those for PbF(g).

Dec. 31, 1960; June 30, 1967

SULFUR MONOHYDRIDE (SH) (IDEAL GAS) GFW = 33.07197

Ground State Configuration $^2\Pi$ $\Delta Hf^\circ_0 = 34.4 \pm 4$ kcal/mol

$S^\circ_{298.15} = 46.73$ gibbs/mol $\Delta Hf^\circ_{298.15} = 34.6 \pm 4$ kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i	ϵ_i, cm^{-1}	g_i
0	2	59636	2
376.9	2	[63850]	4
30662.4	2	75000	18

$\omega_e = 2702$ cm^{-1} $\omega_e x_e = 60$ cm^{-1} $\sigma = 1$

$B_e = 9.611$ cm^{-1} $\alpha_e = [0.3]$ cm^{-1} $r_e = 1.3397$ Å

Heat of Formation

Mackle (1) estimated ΔHf°_{298} of SH(g) as 34.6 ± 4 kcal/mol, this value being an average of three independent determinations.

He obtained these three values by the following methods: (A) He calculated ΔHf°_{298} of SH(g) as 34.9 ± 4.5 kcal/mol from ΔHf°_{298} of thiobenzyl alcohol (g), ΔHf°_{298} of the benzyl radical (g) and the heat of dissociation (D°_0) of thiobenzyl alcohol reported by Sehon and Darwent (2). (B) A value of 35.2 ± 4.5 kcal/mol was calculated from ΔHf°_{298} of $C_2H_5{}^+(g)$, ΔHf°_{298} of $C_2H_5SH(g)$ and the appearance potential of $C_2H_5{}^+$ reported by Franklin and Lumpkin (3). (C) He calculated that ΔHf°_{298} of SH(g) is 33.7 ± 3 kcal/mol from ΔHf°_{298} of $H_2S(g)$ and the mass spectrographic data for the reactions $H_2S = SH^+ + H + e^-$ and $SH = SH^+ + e^-$ reported by Palmer and Lossing (4). The adopted value of 34.5 ± 4 kcal/mol compares with a value of 34.9 kcal/mol obtained from a linear Birge-Sponer extrapolation of the potential function.

Heat Capacity and Entropy

The high resolution spectra of SH(g) have been studied by Ramsay (5) and Johns and Ramsay (6) in the near UV and by Morrow (7) in the vacuum UV. The energy levels of the doublet ground state and of the first excited state ($^2\Sigma$) were reported by Ramsay (6). Six of the seven higher excited levels ($B^2\Sigma$, $D^2\Delta$, $E^2\Sigma$, $F^2\Delta$, $G^2\Delta$, $H^2\Delta$) were reported by Morrow (7), the last five of which are shown as an average of 75000 cm^{-1}. The remaining electronic level ($C^2\Delta$) is estimated by analogy with the electronic levels of SD(g) reported by Morrow (7).

Ramsay (5) reported the following rotational and vibrational constants: $B_0 = 9.461$ cm^{-1}, $\omega_e = 2702$ cm^{-1}, and $\omega_e x_e = 60$ cm^{-1}. The value of α_e is calculated from the Morse potential function. The rotational constant B_e is calculated from $B_e = B_0 + \alpha_e/2$. The bond distance is calculated from B_e.

SILICON MONOHYDRIDE (SiH) (IDEAL GAS) GFW = 29.09397

Ground State Configuration $^2\Pi$

ΔHf°_0 = 89.6 ± 2 kcal/mol

$S^\circ_{298.15}$ = 47.306 ± 0.05 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 90 ± 2 kcal/mol

Electronic Levels and Degeneracies

State	ε_i, cm^{-1}	g_i
$X^2\Pi$	0	2
	142.83	2
$^4\Sigma^-$	[21510]	4
$A^2\Delta$	24193	4
$^2\Sigma^-$	[24730]	2
$B^2\Sigma^+$	30808	2
$C^2\Sigma^+$	30842	2
$D^2\Delta$	48510	4
$E^2\Sigma^+$	52399	2

ω_e = 2041.8 cm^{-1} $\omega_e x_e$ = 35.51 cm^{-1} σ = 1

B_e = 7.4996 cm^{-1} α_e = 0.219 cm^{-1} r_e = 1.5201 Å

Heat of Formation

Verma (1) has derived an upper limit to the dissociation energy of 24680 cm^{-1} (70.56 kcal) from predissociation in the $B^2\Sigma^+$ state. With JANAF values for Si(g) and H(g) this yields ΔHf°_0(SiH, g) ≥ 87.73 kcal/mol. We adopt a value of ΔHf°_{298}(SiH, g) = 90 ± 2 kcal/mol, assuming that the predissociation has a 2 kcal barrier similar to that in the predissociation of the $A^1\Pi$ state of AlH. Hildenbrand (5) has applied an ionic-covalent correction to the linear Birge-Sponer extrapolation of the ground state dissociation energy and obtains D°_0(SiH, g) = 70 kcal in excellent agreement with the predissociation value.

Heat Capacity and Entropy

The observed electronic levels and rotational and vibrational constants are from Herzberg et al. (2), Klynning and Lindgren (3), and Verma (1). The estimated levels are from the calculations of Jordan (4). The upper states are all assumed to have ground state molecular constants. This approximation introduces negligible error when the first state is as high as 21000 cm^{-1} and has the same multiplicity as the ground state.

ZIRCONIUM HYDRIDE (ZrH) (IDEAL GAS) MOL. WT. = 92.228

Ground State Configuration [$^2\Pi$]

$S^\circ_{298.15}$ = [51.638] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = [123.7] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [123.4] kcal. mole^{-1}

Electronic Levels and Multiplicities

ϵ_1, cm.$^{-1}$	g_1
0	[4]

ω_e = [1400] cm.$^{-1}$

B_e = [5.1] cm.$^{-1}$

$\omega_e x_e$ = [19] cm.$^{-1}$

α_e = [0.09] cm.$^{-1}$

σ = 1

r_e = [1.821] Å

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was estimated as 123.7 kcal. mole^{-1} by J. S. Gordon, Astrosystems International, Livingston, New Jersey, private communication, January 10, 1963. $\Delta H^\circ_{f\ 298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. r_e was calculated from the relationship $r_e = (16.858778/\mu B_e)^{1/2}$ Å.

Hydrogen (H_2)

(Ideal Gas - Reference State) Mol. Wt. = 2.016

Hydrogen (H_2) (Ideal Gas - Reference State) Mol. Wt. = 2.016

D_0° = 103.266 ± 0.15 kcal. mole^{-1}

Ground State Configuration $^1\Sigma_g^+$

$\Delta H_{f\,298.15}^\circ = 0$

$S^\circ_{298.15}$ = 31.21 ± 0.01 cal. deg.$^{-1}$ mole^{-1}

ω_e = 4405.3 cm.$^{-1}$

$\omega_e x_e$ = 125.325 cm.$^{-1}$

D_e = 0.04644 cm.$^{-1}$

$\sigma = 2$

B_e = 60.848 cm.$^{-1}$

α_e = 3.0664 cm.$^{-1}$

r_e = 0.7417 Å

Heat Capacities and Entropy

H. W. Woolley, R. B. Scott and F. G. Brickwedde, J. Research Nat. Bur. Standards 41, 379 (1948), calculated the thermodynamic functions by a method of direct summation for normal H_2 (75% ortho and 25% para) using spectroscopic constants derived from an analysis of U. V. band spectra. These constants are more preferable for use in a summation method than those obtained by G. Herzberg, Can. J. Res. A28, 144 (1950) from the measured quadrupole transitions in the ground state which accurately describe the lower vibrational levels only. In any case the difference in the functions resulting from the two sets of data are less than 0.2%.

Since the entropies of Woolley et al. contain a contribution from nuclear spin, a correction of -Rln4 was applied. However, the entropy due to the mixing of ortho and para hydrogen which is a consequence of nuclear spin is included in the total entropy since this results in correct equilibrium constants based upon third law calculations. Differences in the values of R and c_2 were found to have a negligible effect upon the functions.

Similar calculations with a different method of estimating the higher rotational levels by H. L. Johnston, L. G. Savedoff, and J. Belzer, Technical Report No. 2, Project R.F-316, Ohio State Univ. (1949), result in functions that are 0.5% lower above 5000°K.

For details concerning the dissociation energy see the monatomic hydrogen sheet.

Heat Capacity and Entropy.

S. H. Bauer, R. H. Diner and R. F. Porter, J. Chem. Phys. 29, 991 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 31, 830 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have also postulated a model for $Li_2(OH)_2(g)$ which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the bond angle O-Li-O = 100°. The last one was adopted for the molecular configuration of $K_2(OH)_2$, but the bond angle O-K-O was modified to 90° (i.e. a square planar configuration for potassium and oxygen atoms). The bond angle K-O-H in $K_2(OH)_2(g)$ was assumed to be 110°. The bond distance K-O in $K_2(OH)_2(g)$ was estimated 10% longer than that in KOH(g). The bond distance O-H was estimated to be the same in $H_2O(g)$. The three principal moments of inertia are I_A = [17.5202] X 10^{-39}, I_B = [38.5534] X 10^{-39} and I_C = [55.6452] X 10^{-39} g. cm.^{2}

The first six selected vibrational frequencies were taken to be equal to those for $K_2F_2(g)$ (see $K_2F_2(g)$ table), and the rest were O-H stretching and bending frequencies which have been suggested by Berkowitz et al., loc. cit.

Heat of Formation.

J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have studied the $Li_2O(c)$-$H_2O(g)$ equilibrium by the mass-spectrometric method. Using the reported equilibrium constants in the temperature range from 1100° to 1450°K. the heat of reaction $Li_2(OH)_2(g) \rightarrow 2LiOH(g)$ at 298° has been calculated by the second law and the third law methods as 63.2 and 63.7 kcal. mole^{-1}, respectively. (The third law drift is 0.5 ± 1.5 e.u.) Combination of the third law value ($\Delta H^\circ_{r\ 298}$ = 63.7 kcal. mole^{-1}) with the heat of formation of lithium hydroxide(g) ($\Delta H^\circ_{f\ 298}$ = -58.8 kcal. mole^{-1}) gives the heat of formation of dimeric lithium hydroxide (g) ($\Delta H^\circ_{f\ 298}$ = -181.4 kcal. mole^{-1}) which has been adopted in the tabulation.

J. B. Berkowitz-Mattuck and A. Buchler, J. Phys. Chem. 67, 1386 (1963), have also studied the $Li_2O(c)$-$H_2O(g)$ equilibrium by the transpiration method, and reported two equilibrium constants (K_{1095}° = 0.105 and K_{1145}° = 0.357) for the reaction $Li_2O(c) + H_2O(g) \rightarrow Li_2(OH)_2(g)$. Using the third law method, the heat of reaction has been calculated from the equilibrium constants as 12.7 kcal. mole^{-1} at 298.15°K. The heat of formation of $Li_2(OH)_2(g)$ can be derived as $\Delta H^\circ_{f\ 298}$ = -188.2 ± 3.5 kcal. mole^{-1} which is different from the adopted value of Berkowitz, Meschi and Chupka, loc. cit. Berkowitz-Mattuck and Buchler attempted to explain the difference by inferring that the solid-gas equilibrium was not properly established in the measurement of Berkowitz, Meschi and Chupka, however, the absence of drift in the third law analysis does not support this conclusion.

Heat Capacity and Entropy.

S. H. Bauer, R. M. Diner and R. F. Porter, J. Chem. Phys. 29, 991 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 31, 830 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have also postulated a model for $Li_2(OH)_2(g)$ which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the bond angle O-Li-O = 100°. The last one was adopted for the molecular configuration of $Li_2(OH)_2(g)$, but the bond angle O-Li-O was modified to 90° (i.e. a square planar configuration for lithium and oxygen atoms). The bond angle Li-O-H in $Li_2(OH)_2(g)$ was assumed to be 110°. The bond distance Li-O in $Li_2(OH)_2(g)$ was estimated 10% longer than that in LiOH(g). The bond distance O-H was estimated to be the same in $H_2O(g)$. The three principal moments of inertia are: I_A = [9.445] X 10^{-39}, I_B = [3.7789] X 10^{-39} and I_C = [12.8035] X 10^{-39} g. cm.^{2}

The first six selected vibrational frequencies were taken to be equal to those for $Li_2F_2(g)$ (see $Li_2F_2(g)$ table) and the rest were O-H stretching and bending frequencies.

Dec. 31, 1960; June 30, 1963; Sept. 30, 1963

MAGNESIUM DIHYDRIDE (MgH_2) (CRYSTAL) MOL. WT. = 26.336

$\Delta H_f^\circ{}_0$ = -16.3 ± 2.2 kcal. mole^{-1}

$S^\circ_{298.15}$ = 7.43 ± 0.20 cal. deg.$^{-1}$ mole^{-1} $\Delta H_f^\circ{}_{298.15}$ = -18.2 ± 2.2 kcal. mole^{-1}

T_d = [560]°K.

Heat of Formation.

The heat of hydrolysis of MgH_2(c) was measured by G. C. Sinke and D. R. Stull, Thermal Laboratory, The Dow Chemical Company, private communication, July, 1956. The value of $\Delta H_f^\circ{}_{298.15}$ was calculated to be -19.1 ± 2 kcal. mole^{-1}. From the decomposition pressure measurements for MgH_2(c) reported by F. H. Ellinger, et al., J. Am. Chem. Soc. 77, 2647 (1955) and J. F. Stampfer, Jr., C. E. Holley, Jr. and J. F. Suttle, J. Am. Chem. Soc. 82, 3504 (1960), the values of $\Delta H_f^\circ{}_{298.15}$ for MgH_2(c) were found to be -17.9 ± 1.0 and -17.7 kcal. mole^{-1}, respectively. The value used was the average of these three.

Heat Capacity and Entropy.

The low temperature heat capacities (25-300°K.) was measured by G. C. Sinke and D. L. Hildenbrand, Thermal Laboratory, The Dow Chemical Company, private communication, February 1958. Above 300°K. the C_p values were estimated by comparison with those for MgF_2(c). $S^\circ_{298.15}$ was obtained from G. C. Sinke and D. L. Hildenbrand, loc. cit., using S°_{25} (extrap.) = 0.037 cal. deg.$^{-1}$ mole^{-1}.

Temperature of Decomposition.

T_d was estimated from the value of ΔF_f° in the table.

Magnesium Dihydroxide ($Mg(OH)_2$)

Dec. 31, 1960; Dec. 31, 1966; Mar. 31, 1967

MAGNESIUM DIHYDROXIDE ($Mg(OH)_2$) (CRYSTAL) GFW = 58.32674

$\Delta Hf^\circ_0 = -218.43 \pm 0.5$ kcal/mol

$S^\circ_{298.15} = 15.10$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -221.0 \pm 0.5$ kcal/mol

$T_d = [541]$°K

Heat of Formation.

The adopted value is an average of -221.10 and -220.86 kcal/mol obtained from $\Delta Hr^\circ_{298} = 9.08$ and 8.84 kcal/mol for the dehydration reaction $Mg(OH)_2(c) = MgO(c) + H_2O(l)$. The two values correspond to naturally occurring brucite and to synthetic $Mg(OH)_2$ prepared from MgO by hydration at 177°C under a steam pressure of about 9 atm. The enthalpies of reaction are derived from studies of Taylor and Wells on the heats of solution of various samples of $Mg(OH)_2$ and MgO in aqueous HCl. These studies show that the heat of dehydration is quite dependent on the nature of the MgO sample; e.g., values for synthetic $Mg(OH)_2$ vary monotonically from 9.79 to 8.84 kcal/mol for MgO ignited at temperatures from 450 to 1425°C, respectively. The authors ascribe this difference primarily to increase in particle size at the higher ignition temperatures. We have adopted the results at 1425°C, since they are reasonably consistent with the high temperature samples on which the JANAF heat of formation for MgO is based. The uncertainty is estimated as ± 0.5 kcal/mol.

Shomate and Huffman have confirmed the heat of solution of MgO (ignited at 1000°C) within about 0.3 kcal. Their value may be combined with the heat of solution for synthetic $Mg(OH)_2$, determined under similar conditions by Torgeson and Sahama, to obtain $\Delta Hr^\circ = 8.85$ kcal/mol for the dehydration reaction. At the other extreme, the heat of solution data of Giauque and Archibald lead to $\Delta Hr^\circ = 9.74$ kcal/mol; however, this value corresponds to MgO ignited at 350°C. The MgO sample was microcrystalline and had significant excess Cp°, as suggested by Giauque and Archibald and later confirmed by data of T. H. K. Barron et al., Proc. Roy. Soc. (London) A250, 70 (1959). Giauque and Archibald intentionally used the microcrystalline form which would be similar to the product in their decomposition pressure measurements (190 and 212°C). Thus, it is not surprising that third law analysis of their decomposition pressures yields essentially the same heat of formation as their solution data (see summary below). Decomposition data at higher pressures have been reported by W. S. Fyfe, Am. J. Sci. 256, 729 (1958); D. M. Roy and R. Roy, ibid. 255, 573 (1957); G. C. Kennedy, ibid. 254, 567 (1956); G. M. Zhabrova and B. M. Kadenatsi, J. Gen. Chem. USSR (Eng. Transl.) 24, 1129 (1954); and L. G. Berg and I. S. Rassonskaya, Dokl. Akad. Nauk SSSR 81, 855 (1951). These data do not significantly affect the heat of formation, however, because of uncertainties in the attainment of equilibrium and in reduction to standard state values.

Heat Capacity and Entropy.

Low temperature heat capacities are from the data (22-321°K) of Giauque and Archibald, loc. cit., who used a synthetic, macrocrystalline sample prepared by reaction of KOH with aqueous $MgCl_2$ at 210°C. The entropy is derived from the heat capacities using $S^\circ_{20} = 0.027$ eu. Above 321°K the heat capacities are extrapolated graphically. Enthalpy data (393-667°K) reported by P. N. Lashchenko and D. I. Kompanskii, Zh. Prikl. Khim. 8, 628 (1935), were stated to be based on a calorimeter temperature close to room temperature. Within this uncertainty and the experimental scatter of about ± 5%, the enthalpy data are consistent with the selected values.

Temperature of Decomposition.

Td is calculated as the temperature at which $\Delta Gr^\circ = 0$ for $Mg(OH)_2(c) = MgO(c) + H_2O(g)$.

Bond Distances: Mg-O = [1.80] Å   O-H = [0.97] Å

Bond Angles: Mg-O-H = [105°]   O-Mg-O = [180°]   σ = [2]

Product of the Moments of Inertia: $I_AI_BI_C$ = [95.6929] x 10^{-117} g^3 cm^6

Heat of Formation

Vapor densities of magnesium-bearing species over magnesium oxide were determined, using the transpiration method, by C. A. Alexander, J. S. Ogden and A. Levy, J. Chem. Phys. 39, 3057 (1963). The MgO reacted with water vapor present in the carrier gas to form a gaseous product, presumably $Mg(OH)_2$. The authors eliminated MgOH (and other species requiring the formation of gaseous oxygen) as a likely product by holding constant the partial pressure of water but varying the ratio of oxygen and argon in the carrier gas. Experiments with different partial pressures of water indicated that each mole of water produced an equivalent number of moles of product in the vapor. This eliminates $[Mg(OH)_2]_2$ as a possible product, but not, for example, $(MgO)_2 \cdot H_2O$. Species of the latter type are quite unlikely with magnesium, so the reaction is considered to be $MgO(c) + H_2O(g) = Mg(OH)_2(g)$. Equilibrium data (1653-2020°K) given graphically by Alexander et al. yield ΔHr°_{298} = 67.6 ± 1.9 kcal/mol by second law analysis and ΔHr°_{298} = 65.2 kcal/mol with a drift of -1.5 ± 1 eu by third law analysis.

Heat Capacity and Entropy

The infrared spectra of $Mg(OH)_2(c)$ were observed in the region 365-3700 cm^{-1} by C. Cabannes-Ott, Ann. Chim. (Paris) 5, 905-60 (1960). The vibrational frequencies of the gas are estimated by comparison with those for $Mg(OH)_2(c)$, $H_2O(g)$, $H_2O_2(g)$, MgO(g) and $MgF_2(g)$, and are adjusted to give reasonable agreement between the second and third law heats of reaction. The bond distances are estimated by comparison with those of $MgF_2(g)$, MgO(g) and $H_2O(g)$. The O-Mg-O angle is assumed to be 180°, while the Mg-O-H angle is assumed to be the same as that in $H_2O(g)$. The three principal moments of inertia are $I_A = 2.713 \times 10^{-40}$, $I_B = 18.6455 \times 10^{-39}$ and $I_C = 18.9168 \times 10^{-39}$ g cm^2.

Heat of Formation

The enhanced volatility of metallic molybdenum and molybdenum trioxide in the presence of water vapor at high temperatures has been investigated by several workers (1, 2, 3) using transpiration techniques. Glemser and Haeseler (1) and Buiten (2) have shown that the major volatilization reaction of the oxide is:

$$\text{A.}\quad MoO_3(c) + H_2O(g) \rightleftarrows MoO_2(OH_2)(g).$$

For the reaction of metallic molybdenum with water vapor, Belton and Jordan (3) reported the existence of $MoO_2(OH)_2(g)$ according to the equilibrium:

$$\text{B.}\quad Mo(c) + 4H_2O(g) \rightleftarrows MoO_2(OH)_2(g) + 3H_2(g).$$

Second and third law analyses of these equilibrium data are summarized below.

Investigator	Reaction	Range, °K	No. of Points	ΔHr_{298}(kcal/mol) 2nd Law	ΔHr_{298}(kcal/mol) 3rd Law	Drift gibbs/mol	*ΔHf°($MoO_2(OH)_2$) kcal/mol
Glemser and Haeseler (1)	A	873-963	Equation	36.2	31.9±0.3	-4.2	-204.0 ± 0.5
Buiten (2)	A	673-773	Equation	30.0	32.2±0.3	3.6	-203.7 ± 0.5
Belton and Jordan (3)	B	1473-1773	Equation	30.1	28.6±0.1	-0.1	-202.6 ± 0.3

* Third law values

The adopted value, ΔHf°($MoO_2(OH)_2$, g) = -203.4 ± 1.0 kcal/mol, is an average of these three results.

Heat Capacity and Entropy

The assumed tetrahedral structure for $MoO_2(OH)_2$ is from Jordan (4). The O-H bond length and H-O-Mo bond angle are assumed to be the same as for $H_2O(g)$. The Mo-O bond length is from the compilation of Sutton (5) and assumed to be the same as for Ag_2MoO_4. Individual moments of inertia are $I_A = 23.782 \times 10^{-39}$, $I_B = 25.415 \times 10^{-39}$, and $I_C = 25.478 \times 10^{-39}$ g cm^2.

The vibrational frequencies are estimated by comparison with those for $H_2SO_4(g)$ (6, 7) and are adjusted to give S°($MoO_2(OH)_2$, g) = 137.4 gibbs/mol at 1600°K. This entropy value is derived from a second law analysis of the equilibrium data for reaction B reported by Belton and Jordan (3).

Bond Distance: N-H = 1.024 Å

Bond Angle: H-N-H = 103°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = 8.5 \times 10^{-120}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation of amidogen at 298.15°K., ΔH_f° (NH_2, g) = 39.8 kcal. mole^{-1}, was obtained from the pyrolysis of N_2H_4 by J. A. Kerr, R. C. Sekhar and A. F. Trotman-Dickenson, J. Chem. Soc. 3217 (1963). They have reinvestigated the rate constants of the thermal decomposition $N_2H_4 \rightarrow 2NH_2$ at different temperatures using the same techniques as M. Szwarc, J. Chem. Phys. 17, 505 (1949), and revised the activation energy to 57.1 kcal. mole^{-1} for the reaction at 874°K. (instead of 60 kcal. mole^{-1} at 1000°K. reported by Szwarc). The activation energy was assumed to be the same as the dissociation energy of the N-N bond in hydrazine. Using all JANAF auxiliary data, one obtains D_0° (H_2N-NH_2) = 55.4 ± 3 kcal. mole^{-1} and $\Delta H^\circ_{f\ 298}$ (NH_2, g) = 40.1 ± 3 kcal. mole^{-1}.

F. M. Page, Trans Faraday Soc. 57, 1254 (1961), has measured the electron affinity of NH_2 and has applied the results to calculate the dissociation energy, D_0 (H-NH_2) = 102 ± 3 kcal. mole^{-1}. This value leads to the heat of formation $\Delta H^\circ_{f\ 298}$ (NH_2, g) = 40.4 ± 3 kcal. mole^{-1} which is in good agreement with the value selected. E. R. Lippincott and M. O. Dayhoff, Spectrochim. Acta, 16, 807 (1960) calculated theoretically the dissociation energy D_0 (H_2N-NH_2) = 59 kcal. mole^{-1} which gives $\Delta H^\circ_{f\ 298}$ (NH_2, g) = 41.9 kcal. mole^{-1}.

Heat Capacity and Entropy.

The bond distance and angle were measured from the electronic absorption spectra of NH_2 by K. Dressler and D. A. Ramsay, Phil. Trans. Roy. Soc. London Ser. A 251, 553 (1959). The three principal moments of inertia are $I_A = 0.1189 \times 10^{-39}$ g. cm.^{2}, $I_B = 0.2149 \times 10^{-39}$ g. cm.^{2} and $I_C = 0.3338 \times 10^{-39}$ g. cm.^{2}

The selected vibrational frequencies were obtained from the infrared spectrum of NH_2 by matrix isolation by D. E. Milligan and M. E. Jacox, J. Chem. Phys. 43, 4487 (1965). K. N. Tanner and R. L. King, Nature 181, 963 (1958) have also determined the vibrational frequencies ω_1 = 3200 cm.$^{-1}$ and ω_3 = 3280 cm.$^{-1}$ by flash photolysis and calculated ω_2 = 1060 cm.$^{-1}$ The symmetric and the antisymmetric stretching frequencies are in good agreement. M. Tsuboi, Spectrochim. Acta 16, 505 (1960), has observed NH_2 bending frequencies, 1572 cm.$^{-1}$, 1619 cm.$^{-1}$ and 1623 cm.$^{-1}$, in $HCONH_2$(g), $C_6H_5NH_2$(g) and CH_3NH_2(g), respectively. In light of these observations and the adopted ω_2, Tanner and King's bending frequency seems to be in error.

[3095](1)	[3205](1)
[1406](1)	[1495](1)
[1360](1)	[910](1)

Bond Distance: N-H = [1.014] Å N-N = [1.23] Å

Bond Angle: H-N-N = [100]°

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.3988] X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

The standard enthalpy of formation, $\Delta H^\circ_{f\ 298}$ (N_2H_2; g) = 50.9 kcal. mole^{-1}, was calculated from the appearance and ionization potentials of di-imide reported by S. N. Foner and R. L. Hudson, J. Chem. Phys. 29, 442 (1958), using the JANAF $\Delta H^\circ_{f\ 0}$ (N_2H_4; g) = 26.1 kcal. mole^{-1} in calculation. For example:

	$\Delta H^\circ_{r\ 0}$
$N_2H_4(g) \rightarrow N_2H_2^+ + H_2(g) + e$	11.0 ± 0.2 e.v.
$N_2H_2(g) \rightarrow N_2H_2^+ + e$	9.85 ± 0.1 e.v.
$N_2H_4(g) \rightarrow N_2H_2(g) + H_2$	1.15 ± 0.2 e.v. (26.5 ± 5 kcal. mole^{-1})

From the above heat of formation and that for NH(g) in the JANAF Tables 12-31-65, one can calculate a N-N bond energy of 109.4 ± 5 kcal. mole^{-1} at 0°K. This is in agreement with the N-N bond in molecules such as N_2F_2.

Heat Capacity and Entropy.

The bond distances and angle were obtained from a quantum-mechanical calculation by W. Wheland and P. S. K. Chen, J. Chem. Phys. 24, 67 (1956). The three principal moments of inertia are I_A = [0.3116] X 10^{-39}, I_B = [1.9686] X 10^{-39} and I_C = [2.2802] X 10^{-39} g. cm.^{2}

Since there are 12 valency electrons in N_2H_2, A. D. Walsh, J. Chem. Soc. 2288 (1953), has predicted a bent ground state, existing in either a cis or a trans configuration for diimide. E. J. Blau and B. F. Hochheimer, J. Chem. Phys. 41, 1174 (1964), have measured the infrared spectrum of diimide which was frozen in a cold trap as one of the decomposition products of N_2H_4. The spectrum of the solid N_2H_2 at liquid nitrogen temperature agrees with the predicted non-linear planar structure, and the molecule N_2H_2 appears mainly in cis form. They have also assigned six fundamental vibrational frequencies for cis N_2H_2(s) which have been adopted here for gaseous cis N_2H_2. Blau and Hochheimer also observed two gas phase bands (1277 - 1314 and 3050 - 3190 cm.$^{-1}$). K. Rosengren and G. C. Pimentel, J. Chem. Phys. 43, 507 (1965), have observed these bands in matrix isolation studies. They assigned ω_1 or ω_4 = 3074 cm.$^{-1}$ and ω_3 = 1279 cm.$^{-1}$ which are in satisfactory agreement with the selected frequencies.

Bond Distance: Na-O = [2.17] Å O-H = [0.96] Å

Bond Angle: Na-O-Na = [90°] Na-O-H = [110]° σ = 2

Products of the Moments of Inertia: $I_AI_BI_C$ = [8.156754] X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

See NaOH(g) table for details.

Heat Capacity and Entropy.

S. H. Bauer, R. H. Diner and R. F. Porter, J. Chem. Phys. 29, 991 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 31, 830 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have also postulated a model for $Li_2(OH)_2(g)$ which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the angle O-Li-O = 100°. The last one was adopted for the molecular configuration of $Na_2(OH)_2$, but the bond angle O-Na-O was modified to 90° (i.e. a square planar configuration for sodium and oxygen atoms). The bond angle Na-O-H in $Na_2(OH)_2(g)$ was assumed to be 110°. The bond distance O-H was estimated to be the same in $H_2O(g)$. The three principal moments of inertia are I_A = [14.0831] X 10^{-39}, I_B = [18.1878] X 10^{-39} and I_C = [31.8449] X 10^{-39} g. cm.^{2}

The first six selected vibrational frequencies were taken to be equal to those for $Na_2F_2(g)$ (see $Na_2F_2(g)$ table), and the rest were O-H stretching and bending frequencies which have been suggested by Berkowitz et al., loc. cit.

Heat of Formation

Taken from National Bureau of Standards Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952.

Heat Capacity and Entropy

A. S. Friedman and L. Haar, J. Chem. Phys. 22, 2051 (1954), using the infra-red spectra analysis of W. S. Benedict, H. H. Claassen and J. H. Shaw, J. Research Natl. Bur. Standards 49, 91 (1952), have calculated the thermodynamic functions for water including the anharmonic corrections. Friedman and Haar in comparing their calculation to that of a direct summation by Glatt, Adams, and Johnston, Ohio State University Res. Foundation Tech. Report No. 316-8 (1953), found that the difference between the two calculations was less than the uncertainty in the direct summation.

C_p values from 100° to 5000°K. are from Friedman and Haar. C_p from 5000° to 6000°K was extrapolated linearly. Using the tabulated functions of Friedman and Haar C_p, S, and H_T-H_0 at T = 298.15°K. was calculated by the method of Lagrangian curvilinear interpolation, W. J. Taylor, J. Research Natl. Bur. Standards 35, 151 (1945).

The bond length and angle were obtained from a compilation by L. E. Sutton, "Tables of Interatomic Distances and Configurations in Molecules and Ions," The Chem. Soc., Burlington House, London W1, 1958.

Hydrogen Peroxide (H_2O_2)

SULFURIC ACID (H_2SO_4) (LIQUID) GFW = 98.07754

$S^\circ_{298.15}$ = 37.501 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -194.548 kcal/mol

Tm = 283.53°K

ΔHm° = 2.56 kcal/mol

Tb = [608.6]°K

ΔHv° = [13.39] kcal/mol

Heat of Formation.

The heat of combustion (ΔHc°) of rhombic sulfur (c) to H_2SO_4(aq), i.e. S(c, rhombic) + 3/2 O_2(g) + H_2O(l) = $H_2SO_4(nH_2O)$, has been determined by many investigators. Based on the reported ΔHc° data, values of $\Delta Hf^\circ_{298}(H_2SO_4,l)$ are derived using heats of solution and dilution for H_2SO_4(l), taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Technical Note 270-1, Natl. Bur. Std., 1965. The results obtained are presented in the table below. The value of $\Delta Hf^\circ_{298}(H_2SO_4,l)$ is adopted as -194.548 ± 0.10 kcal/mol, which is the same as that given by Technical Note 270-1, loc. cit.

Investigator	Product	ΔHc°, kcal/mol	ΔHf°_{298}, kcal/mol
1. McCullough et al. (1953)	$H_2SO_4(70H_2O)$	-143.58 ± 0.09	-194.400
2. Scott et al. (1956)	$H_2SO_4(75H_2O)$	-143.98 ± 0.22	-194.775
3. Good et al. (1960)	$H_2SO_4(115H_2O)$	-143.85 ± 0.06	-194.521
4. Mansson and Sunner (1963)	$H_2SO_4(115H_2O)$	-143.93 ± 0.07	-194.601

2. D. W. Scott, J. P. McCullough, W. N. Hubbard, J. F. Messerly, I. A. Hossenlopp, F. R. Frow and G. Waddington, J. Am. Chem. Soc. 78, 5463 (1956).
3. W. D. Good, J. L. Lacina and J. P. McCullough, J. Am. Chem. Soc. 82, 5589 (1960).
4. M. Mansson and S. Sunner, Acta Chem. Scand. 17, 723 (1963).

Heat Capacity and Entropy.

The heat capacities, 283.46 to 300°K, were measured by W. F. Giauque, E. W. Hornung, J. E. Kunzler, and T. R. Rubin, J. Am. Chem. Soc. 82, 62 (1960). The Cp values above 300°C are obtained from graphical extrapolation. The value of S°_{298} was reported by Giauque, Hornung, Kunzler and Rubin, loc. cit., based on low temperature heat capacity measurements of H_2SO_4(c).

Melting Data.

Tm and ΔHm° are taken from T. R. Rubin and W. F. Giauque, J. Am. Chem. Soc. 74, 800 (1952). The value, Tm=283.53°K, has been reported by C. M. Gable, H. F. Betz and S. H. Maron, J. Am. Chem. Soc. 72, 1445 (1950), as well as J. E. Kunzler and W. F. Giauque, J. Am. Chem. Soc. 74, 797 (1952). The heat of melting (ΔHm°) has also been determined by the following investigators:

Hm° kcal/mol	Source
2.35	Pickering, Proc. Roy. Soc. (London) 49, 11 (1891).
2.25	Hantzsch, Z. Physik, Chem. 61, 262 (1907).
2.24	Knietsch, quoted by Hantsch, loc. cit.
2.55	Brönsted, Z. Physik, Chem. 68, 693 (1910).
2.56	Rubin and Giauque, J. Am. Chem. Soc. 74, 800 (1952).

Vaporization Data.

Tb is the temperature at which the Gibbs energy change (ΔGr°) for the reaction H_2SO_4(l) = H_2SO_4(g) approaches zero. The difference between ΔHf° for H_2SO_4(g) and H_2SO_4(l) at Tb is ΔHv°.

According to G. P. Luchinskii, Zh. Fiz. Khim. 30, 1207 (1956), the total vapor pressure over H_2SO_4(l) reaches one atmosphere at 553°K with a vapor composition of 76.6 mole percent SO_3, 22.6% H_2SO_4, and 0.8% H_2O. This composition implies that the real liquid phase enhances the vapor decomposition by reducing the partial pressure of water vapor.

Product of the Moments of Inertia: $I_AI_BI_C$ = [4.237×10^{-144}] g^3cm^6

Heat of Formation.

The vapor phase equilibria of the H_2SO_4, H_2O and SO_3 system have been studied by (1) B. Bodenstein and M. Katayama, Z. Elektrochem. 15, 244 (1909), Z. Physik. Chem. 69, 26 (1909); (2) G. P. Luchinskii, Zh. Fiz. Khim. 30, 1207 (1956), and (3) A. V. Suvorov, R. B. Dobrotin and S. M. Gadzhiev, Russ. J. Inorg. Chem. (English Transl.) 10, 710 (1965). The data of Bodenstein and Katayama and of Suvorov et al. were obtained from PVT studies, while those of Luchinskii were based on vapor pressure measurements. A translation of Luchinskii's paper is not yet available, so it is not known whether he obtained the vapor composition experimentally or by calculation. Using the reported equilibrium values for the reaction $H_2SO_4(g) = H_2O(g) + SO_3(g)$, we evaluate the corresponding enthalpy changes by both the second and third law methods. The results are presented in the table below. The value of $Hf°_{298}$ for $H_2SO_4(g)$ is adopted as -177 ± 2 kcal/mol.

	Investigator	Temp., °K	No. of Points	$\Delta Hr°_{298}$, kcal/mol Second Law	Third Law	Drift eu	$\Delta Hf°_{298}$ kcal/mol*
1.	Bodenstein & Katayama (1909)	596.2-756.2	53	-22.95 ± 0.66	-24.55	-2.3 ± 1.0	-176.94

*Calculation based on the third law $\Delta Hr°_{298}$ value.

Heat Capacity and Entropy.

The molecular structure and bond angles (O-S-O, HO-S-OH) are estimated by comparison with those for $SF_2O_2(g)$ reported by D. R. Lide, D. E. Mann and R. M. Fristrom, J. Chem. Phys. 26, 734 (1957). The S-O and S-OH bond distances are assumed to be the same as those in $H_2SO_4(c)$, determined by R. Pascard, Compt. Rend. 240, 2162 (1955). The OH distance and S-O-H angle are taken from those for $H_2O(g)$. Electric deflection studies by A. Büchler, J. L. Stauffer and W. Klemperer, J. Chem. Phys. 46, 605 (1967), indicate that $H_2SO_4(g)$ is polar, which is consistent with the assumed C_{2v} structure.

The infrared absorption spectrum in the range 4000 to 400 cm^{-1} of normal and deuterated $H_2SO_4(g)$ above $H_2SO_4(l)$ was observed by S. M. Chackalackal and F. E. Stafford, J. Am. Chem. Soc. 88, 723 (1966). The authors assigned nine vibrational frequencies, which are adopted here. The three principal moments of inertia are: $I_A = 1.570 \times 10^{-38}$, $I_B = 1.586 \times 10^{-38}$, and $I_C = 1.702 \times 10^{-38}$ g cm^2.

Four of the six missing frequencies are obtained from P. A. Giguère and R. Savoie, J. Am. Chem. Soc. 85, 287 (1963), which were estimated by comparison with infrared frequencies for the crystal and Raman values for the liquid. The remaining two frequencies, ν_7 = 450 and ν_{14} = 450 cm^{-1}, are assigned arbitrarily so that the second and third law values for $\Delta Hr°_{298.15}$ derived from equilibrium data are in reasonable agreement.

TUNGSTIC ACID (H_2WO_4) (CRYSTAL) GFW = 249.86354

$S^\circ_{298.15}$ = [34.6 ± 6] gibbs/mol

Td = [393]°K

ΔHf°_0 = Unknown

$\Delta Hf^\circ_{298.15}$ = -270.5 ± 0.4 kcal/mol

Heat of Formation

V. I. Spitsyn and N. N. Patsukova[1] have measured calorimetrically the heats of reaction (1) and (2) at 298°K as -13.80 ± 0.01 and -13.05 ± 0.02 kcal/mol, respectively. The reactions are given as follows:

(1) $WO_3(c) + 2\ NaOH(66H_2O) \rightarrow Na_2WO_4(4200\ H_2O) + H_2O(l)$

(2) $H_2WO_4(c) + 2\ NaOH(66H_2O) \rightarrow Na_2WO_4(4200\ H_2O) + 2\ H_2O(l)$

Combination of reactions(1) and (2) gives ΔHr°_{298} = -0.75 ± 0.04 kcal/mol for $WO_3(c) + H_2O(l) \rightarrow H_2WO_4(c)$, which leads to $\Delta Hf^\circ_{298}(H_2WO_4, c)$ = -270.5 ± 0.4 kcal/mol.

To obtain $WO_3(c)$ in a form soluble in the calorimetric solution, Spitsyn and Patsukova dehydrated $H_2WO_4(c)$ at the relatively low temperature of 250°C. The resulting $WO_3(c)$ was a very fine lemon-yellow powder which may have excess surface free energy compared with the JANAF standard state. The latter is WO_3 formed at high temperature in a calorimetric bomb. The actual heat of formation of tungstic acid should be less negative if this effect is significant.

The previously accepted value[2,3,4], -280.2 ± 0.4 kcal/mol, was based on the pressure-temperature-composition studies of G. F. Huttig and B. Kurre[5] for the WO_3-H_2O system. We suspect that the data do not correspond to equilibrium (see entropy section) for the reaction $H_2WO_4(c) = WO_3(c) + H_2O(g)$.

Heat Capacity and Entropy

Cp_{300} = 27.0 gibbs/mol is estimated using Kopp's rule. Since the decomposition temperature of $H_2WO_4(c)$ is approximately 400°K, which is relatively low for hydrogen and oxygen to reach their maximum Cp contribution, we estimate Cp_{400} = 31.0 gibbs/mol for $H_2WO_4(c)$.

The entropy, S°_{298} = 34.6 eu, is estimated so that the decomposition pressure of water is one atmosphere at 120°C. This value is quite uncertain as suggested by comparison with the following estimates. A lower limit may be obtained from $S^\circ_{283.5}$ = 26.8 eu for $H_2SO_4(c)$. Summation of the entropies for $WO_3(c)$ and $H_2O(c)$ [10.7 eu] yields 28.8 eu, an estimate which is somewhat larger than the lower limit. An upper limit may be obtained by assuming that the pressure of about 14 mm at 190°C corresponds to equilibrium for the reaction $H_2WO_4(c) = WO_3(c) + H_2O(g)$. This pressure, based on the plateau in the temperature-composition data of Huttig and Kurre[5], yields S°_{298} = 46.5 eu when combined with the adopted ΔHf°_{298} and JANAF auxiliary data. Since the estimate appears to be unreasonably large, we suggest that this region of the curve may correspond to the reaction $WO_3 \cdot 0.5\ H_2O(c) = WO_3(c) + 0.5\ H_2O(g)$. In contrast, the observed pressures[5] for samples having mole ratios (H_2O/WO_3) of 1.2 - 1.35 leads to S°_{298} = 34 eu, if the reaction is $WO_3 \cdot H_2O(c) = WO_3(c) + H_2O(g)$.

Temperature of Decomposition

Td is calculated as the temperature at which the Gibbs energy change of the reaction $H_2WO_4(c) \rightarrow WO_3(c) + H_2O(g)$ approaches zero.

Spitsyn and Patsukova[1] observed that some dehydration of stoichiometric $H_2WO_4(c)$ occurs at temperatures as low as 90°C. Thermal studies[6,7] on tungstic acid containing some excess water indicated the start of dehydration somewhere in the region of 60 - 120°C. These temperatures yield a lower limit for Td on the presumption that the experiments correspond to a partial pressure of water of less than one atmosphere.

Bond Distance: W-O = [1.81] Å O-H = [0.97] Å

Bond Angle: O-W-O = [109.47]° W-O-H = [105]° σ = [2]

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.443×10^{-113}] g^3 cm^6

Heat of Formation.

The adopted heat of formation, $\Delta Hf°_{298}$ = -216.5 ± 1.0 kcal/mol, is derived from equilibrium data[1,2,3,4,5] obtained by the transpiration method. The data are in reasonable agreement and they are summarized below. Belton and McCarron[1] have concluded that $WO_3 \cdot H_2O$ is the species responsible for the increased volatilization of W(c) and WO_3(c) in the presence of water vapor. Based on their data for W(c) and the earlier data for WO_3(c), Belton and McCarron[1] ruled out the possibility of significant amounts of $(WO_3)_2 \cdot H_2O$ and $WO_3 \cdot 2\ H_2O$.

Investigator	Reaction*	Temp.(°K)	No. of Points	$\Delta Hr°_{298}$(kcal/mol) 2nd law	3rd law	Drift (eu)	$\Delta Hf°_{298}$** (kcal/mol)
Belton & McCarron[1]	A	1473-1773	Equation	14.70	14.63	-0.1±1.1	-216.56
Glemser & Ackermann[2]	B	673-1173	6	38.56	41.67	3.2±0.9	-217.59
Glemser & Haeseler[3]	B	1173-1373	Equation	38.27	42.27	1.6	-216.99

Heat Capacity and Entropy.

The vibrational frequencies are estimated by comparison with those for H_2SO_4(g) reported by P. A. Giguere and R. Savoie, J. Am. Chem. Soc. 85, 287 (1963), and S. M. Chackalackal and F. E. Stafford, J. Am. Chem. Soc. 88, 723 (1966). These frequencies are also adjusted so that $S°_{1600}(H_2WO_4,g)$ is 136.7 eu as reported by Belton and McCarron, loc. cit. This entropy was derived from second law analysis of the equilibrium constants for reaction A.

The configuration of $WO_4^{=}$ group is assumed to be tetrahedral. The bond angle W-O-H is estimated to be the same as the angle of H_2O(g). The bond distances are assumed to be the same as those in WO_3(g) and H_2O(g). The three principal moments of inertia are $I_A = 2.328 \times 10^{-38}$, $I_B = 2.487 \times 10^{-38}$ and $I_C = 2.493 \times 10^{-38}$ g cm^2.

PHOSPHORUS HYDRIDE (PH_2) (IDEAL GAS) MOL. WT. = 32.991

Point Group [C_{2v}]

$S^\circ_{298.15}$ = [50.8] cal. deg.$^{-1}$ mole^{-1}

Ground State Multiplicity = [2]

$\Delta H^\circ_{f\ 0}$ = [30.6 ± 23] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [30.1 ± 23] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[2327] (1)
[1020] (1)
[2322] (1)

Bond Distance: P-H = [1.419] Å

Bond Angle: H-P-H = [93.7]°

σ = 2

Product of Moments of Inertia: $I_A I_B I_C$ = [6.95 X 10^{-119}] g.^{3} cm.^{6}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ was estimated by V. N. DiStefano, R. L. Potter, and S. N. Fox, "The Thermodynamic Functions of Some Combustion Products Containing Phosphorus-I.", American Cyanamid Company. The $\Delta H^\circ_{f\ 298.15}$ was estimated by taking 63% of the dissociation energy of PH_3 and using it as the dissociation energy of PH_2. D. Willes and C. Winkler, J. Phys. Chem. 61, 902 (1957) have estimated the $\Delta H^\circ_{f\ 298.15}$ for $PH_2(g)$ to be 30 kcal. mole^{-1}.

Heat Capacity and Entropy.

The vibrational spectra of PH_2 from the flash photolysis of PH_3 has been reported by D. A. Ramsey, Nature 178, 375 (1956) and in N. Y. Acad. Sci. 67, 485, (1957). Similarities between the spectra of NH_2 and PH_2 were found. For NH_2 and NH_3 bond angles and bond distances were reported to be about the same. By analogy then the bond angles and bond distances of PH_2 and PH_3 should be nearly the same. The moments of inertia for PH_2 were therefore calculated from the molecular constants for PH_3. The principal moments were found to be I_A = 3.587 X 10^{-40} g. cm.^{3}, I_B = 2.959 X 10^{-40} g. cm.^{3}, and I_C = 6.546 g. cm.^{3} X 10^{-40}.

DiStefano and Potter (loc. cit.) have assumed the ground state degeneracy to be 2, because of the unpaired electron. The vibrational frequencies reported by DiStefano and Potter (loc. cit.) have been used. They used a simple force field and the force constants of PH_3 to obtain the vibrational frequencies.

Moments of Inertia: $I_AI_BI_C = 4.69 \times 10^{-119}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation of hydrogen sulfide has been calorimetrically measured by H. Zeumer and W. A. Roth, Z. Elektrochem. 40, 777 (1934), and A. F. Kapustinskii and R. T. Kankovskii, Zhur. Fiz. Khim. 32, 2810 (1958), as $\Delta H^\circ_{f\ 293} = -4.80 \pm 0.15$ kcal. mole^{-1} and $\Delta H^\circ_{f\ 298} = -4.94 \pm 0.08$ kcal. mole^{-1}, respectively. A weighted average of these two values was taken for the standard enthalpy of formation of hydrogen sulfide.

Heat Capacity and Entropy.

The bond distance, angle and vibrational frequencies were obtained from H. C. Allen, Jr. and E. K. Plyler, J. Chem. Phys. 25, 1132 (1956).

J. S. Gordon, private communication, Feb. 7, 1961,has calculated C_p from 298 to 6000°K. by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes second order corrections for vibrational anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The correction constants were obtained from Allen and Plyler, loc. cit. Below 298°K. the rigid-rotator harmonic oscillator method was used to calculate the functions, but at 298°K. and above Gordon's thermodynamic functions were adopted in this tabulation.

TITANIUM DIHYDRIDE (TiH_2) (CRYSTAL) MOL. WT. = 49.916

$\Delta H^\circ_{f\ 0}$ = [-32.5 ± 2.0] kcal. mole^{-1}

$S^\circ_{298.15}$ = 7.101 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-34.5 ± 2.0] kcal. mole^{-1}

Heat of Formation.

The heat of combustion of $TiH_{1.73}$(c), the stable species of titanium hydride, was reported to be -247.8 kcal. by A. Sieverts and A. Gotta, Z. anorg. allgem. Chem. 199, 384 (1931). From this data the value of $\Delta H^\circ_{f\ 298.15}$ for $TiH_{1.73}$(c) was calculated to be -29.40 kcal. mole^{-1}. The heat of dissociation of titanium hydride having compositions between the rough limits $TiH_{1.75}$-$TiH_{1.93}$ was given as 19.15 kcal. per mole of H_2 dissociated by T. R. P. Gibb, Jr., J. J. McSharry, and R. W. Bragdon, J. Am. Chem. Soc. 73, 1751 (1951). Assuming this value is applicable to compositions between the limits $TiH_{1.73}$-TiH_2, the difference in the heat of formation of titanium hydride between $TiH_{1.73}$ and TiH_2 was estimated to be -5.17 kcal. mole^{-1}. Thus the value of $\Delta H^\circ_{f\ 298.15}$ for TiH_2(c) was calculated.

Heat Capacity and Entropy.

The low temperature C_p for $TiH_{1.97}$(c), 24-363°K., were measured by B. Stalinski and Z. Bieganski, Bull. Acad. Polon. Sci., Ser. Sci. Chim., 8, No. 5, 243 (1960). This data were adopted for TiH_2(c) due to lack of the measured C_p values. A small but well marked λ-type anomaly with a maximal value of C_p at 288.5°K. in the C_p vs. T curve was observed. $S^\circ_{298.15}$ was reported by B. Stalinski and Z. Bieganski, loc. cit., based on S°_{25}(extrap.) = 0.065 cal. deg.$^{-1}$ mole^{-1}.

Heat of Formation.

A weighted average based on analysis using JANAF functions was selected. Haber, Tamaru and Oeholm, Z. Elektrochem. 21, 206 (1915) obtained ΔH_{298} = 11.10 for $NH_3 \rightarrow 0.5\ N_2 + 1.5\ H_2$ by flow calorimetry. Estimated uncertainty is 1% and the formation value was corrected by 0.025 kcal. for non-ideality of NH_3. Becker and Roth, ibid. 40, 836 (1934) measured ΔH_N [$NH_3(g) + H_2C_2O_4(aq)$], ΔH_C [hydrates of $H_2C_2O_4$ and $(NH_4)_2C_2O_4$], and the necessary ΔH_{Soln} leading to ΔH°_{298} = 182.9 ± 0.24 for $3H_2O(l) + N_2(g) \rightarrow 1.5\ O_2(g) + 2NH_3(g)$. Equilibrium data from Larson and Dodge, J. Am. Chem. Soc. 45, 2918 (1923) and Haber, Tamaru and Ponnaz, Z. Elektrochem. 21, 89 (1915) were analyzed as tabulated by Stephenson and McMahon, J. Am. Chem. Soc. 61, 437 (1939) from the non-ideality corrections of Gillespie and Beattie, Phys. Rev. 36, 743 (1930). Data (1000-3000 atm) from Winchester and Dodge, A.I.Ch.E. Journal 2, 431-6 (1956) were omitted because of uncertainty in non-ideality while data (1 atm) of Haber and Maschke, Z. Elektrochem. 21, 128 (1915) were assumed ideal. High-temperature calorimetry of the direct decomposition includes Haber and Tamaru, Z. Elektrochem. 21, 191 (1915) and Wittig and Schmatz, ibid. 63, 470 (1959).

*Third law values for equilibrium data are followed by second law values in parentheses.

Heat Capacity and Entropy.

The functions are an approximation of the non-rigid rotator anharmonic oscillator based on calculations of Harrison and Kobe, Chem. Eng. Progr. 49, No. 7, 349 (1953) and Yungman, Gurvich and Rtischeva, Trudy Gosudarst. Inst. Priklad. Khim. 49, 20 (1962). In these calculations anharmonicity of ν_2 associated with inversion doubling was treated by summation over the energy levels. Both calculations include rotational distortion corrections while Yungman, et al., also allow for anharmonicity and vibration-rotation interaction of the other fundamentals. JANAF functions agree with the results to within 0.02 e.u. in the range 298-1500°K.

Two sets of rigid rotator harmonic oscillator functions were also tested for consistency with the ammonia data (see below). These were obtained from molecular dimensions and either calculated zero order frequencies (ω) or observed wave numbers (ν) obtained by Benedict and Plyler, Can. J. Phys. 35, 1235 (1957) from high resolution infrared studies. Herzberg, "Infrared and Raman Spectra", pp. 503-4, 1945 states that ν should be used and the RRHOν functions give better, but not perfect, agreement with the observed C_p° for NH_3. Principal moments of inertia are I_A = 4.414 X 10^{-40} and $I_B = I_C$ = 2.809 X 10^{-40} g. cm.^{3} Electron diffraction studies by Bastiansen and Beagley, Acta Chem. Scand. 18, 2077 (1964) give slightly different constants (bond distance 1.019 Å and angle = 109.1°).

(a) N. S. Osborne, H. F. Stimson, T. S. Sligh, Jr., and C. S. Cragoe, NBS Sci. Papers 20, 65 (1924-6) measured C_p of gaseous NH_3 (258 to 423°K and 0.5 to 20 atm) within an estimated maximum error of 0.3% (about 0.03 cal. deg.$^{-1}$ mole^{-1}) and obtained C_p° by use of a suitable equation of state.

(b) R. Overstreet and W. F. Giauque, J. Am. Chem. Soc. 59, 254 (1937) determined the entropy of the real gas at the normal boiling point as $S_{239.72}$ = 44.06 ± 0.10 cal. deg.$^{-1}$ mole^{-1}.

(c) $(S^\circ-S)_{239.72}$ = 0.17 cal. deg.$^{-1}$ mole^{-1} from the virial coefficient equation derived by Hirschfelder, McClure and Weeks, J. Chem. Phys. 10, 201 (1942) from the PVT data of Meyers and Jessup, Refrig. Eng. 11, 345 (1925).

(d) Combination of $\Delta H^\circ_{f\ 800}$ = -12.83 kcal. mole^{-1} from the calorimetric measurement of F. E. Wittig and W. Schmatz, Z. Elektrochem. 63, 470 (1959) with ΔG°_{800} = 9.315 kcal. mole^{-1} from equilibrium data (f).

(e) Σ second law analysis of the equilibrium data (f).

(f) K_p° values based on the equilibrium data of Haber, Tamaru and Ponnaz and of Larson and Dodge were analyzed by regression analysis to give ΔG°_{800} = 9.315 ± 0.004, ΔH°_{800} = -12.666 ± 0.017 and $\Delta C^\circ_{p\ 800}$ = -2.31 ± 0.20.

Bond Angle: H-O-H = [109]°

σ = 3

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.39] X 10^{-119} g^3 cm^6

Heat of Formation.

The proton affinity of water has been measured by the ion impact method as -169 kcal/mol by V. L. Tal'rose and E. L. Frankevitch, Doklady Akad. Nauk SSSR 111, 376 (1956), J. Am. Chem. Soc. 80, 2344 (1958). The selected heat of formation of hydronium ion, $\Delta Hf^\circ_0(H_3O^+, g)$ = 139.1 kcal/mol, was derived from the ΔHr°_0 = -169 kcal/mol for $H_2O(g) + H^+(g) \rightarrow H_3O^+(g)$, using the JANAF ΔHf°_0 (H_2O, g) = -57.1 and ΔHf°_0 (H^+, g) = 365.2 kcal/mol.

The values of 195 and 207 kcal/mol for the heat of formation of $H_3O^+(g)$ have also been reported by F. M. Field and J. L. Franklin, "Electron Impact Phenomena," Academic Press, New York, 1957, and R. R. Bernecker and F. A. Long, J. Phys. Chem. 65, 1565 (1961), respectively. These two values were based on the electron impact studies which may involve unaccounted excitations and excess energy in the fragments. Other literature values have been reviewed by D. M. Bishop, J. Chem. Phys. 43, 4453 (1965).

J. A. Green and T. M. Sugden, Ninth Symposium (International) on Combustion, Academic Press, New York, 1963, based on the studies of the positive ions in flames by mass spectrometry, prefer the value derived from the proton affinity of water obtained by Tal'rose and Frankevitch, rather than the electron impact data. From the approximate equilibrium constant calculations for the reaction $HCO^+(g) + H_2O(g) \rightleftarrows H_3O^+(g) + CO(g)$, D. G. Clifton, AD444078, G. M. Defense Research Laboratory, General Motors Corp., Santa Barbara, Calif., July 1964, has also found that the heat of formation of $H_3O^+(g)$ derived from the proton affinity of water, not from the electron impact data, leads to agreement with the experimental data given by Green and Sugden.

Heat Capacity and Entropy.

Since the molecule $H_3O^+(g)$ has the same number of valence electrons as $NH_3(g)$, a pyramidal molecular configuration (C_{3v}) is assumed for $H_3O^+(g)$ in the tabulation. D. G. Clifton, J. Chem. Phys. 41, 3656 (1964), has obtained a bond distance O-H of 0.95 Å from an application of covalent bond radii and the effect of electric charge, and a bond angle H-O-H of 109° by extrapolating a plot of bond length versus bond angle for $NH_3(g)$ and $PH_3(g)$ to 0.95 Å. Both values are adopted in the tabulation. The three principal moments of inertia are I_A = 0.4004 X 10^{-39}, I_B = I_C = 0.2445 X 10^{-39} g cm^2. D. M. Bishop, loc. cit., has calculated theoretically the bond distance H-O of 0.95 Å and the bond angle H-O-H of 114° 26' with a planar D_{3h} molecular configuration. The vibrational frequencies were calculated by the valence force method from the estimated stretching and bending force constants of Clifton.

$T_m = 315.51$°K

$\Delta H_f^\circ{}_{298.15} = -301.5 \pm 0.3$ kcal. mole^{-1}

$S^\circ_{298.15} = 26.42$ cal. deg.$^{-1}$ mole^{-1}

Heat of Formation.

The heat of formation was determined by W. S. Holmes [private communication July 5, 1962, Albright and Wilson (MFG) Ltd., Oldbury, Birmingham, Great Britain (in press by Faraday Society)]. W. S. Holmes measured the enthalpy of combustion of white phosphorus (α form) in oxygen in a bomb calorimeter. The product, P_4O_{10}(hexagonal), was hydrolyzed in 10N perchloric acid to give H_3PO_4. Measurement of the enthalpy of solution of $H_3PO_4(c)$ then enabled the $\Delta H_f^\circ{}_{298.15}$ to be calculated according to the following cycle:

$$\begin{tikzcd}
4P_{(\alpha)} + 5O_2(g) \arrow[r, "\Delta H_r^*"] & P_4O_{10}(\text{hexagonal}) + 6H_2O(HClO_4) \arrow[r, "\Delta H_r^*"] & 4H_3PO_4(HClO_4) \\
6H_2O \arrow[r, "\Delta H_f\ \text{N.B.S. Cir 500}"] & 6H_2O(l) \arrow[u, "\Delta H_r^*"] & 4H_3PO_4(c) \arrow[u, "\Delta H_r^*"]
\end{tikzcd}$$

* All ΔH_r's were measured.

E. P. Egan, Jr. and B. B. Luff, J. Phys. Chem., 65, 523 (1961), from partial molal heat contents of H_3PO_4 solutions found that a smooth extrapolation to 100% H_3PO_4 would give them a $\Delta H_f^\circ{}_{298.15}$ for H_3PO_4 (c) which was 755 cal. mole^{-1} greater than the $\Delta H_f^\circ{}_{298.15}$ reported in the National Bureau of Standards Circular 500. The Circular 500 (loc. cit.) heat of formation refers to the work of Thomsen, "Thermochemische Untersuchungen," Vol. 2, Barth, Leipzig (1882-1886). The heats of formation summarized:

$\Delta H_f^\circ{}_{298.15}$	Source
-305.7 ± 0.3 kcal. mole^{-1}	W. S. Holmes (loc. cit.)
-306.2 kcal. mole^{-1}	Circular 500 (loc. cit.)
-305.4 kcal. mole^{-1}	Egan and Luff (loc. cit.)

The selected $\Delta H_f^\circ{}_{298.15}$, -305.7 ± 0.3 kcal. mole^{-1}, was corrected by +4.17 kcal. mole^{-1}, which is the $\Delta H_f^\circ{}_{298.15}$ of white (α) phosphorus.

Heat Capacity and Entropy.

Third law entropy was calculated from the low temperature heat capacities measured by E. P. Egan, Jr. and Z. T. Wakefield, J. Phys. Chem. 61, 1500 (1957).

Melting.

The heat of fusion, ΔH_m, was reported by E. P. Egan, Jr. and B. B. Luff, J. Phys. Chem. 65, 523 (1961) from ΔH_m data measured by E. P. Egan, Jr. and Z. T. Wakefield, J. Phys. Chem. 61, 1500 (1957). The melting point T_m = 315.51°K was taken from the work of W. H. Ross and R. M. Jones, J. Am. Chem. Soc. 47, 2165 (1925).

Orthophosphoric Acid (H_3PO_4) (Liquid)

Mol. Wt. = 97.999

ΔH_f° 298.15 = -298.81 ± 0.5 kcal. mole^{-1}

$S^\circ_{298.15}$ = 35.0 cal. deg.$^{-1}$ mole^{-1}

T_m = 315.51°K

ΔH_m = 3.100 kcal. mole^{-1}

Heat of Formation. Calculated from ΔH_f° 298.15 for H_3PO_4(c) and ΔH_m° given by E. P. Egan, Jr., and B. B. Luff, J. Phys. Chem. 65, 523 (1961) using the ΔH_m data reported by E. P. Egan, Jr., and Z. T. Wakefield, J. Phys. Chem. 61, 1500 (1957).

Heat Capacity and Entropy. The heat capacity is estimated. The entropy at 298.15°K. is calculated using $S^\circ_{298.15}$ of H_3PO_4(c) and the ΔH_m at 298.15°K.

Melting Data. T_m reported by W. H. Ross and R. M. Jones, J. Am. Chem. Soc. 47, 2165 (1925). ΔH_m from E. P. Egan, Jr., and Z. T. Wakefield (loc. cit.).

Heat of Formation

The heat of formation was derived by S. R. Gunn and L. G. Green, J. Phys. Chem., 65, 779 (1961). In order to obtain the $\Delta H^\circ_{f\ 298.15}$ they measured the heat of explosive decomposition of phosphine gas. There is a good deal of uncertainty about the heat of formation of $PH_3(g)$, for instance:

$\Delta H^\circ_{f\ 298.15}$	Source
+3.6 kcal mole⁻¹	The heat of reaction between gaseous PH_3 and saturated bromine water. M. J. Ogier, Ann. Chim. Phys., 20, 5 (1880).
+6.3 kcal mole⁻¹	The heat of combustion of $PH_3(g)$ in $O_2(g)$ to form H_3PO_4. M. P. Lemoult, Compt. Rend., 145, 374 (1907).
-2.34 kcal mole⁻¹	Equilibrium data of W. N. Ipatiew, and A. W. Frost, Ber. dtsch. chem. Ges., 63B, 1104 (1930). Their data showed a wide variation in ΔH, as much as 11 kcal mole⁻¹.
+1.5 kcal mole⁻¹	National Bureau of Standards, Report No. 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," 1 January 1962 (page 80-91).

The heats of formation have been reviewed by T. L. Cottrell, "The Strength of Chemical Bonds," Butterworth's Scientific Publications, London, (1958); and by F. R. Bichowsky and F. D. Rossini, "The Thermochemistry of The Chemical Substances," Reinhold Publishing Corp., New York (1936).

The heat of formation selected was, +1.3 ± 0.4 kcal mole⁻¹, as reported by Gunn and Green (loc. cit.). The selected heat of formation was based on white (α) phosphorus and thus required an adjustment for the red (V) phosphorus reference state.

Heat Capacity and Entropy

The fundamental wave number and degeneracy assignments are from the infrared spectral data by V. N. McConaghie and H. H. Nielsen, J. Chem. Phys., 21, 1836, (1953). The molecular constants are those obtained from infrared data by H. H. Nielsen, J. Chem. Phys., 20, 759 (1952). Nielsen (loc. cit.) has reported the molecular constants after calculating the Coriolis coupling effect between the wave numbers 2 and 4, or (992 cm⁻¹) and (1122.4 cm⁻¹).

HYDRAZINE (N_2H_4) (LIQUID) MOL. WT. = 32.04528

$S_{298.15}$ = 29.05 ± 0.1 cal. deg.$^{-1}$ mole^{-1}

T_m = 274.69°K.

T_b = 386.9°K.

$\Delta H^\circ_{f\ 298.15}$ = 12.10 ± 0.1 kcal. mole^{-1}

ΔH°_m = 3.025 kcal. mole^{-1}

ΔH°_v = 9.70 kcal. mole^{-1}

Heat of Formation.

A. M. Hughes, R. J. Corruccini and E. C. Gilbert, J. Am. Chem. Soc. 61, 2639 (1939), measured the heats of combustion of hydrazine and hydrazine monohydrate. The data, adjusted as suggested by L. G. Cole and E. C. Gilbert, J. Am. Chem. Soc. 73, 5423 (1951), are summarized below. Heats of solution determined by V. C. Bushnell, A. M. Hughes and E. C. Gilbert, J. Am. Chem. Soc. 59, 2142 (1937) interrelate $N_2H_4(l)$ and $N_2H_4 \cdot H_2O(l)$. An intermediate value was selected from the resulting heats of formation.

Source	Reaction	$\Delta H^\circ_{r\ 298}$	$\Delta H^\circ_{f\ 298}$
Hughes	$N_2H_4(l) + O_2(g) \rightarrow N_2(g) + 2H_2O(l)$	-148.68 ± 0.06	12.05
Hughes	$N_2H_4 \cdot H_2O(l) + O_2(g) \rightarrow N_2(g) + 3H_2O(l)$	-147.00 ± 0.06	——
Bushnell	$N_2H_4(l) + H_2O(l) \rightarrow N_2H_4 \cdot H_2O(l)$	-1.80	12.17*

*From combination of second and third reactions.

Heat Capacity and Entropy.

Heat capacities (12-340°K) of hydrazine crystal and liquid were determined by D. W. Scott, G. D. Oliver, M. E. Gross, W. N. Hubbard and H. M. Huffman, J. Am. Chem. Soc. 71, 2293 (1949). Values beyond the experimental range for the liquid were extrapolated linearly. The entropy was obtained from the heat of melting and the smoothed heat capacities of the crystal using S°_{12} = 0.023 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

Taken from Scott et al., loc. cit.

Vaporization Data.

The normal boiling point and heat of vaporization are those calculated for the ideal gas from these tables. The boiling point found for the real gas (387.3°K) by W. Hieber and A. Woerner, Z. Elektrochem. 40, 252 (1934) is in good agreement. The selected heat of vaporization, ΔH°_{298} = 10.69 kcal. mole^{-1}, is based on the vapor pressure data of Scott et al., loc. cit., series III. Vapor pressure measurements of Hieber and Woerner, loc. cit., and E. T. Chang and N. A. Gokcen, AD-458288, Defense Documentation Center, January, 1964, are in satisfactory agreement as shown below.

Source	Temp. Range °K.	$\Delta H^\circ_{v\ 298}$(kcal. mole^{-1}) 2nd Law	3rd Law	3rd Law Drift e.u.
Scott, et al. (1949)	273-343	10.683 ± 0.003	10.696	0.05 ± 0.01
Chang, Gockcen (1964)	276-325	10.40 ± 0.03	10.68	0.91 ± 0.09
Hieber, Woerner (1934)	293-387	10.82 ± 0.03	10.71	-0.33 ± 0.07

The second law-third law consistency of Scott et al. reflects the use of these data in selection of the gas phase functions (see H_4N_2 gas).

Torsional angle between two NH_2 groups ⩾ 90° from eclipsed position.

Product of the Moments of Inertia: $I_AI_BI_C$ = 7.307 X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

This was obtained from the heat of formation of the liquid and the selected heat of vaporization, ΔH°_{298} = 10.69 kcal. mole^{-1}, derived from the vapor pressure data (Series III) of D. W. Scott, G. D. Oliver, M. E. Gross, W. N. Hubbard and H. M. Huffman, J. Am. Chem. Soc. 71, 2293 (1949). Other vapor pressure data from W. Hieber and A. Woerner, Z. Elektrochem. 40, 252 (1934) and E. T. Chang and N. A. Gokcen, AD-458288, Defense Documentation Center, January, 1964, are in satisfactory agreement (see N_2H_4 liquid table).

Heat Capacity and Entropy.

Functions were calculated from the constants given above using the rigid rotator harmonic oscillator method. The entropy was increased by R ln 2 because two rotameric forms are implied by use of the torsional frequency. Small but arbitrary adjustments were made in the assignment of the bending mode frequencies in order to reproduce the vapor pressure data of Scott et al., loc. cit., as closely as possible. Calculated values of S°_{298} = 57.03 and S°_{340} = 58.70 cal. deg.$^{-1}$ mole^{-1} may be compared with 56.99 and 58.69, respectively, derived from the data of Scott et al.. Internal rotation calculations would require a complex potential function in order to fit the data. The barrier to inversion (990 cm.$^{-1}$ ~ 2.8 kcal.) is slightly less than the barrier to internal rotation at the trans position (1110 cm.$^{-1}$ ~ 3.2 kcal.) according to analyses of the microwave data by T. Kasuya, Sci. Papers. Inst. Phys. Chem. Res. (Tokyo) 56, No. 1, 1-39 (1962) and T. Kasuya and T. Kojima, J. Phys. Soc. Japan 18, 364-8 (1963).

From matrix isolation and gas phase infrared studies, E. Catalano, R. H. Sanborn and J. W. Frazer, J. Chem. Phys. 38, 2265 (1963), have suggested possible uncertainties in the assignment of the bending mode frequencies in the region from 1630 to 740 cm.$^{-1}$ The question hinges on the uncertain existence of a gas phase fundamental at about 1600 cm.$^{-1}$ as observed by P. A. Giguere and I. D. Liu, J. Chem. Phys. 20, 136 (1952). No corresponding matrix band was found and the gas phase band appeared to be due to absorption on the cell windows. A vapor phase Raman frequency at 1564 cm.$^{-1}$ was observed, however, by Yu. I. Kotov and V. M. Tatevskii, Opt. i Spektroskopiya 15, 65 (1963). Catalano et al. suggest one assignment based on the uncertain fundamental and a tentative alternative assignment excluding it. The two assignments give entropies that are 0.26 cal. deg.$^{-1}$ mole^{-1} lower and 0.12 higher than the third law value. The lower calculated entropy is probably more reasonable, but the higher value could be more easily modified to agree with the third law value. Thus the alternative assignment was adopted with ν_{11} arbitrarily increased from ~810 to 933 cm.$^{-1}$

The structural constants are based primarily on the electron diffraction study of Y. Morino, T. Iijima and Y. Murata, Bull. Chem. Soc. Japan 33, 46 (1960). Related analyses of the infrared fine structure of the torsional frequency (377 cm.$^{-1}$), A. Yamaguchi, I. Ichishima, T. Shimanouchi and S. Mizushima, Spectrochim. Acta 16, 1471 (1960), and of the microwave spectra, Kasuya and Kojima, loc. cit., are in close agreement. The microwave data give an H-N-H angle of 106° and a torsional angle of 90°2'. Principal moments of inertia of the adopted structure are I_A = 0.574 X 10^{-39}, I_B = 3.573 X 10^{-39} and I_C = 3.563 X 10^{-39} g. cm.^{2}

Silane (SiH_4) (Ideal Gas)

Mol. Wt. = 32.122

ΔH_f° 298.15 = 7.3 ± 0.3 kcal. mole^{-1}

$S^\circ_{298.15}$ = 48.789 cal. deg.$^{-1}$ mole^{-1}

Point Group T_d

Vibrational Frequencies and Degeneracies

ω cm.$^{-1}$
2183 (3)
910 (3)
978 (2)
2187 (1)

Si-H distance = 1.457 Å   H-Si-H angle = 109° 28' σ = 12

Product of Moments of Inertia: $I_AI_BI_C$ = 0.84659 X 10^{-117} g.^{3} cm.^{6}

Heat of Formation. ΔH_f° 298.15 was determined by S. Gunn and L. Greene, J. Phys. Chem. 65, 779 (1961). A value of 7.8 kcal. mole^{-1} was selected by J. S. Gordon, Thiokol Chemical Corp., Reaction Motors Division, Denville, N. J., "Thermodynamic Data for Combustion Products", January, 1960.

Heat Capacity and Entropy. Molecular constants were taken from J. S. Gordon, op. cit.. G. Janz and Y. Mikawa, Bull. Chem. Soc. Japan, 34, 1495 (1961) reported slightly different values for the vibrational levels.

December 31, 1961

MERCURY (Hg) (REFERENCE STATE) MOL. WT. = 200.61

The reference state is chosen as follows:

0° to 234.29°K	Crystal
234.29° to 629.73°K	Liquid
629.73° to 6000°K	Ideal Gas

$S^\circ_{298.15}$ = 18.171 cal. deg.$^{-1}$ mole^{-1}

T_m = 234.29°K

T_b = 629.73°K

ΔH°_v $_{298.15}$ = 14.652 ± 0.015 kcal. mole^{-1}

ΔH_m = 0.5486 ± 0.0001 kcal. mole^{-1}

ΔH°_v $_{629.73}$ = 14.133 ± 0.020 kcal. mole^{-1}

Heat Capacity.

The heat capacities of P. L. Smith and N. M. Wolcott, Phil. Mag. 1 [8], 854 (1956), 1.2°-20.2°K, R. H. Busey and W. F. Giauque, J. Am. Chem. Soc. 75, 806 (1953), 15°-330°K, and T. B. Douglas, A. F. Ball, and D. C. Ginnings, J. Research Natl. Bur. Standards, 46, 334 (1951), 300°-770°K, have been smoothly joined. There is fair agreement between the selected values and those of G. L. Pickard and F. E. Simon, Proc. Phys. Soc. A61, 1 (1948), L. G. Carpenter and F. H. Oakley, Phil. Mag. 12, 511 (1931), L. G. Carpenter and L. G. Stoodley, Phil. Mag. 10, 249 (1930), E. Cohen, C. I. Kruisheer, and A. L. Moesveld, Z. phys. Chem. A96, 437 (1920), A. L. Dixon and W. H. Rodebush, J. Am. Chem. Soc. 49, 1162 (1927), F. Simon, Z. phys. Chem. 107, 282 (1923), Ann. Physik 68, 241 (1922), J. N. Brönsted, Z. Elektrochem. 18, 714 (1912), and F. Pollitzer, Z. Elektrochem. 17, 5 (1911).

Melting Data.

From Busey and Giauque, loc. cit.

Boiling Point and Heat of Vaporization.

Calculated from the vapor pressures determined by K. D. Carlson, R. J. Thorn, and P. W. Gilles, private communication, October 1961, F. M. Ernsberger and H. W. Pitman, Rev. Sci. Instrum. 26, 584 (1955), F. H. Spedding and J. L. Dye, J. Phys. Chem. 59, 581 (1955), and J. A. Beattie, B. E. Blaisdell, and J. Kaminsky, Proc. Am. Acad. Arts Sciences 71, 375 (1937). Earlier measurements are less accurate and have not been used. Gas imperfection has been allowed for by the method of Busey and Giauque, loc. cit.

Heat of Formation.

The same as the heat of vaporization; see notes on reference state.

Heat Capacity and Entropy.

The electronic levels and multiplicities are from C. E. Moore, Natl. Bur. Standards Circular 467, Vol. 3 (1958).

MERCURY MONOIODIDE (HgI) (IDEAL GAS) MOL. WT. = 327.52

Ground State Configuration $^2\Sigma$

$\Delta H^\circ_{f\ 298.15} = 31.9 \pm 1.1$ kcal mole^{-1}

$S^\circ_{298.15} = 67.068$ cal deg^{-1} mole^{-1}

Electronic Level and Multiplicity

ϵ, cm^{-1}	g_i
0	2

$\omega_e = 125.0$ cm^{-1}

$\omega_e x_e = 1.00$ cm^{-1}

$\sigma = 1$

$B_e = [0.0351]$ cm^{-1}

$\alpha_e = [0.0003]$ cm^{-1}

$r_e = [2.49]$ Å

Heat of Formation

K. Wieland and A. Herczog, Helv. Chim. Acta, 32, 889 (1949) gave 8.3 ± 1.1 kcal for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants were taken from K. Wieland, Zeits, f. Electrochemie 64, 761 (1960). Rotational constants were estimated using equation III 123, p. 108, G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. The bond length was estimated to be 0.965 of the mercuric bond length by analogy with the mercury chlorides.

Mercury Diiodide (HgI_2)

MERCURY DIIODIDE (HgI_2) (Crystal)

Mol. Wt. = 454.43

$\Delta H_f^\circ{}_{298.15} = -25.2 \pm 0.4$ kcal. mole^{-1}

$S^\circ_{298.15} = [43.338] \pm 1.5$ cal. deg.$^{-1}$ mole^{-1}

$T_t = 402°K$

$\Delta H_t = 0.601 \pm 0.04$ kcal. mole^{-1}

$T_m = 530°K$

$\Delta H_m = 4.533 \pm 0.05$ kcal. mole^{-1}

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties", (1952).

Heat Capacity and Entropy. The heat capacity was calculated from the heat content data of M. Guinchant, Comp. Rend. 68, 145 (1907) and R. Ewald, Ann. d. Physik (4) 44, 1213 (1914). The entropy was estimated by adjusting its value to provide the best fit of the melting, sublimation and vaporization phenomena.

Transition. The heat and temperature of transition were taken from National Bureau of Standards Circular 500 (loc. cit.).

Melting. The heat of melting was taken from M. Guinchant (loc. cit.), the temperature of melting from National Bureau of Standards Circular 500 (loc. cit.).

MERCURY DIIODIDE (HgI_2) (Liquid)

Mol. Wt. = 454.43

ΔH_f° 298.15 = [-20.862] ± 0.45 kcal. mole^{-1}

$S^\circ_{298.15}$ = [51.544] ± 1.5 cal. deg.$^{-1}$ mole^{-1}

T_m = 530°K

ΔH_m = 4.533 ± 0.05 kcal. mole^{-1}

T_b = 627°K

ΔH_v = 14.141 ± 0.25 kcal. mole^{-1}

Heat of Formation. Calculated from $\Delta H_f^\circ{}_{298}(c)$.

Heat Capacity and Entropy. Heat capacity measurements were obtained from the data of M. Guinchant, Comp. Rend. 68, 145 (1907) in the range 540-600°K and were assumed constant above and below this range. A glass type transition was assumed at 353°K below which the heat capacity was that of $HgI_2(c)$. The entropy was calculated from the entropy of the crystal and the measured entropy of fusion.

Fusion and Vaporization. T_m and T_b are taken from National Bur. of Standards (U.S.) Circular 500 (1952). ΔH_m is from the data of M. Guinchant (loc. cit.) and ΔH_v was obtained from the data of E. B. R. Prideaux, J. Chem. Soc. (London) 97, 2032 (1910) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Hg-I distance = 2.58 Å

Moment of Inertia = 280.5×10^{-39} g. cm.^{2}

$\sigma = 2$

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties", 1952 was combined with the 3rd law heat of sublimation at 298°K derived from the data of K. Niwa and Z. Shibata, J. Fac. Sci. Hokkaido Imp. Univ. Ser. III 2, 183 (1938); D. W. Magee, Univ. Microfilms No. 14474 Ann Arbor, Mich., and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The anti-symmetric stretching frequency was estimated by analogy with the bromide and chloride. The bond length was an average of the values given by H. Braune and S. Knoke, Naturwiss. 21, 349 (1933); A. H. Gregg, G. C. Hampson, G. I. Jenkins, P. L. F. Jones and L. E. Sutton, Trans. Farad. Soc. 33, 852 (1937) and P. A. Akishin, V. P. Spiridinov and A. N. Khodchenkov, Zhur. Fiz. Khim. 33, 20 (1959).

MERCURY MONOXIDE (HgO) (CRYSTAL) MOL. WT. = 216.61

$\Delta H_f^\circ{}_{298.15} = -21.699 \pm 0.024$ kcal. mole^{-1} $S^\circ_{298.15} = 16.795 \pm 0.03$ cal. deg.$^{-1}$ mole^{-1}

$T_{decomp} = 749°K.$

Heat of Formation.

Obtained from the entropy obtained by T. W. Bauer and H. L. Johnston, J. Am. Chem. Soc. 75, 2217 (1953) and the free energy of formation as determined from the numerous cell measurements described by Bauer and Johnston. The value adopted for $\Delta F_f^\circ{}_{298.15}$ was -42,707 ± 14 cal. mole^{-1}.

Heat Capacity and Entropy.

The heat capacity has been measured from 15° to 298°K. by Bauer and Johnston loc. cit. The extrapolation below 15°K was done assuming a T^3 law and gave $S_{15} = 0.264$ e.u. Above 298° the data was extrapolated smoothly and adjusted to give the observed decomposition vapor pressures of G. B. Taylor and G. A. Hulett, J. Phys. Chem. 17, 565 (1913).

Decomposition.

According to Taylor and Hulett, loc. cit., the vapor pressure reaches 1.89 atmospheres at 749°K. This corresponds to the decomposition to 2 Hg(g) + O_2(g), the equilibrium constant being unity at 1.89 atm.

Mercury Monoxide (HgO)

MERCURY MONOXIDE (HgO) (IDEAL GAS) GFW = 216.5894

Ground State Configuration $^1\Sigma$

ΔHf°_0 = [11] kcal/mol

$S^\circ_{298.15}$ = [57] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [10] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	1

ω_e = [680] cm^{-1}

$\omega_e x_e$ = [4.7] cm^{-1}

σ = 1

B_e = [0.336] cm^{-1}

α_e = [0.0027] cm^{-1}

r_e = [1.84] Å

Heat of Formation

The heat of formation (ΔHf°_{298}) of HgO(g) is estimated to be 10 ± 15 kcal/mol. This value is obtained from the heat of formation of PbO(g) and comparison of the heats of formation of analogous lead and mercury compounds using the method of Karapet'yants (1). The corresponding dissociation energy (D°_0) of HgO(g) is 64 ± 15 kcal/mol.

Heat Capacity and Entropy

The equilibrium internuclear separation (r_e) of HgO(g) is estimated from the corresponding quantity for PbO(g) and comparison of Hg-X and Pb-X bond distances for cases in which values of both distances are known. The rotational constant B_e is calculated from r_e. The fundamental vibrational frequency ω_e is estimated from Guggenheimer's relation for multiple bonded molecules (2). The anharmonic vibrational term $\omega_e x_e$ is calculated from $\omega_e x_e = \omega_e^2/(4D_0 + 2\omega_e)$. The value of α_e is calculated from the Morse potential function. The ground state configuration is estimated from the building-up principle (3), the united atom theory (3), and from analogy with BeO.

MERCURY MONOIODIDE, DIMERIC (Hg_2I_2) (Crystal)

Mol. Wt. = 655.04

$\Delta H^\circ_{f\ 298.15} = -28.462 \pm 0.5$ kcal. mole^{-1}

$S^\circ_{298.15} = 57.670 \pm 2.0$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 563°K$

$\Delta H_m = [6.5] \pm 2.0$ kcal. mole^{-1}

Heat of Formation. The average value of the cell measurements of W. C. Vosburgh, J. Amer. Chem. Soc. 50, 2386 (1928); E. Cohen Zeits. f. physik, Chemie 94, 210 (1920); T. Yoshida, J. Chem. Soc. Japan 48, 435 (1927); L. W. Öholm, Acta. Soc. Scientarum Fennicae 41, 1 (1913) and the calorimetric values of R. Varet, Ann. Chim. Phys. (7) 8, 91 (1896) and W. Nernst, Zeits. f. physik. Chemie 2, 23 (1888) was adopted.

Heat Capacity and Entropy. The heat capacity at 298.15° was taken from National Bureau of Standards (U.S.) Circular 500 (1952) and was estimated above this by analogy with mercurous chloride. The entropy was obtained from the heat and free energy of formation obtained from the cell measurements listed under heat of formation.

Melting. P. Yvon, Comp. Rend. 76, 1607 (1873) gives 563°K for the melting point. The heat of melting was estimated by assuming the entropy of melting per atom to be the same as that for mercuric iodide.

MERCURY MONOIODIDE, DIMERIC (Hg_2I_2) (Liquid)

Mol. Wt. = 655.04

$\Delta H_f^\circ{}_{298.15} = [-23.021 \pm 2.5]$ kcal. mole^{-1}

$S^\circ_{298.15} = [66.868 \pm 6.0]$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 563°K$

$\Delta H_m = [6.5 \pm 2.0]$ kcal. mole^{-1}

$T_b = [630]°K$ (decomp.)

Heat of Formation. Calculated from ΔH_f° (crystal) and the estimated heat of melting and heat capacity.

Heat Capacity and Entropy. C_p was estimated as 1.33 times the heat capacity of mercuric iodide. The entropy was calculated from S° crystal, the estimated ΔH_m and the heat capacities of solid and liquid.

Melting and Vaporization. The melting point was given by P. Yvon, Comp. Rend. 76, 1607 (1873); the heat of melting was estimated from that of mercuric iodide, by assuming the entropies of melting per atom to be equal. Mercurous iodide decomposes to Hg(g) and $HgI_2(g)$ at the boiling point which was estimated from the free energy change of the reaction.

Thermodynamic Functions.

Atomic constants were taken from C. E. Moore [U. S. Natl. Bur. Standards Circ. 467, Vol. III (1958)]. The higher levels were averaged. Calculated thermodynamic functions are in good agreement with those of W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards, 55, 147 (1955)].

Heat of Formation.

The dissociation energy of diatomic iodine is given as D_0° = 12452.5 ± 1.5 cm.$^{-1}$ by R. D. Verma [J. Chem. Phys. 32, 738 (1960)]. Converting to calories and combining with the heat of sublimation of iodine yields the heat of formation of the ideal monatomic gas. Evans, Munson, and Wagman [loc. cit.] list several investigations of the dissociation energy from equilibrium data. These are all less precise than the spectroscopic value and are not given any weight. The "best" average of the thermal data yields D_0° = 35.568 kcal. mole^{-1} (spectroscopic = 35.606 kcal. mole^{-1}).

Dec. 31, 1961; June 30, 1967

POTASSIUM IODIDE (KI) (CRYSTAL) GFW = 166.0064

$\Delta Hf_0^\circ = -78.14 \pm 0.1$ kcal/mol

$S^\circ_{298.15} = 25.427$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -78.37 \pm 0.1$ kcal/mol

Tm = 954°K

$\Delta Hm^\circ = 5.74$ kcal/mol

$\Delta Hs^\circ_{298.15}$(to monomer) = 48.37 kcal/mol

$\Delta Hs^\circ_{298.15}$(to dimer) = 55.84 kcal/mol

Heat of Formation

The heats of solution of KI(c) have been critically reviewed by V. B. Parker, U. S. Natl. Bur. Std. NSRDS-NBS 2, 1965. Six pertinent results are quoted in the table below. Adopting the best value, $\Delta H^\circ_{\infty 298} = 4.86 \pm 0.03$ kcal/mol, reported by Parker, and $\Delta Hf^\circ_{298} = -60.32$ and -13.19 kcal/mol for $K^+(\infty H_2O)$ and $I^-(\infty H_2O)$, respectively, obtained from U.S. Natl. Bur. Std. Tech. Note 270-1, 1965, we obtain ΔHf°_{298}(KI, c) = −78.37 ± 0.1 kcal/mol, which is adopted.

ΔH°_∞, kcal/mol*	Temperature, °C	n**	Investigator
4.830 ± 0.05	19	200	J. Thomsen, Thermochemische Untersuchungen, J. Barth Verlag, Leipzig, 1882-86.

4.873	25	500	E. Lange and W. Martin, Z. Physik. Chem. A180, 233 (1937).
4.790 ± 0.10	20.5	600	M. M. Popov, S. M. Skuratov, and M. M. Strel'tsova, Zhur. Obshch. Khim. 10, 2023 (1940).
5.020	24.5	18.5	M. Bobtelsky and R. D. Lairsch, J. Chem. Soc. 1950, 3612 (1950).
4.830 ± 0.07	25	75000	A. F. Kapustinskii and S. I. Drakin, Zhur. Fiz. Khim. 26, 581 (1952).

*Values are adjusted to 298.15°K and to infinite dilution.

**n is the number of moles of H_2O per mole of KI(c) in solution.

Heat Capacity and Entropy

The low temperature heat capacities are based on those measured by W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) A242, 467 (1957), 2.86 - 268.0°K. The adopted values are in good agreement with the Cp values reported by W. W. Scales, Phys. Rev. 112, 49 (1958), 2 - 7°K. The data of K. Clusius, J. Goldmann, and A. Perlick, Z. Naturforsch. 4A, 424 (1949), 10.27 - 269.9°K, appear to be too low in the temperature range 70 - 270°K and are not used. Low temperature enthalpies, 83 - 273°K, have been measured by F. Koref, Ann. Physik 4, 49 (1911). The value of S°_{298} is derived based on the adopted low tempeature heat capacities, using $S^\circ_{2.86} = 0.0033$ eu.

The high temperature enthalpies were determined by S. M. Skuratov and S. A. Lapushkin, Russ. J. Gen. Chem. (English Transl.) 21, 2485 (1951), 623 - 923°K; A. S. Dworkin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tenn., Dec. 1, 1964, 854 - 954°K; and C. B. Cooper, J. Chem. Phys. 21, 777 (1953), 297 - 973°K. Heat Capacities are derived from the enthalpies by a curve fitting method which requires a smooth joint with the low temperature Cp. Enthalpy values used in the curve fit include smooth values calculated from the equation of Skuratov and the value $H^\circ_{954} - H^\circ_{298} = 9.2$ kcal/mol from Dworkin. Deviation of the input values from the selected enthalpies are all less than 0.3 percent, while the deviations of the data of Cooper range from +1.0 percent at 570°K to -1.6 percent at 974°K. Since the latter point is 20° above the melting point, there appears to be an error in Cooper's measurement of temperature. Cp above the melting point is obtained by graphical extrapolation.

Melting Data

Tm has been reported to be 953, 952 and 954°K by R. C. Ray and V. Dayal, Trans. Faraday Soc. 32, 741 (1936); T. E. Phipps and E. G. Partridge, J. Am. Chem. Soc. 51, 1331 (1929); and J. W. Johnson and M. A. Bredig, J. Phys. Chem. 62, 604 (1958), respectively. The last value is adopted. The heat of melting was determined by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960), using drop calorimetry.

Heat of Sublimation

The difference between ΔHf°_{298} for KI(g) and KI(c) is ΔHs°_{298}(to monomer). The ΔHs°_{298}(to dimer) is calculated as the enthalpy change for the following reaction: $2KI(c) = K_2I_2(g)$.

Dec. 31, 1961; June 30, 1967

POTASSIUM IODIDE (KI) (LIQUID) GFW = 166.0064

$S^\circ_{298.15}$ = 27.273 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -74.771 kcal/mol

Tm = 954°K

ΔHm° = 5.74 kcal/mol

Tb = 1618°K

ΔHv° = 45.62 kcal/mol

Heat of Formation

The heat of formation, ΔHf°_{298}, is obtained from ΔHf°_{298}(KI, c) by adding ΔHm° and the difference between $H^\circ_{954} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived as 17.3 gibbs/mol from the enthalpy measurements, 954 - 1014°K, by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tenn., Dec. 1, 1964. This Cp value is adopted in the temperature range 298 - 2500°K. S°_{298} is obtained in a manner analogous to that of the heat of formation.

Melting Data

See KI(c) table for details.

Vaporization Data

The boiling point, Tb = 1618°K, is calculated as the temperature at which the sum of the partial pressures of KI(g) and K_2I_2(g) over KI(ℓ) equals one atmosphere. The value of ΔHv° is calculated as the heat required to produce one mole of vapor mixture, which contains 78 percent monomer (KI) and 22 percent dimer (K_2I_2) at Tb.

Tb was reported as 1603 and 1590°K by H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 162 (1921), and O. Ruff and S. Mugdan, Z. Anorg. Chem. 117, 147 (1921), respectively.

Heat of Formation

The heat of formation is derived from the sublimation and vaporization data analyzed below. Many investigators have determined the total pressures of KI(g) and K_2I_2(g) over KI(c) or KI(ℓ) by static methods or "apparent" pressures by Knudsen effusion or transpiration. These pressures are converted to monomer pressures by use of functions [see K_2I_2(g) table] which are consistent with the dimer-monomer equilibrium data of Datz (9). Second and third law analyses of the monomer pressures show reasonable agreement. The selected value of ΔHf°_{298} = -30.0 ± 0.5 kcal/mol is also in good agreement with -30.23 ± 1.15 and -30.46 kcal/mol derived from D°_0 = 3.32 ± 0.05 and 3.33 eV reported by Gaydon (10) and Herzberg (11), respectively.

**(A) KI(c) = KI(g); (B) KI(ℓ) = KI(g)

Heat Capacity and Entropy

The ground state configuration is obtained from Herzberg (11). The adopted values of ω_e, $\omega_e x_e$, B_e, α_e and r_e were determined using millimeter wave molecular beam spectroscopy by Rusk and Gordy (12), and corrected to the average isotopic species. Similar values were reported by Honig et al. (13) from microwave spectra, except ω_e which was given as 199.74 cm^{-1}. The value of ω_e was derived to be 200 and 173 cm^{-1} by Barrow and Caunt (14) and Rice and Klemperer (15). The moment of inertia is 4.5979 x 10^{-38} g cm^2.

ΔHf_0° = Unknown

$S^\circ_{298.15}$ = [20.5] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -64.55 ± 0.1 kcal/mol

Tm = 742°K

ΔHm° = 3.50 kcal/mol

Heat of Formation.

The heat of formation, ΔHf°_{298}(LiI, c) = -64.55 kcal/mol, was calculated from the heat of solution of lithium iodide (c) at infinite dilution and the ionic heats of formation of $Li^+(\infty H_2O)$ and $I^-(\infty H_2O)$.

V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS 2, Apr. 1, 1965, reviewed the literature heat of solution data and gave the "best" value, ΔH°_∞ = -15,130 ± 75 cal/mol for LiI(c) → $LiI(\infty H_2O)$ at 298.15°K. The ionic heat of formation, $\Delta Hf^\circ_{298}(Li^+\cdot\infty H_2O)$ = -66.49 kcal/mol, was calculated from ΔH°_{298} $(LiOH\cdot\infty H_2O)$ = -121.46 kcal/mol (see JANAF LiOH(c) Table, Mar. 31, 1966) with ΔHf°_{298} $(OH^-\cdot\infty H_2O)$ = -54.97 kcal/mol from NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Oct. 1, 1965. The value ΔHf°_{298} $(I^-\cdot\infty H_2O)$ = -13.19 kcal/mol was also obtained from NBS Technical Note 270-1. Combination of the ionic heats of formation of $Li^+(\infty H_2O)$ and $I^-(\infty H_2O)$ gives the heat of formation of $LiI(\infty H_2O)$, ΔHf°_{298} = -79.68 kcal/mol.

Heat Capacity and Entropy.

A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1964, has measured the enthalpy changes by the drop method (642-802°K), yielding $(H_{742}-H_{298})$ = 6.0 kcal/mol for the crystal at the melting point. Heat capacities derived from his data were Cp_{692° = 14.8 and Cp_{772} = 15.1 cal/deg-mol for the crystal and liquid, respectively. The tabulated heat capacities were estimated based on these values and on the heat capacities of LiCl(c), NaCl(c) and NaI(c).

The entropy, $S^\circ_{298.15}$ = 20.5 eu, was estimated by adding the entropy difference between NaI(c) and NaCl(c) to the entropy of lithium chloride (c) at 298.15°K. Comparisons with other alkali halides give results within ± 0.5 eu of this value.

K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960), 592 (1961), has estimated the heat capacities ($Cp = 12.30 + 2.44 \times 10^{-3}T$ gibbs/mol) and the entropy (S°_{298} = 17.50 eu).

Melting Data.

The selected heat of fusion (ΔH°_{823} = 3.50 kcal/mol) was obtained from enthalpy measurements in a drop calorimeter by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

Sept. 30, 1961; June 30, 1966

LITHIUM IODIDE (LiI) (LIQUID) GFW = 133.8434

$S°_{298.15}$ = [23.568] gibbs/mol

Tm = 742°K

Tb(to equilibrium mixture) = 1449°K

Tb(to monomer only) = [1497]°K

$\Delta Hf°_{298.15}$ = -61.749 kcal/mol

ΔHm° = 3.50 kcal/mol

ΔHv°(to equilibrium mixture) = 23.3 kcal/mol

ΔHv°(to monomer only) = [32.6] kcal/mol

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding the heat of fusion and the difference between $H°_{742}- H°_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1964, has derived the heat capacity, Cp = 15.1 gibbs/mol, from enthalpy measurements, 742 - 802°K, by the drop method. The liquid heat capacity was assumed to be a constant, 15.1 gibbs/mol. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See LiI(c) table for detail.

Vaporization Data.

Tb (to monomer only) is determined as the temperature at which the Gibbs energy change (ΔGr°) for the reaction LiI(l) = LiI(g) approaches zero. The corresponding enthalpy change (ΔHr°) at boiling point is the heat of vaporization ΔHv°(to monomer only).

Tb (to equilibrium mixture) is the temperature at which the sum of the calculated partial vapor pressures of LiI(g) and $Li_2I_2(g)$ reaches one atmosphere (trimer and higher polymer have been neglected in calculation). This value is in good agreement with the boiling point of 1444°K from the least squares fit of the total vapor pressure data measured by O. Ruff and S. Mugdan, Z. anorg Chem. 117, 147 (1921). ΔHv°(to equilibrium mixture) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 30.44 mole percent of dimer. For detailed information see LiI(g) and $Li_2I_2(g)$ tables.

B_e = 0.44837 cm^{-1} α_e = 0.00416 cm^{-1} r_e = 2.3919 Å

Heat of Formation.

The heat of formation (ΔHf°_{298} (LiI, g) = -21.75 ± 2 kcal/mol) was calculated from the selected heat of sublimation and the heat of formation for lithium iodide (c). The heat of sublimation has been determined mass-spectrometrically from the ion intensity measurement (2nd law method) by L. N. Gorokhov, Dokl. Akad. Nauk SSSR 142, 113 (1962), as ΔHs°(to monomer) = 42.9 ± 0.6 and ΔHs° (to dimer) = 43.2 ± 0.4 kcal/mol in the temperature range from 626-722°K. Gorokhov also reported the partial vapor pressure of monomeric lithium iodide ($P_{monomer}$ = 3 X 10^{-3} mm Hg) and the ratio of dimer to monomer ($P_{dimer}/P_{monomer}$ = 6) which have been used for third law calculation. Using the same technique, L. Friedman, J. Chem. Phys. 23, 477 (1955), reported the heats of sublimation as ΔHs°_{727} (to monomer) = 41.9 ± 0.5 and ΔHs°_{727} (to dimer) = 40.8 ± 0.5 kcal/mol in the temperature range from 630° to 730°K. J. Berkowitz, H. A. Tasman and W. A. Chupka, J. Chem. Phys. 36, 2170 (1962) have also studied the lithium iodide vapor in the mass spectrometer and reported the second law and third law values of the heat of dimerization at 800°K as 37.9 and 40.4 kcal/mol, respectively. Using the JANAF thermodynamic functions, all the heats of sublimation and dimerization at different temperatures have been reduced to 298°K and summarized in the following table. The total vapor pressure over the liquid has been measured by a boiling point method in the temperature range 1223° to 1413°K by O. Ruff and S. Mugdan, Z. anorg. Chem. 117, 147 (1921). (Their data have been quoted by H. von Wartenberg and H. Schulz, Z. Elektrochem. 27, 568 (1921).) In order to have good agreement between the calculated vapor pressure and the observed total vapor pressure, the heats of sublimation have been so chosen as ΔHs°_{298} (to monomer) = 42.8 kcal/mol and ΔHs°_{298} (to dimer) = 42.6 kcal/mol and the heat of dissociation of dimer, ΔHd°_{298} = 43.0 kcal/mol. The calculated boiling point (to equilibrium mixture) is 1449°K which agrees with 1443°K reported by Wartenberg and Schulz, and also 1462°K by Ruff and Mugdan.

Chemical Reaction	Investigator	ΔHr°_{298} kcal/mol 2nd law	3rd law
$LiI(c) \rightarrow LiI(g)$	Gorokhov	44.7	42.2
	Friedman	43.9	—
$2LiI(c) \rightarrow Li_2I_2(g)$	Gorokhov	46.0	41.3
	Friedman	44.1	—
$Li_2I_2(g) \rightarrow 2LiI(g)$	Berkowitz et al.	38.8	41.3
	Friedman	43.7	—
	Gorokov	43.2	43.1

Heat Capacity and Entropy.

The bond distance and the rotational constants (B_e and α_e), corrected to the isotopic abundance of 7.4% Li^6 and 92.6% Li^7, were obtained from the microwave studies by A. Honig, M. Mandel, M. L. Stitch and C. H. Townes, Phys. Rev. 96, 629 (1954). The vibrational constants (ω_e and $\omega_e x_e$) were determined from the infrared spectrum by W. Klemperer, W. G. Norris, A. Büchler and A. G. Emslie, J. Chem. Phys. 33, 1534 (1960).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by R. L. Wilkins, J. Chem. Eng. Data 5, 337 (1960), who used slightly different molecular constants.

Mar. 31, 1962; Dec. 31, 1966

NITROSYL IODIDE (NOI) (IDEAL GAS) GFW = 156.9105

Point Group C_s

ΔHf°_0 = [27.6 ± 5] kcal/mol

$S^\circ_{298.15}$ = [67.58] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [26.8 ± 5] kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[1780] (1)
[440] (1)
[200] (1)

Bond Distance: O-N = [1.15] Å N-I = [2.3] Å

Bond Angle: O-N-I = [120]°

Product of the Moment of Inertia: $I_AI_BI_C$ = [7.742 x 10^{-115}] g^3 cm^6

Heat of Formation.

The heat of formation ($\Delta Hf^\circ_{298.15}$) for INO (g) is estimated by comparison with those for FNO(g), ClNO(g), BrNO(g), and the related cyanogen halides.

Heat Capacity and Entropy.

The molecular structure and bond angle are estimated by comparison with those for ClNO(g) and BrNO(g). The N-O bond distance is assumed to be the same as that in NO(g). The N-I bond distance (r_{N-I}) is calculated based on an assumption that $r_{ON-Cl} - r_{ON-I} = r_{I-Cl} - r_{I-I}$. The vibrational frequencies are estimated by comparison with those for FNO(g), ClNO(g) and BrNO(g). The three principal moments of inertia are: $I_A = 8.834 \times 10^{-40}$, $I_B = 2.916 \times 10^{-38}$ and $I_C = 3.005 \times 10^{-38}$ g cm^2.

SODIUM IODIDE (NaI) (CRYSTAL) MOL. WT. = 149.901

$S^\circ_{298.15}$ = 23.5 cal. deg.$^{-1}$ mole^{-1}

T_m = 933°K.

$\Delta H_f^\circ{}_0$ = -68.6 ± 0.2 kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -68.8 ± 0.2 kcal. mole^{-1}

ΔH_m = 5.64 kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained as follows:

		ΔH_{298}(kcal. mole^{-1})
(1)	$HI \cdot 100H_2O + NaOH \cdot 100H_2O \rightarrow NaI \cdot 201H_2O$ T. W. Richards, A. W. Rowe, J. Am. Chem. Soc. 44, 684 (1922).	-13.51 ± 0.02
(2)	$Na(c) + 1001H_2O(l) \rightarrow NaOH \cdot 1000H_2O + 1/2H_2(g)$ S. R. Gunn, L. G. Green, J. Am. Chem. Soc. 80, 4782 (1958).	-44.069 ± 0.006
(3)	$NaOH \cdot 1000H_2O \rightarrow NaOH \cdot 100H_2O + 900H_2O(l)$ National Bureau of Standards Circular 500.	+0.031 ± 0.004
(4)	$1/2H_2(g) + 1/2I_2(s) \rightarrow HI(g)$ JANAF Tables.	+6.30 ± 0.05
(5)	$HI(g) + 100H_2O(l) \rightarrow HI \cdot 100H_2O$ W. A. Roth, Z. Elektrochem. 50, 107 (1944).	-19.30 ± 0.05
(6)	$NaI \cdot 201H_2O \rightarrow NaI(c) + 201H_2O(l)$ J. Wust, E. Lange, Z. physik. Chem. 116, 161 (1925). E. Lange, A. L. Robinson, Chem. Revs. 9, 89 (1931). Askew, Bullock, Smith, Tinkler, Gatty, Wolfenden, J. Chem. Soc., 1934, 1368.	+1.75 ± 0.06
	(1) + (2) + (3) + (4) + (5) + (6) gives $Na(c) + 1/2I_2(s) \rightarrow NaI(c)$	-68.80 ± 0.2

Heat Capacity and Entropy.

Smoothed heat capacities between 3° and 270°K. have been presented by W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) 242A, 467 (1957). Above 270°K. the heat capacity was obtained by comparing with KI(c) on a reduced temperature plot of C_p/T versus T. The values so obtained were increased by 1.4% to bring them into line with the low temperature data.

Melting Data.

A. Dworkin and M. Bredig, J. Phys. Chem. 64, 269 (1960) have measured both T_m and ΔH_m.

SODIUM IODIDE (NaI) (LIQUID) MOL. WT. = 149.901

$S^\circ_{298.15}$ = 28.862 cal. deg.$^{-1}$ mole^{-1}

ΔH_f° 298.15 = -63.695 kcal. mole^{-1}

T_m = 933°K.

ΔH_m = 5.64 kcal. mole^{-1}

T_b = 1577°K. (equilibrium mixture)

Heat of Formation.

ΔH_f° 298.15 was calculated from the heat of formation of the crystal plus the heat of melting and the difference between $H_{933}-H_{293}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p was estimated assuming each atom contributed 7.75 cal. deg.$^{-1}$ mole^{-1}. $S^\circ_{298.15}$ was calculated in a manner similar to ΔH_f° 298.15.

Melting Data.

See table for crystal.

Vaporization Data.

The boiling point is that given by K. K. Kelley, U. S. Bureau of Mines Bulletin 383, 1935 from examination of the high temperature vapor pressure.

Lead Monoiodide (PbI) (Ideal Gas)

Mol. Wt. = 334.12

ΔH_f° 298.15 = 25.7 ± 9.2 kcal. mole^{-1}

$S^\circ_{298.15}$ = 66.855 cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^2\Pi_{1/2}$

Electronic Levels and Multiplicities

ϵ, cm.$^{-1}$	g_i
0	2
[8000]	2

ω_e = 160.5 cm.$^{-1}$ $\omega_e x_e$ = 0.25 cm.$^{-1}$

B_e = [0.02940] cm.$^{-1}$ α_e = [0.00000] cm.$^{-1}$

σ = 1

Heat of Formation. ΔH_f° 298.15 was calculated from the dissociation energy of PbI(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e and $\omega_e x_e$ were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York, 1950. B_e and α_e were estimated by comparison with the corresponding values for the other diatomic halide molecules. Electronic levels and multiplicities were estimated from those for PbF(g).

Heat of Formation

The heat of formation, ΔHf°_{298}, of TiI (g) is calculated from the dissociation energy, D°_0, which is estimated as 73 kcal/mol. This estimate is obtained from the relation $D(TiI_4) < D^\circ_0(TiI) < D(TiI_3)$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF_2(g) by Zmbov and Margrave (1).

Heat Capacity and Entropy

The vibrational frequency, ω_e, and the anharmonic vibrational term, $\omega_e x_e$, are estimated from those of TiCl(g) and comparisons of the mercury and alkali monohalides. The interatomic distance is estimated from Guggenheimer's relation (2). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti^+ (3). α_e is estimated from the Morse potential function.

ZIRCONIUM MONOIODIDE (ZrI) (IDEAL GAS) MOL. WT. = 218.13

Ground State Configuration $^4\Sigma$

$S^\circ_{298.15}$ = [65.87] cal. deg.⁻¹ mole⁻¹

$\Delta H_f^\circ{}_0$ = [141.8 ± 10.0] kcal. mole⁻¹

$\Delta H_f^\circ{}_{298.15}$ = [141.3 ± 10.0] kcal. mole⁻¹

Electronic Levels and Multiplicities

ϵ_i cm.⁻¹	g_i
0	4

ω_e = [223] cm.⁻¹

$\omega_e x_e$ = [1.2] cm.⁻¹

σ = 1

B_e = [0.03789] cm.⁻¹

α_e = [0.00020] cm.⁻¹

r_e = [2.9] Å

Heat of Formation.

The dissociation energy was estimated from a correlation of the JANAF values for TiCl(g), TiI(g), and ZrCl(g). The resulting value, 29.7 kcal. mole⁻¹, was employed with auxiliary JANAF heats of formation for Zr(g) and I(g) in calculating $\Delta H_f^\circ{}_{298.15}$.

Heat Capacity and Entropy.

The vibrational frequency was estimated from those of TiI(g), TiCl(g), ZrCl(g), and the alkali halides. The ground state configuration was assumed to be analogous to the ground term of TiCl(g) as given by E. A. Shenyavskaya, et al., Optics and Spectroscopy, 12, 359 (1962). The interatomic distance was estimated from those of TiBr(g), TiI_4(g) and ZrI_4(g).

IODINE (I_2) (REFERENCE STATE) MOL. WT. = 253.82

0°K to 386.75°K	Crystal
386.75°K to 458.39°K	Liquid
458.39°K to 6000°K	Ideal Diatomic Gas

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal.

The recent measurements of D. A. Shirley and W. F. Giauque [J. Am. Chem. Soc. 81, 4778 (1959)] over the temperature range 13° to 327°K are adopted, no weight being given to the earlier work of E. Lange [Z. physik. Chem. 110, 343 (1924)], which deviate by 1% or more. L. G. Carpenter and T. F. Harle [Phil. Mag. 23, 193 (1937)] measured the heat capacity of crystalline and liquid iodine by an adiabatic method. Their data are in poor agreement with Shirley and Giauque in the range 275° to 330°K and are given no weight. K. J. Frederick and J. H. Hildebrand [J. Am. Chem. Soc. 60, 1436 (1938)] measured the enthalpy of crystalline and liquid iodine relative to 298°K by the method of mixtures. For calibration they used a slug of copper. The enthalpy of copper which they used now appears to be too high [K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960)]. The results of Frederick and Hildebrand were corrected by a factor which varied linearly from zero at 300°K to 0.995 at 400°K and 0.990 at 500°K. These corrected enthalpies and the heat capacities of Shirley and Giauque above 298°K were used to derive the equations for crystalline iodine:

$$H_T - H_{298} = -12.1048\ T + 0.029506\ T^2 - 6.686 \times 10^5\ T^{-1} + 3228.65$$

$$C_p = -12.1048 \quad + 0.059012\ T + 6.686 \times 10^5\ T^{-2}$$

Heat Capacity of Liquid, Melting Point, and Heat of Melting.

For the liquid, the corrected results of Frederick and Hildebrand give:

$$H_T - H_{298} = 19.281\ T - 2516.5$$

$$C_p = 19.281$$

The melting point given by Frederick and Hildebrand is 113.6°C. The difference in the heat content equations at the melting point gives the heat of melting as 3708.7 cal. mole^{-1}.

Heat of Sublimation, Ideal Gas Functions.

See tables for ideal gases for details.

September 30, 1961

IODINE (I_2) (LIQUID) MOL. WT. = 253.82

T_m = 386.75°K

T_b = 458.39°K

$\Delta H_f^\circ{}_{298}$ = +3.232 kcal. mole^{-1}

S°_{298} = 35.936 cal. mole^{-1} deg.$^{-1}$

ΔH_m = 3708.7 cal. mole^{-1}

ΔH_v = 10025.5 cal. mole^{-1}

Heat of Formation.

Obtained as the heat of fusion calculated to 298.15°K by adding $H_{386.75}-H_{298.15}$ for solid and subtracting $H_{386.75}-H_{298.15}$ for liquid.

Heat Capacity.

The liquid heat capacity of 19.281 cal. mole^{-1} deg.$^{-1}$ derived from the data of Frederick and Hildebrand (see Reference State) was extrapolated back to 298.15°K and up to 1000°K.

Entropy.

The value at 400°K calculated for the reference state was back calculated to 298.15°K by means of the constant heat capacity of 19.281 cal. mole^{-1} deg.$^{-1}$

Vaporization.

See ideal gas tables for details.

September 30, 1961

IODINE, DIATOMIC (I_2) (IDEAL GAS) MOL. WT. = 253.82

$\Delta H_{f0}^\circ = 15.66 \pm .01$ kcal. mole^{-1}

$\Delta H_{f\ 298}^\circ = 14.924$ kcal. mole^{-1}

Ground State = $^1\Sigma$

$S_{298}^\circ = 62.281$ cal. mole^{-1} deg.$^{-1}$

$\omega_e = 214.52$ cm.$^{-1}$

$\omega_e x_e = 0.6133$ cm.$^{-1}$

$D_e = 0.455 \times 10^{-8}$ cm.$^{-1}$

$B_e = 0.037364$ cm.$^{-1}$

$\alpha_e = 0.0001206$ cm.$^{-1}$

$\sigma = 2$

Thermodynamic Functions.

The molecular constants are from the work of D. H. Rank and W. M. Baldwin [J. Chem. Phys. 19, 1210 (1951)] with a revised value of $\omega_e = 214.52$ as given by R. D. Verma [J. Chem. Phys. 32, 738 (1960)]. The value of $\omega_e x_e$ has been adjusted to allow for the dropping of higher order corrections not used in the computer program. The calculated thermodynamic functions are in good agreement with those of W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 147 (1955)], who used very slightly different constants. L. Mathieson and A. L. G. Rees [J. Chem. Phys. 25, 753 (1956)] give further refinements to the spectroscopic data which are negligible for our purpose. Their ω_e is also slightly low since it is based on Rank and Baldwin.

Heat of Formation.

The heat of sublimation of iodine was calculated from published vapor pressure data as follows, using thermodynamic functions of condensed and gaseous phases described above.

	ΔH_0°, kcal. mole^{-1}
Baxter, Hickey, and Holmes[1] (273° to 328°K)	15.657 ± .004
Baxter and Grose[2] (323° to 368°K)	15.657 ± .002
Ramsay and Young[3] (solid) (331° to 386°K)	15.671 ± .018
Ramsay and Young[3] (liquid) (386° to 454°K)	15.676 ± .007
Haber and Kerschbaum[4] (225° to 263°K)	15.765 ± .012
Gillespie and Fraser[5] (303° to 333°K)	15.655 ± .005
Sklyarenko, Markin, and Belyaeva[6] (283° to 303°K)	15.813
Naumann[7] (as given by Haber and Kerschbaum) (232° to 292°K)	15.899 ± .034
Wiedemann[8] (393° to 453°K)	15.635 ± .008
Braune and Strassman[9] (305° to 358°K)	15.658 ± .012
Arctowski[10] (286° to 345°K)	15.623 ± .080
Wright[11] (352° to 372°K)	15.659 ± .003
Dewar[12] (273° to 303°K)	15.821 ± .103
Richter[13] (358° to 383°K)	15.639 ± .043

The uncertainties given are the average deviation from the mean. The data of Braune and Strassman are as recalculated by Gerry and Gillespie[14]. The data of Haber and Kerschbaum appear systematically too high. The results of Sklyarenko, et al., Naumann, Arctowski, Dewar, and Richter are scattered and are not given any weight. A weighted average of the remaining data yield $\Delta H_0^\circ = 15.66 \pm 0.01$ kcal. mole^{-1}, which calculates to ΔH_{298}° = 14.924 cal. mole^{-1}.

Bond Distance: K-I = [3.29] Å

Bond Angles: K-I-K = [75°] I-K-I = [105°] σ = [4]

Product of the Moments of Inertia: $I_AI_BI_C$ = [5.041 x 10^{-111}] g^3 cm^6

Heat of Formation

The chemical equilibrium for the reaction $K_2I_2(g) = 2KI(g)$ has been studied by S. Datz, ORNL-2933, Oak Ridge, Tenn., 1960, and S. Datz, W. T. Smith, Jr. and E. H. Taylor, J. Chem. Phys. 34, 558 (1961). They measured the temperature dependence of the molecular weight of KI(g) which was determined by measurement of the absolute pressure exerted by a known weight of completely vaporized salt contained in an isothermal fused silica bulb of known volume. Based on the reported P-V-T measurements, the enthalpy change of the reaction at 298°K is evaluated by the second and third law methods. The results are given in the table below.

R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1956), determined the molecular composition of KI vapor by measurement of the velocity distribution of the molecules in the beam produced as the vapor effused through a small slit in a source. The analysis was based on an assumption that the velocity distribution within the oven is Maxwellian and that the vapor effuses through the ideal slit of kinetic theory. The velocity distributions of potassium and thallium atomic beams were found to be in excellent agreement with the theoretical distributions, so the determination of the molecular composition of KI beams was tried. Using the derived equilibrium constants, we calculate the enthalpy change of the dissociation reaction by the second and third law methods. The results are presented in the following table.

The value of $\Delta Hf^\circ_{298}(K_2I_2,g)$ is adopted as -100.9± 1 kcal/mol.

			ΔHr°_{298}, kcal/mol			
Investigator	Temperature, °K	No. of Points	Second Law	Third Law	Drift eu	ΔHf°_{298} kcal/mol
Datz	1226-1385	10	40.09±0.82	40.66	0.4±0.6	-100.66
	1292-1408	6	41.37±1.91	41.01	-0.2±1.4	-101.01
Miller-Kusch	816-921	10	54.62±2.46	36.28	-21.4±2.8	-96.28

Heat Capacity

The molecular structure and bond distance and angles were estimated by J. Berkowitz, J. Chem. Phys. 29, 1386 (1958). The vibrational frequencies are estimated by comparison with those calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), and adjusted to give good agreement between second and third law evaluations of the equilibrium data. The three principal moments of inertia are: $I_A = 5.194 \times 10^{-38}$, $I_B = 2.866 \times 10^{-37}$ and $I_C = 3.386 \times 10^{-37}$ g cm^2.

Bond Distance: Li-I = 2.54 Å   Li-Li = 2.71 Å

Bond Angle: I-Li-I = 116° ± 4° $\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C = 1.63429 \times 10^{-112}$ g^3 cm^6

Heat of Formation.

This was obtained from the heat of formation of the crystal and the heat of sublimation of the dimer, which derivation has been given in the LiI(g) table.

Heat Capacity and Entropy.

J. Berkowitz, J. Chem. Phys. 29, 1386 (1958), 32, 1519 (1960), has calculated the molecular structure and vibrational frequencies based on an ionic model. The planar rhombic structure, proposed by Berkowitz, has been confirmed by the lack of polarity in electric deflection by A. Büchler, J. L. Stauffer and W. Klemperer, J. Am. Chem. Soc. 86, 4544 (1964). The selected bond distances and angle were obtained from the electron diffraction studies of monomer-dimer vapor by P. A. Akischin and N. G. Rambidi, Z. Physik Chem. 213, 111 (1960). The bond distances (r_{Li-Li} = 2.712 Å and r_{I-I} = 4.520 Å) calculated by Berkowitz are in good agreement with those from Akischin and Rambidi. The three principal moments of inertia are $I_A = 4.2152 \times 10^{-39}$, $I_B = 194.8074 \times 10^{-39}$ and $I_C = 199.0226 \times 10^{-39}$ g cm^2.

S. H. Bauer, T. Ino and R. F. Porter, J. Chem. Phys. 33, 685 (1960), have estimated six vibrational frequencies (501, 501, 148, 200, 294, 360 cm^{-1}) for $Li_2I_2(g)$ in the electron diffraction studies of the $Li_2Cl_2(g)$. W. Klemperer and W. G. Norris, J. Chem. Phys. 34, 1071 (1961), have observed two fundamental vibrational frequencies (248 and 375 cm^{-1}) in the infrared spectrum and tentatively assigned them as B_{2u} and B_{3u} modes; these have been adopted in the tabulation. The remaining four vibrational frequencies were obtained from J. Berkowitz, loc. cit., because his model and derivation are self-consistent.

Lead Diiodide (PbI_2)

Lead Diiodide (PbI_2) (Crystal)

Mol. Wt. = 461.03

ΔH_f° 298.15 = -41.86 ± 0.06 kcal. mole^{-1}

$S^\circ_{298.15}$ = 41.869 cal. deg.$^{-1}$ mole^{-1}

ΔH_s° 298.15 = 41.70 ± 0.10 kcal. mole^{-1}

T_m = 680°K.

ΔH_m° = 3.87 kcal. mole^{-1}

Heat of Formation. Calculated from the data reported by H. Braune and F. Koref, Z. anorg. Chem. 87, 175 (1914) and R. H. Gerke, J. Am. Chem. Soc. 44, 1684 (1922).

Heat Capacity, Entropy, and Melting Data. C_p (10° to 298.15°K.) obtained from Edgar F. Westrum, Jr., University of Michigan, Ann Arbor, Michigan, private communication, May, 1961. Above 298.15°K., C_p given by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation. T_m and ΔH_m° reported by M. Blanc and G. Petit, Compt. rend., 248, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of K. Jellinek and A. Rudat, Z. physik. Chem., A143, 55 (1929) and B. Greiner and K. Jellinek, Z. physik. Chem., A165, 97 (1933).

Lead Diiodide (PbI_2) (Liquid)

Mol. Wt. = 461.03

ΔH_f° 298.15 = [-40.637] kcal. mole^{-1}

$S_{298.15}^\circ$ = [42.786] cal. deg.$^{-1}$ mole^{-1}

T_m = 680°K.

ΔH_m° = 3.87 kcal. mole^{-1}

T_b = 1135°K.

ΔH_v° = 26.99 ± 0.10 kcal. mole^{-1}

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy, and Melting Data. C_p obtained from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). T_m and ΔH_m° reported by M. Blanc and G. Petit, Compt. rend. 248, 1305-6 (1959). A glass transition temperature of 454°K. is assumed.

Vaporization Phenomena. T_b and ΔH_v° calculated from ΔH_s° 298.15 and free energy functions for condensed and gaseous states.

Dec. 31, 1961; June 30, 1964; Dec. 31, 1968

TITANIUM DIIODIDE (TiI_2) (CRYSTAL) GFW = 301.7088

ΔHf_0° = unknown

$S^\circ_{298.15}$ = [29.3 ± 3.0] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -63.6 ± 3.0 kcal/mol

Ts = [1358.2]°K

ΔHs° = [51.80] kcal/mol

Heat of Formation

The heat of formation of $TiI_2(c)$ is calculated from the heat of reaction for the process $2TiI_2(c) = Ti(c) + TiI_4(g)$, and the heat of formation of $TiI_4(c)$. Vapor pressure data for this reaction were reported by Herczog and Pidgeon (1) over the temperature range 750° to 902°K. Second and third law analyses of these data give values for ΔHr°_{298} of 60.5 ± 0.8 and 60.85 kcal/mol respectively, the third law drift being 0.4 ± 1.0 eu. The third law ΔHr°_{298} is used to obtain the adopted value of ΔHf°_{298}.

Heat Capacity and Entropy

The estimated heat capacity is that reported by Kelley (2). The value of $S^\circ_{298.15}$ is estimated from that of $TiCl_2(c)$ and the difference between ionic entropy contributions of Cl^- and I^-.

Heat of Sublimation

The heat of sublimation of $TiI_2(c)$ is taken as the difference in the heats of formation of $TiI_2(c)$ and $TiI_2(g)$ at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta Gr^\circ = 0$ for the reaction $TiI_2(c) = TiI_2(g)$.

Heat of Formation

The heat of formation of $TiI_2(g)$ is calculated from that of $TiI_2(c)$ and the heat of vaporization. Vapor pressure data over the temperature range 750°K to 902°K have been reported by Herczog and Pidgeon (1). Second and third law analyses of these data give values for ΔHv°_{298} of 51.9 and 58.9 kcal/mol, respectively. The third law drift for these data is 8.3 ± 1.1 eu, with one point rejected due to failure of a statistical test. The adopted value of ΔHf°_{298} is calculated from the third law heat of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2(g)$, $TiCl_4(g)$, $TiBr_2(g)$, $TiBr_4(g)$ and $TiI_4(g)$. The vibrational frequencies are estimated from a valence force field model. The force constant K is estimated as 1.0 millidynes/Å and the constant K_δ/ℓ^2 is assumed to be 0.05 millidynes/Å.

The electronic levels are assumed to be the same as $TiCl_2(g)$. The levels of $TiCl_2$ are estimated by assuming they correspond to the inverted states of $NiCl_2(g)$ (2). The linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (3, 4, 5, 6).

Zirconium Diiodide (ZrI_2) (Liquid)

Mol. Wt. = 345.04

$\Delta H_f^\circ{}_{298.15}$ = [-56] kcal. mole^{-1}

$S^\circ_{298.15}$ = [44.5] cal. deg.$^{-1}$ mole^{-1}

T_m = [700]°K.

ΔH_m = [6] kcal. mole^{-1}

T_b = [1300]°K.

ΔH_v = [27] kcal. mole^{-1}

Heat of Formation. Based upon the ΔH_f ZrI_2(c) and the estimated functions of both crystal and liquid.

Heat Capacity and Entropy. Entropy based upon the estimated values for C_p(c), ΔH_m, and C_p(l).

Melting and Vaporization. ΔH_m was estimated. T_m, T_b, and ΔH_v from L. Brewer, National Nuclear Energy Series, Div. IV, 19B, paper 7, McGraw-Hill Book Co., Inc., 1950.

TITANIUM TRIIODIDE (TiI_3) (CRYSTAL) GFW = 428.6132

ΔHf°_0 = unknown

$S^\circ_{298.15}$ = [46.0 ± 2.0] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-77 ±5] kcal/mol

Ts = [1000]°K

ΔHs° = [35.4] kcal/mol

Heat of Formation

The heat of formation of $TiI_3(c)$ is calculated from the free energy of formation at 623°K combined with the increment $\Delta Gf^\circ_{623} - \Delta Gf^\circ_{298.15}$ and the entropies, $S^\circ_{298.15}$, of $TiI_2(c)$, $TiI_3(c)$ and $TiI_4(g)$. The free energy of formation, ΔGf°_{623}, is estimated such that $\Delta Gr^\circ_{623} = 0$ for the process $2TiI_3(c) = TiI_2(c) + TiI_4(g)$. This assumption is based on the observations of Herczog and Pidgeon (1) and Fast (2).

Heat Capacity and Entropy

The heat capacities of $TiI_3(c)$ and the value of $S^\circ_{298.15}$ estimated by Kelley (3) have been adopted.

Heat of Sublimation

The heat of sublimation of $TiI_3(c)$ is taken as the difference in the heats of formation of $TiI_3(c)$ and $TiI_3(g)$ at the sublimation temperature. The sublimation temperature is estimated as the point at which $\Delta Gr^\circ = 0$ for the process $TiI_3(c) = TiI_3(g)$.

Bond Distance: Ti-I = [2.7] Å

Bond Angle: I-Ti-I = [100°] σ = 3

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.3 x 10^{-110}] g^3 cm^6

Heat of Formation

The heat of formation, $\Delta Hf^\circ_{298.15}$, of $TiI_3(g)$ is estimated from the average Ti-I bond energy. The bond energy is estimated from the corresponding quantities for $TiBr_4(g)$, $TiBr_3(g)$ and $TiI_4(g)$.

Heat Capacity and Entropy

The interatomic distance is estimated from those of TiI_4, $TiCl_4$ and $TiCl_3$. The pyramidal bond angle is estimated by assuming that $TiI_3(g)$ is similar to the group V trihalides. The principal moments of inertia are $I_A = I_B = 1.9 \times 10^{-37}$ g cm^2 and $I_C = 3.6 \times 10^{-37}$ g cm^2. The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti^{+3} reported by C. E. Moore, U. S. Natl. Bur. Std., Circ. 467, 1949.

June 30, 1962; June 30, 1964

ZIRCONIUM TRIIODIDE (ZrI_3) (CRYSTAL) MOL. WT. = 471.950

$S^\circ_{298.15}$ = [48.90] cal. mole^{-1} deg.$^{-1}$

T_s = [970]°K.

Td = [1000]°K.

$\Delta H_f^\circ{}_0$ = [-95] kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = [-95] kcal. mole^{-1}

$\Delta H_s^\circ{}_{298.15}$ = [42] kcal. mole^{-1}

Heat of Formation.

E. M. Larsen and J. J. Leddy, J. Am. Chem. Soc. 78, 5983 (1956), studied the reaction $Zr(c) + 3ZrI_4(g) = 4ZrI_3(c)$ in the temperature range 473 to 973°K. and pressure range 5 to 15 atm. They present a plot of the fractional reaction, at a number of temperatures, as a function of reaction time; however, they express doubt concerning the attainment of thermodynamic equilibrium.

The free energy function change for this reaction was calculated at 100° intervals from 500 to 1100°K. At each temperature the equilibrium constant was assumed to be 1, and $\Delta H_{r\ 298}$ accordingly calculated. These values and the heat of formation of $ZrI_4(g)$ [see ZrI_4 table] were used to compute a series of values for the heat of formation of $ZrI_3(c)$ at 298.15°K. The following table gives representative values at four temperatures.

T(°K.)	K_p	$\Delta H_{r\ 298}$	$\Delta H_f^\circ{}_{298.15}$ [$ZrI_3(c)$]
500	1	-66.0 kcal. mole^{-1}	-80.2 kcal. mole^{-1}
700	1	-90.3 kcal. mole^{-1}	-86.2 kcal. mole^{-1}
900	1	-113.5 kcal. mole^{-1}	-92.1 kcal. mole^{-1}
1100	1	-135.9 kcal. mole^{-1}	-97.7 kcal. mole^{-1}

If one assumes an initial pressure of from 5 to 10 atm. for ZrI_4 and stoichiometric amounts of reactants, then, on the basis of zirconium, the reaction must proceed to the extent of 80 to 90% for the pressure of ZrI_4 to attain a value of 1 atm. and hence an equilibrium constant of 1. The data of Larsen and Leddy indicate that the reaction proceeds to the extent of 88% at 973°K. From this it was assumed that at around 1000°K. the equilibrium constant attains a value of 1 giving -95 kcal. mole^{-1} for the heat of formation of ZrI_3 at 298.15°K.

Their data was subjected to a second law calculation but the results are of doubtful value in view of the uncertainty in the attainment of thermodynamic equilibrium at the lower temperatures. The limits of error assigned to the heat of formation are ±15 kcal. mole^{-1} corresponding to a temperature spread of ±500° in the above table.

Heat Capacity and Entropy.

The heat capacity was estimated in the same manner as for $ZrBr_4(c)$ [see $ZrBr_4(c)$ table]. The values Θ_D = 60°K. and Θ_E = 115°K. were taken to be the same as those estimated for $ZrI_4(c)$. The internal contribution was obtained from the estimated ZrI_3 vibrational frequencies and the anharmonicity factor, "a", was taken to be 2.5 X 10^{-3}. The specific heat above 300°K. was obtained by graphical extrapolation.

For the above estimation, it was assumed that the crystalline lattice is made up of ZrI_3 molecules. However, E. Holze [see R. F. Rolsten, "Iodide Metals and Metal Iodides", John Wiley & Sons, Inc., New York, 1961, page 46] came to the conclusion that crystalline ZrI_3 is composed of a chain lattice of $(Zr_2I_6)_n$ units. The results of an analysis for a crystalline lattice composed of Zr_2I_6 units would probably not differ significantly from that for a crystalline lattice composed of ZrI_3 units since both are approaching the classical harmonic heat capacity of 12R calories per formula weight of ZrI_3 at relatively low temperatures.

Until more quantitative information becomes available, it is felt that the above analysis gives a fair approximation to the heat capacity of ZrI_3.

Temperature of Disproportionation.

As described in the "Heat of Formation" section, this was assumed to be 1000° ± 500°K.

Liquid Phase.

It is assumed that the liquid phase is thermodynamically unstable under ordinary conditions.

Sublimation Data.

The heat of sublimation at 298.15°K. was obtained from the difference in the heats of formation of the gas and solid at 298.15°K. The sublimation point was obtained from the free energy crossover between gas and solid.

ZIRCONIUM TRIIODIDE (ZrI_3) (IDEAL GAS) MOL. WT. = 471.950

Point Group = [C_{3v}]

$S^\circ_{298.15}$ = [95.05] cal. mole^{-1} deg.$^{-1}$

Ground State Quantum Weight = [2]

$\Delta H^\circ_{f\ 0}$ = [-52] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-53] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[195] (1)
[88] (1)
[220] (2)
[65] (2)

Bond Distance: Zr-I = [2.59] Å

Bond Angle: I-Zr-I = [101]°

σ = [3]

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.1545 X 10^{-110}] gm.^{3} cm.^{6}

Heat of Formation.

The heats of formation, from the gaseous atoms, of the gaseous zirconium tetrahalides were computed from data issued in these tables. The zirconium-halide bond energy, taken as 1/4 of this heat of formation, was found to be linear with internuclear separation. From gaseous titanium tri- and tetrachloride, it was found that the bond energy of the trichloride was around 7 kcal. mole^{-1} greater than that for titanium tetrachloride. This amount was added to the bond energy of zirconium tetrachloride to get that of zirconium trichloride which, when used with its estimated internuclear distance, was found to lie almost exactly on the bond energy versus internuclear distance curve for the tetrahalides. The bond energy for each of the gaseous trihalides of zirconium was determined from this curve and their estimated bond distances.

For zirconium triiodide, the heat of formation from the gaseous atoms was -275 kcal. mole^{-1} and from the elements in their standard state, -53 kcal. mole^{-1}.

Heat Capacity and Entropy.

The measured internuclear distances for the triiodides of phosphorus, arsenic, and antimony were plotted as a function of the atomic weight of these elements and a smooth curve was drawn through the points. The bond distance in ZrI_3 was taken from this plot. The bond angle was assumed to be 101°. The individual moments of inertia are: $I_A = I_B = 1.8520 \times 10^{-37}$ gm. cm.^{2}, $I_C = 3.3661 \times 10^{-37}$ gm. cm.^{2}.

Force constants for ZrI_3 were estimated from those of the triiodides of phosphorus and arsenic. These were used in a valence force field calculation giving $\omega_1 = 195$, $\omega_2 = 88$, $\omega_3 = 181$, and $\omega_4 = 65$ cm.$^{-1}$ For the fluorides and chlorides of P, As, and Sb, ω_1 is greater than ω_3 but there appears to be a reversal as one goes to the bromides and iodides with ω_3 becoming greater than ω_1. An empirical correlation procedure for ZrI_3 gave $\omega_1 = 195$, $\omega_2 = 90$, $\omega_3 = 220$, and $\omega_4 = 65$ cm.$^{-1}$ in which $\omega_3 > \omega_1$. Since $\omega_3 > \omega_1$ for PI_3 and AsI_3, the correlation value for ω_3 was used to represent this frequency in ZrI_3.

Heat of Formation

The heat of formation of TiI_4(c) was measured by Johnson et al. (1), based on the heats of hydrolysis of $TiBr_4$(c) and TiI_4(c) in sulfuric acid. These data result in a heat of reaction of -57.88 kcal/mol for the process $TiI_4(c) + 2Br_2(\ell) = TiBr_4(c) + 2I_2(c)$, when recalculated with revised values of $\Delta Hf°_{298}$ for HBr(aq) and HI(aq) (2). Combination of $\Delta Hr°_{298}$ with auxiliary JANAF data gives the adopted value of $\Delta Hf°_{298}$.

Heat Capacity and Entropy

King et al. (3) reported the heat capacity and enthalpy of TiI_4(c) over the temperature range 51° to 428°K. The value of $S°_{298}$ is calculated from these data based on $S°_{51}$ = 14.62 eu. The value of $H°_{51} - H°_0$ is calculated to be 0.356 kcal/mol from a Debye-Einstein extrapolation of the measured heat capacities.

Transition Data

A first order transition was observed by King et al. (2) at 379°K. They reported the measured value of 2.37 kcal/mol, noting that this value had an uncertainty of 0.15 kcal/mol due to hysteresis in the transition.

Melting Data

The melting temperature and heat of melting were reported by King et al. (2). The large uncertainty on ΔHm° is due to the uncertainty and close proximity of the transition at 379°K.

Dec. 31, 1961; June 30, 1964; Dec. 31, 1968

TITANIUM TETRAIODIDE (TiI_4) (LIQUID) GFW = 555.5176

$S^\circ_{298.15}$ = 74.532 gibbs/mol

Tm = 428°K

Tb = 652.6°K

ΔHf°_0 = unknown

$\Delta Hf^\circ_{298.15}$ = -83.25 kcal/mol

ΔHm° = 4.74 ± 0.15 kcal/mol

ΔHv° = 13.50 ± 0.5 kcal/mol

Heat of Formation

The heat of formation of $TiI_4(\ell)$ is calculated from the heat of melting, ΔHm°_{428}, the heat of formation of $TiI_4(c)$, and the values of $H^\circ_{428} - H^\circ_{298.15}$ for both crystal and liquid.

Heat Capacity and Entropy

King et al. (1) reported the enthalpy of $TiI_4(\ell)$ above the melting temperature. The heat capacity derived from these data is constant. The entropy, S°_{298}, of $TiI_4(\ell)$ is calculated from ΔSm°_{428} and the values of $S^\circ_{428} - S^\circ_{298.15}$ of both crystal and liquid.

Melting Data

The melting temperature and heat of melting were reported by King et al. (1).

Vaporization Data

The boiling temperature, Tb, is taken as the point at which Kp = 1 for the reaction $TiI_4(\ell) = TiI_4(g)$. The heat of vaporization is calculated as the difference between ΔHf° of the liquid and gas at the boiling temperature. The vapor pressure data are discussed in the table for $TiI_4(g)$.

[55] (2)	[69] (3)

Bond Distance: Ti-I = [2.5] Å

Bond Angle: I-Ti-I = [109°28']

σ = 12

Product of the Moments of Inertia: $I_AI_BI_C$ = [4.33 x 10^{-110}] g^3cm^6

Heat of Formation

The heat of formation of $TiI_4(g)$ is calculated from that of $TiI_4(\ell)$ and the heat of vaporization of the liquid. Blocher and Campbell (1) reported vapor pressure data for $TiI_4(\ell)$ over the temperature range 473° to 655°K. Second and third law analyses of these data give values for ΔHv°_{298} of 17.2 ± 0.1 and 16.98 kcal/mol, respectively, the third law drift being -0.4 ± 0.2 eu. The adopted value of ΔHf°_{298} is based on the third law heat of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiBr_4(c)$, $TiBr_4(g)$ and $TiI_4(c)$ (2). The tetrahedral model is assumed by analogy with $TiCl_4(g)$ and $TiBr_4(g)$. The principal moments of inertia are: $I_A = I_B = I_C = 3.51 \times 10^{-37}$ g cm^2.

The vibrational frequencies of $TiI_4(g)$ have been estimated by Ushanova et al. (3). The given estimates are based on their predictions and valence force field calculations.

ZIRCONIUM TETRAIODIDE (ZrI_4) (CRYSTAL) MOL. WT. = 598.86

$\Delta H_f^\circ{}_0$ = [-115.4] ± 1.0 kcal. mole⁻¹

$S^\circ_{298.15}$ = [61.41] cal. mole⁻¹ deg.⁻¹

$\Delta H_f^\circ{}_{298.15}$ = -115.9 ± 0.8 kcal. mole⁻¹

T_s = 704°K.

$\Delta H_s^\circ{}_{298.15}$ = 31.0 ± 0.7 kcal. mole⁻¹

Heat of Formation.

A. G. Turnbull, J. Phys. Chem. 65, 1652 (1961), measured the heat of reaction for the following reactions:

(1) $ZrI_4(c) + 4NaOH(aq.) = ZrO_2(hyd.) + 4NaI(aq.) + 2H_2O$

(2) $ZrI_4(c) + 2H_2O = ZrOOH^+(aq.) + 4I^-(aq.) + 3H^+(aq.)$

Turnbull used the same procedure to calculate the heat of formation of zirconium tetraiodide as he did for zirconium tetrabromide [see $ZrBr_4$ table]. The heat of formation of the solid zirconium tetraiodide from reaction (1) was -115.6 ± 0.8 kcal. mole⁻¹ and from reaction (2) was -116.3 ± 0.8 kcal. mole⁻¹. An average of these was taken as the heat of formation of the tetraiodide.

Heat Capacity and Entropy.

The heat capacity from 0 to 300°K. was calculated in the same manner as for $ZrBr_4(c)$ [see $ZrBr_4(c)$ table]. The values, $\Theta_D^{3^\circ}$ = 60°K. and $\Theta_E^{3^\circ}$ = 115°K. were used in the analysis. The value, a = 1.5 X 10⁻³, was obtained from a consideration of the sublimation calculations [see below]. The heat capacity above 300°K. represents a graphical extrapolation.

Melting.

T_m = 772°K. was reported by O. Rahlfs and W. Fischer, Z. anorg. allgem. Chem. 211, 349 (1933).

Sublimation Data.

Vapor pressure measurements have been reported by Rahlfs and Fischer (loc. cit.). Four values of "a" were used to compute the thermodynamic functions of the solid. That value of "a" was chosen which gave agreement between 2nd and 3rd law values for the heat of sublimation. The sublimation results for the four values of "a" are given in the following table.

"a"	$\Delta H_{s(298)}$ [3rd law]	$\Delta H_{s(298)}$ [2nd law]
3.0 X 10⁻³	29.98 kcal. mole⁻¹	31.65 kcal. mole⁻¹
2.5 X 10⁻³	30.39 kcal. mole⁻¹	31.34 kcal. mole⁻¹
2.0 X 10⁻³	30.76 kcal. mole⁻¹	31.17 kcal. mole⁻¹
1.5 X 10⁻³	31.02 kcal. mole⁻¹	31.04 kcal. mole⁻¹

A temperature dependent third law heat of sublimation at 298°K. was obtained for "a = 3.0 X 10⁻³"; this temperature trend decreased for smaller values of "a" and there was essentially no temperature dependnece for "a = 1.5 X 10⁻³". Various high temperature extrapolations were not used since, by experience with $ZrBr_4(c)$, they produced insignificant changes in the heat values. The heat of sublimation was taken to be 31.0 kcal. mole⁻¹ since the entire analysis was conducted to obtain 2nd and 3rd law agreement.

From experience with a number of other compounds, that were found to be amenable to the theoretical treatment used here, the value "a = 1.5 X 10⁻³" appears to be rather low, but no further analysis was deemed practical since all parameters for the gas and solid are estimated.

The sublimation point obtained from the free energy crossover of solid and gas was 703°K. The value reported by Rahlfs and Fischer (loc. cit.), was 704°K. The sublimation point was taken as 704°K.

Since the sublimation point is lower than the melting point, the liquid phase is thermodynamically unstable under ordinary conditions.

Zirconium Tetraiodide (ZrI_4)

[237] (3)
[58] (3)

Bond Distance: Zr-I = [2.68] Å

σ = [12]

Bond Angle: I-Zr-I = [109° 28']

Product of the Moments of Inertia: $I_AI_BI_C$ = [6.5718 X 10^{-110}] gm.^{3} cm.^{6}

Heat of Formation.

Calculated from the heats of formation and sublimation for the crystal at 298.15°K. (see crystal table for details).

Heat Capacity and Entropy.

The interatomic distance was obtained from an involved correlation of the interatomic distances and covalent radii of the tetrahalides of Pb, Si, Ti, Ge, and Sn. I. N. Godnev, A. M. Aleksandrovskaya, and I. V. Regina, Optics and Spectroscopy 7, 172 (1959), estimated the interatomic distance and report 2.67 Å as the Zr-I distance. The I-Zr-I angle was taken as the tetrahedral angle. The three principal moments of inertia are: $I_A = I_B = I_C$ = 4.0355 X 10^{-37} gm. cm.^{2}.

The fundamental vibrational frequencies are estimated. The product of ω_1 and internuclear distance for the tetraiodides of Pb, Ti, Ge, and Sn was found to be approximately constant. Using the estimated Zr-I internuclear distance a value of 147 cm.$^{-1}$ was obtained for ω_1. Plots of ω_1 and ω_2 versus internuclear distance for these molecules were constructed and smooth curves drawn through the points. Values of ω_1 and ω_2 for ZrI_4 were read off from these plots; they were 146 cm.$^{-1}$ and 44 cm.$^{-1}$ respectively. Using ω_1 = 146 cm.$^{-1}$ and ω_2 = 45 cm.$^{-1}$, ω_3 = 237 cm.$^{-1}$ and ω_4 = 58 cm.$^{-1}$ were obtained from a valence force field calculation. Godnev, Aleksandrovskaya, and Regina (loc. cit.) estimated the vibrational frequencies and reported ω_1 = 152 cm.$^{-1}$, ω_2 = 44 cm.$^{-1}$, ω_3 = 211 cm.$^{-1}$ and ω_4 = 55 cm.$^{-1}$.

POTASSIUM (K) (REFERENCE STATE) MOL. WT. = 39.100

0°K. to 336.35°K.	Crystal
336.35°K. to 1043.7°K.	Liquid
1043.7°K. to 6000°K.	Ideal Monatomic Gas

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal.

Low temperature heat capacity measurements have been reported by L. M. Roberts [Proc. Phys. Soc. (London) 70B, 744-52 (1957)] (1.5°-20°K), by C. A. Krier, R. S. Craig, and W. E. Wallace [J. Phys. Chem. 61, 522 (1957)] (12°-320°K), by T. M. Dauphinee, D. L. Martin, and H. Preston-Thomas [Proc. Roy. Soc. (London), A233, 214 (1955)] (20°-330°K), by F. Simon and W. Zeidler [Z. physikal. Chem. 123, 383 (1926)] (15°-300°K), and by E. D. Eastman and W. H. Rodebush [J. Am. Chem. Soc. 40, 489 (1918)] (70°-290°K). A smooth curve was drawn through a large scale plot of the data, giving the most weight to the first three references. Above 300°K, the heat capacity data were adjusted to join smoothly with the heat content measurements of T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis [J. Am. Chem. Soc. 74, 2472 (1952)].

Heat Capacity of Liquid and Heat of Melting.

The heat of melting and liquid heat capacity are from the heat content measurements of T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis (loc. cit.).

Heat of Sublimation, Ideal Gas Functions.

See tables for K(g) and $K_2(g)$ for details.

December 31, 1961

POTASSIUM (K) (LIQUID) MOL. WT. = 39.100

$\Delta H_f^\circ{}_{298}$ = 0.546 kcal. mole^{-1}

T_m = 336.35°K.

T_b = 1037°K

ΔH_m = 0.558 kcal. mole^{-1}

ΔH_v = 18.38 kcal. per formula weight

Heat of Formation.

Back calculated from the heat of melting and the heat contents of solid and liquid at the melting point.

Heat of Melting and Heat Capacity.

The heat of melting, melting point, and liquid heat capacity were measured by T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis [J. Am. Chem. Soc. 74, 2472 (1952)]. The heat capacity curve was extrapolated back to 298°K. and up to 2000°K. in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K.

Vaporization.

Potassium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1037°K. The vapor composition at this temperature is 94.5 mole % monatomic and 5.5 mole % diatomic gas. The heat of vaporization of 39.1 grams of liquid potassium to this equilibrium mixture is 18.38 kcal. See also tables for K(g) and $K_2(g)$.

Thermodynamic Functions.

Thermodynamic functions were calculated using electronic levels and multiplicities from P. Risberg [Arkiv. Fysik 10, 583 (1956)] and C. E. Moore [Natl. Bur. Standards Circ. 467 (1949)]. Higher levels were averaged. The results are in excellent agreement with W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 83 (1955)].

Heat of Formation.

Evans, Munson, and Wagman (loc. cit.) have reviewed the vapor pressure data on potassium. Their calculations were revised slightly for the changes made in the functions for the condensed state. In addition, the recent data of M. M. Makansi, M. Madsen, W. A. Selke, and C. F. Bonilla, [J. Phys. Chem. 60, 138 (1956)] were considered in selecting the heat of sublimation of 21.31 ± 0.20 kcal. mole^{-1}. A review of the properties of potassium vapor using imperfect gas theory to establish the dimer dissociation energy has recently been published by R. J. Thorn and G. H. Winslow [J. Phys. Chem. 65, 1297 (1961)]. Although the imperfect gas treatment appears to be favored by the experimental data available, this could not be unequivocally established. Unpublished vapor pressure data cited by Thorn and Winslow are in agreement with the values selected here, assuming ideal gas behavior.

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic potassium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels", Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation K(ref. state) - e^-(ref. state) = K^+(monatomic gas), thus K^+ involves the difference in enthalpies of two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore, loc. cit.

Potassium Monoxide (KO)

$B_e = [0.3068]$ cm^{-1} $\alpha_e = [0.0027]$ cm^{-1} $r_e = [2.2]$ Å

Heat of Formation

Brewer and Margrave (1) suggested that the ΔHf° value for MO(g) from the gaseous ions can be taken as the mean of the corresponding ΔHf° values for the alkali fluoride and chloride with a maximum uncertainty of 10 kcal/mol. We obtain the values $\Delta Hr°_0 = -137.94$ and -117.7 kcal/mol for the reactions $K^+(g) + F^-(g) = KF(g)$ and $K^+(g) + Cl^-(g) = KCl(g)$, respectively. Assuming $\Delta Hr°_0 = -127.83$ kcal/mol for the reaction $K^+(g) + O^-(g) = KO(g)$, we calculate $\Delta Hf°_{298}(KO, g) = 19.0$ kcal/mol with the JANAF auxiliary values for the gaseous ions.

Based on the assumption that $D_0(KO) = 1/2[D_0(K_2) + D_0(O_2)]$, or $\Delta Hr°_0 = 64.9$ kcal/mol for the reaction $KO(g) = K(g) + O(g)$, we evaluate $\Delta Hf°_0(KO, g) = 15.6$ kcal/mol or $\Delta Hf°_{298}(KO, g) = 15.2$ kcal/mol.

According to Somayajulu (2), in a sequence of similar diatomic molecules, $k_e r_e/D_0$ = constant, where k_e = force constant, r_e = equilibrium bond distance and D_0 = dissociation energy. Using $r_e = 1.62$ Å, $D_0 = 77.9$ kcal/mol for LiO(g), $r_e = 2.2$ Å and $k_e(KO)/k_e(LiO) = 0.3015$, we calculate $D_0 = 55$ kcal/mol for KO(g), yielding $\Delta Hf°_{298}(KO, g) = 26.1$ kcal/mol. The value k_e is derived from the relation $k_e = 4\Pi^2\nu^2\mu$ where ν is the vibrational frequency of the diatomic molecule and μ is the reduced mass.

The value of $\Delta Hf°_{298}(KO, g)$ is tentatively adopted as 17 ± 10 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for the OH(g) molecule, which has the same number of valence electrons. The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for LiF(g) and KF(g). The bond distance is estimated from those for HO(g), HF(g) and KF(g). B_e and α_e are derived from r_e, ω_e and $\omega_e x_e$ by the method suggested by Herzberg (3).

Dec. 31, 1967

POTASSIUM MONOXIDE UNINEGATIVE ION (KO$^-$) (IDEAL GAS) GFW = 55.10195

Ground State Configuration [$^1\Sigma$]

ΔHf°_0 = [-33 ± 20] kcal/mol

$S^\circ_{298.15}$ = [54.1 ± 0.3] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-33 ± 20] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	[1]

ω_e = [360] cm^{-1}

B_e = [0.3068] cm^{-1}

$\omega_e x_e$ = [2.3] cm^{-1}

α_e = [0.0027] cm^{-1}

σ = 1

r_e = [2.2] Å

Heat of Formation

The electron affinity (E. A.) of KO$^-$(g) is unavailable, therefore the value of ΔHf°_{298}(KO$^-$, g) is estimated. Assuming that the enthalpy change (ΔHr°_0) of the reaction (1) KO$^-$(g) = K(g) + O$^-$(g) is approximately the average of the ΔHr°_0 value for the reaction (2) KO(g) = K(g) + O(g) and (3) KF(g) = K(g) + F(g), we obtain ΔHr°_0 = 1/2(63.5 + 117.3) = 90.4 kcal/mol for reaction (1). However, we compare the ΔHr°_0 values for the reactions (4) HO(g) = H(g) + O(g), (5) HO$^-$(g) = H(g) + O$^-$(g), and (6) HF(g) = H(g) + F(g), and find that ΔHr°_0 for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔHr°_0 values for reactions (4) and (6). Based on this fact we estimated ΔHr°_0 = 80 kcal/mol for reaction (1), yielding ΔHf°_{298}(KO$^-$, g) = -33 kcal/mol. The value of ΔHf°_{298}(KO$^-$, g) is tentatively adopted as -33 ± 20 kcal/mol. The electronic affinity of KO(g) is derived to be 2.2 ± 0.9 eV. The value of E. A. for HO(g) is determined as 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of KF(g) which is isoelectronic with KO$^-$(g). The values of ω_e, $\omega_e x_e$ and r_e are estimated by comparison with those for KF(g). The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ using the method recommended by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc. New York, 1950. The enthalpy at 0°K is -2.303 kcal/mol.

Thermodynamic Functions.

Spectroscopic data are the same as that selected by W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 83 (1955)]. The calculated functions are in excellent agreement with their results.

Heat of Formation.

The heat of dissociation selected by Evans, Munson, and Wagman (loc. cit.) was used with the previously adopted heat of sublimation of the monomer to derive the heat of formation.

K_2O

DIPOTASSIUM MONOXIDE (K_2O) (CRYSTAL) MOL. WT. = 94.20

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [22.5 ± 1.5] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -86.8 ± 0.5 kcal. mole^{-1}

T_d = 1154°K. (600 mm Hg)

Heat of Formation.

$\Delta H_f^\circ{}_{298.15}$ was reported by M. Rengade, Ann. Chim. et phys. [8] 14, 540 (1908), based on the measurements of the heats of solution of K(c) and K_2O(c) in H_2O. The same value of $\Delta H_f^\circ{}_{298.15}$ was also given by R. de Forcrand, Compt. rend. 158, 991 (1914).

Heat Capacity and Entropy.

Both C_p and $S^\circ_{298.15}$ were estimated by comparison with those of the Na_2O(c).

Temperature of Decomposition.

T_d was taken from, "Data on Chemicals for Ceramic Use", National Research Council Bulletin 118 (1949).

Dipotassium Dioxide (K_2O_2)

June 30, 1963; Sept. 30, 1963

DIPOTASSIUM DIOXIDE (K_2O_2) (CRYSTAL) MOL. WT. = 110.20

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [27.0 ± 1.5] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -118.5 ± 1.0 kcal. mole^{-1}

T_m = 763°K.

ΔH_m° = Unknown

Heat of Formation.

$\Delta H_f^\circ{}_{298.15}$ was reported by National Bureau of Standards Report 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," January 1, 1962. The value was based on the measured decomposition pressure of K_2O_2(c) by M. Centnerzwer and M. Blumenthal, IX Congr. IUPAC, 3A, 201 (1935).

Heat Capacity and Entropy.

The heat capacities and $S^\circ_{298.15}$ were estimated by comparison with those for Na_2O_2(c), Na_2O(c), and K_2O(c).

Temperature of Melting.

T_m was reported by Centnerzwer and Blumenthal, loc. cit.

$\Delta H_m = 0.7171 \pm 0.0037$ kcal. mole^{-1}

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Heat capacities have been reported by the following authors for the temperature ranges indicated: L. M. Roberts, Proc. Phys. Soc. 70, 744 (1957), 1.5 to 20°K (Li 99.5% pure); F. Simon and R. C. Swain, Z. phys. Chem. B28, 189 (1935), 15° to 300°K; D. L. Martin, Proc. Roy. Soc. A254, 444 (1960), 22° to 300°K (Li 99.95% pure); T. B. Douglas, L. F. Epstein, J. L. Dever, and W. H. Howland, J. Am. Chem. Soc. 77, 2144 (1955), 298° to 1200°K (Li 99.98% pure). Martin, in a series of determinations, found that C_p depended on the thermal history of the sample; a peak at roughly 107°K was ascribed to a martensitic transformation. There is excellent continuity between the results of Roberts and of Martin, while those of Martin and Douglas et al. differ by 1% at 300°K and have been smoothly joined. The values of Simon and Swain were not used as they were 5% lower than Martin's and did not show the peak at 107°K; also their values for Al_2O_3, reported at the same time, are lower than recent measurements. Heat capacities between 1200°K and the normal boiling point were obtained from the heat content equation given by Douglas et al. between 420° and 900°C.

Melting.

Douglas et al. (loc. cit.) report the triple point to be 180.54°C, which is here adopted as the melting point since the densities of solid and liquid lithium at 180°C are not available for calculating dT_m/dP. The same authors give the heat of melting as 432.3 ± 2.2 abs. joule g.$^{-1}$

Heat of Sublimation.

Lithium vapor contains an appreciable amount of dimer, whose heat of dissociation has been selected by W. H. Evans, R. Jacobson, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bureau of Standards 55, 83 (1955), from spectroscopic and molecular beam measurements to be 25.76 ± 0.10 kcal. mole^{-1} at 0°K. This heat of dissociation, together with the thermodynamic functions calculated in this work, has been used to find the partial pressures of Li(g) and Li_2(g) from the measured total vapor pressures. H. Hartmann and R. Schneider, Z. anorg. allgem. Chem. 180, 275 (1929), report values from 1204° to 1353°K; while M. Mancherat, C. Rendus 208, 499 (1939), reports effusion measurements from 735° to 915°K. Mancherat's pressures are calculated on the assumption of monatomic vapor and have been recalculated to find the true total pressure. Effusion measurements by L. C. Lewis, Z. Physik 69, 786 (1931), and A. Bogros, C. Rendus 191, 560 (1930) and Ann. Phys. 17, 199 (1932), have been disregarded. Mancherat considers them to be inaccurate because of impurities in the lithium used, and Lewis used a doubtful calibration method. Heats of sublimation to monatomic vapor calculated from the vapor pressures of Hartmann and Schneider and of Mancherat agree to within 2% and the average value has been adopted. The heat of sublimation of the dimer was then calculated using this value.

June 30, 1962

LITHIUM (Li) (LIQUID) AT. WT. = 6.940

ΔH_f° 298.15 = 0.569 kcal. mole^{-1}

$S^\circ_{298.15}$ = 8.113 cal. deg.$^{-1}$ mole^{-1}

T_m = 453.69°K

ΔH_m = 0.7171 ± 0.0035 kcal. mole^{-1}

T_b = 1620°K (Equilibrium mixture)

T_b (Monatomic gas) = 1638°K

ΔH_v 1638 = 35.16 kcal. mole^{-1}

Heat of Formation.

Obtained from the heat of fusion by adding $H_{453.69}-H_{298.15}$ for the solid and subtracting $H_{453.69}-H_{298.15}$ for the liquid.

Heat Capacity.

The data of T. B. Douglas, L. F. Epstein, J. L. Dever, and W. H. Howland, J. Am. Chem. Soc. 77, 2144 (1955) were taken and extrapolated below T_m and above 1200°K in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K.

Vaporization.

Lithium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1620°K; the vapor pressure of the monatomic gas reaches 1 atm. at 1638°K and the heat of vaporization to monatomic gas is 35.16 kcal. mole^{-1}. See also Li(crystal).

LITHIUM, MONATOMIC (Li) (IDEAL GAS) AT. WT. = 6.940

ΔH°_{f0} = 38.034 kcal. mole^{-1}

ΔH°_f 298.15 = 38.41 ± 0.40 kcal. mole^{-1}

Ground State Configuration $^2S_{1/2}$

$S^\circ_{298.15}$ = 33.143 cal. deg. mole^{-1}

Electronic Levels and Multiplicities

ϵ_i cm.$^{-1}$	g_i	ϵ_i cm.$^{-1}$	g_i
0	2	36596	30
14904	6	38300	2
27206	2	39623	50
30925	6	41756	70
31283	10	42736	52
35012	2	43319	162

Heat of Formation.

Same as the heat of sublimation to the monatomic gas; see notes on Li(crystal).

Heat Capacity and Entropy.

The energy levels have been taken from C. E. Moore, "National Bureau of Standards Circular 467," U. S. Government Printing Office, Washington (1949) p. 9. Closely spaced levels have been averaged and the appropriate multiplicities assigned to the averages.

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic lithium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels" Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation Li(ref. state) - e^-(ref. state) = Li^+(monatomic gas), thus Li^+ involves the difference in enthalpies of two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore loc. cit.

Dec. 31, 1960; Sept. 30, 1966; Dec. 31, 1966

LITHIUM NITRIDE (LiN) (IDEAL GAS) GFW = 20.9457

Ground State Configuration [$^3\Sigma$]

ΔHf°_0 = 80 ± 40 kcal/mol

$S^\circ_{298.15}$ = [49.7] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 80 ± 40 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	[3]

ω_e = [700] cm^{-1}

$\omega_e x_e$ = [7] cm^{-1}

σ = 1

B_e = [1.25] cm^{-1}

α_e = [0.0183] cm^{-1}

r_e = [1.71] Å

Heat of Formation.

The adopted $\Delta Hf^\circ_{298.15}$, 80 ± 40 kcal/mol, is calculated from the following estimates:

Method	D°_0 kcal/mol	$\Delta Hf^\circ_{298.15}$ kcal/mol
Estimate D°_0 from geometric mean for Li_2 and N_2	76	75
Estimate from D°_0 for series N_2(g), CN(g), BN(g) and BeN(g)	40 - 100	110 - 50
Estimate from D°_0 for series HN(g), HO(g), HF(g), LiF(g) and LiO(g)	20 - 60	130 - 90

J. L. Margrave and P. Sthapitanonda, J. Phys. Chem. 59, 1231 (1955), report estimated dissociation energies in the range 111-178 kcal/mol, based on approximate ionic binding energies calculated from ionic radii for N^- in the range 0.70 to 1.08 Å.

Heat Capacity and Entropy.

The molecular constants ω_e, r_e and $\omega_e x_e$ are estimated by comparison with those of CN, BN, CO, BO and LiO. The values of α_e and B_e are calculated from the above constants. The ground state configuration is assumed to be $^3\Sigma$ by analogy with NH and OH^+.

Sept. 30, 1966

LITHIUM NITROXIDE (LiON) (IDEAL GAS) GFW = 36.9451

Point Group C_s

$S^\circ_{298.15}$ = 58.61 gibbs/mol

Ground State Quantum Weight = [1]

ΔHf°_0 = [43.5 ± 10] kcal/mol

$\Delta Hf^\circ_{298.15}$ = [43.0 ± 10] kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
1350 (1)
330 (1)
650 (1)

Bond Distance: O-Li = 1.63 ± 0.07 Å

O-N = 1.30 ± 0.05 Å

Bond Angle: Li-O-N = 100 ± 10°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = 2.6523 x 10^{-116} g^3 cm^6

Heat of Formation

The heat of formation (ΔHf°_{298}) for LiON(g) has not been determined experimentally. The ΔHf°_{298} value adopted is calculated from the estimated Li-O and O-N bond energies. The value, D(Li-O) = 88 kcal/mol, is obtained by averaging the bonds in Li_2O(g). The value, D(O-N) = 69 kcal/mol, is calculated on the assumption that D(ClON-O) = D(N-OLi). The ΔHf°_{298} of LiOH(g), calculated similarly from bond energies (i.e. D(Li-O) = 88 kcal/mol and D(O-H) = 111 kcal/mol), is 10 kcal/mol more than the measured value. Therefore, we subtract 10 kcal/mol from the ΔHf°_{298} of LiON, 53 kcal/mol, estimated from the above bond energies, and arrive at 43 kcal/mol for the adopted value.

Heat Capacity and Entropy

The vibrational frequencies, bond distances and bond angle were obtained from W. L. S. Andrews and G. C. Pimentel, loc. cit. The three principal moments of inertia are: I_A = 1.2706 x 10^{-36}, I_B = 3.9776 x 10^{-39} and I_C = 5.2482 x 10^{-39} g cm^2.

Lithium Sodium Oxide (LiNaO)

(Ideal Gas) Mol. Wt. = 45.931

Heat of Formation.

D. White, K. S. Seshadri, D. F. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963) calculated the heat of formation from their mass spectral data by two different methods.

For the first calculation (a) they combined the slope of the log IT vs 1/T curve for LiO^+ with the slopes for Li^+ and Li_2O^+ for the reaction $Li_2O\ (g) \rightarrow Li(g) + LiO(g)$. For the second calculation (b) they assumed a cross section $\sigma_{LiO}/\sigma_{Li_2O} = 1$ and from this they calculated a partial pressure for LiO(g) at 1500°K and an equilibrium constant for the reaction $Li_2O(g) \rightarrow Li(g) + LiO(g)$. They obtained (a) $\Delta H^\circ_{f\ 298}$ = 18.3 kcal. mole^{-1} and (b) $\Delta H^\circ_{f\ 298}$ = 16.3 kcal. mole^{-1}, and used the average value from the two methods for the heat of formation of LiO(g). The JANAF heat of formation, 20.1 ± 5 kcal. mole^{-1}, was obtained in the same way using their data and the present tables i.e. (a) $\Delta H^\circ_{f\ 298}$ = 22.0 kcal. mole^{-1} and (b) $\Delta H^\circ_{f\ 298}$ = 18.3 kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular constants, $\omega_e x_e$, Be, and α_e, were calculated from ω_e and r_e, reported by White et al. The ground state configuration, $^2\Pi$, was estimated by J. S. Gordon, Thiokol Chemical Corp., Reaction Motor Division, Denville, N. J., "Thermodynamic Data for Combustion Products", January, 1960, by A Buchler and J. L. Stauffer, J. Chem. Phys. 39, 2299 (1963) and by White et al.

$\omega_e x_e$ = [4.5] cm^{-1}

α_e = [0.0121] cm^{-1}

σ = 1

r_e = [1.6] Å

Heat of Formation

Data on the electron affinity (E.A.) of LiO (g) are unavailable, therefore the value of $\Delta Hf_{298}^\circ(LiO^-, g)$ is estimated. We first assume that the enthalpy change (ΔHr_0°) of the reaction (1) $LiO^-(g) = Li(g) + O^-(g)$ is close to the average of the ΔHr_0° values for the reactions (2) $LiO(g) = Li(g) + O(g)$ and (3) $LiF(g) = Li(g) + F(g)$. The atom F(g) is isoelectronic with $O^-(g)$. In other words, the ΔHr_0° for reaction (1) is approximately 1/2(76.91 + 135.84) = 106.4 kcal/mol. Then we compare the ΔHr_0° values for the reactions (4) $HO(g) = H(g) + O(g)$, (5) $HO^-(g) = H(g) + O^-(g)$, and (6) $HF(g) = H(g) + F(g)$, and find that ΔHr_0° for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔHr_0° values for reactions (4) and (6). Based on this fact we estimate ΔHr_0° = 96.4 kcal/mol for reaction (1), yielding $\Delta Hf_{298}^\circ(LiO^-, g)$ = -15.5 kcal/mol.

Applying the difference in electron affinity between H(g) and Li(g) to OH(g) gives an approximate value, E. A. = 1.7 eV (39.2 kcal/mol) for LiO(g). The value of E. A. for H(g), Li(g) and OH(g) are taken from U. S. Bur. Std. Rept. 8628, Jan. 1, 1965. Based on ΔHr_0° = 39.2 kcal/mol for the reaction $LiO^-(g) = LiO(g) + e^-(g)$, we derive ΔHf_{298}° = -19.1 kcal/mol for $LiO^-(g)$, which is in reasonable agreement with the above estimated value.

The value of ΔHf_{298}° for $LiO^-(g)$ is tentatively adopted as -16 ± 15 kcal/mol. Using this ΔHf_{298}° value, we derive E. A. = 1.6 ± 0.7 eV for LiO(g). The electron affinity of OH(g) is 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of LiF(g) which is isoelectronic with $LiO^-(g)$. The values of ω_e, $\omega_e x_e$ and r_e are estimated by comparison with the observed data for LiF(g). The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ by use of the method suggested by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950. The enthalpy at 0°K is -2.137 kcal/mol.

June 0, 1960

LITHIUM, DIATOMIC (Li_2) (IDEAL GAS) MOL. WT. = 13.880

$\Delta H^\circ_{f0} = 50.298$ kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15} = 50.4 \pm 0.9$ kcal. mole^{-1}

Ground State Configuration $^1\Sigma^+$

$S^\circ_{298.15} = 47.050$ cal. deg. mole^{-1}

$\omega_e = 353.59$ cm.$^{-1}$

$\omega_e x_e = 2.625$ cm.$^{-1}$

$\sigma = 2$

$B_e = 0.6812$ cm.$^{-1}$

$\alpha_e = 0.00718$ cm.$^{-1}$

$r_e = 2.673$ Å

Heat of Formation.

Same as the heat of sublimation to the diatomic gas; see notes on Li (crystal).

Heat Capacity and Entropy.

The spectroscopic constants of Li_2^7 listed by G. Hertzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Co., Inc., New York (1950) have been corrected for the presence of 7.5% Li^6 in naturally occuring lithium, J. R. Stehn and E. F. Clancy, "Chart of the Nuclides", General Electric Co., Schenectady (1956).

Dec. 31, 1960; Mar. 31, 1964

DILITHIUM MONOXIDE (Li_2O) (CRYSTAL) MOL. WT. = 29.880

$S^\circ_{298.15}$ = 9.056 cal. deg.$^{-1}$ mole^{-1}

T_m = 1843°K.

$\Delta H^\circ_{f\ 0}$ = -141.6 ± 0.5 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -143.1 ± 0.5 kcal. mole^{-1}

ΔH_m = [14] kcal. mole^{-1}

Heat of Formation.

The selected heat of formation was calculated as follows:

	Reaction	$\Delta H^\circ_{r\ 298.15}$ kcal. mole^{-1}	Ref.
(I)	$Li_2O(c) + H_2O(l) = 2LiOH(\infty H_2O)$	-31.74 ± 0.08	(a)
(II)	$Li(c) + 1/2\ O_2(g) = LiOH(\infty H_2O)$	-121.572 ± 0.019	(b)
(III)	$H_2(g) + 1/2\ O_2(g) = H_2O(l)$	-68.3174	(c)
(IV)	$2Li(c) + 1/2\ O_2(g) = Li_2O(c)$	-143.1 ± 0.5	(d)

(a) V. P. Kolesov, S. M. Skuratov, and I. D. Zaikin, Russian J. Inorganic Chemistry, 4, 558 (1959).

(b) S. R. Gunn and L. G. Green, J. Am. Chem. Soc., 80, 4782 (1958).

(c) F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and I. Jaffe, "Selected Values of Chemical Thermodynamic Properties" National Bureau of Standards Circular 500, 1952 (reprinted 1961).

(d) Reaction (IV) is the sum of -(I) + 2(II) - (III).

Kolesov, et al. (loc. cit) measured the enthalpy of the reaction of Li_2O with water at 20° in 5 experiments. The mean ΔH°_r was -31.41 ± 0.08 kcal. This was brought to 298°K by Kolesov using enthalpy data of (a) H. L. Johnston and T. W. Bauer, J. Am. Chem. Soc. 73, 1119 (1951), for Li_2O, (b) N. S. Osborne, J. F. Stimson, and D. C. Ginnings, J. Res. Natl. Bur. Stds. A, 23, 197 (1939) for H_2O, (c) F. T. Gucker and K. N. Schminke, J. Am. Chem. Soc., 55, 1013 (1933) for C_p of LiOH(aq) and (d) Rossini, et al., (loc. cit) for aqueous LiOH. In addition to the above, N. N. Beketov, Bull. Acad. Sci. Russ. 32, 186 (1888) and H. R. Forcrand, Compt Rend. 144, 1403 (1907) have reported experimental heats for Li_2O. Rossini et al. and Johnston and Bauer have reported heats of formation for Li_2O recalculated from older data. L. G. Fasolino, in a Natl. Research Corp. Quarterly Report, July 1 to Sept. 30, 1962, reported a $\Delta H^\circ_{f\ 298}$ of -141.1 ± 4.2 kcal. He measured the heat of combustion of Li(c) in $O_2(g)$ in a Parr bomb.

Heat Capacity and Entropy.

The low temperature C_p data of H. L. Johnston and T. W. Bauer, (loc. cit.) from [17° -298°K.] was joined graphically to the high temperature C_p data of C. H. Shomate and A. J. Cohen, J. Am. Chem. Soc. 77, 285 (1955) [425°-1045°K] and E. N. Rodigina, and K. A. Gomelskii, Russian J. Phys. Chem. 35, 898 (1961) [370°-1125°K]. The $S^\circ_{298.15}$ was reported by Johnston and Bauer using S°_{16} (extrap.) = 0.003 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

The melting point of Li_2O is uncertain. The selected melting point, 1843°K., was measured by A. E. van Arkel, E. A. Flood, and N. F. H. Bright, Can. J. Chem. 31, 1009 (1953). L. Brewer and J. L. Margrave, J. Phys. Chem. 59, 421 (1955) reported the melting point 1700°K. They also stated that H. van Kooster and F. Jaeger, Proc. Roy. Acad. Sco., Amsterdam 16, 857 (1914) had reported 1700° (1973°K) as the melting point. The heat of melting, [14] kcal. mole^{-1}, was estimated by A. Glassner, "The Thermochemical Properties of the Oxides, Fluorides, and Chlorides to 2500°K", Argonne National Laboratory, University of Chicago, ANL-5750, 1957.

Heat of Sublimation.

$Li_2O(c)$ vaporizes to $Li_2O(g)$, LiO(g), $Li_2O_2(g)$, Li(g), and $O_2(g)$ [J. Berkowitz, W. A. Chupka, G. D. Blue and J. L. Margrave, J. Phys. Chem., 63, 644 (1959); D. White, K. S. Seshadri, D. F. Dever, D. E. Mann, and M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963); D. L. Hildenbrand, W. F. Hall, and N. D. Potter, J. Chem. Phy. 39, 296 (1963); D. L. Hildenbrand, L. P. Theard, W. F. Hall, and N. D. Potter, Fifth Quarterly Technical Report, U-2289, Aeronutronic Division of Philco Corporation, 15 September 1963; L. P. Firsova and A. N. Nesmeyanov, Russian J. Phys. Chem., 34, 1232 (1960). The major species (0°-1700°K.) are reported to be $Li_2O(g)$, Li(g), and $O_2(g)$ with lesser amounts of LiO(g) and $Li_2O_2(g)$. Hildenbrand, et al., U-2298, have reported about equal amounts of Li_2O^+ and Li^+ (1300 to 1550°K.) and about 1/30th of this amount of LiO^+. White, et al., calculated ΔH_s from their mass spectra data. They made two different calculations: (a) for $Li_2O(c) \rightarrow Li_2O(g)$, and (b) for $Li_2O(g) \rightarrow 2Li(g) + 1/2\ O_2(g)$, and found: (a) 102.5 kcal. and (b) 99.0 kcal. They used a weighted average of (a) and (b) and obtained 101.6 kcal. at 0°K. The selected $\Delta H^\circ_{s\ 298}$ of 102.3 ± 3 kcal. was obtained in the same manner using their data and the present JANAF functions, i.e. (a) 104.2 kcal. and (b) 100.3 kcal. Knudson-effusion data of White et al., corrected for dissociation gave 3rd law heats at 298°K of 101.9 kcal. and a 2nd law heat of 94 kcal. Recalculation of Hildenbrand's dissociation pressure with JANAF values gives Li_2O pressures slightly different than those reported. The recalculated pressures give a 3rd law $\Delta H^\circ_{s\ 298}$ of 101.7 kcal. for both cells. The corresponding 2nd law values are 85 and 95.5 kcal. for cell 7 and 8. The 3rd law treatment of both sets of data show relatively large trends of ΔH_s with T which are probably too large to be only due to errors in the functions. (Continued on Lithium Oxide $Li_2O(g)$ table)

Dec. 31, 1960; Mar. 31, 1964

DILITHIUM MONOXIDE (Li_2O) (LIQUID) MOL. WT. = 29.880

$S^\circ_{298.15}$ = 13.160 cal. deg.$^{-1}$ mole^{-1}

T_m = 1843°K.

T_b = [2836°K.]

ΔH_f° 298.15 = -132.129 kcal. mole^{-1}

ΔH_m° = [14] kcal. mole^{-1}

ΔH_v° = Unknown

Heat of Formation.

ΔH_f° (l) was obtained from ΔH_f° (c) by adding ΔH_m and the difference between $H_{1843}-H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated at 8 cal. deg.$^{-1}$ g. atom^{-1} from comparisons with similar compounds and from Kopp's rule. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See melting data given on the Li_2O crystal table.

Vaporization Data.

The vapor over Li_2O(c) at 1700°K. is composed of Li_2O(g), Li(g), O_2(g), LiO(g), and Li_2O_2(g). Thus a boiling point becomes almost meaningless. The value, 2836°K, listed above is the temperature at which the free energy of Li_2O(g) and the free energy of Li_2O(l) are equal. L. Brewer, Chem. Rev. 52, (1953) estimated a boiling point of 2600°K.

Bond Distance: Li-O = [1.59] Å

Bond Angle: Li-O-Li = 180°

$\sigma = 2$

Rotational Constant: B_0 = 0.48045 cm.$^{-1}$

Heat of Formation.

The heat of formation was calculated from the heat of formation of the crystal and the heat of sublimation.

Heat Capacity and Entropy.

D. White, K. S. Seshadri, and D. F. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963) made an estimate of the bond distance Li-O = 1.59 Å based on an analysis of their vibrational spectra. They found that Li_2O was a linear molecule. A. Buchler and J. L Stauffer, J. Chem. Phys. 39, 2299 (1963) have shown from electric deflection experiments that Li_2O is very probably linear. They also report from the results of an effusion experiment evidence that the electron diffraction data and Li-O bond distance, 1.82 Å reported by P. A. Akishin and N. G. Rambidi, Dokl. Akad. Nauk. SSSR 118, 973 (1958) [English Translation, Proc. Acad. Sci. USSR, Phys. Chem. Sect. 118, 83 (1958)] are for Mo-O in Li_2MoO_4 rather than for Li-O in Li_2O. Buchler and Stauffer (loc. cit.) estimate an Li-O distance of 1.55 Å. White, et al., (loc. cit.) have estimated the vibrational frequencies ν_1 = [760] cm.$^{-1}$ and ν_2 = [140] cm.$^{-1}$ and assigned ν_3 = 987 cm.$^{-1}$ from their infrared matrix spectra. The principal moments of inertia calculated from the molecular constants are: $I_A = 0$, and $I_B = I_C$ = 5.8256 X 10^{-39} g. cm.^{2}.

Heat of Sublimation (continued from $Li_2O(c)$ table).

A sample of $LiAlO_2$ was melted 7 times in argon in an arc-image furnace, H. Prophet, "Melting Point of Lithium Aluminate", ARPA-1-150, Dow Chemical Co., Mar. 9, 1961. The sample decomposed on fusion and successive melting points approached that of Al_2O_3. The residue was found to be 95% Al_2O_3 and 5% $LiAl_5O_8$. The sample and residue were characterized by X-ray diffraction. A reasonable assumption from this is that ΔF_r (2000°K) = 0 for $2LiAlO_2(c) = Al_2O_3(c) + Li_2O(g)$. From this ΔF, a $\Delta H^\circ_{s\ 298}$ for Li_2O of 50 kcal. was calculated. A vapor pressure study of the molecular species over the decomposing $LiAlO_2$ might help resolve the discrepancies in lithium oxide ΔH_s° values.

June 30, 1963; Sept. 30, 1963

DILITHIUM DIOXIDE (Li_2O_2) (CRYSTAL) MOL. WT. = 45.880

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [13.5 ± 1.0] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -151.2 ± 2.0 kcal. mole^{-1}

T_d = 468°K.

Heat of Formation.

$\Delta H_f^\circ{}_{298.15}$ was reported by R. de Forcrand, Compt. rend. 130, 1465 (1900), based on the measured heats of the reactions of Li_2O_2(c) with HCl(aq.) and LiOH(aq.) with H_2O_2(aq.).

Heat Capacity and Entropy.

Both C_p and $S^\circ_{298.15}$ were estimated by comparison with those of the Na_2O_2(c), respectively.

Temperature of Decomposition.

T_d was reported to be about 300°C. by N. M. Wiederhorn, N. F. Surprenant, and A. J. Leffler, "Research on New Methods of Separation of Air into O_2 and N_2 Components," C-63825, First-Quarterly Progress Report, September 1961, Arthur D. Little, Inc. The value adopted was reported by Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use", June, 1949, obtained from M. Centnerzwer and M. Blumenthal, Bull. intern. acad. polonaise, Classe. sci. math. nat., A 499 (1933).

Heat of Formation.

The heat of formation, -58 kcal., was calculated from an equilibrium constant for the reaction 1/2 $O_2(g) + Li_2O(g) \rightarrow Li_2O_2(g)$ and the current JANAF functions. The equilibrium constant, 0.39, was estimated by D. White, K. S. Seshadri, D. F. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963), from their mass spectrometric data.

Heat Capacity and Entropy.

White, et al., (loc. cit.), from their spectral data have assigned two observed frequencies and estimated the remaining frequencies using the ionic model calculations of J. Berkowitz, J. Chem. Phys. 29, 1386 (1958); 32, 1519 (1960) as a guide. They proposed a planar rhombic structure of D_{2h} symmetry, similar to the alkali halide dimers, for the previously undetected Li_2O_2 molecule, and estimated the angle, 116°, and bond distance, 1.90 Å, from their matrix spectra. The principal moments calculated from these molecular constants are: I_A = 13.793 X 10^{-39}, I_B = 2.336 X 10^{-39}, and I_C = 16.129 X 10^{-39} g. cm.^{2}.

Sept. 30, 1961; March 31, 1964; June 30, 1967

LITHIUM METASILICATE (Li_2SiO_3) (CRYSTAL) GFW = 89.9622

$\Delta Hf^\circ_0 = -391.63 \pm 1.0$ kcal/mol

$S^\circ_{298.15} = 19.19 \pm 0.3$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -394.24 \pm 1.0$ kcal/mol

$Tm = 1474 \pm 1°K$

$\Delta Hm^\circ = 6.7 \pm 0.5$ kcal/mol

Heat of Formation

The heats of solution of LiCl(c), Li_2SO_4(c), SiO_2(quartz) and Li_2SiO_3(c) in 20 per cent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). The authors derived two values of ΔHsoln of Li_2O(c) from those of LiCl(c) and Li_2SO_4(c), presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate ΔHsoln of Li_2O(c) as -58.74 (chloride scheme, originally -59.36) and -59.83 kcal/mol (sulfate scheme, originally -60.86), using recent ΔHf°_{298} values for LiCl(c), Li_2SO_4(c), HCl(aq), H_2SO_4(aq), and Li_2O(c). The corresponding enthalpy changes, ΔHr°_{298}, for the reaction $Li_2O(c) + SiO_2(quartz) = Li_2SiO_3(c)$ are derived as -33.08 and -34.17 kcal/mol. Adopting the weighted average $\Delta Hr^\circ_{298} = -33.44$ kcal/mol with $\Delta Hf^\circ_{298}(Li_2O,c) = -143.1$ kcal/mol and $\Delta Hf^\circ_{298}(SiO_2, quartz) = -217.7$ kcal/mol, we obtain $\Delta Hf^\circ_{298} = -394.24$ kcal/mol for Li_2SiO_3(c). This $\Delta Hf^\circ_{298}(Li_2SiO_3, c)$ value is independent of future changes in ΔHf°_{298} of Li_2O(c) but the values of ΔHsoln and ΔHr° are not independent.

The heats of solution of LiOH(c) and Li_2SiO_3(c) in 20 percent HF(aq) at 50°C were measured by W. E. Hatton, D. L. Hildenbrand, G. C. Sinke, and D. R. Stull, unpublished work, Thermal Laboratory, The Dow Chemical Co., Midland, Michigan, 1959. The Li_2SiO_3 sample was prepared from lithium carbonate and silica by fusion under vacuum at 1500°K. Analysis gave 66.74 percent SiO_2 and 15.12 percent Li. The corresponding calculated values are 66.79 and 15.43. Also present were 0.5 percent K and 0.06 percent Na. Corrections were made for impurities in the heat of formation measurements. The results are given as follows:

	ΔHr°_{298}, kcal/mol
$2LiOH(c, 25°C) + 2HF(sol, 50°C) \rightarrow 2LiF(sol, 50°C) + 2H_2O(sol, 50°C)$	-38.728
$SiO_2(c, 25°C) + 6HF(sol, 50°C) \rightarrow H_2SiF_6(sol, 50°C) + 2H_2O(sol, 50°C)$	-32.810
$3H_2O(sol, 50°C) + 2LiF(sol, 50°C) + H_2SiF_6(sol, 50°C) \rightarrow Li_2SiO_3(c, 25°C) + 8HF(sol, 50°C)$	+58.850
$H_2O(sol, 50°C) \rightarrow H_2O(\ell, 25°C)$	-0.450
$2LiOH(c, 25°C) + SiO_2(c, 25°C) \rightarrow Li_2SiO_3(c, 25°C) + H_2O(\ell, 25°C)$	-13.14 ± 0.70

The ΔHr°_{298} for the second reaction was determined by D. R. Torgeson and T. G. Sahama, J. Am. Chem. Soc. 70, 2156 (1948). Based on the calculated enthalpy change for the overall reaction, $\Delta Hr^\circ_{298} = -13.14$ kcal/mol and $\Delta Hf^\circ_{298} = -115.84$, -217.7 and -68.32 kcal/mol for LiOH(c), SiO_2(low quartz), and $H_2O(\ell)$, respectively, we derived $\Delta Hf^\circ_{298}(Li_2SiO_3, c) = -394.21 \pm 1.0$ kcal/mol, which is in agreement with the adopted value.

C. Kroger and E. Fingas, Z. Anorg. Allgem. Chem. 213, 12 (1933), measured the equilibrium pressure of CO_2 over a mixture of Li_2CO_3(c), SiO_2(quartz), and Li_2SiO_3(c) from 585 to 781°K. The enthalpy change (ΔHr°_{298}) of the reaction $Li_2CO_3(c) + SiO_2(c) \rightarrow Li_2SiO_3(c) + CO_2(g)$ is evaluated by the second and third law methods to be 30.94 and 29.47 kcal/mol, respectively. Using $\Delta Hf^\circ_{298} = -290.64$, -217.7 and -94.05 kcal/mol for Li_2CO_3(c), SiO_2(c) and CO_2(g), respectively, and third law ΔHr°_{298}, we obtain $\Delta Hf^\circ_{298}(Li_2SiO_3, c) = -384.82 \pm 5$ kcal/mol, which is not used.

Heat Capacity and Entropy

The low temperature heat capacities, 25 - 340°K, were measured by Hatton et al., loc. cit., with an adiabatic vacuum calorimeter, using a nickel-plated copper sample container. During the filling and sealing of the calorimeter, the compound was handled in an anhydrous, CO_2-free atmosphere so as to avoid contamination. The purity of the sample is not well established. The high temperature heat capacities are estimated by summation of the Cp's of the constituent oxides, Li_2O and SiO_2, and a subsequent correction based upon a comparison of the heat capacities of Na_2SiO_3(c) and its constituent oxides. These estimated Cp values are plotted, and the resulting curve is joined smoothly with the low temperature Cp curve at 298°K. The entropy, S°_{298}, is derived using the measured low temperature heat capacities, based on $S^\circ_{25} = 0.023$ eu.

Melting Data

See $Li_2SiO_3(\ell)$ table for details.

Sept. 30, 1961; March 31, 1964; June 30, 1967

LITHIUM METASILICATE (Li_2SiO_3) (LIQUID) GFW = 89.9622

$S^\circ_{298.15}$ = 22.958 gibbs/mol $\Delta Hf^\circ_{298.15}$ = -388.441 kcal/mol

Tm = 1474 ± 1°K ΔHm° = 6.7 ± 0.5 kcal/mol

Heat of Formation

$\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{1474} - H^\circ_{298}$ for crystal and liquid.

Tschernobaeff, Rev. Met. 21, 729 (1905), measured the heat of reaction between SiO_2 and Li_2CO_3 in a bomb calorimeter, using carbon as the auxiliary combustible material. Based on the derived ΔHr°_{298} = 24.99 kcal/mol for the reaction $Li_2CO_3(c) + SiO_2(c) \rightarrow Li_2SiO_3(gl) + CO_2(g)$, the heat of formation for $Li_2SiO_3(gl)$ is evaluated as -389.30 kcal/mol, which is in fair agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $Na_2SiO_3(\ell)$, $Na_2O(\ell)$ and $Li_2O(\ell)$. A glass transition is assumed at 1000°K; i.e., the heat capacities below 1000°K are taken to be the same as those for $Li_2SiO_3(c)$.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point has been reported as 1474 ± 1 and 1461°K by F. C. Kracek, J. Phys. Chem. 34, 2641 (1930), and H. S. Van Klooster, Z. Anorg. Chem. 69, 135 (1911), respectively. The value reported by Kracek is adopted.

R. Schwarz and H. Sturm, Ber. 47, 1730 (1914), used a cooling-curve method to compare the heats of fusion of $Li_2SiO_3(c)$ and NaCl(c). From the reported ratio, $\varepsilon(Li_2SiO_3)/\varepsilon(NaCl) = 0.261/0.402$, where ε = heat of fusion in kcal/g, and heat of fusion of NaCl(c), the value ΔHm° = 6.7 kcal/mol is derived.

June 30, 1961; Mar. 31, 1964

LITHIUM METATITANATE (Li$_2$TiO$_3$) (CRYSTAL) MOL. WT. = 109.780

$\Delta H^\circ_{f\ 0}$ = -396.8 kcal. mole^{-1}

$S^\circ_{298.15}$ = 21.930 ± 0.1 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -399.3 kcal. mole^{-1}

T_{t_1} = 1485°K.

$\Delta H^\circ_{t_1}$ = 2.75 kcal. mole^{-1}

T_m = 1820°K.

ΔH_m = 26.33 kcal. mole^{-1}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ was calculated from measurements of solution calorimetry by S. S. Todd and K. K. Kelley, "Heat and Free Energy Data for Tricalcium Dititanate, Sphene, Lithium Metatitanate and Zinc Titanium Spinel", U. S. Bureau Mines Report Invest. 5193 (1956), according to the following equation:

$TiO_2(c) + Li_2SO_4(c) + 13.312\ H_2O(l) = Li_2TiO_3(c) + H_2SO_4(12.312\ H_2O) \qquad \Delta H_{r\ 298.15} = 27.04$ kcal.

The $\Delta H_{f\ 298.15}$ $TiO_2(c)$ value for rutile was obtained from the JANAF Tables and the other $\Delta H_{f\ 298.15}$ values were obtained from "Selected Values of Chemical Thermodynamic Properties" NBS Circular 500 (1952).

Heat Capacity and Entropy.

The low temperature heat capacities were taken from E. G. King, J. Am. Chem. Soc. 77, 2150 (1955). These low temperature heat capacities were fit to the high temperature heat contents from A. U. Christensen, K. C. Conway, and K. K. Kelley, "High Temperature Heat Contents and Entropies of Aluminates and Ferrites of Lithium, Sodium, and of Lithium Titanate", U. S. Bur. Mines Rept. Invest. 5565 (1960).

The $S^\circ_{298.15}$ = 21.9 was obtained from E. G. King, loc. cit. based on the measured $S^\circ_{298.15}-S^\circ_{51}$ and the extrapolated $S^\circ_{51}-S^\circ_{0}$.

Transition Data.

A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit. reported that lithium metatitanate undergoes a transition from the α to the β form at 1,485°K. with an absorption of 2.750 kcal. mole^{-1}.

Melting Data.

The T_m and ΔH_m were obtained from A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit.

LITHIUM METATITANATE (Li_2TiO_3) (LIQUID) MOL. WT. = 109.780

$S^\circ_{298.15}$ = 35.355 cal. mole^{-1} deg.$^{-1}$

T_m = 1820°K.

ΔH_f° 298.15 = -374.374 kcal. mole^{-1}

ΔH_m = 26.33 kcal. mole^{-1}

Heat of Formation.

The ΔH_f° 298.15 was obtained from the heat of formation of the crystal by adding ΔH_m and the difference between $H_{1820}-H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacities were reported by A. U. Christensen, K. C. Conway, and K. K. Kelley, "High-Temperature Heat Contents and Entropies of Aluminates and Ferrites of Lithium, Sodium, and of Lithium Titanate", U. S. Bureau Mines Report Invest. 5565 (1960). The measured heat capacity is extrapolated to an assumed glass transition temperature of 1214°K., below which the heat capacity is taken to be equal to that of the crystal.

The $S^\circ_{298.15}$ was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The T_m and ΔH_m were obtained from A. U. Christensen, K. C. Conway and K. K. Kelley, loc. cit.

LITHIUM DISILICATE ($Li_2Si_2O_5$) (CRYSTAL) GFW = 150.047

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [30] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -612.07 ± 1.0 kcal/mol

Tt = 1209°K

ΔHt° = 0.225 kcal/mol

Tm = 1307 ± 1°K

ΔHm° = [12.86] kcal/mol

Heat of Formation

The heats of solution of LiCl(c), Li_2SO_4(c), SiO_2(quartz) and $Li_2Si_2O_5$(c) in 20 per cent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). The authors derived two values of ΔHsoln of Li_2O(c) from those of LiCl(c) and Li_2SO_4(c), presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate ΔHsoln of Li_2O(c) as -58.74 (chloride scheme, originally -59.36) and -59.83 kcal/mol (sulfate scheme, originally -60.86), using recent ΔHf°_{298} values for LiCl(c), Li_2SO_4(c), HCl(aq), H_2SO_4(aq), and Li_2O(c). The corresponding enthalpy changes, ΔHr°_{298}, for the reaction Li_2O(c) + $2SiO_2$(quartz) = $Li_2Si_2O_5$(c) are derived as -33.21 and -34.30 kcal/mol. Adopting the weighted average ΔHr°_{298} = -33.57 kcal/mol with ΔHf°_{298}(Li_2O, c) = -143.1 kcal/mol and ΔHf°_{298}(SiO_2, quartz) = -217.7 kcal/mol, we obtain ΔHf°_{298} = -612.07 kcal/mol for $Li_2Si_2O_5$(c). This ΔHf°_{298}($Li_2Si_2O_5$, c) value is independent of future changes in ΔHf°_{298} of Li_2O(c) but the values of ΔHsoln and ΔHr° are not independent.

The heats of solution of LiOH(c) and $Li_2Si_2O_5$(c) in 20 per cent HF(aq) at 50°C were measured by W. E. Hatton, G. C. Sinke, D. L. Hildenbrand, and D. R. Stull, unpublished work, Thermal Laboratory, The Dow Chemical Co., Midland, Michigan, 1959. By use of a reaction scheme similar to that described on the Li_2SiO_3(c) table, the enthalpy change at 298°K for the reaction 2LiOH(c) + $2SiO_2$(c) → $Li_2Si_2O_5$(c) + H_2O(ℓ) was calculated to be -13.44 kcal/mol. Incorporating this value with ΔHf°_{298} = -115.84, -217.7 and -68.315 kcal/mol for LiOH(c), SiO_2(c), and H_2O(ℓ), respectively, we obtain ΔHf°_{298}($Li_2Si_2O_5$,c) = -612.20 ± 2.0 kcal/mol, which is in excellent agreement with the adopted value.

Heat Capacity and Entropy

Both heat capacities and S°_{298} are estimated by comparison with those for $Na_2Si_2O_5$(c), Na_2O(c) and Li_2O(c).

Transition Data

The transition temperature, Tt = 1209°K, is taken from F. C. Kracek, J. Am. Chem. Soc. 61, 2863 (1939). The author estimated a heat of transition of 1 to 2 cal/g based on the arrest in the cooling and heating curves. The value of ΔHt° is calculated assuming the heat of transition at 1209°K is 1.5 cal/g.

Melting Data

Incongruent melting of $Li_2Si_2O_5$(c) at 1033° has been reported by F. C. Kracek, J. Phys. Chem. 34, 2641 (1930); J. Am. Chem. Soc. 61, 2863 (1939). The liquidus temperature of 1034° at the composition 19.92 per cent Li_2O and 80.08 per cent SiO_2, reported by Kracek (1939), is adopted as Tm. The heat of melting is evaluated such that ΔHm°_{298} + ΔHt°_{298} = 11.43 kcal/mol, where the value 11.43 kcal/mol is the difference between ΔHf°_{298} for $Li_2Si_2O_5$(c) and $Li_2Si_2O_5$(ℓ). The latter were determined by solution calorimetry by Kracek (see Heat of Formation sections in $Li_2Si_2O_5$(c) and $Li_2Si_2O_5$(ℓ) tables).

June 30, 1967

LITHIUM DISILICATE ($Li_2Si_2O_5$) (LIQUID) GFW = 150.047

$S°_{298.15}$ = [38.297] gibbs/mol

$\Delta Hf°_{298.15}$ = -600.640 ± 1.0 kcal/mol

Tm = 1307°K

ΔHm° = [12.86] kcal/mol

Heat of Formation

The heats of solution of LiCl(c), Li_2SO_4(c), SiO_2(quartz) and $Li_2Si_2O_5$(gl) in 20 percent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). Following the same procedure as described in $Li_2Si_2O_5$(c) table, we derived the enthalpy changes, $\Delta Hr°_{298}$, for the reaction Li_2O(c) + $2SiO_2$(quartz) = $Li_2Si_2O_5$(gl) as -21.78 and -22.87 kcal/mol. Adopting the weighted average $\Delta Hr°_{298}$ = -22.14 kcal/mol with $\Delta Hf°_{298}$(Li_2O, c) = -143.1 kcal/mol and $\Delta Hf°_{298}$(SiO_2, quartz) = -217.7 kcal/mol, we obtain $\Delta Hf°_{298}$ = -600.640 kcal/mol for $Li_2Si_2O_5$(gl). This $\Delta Hf°_{298}$($Li_2Si_2O_5$, gl) value is independent of future changes in $\Delta Hf°_{298}$ of Li_2O(c) but the values of ΔHsoln and ΔHr° are not independent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $Na_2Si_2O_5(\ell)$, $Na_2SiO_3(\ell)$ and $Li_2SiO_3(\ell)$. A glass transition temperature at 800°K is assumed, i.e. the heat capacities below 800°K are taken from those for $Li_2Si_2O_5$(c) and above 800°K are assumed to be constant.

The $S°_{298}$ value is obtained from $S°_{298}$(c) by adding ΔSm° and the difference between $S°_{1307} - S°_{298}$ for crystal and liquid.

Melting Data

See $Li_2Si_2O_5$(c) table for details.

Dec. 31, 1960; Sept. 30, 1966

LITHIUM NITRIDE (Li_3N)   (CRYSTAL)   GFW = 34.8237

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [9 + 2] gibbs/mol $\Delta Hf^\circ_{298.15} = -47.2 \pm 1.0$ kcal/mol

Heat of Formation.

The adopted $\Delta Hf^\circ_{298.15} = -47.2 \pm 1.0$ kcal/mol was determined calorimetrically by Neumann et al[1]. by heating Li (c) at 600°C under 5 atm N_2 pressure for 1 minute. The $\Delta Hr^\circ_{291} = -131.1$ kcal/mol of reaction $Li_3N(c) + 3\ H_2O\ (l) = 3\ LiOH\ (aq) + NH_3\ (aq)$ was measured by Guntz[2]. Based on this ΔHr°_{291} the heat of formation was calculated to be -47.02 ± 2 kcal/mol which is in very good agreement with that of Neumann et al[1]. Unfortunately the author does not report the amount of water in LiOH (aq) and we assumed 300 H_2O as the best estimate. Heats of formation for $NH_3(aq)$ = [-19.17] kcal/mol and H_2O (l) = [-68.315] kcal/mol were taken from Wagman et al[3]. The ΔHf of $LiOH \cdot 300\ H_2$ (-121.30 kcal/mol) was derived from the heats of formation and solution of LiOH(c) (see JANAF table) and the heat of dilution selected by Parker[4].

Heat Capacity and Entropy.

S. Satoh, Sci. Papers Inst. Phys. Chem. Research (Tokyo) 35, 182 (1939), has measured enthalpies (273-578°K) and derived an equation for the specific heat of Li_3N. The adopted heat capacities were obtained from this equation. Above 773°K the heat capacities were graphically extrapolated. The entropy was estimated from the contribution 3.5 eu per Li given by W. M. Latimer, "Oxidation Potentials," 2nd Edition, Prentice-Hall, Inc., New York, 1952, and a -1.5 eu contribution for N.

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The following heat capacity measurements were considered in drawing a smooth curve of C_p with T: P. L. Smith (1.25-4.2°K) Phil. Mag. 46, 744 (1955); J. R. Clement and H. R. Jeffers (3-13°K) Phys. Rev. 105, 1435 (1957); K. Clusius and J. V. Vaughn (11.3-228.4°K) J. Am. Chem. Soc. 52, 4686, (1930); R. S. Craig, C. A. Krier, L. W. Coffer, E. A. Bates, and W. E. Wallace (12-320°K) J. Am. Chem. Soc. 76, 238 (1954); W. Mannchen and K. Bornkessel (190-300°K) Z. Metallkunde 51, 482-5 (1960); H. Seekamp (291-773°K) Z. anorg. Chem. 195, 345 (1931); and D. R. Stull and R. A. McDonald (700-900°K) J Am. Chem. Soc. 77, 5293 (1955). The following heat capacity measurements were noted but not used as the data were either not tabulated, or erratic, or inconsistent or would not have altered the C_p-T curve: D. L. Martin (0.4-1.5°K) Proc. Phys. Soc (London) 78, 1482-8 (1961); I. Estermann, S. A. Friedberg, and J. E. Goldman (1.8-4.2°K) Phys. Rev. 87, 582 (1952); E. P. Eastman and W. H. Rodebush (74.9-288.5°K) J. Am. Chem. Soc. 40 489 (1918); W. G. Saba, K. F. Sterrett, R. S. Craig, and W. E. Wallace (298-543°K) J. Am. Chem. Soc. 79, 3637 (1957); F. M. Jaeger and T. J. Poppema (273-873°K) Rec. Trav. chim. 55, 492 (1936); J. H. Awbery and E. Griffiths (323-898°K) Proc. Phys. Soc. 38, 378 (1926); E. D. Eastman, A. M. Williams and T. F. Young (373-873°K) J. Am. Chem. Soc. 46, 1178 (1926); and P. Schübel (323-773°K) Z. anorg. chem. 87, 81 (1914). $S^\circ_{298.15}$ was obtained by numerical integration using the low temperature C_p data cited above.

Melting.

Melting point is from J. L. Haughton and R. J. M. Payne (922 ± 0.5°K) J. Inst. Met. 54, 279 (1934). Also noted but not used were: R. Chadwick (923°K) J. Inst. Met. 39, 285-300 (1928); W. R. D. Jones (920.5°K) J. Inst. Met. 46, 395-419 (1931).

The heat of melting is from D. R. Stull and R. A. McDonald (loc. cit.)

Heat of Sublimation.

Is obtained by third law calculations from the vapor pressure data on the solid by F. F. Coleman and A. E. Egerton, Phil. Trans Roy. Soc. (London) A234, 177-204 (1935) and the value is confirmed by similar use of the vapor pressure data on the liquid by E. Scheil and F. Wolf, Z. Metallkunde 50, 229-33 (1959); A. Wejnarth, Tek. Tid. 72, 33-9, 44-8 (1942); A. Schneider and E. K. Stoll. Z. Elektrochem. 47, 519-26 (1941); E. Baur and R. Brunner, Helv. Chim. Acta, 17, 958-69 (1934); and H. Hartmann and R. Schneider, Z. anorg. Chem. 180, 275-83 (1929). Additional data noted but not used on the vapor pressure, as values were not tabulated or they were erratic, of the solid are by J. F. Smith and R. L. Smythe, Acta Metallurgica, 7, 261-7 (1959); A. Eucken, Metallwirtschaft, 15, 64-5 (1936); W. Leitgebel, Metallwirtschaft, 14, 269 (1935); and of the liquid by F. A. Vetter and O. Kubaschewski, Z. Elektrochem. 57, 243 (1953); W. Leitgebel, Z. anorg. Chem. 202, 312 (1931); C. Zwikker, Physica, 8, 246 (1928); O. Ruff and H. Hartmann, Z. anorg. Chem., 133, 29-45 (1924); and J. Johnston, Ind. Eng. Chem. 9, 876 (1917).

Dec. 31, 1960; Sept. 30, 1962

MAGNESIUM (Mg) (LIQUID) AT. WT. = 24.32

$\Delta H^\circ_{f\ 298.15}$ = [2.158] kcal. mole^{-1}

T_m = 922 ± 0.5°K

T_b = 1378°K

$S^\circ_{298.15}$ = [10.159] cal. deg.$^{-1}$ mole^{-1}

ΔH°_m = 2,140 cal. mole^{-1}

ΔH_v = 30.5 kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ (= $\Delta H_{m\ 298.15}$) obtained from $\Delta H_{m\ 922}$ by adding H_{922}-$H_{298.15}$ for solid and subtracting H_{922}-$H_{298.15}$ for liquid.

Heat Capacity and Entropy.

The heat capacity measurements of D. R. Stull and R. A. McDonald (950-1100°K) J. Am. Chem. Soc. 77, 5293 (1955) were used. Outside of the observed range C_p was extrapolated linearly with temperature. Below T_m the linear extrapolation was continued until the C_p curve for the solid is encountered at 710°K. At lower temperatures the C_p of the crystal is used. $S^\circ_{298.15}$ was calculated from that of the solid.

Melting.

See crystal for details.

Vaporization.

The normal boiling point was calculated by the third law and $\Delta H_{s\ 298.15}$. This compares with 1377°K computed from the general vapor pressure equation for liquid Mg given on p 221 of Gmelins Handbuch der anorganischen Chemie, System-Nummer 27 (1952), and experimentally determined values: 1376 ± 5°K by A. Schneider and U. Esch, Z. Elektrochem 45, 888 (1939); 1380°K by E. Baur and R. Brunner, Helv. Chim. Acta 17, 958 (1934); 1370°K by W. Leitgebel, Z. anorg. Chem. 202, 305 (1931); and 1393°K by Greenwood, Chem. News 104, 31 (1911).

The $\Delta H_{v\ 1378}$ is based on the liquid and ideal gas tables.

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ $(=\Delta H_{s\ 298.15})$ is calculated as described on the table for crystal.

Heat Capacity and Entropy.

Thermodynamic functions were calculated using electronic levels and multiplicities from C. E. Moore [Natl. Bur. Standards Circ. 467, Vol. 1 (1949)]. Higher levels were averaged.

Heat of Formation

We derive the heat of formation at 0°K from the reaction Mg(g) - e$^-$(g) → Mg$^+$(g) using the JANAF auxiliary value for Mg(g) and an ionization potential of 176.278 kcal/mol from C. E. Moore, U. S. Natl. Bur. Std. Circ. 467,Vol. I, 1949.

Heat Capacity and Entropy

We take the electronic levels and quantum weights from C. E. Moore, loc. cit. $H^\circ_0 - H^\circ_{298}$ = -1.481 kcal/mol at 0°K.

Monomagnesium Mononitride (MgN)

MONOMAGNESIUM MONONITRIDE (MgN) (IDEAL GAS) MOL. WT. = 38.328

Ground State Configuration $[^2\Pi]$

$S^\circ_{298.15}$ = [53.713] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = [69 ± 6] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [69 ± 6] kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ_1, cm.$^{-1}$	g_1
0	[4]

ω_e = [700] cm.$^{-1}$

B_e = [0.5542] cm.$^{-1}$

$\omega_e x_e$ = [4.8] cm.$^{-1}$

α_e = [0.0052]

σ = 1

r_e = [1.85] Å

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ for MgN was estimated from bond strengths using MgO and comparison with analogous pairs of compounds such as, PN and PO, and also the bond strengths of C-N and C-O in organic compounds.

Heat Capacity and Entropy.

The r_e value for MgN was estimated from MgO by comparison with similar pairs PO and PN, SiO and SiN, and AlO and AlN. Using Guggenheimer's Relation, Proc. Phys. Soc. (London) 58, 456 (1946), ω for MgO was found to lie between the single and multiple bonding cases. Magnesium nitride was assumed to be similar to MgO and ω_e = 700 cm.$^{-1}$ was obtained. It was assumed that the $x_e\mu^{1/2}$ value for MgN was equal to that for MgO thus giving $\omega_e x_e$ = 4.8 cm.$^{-1}$. B_e was calculated from r_e. The α_e value was calculated from B_e, ω_e and $\omega_e x_e$.

Dec. 31, 1960; Dec. 31, 1965

MAGNESIUM OXIDE (MgO) (CRYSTAL) MOL. WT. = 40.311*

$S^\circ_{298.15}$ = 6.44 cal. deg.$^{-1}$ mole^{-1}

T_m = 3098 ± 20 °K.

T_s = 3466°K.

$\Delta H^\circ_{f\ 0}$ = -142.7 ± 0.3 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -143.7 ± 0.3 kcal. mole^{-1}

ΔH_m = [18.5 ± 1.5] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298}$ = 144.7 ± 20 kcal. mole^{-1}

Heat of Formation.

C. E. Holley and E. J. Huber, J. Am. Chem. Soc. 73, 5577 (1951) reported $\Delta H^\circ_{f\ 298}$ (MgO, c) = -143.7 kcal. mole^{-1} by combustion calorimetry. Heat of solution measurements by C. H. Shomate and E. H. Huffman, J. Am. Chem. Soc. 65, 1625 (1943) yielded $\Delta H^\circ_{f\ 298}$ (MgO, c) = -143.84 kcal. mole^{-1}, well within the adopted $\Delta H^\circ_{f\ 298}$ (MgO, c) = -143.7 ± 0.3 kcal. mole^{-1}.

Heat Capacity and Entropy.

Low temperature heat capacities have been reported by:

1. W. Lien and N. Phillips, J. Chem. Phys. 29, 1415 (1958), 1.5-4°K.
2. W. F. Giauque and R. C. Archibald, J. Am. Chem. Soc. 59, 561 (1937), 20-301°K.
3. G. S. Parks and K. K. Kelley, J. Phys. Chem. 30, 47 (1926), 94-291°K.
4. T. H. K. Barron, W. T. Berg, and J. A. Morrison, Proc. Roy. Soc. (London) A250, 70 (1959), 10-270°K.
5. P. Gunther, Ann. Physik 51, 828 (1916), 21-84°K.

High temperature heat contents have been reported by:

6. A. C. Victor and T. B. Douglas, J. Res. N.B.S. 67A, 325 (1963), 373-1173°K.
7. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6295, (1963), 400-1800°K.

The samples of (1) and (2) were finely divided magnesia and the other samples were periclase. Periclase is taken to be the standard state. The high temperature heat content data of (6) and (7) were joined by a Shomate plot with the low temperature C_p data of (4). The heat capacity was extrapolated linearly above 1800°K to a value of 14 cal. mole^{-1} deg.$^{-1}$ at 3100°K. $S^\circ_{298.15}$ = 6.44 cal. deg.$^{-1}$ mole^{-1} is from (4).

Melting Data.

T_m(MgO, c) = 3098 ± 20°K by R. N. McNally, F. I. Peters, and P. H. Ribbe, J. Am. Ceram. Soc. 44, 491 (1961) was adopted. Their value is 41°K higher than the earlier measurements of C. W. Kanolt, J. Wash. Acad. Sci. 3, 315 (1913). K. K. Kelley, Bur. Mines Bull. 393 (1936) calculated ΔH_m (MgO, c) = 18.5 ± 1.5 kcal./mole from melting point measurements in the MgO - ZrO_2 system.

Sublimation Data.

T_s is the temperature at which the free energy change of the reaction MgO(c) = MgO(g) approaches zero. The difference between $\Delta H^\circ_{f\ 298.15}$ for MgO(c) and MgO(g) is $\Delta H^\circ_{s\ 298.15}$.

Magnesium Oxide (MgO)

MgO

MAGNESIUM OXIDE (MgO) (LIQUID) MOL. WT. = 40.3114

$S^\circ_{298.15}$ = [12.033] cal. deg.$^{-1}$ mole^{-1}

T_m = 3098°K.

T_B = [3533]°K.

ΔH_f° 298.15 = [-126.137] kcal. mole^{-1}

ΔH_m° = [18.5 ± 1.5] kcal. mole^{-1}

ΔH_v° = [113.4] kcal. mole^{-1}

Heat of Formation.

ΔH_f° 298.15(l) was calculated from ΔH_f° 298.15(c) by adding ΔH_m° and the difference between $H^\circ_{T_m}-H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition is assumed at 2066°K. C_p(l) below 2066°K. were assumed to be equal to those of MgO(c). At and above 2066°K. the heat capacities were assumed to be constant at 7.25 cal. deg.$^{-1}$ g. atom^{-1}. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See MgO(c) table for details.

Vaporization Data.

W. R. Mott, Tran. Am. Electrochem. Soc. 34, 255 (1918) estimated the boiling point at 3873°K. by comparing crater distances of arc image deposits with reference compounds. T_B = 3533°K. is the temperature at which the free energy change of the reaction MgO(l) = MgO(g) approaches zero. The difference between ΔH_f° 3533 for MgO(g) and MgO(l) is ΔH_v°.

r_e = [1.672] Å

Heat of Formation.

There is considerable discordance in the heat of formation results even though results were adjusted to a common $^3\Sigma$ ground state where necessary. A mean $\Delta H^\circ_{f\ 298}$ (MgO, g) = 1.0 ± 20 kcal. mole^{-1} was selected.

R. L. Altman, J. Phys. Chem. 67, 366 (1963) made a Knudsen effusion and oxygen transpiration study of the vaporization of MgO. The predominant vapor species over MgO(c) were shown to be Mg(g) and O_2(g). MgO transpiration results with oxygen at 1 atm yielded a 3rd law heat of sublimation $\Delta H^\circ_{s\ 298}$ (MgO, g) = 162.3 kcal. mole^{-1} and $\Delta H^\circ_{f\ 298}$ (MgO, g) = 18.6 kcal. mole^{-1}.

J. Drowart, G. Exsteen and G. Verhaegen, Trans. Far. Soc. 60, 1920 (1964) used the Knudsen effusion-mass spectrometer technique to determine relative ion intensities and enthalpies for the reaction MgO(g) + O(g) → Mg(g) + O_2(g). After adjusting their values for a $^3\Sigma$ ground state we calculated $\Delta H^\circ_{f\ 298}$ (MgO, g) = 11.9 kcal. mole^{-1}. Similar calculations for their data on MgO(g) + WO_2(g) → Mg(g) + WO_3(g) yielded $\Delta H^\circ_{f\ 298}$ = 10.5 kcal. mole^{-1}. The agreement is fortuitous, however, since uncertainties in the JANAF values for WO_2(g) and WO_3(g) are on the order of 7 kcal. each.

R. F. Porter, W. A. Chupka and M. G. Inghram, J. Chem. Phys. 23, 1347 (1955) mass spectrometrically determined an upper limit for the vapor pressure of MgO(g) over MgO(c) at 1950°K. Their results reduce to a lower limit of 148.6 kcal. mole^{-1} for $\Delta H^\circ_{s\ 298.15}$ (MgO, c) or a lower limit of 4.9 kcal. mole^{-1} for $\Delta H^\circ_{f\ 298}$ (MgO, g).

E. Bulewicz and T. Sugden, Trans. Far. Soc. 55, 720 (1959), using a flame photometric technique, reported D°_0 = 98 ± 2 kcal. mole^{-1} for MgO. $\Delta H^\circ_{f\ 298}$ (MgO, g) = -4.1 kcal. mole^{-1} was calculated.

I. Veits and L. Gurvich, Optika and Spektroskopiya 1, 22 (1956) used a flame technique to obtain D°_0 = 100 kcal. mole^{-1}. A 4 kcal. mole^{-1} adjustment for $^1\Sigma$ to $^3\Sigma$ yields $\Delta H^\circ_{f\ 298}$ (MgO, g) = -2.1 kcal. mole^{-1}.

The flame method data of L. Huldt and A. Lagerquist, Arkiv Fysik 2, 333 (1950) yielded a $^3\Sigma$ adjusted D°_0 = 115 kcal. mole^{-1}. $\Delta H^\circ_{f\ 298}$ (MgO, g) = -21.1 kcal. mole^{-1} was calculated.

L. Brewer and R. F. Porter, J. Chem. Phys. 22, 1876 (1954) have shown by vapor pressure measurements on MgO(c) that the solid vaporizes mainly into molecular species. They gave spectroscopic evidence that the $^1\Sigma$ electronic state of MgO(g) is not the principal vaporizing species. Using their vapor pressures for the reaction MgO(c) = MgO(g) and a $^3\Sigma$ ground state we calculated 2nd and 3rd law heat of sublimation at 298°K. of 120.0 and 129.1 kcal. mole^{-1}. The 3rd law value yields $\Delta H^\circ_{f\ 298}$ (MgO, g) = -14.6 kcal. mole^{-1}.

Heat Capacity and Entropy.

The fundamental frequency and anharmonicity correction were reported by L. Brewer and R. Porter, J. Chem. Phys. 22, 1876 (1954) and are based on a $^3\Sigma$ ground state. The rotational constants were estimated by H. L. Schick 35 al. AVCO Corp. RAD-SR-62-251, 15 Dec. 1962. Although the ground state and spectroscopic constants are in doubt, the free energies are probably within RT ln 3 of true values.

MAGNESIUM METASILICATE ($MgSiO_3$) (CRYSTAL) GFW = 100.3962

ΔHf_0° = -368.02 ± 1.0 kcal/mol

$S_{298.15}^\circ$ = 16.197 ± 0.2 gibbs/mol

$\Delta Hf_{298.15}^\circ$ = -370.20 ± 1.0 kcal/mol

Tt_1 = 903 °K

ΔHt_1° = 0.16 kcal/mol

Tt_2 = 1258 °K

ΔHt_2° = 0.39 kcal/mol

Tm = 1850 ± 2 °K

ΔHm° = [18 ± 5] kcal/mol

Heat of Formation

Torgeson et al. (1) report a ΔHr_{298}° = -8.69 ± 0.15 kcal/mol for reaction (a). They used a hydrofluoric acid solution calorimeter and measured the heats of solution of each component. They appear to have made the water-absorption correction to the heat of solution of SiO_2(c) in the wrong direction. We reverse the correction so that the new ΔHsoln almost overlaps the range observed by King (11). We derive $\Delta Hf_{298}^\circ(MgSiO_3$, c) = -370.20 ± 1.0 kcal/mol using the ΔHf_{298}° of MgO(c) and SiO_2 (c, low quartz) from the JANAF tables.

Reesman et al. (2) calculated a ΔGr_{298}° = 23.72 kcal/mol for reaction (b) using aqueous solubility data. We use the ΔGf_{298}° of $H_2O(\ell)$ and OH^-(aq) from source 3, ΔGf_{298}° of H_4SiO_4(aq) from source 4 and ΔGf_{298}° of Mg^{++}(aq) from source 5 and we obtain a $\Delta Gf_{298}^\circ(MgSiO_3$, c) = -352.534 kcal/mol. We derive a $\Delta Hf_{298}^\circ(MgSiO_3$, c) = -373.293 kcal/mol using the above ΔGf_{298}° of $MgSiO_3$(c) and the entropies of Mg(c), Si(c) and O_2(g) from the JANAF tables.

We choose the heat of formation derived from the result of Torgeson et al. (1) which is considered to be better since it relates directly to the oxides. Also the $\Delta Gf_{1873}^\circ(MgSiO_2, \ell)$ thus calculated is in very good agreement with that derived from the activities of SiO_2 and MgO (in the SiO_2 - MgO system) measured by Rein et al. (6). The $\Delta Hf_{298}^\circ(MgSiO_3$, c) derived from the work of Reesman et al. is less accurate and involves uncertainties in the auxiliary data used to calculate the value.

Source	Method	Reaction	ΔHr_{298}° kcal/mol	ΔGr_{298}° kcal/mol	ΔHf_{298}° kcal/mol

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53 - 295°K) of Kelley (7). Wagner (8) measured the average heat capacities in the temperature range 580 - 1570°K. Using his data we derive the high temperature heat capacities which are joined smoothly with the low temperature values by a constrained fitting technique. The Cp values at 903 - 1258°K and above 1258°K are derived as 28.762 and 29.262 gibbs/mol, respectively, by assuming that the data of Wagner (8) pertain to the stable phase in these regions. The entropy is based on S_{50}° = 0.49 eu.

Transition Data

Tt_1 = 903°K is obtained from Boyd et al. (9). The authors determined the phase diagram boundary at high pressures and extrapolated to one atmosphere. Tt_2 = 1258°K is taken from Atlas (10). Below 903 °K the phase is known as clinoenstatite. Between 903° and 1258°K it is rhombic enstatite and above 1258°K it is protoenstatite. We calculate ΔHt_1° and ΔHt_2° from dT/dP (slopes of the inversion) = 2.6°/kbar and 84°/kbar reported by Boyd et al. (9, 13) and from the densities of clinoenstatite (3.210 gm/cc) and rhombic enstatite (3.208 gm/cc) reported by Stephenson et al. (11) and the density of protoenstatite (3.10 gm/cc) reported by Smith (12).

MAGNESIUM METASILICATE ($MgSiO_3$) (LIQUID) GFW = 100.3962

$S^\circ_{298.15}$ = [22.112] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-357.281 ± 5] kcal/mol

Tt_1 = 903 °K

ΔHt°_1 = 0.16 kcal/mol

Tt_2 = 1258 °K

ΔHt°_2 = 0.39 kcal/mol

Tm = 1850 ± 2 °K

ΔHm° = [18 ± 5] kcal/mol

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(c) by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 900°K. Below 900°K the heat capacity is obtained from the heat capacity of the crystal. Above 900°K the heat capacity is assumed constant and estimated as 35 gibbs/mol or 7 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Transition Data

See crystal table.

Melting Data

Tm is taken from N. L. Bowen and O. Andersen, Am. J. Sci. 37, 487 (1914). $MgSiO_3$(c) melts incongruently in the temperature range 1830 - 1850°K at atmospheric pressure. ΔHm° is estimated from the phase diagrams of the $MgSiO_3$ - TiO_2 system reported by I. D. MacGregor, Ann. Rept. Director of the Geophysical Laboratory, No. 1455, 135-9 (1965). The phase diagrams were determined at 10 and 20 kbars pressure where $MgSiO_3$(c) melts congruently.

June 30, 1961; June 30, 1967

MAGNESIUM METATITANATE ($MgTiO_3$) (CRYSTAL) GFW = 120.2102

ΔHf°_0 = -373.63 ± 1.5 kcal/mol

$S^\circ_{298.15}$ = 17.82 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -375.85 ± 1.5 kcal/mol

Tm = 1953 ± 20°K

ΔHm° = [21.6] kcal/mol

Heat of Formation

The adopted heat of formation is calculated from $\Delta Hr^\circ_{298.15}$ = -6.35 ± 0.25 kcal/mol for the reaction MgO(c) + TiO_2(rutile) → $MgTiO_3$(c) measured by K. K. Kelley, S. S. Todd and E. G. King, U. S. Bur. Mines RI 5059, 1954, using a solution calorimetric method. For the same reaction a value of $\Delta Hr^\circ_{298.15}$ = -5.5 ± 0.1 kcal/mol was obtained with a calorimetric bomb method by B. I. Ronfilov and N. N. Feodos'ev, Russ. J. Inorg. Chem. (English Transl.) 9, 1452 (1964). These authors used the oxidation of lampblack in order to initiate the formation of the titanate from the oxides. Unfortunately the desired heat of reaction was only 1.2 to 1.5 percent of the total measured heat, and consequently this result appears to be more uncertain than that measured by the solution calorimetric method.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52 - 296°K) of C. H. Shomate, J. Am. Chem. Soc. 67, 964 (1946). High temperature enthalpies have been measured (402 - 1720°K) by B. F. Naylor and O. A. Cook, J. Am. Chem. Soc. 68, 1003 (1946). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on S°_{52} = 0.45 eu.

Melting Data

See liquid table.

MAGNESIUM METATITANATE ($MgTiO_3$) (LIQUID) GFW = 120.2102

$S°_{298.15}$ = [26.549] gibbs/mol

$\Delta Hf°_{298.15}$ = [-357.942 ± 1.5] kcal/mol

Tm = 1953 ± 20°K

ΔHm° = [21.6] kcal/mol

Heat of Formation

$\Delta Hf°_{298}$ is obtained from $\Delta Hf°_{298}$(c) by adding ΔHm° and the difference between $H°_{Tm} - H°_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300°K. The heat capacity below 1300°K is obtained from the heat capacity of the crystal. Above 1300°K the heat capacity is assumed constant and estimated as 39 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting point at 1903°K. The ΔHm° is estimated from those of $Na_2O \cdot 2TiO_2$ and $Na_2O \cdot TiO_2$ observed by Naylor (3) and $CaO \cdot TiO_2 \cdot SiO_2$ observed by King (4).

Dec. 31, 1960; Mar. 31, 1966

MAGNESIUM SULFATE ($MgSO_4$) (CRYSTAL) MOL. WT. = 120.3736

$S^\circ_{298.15}$ = 21.844 ± 0.2 cal. deg.$^{-1}$ mole^{-1}

T_m = 1400°K.

$\Delta H_f^\circ{}_0$ = -298.8 ± 5 kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -301.6 ± 5 kcal. mole^{-1}

ΔH_m° = 3.5 kcal. mole^{-1}

Heat of Formation.

The adopted $\Delta H_f^\circ{}_{298.15}$ = -301.6 ± 5 kcal. mole^{-1} was calculated from the $\Delta H_r^\circ{}_{298.15}$ = 63.3 ± 5 kcal. mole^{-1} for the reaction $MgO(c) + SO_3(g) = MgSO_4(c)$. The value of $\Delta H_r^\circ{}_{298.15}$ was calculated by the third law method using the equilibrium data obtained from a transpiration study by Knopf and Staude.[1] In addition Marchal[2] measured the total pressure of $SO_3(g)$, $SO_2(g)$ and $O_2(g)$ above $MgSO_4(c)$ and partial pressures were obtained by application of the SO_3-SO_2 equilibrium data. Another value of $\Delta H_f^\circ{}_{298.15}$ ($MgSO_4$, c) may be derived from the measured heat of solution of $MgSO_4(c)$ by Thomsen[3a] and the measured heats of mixing of $MgCl_2(200\ H_2O)$ with $H_2SO_4(200\ H_2O)$ and $MgSO_4(200\ H_2O)$ with $2HCl(100\ H_2O)$ by Thomsen[3b].

Heat Capacity and Entropy.

The low temperature heat capacities 53.3-295.4°K. were measured by G. E. Moore and K. K. Kelley, J. Am. Chem. Soc. 64, 2949 (1942). The heat capacities in the temperature range 298-1400°K. were estimated from the equation $MgSO_4(c) = CaSO_4(c) + MgO(c) - CaO(c)$. $CaSO_4(c)$ and $CaO(c)$ C_p were calculated using the equations $C_p = 16.78 + 23.60 \times 10^{-3}T$ and $C_p = 11.67 + 1.08 \times 10^{-3}T - 1.56 \times 10^{5}T^{-2}$ respectively, K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). The heat capacity of $MgO(c)$ was calculated from the correlation of the low temperature heat capacities and high temperature heat content using the Shomate functions to back calculate the heat capacities. The values from the two sources join smoothly at 298°K. Above the melting point (1400°K.) the heat capacity was graphically extrapolated. The entropy was calculated at 50.12°K. using the Debye and Einstein function $D(\frac{242}{T}) + 2E(\frac{378}{T}) + 2E(\frac{866}{T}) + E(\frac{1683}{T})$ given by G. E. Moore and K. K. Kelley loc. cit. The value of $S^\circ_{50.12}$ = 1.08 cal. deg.$^{-1}$ mole^{-1}.

Dec. 31, 1960; Mar. 31, 1966

MAGNESIUM SULFATE ($MgSO_4$) (LIQUID) MOL. WT. = 120.3736

$S^\circ_{298.15}$ = 24.464 ± 0.2 cal. deg.$^{-1}$ mole^{-1}

ΔH_f° 298.15 = -297.9 ± 5 kcal. mole^{-1}

T_m = 1400°K.

ΔH_m° = 3.5 kcal. mole^{-1}

Heat of Formation.

The ΔH_f° 298.15 was obtained from ΔH_f° 298.15(c) by adding ΔH_m° and the difference between $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 1000°K. The heat capacity below 1000°K. was obtained from the heat capacity of the crystal. Above 1000°K. the heat capacity was assumed constant and estimated as 38.0 cal. deg.$^{-1}$ mole^{-1} by comparison with those for $MgCl_2(l)$, KCl(l) and $K_2SO_4(l)$. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $MgSO_4(c)$ table.

MAGNESIUM TUNGSTATE ($MgWO_4$) (CRYSTAL) GFW = 272.1596

$S^\circ_{298.15}$ = 24.18 ± 0.2 gibbs/mol

Tm = Unknown

ΔHf°_0 = -359.9 ± 8 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -362.3 ± 8 kcal/mol

ΔHm° = Unknown

Heat of Formation.

T. N. Rezukhina and V. A. Levitskii[1] measured the emf, E = 0.2433 - 0.0001264T, for the cell reaction $MgO(c) + W(c) + 3Fe_{0.95}O(c) \rightarrow MgWO_4(c) + 2.85\ Fe(c)$, in the temperature range 1220° - 1370°K. Incorporating the results with auxiliary thermal data, the authors obtained ΔGr° = -224,370 + 65.67T (cal/mol) for $MgO(c) + W(c) + 3/2O_2(g) \rightarrow MgWO_4(c)$. Third law analysis of the ΔGr° equation gives ΔHr°_{298} = -218.6 kcal/mol, from which the adopted $\Delta Hf^\circ_{298}(MgWO_4,c)$, -362.3 kcal/mol, is calculated. The second law analysis gives $\Delta Hf^\circ_{298}(MgWO_4,c)$ = -372.7 kcal/mol. The drift in the third law analysis is 8.0 eu.

T. N. Rezukhina, Ya. I. Gerasimov and Yu. P. Simanov[2] determined the Gibbs energy changes ΔGr° = 51,300 - 27.67T (cal/mol) for the reaction $MgWO_4(c) + 3H_2(g) \rightarrow MgO(c) + W(c) + 3H_2O(g)$ in the temperature range 1073°K - 1273°K by a circulation method. This leads to heats of formation of -366.1 kcal/mol by the third law method and -377.2 kcal/mol by the second law method. Both determinations were performed by Rezukhina and his co-workers, but they considered the data obtained by the emf method to be more reliable than that derived from heterogeneous equilibria.

Heat Capacity and Entropy.

Low temperature heat capacities, 52.92° - 296.09°K, were measured calorimetrically by E. G. King and W. W. Weller[3]. The heat capacities above 300°K are estimated by comparison with those of $CaWO_4(c)$[4], CaO(c)[5], and MgO(c)[6]. These two sets of data are joined smoothly at 298°K by a graphical method.

The entropy, S°_{298} = 21.184 eu, is taken from King and Weller[3], based on an extrapolation of S°_{51} = 1.27 eu. No spin-magnetic entropy is predicted below 51°K based on the diamagnetism observed by Ya. I. Gerasimov[7].

MAGNESIUM DITITANATE ($MgTi_2O_5$) (CRYSTAL) GFW = 200.109

ΔHf°_0 = -596.43 ± 2.5 kcal/mol

$S^\circ_{298.15}$ = 32.41 ± 1.5 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -599.75 ± 2.5 kcal/mol

Tm = 1963 ± 20°K

ΔHm° = [35] kcal/mol

Heat of Formation

ΔHf°_{298} is calculated from ΔHr°_{298} = -4.45 ± 0.45 kcal/mol for the reaction MgO(c) + 2TiO$_2$(rutile) = $MgTi_2O_5$(c) measured by K. K. Kelley, S. S. Todd and E. G. King, U. S. Bur. Mines RI 5059, 1954, using a solution calorimetric method. The uncertainty of ±2.5 kcal/mol assigned to the heat of formation is due primarily to TiO_2(rutile).

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52 - 296°K) of S. S. Todd, J. Am. Chem. Soc. 74, 4669 (1952). High temperature enthalpies have been measured (397 - 1812°K) by R. L. Orr and J. P. Coughlin, J. Am. Chem. Soc. 74, 3186 (1952). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S^\circ_{51} - S^\circ_0$ = 1.11 eu.

Kelley et al., loc. cit., suggested that there may be a zero-point entropy due to randomness of the cations. The authors estimated S°_0 from the following alternative assumptions: (a) all the Mg and Ti ions are randomly distributed among the latice sites giving 3.79 eu and (b) all the Mg and one-half of the Ti ions are randomly distributed giving 2.75 eu. These assumptions were proposed in order to make $MgTi_2O_5$ stable relative to $MgTiO_3$ at high temperatures. Phase data of F. Massazza and E. Sirchia, 16th Int. Congress of Pure and Appl. Chem., Inorg. Sect., Paris (1957), pp. 161-8, Butterworths Scientific Publications, London, 1958, indicate that $MgTi_2O_5$ melts congruently at 1963±20°K and that there is a eutectic with $MgTiO_3$ at 1873±20°K. These data require that ΔGr°<0 for $MgTiO_3$(c) + TiO_2(rutile) → $MgTi_2O_5$(c) in this temperature range. To make $\Delta Gr^\circ_{1800}<0$ would require that $S^\circ_0 \geq 0.35$ eu. We adopt a compromise zero-point entropy of 2 eu between the upper (3.79 eu) and the lower (0.35 eu) limits.

Melting Data

June 30, 1961; June 30, 1967

MAGNESIUM DITITANATE ($MgTi_2O_5$) (LIQUID) GFW = 200.109

$S^\circ_{298.15}$ = [47.27] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-569.385 ± 2] kcal/mol

Tm = 1963 ± 20°K

ΔHm° = [35] kcal/mol

Heat of Formation

The heat of formation is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300°K. Below 1300°K the heat capacity is obtained from the heat capacity of the crystal. Above 1300°K the heat capacity is assumed constant and estimated as 62/4 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The congruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting at 1925°K. The ΔHm° is estimated from those of $Na_2O\cdot 2TiO_2$ and $Na_2O\cdot TiO_2$ observed by Naylor (3) and $CaO\cdot TiO_2\cdot SiO_2$ observed by King (4).

Dec. 31, 1960; Sept. 30, 1964; Dec. 31, 1967

MAGNESIUM ORTHOSILICATE (Mg_2SiO_4) (CRYSTAL) GFW = 1400.7076

ΔHf°_0 = -517.12 ± 1.0 kcal/mol

$S^\circ_{298.15}$ = 22.739 ± 0.2 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -520.30 ± 1.0 kcal/mol

Tm = 2171 ± 11 °K

ΔHm° = [17 ± 5] kcal/mol

Heat of Formation

Torgeson et al. (1) have reported a ΔHr°_{298} = -15.1 ± 0.2 kcal/mol for reaction (a). They used an HF solution calorimeter and measured the heats of solution of each component. We derive $\Delta Hf^\circ_{298}(Mg_2SiO_4, c)$ = -520.30 ± 1.0 kcal/mol using the ΔHf°_{298} of MgO(c) and SiO_2 (c, low quartz) from JANAF tables.

Kapustinskii et al. (2) used the same method but measured only ΔHr°_{298} = 95.00 ± 0.47 kcal/mol for reaction (b). We calculate $\Delta Hf^\circ_{298}(Mg_2SiO_4, c)$ = -522.27 kcal/mol using the ΔHf°_{298} of H_2SiF_6(aq) from source 3 and the ΔHf°_{298} of $H_2O(\ell)$ and HF(aq) from source 4.

Reesman et al. (5) calculated a ΔGr°_{298} = 42.46 kcal/mol for reaction (c) using aqueous solubility data. We use the ΔGf°_{298} of $H_2O(\ell)$ and OH^-(aq) from source 4, ΔGf°_{298} of H_4SiO_4(aq) from source 3 and ΔGf°_{298} of Mg^{++}(aq) from source 6 and we obtain a $\Delta Gf^\circ_{298}(Mg_2SiO_4, c)$ = -498.764 kcal/mol. We derive a $\Delta Hf^\circ_{298}(Mg_2SiO_4, c)$ = -524.848 kcal/mol using the above ΔGf°_{298} of Mg_2SiO_4(c) and the entropies of Mg(c), Si(c) and O_2(g) from the JANAF tables.

The adopted value is from the work of Torgeson et al. (1) which is considered to be the most reliable since it relates directly to the oxides. The other reported values are less accurate and involve uncertainties in the auxiliary data used to derive the heat of formation.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53-295°K) of Kelley (7). High temperature enthalpies have been measured (398-1808 °K) by Orr (8). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on S°_{50} = 0.60 eu.

Melting Data

Tm is obtained from Davis et al. (9). ΔHm° is estimated from MacGregor's (10) phase diagrams of the Mg_2SiO_4 - TiO_2 system. The phase diagrams were determined at 10 and 20 kbars pressure.

Dec. 31, 1960; Sept. 30, 1964; Dec. 31, 1967

MAGNESIUM ORTHOSILICATE (Mg_2SiO_4) (LIQUID) GFW = 140.7076

$S^\circ_{298.15}$ = [29.407] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-505.229 ± 5] kcal/mol

Tm = 2171 ± 11°K

ΔHm° = [17 ± 5] kcal/mol

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(c) by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1400°K. Below 1400°K the heat capacity is obtained from the heat capacity of the crystal. Above 1400°K the heat capacity is assumed constant and estimated as 49 gibbs/mol or 7 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See crystal table.

MAGNESIUM ORTHOTITANATE (Mg_2TiO_4) (CRYSTAL) GFW = 160.5216

$S^\circ_{298.15}$ = 27.51 ± 1.5 gibbs/mol

Tm = 2013 ± 20°K

ΔHf°_0 = -514.11 ± 1.5 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -517.3 ± 1.5 kcal/mol

ΔHm° = [31] kcal/mol

Heat of Formation

The heat of formation is calculated from ΔHr°_{298} = -4.1 ± 0.25 kcal/mol for the reaction 2 MgO(c) + TiO_2(rutile) → Mg_2TiO_4(c) measured by Kelley (1), using a solution calorimetric method. The uncertainty of ± 1.5 kcal/mol assigned to the heat of formation is due primarily to TiO_2(rutile).

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52 - 296°K) of Todd (2).

High temperature enthalpies have been measured (392 - 1817°K) by Orr (3). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values.

The entropy is based on S°_{51} = 0.66 + 2.75 = 3.41 eu, where the first term is a lattice contribution and the second term is a zero-point entropy of 2Rℓn2 corresponding to random distribution of Ti and Mg on the octahedral sites of the spinel lattice. The adopted value is S°_{298} = 27.51 ± 1.5 eu instead of 24.76 ± 0.15 eu as given by Todd.

Barth (4) showed from intensities of the X-ray diffraction lines that Mg_2TiO_4 is a spinel of the inverse (or variate) class. Thus, half of the Mg ions occupy the tetrahedral interstices in the oxygen lattice, while the remaining Mg ions and the Ti ions are (presumably) randomly located in the octahedral interstices. This conclusion was confirmed by Romeijn (5).

King and Kelley (6) suggested that the degree of structural randomness is not established and that it may vary with the sample of Mg_2TiO_4; thus, they recommended an intermediate value of Rℓn2 for the zero-point entropy. In a previous review, however, Kelley (1) used the theoretical value of 2Rℓn2 in order to make Mg_2TiO_4 stable relative to $MgTiO_3$ at high temperatures. We choose to adopt 2Rℓn2, although the evidence is not conclusive. Recent studies of solid state reactions by Bautsch and Werner (7) indicate that ΔGr° is negative for $MgTiO_3$(c) + MgO(c) → Mg_2TiO_4(c) at temperatures of 1673°K and above. Both Rℓn2 and 2Rℓ2 are consistent with this evidence.

Melting Data

See liquid table.

June 30, 1961; June 30, 1967

MAGNESIUM ORTHOTITANATE (Mg_2TiO_4) (LIQUID) GFW = 160.5216

$S°_{298.15}$ = [41.208] gibbs/mol $\Delta Hf°_{298.15}$ = [-489.084 ± 1.5] kcal/mol

Tm = 2013 ± 20°K $\Delta Hm°$ = [31] kcal/mol

Heat of Formation

$\Delta Hf°_{298}$ is obtained from $\Delta Hf°_{298}$(c) by adding ΔHm° and the difference between $H°_{Tm} - H°_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1400°K. Below 1400°K the heat capacity is obtained from the heat capacity of the crystal. Above 1400°K the heat capacity is assumed constant and estimated as 54.6 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) suggested congruent melting at 2005°K. The ΔHm° is estimated from those of $Na_2O \cdot 2TiO_2$ and $Na_2O \cdot TiO_2$ observed by Naylor (3) and $CaO \cdot TiO_2 \cdot SiO_2$ observed by King (4).

DIMAGNESIUM SILICIDE (Mg_2Si) (Crystal)

Mol. Wt. = 76.73

$\Delta H_f^\circ{}_{298.15} = -18.6$ kcal. mole^{-1}

$S^\circ_{298.15} = [19.5]$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 1375$°K

$\Delta H_m = [15.33]$ kcal. mole^{-1}

Heat of Formation. $\Delta H_f^\circ{}_{298.15}$ was found in the National Bureau of Standards Circular 500 (1952).

Heat Capacity and Entropy. C_p taken from Kubaschewski and Evans, "Metallurgical Thermochemistry," 3rd Edition, Pergamon Press Ltd., New York, (1958). $S^\circ_{298.15}$ was estimated.

Melting Data. T_m was taken from NBS Circular 500 (1952). ΔH_m was found in Wilson, Beahm, and Cooper, "Determination and Analysis of the Potentialities of Thermal Energy Storage Materials," Callery Chemical Co., Callery, Pa., June 30, 1961.

DIMAGNESIUM SILICIDE (Mg_2Si) (Liquid)

Mol. Wt. = 76.73

ΔH_f° 298.15 = -3.749 kcal. mole^{-1}

$S_{298.15}^\circ$ = [30.2] cal. deg.$^{-1}$ mole^{-1}

T_m = 1375°K

ΔH_m = [15.33] kcal. mole^{-1}

Heat of Formation. ΔH_f° 298.15 was based on ΔH_f° 298.15 of the crystal and the heat of melting.

Heat Capacity and Entropy. C_p was estimated. A glass transition was assumed at 916°K. $S_{298.15}^\circ$ was calculated from the entropy of the crystal and the entropy of melting.

Trimagnesium Dinitride (Mg_3N_2)

(Solid) Mol. Wt. = 100.98

Dec. 31, 1960; Mar. 31, 1963

MAGNESIUM ORTHOPHOSPHATE ($Mg_3P_2O_8$) (CRYSTAL) MOL. WT. = 262.91

$S^\circ_{298.15}$ = [45] cal. deg.$^{-1}$ mole^{-1}

T_m = 1621°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -895.1 ± 2.5 kcal. mole^{-1}

ΔH_m = [29 ± 10] kcal. mole^{-1}

Heat of Formation.

The selected $\Delta H^\circ_{f\ 298.15}$ is a weighted average of a revised calorimetric determination and a third law calculation using equilibrium data.

A calorimetric determination of the heat of formation reported by C. G. Stevens and E. T. Turkdogan, Trans. Faraday Soc. 50, 370 (1954) was revised three ways:

1. The heat of reaction for the reaction $3MgO(c) + P_2O_5$(orthorhombic) → $Mg_3P_2O_8(c)$ had been evaluated at 348°K. A small temperature correction to 298.15 was made with thermal data not available to Stevens and Turkdogan (loc. cit.) on MgO (W. F. Giauque, J. Am. Chem. Soc. 71, 3192 (1949)), P_2O_5 (JANAF Table, Dec. 31, 1962) and $Mg_3P_2O_8$ (this table).
2. A new $\Delta H^\circ_{f\ 298.15}$ for P_2O_5(hexagonal) as reported by W. S. Holmes, Trans. Faraday Soc. 58, 1916 (1962) was combined with the heat of reaction, -6.85 ± 1.0 kcal. mole^{-1}, for the reaction: P_2O_5(hexagonal) → P_2O_5(orthorhombic) as reported by W. L. Hill, G. T. Faust, and S. B. Hendricks, J. Am. Chem. Soc. 65, 794 (1943).
3. A correction of +8.35 kcal. mole^{-1} was made for the change in phosphorus reference state from white (α) → red (V). (The correction is +8.35 kcal./mole of $Mg_3P_2O_8$ or +4.173 kcal. mole^{-1} of P.)

This revised $\Delta H^\circ_{f\ 298.15}$, -897.60 ± 2.0 kcal. mole^{-1}, would appear to be more reliable than the original value reported by Stevens and Turkdogan (loc. cit.).

For the reaction

$$Mg_3P_2O_8(c) + 5H_2(g) \rightarrow 3MgO(c) + P_2(g) + 5H_2O(g)$$

the third law treatment of the equilibrium data of J. B. Bookey, J. Iron Steel Institute (London) 172, 66 (1952) and the JANAF Table free energy functions gave a $\Delta H^\circ_{f\ 298.15}$ = -893.11 kcal. mole^{-1}.

The quantity, -895.10 ± 2.50 kcal. mole^{-1}, is taken as the most probable value for the heat of formation of magnesium orthophosphate.

Heat Capacity and Entropy.

The entropy at 298.15 was estimated by considering the additive entropy constants of K. K. Kelley, private communication, June 1960, and E. L. Evans and O. Kubaschewski, "Metallurgical Thermochemistry, 1958. The heat capacity was estimated in a similar manner by considering the heat capacities of the constituent elements and related compounds such as Mg, O_2, MgO, P, P_2O_5, $Ca_2P_2O_7$, and $Ca_3P_2O_8$.

Melting Data.

The melting point, 1621°K, as reported by Stevens and Turkdogan (loc. cit.) was selected. There is disagreement on the melting point in the literature. From the work of H. Winter, Diss. Universitats zu Leipzig 1913, K. K. Kelley, U. S. Bureau of Mines Bulletin 393, (1936) has quoted a melting point of 1457°K and has calculated a "rather uncertain value" of 11.300 kcal./mole for the heat of fusion. J. B. Bookey (loc. cit.) has found a melting point of 1703°K. J. Berak, Roczniki Chim. 32, 17 (1958) gives 1630°K as the melting point.

Dec. 31, 1960; Mar. 31, 1963

MAGNESIUM ORTHOPHOSPHATE ($Mg_3P_2O_8$) (LIQUID) MOL. WT. = 262.91

$S^\circ_{298.15}$ = [54.8] cal. deg.$^{-1}$ mole^{-1}

T_m = 1621°K

T_b = Unknown

$\Delta H^\circ_{f\ 298.15}$ = [-877 ± 10] kcal. mole^{-1}

ΔH°_m = [29 ± 10] kcal. mole^{-1}

ΔH°_v = Unknown

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ was calculated from the estimated ΔH_m and the $\Delta H^\circ_{f\ 298.15}$ of the crystal.

Heat Capacity and Entropy.

The heat capacity was estimated as 13/11 of the corresponding heat capacity of $Ca_2P_2O_7$ as given in K. K. Kelley, U. S. Bur. Mines Bull. 5841 (1960).

Melting Data.

The heat of melting was estimated by taking 13/11 of the ΔH_m of $Ca_2P_2O_7$ as given in K. K. Kelley (loc. cit.)

Dec. 31, 1966

MOLYBDENUM (Mo) (CRYSTAL) GFW = 95.94

ΔHf°_0 = 0 kcal/mol

$S^\circ_{298.15}$ = 6.837 ± 0.01 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 0 kcal/mol

Tm = 2892 ± 10°K

ΔHm° = [6652 ± 600] kcal/mol

$\Delta Hs^\circ_{298.15}$ = 157.3 ± 0.5 kcal/mol

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Below 20°K several investigators [1,2,3,4,5,6] have determined the heat capacity, and an average of these determinations was used to obtain a Debye theta = 440 and an electronic gamma = 4.7 x 10^{-4} gibbs/mol-deg. From these the entropy at 20°K was calculated as 0.024 gibbs/mol and the enthalpy as 0.265 cal. Between 20°K and 271°K the data of Clusius and Franzosini[2] are the adopted heat capacities. The data of Simon and Zeidler[5] are as much as 2.5% high below 78°K and as much as 1% low above this.

Both the high temperature enthalpies and heat capacity have been measured by several investigators and there is generally good agreement in the 1000-2000°K range. A smooth curve was drawn through the high temperature enthalpy data of several investigators [7,8,9,10,11,12], which was also joined smoothly to the integrated low temperature data of Clusius and Franzosini. The heat capacity was obtained by fitting the smoothed enthalpy data with a polynomial and differentiating. The heat capacity obtained agreed satisfactorily with that reported in several investigations [13,14,15,16,17,18,19].

Dec. 31, 1966

MOLYBDENUM (Mo) (LIQUID) GFW = 95.94

$S^\circ_{298.15}$ = [9.261] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [7.076] kcal/mol

Tm = 2892 ± 10°K

ΔHm° = [6652 ± 600] kcal/mol

Tb = [4919°K]

ΔHv° = [140.812] kcal/mol

Heat of Formation.

The ΔHf°_{298} was obtained from that of the crystal plus ΔHm° and the difference between $H_{2892} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated as 10 gibbs/mol in the real range in order to be comparable with the value in the crystal below the melting point. Below the melting point the heat capacity was assumed constant to a glass transition, assumed to be 2000°K, below which the heat capacity was that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

The heat of melting was obtained from an entropy of melting of 2.3 eu, assumed by comparison with Fe, Cu, Co, Mg and Al. The melting point was reported by E. Rudy and S. Windisch, Aerojet-General Corporation, Report No. AFML-TR-65-2, Part 1, Vol. III, July 1965. A. G. Worthing, Phys. Rev. 25, 846 (1925), reports a melting point of 2895°K which, corrected to the 1948 International Temperature Scale, is 2882°K.

Vaporization Data.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Heat of Formation.

The heat of formation is simply the heat of sublimation at 298°K; this is obtained by second and third law analysis of several vapor pressure sets. A comparison of the results is tabulated below.

Reference	Method	Points	Range °K	ΔHs°_{298} kcal/mol 2nd law	ΔHs°_{298} kcal/mol 3rd law	Drift in 3rd law
1. Vozella	Langmuir	12	2140-2533°	156.4 ± 2.9	157.6 ± 0.9	0.2 ± 1.3 eu
2. Edwards	Langmuir	9	2150-2460°	146.7 ± 1.5	158.2 ± 1.2	5.0 ± 0.6 eu
3. Fries	Langmuir	12	2086-2489°	156.5 ± 1.6	156.7 ± 0.7	0.1 ± 0.7 eu
4. Jones	Langmuir	9*	2113-2496°	161.6 ± 3.8	156.0 ± 1.4	-2.6 ± 1.6 eu
5. Norris	Langmuir	Equn.	2000-2600°	131.1	148.6 ± 4.3	8.8 eu
6. Zwikker	Langmuir	Equn.	1200-2500°	159.1	158.2 ± 0.8	-0.8 eu
7. Babeliewsky	Mass Spec.		2220-2603°	149.6 ± 2.2		

* One point rejected due to failure of statistical test

The data of references 1 and 3 show no drift and thus indicate that the accommodation coefficient is essentially unity. A median value of the 3rd law heat is adopted as 157.3 ± 0.5 kcal/mol.

Heat Capacity and Entropy.

The electronic energy levels are those listed by C. E. Moore, U. S. Natl. Bur. Std. Circular 467, Washington D. C. (1958). Several individual lines missing from given terms were estimated by analogy with the observed lines in the term. In addition, an estimate of the values of completely missing terms, arising out of low lying multiplets, was made as follows: The ^1D and ^1S; ^1D and ^1G; ^3D; ^3P and ^3F terms of the [Kr] $4d^45s^2$ multiplet were estimated at 25000, 30000, 34000 and 36000 cm^{-1}. The triplet P,D,F and G levels and the singlet S,D,F and G levels of the [Kr] $4d^6$ configuration were estimated at 30000 cm^{-1} and 40000 cm^{-1} respectively.

Higher configurations such as [Kr] $4d^45s(^6D)$ 5d which have many septuplet and quintuplet terms were thought to lie close to the ionization limit. However, upon calculating a table which contains an extra 100 levels at 35000 m^{-1} and 200 levels each at 40000 and 45000 cm^{-1}, the difference in free energy function at 6000°K is a negligible 0.008 gibbs/mol.

Heat of Formation.

The heat of formation is obtained by adding the heat of ionization to the heat of formation of the gas at 0°K. The heat of ionization, 163.742 kcal/mol (7.10 eV), is obtained from C. E. Moore, Natl. Bur. Std. Circular 467, Vol. III, Washington, D. C. (1958).

Heat Capacity and Entropy.

The electronic energy levels are taken from C. E. Moore, loc. cit. The configuration [Kr] $4d^4 5s^2$ is completely missing in Mo^+, while in the isoelectronic Nb(g) this is a very low lying configuration. However, a comparison of Cr^+ with Mo^+, and V(g) with Nb(g) indicates that the similarities are much closer down a given group than across a row to an isoelectronic neighbor. Thus, by analogy with Cr^+, the missing configuration is expected to lie $>$ 50,000 cm^{-1} and thus be negligible.

The enthalpy at 0°K is calculated to be -1.481 kcal/mol.

MOLYBDENUM MONOXIDE (MoO) (IDEAL GAS) GFW = 111.9394

Ground State Configuration [$^3\Sigma$] ΔHf°_0 = 92.5 ± 15 kcal/mol

$S^\circ_{298.15}$ = [56.9 ± 2] gibbs/mol $\Delta Hf^\circ_{298.15}$ = 92.5 ± 15 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
[0]	[3]
[14000]	[1]
[17000]	[2]
[19000]	[6]

ω_e = [955] cm^{-1} $\omega_e x_e$ = [3.61] cm^{-1} σ = 1

B_e = [0.37943] cm^{-1} α_e = [0.00188] cm^{-1} r_e = [1.80] Å

Heat of Formation

The heat of formation, ΔHf°_{298}(MoO,g) = 92.5 ± 15 kcal/mol, is derived from the heat of reaction, ΔHr°_{298} = 32.9 kcal/mol for Mo(c) + O(g) → MoO(g) with all JANAF auxiliary data. The value of ΔHr°_{298} is calculated by the third law method from the partial pressure data determined mass-spectrometrically in the temperature range from 2262 to 2466°K by G. DeMaria, et al. (1). The drift in the third law analysis is -14 ± 11 eu.

Heat Capacity and Entropy

The ground state configuration and the probable electronic levels are assumed to be similar to those for WO(g) (see JANAF WO(g) table of Sept. 30, 1966). T. M. Swaminathan and S. G. Krishnamurthy (2) observed ten band systems attributed to molybdenum oxide with lower state values of ω_e = 950 ± 10 cm^{-1}. T. V. Iorns and F. E. Stafford (3) also observed a band with a peak at 969 cm^{-1} in the vapor above MoO_3(c). It is surprising that the observed vibrational frequency of MoO(g) is lower than 1055 cm^{-1} observed for WO(g). The latter comes not only from electronic spectra of the gas but also from infrared observation in matrix isolation; the former comes only from tentative assignments of electronic spectra presumably arising from MoO(g). It is possible that the observed states could be low lying excited states. We tentatively assume the fundamental vibrational frequency to be 955 cm^{-1}. The bond distance is then calculated by Guggenheimer's relation (4) for multiple bond molecules from the estimated vibrational frequency. The anharmonicity correction x_e is estimated from the relation $x_e\mu^{1/2}$ = 0.014 given by R. F. Barrow and A. D. Caunt (5). The constant (0.014) is assumed to be the same as that for WO(g). The value of α_e is calculated from the Morse potential function. The rotational constant B_e is calculated from the estimated bond distance.

$\Delta Hf^\circ_0 = -139.3 \pm 0.5$ kcal/mol

$S^\circ_{298.15} = 11.95 \pm 2$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -140.5 \pm 0.5$ kcal/mol

Td = Unknown

Heat of Formation

The adopted heat of formation, -140.5 kcal/mol, is a weighted average of values derived from calorimetric determinations, emf measurements and equilibrium studies. The results are given below.

Ignition of the bomb products from the calorimetric studies of Staskiewicz et al. indicated that oxidation was only about 70 per cent complete. The authors also digested the products with NH_4OH to remove the trioxide. The residue was the dioxide, as indicated by both oxidation and reduction. This evidence does not necessarily eliminate the possibility of known intermediate oxides in the combustion products. Mah found 72 - 75 per cent conversion to trioxide by weighing the total combustion products; he performed no additional analysis.

**Auxiliary data for $MoO_3(c)$ are taken from corresponding measurements of the same authors. See JANAF $MoO_3(c)$ table for details.

Reaction:
- A. $MoO_2(c) + 1/2\ O_2(g) = MoO_3(c)$.
- B. $2Fe_xO(c) + Mo(c) = MoO_2(c) + 2xFe(c)$.
- C. $2NiO(c) + Mo(c) = MoO_2(c) + 2Ni(c)$.
- D. $Mo(c) + 2CO_2(g) = MoO_2(c) + 2CO(g)$.
- E. $Mo(c) + 2H_2O(g) = MoO_2(c) + 2H_2(g)$.
- F. $Mo(c) + O_2(g) = MoO_2(c)$ derived by the author from the cell reaction $2Fe_xO(c) + Mo(c) = MoO_2(c) + 2xFe(c)$ using ΔGf° data for $Fe_xO(c)$.

Heat Capacity and Entropy

E. G. King, J. Am. Chem. Soc. 80, 1799 (1958), measured the low temperature heat capacities from 53.3° to 296°K. E. G. King, W. W. Weller and A.U . Christensen, U. S. Bur. Mines RI 5664, 1960, measured the high temperature enthalpy changes from 399° to 1801°K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that there be a smooth joint at 298°K. Deviations of the enthalpy data from the adopted values are -1.3 to +0.7 percent, excluding the point at 1801°K. This point at the highest temperature deviates by +2.3 percent, which suggests that the apparent heat capacity is rising very rapidly. No explanation for this rapid rise is available.

The entropy $S^\circ_{298} = 11.054$ eu is obtained from the low temperature heat capacity data, based on $S^\circ_{51} = 0.31$ eu. B. N. Figgis and J. Lewis, "Progress in Inorg. Chem.," Vol. 6, page 123, Interscience Publishers, New York, 1964, indicated that MoO_2 is probably antiferromagnetic. Its small susceptibility is presumably due to Mo-Mo interactions. It is possible that at temperatures below 50°K entropy due to spin interactions of the d^2 electrons will appear, contributing up to 2.2 eu. The drifts in the equilibrium data do suggest that additional entropy may be appropriate; however, only the EMF data of Rapp appear to be sufficiently precise to influence the decision. These data suggest addition of 0.8±0.1 eu and 0.9±0.1 eu based on auxiliary data for Wüstite and NiO(c), respectively. We select the entropy of 11.954 eu from equilibrium data for NiO.

Heat of Formation

Burns et al. (1) have investigated mass-spectrometrically the vapor in equilibrium with powdered $MoO_2(c)$ and also reported the partial pressures of $MoO_2(g)$, $MoO_3(g)$, $(MoO_3)_2(g)$, and $(MoO_3)_3(g)$. Second and third analyses of their partial pressure data are given in the table below. The adopted value, $\Delta Hf^\circ_{298}(MoO_2, g)$ = -3.1 kcal/mol, is calculated from their 3rd law value of ΔHr°_{298} = 137.4 kcal/mol for $MoO_2(c) \rightarrow MoO_2(g)$, using all JANAF functions.

DeMaria et al. (2) have measured the partial pressures of gaseous oxides MoO, MoO_2, MoO_3 and O(g) in the Mo-Al_2O_3 system by mass spectrometry. Blackburn et al. (3) and Plante (4) have studied the vapor pressures above molybdenum dioxide(c) by the Knudsen effusion method. Second and third law analyses of these three sets of partial pressure data are reported in the following table.

	Investigator	Reaction	Temp. °K	No. of Points	ΔHr°_{298}, kcal/mol 2nd law	ΔHr°_{298}, kcal/mol 3rd law	Drift eu	$\Delta Hf^\circ_{298}(MoO_2, g)$ kcal/mol**

Heat Capacity and Entropy

The $MoO_2(g)$ is assumed to have a C_{2v} symmetry similar to that of TaO_2 reported by Weltner and McLeod (5). The bond angle O-Mo-O is estimated to be 110°. The bond distance Mo-O is estimated to be 1.80 Å, the same as that in MoO(g). The symmetric and asymmetric stretching frequencies were obtained from the infrared spectra of gaseous MoO_2Cl_2 and MoO_2Br_2, reported by Iorns and Stafford (6). The bending vibrational frequency (300 cm^{-1}) is estimated by comparison with other transition metal dioxides. The three principal moments of inertia are: I_A = 4.2470 x 10^{-39}, I_B = 11.5512 x 10^{-39} and I_C = 15.7982 x 10^{-39} g cm^2.

The electronic levels and quantum weights are estimated from the data reported by Weltner and McLeod (7) on WO_2. The ground state is assumed to be $^3A_1$ and the first excited level is assumed to lie close to the observed transitions at 7890Å and 7806Å in WO_2. Since both these states are presumed to be triplet, we have assigned a total degeneracy of 6. In addition, we expect from the electronic levels of $Mo^{+4}(g)$ (8) that other electronic states will also be found and these are arbitrarily estimated in the level at 25000 cm^{-1}.

MOLYBDENUM TRIOXIDE (MoO_3) (CRYSTAL) GFW = 143.9382

ΔHf°_0 = -176.9 ± 0.1 kcal/mol

$S^\circ_{298.15}$ = 18.585 ± 0.15 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -178.1 ± 0.1 kcal/mol

Tm = 1074°K

ΔHm° = 11.60 kcal/mol

Heat of Formation

The adopted heat of formation, -178.1 kcal/mol, is the weighted average of two recent calorimetric determinations. The results are given below.

Staskiewicz et al. (2) found that oxidation was only about 80 per cent complete and tentatively attributed this to formation of MoO_2(c). The table for MoO_2(c) details the analytical methods applied to the combustion products and the heat of combustion of the dioxide which is necessary for reduction of the data of the trioxide. Combination of these investigations gives $\Delta Hf^\circ_{298}(MoO_3, c)$ = -177.98 kcal/mol. Subsequent discovery of oxides intermediate between MoO_2 and MoO_3 raises a possible uncertainty concerning the incomplete oxidation. Mah (1) also reported that completion of the combustion of Mo(c) sample ranged from 84 to 93 per cent, as determined only by weight gain of the total combustion products upon prolonged low temperature ignition. In contrast, the earlier workers reported almost complete combustion. Neumann et al. (3) found about 97 per cent completion using a wet analysis involving aqua regia. Moose and Parr (4) found that in several combustions, they obtained over 99 per cent completion, based on the weight of the oxide formed.

	Investigator	Year	Method	Reaction	ΔHf°_{298} (kcal/mol)
1.	Mah	1957	Calorimetric	$Mo(c) + 3/2O_2(g) \rightarrow MoO_3(c)$	-178.16
2.	Staskiewicz et al.	1955	Calorimetric	$Mo(c) + 3/2O_2(g) \rightarrow MoO_3(c)$	-177.98
3.	Neumann et al.	1934	Calorimetric	$Mo(c) + 3/2O_2(g) \rightarrow MoO_3(c)$	-180.4
4.	Moose and Parr	1924	Calorimetric	$Mo(c) + 3/2O_2(g) \rightarrow MoO_3(c)$	-175.6

Heat Capacity and Entropy

Smith et al. (5) measured low temperature heat capacities from 18.3 to 299.8°K. King et al. (6) measured high temperature enthalpy data from 399.3° to 1063.9°K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that there be a smooth joint at 298°K. Deviations of the enthalpy data from the adopted values are -0.65 percent to +0.17 percent. Seltz et al. (7) have also measured low temperature heat capacities from 70° to 298.7°K which are not in agreement with the values adopted. (The discrepancy has been discussed by Smith.) Cosgrove and Snyder (8) have also measured high temperature enthalpy data from 273° to 1068°K by drop calorimetry. Their smooth values are about 2 percent higher than the values adopted in the tabulation.

The entropy, S°_{298} = 18.585 eu, is obtained from the low temperature heat capacity data of Smith (5), based on S°_{20} = 0.197 eu. This starting entropy was obtained by the authors from a T^2 extrapolation of the data. It is surprising that the entropy of MoO_3(c) is larger than that of WO_3(c) by about 0.4 eu. This may be due to the difference in the crystal structures, MoO_3 being orthorhombic and WO_3 monoclinic, and also to uncertainty in the entropy extrapolation below 50°K for WO_3(c).

Melting Data

The adopted melting point is obtained from King (6), and the heat of melting is calculated from the adopted enthalpies of the crystal and liquid based on the enthalpy data of King. Cosgrove and Snyder (8) found the melting point 1068°K by the cooling curve method, and derived ΔHm° = 12.54 kcal/mol from their smooth enthalpy values at the melting point.

June 30, 1967

MOLYBDENUM TRIOXIDE (MoO_3) (LIQUID) GFW = 143.9382

$S°_{298.15}$ = 26.971 gibbs/mol

$\Delta Hf°_{298.15}$ = -168.555 ± 0.1 kcal/mol

Tm = 1074°

ΔHm° = 11.60 kcal/mol

Heat of Formation

The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between $H°_{1074} - H°_{298}$ for the crystal and liquid.

Heat Capacity and Entropy

The heat capacity between the melting point and 1392.4°K is derived from the enthalpy data measured by E. G. King, W. W. Weller and A. U. Christensen, U. S. Bur. Mines RI 5664 (1960). The heat capacity is assumed constant above and below the measured range. At 700°K, a glass transition is assumed, below which the heat capacity is taken to be the same as that of the crystal. The entropy at 298°K is obtained in a manner analogous to that of the heat of formation.

L. A. Cosgrove and P. E. Snyder, J. Am. Chem. Soc. 75, 1227 (1953), also measured the enthalpy changes for $MoO_3(\ell)$ in the temperature range from 1068° to 1300°K. Their smooth values are +2.5 percent to +4.0 percent higher than our tabulated values. They have also found the melting point at 1068°K by the cooling curve method.

Melting Data

See JANAF MoO_3(c) table dated June 30, 1967.

MOLYBDENUM TRIOXIDE (MoO_3) (IDEAL GAS) GFW = 143.9382

Point Group [D_{3h}]

$\Delta Hf°_0$ = -85.2 ± 5 kcal/mol

$S°_{298.15}$ = [66.9 ± 4] gibbs/mol

$\Delta Hf°_{298.15}$ = -86.2 ± 5 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[800] (1)	969 (2)
[350] (1)	[300](2)

Bond Distance: Mo-O = [1.80] Å

Bond Angle: O-Mo-O = [120°]

σ = [6]

Product of the Moments of Inertia: $I_AI_BI_C$ = [4.304×10^{-114}] $g^3\ cm^6$

Heat of Formation

Burns et al. (1) have determined the partial pressures of gaseous oxides MoO_2, MoO_3, $(MoO_3)_2$ and $(MoO_3)_3$ in equilibrium with powdered MoO_2(c) by mass spectrometry. Plante (2) and Blackburn et al. (3) have also investigated the vapor pressures above molybdenum dioxide (c) by the Knudsen effusion method. They all involve the disproportionation of MoO_2(c) to Mo(c) and MoO_3(g). DeMaria et al. (4) have reported the partial pressures of MoO(g), MoO_2(g), MoO_3(g) and O(g) in the Mo-Al_2O_3 system by mass spectrometry. Second and third law analyses of these partial pressure data are listed in the following table, using all JANAF functions.

				$\Delta Hr°_{298}$, kcal/mol			
Investigator	Reaction	Temp. °K	No. of Points	2nd law	3rd law	Drift eu	$\Delta Hf°_{298}(MoO_3, g)$ kcal/mol*
1. Burns et al.	$1.5MoO_2(c) \rightarrow MoO_3(g) + 0.5\ Mo(c)$	1481-1777	34	131.6±1.5	124.5	-4.2±0.9	-86.2
2. Plante	$1.5MoO_2(c) \rightarrow MoO_3(g) + 0.5Mo(c)$	1592-1918	119	134.6±1.4	120.3	-8.3±0.7	-90.4
3. Blackburn et al.	$1.5MoO_2(c) \rightarrow MoO_3(g) + 0.5Mo(c)$	1818-2028	7	108.7±6.4	117.2	4.2±3.4	-93.4
4. DeMaria et al.	$Mo(c) + 3\ O(g) \rightarrow MoO_3(g)$	2281-2416	5	-225.1±39.9	-255.1	-12.8±17.1	-76.4

*Based on the third law $\Delta Hr°_{298}$ value

The selected heat of formation is -86.2 kcal/mol, based on the third law value of $\Delta Hf°_{298}$ of Burns et al. The choice is made because there is serious doubt about the data of Blackburn as discussed by Burns et al. In addition the assumption made by Plante that the only vapor species of any importance is MoO_3 may be erroneous. The mass spectrometric work of Burns et al. is thus preferred.

Heat Capacity and Entropy

The MoO_3(g) is assumed to be a planar D_{3h} molecule with a bond angle O-Mo-O = 120°. The bond distance Mo-O is estimated to be 1.80 Å, the same as that of MoO(g). The three principal moments of inertia are $I_A = I_B = 12.9111 \times 10^{-39}$ and $I_C = 25.8222 \times 10^{-39}\ g\ cm^2$.

Iorns and Stafford (5) have observed two vibrational frequencies (969 and 715 cm^{-1}) in the infrared spectra of the vapor above MoO_3(c). They assigned the Mo-O stretching frequency at 969 cm^{-1} and the trimer ring vibration at 815 cm^{-1}, based on their infrared spectrum observations of gaseous molybdenum oxides and oxyhalides. Barraclough et al. (6) have also concluded that the presence of a metal-oxygen double bond can be correlated with a stretching frequency in the range 900-1100 cm^{-1}. For the MoO_3 molecule, they found the stretching frequency at 985 cm^{-1} in their spectrometric studies.

Based on the vibrational frequencies of MoO_4^{-2}(aq) reported by Nakamoto (7) and Siebert (8), and those of WO_3, WO_4^{2-}, SO_3 and SO_4^{2-}, we have estimated 800, 350 and 300 cm^{-1} for MoO_3(g).

Heat of Formation

The dissociation energy of N_2 has been the subject of considerable controversy and is presented by A. G. Gaydon, "Dissociation Energies", Chapman and Hall, London, 1953. L. Brewer and A. W. Searcy, Ann. Rev. Phys. Chem., 7, 259 (1956), discuss extensive and varied experiments which have now fixed the value of 9.76 e.v. as being highly probable. Additional support for this value is afforded by the recently observed predissociation in the x $^1\Sigma^-_g$ state by A. Loftus, Nature 186, 302 (1960).

Heat Capacities and Entropies

The electronic levels noted above are listed by C. E. Moore, Nat. Bur. Standards (U.S.) Circ. 467, Vol. I (1949), Vol. III (1958).

Heat of Formation.

G. Herzberg, Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules, D. van Nostrand Co., Inc., New York, 1950, lists two D_0(NO) values, 5.296 and 6.487 e.v. A. G. Gaydon, Dissociation Energies and Spectra of Diatomic Molecules, Chapman and Hall, Ltd., London, 1953, lists D_0(NO) = 6.49 ± 0.05 e.v. A Birge-Sponer extrapolation of the vibrational levels, up to v = 18, of the ground state leads to a D_0 of about 6.5 e.v. Gaydon's, loc. cit., analysis on the predissociation of NO also leads to the higher value for D_0(NO).

Y. Tanaka, J. Chem. Phys. 22, 2045 (1954), has observed and analyzed the emmission bands of NO in the vacuum ultraviolet region. Tanaka's, loc. cit., observation and interpretation of the abrupt cutoff (predissociation) of certain v' values in the β, γ, and δ bands and of the complete non appearance of ϵ and β' bands strongly favors a D_0(NO) = 6.48 e.v. $\Delta H^\circ_{f\ 298.15}$(NO)g was calculated on this basis to be 22.033 ± 1 kcal. mole^{-1}.

More recently M. A. Frisch, Diss. Absts. 23, 1940 (1961), Thesis, University of Wisconsin, Madison, Wisconsin, 1962, has calorimetrically determined the heat of reaction for:

$$NO(g) + CO(g) \rightarrow CO_2(g) + 1/2N_2(g)$$

at 298.15°K., from which the author derives a $\Delta H^\circ_{f\ 298.15}$ NO(g) = 21.58 ± 0.04 kcal. mole^{-1}. The auxiliary values used by Frisch to calculate the heat of formation of nitric oxide were based upon the 1961 atomic weight scale. Recalculating $\Delta H^\circ_{f\ 298.15}$ NO(g) using auxiliary functions based on the 1956 atomic weight scale had a negligible effect on the final result.

The calorimetrically determined heat of formation for nitric oxide, 21.58 ± 0.04 kcal. mole^{-1}, was selected as the best value.

Heat Capacity and Entropy.

The spectroscopic constants were taken from R. H. Gillette and E. H. Eyster, Phys. Revs. 56, 1113 (1939), who measured and analyzed the fundamental rotation-vibration band of nitric oxide using a grating spectrometer. The constants used in this calculation were adjusted to correspond to the naturally occurring isotopic mixture.

Heat of Formation.

K. Watanabe, J. Chem. Phys. 22, 1564 (1954), and W. C. Walker and G. L. Weissler, J. Chem. Phys. 23, 1962 (1955), have measured the ionization potential of NO(g) by photoionization, yielding I.P. = 9.25 ± 0.02 and 9.20 ± 0.03 eV, respectively. H. D. Hagstrum, J. Chem. Phys. 23, 1178 (1955), reported I.P. = 9.4 ± 0.2 eV by electron impact. K. P. Huber, Helv. Phys. Acta 34, 929 (1961), determined spectroscopcially the ionization potential for NO(g), I.P. = 9.267 ± 0.005 eV (213.72 ± 0.1 kcal/mol). The last value has been selected, and yields the heat of formation of NO^+(g), ΔHf°_0 (NO^+, g) = 235.18 kcal/mol, using ΔHf°_0 (NO, g) = 21.46 ± 0.04 kcal/mol.

Heat Capacity and Entropy.

The selected molecular constants were obtained from the ultraviolet spectra by E. Miescher, Can. J. Phys. 33, 355 (1955), Helv. Phys. Acta 29, 135 (1956).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by J. Hilsenrath and Carla G. Messina, NBS Report 8504, July 1, 1964, who have used slightly different molecular constants.

Heat of Formation.

The equilibrium constants for $NO(g) + 1/2\ O_2 \rightarrow NO_2(g)$ of Bodenstein and Lindner, Zeits. fur physik. Chem. 100, 82 (1922) as given by W. F. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) were subjected to 2nd and 3rd law analysis. Third law analysis gave $\Delta H_{298} = -13.67$ kcal. and 2nd law $\Delta H_{298}^\circ = -13.52 \pm 0.01$ kcal. The third law value had a very slight trend with temperature which was consistent with an entropy error of 0.25 cal. deg.$^{-1}$ mole^{-1}, the second law entropy was also consistent with an entropy error of 0.25 cal. deg.$^{-1}$ mole^{-1}. However the functions for all three gases are well established to about 0.03 cal. deg.$^{-1}$ mole^{-1} or better and so this must be interpreted as due to errors in the data. On this basis the 3rd law value of the heat was chosen and combined with JANAF auxiliary data to give $\Delta H_{f\ 298}^\circ$ = 7.91 ± 0.2 kcal. mole^{-1}, where the uncertainty includes that due to the possible error in the equilibrium constants.

Heat Capacity and Entropy.

G. R. Bird, J. C. Baird, A. W. Jache, J. A. Hodgeson, R. F. Curl Jr., A. C. Kunkle, J. W. Bransford, J. Rastrup-Andersen and J. Rosenthal, J. Chem. Phys. 40, 3378 (1964) have given a complete review of the microwave spectrum of NO_2. They also give a corrected infra-red vibrational assignment, adopted here, which is in excellent agreement with calculations from the microwave data. They report $I_A = 0.34981 \times 10^{-39}$ g. cm.^{2} and $I_B = 6.45446 \times 10^{-39}$ g. cm.^{2} and $I_C = 6.81994 \times 10^{-39}$ g. cm.^{2} The bond length and angle were chosen to give the best fit of the moments of inertia.

Dec. 31, 1965

NITROGEN DIOXIDE UNINEGATIVE ION (NO_2^-) (IDEAL GAS) MOL. WT. = 46.00605

Point Group C_{2v}

$S^\circ_{298.15}$ = [56.5] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 1

$\Delta H^\circ_{f\ 0}$ = -83.7 ± 12 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -85.9 ± 12 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$

[1320] (1)
[750] (1)
[1220] (1)

Bond Distance: N-O = [1.23] Å

Bond Angle: O-N-O = [116]°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = [25.6905] X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation of $NO_2^-(g)$ was calculated from the electron affinity of $NO_2(g)$ and the JANAF value of $\Delta H^\circ_{f\ 0}$ for $NO_2(g)$, 4.0 ± 0.5 ev and 8.6 ± 0.2 kcal. mole^{-1}, respectively. The former was obtained from the National Bureau of Standards Report 8628, "Preliminary Report on the Thermodynamic Properties of Selected Light Element and Some Related Compounds", January 1965.

Heat Capacity and Entropy.

The bond distance N-O and the angle O-N-O of $NO_2^-(g)$ were estimated to be the same as those in $NaNO_2(c)$ which have been determined by G. B. Carpenter, Acta Cryst. 5, 132(1952). The three individual moments of inertia are I_A =[0.6872] X 10^{-39}g. cm.^{2}, I_B =[5.7804] X 10^{-39} g. cm.^{2} and I_C =[6.4676] X 10^{-39} g. cm.^{2}

The vibrational frequencies of $NO_2^-(g)$ were assumed to be the same as those for nitrite ion in solution which have been measured by D. Williams, J. Am. Chem. Soc. 61, 2987(1939). These measured frequencies in nitrite solution are comparable to those in $NO_2(g)$ (1357.8, 756.8 and 1665.5 cm.$^{-1}$), reported by G. R. Bird et al., J. Chem. Phys. 40, 3378 (1964).

Bond Distance: O-N = [1.27] Å

Bond Angle: O-N-O = [120°]

σ = [6]

Product of the Moments of Inertia: $I_AI_BI_C$ = [5.309 X 10^{-115}] g.^{3} cm.^{6}

Heat of Formation.

The heat of formation is based on equilibrium constants for the reaction $N_2O_5(g) \rightarrow NO_2(g) + NO_3(g)$ obtained from shock wave studies by Schott and Davidson, J. Am. Chem. Soc. 80, 1941 (1958). These equilibria give a second law value of $\Delta H_r^\circ{}_{495}$ = 21.5 ± 1.4 kcal., corresponding to $\Delta H_r^\circ{}_{298.15}$ = 22.2 kcal., and a third law value of $\Delta H_r^\circ{}_{298.15}$ = 22.2 kcal. The resulting heat of formation is 17.0 kcal. mole^{-1}.

Guillory and Johnston, J. Am. Chem. Soc. 85, 1695 (1963) report an equilibrium constant based on estimated Beer's law constants for NO_3 and attributed to the reaction $O_2 + NO \rightarrow NO_3$. This gives a third law heat of formation of 12 ± 2 kcal. mole^{-1}, which was not considered. A tentative value of 23 kcal. mole^{-1} (or greater) may be derived from the D_0 given by D. A. Ramsay, Proc. 10th Colloq. Spect. Intnl. (1962), Univ. Maryland, pp. 583-596, 1963.

Heat Capacity and Entropy.

The structure and frequencies are those estimated by I. C. Hisatsune, J. Phys. Chem. 65, 2249 (1961). A symmetry of D_{3h} was chosen on the basis of Walsh's correlation, J. Chem. Soc. 1953, 2301 (1953) and the bond distance was taken as 2% longer than in the nitrate ion. The planar mode frequencies were calculated from estimated Urey-Bradley force constants, while the out-of-plane wagging frequency (765 cm.$^{-1}$) was assumed the same as in $HNO_3(g)$.

There are several conflicting bits of information concerning NO_3 radicals. Chantry, Horsefield, Morton and Whiffen, Mol. Phys. 5,589 (1962) studied the electron resonance and optical absorption spectra of what appear to be NO_3 radicals trapped in crystals of urea nitrate. The authors suggest a planar structure without a threefold axis (thus C_s or C_{2v} symmetry), at least for the trapped radicals. Guillory and Johnston, loc. cit., report for gaseous NO_3 radicals an infrared frequency at 1840 cm.$^{-1}$ which they assign as the N-O stretch. The similarity of this frequency to those in N-O and X-N-O molecules led the authors to suggest an OONO structure (thus C_s symmetry) rather than the nitrate structure. The remaining frequencies for such a structure may be crudely estimated by analogy with those measured for $(NO)_2$ by Smith, Keller & Johnston, J. Chem. Phys. 19, 189 (1951). Based on such frequencies and reasonable bond distances, the room temperature entropy for the OONO structure would be 68-72 cal. deg.$^{-1}$ mole^{-1}. Such an entropy is quite inconsistent with the second law $\Delta S_r^\circ{}_{495}$ = 33.2 ± 3 cal. deg.$^{-1}$ mole^{-1} for $N_2O_5(g) \rightarrow NO_2(g) + NO_3(g)$ obtained from the shock wave studies of Schott and Davidson. The Hisatsune functions based on the nitrate structure were selected because they are consistent with the experimental entropy. The principal moments of inertia for this structure are I_A = 6.427 X 10^{-39}, I_B = 6.427 X 10^{-39} and I_C = 12.853 X 10^{-39} g. cm.^{2} A structure of C_{2v} symmetry would result if the nitrate structure were distorted to give one non-equivalent oxygen. Ramsay, loc. cit., suggests that such distortion can only be small, based on the high dispersion optical spectra of the gas phase.

Dec. 31, 1960; Sept. 30, 1962

MONOPHOSPHORUS MONONITRIDE (PN) (IDEAL GAS) MOL. WT. = 44.983

$\Delta H_{f\ 0}^\circ$ = 24.9 ± 1.2 kcal. mole^{-1}

$\Delta H_{f\ 298.15}^\circ$ = 25.0 ± 1.2 kcal. mole^{-1}

Ground State Configuration $^1\Sigma^+$

$S_{298.15}^\circ$ = 50.437 cal. deg.$^{-1}$ mole^{-1}

Electronic Level and Multiplicity

ϵ, cm.$^{-1}$	g_1
0	1

ω_e = 1337.24 cm.$^{-1}$

$\omega_e x_e$ = 6.983 cm.$^{-1}$

D_e = 1.09 X 10^{-6} cm.$^{-1}$

B_e = 0.7862 cm.$^{-1}$

α_e = 0.00557 cm.$^{-1}$

r_e = 1.4910 Å

σ = 1

Heat of Formation.

The selected $\Delta H_{f\ 298.15}^\circ$ was calculated from the D_0° = 165.8±1.2 kcal. mole^{-1} reported by R. L. Potter and V. N. DiStefano, J. Phys. Chem., 65, 849 (1961). A D_0° = 163.7±1.2 kcal. mole^{-1} was experimentally determined by E. O. Huffman, G. Tarbutton, K. L. Elmore, W. E. Cate, H. K. Walters, Jr., and G. V. Elmore, J. Am. Chem. Soc., 76, 6239 (1954). The D_0° reported by Huffman et. al was derived using a pressure-composition method i.e. measurement of equilibrium vapor pressure at 1173°K for the reaction [PN(g) → P_2(g) + N_2(g)]. Potter and DiStefano (loc. cit.) recalculated Huffman's results to obtain their D_0° value. A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall (1953), lists a D_0° = 138.4 ± 19 kcal. mole^{-1}. The corresponding heats of formation are:

$\Delta H_{f\ 298.15}^\circ$	Source
25.0 ± 1.2 kcal. mole^{-1}	Potter and DiStefano (loc. cit.)
27.1 ± 1.2 kcal. mole^{-1}	Huffman et al. (loc. cit.).
53 ± 19 kcal. mole^{-1}	Gaydon (loc. cit.).

Heat Capacity and Entropy.

The molecular constants are taken from G. Herzburg, "Diatomic Molecules," D. Van Nostrand Co., New York, N. Y., (1960) 2nd Ed.

ω_e = 1220.0 cm.$^{-1}$

B_e = [0.7762] cm.$^{-1}$

$\omega_e x_e$ = 7.75 cm.$^{-1}$

α_e = [0.0064] cm.$^{-1}$

σ = 1

r_e = 1.495(7) Å

Heat of Formation

The dissociation energy is listed by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", 2nd Edn., Chapman and Hall, London (1953).

Heat Capacity and Entropy

The spectroscopic constants other than B_e and α_e are from G. Herzberg "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Company, New York (1950). r_e is from "Tables of Interatomic Distances and Configuration in Molecules and Ions", The Chemical Society, London (1958), and has been used, together with the equation

$$\alpha_e = 6\,(\sqrt{\omega_e x_e B_e{}^3} - 6B_e{}^2)/\omega_e \text{ (Herzberg, op. cit., p. 108)}$$

to calculate B_e and α_e.

Silicon Nitride (SiN)

Dec. 31, 1960; Mar. 31, 1967

SILICON NITRIDE (SiN) (IDEAL GAS) GFW = 42.0927

Ground State Configuration $^2\Sigma^+$

$S^\circ_{298.15}$ = 51.792 gibbs/mol

ΔHf°_0 = 88.7 ± 15 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 89 ± 15 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	2
[6000]	4
24299.4	2
[31000]	4

ω_e = 1150.8 cm^{-1}

$\omega_e x_e$ = 6.55 cm^{-1}

σ = 1

B_e = 0.7299 cm^{-1}

α_e = 0.00567

r_e = 1.5718 Å

Heat of Formation

A linear Birge-Sponer extrapolation of the ground state gives a dissociation energy of 142.9 kcal. The ground state can correlate with normal atoms Si(^3P) + N(^4S) or with Si(^3P) + N(^2D); in this latter case D°_0 would be 88 kcal. The uncertainty in the extrapolation is quite large, ± 30 kcal, since only 6 levels, of the estimated total of 87 levels, are observed.

A dissociation energy can also be calculated from the $B^2\Sigma^+$ state by a much shorter extrapolation. This extrapolation is done graphically since some curvature is evident in the first six levels. A value of $D^\circ_0(B^2\Sigma)$ = 50.4 kcal is obtained. This corresponds to $D^\circ_0(X^2\Sigma)$ = 119.9 kcal for normal products or $D^\circ_0(X^2\Sigma)$ = 65 kcal for excited nitrogen as a product. The uncertainty in this extrapolation is less than the ground state and is probably ± 20 kcal.

An estimate of D°_0(SiN) may be obtained by equating D_0(SiN)/D_0(SiO) = D_0(CN)/D_0(CO); this yields D_0(SiN) = 135 kcal.

A comparison of the isoelectronic molecules CP, BS and BeCl and the related molecules CN, BO, BeF indicates D_0(SiN) > 115 kcal.

A value of D_0(SiN) = 130 ± 15 kcal/mol is in agreement within the uncertainties of both ground state and B state extrapolations assuming normal atoms as products, and is in agreement with the other estimates. This value is adopted and yields ΔHf°_{298}(SiN,g) = 89 kcal/mol.

Heat Capacity and Entropy

The B-X transition has been reported by F. A. Jenkins and H. de Laszlo, Proc. Roy. Soc.(London) 122, 103 (1929). The rotational and vibrational constants are derived from their work and adjusted to normal isotopic abundance. The $A^2\Pi - C^2\Pi$ transition has been observed by M. D. Shetlar, Ph.D. Thesis, Univ. of California, Berkeley (1965). The height of the A state is estimated by correlation with CP(g). The level of the B state is taken from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., 2nd Edition, New York, 1950.

Heat of Formation.

K. F. Zmbov and J. L. Margrave, Rice University, private communication, March 1967, have identified $Si_2N(g)$ in a mass spectrometer. They also determined partial pressures of $Si_2N(g)$ in equilibrium with Si(g) and $N_2(g)$. From four of these measurements, in the temperature range 1742° - 1846°K, we obtain a second law ΔHr°_{298} = 99.6 ± 6 kcal/mol for the reaction $Si_2N(g) = 2\,Si(g) + 0.5\,N_2(g)$; and a third law ΔHr°_{298} = 120.2 kcal/mol with a drift of -11.4 ± 3.4 eu. Considering the small temperature range and the uncertainties in the free energy functions, the data appear consistent. We adopt the 3rd law heat of reaction which yields $\Delta Hf^\circ_{298}(Si_2N,g))$ = 95 kcal/mol.

Heat Capacity and Entropy.

$Si_2N(g)$ is considered to be closely related to $C_2N(g)$, and its structure and electronic configuration are adopted by analogy to this species. The bond length was obtained by adding the difference between the bond distances of SiN(g) and CN(g) to the bond length in CNC(g). The vibrational frequencies were estimated by comparison with several molecules, CNC(g); $^1\Pi$ state of $C_3(g)$; NCN(g); and $Si_2C(g)$. It should be noted that there is a wide variation in observed frequencies for these molecules and ω_1 and ω_3 may be significantly different from the chosen values.

The electronic ground state is considered to be $^2\Pi_g$ with excited states of $^2\Delta_u$ and $^2\Sigma_u^-$ as in the case of CNC(g). The levels are obtained from those in CNC(g) by use of the shift between $C_3(g)$ and SiCSi(g).

Dec. 30, 1960; June 30, 1968

TITANIUM NITRIDE (TiN) (CRYSTAL) GFW = 61.9067

$\Delta Hf°_0$ = -79.8 ± 1 kcal/mol

$S°_{298.15}$ = 7.23 ± 0.05 gibbs/mol

$\Delta Hf°_{298.15}$ = -80.7 ± 1 kcal/mol

Tm = 3220 ± 50°K

$\Delta Hm°$ = [16] kcal/mol

Heat of Formation

Humphrey (1) and Neumann et al. (2) determined the heat of combustion of titanium nitride by burning the material in an oxygen bomb calorimeter. For reaction (a) Humphrey obtained $\Delta Hr°_{298}$ = -145.05 ± 0.14 kcal/mol and Nuemann et al. $\Delta Hr°_{298}$ = -145.0 kcal/mol. From an examination of the combustion products Humphrey reported that the TiO_2 was >95 per cent rutile and <5 per cent anatase, but made no correction for the anatase. The adopted $\Delta Hf°_{298}$ = -80.7 kcal/mol is the average of three values, two from Humphrey (-80.75, -80.61), one as reported, and one corrected for anatase, and one from Neumann et al. (-80.8). The uncertainty in the adopted heat is due mainly to the uncertainty in the heat of formation of rutile. Hoch et al. (3) determined the vapor pressure of reaction (b), in the temperature range 1987-2241°K, using a Knudsen effusion method. Third law analysis of the data yields a $\Delta Hf°_{298}$ = -79.5 ± 9 kcal/mol. Linevsky (4) obtained the titanium partial pressures of reaction (c) (2088-2141°K) at fixed nitrogen pressures using atomic absorption spectroscopy. Third law analysis of the data gives a $\Delta Hf°_{298}$ = -81 ± 18 kcal/mol. These equilbrium measurements were not considered in deriving the heat of formation due to their large uncertainties in comparison to the calorimetric data.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52-296°K) of Shomate (5). Naylor (6) measured high temperature heat contents (388-1738°K). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. Above 1738°K the heat capacity is graphically extrapolated. The entropy is based on $S°_{50} - S°_0$ = 0.138 eu.

Melting Data

See liquid table.

Dec. 30, 1960; June 30, 1968

TITANIUM NITRIDE (TiN) (LIQUID) GFW = 61.9067

$S^\circ_{298.15}$ = [12.603] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [-63.531 ± 1] kcal/mol

Tm = 3220 ± 50°K ΔHm° = [16] kcal/mol

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(c) by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2200°K. Below 2200°K the heat capacity is obtained from the heat capacity of the crystal. Above 2200°K it is assumed constant and estimated as 15 gibbs/mol or 7.5 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Tm is taken from C. Agte and K. Moers, Z. Anorg. Allgem. Chem. 198, 233-43 (1931). ΔHm° is derived from an estimated ΔSm = 2.5 gibbs/g-atom as suggested by O. Kubaschewski, E. Ll. Evans and C. B. Alcock, "Metallurgical Thermochemistry," Pergamon Press, New York, 1967.

NZr

MONOZIRCONIUM MONONITRIDE (ZrN) (Crystal)

Mol. Wt. = 105.228

ΔH_{f0}° = -86.5 ± 2 kcal. mole^{-1}

ΔH_f° 298.15 = -87.3 ± 2 kcal. mole^{-1}

T_m = [3225°K]

$S^\circ_{298.15}$ = 9.29 ± 0.05 cal. deg.$^{-1}$ mole^{-1}

ΔH_m = [16.1] kcal. mole^{-1}

Heat of Formation. The heat of reaction I, -174.25 ± 0.30 kcal. mole^{-1}, was measured by A. D. Mah and N. L. Gelbert. The ΔH_f° 298.15 of ZrN was obtained using -261.5 ± 0.2 kcal. mole^{-1} for ΔH_f° 298.15 of ZrO_2. For the same reaction B. Neumann, C. Kroger and H. Kunz, Z. anorg. Chem. 218, 379 (1934) obtain -176.0 kcal. mole^{-1} on a sample of unspecified purity. Vapor pressure measurements of M. Hoch, D. P. Dingledy and H. L. Johnston, J. Am. Chem. Soc. 77, 304 (1955) lead to -81 kcal. mole^{-1} for the ΔH_f° 298.15 of ZrN. However, this value is uncertain by 10% as evidenced by the work on ZrO_2 by W. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 26, 1207 (1957).

$$\text{(I)}\quad ZrN(c) + O_2(g) = ZrO_2(c) + 1/2\ N_2(g)$$

Heat Capacity and Entropy. Low temperature measurements, 53-297°K, of S. S. Todd, J. Am. Chem. Soc. 72, 2914 (1950), were smoothly joined to those of J. P. Coughlin and E. G. King, J. Am. Chem. Soc. 72, 2262 (1950), 298-1073°K.

Melting. Estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

MONOZIRCONIUM MONONITRIDE (ZrN) (Liquid)

Mol. Wt. = 105.228

ΔH_f° 298.15 = [-69.5] cal. deg.$^{-1}$ mole^{-1}

T_m = [3225]°K

ΔH_m = [16.1] kcal. mole^{-1}

Heat of Formation. Calculated from the solid.

Entropy. Calculated from the solid.

Heat Capacity. The heat capacity function of the solid was assumed to approximate those of the liquid up to the estimated glass point of 2150°K. Above the glass point the heat capacity was estimated.

Monozirconium Mononitride (ZrN)

June 30, 1963

MONOZIRCONIUM MONONITRIDE (ZrN) (IDEAL GAS) MOL. WT. = 105.228

Ground State Configuration [$^2\Sigma$]

$S^\circ_{298.15}$ = [55.78] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = [169.4] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [170.5] kcal. mole^{-1}

Electronic Levels and Multiplicities

ϵ_i, cm.$^{-1}$	g_i
0	[2]

ω_e = [840] cm.$^{-1}$

B_e = [0.4146] cm.$^{-1}$

$\omega_e x_e$ = [5] cm.$^{-1}$

α_e = [0.0025] cm.$^{-1}$

σ = 1

r_e = [1.83] Å

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was estimated as 170.7 kcal. mole^{-1} by J. S. Gordon, Astrosystems International, Livingston, New Jersey, private communication, January 10, 1963. $\Delta H^\circ_{f\ 298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. r_e was calculated from the relationship $r_e = (16.858778/\mu B_e)^{1/2}$ Å.

Nitrogen, Diatomic (N_2)

(Reference State - Ideal Gas) Mol. Wt. = 28.0134

Dec. 31, 1960; Mar. 31, 1961; Sept. 30, 1965

NITROGEN, DIATOMIC (N_2) (IDEAL GAS - REFERENCE STATE) MOL. WT. = 28.0134

Ground State Configuration $^1\Sigma_g^+$

$\Delta H^\circ_{f\ 0} = 0$

$S^\circ_{298.15} = 45.77 \pm 0.01$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15} = 0$

$\omega_e = 2357.55$ cm.$^{-1}$

$\omega_e x_e = 14.059$ cm.$^{-1}$

$\sigma = 2$

$B_e = 1.99825$ cm.$^{-1}$

$\alpha_e = 0.01791 \pm 0.0001$ cm.$^{-1}$

$r_e = 1.08758 \pm 0.0001$ Å

Heat of Formation.

The heat of formation (ΔH_f°) for $N_2(g)$ is zero at all temperatures by definition.

Heat Capacity and Entropy.

The functions adopted here are based on the direct summation calculations of L. Glatt, J. Belzer and H. L. Johnston, Ohio State Univ. Res. Found. Proj. 316, Report No. 9, 1953. They calculated the functions for $N^{14}N^{14}$ by a direct summation using spectroscopic data given by G. Herzberg, "Diatomic Molecules", D. Van Nostrand Co., New York, 1950. The entropies were changed by -Rln9 to remove the effects of nuclear spin included by Glatt, Belzer, and Johnston, and by 0.012 for the difference in spectroscopic constants. J. A. Goff and S. Gratch, Trans. Am. Soc. Mech. Engrs., 72, 741 (1950), calculated a set of functions by a direct summation over the ground state levels only. Agreement with the functions of Glatt, Belzer, and Johnston is within 0.1%.

B. P. Stoicheff, Can. J. Phys. 32, 630 (1954), determined the spectroscopic constants of $N^{14}N^{14}$ by combining his measured rotational spectra with the results of band spectra given in the literature. The constants listed above have been corrected to apply to the naturally occurring isotopic composition listed by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys., 30, 585 (1958).

B_e = 0.42109 cm.$^{-1}$

σ = 1

Heat of Formation.

An analysis of the heat of reaction data is summarized below. Carlton-Sutton, et al., studied the direct decomposition at pressures of 40 to 50 atmospheres and made P-V-T measurements in order to reduce the data. They obtained a similar but less certain heat of formation by combustion of N_2O in CO. Flame calorimetric measurements of the combustion by Awberry and Griffiths are in good agreement, but the bomb calorimetry of Fenning and Cotton gives a heat of formation about 0.2 kcal. larger. The selected heat of formation is a weighted average of these values.

Source	Method	Reaction	$\Delta H^\circ_{r\ 298.15}$ (kcal. mole^{-1})	$\Delta H^\circ_{f\ 298.15}$
1	Bomb Calorimetry	$N_2O(g) \rightarrow N_2(g) + 0.5\ O_2(g)$	-19.52 ± 0.10	19.52
1	Bomb Calorimetry	$N_2O(g) + CO(g) \rightarrow CO_2(g) + N_2(g)$	-87.10 ± 0.30	19.46*
2	Flame Calorimetry	$N_2O(g) + CO(g) \rightarrow CO_2(g) + N_2(g)$	-87.09 ± 0.22	19.45*
3	Bomb Calorimetry	$N_2O(g) + CO(g) \rightarrow CO_2(g) + N_2(g)$	-87.37 ± 0.12	19.73*
3	Bomb Calorimetry	$N_2O(g) + H_2(g) \rightarrow H_2O(l) + N_2(g)$	-88.03 ± 0.12	19.71*

*Based on $\Delta H^\circ_{f\ 298.15}$ = -68.32 (H_2O, l), - 94.054(CO_2, g), -26.417 (CO, g)

2) J. H. Awberry, E. Griffiths, Proc. Roy. Soc. (London) A141, 17 (1933).
3) R. W. Fenning, F. T. Cotton, ibid., 1 (1933).

Heat Capacity and Entropy.

The functions are based on the rotational constants of Pliva, J. Mol. Spect. 12, 360 (1964), and the frequencies determined by Tidwell, Plyler and Benedict, J. Opt. Soc. Am. 50, 1243 (1960). The bond distances reported by Pliva were obtained from measurements of isotopic shifts in the infrared. They include higher-order corrections for vibration-rotation interaction and are in satisfactory agreement with the infrared and microwave studies of Douglas and Moller, J. Chem. Phys. 22, 275 (1954) and the electron diffraction data of Schomaker and Spurr, J. Am. Chem. Soc. 64, 1184 (1942).

Heat of Formation.

Equilibria for the reaction $N_2O_3(g) \rightarrow NO(g) + NO_2(g)$ have been studied by Beattie and Bell, J. Chem. Soc. 1957, 1681 (1957), Verhoek and Daniels, J. Am. Chem. Soc. 53, 1250 (1931) and Abel and Proisl, Z. Elektrochem. 35, 712 (1929). The results of Beattie and Bell are the most extensive, but they depend on the early analysis of Giauque and Kemp, J. Chem. Phys. 6, 40 (1938), for the simultaneous equilibrium $N_2O_4(g) \rightarrow 2NO_2(g)$. The JANAF analysis of the tetroxide dissociation has been used to recalculate the data of Beattie and Bell. Non-ideality of N_2O_4 and NO_2 was allowed for by use of the equations of state of Giauque and Kemp, while non-ideality of NO and N_2O_3 was removed by extrapolation of the equilibrium constants to zero pressure in a manner similar to that of Beattie and Bell. The data of Verhoek and Daniels and of Abel and Proisl have not been recalculated. Second and third law analyses of the results are summarized below. The heat of formation was obtained from $\Delta H_r^\circ{}_{298} = 9.70$ kcal. mole^{-1}.

Source	Temp. Range °K	T °K	Third Law ΔS_T°	Second Law ΔS_T°	Second Law ΔH_{298}°	Third Law ΔH_{298}°
			(cal. deg.$^{-1}$ mole-1)		(kcal. mole^{-1})	
Beattie - Bell[a]	278 - 318	298	——	33.25 ± 0.35	9.527 ±0.096	——
Beattie - Bell[b]	278 - 318	298	33.77	33.04 ± 0.31	9.476 ±0.093	9.695
Beattie - Bell[c]	278 - 318	298	33.77	33.56 ± 0.52	9.642 ±0.155	9.706

Abel - Proisl	281 - 308	294	33.77	32.9	9.60	9.86

a) Given by authors b) From author's K_p values c) From recalculated K_p values

Heat Capacity and Entropy.

The functions are similar to those calculated by I. C. Hisatsune, J. Phys. Chem 65, 2249 (1961), based on the analysis of Devlin and Hisatsune, Spectrochim. Acta 17, 218 (1961), of the Raman and infrared spectra in terms of Urey - Bradley force constants. Devlin and Hisatsune used observed isotopic shifts in the spectra along with force constants transferred from nitrogen oxides and oxyhalides in order to select the N-N bond distance and the O-N-N bond angle.

The unobserved mode was assumed to be free internal rotation around the N-N bond, leading to $S^\circ_{298} = 73.91$ cal. deg.$^{-1}$ mole^{-1} which is in good agreement with 74.13 ± 0.52 cal. deg.$^{-1}$ mole^{-1} obtained from the recalculated second law of Beattie and Bell. The principal moments of inertia are $I_A = 22.694 \times 10^{-39}$, $I_B = 29.577 \times 10^{-39}$, and $I_C = 6.883 \times 10^{-39}$ g. cm.^{2}, while the reduced moment for internal rotation was calculated as $I_r = 0.990 \times 10^{-39}$ g. cm.^{2}

$T_m = 261.95 \pm 0.05$°K.

$\Delta H_m^\circ = 3.502 \pm 0.003$ kcal. mole^{-1}

Heat of Formation.

The heat of formation was back calculated from that of the liquid using the measured heat of melting and the enthalpy of the crystal and liquid.

Heat Capacity and Entropy.

W. F. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) measured the low temperature heat capacity from 15-295°K. The entropy was obtained by integration of this data using $S_{15} = 0.34$ cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

The temperature and heat of melting were also measured by Giauque and Kemp, loc. cit.

$\Delta H^\circ_v = 9.11 \pm 0.1$ kcal. mole^{-1} (to $N_2O_4 + NO_2$)

$T_b = [301.4$°K.$]$ (to N_2O_4)

$\Delta H^\circ_v = [6.79]$ kcal. mole^{-1} (to N_2O_4)

Heat of Formation.

The heat of formation was back calculated from that of the gas using the calorimetrically measured heat of vaporization to the equilibrium mixture, in conjunction with a dissociation constant $\alpha = 0.161$.

Heat Capacity and Entropy.

W. F. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) measured the low temperature heat capacity from 15°-295°K., above 295°K. the heat capacity was smoothly extrapolated.

Melting and Vaporization Data.

Giauque and Kemp, loc. cit. measured the temperature and heat of melting and also the boiling point and the calorimetric value of the heat of vaporization to the equilibrium mixture. The heat of vaporization to a hypothetical pure N_2O_4 gas at 294.25°K. was calculated to be 6.91 kcal. mole^{-1}.

Bond Distance: N-N = 1.750Å N-O = 1.180Å

Bond Angle: O-N-O = 133.7°

$\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C$ = 9.9304 X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

W. F. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) calculated idealized equilibrium constants for the reaction $N_2O_4(g) = 2NO_2(g)$ from the work of Bodenstein and Boës$^{(1)}$, Zeits. fur physik. Chem. 100, 75 (1922), Verhoek and Daniels$^{(2)}$, J. Am. Chem. Soc. 53, 1250 (1931) and Wourtzel$^{(3)}$, Compt. Rend. 169, 1397 (1919). The second and third law analysis of these equilibrium constants has been repeated using more recent functions. The results are shown below.

Ref.	Third Law ΔH_{298}	Second Law ΔH_{298}
1.	13.644	13.634 ± 0.015*
2.	13.672	14.429 ± 0.126
3.	13.657	13.599 ± 0.019**

* Ten points rejected because of statistically significant scatter.

** One point rejected.

The second law value of Verhoek and Daniels was not considered significant due to the extremely small temperature range and the use of only three temperatures. The adopted value was 13.65 ± 0.03 kcal. which leads to 2.17 kcal. mole^{-1} for the heat of formation of $N_2O_4(g)$.

Heat Capacity and Entropy.

The structural parameters were taken from the electron diffraction measurements of D. W. Smith and K. Hedberg, J. Chem. Phys. 25, 1282 (1956). The vibrational frequencies are those chosen by I. C. Hitsatsune, J. P. Devlin and Y. Wade, J. Chem. Phys. 33, 714 (1960). The torsional frequency of 50 cm.$^{-1}$ was estimated in order to bring the entropy of the gas into agreement with that determined by Giauque and Kemp loc. cit. from low temperature heat capacities and heats of fusion and vaporization. The individual moments of inertia were I_A = 12.508 X 10^{-39} g. cm.^{2}, I_B = 22.609 X 10^{-39} g. cm.^{2}, and I_C = 35.117 X 10^{-39} g. cm.^{2}

Bond Angle: O-N-O = 134° N-O'-N = 95°

O-N-O planes perpendicular to N-O'-N plane

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 2.066 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was obtained by recalculation of the calorimetric data of Ray and Ogg for the reaction of $N_2O_5(g)$ with NO. The stoichiometry of the reaction products, originally based on the results for $N_2O_4 \rightarrow 2\ NO_2$ from Giauque and Kemp, J. Chem. Phys. 6, 40 (1938), was based on the JANAF analysis of this simultaneous equilibrium. A correction of 0.29 kcal. was made in the heat of reaction because of the additional formation of N_2O_3 from NO and NO_2.

Confirmation of the heat of formation was obtained by combination of the heats of hydrolysis and sublimation of $N_2O_5(c)$. The results are summarized below. Second law values are given for the heats of sublimation, but third law analyses suggest that the value from Russ and Pokorny is more reliable. Most of the uncertainty in this path, however, arises from the heat of hydrolysis.

Source	Method	Reaction	$\Delta H^\circ_{r\ 298.15}$ (kcal. mole^{-1})	$\Delta H^\circ_{f\ 298.15}$
1	Calorimetric	$N_2O_5(g) + NO(g) \rightarrow$ $0.724\ NO_2(g) + 1.138\ N_2O_4(g)$	-16.05 ± 0.20	2.67
2	Calorimetric	$N_2O_5(c) + H_2O(l) \rightarrow 2\ HNO_3(aq)$	-20.2 ± 0.5	——
3	Vapor Pressure	$N_2O_5(c) \rightarrow N_2O_5(g)$	13.37 ± 0.06	2.79*
4	Vapor Pressure	$N_2O_5(c) \rightarrow N_2O_5(g)$	13.25 ± 0.12	2.67*

*Using reaction 2 and $\Delta H^\circ_{f\ 298.15} = -68.32(H_2O,\ l),\ -49.55(HNO_3,\ aq)$

Heat Capacity and Entropy.

Ray and Ogg, J. Chem. Phys. 26, 984 (1957) reported $S^\circ_{298.15}$ = 85 ± 0.5 cal. deg. mole^{-1} from combination of kinetic and thermochemical values. This entropy was recalculated as follows. The rate data of Ray and Ogg, loc. cit., and of Daniels and Johnston, J. Am. Chem. Soc. 43, 53 (1921) give for the reaction $N_2O_5(g) \rightarrow NO(g) + NO_2(g) + O_2(g)$ at 25°C the equilibrium constant $K = 5.15 \times 10^{-7}$ moles^2 liter^{-2} = 3.08×10^{-4} atm^2. The resulting value of $\Delta F^\circ_{r\ 298.15}$ = 4.79 kcal. mole^{-1} leads to $S^\circ_{298.15}$ = 82.8 cal. deg. mole^{-1} for $N_2O_5(g)$ when combined with the JANAF entropies and heats of formation of the components of the reaction.

The molecular structure is the nonplanar configuration derived from the electron diffraction study of Akishin, Vilkov and Rosolovskii, Zhur. Strukt. Khim. 1, 1 (1960). A planar model (also point group C_{2v}) was assumed by Hisatsune, Devlin and Wada, Spectrochim. Acta 18, 1641 (1962) in their approximate normal coordinate analysis of the infrared and Raman spectra. The frequency assignments of these authors are listed above in the order for the planar model, although the vibrations for the nonplanar form will separate differently into the species $5A_1$, $3A_2$, $3B_1$ and $4B_2$. Hisatsune, et al., estimated the N-O'-N deformation frequency (85 cm.$^{-1}$) from combination bands in the solid and gas phase spectra. The JANAF thermodynamic functions were obtained using these frequencies and assuming the two NO_2 groups to be hindered internal rotators. Barriers to internal rotation of 4.4 kcal. (corresponding to torsional vibrations of about 55 cm.$^{-1}$) were selected in order to give the observed entropy at room temperature. The principal moments of inertia for the nonplanar model were taken as $I_A = 30.60 \times 10^{-39}$, $I_B = 40.15 \times 10^{-39}$ and $I_C = 16.82 \times 10^{-39}$ g. cm.^{2}, while $I_r = 4.693 \times 10^{-39}$ g. cm.^{2} was used for the reduced moment of inertia of the O_2 tops.

SILICON NITRIDE, ALPHA (α-Si_3N_4) (CRYSTAL) GFW = 140.2848

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [27 ± 4] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -178 ± 7 kcal/mol

Td = [2151]°K

Heat of Formation.

The equilibria (A) $Si_3N_4(c) = 3\ Si(l) + 2\ N_2(g)$ and (B) $Si_3N_4(c) = 3\ Si(c) + 2\ N_2(g)$ have been investigated by three groups. R. D. Pehlke and J. F. Elliott, Trans. Met. Soc. AIME 215, 781 (1959), made four series of measurements which mainly concerned reaction (A). W. B. Hincke and L. R. Brantley, J. Amer. Chem. Soc. 52, 48 (1930), made a single series of measurements which covered reactions (A) and (B). C. Matignon, Bull. Soc. Chim. France 13, 791 (1913), also gave a single equilibrium point for reaction (C) $3\ SiO_2(c) + 6\ C + 2\ N_2 = Si_3N_4(c) + 6\ CO(g)$. Below are shown 2nd and 3rd law analyses of the data. It should be noted that these analyses are based on the estimated heat capacities above 900°K, and on an estimated entropy. The uncertainty due to these estimates is estimated as ± 7 kcal in ΔHf°_{298}.

Reference	Points	Range °K	Reaction	ΔHr°_{298} kcal/mol 2nd law	ΔHr°_{298} kcal/mol 3rd law	Drift eu	*ΔHf°_{298} kcal/mol

*Calculated from the third law ΔHr°_{298} values.

**Four points rejected due to failure of a statistical test; this set is a combination of the first four sets.

The adopted ΔHf°_{298}(α-Si_3N_4) = -178±7 kcal/mol.

L. A. McClaine and C. P. Coppel, A. D. Little, Inc., "Equilibrium Studies of Refractory Nitrides," Tech. Rept. AFML-TR-65-99, Part 11, Dec. 1966, have investigated the decomposition reaction (B). They conclude that at 1618°K the equilibrium pressure is roughly 0.15 mm. This corresponds to ΔHf°_{298} =-182.3 kcal, and was not given any weight in the adopted value.

Heat Capacity and Entropy.

The enthalpy of α-Si_3N_4 has been measured at three temperatures, in the range 373° - 858°K, by S. Sato, Bull. Chem. Soc. Japan 13, 41 (1938). The heat capacity is calculated from the data assuming that a limit of 45 gibbs/mol is attained by 3000°K. The entropy is obtained from the equilibrium data of Pehlke and Elliott, loc. cit.

Decomposition Data.

The temperature of decomposition is calculated as the point at which the decomposition pressure of nitrogen reaches 1 atm.

TRIPHOSPHORUS PENTANITRIDE (P_3N_5) (CRYSTAL) GFW = 162.9549

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [44 ± 6] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -64 ± 5 kcal/mol

Td = [730]°K

Heat of Formation.

The heat of formation is based on the work of A. Stock and F. Wrede, Chem. Ber. 40, 2923 (1907), who burned P_3N_5 in oxygen. They report a ΔHr°_{298} = -949.4 kcal for the reaction 2 $P_3N_5(c) + 7.5O_2(g) = 1.5\ P_4O_{10}(amorph) + 5N_2(g)$. In NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Washington, D.C. (1965), a value of -947.7 kcal is used for the above reaction and we adopt this value. Using the JANAF value for $P_4O_{10}(c)$ and correcting this to P_4O_{10}(amorph) by adding -13.8 kcal/mol, from Technical Note 270-1, we obtain ΔHf°_{298} P_4O_{10}(amorph) = -716.5 kcal/mol. Thus, we derive ΔHf°_{298} $P_3N_5(c)$ = -63.525 kcal/mol; however, because of the uncertainties in the heat of reaction and correction for amorphous P_4O_{10} we round the value to -64 ± 5 kcal/mol.

Heat Capacity and Entropy.

S. Sato, Sci. Papers Inst. Phys. Chem. Res. (Tokyo) 34, 584 (1938), gave an equation for the heat capacity in the range 273° - 578°K. Judging from his results for $Be_3N_2(c)$ in the same paper, we believe his values will be slightly high at the upper end of the range. Thus, taking 8.2 gibbs/g-atom as the limiting value, a curve was drawn through Sato's values at the low end and approaching the limit asymptotically. The entropy was estimated from that of $Si_3N_4(c)$ by assuming that the ratio Cp_{298}/S_{298} on a gram atom basis would be the same for $P_3N_5(c)$.

Temperature of Decomposition.

Td is calculated as the point at which the total pressure reaches 1 atm. This corresponds to log Kp = -0.76 for the reaction $P_3N_5(c) = 0.75P_4(g) + 2.5N_2(g)$. The temperature of decomposition has been reported by V. F. Postnikov and L. L. Kuzmin, J. Appl. Chem. (USSR) 8, 429 (1935) as 1073°K. This has been confirmed by H. Moreau and P. Rocquet, Compt. Rend. 198, 1691 (1934) and Bull. Soc. Chim. France, 3, 1801 (1936); and E. O. Huffman, G. Tarbutton, G. V. Elmore, A. J. Smith and M. G. Rountree, J. Am. Chem. Soc. 79, 1765 (1957). However, it was also noted that $P_3N_5(c)$ is not reformed on cooling the decomposition products; thus the decomposition is non-equilibrium. It is known that the decomposition of AlN, BN and Be_3N_2 is kinetically limited and the equilibrium pressure is not attained until the average energy is greater than the activation energy. It appears that this is also the case for P_3N_5 and a high activation energy is expected.

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

D. L. Martin, Proc. Roy. Soc. A254, 433 (1960) reports that the low temperature heat capacity of sodium depends on the thermal history of the sample and ascribes this to a martensitic transformation. The effect is most pronounced in the range 40-80°K., where the graph of C_p against T increases continuously for some samples and rises to a peak at 55°K. for others. Martin lists heat capacities obtained in several runs on "high purity" sodium at 21° to 300°K. and the higher values, those defining the peak at 55°K., have been selected here. The heat capacities reported by T. M. Dauphinee, D. L. Martin, and H. Preston-Thomas, Proc. Roy. Soc. A233, 214 (1955), have not been used, since one of the authors in a later publication (Martin, loc. cit.) questions the accuracy of the measurements above 100°K, and at lower temperatures there is no rise to a peak at 55°K. In the range 1.5° to 20°K., L. M. Roberts, Proc. Phys. Soc. B70, 744 (1957) and D. H. Parkinson and J. E. Quarrington Proc. Phys. Soc. A68, 762 (1955) have measured the heat capacity of very high purity sodium. The values of Parkinson and Quarrington are somewhat higher than those of Roberts and have been given greater weight, since they show better continuity with Martin's results. The results of G. L. Pickard and F. E. Simon, Proc. Phys. Soc. 61, 1 (1948) have been rejected below 10°K, since they show a peak between 5° and 8°, a feature not verified by other workers; between 10° and 25°K they agree exactly with the results of Parkinson and Quarrington. J. Rayne, Phys. Rev. 95, 1428 (1954) states that the graph of C_p against T has a small peak at about 0.9°K. This peak has not been observed in the work of W. H. Lien and N. E. Phillips, Phys. Rev. 118, 958 (1960) from 0.15° to 1°K; R. E. Gaumer and C. V. Heer, Phys. Rev. 118, 955 (1960) from 0.4° to 2°K and D. L. Martin, Phys. Rev. 124, 438 (1961) from 0.4 to 1.5°K.

T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis, J. Am. Chem. Soc. 74, 2472 (1952) report heat capacities in the range 273° to 1173°K on a sample of not less than 99.9% purity. These values agree to within 1% with those of Martin in the range 273° to 300°K, and the two sets of dates have been smoothly joined.

Melting.

Douglas et al. (loc. cit.) have determined the triple point to be 97.82 ± 0.02°C., from which the melting point is calculated to be 97.83 ± 0.02°C., and have measured the heat of fusion.

Heat of Sublimation.

At the boiling point and higher temperatures sodium vapor contains an appreciable proportion of diatomic molecules. G. W. Thompson and E. Garelis "Sodium - its Manufacture, Properties and Uses," Ed. M. Sittig, Chapter 3, Reinhold Publishing Corporation, Inc., New York (1956), have made a careful analysis of the available vapor pressure data. Their results are consistent with the free energy functions calculated in the present work and have been adopted.

June 30, 1962

SODIUM (Na) (LIQUID) AT. WT. = 22.991

ΔH_f° 298.15 = 0.575 kcal. mole^{-1}

T_m = 370.98 ± 0.02°K

T_b = 1156°K (Equilibrium mixture)

ΔH_v 1176.9 = 23.285 kcal. mole^{-1}

$S^\circ_{298.15}$ = 13.827 cal. deg.$^{-1}$ mole^{-1}

ΔH_m = 0.622 kcal. mole^{-1}

T_b (Monatomic gas) = 1176.9°K

Heat of Formation.

Obtained from the heat of fusion by adding $H_{370.98}-H_{298.15}$ for the solid and subtracting $H_{370.98}-H_{298.15}$ for the liquid.

Heat Capacity.

The heat capacity data of T. B. Douglas, A. F. Ball, D. C. Ginnings and W. D. Davis, J. Am. Chem. Soc. 74, 2472 (1952) were used and were extrapolated below T_m and above 1173°K in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K.

Vaporization.

Sodium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1156°K. The vapor pressure of the monatomic gas reaches 1 atm. at 1176.9°K and the heat of vaporization to monatomic gas is 23.285 kcal. mole^{-1} [See Na(crystal)].

Heat of Formation.

Same as the heat of sublimation to the monatomic species; see notes on Na(crystal)

Heat Capacity and Entropy.

The energy levels have been taken from C. E. Moore, "National Bureau of Standards Circular 467," U. S. Government Printing Office, Washington (1949) p. 89-91. Closely spaced levels have been averaged and the appropriate multiplicities assigned to the averages.

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic sodium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels" Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation Na(ref. state) - e$^-$(ref. state) = Na$^+$(monatomic gas), thus Na$^+$ involves the difference in enthalpies of the two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore loc. cit.

Sodium Monoxide (NaO)

(Ideal Gas) GFW = 38.9892

SODIUM MONOXIDE (NaO) (IDEAL GAS) GFW = 38.9892

Ground State Configuration [$^2\Pi$]

$S°_{298.15}$ = [54.7 ± 0.5] gibbs/mol

$\Delta Hf°_0$ = [20.3 ± 10] kcal/mol

$\Delta Hf°_{298.15}$ = [20.0 ± 10] kcal/mol

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	[4]

ω_e = [440] cm^{-1}

B_e = [0.4467] cm^{-1}

$\omega_e x_e$ = [3.0] cm^{-1}

α_e = [0.0043] cm^{-1}

σ = 1

r_e = [2.0] Å

Heat of Formation

Bawn and Evans (1) have studied the reaction rate of sodium vapor with nitrous oxide, nitrogen peroxide, nitromethane, ethyl nitrate and amyl nitrite, using the diffusion flame method. On the evidence of reaction rate measurements they estimated the value, $\Delta Hr°_{298} < 0$, for the reaction Na(g) + NO_2(g) = NaO(g) + NO(g). Based on this result, we calculate $\Delta Hf°_{298}$(NaO, g) > 12 kcal/mol, using $\Delta Hf°_{298}$ = 25.8, 7.9 and 21.6 kcal/mol for Na(g), NO_2(g) and NO(g), respectively.

Assuming that D_0(NaO) = 1/2[$D_0(Na_2)$ + $D_0(O_2)$], or $\Delta Hr°_0$ = 68.1 kcal/mol for the reaction NaO(g) = Na(g) + O(g), we derive $\Delta Hf°_0$ = 16.7 and $\Delta Hf°_{298}$ = 16.4 kcal/mol, using $\Delta Hf°_0$ = 25.8 and 59.0 kcal/mol for Na(g) and O(g), respectively.

Somayajulu (2) found that in a sequence of similar diatomic molecules the force constant (k_e), dissociation energy (D_0) and equilibrium bond distance (r_e) are related by the expression $k_e r_e/D_0$ = constant. Using r_e = 1.62 Å, D_0 = 77.9 kcal/mol for LiO(g), r_e = 2.0 Å for NaO(g) and k_e(NaO)/k_e(LiO) = 0.4827, we evaluate D_0 = 65.4 kcal/mol for NaO(g), yielding $\Delta Hf°_{298}$(NaO, g) = 19.4 kcal/mol. The value k_e is calculated from the relation $k_e = 4\Pi^2 \nu^2 \mu$ where ν is the vibrational frequency of the diatomic molecule and μ is the reduced mass.

The value of $\Delta Hf°_{298}$(NaO, g) is tentatively adopted as 20 ± 10 kcal/mol. The corresponding $D°_0$(NaO) is 65 ± 10 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for OH(g) which has the same number of valence electrons as NaO(g). The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for LiO(g), LiF(g) and NaF(g). The value of r_e is estimated from those for OH(g), HF(g) and NaF(g). B_e and α_e are derived from r_e, ω_e and $\omega_e x_e$ by the method suggested by Herzberg (3).

$\omega_e x_e$ = [3.2] cm^{-1}

α_e = [0.00495] cm^{-1}

σ = 1

r_e = [2.0] Å

Heat of Formation

The electron affinity (E. A.) of $NaO^-(g)$ is unavailable, therefore the value of $\Delta Hf°_{298}(NaO^-, g)$ is estimated. We first assume that the enthalpy change ($\Delta Hr°_0$) of the reaction (1) $NaO^-(g) = Na(g) + O^-(g)$ is close to the average of the $\Delta Hr°_0$ values for the reactions (2) $NaO(g) = Na(g) + O(g)$ and (3) $NaF(g) = Na(g) + F(g)$. The atom F(g) is isoelectronic with $O^-(g)$. In other words, the $\Delta Hr°_0$ for reaction (1) is approximately 1/2(64.8 + 113.9) = 89.3 kcal/mol. Then we compare the $\Delta Hr°_0$ values for the reactions (4) $HO(g) = H(g) + O(g)$, (5) $HO^-(g) = H(g) + O^-(g)$, and (6) $HF(g) = H(g) + F(g)$, and find that $\Delta Hr°_0$ for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of $\Delta Hr°_0$ values for reactions (4) and (6). Based on this fact we estimate $\Delta Hr°_0$ = 80 kcal/mol for reaction (1), yielding $\Delta Hf°_{298}(NaO^-, g)$ = -29 kcal/mol which is tentatively adopted. The uncertainty of this value may be ±20 kcal/mol. Based on this $\Delta Hf°_{298}$ value we calculate E. A. = 2.1 ± 0.9 eV for NaO(g). The corresponding value for HO(g) is 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of NaF(g) which is isoelectronic with $NaO^-(g)$. The values of ω_e, $\omega_e x_e$ and r_e are estimated by comparison with the observed data for NaF(g). The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ using the method recommended by G. Herzberg, "Spectra of Diatomic Molecules." D. Van Nostrand Co., Inc., New York, 1950. The enthalpy at 0°K is -2.248 kcal/mol.

June 30, 1963

SODIUM DIOXIDE (NaO_2) (CRYSTAL) MOL. WT. = 54.991

$S^\circ_{298.15}$ = 27.7 ± 0.3 cal. deg.$^{-1}$ mole^{-1}

T_{t_1} = 196.5°K.

T_{t_2} = 223.3°K.

T_m = 825° ± 10°K.

$\Delta H^\circ_{f\ 0}$ = -63.1 ± 0.7 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -62.3 ± 0.7 kcal. mole^{-1}

$\Delta H^\circ_{t_1}$ = 350 cal. mole^{-1}

$\Delta H^\circ_{t_2}$ = 370 cal. mole^{-1}

ΔH°_m = Unknown

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ was obtained from National Bureau of Standards Report 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," January 1, 1962. P. W. Gilles and J. L. Margrave, J. Phys. Chem. 60, 1333 (1956) measured the heat of decomposition of $NaO_2(c)$ in H_2O, yielding $\Delta H^\circ_{f\ 298.15}$ = -62.1 ± 0.7 kcal. mole^{-1}. From the original experimental data by R. de Forcrand, Compt. rend., 127, 514 (1898); 158, 843, 991 (1914), the value of $\Delta H^\circ_{f\ 298.15}$ was recalculated to be -65.0 kcal. mole^{-1} by P. W. Gilles and J. L. Margrave. loc. cit.

Heat Capacity and Entropy.

The low temperature heat capacities, 52.13° ~ 296.46°K., were measured by S. S. Todd, J. Am. Chem. Soc., 75, 1229 (1953). The heat capacities above 298.15°K. were estimated by comparison with those for $Na_2O(c)$. $S^\circ_{298.15}$ was given by S. S. Todd, loc. cit., using S°_{51}(extrap.) = 2.23 cal. deg.$^{-1}$ mole^{-1}.

Transition Data.

T_{t_1}, T_{t_2}, $\Delta H^\circ_{t_1}$ and $\Delta H^\circ_{t_2}$ were calculated from the data reported by S. S. Todd, loc. cit.

Temperature of Melting.

The melting temperature was obtained from J. L. Margrave, private communication, May 21, 1963.

DISODIUM MONOXIDE (Na_2O) (CRYSTAL) GFW = 61.979

$S^\circ_{298.15}$ = 17.935 gibbs/mol

$Tt(\gamma \rightarrow \beta)$ = 1023.2°K

$Tt(\beta \rightarrow \alpha)$ = 1243.2°K

Tm = 1405.2°K

ΔHf°_0 = -98.74 ± 1.0 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -99.90 ± 1.0 kcal/mol

$\Delta Ht^\circ(\gamma \rightarrow \beta)$ = 0.42 kcal/mol

$\Delta Ht^\circ(\beta \rightarrow \alpha)$ = 2.85 kcal/mol

ΔHm° = 11.4 kcal/mol

Heat of Formation

The enthalpy change of the reaction $Na_2O(c) + H_2O(\ell) = 2NaOH(aq)$ has been determined by Matsui (1, 2), Roth (3, 4) and Rengade (5). Based on their reported ΔHr° values, the corresponding ΔHf°_{298} for $Na_2O(c)$ are calculated, using $\Delta Hf^\circ_{298}(H_2O, \ell)$ = -68.315 kcal/mol obtained from U. S. Natl. Bur. Std. Tech. Note 270-1, 1965, and $\Delta Hf^\circ_{298}(NaOH, nH_2O)$ derived from JANAF $\Delta Hf^\circ_{298}(NaOH, c)$ and ΔHsoln and ΔHdil reported by V. B. Parker, U. S. Natl. Bur. Std. NSRDS-NBS 2, 1965. The sample employed by Matsui was prepared by the method of Rengade (7) and contains $Na_2O_2(c)$ and Na(c) as impurities. The sample used by Roth also contains 3.96 per cent (by weight) $Na_2O_2(c)$. Corrections in the reported results for such impurities have been made by the authors. However, in order to obtain better results, more measurements using purer samples are necessary. The enthalpy change of the reaction $2Na(c) + H_2O(\ell) = Na_2O(c) + H_2(g)$ was calculated by Rengade (5) from his measurements (5) incorporating with ΔHr = -85.2 kcal/mol for the reaction $2Na(c) + 2H_2O(\ell) = 2NaOH(aq) + H_2(g)$ determined by Joannis (8). The value ΔHf°_{298} = -94.9 kcal/mol is derived from the data of Forcrand (6) using $\Delta Hf^\circ_{298}(Na_2O_2, c)$ = -122.66 kcal/mol. The results are presented in the table below.

Brewer (11) determined the equilibrium constants, 918-1467°K, for the vaporization of $Na_2O(c)$, using an effusion method. The Na_2O vapor consists predominately of Na(g) and $O_2(g)$ molecules with any oxide molecules being not important. The Na/O ratio was not measured and assumed to be 2/1 in all calculations on Na_2O. Based on the reported data, we derive the equilibrium constants for the reaction $Na_2O(c) = 2Na(g) + 1/2O_2(g)$ and evaluate the third law ΔHr°_{298} as 117.1 ± 10 kcal/mol. From this ΔHr°_{298} value, we obtain $\Delta Hf^\circ_{298}(Na_2O, c)$ = -65.6 ± 10 kcal/mol, employing ΔHf°_{298}= 25.76 kcal/mol for Na(g). The value -65.6 kcal/mol is not consistent with the other values described above. This may be caused by an invalid assumption used in the calculation.

The heat of formation at 298°K for $Na_2O(c)$ is tentatively selected as -99.90 ± 1.0 kcal/mol.

Investigator	Reaction	ΔHr°, kcal/mol	ΔHf°_{298}, kcal/mol
1. Matsui (1929)	$Na_2O(c)+H_2O(\ell) = 2NaOH(7890\ H_2O)$	-56.61 ± 0.16	-100.08
2. Matsui (1929)	$Na_2O(c)+H_2O(\ell) = 2NaOH(4600\ H_2O)$	-56.70 ± 0.07	-99.89
3. Roth (1947)	$Na_2O(c)+H_2O(\ell) = 2NaOH(825\ H_2O)$	-56.03 ± 0.13	-100.55
4. Roth (1948)	$Na_2O(c)+H_2O(\ell) = 2NaOH(825\ H_2O)$	-55.98 ± 0.13	-100.60
5. Rengade (1907)	$Na_2O(c)+H_2O(\ell) = 2NaOH(aq)$	-56.50	-100.09
	$2Na(c)+H_2O(\ell) = Na_2O(c)+H_2(g)$	-28.70	-97.02
6. Forcrand (1900)	$Na_2O(c)+1/2O_2(g) = Na_2O_2(c)$	-27.76	-94.90

Heat Capacity and Entropy

The low temperature heat capacities, 15-380°K, were obtained from Furukawa (9). We make the corrections in the reported Cp values for impurity $Na_2CO_3(c)$ 2.33 per cent (by weight), analyzed by Grimley (10). The effect on heat capacity due to the presence of Na_2O_2(0.91 per cent) impurity is insignificant. Using the smoothed low temperature Cp data the $S^\circ_{298.15}$ is calculated, based on S°_{15} = 0.0122 eu.

Grimley (10) measured the high temperature enthalpies, 380.1-1174.6°K, with a copper block drop-type calorimeter. The enthalpies for the γ phase, 380.1-980.4°K, are joined smoothly with the low temperature data and extrapolated to 1023.2°K (the $\gamma \rightarrow \beta$ transition temperature). The enthalpies above 1023.2°K are obtained by extrapolation. The enthalpies measured at 1078.3 and 1174.6°K by Grimley are unreasonably large, and are not adopted.

Transition Data

The transition temperature and heats of transition were determined calorimetrically by Bouaziz (12) who used a very pure sample. The adopted ΔHt° = 0.42 and 2.85 kcal/mol, are averages of the derived values, 0.36 ~ 0.48 and 2.7 ~ 3.0 kcal/mol, respectively.

Melting Data

Tm and ΔHm° were obtained from Bouaziz (12). The adopted ΔHm° is an average of the reported 10.8-12.0 kcal/mol. Tm has been reported as 1193 and 1190 ± 10°K by Bunzel (13) and Brewer (11), respectively, which are not adopted.

DISODIUM MONOXIDE (Na_2O) (LIQUID) GFW = 61.979

$S^\circ_{298.15}$ = [21.895] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [-89.112] kcal/mol

Tm = 1405.2°K ΔHm° = 11.4 kcal/mol

Td = 2223°K

Heat of Formation

The heat of formation is obtained from $\Delta Hf^\circ_{298.15}(c)$ by adding ΔHm° and the difference between $H^\circ_{1405.2} - H^\circ_{298}$ for $Na_2O(c)$ and $Na_2O(\ell)$.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $Na_2SiO_3(\ell)$ and $SiO_2(\ell)$. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the $Na_2O(c)$ table.

Decomposition Temperature

Td is the temperature at which the Gibbs energy change of the decomposition reaction $Na_2O(\ell) = 2Na(g) + 1/2O_2(g)$ approaches zero.

Heat of Formation

The enthalpy change of the reaction $Na_2O_2(c) + H_2O(\ell) = 2NaOH(1200\ H_2O) + 1/2O_2(g)$ was measured at 18.5°C by Roth (1). He employed a sample with composition 96.81 per cent Na_2O_2 and 3.43 per cent Na_2O by weight. Using $\Delta H^\circ soln(Na_2O_2,\ c) = -56.02$ kcal/mol, Roth derived the value $\Delta H^\circ soln(Na_2O_2,\ c) = -34.85$kcal/mol. This value was later corrected to be -35.75 kcal/mol (2). From this data we calculate the heat of formation (298°K) of $Na_2O_2(c)$ as -121.0 kcal/mol. Forcrand obtained ΔHsoln = -36.65 kcal/mol for the same reaction, quoted by Roth (1), yielding $\Delta Hf^\circ_{298}(Na_2O_2,c\ ) = -120.0$ kcal/mol. The auxiliary data $\Delta Hf^\circ_{298}(H_2O,\ \ell) = -68.315$ kcal/mol is taken from U. S. Natl. Bur. Std. Tech. Note 270-1, 1965; and $\Delta Hf^\circ_{298}(NaOH \cdot 1200\ H_2O) = -112.458$ kcal/mol is derived based on $\Delta Hf^\circ_{298}(NaOH,\ c) = -101.90$ kcal/mol from JANAF Table and $\Delta H^\circ_\infty = -10.637$ kcal/mol and $\Delta Hdil(1200\ H_2O \rightarrow \infty H_2O) = -0.079$ kcal/mol from V. B. Parker, U. S.Natl. Bur. Std. NSRDS-NBS 2, 1965.

Gilles (3) determined the enthalpy change of the reaction $Na_2O_2(c) + H_2O(\ell) = 2NaOH(3800\ H_2O) + 1/2O_2(g)$, using a purer sample ($Na_2O_2$ 99.2 per cent, Na_2O 0.8 per cent). Based on the reported value $\Delta Hr^\circ_{298} = -34.0 \pm 0.3$ kcal/mol and derived $\Delta Hf^\circ_{298}(NaOH \cdot 3800\ H_2O) = -112.487$ kcal/mol, we calculate $\Delta Hf^\circ_{298} = -122.66 \pm 1.2$ kcal/mol for $Na_2O_2(c)$.

Leffler (4) studied the oxygen pressure-melt composition for the liquid sodium-oxygen system between 780 and 980°C. These results,together with the thermodynamic data for Na_2O_2,were used to calculate the heats and free energies of formation of melt compositions betwen $NaO_{1.0}$ and $NaO_{0.5}$. However, there are no numerical results reported. Therefore this data is not used for evaluation.

The heat of formation at 298°K is adopted as -122.66 ± 1.2 kcal/mol.

Heat Capacity and Entropy

The low temperature heat capacities, 52.31-296.22°K, were measured by Todd (5). His sample contains (per cent) 94 $Na_2O_2(c)$, 3.6 $Na_2O(c)$ and 2.4 Na_2CO_3. Corrections in the reported results have been made for Na_2CO_3 content, but not for Na_2O content which was estimated to be small. The Cp values below 52.31°K are calculated using the equation $Cp = D(\frac{252}{T}) + 3E(\frac{399}{T})$,reported by Todd. S°_{298} is derived from the adopted Cp,based on $S^\circ_{50} = 1.012$ eu.

The high temperature enthalpies, 375.4-869.2°K, were determined by Chandrasekharaiah (6), using drop calorimetry. Corrections were made for the contributions from impurities (Na_2CO_3 1.5 and Na_2O 0.2 per cent). A discontinuity was observed in the enthalpies between 773 and 793°K, indicating some kind of transition (see Transition Data). The Cp for $Na_2O_2(\alpha)$ at temperatures 298-769.5°K are derived from the enthalpy measurements, 375.4-769.5°K, and joined smoothly with the low temperature data at 298°K,and extrapolated to 785°K(Tt). The Cp for $Na_2O_2(\beta)$ is derived from the enthalpy data, 794-869.2°K, as constant, 27.15 gibbs/mol, and extrapolated to 2500°K.

Vedeneev (7) measured the high temperature specific heat of $Na_2O_2(c)$ in the temperature interval 292-373°K using adiabatic calorimetry. The reported average value, 21.46 gibbs/mol, is in fair agreement with the adopted ones.

Transition Data

Tt was reported by Tallman (8),who measured the X-ray power diffraction pattern by a Geiger-counter diffractometer and found that at about 510°C the pattern changes entirely and a new set of peaks indicates a new phase. Separate thermal analysis measurements (8) confirm the transition temperature (α → β) is 512 ± 1°C or 785 ± 1°K, which is adopted here. Foppl (9) found a thermal anomaly at 485°C in both heating and cooling curves. ΔHt° is derived from the adopted enthalpy and Cp data on $Na_2O_2(\alpha)$ and $Na_2O_2(\beta)$.

Melting Data

Tm is obtained from Benzel (10). Tm = 733 and 783°K were reported by Blumenthal (11) and Rode (12), respectively, which are not adopted.

Dec. 31, 1960; June 30, 1965; Sept. 30, 1967

SODIUM METASILICATE (Na_2SiO_3) (CRYSTAL) GFW = 122.0738

ΔHf°_0 = -370.75 ± 1.0 kcal/mol

$S^\circ_{298.15}$ = 27.21 ± 0.3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -373.19 ± 1.0 kcal/mol

Tm = 1362 ± 0.5°K

ΔHm° = 12.38 kcal/mol

Heat of Formation

The heats of solution of NaCl(c), Na_2SO_4(c), SiO_2(quartz),Na_2SiO_3(c), HCl(aq) and H_2SO_4(aq) in 20 percent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). The author derived two values of ΔHsoln of Na_2O(c) from those of NaCl(c), Na_2SO_4(c), HCl(aq) and H_2SO_4(aq) presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate ΔHsoln of Na_2O(c) in the calorimetric solution as -87.50 (chloride scheme, originally -87.66) and -88.74 kcal/mol (sulfate scheme, originally -89.19), using recent ΔHf°_{298} values for NaCl(c), Na_2SO_4(c), HCl(aq), H_2SO_4(aq), and Na_2O(c). The corresponding enthalpy changes, ΔHr°_{298}, for the reaction Na_2O(c) + SiO_2(quartz) = Na_2SiO_3(c) are derived as -55.20 and -56.38 kcal/mol. Adopting the weighted average ΔHr°_{298} = -55.59 kcal/mol with ΔHf°_{298}(Na_2O, c) = -99.9 kcal/mol and ΔHf°_{298}(SiO_2, quartz) = -217.7 kcal/mol, we obtain ΔHf°_{298} = -373.19 kcal/mol for Na_2SiO_3(c). This ΔHf°_{298}(Na_2SiO_3, c) value is independent of future changes in ΔHf°_{298} of Na_2O(c) but the values of ΔHsoln and ΔHr° are not independent. The adopted value of ΔHf°_{298}(Na_2O, c) is the average of -100.1 and -99.7 kcal/mol reported by W. A. Roth and H. L. Kaule, Z. Anorg. Chem. 253, 352 (1947); ibid. 255, 324 (1948), and M. Matsui and S. Oka, J. Soc. Chem. Ind. (Japan) 32, 79 (1929), respectively.

W. A. Roth and H. Troitzsch, Z. Anorg. Chem. 260, 337 (1949), have measured the heats of solution of SiO_2(quartz), Na_2SiO_3(c) and Na_2O(c) in 10.3 percent HF at 22°C to be -32.85, -67.96 and -88.9 kcal/mol, respectively. Using these results, we calculate the enthalpy change of the reaction Na_2O(c) + SiO_2(quartz) = Na_2SiO_3(c) as -53.79 kcal/mol and ΔHf°_{298}(Na_2SiO_3, c) = -371.39 kcal/mol.

By use of high temperature reaction calorimetry D. C. Kroger and W. Janetzko, Z. Anorg. Allgem Chem. 284, 83 (1956), have determined the enthalpy change of the reaction Na_2C_3(c) + $Na_2Si_2O_5$(gl) = 2Na_2SiO_3(c) + CO_2(g) as 17.99 kcal/mol. Based on ΔHf°_{298} = -270.26, -582.92 and -94.05 kcal/mol for Na_2CO_3(c), $Na_2Si_2O_5$(gl) and CO_2(g), respectively, we evaluate ΔHf°_{298} = =370.57 kcal/mol for Na_2SiO_3(c).

The heats of solution of Na_2CO_3(c), SiO_2(quartz) and Na_2SiO_3(c) in 39 percent HF at 26.5°C were measured to be -244.1, -564.5 and -673.6 cal/g, by C. Hummel and H. E. Schwiete, Glastech. Ber. 32, 327 (1959). From these results we calculate the enthalpy change to be 22.43 kcal/mol for the reaction Na_2CO_3(c) + SiO_2(quartz) = Na_2SiO_3(c) + CO_2(g), yielding ΔHf°_{298} (Na_2SiO_3,c) = -371.48 kcal/mol.

Many other older calorimetric measurements have been made in order to derive the heat of formation for Na_2SiO_2(c), but most of these are of questionable accuracy and in some cases the products of the reaction are uncertain. For further details the review by N. W. McCready, J. Phys. Colloid. Chem. 52, 1277 (1948).

Heat Capacity and Entropy

The low temperature heat capacities, 53.6 - 294.5°K, were measured by K. K. Kelley, J. Am. Chem. Soc. 61, 471 (1939), and high temperature enthalpies, 360.5 - 1747°K were determined by B. F. Naylor, J. Am. Chem. Soc. 67, 466 (1945). The high temperature heat capacities are derived from the measured enthalpy data and joined smoothly with the low temperature Cp values. The entropy at 298°K is calculated using the adopted low temperature heat capacities, based on S°_{50} = 1.195 eu.

Melting Data

See Na_2SiO_3(ℓ) table for details.

Dec. 31, 1960; June 30, 1965; Sept. 30, 1967

SODIUM METASILICATE (Na_2SiO_3) (LIQUID) GFW = 122.0738

$S^\circ_{298.15}$ = 35.967 gibbs/mol $\Delta Hf^\circ_{298.15}$ = -361.107 kcal/mol

Tm = 1362 ± 0.5°K ΔHm = 12.38 kcal/mol

Heat of Formation

$\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{1362} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity above 900°K is derived as constant from the high temperature enthalpy data, 1414 - 1747°K, measured by B. F. Naylor, J. Am. Chem. Soc. 67, 466 (1945). A glass transition temperature is assumed at 900°K; i.e. the heat capacities below 900°K are taken to be the same as those for $Na_2SiO_3(c)$.

The entropy is obtained in a manner analogous to that of the heat of formation. The low temperature heat capacities, 63.74 - 162.48°K, have been measured by V. V. Tarasov and Y. S. Savitskaya, Dokl. Akad. Nauk SSSR, 88, 1019 (1953); however, these are not adequate to be used to evaluate S°_{298}.

Melting Data

The adopted Tm = 1362°K, determined by F. C. Kracek, J. Phys. Chem. 34, 1583 (1930), is in good agreement with the value 1261°K reported by F. M. Jaeger, J. Wash. Acad. Sci. 1, 49 (1911), and later confirmed by G. W. Morey and N. L. Bowen, J. Phys. Chem. 28, 1167 (1924).

Other reported Tm values are 1280, 1291 and 1329°K by N. V. Kultascheff, Z. Anorg. Chem. 35, 186 (1903); R. C. Wallace, ibid., 63, 1 (1909); and H. S. van Klooster, ibid., 69, 135 (1910), respectively. These values are all lower than the adopted Tm value, probably because the sample compositions were not the exact composition of metasilicate.

The value of ΔHm° is evaluated from the adopted heat capacities for $Na_2SiO_3(c)$ and $Na_2SiO_3(\ell)$, and the enthalpy data reported by B. F. Naylor, loc. cit., assuming the final state of the calorimetric sample to be $Na_2SiO_3(c)$. From the phase diagrams of Na_2SiO_3 with other compounds, K. K. Kelley, U. S. Bur. Mines Bull. 393, 1936, derived the values of ΔHm° of 9.8 - 10.5 kcal/mol.

Dec. 31, 1966

SODIUM SULFATE, V (Na_2SO_4) (CRYSTAL) GFW = 142.0412

$S^\circ_{298.15}$ = 35.76 ± 0.1 gibbs/mol

Tt(V→I) = 521.7°K

ΔHf°_0 = -328.82 ± 0.2 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -331.55 ± 0.2 kcal/mol

$\Delta H^\circ_t(V \rightarrow I)$ = 2.584 kcal/mol

Heat of Formation.

F. L. E. Shibata, S. Oda and S. Furukawa, J. Sci. Hiroshima Univ. (Japan) Ser. A, 3, 227 (1933), measured the emf of the cell: Na-amalg. (0.2077%)$|Na_2SO_4$ (sat. soln.), $Hg_2SO_4|Hg$ at 33-37°C. Extrapolating their results to 25°C, we obtain the $\Delta Gr^\circ_{298.15}$ = -153.77 kcal/mol for the reaction $2Na(c) + Hg_2SO_4(c) = 2Hg(l) + Na_2SO_4(c)$, which yields $\Delta Gf^\circ_{298.15}$ = -303.36 and $\Delta Hf^\circ_{298.15}$ = -331.53 kcal/mol for $Na_2SO_4(c)$. The auxiliary value, $\Delta Gf^\circ_{298.15}$ = -149.59 kcal/mol, for $Hg_2SO_4(c)$ is obtained from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Tech. Note 270-1, Natl. Bur. Std., Washington, D.C., 1965.

The heat of formation for $Na_2SO_4(\infty H_2O)$ is evaluated as -332.10 kcal/mol, using $\Delta Hf^\circ_{298.15}$ = -57.39 and -217.32 kcal/mol for $Na^+(\infty H_2O)$ and $SO_4^=(\infty H_2O)$, respectively, from Tech. Note 270-1, loc. cit. J.P. Coughlin, J. Am. Chem. Soc. 77, 868 (1955), determined the enthalpy change, $\Delta Hr^\circ_{298.15}$ = -0.301 ± 0.035 kcal/mol for the reaction $Na_2SO_4(c,V) = Na_2SO_4(1050\ H_2O)$. Adopting $\Delta Hr^\circ_{298.15}$ = 0.244 kacl/mol for the reaction $Na_2SO_4(\infty H_2O) = Na_2SO_4\ (1050\ H_2O)$ from Natl. Bur. Std. Circ. 500, Washington, D.C., 1952, we derive the value, $\Delta Hr^\circ_{298.15}$ = 0.545 kcal/mol for the reaction $Na_2SO_4(\infty H_2O) = Na_2SO_4(c,V)$, yielding $\Delta Hf^\circ_{298.15}$ = -331.56 kcal/mol for $Na_2SO_4(c,V)$.

The heat of formation for $Na_2SO_4(c,V)$ is adopted as -331.55 ± 0.2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities,13.74 - 313.44°K, have been measured by K. S. Pitzer and L. V. Coulter, J. Am. Chem. Soc. 60, 1310 (1938). The heat capacities in the temperature range 324.61 - 503.05°K were determined by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. 6, 1321 (1961), using an adiabatic calorimeter. These two sets of data are joined smoothly and extrapolated graphically to 1500°K. The enthalpy values derived from the adopted Cp data are in fair agreement with those determined by J. P. Coughlin, J. Am. Chem. Soc. 77, 868 (1955). The corresponding Cp values, reported by M. M. Popov and G. L. Galchenko, J. Gen. Chem. USSR, 21, 2489 (1951), seem too high at the high temperature end. $S^\circ_{298.15}$ is derived using the low temperature Cp data reported by K. S. Pitzer and L. V. Coulter, loc. cit., based on S°_{14} = 0.057 eu.

Transition Data.

Polymorphism studies by F. C. Kracek, J. Phys. Chem. 33, 1281 (1929), and F. C. Kracek and R. E. Gibson, J. Phys. Chem. 33, 1304 (1929); ibid, 34, 188 (1930), indicate five distinct modifications, i.e. V, IV, III, II, I, of which only V and I are stable forms. Calorimetric studies of Shmidt and Sokolov, loc. cit., suggest another form, stable at high temperatures, which is labeled as δ.

The transition temperature and heat of transition are from the calorimetric data for thenardite reported by Shmidt and Sokolov, loc. cit.

Dec. 31, 1966

SODIUM SULFATE, III (Na_2SO_4) (CRYSTAL) GFW = 142.0412

$S^\circ_{298.15}$ = 36.653 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = −331.005 kcal/mol

Tt(III → I) = 521.7°K

ΔHt°(III → I) = 1.630 kcal/mol

Heat of Formation.

The $\Delta Hf^\circ_{298.15}(Na_2SO_4$, III) value is obtained from $\Delta Hf^\circ_{298.15}(Na_2SO_4$, I) by subtracting ΔHt°(III → I) and the difference between $H^\circ_{521.7} - H^\circ_{298.15}$ for Na_2SO_4(III) and Na_2SO_4(I).

J. P. Coughlin, J. Am. Chem. Soc. <u>77</u>, 868 (1955), determined the heat of reaction of $Na_2SO_4(V) \rightarrow Na_2SO_4(III)$ as 0.735 ± 0.015 kcal/mol at 303.16°K by solution calorimetry. This value is in reasonable agreement with 0.55 kcal/mol obtained from the selected heat of formation.

Heat Capacity and Entropy.

The heat capacities in the temperature range 319.02 - 521.65°K were measured with an adiabatic calorimeter by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. <u>6</u>, 1321 (1961). The Cp values below 319°K and above 521°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data.

Na_2SO_4(III) is the meltable form obtained by cooling Na_2SO_4(I) in the absence of moisture. The temperature and heat of transition are taken from the calorimetric data of Shmidt and Sokolov, loc. cit. The value ΔHt°(III → I) = 1.630 + 0.005 kcal/mol is the average of three determinations.

J. P. Coughlin, loc. cit., reported the heat of transition (III → I) at 514°K to be 1.680 kcal/mol, obtained by drop calorimetry, which is in good agreement with the value adopted.

Dec. 31, 1966

SODIUM SULFATE, I (Na_2SO_4) (CRYSTAL) GFW = 142.0412

$S^\circ_{298.15}$ = 37.733 gibbs/mol

$Tt(V \rightarrow I)$ = 521.7°K

$Tt(I \rightarrow \delta)$ = 980°K

Tm = 1157°K

$\Delta Hf^\circ_{298.15}$ = -330.096 kcal/mol

$\Delta Ht^\circ(V \rightarrow I)$ = 2.584 kcal/mol

$\Delta Ht^\circ(I \rightarrow \delta)$ = 0.08 kcal/mol

ΔHm° = 5.67 kcal/mol

Heat of Formation.

The $\Delta Hf^\circ_{298.15}(Na_2SO_4,I)$ is obtained from $\Delta Hf^\circ_{298.15}(Na_2SO_4,V)$ by adding $\Delta Ht^\circ(V \rightarrow I)$ and the difference between $H^\circ_{521.7} - H^\circ_{298.15}$ for $Na_2SO_4(V)$ and $Na_2SO_4(I)$.

Heat Capacity and Entropy.

The heat capacities in the temperature range 538.65 - 917.65°K were measured with an adiabatic calorimeter by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. 6, 1321 (1961). The Cp values below 538.65°K and above 917.65°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data.

The value $\Delta Ht^\circ(V \rightarrow I) = 2.584 \pm 0.015$ kcal/mol is the average of two determinations from the calorimetric studies of Shmidt and Sokolov, loc. cit. The transition temperature was derived from the heating curve obtained in measuring the heat of transition. It was taken to be the temperature at which the specimen began to show its lowest heating rate. The heat of transition was the difference between the quantity of heat actually dissipated and the sum of the heats calculated from the heat capacity curve of the apparatus and from the specific heat curves of (V) and (I) linearly extrapolated to the transition temperature.

The values of Tt and ΔHt° for $Na_2SO_4(I) \rightarrow Na_2SO_4(\delta)$ transition were reported by Shmidt and Sokolov, loc. cit. See $Na_2SO_4(\delta)$ table for details.

Melting Data.

See $Na_2SO_4(l)$ table for details.

Dec. 31, 1966

SODIUM SULFATE, δ (Na_2SO_4) (CRYSTAL) GFW = 142.0412

$S°_{298.15}$ = 37.741 gibbs/mol

Tt (I → δ) = 980°K

Tm = 1157°K

$\Delta Hf°_{298.15}$ = -330.089 kcal/mol

ΔHt° (I → δ) = 0.08 kcal/mol

ΔHm° = 5.50 kcal/mol

Heat of Formation

The heat of formation ($\Delta Ht°_{298.15}$) is obtained from $\Delta Hf°_{298.15}$ for Na_2SO_4 (I) by adding ΔHt° (I → δ) and the difference between $H°_{980}$ - $H°_{298.15}$ for Na_2SO_4(I) and Na_2SO_4 (δ).

Heat Capacity and Entropy

The heat capacities in the temperature range 930 - 1010°K were measured by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. 6, 1321 (1961). The Cp values below 900°K are assumed to be the same as those for Na_2SO_4 (I). The heat capacities above 1010°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data

A small anomalous region between 690 - 720°C (963.15 - 993.15°K) on the Cp curve for Na_2SO_4(c) was reported by N. E. Shmidt and V. A. Sokolov, loc. cit. By use of graphical integration of the area between the measured Cp curve and an arbitrary base line over the region 900 - 1100°K, a value of ΔHt° (I → δ) = 0.08 kcal/mol was obtained. Tt is assumed to be 980°K. This anomalous region was first observed by G. W. Wyrouboff, Z. Krist. 21, 284 (1893), and later confirmed by Y. P. Simanov and D. F. Kirkina, Zh. Neorg. Khim. 2, 699 (1957), as a transition from a hexagonal to an orthorhombic structure. This transition was not observed by the earlier investigators because their measurements did not extend to that temperature range.

Melting Data

The temperature and heat of melting of Na_2SO_4 (I) → Na_2SO_4 (l) were reported to be 1157°K and 5.67 kcal/mol, respectively, by Coughlin, loc. cit. No mention was made of the δ phase and the enthalpy measurements were probably not sensitive enough to detect this phase. Based on our selected Cp values for δ and liquid Na_2SO_4, we derive Hm°(δ → l) = 5.50 kcal/mol, using Coughlin's enthalpy data on Na_2SO_4 (l). The melting temperature is assumed to be the same as that reported by Coughlin.

Tm was reported to be 880°C (1153°K), 897°C (1170°K) and 888°C (1161°K) by Ruff and Plato, Ber. Deutsch. Chem. Ges. 36, 2357 (1903); K. Hüttner and G. Tammann, Z. Anorg. Chem. 43, 215 (1905); and H. E. Boeke, Z. Anorg. Chem. 50, 355 (1906), respectively.

Dec. 31, 1966

Na_2O_4S

SODIUM SULFATE (Na_2SO_4) (LIQUID) GFW = 142.0412

$S^\circ_{298.15}$ = 42.777 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -324.241 kcal/mol

$Tm(\delta \rightarrow l)$ = 1157°K

$\Delta Hm^\circ(\delta \rightarrow l)$ = 5.50 kcal/mol

<u>Heat of Formation.</u>

The value of $\Delta Hf^\circ_{298.15}(l)$ is obtained from $\Delta Hf^\circ_{298.15}(I)$ by adding ΔHm° and the difference between $H^\circ_{1157} - H^\circ_{298.15}$ for $Na_2SO_4(\delta)$ and $Na_2SO_4(l)$.

<u>Heat Capacity and Entropy.</u>

The enthalpies for $Na_2SO_4(l)$ were measured by drop calorimetry in the temperature range 1157 - 1826°K by J. P. Coughlin, J. Am. Chem. Soc. <u>77</u>, 868 (1955); and in the temperature range 1173 - 1290°K by M. M. Popov and D. M. Ginzburg, J. Gen. Chem. USSR <u>26</u>, 1107 (1956). The constant heat capacity adopted here is derived from the enthalpy measurements reported by J. P. Coughlin, loc. cit. Below 800°K, the heat capacities are assumed to be the same as those of the δ phase. The entropy is calculated in a manner analogous to that of the heat of formation.

<u>Melting Data.</u>

The temperature and heat of melting of $Na_2SO_4(I) \rightarrow Na_2SO_4(l)$ were reported to be 1157°K and 5.67 kcal/mol, respectively, by Coughlin, loc. cit. No mention was made of the δ phase, and the enthalpy measurements were probably not sensitive enough to detect this phase. Based on our selected Cp values for δ liquid Na_2SO_4, we derive $\Delta Hm^\circ(\delta \rightarrow l)$ = 5.50 kcal/mol, using Coughlin's enthalpy data on $Na_2SO_4(l)$. The melting temperature is assumed to be the same as that reported by Coughlin.

Tm was reported to be 880°C(1153°K), 897°C(1170°K) and 888°C(1161°K) by Ruff and Plato, Ber. Deutsch. Chem. Ges. <u>36</u>, 2357 (1903); K. Hüttner and G. Tammann, Z. Anorg. Chem. <u>43</u>, 215 (1905); and H. E. Boeke, Z. Anorg. Chem. <u>50</u>, 355 (1906), respectively.

June 30, 1967

SODIUM TUNGSTATE (Na_2WO_4) (CRYSTAL) GFW = 293.8272

ΔHf_0° = -366.8 ± 2 kcal/mol

$S^\circ_{298.15}$ = 38.32 ± 0.5 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -369.2 ± 2 kcal/mol

Tt_1 = 862.0°K

ΔHt_1° = 0.983 kcal/mol

Tt_2 = 860.8°K

ΔHt_2° = 7.373 kcal/mol

Tm = 968.7°K

ΔHm° = 5.688 kcal/mol

Heat of Formation

The adopted heat of formation, ΔHf°_{298} (Na_2WO_4,c) = -369.2 kcal/mol, is calculated from $\Delta Hr^\circ_{303.15}$ = 19.44 ± 0.08 kcal/mol for the reaction H_2WO_4(c) + 2NaCl(c) = Na_2WO_4(c) + 2HCl(12.731 H_2O), using the JANAF value of ΔHf°_{298} (H_2WO_4,c) = -270.5 kcal/mol and ΔHf°_{298} (NaCl,c) = -98.26 kcal/mol, and auxiliary data for HCl(aq) (11). The value of $\Delta Hr^\circ_{303.15}$ was determined by solution calorimetry by M. F. Koehler, L. B. Pankratz and R. Barany (1).

J. M. Sherfey and A. Brenner (2) measured by electrochemical calorimetry the heat of reaction ΔHr°_{298} = -7 ± 1.5 kcal/mol for W(c) + 2NaOH(55.55H_2O) + $2H_2O(\ell)$ = Na_2WO_4 (∞H_2O) + $3H_2$(g). This value, combined with the heat of solution (1,3,9), ΔH°_{sol} = -1.7 ± 0.1 kcal/mol for Na_2WO_4(c) = Na_2WO_4 (∞H_2O), gives ΔHf°_{298} (Na_2WO_4,c) = -368.4 kcal/mol, which is in good agreement with the value adopted.

The previously accepted value (1,3), ΔHf°_{298} (Na_2WO_4,c) = -379 ± 0.5 kcal/mol, was based on the unreliable ΔHf°_{298} (H_2WO_4,c) = -280.2 ± 0.4 kcal/mol. (See JANAF H_2WO_4(c) table of March 31, 1967.) The other quoted value (4), ΔHf°_{298} (Na_2WO_4,c) = -395 kcal/mol, was obtained from W. G. Mixter's (5) measurement of the heat of reaction of tungsten powder with excess Na_2O_2. This value was probably in error because the complex tungstate and peroxytungstates were formed in the reaction.

Heat Capacity and Entropy

Low temperature heat capacities (52-299.87°K) were measured calorimetrically by E. G. King and W. W. Weller (6). The heat capacities above 300°K are estimated by extrapolation of the low temperature heat capacity curve to Cp_{860} = 49.0 gibbs/mol. The latter is obtained from an estimate of Cp equal to 7 gibbs/g-atom at the first transition temperature.

The entropy, S°_{298} = 38.32 ± 0.5 eu, is calculated from low temperature heat capacity data of King and Weller (6), based on an extrapolation of S°_{51} = 2.77 ± 0.5 eu.

Transition Data

Transition temperatures and heats were obtained from differential heating and cooling curves both at atmospheric and higher pressures by R. W. Goranson and F. C. Kracek (7). Existence of three phases is confirmed by the earlier birefringence studies of H. E. Boeke (8).

R. Riccardi and C. Sinistri (10) found only one transition at 864°K with ΔHt° = 8.23 kcal/mol by differential thermal analysis. This heat is apparently the sum of the two adopted heats of transition.

Melting Data

The adopted melting data were measured by the differential heating and cooling curve method by Goranson and Kracek (7). R. Riccardi and C. Sinistri (10) found the melting point at 971°K with ΔHm° = 7.52 kcal/mol by differential thermal analysis.

Dec. 31, 1960; June 30, 1965; Sept. 30, 1967

$S^\circ_{298.15}$ = 39.21 ± 1.0 gibbs/mol
Tt(B → Aβ) = 951°K
Tt(Aβ → Aα) = 980°K
Tm = 1147°K

ΔHf°_0 = -586.87 ± 1.0 kcal/mol
$\Delta Hf^\circ_{298.15}$ = -590.36 ± 1.0 kcal/mol
ΔHt° = 0.1 kcal/mol
ΔHt° = 0.15 kcal/mol
ΔHm° = 8.5 kcal/mol

Heat of Formation

The heats of solution of NaCl(c), Na_2SO_4(c), SiO_2(quartz), $Na_2Si_2O_5$(c), HCl(aq) and H_2SO_4(aq), in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (1). The author derived two values of ΔHsoln of Na_2O(c) from those of NaCl(c), Na_2SO_4(c), HCl(aq) and H_2SO_4(aq), presumably employing auxiliary data from (2). We recalculate ΔHsoln of Na_2O(c) in the calorimetric solution as -87.50 (chlorine scheme,originally -87.66) and -88.74 kcal/mol (sulfate scheme, originally -89.19), using recent ΔHf°_{298} values (16, 17, 18) for NaCl(c), HCl(aq), H_2SO_4(aq), Na_2SO_4(c), and Na_2O(c). The corresponding enthalpy changes, ΔHr°_{298}, for the reaction Na_2O(c) + $2SiO_2$(quartz) = $Na_2Si_2O_5$(c) are derived as -54.65 and -55.89 kcal/mol. Adopting the weighted average ΔHr°_{298} = -55.06 kcal/mol with ΔHf°_{298}(Na_2O, c) = -99.9 kcal/mol and ΔHf°_{298}(SiO_2, quartz) = -217.7 kcal/mol, we obtain ΔHf°_{298} = -590.36 kcal/mol for $Na_2Si_2O_5$(c). This ΔHf°_{298}($Na_2Si_2O_5$, c) value is independent of future changes in ΔHf°_{298} of Na_2O(c), but the values of ΔHsoln and ΔHr° are not independent.

Stevens et al. (3) measured the heats of solution of $Na_2Si_2O_5$(c), Na_2O(c) and SiO_2(quartz) in HF(aq) at 25°C. Based on the reported results, the enthalpy change for the reaction Na_2O(c) + $2SiO_2$(quartz) = $Na_2Si_2O_5$(c) is calculated as -53.25 ± 0.32 kcal/mol, yielding ΔHf°_{298}($Na_2Si_2O_5$, c) = -588.55 kcal/mol.

Hummel (4) determined the heats of solution of $Na_2Si_2O_5$(c), SiO_2(quartz) and Na_2CO_3(c) in 39 percent HF at 26.5°C. From the data reported we derive the enthalpy change to be 20.88 kcal/mol for the reaction Na_2CO_3(c) + $2SiO_2$(quartz) = $Na_2Si_2O_5$(c) + CO_2(g). Employing ΔHf°_{298} = -270.26, -217.7 and -94.05 kcal/mol for Na_2CO_3(c), SiO_2(quartz) and CO_2(g), respectively, we obtain ΔHf°_{298} = -590.73 kcal/mol for $Na_2Si_2O_5$(c) which is in good agreement with the adopted one.

Heat Capacity and Entropy

The low temperature heat capacities, 54.3 - 294.7°K, have been measured by Kelley (5) and the high temperature enthalpies, 376.8 - 1100.2°K, by Naylor (6). The derived high temperature heat capacities are joined smoothly with the low temperature ones at 298°K. An approximate Cp of 70 gibbs/mol is derived from the enthalpies above 980°K; this value is extrapolated to 2000°K. The value of S°_{298} is calculated from the adopted low temperature heat capacities based on S°_{50} = 2.945 eu. The entropy extrapolation derives from the Debye-Einstein extrapolation of Kelley (5) which yields a Cp curve with an extra inflection in the region from 15 to 50°K. A more normal extrapolation would lead to a value of S°_{50} which is lower by 0.5 eu.

Transition Data

There are six slowly inverting polymorphous phases (1, 7-9), namely A, B, C, D, E and F, of which only the first two phases are stable. Two rapid transitions have been reported at 951 and 980°K (1, 10). Phase A, which has two subphases, Aα and Aβ, is stable above 951°K. The stable phase below 951°K is known as phase B, previously called β-$Na_2Si_2O_5$. The two values of ΔHt° are derived from the enthalpy data of Naylor (6) using the adopted Cp values. Three more rapid transitions have been reported at 822, 846 and 866°K (1, 10) in E, previously called γ-$Na_2Si_2O_5$. A recent examination of these transitions was reported by Willgallis and Range (10).

Melting Data

Tm is obtained from Morey (11). The selected value of ΔHm° is based on the following ΔHm° values derived from four different kinds of measurements.

Investigator	ΔHm°, kcal/mol* at 298°K	ΔHm°, kcal/mol* at 1147°K	Method**	Reference
Kelley (1936)	(7.51)	8.46	I	12
Kracek (1953)	5.25	(6.20)	II	1
Kröger-Janetzko (1956)	8.81	(9.76)	III	13
Kröger-Kreitlow (1956)	8.83	(9.78)	II	14
Schwiete-Ziegler (1958)	(7.50)	8.45	IV	15
Hummel-Schwiete (1959)	8.09	(9.04)	II	4

*The numbers in parentheses are derived from the measured ones at the other listed temperatures.

**I = phase diagram; II = solution calorimetry; III = high temperature reaction calorimetry; and IV = dynamic-differential calorimetric method.

Dec. 31, 1960; June 30, 1965; Sept. 30, 1967

SODIUM DISILICATE ($Na_2Si_2O_5$) (LIQUID) GFW = 182.1586

$S°_{298.15}$ = 45.101 gibbs/mol

$\Delta Hf°_{298.15}$ = -582.811 kcal/mol

Tm = 1147°K

ΔHm° = 8.5 kcal/mol

Heat of Formation

The $\Delta Hf°_{298}(\ell)$ is obtained from $\Delta Hf°_{298}(c)$ by adding ΔHm° and the difference between $H°_{1147} - H°_{298}$ for crystal and liquid.

The heats of solution of NaCl(c), Na_2SO_4(c), HCl(aq), H_2SO_4(aq), SiO_2(quartz) and $Na_2Si_2O_5$(gl) in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (1). Following the same procedure as described in the $Na_2Si_2O_5$(c) table, we derive the enthalpy changes, $\Delta Hr°_{298}$, for the reaction $Na_2O(c) + 2SiO_2(quartz) = Na_2Si_2O_5(gl)$ as -49.40 and -50.64 kcal/mol using the heats of solution of Na_2O(c) as -87.50 (chloride scheme) and -88.74 kcal/mol (sulfate scheme), respectively. Adopting the weighted average $\Delta Hr°_{298}$ = -49.81 kcal/mol with $\Delta Hf°_{298}(Na_2O, c)$ = -99.9 kcal/mol and $\Delta Hf°_{298}(SiO_2, quartz)$ = -217.7 kcal/mol, we obtain $\Delta Hf°_{298}$ = -585.113 kcal/mol for $Na_2Si_2O_5$(gl).

Using high temperature reaction calorimetry, Kröger (2) determined the enthalpy changes as 25.28 ± 0.22 and -18.58 ± 0.36 kcal/mol for the reactions $Na_2CO_3(c) + 2SiO_2(quartz) = Na_2Si_2O_5(gl) + CO_2(g)$ and $2NaOH(c) + 2SiO_2(quartz) = Na_2Si_2O_5(gl) + H_2O(\ell)$, respectively. From the given results, we calculate the corresponding values of $\Delta Hf°_{298}(Na_2Si_2O_5, gl)$ to be -586.32 and -589.46 kcal/mol, using $\Delta Hf°_{298}$ = -270.26, -217.70, -94.05, -101.90 and -68.32 kcal/mol for Na_2CO_3(c), SiO_2(quartz), CO_2(g), NaOH(c) and $H_2O(\ell)$, respectively. These two $\Delta Hf°_{298}[Na_2Si_2O_5, (\ell)]$ values, as well as the value -585.113 kcal/mol based on Kracek's data, are not adopted, because incorporating these $\Delta Hf°_{298}$(gl) values with the value of $\Delta Hf°_{298}$(c), gives values of the heat of melting at 298°K which are too low in comparison with the other values (see the $Na_2Si_2O_5$(c) table).

Hummel (3) measured the heats of solution of Na_2CO_3(c), SiO_2(quartz) and $Na_2Si_2O_5$(gl) in 39 percent hydrofluoric acid at 26.5°C, as -244.1, -564.5 and -673.7 cal/g, respectively. Based on these results, we derive the enthalpy change for the reaction $Na_2CO_3(c) + 2SiO_2(quartz) = Na_2Si_2O_5(gl) + CO_2(g)$ to be 29.01 kcal/mol, yielding $\Delta Hf°_{298}(Na_2Si_2O_5, gl)$ = -582.6 kcal/mol which is in good agreement with the adopted value.

Heat Capacity and Entropy

Using drop calorimetry, Naylor (4) has measured the enthalpies of $Na_2Si_2O_5$(gl), 445.5 - 1120.7°K, and $Na_2Si_2O_5(\ell)$, 1173.2 - 1744°K. Based on the liquid enthalpy data, we evaluate the heat capacity of $Na_2Si_2O_5(\ell)$ to be 62.43 gibbs/mol. The Cp values below 1147°K are derived from the enthalpies measured at 445.5 - 1120.7°K by Naylor (4). Below 600°K, Cp is identical with that of the crystal. The adopted curve rises rapidly to a maximum in the glass transition region, 650-950°K, then smoothly approaches the value of the real liquid near Tm. The heat capacity of $Na_2Si_2O_5(\ell)$ is assumed to be constant in the temperature range 1147 to 2500°K.

$S°_{298}$ is obtained in a manner analogous to that of the heat of formation.

Melting Data

See $Na_2Si_2O_5$(c) table for details.

Heat of Formation.

P. Brix and G. Herzberg, Can. J. Phys. 32, 110 (1954), observed 21 bands in the transition $X^3\Sigma^-_g \longleftrightarrow B^3\Sigma^-_u$. The Birge-Sponer extrapolation to the dissociation products $^3P_2 + {}^1D_2$ was corrected to the zero levels, $^3P_2 + {}^3P_2$, to give the dissociation energy 41260 ± 15 cm.$^{-1}$ This is in agreement with the extrapolation of the band heads of the $X^3\Sigma^-_g \longleftrightarrow A^3\Sigma^+_u$ transition which goes to the normal products. The extrapolation of the B level is very small, the lowest $\Delta G_{1/2}$ is 34 cm.$^{-1}$

Heat Capacity and Entropy.

The electronic levels from C. E. Moore, Nat. Bur. Standards, Circ. 467, (1949), were averaged above 80,000 cm.$^{-1}$

OXYGEN UNINEGATIVE ION (O^-) (IDEAL GAS) MOL. WT. = 15.99995

Ground State Configuration $^2P^\circ_{3/2}$

$S^\circ_{298.15}$ = 37.712 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 25.2 ± .5 kcal/mole

$\Delta H^\circ_{f\ 298.15}$ = 24.3 ± .5 kcal/mole

Electronic Levels and Quantum Weight

$\mathcal{E}_1$, cm.$^{-1}$	g_1
0.0	4
[160.0]	2

Heat of Formation.

The heat of formation was calculated from the equation: $O(g) + e^- \rightarrow O^-(g)$ with the JANAF auxiliary value for O(g); using the measured electron affinity = 1.465 e.v. (33.783 kcal/mole) obtained from L. M. Branscomb, D. S. Burch, S. J. Smith and S. Geltman, Phys. Rev. 111, 504 (1958). Other calculated values for the electron affinity are: 1.22 e.v. E. Clementi and A. D. McLean, Phys. Rev. 133, A419 (1964); 1.16 e.v. E. Clementi, A. D. McLean, D. L. Raimondi, and M. Yoshimine, Phys. Rev. 133, A1274 (1964); and 1.47 e.v. B. Edlén, J. Chem. Phys. 33, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were estimated by assuming that the extra electron would produce an electronic structure similar to the next higher atomic numbered element, in this case F(I). An analogy was then made between O^- and F(I) with O(I) and F(II), and O(II) and F(III) in order to estimate the height of the first level above the ground state. The data for F(I), O(I), F(II), O(II) and F(III) were obtained from C. E. Moore, "Atomic Energy Levels", Vol I, Circular of the National Bureau of Standards 467, June 15, 1949. It is possible that the entropy below 3000°K. could be in error by 0.5 e.v. due to the estimation of the low lying electronic level. The electronic levels above 1 X 10^5 cm.$^{-1}$ were omitted because their contribution is negligible below 6000°K. The $H^\circ-H^\circ_{298}$ value at 0°K. is -1.567 kcal/mole.

Phosphorus Monoxide (PO) (Ideal Gas)

Mol. Wt. = 46.975

$\Delta H^\circ_{f\ 298.15} = -1.46 \pm 2$ kcal. mole^{-1}

$S^\circ_{298.15} = 53.22$ cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^2\Pi$

Electronic Levels and Multiplicities

ϵ_i, cm.$^{-1}$	g_i
0	2
222.6	2

$\omega_e = 1233.42$ cm.$^{-1}$

$\omega_e x_e = 6.57$ cm.$^{-1}$

$B_e = 0.734$ cm.$^{-1}$

$\alpha_e = 0.0055$ cm.$^{-1}$

$\sigma = 1$

$r_e = 1.473$ Å

Heat of formation based upon a dissociation energy of 49,000 cm.$^{-1}$, which is the value of two predissociations observed by K. Dressler, Helv. Phys. Acta 29, 563 (1955).

Heat Capacities and Entropies. Molecular and spectroscopic constants based upon measurements of K. Dressler, loc. cit., K. S. Rao, Can. J. Phys. 36, 1526 (1958), and those of N. L. Singh, Can. J. Phys. 37, 136 (1959).

Lead Monoxide, Red (PbO)

(Crystal) Mol. Wt. = 223.21

March 31, 1962

Lead Monoxide, Red (PbO) (Crystal)

Mol. Wt. = 223.21

$\Delta H_f^\circ\ _{298.15} = -52.41 \pm 0.16$ kcal. mole^{-1}

$S^\circ_{298.15} = 15.6 \pm 0.2$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_s^\circ\ _{298.15} = 63.88 \pm 0.22$ kcal. mole^{-1}

$T_t = 762°K$

$\Delta H_t^\circ = 0.18 \pm 0.23$ kcal. mole^{-1}

Heat of Formation. Calculated from the cell reaction

$H_2(g) \mid Ba(OH)_2\ (0.766 \sim 0.2242M) \mid PbO(c) + Pb(c)$

reported by D. F. Smith and H. K. Woods, J. Am. Chem. Soc., 45, 2632 (1923), using $\Delta H_f^\circ\ _{298.15}$ for $H_2O(l)$, -68.317 kcal. mole^{-1}, given by Natl. Bur. Standards Circular 500 (1952). ΔH_f° values reported by other investigators were discussed by R. W. Millar, J. Am. Chem. Soc., 51, 207 (1929).

Heat Capacity and Entropy. Heat capacity values (51° to 298.15°K) were obtained from E. G. King, J. Am. Chem. Soc., 80, 2400 (1958). For the higher temperature range, heat capacity given by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used and joined smoothly to data of King at 298.15°K by graphical extrapolation. King obtained entropies below 51°K by empirical extrapolation of the heat capacity curve which fits the measured heat capacities within 1.3%.

Transition Data. Heat of transition recalculated from the data given by E. G. King, loc. cit.

Heat of Sublimation. Calculated from free-energy functions and vapor pressure reported by A. N. Nesmeyanov, L. P. Firsova and E. P. Isakova, Zhur. Fiz. Khim. 34, 1699 (1960) and R. Hörbe and O. Knacke, Z. Erzbergbau u. Metallhuttenw. 12, 321 (1959).

Lead Monoxide, Yellow (PbO)

(Crystal) Mol. Wt. = 223.21

Lead Monoxide, Yellow (PbO) (Crystal)

Mol. Wt. = 223.21

ΔH_f° 298.15 = -52.07 ± 0.28 kcal. mole^{-1}

$S^\circ_{298.15}$ = 16.1 ± 0.2 cal. deg.$^{-1}$ mole^{-1}

ΔH_s° 298.15 = 63.54 ± 0.32 kcal. mole^{-1}

T_m = 1170 ± 4°K.

ΔH_m° = 6.1 ± 0.1 kcal. mole^{-1}

Heat of Formation. Calculated from ΔH_f° 298.15 for PbO (c, red) and ΔH_t° 298.15 between PbO (c, red) and PbO (c, yellow).

Heat Capacity, Entropy, and Melting Data. C_p values (51° to 298.15°K.) obtained from E. G. King, J. Am. Chem. Soc., 80, 2400 (1958). For the higher temperature range, the heat capacity reported by E. N. Rodigina, K. Z. Gomel'skii and V. F. Luginina, Zhur. Fiz. Khim., 35, 1799 (1961) was used and joined smoothly to data of King at 298.15°K. by graphical extrapolation. T_m and ΔH_m° given by E. N. Rodigina, K. Z. Gomel'skii and V. F. Luginina, loc. cit.

Heat of Sublimation. Calculated from ΔH_t° 298.15 and ΔH_s° 298.15 for PbO (c, red).

Lead Monoxide (PbO)
(Liquid) Mol. Wt. = 223.21

March 31, 1962

Lead Monoxide (PbO) (Liquid)

Mol. Wt. = 223.21

ΔH_f° 298.15 = [-46.712] kcal. mole^{-1}

$S_{298.15}^\circ$ = [20.546] cal. deg.$^{-1}$ mole^{-1}

T_m = 1170 ± 4°K.

ΔH_m° = 6.1 ± 0.1 kcal. mole^{-1}

T_b = 1789°K.

ΔH_v° = 49.53 ± 0.22 kcal. mole^{-1}

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy, and Melting Data. C_p, T_m, and ΔH_m° are obtained from E. N. Rodigina, K. Z. Gomel'skii and V. F. Luginina, Zhur. Fiz. Khim., 35, 1799 (1961). The reported heat capacity is extrapolated to an assumed glass transition temperature of 780°K., below which the heat capacity is taken to be equal to that of the crystal, PbO (c, red).

Vaporization Phenomena. T_b and ΔH_v° calculated from ΔH_s° 298.15 for PbO (c, red) and functions for condensed and gaseous states.

Lead Monoxide (PbO)

(Ideal Gas) Mol. Wt. = 223.21 **INTERIM TABLE**

Lead Monoxide (PbO) (Ideal Gas)

Mol. Wt. = 223.21

$\Delta H_f^\circ{}_{298.15} = 11.48 \pm 0.27$ kcal. mole^{-1}

$S^\circ_{298.15} = 57.346$ cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^1\Sigma^+$

<u>Electronic Level and Multiplicity</u>

ϵ cm.$^{-1}$	g_1
0	1

$\omega_e = 721.8$ cm.$^{-1}$

$B_e = 0.3072$ cm.$^{-1}$

$\sigma = 1$

$\omega_e x_e = 3.70$ cm.$^{-1}$

$\alpha_e = 0.0019$ cm.$^{-1}$

$r_e = 1.922$ Å

<u>Heat of Formation</u>. Calculated from $\Delta H_f^\circ{}_{298.15}$ for PbO (c, red) and $\Delta H_s^\circ{}_{298.15}$.

<u>Heat Capacity and Entropy</u>. The ground state configuration, molecular and spectroscopic constants are obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York (1950), modified for the natural isotopic abundances reported by J. R. Stehn and E. F. Clancy, "Chart of the Nuclides", General Electric Co., N. Y. (1956).

α_e = 0.00562 cm.$^{-1}$

σ = 1

r_e = 1.481 Å

Heat of Formation.

The dissociation energy of sulfur monoxide has been reported by following investigators:

D_0 (SO) e.v.	(kcal. mole^{-1})	Investigator
5.053	(116.5)	E. V. Martin, Phys. Rev. 41, 167 (1932).
5.184	(119.5)	A. G. Gaydon, "Dissociation Energies", Chapman & Hall Ltd. London, 1953.
4.001	(92.3)	G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. 2nd Ed., 1950.
5.357	(123.5)	R. G. W. Norrish and G. A. Oldershaw, Proc. Roy. Soc. A249, 498 (1959).
5.510	(127.1)	J. J. McGarvey, W. D. McGrath, Proc. Roy. Soc. A278, 490 (1964).

E. V. Martin, loc. cit., has measured the spectrum of SO(g) in the region 2400-4000 Å, and both Herzberg's and Gaydon's data were based on Martin's spectroscopic measurement. Because of the ambiguity of defining the state of excitation of the atomic products resulting from predissociation, the dissociation energy of SO was in question. Herzberg favored D_0 (SO) = 92.3 kcal. mole^{-1} but Gaydon D_0 (SO) = 119.5 kcal. mole^{-1}.

Norrish and Oldershaw, loc. cit., redetermined the absorption spectrum of SO by flash photolysis, and also corrected Martin's original vibrational numbering, and then obtained the dissociation energy, D_0(SO) = 123.5 kcal. mole^{-1}, based on the assumption of predissociation into $S(^1D)$ and $O(^3P)$. This value, D_0 = 123.5 kcal. mole^{-1}, has been selected as the dissociation energy for SO(g) and combination with JANAF values of ΔH_f° (S; g) and ΔH_f° (O; g) gives the heat of formation of sulfur monoxide, $\Delta H^\circ_{f\ 298}$ = 1.64 ± 0.3 kcal. mole^{-1}, which is adopted in this tabulation.

R. Colin, P. Goldfinger and M. Jeunehomme, Trans. Faraday Soc. 60, 306 (1964), have confirmed the selected D_0 (SO) = 123.5 kcal. mole^{-1} in their mass spectrometric studies on the vaporization of CaS, SrS and BaS. J. J. McGarvey and W. D. McGrath, loc. cit., reported the dissociation energy to be 127.1 kcal. mole^{-1} based on their ultraviolet spectroscopic studies. This value appears to be the D_e from the minimum of the potential curve which corresponds to D_0 (SO) = 125 ± 1.5 kcal. mole^{-1}.

Besides the spectroscopic information , G. St. Pierre and J. Chipman, J. Am. Chem. Soc. 76, 4787 (1954), have reported $\Delta H^\circ_{r\ 298}$ = -19 kcal. mole^{-1} for the reaction 0.5 S_2(g) + 0.5 O_2(g) → SO(g) in the equilibrium study of lime-iron oxide slags with SO_2 or SO_2-CO mixtures. Using $\Delta H^\circ_{f\ 298}$ (S_2; g) = 30.8 kcal. mole^{-1}, the derived heat of formation, $\Delta H^\circ_{f\ 298}$ (SO; g) = -3.6 kcal. mole^{-1} was obtained. However, this value is doubtful because the reported $\Delta H^\circ_{r\ 298}$ = -19 kcal. mole^{-1} was dependent upon many assumptions and subsidiary data. E. W. Dewing and F. D. Richardson, Trans. Faraday Soc. 54, 679(1958) have measured the equilibrium constants for the reaction $S_2(g) + 2SO_2(g) \rightarrow 4SO(g)$ at 1250°C. and $SO_2(g) \rightarrow SO(g) + 1/2\ O_2(g)$ at 1500°C. Using the JANAF auxiliary data, the former yields $\Delta H^\circ_{f\ 298}$ (SO; g) = +0.13 kcal. mole^{-1} and the latter -0.17 kcal. mole^{-1}, respectively. The average of these two values is $\Delta H^\circ_{f\ 298}$ = 0 kcal. mole^{-1}. Although D. Meschi and R. Myers, J. Mol. Spectry. 3, 405 (1959) and U. Blukis and R. Myers, J. Phys. Chem. 69, 1154 (1965), have certainly concluded in their microwave spectroscopic studies that the S_2O species was one of the important products in the Sulfur - SO_2 equilibrium which was considered as unimportant by Dewing and Richardson, the value, $\Delta H^\circ_{f\ 298}$ (SO; g) = 0 kcal. mole^{-1}, derived from Dewing and Richardson is still very close to the selected value, $\Delta H^\circ_{f\ 298}$ (SO; g) = 1.64 kcal. mole^{-1}.

OS

Heat Capacity and Entropy.

The molecular constants ω_e, $\omega_e x_e$ and α_e were obtained from R. Norrish and G. Oldershaw, loc. cit., and the values of r_e and B_e were recently measured in the microwave spectrum by F. X. Powell and D. R. Lide, Jr., J. Chem. Phys. 41, 1413 (1964).

Heat of Formation.

There is no direct measurement of the standard enthalpy of formation for $S_2O(g)$. U. Blukis and R. Myers, J. Phys. Chem., 69, 1154 (1965), have discussed the discrepancy of the values of $\Delta H^\circ_{f\ 0}$ which vary from -1 to -35 kcal. mole^{-1}. R. Hagmann, Compt. Rend., 225, 1102 (1962), reported $\Delta H^\circ_{f\ 0}$ = -17 kcal. mole^{-1} from his ionization and appearance potential measurements by mass spectrometry. R. Steudel and P. W. Schenk, Z. Physik Chem., 43, 33 (1964), estimated the enthalpy of formation as -22.7 kcal. mole^{-1}. If the bond dissociation energies D_0(S-O) = 123.5 kcal. mole^{-1} and D_0(S-S) = 101 kcal. mole^{-1} were used to estimate the dissociation energy of S_2O (i.e. $D_0(S_2O)$ = 224.5 kcal. mole^{-1}), one will obtain $\Delta H^\circ_{f\ 0}$ = -35.3 kcal. mole^{-1}. A. V. Jones, J. Chem. Phys. 18, 1263 (1950), reported the predissociation energy, 91 kcal. mole^{-1}, for sulfur monoxide from the infrared and ultraviolet spectra. [D. Meschi and R. Myers, J. Mol. Spectro. 3, 405 (1959), have concluded from their experiment that the so called sulfur monoxide is S_2O.] Therefore, if SO(g) + S(g), were the dissociation products, the $\Delta H^\circ_{f\ 0}$ would be -25.4 kcal. mole^{-1}; and if $S_2(g)$ + O(g) were the products, the $\Delta H^\circ_{f\ 0}$ would be -1.2 kcal. mole^{-1}. (All JANAF auxiliary data used in calculation.)

E. Dewing and F. Richardson, Trans. Faraday Soc., 54, 679 (1958), have investigated the gas phase equilibria in the sulfur-oxygen vapor at 1250° and 1500°C respectively. U. Blukis and R. Myers (loc. cit.) recalculated their data based on the assumption that the S_2O (instead of SO) was the major product in the equilibrium, and obtained $\Delta H^\circ_{f\ 0}$ = -13 kcal. mole^{-1} for $S_2O(g)$ which is adopted in this table.

Heat Capacity and Entropy.

The bond distance, angle, and vibrational frequencies were obtained from the microwave and infrared spectra measurements by D. Meschi and R. Myers, loc. cit., and U. Blukis and R. Myers, loc. cit. The three principal moments of intertia are I_A = 2.0219 X 10^{-39}, I_B = 16.6342 X 10^{-39} and I_C = 18.6560 X 10^{-39} g. cm.^{2}

B_e = 0.7273 α_e = 0.00508 r_e = 1.509 Å

Heat of Formation

The adopted value is based on equilibrium data summarized below. The more reliable results from three different reactions lie in the range from about -23 to -26 kcal/mol. Extreme values, including -20 and -32 kcal/mol, can be discounted on experimental grounds. Margrave (1) recently reported ΔHr°_{298} = 82.8±1.5 kcal/mol for $0.5SiO_2(s)+0.5Si(s) = SiO(g)$, but details are not yet available. Assuming that this corresponds to reaction A below, we calculate ΔHf°_{298} = -25.4 kcal/mol. Reaction A involves the nominal composition SiO(s) which is treated as an intimate mixture of $0.5Si(c)+0.5SiO_2$(high cristobalite). X-ray studies (13, 14) suggest that the condensed "SiO" used in (4, 8) is probably a mixture of Si and amorphous or vitreous SiO_2. The adopted ΔHf° corresponds to D_0° = 190±3 kcal/mol. This may be compared with D_0'' = 179 kcal/mol obtained by linear Birge-Sponer extrapolation of the ground state vibrational constants and with D_0 = 185±7 kcal/mol obtained by Barrow (15) from D_0'(LBX) = 77.5 kcal/mol for the excited state at 52580 cm^{-1}. Barrow assumed D_0'/D_0'(LBX) = 0.456 based on related molecules.

Heat Capacity and Entropy

All constants for the ground state and the $A^1\Pi$ State at 42640 cm^{-1} are taken from the analysis of the A→X system reported by Lagerqvist (16). An intercombination transition has been observed and assigned as $^1\Sigma^- \leftarrow a^3\Pi_r$ by Verma (17). The value of the a-X excitation energy is unknown but is estimated here as 30000±5000 cm^{-1} by comparison with the a and A states of CO and AℓCl. Several additional excited states are known (15, 16) to lie near or above the A state, but they are omitted because their contribution to the thermal functions is negligible.

Dec. 31, 1960; Mar. 31, 1967

TITANIUM MONOXIDE, ALPHA (α-TiO) (CRYSTAL) GFW = 63.8994

$S°_{298.15}$ = [12.2] gibbs/mol

Tt = 1264°K

$\Delta Hf°_0 = -123.48 \pm 1$ kcal/mol

$\Delta Hf°_{298.15} = -124.19 \pm 1$ kcal/mol

$\Delta Ht° = 0.83$ kcal/mol

$\Delta Hs°_{298.15} = 128 \pm 10$ kcal/mol

Heat of Formation.

G. L. Humphrey, J. Am. Chem. Soc. 73, 1587 (1951), determined the heat of combustion $\Delta Hr°_{298} = -101.61 \pm 0.12$ kcal/mol for the reaction $TiO(\alpha) + 1/2O_2(g) = TiO_2(rutile)$. Based on this result and on $\Delta Hf°_{298}(rutile) = -225.8 \pm 1$ kcal/mol, the adopted $\Delta Hf°_{298}$ for TiO(α) is calculated to be -124.19 ± 1 kcal/mol. A value of -125.4 ± 0.4 kcal/mol was reported by S. M. Ariya, M. P. Morozova and E. Vol'f, Russ. J. Inorg. Chem. (English Transl.) 2, 16 (1957), who measured the heats of combustion of various compositions in the Ti-O system. Ariya et al. used an estimated correction for the formation of TiO_{2-x}, while Humphrey obtained values of 0.2 - 0.4 kcal/mol by grinding the product and reburning it with white oil. Most of the assigned uncertainty arises from this problem of non-stoichiometry [see TiO_2(rutile) for further details].

Heat Capacity and Entropy.

The low temperature heat capacities, 52.6 - 296.3°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 68, 310 (1946). The high temperature enthalpies, 357.0 - 1771°K, were determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), by use of drop calorimetry. The high temperature Cp's, 357 - 1200.5°K, derived from the enthalpy data, are joined smoothly with the low temperature heat capacities at 298°K. The Cp values above 1200°K are obtained by extrapolation. The entropy is obtained from Cp° using $S°_{50} = 4.13$ eu; this extrapolation includes 0.23, 1.7 and 2.2 eu for contributions of the lattice, of vacancies and of spin magnetic effects, respectively.

P. W. Gilles, J. Chem. Phys. (in press), discussed the inconsistencies in the thermodynamic properties of TiO as derived from widely different measurements. These inconsistencies include(1) a difference of 10 kcal/mol in $D°_0$ values for TiO(g) obtained from vaporization of TiO and Ti_3O_5,(2) a difference of about 10 kcal/mol between the calorimetric data for TiO(β) and a recent re-assessment of the partial free energy of dissociation for the TiO system, and(3) emf. data which suggest that the entropy of TiO(β) should be increased relative to those of Ti and Ti_2O_3. In order to minimize these discrepancies, we tentatively increase the experimental value of $S°_{298}$ by addition of estimated contributions due to vacancies in the crystal lattice and to spin-magnetic effects of Ti^{++} ion.

P. Ehrlich, Z. Elektrochem. 45, 362 (1939) and Z. Anorg. Chem. 247, 53 (1941), concluded from the difference in pycnometric and X-ray densities of TiO(β) that about 15 percent of the Ti and O lattice sites are vacant. This was confirmed later by S. Anderson, B. Collen, U. Kuylenstierna and A. Magneli, Acta. Chem. Scand. 11, 1641 (1957), A. D. Pearson, J. Phys. Chem. Solids 5, 316 (1958), and M. E. Straumanis and H. W. Li, Z. Anorg. Allgem. Chem. 305, 143 (1960). Andersson et al. noted that there may be a "close structural kinship" between the α and β forms, based on the similarity of their densities and the pronounced relationship between their powder diffraction patterns. The authors suggested that the (presumably) random vacancies in TiO(β) may occur in an ordered way in TiO(α). Recent electron diffraction studies by J. M. Cowley, Acta Cryst. (to be published), may provide an answer to this problem. Assuming the vacancies to be randomly arranged, we estimate the residual entropy of TiO(α) due to vacancies as $-2R(0.85 \ln 0.85 + 0.15 \ln 0.15) = 1.7$ eu, based on the method proposed by M. Hoch, A. S. Iyer and J. Nelken, J. Phys. Chem. Solids 23, 1463 (1962). An alternative possibility for increasing the entropy of TiO(β) is discussed in the Transition Data section of the table for TiO(β).

Metallic-type conductivity of TiO(α) at temperatures 80 - 1000°K was reported by A. D. Pearson, loc. cit., and F. J. Morin, Phys. Rev. Letters 3, 34 (1959). This led J. B. Goodenough, Phys. Rev. 117, 1442 (1960), to suggest the existence of strong cation-cation interactions and the possibility of a low temperature transformation of the martensitic or antiferromagnetic type. Goodenough noted that the isoelectric compound VN becomes superconducting below 8.2°K. We approximate the entropy contribution of these various possibilities at 50°K by a spin-magnetic term of $R\ln 3 = 2.2$ eu.

Transition Data.

See TiO(β) table.

Heat of Sublimation.

The difference between $\Delta Hf°_{298}$ for TiO(g) and TiO(α) is $\Delta Hs°_{298}$.

Mar. 31, 1967

TITANIUM MONOXIDE, BETA (β-TiO) (CRYSTAL) GFW = 63.8994

$S^\circ_{298.15}$ = [12.372] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [-123.872] kcal/mol

Tt = 1264°K ΔHt° = 0.83 kcal/mol

Tm = 2023°K ΔHm° = [13] kcal/mol

Heat of Formation.

The $\Delta Hf^\circ_{298}(\beta)$ is obtained from $\Delta Hf^\circ_{298}(\alpha)$ by adding ΔHt° and the difference between $H^\circ_{1264} - H^\circ_{298}$ for TiO(α) and TiO(β).

Heat Capacity and Entropy.

High temperature enthalpies, 1273 - 1771°K, have been measured with a drop calorimeter by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946). The adopted heat capacities are derived from these data, assuming the final state to be TiO(α). This problem is discussed in the Transition Data section. Cp values below 900°K are assumed to be the same as those for TiO(α). The heat capacities at temperatures 900 - 1273°K and above 1771°K are obtained by extrapolation.

The S°_{298} is derived in a manner analogous to that of the heat of formation.

Transition Data.

Tt and ΔHt° are derived from the enthalpy data of Naylor, loc. cit., assuming that TiO(α)is the final state of the drop experiment. The X-ray studies of C. C. Wang and N. J. Grant, J. Metals 8, 184 (1956), and A. D. Pearson, J. Phys. Chem. Solids 5, 316 (1958), appear to contradict this assumption. These authors found that the α form of stoichiometric TiO was obtained at room temperature only by annealing the β phase for long periods below 1223°K. Samples quenched from temperatures of 1223°K or higher retained the NaCl structure of the β form. Since the drop calorimetric experiment is similar to quenching, it is possible that the final state was mostly the β form. If this is the case, then the derived values of ΔHt° and ΔSt° are probably much too small. This would be an alternative means for increasing the entropy of TiO(β). It is possible, however, that differences in particle size allowed Naylor's sample to drop to the α form, or that the β form was stabilized by impurities in the X-ray studies. Further experiments are desirable in order to resolve this question. Also related to the question is the fact that the structure of TiO(α) has not been reported, probably because the X-ray diffraction pattern is quite complex.

P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), reviewed the phase data and presented the most current phase diagram for the Ti-O system. This diagram suggests that stoichiometric TiO(α) starts to transform near 1210°K with formation of the two phases $TiO_{1+x}(\beta)$ and Ti_2O. Transformation to stoichiometric TiO(β) is complete near 1270°K, which is essentially the Tt chosen by Naylor. This behavior is consistent with Naylor's observation of "pre-transition effects" in the enthalpy between 1224 and 1264°K.

Melting Data.

See TiO(l) table for details.

Dec. 31, 1960; Mar. 31, 1967

TITANIUM MONOXIDE (TiO) (LIQUID) GFW = 63.8994

$S^\circ_{298.15}$ = [14.235] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [-112.801] kcal/mol

Tm = 2023°K ΔHm° = [13] kcal/mol

Tb = [3934] °K ΔHv° = [91.6] kcal/mol

Heat of Formation.

The value of ΔHf°_{298} for TiO(l) is obtained from that of TiO(β) by adding ΔHm° and the difference between $H^\circ_{2023} - H^\circ_{298}$ for TiO(β) and TiO(l).

Heat Capacity and Entropy.

The heat capacity for TiO(l) is estimated on the basis of 8 cal/g-atom. S°_{298} is obtained in a manner analogous to that of the heat of formation.

Melting Data.

Tm is taken from W. Dawihl and K. Schröter, Z. Anorg. Allgem. Chem. 233, 178 (1937). The heat of melting is estimated by comparison with that of VO(c) reported by C. E. Wicks and F. E. Block, U. S. Bur. Mines Bull. 605, 1963.

Tm has also been reported as 2023 and 2103°K by H. Nishimura and H. Kimura, J. Japan Inst. Metals (Sendai) 20, 589 (1956), and R. DeVries, R. Roy, and E. Osborne, Trans. Brit. Ceram. Soc. 53, 525 (1954), respectively. According to the Ti-O phase diagram reported by P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), TiO melts incongruently.

Vaporization Data.

Tb is calculated as the temperature at which the Gibbs energy change of the reaction TiO(l) = TiO(g) approaches zero. The difference between ΔHf° for TiO(g) and TiO(l) at Tb is ΔHv°.

Heat of Formation.

P. W. Gilles, J. Chem. Phys. (to be published), has discussed the difference of about 10 kcal/mol in the dissociation energies of TiO(g) obtained from vaporization of $Ti_3O_5(\beta)$ and TiO(β). By mass spectrometric and Knudsen effusion techniques, P. G. Wahlbeck and P. W. Gilles, J. Chem. Phys. 46, 2465 (1967), studied congruently vaporizing $Ti_3O_5(\beta)$ and derived D°_0(TiO, g) = 7.26 ± 0.10 eV. Values of 6.88, 6.93 and 6.8 eV were derived from incongruently vaporizing TiO(β) in earlier studies reported by G. D. Wheatley, Ph. D. Thesis, University of Kansas, 1954; W. O. Groves, M. Hoch, and H. L. Johnston, J. Phys. Chem. 59, 127 (1955); and J. Berkowitz, W. A. Chupka, and M. G. Inghram, J. Phys. Chem. 61, 1569 (1957). A spectroscopic value of 6.8 eV is obtained by Birge-Sponer extrapolation of the vibrational constants given on this table. Related discrepancies are listed in the Heat Capacity and Entropy section of the table for TiO(α).

G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950, reported D°_0 = 6.9 eV.

In order to minimize these discrepancies, we tentatively increase the entropy of TiO(α) [see TiO(α) table for details] and re-evaluate the vapor pressure data by the second and third law methods. The results are given in the table below. Values derived from TiO(β) are uncertain due to excess oxygen in the condensed phase; e.g., the sample of Groves et al. contained an excess of about 3%. Our analysis assumes that the activity of TiO is unity in the actual condensed phase. The value of ΔHf°_{298}(TiO, g) adopted is 3.75 ± 5 kcal/mol.

Investigator	Reaction	Temperature, °K	No. of Points	ΔHr°_{298}, kcal/mol 2nd law	ΔHr°_{298}, kcal/mol 3rd law	Drift eu	ΔHf°_{298}* kcal/mol
Wahlbeck-Gilles	(A)	1837 - 2014	24	711.3 ± 7.7	715.72	2.2 ± 4.1	3.75
Groves et al.	(B)	1847 - 1968	8	157.7 ± 5.0	128.7	-15.1 + 2.6	4.83
Berkowitz et al.	(B)	2027, 2072	2	139.4**	129.4		5.53

(A) $Ti_3O_5(\beta) = TiO(g) + 2O(g)$. (B) $TiO(\beta) = TiO(g)$

*Calculation based on the third law ΔHr°_{298} value. The corresponding D°_0(TiO, g) values are 167.83, 166.75 and 166.05 kcal/mol.

**Average 2nd law value from ion intensities.

Heat Capacity and Entropy.

The electronic spectrum of TiO(g) consists of both singlet and triplet systems with near-degenerate low-lying states. The lowest-lying triplet was originally thought to be $^3\Pi$ by Herzberg, loc. cit., B. Rosen, "Selected Constants," Hermann & Co., Paris, 1951, and J. G. Phillips, J. Astrophys. 115, 567 (1952); ibid., 119, 274 (1954), but has been reidentified as $X^3\Delta_r$ by U. Uhler, Dissertation, University of Stockholm, Sweden, 1954, and W. Weltner, Jr. and D. McLeod, Jr., J. Phys. Chem. 69, 3488 (1965). The values of the three lowest electronic levels and quantum weights are obtained from Herzberg. A $a^1\Delta$ state lying about 581 cm^{-1} above the ground state was reported by Phillips, loc. cit. A. V. Pettersson and B. Lindgren, Arkiv Fysik 22, 491 (1962); A. V. Pettersson, ibid., 16, 185 (1959), reported two electronic states, $d^1\Sigma$ and $b^1\Pi$, at 1708.0 and 10814.4 cm^{-1} above $^1\Delta$; thus, the values of 2289 and 11395.4 are derived. The next two electronic levels, $^3\Phi$ and $^3\Pi$, are obtained from Weltner et al., and the value $^1\Phi$ = 18502 cm^{-1} is obtained from Rosen. The last three levels and the values of $\omega_e x_e$, ω_e, B_e, α_e and r_e are taken from Herzberg, loc. cit. The moment of inertia is 5.226 x 10^{-39} g cm^2.

The rather thorough studies of the emission spectra of TiO(g) have been summarized by R. W. B. Pearse and A. G. Gaydon, "The Identification of Molecular Spectra," 3rd Ed., John Wiley & Sons, Inc., New York, 1963, and A. Gatterer, J. Junkes, E. W. Salpeter, and B. Rosen, "Molecular Spectra of Metallic Oxides," Vatican Press, Vatican City, 1957.

June 30, 1962; Mar. 31, 1963; Sept. 30, 1966

TUNGSTEN MONOXIDE (WO) (IDEAL GAS) GFW = 199.8494

Ground State Configuration $[^3\Sigma^-]$

$S^\circ_{298.15}$ = [58.7] gibbs/mol

ΔHf°_0 = 101.7 ± 10 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 101.6 ± 10 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
[0]	[3]
[14160]	[1]
[17211]	[2]
[19189]	[6]

ω_e = 1055 cm^{-1} $\omega_e x_e$ = [3.85] cm^{-1} σ = 1

B_e = [0.3498] cm^{-1} α_e = [0.0016] cm^{-1} r_e = [1.81] Å

Heat of Formation

The heat of formation, $\Delta Hf^\circ_{298}(WO,g)$ = 101.6 kcal/mol, was derived from the heat of reaction, ΔHr°_{298} = -42.0 kcal/mol for $WO(g) \rightarrow W(c) + O(g)$ with all JANAF auxiliary data. The value of ΔHr°_{298} was calculated by the third law method from the partial pressure data, which were determined mass-spectrometrically in the temperature range 2188° to 2475°K, by G. DeMaria, R. P. Burns, J. Drowart and M. G. Inghram, J. Chem. Phys. 32, 1373 (1960). The drift in the third law analysis was -20 ± 7 eu.

Heat Capacity and Entropy

The fundamental vibrational frequency, the ground state configuration, and the probable electronic levels for tungsten monoxide (g) were obtained from the infrared and ultraviolet spectroscopic investigations by matrix isolation by W. Weltner, Jr., and D. McLeod, Jr., J. Mol Spectry. 17, 276 (1965). The rotational constant B_e was calculated from an estimated bond distance, W-O = 1.81 Å. The value of x_e was calculated from the relation $x_e u_e^{1/2}$ = 0.014 which was given by R. F. Barrow and A. D. Caunt, Proc. Roy. Soc. (London) 219A, 120 (1953). The constant, 0.014, was estimated, based on those for ZrO(g) and VO(g). The value of α_e was calculated from the Morse potential function.

$\omega_e x_e$ = 4 cm.$^{-1}$

α_e = 0.0023 cm.$^{-1}$

r_e = 1.711 Å

σ = 1

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ = 14.0 ± 12 kcal. mole^{-1} was calculated from the $\Delta H^\circ_{r\ 298.15}$ = 290.342 ± 12.8 kcal. mole^{-1} for the reaction $Zr(c) + ZrO_2(c) = 2ZrO(g)$. The value of $\Delta H^\circ_{r\ 298.15}$ was obtained by the third law analysis from the mass spectrometric studies of W. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 26, 1207 (1957). They observed the variation of the ZrO^+ ion intensity over the system $Zr + ZrO_2$ and reported equilibrium constants for the reaction $Zr + ZrO_2 \rightarrow 2ZrO$ in the range 2124-2322°K. The third law drift is -58 ± 28 e.u.

Heat Capacity and Entropy.

The ground state of ZrO(g) was assumed to be $^1\Sigma^+$ as determined from the matrix isolation spectra of W. Weltner, Jr., and D. McLeod, Jr., J. Phys. Chem. 69, 3488 (1965). Previously this had been described as the lower state in the A band system reported by V. Uhler and L. Akerlind, Arkiv Fysik 10, 431 (1955).

All molecular constants were obtained from Uhler and Akerlind,loc. cit.,except ω_e = 978 cm.$^{-1}$ and $\omega_e x_e$ = 4 cm.$^{-1}$ which were calculated from ω and α_e = 0.0023 cm.$^{-1}$ using the equations

$$\alpha_e = \frac{6\sqrt{\omega_e x_e \cdot B_e^{\,3}}}{\omega_e} - \frac{6\,B_e^{\,2}}{\omega_e} \quad \text{and} \quad \omega = \omega_e - 2\,\omega_e x_e = 969.76 \text{ cm.}^{-1}$$

The higher electronic levels were obtained or estimated from the correlation diagram given by Weltner and McLeon,loc. cit.

OXYGEN, DIATOMIC (O_2)   (REFERENCE STATE - IDEAL GAS)   MOL. WT. = 31.9988

Ground State Configuration $^3\Sigma_g^-$ $\Delta H^\circ_{f\ 0} = 0$

$S^\circ_{298.15} = 49.00 \pm 0.01$ cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15} = 0$

$\omega_e = 1580.246$ cm.$^{-1}$ $\omega_e x_e = 12.071$ cm.$^{-1}$ $\sigma = 2$

$B_e = 1.445$ cm.$^{-1}$ $\alpha_e = 0.0158$ cm.$^{-1}$ $r_e = 1.2074$ Å

Heat of Formation.

The heat of formation (ΔH_f°) for O_2(g) is zero at all temperatures, by definition.

Heat Capacity and Entropy.

The functions adopted here are based on those of H. W. Woolley, J. Research, Nat. Bur. Standards 40, 163 (1948), who used a direct summation to 5000°K. The spectroscopic constants used were the same as those listed by G. Herzberg, Spectra of Diatomic Molecules", D. Van Nostrand Co., 1950. Raman measurements of rotation-vibration levels by A. Weber and E. A. McGinnis, J. Molec. Spect. 4, 195 (1960), support the constants selected by Herzberg which were changed on this table to apply to the naturally occurring isotopic composition given by D. Strominger, J. M. Hollander, and T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

The entropies listed by Woolley were reduced by 0.0065 cal. deg.$^{-1}$ mole^{-1} which was added by Woolley to account for the contribution due to the presence of both odd and even rotational levels in O^{16}-O^{17} and O^{16}-O^{18} molecules. This correction is not necessary when isotope mixing entropy is neglected, cf. W. F. Giauque and R. Overstreet, J. Am. Chem. Soc. 54, 1731 (1932).

σ = 2

B_e = 1.247 cm^{-1}

α_e = [0.013] cm^{-1}

r_e = 1.30 Å

Heat of Formation.

The electron affinity of O_2(g) has been measured in the electron detachment experiments of J. L. Pack and A. V. Phelps, J. Chem. Phys. 44, 1870 (1966). The value reported is 0.43 ± 0.02eV (9.92 ± 0.46 kcal/mol) which is in good agreement with the value 0.46 ± 0.1eV selected by C. W. Beckett and E. C. Cassidy, Natl. Bur. Std. Report 8628, Jan. 1, 1965.

Heat Capacity and Entropy.

J. Rolfe, J. Chem. Phys. 40, 1664 (1964), has deduced from fluorescence emission spectra of O_2^-, in alkali halides, the vibrational constants and an exited electronic level. The $^2\Pi$ ground state is that predicted by molecular orbital theory and the first excited state should also be $^2\Pi$. By analogy with Cl_2^+, which is isoelectronic, the first excited level is estimated to lie in the 20000 - 30000 cm^{-1} region. Thus, the level observed by Rolfe is assumed to be the first excited $^2\Pi_u$ state. The bond length is taken from F. R. Gilmore, The Rand Corporation, Memorandum RM-4034-1-PR, AD 630997. B_e was calculated from the bond length,and α_e was estimated from the above quantities using the Morse potential function relation.

The enthalpy at 0°K is -2.086 kcal/mol.

Dec. 31, 1960; Sept. 30, 1962

Phosphorus Dioxide (PO_2) (Ideal Gas)

Mol. Wt. = 62.975

ΔH_f° 298.15 = [-71] kcal. mole^{-1}

$S^\circ_{298.15}$ = [60.6] cal. deg.$^{-1}$ mole^{-1}

Point Group = C_{2v}

Ground State Degeneracy = 2

<u>Vibrational Frequencies and Degeneracies</u>

ω, cm.$^{-1}$
[980] (1)
[515] (1)
[1044] (1)

Angle O-P-O = 134° 4'　　P-O distance = 1.485 Å

I_A = [10.81 X 10^{-39}] g. cm.^{2}　　I_B = [9.933 X 10^{-39}] g. cm.^{2}

I_C = [0.877 X 10^{-39}] g. cm.^{2}　　σ = 2

<u>Heat of Formation</u>. ΔH_f° 298.15 was calculated from an estimated heat of dissociation (270 ± 25 kcal. mole^{-1}) reported by L. Brewer and G. M. Rosenblatt, Chem. Reviews, <u>61</u>, 257 (1961).

<u>Heat Capacity and Entropy</u>. The molecular constants selected for this table were estimated by J. S. Gordon. The molecular constants for $PO_2(g)$ have been estimated by (1) J. S. Gordon, "Thermodynamic Data for Combustion Products," January 1960, Thiokol Chemical Corp., Reaction Motor Division, Denville, N. J.; (2) R. L. Potter, V. N. DiStefano and S. N. Fox, "The Thermodynamic Functions of Some Combustion Products Containing Phosphorus-I," American Cyanamid Company; and (3) C. B. Henderson and R. S. Scheffee, "Survey of Thermochemical Data," January 1960, Atlantic Research Corp., Alexandria, Virginia. The entropies at 3000° calculated from these three estimates differ by less than 0.8 cal. deg.$^{-1}$ mole^{-1}.

Lead Dioxide (PbO_2)

O_2Pb

Lead Dioxide (PbO_2) (Crystal)

Mol. Wt. = 239.21

$\Delta H_f^\circ{}_{298.15} = -64.55 \pm 0.16$ kcal. mole^{-1}

$S^\circ_{298.15} = 18.3 \pm 0.5$ cal. deg.$^{-1}$ mole^{-1}

Heat of Formation. Recalculated from $\Delta H^\circ_{290.15} = 12.14$ kcal. mole^{-1} for the reaction: $PbO(c) + 1/2O_2(g) = PbO_2(c)$ reported by M. Tscheltzow, Compt. rend., 100, 1458 (1885).

Heat Capacity and Entropy. C_p (69.9° to 297.2°K.) reported by R. W. Millar, J. Am. Chem. Soc. 51, 207 (1929). Above 298.15°K., the heat capacity value estimated by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation.

Heat of Formation

J. R. Eckman and F. D. Rossini, J. Research Nat. Bur. Standards 3, 597 (1929), measured the heat of combustion of rhombic sulfur to SO_2. Changes due to different atomic weights and electrical constants though negligible have been made.

Heat Capacities and Entropies

The functions were calculated by J. Gordon, private communication, Feb. 2, 1961, using the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954). Structural parameters are given by M. H. Sirvetz, J. Chem. Phys. 19, 938 (1951), obtained from microwave measurements. Frequencies were measured by R. D. Shelton, A. H. Nielsen, W. H. Fletcher, J. Chem. Phys. 21, 2178 (1953) and ibid., 22, 1791 (1954). A third law value of $S_{298.15} = 59.24$ cal. deg.$^{-1}$ mole^{-1} was obtained by W. F. Giauque and C. C. Stevenson, J. Am. Chem. Soc. 60, 1389 (1938).

QUARTZ (SiO_2) (CRYSTAL) GFW = 60.0848 O_2Si

$S^\circ_{298.15}$ = 9.91 ± 0.03 gibbs/mol

Tt_1 = 847 ± 1.5°K(low quartz → high quartz)

Tt_2 = 1079 ± 250°K(high quartz → high cristobalite)

Tm = 1696 ± 50°K(high quartz → liquid)

ΔHf°_0 = −216.5 ± 0.4 kcal/mol

$\Delta Hf^\circ_{298.15}$ = −217.7 ± 0.4 kcal/mol

ΔHt°_1 = 0.174 ± 0.04 kcal/mol

ΔHt°_2 = 0.48 ± 0.15 kcal/mol

ΔHm° = 1.84 ± 0.2 kcal/mol

Heat of Formation

The heat of formation is based on data of Wise (1) for combustion of SiO_2(low quartz) and Si(c) in F_2 to form SiF_4(g). Good (2) burned a mixture of Si(c) and vinylidene fluoride polymer in oxygen in the presence of HF(aq) to form H_2SiF_6(aq HF). Combining this result with a previous heat of solution of quartz (3), the authors derived ΔHf°_{298} = −217.5 ± 0.5 kcal/mol. Agreement with the adopted value is excellent, considering the complexity of the latter scheme. Both schemes are independent of ΔHf°(HF), although the polymer-Si scheme depends on the heat of dilution of HF(aq). Wise (1) has reviewed other data which confirm the adopted value rather than the oxygen combustion value (4) of −209.9 kcal/mol. Pertinent equilibrium data are analyzed on the table for SiO_2(low cristobalite), while the calorimetric results are summarized below.

Source	Reaction	ΔHr°_{298}, kcal/mol	ΔHf°_{298}, kcal/mol
1. Wise (1963)	SiO_2(low quartz) + $2F_2$(g) → SiF_4(g) + O_2(g)	−168.26 ± 0.28	−217.72 ± 0.34
2. Good (1964)	See text.	-	−217.5
3. Humphrey (1952)	Si(c) + $2O_2$(g) → SiO_2(low quartz)	−209.9	−209.9

Heat Capacity and Entropy

Heat capacities below 300°K are based on data of Jones (5) and Westrum (6). Earlier data of Anderson (7) are in good agreement. The entropy is obtained from Cp° using S°_2 = 0.00001 eu. Cp° from 300° to 847°K is derived from adiabatic calorimetric data of Moser (8) and Sinel'nikov (9). The adopted Cp° is discontinuous at 847°K and ΔCp° = −2.17 gibbs/mol. Values above the transition temperature are based on data of Moser and on data up to 1473°K obtained with a thermal analysis method by Leonidov (10). Cp° is extrapolated linearly to higher temperatures.

From a review of data available before 1953, Kelley (11) selected almost identical enthalpies below 847°K but a value higher by 96 cal/mol at 900°K. The higher value, due to use of a larger ΔHt°_1, was presumably based on Roth (12), Wietzel (13) and White 14) whose enthalpy data were given the most weight by Kelley. Near 900°K these three sets of data deviate from the adopted function by −150±30, +130±40 and +15±35 cal/mol, respectively; however, a recent enthalpy datum (15) obtained by transposed temperature drop calorimetry deviates by +75 cal/mol at 968°K.

Transition Data

Tt_1 is taken as 847 ± 1.5°K based on thermal analysis of many specimens by Kieth and Tuttle (16). Wide variations in Tt_1 for some specimens were attributed by the authors to small amounts of impurities. The discontinuity in the volume curve (17) during inversion from trigonal low quartz to hexagonal high quartz suggests that the transition should be treated as first order. Thus, the heat of transition is derived as (1011-854+17) = 174 cal/mol, where 1011 ± 6 is ($H^\circ_{873.15} - H^\circ_{823.15}$) measured by Moser (8), 854 is the corresponding increment calculated from the JANAF Cp°, and 17 is an endpoint correction for the difference between the observed and adopted curves below 823.15°K. Some of the more recent data which confirm the adopted ΔHt°_1 are summarized below.

Source	Method		ΔHt°_1, kcal/mol
8. Moser (1936)	H and Cp from adiabatic calorimetry		0.174
9. Sinel'nikov (1953)	Integration of Cp from adiabatic calorimetry		0.143
10. Leonidov (1964)	Thermal analysis		0.198
17. Berger (1964)	ΔV with dT/dP = 0.026°K/atm		0.12
18. Berger (1965)	Microcalorimetric thermal analysis	Single crystal	0.156, 0.165, 0.178 ± 0.010
		Various crushed samples	0.124 to 0.193

Additional polymorphism of SiO_2 is discussed on the table for high cristobalite. Quartz has been superheated through the cristobalite region to some 300° above its metastable melting point. This melting point is calculated from the adopted tables as 1696 ± 50°K, which agrees well with the range 1673 - 1723°K indicated by the data of Mackenzie (19). The adopted tables predict the inversion of high quartz to high cristobalite at 1079 ± 250°K. Holmquist (20) tentatively placed this inversion at 1298 ± 25°K. ΔHt°_2 and ΔHm° are calculated from the differences in heats of formation of the appropriate phases at Tt_2 and Tm.

CRISTOBALITE, LOW (SiO_2) (CRYSTAL) GFW = 60.0848 O_2Si

ΔHf°_0 = -215.9 ± 0.5 kcal/mol

$S^\circ_{298.15}$ = 10.372 ± 0.03 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -217.1 ± 0.5 kcal/mol

Tt = 543 ± 3°K(low cristobalite → high cristobalite)

ΔHt° = 0.321 ± 0.06 kcal/mol

Heat of Formation

The heat of formation is calculated from that of quartz using ΔHr°_{970} = 0.45 ± 0.15 kcal/mol for high quartz → high cristobalite, as determined by Holm(1) from ΔHsoln in an oxide melt. This value reduces to ΔHr°_{298} = 0.60 kcal/mol for low quartz → low cristobalite. Kracek(2) obtained essentially the same value, ΔHr°_{298} = 0.63 kcal/mol, from ΔHsoln in HF(aq, 74.7°C), while Hummel(3) found ΔHr°_{298} = 1.80 kcal/mol from ΔHsoln in HF(aq, 26.5°C). The larger ΔHr° corresponds to a less negative ΔHf° (i.e., less stable) and suggests that the sample of Hummel has disorder approaching that of vitreous silica. Presumably, this disagreement arises from different methods of preparation of cristobalite from quartz. Holm heated for 24 hours at 1743°K, while Hummel heated for 4 hours at 1973°K. Hummel's sample was then ground and treated with dilute HF to remove amorphous surface layers created by grinding; particles smaller than 2.5 microns were used in order to obtain adequate rates of dissolution. Neither author gave X-ray or DTA evidence to confirm that the samples were the more stable, ordered form of cristobalite(15).

The calorimetric data are summarized below along with equilibrium data which confirm the adopted values of ΔHf° for cristobalite and quartz. Data from Matoba(5) and Rein(6) were reduced to the standard state of Si(ℓ) using activity coefficients from the curves of (10).

Source	Method	Reaction	Range T, °K	No. of Points	ΔHr°_T kcal/mol	ΔHr°_{298} kcal/mol	Drift eu	ΔHf°_{298} kcal/mol

*Values at T are from second law analysis while those at 298.15°K are from third law.

A. SiO_2(quartz, low or high) = SiO_2(cristobalite, low or high)

B. SiO_2(high cristobalite) + $2H_2(g)$ = Si(ℓ) + $2H_2O(g)$

C. SiO_2(high cristobalite) + 2C(graph) = Si(ℓ) + 2CO(g)

D. SiO_2(high cristobalite) + 2SiC(β) = 3Si(ℓ) + 2CO(g)

E. SiO_2(high cristobalite) + 3C(graph) = SiC(β) + 2CO(g)

Heat Capacity and Entropy

Cp° below 300°K is based on data of Westrum(11). Earlier data of Anderson(12) are in satisfactory agreement. The entropy is obtained from Cp° using S°_5 = 0.0007 eu. Cp° above 300°K is derived from enthalpy data of Mosesman(13) and White(14). The former deviate from the adopted functions by -0.7 to 0.5% and the latter by +0.4%. Although the functions above 300°K appear to be reliable, it would be desirable to have new data for a well-characterized sample (see Transition Data).

Transition Data

Low cristobalite is metastable with respect to quartz but persists up to Tt. Tt is taken as the temperature at the peak in the heating curve for well-ordered cristobalite; however, see (15, 16) for detailed discussions of temperatures about 25° lower which were found from cooling curves. ΔHt° is derived from enthalpy data(13, 14) for high cristobalite using the adopted enthalpy for the low form. The enthalpy data of Mosesman(13) gave a lower Tt which suggests that the sample was less well-ordered than desirable. ΔHt° is confirmed, however, by other data which are summarized below. Additional polymorphism is discussed on the table for high cristobalite.

CRISTOBALITE, HIGH (SiO_2) (CRYSTAL) GFW = 60.0848

$S^\circ_{298.15}$ = 11.963 gibbs/mol

Tt = 543 ± 3°K(low cristobalite → high cristobalite)

Tt = 1079 ± 250°K(high quartz → high cristobalite)

Tm = 1996 ± 5°K(high cristobalite → liquid)

$\Delta Hf^\circ_{298.15}$ = -216.417 kcal/mol

ΔHt° = 0.321 ± 0.06 kcal/mol

ΔHt° = 0.48 ± 0.15 kcal/mol

ΔHm° = 2.29 ± 0.5 kcal/mol

Heat of Formation

The heat of formation is calculated from that of low cristobalite by addition of ΔHt° = 0.321 kcal/mol and the difference between $H^\circ_{543} - H^\circ_{298}$ for low and high forms.

Heat Capacity and Entropy

Cp° is derived from enthalpies of Mosesman (1) and White (2), whose data deviate from the adopted functions by -0.6 to + 0.5% and +0.9 to 0.0%, respectively. White's deviations for cristobalite have a magnitude and trend similar to his deviations for quartz and vitreous silica. Data of Wietzel (3) for his sample prepared at 1600°C deviate by +3% at 673°K and +1.6% at 1973°K. Cp° below 543°K is smoothly extrapolated to give the proper trend in the Gibbs energy, but the heat capacity at 298°K is not realistic. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data

Literature on the polymorphism of SiO_2 is voluminous but is summarized in detail in recent books by Sosman (4) and Eitel (5). The known phases of SiO_2 include quartz, tridymite(?), cristobalite, vitreous silica and the more recently discovered high pressure phases. Muan (6) concisely reviewed the still controversial question of whether tridymite is stabilized only by the presence of foreign ions or whether it is a stable phase of SiO_2 intermediate between quartz and cristobalite. Transitions among the different phases are generally sluggish because of large energy barriers to the structural change and small differences in Gibbs free energies. As a result, the phases often persist far into metastable regions. In contrast, transitions within a particular phase are rapid and reversible (i.e., the low → high inversions of quartz or cristobalite).

High cristobalite is the stable phase near Tm. It becomes metastable with respect to quartz at lower temperatures but persists down to the high → low inversion at 543°K (see table for low cristobalite). The high form is cubic and the low form tetragonal (12, 13).

The adopted tables give 1079±250°K as the temperature at which ΔGr° = 0 for high quartz → high cristobalite; ΔHt° = 0.48±0.15 kcal/mol is the corresponding enthalpy difference. The uncertainty in Tt is derived from that in ΔHt° which, in turn, is taken from ΔHr°_{970} = 0.45±0.15 kcal/mol obtained by Holm (7) from ΔHsoln measurements in an oxide melt. It is apparent that Tt is extremely sensitive to small changes in G or H. Holmquist (8) tentatively placed this inversion at 1298±25°K but did observe cristobalite formation at temperatures as low as 1171°K.

Melting Data

Melting point data were reviewed by Schneider (9) and adjusted to the 1948 International Temperature Scale. The adopted melting point for cristobalite is based on Greig (10). ΔHm° is calculated as the difference in ΔHf° for liquid and crystal at Tm. Mackenzie et al. (11) showed that cristobalite may be superheated by as much as 40° above Tm due to its slow rate of fusion.

Dec. 31, 1960; Dec. 31, 1962; June 30, 1967

SILICON DIOXIDE (SiO_2) (LIQUID) GFW = 64.0848

$S^\circ_{298.15}$ = 11.455 ± 0.3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -215.74 kcal/mol

O_2Si

Tm = 1996 ± 5°K(high cristobalite → liquid)

ΔHm° = 2.29 ± 0.5 kcal/mol

Heat of Formation

The heat of formation is calculated from that of quartz using ΔHr°_{970} = 1.45 ± 0.15 kcal/mol for high quartz → $SiO_2(\ell)$, as determined by Holm (1) from ΔHsoln in an oxide melt. This value reduces to ΔHr°_{298} = 1.96 kcal/mol for low quartz → $SiO_2(\ell)$ and is consistent within ±0.3 kcal/mol with other calorimetric data summarized below. Earlier results were reviewed by Hummel (4).

Source	Method	Reaction	T, °K	ΔHr°_T kcal/mol	ΔHr°_{298} kcal/mol	ΔHf°_{298} kcal/mol
1. Holm (1967)	ΔHsoln in oxide melt	A	970	1.45±0.15	1.96	-215.74
2. Wise (1963)	ΔHc in fluorine	B	298	1.78±0.46	1.78	-215.92
3. Kracek (1953)	ΔHsoln in HF(aq, 74.7°C)	A	298-348	-	2.18±0.05	-215.52
4. Hummel (1959)	ΔHsoln in HF(aq, 26.5°C)	A	300	2.27±0.2	2.27	-215.43

A. SiO_2(quartz, low or high) → $SiO_2(\ell)$

B. $SiO_2(\ell) + 2F_2(g) \rightarrow SiF_4(g) + O_2(g)$

Heat Capacity and Entropy

Cp° below 300°K is based on data of Flubacher (5) and Westrum (6) for samples annealed at 1100 and 1070°C, respectively. Data of Turdakin (7) are higher by about 1 percent in the range 60-160°K and at 300°K but are in agreement elsewhere. The entropy is calculated from Cp° using $S^\circ_{2.34} - S^\circ_0$ = 0.0001 eu and S°_0 = 1.098 eu. Cp° data (6) for a different sample annealed at 1300°C yield an entropy larger by <0.04 eu. Earlier data were reviewed by Kelley (8). The residual entropy is calculated from $S^\circ_0 = S^\circ_{1996} - (S^\circ_{1996} - S^\circ_0)$ = 41.258 - 40.160 = 1.098 eu, where 40.160 is obtained from the adopted functions, while 41.258 is the sum of ΔSm° = 1.147 eu and S°_{1996} = 40.111 eu for high cristobalite. We estimate the uncertainty as ±0.3 eu, primarily from the uncertainty in ΔHm°.

Cp° above 300°K is based on adiabatic calorimetric data of Moser (9) up to 900°K. Enthalpy data of White (10) and Fischer (11) are in excellent agreement. Cp° from 900 to 1500°K is derived from enthalpy data of Southard (12) and White (10). Maximum deviation of the data from the adopted values in this range is 0.5 percent. Enthalpy data of Egan (13) and Kelley (14) deviate from the adopted values by less than 1 percent in the range 1000-1500°K, although large positive deviations appear at lower temperatures.

In the region 1500-1700°K, the adopted Cp° shows a rapid, sigmoidal rise which is suggested by the enthalpy data of Wietzel (15). This is presumed to be the glass transition region in which Cp° rises to that of the stable liquid. Cp° above 1700°K is estimated as 20.5 gibbs/mol or 6.83 gibbs/g-atom. This value is consistent with the enthalpy data (15) and with liquid heat capacities of Al_2O_3, $Na_2Si_2O_5$ and Na_2SiO_3.

Melting Data

The melting point of high cristobalite is 1996 ± 5°K, while the metastable melting point of high quartz is 1696 ± 50°K. ΔHm° is the difference between ΔHf° for liquid and high cristobalite at Tm. Values ranging from 1.8 to 3.6 kcal/mol have been derived from various interpretations of phase diagrams (1).

SILICON DIOXIDE (SiO_2) (IDEAL GAS) GFW = 60.0848

Point Group [$D_{\infty h}$]

$S^\circ_{298.15}$ = [54.7] gibbs/mol

Ground State Quantum Weight = [1]

ΔHf°_0 = -72.7 ± 8 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -73 ± 8 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[980] (1)
[370] (2)
[1430] (1)

Bond Distance: Si-O = [1.55] Å

Bond Angle: O-Si-O = [180°]

Rotational Constant: B_0 = [0.2193] cm^{-1}

Heat of Formation

The adopted value is based on the data summarized below. Margrave (1) has reported a value of ΔHs°_{298} = 140.9±1 kcal/mol but details are not yet available. Assuming that this corresponds to reaction A below, we calculate ΔHf°_{298} = -75.5 kcal/mol. Firsova(2) reported two values of the sublimation pressure which were derived from Knudsen effusion data using auxiliary data for SiO(g). Porter (4) derived two pressures from a mass spectrometric study and also obtained a 2nd Law value for ΔHs° from ion intensities. The resulting range for ΔHs°_{298}, 136 to 141 kcal/mol, is consistent with the lower limit of 130 kcal/mol obtained by Bergman (3) from a method involving explosion in a spherical bomb. An alternative analysis of the mass spectrometric data (4) using the gas phase reaction B suggests an even higher ΔHs° of 148 kcal/mol. The adopted ΔHf° corresponds to ΔHs°_{298} = 143.4±8 kcal/mol and to $\Delta Hatom^\circ_0$ = 297.3±8 kcal/mol.

Source	Reaction	Method	Range, T°K	ΔHr°_{298}, kcal/mol 2nd Law	3rd Law	Drift eu	ΔHf°_{298}, kcal/mol

A. SiO_2(high cristobalite) = SiO_2(g)   B. SiO(g)+1/2O_2(g) = SiO_2(g)

Heat Capacity and Entropy

Point group, ground state quantum weight and the linear symmetrical configuration are estimated by analogy with the properties of CO_2. From the bond lengths in SiO, CO_2 and CO, the length in SiO_2 is estimated as 1.509 x 1.160/1.128. Bond lengths and atomization energies for these molecules are reasonably consistent with the existence of six-electron bonds in the monoxides and four-electron bonds in the dioxides (5). Vibrational frequencies are estimated from a valence bond calculation using force constants, $k = 9 \times 10^5$ and $k\delta/\ell^2 = 0.3 \times 10^5$ dyne/cm, which are obtained from those of SiO, CO_2 and CO. The moment of inertia is 12.76×10^{-39} g cm^2.

TITANIUM DIOXIDE, ANATASE (TiO_2) (CRYSTAL) GFW = 79.8988

$S^\circ_{298.15}$ = 11.93 gibbs/mol

Tt = 918 °K

Tm = Unknown

ΔHf°_0 = -221.8 ± 1 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -223.0 ± 1 kcal/mol

ΔHt° = [0.0] kcal/mol

ΔHm° = Unknown

$\Delta Hs^\circ_{298.15}$ = 161 kcal/mol

Heat of Formation.

The value of ΔHf°_{298} (anatase) is obtained from J. L. Margrave and B. D. Kybett, "Thermodynamic and Kinetic Studies of Borides and Other Refractory Materials at High Temperatures," Tech. Rept. AFML-TR-65-123, August 1965, Rice University, Houston, Texas. The authors measured the heat of fluorination of anatase, according to the reaction TiO_2 (anatase) + $2F_2(g)$ = $TiF_4(c)$ + $O_2(g)$, but no experimental data were given.

F. W. Vahldiek, J. Less-Common Metals 11, 99 (1966), studied the irreversible anatase-rutile phase transition at pressures of 3.8 to 24 kbars and temperatures 20 to 1000°C. Isothermal phase-transition studies were also carried out at 1 bar pressure and 880-950°C. From the slope, dT/dP, the enthalpy differences between rutile and anatase were calculated to be -2.79 and -2.89 kcal/mol at 1183 and 1223°K, respectively. Using these data and ΔHf°_{298}(rutile) = -225.8 kcal/mol, the value of ΔHf°_{298}(anatase) is derived as -223.23 kcal/mol,which is in excellent agreement with the adopted value.

Heat Capacity and Entropy.

Low temperature heat capacities, 52-296°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 69, 218 (1947). Enthalpy data were determined in the range 416-1305°K by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), and in the range 580 - 1000°K by J. Lietz, Hamburger Beitr. Angew. Mineral. Kristallphysik 1, 229 (1956). High temperature heat capacities are derived from the enthalpy data, subject to the constraint that there be a smooth joint at 298°K. The resulting enthalpies are higher by 1 to 3% than those measured by Lietz and lower by 1 to 4% than those measured by Naylor. Values above 1300°K are smoothly extrapolated. S°_{298} is calculated from the low temperature Cp° using S°_{50} = 0.45 eu.

In view of the discrepancies in the enthalpy data, a review of the anatase samples is pertinent. Those of Shomate and Lietz were prepared by precipitation of the hydrated oxide and conversion to the oxide at 550 - 565°C. Shomate's starting material was high purity Ti and the product analyzed as 99.3% TiO_2. Lietz' starting material was high purity $TiCl_4$. Naylor's sample, obtained from J. T. Baker Co., was dried at 1050°C; spectrographic analysis indicated 0.3% SiO_2 and 0.15% CaO. All three samples gave only the X-ray lines of anatase.

Transition Data.

Tm = 918°K and ΔHt° = 0.040 kcal/mol have been reported by J. Lietz, loc. cit. A. Schröder, Z. Kryst. 66, 493 (1928), suggested a transition temperature at 915°K on the basis of a peak in the thermal expansion curve. Lietz reported ΔHt° = 0.04 kcal/mol,but this value is not adopted since its magnitude is much less than the uncertainty in the selected enthalpies. Further study is desirable to confirm this transition.

Heat of Sublimation.

ΔHs°_{298} is calculated as the difference between ΔHf°_{298} for $TiO_2(g)$ and TiO_2(anatase).

Dec. 31, 1960; Mar. 31, 1967

TITANIUM DIOXIDE, RUTILE (TiO_2) (CRYSTAL) GFW = 79.8988

$S^\circ_{298.15}$ = 12.03 gibbs/mol

Tm = 2143°K

ΔHf°_0 = -224.6 ± 1 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -225.8 ± 1 kcal/mol

ΔHm° = [16] kcal/mol

$\Delta Hs^\circ_{298.15}$ = 163.8 kcal/mol

Heat of Formation.

The heat of formation for rutile has been determined from combustion calorimetry by many investigators. Several of the more consistent ΔHf°_{298} values are listed in the table below. Ariya et al.[3] reported that the composition of the rutile obtained from combustion of Ti(c) was between $TiO_{1.94}$ and $TiO_{1.95}$. Emf studies by R. N. Blumenthal and D. H. Whitmore, J. Electrochem. Soc. 110, 92 (1963), indicate that at 1200°K there is a two-phase region beginning at about $TiO_{1.99}$. If this region extends to 298°K, then the non-stoichiometric combustion products probably involve a mixture of two phases. Mah et al.[4] applied an approximate energy correction for incomplete combustion which corresponds to 0.7 - 1.5 kcal/mol in ΔHf°_{298}. Analogous corrections were applied by Ariya et al.[3] but were not mentioned by Neumann et al.[1] and Humphrey[2].

The ΔHf°_{298} value reported by Margrave and Kybett[5] was obtained by fluorine bomb calorimetry, according to the reaction $TiO_2(rutile) + 2F_2(g) = TiF_4(c) + O_2(g)$. No experimental data were given.

Comparison of the fluorine result with the oxygen results indicates that the magnitude of the corrections for the oxygen data is reasonable, probably within ± 1 kcal/mol, provided that the fluorine data refer to stoichiometric TiO_2. Corresponding ΔGf° corrections for TiO_{2-x} are of the same order of magnitude when estimated from the partial molar free energy values given by P. Kofstad, J. Phys. Chem. Solids 23, 1579 (1962), and J. B. Moser, R. N. Blumenthal and D. H. Whitmore, J. Am. Ceram. Soc. 48, 384 (1965).

The ΔHf°_{298} value determined by Mah et al.[4] is adopted.

Heat Capacity and Entropy.

The low temperature heat capacities, 10 - 297.7°K, have been measured by the following investigators: P. H. Keesom and N. Pearlman, Phys. Rev. 112, 800 (1958), 10 - 20°K; J. S. Dugdale, J. A. Morrison and D. Patterson, Proc. Roy. Soc. (London) A224, 228(1954), 20 - 50°K; H. Shomate, J. Am. Chem. Soc. 69, 218 (1947), 52.5 - 297.7°K; and H. J. McDonald and H. Seltz, J. Am. Chem. Soc. 61, 2405 (1939), 68.78 - 295.07°K. The first three sets of Cp data are joined smoothly and extrapolated to 298°K, yielding S°_{298} = 12.03 eu, based on S°_{10} = 0.0014 eu. The Cp values reported by McDonald and Seltz seem too high and are not used.

The high temperature enthalpies have been determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), 393.5 - 1746°K; J. S. Arthur, J. Appl. Phys. 21, 732 (1950), 293.2 - 1073.2°K; and J. Lietz, Hamburger Beitrage Angew. Mineral u. Kristall Phys. 1, 229 (1956), 577.7 - 1283.0°K. The Cp values are derived from the data of Lietz and join smoothly at 298°K with the low temperature data. Deviations from the selected values are -1.6 to+1.0% for Lietz, -6.1to + 4.0% for Arthur, and +8.6 to+0.8% for Naylor. The data point of Lietz at 947.95°K is omitted as a probable typographical error. The largest deviations in the case of Naylor and Arthur are near 400 and 500°K, respectively.

The mean specific enthalpies have also been measured by L. F. Nilson and O. Pettersson, Z. Physik, Chem. 1, 27 (1887), 373.2 - 717.2 °K.

The samples used by Keesom and Pearlman, Dugdale et al., Shomate, Arthur and Lietz were of high purity, according to chemical and spectroscopic analysis. However, the sample employed by Naylor was black-colored and chemical analysis gave 97.9% TiO_2. The main impurities were: 0.55% ZrO_2, 0.50% SiO_2, 0.27% V_2O_5, 0.15% CaO, 0.15% Fe_2O_3 and 0.12% Al_2O_3. The sample of McDonald and Seltz was obtained commercially. Therefore the results reported by Naylor and McDonald et al. are given the least weight.

Melting Data.

See TiO_2(l) table for details.

Heat of Sublimation.

The difference between ΔHf°_{298} for $TiO_2(g)$ and $TiO_2(rutile)$ is ΔHs°_{298}.

Dec. 31, 1960; Mar. 31, 1967

TITANIUM DIOXIDE (TiO_2) (LIQUID) GFW = 79.8988

$S°_{298.15}$ = [18.934] gibbs/mol $\Delta Hf°_{298.15}$ = [-210.726] kcal/mol

Tm = 2143°K $\Delta Hm°$ = [16] kcal/mol

Heat of Formation.

The $\Delta Hf°_{298}(l)$ is calculated from $\Delta Hf°_{298}$(rutile, c) by adding ΔHm° and the difference between $H°_{2143} - H°_{298.15}$ for TiO_2(rutile, c) and $TiO_2(l)$.

Heat Capacity and Entropy.

The heat capacity of $TiO_2(l)$ is estimated on the basis of 7.0 gibbs/g-atom. The value of $S°_{298}$ is obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting point of TiO_2(rutile) has been measured by many investigators. Eleven pertinent Tm values were reviewed and corrected, according to the International Temperature Scale of 1948, by S. J. Schneider, Natl. Bur. Std. Monograph 68, October 10, 1963. The adopted melting point is obtained from G. Brauer and W. Littke, J. Inorg. Nucl. Chem. 16, 67 (1960). These authors found that TiO_2 loses oxygen on heating and the solid residue consists of a non-stoichiometric compound of the composition TiO_{2-x}. The value of the coefficient x depends on the temperature and on the oxygen pressure of the gaseous phase. Under oxygen pressures greater than or equal to 300 torr, the solid residue was $TiO_{2.000}$ within the sensitivity of chemical analysis; however, color of the residue was a more sensitive indicator of composition. At pressures of 600 torr or greater, the residue was bright yellow rather than blue-gray and the melting point was constant at the maximum value of 2143 ± 15°K. This value is adopted.

The heat of melting is calculated using an estimated entropy of melting, ΔSm° = 2.5 eu/g-atom.

Bond Distance: Ti-O = [1.62] Å

Bond Angle: O-Ti-O = [180]°

Rotational Constant: B_0 = [0.2007] cm^{-1}

σ = 2

Heat of Formation.

P. W. Gilles, K. D. Carlson, H. F. Franzen, and P. G. Wahlbeck, J. Chem. Phys. 46, 2461 (1967), studied the vaporization behavior of the titanium-oxygen system and found that Ti_3O_5 is the final residue of both higher and lower titanium oxides; hence Ti_3O_5 is the congruently vaporizing phase. This conclusion was obtained by measurement of the change in composition of the solid residue accompanying vaporization as determined by x-ray diffraction, chemical analysis, and color of sample.

From mass spectrometric studies over $Ti_3O_5(\beta)$ near 2000°K, P. G. Wahlbeck and P. W. Gilles, J. Chem. Phys. 46, 2465 (1967), concluded that the partial pressure of TiO_2 is probably less than 1% of the pressure of TiO produced by the main vaporization, $Ti_3O_5(\beta) = 3\ TiO(g) + 2\ O(g)$. This yields $\Delta Gr°_{2000} \geq 228$ kcal for the reaction $Ti_3O_5(\beta) = 2\ TiO_2(g) + TiO(g)$ and $\Delta Hf°_{298}(TiO_2,g) \geq -62$ kcal/mol, which is the value adopted. The corresponding atomization energy is $D°_0 \leq 292$ kcal/mol.

Earlier vaporization studies over TiO_{2-x} gave apparent heats of formation which are more negative by 20-35 kcal; however, the results appear to be uncertain due to lack of sufficient auxiliary data for the oxygen-deficient condensed phase. Knudsen effusion-mass spectrometric studies of J. Berkowitz, W. A. Chupka and M. G. Inghram, J. Phys. Chem. 61, 1569 (1957), revealed the initial evolution of large amounts of $MoO_3(g)$, suggesting that the reduction of TiO_2 is enhanced by the Mo cell. In order to reduce the effect of the initial high rate of evaporation, W. O. Groves, M. Hoch and H. L. Johnston, J. Phys. Chem. 59, 127 (1955), conducted their Knudsen effusion-weight loss studies on $TiO_{1.94}$. Preferential loss of oxygen during the experiment, as indicated by a residue of $TiO_{1.85}$, was apparently ignored. Groves et al. estimated the activity of TiO_2(rutile) as 0.53; Berkowitz et al. assumed unit activity but did not indicate the composition of their condensed phase. These activities may be in serious error due to the presence of a series of distinct phases between $TiO_{1.8}$ and $TiO_{1.9}$ [cf. S. Andersson, Acta Chem. Scand. 14, 1161 (1960)] and to the possible existence of a two phase region near $TiO_{1.99}$ [cf. R. N. Blumenthal and D. H. Whitmore, J. Electrochem. Soc. 110, 92 (1963)]. Second and third law analyses of the data, using the authors' original assumptions, are summarized below. No weight is given to these results.

			$\Delta Hr°_{298}$ kcal/mol			$\Delta Hf°_{298}$*
Investigator	Temperature, °K	No. of Points	2nd law	3rd law	Drift eu	kcal/mol
Groves et al.	1849 - 2010	14	128.7 ± 7.5	130.1	1.1 ± 4.0	-95.7
Berkowitz et al.	1881	3	142.7 ± 5**	142.8	-	-83.0

*Calculation based on the third law $\Delta Hr°_{298}$.

**Obtained from the temperature variation experiments, reported in the original paper.

Heat Capacity and Entropy.

The molecular structure is assumed to be linear. The Ti-O bond distance is estimated as the same as that in TiO(g). The vibrational frequency 940 cm^{-1} was observed in matrix isolation by W. Weltner, Jr., and D. McLeod, Jr., J. Phys. Chem. 69, 3488 (1965). The other two frequencies are calculated, based on the valence bond method as suggested by Berkowitz, Chupka and Inghram, loc. cit. The moment of inertia is 1.3944×10^{-38} g cm^2.

TUNGSTEN DIOXIDE (WO_2) (CRYSTAL) GFW = 215.8488

$S^\circ_{298.15}$ = 12.08 ± 0.07 gibbs/mol

Td = 1997°K

ΔHf°_0 = -139.76 ± 0.21 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -140.94 ± 0.21 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 159.24 kcal/mol

Heat of Formation.

The adopted heat of formation, − 140.94 ± 0.21 kcal/mol, was determined by combustion calorimetry by A. D. Mah, J. Am. Chem. Soc. 81, 1582 (1959). R. C. Griffis, J. Electrochem. Soc. 105, 398 (1958), has measured the heat of combustion to WO_3(c) which yields ΔHf°_{298} (WO_2, c) = -139.8 ± 1.5 kcal/mol when recalculated with ΔHf°_{298}(WO_3,c) = -201.46 kcal/mol. This result is less certain because of the incomplete characterization of the final products.

Recent equilibrium data yield essentially the same average of the heat of formation by the third law method. The results are presented as follows.

Author	Reaction*	Temp. (°K)	No. of Points	ΔHr°_{298} (kcal/mol) 3rd law	2nd law	Drift (eu)	ΔHf°_{298} (kcal/mol)

Heat Capacity and Entropy.

E. G. King, W. W. Weller, and A. U. Christensen, U. S. Bur. Mines RI 5664,(1960), have measured the low temperature heat capacities from 53° to 297°K and high temperature enthalpy changes from 396° to 1800°K by drop calorimetry. The low temperature and high temperature heat capacities were joined smoothly at 298.15°K. The entropy was obtained from the heat capacities based on S°_{51} = 0.52 eu. It is possible that at temperatures below 50°K the entropy due to the uncoupling of the d^2 electrons will appear, contributing an additional 2.2 eu.

Temperature of Decomposition.

Tungsten dioxide (c) has no melting point, since disproportionation occurs to yield W(c) and WO_3(l) before melting starts. The Td is calculated as the temperature at which ΔG equals zero for 3 WO_2(c) = 2 WO_3(l) + W(c).

Heat of Sublimation.

The heat of sublimation was calculated from the difference between the heats of formation of WO_2(g) and WO_2(c).

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O = [110°]

σ = [2]

Product of the Moments of Inertia: $I_AI_BI_C$ = [9.433 x 10^{-115}] g^3cm^6

Heat of Formation.

G. DeMaria, R. P. Burns, J. Drowart and M. G. Inghram, J. Chem. Phys. 32, 1373 (1960), have reported the partial pressures of WO(g), WO_2(g), WO_3(g) and O(g) in a mass spectrometric study of aluminum oxide vaporized from a tungsten cell from 2188° to 2475°K. The adopted value, $\Delta Hf°_{298}$ (WO_2,g) = 18.3 ± 7 kcal/mol, was calculated from $\Delta Hr°_{298}$ = -100.9 kcal/mol for W(c) + 2 O(g) → WO_2(g), which was obtained from third law treatment of their partial pressure data, using all JANAF functions. The third law drift is 15.0 ± 5.2 eu. Partial pressures of WO_2(g), WO_3(g) and O(g) at 2242°K have also been reported by W. A. Chupka, J. Berkowitz and C. F. Giese, J. Chem. Phys. 30, 827 (1959), in a mass spectrometric study of beryllium oxide in a tungsten cell. Similar calculation gives $\Delta Hr°_{298}$ = -105.9 kcal/mol, which yields $\Delta Hf°_{298}$ (WO_2,g) = 13.2 kcal/mol.

Heat Capacity and Entropy.

The WO_2(g) was assumed to have a C_{2v} symmetry with a bond angle O-W-O = 110°. The bond distance W-O was estimated to be the same as that in WO(g). The symmetric and asymmetric stretching frequencies were obtained from the infrared spectrum of WO_2 in a neon matrix by W. Weltner, Jr., and D. McLeod, Jr., J. Mol. Spectry. 17, 276 (1965). The bending vibrational frequency (300 cm^{-1}) was estimated by comparison with other dioxides. The electronic levels and quantum weights were estimated from W^{+4} ion by analogy with Mo^{+4} ion. The three principal moments of inertia are: I_A = 4.8776 x 10^{-39}, I_B = 1.1680 x 10^{-38} and I_C = 1.6558 x 10^{-38} g cm^2.

June 30, 1961; Dec. 31, 1965

ZICONIUM DIOXIDE (ZrO_2) (CRYSTAL) MOL. WT. = 123.2188

$\Delta H^\circ_{f\ 0}$ = -261.0 ± 0.4 kcal. mole^{-1}

$S^\circ_{298.15}$ = [12.036 ± 0.08] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -262.3 ± 0.4 kcal. mole^{-1}

T_t = 1478 ± 5°K.

ΔH°_t = 1.42 ± 0.1 kcal. mole^{-1}

T_m = 2950°K.

ΔH°_m = [20.8] kcal. mole^{-1}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ = -262.3 ± 0.4 kcal. mole^{-1} is the average value of the $\Delta H^\circ_{f\ 298.15}$ = -261.5 ± 0.2 kcal. mole^{-1} and $\Delta H^\circ_{f\ 298.15}$ = -263.1 ± 0.5 kcal. mole^{-1} measured (by combustion calorimetry) by G. L. Humphrey, J. Am. Chem. Soc. 76, 978 (1954) and E. J. Huber, Jr., E. L. Head and C. E. Holley, Jr., J. Phys. Chem. 68, 3040 (1964) respectively. Also the heat of formation was measured calorimetrically by B. Neumann, C. Kröger and H. Kunz, Z. anorg. Chem. 218, 379 (1934), by W. A. Roth, E. Börger, and H. Siemonsen, ibid., 239, 321 (1938) and by A. Sieverts, A. Gotta and S. Halberstadt, ibid., 187, 155 (1930) and was found -258.2, -258.8 and -256.1 kcal. mole^{-1} respectively. However more weight was given to the Humphrey and Huber values.

Heat Capacity and Entropy.

The low temperature heat capacities, 54.3-295°K., were measured by K. K. Kelley, Ind. Eng. Chem. 36, 377 (1944). The heat capacities in the temperature range 298-1478°K. were calculated by using the J. P. Coughlin and E. G. King equation $C_p = 16.64 + 1.80 \times 10^{-3}T - 3.36 \times 10^5\ T^{-2}$ obtained from their measured enthalpy data in the range 396.8 - 1841°K., J. Am. Chem. Soc. 72, 2262 (1950). The values from the two sources join smoothly at 298°K. Above the transition 1478°K. the heat capacity was taken as constant at 17.80 cal. mole^{-1} deg.$^{-1}$, Coughlin and King, loc. cit. The entropy was calculated at 54.30° using the Debye and Einstein function $D(\frac{345}{T}) + E(\frac{513}{T}) + E(\frac{861}{T})$ given by Kelley, loc. cit. The value of $S^\circ_{54.3}$ = 0.5507 cal. deg.$^{-1}$ mole^{-1}.

Transition Data.

T_t and ΔH°_t were taken from Coughlin and King loc. cit.

Melting Data.

The T_m and ΔH°_m were taken from Natl. Bur. Standards Circ. 500 Washington (1952).

June 30, 1961; Dec. 31, 1965

ZIRCONIUM DIOXIDE (ZrO_2) (LIQUID) MOL. WT. = 123.2188

$S^\circ_{298.15}$ =[17.841]cal. deg.

T_m = 2950°K.

T_b = 4548°K.

ΔH°_f 298.15 = [-244.55] kcal. mole^{-1}

ΔH°_m = [20.8] kcal. mole^{-1}

ΔH°_v = [149.2] kcal. mole^{-1}

Heat of Formation.

The ΔH°_f 298.15 (l) was obtained from ΔH°_f 298.15 (c) by adding ΔH°_m and the difference between $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 2000°K. The heat capacity below 2000°K. was obtained from the heat capacity of the crystal. Above 2000°K. the heat capacity was assumed constant and estimated to be 21.0 cal. deg.$^{-1}$ mole^{-1} or 7 cal. deg.$^{-1}$ per g-atom as suggested by O. Kubaschewski and E. LL. Evans, "Metallurgical Thermochemistry" Pergamon Press, New York (1958). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See ZrO_2(c) table.

Vaporization Data.

T_b was calculated as the temperature at which the free energy change of the reaction $ZrO_2(l) \rightarrow ZrO_2(g)$ approaches zero. The difference between $\Delta H^\circ_{f\ 4548}$ for ZrO_2(g) and ZrO_2(l) is ΔH°_v.

818 (1)

Bond Distance: O -Zr = 1.711 Å

Bond Angle: O-Zr-O = 109°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 5.679636 X 10^{-115} g.^{3} cm.^{6}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ = -68.4 ± 11 kcal. mole^{-1} was calculated from the $\Delta H^\circ_{r\ 298.15}$ = 193.867 ± 11.25 kcal. mole^{-1} for the reaction $ZrO_2(c) \rightarrow ZrO_2(g)$. The value of $\Delta H^\circ_{r\ 298.15}$ was obtained by the third law method using the determined vapor pressures (at the range 2331-2480°K) by W. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 26, 1207 (1957). They observed the variation of the ZrO_2^+ ion intensity over ZrO_2 and reported equilibrium constants for the reaction $ZrO_2(c) \rightarrow ZrO_2(g)$ in the range 2331-2480°K. The third law drift is 80 ± 23 e.u.

Heat Capacity and Entropy.

The vibrational frequencies ν_1 = 884, ν_2 = [137], ν_3 = 818 and angle O -Zr-O = 109° were obtained from M. J. Linevsky, Spectroscopic Studies of the Vaporization of Refractory Materials, Technical Report Nr. AFML TR-64-420 Air Force Materials Lab. Research and Technology Division, Wright Patterson Air Force Base, Ohio (1965). The bond distances (r_e) O-Zr = 1.711 Å was obtained from U. Uhler and L. Akerlind, Arkiv Fysik 10, 431 (1955). The three principal moments of inertia are: I_A = 1.03083 X 10^{-38}, I_B = 3.8826 X 10^{-39}, I_C = 1.41909 X 10^{-38} g. cm.^{2}

TUNGSTEN OXIDE ($WO_{2.72}$) (CRYSTAL) GFW = 227.3684

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [16.35] gibbs/mol

$\Delta Hf^\circ_{298.15} = -186.70 \pm 0.5$ kcal/mol

Heat of Formation.

The adopted heat of formation, -186.7 ± 0.5 kcal/mol, is derived from recent equilibrium data which are in excellent agreement; the results are summarized below. In addition R. C. Griffis, J. Electrochem. Soc. 105, 398 (1958), has measured the heat of combustion to $WO_3(c)$ which yields $\Delta Hf^\circ_{298}(WO_{2.72}, c) = -185.4 \pm 1$ kcal/mol when recalculated with $\Delta Hf^\circ_{298}(WO_3,c) = -201.46$ kcal/mol. This result is less certain because of the incomplete characterization of the final products. The EMF data reported by Ya. I. Gerasimov, I. A. Vasil'eva, T. P. Chusova, V. A. Geiderikh, and M. A. Timofeeva, Zh. Fiz. Khim. 36, 358 (1962), give the value of -186.89 kcal/mol for the heat of formation at 298° K. R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2596 (1963), have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy, and X-ray diffraction. In the temperature range from 1300° to 1600° K, they have derived indirectly from their measurements the heat of formation, -182.2 kcal/mol (corresponding to -187.2 kcal/mol at 298°K, using the JANAF functions).

Heat Capacity and Entropy.

The monoclinic unit cell of $WO_{2.72}$ corresponds to $W_{18}O_{49}$, as shown by the X-ray diffraction studies of A. Magneli, G. Anderson, B. Blomberg and L. Kihlborg, Anal. Chem. 24, 1998 (1952). The tabulated heat capacities of $WO_{2.72}(c)$ were estimated from those of $WO_2(c)$ and $WO_3(c)$, because all three have similar monoclinic structures as identified by Magneli et al.

The entropy ($S^\circ_{298} = 16.35$ eu) was calculated from $\Delta S^\circ_{298} = 7.96 \pm 0.09$ eu for reaction A, using all JANAF values. The value of ΔS°_{298} was derived from the second law analysis of Griffis' data, loc. cit.

Sept. 30, 1966

TUNGSTEN OXIDE ($WO_{2.90}$) (CRYSTAL) GFW = 230.2483

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [17.54] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = −196.0 ± 3 kcal/mol

Heat of Formation.

The adopted heat of formation, −196.0 ± 3 kcal/mol, is a weighted average of those derived from equilibrium data; in addition the following results have been reported.

R. C. Griffis, J. Electrochem. Soc. 105, 398 (1958), has measured the heat of combustion to WO_3(c), which yields −195.6 kcal/mol when recalculated with ΔHf°_{298} (WO_3, c) = −201.46 kcal/mol. This result is less certain because of the incomplete characterization of the final products. R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2596 (1963), have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy, and X-ray diffraction. In the temperature range from 1300° to 1600°K, they have derived indirectly two values of ΔHf° ($WO_{2.90}$,c) −190.9 and −188.0 kcal/mol (corresponding to −196.1 and −193.3 kcal/mol, respectively, at 298.15°K, using all JANAF functions).

Sept. 30, 1966

TUNGSTEN OXIDE ($WO_{2.96}$) (CRYSTAL) GFW = 231.2082

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [17.90] gibbs/mol $\Delta Hf^\circ_{298.15}$ = -199.56 ± 3 kcal/mol

Heat of Formation.

The adopted value, $\Delta Hf^\circ_{298}(WO_{2.96}, c)$ = -199.56 kcal/mol, was obtained by third law treatment of ΔGf° = 191,600 + 54.0 T (cal/mol) in the temperature range from 1300 - 1550°K, using all JANAF functions. The equation for ΔGf° was reported by R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2596 (1963), based on studies by mass spectroscopy and X-ray diffraction. In this study ΔGf° was obtained by comparison of the gibbs energies of sublimation (to gaseous W_2O_6, W_3O_8, W_3O_9 and W_4O_{12}) over the two systems W-$WO_2(c)$ and $WO_{2.96}(c)$; thus $WO_{2.96}(c)$ was related to $WO_2(c)$ through the gaseous species.

J. E. Battles, Ph. D. Thesis, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide," The Ohio State University, (1964), has reported partial pressures of $W_3O_9(g)$ and $W_4O_{12}(g)$ in equilibrium with WO_3 - $WO_{2.90}(c)$. In light of Ackermann and Rauh's observation, the condensed phase was presumed to have the composition of $WO_{2.96}(c)$. The pressure data are in reasonable agreement with the studies of Ackermann and Rauh as summarized below. Values of ΔHf°_{298} for $WO_{2.96}(c)$ derived from the data of Battles are based on the same author's data for $W_3O_9(g)$, and $W_4O_{12}(g)$ in order to relate $WO_{2.96}$ to WO_2 directly.

Reaction: A: $WO_{2.96}(c) = 0.44\ W_2O_6(g) + 0.04\ W_3O_8(g)$

B: $WO_{2.96}(c) = 0.29333\ W_3O_9(g) + 0.04\ W_3O_8(g)$

C: $WO_{2.96}(c) = 0.22\ W_4O_{12}(g) + 0.04\ W_3O_8(g)$

* Third law value adopted in calculation.

Heat Capacity and Entropy.

The tabulated heat capacities and the entropy at 298.15°K were estimated from those of $WO_2(c)$ and $WO_3(c)$.

Ackermann and Rauh, loc. cit., have found that the composition $WO_{2.96}$ probably represents the azeotropic composition of the WO_{3-x} solid solution and is the only single phase which evaporates congruently below 1550°K.

Heat of Formation

P. Günther, E. Wassmuth, and L. A. Schryver, Z. phys. Chem. 158, 297 (1932), measured ΔE for the reaction $O_3(g) \rightarrow 3/2\ O_2(g)$ in a calorimeter calibrated my means of the reaction $CO(g) + 1/2\ O_2(g) \rightarrow CO_2(g)$, and found the ratio of the ΔE values for these reactions to be 0.5077 ± 0.0024. The temperature of the experiments is not reported and is assumed to have been 18°C. From the above ratio, $\Delta H^\circ_{f\ 298.15}$ is calculated to be 33.89 ± 0.36 cal. mole^{-1}. A. Kailan and S. Jahn, Z. anorg. Chem. 68, 243 (1910), measured ΔH at an unspecified temperature for the reaction $O_3(g) \rightarrow 3/2\ O_2(g)$ in an electrically calibrated calorimeter. If the temperature of the experiments is assumed to have been 18°C and the modern joule-calorie conversion factor is used, $\Delta H^\circ_{f\ 298.15}$ is found to be 34.3 ± 0.6 kcal. mole^{-1}. Variability in the O_3 content of the feed gas is allowed for in the uncertainty. The value adopted here is 34.2 ± 0.4 kcal. mole^{-1}.

Heat Capacity and Entropy

J. S. Gordon, private communication, April, 1961, has calculated the thermodynamic functions from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from L. Pierce, J. Chem. Phys. 24, 139 (1956). The functions below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

June 30, 1965

LEAD METASILICATE ($PbSiO_3$) (CRYSTAL) MOL. WT. = 283.2742

$\Delta H_f^\circ{}_0 = -272.01 \pm 1$ kcal. mole^{-1}

$S^\circ_{298.15} = 26.273 \pm 0.3$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = -273.66 \pm 1$ kcal. mole^{-1}

$T_m = 1037$°K.

Heat of Formation.

The heat of the reaction $PbO_{(red)} + SiO_2 \rightarrow PbSiO_3(c)$ was reported by K. K. Kelley, U. S. Bureau of Mines, Report Investigation 5901 (1962). This value for the heat of reaction of the oxides has been converted to the heat of formation using JANAF values for PbO(c) (March 31, 1962) and for SiO_2(c) (Dec. 31, 1962). The above $\Delta H_r^\circ{}_{298.15} = -3.75 \pm 0.12$ kcal. mole^{-1}.

Heat Capacity and Entropy.

In the low temperature region (53.25-298.15°K.) the C_p values are those determined by E. G. King, J. Am. Chem. Soc. 81, 799-800 (1959). Above 298.15 C_p values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.25°K. using the Debye and Einstein functions $D(\frac{140}{T}) + E(\frac{213}{T}) + 2E(\frac{596}{T}) + E(\frac{1440}{T})$ given by E. G. King, J. Am. Chem. Soc. 81, 799-800 (1959). The $S^\circ_{53.25} = 3.662$ cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

T_m was taken from Geller, Creamer and Bunting, J. Research Natl. Bureau of Standards, 13, 237 (1934).

Bond Distance: S-O = 1.43 Å

Bond Angle: O-S-O = 120°

σ = 6

Product of the Moments of Inertia: $I_AI_BI_C = 1.0813 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was calculated from the reaction $SO_2 + 1/2\ O_2 \rightarrow SO_3$ for which three sets of equilibrium constants are available. A summary of the second and third law treatment of the data is given below.

Ref.	Temp. Range	Points	2nd law ΔH°_{298} kcal. mole^{-1}	3rd law ΔH°_{298} kcal. mole^{-1}	Drift cal. mole^{-1} deg.$^{-1}$

4. Combination of above references, with one point omitted due to failure of a statistical test.

The combined set was adopted though it appears that the three sets are not in excellent agreement, and the combination heavily favors Ref. 2. Although there is a definite trend in all the data it cannot be considered definitive enough for use in the modification of the SO_3 functions.

Heat Capacity and Entropy.

The bond length and angles were taken from the electron diffraction data of K. J. Palmer, J. Am. Chem. Soc. 60, 2360 (1938). The vibrational frequencies were taken from the infrared studies of R. W. Lovejoy, J. H. Colwell, D. F. Eggers and G. D. Halsey, J. Chem. Phys. 36, 612 (1962), which are in excellent accord with those of R. Bent and W. R. Ladner, Spectrochim. Acta 19, 931 (1963) using different techniques. These values differ from the assignment used by W. H. Stockmayer, G. M. Kavanagh and H. S. Mickley, J. Chem. Phys. 12, 408 (1944) in their analysis of the thermodynamic properties of SO_3.

The individual moments of inertia were $I_A = I_B = 8.148 \times 10^{-39}$ g. cm.^{2} and $I_C = 16.296 \times 10^{-39}$ g. cm.^{2}

DITITANIUM TRIOXIDE (Ti_2O_3) (CRYSTAL) GFW = 143.7982

$S^\circ_{298.15}$ = 18.83 gibbs/mol

Tt = 473°K

Tm = 2112°K

ΔHf°_0 = -361.50 ± 2 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -363.49 ± 2 kcal/mol

ΔHt° = 0.215 kcal/mol

ΔHm° = [26.4] kcal/mol

Heat of Formation

G. L. Humphrey, J. Am. Chem. Soc. 73, 1587 (1951), determined the enthalpy change ΔHr°_{298} = -88.11 ± 0.1 kcal/mol for the reaction Ti_2O_3(c) + 1/2O_2(g) = 2TiO_2(rutile) using bomb calorimetry. Based on this result and ΔHf°_{298}(rutile) = -225.8 kcal/mol, the adopted value of ΔHf°_{298} for Ti_2O_3(c) is calculated to be -363.49 ± 2 kcal/mol. A value of ΔHf°_{298}(Ti_2O_3, c) = -362.8 ± 0.6 kcal/mol was reported by S. M. Ariya, M. P. Morozova, and E. Vol'f, Russ. J. Inorg. Chem. (English Transl.) 2, 16 (1957), who measured the heat of combustion of various compositions in the Ti-O system. Ariya et al. used an estimated correction for the formation of TiO_{2-x}, while Humphrey obtained values of 0.1 - 1.3 kcal/mol by grinding the product and reburning it with white oil. Most of the assigned uncertainty arises from this problem. [See TiO_2(rutile) for further details.]

Heat Capacity and Entropy

The low temperature heat capacities, 53 - 296°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 68, 310 (1946). The data indicate a small anomaly in Cp near 240°K. High temperature enthalpies, 375 - 1750°K, were determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), by drop calorimetry. The heat capacities, 298 - 473°K, derived by Naylor, loc. cit., are joined smoothly with the low temperature Cp at 298°K. Cp values above 473°K are calculated from the heat capacity equation for the β phase derived by Naylor.

S. Nomura, T. Kawakubo, and T. Yanagi, J. Phys. Soc. Japan, 16, 706 (1961), measured the specific heat in the range 70 - 250°C with a conduction-type calorimeter. A broad anomaly in the specific heat was observed from 160 to 200°C. Below this region the Cp° values are unreasonably small, but near 200°C the data are closer to the adopted values.

The S°_{298} is calculated from the adopted low temperature Cp based on S°_{50} = 0.442 eu. A. D. Pearson, J. Phys. Chem. Solids, 5, 316 (1958), studied the crystal structure of Ti_2O_3 by X-ray method and found that the agreement between calculated and observed density values is good; in other words, there are no significant vacant sites in Ti_2O_3 crystal lattice. This was later confirmed by S. C. Abrahams, Phys. Rev. 130, 2230 (1963). Therefore we do not add vacancy entropy to S°_{298}. Because of the magnetic transition (α→β) at 473°K, we have assumed that no spin-magnetic entropy is likely below 50°K. See Transition Data for more information.

Transition Data

Tt and ΔHt° were obtained from B. F. Naylor, loc. cit. S. Nomura, T. Kawakubo and T. Yanagi, J. Phys. Soc. Japan 16, 706 (1961), derived the much smaller ΔHt° = 0.036 kcal/mol from their observations with a conduction-type calorimeter. These authors suggested that the discrepancy may be due to non-stoichiometry or to impurities in the sample studied by Naylor.

Single-crystal neutron diffraction studied by S. C. Abrahams, Phys. Rev. 130, 2230 (1963), indicate that Ti_2O_3 undergoes an antiferromagnetic ordering of small magnetic moment, associated with the Ti^{3+} cations, below a Néel temperature of about 660°K. The temperature of this transition has been reported variously as about 450 to 600°K based on other properties. A. D. Pearson, J. Phys. Chem. Solids 5, 316 (1958), found no change in the Ti_2O_3 corundum-type structure, but noted a rapid change in the lattice parameters between 430 and 473°K. Observations of corresponding changes in magnetic susceptibility, resistivity and thermoelectric power have been summarized by the same authors and by J. B. Goodenough, Phys. Rev. 117, 1442 (1960). Goodenough attempted to interpret the earlier observations in terms of strong cation-cation interactions.

The magnetic nature of the transition suggests that any spin-magnetic entropy in Ti_2O_3 would be included in ΔHt° and in the observed Cp° values for α and β phases. Magnetic contributions are thus unlikely below 50°K.

Melting Data

See Ti_2O_3(ℓ) table for details.

DITITANIUM TRIOXIDE (Ti_2O_3) (LIQUID) GFW = 143.7982

$S^\circ_{298.15}$ = [22.952] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [-342.087] kacl/mol

Tm = 2112 ± 10°K ΔHm° = [26.4] kcal/mol

Heat of Formation

The heat of formation , ΔHf°_{298}, for $Ti_2O_3(\ell)$ is obtained from that of the crystal by adding ΔHm° and the difference between $H^\circ_{2112} - H^\circ_{298}$ for $Ti_2O_3(c)$ and $Ti_2O_3(\ell)$.

Heat Capacity and Entropy

The heat capacity of $Ti_2O_3(\ell)$ is estimated on the basis of 7.5 gibbs/g-atom. The S°_{298} is derived in a manner analogous to that of the heat of formation.

Melting Data

The adopted Tm was determined by P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 18) (1966). ΔHm° is estimated based on the assumption that at Tm the entropy of melting is 2.5 eu/g-atom. Other Tm values reported are listed as follows:

Tm, °K	Source
2073	T. H. Schofield and A. E. Bacon, J. Inst. Metals 84, 47 (1956).
2093	G. Brauer and W. Littke, J. Inorg. Nucl. Chem. 16, 67 (1960).

June 30, 1962; Mar. 31, 1963; Sept. 30, 1966

TUNGSTEN TRIOXIDE (WO_3) (CRYSTAL) GFW = 231.8482

ΔHf°_0 = -200.11 ± 0.2 kcal/mol

$S^\circ_{298.15}$ = 18.14 ± 0.3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -201.46 ± 0.2 kcal/mol

Tt = 1050°K

ΔHt° = 0.355 kcal/mol

Tm = 1745°K

ΔHm° = 17.55 kcal/mol

$\Delta Hs^\circ_{298.15}$ (to monomer) = 131.46 kcal/mol

$\Delta Hs^\circ_{298.15}$ (to dimer) = 62.36 kcal/mol

$\Delta Hs^\circ_{298.15}$ (to trimer) = 40.26 kcal/mol

$\Delta Hs^\circ_{298.15}$ (to tetramer) = 33.91 kcal/mol

Heat of Formation.

The selected heat of formation, ΔHf°_{298} (WO_3, c) = -201.46 ±0.2 kcal/mol, was determined by A. D. Mah, J. Am. Chem. Soc. 81, 1582 (1959), using bomb calorimetry. G. Huff, E. Squitieri and P. E. Snyder, J. Am. Chem. Soc. 70, 3380 (1948), have reviewed the literature heat of formation data and also measured calorimetrically the heat of formation, -201.84 ± 0.1 kcal/mol, which is in good agreement with the value selected. Other combustion values were reported as ΔHf°_{298} = -199 ± 1 kcal/mol by R. C. Griffis, J. Electrochem. Soc. 105, 398 (1958); and ΔHf°_{298} = -205.3 kcal/mol by I. A. Vasil'eva, V. I. Gerasimov, and Y. P. Simanov, Zh. Fiz. Khim. 31, 682 (1957). R. C. Griffis, J. Electrochem. Soc. 106, 418 (1959), also derived the heat of formation, -202.8 ± 1.4 kcal/mol from equilibrium data.

Heat Capacity and Entropy.

The low temperature (53-296.7°K) heat capacities and high temperature (399.6 - 1835.8°K) enthalpy changes have been measured by E. G. King, W. W. Weller, and A. U. Christensen, U.S. Bur. Mines R.I. 5664 (1960); and these data have been used to derive the tabulated heat capacities. Low temperature and high temperature values were joined smoothly at 298.15°K. The entropy was calculated from the heat capacities based on S°_{51} = 1.31 eu.

King et al. were apparently unaware of the transition near 593°K which was reported by J. A. Perri, E. Banks, and B. Post, J. Appl. Phys. 28, 1272 (1957), and they did not take sufficient points in that region to fix the precise enthalpy curve. We have adopted only one curve through the region because of the insufficiency of the data and also because the heat effects appear to be small or gradual.

Transition and Melting Data.

The heat of transition, the transition point, the heat of melting and the melting point were derived from the high temperature enthalpy data of King et al., loc. cit.

The melting point, 1746 ± 1°K, has also been quoted by S. J. Schneider, NBS Monograph 68, "Compilation of the Melting Points of the Metal Oxides," October 10, 1963.

In the high temperature X-ray diffractometric studies, Perri et al., loc. cit., indicate that WO_3 undergoes a phase transition from monoclinic to orthorhombic at approximately 593°K and from orthorhombic to tetragonal at 993°K.

Heat of Sublimation.

The values of ΔHs° at 298.15°K are calculated as the heat of sublimation of one mole of crystal to one mole of monomer, 1/2 mole of dimer, 1/3 mole of trimer and 1/4 mole of tetramer, respectively.

TUNGSTEN TRIOXIDE (WO_3) **(LIQUID)** **GFW = 231.8484**

$S^\circ_{298.15}$ = 24.738 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -188.555 kcal/mol

Tm = 1745°K

ΔHm° = 17.55 kcal/mol

Tb (to equilibrium vapor) = 2110°K

ΔHv° (to equilibrium vapor) = 18.3 kcal/mol

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding the heat of melting and the difference between $H_{1745} - H_{298}$ for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity between the melting point and 1836°K was determined from the enthalpy measurement by E. G. King, W. W. Weller, and A. U. Christensen, U. S. Bur. Mines RI 5664 (1960). The heat capacity was assumed constant above and below the measured range. At 1000°K, a glass transition was assumed, below which the heat capacity was assumed to be that of the crystal. The entropy at 298.15°K was obtained in a manner analogous to that of the heat of formation.

Melting and Vaporization Data.

The heat and temperature of melting were obtained from E. G. King et al., loc. cit.

Tb (to equilibrium vapor) is the temperature at which the total pressure reaches one atm based on the calculated partial pressures of $WO_3(g)$, $W_2O_6(g)$, $W_3O_8(g)$, $W_3O_9(g)$, and $W_4O_{12}(g)$. ΔHv° (to equilibrium vapor) at the boiling point is calculated as the heat of vaporization of one mole of the liquid to vapor containing 23.7 mole percent of $W_2O_6(g)$, 0.57 mole percent of $W_3O_8(g)$, 58.2 mole percent of $W_3O_9(g)$, and 17.53 mole percent of $W_4O_{12}(g)$.

TUNGSTEN TRIOXIDE (WO_3) (IDEAL GAS) GFW = 231.8484

Point Group [D_{3h}]

$S^\circ_{298.15}$ = [68.4] gibbs/mol

Ground State Quantum Weight = 1

ΔHf°_0 = -68.9 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -70 ± 7 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[564] (1)	1040 (2)
[347] (1)	[320](2)

Bond Distance: W-O = [1.81] A°

Bond Angle: O-W-O = [120°]

σ = [6]

Product of the Moments of Inertia: $I_A I_B I_C$ = [4.450×10^{-114}] $g^3 cm^6$

Heat of Formation.

The gibbs energy of formation of gaseous tungsten trioxide, ΔGf° (WO_3, g) = -75,700 + 15.54 T cal/mol, over the temperature range 1920° - 2020°K has been reported by R. J. Ackermann and R. J. Thorn, J. Phys. Chem. 64, 350 (1960), using the reaction 3 MgO (c) + W(c) → 3 Mg(g) + WO_3(g). Third law calculation gives ΔHf°_{298} (WO_3, g) = -71.3 kcal/mol, using JANAF functions. The second law value of ΔHf°_{298} is -74.8 kcal/mol.

G. DeMaria, R. P. Burns, J. Drowart and M. G. Inghram, J. Chem. Phys. 32, 1373 (1960), have reported the partial pressures of WO(g), WO_2(g), WO_3(g) and O(g) in a mass spectrometric study of aluminum oxide vaporized from a tungsten cell from 2188° to 2475°K. Third law treatment of their partial pressure data gives ΔHr°_{298} = -245.2 kcal/mol for W(c) + 3 O(g) → WO_3(g) which yields ΔHf°_{298}(WO_3,g) = -66.5 kcal/mol. The third law drift is 21 ± 7 eu. Partial pressures of WO_2(g), WO_3(g), and O(g) at 2242°K have also been reported by W. A. Chupka, J. Berkowitz and C. F. Giese, J. Chem. Phys. 30, 827 (1959), in a mass spectrometric study of beryllium oxide in a tungsten cell. Similar calculation gives ΔHr°_{298}(WO_3,g) = -73.0 kcal/mol.

The value, -70 ± 7 kcal/mol, is selected for the heat of formation at 298°K.

Heat Capacity and Entropy.

The WO_3(g) was assumed to be a planar D_{3h} molecule with a bond angle ∡ OWO = 120°. The bond distance W-O was estimated to be the same as that in WO(g). W. Weltner, Jr., and D. McLeod, Jr., J. Mol. Spectry. 17, 276 (1965), have observed the vibrational frequency of 1040 cm^{-1} in the infrared spectrum by matrix isolation, and also estimated the frequencies 347 and 564 cm^{-1} based on the stretching force constant of WO(g). The estimation of 320 cm^{-1}(2) was obtained from DeMaria et al., loc. cit. These frequencies have been adopted in the tabulation. The three principal moments of inertia are $I_A = I_B = 1.3055 \times 10^{-38}$ and $I_C = 2.611 \times 10^{-38}$ g cm^2.

LEAD ORTHOSILICATE (Pb_2SiO_4) (CRYSTAL) MOL. WT. = 506.4636

$\Delta H^\circ_{f\ 0} = -327.3 \pm 3.5$ kcal. mole^{-1}

$S^\circ_{298.15} = 44.654 \pm 0.5$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15} = -329.3 \pm 3.5$ kcal. mole^{-1}

$T_m = 1016$°K.

Heat of Formation.

The heat of the reaction $2PbO(c) + SiO_2(c) \rightarrow Pb_2SiO_4(c)$ was reported by O. Kubaschewski and E. L. Evans, Metallurgical Thermochemistry, Pergamon Press, New York (1958). This value for the heat of reaction of the oxides has been converted to the heat of formation using JANAF values for PbO(c) (March 31, 1962) and for $SiO_2(c)$ (Dec. 31, 1962). The above $\Delta H^\circ_{r\ 298.15} = -7.00 \pm 3.5$ kcal. mole^{-1}.

Heat Capacity and Entropy.

In the low temperature region (53.07-298.15°K.) the C_p values are those determined by E. G. King, J. Am. Chem. Soc., 81, 799-800 (1959). Above 298.15 C_p values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.07°K. using the Debye and Einstein functions $D(\frac{78.5}{T}) + 2E(\frac{164}{T}) + 3E(\frac{547}{T}) + E(\frac{1379}{T})$ given by E. G. King, J. Am. Chem. Soc., 81, 799-800 (1959). The $S^\circ_{53.07} = 8.248$ cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

T_m was taken from Geller, Creamer and Bunting, J. Research Natl. Bureau of Standards, 13, 237 (1934).

TRILEAD TETROXIDE (Pb_3O_4) (Crystal)

Mol. Wt. = 685.63

ΔH_f° 298.15 = -175.31 ± 0.48 kcal. mole^{-1}

$S^\circ_{298.15}$ = 50.4 ± 1.6 cal. deg.$^{-1}$ mole^{-1}

Heat of Formation. Calculated from $\Delta F^\circ_{298.15}$ = -147.27 kcal. mole^{-1} for the reaction: $3Pb(c) + 2O_2(g) = Pb_3O_4(c)$ given by R. W. Millar, J. Am. Chem. Soc., 51, 207 (1929).

Heat Capacity and Entropy. C_p (71.5° to 292.6°K.) reported by R. W. Millar, loc. cit. Above 298.15°K., heat capacity values were estimated by comparison with C_p values for the other lead oxides. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation.

Sept. 30, 1961; June 30, 1965

ZIRCONIUM ORTHOSILICATE ($ZrSiO_4$)   (CRYSTAL)   MOL. WT. = 183.3036

$S^\circ_{298.15}$ = 20.083 ± 0.3 cal. deg.$^{-1}$ mole^{-1}

T_d = 1811°K.

$\Delta H^\circ_{f\ 0}$ = -481.1 ± 0.7 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -483.7 ± 0.7 kcal. mole^{-1}

Heat of Formation.

The ΔH°_f 298.15 was calculated from the ΔH°_r 298.15 of its constituent oxides $ZrO_2(c) + SiO_2(c) = ZrSiO_4(c)$ and from the ΔH°_f 298.15 of $ZrO_2(c)$ (June 30, 1961) and $SiO_2(c)$ (Dec. 31, 1962) in JANAF tables. The ΔH°_r 298.15 = -4.736 kcal. mole^{-1} was based on the free energy of formation of its constituent oxides at the decomposition temperature 1811°K.

Heat Capacity and Entropy.

At low temperatures C_p were used from K. K. Kelley, J. Am. Chem. Soc. 63, 2750 (1941). From 298-940°K. C_p was calculated by using the J. P. Coughlin and E. G. King equation $C_p = 31.48 + 3.92 \times 10^{-3}T - 8.08 \times 10^5T^{-2}$, J. Am. Chem. Soc., 72, 2262 (1950), which joined smoothly with the low temperature data. Above 940°K. the data was estimated by extending the curve smoothly. The entropy was calculated at 52.7°K. using the Debye and Einstein functions $D(\frac{321}{T}) + 2E(\frac{407}{T}) + 2E(\frac{796}{T}) + E(\frac{1624}{T})$ given by K. K. Kelley, J. Am. Chem. Soc., 63, 2750 (1941). $S^\circ_{52.7}$ = 0.65404 cal. deg.$^{-1}$ mole^{-1}.

Temperature of Decomposition.

T_d is the temperature at which $\Delta F^\circ_r = 0$ for the reaction $ZrSiO_4(c) \rightarrow ZrO_2(c) + SiO_2(c)$. T_d = 1811°K. was taken from C. E. Curtis and H. G. Sowman, J. Am. Soc., 36, 190 (1953).

Dec. 31, 1960; Mar. 31, 1967

TRITITANIUM PENTOXIDE, ALPHA (α- Ti_3O_5) (CRYSTAL) GFW = 223.697

$S^\circ_{298.15}$ = 30.935 gibbs/mol

Tt = 450°K

ΔHf°_0 = -584.63 ± 0.7 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -587.75 ± 3.0 kcal/mol

ΔHt° = [2.81] kcal/mol

Heat of Formation

The enthalpy change, ΔHr°_{298} = -89.65 ± 0.05 kcal/mol, for the reaction $Ti_3O_5(c) + 1/2\ O_2(g) = 3\ TiO_2$(rutile) has been measured by G. L. Humphrey, J. Am. Chem. Soc. 73, 1587 (1951), using combustion bomb calorimetry. Based on the reported ΔHr°_{298} and ΔHf°_{298}(rutile) = -225.8 kcal/mol, the value of ΔHf°_{298} for $Ti_3O_5(\alpha)$ is derived as -587.75 ± 0.7 kcal/mol. A value of -587.0 ± 1.0 kcal/mol was obtained by S. M. Ariya, M. P. Morozova, and E. Vol'f, Russ. J. Inorg. Chem. (English transl.) 2, 16 (1957), from a similar calorimetric study on Ti-O compounds of various compositions. The latter authors observed that their combustion product had a composition of about $TiO_{1.95}$, so they applied an approximate correction to their data. Presumably, the rutile in Humphrey's combustion was also deficient in oxygen, but we have not attempted to make a correction (see TiO_2 (rutile) table for further details).

Heat Capacity and Entropy

Low temperature heat capacities, 53.1 - 296.6°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 68, 310 (1946). High temperature enthalpies, 360.5 - 1340°K, were determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), by use of drop calorimetry. The heat capacities, 298 - 450°K, derived by Naylor are too high to join smoothly at 298°K with the low temperature data, hence they are not used. The Cp values above 296.6°K are obtained by graphical extrapolation of the adopted low temperature Cp.

The samples used by both Shomate and Naylor were prepared by reduction of titanium dioxide with carbon at 1350°C. Analysis of the product gave 99.1% Ti_3O_5, 0.2% TiC and 0.7% SiO_2. X-ray lines from the sample were weak and fuzzy but no data were given. Thus comparison with subsequent studies is not possible. According to Naylor, the enthalpy measurements showed a transition at about 450°K. When Ti_3O_5 was heated above this temperature, it did not return to the original state on cooling. Enthalpies were then systematically higher by up to 10 percent. The change in the enthalpy curve seemed to depend upon both the temperature and time of heating above Tt. Regrinding was the only method found for returning the sample to its original state. Possible explanations are presented in the Transition Data.

S°_{298} is calculated from S°_{50} = 0.88 eu using the low temperature Cp reported by Shomate, loc. cit. It is pertinent to ask if there should be entropy contributions due to vacancies in the crystal lattice or to spin-magnetic effects below 50°K. S. Asbrink and A. Magneli, Acta Cryst. 12, 575 (1959), showed that the X-ray crystallographic density is greater than the experimental density by less than 1%, thus the entropy due to the presence of vacancies is considered to be negligible. We also assume that any spin-magnetic entropy is related to the $\alpha \rightarrow \beta$ transition, by analogy with the $\alpha \rightarrow \beta$ transition of Ti_2O_3. Consistent with this assumption is the observation that the entropy of β-Ti_3O_5 is already larger than the sum of entropies for β-Ti_2O_3 and TiO_2.

Transition Data

See $Ti_3O_5(\beta)$ table.

Mar. 31, 1967

TRITITANIUM PENTOXIDE, BETA (β-Ti_3O_5) (CRYSTAL) GFW = 223.697

$S^\circ_{298.15}$ = [35.913] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-585.354] kcal/mol

Tt = 450°K

ΔHt° = [2.81] kcal/mol

Tm = 2047 ± 10°K

ΔHm° = [33] kcal/mol

Heat of Formation

The value of $\Delta Hf^\circ_{298}(\beta)$ is obtained from $\Delta Hf^\circ_{298}(\alpha)$ by adding ΔHt° and the difference between $H^\circ_{450} - H^\circ_{298}$ for $Ti_3O_5(\alpha)$ and $Ti_3O_5(\beta)$.

Heat Capacity and Entropy

The heat capacities are derived from the enthalpy data, 452 - 1340°K, measured by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946). The Cp values beyond the experimental range are obtained by linear extrapolation.

The S°_{298} is calculated in a manner analogous to that of the heat of formation. For a discussion pertaining to the entropy uncertainty, see the Transition Data.

Transition Data

Tt and ΔHt° are based on the β-phase enthalpy data of Naylor, loc. cit., and on the selected enthalpies of the α-phase. ΔHt° is thus subject to an unknown error since the β-phase enthalpies correspond to a somewhat different state than do the α-phase values (see α-Ti_3O_5). The enthalpy data also show unusual scatter in the range 452-530°K. Because of these uncertainties, the more recent X-ray studies are summarized below.

S. Asbrink and A. Magneli, Acta Cryst. 12, 575 (1959), found that monoclinic α-Ti_3O_5 transforms to a β form of the anosovite type (slightly deformed pseudo-brookite) at about 393°K, i. e., over 50° lower than Naylor's value. P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), confirmed that the transition occurs between 373 and 473°K but did not measure the temperature accurately. In both studies only the α form was observed on cooling the samples to room temperature. Asbrink and Magneli noted the following in X-ray studies at elevated temperatures. In a wide region around 393°K, the powder reflections of the unstable phase disappeared, while the general characteristics of the stable one formed within considerably less than one hour. Complete development of some reflections of the stable phase took several hours, while some lines appeared with anomalous intensities at temperatures approaching the transformation point, thus "forewarning" the change of structure. Small contents of Fe or Mg stabilized the β form at room temperature.

These observations suggest that the transformation may be considered as a "pernt" which occurs over a range of temperatures. The anomalous enthalpy data observed by Naylor may arise from slow completion of the transition and from stabilization of part of the sample in the β form due to impurities. The latter suggestion is consistent with Naylor's observation that regrinding returned the sample to its normal α form. Correction of the enthalpy data based on these assumptions does not appear practical. Pending new data for a well-characterized sample, we must rely on the results of Naylor.

Melting Data.

P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), found that Ti_3O_5 melts incongruently at 2047 ± 10°K which is adopted. ΔHm° is estimated assuming that at Tm the entropy of melting is 2 eu/g-atom. Melting points of 2173 and 1983°K were reported by R. DeVries and R. Roy, Bull. Am. Ceram. Soc. 33, 370 (1954), and G. Brauer and W. Littke, J. Inorg. Nucl. Chem. 16, 67 (1960), respectively.

Mar. 31, 1967

TRITITANIUM PENTOXIDE (Ti_3O_5) (LIQUID) GFW = 223.697

$S°_{298.15}$ = [38.679] gibbs/mol

$\Delta Hf°_{298.15}$ = [-560.754] kcal/mol

Tm = 2047 ± 10°K

ΔHm° = [33] kcal/mol

Heat of Formation

The $\Delta Hf°_{298.15}(l)$ is obtained from $\Delta Hf°_{298.15}(\beta)$ by adding ΔHm° and the difference between $H°_{2047} - H°_{298}$ for $Ti_3O_5(\beta)$ and $Ti_3O_5(l)$.

Heat Capacity and Entropy

The heat capacity is estimated on the basis of 7.0 gibbs/g-atom. $S°_{298}$ is obtained in a manner analogous to that of the heat of formation.

Melting Data

See $Ti_3O_5(\beta)$ table for details.

Bond Lengths and Angles: P-O distance = 1.65 ± 0.02 Å

P-O-P angle = 127.5 ± 1.0° O-P-O angle = 99° ± 1° σ = 12

Product of Moments of Inertia: $I_AI_BI_C$ = 4.832 X 10^{-112} g.^{3} cm.^{6}

Heat of Formation. ΔH_f° 298.15 for liquid P_4O_6 was measured by W. E. Koerner and F. Daniels, J. Chem. Phys. 20, 113 (1952). The measurement was made by burning samples of red phosphorus in nitric oxide in a flow calorimeter. Calculation of the heat of formation of the gas was made using ΔH_v° 298.15 = 11.46 kcal. mole^{-1} as reported by T. D. Farr, Tenn. Valley Authority, Chem. Engr. Report No. 8 (1950).

Heat Capacity and Entropy. The vibrational levels are from the Raman data of H. Gerding, H. van Brederode and H. C. J. de Decker, Rec. Trav. Chim. 61, 549 (1942), and infra-red spectra data of T. A. Sidorov and N. N. Sobolev, Optics and Spect. 2, 710 (1957). Bond lengths and angles are from electron diffraction data by G. C. Hampson and A. J. Stosick, J. Am. Chem. Soc. 60, 1814 (1938).

Sept. 30, 1966

TUNGSTEN TRIOXIDE, DIMERIC $((WO_3)_2)$ (IDEAL GAS) GFW = 463.6964

Point Group $[D_{2h}]$

$S°_{298.15}$ = [99.3] gibbs/mol

Ground State Quantum Weight = [1]

$\Delta Hf°_0$ = -276.8 kcal/mol

$\Delta Hf°_{298.15}$ = -278.2 ± 10 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[600] (4)
[300] (8)
[172] (6)

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O =[109.47°] , $W\text{-}O_{bridge}\text{-}W$ = [70.53°] σ = [4]

Product of the Moments of Inertia: $I_AI_BI_C$=[5.917 x 10^{-112}] g^3 cm^6

Heat of Formation.

The adopted value, $\Delta Hf°_{298}$ (W_2O_6, g) = -278.2 kcal/mol, was reduced from $\Delta Hf°_{1450}$ = -272.5 kcal/mol, reported by R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2596 (1963). They have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion, and X-ray diffraction, and also have determined ΔGf° (W_2O_6,g) = - 272,500 + 54.98T (cal/mol) from partial pressure measurements over the W-WO_2(c) system.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide," The Ohio State University, 1964, has also studied the same system in the temperature range from 1418 to 1527° K. Third law calculation of the partial pressure data gives $\Delta Hr°_{298}$ = 144.0 kcal/mol for 3 WO_2(c) = W_2O_6(g) + W(c) which yields $\Delta Hf°_{298}$ (W_2O_6,g) = -278.8 kcal/mol, using all JANAF functions. This value is in good agreement with the value adopted.

J. H. Norman and H. G. Staley, J. Chem. Phys. 43, 3804 (1965), have obtained $\Delta Hr°_{1800}$ = -127 kcal/mol for 2 WO_3(g) = W_2O_6(g) by mass spectrometric study of the vapor over WO_3 dissolved in CaO-Al_2O_3-SiO_2. The value of ΔHr° was determined by the second law method from ion intensities and leads to $\Delta Hf°_{298}$ (W_2O_6,g) = -275 kcal/mol, using all JANAF functions (dated Sept. 30, 1966). The absolute pressure values reported by Norman and Staley appear to be quite inconsistent with the JANAF functions, since they lead to $\Delta Hf°_{298}$ (W_2O_6,g) = -246 kcal/mol by the third law method.

		Temperature	$\Delta Hr°_{298}$ (kcal/mol)		Drift	$\Delta Hf°_{298}$(W_2O_6,g)
Investigator	Chemical Reaction	(°K)	2nd law	3rd law	(eu)	(kcal/mol)
Ackermann & Rauh	3 WO_2(c) = W_2O_6(g) + W(c)	1300-1600	144.54	144.63	0.01	-278.2*
Battles	3 WO_2(c) = W_2O_6(g) + W(c)	1418-1527	142.66	143.97	0.85 ± 0.40	-278.8*
Norman & Staley	2 WO_3(g) = W_2O_6(g)	1700-1900	-135	-106		-275 **

* Third law value adopted in calculation.

** Second law value adopted in calculation.

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 600 cm^{-1}(4), 300 cm^{-1}(8), and 172 cm^{-1}(6) in order to give the entropy at 1450°K, $S°_{1450}$ = 164.66 eu, corresponding to $\Delta Sf°_{1450}$ = 54.98 eu which was reported by Ackermann and Rauh. The adopted value, $S°_{298}$ (W_2O_6,g) = 99.3 eu, was reduced from the entropy at 1450°K, using JANAF functions. Second law calculation of the partial pressure data of Battles gives $\Delta S°_{1470}$ = 63.5 eu for 3 WO_2(c) = W_2O_6(g) + W(c). This yields $S°_{298}$ (W_2O_6,g) = 97.9 eu.

The molecular configuration for W_2O_6(g) was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and two of these tetrahedra share a common oxygen edge to form a planar four-member ring. The bond distance W-O was estimated as 1.81 Å and the bond angle O-W-O = 109.47° and $W\text{-}O_{bridge}\text{-}W$ = 70.53°. The three principal moments of inertia are: I_A = 3.481 x 10^{-38}, I_B = 1.363 x 10^{-37} and I_C = 1.247 x 10^{-37} g cm^2.

Heat of Formation.

R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2596 (1963), have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion and X-ray diffraction, and also have determined the $\Delta Gf^\circ(W_3O_8, g)$ = -400,900 + 9054 T (cal/mol) from partial pressure measurements over W-WO_2 (c). The adopted value, ΔHf°_{298} (W_3O_8, g) = -408.7 kcal/mol, was reduced from ΔHf°_{1450} (W_3O_8, g) = -400.9 kcal/mol, using JANAF functions.

Ackermann & Rauh	4 $WO_2(c) = W_3O_8(g)+W(c)$	1300-1600°	155.05	155.09	-0.04	-408.7

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1}(6), 350 cm^{-1}(4), 242 cm^{-1} (8), 199 cm^{-1}(3) and 150 cm^{-1} (6) in order to give the entropy at 1450°K, S°_{1450} = 208.18 eu, corresponding to ΔSf°_{1450} = -90.54 eu, which was reported by Ackermann and Rauh.

The molecular configuration for $W_3O_8(g)$ was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, the three tetrahedra are connected by two common edges, and also the three tungsten atoms are in the same axis. The bond distance W-O was estimated as 1.81 A° and the bond angle ∡OWO = 109.47°. The three principal moments of inertia are: $I_A = I_B = 4.060 \times 10^{-37}$ and $I_C = 4.641 \times 10^{-38}$ g cm^2.

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O = [109.47°], W-O_{bridge}-W = [130.53°]

σ = [6]

Product of the Moments of Inertia: $I_AI_BI_C$ = [3.865 x 10^{-110}] g^3cm^6

Heat of Formation.

The adopted value, ΔHf°_{298} (W_3O_9,g) = -483.6 kcal/mol, was reduced from $\Delta Hf^\circ_{1450}(W_3O_9,g)$ = -474.1 kcal/mol of R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2596 (1963), who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600 °K by mass spectrometry, mass effusion, and X-ray diffraction, and determined ΔGf° (W_3O_9,g) = -474,100 + 110.26T (cal/mol) from partial pressure measurements over W-WO_2(c). They reviewed the previous determinations [1, 2, 3, 4] of the thermodynamic properties of sublimation of WO_3, and also pointed out that it was not possible to make quantitative observations on stoichiometric WO_3 in vacuo, since it is a "bivariant" system and the ion current is not constant until the composition of the sample reaches $WO_{2.96}$. This is probably the cause of previous discrepancies in sublimation studies.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide", The Ohio State University, 1964, has also studied the partial pressure of W_3O_9(g) over W-WO_2(c) in the temperature range from 1389° to 1527°K. Third law calculation of the partial pressure data gives ΔHr°_{298} = 148.2 kcal/mol for 4.5 WO_2(c) = W_3O_9(g) + 1.5 W (c), which yields ΔHf°_{298} (W_3O_9,g) = -486.0 kcal/mol, using all JANAF functions.

J. H. Norman and H. G. Staley, J. Chem. Phys. 43, 3804 (1965), have obtained ΔHr°_{1800} = -240 kcal/mol for 3 WO_3(g) = W_3O_9(g) by mass spectrometric study of the vapor over WO_3 dissolved in CaO-Al_2O_3-SiO_2. The value of $\Delta H\overset{\circ}{r}$ was determined by the second law method from ion intensities and leads to ΔHf°_{298} (W_3O_9,g) = -463.4 kcal/mol, using all JANAF functions (dated September 30, 1966). The absolute pressure values reported by Norman and Staley also appear to be quite inconsistent with the JANAF functions, since they lead to -443 kcal/mol by the third law method.

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1} (6), 396 cm^{-1}(3), 330 cm^{-1}(9), 200 cm^{-1}(6), and 150 cm^{-1}(6) in order to give the entropy at 1450°K, S°_{1450} = 219.14 eu, corresponding to ΔSf°_{1450} = 110.26 eu, reported by Ackermann and Rauh. The adopted value, S°_{298} $(W_3O_9,$ g) = 120.6 eu, was reduced from the entropy at 1450°K, using JANAF functions. Second law calculation of the partial pressure data of Battles gives ΔS°_{1455} = 71.7 eu for 4.5 WO_2(c) = W_3O_9(g) + 1.5 W (c). This yields $S^\circ_{298}(W_3O_9,g)$ = 122.4 eu.

The molecular configuration for W_3O_9(g) is estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and that each tetrahedron shares two oxygen atoms to form a planar six-member ring. The bond distance W-O is estimated as 1.81 Å and the bond angles O-W-O = 109.47° and W-O_{bridge}-W = 130.53°. The three principal moments of inertia are: $I_A = I_B$ = 2.805 x 10^{-37} and I_C = 4.913 x 10^{-37} g cm^2.

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) of P_4O_{10}(c) has been reported by many investigators. The most recent value, $\Delta H^\circ_{r\ 298.15} = -719.4 \pm 2.0$ kcal. mole^{-1} for the reaction $P_4(\alpha$, white, c) + $5O_2$(g) = P_4O_{10}(hex., c), was determined by E. P. Egan, Jr. and B. B. Luff, "Heats of Formation of Phosphorus Oxides", June 1, 1963 to Nov. 30, 1963, Tennessee Valley Authority, Office of Agriculture and Chemical Development, Fundamental Research Branch, Wilson Dam, Alabama. This $\Delta H^\circ_{r\ 298.15}$ value was derived from energy of combustion, $\Delta E_c = -716.397$ kcal. mole^{-1}, which is an average value of many measurements using three different sample forms, i.e. uncoated phosphorus, lucite-coated phosphorus and cellulose acetate-coated phosphorus. The adopted $\Delta H^\circ_{f\ 298.15}$ (P_4O_{10}, c) value was recalculated based on the P(red, V, c) as reference state.

The heat of combustion of white phosphorus was determined as -713.2 ± 1.0 kcal. mole^{-1} by W. S. Holmes, Trans. Faraday Soc. 58, 1916 (1962), yielding $\Delta H^\circ_{f\ 298.15}$ (P_4O_{10}, c) = -696.5 ± 1.3 kcal. mole^{-1}, based on P(red, V, c) as reference state. The heat of formation of P_2O_5 from red phosphorus was reported to be -355 ± 2 kcal. mole^{-1} by W. E. Koerner and F. Daniels, J. Chem. Phys. 20, 113 (1952). The product, P_2O_5, was considered to be a mixture of two forms, i.e. crystalline and amorphous. The other $\Delta H^\circ_{f\ 298.15}$ (P_4O_{10}, c) values reported by early investigators were reviewed by Egan and Luff, loc. cit.

Heat Capacity and Entropy.

The heat capacities (12-324°K.) and $S^\circ_{298.15}$ adopted were taken from R. J. L. Andon, J. F. Counsell, H. McKerrell and J. F. Martin, Trans. Faraday Soc. 59, 2702 (1963). The C_p values above 324°K. were obtained by graphical extrapolation. The $S^\circ_{298.15}$ value was calculated based on $S^\circ_{10} = 0.36$ e.u.

Low temperature (15-310°K.) and high temperature (298.15-623.15°K.) heat capacities were also measured by Thermal Laboratory, The Dow hemical Company, private communication, June 18, 1962, and M. Frandsen, J. Res. Natl. Bur. Std. 10, 35 (1933), respectively. The low temperature data were not adopted becuase they are less satisfactory than the data of Andon et al. The high temperature data were not used because the sample employed for enthalpy measurements was not explicitly reported as pure hexagonal form.

Sublimation Data.

The value of $\Delta H^\circ_{s\ 298.15}$ was derived from the vapor pressure data by both the second and third law analyses. See the P_4O_{10}(g) table for details. T_s is the temperature at which the free energy change of the reaction P_4O_{10}(hex. c) = P_4O_{10}(g) approaches zero. Sublimation temperature for P_4O_{10}(c) was derived to be 632°K., 636°K. (average of three determinations) and 623.7°K. (average of two determinations) by M. Frandsen, loc. cit. from the vapor pressure data reported by J. M. Hoeflake and M. F. Scheffer, Rec. trav. chim. 45, 191 (1926); A. Smits, Z. physik. Chem. A149, 337 (1930); and A. Smits and A. J. Rutgers, J. Chem. Soc. 125, 2573 (1924), respectively.

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ (P_4O_{10}, g) was calculated from the heats of formation and sublimation for P_4O_{10} (hex., c). The heat of sublimation ($\Delta H^\circ_{s\ 298.15}$) was derived from vapor pressure data by the second and third law methods. The results obtained are presented as follows.

Investigator	Temperature, °K	$\Delta H^\circ_{s\ 298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	Drift, e.u.
Hoeflake and Scheffer[1]	260 -401	25.42±0.07	25.33	-0.39±0.13
Southard and Nelson[2]	216.2-300.4	25.59±0.06	25.35	-0.18±0.14
	283.6-389.3	25.45±0.07	25.35	-0.10±0.07

1. J. M. A. Hoeflake and F. E. C. Scheffer, Rec. trav. chim. 45, 191 (1926).
2. J. C. Southard and R. A. Nelson, J. Am. Chem. Soc. 59, 911 (1937).

The value of $\Delta H^\circ_{s\ 298.15}$ adopted was 25.34 ± 0.08 kcal. mole^{-1}. There are many vapor pressure measurements reported but only the above two over P_4O_{10}(hex., c).

It has been shown that P_4O_{10} has three solid phases and two liquid phases. The three solid phases are hexagonal, orthorhombic and tetragonal. As temperature increases, the thermal stability of P_4O_{10} follows the same order. The metastable liquid, according to data of Hoeflake and Scheffer, loc. cit., is from hexagonal form. The stable liquid is from tetragonal form. W. L. Hill, G. T. Faust and S. B. Hendricks, J. Am. Chem. Soc. 65, 794 (1943) reported that molecules of P_4O_{10} having the same structure as in the vapor are present in the hexagonal form of the solid. The vapor pressures of P_4O_{10} over different condensed phases have been measured by many investigators and reviewed by T. D. Farr, "Phosphorus, Properties of the Elements and Some of Its Compounds", Tennessee Valley Authority, Wilson Dam, Alabama, 1950. The complexity of the solid state of P_4O_{10} has also been discussed by A. Smits and A. J. Rutgers, J. Chem. Soc. 125, 2573 (1924); A. Smits, Z. physik. Chem. A149, 337 (1930); A. Smits, J. A. A. Ketelaar and J. L. Meyering, ibid., B41, 87 (1938); and A. Smits, ibid., B46, 43 (1940).

Heat Capacity and Entropy.

The molecular structure and constants were obtained from P. A. Akishin, N. G. Rambidi and E. Z. Zasorin, Kristallografiya, 4, 360 (1959). The molecular structure of P_4O_{10}(g) has also been studied by the electron diffraction method by L. R. Maxwell, S. B. Hendricks and L. S. Deming, J. Chem. Phys. 5, 626 (1937), and G. C. Hampson and A. J. Stosick, J. Am. Chem. Soc. 60, 1814 (1938). The model of the P_4O_{10} molecule was later confirmed by the X-ray method reported by H. C. J. Decker and C. H. MacGillavry, Rec. trav. chim. 60, 153 (1941); and spectroscopic studies reported by H. Gerding and H. C. J. DeDecker, Rec. trav. chim. 64, 191 (1945), and T. A. Sidorov and N. N. Sobolev, Opt. Spectr. (USSR) 2, 717 (1957). All vibrational frequencies were obtained from E. P. Egan, Jr., private communication, Feb. 23, 1960, except nine frequencies, i.e. 170 (3), 470 (3) and 750 (3) cm.$^{-1}$ which were estimated in order To make the second and third law values of $\Delta H^\circ_{s\ 298.15}$ agree. The three principal moments of inertia are: $I_A = I_B = I_C$ = 1.4322 X 10^{-37} g. cm.^{2} The heat capacities (549-1098°C. or 822-1371°K.) of P_4O_{10}(g) have been determined by M. Frandsen, J. Res. Natl. Bur. Std. 10, 35 (1933). His results are in fair agreement with the calculated ones.

Mar. 31, 1963; Sept. 30, 1966

TUNGSTEN TRIOXIDE, TETRAMERIC $((WO_3)_4)$ (IDEAL GAS) GFW = 927.3928

Point Group $[D_{4h}]$

$S°_{298.15}$ = [144.6] gibbs/mol

Ground State Quantum Weight = [1]

$\Delta Hf°_0$ = -666.7 kcal/mol

$\Delta Hf°_{298.15}$ = -670.2 ± 10 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[800] (8)	[240] (8)
[300] (8)	[200] (18)

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O= [109.47°], $W-O_{bridge}-W$ = [160.53°] σ = [8]

Product of the Moments of Inertia: $I_AI_BI_C$ = [3.854 x 10^{-109}] g^3cm^6

Heat of Formation.

The adopted value, $\Delta Hf°_{298}$ (W_4O_{12}, g) = -670.2 kcal/mol, was reduced from $\Delta Hf°_{1450}$ (W_4O_{12}, g) =-655.6 kcal/mol of R. J. Ackermann and E. G. Rauh, J. Phys, Chem. 67, 2596 (1963), who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion and x-ray diffraction, and determined ΔGf° (W_4O_{12}, g) = -655,600 + 160.29 T (cal/mol) from partial pressure measurements over the $W-WO_2(c)$. They reviewed the previous determinations [1,2,3,4] of the thermodynamic properties of sublimation of WO_3, and also pointed out that it was not possible to make quantitative observations on stoichiometric WO_3 in vacuo,since it is a "bivariant" system and the ion current is not constant until the composition of the sample reaches $WO_{2.96}$. This is probably the cause of previous discrepancies in sublimation studies.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide", The Ohio State University, 1964, has also studied the partial pressure of $W_4O_{12}(g)$ over $W-WO_2(c)$ in the temperature range from 1449 to 1527°K. Third law calculation of the partial pressure data gives $\Delta Hr°_{298}$ = 172.0 kcal/mol for 6 $WO_2(c) = W_4O_{12}(g) + 2 W(c)$, which yields $\Delta Hf°_{298}$ (W_4O_{12}, g) = -673.6 kcal/mol, using all JANAF functions.

Investigator	Chemical Reaction	Temperature (°K)	$\Delta Hr°_{298}$(kcal/mol) 2nd law	 3rd law	Drift (eu)	$\Delta Hf°_{298}(W_4O_2, g)$* (kcal/mol)
Ackermann & Rauh	6 $WO_2(c) = W_4O_{12}(g) + 2W(c)$	1300 - 1600°	175.41	175.55	0.01	-670.2
Battles	6 $WO_2(c) = W_4O_{12}(g) + 2W(c)$	1449 - 1527°	176.16	172.01	-2.90 ± 0.39	-673.6

* Third law value adopted in calculation.

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1}(8), 300 cm^{-1} (8), 240 cm^{-1} (8), and 200 cm^{-1} (18) in order to give the entropy at 1450°K, $S°_{1450}$ = 278.9 eu, corresponding to $\Delta Sf°_{1450}$ = -160.29 eu, reported by Ackermann and Rauh. The adopted value, $S°_{298}$ (W_4O_{12}, g) = 144.6 eu, was reduced from the entropy at 1450°K, using JANAF functions. Second law calculation of the partial pressure data of Battles gives $\Delta S°_{1487}$ = 82.3 eu for 6 $WO_2(c) = W_4O_{12}(g) + 2W(c)$. This yields $S°_{298}$ (W_4O_{12}, g) = 147.4 eu.

The molecular configuration for $W_4O_{12}(g)$ is estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and that each tetrahedron shares two oxygen atoms to form a planar eight-member ring. The bond distance W-O is estimated as 1.81 Å and the bond angles O-W-O = 109.47° and $W-O_{bridge}-W$ = 160.53°. The three principal moments of inertia are: $I_A = I_B$ = 5.935 x 10^{-37} g cm^2, and I_C = 1.094 x 10^{-36} g cm^2.

PHOSPHORUS, RED, V, (P) (CRYSTAL) AT. WT. = 30.975

ΔH_{f0}° = 0 kcal. mole^{-1}

ΔH_s 298.15 = 7.69 ± 0.1 kcal. mole^{-1}

T_m = 870°K

ΔH_f° 298.15 = 0 kcal. mole^{-1}

$S^\circ_{298.15}$ = 5.45 ± 0.02 cal. deg.$^{-1}$ mole^{-1}

ΔH_m = 4.5 ± 0.2 kcal. mole^{-1}

Heat of Formation

Zero by definition below 704°K. See P_2(g) sheet for details above 704°K.

Heat Capacity and Extrapolation

The only reliable low temperature measurements, 15 to 305°K, are reported by R. L. Potter, Dissertation, Massachusetts Institute of Technology (1946). A value at 10°K was obtained by graphical extrapolation and a T^3 function was assumed from 0 to 10°K. High temperature heat capacities were obtained from a smooth curve joining the measurements of O. Kubashewski and G. Schrag, Z. Elektrochem. 46, 675 (1940), in the range 573 to 773°K and that of V. Regnault, Ann. chim. phys. 9, 322 (1843) at 331°K with those of Potter. Measurements of A. Wigand, Ann. Physik, 22, 64 (1907), are too high. The uncertainty in the high temperature heat capacity is about 2%.

Melting

The values of ΔH_m and T_m were calculated from the functions of the solid and liquid. This may be compared with a reported triple point of 862.7°K by A. Smits and S. C. Bokhorst, Verslag. Akad. Wetenschap. 23, 930 (1914).

Heat of Sublimation

Vapor pressure measurements on the triclinic allotrope, T. V. A. designation V, are reported by T. D. Farr, Tennessee Valley Authority Chemical Engineering Report No. 8 (1950). These data lead to a sublimation point of 704°K and ΔH_s 298.15 of 30.77 ± 0.4 kcal. mole^{-1} of P_4. A. Smits and S. C. Bokhorst, Z. phys. Chem. 91, 248 (1916), measured the vapor pressure of a sample whose preparation indicates that it was probably P, V. These results lead to ΔH_s 298.15 = 30.6 ± 1 kcal. An unpublished value of 30.84 kcal. mole^{-1} of P_4 by C. C. Stephenson is quoted by J. S. Kane, Thesis Univ. of California (1955).

D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941), show that the vapor density measurements of A. Stock, G. E. Gibson and E. Stamm, Ber. 45, 3527 (1912) are best explained by a vapor essentially composed of only P_4(g) below 800°K. This conclusion is supported by recent mass spectrometer measurements of J. S. Kane and J. H. Reynolds, J. Chem. Phys. 25, 342 (1956).

June 30, 1961

PHOSPHORUS, WHITE (P) (CRYSTAL) AT. WT. = 30.975

$\Delta H_f^\circ = 3.75 \pm 0.2$ kcal. mole^{-1}

ΔH_s $_{298.15} = 3.52 \pm 0.05$ kcal. mole^{-1}

$T_t = 195.4 \pm 0.1$°K (white $\beta \rightarrow$ white α)

$T_m = 317.30 \pm 0.05$°K

ΔH_f° $_{298.15} = 4.17 \pm 0.2$ kcal. mole^{-1}

$S^\circ_{298.15} = 9.82 \pm 0.02$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_t = 124.62 \pm 0.2$ cal. mole^{-1}

$\Delta H_m = 157.43 \pm 0.5$ cal. mole^{-1}

Heat Capacity and Extrapolation

Low temperature measurements, 15-315°K, were made by R. T. Maples, Dissertation, Massachusetts Institute of Technology (1949). A Debye θ temperature of 124 was used to extrapolate to 0°K. F. E. Young and J. H. Hildenbrand, J. Am. Chem. Soc. 64, 839 (1942), obtained heat capacities from enthalpy measurements that are 4% higher than those from the low temperature calorimeter which are preferred because of the proximity to the melting point.

Transition

Observed by Maples.

Melting

The selected heat of fusion is that observed by Maples. Young and Hildenbrand obtain 125 cal. mole^{-1} for the same quantity. Maples' value is consistent with vapor pressures and other thermochemical data; see P(liq) and P_4(g) sheets.

Heat of Sublimation

The vapor pressure measurements of F. S. Dainton and H. M. Kimberly, Trans. Faraday Soc. 46, 912 (1950), are the most precise and lead to ΔH_s $_{298.15} = 14.08 \pm 0.2$ kcal. mole^{-1} of P_4. Measurements of A. Jolibois, Compt. rend. 149, 287 (1908), A. Smits and S. C. Bokhorst, Z. Phys. Chem. 91, 248 (1916), and M. Centzwer, Z. phys. Chem. 85, 99 (1913) lead to values that agree within the assigned uncertainty.

Heat of Formation

The heat of formation is obtained from the heats of sublimation represented by reaction I and II at 298.15°K. See P, V sheet for details.

(I) $4P_\alpha(c) = P_4(g)$ 14.08 kcal.

(II) $4P_V(c) = P_4(g)$ 30.771 kcal.

Of the calorimetric determinations only those of H. Giran, Ann Chim. Phys. 30, 203 (1903) result in a reliable value for the heat of formation, 4.4 ± 0.4 kcal. mole^{-1}. A comprehensive review is given by H. J. Rodewald, Helv. Chim. Acta 43, 878 (1960).

June 30, 1961

PHOSPHORUS (P) (LIQUID) AT. WT. = 30.975

$\Delta H_{f0}^\circ = 5.2 \pm 0.3$ kcal. mole^{-1}

$T_m = 317.30 \pm 0.05$°K, $P_\alpha \rightarrow P(liq)$

$T_m = 870$°K , $P_V \rightarrow P(liq)$

$T_b = 550 \pm 3$°K

$T_c = 993.8$°K

$\Delta H_f^\circ{}_{298.15} = 4.32 \pm 0.2$ kcal. mole^{-1}

$S^\circ_{298.15} = 10.25 \pm 0.03$ cal. deg.$^{-1}$ mole^{-1}

ΔH_m, $P_\alpha \rightarrow P(liq) = 157.43 \pm 0.5$ cal. mole^{-1}

ΔH_m, $P_V \rightarrow P(liq) = 4.5 \pm 0.2$ kcal. mole^{-1}

$\Delta H_{V\ 298.15} = 3.37 \pm 0.03$ kcal. mole^{-1}

$P_c = [93.3]$ atm.

Heat of Formation

Derived from the ΔH_m by the following cycle:

(I)	$P_{317.30} = P(liq)$	0.157 kcal.
(II)	$P_{\alpha\ 298.15} = P_{\alpha\ 317.30}$	0.113
(III)	$P(liq)_{317.30} = P(liq)_{298.15}$	-0.121
(IV)	$P_{V\ 298.15} = P_{\alpha\ 298.15}$	4.08

The $\Delta H_f^{\circ\prime}{}_{289.15}$ obtained from vapor pressure measurements on P_V and on the liquid is 4.32 kcal. mole^{-1} in agreement with that derived from the melting point.

Heat Capacity

F. E. Young and J. H. Hildenbrand, J. Am. Chem. Soc. 64, 839 (1942), obtained an equation from enthalpy measurements which decreased with temperature. However, a better fit to the thermochemical data realts if a constant heat capacity is assumed.

Entropy

Derived from low temperature measurements on P, White. See P, White sheet for details.

Vaporization Phenomena

D. MacRae and C. C. Van Voorhis, J. Am. Chem. Soc. 43, 547 (1921), determinations of the vapor pressure, 44 to 150°C, are the most precise and lead to a $\Delta H_{v\ 298.15}$ of 13.504 ± 0.1 kcal. mole^{-1} of P_4. A vapor pressure equation derived by T. D. Farr, Tennessee Valley Authority Chemical Engineering Report No. 8 (1950) to fit the measurements reported in the literature leads to a value of 13.6 ± 0.1 kcal. mole^{-1} of P_4. The boiling point is calculated from the functions of P(liq) and $P_4(g)$, and may be compared with the values of 552.7 and 553.7 resulting from Farr's equation and observations of A Smits and S. C. Bokhorst, Proc. Akad. Wetenschop. 18, 106 (1915) respectively.

Critical Phenomena

T_c determined and P_c estimated by W. Marckwald and R. Helmholtz, Z. anorg. Chem. 124, 81 (1922).

Heat of Formation.

The $\Delta H_f^\circ{}_{298.15}$ was derived by the following cycle:

(1) 4 $P_{red(V)}$[298.15°] = P_4(g)[298.15°]	ΔH_r = 30.77 kcal. mole^{-1} of P_4	See $P_{red(V)}$ sheet under Heat of Sublimation.
(2) P_4(g)[298.15°] = 2P_2(g)[298.15°]	ΔH_r = 54.59 kcal. mole^{-1} of P_4	See P_2(g) sheet under Heat of Formation.
(3) 2P_2(g)[298.15°] = 2P_2(g)[0°]	ΔH_r = 2(-2.128) kcal. mole^{-1} of P_4	See P_2(g) table.
(4) 2P_2(g)[0°] = 4P(g)[0°]	ΔH_r = 2(116.075) kcal. mole^{-1}of P_4	A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, 1953.
(5) 4 P(g)[0°] = 4 P(g)[298.15°]	ΔH_r = 4(1.481) kcal. mole^{-1} of P_4	See P(g) table.

D_0° for reaction (4) was given by A. G. Gaydon (loc. cit.). He reported a predissociation limit at 51,958 ± 9 cm.$^{-1}$ He considered the dissociation to be $P_2 \rightarrow P(^4S) + P(^2D)$. From the predissociation limit and the energy level of the excited $P(^2D)$ state [11,360.8 cm.$^{-1}$] Gaydon (loc. cit.) obtained a D_0° = 5.033 e.v. or 116.075 kcal. mole^{-1}. As a check, a graphical Birge-Sponer extrapolation by Gaydon (loc. cit.) [$X^1\Sigma_g^+(\nu, 4\text{-}32)$] agrees with a D_0° = 5.0 e.v.

The vapor equilibrium data of G. Preuner and I. Brockmoller, Z. physik Chem. 81, 129 (1913) gave a ΔH_r for reaction (4) which was much lower than the spectroscopic value i.e. $31.5_{(1073°K)}$ vs. $116_{(0°)}$ kcal. mole^{-1} of P_2. D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941) reported that the vapor equilibrium measurements of G. Preuner and I. Brockmoller (loc. cit.) were doubtful while the measurements of A. Stock, G. E. Gibson, and E. Stamm Ber 45, 3527 (1913) were correct. Stock et al. (loc. cit.) have shown that the reaction $P_2(g) \rightarrow 2P(g)$ is extremely slight even at 1473°K which is the highest temperature of the vapor equilibrium studies.

Heat Capacity and Entropy.

The thermodynamic functions were calculated from the electronic levels which were evaluated by averaging the spectroscopic values of W. C. Martin, J. Opt. Soc. Am. 49, 1071, (1959).

MONOPHOSPHORUS MONOSULFIDE (PS) (IDEAL GAS) GFW = 63.0378

Ground State Configuration $^2\Pi$

$S^\circ_{298.15}$ = 56 ± 0.2 gibbs/mol

ΔHf°_0 = 36.9 ± 10 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 37.3 ± 10 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1} g	g_i
0	2
324	2
[20000]	2
22000	4
34594	2

ω_e = 743.5 ± 3.8 cm^{-1} $\omega_e x_e$ = 3.8 ± 0.9 cm^{-1} σ = 1

B_e = [0.29] cm^{-1} α_e = [0.0016] cm^{-1} r_e = [1.92] Å

Heat of Formation

The dissociation energy (D°_0) of PS(g) is estimated to be 140 ± 25 kcal/mol by comparison with the corresponding quantity for PO(g) and from a linear Birge-Sponer extrapolation of the third excited ($C^2\Sigma$) electronic state potential function. It is assumed that the $C^2\Sigma$ state dissociates to S(g) in its ground (^3P) state and P(g) in its first excited (^2D) state. The fundamental vibrational frequency in the $C^2\Sigma$ state (ω_e') is 531.8 ± 2.5 cm^{-1} and the corresponding anharmonic term ($\omega_e x_e'$) is 2.6 ± 0.5 cm^{-1}. These constants are calculated from a reanalysis of the spectral data of Dressler (1). The corresponding heat of formation of PS(g) is 37.3 ± 25 kcal/mol. The excited state ($C^2\Sigma$) data are used to calculate D°_0 instead of the ground state($X^2\Pi$) data because the vibrational constants of the upper level are known more accurately and because the extrapolation is 50 kcal/mol smaller for this level.

Heat Capacity and Entropy

The spectra of PS(g) have been studied by Dressler (1) in the near UV and visible regions. He reported the above electronic levels which correspond to the doublet pi ground state and two of the excited levels ($B^2\Pi$, $C^2\Sigma$). The level of the first excited electronic state ($A^2\Sigma$) is estimated by analogy with NO(g).

Dressler (1) estimated the value of the rotational constant B_e. The value of α_e is calculated from the Morse potential function. The bond distance is calculated from B_e. The fundamental vibrational frequency ω_e and the anharmonic vibrational term $\omega_e x_e$ are calculated from a reanalysis of the spectral data reported by Dressler (1).

PHOSPHORUS, DIATOMIC (P_2) (IDEAL GAS) MOL. WT. = 61.950

D_0° = 116 ± 1 kcal. mole^{-1}

Ground State Configuration $^1\Sigma^+$

ΔH_f° 298.15 = 42.68 ± 0.5 kcal. mole^{-1}

S°_{298} = 52.11 ± 0.1 cal. deg.$^{-1}$ mole^{-1}

ω_e = 780.43 cm.$^{-1}$

B_e = 0.30327 cm.$^{-1}$

$\omega_e x_e$ = 2.804 cm.$^{-1}$

α_e = 0.00142 cm.$^{-1}$

D_e = 0.21 X 10^{-6} cm.$^{-1}$

r_e = 1.8943 Å

Heat of Formation

D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941), have shown that the vapor density measurements of A Stock, G. E. Gibson and E. Stamm, Ber. 45, 3527 (1912), best fit a vapor composed of P_2 and P_4 molecular specie. From these data T. D. Farr, Tennessee Valley Authority, Chemical Engineering Report No. 8, calculated the equilibrium constants which lead to a ΔH_r for I. From which ΔH_f° of P_2 is obtained based upon a ΔH_f° 298.15 of 30.77 kcal. mole^{-1} of $P_4(g)$.

(I) $P_4(g)_{298.15} = P_2(g)_{298.15}$ ΔH_r = 54.59 ± 0.1 kcal. mole^{-1}

Heat Capacity and Entropy

Molecular and spectroscopic constants are those listed by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co. Inc., New York, 1945. More recent measurements of K. Dressler, Helv. Phys. Acta 28, 563 (1955) are in agreement with the values selected by Herzberg.

The dissociation energy is given by A. G. Gaydon, "Dissociation Energies", Chapman and Hall, Ltd., London, 1953.

PHOSPHORUS, TETRATOMIC (P_4) (IDEAL GAS) MOL. WT. = 123.90

ΔH°_{f0} = 30.84 ± 0.5 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 30.77 ± 0.5 kcal. mole^{-1}

Point Group T_d

$S^\circ_{298.15}$ = 66.89 ± 0.1 cal. deg.$^{-1}$ mole^{-1}

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$	
606	(1)
363	(2)
464.5	(3)

Bond Lengths and Angles P-P = 2.21 ± 0.2 Å ∢P-P-P = 109°.28'

Moments of Inertia $I_A = I_B = I_C = 25.1 \times 10^{-39}$ g. cm.^{2} σ = 12

Heat of Formation

Taken as the heat of sublimation of P (Red,V).

Heat Capacity and Entropy

The frequency and multiplicities are those assigned by H. S. Gutowsky and G. S. Hoffman, J. Am. Chem. Soc. 72, 5751 (1950). Molecular parameters of the gas were determined from electron diffraction measurements by L. R. Maxwell, S. B. Hendricks and V. M. Moseley, J. Chem. Phys. 3, 699 (1935). C. D. Thomas and N. S. Gingrich, J. Chem. Phys. 6, 659 (1938) obtained a P-P distance of 2.25 Å from x-ray studies on the liquid. On the basis of the selected values for P, White (see sheet) a third law entropy of 66.89 cal. deg.$^{-1}$ mole^{-1} is derived for P_4(g) at 298.15°K.

Tetraphosphorus Trisulfide (P_4S_3)

(Solid) Mol. Wt. = 220.098

TETRAPHOSPHORUS TRISULFIDE (P_4S_3) (Solid)

Mol. Wt. = 220.098

ΔH_f° 298.15 = [-37] kcal. mole^{-1}

$S^\circ_{298.15}$ = [48] cal. deg.$^{-1}$ mole^{-1}

T_m = 440°K.

ΔH_m = [2.2] kcal. mole^{-1}

ΔH_f° 298.15 estimated from vapor density reported by D. M. Yost and H. Russell, "Systematic Inorganic Chemistry of the Fifth- and Sixth- Group Nonmetallic Elements", Prentice-Hall, New York (1944). T_m from Yost and Russell, loc. cit. Other data estimated.

March 31, 1962

LEAD (Pb) (CRYSTAL) AT. WT. = 207.21

$\Delta H_{f0}^\circ = 0$

ΔH_s° 298.15 = 46.75 ± 0.13 kcal. mole^{-1}

T_m = 600.58 ± 0.00°K

ΔH_f° 298.15 = 0

$S_{298.15}^\circ$ = 15.484 cal. deg.$^{-1}$ mole^{-1}

ΔH_m° = 1.141 kcal. mole^{-1}

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Heat capacity measurements have been reported by M. Horowitz, A. A. Silvidi, S. F. Malaker and J. G. Daunt, (1° to 4°, 14° to 21°, and 64° to 77°K.), Phys. Rev. 88, 1182 (1952); P. F. Meads, W. R. Forsythe and W. F. Giauque, (15° to 300°K.), J. Am. Chem. Soc. 63, 1902 (1941); T. B. Douglas and J. L. Dever, (298.16° to 1200°K.), J. Am. Chem. Soc. 76, 4824 (1954), and many others whose work is listed by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960).

Heat capacities from 15° to 300° and 1° to 4°K. (in superconducting state) were taken from Meads, Forsythe, and Giauque, and Horowitz, Silvidi, Malaker, and Daunt, respectively. The missing data below the melting point were obtained by graphical extrapolation and joined smoothly to data of Douglas and Dever on approaching the melting point.

Melting.

The melting point of pure Pb(c) was found by E. H. McLaren and E. G. Mardock, Can. J. Phys. 38, 577 (1960) to be 327.426 ± 0.002°C. ΔH_m given by Douglas and Dever, loc. cit.

Heat of Sublimation.

ΔH_s° 298.15 was derived from third law analysis of the vapor pressure data of W. H. Rodebush and A. L. Dixon, J. Am. Chem. Soc. 47, 1036 (1925) and Phys. Rev. 26, 851 (1925); A. C. G. Egerton, Proc. Roy. Soc. (London) A103, 469 (1923); P. Harteck, Z. physik. Chem. 134, 1 (1928); A. T. Aldsed and J. N. Pratt, Trans. Faraday Soc. 57, 611 (1961); E. Baur and R. Brunner, Helv. Chim. Acta. 17, 958 (1934), and J. Fischer, Z. anorg. Chem. 219, 1, 367 (1934), which are in good agreement. Most weight was given to the results of Rodebush and Dixon. Older vapor pressure data of lower accuracy have not been used.

LEAD (Pb) (LIQUID) AT. WT. = 207.21

ΔH_f° 298.15 = [1.025] kcal. mole^{-1}

T_m = 600.58 ± 0.00°K

T_b = 2026°K

$S^\circ_{298.15}$ = [17.141] cal. deg.$^{-1}$ mole^{-1}

ΔH_m° = 1.141 kcal. mole^{-1}

ΔH_v° = 42.53 ± 0.13 kcal. mole^{-1}

Heat of Formation.

Obtained from ΔH_m°.

Heat Capacity and Extrapolation.

Heat capacity from T_m to 1200°K taken from T. B. Douglas and J. L. Dever, J. Am. Chem. Soc. 76, 4824 (1954). C_p values below T_m and above 1200°K were extrapolated, a glass transition being assumed at 400°K.

Entropy.

Calculated from that of crystal.

Vaporization Phenomena.

T_b and ΔH_v° calculated from ΔH_s° 298.15 and functions for condensed and gaseous states.

From the vapor pressure, the free energy functions of Pb(g) and Pb_2(g), and the dissociation energy of Pb_2 (g), it appears that below the boiling point the amount of Pb_2(g) in the vapor is negligible.

LEAD, DIATOMIC (Pb_2) (IDEAL GAS) MOL. WT. = 414.42

Ground State Configuration $[{}^3\Sigma_g^-]$

$S^\circ_{298.15}$ = [67.216] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 80.4 ± 4.6 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 79.5 ± 4.6 kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ_i, cm.$^{-1}$	g_i
0	[3]

ω_e = 256.5 cm.$^{-1}$

B_e = [0.01727] cm.$^{-1}$

$\omega_e x_e$ = 2.96 cm.$^{-1}$

α_e = [0.00020] cm.$^{-1}$

σ = 2

r_e = [3.08] Å

Heat of Formation.

Heat of formation was calculated from the dissociation energy of Pb_2(g) reported by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953.

Heat Capacity and Entropy.

The values of ω_e and $\omega_e x_e$ were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York, 1950. Those for B_e and α_e were estimated according to the method suggested by G. Herzberg, loc..cit. The bond distance (r_e) was calculated from the moment of inertia, I = 1630 X 10^{-40} g. cm.^{2}, estimated by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592, 1961. The ground state configuration was assumed to be ${}^3\Sigma$ by comparison to that for Si_2(g) reported by A. E. Douglas, Can. J. Phys. 33, 801 (1955).

Dec. 31, 1960; Dec. 31, 1965

SULFUR (S) (CRYSTAL) AT. WT. = 32.064

$S^\circ_{298.15}$ = 7.63 ± 0.5 cal. deg.$^{-1}$ mole^{-1}

T_{t_1} = 368.54°K.

T_{t_2} = 374°K.

T_m = 388.36°K.

$\Delta H^\circ_{f\ 0}$ = 0 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 0 kcal. mole^{-1}

ΔH_{t_1} = 96.01 ± 0.5 cal. mole^{-1}

ΔH_{t_2} = 0.38 ± 0.2 cal. mole^{-1}

ΔH_m = 410.52 ± 0.5 cal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 66.68 ± 0.3 kcal. mole^{-1}

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

E. D. Eastman and W. C. McGavock, J. Am. Chem. Soc. 59, 145 (1937), have measured the low temperature heat capacities of sulfur from 15° to 375°K. E. D. West, J. Am. Chem. Soc. 81, 29 (1959), has measured the high temperature heat capacities from 298° to 678°K. These two sets of data were joined smoothly at 298.15 K.by a graphical method.

The values of entropy at 110°C and above in E. D. West's paper (table VIII) have been lowered by 0.5841 Joule. deg.$^{-1}$ mole^{-1} because of a calculational error which was pointed out by J. P. McCullough and D. W. Scott, private communication, Sept. 27, 1960.

The entropy of rhombic sulfur at 298.15°K.was taken from E. D. Eastman and W. C. McGavock, loc. cit., based on an extrapolation of S°_{15} = 0.12 cal. deg.$^{-1}$ mole^{-1}.

Transition Data.

The enthalpies of transition at 368.54°K.and 374°K.were obtained from E. D. West, loc. cit. The first transition at 368.54°K.was the known rhombic-monoclinic transition, but the second one near 374°K.was a previously unreported transition.

Melting Data.

The heat of melting and the temperature were obtained from E. D. West, loc. cit.

Heat of Sublimation.

The heat of sublimation of sulfur (c) is the heat of formation of monatomic sulfur (g). See S(g) table for details. Since S_8 and lower polymers are major vapor species at room temperature, the heat of sublimation to the equilibrium gas is much smaller. See S_8(g) table for details.

Dec. 31, 1960; Dec. 31, 1965

SULFUR (S)   (LIQUID)   AT. WT. = 32.064

$S^\circ_{298.15}$ = 8.44 ± 0.5 cal. deg.$^{-1}$ mole^{-1}

T_m = 388.36°K.

T_b = 717.75°K.

ΔH°_f 298.15 = 0.34 ± 0.01 kcal. mole^{-1}

ΔH°_m = 410.52 ± 0.5 cal. mole^{-1}

ΔH°_v = [2.30] kcal. mole^{-1}

Heat of Formation.

The ΔH°_f 298.15 (S, l) was obtained from that of the crystal by adding ΔH°_m and the difference between $H_{388.36}$-$H_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase was obtained from E. D. West, J. Am. Chem. Soc. 81, 29 (1959). No simple equation fits the curve of C_p against T which shows a peak.

The value of $S^\circ_{298.15}$ (S, l) was obtained in a manner analogous to that of the heat of formation. The heat capacity of sulfur (liquid) below the melting point was assumed to be constant as 7.579 cal. deg.$^{-1}$ mole^{-1}; and above the boiling point, it was assumed as 7.694 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

The heat of melting and the temperature were obtained from E. D. West, loc. cit.

Vaporization Data.

According to the international practical temperature scale, the boiling point is 717.75°K. The heat of vaporization to the equilibrium vapor mixture was estimated by D. R. Stull and G. C. Sinke, "Thermodynamic Properties of the Elements," American Chemical Society, Washington, D.C., 1956. The equilibrium vapor involves monomeric and several polymeric species; S_2 and S predominate above 1000°K. while S_8, S_6 and possible S_4 and S_3 are favored at lower temperatures.

Heat of Formation.

L. Brewer, J. Chem. Phys. 31, 1143 (1959), has reviewed the three possible values of D_0° (S_2), i.e. 4.4 e.V., 3.6 e.V. and 3.3 e.V., which were due to the ambiguity of defining the excitation state of the atomic products resulting from predissociation in the spectroscopic measurements. The value of 4.4 e.V. (101.5 kcal. mole^{-1}) was shown to be the most probable one. Since this review, further support for his value have been given by the following investigators. J. R. Marquart, Dissertation Abstract 24, 5027 (1964), has found that the value of D_0° (S_2) to be consistent with the value of 4.4 e.V. in mass spectrometric studies. R. Colin, P. Goldfinger and M. Jeunehomme, Trans. Faraday Soc. 60, 306 (1964), have found D_0° (S_2) = 97 ± 5 kcal. mole^{-1} in their mass-spectrometric studies of the vaporization of CaS, BaS, SnS and PbS, but they reported a revised value, i.e. D_0° (S_2) = 101 ± 1 kcal. mole^{-1}, which was given in the note in proof. A. N. Singh and D. K. Rai, J. Chem. Phys. 43, 2151 (1965), have selected the best value of D_0° (S_2) = 4.4 e.V. in theoretical comparisons of the potential-energy curve. As pointed out by L. Brewer, loc. cit., and A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., 2nd. Ed., London, 1953, the old vapor pressure measurements which are not consistent with D_0 (S_2) = 4.4 e.V. (101.5 kcal. mole^{-1}) are probably not reliable.

The value D_0 (S_2, g) = 4.4 e.V. (101.5 kcal. mole^{-1}) was selected as the dissociation energy of diatomic sulfur, and combination of this value with heat of formation of diatomic sulfur gives the heat of formation of monatomic sulfur, $\Delta H^\circ_{f\ 298}$ (S, g) = 66.68 kcal. mole^{-1}.

Heat Capacity and Entropy.

The ground state configuration, electronic levels and quantum weight were obtained from C. E. Moore, "Atomic Energy Levels", Vol. 1, National Bureau of Standards Circular 467, June, 1949.

Silicon Monosulfide (SiS)

(Ideal Gas) Mol. Wt. = 60.156

r_e = 1.889 Å

Heat of Formation.

The standard enthalpy of formation of gaseous diatomic sulfur, $\Delta H^\circ_{f\ 298}$ = 30.84 kcal. $mole^{-1}$, was calculated from $\Delta H^\circ_{r\ 298}$ = -20.30 kcal. $mole^{-1}$ for the reaction $H_2(g) + 0.5\ S_2(g) \rightarrow H_2S(g)$ with JANAF value $\Delta H^\circ_{f\ 298}(H_2S, g)$ = -4.88 ± 0.15 kcal. $mole^{-1}$. The $\Delta H^\circ_{r\ 298}$ was obtained by the second and third law analyses of equilibrium constants which have been determined by G. Preuner and W. Schupp (ref. 1) and M. Randall and F. R. Bichowsky (ref. 2). The results obtained are presented as follows:

Ref.	Temp. Range	Points	2nd law $\Delta H^\circ_{r\ 298}$ kcal. $mole^{-1}$	3rd law $\Delta H^\circ_{r\ 298}$ kcal. mole	Drift cal. $mole^{-1}$ $deg.^{-1}$
1	1023-1405°K	5	-19.92 ± 0.13	-20.295	-0.282 ± 0.097
2	1362-1667°K	4	-20.74 ± 0.40	-20.307	+0.281 ± 0.269
3	1023-1667°K	9	-20.13 ± 0.12	-20.300	-0.066 ± 0.093

The third law value of the combination set was selected to calculate the heat of formation of diatomic sulfur.

The dissociation energy of gaseous diatomic sulfur, D°_0 (S_2) = 101.5 kcal. $mole^{-1}$, was chosen. For discussions see JANAF monatomic sulfur (g) and sulfur monoxide (g) tables.

Heat Capacity and Entropy.

The molecular constants which were taken from G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., D. Van Nostrand Company, New York, have been modified for the natural isotopic abundances reported by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

December 31, 1960.

Silicon Disulfide (SiS_2) (Crystal)

Mol. Wt. = 92.222

$\Delta H_f^\circ{}_{298.15} = -50.7$ kcal. mole^{-1}

$S^\circ_{298.15} = [16.0]$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 1363$°K.

$\Delta H_m = [5.0]$ kcal. mole^{-1}

Heat of Formation. $\Delta H_f^\circ{}_{298.15}$ was calculated from the measured ΔH_R's of the following reactions:

$$SiS_2(c) + HF(aq) \rightarrow H_2SiF_6(l) + 2H_2S(g)$$
$$\Delta H_{R1} = 72.8 \pm 2.2 \text{ kcal. mole}^{-1}$$

$$SiO_2(c) + HF(aq) \rightarrow H_2SiF_6(l) + 2H_2O(l)$$
$$\Delta H_{R2} = -33.00 \pm .02 \text{ kcal. mole}^{-1}$$

ΔH_{R1} was taken from R. Rocquet, M. T. Ancey-Maret, Bull. Soc. Chim. France 1954, 1039 (1954); ΔH_{R2} was from D. Torgeson and Th. G. Samaha, J. Am. Chem. Soc. 70, 2156 (1948). $\Delta H_f^\circ{}_{298.15}$ of SiS_2 was recalculated using the corrected value for $\Delta H_f^\circ{}_{298.15}$ of SiO_2.

Heat Capacity and Entropy. C_p and $S^\circ_{298.15}$ values are estimated.

Melting Data. T_m was from National Bureau of Standards Circular 500, "Selected Values of Chemical Thermodynamic Properties", 1952. ΔH_m was estimated.

Bond Distance: S-S = 2.059 ± 0.002 Å

Bond Angle: S-S-S = 107.9 ± 0.6°

$\sigma = 8$

Product of the Moments of Inertia: $I_AI_BI_C = 3.90326 \times 10^{-111}$ g.^{3} cm.^{6}

Heat of Formation.

The vapor pressure of S(c) has been measured by many investigators. Using the seven more recent vapor pressure date, the respective heat of sublimation ($\Delta H_s^\circ{}_{298.15}$) was calculated by both the third and second law methods. The values obtained are tabulated as follows:

Investigator	Temperature Range, °K.	$\Delta H_s^\circ{}_{298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value
West-Menzies [1]	376.6 - 448.8	24.29	21.29
Neumann [2]	332.6 - 362.1	24.35	26.47
Fouretier [3]	304.1 - 351.6	24.36	24.10
Taillade [4]	303.6 - 352.5	24.29	24.87
Bradley [5]	288.3 - 305.7	24.29	23.80
Magee [6]	331.9 - 368.0	24.11	24.44
	332.7 - 367.4	24.12	23.88
Briske [7]	273.2 - 313.2	24.28	24.00

1 W. A. West and A. W. Menzies, J. Phys. Chem. 33, 1880 (1929).
2 K. Neumann, Z. physik. Chem. A171, 416 (1934).
3 G. Fouretier, Compt. rend. 218, 194 (1944).
4 M. Taillade, Compt. rend. 218, 836 (1944).
5 R. S. Bradley, Proc. Roy. Soc. (London) A 205, 553 (1951).
6 D. W. Magee, Ph. D. Thesis, The Ohio State University, 1955.
7 C. Briske, N. H. Hartshorne and D. R. Stranks, J. Chem. Soc. (London), 1200 (1960).

Due to the presence of S_6(g) in S_8(g), the measured total pressures were corrected to give the partial pressures of S_8(g) for the first five sets of vapor pressure data, according to D. W. Scott, U. S. Bureau of Mines, Bartlesville, Oklahoma, private communication, May 22, 1964. However, the magnitude of the correction is only 0.1 - 0.2 kcal. mole^{-1}. The adopted value is the weighted average of both the third and second law values.

Heat Capacity and Entropy.

The vibrational frequencies were taken from D. W. Scott, J. P. McCullough and F. H. Kruse, "Vibrational Assignment and Force Constants of S_8 (condensed States) from a Normal-Coordinate Treatment", Prepublication Report 64, U. S. Bureau of Mines, May 20, 1963. Four of the eighteen frequencies, i.e. 86(2) and 218(2) cm.$^{-1}$, were changed to 56(2) and 248(2) cm.$^{-1}$, respective, suggested by D. W. Scott, loc. cit., private communication, April 23, 1964. The molecular structure and bond distance and angle were reported by J. Donohur, A. Caron and E. Goldish, J. Am. Chem. Soc. 83, 3748 (1961). The three principle moments of inertia are: $I_A = I_B = 1.28594 \times 10^{-37}$ and $I_C = 2.36042 \times 10^{-37}$ g. cm.^{2}.

$S^\circ_{298.15} = 4.498 \pm 0.01$ gibbs/mol

$\Delta Hf^\circ_{298.15} = 0$ kcal/mol

$T_m = 1685 \pm 3$ °K

$\Delta Hm^\circ = 12.0 \pm 0.1$ kcal/mol

$\Delta Hs^\circ_{298.15} = 107.7 \pm 1$ kcal/mol

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Low temperature heat capacities are based on the precise data (8-300°K) of Flubacher, Leadbetter and Morrison. The entropy is obtained from the heat capacity using $S^\circ_8 = 0.0003$ eu. The selected values are consistent with recent data of Keesom and Seidel (1.2 - 4.2°K) and Kalishevich et al. (60-300°K). Earlier data have been reviewed by R. Hultgren, R. L. Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1965.

High temperature studies are summarized below, along with the pertinent low temperature studies. The selected heat capacities above 300°K are obtained from a Shomate plot of the adopted low temperature heat capacities and the enthalpies reported or derived from the work of Dennison (1963), Kantor et al. (1960), Olette (1956), Serebrennikov and Gel'd (1952), and Magnus (1923). Discrepancies are apparent in the enthalpy data, particularly in the range of 370 to 1100°K, where only the recent study of Dennison made use of a high purity sample. Enthalpies from Dennison join most smoothly with the low temperature Cp° but deviate increasingly at higher temperatures, being 1-2% lower than the other measurements above 1000°K. The selected functions agree with Dennison below 600°K, with Magnus from 600 to 1200°K, and with Kantor et al. above 1200°K. The resulting heat capacities are slightly different from those selected by Hultgren et al., loc. cit.; the latter are 0.07 gibbs/mol higher at 800°K and 0.21 gibbs/mol lower at the melting point.

Investigators	Method	Quantity Reported	T Range, °K	Sample
1. Flubacher et al. (1959)	Calorimetry	Cp°	7.7 - 300	Single crystal, 3mm pieces, Resistance (300°K) = 100 ohm cm, Carrier Concentration ⩽ 10^{15} cm^{-3}
2. Keesom et al. (1959)	Calorimetry	Specific Heat	1.2 - 4.2

Dec. 31, 1960; Dec. 31, 1962; Dec. 31, 1966; Mar. 31, 1967

SILICON (Si) (LIQUID) GFW = 28.086

$S^\circ_{298.15}$ = 10.626 gibbs/mol

Tm = 1685 ± 3°K

Tb = [3513.8] °K (to monomer only)

Tb = [3492] °K (to equilibrium mixture)

$\Delta Hf^\circ_{298.15}$ = 11.585 kcal/mol

ΔHm° = 12.0 ± 0.1 kcal/mol

ΔHv° = [92.047] kcal/mol

ΔHv° = [85.8] kcal/mol

Heat of Formation.

The heat of formation is obtained from that of the crystal by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

Enthalpy data for high purity samples in quartz or vitreous silica capsules have been reported for the range 1698-1915°K by P.B. Kantor, A. M. Kisil and E. M. Fomichev, Ukrain. Fiz. Zhur. 5, 358 (1960), and for the range 1686-1825°K by M. Olette, Phys. Chem. Steelmaking, Proc. Dedham, Mass. 1956, 18-26 (Pub. 1958). Due to the limited temperature range and the experimental uncertainty, the data do not appear to justify more than a constant heat capacity. A value of 6.5 gibbs/mol is selected, intermediate between the values of 6.75 and 6.15 obtained from the separate experiments. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data.

Modern determinations of the melting point range from 1683 ± 1 to 1690 ± 4 °K, the former from the specific volume study of L. D. Lucas and G. Urbain, Compt. Rend. 255, 2414 (1962), and the latter from the enthalpy study of Kantor et al. The selected value of Tm = 1685°K is taken from R. Hultgren, R. L. Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1965, who have reviewed the melting data. The heat of melting is calculated from the selected enthalpy of the crystal and the liquid enthalpy measurements of Kantor et al. and Olette, who reported comparable values of ΔHm° = 11.95 ± 0.18 and 12.095 ± 0.1 kcal/mol, respectively.

Vaporization Data.

Tb is calculated as the temperature for which the ΔGr° = 0 for Si(l) = Si(g). ΔHv° is calculated as the difference between ΔHf°(g) and ΔHf°(l) at Tb. The normal boiling for the equilibrium vapor is calculated as the temperature at which Si, Si_2 and Si_3 attain a total pressure of one atm. ΔHv° at this temperature is calculated as the enthalpy of vaporization of one GFW of liquid to vapor containing 92.1, 7.0 and 0.9 mole percent of monomer, dimer and trimer, respectively. Tetramer and higher polymers, which are ignored in the equilibrium calculation, are probably negligible at this temperature.

Heat of Formation.

The heat of formation is the heat of sublimation, $\Delta Hs^\circ_{298.15}$ = 107.7 kcal/mol, selected from third law analyses of the vapor pressure data reviewed below. Langmuir, Knudsen and transport studies are all in satisfactory agreement throughout the range of 1400 - 2000°K. In addition, O. C. Trulson and P. O. Schissel, Condensation Evaporation Solids Proc. Symp., Dayton, Ohio 1962, 313-17 (Pub. 1964), have experimentally verified that the vaporization coefficient is about 0.8 at 1300°K. This was accomplished by mass spectrometric determination of the Langmuir and Knudsen rates of sublimation from a single crystal sample in a cell designed to give Knudsen effusion from one end and free evaporation from the other end.

The recent studies confirm the mass spectrometric data of R. E. Honig, J. Chem. Phys. 22, 1610 (1954), and substantiate the author's postulate that vapor pressures obtained in early boiling point experiments are too large due to reaction or decomposition of the alumina and silicon carbide containers. In their review of the earlier experiments, R. Hultgren, R. L Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1965, calculated apparent heats of sublimation of less than 90 kcal/mol from the data. Neither these values nor the value of 92 kcal/mol, obtained from the Knudsen data (1485 - 1593°K) of A. V. Tseplyaeva, Yu. A. Priselkov and V. V. Karelin, Vestnik Moskov. Univ., Ser. 2 Khim. 15, No. 5, 36 (1960), were considered in the JANAF selection. It is not clear why Tseplyaeva et al. obtain pressures larger by a factor of 200 from their molybdenum cell.

5. P. Grieveson and C. B. Alcock, Special Ceramics, Proc. Symposium Brit. Ceram. Research Assoc., Stoke-on-Trent 1959, 183-208 (Pub. 1960). Points above 1900°K are omitted.
6. J. Drowart and G. De Maria, pp. 16-23 in "Silicon Carbide," Edited by J. R. O'Connor and J. Smiltens, Pergamon Press, London, 1960.

Heat Capacity and Entropy.

Electronic levels and quantum weights are from L. J. Radziemski and K. L. Andrew, J. Opt. Soc. Am. 55, 474 (1965), and V. Kaufman, L. J. Radziemski and K. L. Andrew, ibid. 56, 911 (1966). An additional level with quantum weight of 200 is estimated above the observed levels and below the dissociation limit; however, the effect of this level on the entropy at 6000°K is negligible. Levels above 39000 cm^{-1} are averaged.

						$^3\Sigma_u^-$	46762	3

ω_e = 510.98 cm^{-1} $\omega_e x_e$ = 2.02 cm^{-1} σ = 2

B_e = 0.2390 cm^{-1} α_e = 0.0013 cm^{-1} r_e = 2.246 Å

Heat of Formation.

The selected value is based on the spectroscopic and equilibrium data summarized below. Verma and Warsop[1] concluded from analysis of the absorption spectra that $D_0°$ = 70 ± 4 kcal/mol. Predissociation of the H state suggested the upper limit $D_0° \leq 74.0$, while linear Birge-Sponer extrapolations of the H and K states gave 78.4 and 68.9 kcal/mol for the ground state. By assuming that the true extrapolation would not reduce the linear extrapolation for the H state by more than half, i.e. from 26 to 13 kcal, the authors arrived at the lower limit of $D_0° \geq 65.5$ for the ground state.

Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibria over the systems SiC-graphite[2], SiC-silicon[3] and boron-carbon-silicon[4]. Third law analysis of the partial pressures of Si_2 and Si over the three systems yields $D_0°$ values of 73.3, 74.3 and 70.4 kcal/mol, which are in good agreement with the spectroscopic values. The selected value, $\Delta Hf°_{298}$ = 141 ± 3 kcal/mol, corresponds to $D_0°$ = 73.0 kcal/mol.

Source	Method	Range, T°K	No. of Points	$\Delta Hr°_{298}$ (kcal/mol)*		Drift (eu)	$\Delta Hf°_{298}$ (kcal/mol)
				2nd law	3rd law		
Verma (1963)	Prediss. of H state		-	≤75.4		-	≥140.0
	LBX of K state		-	70.3			145.1
	Extrap. of H state		-	≥66.9			≤148.5
Drowart (1958)	Mass Spec.	2149-2316	7	95.3±7.1	74.68	-9±3	140.7
Drowart (1960)	Mass Spec.	1703-2160	9	81.0±1.1	75.71	-2.7±0.6	139.7
Verhaegen (1964)	Mass Spec.	2166-2344	4	68 ± 16	71.76	2±7	143.6

*For the reaction $Si_2(g) = 2\ Si(g)$

Heat Capacity and Entropy.

Vibrational and rotational constants are those obtained by Verma and Warsop[1] through combination of their data for the H-X system with those of Douglas[5]. Observation of the same H-X system in matrix isolation by Weltner and McLeod[6] confirms that the lower state is the ground state. Comparison with the isoelectronic molecules C_2, BN, BeO and MgO (7,8,9,10) suggests that there are several possible low-lying excited states in Si_2. Tentative estimates for these levels are given above, based on this comparison and on the observed states (1,5). These estimates are relatively uncertain and probably yield an upper limit for the entropy at temperatures where Si_2 is significant. A probable lower limit may be obtained by increasing the two $^3\Pi$ states by 8000 cm^{-1} and omitting the other estimated levels. This would reduce the entropy by 1.7 eu at 2000°K, corresponding to a change of 3.4 kcal/mol in ΔHr° values based on equilibrium data.

SILICON, TRIATOMIC (Si_3) (IDEAL GAS) GFW = 84.258

Point Group [$D_{\infty h}$]

$S^\circ_{298.15}$ = [64.0] gibbs/mol

ΔHf°_0 = 151.2 ± 10 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 152 ± 10 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	3
[10000]	[6]
[18000]	[2]
21460	3

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[360] (1)
[200] (2)
[630] (1)

Bond Distance: Si-Si = [2.25] Å

Bond Angle: Si-Si-Si = [180°]

σ = [2]

Rotational Constant: B_0 = [0.05928] cm^{-1}

Heat of Formation.

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor species over the systems SiC-graphite[1] and SiC-silicon[2]. Third law analysis of the partial pressures of Si_3 and Si yields the values 154.0 and 149.9 kcal/mol. Both drifts suggest that the entropy may be lower than the tabulated values. It is unlikely that the entropy is in error by more than 5 eu so that most of the drift is inherent in the data. The adopted value of ΔHf°_{298} = 152 ± 10 kcal/mol includes allowance for an error of up to 5 eu.

Source	Method	Range, T°K	No. of Points	ΔHr°_{298} (kcal/mol)* 2nd Law	3rd Law	Drift (eu)	ΔHf°_{298} (kcal/mol)
Drowart (1958)	Mass Spec.	2230-2316	2	209	169.1	-18	154.0
Drowart (1960)	" "	1703-1890	4	204±3	173.2	-17±2	149.9

*For reaction $Si_3(g) = 3\ Si(g)$

Heat Capacity and Entropy.

Weltner and McLeod[3] observed an absorption band near 4660 Å in matrix isolation studies. Their tentative assignment of this band as the $^3\Sigma^-_u \leftarrow {}^3\Sigma^-_g$ transition of Si_3 is adopted here. A $^1\Pi_u$ state is assumed at 18000 cm^{-1}, which is 7000 and 2000 cm^{-1} below the analogous levels[3] for C_3 and C_2Si. Also a $^3\Pi_u$ level is assumed at 10000 cm^{-1}, presumably arising from the same molecular orbital configuration as the $^1\Pi_u$ state. The molecule is assumed to be linear with a bond distance equal to that in Si_2. Vibrational frequencies are estimated from a valence bond calculation using $k_1 = 2.16 \times 10^5$ and $k\delta/l^2 = 0.11 \times 10^5$ dyn/cm. The stretching force constant is obtained from Si_2, while the bending force constant is based on C_2Si and the $^1\Pi_u$ excited state[3] of C_3. The moment of inertia is 47.22×10^{-39} g cm^2.

ΔHf°_0 = 0 kcal/mol

$S^\circ_{298.15}$ = 7.325 ± 0.02 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 0 kcal/mol

Tt = 1155 ± 3 °K

ΔHt° = 0.99 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 113.0 ± 1.0 kcal/mol

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The low temperature heat capacities, 1.1 - 305.51°K, have been measured by many investigators. Their measured temperature range, specimen purity and value of $S^\circ_{298.15}$ reported are listed in the following table. The Cp values, below 298°K, adopted were mainly derived from the data obtained from references 3, 5 and 6, which are in good agreement with other sets of Cp data.

Investigator	Temperature, °K	Purity, %	$S^\circ_{298.15}$, eu

2. C. W. Kothen, Ph. D. Dissertation, The Ohio State University, 1952. Sample purity 99.96%.
3. J. L. Scott, ORNL -2328, Oak Ridge National Laboratory, July 1957.
4. I. Backhurst, J. Iron Steel Inst. (London) 189, 124 (1958).
5. Y. M. Golutvin, Russ. J. Phys. Chem. 33, 164 (1959).
6. L. R. Holland, J. Appl. Phys. 34, 2350 (1963).
7. R. Kohlhaas, M. Braun and O. Vollmer, Z. Naturforsch. 20A, 1077 (1965). Sample purity 99.8%.

The adopted Cp values, 298.15 - 1155°K, were mainly derived from the Cp data reported by reference 7. The low temperature and high temperature Cp data were joined smoothly at 298°K. The Cp values above 1155°K were estimated by graphical extrapolation. $S^\circ_{298.15}$ was derived from the adopted Cp, based on S°_{13} = 0.015 eu.

Transition Data.

See the Ti (β , c) table for details.

Heat of Sublimation.

$\Delta Hs^\circ_{298.15}$ is calculated as the difference between $\Delta Hf^\circ_{298.15}$ for Ti(g) and Ti (α ,c).

Sept. 30, 1966

TITANIUM, BETA (Ti) (CRYSTAL) GFW = 47.90

$S^\circ_{298.15}$ = 8.691 gibbs/mol

Tt = 1155 ± 3 °K

Tm = 1933 ± 10 °K

ΔHf°_0 = Unknown

$\Delta Hf^\circ_{298.15}$ = 1.433 kcal/mol

ΔHt° = 0.99 kcal/mol

ΔHm° = [4.45] kcal/mol

$\Delta Hs^\circ_{298.15}$ = [111.57] kcal/mol

Heat of Formation.

The heat of formation ($\Delta Hf^\circ_{298.15}$) was obtained from $\Delta Hf^\circ_{298.15}$ (α , c) by adding ΔHt° and the difference $H^\circ_{Tt} - H^\circ_{298.15}$ for Ti (α, c) and Ti (β, c).

Heat Capacity and Entropy.

The heat capacities, 1155 - 1856°K, have been determined by many investigators. See the Ti (α , c) table for details. The selected Cp values were evaluated based on the data reported by C. W. Kothen, Ph. D. dissertation, The Ohio State University, 1952, and R. Kohlhaas, M. Braun and O. Vollmer, Z. Naturforsch. 20A, 1077 (1965). The heat capacities below 1155°K and above 1800°K were estimated by graphical extrapolation. The entropy was obtained in a manner analogous to that of the heat of formation.

Transition Data.

Titanium has two crystal forms, i.e. the hexagonal close-packed low-temperature form and the body-centered cubic high-temperature form. The α→β transition temperature has been determined and reported over a range of temperatures, 1154-1167°K, by many investigators. The value of Tt is affected by the impurities in the specimen or adsorbed by the specimen during the measurement and the method used for the determination. The following table indicates the values of Tt reported by different investigators. Also included are the heats of transition (ΔHt°), purity of specimen and property measured. The value of Tt adopted is 1155 ± 3°K, and the value of ΔHt° is selected as 0.99 kcal/mol.

Dec. 31, 1960; Sept. 30, 1966

TITANIUM (Ti) (LIQUID) GFW = 47.90

$S^\circ_{298.15}$ = [10.695] gibbs/mol

Tm = 1933 ± 10°K

Tb = [3591]°K

$\Delta Hf^\circ_{298.15}$ = [5.433] kcal/mol

ΔHm° = [4.45] kcal/mol

ΔHv° = [101.83] kcal/mol

Heat of Formation.

The heat of formation ($\Delta Hf^\circ_{298.15}$) was obtained from $\Delta Hf^\circ_{298.15}$ (β, c) by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298.15}$ for Ti (β , c) and Ti(l).

Heat Capacity and Entropy.

A glass transition temperature at 1300°K was assumed. The heat capacities below 1300°K were obtained from those for Ti (β, c). The Cp value above 1300°K was estimated by comparison with those for the other transition elements and assumed to be constant in the temperature range 1300 - 4500°K. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

Because of the highly reactive nature of Ti(c), the accurate determination of the melting point is difficult. The results reported by different investigators show wide discrepancies. The Tm value adopted was determined by Schofield and Bacon (1953) and later confirmed by Westrum and Feick (1963). The other values of Tm reported are presented in the table below. The heat of melting was calculated based on an estimated entropy of melting, ΔSm°_{1933} = 2.3 eu.

1933	E. F. Westrum, Jr. and G. Feick, ASD-TDR-62-204, Part II, University of Michigan, Ann Arbor, Michigan, May 1963.

Vaporization Data.

Tb is the temperature at which the gibbs energy change (ΔGr°) for the reaction Ti(l) = Ti(g) approaches zero. The difference between ΔHf° (Ti,g) and ΔHf° (Ti,l) at Tb is ΔHv°.

Heat of Formation

The vapor pressure of Ti(β), 1510-1822°K, has been measured in three separate investigations. Based on the reported vapor pressures, the enthalpies of sublimation ($\Delta Hs^\circ_{298.15}$) are evaluated by both the second and third law methods. The results obtained are presented in the following table. The adopted value of $\Delta Hf^\circ_{298.15}$ for Ti(g) is 113.0 ± 1.0 kcal/mol.

Reference	Temperature, °K	$\Delta Hr^\circ_{298.15}$, kcal/mol Second Law Value	$\Delta Hr^\circ_{298.15}$, kcal/mol Third Law Value	Drift eu	$\Delta Hf^\circ_{298.15}$* kcal/mol
1	1510 - 1822	112.23 ± 1.91	110.26 ± 0.81	-1.3 ± 1.2	111.69
2	1658 - 1808	112.41 ± 6.30	110.71 ± 1.10	-1.1 ± 3.7	112.14
3	1587 - 1764	112.26 ± 1.12	111.79 ± 0.18	-0.2 ± 0.6	113.22

*Calculation based on the third law ΔHr°_{298} and $\Delta Hf^\circ_{298}(\beta)$ = 1.43 kcal/mol.

1. J. M. Blocher, Jr., and I. E. Campbell, J. Am. Chem. Soc. 71, 4040 (1949).
2. L. G. Carpenter and W. N. Mair, Proc. Phys. Soc. 64, 57 (1951). The preliminary results were reported by L. G. Carpenter and F. R. Reavell, Nature, 163, 527 (1949).
3. J. W. Edwards, H. L. Johnston and W. E. Ditmars, J. Am. Chem. Soc. 75, 2467 (1953).

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from C. E. Moore, National Bureau of Standards Circular 467 (1949). However, above the level ε_i = 15877.17 cm^{-1}, the values of ε_i and g_i listed in the above table are average values calculated from those given by Moore. The $^1S_0$ level of the ground multiplet which has not been observed is estimated to lie at 12000 cm^{-1} by comparison with the corresponding levels for Ti^{++} ion, Zr and Zr^{++} ion reported by C. E. Moore, loc. cit.

Heat of Formation

The heat of formation is calculated from the reaction $Ti(g) = Ti^+(g) + e^-(g)$ with the JANAF auxiliary value for Ti(g) and an ionization potential = 6.82 eV or 157.276 kcal/mol, obtained from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. III, 1958.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. I, 1949. The electronic levels above 4700 cm^{-1} are averaged. The $H^\circ - H^\circ_{298}$ value at 0°K is -1.888 kcal/mol.

Dec. 31, 1961; June 30, 1966

TUNGSTEN (W) (CRYSTAL) GFW = 183.85

$S^\circ_{298.15}$ = 7.806 gibbs/mol

Tm = 3680 ± 20°K

ΔHf°_0 = 0 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 0 kcal/mol

ΔHm° = [8.46 ± 2.5] kcal/mol

$\Delta Hs^\circ_{298.15}$ = 203.4 ± 1.5 kcal/mol

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

There have been several investigations of the low temperature heat capacity of tungsten: F. Lange, Z. physik. Chem. 110, 343 (1924), covered the range 26-91°K. M. Horowitz and J. G. Daunt, Phys. Rev. 91, 1099 (1953), reported values in the range 1-77°K, while T. R. Waite, R. S. Craig, and W. E. Wallace, Phys. Rev. 104, 1240 (1956), worked from 4-15° and W. DeSorbo, J. Phys. Chem. 62, 965 (1958), from 15-90°K. C. Zwikker and G. Schmidt, Z. Physik. 52, 668 (1928), covered the range from 90 to 2521°K. K. Clusius and P. Franzozini, Z. Naturforsch. 14A, 99 (1959), made a thorough study of the heat capacity in the range 12-274°K, and their measurements were adopted leading to S°_{298} = 7.806 eu based on $S_{12.5^\circ}$ = 0.0088 eu. This value is in disagreement with the quoted value of 7.83 eu but agrees exactly with a separate integration by V. A. Kirillin, A. E. Sheindlin, V. Ya. Chekhovskoi and V. A. Petrov, Zhur. Fiz. Khim. 37, 2249 (1963). In the intermediate temperature range the adiabatic heat capacity measurements of H. L. Bronson, H. M. Chisholm and S. M. Dockerty, Can. J. Res. 8, 282 (1933), from 253 to 773°K joined well with the low temperature measurements and were adopted. The high temperature enthalpies have been measured by several investigators from which were selected the values of F. M. Jaeger and E. Rosenbohm, Rec. trav. chim. 51, 1 (1932), from 273-1800°K; A. Magnus and H. Holzmann, Ann. Physik Ser 5, 3, 585 (1929), who covered the range 373 to 1173°K; M. Hoch and H. L. Johnston, J. Phys. Chem. 65, 855 (1961) who made measurements between 1382 and 2900°K; Kirillin et al., loc. cit., who have made several determinations over the range 600 to 3100°K, and have also analysed the above data and have presented smooth functions from 0 to 3500°K. The present table agrees with that of Kirillin et al. up to 2700°K. Above this temperature the values of Cp adopted follow those reported by I. I. Novikov and P. G. Strelkov, Vestnik. Akad. Nauk SSSR 34, 26(1964), measured by an electric modulation method, up to the melting point. These values rise rapidly above 2700°K and are not inconsistent with the individual measurements of Kirillin et al. at their highest temperatures.

Melting Data.

I. Langmuir, Phys. Rev. 6, 138 (1915), determined the melting point as 3540°K from intrinsic brilliance measurements; this was later corrected to 3655 ± 30°K by H. A. Jones, I. Langmuir and G. M. J. Mackay, Phys. Rev. 30, 201 (1927). M. Pirani and H. Alterthum, Z. Elektrochem. 29, 5 (1923), from pyrometer measurements on a black body hole found 3660 ± 60°K. Using the same technique C. F. Zalabak, NASA Tech. Note D-761 (1961), reports 3680°K on a low carbon specimen; he reports a decrease of the melting point with increasing carbon content. E. Rudy and S. Windisch, Aerojet-General Tech. Rept. No. AFML- TR-65-2 Part 1, Vol. III July 1965, report a melting point of 3696 ± 20°K. The value adopted was 3680 ± 20°K. The heat of melting was obtained by assuming an entropy of melting of 2.3 eu obtained from a comparison of several high melting metals (Fe, Cu, Co, Mg, Al).

Sublimation Data.

See W(g) for details.

Dec. 31, 1961; June 30, 1966

TUNGSTEN (W) (LIQUID) GFW = 183.85

$S^\circ_{298.15}$ = 10.923 gibbs/mol

Tm° = 3680 ± 20°K

Tb° = [5936]°K

$\Delta Hf^\circ_{298.15}$ = 11.223 kcal/mol

ΔHm° = [8.46 ± 2.5] kcal/mol

ΔHv° = [192.824] kcal/mol

<u>Heat of Formation</u>.

The heat of formation at 298°K was calculated from that of the crystal by adding ΔHm° and the difference between $H_{3680}-H_{298}$ for (c) and (l).

<u>Heat Capacity and Entropy</u>.

The heat capacity was estimated as 8.5 gibbs/g-atom by analogy with other monatomic metals. The entropy at 298°K was calculated in a manner analogous to that of the heat of formation. At 2500°K a glass transition was assumed, below which the heat capacity was that of the crystal.

<u>Melting Data</u>.

See crystal table for details.

<u>Vaporization Data</u>.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Heat of Formation.

ΔHf°_{298} is the heat of sublimation of the crystal at 298°K; this has been obtained by 2nd and 3rd law analysis of the vapor pressure data of three investigators. The results are summarized below:

			$\Delta Hs^\circ_{298.15}$ kcal/mol		
Ref.	Range°K**	Points	2nd law	3rd law	3rd law drift eu
1	2511-3053	12*	200.9 ± 3.6	201.57 ± 1.6	0.1 ± 1.4
2	2383-3123	14	214.8 ± 1.4	202.17 ± 2.5	-4.7 ± 0.5
3	2574-3183	10	202.4 ± 2.7	203.35 ± 1.2	0.4 ± 1.0

*1 point rejected due to failure of a statistical test.

**All temperatures are taken from Ref. 3, in which the earlier measurements have been corrected.

The values are remarkably good, since even at the highest temperature the pressures are less than 10^{-6} atm; all workers used the Langmuir technique. Since the data of Refs. 1 and 3 do not drift, it may be assumed that the accommodation coefficient is unity or close to unity. The drift in the second set cannot be eliminated by assuming a non-unity accomodation coefficient, nor does there appear to be a constant pressure error. Most probably the drift is due to slight errors in temperature. For example, if the readings were 24° high at the low end and 10° low at the high end, the drift would be eliminated; errors of this magnitude are quite possible. The value adopted for $\Delta Hs^\circ_{298.15}$ is 203.4 ± 1.5 kcal/mol.

Heat Capacity and Entropy.

The electronic energy levels were taken from those listed by C. E. Moore, U. S. Natl. Bur. Std. Circular 467 (1958). Levels above 25000 cm^{-1} were averaged.

Heat of Formation.

The heat of formation is obtained by adding the heat of ionization at 0°K to the ΔHf°_0 W(g). The heat of ionization, 184.036 kcal (7.98 eV), is obtained from C. E. Moore, Natl. Bur. Std. Circular 467, Vol. III, Washington D. C. (1958).

Heat Capacity and Entropy.

The electronic energy levels are obtained from C. E. Moore, loc. cit. In the low lying configuration [Xe] $4f^1 5d^5$ the ^2F, ^2G, ^2F, ^2H and ^2S multiplets have not been observed. The total degeneracy of these levels (70) is split among three estimated levels of 20000, 21000, and 22000 cm^{-1}, obtained by analogy with Mo^+. A realistic uncertainty in these levels would produce a maximum uncertainty of 0.03 gibbs/mol in the free energy function and 0.09 gibbs/mol in the entropy at 6000°K.

The enthalpy at 0°K is -1.487 kcal/mol.

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacities, 1.1 - 298.2°K, have been measured by Todd (1), Skinner (2), Eastermann (3), Wolcott (4), Burk (5), and Kneip (6). Values of $Cp_{298.15}$ were reported as 6.19 and 6.01 gibbs/mol by Todd (1) and Skinner (2), respectively. The difference (beginning at 150°K) is probably caused by different amounts of impurities (e.g. O_2, H_2, N_2) in the samples. Neither sample was analyzed for hydrogen and oxygen content. Small amounts of either of these impurities would cause important changes in Cp. Remeasurement of Cp using a high purity sample is desirable to resolve the difference. Tentatively, we adopt smooth Cp values which are intermediate between those of Todd and Skinner in the temperature range 200 - 298°K. The curve at lower temperatures is based on references 1, 2, 4, 5 and 6. $S^\circ_{298.15}$ is derived from the adopted Cp based on $S^\circ_{1.16}$ = 0.0008 eu.

Enthalpies have been measured using drop calorimetry by Jaeger (7), Coughlin (8), Skinner (9), Redmond (10), Adenstedt (11) and Douglas (13). Cp above 298°K has been measured by Scott (12) and Vollmer (15) using adiabatic calorimetry and by Klein (14) using pulse heating. The data lead to differences in Cp which are even greater than those noted at 298°K. Observed Cp's are lower than the adopted curve by roughly 3 to 6 per cent, but the observed enthalpies are generally higher by 0 to 10 per cent. Impurities are partly to blame but there also may be a systematic difference between the methods. The purest and best-characterized samples are those of Douglas (13) and Vollmer (15). Even the high-purity sample of Douglas gives H values which are abnormally high at 573°K, suggesting the presence of thermal effects of solid solution and precipitation due to a small amount of hydrogen in the sample (12).

The adopted Cp is based mainly on Douglas (13), but references (7, 9, 15) were also given some weight. Deviations of (13) from the adopted values range from +3.3 per cent at 573°K to +0.3 at 1123°K. Other deviations (each in order of increasing T) are 3 to 0 per cent (7), 1.3 to -1.7 per cent (9), -4 to -6 per cent (15), 5.4 to 1.7 per cent (8) and -1 to 9.5 per cent (10) in terms of enthalpy. Cp is extrapolated linearly above 1133°K.

Transition Data

See Zr(β) table for details.

Heat of Sublimation

$\Delta Hs^\circ_{298.15}$ is calculated as the difference between $\Delta Hf^\circ_{298.15}$ for Zr(g) and Zr(α).

Dec. 31, 1967

ZIRCONIUM, BETA (Zr) (CRYSTAL) GFW = 91.22

$S^\circ_{298.15}$ = 11.152 gibbs/mol $\Delta Hf^\circ_{298.15}$ = 1.706 kcal/mol

T_t = 1135 ± 10°K ΔHt° = 0.96 kcal/mol

Tm = 2125 ± 2 °K ΔHm° = 5.0 ± 0.3 kcal/mol

Heat of Formation

The heat of formation is obtained from $\Delta Hf^\circ_{298}(\alpha)$ by adding ΔHt° and the difference between $H^\circ_{Tt} - H^\circ_{298}$ for Zr(α) and Zr(β).

Heat Capacity and Entropy

The enthalpies and Cp of Zr(β), at temperatures 1135 - 2118.2 °K, have been measured by many investigators (see Zr(α) table for details). The selected Cp values are based on the data reported by Douglas (1) and Skinner (2). Deviations from the adopted enthalpies are -1.4 to 0.8 per cent (1), -0.4 to 0.3 (2), and 0.2 to 3.0 per cent (7). Deviations of the measured Cp from the adopted values are -5 to -3 per cent (14) and about -6 per cent (10). The heat capacities below 1143.2 and above 1798°K are estimated by linear extrapolation.

The entropy is obtained in a manner analogous to that of the heat of formation.

Transition Data

Zirconium has two crystal forms, i.e. the hexagonal-close-packed α-form and the cubic-body-centered β-form (3, 4, 5). The value and range of Tt for α → β depends strongly on the kind and amount of impurities (5, 15). For example, nitrogen and oxygen increase Tt while hydrogen decreases it. The adopted value is Tt = 1135 ± 10°K, although recent measurements using purer samples indicate a somewhat higher value. These are summarized below along with the data for ΔHt°. The value ΔHt° = 0.96 kcal/mol is derived from the adopted enthalpy and Cp data on Zr(α) and Zr(β).

Dec. 31, 1960; June 30, 1961; Dec. 31, 1967

ZIRCONIUM (Zr) (LIQUID) GFW = 91.22

$S^\circ_{298.15}$ = [13.289] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [6.351] kcal/mol

Tm = 2125 ± 5 °K ΔHm° = 5.0 ± 0.4 kcal/mol

Tb = [4776.9] °K ΔHv° = 141.13 kcal/mol

Heat of Formation

The heat of formation is obtained from $\Delta Hf^\circ_{298}(\beta)$ by adding ΔHm° and the difference between $H^\circ_{2125} - H^\circ_{298}$ for Zr(β) and Zr(ℓ).

Heat Capacity and Entropy

A glass transition temperature at 1400°K is assumed. The heat capacities below 1400°K are taken from those for Zr(β). The Cp value above 1400°K is estimated by comparison with that of Zr(β) at Tm and assumed to be constant in the temperature range 1400 - 5500°K. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point of Zr(β) has been determined by many investigators. The results reported show wide discrepancies, probably caused by the differences in purity of the samples used for determination. The Tm value adopted is obtained from Oriani and Jones. The other values of Tm reported are presented in the table below.

The adopted heat of melting was determined calorimetrically by V. P. Elyntin, M. A. Maurakh and G. M. Sverdlov, Izv. Vysshikh Uchebn. Zavedenii, Tsvetn. Met. 10, No. 2, 87 (1967). Zirconium samples from two different sources were melted in an Arc-crucible furnace. The crucible contained an insert of graphite which had a thick lining (presumably of zirconium carbide) in order to minimize carbonization of Zr(ℓ). The molten Zr was poured through an opening in the bottom of the crucible into a calorimeter containing molten Mg as the calorimetric fluid. The method of calculating the value of ΔHm° was described in detail by V. P. Elytin, M. A. Maurakh, V. Y. Mishuk, and G. M. Sverdlov, Izv. Vyssihikh Uchebn. Zavendenii, Tsvetn. Met. 10, 60 (1967). The authors estimated the uncertainty as about 7 percent in ΔHm°.

Vaporization Data

Tb is the temperature at which the Gibbs energy change (ΔGr°) for the reaction Zr(ℓ) = Zr(g) approaches zero. The difference between ΔHf°(Zr, g) and ΔHf°(Zr, ℓ) at Tb is ΔHv°.

Zirconium (Zr)

Heat of Formation

Vapor pressures of Zr(β) and Zr(ℓ) were measured, using the Langmuir free-vaporization method, by Skinner (1) and Koch (3), respectively. Based on the reported results, the corresponding enthalpies of sublimation and vaporization are evaluated by the second and third law methods. See the table below for details. The values of evaporation rate and vapor pressure given by Koch in Table 2 on page 9 are too big by a factor of 10 due to typographical errors. The samples employed by Koch were prepared from iodide-process zirconium of 99.9 percent purity by tungsten-electrode melting in an inert atmosphere. The measured weight losses were in general more than one hundred times greater than those reported by Skinner. The value of ΔHf°_{298}(Zr, g) adopted is 148.3 ± 3.5 kcal/mol, which is derived using the data of Koch.

Trulson (2) used a mass spectrometer with a high temperature Knudsen effusion source to obtain the vapor pressure for Zr(β) and Zr(ℓ). Based on the reported vapor pressures the values of heat of sublimation of Zr(β) are evaluated by the second and third law methods. The results are presented in the table below. Because of the uncertainties in obtaining absolute pressures from ion intensities, these results are not adopted.

Zwikker (4) determined the vapor pressures of Zr(β) by the Langmuir method. However, the zirconium sample was reported to be covered by an oxide layer during the measurement. Therefore, the pressures obtained are probably not the vapor pressures of pure zirconium and are not used for evaluation.

Investigator	Temperature, °K	No. of Points	ΔHr°_{298}, kcal/mol Second Law	Third Law	Drift eu	ΔHf°_{298}* kcal/mol
1. Skinner (1951)	1951 - 2047	12	138.6±2.1	144.2	2.8±1.0	145.9
2. Trulson (1965)	1968 - 2274	22	141.3±1.5	142.1	0.4±0.7	143.8
3. Koch (1968)	2229 - 2795	16	142.7±4.3	141.9	-0.3±1.7	148.3

*Calculation based on the third law ΔHr°_{298}, $\Delta Hf^\circ_{298}(\beta)$ = 1.706 and $\Delta Hf^\circ_{298}(\ell)$ = 6.351 kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from Moore (5). Above the level ε_i = 15932.10 cm^{-1}, the values of ε_i and g_i listed in the above table are average values calculated from those given by Moore. The entropy contributed by the the unobserved electronic is estimated to be less than 0.1 eu at 6000°K.

Heat of Formation

The heat of formation is calculated from the reaction $Zr(g) - e^-(g) = Zr+(g)$ with the JANAF auxiliary value for Zr(g); and an ionization potential = 6.84 eV or 157.737 kcal/mol, obtained from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. III, 1958.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. II, 1952 and Vol. III, 1958. The electronic levels above 2500 cm^{-1} are averaged. The $H° - H°_{298}$ value at 0°K is -1.786 kcal/mol.

ELECTRON GAS (e^-) (REFERENCE STATE) AT. WT. = 0.00054876

0 to 6000°K. IDEAL GAS

$S^\circ_{298.15}$ = 4.988 cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15} = 0$

Electronic Levels and Multiplicities

ϵ_1 cm.$^{-1}$,	g_1
0	2

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Calculated by assuming to be an ideal monatomic gas of mass 0.00054876 with two equivalent spin states. The enthalpy between 298 and 0°K. is 1.481 kcal. mole^{-1} as for all unexcited monatomic gases.

Publications in the National Standard Reference Data Series National Bureau of Standards

You may use this listing as your order form by checking the proper box of the publication(s) you desire or by providing the full identification of the publication you wish to purchase. The full letter symbols with each publication number and full title of the publication and author must be given in your order, e.g. NSRDS–NBS–17, Tables of Molecular Vibrational Frequencies, Part 3, by T. Shimanouchi.

Pay for publications by check, money order, or Superintendent of Documents coupons or deposit account. Make checks and money orders payable to Superintendent of Documents. Foreign remittances should be made either by international money order or draft on an American bank. Postage stamps are not acceptable.

No charge is made for postage to destinations in the United States and possessions, Canada, Mexico, and certain Central and South American countries. To other countries, payments for documents must cover postage. Therefore, one-fourth of the price of the publication should be added for postage.

Send your order together with remittance to Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.

☐ NSRDS-NBS 1, **National Standard Reference Data System—Plan of Operation,** by E. L. Brady and M. B. Wallenstein, 1964 (15 cents), SD Catalog No. C13.48:1.

☐ NSRDS-NBS 2, **Thermal Properties of Aqueous Uni-univalent Electrolytes,** by V. B. Parker, 1965 (45 cents), SD Catalog No. C13.48:2.

☐ NSRDS-NBS 3, Sec. 1, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si II, Si III, Si IV,** by C. E. Moore, 1965 (35 cents), SD Catalog No. C13.48:3/Sec.1.

☐ NSRDS-NBS 3, Sec. 2, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si I,** by C. E. Moore, 1967 (20 cents), SD Catalog No. C13.48:3/Sec.2.

☐ NSRDS-NBS 3, Sec. 3, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, C I, C II, C III, C IV, C V, C VI,** by C. E. Moore, 1970 ($1), SD Catalog No. C13.48:3/Sec.3.

☐ NSRDS-NBS 3, Sec. 4, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, N IV, N VI, N VII,** by C. E. Moore, (in press).

☐ NSRDS-NBS 4, **Atomic Transition Probabilities, Volume I, Hydrogen Through Neon,** by W. L. Wiese, M. W. Smith and B. M. Glennon, 1966 ($2.50), SD Catalog No. C13.48:4/Vol.I.

☐ NSRDS-NBS 5, **The Band Spectrum of Carbon Monoxide,** by P. H. Krupenie, 1966 (70 cents), SD Catalog No. C13.48:5.

☐ NSRDS-NBS 6, **Tables of Molecular Vibrational Frequencies, Part 1,** by T. Shimanouchi, 1967 (40 cents), SD Catalog No. C13.48:6/Pt.1.

☐ NSRDS-NBS 7, **High Temperature Properties and Decomposition of Inorganic Salts, Part 1, Sulfates,** by K. H. Stern and E. L. Weise, 1966 (35 cents), SD Catalog No. C13.48:7/Pt.1.

☐ NSRDS-NBS 8, **Thermal Conductivity of Selected Materials,** by R. W. Powell, C. Y. Ho, and P. E. Liley, 1966 ($1). PB189698

☐ NSRDS-NBS 9, **Tables of Bimolecular Gas Reactions,** by A. F. Trotman-Dickenson and G. S. Milne, 1967 ($2), SD Catalog No. C13.48:9.

☐ NSRDS-NBS 10, **Selected Values of Electric Dipole Moments for Molecules in the Gas Phase,** by R. D. Nelson, Jr., D. R. Lide, Jr., and A. A. Maryott, 1967 (40 cents), SD Catalog No. C13.48:10.

☐ NSRDS-NBS 11, **Tables of Molecular Vibrational Frequencies, Part 2,** by T. Shimanouchi, 1967 (30 cents), SD Catalog No. C13.48:11/Part 2.

☐ NSRDS-NBS 12, **Tables for the Rigid Asymmetric Rotor: Transformation Coefficients from Symmetric to Asymmetric Bases and Expectation Values of P_z^2, P_z^4, and P_z^6,** by R. H. Schwendeman, 1968 (60 cents), SD Catalog No. 13.48:12.

☐ NSRDS-NBS 13, **Hydrogenation of Ethylene on Metallic Catalysts,** by J. Horiuti and K. Miyahara, 1968 ($1), SD Catalog No. C13.48:13.

☐ NSRDS-NBS 14, **X-Ray Wavelengths and X-Ray Atomic Energy Levels,** by J. A. Bearden, 1967 (40 cents), SD Catalog No. C13.48:14.

☐ NSRDS-NBS 15, **Molten Salts, Vol. 1, Electrical Conductance, Density, and Viscosity Data,** by G. J. Janz, F. W. Dampier, G. R. Lakshminarayanan, P. K. Lorenz, and R. P. T. Tomkins, 1968 ($3), SD Catalog No. C13.48:15/Vol.1.

☐ NSRDS-NBS 16, **Thermal Conductivity of Selected Materials, Part 2,** by C. Y. Ho, R. W. Powell, and P. E. Liley, 1968 ($2), SD Catalog No. C13.48:16/Pt.2.

☐ NSRDS-NBS 17, **Tables of Molecular Vibrational Frequencies, Part 3,** by T. Shimanouchi, 1968 (30 cents), SD Catalog No. C13.48:17/Pt.3.

☐ NSRDS-NBS 18, **Critical Analysis of the Heat-Capacity Data of the Literature and Evaluation of Thermodynamic Properties of Copper, Silver, and Gold From 0 to 300°K,** by G. T. Furukawa, W. G. Saba, and M. L. Reilly, 1968 (40 cents), SD Catalog No. C13.48:18.

☐ NSRDS-NBS 19, **Thermodynamic Properties of Ammonia as an Ideal Gas,** by L. Haar, 1968 (20 cents), SD Catalog No. C13.48:19.

☐ NSRDS-NBS 20, **Gas Phase Reaction Kinetics of Neutral Oxygen Species,** by H. S. Johnston, 1968 (45 cents), SD Catalog No. C13.48:20.

☐ NSRDS-NBS 21, **Kinetic Data on Gas Phase Unimolecular Reactions,** by S. W. Benson and H. E. O'Neal, 1970 ($7), SD Catalog No. C13.48:21.

☐ NSRDS-NBS 22, **Atomic Transition Probabilities, Vol II, Sodium Through Calcium, A Critical Data Compilation,** by W. L. Wiese, M. W. Smith, and B. M. Miles, 1969 ($4.50), SD Catalog No. C13.48:22/Vol.II.

☐ NSRDS-NBS 23, **Partial Grotrian Diagrams of Astrophysical Interest,** by C. E. Moore and P. W. Merrill, 1968 (55 cents), SD Catalog No. C13.48:23.

☐ NSRDS-NBS 24, **Theoretical Mean Activity Coefficients of Strong Electrolytes in Aqueous Solutions from 0 to 100° C,** by Walter J. Hamer, 1968 ($4.25), SD Catalog No. C13.48:24.

☐ NSRDS-NBS 25, **Electron Impact Excitation of Atoms,** by B. L. Moiseiwitsch and S. J. Smith, 1968 ($2), SD Catalog No. C13.48:25.

☐ NSRDS-NBS 26, **Ionization Potentials, Appearance Potentials, and Heats of Formation of Gaseous Positive Ions,** by J. L. Franklin, J. G. Dillard, H. M. Rosenstock, J. T. Herron, K. Draxl, and F. H. Field, 1969 ($4), SD Catalog No. C13.48:26.

☐ NSRDS-NBS 27, **Thermodynamic Properties of Argon from the Triple Point to 300 K at Pressures to 1000 Atmospheres,** by A. L. Gosman, R. D. McCarty, and J. G. Hust, 1969 ($1.25), SD Catalog No. C13.48:27.

☐ NSRDS-NBS 28, **Molten Salts, Vol. 2, Section 1, Electrochemistry of Molten Salts: Gibbs Free Energies and Excess Free Energies From Equilibrium-Type Cells,** by G. J. Janz and C. G. M. Dijkhuis. **Section 2, Surface Tension Data,** by G. J. Janz, G. R. Lakshminarayanan, R. P. T. Tomkins, and J. Wong, 1969 ($2.75), SD Catalog No. C13.48:28/Vol.2.

☐ NSRDS-NBS 29, **Photon Cross Sections, Attenuation Coefficients and Energy Absorption Coefficients From 10 keV to 100 GeV,** by J. H. Hubbell, 1969 (75 cents), SD Catalog No. C13.48:29.

☐ NSRDS-NBS 30, **High Temperature Properties and Decomposition of Inorganic Salts, Part 2, Carbonates,** by K. H. Stern and E. L. Weise, 1969 (45 cents), SD Catalog No. C13.48:30.

☐ NSRDS-NBS 31, **Bond Dissociation Energies in Simple Molecules,** by B. deB. Darwent, 1970 (55 cents), SD Catalog No. C13.48:31.

☐ NSRDS-NBS 32, **Phase Behavior in Binary and Multicomponent Systems at Elevated Pressures: *n*-Pentane and Methane-*n*-Pentane,** by V. M. Berry and B. H. Sage, 1970 (70 cents), SD Catalog No. C13.48:32.

☐ NSRDS-NBS 33, **Electrolytic Conductance and the Conductances of the Halogen Acids in Water,** by W. J. Hamer and H. J. DeWane, 1970 (50 cents), SD Catalog No. C13.48:33.

☐ NSRDS-NBS 34, **Ionization Potentials and Ionization Limits Derived from the Analyses of Optical Spectra,** by C. E. Moore, 1970 (75 cents), SD Catalog No. C13.48:34.

Announcement of New Publications in National Standard Reference Data Series

Superintendent of Documents,
Government Printing Office,
Washington, D.C. 20402

Dear Sir:

Please add my name to the announcement list of new publications to be issued in the series: National Standard Reference Data Series—National Bureau of Standards.

Name____

Company____

Address____

16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.)

This monograph is the second edition of the JANAF Thermochemical Tables. It contains thermodynamic properties for some 1099 chemical species. The following properties are tabulated as functions of temperatures: C°_p, S°, $(F^\circ-H^\circ_{298})/T$, $H^\circ-H^\circ_{298}$, ΔH°_f and Log Kp.

17. KEY WORDS (Alphabetical order, separated by semicolons) Evaluated Data; Thermal Functions; Thermodynamic Properties of Materials; Thermodynamics.

18. AVAILABILITY STATEMENT

☒ UNLIMITED.

☐ FOR OFFICIAL DISTRIBUTION. DO NOT RELEASE TO NTIS.
