The available data on the microwave spectrum of methanol are critically reviewed for information applicable to radio astronomy. Molecular data such as moments and product of inertia, torsional potential constants, centrifugal distortion and torsion-rotation interaction constants, dipole moment, and structural parameters are tabulated. Observed rotational transitions are presented for the astronomically interesting isotopic forms of methanol when available. Detailed centrifugal distortion and torsion-rotation interaction calculations have been carried out for the most abundant isotopic form of methanol. Transitions are tabulated for the frequency range from 500 MHz to 200 GHz. Measured transition error limits have been reproduced from the original literature. References are given for all data included.

Key words: Internal rotation; interstellar molecules; methanol; microwave spectra; molecular parameters; radio astronomy; rotational transitions; torsion.

1. Introduction

The present tables represent the third part of a series of critical reviews [1, 2]¹ which are intended to update and revise the existing tabulated literature on molecules already identified in interstellar observations. The spectral information reported includes predicted as well as observed transitions between 500 MHz and 200 GHz. The reported transitions are further limited by fixing a maximum value for the total rotational and torsional energy of the lower state of the transition.

This upper limit must logically vary with the molecule being reviewed and was set at 125 cm⁻¹ for methanol. It is felt that this limit is generous enough to allow for the presentation of all methanol transitions which might be observed by existing telescopes. Spectral data on the less abundant isotopic forms have been included where available. Deuterated species have been purposely neglected because of the expected low cosmic abundance of the deuterium atom.

2. Organization of Tables

In order to reduce transcription errors, the tables of spectra have been reproduced directly from computer printout wherever possible. The open literature has been searched to October 1, 1972, for information relating to the microwave spectrum of methanol. All reports published prior to 1960 were included in Volume III of NBS Monograph 70 [3] and will not be directly referenced in the present review. Data taken from these reports are referenced MON 70.

2.1. Molecular Parameter Table

The inertial, torsional potential, centrifugal distortion, and torsion-rotation interaction constants in table 1 were obtained from least squares analyses of the observed spectral lines with a computer program which includes these interaction terms in the computation of the rotational energies. The specific formulas used are described by Lees and Baker [4]. The molecular constants I_b , I_c , I_{ab} , F_v , G_v , L_v , D_{JK} and D_J were obtained from a least squares fit to those observed lines arising from μ_a , the component of the dipole moment parallel to the methyl top axis, the a -axis in the internal axis system. The remaining constants were determined from a least squares fit to the hypothetical $J = 0$ origins of $\Delta k = 1$ Q branches, which arise from the μ_b dipole component. These were obtained by extrapolating observed series back to their origins. Because a fundamental indeterminacy exists among I_{a1} , I_{a2} , V_3 , V_6 , k_6 , and k_7 , one of them must be fixed for the nonlinear least squares fit to converge [4, 5]. The values given here correspond to k_7 fixed at zero, but the large errors given for the six parameters reflect their variation with choice of the fixed parameter. The Q branch fit included a large number of infrared data, which were weighted according to the inverse square of their uncertainties.

Recently, more accurate infrared data have been obtained and a new fit was carried out [6] with the infrared data more heavily weighted relative to the microwave data. The new interaction constants give a better overall fit, but reproduce the microwave frequencies less accurately than the present constants. The available data on $^{13}\text{CH}_3\text{OH}$ and $\text{CH}_3^{18}\text{OH}$ were not sufficient to allow a complete least squares treatment of these species. Several of the inertial parameters for these species shown in table 1 were calculated from the structural parameters of $^{12}\text{CH}_3^{16}\text{OH}$. The structural parameters and electric dipole moment were taken directly from the literature cited.

2.2. Microwave Spectral Tables

For each spectral line the first column of table 2 contains the upper state and lower state quantum numbers in the form J and k followed by the torsional symmetry species. Transitions are ordered by symmetry with the A species listed first, followed by the E species with positive or zero k , and, finally, the E species with negative k . Lower case k is used here to denote a signed quantum number. Capital K is defined as positive or zero, with $K = |k|$. The k E levels were previously labelled by Lees and Baker [4] as $K E_1$ for $k > 0$, and $K E_2$ for $k < 0$. In most instances the K -doublets are resolved for the A species so that the two components are distinguished by A^+ and A^- . Transitions between the two levels of a K -doublet ($A^+ \rightleftharpoons A^-$) are designated simply as A . Each symmetry type is then ordered by increasing J .

The quantum numbers are followed by the observed line frequency and, in parentheses, the experimentally estimated uncertainty in MHz. Where an experimental measurement is not available, the line frequency given is enclosed in double asterisks and is actually a calculated frequency obtained by interpolation from the calculations and observations of adjacent transitions of the same Q or P branch. The uncertainty listed is the estimated accuracy of the interpolation, which is generally substantially better than the accuracy of the computer calculated frequency, given in the third column. References to the laboratory measurements are shown in the last column of the table.

The line strengths for the rotational transitions are shown in column 4. For a transition $J'_{k'_\sigma} \leftarrow J''_{k''_\sigma}$, where σ denotes the symmetry species of the torsional state and is listed under "Species" in table 2, the line strength is defined as

$${}^xS(J'_{k'_\sigma}; J''_{k''_\sigma}) = \frac{(2J'' + 1) |\mu_{J' \leftarrow J''}|^2 |\langle k'_\sigma | k''_\sigma \rangle|^2}{\mu_x^2},$$

where the superscript x indicates the axis parallel to the dipole moment component μ_x which produces the transition, $|\mu_{J' \leftarrow J''}|$ indicates the dipole moment rotational matrix element connecting the upper and lower rotational levels involved in the transition, and $\langle k'_\sigma | k''_\sigma \rangle$ indicates the torsional overlap matrix element for the two states. The line strength may be related to the Einstein coefficient A in the following manner. The probability, $A(J'_{k'_\sigma}; J''_{k''_\sigma})$, of a spontaneous transition per molecule in one second from the higher state, $J'_{k'_\sigma}$, to the lower state, $J''_{k''_\sigma}$ is

$$A(J'_{k'_\sigma}; J''_{k''_\sigma}) = \frac{1.1639 \times 10^{-20} \nu^3 \mu_x^2}{2J' + 1} {}^xS(J'_{k'_\sigma}; J''_{k''_\sigma}),$$

where ν is the transition frequency in MHz and μ_x the electric dipole component in Debye as defined above.

The total rotational and torsional energy of each level was calculated using the constants of table 1. The energies are given in columns 5 and 6 in units of cm^{-1} . Because the two torsional symmetry species do not interconvert, the zero energy for a species was chosen to be that of the lowest level of that species. The lowest energy levels, namely the 0_0 level for the A species and the 1_{-1} level for the E species are located at 127.817 cm^{-1} and 133.307 cm^{-1} , respectively, above the bottom of the barrier to internal rotation.

As a convenience to the user, the transition frequencies from table 2 have been listed according to increasing frequency in table 3. Observed transitions for $^{13}\text{CH}_3^{16}\text{OH}$ and $^{12}\text{CH}_3^{18}\text{OH}$ are listed in tables 4 and 5.

2.3. List of Symbols and Conversion Factors

a. Symbols

$I_{a,b,c,ab}$	Moments and product of inertia with respect to the indicated internal axis (amu \AA^2). Note that these are not principal axes.
I_{a2}	Moment of inertia of CH_3 group about its axis.
I_{a1}	Moment of inertia of the framework ($I_a = I_{a1} + I_{a2}$).
Δ	Inertial defect (amu \AA^2). $\Delta = I_c - I_{a1} - I_b$.
a, b, c	Internal axes with a -axis parallel to CH_3 symmetry axis, and c -axis perpendicular to COH plane.
$V_{3,6}$	3-fold and 6-fold components of torsional barrier potential (cm^{-1}).
F_v, G_v, L_v	Interaction constants for a -type lines (MHz).
$D_{JK, J, K}$	Centrifugal distortion constants (MHz).
$k_{1,\dots,7}$	Interaction constants for Q branch origins (MHz).
$\mu_{a,b}$	Components of the dipole moment along the internal axes (Debye).
D	Abbreviation for Debye units ($1D = 10^{-18}$ electrostatic units of charge \times centimeters, or $1D = 3.33564 \times 10^{-30}$ coulomb-meter).
$r(X-Y)$	Distance between centers of mass of atoms X and Y (\AA).
$\angle XYZ$	Angle formed by atoms X, Y and Z (degrees).
CH_3 tilt	Angle between a -axis (CH_3 axis) and C-O bond (degrees).
J	Total rotational angular momentum quantum number.
k	Projection of J on the a -axis.
K	Absolute value of k , $K = k $.
$A \pm, E$	Torsional symmetry species. (\pm refers to K -doublet).
σ	Torsional symmetry quantum number ($\sigma = 0, +1$ for A, E species).

(. . .)

Parentheses in the numerical listings contain measured or estimated uncertainties. These should be interpreted as: $1.409(0.083) = 1.409(83) = 1.409 \pm 0.083$ MHz.

b. Conversion Factors

The following conversion factors have been used:

$$C \text{ (MHz)} = \frac{5.05375 \times 10^5}{I_c \text{ (amu } \text{\AA}^2)}$$

$$1 \text{ cm}^{-1} = 29,979.25 \text{ MHz}$$

2.4. Acknowledgments

The authors are indebted to Dr. Y. Y. Kwan and Dr. D. M. Dennison of the University of Michigan for preliminary communication of their work, and to Dr. B. E. Turner of the National Radio Astronomy Observatory for pointing out an error in the original tables. One of us (R.M.L.) gratefully acknowledges financial support from the National Research Council of Canada, and the University of New Brunswick Research Fund. We thank Mr. S. S. Haque of the University of New Brunswick for some of the $^{13}\text{CH}_3^{16}\text{OH}$ measurements.

^a The listing includes all transitions in the range 500 MHz to 200 GHz involving energy levels less than 125 cm^{-1} above the lowest levels of the symmetry species.

^b Heights of the ground levels above the bottom of the barrier are: A ($J = 0, K = 0$) 127.817

E ($J = 1, K = -1$) 133.307

^c Observed frequencies enclosed in asterisks are actually hand-calculated by interpolation from the (Obs-Calc) of transitions of the same series. They represent the best calculations available.

^a The listing includes all transitions in the range 500 MHz to 200 GHz involving energy levels less than 125 cm^{-1} above the lowest levels of the symmetry species.

^b Observed frequencies enclosed in asterisks are actually hand-calculated by interpolation from the (Obs-Calc) of transitions of the same series. They represent the best calculations available.

TABLE 4. Observed microwave transitions in $^{13}\text{CH}_3\text{OH}$ (MHz)

Transition			Observed frequency (estimated uncertainty)	Reference
Upper state	Lower state	Species		
1 0	0 0	A+	47205.20 (0.5)	MON70
2 0	1 0	A+	94407.02 (0.1)	73A
