

Evaluation of Binary Excess Volume Data for the Methanol + Hydrocarbon Systems

R. Srivastava and B. D. Smith

Thermodynamics Research Laboratory, Washington University, St. Louis, Missouri 63130

Received March 25, 1986; revised manuscript received November 6, 1986

The volume change of mixing data for the methanol + hydrocarbon binary mixtures have been compiled and the best sets of data identified. The needs for new experimental data have been defined.

Key words: excess volume; hydrocarbons; methanol; volume change of mixing.

1. Introduction

Previous papers^{1,2} have evaluated the vapor-liquid equilibrium (VLE), heat of mixing (H^E) and volume

change of mixing (V^E) data for two C₆ hydrocarbon + C₆ hydrocarbon binary systems. The objective was to identify the best data sets and to define the most pressing needs for new experimental data. The reports were designed to meet the needs of three types of users: experimentalists who need well-established test systems to check new experimental apparatuses; correlators who need thermodynamically consistent sets of VLE, H^E , and V^E data to test and support new correlations; and designers who need the best available data to design process equipment.

This report extends that work to include the excess volume data for the important alcohol + hydrocarbon systems. As in the preceding evaluation papers, an attempt is made to establish selected values of V^E at mole fractions of 0.25, 0.50, and 0.75. Hopefully, the availability of selected values at three mole fractions will reduce the practice of comparing data sets at only the midpoint.

Whenever possible, recommended data sets are identified. If no data set can be recommended, the best data sets are identified. Needed new experimental measurements are defined when appropriate.

The excess volume is the difference between the mixture molar volume and the pure component volumes,

$$V^E = V - x_1 V_1 - x_2 V_2. \quad (1)$$

The procedures used to evaluate the worthiness of V^E data have been described and illustrated in detail in the first and last articles of a series of four back-to-back articles published previously.¹

2. Compounds Covered

Because of the large number of alcohol + hydrocarbon data sets in the literature, it was necessary to restrict the first part of the alcohol + hydrocarbon project to the methanol systems. Hydrocarbons of all carbon numbers were covered in a comprehensive literature research, but data of interest (V^E , mixture volume or mixture density) were found only for hydrocarbons in the C₅ to C₇ range. No data sets of any kind were found for hydrocarbons with more than seven carbon atoms. Volumetric data both below and above the critical temperature of the hydrocarbon components do exist in the literature for the methanol + acetylene,³ methanol + ethane,⁴ and the methanol + butane⁵ systems. Those data are not given in a form which permitted conversion to V^E values and therefore had to be excluded from the project.

3. Summary of Evaluation Results

The evaluation results for all of the useful methanol + hydrocarbon excess volume data sets found are summarized in Table 1. Each set of data is represented by a single line in the table. The literature reference numbers are the Master Reference List (MRL) numbers which were assigned to the individual documents when they were retrieved. Those numbers key the data set to the literature citations in Table 11. The data sets listed for each system are ordered with respect to temperature. In most cases, the data were measured at atmospheric pressure and a specific experimental pressure was not reported because of the insensi-

tivity of such data to pressure. A pressure of 0.1013 MPa was assumed for those data sets.

Previous papers¹ have described the evaluation methods and the significance of the reported results. The five possible quality ratings range from A for excellent data to E for very bad data. An N means the data were not sufficient to support any evaluation test and therefore no quality rating could be assigned. A multiple-letter quality rating is assigned in those cases where the evaluation tests which could be performed eliminated some quality ratings but did not distinguish between the remaining ones. For example, a data set with an F (fair) scatter rating cannot have a quality rating of A or B. In the absence of the comparison test to further characterize the data set, a CDE quality rating is assigned. In any event, the quality rating assigned to a set of data represents a summary of the individual test results.

Only two kinds of tests are applied to V^E data. The first is a scatter rating which not only reflects scatter in the experimental data points but also reflects how well the shapes of the experimental data plots agree with the characteristic shape for the particular system. Seven scatter ratings are used: E = excellent, G = good, F = fair, M = marginal, U = unacceptable, S = smoothed, and N = none.

The second test is a comparison of the data set values to the "best" V^E vs T curves at three mole fractions: $x_1 = 0.25$,

0.50, and 0.75. Usually, the deviation of an experimental data set point from the best curve drawn by the evaluator through all the data sets' points is expressed as a percentage. (The procedure for locating the best curve has been described in the V^E paper in Ref. 1.) For the methanol + hydrocarbon systems, that approach was not feasible because some of the systems have S-shaped V^E curves and some of the V^E values involved in the calculation are close to zero. Hence, the deviation values in Table 1 are exposed as

$$100(\text{experimental value} - \text{best curve value}).$$

Those deviation values show how far the individual data set points deviate from the best curves established by the evaluator. The test compares data sets at the same temperature and also at different temperatures.

The use of a V^E data set as a test system for a new experimental apparatus should be restricted to data sets with an A rating. A well-established test system requires multiple A-rated data sets at the given temperature.

The use of V^E data sets for correlation purposes usually should be restricted to those with a quality rating of A or B. In some cases one of the better C sets can be used when no A or B sets are available.

4. Selected Point Values

Before the three best V^E vs T curves can be drawn at mole fractions of 0.25, 0.50, and 0.75, it is necessary to select the best point values at each temperature where multiple data sets exist. Often there will be enough good data sets at a given temperature—e.g., 298.15 K¹—to select a very firm value which positions the best curve accurately at that temperature. Unfortunately, that is not the case at any temperature for any of the methanol + hydrocarbon systems.

It was possible to establish V^E vs T curves only for the methanol + benzene system—but without any firmly established “anchor” points. The methanol + pentane and the methanol + hexane systems have only one set of data each. All of the data sets for the methanol + cyclohexane system except two are below the upper critical solution temperature of 45.87 °C (319.02 K),⁶ and their regions of partial miscibility all include the $x_1 = 0.25, 0.50$, and 0.75 points. The methanol + toluene system is miscible over the 252.05–333.26 K range for which data are available, but the points obtained from the one set with an E scatter rating and the four sets with an F scatter rating were too scattered to permit the location of meaningful V^E vs T curves. As indicated by the reported V^E data, the methanol + heptane system is partially miscible over the 291.50–298.15 K range covered by the available four data sets, and three of those four data sets report data on only one side or the other of the region of partial miscibility, which includes the $x_1 = 0.25, 0.50$, and 0.75 points at all the data set temperatures.

There was no justification for anything but linear V^E vs T curves for the methanol + benzene system. As shown in Table 1, V^E values at 0.25, 0.50, and 0.75 mole fraction could be determined with some degree of certainty only for eight data sets. The three sets with G scatter ratings were used to locate the straight lines: the Ocon, Tojo, and Espada (MRL 21323) set at 293.15 K; the Wood, Langer, and Battino

Table 2. Best curve V^E values for the methanol(1) + benzene(2) system

$t, ^\circ\text{C}$	T, K	Values from best curves		
		$x_1 = 0.25$	$x_1 = 0.50$	$x_1 = 0.75$
20	293.15	0.0171	-0.0095	-0.0242
23	296.15	0.0215	-0.0051	-0.0219
25	298.15	0.0244	-0.0022	-0.0204
30	303.15	0.0318	0.0050	-0.0166
40	313.15	0.0465	0.0195	-0.0089
50	323.15	0.0612	0.0340	-0.0012

(MRL 18139) set at 298.15 K; and the Cibulka, Hynek, Holub, and Pick (MRL 41405) set at 313.50 K. At $x_1 = 0.25$, the Wood *et al.* set at 298.15 fell slightly below the straight line. At $x_1 = 0.75$, the Ocon *et al.* set at 293.15 K also fell below the line drawn.

Table 2 lists the V^E values read from the best curves at the three mole fractions. Because of the lack of multiple reliable data sets, at the various temperatures, those values are not firmly established as were the values for the benzene + cyclohexane system.¹ Nevertheless, the values indicate to the experimentalist what the V^E values appear to be at each temperature-mole fraction combination, based on the existing information in the literature. Those values will undoubtedly change to some degree as additional good data are reported.

5. Best Data Sets

Multiple data sets are available for only four methanol + hydrocarbon systems: methanol + benzene (22 sets), methanol + cyclohexane (eight sets), methanol + toluene (16 sets), and methanol + heptane (four sets).

Inspection of all the benzene + methanol data sets indicated that the V^E and V^E/x_1x_2 curves should have the shapes best illustrated by the Cibulka *et al.* data set (MRL 41405) at 298.15 K in Figs. 1 and 2. The three data sets used to establish the best V^E vs T curves are shown in Tables 3–5 and Figs. 3–5. The change in V^E with temperature was small and obscured by scatter in the data. However, it appears that the V^E curve is moving slowly toward positive deviation at all mole fractions. The maximum V^E value appears to increase, and the negative V^E value at the minimum appears to decrease slightly in absolute value, as the temperature increases from 293.15 to 313.15 K. The mole fractions at which the maximum and minimum V^E values occur appear to move slightly to the right (higher x_1 values) as temperature increases. Comparison of the V^E/x_1x_2 curves for the two Cibulka *et al.* data sets at 298.15 and 313.15 (MRL 41405) also indicates that V^E is moving toward larger positive values as temperature increases.

The methanol + cyclohexane system is partially misci-

two data sets reported by Harms (MRL 4487) at 279.15 and 303.15 K probably define the sides of the V^E curve better than do the Campbell and Anand sets below the critical solution temperature. Tables 6 and 7, and Figs. 6 and 7 show the two Campbell and Anand sets above the upper critical solution temperature.

The methanol + toluene system is miscible over the 252.05–333.26 K temperature range for which data are available. The Ocon *et al.* data set at 293.15 K (MRL 1398) shown in Table 8 and in Figs. 8 and 9 indicates that the V^E vs x_1 curve is S-shaped with a maximum at about 0.08 mole fraction methanol and a minimum at about 0.69. Unfortunately, none of the other data sets report V^E values below $x_1 = 0.10$ (only two of the other sets report values below

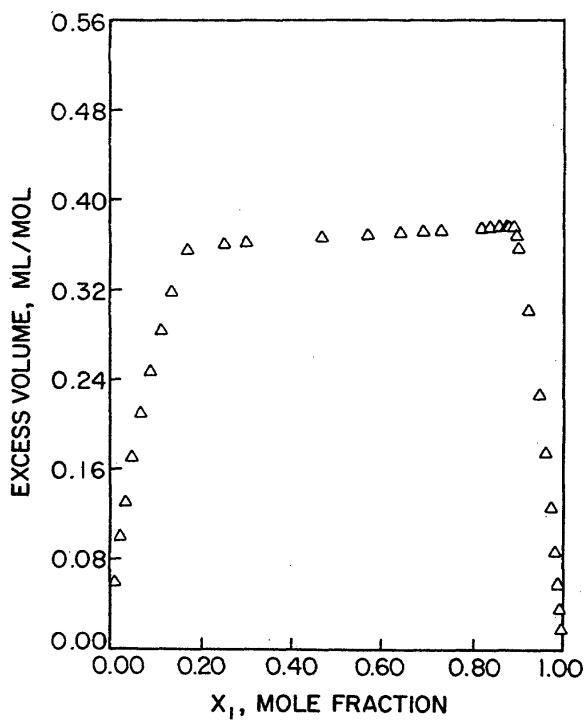

FIG. 10. V^E values from Treszczanowicz and Benson for methanol (1) + heptane(2) at 298.15 K, MRL 40893.

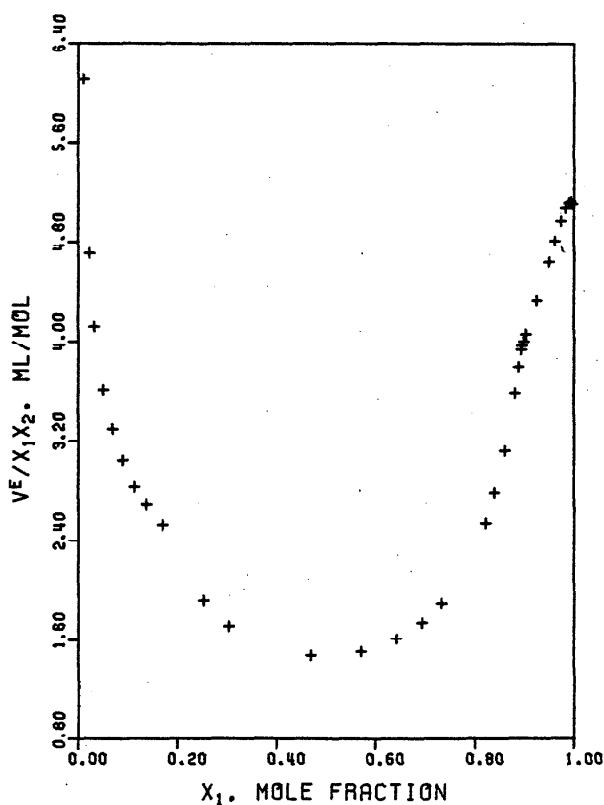

FIG. 11. V^E/X_1X_2 plot of the data in Fig. 10.

point decreases slowly as temperature increases, which implies that the system is moving toward positive deviation at all mole fractions. The data are too scattered to indicate which way the mole fraction of the minimum point changes with temperature.

The four sets of data listed in Table 1 for the methanol + heptane binary are all in the partially miscible temperature range. Only the set by Treszczanowicz and Benson (MRL 40893) is complete; the other three sources report only a few points on one side or the other of the two-phase region. Hence, the system is represented only by the Treszczanowicz and Benson data shown in Table 9 and Figs. 10 and 11.

6. Experimental Measurements Needed

Obviously, good experimental measurements are needed for any methanol + hydrocarbon binary system. However, insofar as experimentalists are concerned, new efforts should concentrate first on the methanol + benzene system. Dependable data are needed at 293.15, 298.15, and 313.15 K to firmly establish the best V^E vs T curve in that region but first, it would be wise to concentrate on 298.15 K until the behavior at that temperature is firmly established. That would provide a test system with an S-shaped V^E vs x_1 curve.

Correlators need firmly established V^E data for methanol plus each of at least three hydrocarbon types: aromatic, cycloalkane, and alkane. Also they need data for each system over as wide a temperature range as possible.

Miscibility gaps affect the choices of compounds and temperatures for the new cycloalkane and alkane data. The critical solution temperature is 45.87 °C (319.02 K)⁶ for the methanol + cyclohexane system. The data of Campbell and Anand (MRL 4886) at 50 °C should be checked by duplicate measurements, and then new data should be accumulated at spaced temperatures up to the temperature limit of the apparatus being used.

The methanol + pentane system is miscible at 298.15 K (Tenn and Missen, MRL 27). Joerges *et al.* (MRL 23528) report a wide miscibility gap at 20 °C for the methanol + hexane system. Figure 10 shows the miscibility gap at 298.15 K for methanol + heptane. Systems with miscibility gaps must of course be handled by a general correlation of mixture properties but first a new correlation formalism should be tested on miscible systems. Hence, new experimental work should concentrate first on the methanol + pentane system, and then move to the partially miscible and miscible temperature ranges for methanol + hexane and heptane. Hexane complements benzene and cyclohexane better than does heptane for the initial tests of a new correlation formalism.

7. Pure Compound Densities

Pure Compound volume values are needed to calculate V^E values from

$$V^E = V - x_1 V_1 - x_2 V_2, \quad (1)$$

when mixture density or volume values are reported. The author's pure compound values are always used if they are

Table 10. Pure compound density data

	Methanol	Heptane	Toluene
	183 to 341 K 52 points RMSD = 0.00036	183 to 384 K 123 points RMSD = 0.00023	179 to 400 K 253 points RMSD = 0.00033
A	0.10709171D+01	0.92942894D+00	0.11439199D+01
B	0.95429528D-03	0.75804070D-03	0.87978248D-03
C	0.49999952D-02	0.59999990D+01	0.60034208D+01
D	0.35699976D+03	0.54864941D+03	0.60689600D+03

given. If not, pure compound density values are obtained from an evaluated data file. The general procedures used to select and correlate the pure compound saturated liquid density data have been described in preceding papers.¹

The pure compound volume values used for each set of data appear in the tabulation for the set (for examples, see Tables 3-9). When obtained from the evaluated data file, those values were calculated from a Francis equation,

$$\text{Density, g/ml} = A - BT - C/(E - T) \quad (2)$$

correlation using constants such as those listed in Table 10. The Francis equation constants for benzene, cyclohexane, and hexane have been listed in previous papers.^{1,2} The molar volume used for pentane for the single data set for methanol + pentane appears on the tabulation for that system. Table 10 presents the Francis equation constants for methanol, heptane, and toluene. The numbers of literature documents reporting liquid density or volume data for methanol, heptane, and toluene were 116, 50, and 111, respectively. The numbers of documents from which one or more data points were selected for fitting were 18, 46, and 78, respectively.

8. Data Set Tabulations

Only the best data for the various binary systems are tabulated in this paper. Copies of the tables and plots for the other data sets can be obtained from Professor Buford D. Smith, Box 1198, Washington University, St. Louis, Missouri 63130.

9. Bibliography

Table 11 is the bibliography for the excess volume data for the methanol + hydrocarbon systems covered by this evaluation project. As explained above, the literature data for the methanol + acetylene,³ methanol + ethane,⁴ and the methanol + butane⁵ systems could not be evaluated as V^E data.

The identifying numbers in Table 11 are the Laboratory's Master Reference List (MRL) numbers. The MRL numbers relate the literature documents listed in Table 11 to the individual data sets listed in Table 1.

Sometimes documents report data in a form which does not permit transcription and evaluation. In most such cases, the data are presented only in graphical form. Even though their data sets do not appear in Table 1, such documents are listed in Table 11 to provide complete coverage of all the literature data.

10. Nomenclature

MRL	Acronym for Master Reference List.
RMSD	Acronym for root-mean-squared deviation.
V	Liquid molar volume of mixture.
V_i	Liquid molar volume of component i .
V^E	Excess volume. Defined by Eq. (1).
x_i	Liquid mole fraction of component i .

Evaluation of Binary Excess Enthalpy Data for the Methanol + Hydrocarbon Systems

R. Srivastava and B. D. Smith

Thermodynamics Research Laboratory, Washington University, St. Louis, Missouri 63130

Received March 25, 1986; revised manuscript received November 6, 1986

The heat of mixing data for the methanol + hydrocarbon binary mixtures have been compiled and the best sets of data identified. The needs for new experimental data have been defined.

Key words: excess enthalpy; heat of mixing; hydrocarbons; methanol.

1. Introduction

Previous papers^{1,2} have evaluated the vapor-liquid equilibrium (VLE), heat of mixing (H^E) and volume change of mixing data for selected C₆ hydrocarbon + C₆ hydrocarbon binary systems. The objective was to identify the best data sets and to define the most pressing needs for new experimental data. The reports were designed to meet the needs of three types of users: experimentalists who need well-established test systems to check new experimental apparatuses; correlators who need thermodynamically consistent sets of VLE, H^E , and V^E data to test new correlations; and designers who need the best available data to design process equipment.

This report extends that work to include the excess enthalpy data for the important alcohol + hydrocarbon systems. As in the preceding evaluation papers, an attempt is

made to establish selected values of H^E at mole fractions of 0.25, 0.50, and 0.75. Hopefully, the availability of selected values at three mole fractions will reduce the practice of comparing data sets at only the midpoint.

Whenever possible, recommended data sets are identified. If no data set can be recommended, the best data sets are identified. Needed new experimental measurements are defined when appropriate.

The excess enthalpy is related to the mixture and pure component molar enthalpies by

$$H^E = H - x_1 H_1 - x_2 H_2.$$

The procedures used to evaluate the accuracy of H^E data have been described and illustrated in detail in the first and third articles of four back-to-back articles published previously.¹

2. Compounds Covered

Because of the large number of alcohol + hydrocarbon data sets in the literature, it was necessary to restrict the first part of the alcohol + hydrocarbon project to the methanol systems. Hydrocarbons of all carbon numbers were covered in a comprehensive literature search. Useable data were found for hydrocarbons in the C₂ to C₈ carbon number range.

3. Summary of Evaluation Results

The evaluation results for all the methanol + hydrocarbon excess enthalpy data sets are summarized in Table 1. Each set of data is represented by a single line in the table. The literature reference numbers are the master reference list (MRL) numbers which were assigned to the individual documents when they were retrieved. Those numbers key the data sets to the literature citations in the Bibliography at the end of this paper. The data sets listed for each system are ordered with respect to temperature. In many cases, the data

were measured at atmospheric pressure and a specific experimental pressure was not reported because of the insensitivity of such data to pressure. A pressure of 0.1013 MPa was assumed for those data sets in Table 1.

Previous papers¹ have described the evaluation methods and the significance of the reported results. The five possible quality ratings range from A for excellent data to E for very bad data. An N means the data were not sufficient to support any evaluation test and therefore no quality rating could be assigned. A multiple-letter quality rating is assigned in those cases where the evaluation tests which could be performed eliminated some quality ratings but did not distinguish between the remaining ones. For example, a data set with an F (fair) scatter rating cannot have a quality rating of A or B. In the absence of the comparison test to further characterize the data set, a CDE quality rating is assigned. In any case, the quality rating assigned to a set of data represents a summary of the individual test results.

Only two kinds of tests are applied to H^E data. The first is a scatter rating which not only reflects scatter in the experimental data points but also reflects how well the shapes of the experimental data plots agree with the characteristic shape for the particular system. Seven scatter ratings are used: E = excellent, G = good, F = fair, M = marginal, U = unacceptable, S = smoothed, and N = none.

The second test is a comparison of the data set values to the "best" H^E vs 1/T curves at three mole fractions: $x_1 = 0.25, 0.50$, and 0.75 . The deviation of an experimental data set point from the best curve drawn by the evaluator through all the data sets' points is expressed as a percentage of the best curve value. The test compares data sets at the same temperature and also at different temperatures.

The use of an H^E data set as a test system for a new experimental apparatus should be restricted to data sets with an A rating. A well-established test system requires multiple A-rated data sets at the given temperature.

The use of H^E data sets for correlation or design purposes should be restricted to those with a quality rating of A or B. In some cases, one of the better C sets can be used when no A or B sets are available.

4. Selected Point Values

Before the three H^E vs 1/T plots can be made for the comparison test, it is necessary to select the best point values at each temperature where multiple data sets appear. Tables 2-4 and Figs. 1-3 for the methanol + benzene system at 298.15 K illustrate the tabulations and plots which can be produced to support those choices.

The S code letter in the tables is the scatter rating. That scatter rating letter also appears above the point symbol in the corresponding figures.

The ET (equipment type) code in the three tables denotes the type of calorimeter used to measure the set of data. In the three figures, the equipment type is denoted by the symbol. A description of each equipment type, and the assignments for the numerical codes in Tables 2-4, and the symbols in the corresponding figures, are given in the benzene + cyclohexane H^E report.¹ A brief description of the

numerical codes appearing in Tables 2–4 follows:

- 01 McGlashan batch vessel;
 - 02 Scatchard batch vessel;
 - 04 miscellaneous batch vessels;
 - 05 Van Ness semi-batch vessel;
 - 06 miscellaneous semi-batch vessels.

In a batch vessel, both pure components are initially present in the vessel and then mixed by some technique such as rocking the vessel, breaking a glass ampoule, etc. A semi-batch vessel is one where only one component is initially present in the vessel and the second component is titrated into the vessel in increments, but no material is withdrawn from the vessel during the run.

The Techner and Strazielle (MRL 4761) points in Tables 2-4 and Figs. 1-3 were obtained from light scattering data rather than calorimetrically.

Table 5. Best curve H^E values for the methanol(1) + benzene(2) system

T, K	$1/T \times 10^2$	Values from best curves		
		$x_1 = 0.25$	$x_1 = 0.50$	$x_1 = 0.75$
297.40	0.3362	703.0	614.0	358.0
298.15	0.3354	712.0	621.7	361.8
308.15	0.3245	832.0	732.6	422.5
318.15	0.3143	953.0	850.0	505.6

Only one methanol + benzene data set at 298.15 K was given an E rating (Mrazek and Van Ness, MRL 686). The Van Ness semi-batch vessel used for that data set has been proven in extensive use by many investigators. As can be seen in Figs. 1-3, that data set avoids the extremes among the rather widely scattered points. Hence, it is reasonable to select that data set as being most representative for the methanol + benzene system at 298.15 K.

Even though the number of data sets at other temperatures are insufficient to require tables and plots such as Tables 2-4 and Figs. 1-3, the reasons for selecting the Mrazek and Van Ness set at 298.15 also lead to the selection of their data sets at 308.15 and 318.15 K.

The best H^E vs $1/T$ curves at $x_1 = 0.25, 0.50$, and 0.75 drawn through the three Mrazek and Van Ness data sets at 298.15, 308.15, and 318.15 K have a negative slope and are slightly concave upward. The values read from those curves are tabulated in Table 5. Note that the curves were extrapolated slightly to the point for the MRL 18302 set at 297.4 K.

As can be seen from Table 1, H^E vs $1/T$ curves could be established for only two other systems besides methanol + benzene: the methanol + hexane and the methanol + toluene binaries. The upper critical solution temperature for the methanol + cyclohexane system is 45.87 °C (319.02 K) (Campbell and Kartzmark, MRL 5768), and only one useable set of data above that temperature is available; the partial miscibility gap in the Touhara *et al.* (MRL 10643) data set at 298.15 K includes the $x_1 = 0.25, 0.50$, and 0.75 points. A similar situation exists for the methanol + heptane system where five of the six available data sets fall below the upper critical solution temperature of about 51.2 °C (324.35 K)³.

The methanol + hexane data are dominated by the data sets of Savini, Winterhalter, and Van Ness (MRL 1080). They provide two sets (at 298.15 and 303.15 K) below and four sets above the critical solution temperature, which they found to be just above 33.7 °C (306.85 K). As in the case of

Table 7. Best curve H^E values for the methanol(1) + toluene(2) system

T, K	$1/T \times 10^2$	Values from best curves		
		$x_1 = 0.25$	$x_1 = 0.50$	$x_1 = 0.75$
298.15	0.3354	704.0	622.5	376.2
308.15	0.3245	846.0	758.0	459.0
318.15	0.3143	981.7	891.0	549.0

the methanol + benzene system, the H^E vs $1/T$ curves fit the four miscible data set points better if they are slightly curved and concave upwards. The values read from those curves are tabulated in Table 6.

The three Mrazek and Van Ness (MRL 686) data sets were used to establish the best curves for the methanol + toluene system. Points from those curves appear in Table 7. The Tsao and Smith (MRL 1953) data set has H^E and H^E/x_1x_2 vs x_1 curves worthy of an E scatter rating except for a large gap in the data above $x_1 = 0.81$; that data set lies close to the curve through the Mrazek *et al.* points. The two Mason and Washburn sets (MRL 8717) present no points below $x_1 = 0.20$, and they differ considerably from the Mrazek *et al.* data sets.

It is not necessary to tabulate best curve values for the methanol + ethylbenzene system; the best values available are those provided by the only three available data sets from Mrazek and Van Ness (MRL 686).

5. Best Data Sets

Two excellent calorimeters have been applied extensively to the measurement of H^E data for methanol + hydrocarbon binaries. The flow calorimeter developed by Christensen and co-workers has been used at 298.15 for the binaries containing methanol with ethane, propane, butane, pentane, and para-xylene. Those single data sets are not confirmed by data from other sources but, based on the very accurate performance of the Christensen vessel on the well-established benzene + cyclohexane system,¹ it is highly probable that those data sets are accurate.

A similar situation exists for the methanol + ethylbenzene system. The only data for that system are the three sets at 298.15, 308.15, and 318.15 K obtained with the Van Ness semi-batch vessel. Based on the proven performance of that vessel on other systems, it is reasonable to assume those data sets are accurate.

The Van Ness vessel has also applied to the methanol + benzene, hexane, toluene and heptane binaries; as discussed in the previous section, the resulting data have been selected as the superior data sets in each instance. The methanol + cyclohexane binary is the only methanol + hydrocarbon system with H^E data which does not have data sets from the Christensen or the Van Ness vessels.

Tables 8-33 and Figs. 4-29 present the best available methanol + hydrocarbon data sets in the order in which they appear in Table 1. All of the sets obtained with the Christensen and the Van Ness apparatuses are shown. For the methanol + cyclohexane system, the Touhara *et al.*

Table 6. Best curve H^E values for the methanol(1) + hexane(2) system

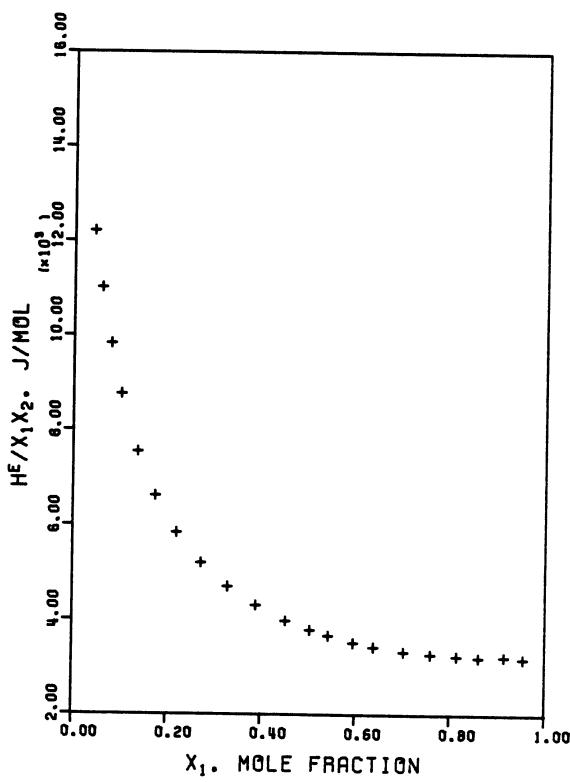

FIG. 28. Data of Mrazek *et al.* for the methanol(1) + ethylbenzene(2) system at 318.15 K, MRL 686.

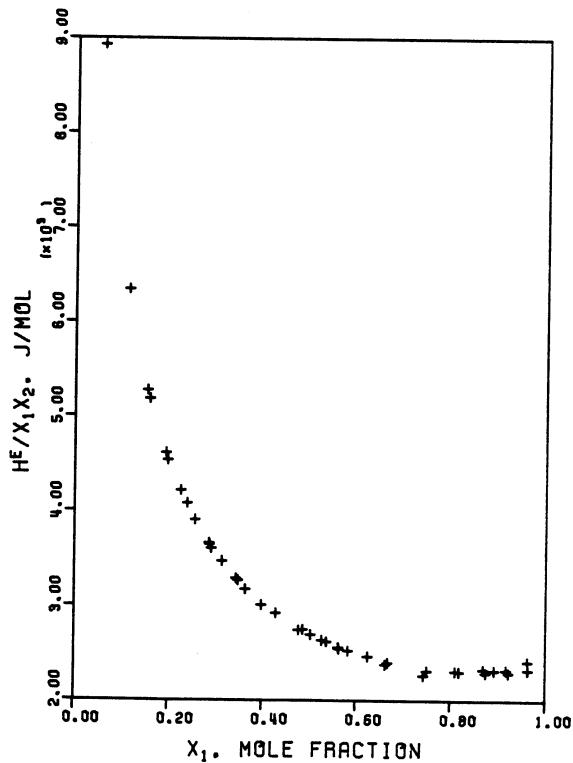

FIG. 29. Data of Christensen *et al.* for the methanol(1) + para-xylene(2) system at 298.15 K, MRL 41007.

(MRL 10643) data set below the critical solution temperature, and the Campbell *et al.* (MRL 5768) data set above the critical solution temperature, are shown. The Campbell *et al.* set is the only one above the critical solution temperature of 319.02 K. (Note: A $\times 10^3$ notation by the figure ordinate scale means the decimal must be shifted three places to the right.)

6. Experimental Measurements Needed

With the benzene + cyclohexane system¹ and the cyclohexane + hexane system² both well established as test systems for new calorimeters, there is little incentive to acquire enough data to establish a methanol + hydrocarbon binary (such as methanol + benzene) as another test system.

The work by Van Ness and co-workers at the Rensselaer Polytechnic Institute, and by Christensen and co-workers at Brigham Young University, has produced more good data for the methanol + hydrocarbon binaries than is usually available for such a group of systems. However, both the correlator and the designer need H^E data over as wide a temperature range as possible, and that is the area where further experimental work is justified for those binaries for which one or more good data sets already exist.

To complete the data base for the correlator, additional data are needed for the methanol + cyclohexane system, both above and below the critical solution temperature. That is the only binary listed in Table 1 for which no reliable data set exists in the miscible region.

7. Other Data Set Tabulations

Only the best data sets for the various binary systems are tabulated in this paper. Copies of the tables and plots for the other data sets can be obtained from Professor Buford D. Smith, Box 1198, Washington University, St. Louis, Missouri 63130.

8. Bibliography

Table 34 is the bibliography for the excess enthalpy data for the methanol + hydrocarbon system. The identifying numbers in Table 34 are the Laboratory's Master Reference List (MRL) numbers. The MRL numbers relate the literature documents listed in Table 34 to the individual data sets listed in Table 1.

Sometimes documents report data in graphical form only. Even though such data sets cannot be transcribed and processed, their citations usually are included in Table 34 in order to provide comprehensive coverage of the literature data.

9. Acknowledgments

This work was supported by the Office of Standard Reference Data of the National Bureau of Standards with funds supplied by the National Science Foundation (under Agreement No. PRM-8005187-AO1) and by the Industrial Participants in the Thermodynamics Research Laboratory.
