DOE based the transportation impact analysis on guidelines from the American Institute of Chemical Engineers with respect to chemical transportation risk analyses (DIRS 182284-Center for Chemical Process Safety 1995, all). The methodology presented in this section uses both qualitative and quantitative components. The number of fatalities and accidents resulting from vehicular and train travel were based on fatality and accident rates provided by Federal Railroad Administration and Nevada Department of Transportation statistics. The rates were used in combination with the specifics of an operation (for example, total distance traveled, route length, and number of trips) to estimate the likelihood of accidents and fatalities. The estimated number of potential vehicular traffic fatalities was based on assuming a total distance traveled from workers commuting during both the construction and operational phases. The estimates for potential rail traffic fatalities and accidents were also based on assuming total distances traveled from material/equipment transport during construction and shipment during operations. Traffic accidents under the Shared-Use Option were qualitatively analyzed based on a proportional comparison to the Proposed Action. Rail line fatalities associated with the Shared-Use Option were evaluated by revising the analyses for the additional rail traffic levels.

4.2.10.2 Proposed Action

4.2.10.2.1 Nonradiological Impacts

Nonradiological health and safety addresses potential occupational incidents to construction and operations workers resulting from physical hazards and exposure to nonradioactive chemicals generated from construction and operations. This section also summarizes impacts associated with nonradiological occupational health and safety hazards from specific resource areas, including biological hazards, dust and soils hazards, air quality hazards, and noise hazards.

4.2.10.2.1.1 Workers. Tables 4-112 and 4-113 summarize nonradiological impacts to workers from industrial hazards associated with construction and operation of the proposed rail line and associated facilities under the Proposed Action. Table 4-112 summarizes impacts for construction and operation of the rail line. Table 4-113 summarizes impacts for construction and operation of facilities. In general, rail line construction would create hazards that are common to heavy construction and earthmoving operations. Accidents that commonly occur at construction workplaces are:

- Trip and fall
- Object falls on worker
- Electrocution
- Asphyxiation (confined space or other)
- Penetrating wounds
- Dermal exposure skin injury
- Jobsite vehicle accident injury
- Hearing injury
- Object in eye
- Welding or laser eye injury
- Injury from trench or slope collapse
- Injury from explosion

Similar types of workplace accidents can occur during operation and maintenance of the proposed rail line and facilities. Workplace incidents also include incidents such as heat stress and workplace exposure to hazardous chemicals. These types of workplace accidents and incidents are included in the Bureau of Labor Statistics incident rate statistics for total recordable cases, lost workday cases, and fatalities summarized in Table 4-111.

DOE would adopt a rigorous safety program that would enable workers to avoid most common accidents as required by DOE Order O 440.1A, *Worker Protection Management for DOE Federal and Contractor Employees*, as codified in 10 CFR Part 851. Chapter 7 of this Rail Alignment EIS describes mitigation measures and safety management practices to address workplace hazards. In accordance with 10 CFR Part 851 DOE would also be required to comply with applicable regulations under 29 CFR Part 1910 *Occupational Health and Safety Standards*, 29 CFR Part 1926, *Safety and Health Regulations for Construction*, and 29 CFR Part 1960, *Basic Program Elements for Federal Employee Occupational Safety and Health Programs and Related Matters* (Section 11.4, Table 11-4, pp. 1 to 3). Code of Federal Regulations 29 Part 1926 applies to DOE contractors; 29 CFR 1960 (Basic Elements for Federal Employees OSHA) applies to DOE employees; 10 CFR 851.23 also requires DOE to apply American Council of Government Industrial Hygienist Threshold Limit Values for Chemical Substances and Physical Agents and Biological Exposure Indices when the Threshold Limit Values are lower (more protective) than permissible exposure limits in 29 CFR 1910.

Table 4-112 includes nonradiological impacts from proposed rail line construction and operations, but does not include facilities construction and operation. Rail line construction impacts are estimated for activities occurring during the minimum 4.5-year construction phase, including construction of the rail line (rail roadbed, track)

Rail line operations impacts include impacts to train crews and escort and security personnel.
The numbers of full-time-equivalent worker years for each-rail line construction and operations activity, summarized in Table 4-112, were obtained from Appendix D of the Air Quality Emissions Factors and Socioeconomic Input-Caliente Rail Corridor, Rev 03, May 15, 2007 (DIRS 180921-Nevada Rail Partners 2007, Appendix D) and the Personnel Breakdown Per Camp shown as Table 4-2 and the schedule shown as Figure 7-A, NRL Construction Schedule, from the Construction Plan-Caliente Rail Corridor, Rev 03, May 15, 2007 (DIRS 180922-Nevada Rail Partners 2007, Figure 7-A).

Impacts from rail line construction support facilities include:

- Construction of the construction camps
- Operation of construction camps
- Construction of ballast quarries
- Operation of ballast quarries
- Construction of water wells
- Operation of water wells
- Construction of concrete batch plants
- Operation of concrete batch plants

Table 4-112. Estimated impacts to workers from nonradiological industrial hazards during proposed railroad construction and railroad operations under the Proposed Action.[a,b]

Group and industrial hazard category	Construction			Operations		
	FTEs[c]	Labor hours worked	Incidents	FTEs[c]	Labor hours worked	Incidents
Involved workers	5,444	10.9 million		1,471	2.9 million	
Total recordable cases[d]			304			37
Lost workday cases			168			28
Fatalities			0.62			0.26
Noninvolved workers	1,350	2.7 million		0	0	
Total recordable cases[d]			32			0
Lost workday cases			18			0
Fatalities			0.05			0
Totals[e]	6,794	13.6 million		1,471	2.9 million	
Total recordable cases[d]			336			37
Lost workday cases			186			28
Fatalities			0.67			0.26

a. Calculations are based on U.S. Department of Labor, Bureau of Labor Statistics, incident rates in Table 4-111 and full-time-equivalent worker year data from Appendix D of the Air Quality Emissions Factors and Socioeconomic Input-Caliente Rail Corridor, Rev 03, May 15, 2007 (DIRS 180921-Nevada Rail Partners 2007) and Table 4-2 and Figure 7-A, NRL Construction Schedule, from the Construction Plan-Caliente Rail Corridor, Rev 03, May 15, 2007 (DIRS 180922-Nevada Rail Partners 2007). All rail line construction workers are considered to be involved workers with the exception of construction camp operating workers.
b. Totals include rail line construction, quarry construction and operation, concrete batch plant construction and operation, construction camp construction and operation, construction train operation, and water-well construction and operation. Totals do not include construction or operation of rail line facilities.
c. FTE = full-time-equivalent worker; one FTE is defined as 2,000 labor hours worked. FTE and labor hours worked values are calculated over the minimum 4.5-year construction phase and 50-year operations phase of the Proposed Action.
d. Total recordable cases include injury and illness.
e. Totals might differ from sums of values due to rounding.

Railroad facility construction and operations impacts include impacts to facility construction workers and facility operations workers during the minimum 4.5-year construction phase and 50-year operations phase for the facilities. Table 4-113 summarizes the nonradiological impacts of constructing and operating rail line construction and operations support facilities under the Proposed Action, including the Rail Equipment Maintenance Yard, the Facilities at the Interface with the Union Pacific Railroad Mainline (including the Interchange Yard and Staging Yard), Nevada Railroad Control Center and National

Table 4-113. Estimated impacts to workers from nonradiological industrial hazards during facility construction and facility operations under the Proposed Action.[a,b]

Group and industrial hazard category	Construction			Operations		
	FTEs[c]	Labor hours worked	Incidents	FTEs[c]	Labor hours worked	Incidents
Involved workers	1,569	3.1 million		6,850	13.7 million	
Total recordable cases[d]			88			377
Lost workday cases			49			233
Fatalities			0.02			1.21
Noninvolved workers	0	0		1,700	3.4 million	
Total recordable cases[d]			0			41
Lost workday cases			0			22
Fatalities			0			0.06
Totals[e]	1,569	3.1 million		8,500	17.0 million	
Total recordable cases[d]			88			418
Lost workday cases			49			255
Fatalities			0.02			1.27

a. Source: Calculations are based on U.S. Department of Labor, Bureau of Labor Statistics, incident rates in Table 4-111 and full-time-equivalent worker year data from Appendix D of the Air Quality Emissions Factors and Socioeconomic Input-Caliente Rail Corridor, Rev 03, May 15, 2007 (DIRS 180921-Nevada Rail Partners 2007, Appendix D).
b. Totals include construction and operation of the Facilities at the Interface with the Union Pacific Railroad Mainline, Maintenance-of-Way Facilities, Cask Maintenance Facility, Nevada Railroad Control Center and National Transportation Operations Center, and Rail Equipment Maintenance Yard. Totals do not include construction or operation of rail line facilities.
c. FTE = full-time-equivalent worker; one FTE is defined as 2,000 labor hours worked. FTE and labor hours worked values are calculated over the minimum 4.5-year construction phase and 50-year operations phase of the Proposed Action.
d. Total recordable cases include injury and illness.
e. Totals might differ from sums of values due to rounding.

Transportation Operations Center, Maintenance-of-Way Trackside Facility, Maintenance-of-Way Headquarters Facility, Satellite Maintenance-of-Way Facilities, and Cask Maintenance Facility. The numbers of full-time-equivalent workers for each facility construction and operations activity were obtained from Appendix D of the *Air Quality Emissions Factors and Socioeconomic Input-Caliente Rail Corridor*, Rev 03, May 15, 2007 (DIRS 180921-Nevada Rail Partners 2007, Appendix D). Construction and operations workers under the Proposed Action could be exposed to nonradiological hazardous chemicals related to operation and maintenance of construction equipment and facility equipment, including maintenance-of-way and management of fleet. Such activities are anticipated to include welding, metal degreasing, painting, and related activities. Occupational health and safety impacts could also result from worker exposure to fuels, lubricants, and other materials used in construction, operation, and maintenance of the proposed rail line and facilities.

Railroad Construction Construction of the proposed railroad would involve 13.6 million labor hours corresponding to a total of 6,794 full-time-equivalent construction workers over the entire construction phase.

For the purposes of this Rail Alignment EIS, nonradiological impacts associated with construction of the proposed rail line are reported separately from the nonradiological impacts associated with construction of the railroad facilities. Table 4-112 summarizes nonradiological occupational health and safety impacts associated with construction of the proposed rail line, not including the Rail Equipment Maintenance Yard and Facilities at the Interface with the Union Pacific Railroad or other facilities.

Facilities Construction Construction of railroad construction support facilities and railroad operations support facilities, including the Facilities at the Interface with the Union Pacific Railroad Mainline (the Interchange Yard and the Staging Yard), Nevada Railroad Control Center and National Transportation Operations Center, Maintenance-of-Way Trackside Facility and Satellite Maintenance-of-Way Facilities, Maintenance-of-Way Headquarters Facility, Cask Maintenance Facility, and Rail Equipment Maintenance Yard, would involve 3.1 million labor hours corresponding to approximately 1,569 full-time-equivalent construction workers over the entire construction phase. Table 4-113 summarizes the nonradiological impacts of constructing rail line operations support facilities.

Railroad Operations The proposed railroad would operate for up to 50 years and would involve approximately 1,471 operations full-time-equivalent workers over the life of the project, corresponding to approximately 2.9 million labor hours.

For the purposes of this Rail Alignment EIS, nonradiological impacts associated with operation of the operations along the rail line are reported separately from the nonradiological impacts associated with operation of the support facilities. Table 4-112 lists nonradiological occupational health and safety impacts associated with operations along the rail line, not including the Rail Equipment Maintenance Yard or Facilities at the Interface with the Union Pacific Railroad or other operations support facilities.

Overall railroad operations, including cask trains, maintenance-of-way trains, and repository construction and supplies trains correspond to approximately 16 million train-kilometers (10 million train-miles) over the 50-year operations phase for the 541-kilometer (336-mile)-long Caliente rail line, based on transporting 9,495 casks (eight cask trains per week) and an additional two maintenance-of-way trains and seven repository construction and supplies trains per week. The 37 total recordable cases and 28 lost-workday cases over the 50-year operations phase (see Table 4-112) correspond to 4.5 total recordable cases and 3.4 lost-workday cases per million train-kilometers traveled.

Railroad Facilities Operations Operation of the operations support facilities under the Proposed Action, including the Facilities at the Interface with the Union Pacific Railroad, Nevada Railroad Control Center and National Transportation Operations Center, Maintenance-of-Way Trackside Facility, Satellite Maintenance-of-Way Facilities and Maintenance-of-Way Headquarters Facility, Cask Maintenance Facility, and the Rail Equipment Maintenance Yard would take place over 50 years and would involve approximately 170 full-time-equivalent operations workers per year of operation (DIRS 180921-Nevada Rail Partners 2007; DIRS 180922-Nevada Rail Partners 2007), corresponding to approximately 17 million labor hours over the 50-year operating phase. Table 4-113 summarizes the nonradiological impacts of operating railroad operations support facilities under the Proposed Action. The 418 total recordable cases and 255 lost-workday cases over the 50-year operating phase (see Table 4-113) correspond to 51 total recordable cases and 31 lost-workday cases per million train-kilometers traveled.

Impacts from Specific Resource Areas Workers constructing the proposed railroad could be exposed to a variety of hazards associated with specific resource areas. These include biological hazards, dust and soils hazards, air-quality hazards, transportation accidents, and noise hazards. Transportation hazards include wild horses, burros, and free-range livestock. Biological hazards include potential human health effects from rodent-borne diseases, soil-borne diseases, insect-borne diseases, and venomous animals. Dust and soils hazards include potential human health effects from exposure to inhalable soils and dusts containing hazardous constituents and potential occupational encounters with unexploded ordnance. Construction workers could also be exposed to air quality hazards, including potential human health effects of exposure to fugitive dust, diesel engine exhaust, and other air emissions associated with construction activities. Workers could also be exposed to noise hazards from operation of equipment. Operations workers, in particular maintenance-of-way workers, could also be exposed to similar hazards. Impacts associated with specific resource areas are discussed in the paragraphs that follow.

Biological Hazards: Biological hazards are any virus, bacteria, fungus, parasite, or other living organism that can cause a disease or otherwise harm human beings. Biological hazards that may be encountered by workers constructing and operating the proposed rail line and associated facilities include disease-causing organisms and venomous animals. Diseases potentially encountered when performing construction activities include West Nile Virus, Valley Fever, Hantavirus, and rabies. Venomous animals potentially encountered include spiders, snakes, scorpions, bees, wasps, and other insects. These biological hazards are described in the following sections. The recorded incidence rates of these biological hazards in the region of influence in Nevada are small, according to statistics published by state and federal agencies including the U.S. Centers for Disease Control and the Nevada State Health Division, as cited below. Therefore, DOE would expect small impacts to construction or operations workers from these biological hazards.

- **Venomous Animals –** Nevada is home to five venomous snake species: Sidewinder, Mohave, Speckled, Western Diamondback and Great Basin rattlesnakes (*Crotalus* spp.). These types of rattlesnakes may inhabit the open grasslands and desert habitat in the construction and operations areas. The Gila Monster, a venomous lizard, also occurs in southern Nevada. There are several types of scorpions (such as *paruroctonus* spp.) native to Nevada that may occur in construction and operations areas. Scorpions are venomous and are most active at night.
A scorpion sting would require medical treatment, but for the specific species of scorpions found in Nevada, would not be fatal. Black widow spiders (*Latrodectus mactans*) and brown recluse spiders (*Loxosceles recluse*) may also occur in construction areas. Bites from these spiders would require medical treatment and are potentially fatal if untreated. Other types of spider bites are generally harmless to most people. Spider bites usually occur when someone is reaching into dark, out-of-the way places. Bees, including Africanized Swarming Bees, and wasps also occur in southern Nevada.

- **West Nile Virus –** West Nile virus is a mosquito-borne virus that can cause illness in humans, including meningitis or arboviral encephalitis, a brain inflammation. Mosquitoes acquire the virus from birds and pass it on to other birds, and occasionally to humans. Mosquitoes spread this virus after they feed on infected birds and then bite other birds, people, or certain domestic animals. The virus is not spread by person-to-person contact. West Nile virus occurs primarily in the late summer or early autumn, although the mosquito season is generally April through October. About 80 percent of people who are infected with West Nile virus exhibit no symptoms, or at most, experience symptoms similar to the flu. People with mild infections, referred to as West Nile fever, may experience fever, headache, body ache, skin rash, and swollen lymph glands. More severe infection can result in more serious symptoms including high fever, headache, disorientation, coma, tremors, occasional convulsions, and paralysis. This form is referred to as West Nile meningitis or encephalitis. In 2004, a total of 44 cases of West Nile virus were reported in Nevada, including 23 cases in Clark County. Of the 44 West Nile virus cases, 19 involved West Nile fever. In 2005, 31 cases of West Nile virus were reported in Nevada, including eight cases in Clark County and three cases in Nye County (DIRS 177618-USGS 2006, all). No human cases of West Nile virus were reported in Nye, Esmeralda, or Lincoln Counties in 2004 (DIRS 175028-USGS 2005, all; DIRS 175026-Nevada State Health Division 2005, all). In 2006 there were a total of 123 reported cases of West Nile virus, including two cases in Nye County, and three cases in Clark County (DIRS 178696-USGS 2007, all). Incident rates of West Nile Virus are affected by the population density and availability of water.

- **Valley Fever –** The technical name for Valley Fever is *Coccidioidomycosis*. It is caused by *Coddidioides immitis*, a fungus that lives in soil. Fungus spores become wind-borne and may be inhaled into the lungs, where infection can occur. Valley Fever is not contagious from person to person.
It appears that after one exposure, the body develops immunity. The Valley Fever fungus is established in the Southern Nevada region of influence. Infection rates, as reflected by positive skin tests, are 2 to 3 percent per year in highly endemic regions, and activities associated with heavy dust exposure (such as

excavation, agricultural labor) increase infection rates (DIRS 175021-Barnato, Sanders, and Owens 2001, p. 1). About 60 percent of people who breathe the spores do not develop any symptoms. About one out of every 200 persons infected with Valley Fever develops the disseminated form, in which the disease spreads beyond the lungs through the bloodstream causing meningitis. Meningitis is a potentially fatal inflammation of the membrane around the brain and the spinal cord.

- **Hantavirus –** A 1993 outbreak of fatal respiratory illness on an Indian Reservation in the Four Corners area (where the states of Arizona, New Mexico, Colorado, and Utah meet) led to the identification of Hantavirus as the causative agent. Hantavirus is a rodent-borne disease. The route of exposure is believed to be inhalation of aerosolized virus, and/or ingestion of rodent excreta through contaminated food or water. Rodent bites and direct contact with broken skin or mucous membranes are also potential sources of infection. Symptoms include pneumonia, fever, and other flu-like symptoms. In 24 to 48 hours after symptoms appear, potentially fatal respiratory failure may occur. As of March 2007, there have been 465 recorded cases of Hantavirus in the U.S., with 18 of the cases recorded in Nevada (DIRS 181391-CDC 2007, all). DOE has implemented procedures for decontamination of any rodent excreta encountered by construction workers during construction activities at the Yucca Mountain Site to prevent Hantavirus infection of workers.

- **Rabies –** Rabies may be a hazard to construction and operation workers through accidental contact with mammalian species in construction and operations areas. The route of exposure is a bite or scratch from an infected animal, or non-bite exposure through inhalation of aerosolized rabies virus. Rabies has been reported in Nevada in bats but not in terrestrial animals (DIRS 177449-Krebs et al. 2005, p. 1917). The incubation period of rabies is variable, ranging from less than 10 days to greater than 6 years, and post exposure treatment is necessary following true exposure unless the subject has been vaccinated. Absent post exposure treatment, the first symptoms may be noted within 30 to 90 days of exposure. Once symptoms occur, death may occur in less than 1 week following the development of initial symptoms, usually as a result of respiratory failure. No human cases of rabies were reported in Nevada between January 2000 and September 2005, the latest period for which data are available (DIRS 177449-Krebs et al. 2005, p. 1920).

Dust and Soils Hazards: Dust and soils hazards include potential occupational exposure to hazardous inhalable soils and dust, including the minerals crystalline silica, cristobalite, and erionite and potential occupational encounters with unexploded ordnance. These hazards are discussed below.

- **Inhalable Dust –** Construction activities such as blasting, scarifying, and excavating create dust that can be inhaled by workers.

Some types of rock and associated soils may contain hazardous minerals such as crystalline silica, cristobalite, and erionite. It is unlikely that any fugitive particulates generated in the construction areas would contain a concentration of crystalline silica, eronite, or cristobalite that would result in exceedance of occupational exposure limits for these materials. Inhaling dust originating from these types of rock and containing these minerals can lead to disease such as silicosis if adequate precautions are not taken when working in dusty areas. However, DOE recognizes the potential for exposure to crystalline silica, cristobalite, or erionite during the development of quarries for production of hard rock ballast, in ballast placement, rock cuts, and other types of excavation. Of the three mineral dust hazards mentioned above, crystalline silica is the most common in hard rock ballast because it is a material of relative abundance in granite and quartz. DOE would be required to comply with Occupational Safety and Health Administration workplace guidance for mineral dusts (29 CFR 1910-1000, Table Z-3, Mineral Dusts).

DOE would therefore conduct routine monitoring of occupational dust exposure during quarry construction and operation and during rail alignment construction activities, such as ballast placement, with the potential for such exposure. DOE would apply best management practices and engineering controls such as application of water for dust suppression and washing the ballast before placement in order to minimize the potential for occupational exposure to dust, and an industrial hygienist would take mineral dust measurements to identify if any potential exposure hazards are present. In the event that these monitoring activities identify potential occupational exposure at levels exceeding Occupational Safety and Health Administration occupational exposure standards for silica, DOE would implement additional processing and engineering controls to mitigate, prevent, or reduce exposures to silica to below occupational exposure standards. Therefore, impacts associated with occupational exposure to these materials are anticipated to be small.

- **Unexploded Ordnance –** Portions of the construction area may have unexploded ordnance in surface or in subsurface locations. The potential areas of concern for unexploded ordnance are sections west of the Nevada Test and Training Range and within the Nevada Test Site. These include areas south of Goldfield and north of Beatty Wash. Unexploded ordnance may include shell casings, projectiles, or fragments, and may include live small arms ammunition, bombs, and rockets. These types of unexploded ordnance may have been generated from historical Air Force and other military training activities in the region. Sections of rail alignment and associated facility locations north and east of Goldfield are considered clear of unexploded ordnance at this time. DOE would coordinate with the U.S. Air Force concerning proposed construction activities and would follow standard and established procedures for unexploded ordnance. An unexploded ordnance specialist would develop a plan, including evaluation of types of unexploded ordnance possible, depths, etc. Unexploded ordnance technicians would be present and screen ahead of the construction crew in areas where there is potential for unexploded ordnance.

Air Quality Hazards: Construction workers could be exposed to air quality hazards, including potential human health effects of occupational exposure to stationary and area source emissions associated with construction activities. Operations workers, in particular maintenance-of-way workers, could also be exposed to similar air quality hazards.

Stationary and area source emissions associated with the construction phase would include exhaust emissions from on-site vehicles and heavy construction equipment, and fugitive dust from excavation and construction activities. Stationary and area source exhaust emissions associated with the operations phase would include emissions from locomotive fueling stations and locomotive and rail line maintenance operations. Section 4.2.4, Air Quality and Climate, describes stationary source and area source emissions associated with the construction and operations phases.

Exposure of construction and operations workers to vehicle exhaust emissions and other air emissions would be subject to exposure standards, including standards established under 10 CFR 851. Threshold Limit Values established by the Occupational Safety and Health Administration and American Council of Government Industrial Hygienists would apply to occupational exposure to vehicle exhaust emissions and other air emissions. DOE would apply administrative controls and conduct workplace monitoring to control exposure to below applicable standards.

Noise Hazards: Workers conducting construction and operation activities under the Proposed Action could be exposed to noise from operation of heavy construction equipment, operation of locomotives, or from conducting blasting operations. Potential sources of occupational noise exposure, applicable noise exposure standards, and requirements for controlling noise exposure are described in this section and further described in Section 4.2.8.

- **Roadbed/Track Structure Construction Noise Exposure –** DOE would require employers of construction workers exposed to heavy equipment noise to comply with Occupational Safety and Health Administration regulation 29 CFR 1910.95 to avoid effects of excessive noise exposure. Hearing damage is related to absolute noise level and duration of exposure. Table 4-114 shows Occupational Safety and Health Administration noise level limits that would require hearing protection. Code of Federal Regulations 10 Part 851 requires DOE to use American Conference of Governmental Industrial Hygienists Threshold Limit Values as occupational exposure standards. Table 4-114 also shows the Threshold Limit Values.

DOE would be required to administer a continuing, effective hearing conservation program whenever employee noise exposures equal or exceed an 8-hour time-weighted average sound level of 85 A-weighted decibels.

- **Railroad Worker Noise Exposure –** Railroad operators are required to comply with Federal Railroad Administration Regulation 49 CFR 229.121 for worker exposure to locomotive cab noise. Applicable noise levels, the exceedance of which would require hearing protection, are shown in Table 4-114.

Table 4-114. Occupational noise exposure limits.[a]

Duration per day, hours	Sound level (decibels slow response)	ACGIH[b] Threshold Limit Value
8	90	85
6	92	86
4	95	88
3	97	89
2	100	91
1.5	102	92
1	105	94
0.5	100	97
0.25 or less	115	100

a. Source: 29 CFR 1910.95 and 30 CFR 62.130 and 10 CFR 851.
b. ACGIH = American Conference of Governmental Industrial Hygienists.

- **Ballast Quarry Noise Exposure –** Employers of quarry workers supplying ballast for the rail bed would be required to comply with Mine Safety and Health Administration Regulation 30 CFR 62. Applicable Mine Safety and Health Administration noise levels, the exceedance of which would require hearing protection, are shown in Table 4-114. Noise levels above 115 dBA are not permitted under the regulation (30 CFR 62.130).

4.2.10.2.2 Radiological Impacts

This section discusses the radiological impacts for workers and members of the public during construction and operation of the railroad and facilities such as the Staging Yard, the Rail Equipment Maintenance Yard, the Maintenance of Way Trackside Facility, and the Cask Maintenance Facility. Both incident-free impacts and radiological accident risks are discussed. Also discussed are the impacts from severe transportation accidents and from acts of sabotage.

Risk Terms

A risk value of 1×10^{-4} is equivalent to 1 in 10,000.
A risk value of 1×10^{-6} is equivalent to 1 in 1,000,000.
A risk value of 1×10^{-8} is equivalent to 1 in 100,000,000.

4.2.10.2.2.1 Workers.

Rail line and Facilities Construction DOE does not anticipate that there would be any radiological occupational health and safety impacts associated with construction of the proposed rail line or facilities for the Proposed Action.

Railroad Operations Occupational radiological impacts associated with incident-free operation of the rail line and rail line facilities are described below. Occupational radiological impacts are quantified in terms of latent cancer fatalities. Occupational radiation doses (effective dose equivalent) are also reported.

Incident-Free Transportation: During the shipment of spent nuclear fuel and high-level radioactive waste from the Caliente-Upland, Caliente-Indian Cove, or Eccles-North Staging Yard to the repository, workers would be exposed to direct radiation from 9,495 shipping casks. These workers would include rail transportation crew members, security escorts, workers exposed when trains with loaded shipping casks passed the Maintenance-of-Way Trackside Facility, and workers exposed when trains with loaded shipping casks passed trains with unloaded casks or other materials at sidings. The methods and data used to estimate the radiation doses for these workers are described in Appendix K.

As discussed in Chapter 2, there are a number of possible combinations of common segments and alternative segments that could make up the rail alignment from the Interchange Yard to the repository. For the radiological impacts analyses, four specific alignments were evaluated: 1) the alignment with the highest exposed population, 2) the shortest alignment, 3) the longest alignment, and 4) the alignment with the lowest exposed population. These alignments are described in Table 3-67.

Table 4-115 lists the radiation doses and impacts for these workers along these four alignments. The collective radiation dose for these workers is estimated to be 310 to 320 person-rem. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.19.

Table 4-115. Estimated radiological impacts for workers along the proposed rail alignment.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.50 rem per year	0.00030
Maximally exposed worker (50-year operation)	25[a] rem	0.015[a,b]
Worker population	310 to 320 person-rem	0.19[c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

The maximally exposed worker would be a security escort. This worker is estimated to receive a radiation dose of 25 rem over the entire operations phase, based on a 0.5 rem per year administrative dose limit for repository facilities (DIRS 174942-BSC 2005, Section 4.9.3.3) and assuming that a person could work for up to 50 years escorting shipments. The probability of a latent cancer fatality for this worker is estimated to be 0.015. Security escort workers and other rail line workers would be subject to a radiation protection program. Workers, including security escort workers, would not be exposed to radiation in excess of the administrative dose limit for repository facilities of 0.5 rem per year. This requirement may in some cases limit the number of hours per year that workers are permitted to work as security escorts to less than 2,000 hours per year.

- **Staging Yard at Caliente-Indian Cove, Caliente-Upland, or Eccles-North, Rail Workers, Inspectors, and Escorts –** When shipping casks arrived at the Staging Yard, the railcars containing the shipping casks would be removed from the train, an inspection would be conducted, and the railcars would be transferred to the train for transport to the Rail Equipment Maintenance Yard. The escorts that had accompanied the shipping cask from its origin would also be present during this inspection. These rail workers, inspectors, and escorts would be exposed to direct radiation from 9,495 shipping casks over the entire shipping campaign. The methods and data used to estimate the radiation doses for these workers are described in Appendix K.

Table 4-116 lists the radiation doses and impacts for the workers involved with these activities. The analysis assumed that noninvolved workers would also be exposed to direct radiation during these activities.

Table 4-116. Estimated radiological impacts for rail workers, inspectors, and escorts at the Staging Yard.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.50 rem per year	0.00030
Maximally exposed worker (50-year operation)	25[a] rem	0.015[a,b]
Worker population (involved workers)	240 person-rem	0.14[c]
Worker population (noninvolved workers)	12 person-rem	0.0074
Worker population (total)	250 person-rem	0.15

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

The collective radiation dose for involved and noninvolved workers is estimated to be 250 person-rem. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.15. The maximally exposed worker is estimated to receive a radiation dose of 25 rem over the 50 years of operation, based on a 0.5 rem per year administrative dose limit for repository facilities (DIRS 174942-BSC 2005, Section 4.9.3.3) and assuming that a person could work for up to 50 years at the Staging Yard. The probability of a latent cancer fatality for this worker is estimated to be 0.015. Staging Yard workers and other facilities workers would be subject to a radiation protection program. Workers, including Staging Yard workers, would not be exposed to radiation in excess of the administrative dose limit for repository facilities of 0.5 rem per year. This requirement may in some cases limit the number of hours per year that workers are permitted to work at the Staging Yard to less than 2,000 hours per year.

- **Rail Equipment Maintenance Yard –** Under the Proposed Action, a Rail Equipment Maintenance Yard would be constructed and operated to transfer cask cars to the repository. The workers at this facility would be exposed to direct radiation from handling 9,495 shipping casks over 50 years of shipping. The radiation doses for these workers would be similar to the radiation doses for handling dedicated rail shipments at other railyards and are described in Neuhauser et al. The methods for estimating these radiation doses are described in Neuhauser et al. (DIRS 155430- Neuhuaser, Kanipe, and Weiner 2000, Section 3.5.2).

Table 4-117 summarizes the radiation doses and impacts for workers involved in these activities. The collective radiation dose for these workers is estimated to be 16 person-rem. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.0096.

Table 4-117. Estimated radiological impacts for workers at the Rail Equipment Maintenance Yard.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.013 rem per year	7.6×10^{-6}[b]
Maximally exposed worker (50-year operation)	0.64[a] rem	0.00038[,b]
Worker population	16[a] person-rem	0.0096[c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

The individual radiation dose for workers at this facility was estimated to be 0.013 rem per year. The probability of a latent cancer fatality for this worker is estimated to be 7.6×10^{-6}. If this individual worked at the facility for 50 years, their radiation dose would be 0.64 rem. The probability of a latent cancer fatality for this worker is estimated to be 0.00038.

- **Cask Maintenance Facility –** Under the Proposed Action, Cask Maintenance Facility operations would include testing, inspection, certification, incidental repair, and minor decontamination and modification of the transportation casks. Impacts to workers from activities at the Cask Maintenance Facility were based on the impacts for a similar facility, the Alaron Regional Service Facility, located in Wampum, PA. This facility provides treatment, decontamination, compaction, and repackaging services for generators of radioactively contaminated materials. One of the services provided by Alaron is the decontamination of spent nuclear fuel casks, which is similar to the activities that would occur at the Cask Maintenance Facility. The activities at Alaron are described in *Environmental Assessment for Alaron Corporation* (DIRS 181886-NRC 1989, all) and *Environmental Assessment Renewal of Materials Licenses for ALARON Corp* (DIRS 151227-Blasing et al. 1998, all).

Radiation dose from cask handling and maintenance activities at the Cask Maintenance Facility could result in radiation dose to workers, primarily as a result of exposure to "crud." Crud is the term used to describe contamination on the outside of spent nuclear fuel and would consist of the radionuclides Co-60, Mn-54, Fe-55, and Zn-65. Crud may be present in reactor spent nuclear fuel pools and may contaminate the inside of the cask during loading, even if the spent nuclear fuel has been placed in canisters. For the radionuclides contained in crud, average radionuclide inventories at the Alaron Regional Service Facility would consist of about 4.7 Ci of Co-60, 0.32 Ci of Mn-54, 7.6 Ci of Fe-55, and 0.061 Ci of Zn-65. Not all of this radionuclide inventory would be from the decontamination of spent nuclear fuel casks; some of the radionuclide inventory would be as a result of other services provided at the Alaron Regional Service Facility.

Workers at Alaron were estimated to receive an individual radiation dose of 0.04 rem per month. Over the course of a year, a worker would receive a radiation dose of 0.480 rem. This radiation dose was used to estimate the radiation dose to a worker at the Cask Maintenance Facility. The probability of a latent cancer fatality for this worker is estimated to be 0.00029.

Based on the total number of workers at the Cask Maintenance Facility, the collective radiation dose at the Cask Maintenance Facility would be 14 person-rem per year. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.0086. Table 4-118 summarizes these impacts and also presents impacts for the entire duration of operations (50 years).

Table 4-118. Estimated radiological impacts for rail workers, inspectors, and escorts at the Cask Maintenance Facility.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.48 rem per year	0.00029[b]
Maximally exposed worker (50-year operation)	24[a] rem	0.014[a,b]
Worker population (annual)	14 person-rem per year	0.0086[c]
Worker population (50-year operation)	720[a] person-rem	0.43[a,c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

- **Other Rail Line Facility Operations –** Under the Proposed Action, other railroad facilities would be constructed and operated, including the Maintenance-of-Way Trackside Facility, Maintenance-of-Way Headquarters Facility, Satellite Maintenance-of-Way Facilities, and Nevada Railroad Control Center and National Transportation Operations Center. Radiological health impacts to workers operating these facilities are anticipated to be minimal, as casks would not be loaded or unloaded at these facilities. Note that the dose impacts for rail facility operations workers in Table 4-118 include radiological exposure to workers at the Maintenance-of-Way Trackside Facility and at workers at sidings who would be exposed when the cask train passes by.

4.2.10.2.2.2 Public.

Construction DOE does not anticipate that there would be any radiological public health and safety impacts associated with construction of the proposed rail line or associated facilities under the Proposed Action.

Operations

Incident-free Rail Transportation:

- **Public along the Proposed Rail Line –** During the shipment of spent nuclear fuel and high-level radioactive waste from the Caliente-Upland, the Caliente-Indian Cove, or the Eccles-North Staging Yard to the Rail Equipment Maintenance Yard, people along the proposed rail line would be exposed to direct radiation from 9,495 shipping casks. These people would include people along the transportation route. Because shipments would be made using dedicated trains, there would be no exposures of members of the public sharing the transportation route or members of the public at stops along the route. The methods and data used to estimate the impacts from direct radiation for these people are described in Appendix K.

As discussed in Chapter 2, there are a number of possible combinations of common segments and alternative segments that could make up the rail alignment from Caliente-Indian Cove, Caliente-Upland, or Eccles-North to the Rail Equipment Maintenance Yard. For the radiological impacts analyses, four specific alignments were evaluated. These alignments are described in Table 3-67.

Table 4-119 lists the radiation impacts for these people. The collective radiation dose for members of the public is estimated to be 0.087 to 0.21 person-rem. In the exposed population, the probability of a latent cancer fatality is estimated to be 5.2×10^{-5} to 1.3×10^{-4}.

Table 4-119. Estimated radiological impacts for the public along the proposed rail line.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.00016 rem	9.4×10^{-8}[a]
Maximally exposed worker (50-year operation)	0.0078 rem	4.7×10^{-6}[a]
Population	0.087 to 0.21 person-rem	5.2×10^{-5} to 1.3×10^{-4}[b]

a. The estimated probability of a latent cancer fatality for an exposed individual worker.
b. The estimated number of latent cancer fatalities in an exposed worker population.

- **Public near the Staging Yard at Caliente-Indian Cove –** The public around the Staging Yard location at Caliente-Indian Cove would be exposed to direct radiation from 9,495 shipping casks over the entire shipping campaign. The methods and data used to estimate the radiation doses for members of the public are described in Appendix K.

Table 4-120 lists the radiation doses and impacts for these people. The collective radiation dose is estimated to be 0.026 person-rem. In the exposed population, the probability of a latent cancer fatality is estimated to be 1.6×10^{-5}. The ***maximally exposed individual*** is a resident who lives 1,600 meters

(5,200 feet) from the Staging Yard. This individual was assumed to be exposed to each of the 9,495 shipping casks for a period of 2 hours per cask. The radiation dose for this individual is estimated to be 3.0×10^{-6} rem for the 9,495 casks over the entire shipping campaign. The probability of a latent cancer fatality for this individual is estimated to be 1.8×10^{-9}.

Table 4-120. Estimated radiological impacts for the public at the Staging Yard at Caliente-Indian Cove.

Group	Radiation dose	Latent cancer fatality
Maximally exposed individual	3.0×10^{-6} rem[a]	1.8×10^{-9}[b]
Population	0.026 person-rem	1.6×10^{-5}[c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual.
c. The estimated number of latent cancer fatalities in an exposed population.

- **Public near the Staging Yard at Caliente-Upland –** The public around the Staging Yard location at Caliente-Upland would be exposed to direct radiation from 9,495 shipping casks over the entire shipping campaign. The methods and data used to estimate the radiation doses for members of the public are described in Appendix K.

Table 4-121 lists the radiation doses and impacts for these people. The collective radiation dose is estimated to be 0.0064 person-rem. In the exposed population, the probability of a latent cancer fatality is estimated to be 3.9×10^{-6}. The maximally exposed individual is a resident who lives 400 meters (1,300 feet) from the Staging Yard. This individual was assumed to be exposed to each of the 9,495 shipping casks for a period of 2 hours per cask. The radiation dose for this individual is estimated to be 0.0027 rem over the entire shipping campaign. The probability of a latent cancer fatality for this individual is estimated to be 1.6×10^{-6}.

Table 4-121. Estimated radiological impacts for the public at the Staging Yard at Caliente-Upland.

Group	Radiation dose	Latent cancer fatality
Maximally exposed individual	0.0027 rem[a]	1.6×10^{-6}[b]
Population	0.0064 person-rem	3.9×10^{-6}[c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual.
c. The estimated number of latent cancer fatalities in an exposed population.

- **Public near the Staging Yard at Eccles-North –** The public around the Staging Yard location at Eccles-North would be exposed to direct radiation from 9,495 shipping casks over the entire shipping campaign. The methods and data used to estimate the radiation doses for members of the public are described in Appendix K.

Table 4-122 lists the radiation doses and impacts for these people. The collective radiation dose is estimated to be 0.0039 person-rem. In the exposed population, the probability of a latent cancer fatality is estimated to be 2.4×10^{-6}. The maximally exposed individual is a resident who lives 1,500 meters (4,900 feet) from the Staging Yard. This individual was assumed to be exposed to each of the 9,495 shipping casks for a period of 2 hours per cask. The radiation dose for this individual is estimated to be 3.4×10^{-6} rem over the entire shipping campaign. The probability of a latent cancer fatality for this individual is estimated to be 2.1×10^{-9}.

Table 4-122. Estimated radiological impacts for the public at the Staging Yard at Eccles-North.

Group	Radiation dose	Latent cancer fatality
Maximally exposed individual	3.4×10^{-6} rem[a]	2.1×10^{-9}[b]
Population	0.0039 person-rem	2.4×10^{-6}[c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual.
c. The estimated number of latent cancer fatalities in an exposed population.

- **Cask Maintenance Facility –** Under the Proposed Action, Cask Maintenance Facility operations would include testing, inspection, certification, incidental repair, and minor decontamination and modification of the transportation casks. Impacts to members of the public from activities at the Cask Maintenance Facility were based on the impacts for a similar facility, the Alaron Regional Service Facility, located in Wampum, Pennsylvania. This facility provides treatment, decontamination, compaction, and repackaging services for generators of radioactively contaminated materials. One of the services provided by Alaron is the decontamination of spent nuclear fuel casks, which is similar to the activities that would occur at the Cask Maintenance Facility. The activities at Alaron are discussed in *Environmental Assessment for Alaron Corporation* and *Environmental Assessment Renewal of Materials Licenses for ALARON Corp* (DIRS 181886-NRC 1989, all; DIRS 151227-Blasing et al. 1998, all).

At the Alaron Regional Service Facility, the maximally exposed member of the public was located 300 meters (984 feet) from the facility. The radiation dose for this individual from emissions through all environmental pathways was estimated to be 2.0×10^{-9} rem per year. The probability of a latent cancer fatality for this individual is estimated to be 1.2×10^{-12}. The radiation dose and latent cancer fatality risk for members of the public from emissions from the Cask Maintenance Facility would be much smaller, because the public is located much further from the facility. For example, the nearest site boundary is 11 kilometers (7 miles) from the repository, while at Alaron, the maximally exposed member of the public was located 300 meters from the facility.

The ***total population*** within 84 kilometers (52 miles) of the Cask Maintenance Facility is estimated to be about 118,000 people in the year 2067. If all of these people were exposed at the same level as the maximally exposed member of the public, the resulting collective radiation dose would be 0.00023 person-rem per year. In this exposed population, the probability of a latent cancer fatality is estimated to be 1.4×10^{-7}. Table 4-123 summarizes these impacts and also presents impacts for the entire duration of operations.

Table 4-123. Estimated radiological impacts for the public from the Cask Maintenance Facility.

Group	Radiation dose	Latent cancer fatality
Individual member of the public (annual)	2.0×10^{-9} rem per year	1.2×10^{-12}[b]
Individual member of the public (50 years)	1.0×10^{-7}[a] rem	6.0×10^{-11}[a,b]
Collective members of the public (annual)	0.00023 person-rem per year	1.4×10^{-7}[c]
Collective members of the public (50 years)	0.012[a] person-rem	7.0×10^{-6}[a,c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual.
c. The estimated number of latent cancer fatalities in an exposed population.

Accidents: To quantify the potential radiological impacts of transportation accidents, DOE performed two types of analyses. The first analysis provided an estimate of the radiological accident risks associated with transporting spent nuclear fuel and high-level radioactive waste along the Caliente rail alignment. The analysis of radiological accident risks takes into account a spectrum of accidents ranging from higher-probability accidents of low severity to hypothetical high-severity accidents that have a correspondingly low probability of occurrence. Included are accidents in which no release of radioactive material occurred, but where there was a deformation of shielding because of lead shield displacement, and accidents in which radioactive material was released from the shipping cask. Radiological accident risks were defined as the probability of occurrence of an accident multiplied by the consequences of the accident, summed over a complete spectrum of accidents. This quantity is known as "dose risk."

The second analysis provided an estimate of the consequences of severe transportation accidents, known as maximum reasonably foreseeable transportation accidents. Historically, maximum reasonably foreseeable transportation accidents were defined as transportation accidents with a frequency of about 1×10^{-7} per year.

Accidents in which no release of radioactive material and no deformation of shielding occurred are discussed in Section 4.2.10.2.3 below.

- **Accident Risks –** The methods and data used to estimate radiological accident risks are discussed in Appendix K. The impacts from these accidents are listed in Table 4-124. The risks from accidents where a release of radioactive material or shielding deformation occurred are estimated to be 6.7×10^{-7} to 1.3×10^{-6} latent cancer fatalities.

Table 4-124. Estimated radiological accidents risks from potential transportation accidents along the proposed rail line.

Risk	Accident dose risk[a]	Latent cancer fatality
Radiological accident risk	1.1×10^{-3} to 2.2×10^{-3}	6.7×10^{-7} to 1.3×10^{-6}

a. Radiological accident dose risk is the sum of the products of the probabilities and consequences in person-rem of all potential transportation accidents. This sum is converted to latent cancer fatalities using the conversion factor of 0.0006 latent cancer fatality per person-rem.

- **Severe Accidents –** Severe accidents having a frequency of about 1×10^{-7} per year are known as ***maximum reasonably foreseeable accidents***. Accidents with frequencies below 1×10^{-7} per year are generally not reasonably foreseeable. In this Rail Alignment EIS, the maximum reasonably foreseeable transportation accident has a frequency of about 6×10^{-7} per year. This accident involves a long duration, high-temperature fire that would engulf a cask. The methods and data used to estimate the impacts of this accident are discussed in Appendix K.

For the four evaluated rail alignments described in Table 3-67, there were no urban areas as defined in U.S. Census Bureau population data. However, there were suburban areas and rural areas. Suburban areas are defined as areas with a population density between 139 and 3,326 people per square mile. Rural areas were defined as areas with a population density less than 139 people per square mile. Using alignment-specific 2000 census population data escalated to the year 2067, the average population density in suburban areas along the alignments was 226 people per square kilometer (585 people per square mile), near Caliente and Goldfield. The average population density along rural areas, escalated to the year 2067, ranged from 0.346 to 0.585 people per square kilometer (0.896 to 1.515 people per square mile).

Table 4-125 lists estimates of the impacts of this severe accident. If the maximum reasonably foreseeable accident were to occur in a suburban area, the population radiation dose would be 770 person-rem. The probability of a latent cancer fatality in the exposed population is estimated to be 0.46. If the maximum reasonably foreseeable accident were to occur in a rural area, the collective radiation dose would be 2.0 person-rem. The probability of a latent cancer fatality in the exposed population is estimated to be 1.2×10^{-3}.

In either a suburban area or rural area, the radiation dose from the maximum reasonably foreseeable transportation accident for the maximally exposed individual located 330 meters from the accident would be 34 rem. The probability of a latent cancer fatality for that individual is estimated to be 0.020.

The radiation dose to a first responder would range from 0.14 to 2.0 rem. The probability of a latent cancer fatality for this first responder is estimated to range from 8.2×10^{-5} to 0.0012.

- **Accidents at the Cask Maintenance Facility –** Under the Proposed Action, Cask Maintenance Facility operations would include testing, inspection, certification, incidental repair, and minor decontamination and modification of the transportation casks.

Table 4-125. Estimated radiological impacts from the maximum reasonably foreseeable transportation accident scenario for suburban and rural areas.[a,b]

Impact	Suburban area[c]	Rural area[c]
Impacts to population		
Population dose (person-rem)	770	2
Latent cancer fatalities	0.46	1.2×10^{-3}
Impacts to maximally exposed individuals		
Maximally exposed individual dose (rem)	34	34
Probability of a latent cancer fatality	0.020	0.020
Impacts to a first responder		
Maximally exposed responder dose (rem)	0.14 to 2.0	0.14 to 2.0
Probability of a latent cancer fatality	8.2×10^{-5} to 0.0012	8.2×10^{-5} to 0.0012

a. There are no urban areas for the four specific alignments.
b. Accident frequency is estimated to be 6×10^{-7} per year.
c. Radiological impacts were based on low wind speeds and stable atmospheric conditions. These were defined as Class F stability and a wind speed of 0.89 meters per second.

Impacts to members of the public from activities at the Cask Maintenance Facility were based on the impacts for a similar facility, the Alaron Regional Service Facility, located in Wampum, Pennsylvania. This facility provides treatment, decontamination, compaction, and repackaging services for generators of

SEVERE TRANSPORTATION ACCIDENTS: AN OPPOSING VIEWPOINT

The State of Nevada has provided analyses that indicate that the consequences of severe transportation accidents would be much higher than those in this Rail Alignment EIS. For example, the state has estimated that the long-term consequences of a rail accident in a rural area could result in 7 to 614 latent cancer fatalities in the exposed population (DIRS 181756-Lamb et al. 2001, Table 41), while DOE estimates that about 1 latent cancer fatality would occur in the exposed population.

The State estimated these consequences using computer programs that DOE developed and uses. However, the state's analysis used values for parameters that would be at or near their maximum values. DOE guidance for the evaluation of accidents in environmental impact statements (DIRS 172283-DOE 2002, p. 6) specifically cautions against the evaluation of scenarios for which conservative (or bounding) values are selected for multiple parameters because the approach yields unrealistically high results.

DOE's approach to accident analysis estimates the consequences of severe accidents having frequencies as low as 1×10^{-7} per year (1 in 10 million) (DIRS 172283-DOE 2002, p. 9) using realistic yet cautious methods and data. DOE believes that the State of Nevada estimates are unrealistic and that they do not represent the reasonably foreseeable consequences of severe transportation accidents.

radioactively contaminated materials. One of the services provided by Alaron is the decontamination of spent nuclear fuel casks, which is similar to the activities that would occur at the Cask Maintenance Facility. The activities at Alaron are discussed in *Environmental Assessment for Alaron Corporation* and *Environmental Assessment Renewal of Materials Licenses for ALARON Corp* (DIRS 181886-NRC 1989, all; DIRS 151227-Blasing et al. 1998).

A fire at the Alaron Regional Service Facility was estimated to result in a radiation dose of 0.00045 rem to a member of the public at a distance of 50 meters (164 feet) from the facility and a radiation dose of 0.000011 rem to a member of the public at a distance of 300 meters (984 feet) from the facility. The probability of a latent cancer fatality for these individuals is estimated to be 2.8×10^{-7} and 6.5×10^{-9}, respectively. For a similar fire at the Cask Maintenance Facility, the impacts would be much lower, because the public is located much further from the facility, about 11 kilometers (7 miles), as opposed to 50 to 300 meters at Alaron.

The total population within 84 kilometers (52 miles) of the Cask Maintenance Facility is estimated to be about 118,000 people in the year 2067. If all of these people were exposed at the same level as the member of the public located 300 meters (984 feet) from the facility, the resulting collective radiation dose would be 1.3 person-rem. The probability of a latent cancer fatality in the exposed population is estimated to be 7.6×10^{-4}.

- **Sabotage** – In response to the terrorist attacks of September 11, 2001, and to intelligence information that has been obtained since then, the United States Government has initiated nationwide measures to reduce the threat of sabotage. These measures include security enhancements intended to prevent terrorists from gaining control of commercial aircraft, such as (1) more stringent screening of airline passengers and baggage by the Transportation Security Administration, (2) increased presence of federal air marshals on many flights, (3) improved training of flight crews, and (4) hardening of aircraft cockpits. Additional measures have been imposed on foreign passenger carriers and domestic and foreign cargo carriers, as well as charter aircraft.

Beyond these measures to reduce the potential for terrorists to gain control of an aircraft, DOE has adopted an approach that focuses on ensuring that safety and security requirements are adequate and effective in countering and mitigating the effects of sabotage events that involve transportation casks. The Federal Government has greatly improved the sharing of intelligence information and the coordination of response actions among federal, state, and local agencies. DOE has been an active participant in these efforts; it now has regular and frequent communications with other federal, state, and local government agencies and industry representatives to discuss and evaluate the current threat environment, to assess the adequacy of security measures at DOE facilities and, when necessary, to recommend additional actions. In addition to its domestic efforts, DOE is a member of the International Working Group on Sabotage for Transport and Storage Casks, which is investigating the consequences of sabotage events and exploring opportunities to enhance the physical protection of casks.

In addition, the Nuclear Regulatory Commission NRC has promulgated rules (10 CFR 73.37) and interim compensatory measures (67 *FR* 63167, October 10, 2002) specifically to protect the public from harm that could result from sabotage of spent nuclear fuel casks. The purposes of these security measures are to minimize the possibility of sabotage and to facilitate recovery of spent nuclear fuel shipments that could come under the control of unauthorized persons. These measures include the use of armed escorts to accompany all shipments, safeguarding of the detailed shipping schedule information, monitoring of shipments through satellite tracking and a communication center with 24-hour staffing, and coordination of logistics with state and local law enforcement agencies, all of which would contribute to shipment security. The Department has committed to following these rules and measures (see 69 *FR* 18557, April 8, 2004).

The Department, as required by the NWPA, would use Nuclear Regulatory Commission-certified shipping casks. Each cask design must meet stringent requirements for structural, thermal, shielding, and criticality performance and confinement integrity for routine (incident-free) and accident events. Spent nuclear fuel is protected by the robust metal structure of the shipping cask, and by cladding that surrounds the fuel pellets in each fuel rod of an assembly. Further, the fuel is in a solid form, which would tend to reduce dispersion of radioactive particulates beyond the immediate vicinity of the cask, even if a sabotage event were to result in a breach of the multiple layers of protection.

Based on this knowledge, the Department has analyzed plausible threat scenarios, required enhanced security measures to protect against these threats, and developed emergency planning requirements that would mitigate potential consequences for certain scenarios. DOE would continue to modify its approach to ensuring safe and secure shipments of spent nuclear fuel and high-level radioactive waste, as appropriate, between now and the time of shipments.

For the reasons stated above, DOE believes that under general credible threat conditions the probability of a sabotage event that would result in a major radiological release would be low. Nevertheless, because of the uncertainty inherent in the assessment of the likelihood of a sabotage event, DOE has evaluated events in which a military jet or commercial airliner would crash into a spent nuclear fuel cask or a modern weapon (high energy density device or) would penetrate a spent nuclear fuel cask.

In the Yucca Mountain FEIS (Appendix J, Section J.3.3.1), DOE evaluated the ability of large aircraft parts to penetrate shipping casks. In that analysis, DOE determined that the parts having the highest probability of penetrating a cask are jet engines and jet engine shafts. Accordingly, DOE undertook a penetration analysis using these parts from military aircraft (F-15/16) and from a commercial airliner (B-767), which found that neither the engines nor shafts would penetrate a cask and cause a release of radiological materials if an aircraft were to crash into a spent nuclear fuel cask.

To estimate the potential consequences of a sabotage event in which an high energy density device penetrates a rail or truck cask, DOE, in the Yucca Mountain FEIS, referred to *Projected Source Terms for Potential Sabotage Events Related to Spent Fuel Shipments* to obtain estimates of the fraction of spent nuclear fuel materials that would be released (release fractions) (DIRS 104918-Luna et al. 1999, all). In this Rail Alignment EIS, the Department used the more recent release fraction estimates from *Release Fractions from Multi-element Spent Fuel Casks Resulting from HEDD* [high energy density device] *Attack* (DIRS 181279-Luna 2006, all) to estimate the consequences of such events involving spent nuclear fuel in rail casks. These more recent estimates of release fractions (DIRS 181279-Luna 2006, all) are based on the release fractions estimated in 1999 from *Projected Source Terms for Potential Sabotage Events Related to Spent Fuel Shipments* (DIRS 104918-Luna et al. 1999, all), but they also incorporate data from additional tests sponsored by *Gesellschaft für Anlagen - und Reaktorsicherheit* in Germany and conducted in France in 1994 that were not available for the 1999 report.

The potential impacts of sabotage were assessed for rail shipments from the Caliente-Upland, Caliente-Indian Cove, or Eccles-North Staging Yard to the repository. As with the maximum reasonably foreseeable accidents discussed in the Accidents section, four specific rail alignments were evaluated. The methods and data used to estimate the impacts of sabotage events are described in Appendix K.

For the four specific alignments there were no urban areas, as defined in U.S. Census Bureau population data. However, there were suburban areas and rural areas. Using alignment-specific 2000 census population data escalated to the year 2067, the average population density in suburban areas along the alignments was 226 people per square kilometer (585 people per square mile), near Caliente and Goldfield. The average population density along rural areas, escalated to the year 2067, ranged from 0.346 to 0.585 people per square kilometer (0.896 to 1.515 people per square mile).

The impacts of a sabotage event are listed in Table 4-126. If a sabotage event occurred in a suburban area, the collective radiation dose is estimated to be 1,800 person-rem. The total latent cancer fatalities for people exposed during a sabotage event is estimated to be 1.1. If the sabotage event occurred in a rural area, the collective radiation dose is estimated to be 4.7 person-rem. The total latent cancer fatalities for people exposed during this sabotage event is estimated to be 0.0028.

In either a suburban area or rural area, the maximally exposed individual would be located 100 meters (330 feet) from the sabotage event. The radiation dose for the maximally exposed individual is estimated to be 27 rem. The probability of a latent cancer fatality for the maximally exposed individual is estimated to be 0.016.

Table 4-126. Estimated radiological impacts for a sabotage event involving a rail shipping cask for suburban and rural areas.[a]

Impact	Suburban area[b]	Rural area[b]
Impacts to populations		
Population dose (person-rem)	1,800	4.7
Latent cancer fatalities	1.1	0.0028
Impacts to maximally exposed individuals		
Maximally exposed individual dose (rem)	27	27
Probability of a latent cancer fatality	0.0016	0.016

a. There are no urban areas for the four specific alignments
b. Based on neutral atmospheric conditions and moderate wind speeds; defined as Class D stability and a wind speed of 4.47 meters per second.

4.2.10.2.3 Transportation Impacts

4.2.10.2.3.1 Construction Impacts.

Nonradiological Roadway Accidents During construction, personnel and equipment would be moved initially by truck and other vehicles, and could be moved by rail once portions of the rail line were completed. Such movements of equipment and personnel could lead to roadway accidents.

DOE estimates that the construction phase would involve approximately 2,160 full-time-equivalent workers during the first three years, 1,080 full-time-equivalent workers in the fourth year, and 540 full-time-equivalent workers in the last year, for a total of 8,100 full-time-equivalent workers, not including the Cask Maintenance Facility (DIRS 174083-WPI 2003, all; DIRS 180921-Nevada Rail Partners 2007, Appendix D, Tables 1 and 2). The construction phase would take a minimum of 4 years and 6 months. The Cask Maintenance Facility construction would involve an additional 150 workers for 88 weeks.

In total, there would be 8,100 full-time-equivalent workers involved in the construction of the rail line and associated facilities and an additional 263 full-time-equivalent workers for construction of the Cask Maintenance Facility. The exact distribution over time is not significant for the traffic safety calculations, which are aggregated over the total construction time. In other words, if the construction phase were assumed to take place over a 10-year period, this would only mean that fewer workers would be making more trips; this would result in a similar total number of trips as the minimum 4.5-year construction phase.

For each year, it is assumed that each worker would make two trips per day over five days a week for 50 weeks a year (that is, 2,000 hours per year full-time-equivalent workers). To provide a conservative upper bound estimate of roadway accidents, DOE assumed that all workers would individually make daily vehicle trips on roadways, even though it is likely that many rail line construction workers would reside in construction camps linked to work sites by access roads. Each trip is assumed to be 80 kilometers (50 miles) in length, which translates to approximately 40,000 kilometers (25,000 miles) per year per worker. While the distances involved for portions of this construction project are obviously much greater, a worker might travel hundreds of miles each way every one to two weeks and stay in the construction camps between these longer trips. This travel pattern would result in approximately the same distance traveled per worker. Collectively, the total distance driven by all workers would be approximately 335 million kilometers (200 million miles).

Based on a fatal accident rate of 1.65 fatalities per 100 million vehicle-kilometers (2.66 per 100 million vehicle-miles) (DIRS 180484-FHWA 2006, p. 1, Section V, Tables FI-20 and VM-2) traveled for light trucks or passenger cars in rural areas in Nevada, approximately six fatalities could occur due to the movement of workers during construction of the rail line and facilities.

These estimates would not vary among the proposed specific alignments, because the number of potential fatalities is based on the total distance traveled and is not dependent on the minor difference in the length or location of the alternative segments. Therefore, the predicted accident rates are the same for each specific alignment.

Nonradiological Rail Line Accidents During the construction phase, there are expected to be up to 992 loaded trains servicing the Caliente area, 1,116 for Garden Valley, and 1,984 near Goldfield (DIRS 180923-Nevada Rail Partners 2007, Appendix A, p. A-9) as the portions of the rail line that had already been completed were used to bring critical materials to the various staging areas (the length of line constructed from a particular staging area would influence the number of trains used on each segment of the partially completed rail line). A shorter construction phase would result in more trains per day, and a more extended construction phase would likely experience the lower end of the range of expected train volume.

Given the variability in the number of trains per day or year, this analysis focuses on the total number of inbound loaded and outbound unloaded construction trains, which is predicted to be 8,184 ([992 + 1,116 + 1,984] × 2). These trains would travel at speeds between 24 and 64 kilometers (15 and 40 miles) per

TRANSPORTATION SABOTAGE: AN OPPOSING VIEWPOINT

The State of Nevada has provided analyses that assert that a sabotage event using a high-energy density device such as an antitank missile would completely penetrate a spent nuclear fuel cask, which would result in consequences 10 times higher than those DOE estimated (DIRS 181892-Lamb, Hintermann, and Resnikoff 2002, p. 19).

Because of the requirements of the DOE classification policy, the Department cannot disclose specifically the devices that the analyses in Luna, Neuhauser, and Vigil (DIRS 104918-1999, all) and Luna (DIRS 181279-2006, all) considered. However, the analyses encompassed the damage that modern weapons could produce in an optimally successful sabotage event. The assertion that modern weapons can produce full penetration of both cask walls is not confirmed by calculations from Luna, Neuhauser, and Vigil (DIRS 104918-1999, all).

In addition, in scoping comments, the State of Nevada recommended that the sabotage analysis address factors such as attacks that involve multiple weapons, attacks that use combinations of weapons designed to maximize release and dispersal of radioactive materials, attacks that involve large groups of well-trained adversaries, suicide attacks, attacks that involve the infiltration of trucking an railroad companies, and attacks at locations with high symbolic value.

Because DOE assumed that the sabotage event would occur, most of the factors listed by the state could affect the chances that such an event could occur but not the outcome of the sabotage event. In addition, even though attacks that use multiple weapons and combinations of weapons designed to maximize release and dispersal of radioactive materials are possible, DOE believes that the sabotage event it analyzed encompasses the damage that modern weapons might produce were a sabotage event to occur.

hour depending on both the load carried and the area in which they operate. DOE assumes that each train would travel one-half of the total route length, or approximately 270 kilometers (170 miles) on average. Therefore, the total number of train kilometers would be approximately 2.2 million train-kilometers (1.4 million train-miles). The total expected number of loaded railcars (including locomotives) during the construction phase are 22,240 for Caliente area, 25,020 for Garden Valley, and 44,480 for Goldfield. The total number of inbound loaded and outbound unloaded construction railcars is predicted to be 183,480 ([22,240 + 25,020 + 44,480] × 2), resulting in approximately 50 million railcar-kilometers (31 million railcar-miles).

The transportation safety impacts of concern during construction focus on rail-related accidents and worker and public fatalities. Based on the same rail accident rates described in the operations phase (Section 4.2.10.2.3.2), accidents associated with train-kilometers and railcar-kilometers are calculated. A total of three rail accidents would be expected to occur for the entire set of estimated train and railcar movements during construction.

Based on Federal Railroad Administration statistics, the fatality rate for workers is 3.46×10^{-10} fatality per railcar kilometer traveled, and the rate for occupants of other vehicles and pedestrians is 1.11×10^{-8} fatality per railcar-kilometer traveled (DIRS 178016-DOT 2005, Chapter 1, all). Rates were derived by considering fatalities associated with freight train operations only (fatalities associated with passenger train operations were omitted for more applicable rates). As a result, the worker category considers *worker-on-duty*, *worker-not-on-duty*, *contractor-on-duty*, and *contractor-other*. Public fatalities include both *trespassers* and *non-trespassers*. Because passenger operations are not relevant to the Proposed Action, there is no consideration of the *passengers-on-train* category.

Based on these fatality rates, a total of 0.6 fatality (that is, not more than one) would be expected to occur for the entire set of estimated railcar movements during construction. No detectable difference is expected for the specific alignments, as the total variation in route lengths is minimal (greatest difference would be between Goldfield alternative segment 1 and Goldfield alternative segment 4, which is a 5-kilometer [3-mile] difference).

Many movements of rail-mounted construction equipment are also anticipated. This equipment would travel fairly short distances each day to conduct such activities as setting out railroad ties or preparing the ballast. These movements have not been included in the count of train-kilometers as they would occur in controlled work areas and in very small increments, rather than at any measurable speed in a publicly accessible area.

4.2.10.2.3.2 Operations Impacts.

Nonradiological Roadway Accidents The assessment of impacts to transportation safety begins with accidents, such as may be experienced by any vehicle, independent of cargo. These accidents typically result in injuries or fatalities to drivers or operators, other motorists, or pedestrians, and could result from the movement of cargo.

Approximately 230 workers would be involved in the operation of the rail line and the facilities. Each year it is assumed that each worker would make two trips per day, over five days a week, for 50 weeks a year. It is assumed that each trip would be 80 kilometers (50 miles). This would result in 40,000 kilometers (25,000 miles) per year per worker. Collectively, over the 50-year operations phase, the total number of kilometers driven by workers would be approximately 460 million kilometers (288 million miles).

Based on a fatal accident rate of 1.65 fatalities per 100 million vehicle-kilometers (2.66 per 100 million vehicle-miles) traveled for light trucks or passenger cars in rural areas in Nevada (DIRS 180484-FHWA 2006, p. 1, Section V, Tables FI-20 and VM-2), approximately eight fatalities would be expected due to the movement of workers during operation of the rail line and facilities over 50 years of operation. These estimates are not specific to the specific alignments, because the small variations in length and location of the alternative segments would not significantly affect the total distance traveled.

Nonradiological Rail Line Accidents The rail transportation safety analysis for the operations phase of the Proposed Action assesses the impacts of transportation, rail facilities, and grade crossings.

Rail Alignment: The proposed rail line would range from 528 to 541 kilometers (approximately 328 to 336 miles) in length, depending on which alternative segments are chosen. Given the similarities in the lengths of the alternative segments, the longest specific alignment has been selected to conservatively estimate the overall accident risks for the rail line.

This analysis includes both dedicated railcar cask trains and other trains not involving casks from the Interchange and Staging Yard to the Rail Equipment Maintenance Yard. A typical spent nuclear fuel or high-level radioactive waste train would have two to three locomotives, followed by a buffer car, one to five cask cars, another buffer car, and an escort car. The actual number of casks per train could vary from one to five, while the number of locomotives could vary from two to three. The total number of casks that would be moved by rail is 9,495. Based on Total System Model runs, there would be 2,833 trains carrying loaded casks and an equal number carrying empty casks. Therefore, to determine the impacts of moving cask cars, the analysis considers 5,666 trains (2,833 × 2) involving cask cars. The Model runs also give the total number of railcars involved in cask trains, with an average of 8.54 cars per train (3.35 cask cars, 2.19 locomotives, two buffer cars, and one escort car). Over the 50-year operations phase, there would be approximately 48,408 railcars associated with cask trains.

In addition to trains involving cask cars, there are also other types of trains that would be operating along the rail line, including maintenance-of-way trains (two one-way trains per week), and repository supply and construction trains (seven one-way trains per week). The total number of trains not involving casks would be 23,400 over 50 years of operation. The total number of railcars not carrying casks would be 58,338, accounting for both loaded and unloaded cars (DIRS 180923-Nevada Rail Partners 2007, Section 4.0, Table 1).

The total number of railcars (all kinds) moved under the Proposed Action would be approximately 106,746 (48,408 + 58,338), considering both directions of travel. Based on the same fatality rates used in the construction analysis, namely 3.46×10^{-10} fatality per worker per railcar-kilometer, and 1.11×10^{-8} fatality per pedestrian per railcar-kilometer, 0.7 fatality (that is, not more than one) would be expected to occur for the entire set of estimated railcar movements during operation.

The Interchange Yard would operate like a typical large siding or other similar types of rail yards, so the hazards associated with its operation would be the potential for transport accidents. However, because the buffer cars, cask cars, and escort car would be separated as a unit from the trains used to transport the casks from their origins, there would be limited chances for derailments involving the cask cars in the Interchange Yard. Accidents in yards typically occur as individual cars are handled, not with complete sets of cars. Accidents during the handling of railcars also occur at very low speeds, further limiting the chance of an accident. Because the trains are expected to enter the Interchange Yard from the Union Pacific Railroad Mainline at normal track speed, the accident rate for the Interchange Yard would be based on mainline accident rates rather than yard accident rates.

Accident rates for rail transportation are generally presented as either accidents per train-kilometers or a combination of accident rates based on both accidents per train-kilometer traveled and accidents per railcar-kilometer traveled, considering these two classes of accident causes separately. Review of Federal Railroad Administration statistics and industry data on the distribution of track classes produced the accident rates given in Table 4-127 for Track Class 3 (DIRS 180220-Bendixen and Facanha 2007, all).

Table 4-127. Estimated rail accident rates.[a]

Accident location	Accident rate per train-kilometer	Accident rate per car-kilometer	Combined accident rate per kilometer for 8-car train
Mainline track	7.50×10^{-7}	0.17×10^{-7}	8.95×10^{-7}

a. Source: DIRS 180220-Bendixen and Facanha 2007, all.

These rates include derailments and collisions from a variety of causes, including track failures resulting from geological hazards. These accident rates reflect railroad operations involving general freight service. Dedicated train service, which would be used to move cask railcars to the Yucca Mountain Repository, would follow stringent safety regulations. Additionally, dedicated train service has increased control and command capabilities, since shorter trains allow better visual monitoring from the locomotive and the escort car. Therefore, the accident rates here included provide a conservative estimate of the number of accidents involved in the operations of the rail line.

While not all accidents would lead to derailments of any railcars, any accident is likely to require the train to be inspected and other precautions to be taken. Hence, this analysis conservatively considers all accidents. In addition, a number of design and operating changes for dedicated trains have been predicted to reduce accident rates for dedicated trains, but to maintain conservatism, these potential benefits are not considered here.

Based on the lengths of each alternative segment and common segment, and the combined accident rate for an 8.54-car train (that is, 8.95×10^{-7} accident per train-kilometer), the predicted accident counts are given in Table 4-128 for the full set of cask shipments expected during the entire operations phase (that is, the analysis considers the 5,666 trains involving cask cars, which includes trains traveling in both directions). For accidents not involving cask trains, the total number of accidents was calculated by adding the accidents associated with the number of trains and the accidents associated with the number of railcars. For purposes of this analysis, DOE used the longest specific alignment. Because the upper bound of the accident rate is so small for the specific alignments, there would be no discernable difference.

As shown in Table 4-128, a total of approximately three accidents involving cask trains could occur over the 50-year operations phase. While potential consequences could involve environmental damage, evacuation costs, and human health impacts, the focus of the frequency analysis is on scenarios that could lead to human health impacts as discussed in greater detail elsewhere in this section. The total number of accidents involving trains that do not carry casks would be 10 for 50 years of operation. Therefore, the total number of predicted rail accidents would be approximately 13.

Rail Facilities: The analysis of potential incidents at rail facilities was based on the types of activities and operations that are expected to be carried out at such facilities. The scenarios of concern relate primarily to transportation accidents at the Interchange and Staging Yards. The likelihoods of accidents are based on both available failure and accident rates, and on the number of switchovers that would need to be made. The results for accident potential at the Interchange and Staging Yards are included within the calculations for Table 4-128 (alternative segments at the Interface with Union Pacific Mainline).

The Rail Equipment Maintenance Yard and the geologic repository operations area interface are essentially rail yards in terms of the operations that would occur there: train make-up and car switching. Casks would be removed from the railcars at the geologic repository operations area and empty casks would be placed back onto railcars at the Rail Equipment Maintenance Yard. The results for accident potential at the Rail Equipment Maintenance Yard and the geologic repository operations area interface are also included within the calculations for Table 4-128 (common segment 6).

Grade Crossings: DOE also examined the consequences of the Proposed Action on delay and safety conditions for at-grade crossings along the proposed rail alignment. Delay considerations are discussed in Section 4.2.9. The examination of grade-crossing safety typically considers the expected numbers and locations of grade crossings, the volume of both vehicle and rail traffic at the crossings, the nature of road traffic (for example, trucks versus passenger vehicles), the design and safety features of the crossings, and train and vehicle speeds in the vicinity of any crossings. Grade crossing collisions reported as train accidents are included in the number of rail accidents estimated in Table 4-128.

Table 4-128. Estimated number of predicted rail accidents.[a]

Rail alignment segment	Segment length (longest alternative segment, in kilometers)[d]	Predicted number of accidents	
		Involving cask trains	Not involving cask trains
Interface with Union Pacific Mainline alternative segments (including the Interchange and Staging Yards)	19[b]	0.10	0.35
Caliente common segment 1	110	0.56	2.04
Garden Valley alternative segments	37[c]	0.19	0.69
Caliente common segment 2	50	0.25	0.93
South Reveille alternative segments	19	0.10	0.35
Caliente common segment 3	110	0.56	2.04
Goldfield alternative segments	53	0.27	0.98
Caliente common segment 4	11	0.06	0.20
Bonnie Claire alternative segments	21	0.11	0.39
Common segment 5	40	0.20	0.74
Oasis Valley alternative segments	14	0.07	0.26
Common segment 6 (including the Rail Equipment Maintenance Yard)	51	0.26	0.95
Totals	541	2.71	9.92

a. During 50-year operation.
b. Eccles alternative segment.
c. Garden Valley alternative segment 3 or 8.
d. To convert kilometers to miles, multiply by 0.62137.

Grade-crossing safety is influenced by the type of protection installed at each crossing. Most of the crossings for this project would involve very low-usage unpaved roads that would mainly involve passive warning systems (such as cross-bucks and stop signs). Public at-grade crossings (paved roads) may have active warning systems that would include flashing lights and gates. Generally, DOE would employ active warning devices for crossings at paved county roads and passive systems at unpaved roads. Although grade-separated crossings are not mandatory for this project, DOE would be providing up to five grade-separated crossings on state and federal highways as identified in Chapter 2. The numbers of crossings with primary roads with each type of protection are listed in Table 4-129 for each rail line-specific alignment and alternative and common segment. Table 2-22 provides a detailed list of grade crossings.

Table 4-129. Number of grade crossings with primary roads.[a]

Rail line segment	Passive protection	Active protection	Grade separation
Alternative segments at the Interface with Union Pacific Mainline (Caliente/Eccles)	None	1	1
Caliente common segment 1	6	None	1
Garden Valley alternative segments	3-4[c]	None	None
Caliente common segment 2	2	None	1
South Reveille alternative segments	2-5[c]	None	None
Caliente common segment 3	2	1	None
Goldfield alternative segments	None	None	None-2[c]
Caliente common segment 4	None	None	None
Bonnie Claire alternative segments	None	None	None
Common segment 5	None	1	None
Oasis Valley alternative segments	1	None	None
Common segment 6	None	None	None
Totals	16/20[b]	3	3/5

a. This list does not include all grade crossings.
b. First number represents scenario under which South Reveille alternative segment 2 and Garden Valley alternative segment 1, 2, or 3 are the selected alternative segments. Second number represents scenario under which South Reveille alternative segment 3 and Garden Valley alternative segment 8 are the selected alternative segments.
c. This depends on the specific alternative segment.

4.2.10.3 Shared-Use Option

4.2.10.3.1 Nonradiological Impacts

4.2.10.3.1.1 Impacts to Workers. Railroad construction and operation nonradiological occupational health and safety impacts for the Shared-Use Option would be approximately the same as for the Proposed Action, based on the construction and operation of the proposed rail line. It is assumed that construction of the proposed rail line for the Shared-Use Option would require approximately the same number of workers and labor hours, and approximately the same amount of construction materials and equipment as would construction of the proposed rail line for the Proposed Action.

Rail line facility construction and operation nonradiological occupational health and safety impacts for the Shared-Use Option would be approximately the same as for the Proposed Action, based on the construction and operation of the proposed rail line and associated facilities. It is assumed that the construction of the railroad facilities under the Shared-Use Option would require approximately the same number of workers and labor hours, and approximately the same amount of construction materials and equipment as would construction of the railroad facilities under the Proposed Action, and that the configuration and operation of the facilities, including emergency response systems, would be the same for both the Proposed Action and Shared-Use Option.

4.2.10.3.1.2 Impacts from Specific Resource Areas. Rail line construction and operation nonradiological occupational health and safety impacts related to the specific resource areas discussed in Section 4.2.10.2.1 would be approximately the same for the Shared-Use Option as for the Proposed Action, based on the construction and operation of the proposed rail line.

4.2.10.3.2 Radiological Impacts

4.2.10.3.2.1 Impacts to Workers. It is anticipated that worker health and safety impacts under the Shared-Use Option would be similar to those under the Proposed Action, with the exception of radiological occupational exposure impacts. One difference would be the number of times a loaded cask train would pass workers at sidings. For the Proposed Action, there could be up to about 50 passes involving loaded cask trains and other trains (DIRS 180923-Nevada Rail Partners 2007, all). Over the life of the rail shipping campaign, a cask train could pass more than one shared-use train between the Staging Yard and Yucca Mountain site boundary. This would result in a collective radiation dose of 0.0024 person-rem for these workers. This is equivalent to a probability of a latent cancer fatality of 1.4×10^{-6}. Under the Shared-Use Option, there could be up to about 100 passes involving loaded cask trains and other trains. This would result in a collective radiation dose of 0.0051 person rem for these workers. This is equivalent to a probability of a latent cancer fatality of 3.0×10^{-6}.

4.2.10.3.2.2 Impacts to the Public. It is anticipated that radiological health and safety impacts for the Shared-Use Option would be similar to those for the Proposed Action with the exception of radiological occupational exposure impacts. The additional trains that would be operated for the Shared-Use Option would not involve transportation of radioactive materials and therefore there would be no additional exposure of the public.

4.2.10.3.3 Transportation Impacts

4.2.10.3.3.1 Construction Impacts.

Nonradiological Roadway Accidents Under the Shared-Use Option, any increase beyond what is described under the Proposed Action for roadway accidents and fatalities would be minimal.
The collective impact would be expected to be less than 1 percent of the overall risk calculated for construction of the Proposed Action rail line. Therefore, impacts are considered to be the same as those identified for the Proposed Action.

Nonradiological Rail Line Accidents No commercial rail transportation would be conducted during construction of the Shared-Use Option. Under the Shared-Use Option, any increase beyond what is described under the Proposed Action for rail line accidents and fatalities would be minimal.
The collective impact would be expected to be less than one percent of the overall risk calculated for construction of the Proposed Action rail line. Therefore, impacts are considered to be the same as those identified for the Proposed Action.

4.2.10.3.3.2 Operations Impacts.

Nonradiological Roadway Accidents Under Shared-Use Option operations, any increase beyond what is described under the Proposed Action for roadway accidents and fatalities would be minimal. Impacts are considered to be the same as those identified for the Proposed Action.

Nonradiological Rail Line Accidents The rail transportation safety analysis for the operations phase of the Shared-Use Option assesses the impacts of transportation, rail facilities, and grade crossings.

Rail Alignment: The Shared-Use Option differs from the Proposed Action only in the amount and type of traffic that would use different portions of the proposed rail line and the composition of some of the trains in terms of both length and materials categories. Up to eight one-way commercial train trips (four round trips) a week would be expected, with each train consisting of up to four locomotives and up to 60 railcars (DIRS 180694-Ang-Olson and Gallivan 2007, all). For comparison, an average total of 17 trains would run one way between the Proposed Action Staging Yard and the geologic repository per week carrying casks, repository construction materials and supplies, and other materials for maintenance-of-way activities. It is anticipated that the trains would travel at 64 kilometers per hour (40 miles per hour). The addition of the commercial trains would have a small impact on the potential for an accident involving a cask car, as operational procedures and controls regarding both scheduling and the use of sidings would restrict the interactions of the two types of trains. Trains carrying cask cars would take precedent. The overall density of trains on the proposed rail line would still be considered low, even with the commercial trains added in, so additional risk of an accident involving cask cars due to increased traffic densities would be minimal.

During the peak level of transportation operations along the rail line, there could be 17 one-way trains servicing the repository each week (8 cask trains, 7 repository construction and supplies trains, and 2 maintenance-of-way trains), and eight one-way commercial trains (four round trips). During these peak years, the transportation safety impacts associated with nonradiological risks might increase by approximately 50 percent. Over the full 50-year operating lifetime of the rail line, the Shared-Use Option could result in additional 20,800 trains, considering each direction separately (eight one-way trains per week). All trains are assumed to travel the full length of the rail line, generating roughly 11.3 million train-kilometers over 50 years. Based on a list of potential shippers, demand estimates were developed (DIRS 180694-Ang-Olson and Gallivan 2007, all). A total of 225 weekly carloads would be expected to be shipped along different portions of the rail line. According to the location and demand of each potential shipper, it was estimated that each loaded car would travel an average of 200 kilometers (124 miles). Considering both directions of travel, this would result in approximately 234 million car-kilometers over 50 years (225 cars × 52 weeks × 50 years × 200 kilometers × 2). Assuming the same rail fatality and accident rates included in Sections 4.2.10.2.3.1 and 4.2.10.2.3.2, respectively, a total of three additional fatalities and 13 additional accidents would be expected to occur for the entire set of estimated railcar movements during Shared-Use Option operations. Rail accidents are not allocated to specific rail line segments due to the uncertainty of where those accidents will occur.

In general, the operating characteristics of these commercial trains are unknown at this time; therefore, the travel times and operational movements of these trains cannot be described. However, the Nevada Railroad Control Center described under the Proposed Action would control and coordinate commercial rail service movements and would therefore maintain overall safety of operations along the rail line to minimize potential rail accidents.

Rail Facilities: The Rail Equipment Maintenance Yard and the geologic repository operations area interface would not be affected by any shared use of the proposed rail line because commercial shippers would not use the DOE Rail Equipment Maintenance Yard. Many of the commercial railcars would be dropped off along the way at intermittent commercial facilities. As a result, the commercial service end-of-line facility would have significantly less car handling than the Rail Equipment Maintenance Yard, and operations at the commercial facility would have no impact on the number of accidents involving the cask cars.

Grade Crossings: The increased number of trains under the Shared-Use Option would slightly increase the potential for accidents because of the increased number of trains crossing each at-grade crossing (at three round trips per week). However, because this volume of commercial traffic would be low, adverse impacts would be small. Delay considerations were included in Section 4.2.9.

4.2.10.4 Summary

This section summarizes nonradiological occupational health and safety impacts, public and occupational radiological impacts, and nonradiological transportation impacts under the Proposed Action and the Shared-Use Option for the Caliente rail alignment.

Alignment segments and facility locations are not relevant to the nonradiological transportation impacts analysis or to the nonradiological occupational health and safety impacts analysis. Nonradiological occupational health and safety impacts depend on the number of construction and operations full-time-equivalent works. Nonradiological transportation impacts depend on the number of construction and operations full-time-equivalent workers and the number of casks transported. Therefore, there are no important differences among alignments or facility locations in relation to nonradiological transportation impacts or nonradiological occupational health and safety impacts.

Radiological impacts for the Caliente rail alignment are estimated based on the longest-distance alignment, the shortest-distance alignment, the alignment with the highest population density, and the alignment with the lowest population density. Radiation dose to the public is estimated for Staging Yard locations (options) for the Caliente rail alignment. There are no important differences among alignments or among Staging Yard locations in relation to radiological impacts for the Caliente rail alignment.

All nonradiological transportation impacts for construction and operation, including vehicle-related fatalities, rail-related accidents, and rail-related fatalities, are considered to be long-term impacts. Nonradiological occupational health and safety incidents for construction and operation could be either short term (such as lost-workday cases involving short-term disability) or long term (such as workday cases involving long-term disability); however, because there is no way to know the duration of a specific lost-workday case, for example, all nonradiological occupational health and safety impacts are deemed to be long-term impacts. All radiological impacts from railroad and facility operations are considered long-term impacts because such impacts would be experienced over the 50-year operating life of the railroad. Nonradiological transportation impacts, nonradiological occupational health and safety impacts, and radiological impacts are direct impacts.

4.2.10.4.1 Nonradiological Impacts

A summary of nonradiological impacts to workers from industrial hazards associated with construction and operation of the proposed rail line and associated facilities under the Proposed Action is included in Table 4-130 and Table 4-131. Impacts to involved workers and noninvolved workers and total impacts are shown in Table 4-112 for rail line construction and operation and in Table 4-113 for associated facility construction and operation. No construction or operation activities would occur under the No-Action Alternative. Therefore, there would be no occupational or public health and safety impacts associated with the No-Action Alternative.

Table 4-130 includes nonradiological impacts of construction and operation of the railroad under the Proposed Action including construction of the rail line, construction and operation of the construction work camps, construction and operation of quarries to produce ballast for construction activities, construction and operation of wells to produce water for construction activities, operation of construction trains, and construction and operation of batch plants to produce concrete for construction activities. Operations impacts include impacts to train crews and escort and security personnel. Table 4-131 summarizes the nonradiological impacts of construction and operation of railroad facilities under the Proposed Action, including the Rail Equipment Maintenance Yard, Facilities at the Interface with the Union Pacific Railroad Mainline, Nevada Railroad Control Center and National Transportation Operations Center, Maintenance-of-Way Facilities, and Cask Maintenance Facility. Table 4-132 summarizes the total impacts from railroad construction and operations under the Proposed Action.

4.2.10.4.1.1 Workers. Nonradiological occupational health and safety impacts from railroad construction and operations under the Proposed Action involve approximately 880 recordable incidents, approximately 520 lost-workday accidents, and approximately three fatalities.

Rail line construction and operations nonradiological occupational health and safety impacts for the Shared-Use Option would be approximately the same as for the Proposed Action, based on the construction and operation of the proposed rail line. It is assumed that construction of the proposed rail line for the Shared-Use Option would require approximately the same number of workers and labor hours, and approximately the same amount of construction materials and equipment as would construction of the proposed rail line for the Proposed Action.

Construction and operations workers under the Proposed Action and Shared-Use Option could potentially be exposed to nonradiological hazardous chemicals related to operation and maintenance of construction equipment and facility equipment, including maintenance-of-way and maintenance of casks. Such activities are anticipated to include welding, metal degreasing, painting, and related activities.

Table 4-130. Estimated impacts to workers from nonradiological industrial hazards during railroad construction and operations under the Proposed Action.

Group and industrial hazard category	Construction		Operations	
	Labor hours worked	Incidents	Labor hours worked	Incidents
	13.6 million		2.9 million	
Total recordable cases		336		37
Lost workday cases		186		28
Fatalities		0.67		0.26

Table 4-131. Estimated impacts to workers from nonradiological industrial hazards during railroad facility construction and operations under the Proposed Action.

Group and industrial hazard category	Construction		Operations	
	Labor hours worked	Incidents	Labor hours worked	Incidents
	3.1 million		17.0 million	
Total recordable cases		88		418
Lost workday cases		49		255
Fatalities		0.02		1.27

Table 4-132. Total estimated impacts to workers from nonradiological industrial hazards during railroad and facility construction and operations under the Proposed Action.

Group and industrial hazard category	Construction		Operations	
	Labor hours worked	Incidents	Labor hours worked	Incidents
	16.7 million		19.9 million	
Total recordable cases		424		455
Lost workday cases		235		283
Fatalities		0.69		1.53

Occupational health and safety impacts could also result from worker exposure to fuels, lubricants, and other materials used in construction, operation, and maintenance of the proposed rail line and associated facilities. The recorded incident rates of these exposure hazards during construction work at the Yucca Mountain Site has also been small and is anticipated to be small for construction and operation of the rail alignment and facilities under the Proposed Action.

Dust and soils hazards include potential occupational exposure to hazardous inhalable dust, including the minerals crystalline silica, cristobalite, and erionite, and potential occupational encounters with unexploded ordnance. It is unlikely that any fugitive particulate generated in the construction areas would contain a concentration of crystalline silica, erionite, or cristobalite that would result in exceedance of occupational exposure limits for these materials. Therefore, impacts associated with occupational exposure to these materials are not anticipated from construction and operation of the railroad and facilities under the Proposed Action.

Impacts to construction or operations workers from unexploded ordnance would be small due to implementation of inspection procedures and mitigation measures if necessary.

Workers may also be exposed to biological hazards including infectious diseases (such as Hantavirus, West Nile Virus) and other biological hazards (such as venomous animals). The recorded incidence rates of these biological hazards in the region of influence in Nevada are small, according to statistics published by state and federal agencies including the U.S. Centers for Disease Control and the Nevada State Health Division, and the recorded incident rates of these biological hazards during construction work at the Yucca Mountain Site has also been small. Therefore, DOE would expect small impacts to construction or operations workers from these biological hazards.

4.2.10.4.1.2 Public. Nonradiological impacts to the public from the construction and operation of the rail line and facilities (other than impacts from transportation accidents) are presented in the air quality section and noise section of this Rail Alignment EIS and are therefore not further discussed in Section 4.2.10. Impacts to the public from transportation accidents (those transportation accidents not involving release of radiation) are discussed in Section 4.2.10.4.3.

4.2.10.4.2 Radiological Impacts

Occupational and public radiological impacts and accident risk of rail line and associated facility operations for the Proposed Action and Shared-Use Option are summarized in Table 4-133. For the radiological impacts analyses, the four specific alignments described in Table 3-67 were evaluated. Table 4-133 summarizes the radiation doses and impacts for these workers along these four classes of alignments.

Table 4-133. Summary of occupational and public estimated radiological impacts for the Proposed Action (expressed as latent cancer fatality units).[a,b,c]

Case	Staging Yard	Workers	Public	Accident risk	Total
Highest population	Caliente-Indian Cove	0.34	1.4 × 10-4	1.3 × 10-6	0.34
Highest population	Caliente-Upland	0.34	1.3 × 10-4	1.3 × 10-6	0.34
Shortest distance	Caliente-Indian Cove	0.34	1.2 × 10-4	1.1 × 10-6	0.34
Shortest distance	Caliente-Upland	0.34	1.1 × 10-4	1.1 × 10-6	0.34
Longest distance	Eccles-North	0.34	6.6 × 10-5	7.6 × 10-7	0.34
Lowest population	Eccles-North	0.34	5.5 × 10-5	6.7 × 10-7	0.34

a. Radiation doses modeled from the point where the proposed railroad would meet the existing Union Pacific Railroad Mainline.
b. The highest population route and the shortest distance route would originate at Caliente-Indian Cove.
c. The lowest population route and the longest distance route would originate at Eccles-North.

Radiological occupational and public health and safety impacts to workers and the public for the Shared Use Option would be approximately the same as those for the Proposed Action, as the additional trains that would be operated for the Shared-Use Option would not involve transportation of radioactive materials that would result in additional occupational or public exposure to radiation.

4.2.10.4.2.1 Workers. For workers, the radiological impacts of the Proposed Action and Shared-Use Option are estimated to result in less than one latent cancer fatality.

4.2.10.4.2.2 Public. For members of the public, radiation doses and radiological impacts of the Proposed Action and Shared-Use Option are estimated to result in less than one latent cancer fatality.

4.2.10.4.2.3 Accidents. For members of the public, radiological impacts of the Proposed Action are estimated to result in less than one latent cancer fatality.

4.2.10.4.3 Transportation Impacts

Table 4-134 summarizes impacts from nonradiological transportation accidents, including vehicular-related accidents and rail-related accidents, from railroad construction and operation under the Proposed Action and Shared-Use Option. Impacts under the Shared-Use Option are considered to be the same as those identified for the Proposed Action for the construction phase.

Table 4-134. Summary of estimated transportation accident impacts.

	Construction	Operations	
	Proposed Action and Shared-Use Option	Proposed Action	Shared-Use Option
Vehicular-related fatalities	6	8	8
Rail-related fatalities	0.6	0.7	4
Rail-related accidents	3	13	26
Rail-related accidents involving cask trains	Not applicable	3	3

4.2.11 UTILITIES, ENERGY, AND MATERIALS

This section describes potential impacts to utilities, energy, and materials from constructing and operating the proposed railroad along the Caliente rail alignment. Section 4.2.11.1 describes the methodology DOE used to assess potential impacts to utilities, energy, and materials; Section 4.2.11.2 describes potential impacts; Section 4.2.11.3 describes potential impacts under the Shared-Use Option; and Section 4.2.11.4 summarizes potential impacts.

Section 3.2.11.1 describes the regions of influence for utilities, energy, and materials. To aid reader understanding, the regions of influence are repeated throughout Section 4.2.11 where appropriate.

4.2.11.1 Impact Assessment Methodology

The utilities, energy, and materials impacts analysis considered whether construction and operation of the proposed railroad along the Caliente rail alignment would:

- Cause utility service outages as a result of construction activities
- Affect the capacity of ***public water systems***, directly or indirectly
- Require extension of water mains involving off-site construction for connection to a public water source
- Impact water-supply capacity needed for fire suppression
- Affect the capacities of public wastewater treatment facilities, directly or indirectly
- Require extension of sewer mains involving off-site construction for connection with a public wastewater treatment system
- Require expansion of telecommunications systems involving off-site construction for connections with the network (including construction of communications towers)
- Affect the capacity and distribution capabilities of local and regional suppliers of fossil fuel
- Cause new sources of construction materials and operations supplies to be built, such as new mining areas, processing plants, or fabrication plants
- Affect the capacity of existing materials suppliers and industries in the region

4.2.11.2 Construction and Operations Impacts

This section describes potential impacts to utilities, energy, and materials resources from constructing and operating the proposed railroad along the Caliente rail alignment. The analysis of impacts to existing utilities considers:

- Potential impacts of constructing the rail line in or near existing utility lines or rights-of-way
- Potential impacts on the capacities of public utilities
- Potential impacts on the availability of fossil fuels (the focus of the energy analysis)
- Potential impacts on the availability of construction materials

4.2.11.2.1 Construction Impacts

4.2.11.2.1.1 Potential Interfaces with Public Utility Corridors and Rights-of-Way. Potential utility conflicts would arise if construction activities could interfere with a public utility's ability to continue service or could prevent future expansion of that utility or its use of a right-of-way. Conflicts could arise in areas where the rail line and its construction and operations support facilities would either cross or overlap an existing utility corridor or right-of-way.

Utility crossings are common to linear projects such as roads, railroads, and pipelines, and they can be accomplished with minimal impact using standard engineering procedures and appropriate design specifications (see Chapter 2).

Utilities that would require the construction of crossings either above or beneath the rail line (new grade crossings) might be subject to temporary interruption as the switch is made from the existing infrastructure to the new routing. Service interruptions for electrical and telephone service, if necessary, could be limited to the time required to throw a transfer switch or to disconnect and reconnect. Service interruptions to pipelines might be longer, but to the greatest extent practicable, would be limited to a few hours.

4.2.11.2.1.2 Public Utility Systems. Potential impacts to public utility systems during the construction phase would be related to the demands on these systems to support construction activity and sustain construction workers. DOE would establish 12 temporary construction camps along the rail alignment within the construction right-of-way to house construction workers, and would fully operate a maximum of six construction camps at any one time (DIRS 180921-Nevada Rail Partners 2007, Table D-1). DOE estimates that 2,160 construction personnel would be employed full-time. Each construction camp would have the capacity to house 360 people (254 construction workers and 106 support staff) for such functions as construction administration, utilities, emergency services, and other support. The personnel at each camp would comprise 40 professional staff, 20 clerical staff, and 300 craftsmen (DIRS 180922-Nevada Rail Partners 2007, p. 4-4). The utilities sector of each construction camp would include areas dedicated to power, wastewater treatment, water treatment, and trash disposal. DOE expects that most construction workers would live in and spend most of their time in these camps, thereby reducing the impacts that these individuals would have on public water and wastewater systems and the use of fuel for travel.

As described in Section 4.2.9, Socioeconomics, population changes are related to changes in employment. DOE expects that most of the full-time construction workers would live in the construction camps, but the Department estimates 40 construction workers might live in Lincoln County, 5 in Esmeralda County, and 15 in Nye County (DIRS 180921-Nevada Rail Partners 2007, Table D-1). There would be some population increases in nearby towns attributable to construction workers and indirect support workers. Because increases in population affect future demand on public utilities in a community, the utilities impacts analysis uses the basic assumptions and expectations regarding population change during the construction phase, as described below.

For purposes of this analysis, and consistent with the methodology described in Section 4.2.9 of this Rail Alignment EIS, DOE assumes that most construction workers would come from outside the region of influence rather than the more sparsely populated Lincoln, Nye, and Esmeralda Counties. Any changes in the populations of Lincoln, Nye, Esmeralda, and Clark Counties and towns within those counties would be small (see Section 4.2.9). Therefore, associated infrastructure impacts at the county and local levels during the construction phase would be small.

Public Water Systems The region of influence for ***public water systems*** is Lincoln, Nye, and Esmeralda Counties and communities within those counties. However, water requirements for the project during the construction phase would be met by new wells.

Because DOE does not plan to rely on ***public water systems*** as primary sources of water during the construction phase, direct impacts to ***public water systems*** would be those related to permanent population increases within the region of influence attributable to the construction phase.

Because, as previously discussed in Section 4.2.9, permanent population increases would be expected to be minor for most areas during the construction phase, DOE expects that existing ***public water systems*** in the region of influence could accommodate the increased demand within existing system capacities without adverse impacts.

Wastewater Treatment Systems The region of influence for wastewater transported offsite for treatment and disposal is the existing permitted treatment facilities in Lincoln, Nye, and Esmeralda Counties and communities within those counties.

DOE estimated that up to 626,000 liters (165,000 gallons) per day of sanitary wastewater could be generated during the construction phase, as summarized in Table 4-135. However, because construction activities would be phased, actual daily maximums would be less. The Department estimates that the amount of sanitary wastewater that would be generated at each construction camp would peak at 95,000 liters (25,000 gallons) per day. Most of this wastewater would be generated from flush toilets and showers. Sanitary sewage generated at the construction camps would be treated on site using portable wastewater treatment facilities, and treated wastewater would be recycled and used for construction purposes (such as soil compaction and dust suppression). DOE would recycle about 90 percent of all construction-generated wastewater. Therefore, there would be no impacts to existing wastewater treatment capacity in the region of influence.

Table 4-135. Wastewater generation during the construction phase – Caliente rail alignment.

Facility	Number of personnel (maximum)	Wastewater generation (liters per day per person)[a,b]	Total wastewater (liters per day)[c]
Construction camps[d]	2,160[e]	265	570,000
Interchange Yard and Staging Yard	220[e]	76	16,700
Maintenance-of-Way Headquarters and Trackside Facilities	170[e]	76	12,900
Rail Equipment Maintenance Yard	150[e]	76	11,400
Cask Maintenance Facility	150[f]	76	11,400
Concrete batch plants	20[e]	76	1,500
Total			626,000

a. Sources: Daily wastewater generation rates from DIRS 176172-Nevada Rail Partners 2006, Section 4.1 (for construction camps); Nevada Administrative Code 444.8312 as an estimated per person wastewater flow from an office (for other facilities).
b. To convert liters to gallons, multiply by 0.26418.
c. Numbers in column are rounded to three significant figures.
d. Six construction camps of a total of 12 would be in operation at one time.
e. Source: DIRS 180921-Nevada Rail Partners 2007, Appendix D.
f. Source: DIRS 181425-MTS 2007, p. 4.

Commercial vendors would provide portable restroom facilities where needed and would transport wastewater off site for treatment, which could include the use of permitted wastewater treatment facilities in the region of influence. As shown in Table 3-72, permitted wastewater treatment facilities in the region of influence have adequate capacity. Therefore, any impacts to those wastewater treatment facilities during the construction phase would be small.

DOE expects permanent population increases would be small for most areas during the construction phase (see Section 4.2.9); therefore, existing publicly owned wastewater treatment works in the region of influence could accommodate the increased wastewater within existing system capacities without adverse impacts.

Telecommunications Systems The region of influence for telephone and fiber-optic telecommunications systems is the southern Nevada region serviced by Nevada Bell Telephone Company (AT&T Nevada), Citizens Telecommunications Company of Nevada, and Lincoln County Telephone System, Inc.

During preliminary grading, construction communications would be provided via short-wave radio and satellite telephone (DIRS 180922-Nevada Rail Partners 2007, p. 2-3). Communications systems during construction would be designed to not interfere with other licensed services operating in the same geographic areas and would remain in place until the communications systems for railroad operations were in place and commissioned. Little or no landline telecommunications service would be required during the construction phase. The installation and use of telecommunications systems would have a small impact on local telecommunications utilities.

Electricity The region of influence for electric power includes areas serviced by the southern Nevada electrical grid operated by Nevada Power Company, Sierra Pacific Power Company, Valley Electric Association, Inc., Caliente Public Utilities, and Lincoln County Power District No. 1. Electric energy demand for initial construction activities would be satisfied with portable generators until electrical connections were established. This section discusses energy needs that would be satisfied through the use of existing electrical utilities.

During the construction phase, DOE proposes to lay an underground 25-kilovolt distribution line under the rail roadbed (DIRS 180922-Nevada Rail Partners 2007, p. 4.6). The primary purpose of the distribution line would be to provide electric power to facilities and equipment needed for routine railroad operations (such as signals, switches, and radio communication towers), and to be able to provide the capacity to meet expected power needs for support facilities; a secondary purpose would be to provide an alternative to diesel-powered generators or local power sources.

Although power might be required during construction or operations only in specific areas along the rail alignment (such as at sidings, radio communication towers, construction camps, and quarries), for purposes of analysis DOE assumed that the 25-kilovolt distribution line would be laid end-to-end in a trench along the entire length of the rail alignment. At the same time the Department was laying the power distribution line, it would also lay the fiber-optic cable to be used as part of a telecommunications system (encased in a polyvinyl-chloride [commonly referred to as PVC] duct), and place it in the same trench as the 25-kilovolt distribution line. Once the cables were placed, the trench would be backfilled to grade.

Based on initial planning studies, power to the distribution system would be fed from locations where the rail line would intersect existing high-voltage transmission lines (DIRS 180922-Nevada Rail Partners 2007, p. 4-6). At this stage in the design process, DOE has not identified specific locations. DOE would construct substations within the nominal width of the construction right-of-way to feed the 25-kilovolt distribution line from the higher-voltage transmission lines at such intersections. At locations along the rail line where lower-voltage power was required for railroad systems, DOE would place step-down transformers from the 25-kilovolt distribution line on the trackside.

Construction camps would be powered one of three ways: (1) from existing transmission or distribution lines where they run alongside the camp sites, (2) from the 25-kilovolt distribution line, or (3) from diesel-powered generators. Option (1) would require access to pre-existing nearby transmission or distribution lines at construction-camp sites and their contracted use. Option (2) would depend on the availability of an energized 25-kilovolt distribution line during the period in which a construction camp would be operated. For options (1) and (2), DOE would place a substation at the construction camp. If neither option (1) nor (2) was available, DOE would select option (3). In addition, for options (1) and (2), the Department would use backup diesel-powered generators at each camp during unexpected power outages. Energy use at each camp during the peak output year would approach 54,000 kilowatt-hours per day, or 20 million kilovolt-hours per year.

Quarry sites would require electric power for conveyor belts, machinery, lighting, and support services. That need would be met by either of three options: (1) from nearby transmission or distribution lines if available, (2) from diesel-powered generators, or (3) from the 25-kilovolt distribution line. DOE would build a substation at each quarry site. Temporary power lines would distribute power at the quarry facility. If DOE selected option (1) or (3), diesel-powered backup generators would always be available at each quarry site for emergencies. Each quarry would be expected to use 27,600 kilowatt-hours of power per day and energy use at each quarry site during the peak output years would approach 10 million kilowatt-hours per year (DIRS 180922-Nevada Rail Partners 2007, p. 3-2).

DOE plans to have 24-meter (80-foot)-long rails delivered by rail from manufacturing plants to Caliente. DOE would set up a portable welding plant at Caliente and would later relocate the plant along the rail alignment at 80- to 160-kilometer (50- to 100-mile) increments to weld 24-meter-long rail into 438-meter (1,440-foot)-long strings to be distributed along the rail alignment by dedicated welding trains (DIRS 180922-Nevada Rail Partners 2007, p. 3-10). Typically, such welding units are powered by diesel generators generating 375 kilowatts of electrical power. DOE might build a substation connected to existing transmission lines to supply this need at Caliente, but this is conceptual at this stage of design. Yard and siding areas would be likely candidate relocation sites, and at these sites DOE would use portable diesel-powered generators, or conceptually, the 25-kilovolt distribution line if available and energized. (Alternatively, off-line welding of the rail would be possible, but would require dedicated welding trains to support track construction activities.)

The major electrical providers in the project region, including Nevada Power Company, Sierra Pacific Power Company, Valley Electric Association, Inc., and Lincoln County Power District No. 1, would have adequate generating capacity or power-purchase capabilities (see Section 3.2.11) to supply the project during peak demand without disrupting service to the providers' respective coverage areas. As discussed in Section 3.2.11, demand is expected to remain relatively stable in the serviced areas, increasing at about 1 to 2 percent annually, and is not expected to impact the capacity of service providers. In cooperation with the affected utilities, DOE would perform electrical-capacity analyses to ensure adequate capacity exists, including evaluation of the conditions of existing electric facilities and determination of appropriate interface equipment to meet the needs of both parties, prior to any connection to a transmission or distribution line; therefore, any impact to electric services would be small.

For purposes of analysis, DOE assumed that electricity requirements for construction of the railroad operations support facilities (Interchange Yard, Staging Yard, the Nevada Railroad Control Center and National Transportation Operations Center, Maintenance-of-Way Facilities, the Rail Equipment Maintenance Yard, and the Cask Maintenance Facility) would be met with portable generating equipment, but could later be met through substations connected to the 25-kilovolt distribution line when it was completed.

4.2.11.2.1.3 Fossil Fuels. At this point in project planning, DOE has not identified specific providers of fossil fuels. However, for purposes of analysis, DOE expects that regional supply systems and suppliers could economically supply the project.

Fossil-fuel consumption during the construction phase would primarily consist of diesel fuel for construction equipment and vehicles. Heavy construction equipment would be diesel-powered, as would electric generators. Fuel and oil would be transported by truck and stored at the hazardous materials storage areas at the construction camps. These materials would be stored in accordance with applicable state and federal regulations (DIRS 176172-Nevada Rail Partners 2006, Section 6.2). DOE estimated that annual consumption of diesel fuel would be 117 million liters (31 million gallons) (DIRS 180921-Nevada Rail Partners 2007, Appendix D, Table 5b). The annual consumption of diesel fuel for the region of influence, as represented by the State of Nevada, is approximately 1.8 billion liters (480 million gallons) (DIRS 176397-EIA 2005, Table 4, 2004 data). Construction fuel consumption would represent 6.5 percent of diesel fuel used annually in Nevada.

Construction of the proposed railroad would have a small impact on the capacity of regional suppliers or the availability of fuel resources. The fuel supply system is such that it can flexibly respond to changes in demand. Fuel consumption for construction of the railroad operations support facilities would be lower; therefore, fuel consumption during construction of those facilities would have a small impact on the capacity of regional suppliers or the availability of fuel resources.

4.2.11.2.1.4 Materials. As described in Section 3.2.11, the region of influence for necessary raw materials is limited to the distribution networks and suppliers that can economically service the general project area. For cast-in-place concrete and subballast, the region of influence is limited to the State of Nevada. DOE would need a ***free-use permit*** from the BLM to use common varieties of sand, stone, and gravel from BLM-administrated public lands during the construction phase, pursuant to the regulations implementing the Materials Act of 1947 (30 U.S.C. 601 through 603) as codified in 43 CFR Part 3600. As described in Chapter 2, the Department could obtain ballast materials from up to four of the six potential quarry sites within Nevada that would be close to the Caliente rail alignment construction right-of-way. Therefore, the region of influence for obtaining ballast would be limited to the immediate area in Nevada. However, if DOE selected the Eccles alternative segment, there would not be a suitable quarry location available along this portion of the rail alignment and the Department would have to obtain ballast from an existing commercial quarry, which most likely would be the Milford Quarry in Utah, approximately 200 kilometers (120 miles) east of Caliente. In this case, the region of influence would extend to Utah. Other materials, including steel, steel rail, concrete ties, and other precast concrete could be procured and shipped from anywhere in the continental United States. Therefore, the region of influence for these materials is considered to be national.

Material needs for construction of the rail line along the Caliente rail alignment would vary among the alternative segments roughly in proportion to their lengths. The primary materials that would be consumed in rail line construction include steel; concrete, principally for rail ties, bridges, and drainage structures; and rock for ballast and subballast. Table 4-136 lists the rail line construction material requirements and current production rates within the respective regions of influence.

Steel DOE has calculated that construction of the proposed rail line along the Caliente rail alignment of approximately 550 kilometers (340 miles), including sidings and yard tracks, would require 2,834 strings of 136 RE welded rail, each string being 439 meters (1,440 feet) long (DIRS 180922-Nevada Rail Partners 2007, p. 3-10). This would correspond to a requirement for 82,000 metric tons (90,000 tons) of steel over an estimated construction period of 4 to 10 years. DOE would acquire the sections of rail from national commercial sources.

Because DOE would purchase steel rail from national suppliers in staggered preordered phases over a 2- to 3-year period, the impact on availability of steel rail would be small.

DOE would need additional steel for rail hardware, bridges, and facility structures. Existing commercial fabricators would supply the steel required for the bridges. The designs of bridges and rail facilities are not sufficiently advanced to tabulate materials needs; however, the quantities required would be substantially less than required for rail line construction.

Table 4-136. Rail line construction material requirements – Caliente rail alignment.

Material	Total requirements	Annual requirements over a 4- to 10- year construction period	Region of influence	Region of influence annual production	Percent of region of influence production
Steel rail	82,000 metric tons[a]	21,000 to 8,200 metric tons	U.S. (all steel)	86,000,000 metric tons	0.024 to 0.01
			U.S. (steel rail)	518,000 metric tons	4.0 to 1.6
Concrete, cast-in-place	120,000 metric tons	30,000 to 12,000 metric tons	Nevada	16,000,000 metric tons[d]	0.19 to 0.07
Concrete, precast (including concrete ties)	450,000 metric tons	113,000 to 45,000 metric tons	U.S.	15,000,000 metric tons[d]	0.75 to 0.03
Concrete ties	1,020,000 ties	250,000 to 100,000 ties	U.S.	1,000,000 ties	25 to 10
Ballast	3.2 million metric tons	800,000 to 320,000 metric tons	Nevada and Utah	24,000,000 metric tons [b,c,d]	3.2 to 1.3
Subballast	2.7 million metric tons	675,000 to 270,000 metric tons	Nevada	9,200,000 metric tons [b,c,d]	7.3 to 2.9

a. To convert metric tons to tons, multiply by 1.1023.
b. Based on use of concrete ties only.
c. Includes granite and traprock production only, 2003 data. Some data withheld to avoid disclosing company proprietary information (DIRS 173393-Tepordei 2003, Table 9).
d. Includes crushed stone of all types, 2003 data (DIRS 173393-Tepordei 2003, Table 6).

Concrete DOE has estimated that 50,000 cubic meters (65,000 cubic yards) of cast-in-place concrete would be required for Caliente rail alignment structures (DIRS 180921-Nevada Rail Partners 2007, p. B-19). Concrete weighs approximately 2.4 metric tons per cubic meter (145 pounds per square foot) and 50,000 cubic meters would translate to an approximate requirement of 120,000 metric tons (132,000 tons) over the 4- to 10-year construction phase. As described in Chapter 2, DOE would obtain concrete for site placement activities at proposed bridges and other structures from two portable batch plants set up near the construction sites. DOE would truck all aggregate and cement from the portable batch plants to the construction sites. Annual production of cast-in-place concrete in Nevada equals approximately 16 million metric tons (18 million tons) per year (DIRS 173400-NRMCA 2004, p. 2).

Based on Yucca Mountain FEIS estimates (DIRS 155970-DOE 2002, Table 6-34), the total precast concrete demand for a rail line along the Caliente rail alignment (that is, the longest alignment at approximately 550 kilometers [340 miles]) would be approximately 450,000 metric tons (500,000 tons). The estimated requirement for precast concrete roadbed ties is approximately 1,020,000 ties for standard track construction (DIRS 176172-Nevada Rail Partners 2006, Section 3.2). Using 318-kilogram (700-pound) ties at 0.61-meter (2-foot) intervals would require 324,000 metric tons (357,000 tons) of concrete to produce the ties. Precast concrete ties would either be supplied through national manufacturers or potentially through a dedicated tie production facility established locally by a commercial manufacturer (DIRS 176172-Nevada Rail Partners, 2006, Section 3.2). Additional precast concrete requirements would include manufactured elements such as culverts, bridge beams, and overpass components. These precast concrete elements would be obtained from commercial sources nationally.

Annual national production of concrete railway ties has been increasing from about 620,000 ties in 2000 (DIRS 173572-RTA 2000, p. 22) to about 720,000 ties in 2004, and is projected to grow to about 1.2 million ties in 2007 (DIRS 173573-Gauntt 2004, p. 17). The 324,000 metric tons (357,000 tons) of concrete ties that would be required to construct the rail line along the Caliente rail alignment represent 10 percent to 25 percent of the annual national production of concrete ties. Although this might seem like a significant requirement, the national production volume for concrete ties does not reflect manufacturing capacity. Concrete tie production is a very scaleable industry, and recent data suggests that, if needed, the industry has the capacity to increase concrete tie production rapidly (DIRS 173573-Gauntt 2004, p. 17). For example, the current national production of concrete ties represents only approximately 0.3 percent of all manufactured (precast) concrete production, which is 15 million metric tons (17 million tons) per year (DIRS 173392-van Oss 2003, Table 15). Because DOE would purchase precast concrete components from national suppliers in staggered preordered phases, and because construction would involve a small amount of cast-in-place concrete via the use of onsite batch plants, the impact on availability of concrete would be small.

Ballast and Subballast Ballast and subballast are essentially crushed rock such as that required for the development of the rail roadbed. DOE has estimated that a total of approximately 3.2 million metric tons (3.5 million tons) of rail roadbed ballast would be required for track construction along the Caliente rail alignment (DIRS 176176-Nevada Rail Partners 2006, p. 4-2). DOE would obtain ballast from new quarries. As discussed in Chapter 2 and Section 3.2.11, the Department has identified six potential quarry sites along the Caliente rail alignment with the potential to provide more than 90 million metric tons (100 million tons) of ballast, and has identified a commercial quarry at Milford, Utah, approximately 200 kilometers (120 miles) east of Caliente, that would be required if DOE selected the Eccles alternative segment. Of the six potential quarry sites, DOE would develop up to four. Each of the potential quarries could produce approximately 3,100 metric tons (3,400 tons) of useable ballast per day. Therefore, the impact to availability of ballast from constructing the rail line along the Caliente rail alignment would be small.

Ballast: Gravel or broken stone laid in a rail roadbed to distribute train weight uniformly across the bed.

Subballast: Gravel or broken stone that does not have to meet the ballast specifications, layered beneath the ballast as a transition between the ballast and the compacted subgrade.

DIRS 180922-Nevada Rail Partners 2007, p. 3.1.

DOE has estimated that a total of approximately 2.7 million metric tons (3.0 million tons) of subballast would be required for track construction along the Caliente rail alignment (DIRS 176176-Nevada Rail Partners 2006, p. 4-2). Material specifications for subballast are less restrictive than for ballast. DOE would obtain subballast from materials excavated during rail roadbed construction or from crushing rock in quarries. To minimize transportation costs, the Department would use multiple source areas. Available quantities of subballast materials in the Caliente rail alignment region of influence should be more than sufficient to supply the project. Thus, impacts on the availability of subballast materials would be small.

DOE would construct 7.3-meter (24-foot)-wide gravel access roads parallel to the rail line and within the construction right-of-way. The rail line and the alignment access roads would be accessed via existing public roads where the rail line would cross an existing roadway. DOE would construct additional access roads to reach features like wells and quarries that are not immediately accessible to the rail alignment. The quarry sites identified would be within 3 kilometers (2 miles) of the alignment, thereby minimizing access-road construction requirements.

Materials for access-road construction or improvement would be obtained primarily from locally available materials such as stone, and gravel resulting from cuts and fills along the alignment and overburden at quarries. Access roads would likely have gravel surfaces. The native material would be supplemented by crushed rock screenings as necessary to provide a serviceable roadway surface.

Sand and Gravel There is a high likelihood DOE would find sands and gravels on the alluvial fans along cuts for the line that would be suitable for construction purposes and road making. Sand and gravel also would be generated from overburden at quarry and borrow sites. DOE would use some natural sand and gravel excavated from cuts and crushed rock from the quarries to make concrete aggregate (DIRS 176034-Shannon & Wilson 2006, pp. 24 to 26). The Department would determine the prime sand and gravel deposits needed before beginning construction. Using locally available sand and gravel would result in the consumption of a nonrenewable resource that could be used as a supply of construction materials for other construction projects in the area. However, alluvial deposits of sand and gravel are commonplace in the Caliente rail alignment region of influence, and their use to construct the rail line would not substantially reduce the area's resources; thus, impacts would be small.

Other Materials Requirements In addition to the materials needed for the rail line, DOE would also need construction materials for railroad operations support facilities. An estimated total of approximately 11,000 square meters (119,000 square feet) of building space would be required for operations support facilities (DIRS 180919-Nevada Rail Partners 2007, Tables 5-B, 6-B, 6-C, 6-D, 7-A, and 7-B; DIRS 181425-MTS 2007, p. 1). By comparison, the Las Vegas market alone had over 186,000 square meters (2 million square feet) of industrial space under construction in 2004 (DIRS 173390-Colliers International Partnership 2004, p. 1) and 160,000 square meters (1.7 million square feet) of office space completed in the 12-month period ending in March 2004 (DIRS 173391-Colliers International Partnership 2004, p. 1). Materials for the construction of rail yards at the operations support facilities are included in the rail line material estimates described in this section. Materials requirements for buildings would not be substantial in comparison to regional demand and would have a small impact on the regional supply system.

4.2.11.2.2 Operations Impacts

4.2.11.2.2.1 Utility Systems. None of the potential utility interfaces identified in Section 4.2.11.2.1.1 would prevent the future expansion of a utility service area. Impacts on infrastructure at the county level associated with railroad operations would be small because regional population projections anticipate modest growth (see Section 4.2.9.3.2). However, there could be some impacts on infrastructure in towns near the proposed railroad operations support facilities. Areas that would be likely to experience the greatest impacts include:

- Caliente/Eccles (Lincoln County), where the Interchange Yard, Staging Yard, and train crew quarters would be located, and which is also a possible location for the Nevada Railroad Control Center and National Transportation Operations Center
- Tonopah (Nye County) and Goldfield (Esmeralda County), the towns that would be closest to the Maintenance-of-Way Headquarters and Trackside Facilities
- Southern Nye County, the location of the Rail Equipment Maintenance Yard, Cask Maintenance Facility, train crew quarters, and possibly the Nevada Railroad Control Center and National Transportation Operations Center

Public Water Systems Water would be needed for railroad operations, particularly at operations support facilities. Because they would be reclaimed after the end of the construction phase, there would be no water demands associated with the quarries.

DOE estimates water consumption at the Rail Equipment Maintenance Yard would be about 23,000 liters (6,000 gallons) per day for personnel and an additional 11,000 liters (3,000 gallons) per day for building and railyard uses, including irrigation and vehicle washing. At the Rail Equipment Maintenance Yard, water needs would be met by using the repository's well system, which would eliminate the need for service by any local public water system. The Staging Yard, Nevada Railroad Control Center and National Transportation Operations Center, and Maintenance-of-Way facilities would all obtain their water from local wells tapping into nearby groundwater systems (see Section 4.2.61, Groundwater Resources). Where water connections into local public systems would be needed, usage would be primarily from employees at the facilities.

Public water systems in Lincoln, Esmeralda, and Nye Counties could be affected by incremental changes in population attributable to railroad operations. Because the population increase attributable to employees at the Interchange Yard and Staging Yard would be relatively small (see Section 4.2.9.3.2), any impacts to ***public water systems*** in Lincoln County that could be attributed to population increase would be small.

As discussed in Section 3.2.11, Lincoln County is able to meet current and future demands for water. Goldfield, in Esmeralda County, has the groundwater resources and infrastructure available to triple the number of users served by its public water system and thus has the potential to meet increased demand for water by additional residential users and by commercial users such as the Staging Yard.

In Nye County, given the level of demand and the limited capacity of groundwater resources (particularly in the Pahrump Valley hydrographic area), water needs could strain supply. Although the Cask Maintenance Facility would be collocated with the Rail Equipment Maintenance Yard and the geologic repository operations area interface in Nye County, the estimates for population increase attributable to the employees at the Yucca Mountain Site (see Section 4.2.9.3.2) would represent a small incremental increase. Therefore, impacts to the ***public water systems*** in Nye County from the demands associated with these potential new residents would be small.

Wastewater Treatment Facilities DOE would dispose of sanitary wastewater in accordance with State of Nevada regulations. Under the Statutory Authority of Nevada Revised Statutes (NRS) 445A.300 through 445A.730, and pursuant to the Nevada Administrative Codes (NAC) 445A.810 through 445A.925, and NAC 444.750 through 444.828, the Nevada Division of Environmental Protection, Bureau of Water Pollution Control, issues wastewater discharge permits, administers loans to publicly owned treatment works, and oversees the certification program for sewer-treatment plant employees. In most cases, DOE would construct onsite sanitary wastewater treatment systems within the railroad operations right-of-way and they would be permitted by the State of Nevada. These would likely be ***package plants***, as described in Section 3.2.11.2.3. If access to nearby existing permitted wastewater treatment facility capacity was available to any on-site facilities, DOE would discharge sanitary waste to those existing facilities. Impacts to existing wastewater treatment capacities of jurisdictions in the region of influence during the operations phase would be small.

Table 4-137 lists the rates of wastewater generation that would be associated with railroad facilities during the operations phase.

Wastewater from the Interchange Yard and the Staging Yard would be disposed of at the permitted wastewater treatment facility in Caliente. Wastewater from the train crew quarters in Caliente, Goldfield, or near the Rail Equipment Maintenance Yard would be disposed of through septic systems or wastewater-treatment facilities (DIRS 180919-Nevada Rail Partners 2007, p. 3-5). The Maintenance-of-Way Headquarters Facility would be 8 kilometers (5 miles) south of Tonopah on U.S. Highway 95, and it would include maintenance work areas, office space, and a material storage area.

Employees at this facility and employees in crew cars that would be outfitted with washing and showering facilities would generate wastewater, which would be disposed of through local septic systems and leach fields (DIRS 180919-p. 3-5). The Nevada Railroad Control Center and National Transportation

Operations Center would be either at the Rail Equipment Maintenance Yard or at the Staging Yard. These facilities would consist primarily of office space, and would generate small amounts of sanitary wastewater.

Table 4-137. Wastewater generation during the operations phase – Caliente rail alignment.

Facility	Number of personnel (maximum)	Total wastewater generation (liters per day)[a]
Facilities at the Interface with the Union Pacific Railroad Mainline (Interchange Yard and Staging Yard)	50[b]	21,000
Maintenance-of-Way Facilities (including staff for the Satellite Maintenance-of-Way Facilities)	50[b]	22,000
Rail Equipment Maintenance Yard, including the Nevada Railroad Control Center and National Transportation Operations Center	70[b,c]	23,000
Totals	170	66,000

a. To convert liters to gallons, multiply by 0.26418.
b. Source: DIRS 180921-Nevada Rail Partners, 2007, p. D-7.
c. Source: DIRS 181425-MTS 2007, p. 5.

The Rail Equipment Maintenance Yard would provide a staging area for delivery of loaded cask cars to the repository, construction materials, and fuel. The facility would include office space, and train crew and escort personnel quarters, all of which would generate sanitary wastewater. Sanitary wastewater disposal at this facility would consist of septic systems or wastewater treatment facilities at the Yucca Mountain Site (DIRS 180919-Nevada Rail Partners 2007, p. 3-5).

The numbers of employees projected to reside in the communities near railroad operations support facilities would represent small fractions of the existing populations (see Section 4.2.9.3). Also, as shown in Table 3-72, most of the existing wastewater treatment facilities are operating well below their capacities, and these facilities would be capable of accommodating the anticipated increases in wastewater attributable to railroad facility employees. In addition, as described in 3.2.11.2.3, a 2003 grant from the U.S. Department of Agriculture Rural Development Nevada allowed Caliente, in Lincoln County, to complete the rehabilitation of its wastewater collection system, and Goldfield has recently been awarded a Water Resource Development Act grant of approximately $3 million for renovations and upgrades. Therefore, the impact on public wastewater systems from operating railroad support facilities would be small.

Telecommunications Systems The communication system required to support railroad operations would utilize four distinct communication technologies: synchronous optical network fiber-optic backbone, very high frequency (VHF) land mobile radio, geosynchronous satellite dispatch radio, and possibly satellite telephone service (DIRS 180923-Nevada Rail Partners 2007, Section 6.1.3). The fiber-optic cable laid along the length of the rail alignment would allow the installation of a VHF land mobile radio system comprising a series of base stations located at points approximately 16 to 32 kilometers (10 to 20 miles) apart along the rail alignment to provide full radio coverage communications with locomotive and maintenance crews. Base stations would consist of an equipment room that would house the radio and fiber-optic electronics and a monopole radio tower to mount an elevated VHF antenna. The Nevada Railroad Control Center would also have a private branch exchange telephone system. In the event of a failure of all or part of the primary VHF radio system, operations would continue via a geosynchronous satellite dispatch radio system. As a backup, DOE could utilize satellite telephone hand sets.

At the Nevada Railroad Control Center, the system would be configured to allow the dispatcher easy access to all of the various communication modes available, including the ability to patch communication modes together if required. However, for external communications, the Staging Yard, the Nevada Railroad Control Center and National Transportation Operations Center, the Maintenance-of-Way Facilities, the Cask Maintenance Facility, and the Rail Equipment Maintenance Yard would each require digital subscriber line and telephone service. The Rail Equipment Maintenance Yard would require the greatest telecommunications capacity, with approximately 75 conventional telephone lines, 50 broadband internet connections, five secure telephone lines, a fiber optic line for closed-circuit television and data communication, and radio communications for railroad operations in conjunction with the centralized traffic control rail signal system (DIRS 180919-Nevada Rail Partners 2007, Section 6.6). The radio communication systems would be designed not to interfere with other licensed systems operating in the same area. The levels of commercially provided service would be small, and would not adversely affect the capacities of commercial telecommunication providers.

Electricity Impacts associated with the underground 25-kilovolt distribution line would be related to utility interfaces, as discussed in Section 4.2.11.2.1.1, and in Section 4.2.2, Land Use and Ownership.

Operation of the proposed railroad would require electricity for buildings, signaling, communications, and control. Twelve-kilovolt electrical service would be required for each facility. Depending on the distance from available power sources, larger distribution lines and intermediate substations might be needed. In addition to commercial sources, electric power could be supplied from the installed power distribution system. Each facility site would require a 12-kilovolt/480-volt transformer with a 480-volt distribution system to power industrial equipment and feed each building where a 480-volt/120-volt transformer would supply the building power (DIRS 180919-Nevada Rail Partners 2007, p. 3-5). Additional transformers could be required for other site requirements such as site lighting, power to yard switches and signals, or power for communications equipment. Each site would require a diesel-powered emergency generator to supply electrical power in case of an outage.

DOE estimates that the Staging Yard facilities (yard office, crew change facility, a Satellite Maintenance-of-Way Facility, and the Nevada Railroad Control Center and National Transportation Operations Center if in Caliente rather than at the Rail Equipment Maintenance Yard) would have a normal power demand of 386 kilowatts (or 290 kilowatts without the Nevada Railroad Control Center and National Transportation Operations Center) (DIRS 180919-Nevada Rail Partners 2007, p. 5-11). DOE would build a substation connected to existing transmission lines to service this power need at the selected alternative for the Staging Yard (Caliente-Indian Cove or Caliente-Upland, or Eccles-North). Diesel-powered generators would provide backup power.

DOE estimates that the Maintenance-of-Way Trackside Facility would have a normal power demand of 78 kilowatts, and the Maintenance-of-Way Headquarters Facility would have a normal power demand of 406 kilowatts (DIRS 180919-Nevada Rail Partners 2007, p. 7-10). Commercial electrical power from nearby Nevada Power Company distribution lines to Tonopah would be available to both the Maintenance-of-Way Headquarters Facility and the Maintenance-of-Way Trackside Facility. In addition, electric power from the proposed railroad distribution line could be available for use at the Maintenance-of-Way Trackside Facility, as would diesel-powered standby generators.

DOE has made separate estimates of power demand at the Rail Equipment Maintenance Yard that range between 722 and 815 kilowatts (DIRS 180919-Nevada Rail Partners 2007, p. 6-20). The Department has established an 8 megawatt power requirement (which includes a 30-percent reserve) for the Rail Equipment Maintenance Yard and Cask Maintenance Facility (DIRS 181033-Hamilton-Ray 2007, all). DOE could obtain power from a newly constructed substation connected to the existing supply system providing power to the Yucca Mountain Site, or from a new 138-kilovolt transmission line DOE plans to build to the geologic repository operations area. The 2003 peak load for the Nevada Power Company was 4,808 megawatts (DIRS 172302-Nevada Power Company 2004, all), whereas DOE has estimated there would be approximately an 8-megawatt demand to operate the proposed railroad. The Department would perform an electrical capacity analysis before connecting into local transmission or distribution lines, and consistent with the demonstration of available capacity. Therefore, impacts to other regional needs for electric power during the railroad operations phase would be small.

4.2.11.2.2.2 Fossil Fuels. DOE has estimated that 119 million liters (31.5 million gallons) of diesel fuel would be consumed over an anticipated 50-year operations phase, and that the annual consumption rate would peak at 4.3 million liters (1.1 million gallons) (DIRS 180921-Nevada Rail Partners 2007, Appendix D, Table 5a), a rate that would be less than 0.25 percent of the current annual vehicular diesel fuel usage in Nevada. Therefore, potential impacts to capacities of national and regional fuel producers and distributors during the operations phase would be small.

4.2.11.2.2.3 Materials. Materials use during the operations phase would be limited to materials for repair and maintenance of the railroad, including the locomotives, railcars, casks, and operations support facilities. The annual rate of material use over the 50-year operations phase would be substantially less than during the construction phase, and materials requirements would be expected to remain well below available capacity.

DOE would reclaim the quarries developed during the construction phase and would not use them during the operations phase. Therefore, the relatively minor amounts of ballast required for repairs and replacements during the operations phase would be met through existing commercial sources that at this stage of the design process have been identified as quarries in Milford, Utah, and Oroville, California, as described in Section 3.2.11.4. The impacts to available supplies of ballast at these existing quarries would be small.

4.2.11.3 Impacts under the Shared-Use Option

Railroad construction under the Shared-Use Option would include all of the features described in Section 4.2.11.2, but would include the construction of commercial sidings and support facilities. All such construction would occur on lands immediately adjacent to the rail alignment within the rail line construction right-of-way and would have impacts related to interfaces with utility corridors and rights-of-way similar to those under the Proposed Action without shared use.

The incremental demands on ***public water systems***, wastewater systems, telecommunications systems, electric power systems, fossil fuels, and materials for construction of commercial sidings and support facilities would be sufficiently small that the anticipated impacts on these resources would be effectively the same as for the Proposed Action without shared use. Therefore, potential impacts to local, regional, or national suppliers of such resources under the Shared-Use Option would be small.

Railroad operations under the Shared-Use Option would be the same as described in Section 4.2.11.2 for the Proposed Action without shared use, but commercial shippers would add to traffic on the rail line.

The incremental demands on ***public water systems***, wastewater systems, telecommunications systems, electric power systems, and materials for the operation and maintenance of commercial sidings and support facilities would be sufficiently small that the anticipated impacts on these resources would be effectively the same as those for the Proposed Action without shared use. Therefore, potential impacts to local, regional, or national suppliers of such resources under the Shared-Use Option would be small.

Fossil-fuel requirements for transporting general freight under the Shared-Use Option would depend on the volume and distance of shared-use traffic. It has been estimated that the incremental annual diesel consumption for commercial shared-use traffic would be 5.5 million liters (1.5 million gallons) (DIRS 180921-Nevada Rail Partners 2007, Appendix D, Table 5a), a rate that is less than 0.3 percent of current annual diesel fuel usage in Nevada. Most, if not all, of this fuel consumption would be offset by diesel fuel that would otherwise be used if the goods or materials were shipped by truck. Therefore, the impact to the capacities of national and regional fuel producers and distributors under the Shared-Use Option would be small.

4.2.11.4 Summary

Table 4-138 summarizes potential impacts to utilities, energy, and materials from constructing and operating the proposed railroad along the Caliente rail alignment. DOE determined that those impacts would be small.

Table 4-138. Summary of potential impacts to utilities, energy, and material resources – Caliente rail alignment.[a]

Resource	Construction impacts	Operations impacts
Utility interfaces	Potential for short-term interruption of service. No permanent or long-term loss of service or prevention of future service-area expansions.	None.
Public water systems	Most water would be supplied by new wells; small effect on ***public water systems*** from population increase attributable to construction employees.	Most water for operations would be supplied by new wells; small effect on ***public water systems*** from population increase attributable to operations employees.
Wastewater treatment systems	Dedicated treatment systems would be provided at construction camps; small impact on public systems from population increase attributable to construction employees.	Dedicated treatment systems would be provided at operations facilities; small impact on public systems from population increase attributable to operations employees.
Telecommunications systems	Dedicated systems; minimal reliance on communications providers.	Dedicated system along rail line; minimal reliance on communications providers.
Electricity	Peak demand would be within capacity of regional providers.	Peak demand would be within capacity of regional providers.
Fossil fuels	Demand would be approximately 6.5 percent of statewide use and could be met by existing regional supply systems and suppliers. Under the Shared-Use Option, demand would be less than 0.3 percent of statewide use during operations. Demand would be met by existing regional supply.	Demand would be less than 0.25 percent of statewide use.
Materials	Requirements generally would be very small in relation to supply capacity.	Requirements would be very small in relation to supply capacity.

a. Impacts under the Shared-Use Option would be similar to those under the Proposed Action without shared use, except as noted for fossil fuels.

4.2.12 HAZARDOUS MATERIALS AND WASTES

This section describes potential impacts of the use of hazardous materials and the management of nonhazardous wastes, ***hazardous wastes***, and ***low-level radioactive wastes*** that would be generated during construction and operation of the proposed railroad along the Caliente rail alignment. The section identifies the types of hazardous materials DOE would use and the hazardous, nonhazardous, and low-level radioactive wastes that would be generated during the construction and operations phases. The applicable guidelines, regulations, and available methods for treatment or ***disposal*** are identified for each waste. DOE evaluated the potential impacts of hazardous materials, hazardous wastes, nonhazardous wastes, and low-level radioactive wastes based on this information.

Section 4.2.12.1 describes the methodology DOE used to assess potential impacts; Section 4.2.12.2 describes potential construction impacts; Section 4.2.12.3 describes potential operations impacts; Section 4.2.12.4 describes potential impacts under the Shared-Use Option; and Section 4.2.12.5 summarizes potential impacts related to the use of hazardous materials and the generation of wastes.

DOE could purchase hazardous materials necessary for railroad construction and operations, such as engine coolant and solvents, through the federal supply chain or through local vendors. The Department anticipates local distributors in Nevada would supply propane and natural gas. The required hazardous materials would consist primarily of products consumers could purchase at most hardware, building-supply, or home-improvement stores. Therefore, DOE does not expect the supply of such products to be limited. As a consequence of using hazardous materials, associated hazardous wastes would be generated.

Section 3.2.12.1 describes the region of influence for hazardous materials and wastes.

4.2.12.1 Impact Assessment Methodology

DOE developed a list of anticipated types of hazardous materials and wastes to evaluate potential impacts from the use of hazardous materials or generation of wastes (see Table 4-139). To avoid or limit adverse impacts, DOE emphasizes adhering to applicable laws, regulations, policies, standards, and directives. The storage and disposal of hazardous and nonhazardous wastes is largely governed by the Resource Conservation and Recovery Act of 1976 (42 U.S.C. 6901 *et seq.*) and State of Nevada waste regulations (see Chapter 6, Statutory, Regulatory, and Other Applicable Requirements).

4.2.12.2 Construction Impacts

This section summarizes the types of hazardous materials DOE would use and the wastes that would be generated during construction of the proposed railroad. DOE would handle all wastes in accordance with applicable federal, state, and local environmental, occupational safety, and public health and safety requirements to minimize the possibility of adverse impacts to plants, animals, soils, and water resources inside or outside the region of influence. Because DOE would manage the use of hazardous materials and the disposal of wastes in accordance with applicable regulations and would implement best management practices (see Chapter 7), adverse impacts to environmental resources would be small.

4.2.12.2.1 Nonhazardous Waste

A total of approximately 2,300 metric tons (2,500 tons) per year of nonhazardous solid waste (such as general trash from kitchens and dormitories) would be generated during the construction phase, for a daily rate of approximately 6.3 metric tons (6.9 tons). Most of the solid waste would be generated at

Table 4-139. General considerations for assessing potential impacts from the use of hazardous materials and the generation of hazardous and nonhazardous wastes.

Material	Basis for assessing adverse impacts
Hazardous materials	Determine if the use of hazardous materials would create reasonably foreseeable conditions that would significantly increase the risk of a release of hazardous materials resulting from not adhering to storage and use standards set in applicable guidelines and regulations
Hazardous waste	Determine if the quantity of hazardous wastes generated would adversely affect the capacity of hazardous-waste collection and disposal services
Nonhazardous waste	Determine if the volume of solid and industrial and special wastes generated would adversely affect the capacity of solid-waste collection service and landfills
Low-level radioactive waste	Determine if the quantity of low-level radioactive wastes generated would adversely affect the capacity of available disposal facilities

construction camps. DOE would dispose of all solid waste in permitted landfills. Table 4-140 summarizes the solid-waste generation rate during the construction phase.

Construction activities would generate approximately 4,020 metric tons (4,380 tons) of ***industrial and special wastes*** (such as construction debris, used tires, and other materials with specific management requirements) per year, for an approximate daily rate of 11 metric tons (12 tons) (DIRS 176172-Nevada Rail Partners 2006, p. 6-6). DOE would minimize the amount of these wastes as much as possible by ordering construction materials in correct sizes and amounts, reusing leftover materials, and recycling appropriate types of materials (DIRS 152540-Hoganson 2000, all).

Almost 1.8 million metric tons (2 million tons) of industrial and special wastes were disposed of in Nevada in 2002, which was 90 percent of the total solid waste (all categories) generated state-wide (DIRS 174663-State of Nevada 2005, slide 8). Nevada has 23 operating municipal landfills that combined accept more than 12,700 metric tons (14,000 tons) of waste per day (DIRS 174663-State of Nevada 2005, slide 5; DIRS 181625-Simpson 2007, all). However, most of this capacity is available through the Apex Landfill, which serves the Las Vegas Valley, and receives an average of 8,000 metric tons (8,800 tons) per day (DIRS 174041-State of Nevada 2004, pp. 6 and 7). Some of the landfills in Esmeralda, Lincoln, and Nye Counties are quite small by comparison, and receive less than 2.7 metric tons (3 tons) of waste per day (DIRS 174041-State of Nevada 2004, p. 6).

It is likely that while some of the larger landfills would not see an appreciable change in the amount of waste received if they were utilized, some of the smaller landfills might see a substantial, although manageable, change in daily receipt of solid and industrial and special wastes if utilized during the construction phase.

As shown in Table 3-74, landfills in Lincoln, Nye, Esmeralda, and Clark Counties accept more than 8,100 metric tons (9,000 tons) of waste per day combined. The addition of about 6.3 metric tons (6.90 tons) per day of solid waste anticipated during the construction phase (see Table 4-140) would raise the total amount disposed of in the four-county area by approximately 0.077 percent. DOE anticipates that about 11 metric tons (12 tons) per day of industrial and special wastes would need to be disposed of due to construction activities, which would result in an increase of approximately 0.13 percent in waste receipt to local landfills (DIRS 176172-Nevada Rail Partners 2006, p. 6-6). Therefore, impacts to local landfills from the disposal of solid and industrial and special wastes would be small (for the relatively large Apex Landfill) to moderate (for the smaller landfills).

Table 4-140. Solid waste generation during the construction phase – Caliente rail alignment.

	Number of personnel (maximum)	Solid-waste generation (kilograms per day per person)[a,b]	Total solid waste (metric tons per day)[c,d]	Total solid waste (metric tons per year)[d]
Workforce	2,160[e]	2.9	6.3	2,300

a. Source: Per person solid waste generation rate is from DIRS 174041-State of Nevada 2004, p. 13.
b. To convert kilograms to pounds, multiply by 2.2046.
c. To convert metric tons to tons, multiply by 1.1023.
d. Numbers are not exact due to rounding.
e. Source: DIRS 176170-Nevada Rail Partners 2006, Appendix D.

The geotechnical exploration program would include drilling approximately 3,200 boreholes at depths of 15 to 60 meters (50 to 200 feet). These borings would generate more than 1,500 cubic meters (2,000 cubic yards) of drill cuttings (DIRS 181867-Holder 2007, all). DOE would not dispose of these drill cuttings in landfills, but would dispose of them through land application, which would involve spreading the drill cuttings on the land surface. All drilling fluids would meet the requirements for standard land disposal. Therefore, there would be no impacts to waste treatment or disposal facilities as a result of the generation of drill cuttings.

Construction activities would include some clearing of land. Wastes generated from this activity, including soil and plant material, would be used to construct fill slopes and contours within the rail line construction right-of-way; therefore, no waste would need to be disposed of and there would be no impacts to local waste disposal facilities from clearing of land (DIRS 176172-Nevada Rail Partners 2006, p. 6-3).

Earthwork cuts and fills for rail line construction would be expected to equal each other or nearly equal each other (DIRS 176165-Nevada Rail Partners 2006, Appendix E). In the event that more cut material was generated than would be needed as fill, DOE would use the excess to strengthen access roads and rail embankments. Therefore, no excess cut material would need to be disposed of and there would be no impacts to disposal facilities from the generation of excess cut material.

4.2.12.2.2 Hazardous-Materials Use and Hazardous-Waste Generation

DOE would store and use hazardous materials such as oil, gasoline, diesel fuel, and solvents during the construction phase primarily for the operation and maintenance of equipment and cleaning of equipment and facilities. The Department would implement an Environmental Management System and a Pollution Prevention/Waste Minimization Program during the construction and operations phases, which would include an evaluation of alternatives to eliminate, reduce, or minimize the amounts of hazardous materials used and hazardous wastes generated. As part of the Environmental Management System, DOE would regularly perform assessments to identify opportunities to reduce the generation of waste (DIRS 182385-Burns 2007, all). The Department would formulate and implement Spill Prevention Control and Countermeasures plans, including the use of secondary containment, to prevent releases of hazardous materials, such as diesel fuel, to the environment.

Table 4-141 lists the anticipated hazardous materials and the waste types that could be generated. The Department expects some materials (such as diesel fuel, lubricants, and hydrocarbons) would be used at each of the construction support facilities. However, most materials used and wastes generated would be specific to certain activities and facilities.

Hazardous wastes, such as used lubricants and solvents, would be accumulated and disposed of in accordance with Resource Conservation and Recovery Act regulations.

Table 4-141. Summary of anticipated types of hazardous materials that would be used and wastes that would be generated during railroad construction and operations – Caliente rail alignment.[a,b]

	Railroad construction	Construction camps	Concrete batch plants	Asphalt plants	Railroad operations[c]
Materials					
Fuel	X	X	X	X	X
Lubricants	X	X	X	X	X
Hydrocarbons (oils, greases)	X	X	X	X	X
Solvents	X	X	-	X	X
Compressed gas (flammable and nonflammable)	X	X	X	-	X
Batteries (such as lead, acid, nickel-cadmium)	X	X	X	-	X
Battery acid	X	X	-	-	X
Reactive (magnesium welding/fusing)	X	X	-	-	X
Explosives	X	X	-	-	-

Low-level radioactive waste	-	-	-	-	X

a. Source: DIRS 176750-Bishop 2006, all.
b. An X indicates that the listed material would be used or the listed waste would be generated during that specific activity or at that specific facility; a dash indicates that the listed material would not be used or the listed waste would not be generated during that specific activity or at that specific facility.
c. Includes only the proposed railroad activities; does not include DOE facilities at the Yucca Mountain Repository.

Hazardous wastes would be shipped in accordance with 49 CFR Parts 171 and 172 and U.S. Department of Transportation Hazardous Materials 215D regulations. The disposal capacity for hazardous wastes in western states has been estimated at 50 times the demand for landfills and 7 times the demand for incineration until at least 2013 (DIRS 103245-EPA 1996, pp. 32, 33, 36, 46, 47, and 50); thus, there would be ample capacity available to dispose of any hazardous wastes. Through compliance with applicable state and federal regulations, adverse impacts from the use of hazardous materials, generation of hazardous waste, and the disposal of hazardous waste would be small.

DOE could use explosives during quarry, access-road, and rail line construction, and would develop a safety program specifically for the storage, transportation, and handling of these materials. The Department would adhere to the requirements of DOE Order 440.1A, *Worker Protection Management for DOE Federal and Contractor Employees* (as described in Chapter 6), which specifies that explosives operations must comply with the DOE Explosives Safety Manual (DOE M 440.1-1A). The manual provides guidance on the storage and transportation of explosives and refers to Occupational Safety and Health Administration safety requirements for routine construction and tunnel-blasting operations.

There could be impacts if hazardous materials, such as fuels, lubricants, and antifreeze, were released and spread. DOE would store such materials at construction camps, and supply trucks would routinely bring new materials and remove used lubricants and coolants from the construction sites. These activities could result in local spills and releases of contaminants. DOE would immediately remediate any areas affected by such spills in accordance with applicable regulations (see Chapter 6).

4.2.12.2.3 Low-Level Radioactive Waste

No low-level radioactive waste would be generated during the construction phase.

4.2.12.3 Operations Impacts

DOE would purchase hazardous and nonhazardous products and materials during the operations phase. The use of hazardous materials and products would lead to the generation of hazardous wastes. Table 4-141 lists the anticipated hazardous materials and the waste types that could be generated during the operations phase.

4.2.12.3.1 Nonhazardous Waste

Railroad operations would generate solid wastes, which DOE would dispose of at facilities along the rail line. Amounts of such wastes would be very small and would not impact disposal capacity in Clark, Esmeralda, Nye, and Lincoln Counties.

Amounts of industrial and special wastes generated during maintenance of fixed equipment such as signals and rail crossings would be very small (DIRS 155560-Hoganson 2001, all). Crossties, ballast, rails, and bridges would not be likely to require replacement before 2033 (DIRS 152540-Hoganson 2000, all). However, when these materials did require maintenance or replacement, they would be reused wherever possible or recycled if reuse was not an option. Therefore, no impacts to local landfills would be anticipated from the disposal of industrial and special wastes during the operations phase.

The anticipated quantity of solid waste generated at all railroad operations support facilities is 190 metric tons (210 tons) per year or 0.51 metric ton (0.56 ton) per day (Table 4-142). DOE would transport solid waste to permitted solid-waste landfills. As shown in Table 3-74, landfills in Lincoln, Nye, Esmeralda, and Clark Counties accept more than 8,100 metric ton (9,000 ton) of waste per day combined.

Table 4-142. Solid waste generation at proposed railroad operations support facilities – Caliente rail alignment.

Facility	Number of personnel (maximum)	Solid-waste generation (kilograms[a] per day per person)[b]	Total solid waste (metric tons per day)[c]	Total solid waste (metric tons per year)
Cask Maintenance Facility	30[d]	2.9	0.087	32
Facilities at the Interface with the Union Pacific Railroad Mainline (Interchange Yard and Staging Yard)	50[d,e]	2.9	0.15	55
Rail Equipment Maintenance Yard (including the Nevada Railroad Control Center and the National Transportation Operations Center)[f]	40[d,e]	2.9	0.12	44
Headquarters, Satellite, and Trackside Maintenance-of-Way Facilities	50[e]	2.9	0.15	55
Totals[g]	170		0.51	190

a. To convert kilograms to pounds, multiply by 2.2046.
b. Sources: Per person solid waste generation rate is from DIRS 174041-State of Nevada 2004, p. 13.
c. To convert metric tons to tons, multiply by 1.1023.
d. Includes four rail-crew members.
e. DIRS 176170-Nevada Rail Partners 2006, Appendix D.
f. The Nevada Railroad Control Center could be at either the Rail Equipment Maintenance Yard or the Staging Yard and the National Transportation Operations Center could be anywhere in the continental United States; for purposes of analysis, DOE assumed these Centers would be at the Rail Equipment Maintenance Yard.
g. Totals might not equal sums of values due to rounding.

The addition of about 0.51 metric ton (0.56 ton) of solid waste anticipated during the operations phase (see Table 4-142) would raise the total amount disposed of in the four-county area by less than 0.01 percent. Nevada has enough landfill capacity to accommodate this additional solid waste; therefore, impacts to landfill capacities would be small.

4.2.12.3.2 Hazardous-Materials Use and Hazardous-Waste Generation

Maintenance of rolling and stationary railroad equipment and track would generate some hazardous wastes, including lubricants from equipment and machinery, solvents, paint, and other hazardous materials typical of railroad operations.

The Facilities at the Interface with the Union Pacific Railroad Mainline would use limited quantities of hazardous materials, such as oils, solvents, and lubricants, and associated wastes would be generated. An off-site contractor would perform diesel fueling at the Staging Yard using a tank truck to service the yard switcher locomotive. DOE would also store propane and natural gas at the Staging Yard (DIRS 176168-Nevada Rail Partners 2006, pp. 5-1 and 5-11).

The Maintenance-of-Way Headquarters Facility would include maintenance work areas, office space, and a material-storage area. DOE would store limited quantities of hazardous materials such as lubricants, solvents, and possibly pesticides (for example, herbicides and rodenticides), at this facility, and associated wastes would be generated. The Department would also store propane or natural gas onsite in tanks (DIRS 176168-Nevada Rail Partners 2006, pp. 7-1 and 7-2).

DOE would store and use hazardous materials, including diesel fuel, gasoline, propane, oils, paints, and solvents, at the Cask Maintenance Facility and associated hazardous wastes (such as oily rags and solvent wastes) would be generated (DIRS 174083-WPI 2003, pp. 30, 39, and 52). Compressed flammable gas and oxygen would also be stored at the Cask Maintenance Facility.

The Nevada Railroad Control Center could be at either the Rail Equipment Maintenance Yard or the Staging Yard and the National Transportation Operations Center could be anywhere in the continental United States, although for purposes of analysis, DOE assumed these Centers would be at the Rail Equipment Maintenance Yard. The Centers would consist primarily of office space (DIRS 176168-Nevada Rail Partners 2006, p. 6-3). DOE would store general cleaning supplies at these facilities.

There would be a diesel fuel storage tank with a 190,000-liter (50,000-gallon) capacity and a diesel fueling depot at the Rail Equipment Maintenance Yard (DIRS 181033-Hamilton-Ray 2007, all). There would also be a staging area where fuel oil and construction materials could be delivered to the repository. DOE would store and use hazardous materials, including lubricating oil, diesel fuel, natural gas or propane, and solvents, at the Rail Equipment Maintenance Yard and associated hazardous wastes would be generated (DIRS 176168-Nevada Rail Partners 2006, Section 6). Locomotive maintenance activities would generate approximately 420 liters (110 gallons) of used oil for each locomotive maintained. During peak operations, a maximum of 442 locomotives would travel on the rail line each year (DIRS 175036-BSC 2005, Table 4-2), which would generate approximately 190,000 liters (50,000 gallons) per year of used oil from locomotive maintenance. The used oil would be reclaimed rather than disposed of (DIRS 155970-DOE 2002, p. 6-89).

There could be small spills of hazardous materials such as oils and fuel along the rail line during the operations phase. DOE would immediately remediate any areas affected by such spills in accordance with applicable regulations (see Chapter 6).

DOE would manage the use of hazardous materials and would follow all federal, state, and local regulations, and would transport hazardous wastes to appropriately permitted disposal facilities that have ample capacities to receive such wastes, as discussed in Section 4.2.12.2.2. Therefore, impacts from the use of hazardous materials and the disposal of hazardous wastes during the operations phase would be small.

4.2.12.3.3 Low-Level Radioactive Waste

Activities at the Cask Maintenance Facility would generate from 3,200 to 7,900 cubic meters (113,000 to 280,000 cubic feet) of Class A low-level radioactive waste throughout the operations phase (DIRS 181425-MTS 2007, p. 6). The Department would control and dispose of site-generated low-level radioactive waste in a DOE low-level waste disposal site, a site in an ***Agreement State***, or in a U.S. Nuclear Regulatory Commission-licensed site.

The Nevada Test Site accepts low-level radioactive waste for disposal and has an estimated disposal capacity of 3.7 million cubic meters (130 million cubic feet). DOE has estimated that approximately 1.1 million cubic meters (39 million cubic feet) of low-level radioactive wastes will be disposed of at the Nevada Test Site by 2070 from all potential sources, but not including Cask Maintenance Facility-generated wastes (DIRS 155970-DOE 2002, Section 3.1.12.4). Commercial disposal capacity for low-level radioactive wastes is currently available in the United States.

Relatively small amounts of low-level radioactive wastes would be generated and the aforementioned potential disposal options would have ample capacities to accept these wastes; therefore, impacts to low-level radioactive waste disposal facilities would be small.

4.2.12.4 Impacts under the Shared-Use Option

Impacts under the Shared-Use Option would be similar to those described for the Proposed Action without shared use. The only difference would be the construction and operation of additional sidings and a slight increase in overall rail traffic. Waste characteristics, generation rates, and disposal requirements would vary only slightly. Therefore, any additional adverse impacts associated with the Shared-Use Option would be small.

4.2.12.5 Summary

Table 4-143 summarizes potential impacts related to the use of hazardous materials and the generation of waste from constructing and operating the proposed railroad along the Caliente rail alignment. Chapter 7 describes mitigation measures DOE could employ to reduce impacts.

Impacts from nonhazardous waste (solid and industrial and special waste) disposal listed in Table 4-143 represent the degree to which potentially affected landfills could be affected by increased waste receipt rates as a result of railroad construction and operation along the Caliente rail alignment. Construction of the proposed railroad along the Caliente rail alignment would raise the disposal rate of nonhazardous waste to landfills in the region of influence by about 0.21 percent. Overall, impacts during the construction phase would be small, for the relatively large Apex Landfill, to moderate for smaller landfills. During the operations phase, impacts to landfills would be small.

Impacts from the use of hazardous materials listed in Table 4-143 represent the likelihood that railroad construction and operation along the Caliente rail alignment would create reasonably foreseeable conditions that would significantly increase the risk of a release of hazardous material. Overall, impacts during the construction and operations phases would be small, considering that DOE would implement proper planning measures in relation to the storage and handling of hazardous materials and would adhere to all applicable regulations.

Impacts from hazardous-waste disposal listed in Table 4-143 represent the degree to which potentially affected hazardous-waste disposal facilities could be affected by increased waste receipt rates as a result of railroad construction and operation along the Caliente rail alignment. Overall, impacts during the construction and operation phases would be small because adequate disposal capacity would be available.

Impacts from low-level radioactive waste disposal listed in Table 4-143 represent the degree to which potentially affected low-level radioactive waste disposal facilities could be affected by increased waste receipt rates as a result of railroad construction and operation along the Caliente rail alignment. No low-level radioactive waste would be generated during the construction phase. During the operations phase, low-level radioactive wastes would be generated during cask maintenance activities at the Cask Maintenance Facility. Impacts to low-level radioactive waste disposal facilities during the operations phase would be small because adequate disposal capacity would be available.

Table 4-143. Summary of potential impacts related to the use of hazardous materials and the generation of waste from constructing and operating the proposed railroad – Caliente rail alignment (page 1 of 2).[a]

Rail line segment/facilities (county)	Construction impacts	Operations impacts
Common to all common segments and alternative segments (Lincoln, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	Small impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.

Table 4-143. Summary of potential impacts related to the use of hazardous materials and the generation of waste from constructing and operating the proposed railroad – Caliente rail alignment (page 2 of 2).[a]

Rail line segment/facilities (county)	Construction impacts	Operations impacts
Facilities at the Interface with the Union Pacific Railroad Mainline (includes the Interchange Yard and Staging Yard) (Lincoln County)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	Small impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.
Maintenance-of-Way Facilities (includes Maintenance-of-Way Headquarters Facility; Maintenance-of-Way Trackside Facility; Satellite Maintenance-of-Way Facilities); Rail Equipment Maintenance Yard; Cask Maintenance Facility; and Nevada Railroad Control Center and National Transportation Operations Center at the Rail Equipment Maintenance Yard (Lincoln, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	Small impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal. Small impacts from low-level radioactive waste disposal for wastes that would be generated at the Cask Maintenance Facility.
Construction camps (Lincoln, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	No impact. There would be no construction camps during railroad operations.
Access roads (including alignment access roads) (Lincoln, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	No impact. Use of access roads during railroad operations would not involve the use of hazardous materials or the generation of wastes.
Quarries (common to all potential quarry locations)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	No impact. DOE would not operate quarries after the end of the construction phase.

a. Impacts under the Shared-Use Option would be similar to those under the Proposed Action without shared use.

4.2.13 CULTURAL RESOURCES

This section describes potential impacts to cultural resources from constructing and operating the proposed railroad along the Caliente rail alignment. Section 4.2.13.1 describes the methods DOE used to assess potential impacts; Section 4.2.13.2 describes potential construction and operations impacts; Section 4.2.13.3 describes potential impacts under the Shared-Use Option; and Section 4.2.13.4 summarizes potential impacts to cultural resources. This section also incorporates American Indian perspectives to assess the potential direct and indirect impacts to assess the potential direct and indirect impacts to important American Indian prehistoric and historic resources.

Section 3.2.13.1 describes the region of influence for cultural resources. Unless specified otherwise, this section describes impacts within the 3.2-kilometer (2-mile)-wide area centered on the rail alignment (the Level II region of influence).

4.2.13.1 Impact Assessment Methodology

Because of the length of the proposed rail line along the Caliente rail alignment, DOE is using a phased cultural resource identification and evaluation approach, as described in 36 CFR 800.4(b) 2, to identify specific cultural resources along the alignment. Under this approach, DOE would defer final field surveys (an intensive BLM ***Class III inventory***) of the actual construction right-of-way, as provided in the programmatic agreement between DOE, the BLM, the STB, and the Nevada State Historic Preservation Office (DIRS 176912-Wenker et al. 2006, p. 15) (see Appendix M).

> A **Class II inventory** is a sample-oriented field inventory designed to locate and record, from surface and exposed profile indications, all cultural resource sites within a portion of a defined area to make possible an objective estimate of the nature and distribution of cultural resources in the entire defined area.
>
> A **Class III inventory** is an intensive field survey designed to locate and record all cultural resource sites within a specified area. Upon completion of such an inventory, no further cultural resource inventory work is normally needed in the area.

The programmatic agreement states that an appropriate level of field investigation – including on-the-ground intensive surveys; evaluations of all recorded resources listed on the *National Register of Historic Places*; assessments of adverse effects; and applicable mitigation of identified impacts – be completed before any ground-disturbing construction activities could begin. This programmatic agreement also stipulates that there be proper tribal consultation activities, and treatment (mitigation) guidelines and measures designed to cover unanticipated discoveries and impacts during the construction and operations phases. The BLM administers most of the potentially affected land along the Caliente rail alignment. Relevant provisions of another programmatic agreement between the BLM, the State of Nevada, and the Nevada State Historic Preservation Office (DIRS 174690-Abbey & Baldrica 2005, all) would apply, along with cultural resources procedures outlined in the BLM *Cultural Resource Inventory Guidelines* (DIRS 174691-BLM 1990, all).

The region of influence for the Class III inventory would include all potential direct and indirect effects to cultural resources and all properties of traditional religious and cultural importance from any construction activities associated with the proposed railroad. Before beginning any ground-disturbing activities, DOE would conduct a Class III inventory for the following specific region of influence for project activities (DIRS 176912-Wenker et al. 2006, p. 2):

> The APE [Area of Potential Effect, referred to in this Rail Alignment EIS as the region of influence] for the rail line will be 200 feet [61 meters] from the centerline of the alignment or the actual ROW [right-of-way]

> application submitted to BLM, whichever is greater. The APE for access roads outside of the alignment will be a minimum of 100 feet [30.5 meters] wide with at least 50 feet [15 meters] on either side of centerline. The minimum APE for any construction areas or other temporary use areas, outside of the alignment, will be the footprint of the area plus 100 feet outward in all directions from the perimeter of each area. The APE for assessing indirect effects on historic properties outside of the rail line alignment will extend at least one mile in all directions from the perimeter of the direct effects APE.

Cultural resource requirements for the portion of common segment 6 (see Figure 2-9) and the Rail Equipment Maintenance Yard within the Yucca Mountain Site boundary would be covered by a separate programmatic agreement addressing development of a geologic repository at Yucca Mountain, Nevada, underway between the DOE Office of Civilian Radioactive Waste Management, the Advisory Council on Historic Preservation, and the Nevada State Historic Preservation Office.

The present evaluation of impacts depends on a comprehensive review of existing literature and site-file databases, sample archaeological inventory, and discussions with responsible federal agencies, State of Nevada agencies, and American Indian groups, which have identified many known and potential archaeological, historical, and American Indian sites and features along the Caliente rail alignment. Section 3.2.13.3 provides pertinent baseline information. American Indian viewpoints for potential impacts to sites and resources important to regional tribes and organizations are expressed in *American Indian Perspectives on the Proposed Rail Alignment Environmental Impact Statement for the U.S. Department of Energy's Yucca Mountain Project* (the American Indian Resource Document; DIRS 174205-Kane et al. 2005, all).

4.2.13.2 Railroad Construction and Operations Impacts

Nearly all potential direct impacts to cultural resources, including those that would physically damage, alter, or disturb a historic property, would occur during the construction phase, specifically within the designated rail line construction right-of-way. There could be additional construction-related ground disturbances at quarry sites, road crossings, temporary access roads, borrow sites, ***spoils areas*** or piles, and 12 temporary construction camps. Each camp would have a construction footprint of about 0.1 square kilometer (25 acres). There would be other ground disturbances at the locations of the railroad operations support facilities, including the Facilities at the Interchange with the Union Pacific Railroad Mainline in the vicinity of either Caliente (0.06 square kilometer [15 acres]) or Eccles (0.12 square kilometer [30 acres]); the Maintenance-of-Way Trackside Facility (0.06 square kilometer [15 acres]), which would be near Goldfield; the Maintenance-of-Way Headquarters Facility (0.01 square kilometer [3 acres]), which would be near Tonopah; the Rail Equipment Maintenance Yard (about 0.41 square kilometer [101 acres]), which would be within the Yucca Mountain Site boundary; and the Cask Maintenance Facility, which would be collocated with the Rail Equipment Maintenance Yard.

There could be various forms of indirect impacts during both the construction and operations phases, such as visual intrusions or increased access and visitation. During construction, large numbers of workers in the vicinity of the construction camps could increase the potential for both intentional and unintentional impacts to nearby cultural resources. Excavation and other construction-related ground-disturbing activities could unearth additional cultural materials that, based on previous archaeological surveys, were either thought to occur only at the surface or were previously undetected because they were completely buried. Improved access to remote areas could also increase the likelihood of looting or other damage to archaeological properties during the construction and operations phases.

Another indirect impact that would be unavoidable from construction in remote areas would be visual intrusion effects to a variety of resources designated as potential cultural resource landscapes. These resources include potential ***ethnographic landscapes***, rural historic landscapes, and historic mining landscapes, and incorporate geographic areas, including both cultural and natural resources associated with historic events or activities. In some instances, the literature reviews, known-site file searches, and the Class II inventory conducted for this Rail Alignment EIS have identified potential areas of specific impacts for some of the alternative segments and common segments. In addition, the American Indian Resource Document (DIRS 174205-Kane et al. 2005, all) provides other relevant information.

4.2.13.2.1 Construction Impacts along Caliente Rail Alignment Alternative Segments and Common Segments

The following sections outline both the direct and indirect construction-related impacts within each of the Caliente rail alignment alternative segments and common segments. Each section begins with a discussion of the direct impacts to cultural resources, which is followed by a discussion of the indirect impacts. These sites include those listed on the *National Register of Historic Places*, those eligible for listing on the National Register, and those known to have cultural significance but are not listed on the National Register.

4.2.13.2.1.1 Alternative Segments at the Interface with Union Pacific Mainline.

Caliente Alternative Segment The Class I site-file search identified 11 previously recorded cultural resources along the Caliente alternative segment, including two within the Level I region of influence and nine within the Level II region of influence. These resources include three prehistoric sites (two rockshelters and a campsite), three isolated artifacts, and five historic sites (two railroad features, two trash scatters, and a cemetery). The search revealed that one site, the Caliente Union Pacific Railroad Depot, is listed on the *National Register of Historic Places* and two sites, the Caliente-Panaca Railroad berm, and a prehistoric rockshelter site, are evaluated as eligible for listing on the *National Register of Historic Places*. DOE did not perform a Class II sample inventory due to private property issues. Most of the lands along the Caliente alternative segment are privately owned. If DOE selected this alternative segment, the Department would complete an inventory before beginning construction.

There could be direct impacts to one *National Register of Historic Places*-eligible site. Construction of the rail roadbed could directly impact the abandoned Caliente-Panaca Railroad berm. The rails have been removed from the berm, but several undocumented wooden and metal bridges remain along the stretch that would be covered by the proposed rail line.

There could be indirect impacts to two National Register-eligible sites, including the Caliente Union Pacific Railroad Depot and a prehistoric rockshelter. The Caliente Union Pacific Railroad Depot is in downtown Caliente, south of the proposed interchange with the Union Pacific Railroad Mainline. Historic maps and photographs indicate that several early buildings, including a depot and a roundhouse, existed in that area and it is probable that subsurface historical archaeological remains exist even though the structures have been removed. The area known as Indian Cove, just north of the City of Caliente, through which the rail line would pass and the possible location of the Staging Yard, has evidence of prehistoric use in the form of a previously recorded rockshelter, an unevaluated rock-art panel, and ***lithic scatters*** and isolates. The rail line would extend through Meadow Valley, and would constitute a possible visual intrusion on the potential early Mormon settlement cultural landscape.

A rail line along the Caliente alternative segment could also directly and indirectly impact unrecorded sites. For example, the unrecorded Caliente Hot Springs Motel and Baths is where the proposed rail line would depart from the Union Pacific Railroad Mainline.

Potential quarry CA-8B would be along the Caliente alternative segment, on the eastern exposure of a rocky ridge overlooking Meadow Valley Wash. Preliminary archaeological reconnaissance of this location indicates that development of a quarry there would not result in direct impacts to known sites.

Eccles Alternative Segment The Class I site-file search identified three cultural resources along the Eccles alternative segment, including one within the Level I region of influence and two within the Level II region of influence. These resources include two prehistoric sites and one isolated artifact. The search revealed no sites have been evaluated as eligible for listing on the *National Register of Historic Places*; however, there could be direct impacts to two previously recorded but unevaluated prehistoric rockshelters in the vicinity of the Eccles-North Staging Yard location. The American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) also indicates that Clover Valley is a culturally important place with associated songs, plants and animals, and water resources.

DOE inventoried three Class II survey sample units along this alternative segment, a total of 2.4 kilometers (1.5 miles) or 13 percent of the segment. No sites were recorded, but five isolated artifacts were found. In the area of Meadow Wash at the northern end of the alternative segment, there is a potential early Mormon settlement cultural landscape.

The sample inventory indicates that approximately eight sites could be present within the Level I region of influence.

4.2.13.2.1.2 Caliente Common Segment 1 (Dry Lake Valley Area). The Class I site-file search identified 39 previously recorded cultural resources along Caliente common segment 1, including nine within the Level I region of influence and 30 within the Level II region of influence. These resources include 11 prehistoric sites (a toolstone quarry locale and 10 lithic scatters), 20 isolated artifacts, and eight historic sites (three ranching campsites, three trash scatters, and Old State Route 38 along the White River).

The Class II field survey inspected a total of 23 sample units along this segment, a total of 19 kilometers (12 miles) or 16 percent of the segment. The survey recorded two sites, a prehistoric lithic scatter and a historic campsite; neither site was recommended as eligible for listing on the *National Register of Historic Places*. Seventeen isolated artifact occurrences were also recorded during the field survey along this segment.

The search revealed no previously recorded National Register-eligible sites within the area that would be directly affected by rail line construction. However, there could be indirect impacts to a National Register-eligible prehistoric/historic campsite in the vicinity of Black Rock Spring. The campsite includes abundant lithics, ceramics, and early historic-period artifacts.

Construction activities along the eastern part of Caliente common segment 1 could result in direct and indirect impacts to the Meadow Valley Wash early Mormon settlement cultural landscape, and a historically important Pioche-Hiko silver mining community route and campsites of the 1849 Bennett-Arcane Party. The 1849 party camped at Bennett Springs, about 1.6 kilometers (1 mile) from the Caliente rail alignment. The party also camped in the vicinity of Black Rock Spring before crossing the North Pahroc Range. The route the party followed, commonly referred to as the Lost ‘49er Trail, has not been physically identified but is known to have crossed Bennett Pass and Pahroc Summit. To date, no archaeological sites associated with the Bennett-Arcane Party have been identified in the present region of influence.

The American Indian Resource Document (DIRS 174205-Kane et al. 2005, all) does not identify any potentially significant American Indian resources in the region of influence along Caliente common segment 1, though the American Indian Writers Subgroup notes that systematic ethnographic studies have not been conducted. The Subgroup does note the significance of cultural resources in the White River Valley, such as the well-known White River Narrows rock-art sites, charcoal ovens, and the area of Pahranagat Valley. These resources would be several kilometers from the Caliente rail alignment region of influence and would not be affected by rail line construction.

Sample inventory indicates that approximately 56 resources may be present within the Level I region of influence.

4.2.13.2.1.3 Garden Valley Alternative Segments.

Garden Valley Alternative Segment 1 The Class I site-file search identified 10 previously recorded cultural resources along Garden Valley alternative segment 1, including one within the Level I region of influence and nine within the Level II region of influence. These resources include five prehistoric sites (two rockshelters and three lithic scatters), four isolated artifacts, and one historic trash scatter. No sites have been evaluated as eligible for listing on the *National Register of Historic Places*. The Class II survey examined five sample units along this alternative segment, a total of 4 kilometers (2.5 miles) or 11 percent of the segment. Only six isolated artifact occurrences were recorded.

The American Indian Resource Document (DIRS 174205-Kane et al. 2005, p. 22) notes that Garden Valley contained extensive American Indian trail systems used for trade, commerce, pilgrimage, and for access to mountain ranges. Because systematic ethnographic studies have not been conducted for this alternative segment, the Resource Document gives no specific locations for trails. Therefore, Garden Valley alternative segment 1 could result in direct and indirect impacts to American Indian trail systems that pass through this part of Garden Valley.

Sample inventory indicates that approximately nine resources could be present within the Level I region of influence.

Garden Valley Alternative Segment 2 The Class I site-file search identified 12 cultural resources along Garden Valley alternative segment 2 (see Figure 3-119), including four prehistoric sites within the Level I region of influence and eight isolates within the Level II region of influence. The Class II survey inspected four sample units along this segment, a total of 3.2 kilometers (2 miles) or 9 percent of the segment; two isolates were recorded. Three cultural resources are evaluated as eligible for listing on the *National Register of Historic Places*, including the two campsites and a lithic scatter associated with a cluster of rock features.

Construction activities could directly impact two archaeological sites evaluated as eligible for listing on the *National Register of Historic Places*, a campsite and a lithic scatter, which would be in the Level I region of influence.

The American Indian Resource Document (DIRS 174205-Kane et al. 2005, p. 22) notes that Garden Valley had extensive American Indian trail systems used for trade, commerce, pilgrimage, and for access to mountain ranges. There could be direct and indirect impacts to early American Indian trails, and construction of Garden Valley alternative segment 2 could result in potential visual intrusions to the Freiberg Mining District cultural landscape in the northern part of the Worthington Mountains.

Sample inventory indicates that approximately 44 resources could be present within the Level I region of influence.

Garden Valley Alternative Segment 3 The Class I site-file search identified 17 previously recorded cultural resources along Garden Valley alternative segment 3, including one within the Level I region of influence and 16 within the Level II region of influence. These resources include two prehistoric sites (a rock feature and lithic scatter), 13 isolated artifacts, and two historic trash scatters. The Class II sample survey examined four sample units along this segment, a total of 3.2 kilometers (2 miles) or 9 percent of the segment. Only two isolates were recorded. No sites are evaluated as National Register-eligible.

Similar to the other Garden Valley alternative segments, the American Indian Resource Document (DIRS 174205-Kane et al. 2005, p. 22) notes that this area had extensive American Indian trail systems used for trade, commerce, pilgrimage, and access to mountain ranges. Construction of Garden Valley alternative segment 3 could result in direct and indirect impacts to these trail systems. The BLM Ely office has suggested that a potential sheep ranching cultural landscape might exist in the northern part of Garden Valley due to the proximity of the Uhalde and Paris Ranches and grazing areas, which included not only northern Garden Valley and the nearby Quinn Canyon Range, but the northern part of Coal Valley and the Seaman Range to the east. Rail line construction could result in indirect visual impacts to these landscapes.

Sample inventory indicates that approximately 12 resources could be present within the Level I region of influence.

Garden Valley Alternative Segment 8 The Class I site-file search identified five previously recorded cultural resources along Garden Valley alternative segment 8, all within the Level II region of influence. These resources include three prehistoric lithic scatters and two isolated artifacts. The Class II sample survey inspected three units along this alternative segment, a total of 2.4 kilometers (1.5 miles) or 7 percent of the segment; eight isolated artifacts were recorded. No cultural resources along Garden Valley alternative segment 8 are evaluated as National Register-eligible.

The American Indian Resource Document (DIRS 174205-Kane et al. 2005, p. 22) notes that Garden Valley had extensive American Indian trail systems used for trade, commerce, pilgrimage, and for access to mountain ranges. Construction of Garden Valley alternative segment 8 could result in direct and indirect visual impacts to these trail systems, and could result in potential visual intrusions to the Freiberg Mining District cultural landscape in the northern part of the Worthington Mountains.

4.2.13.2.1.4 Caliente Common Segment 2 (Quinn Canyon Range Area). The Class I site-file search identified eight cultural resources along Caliente common segment 2, including three within the Level I region of influence and six within the Level II region of influence. These resources include seven prehistoric sites (two campsites, a rockshelter, and four lithic scatters) and one isolated artifact. The Class II sample survey inspected seven sample units, a total of 5.6 kilometers (3.5 miles) or 11 percent of the segment; three sites and 16 isolated artifacts were recorded. Three cultural resources along Caliente common segment 2 are evaluated as eligible for listing on the *National Register of Historic Places*, including two lithic scatters and one locale with rockshelters and an associated scatter of artifacts.

The American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) notes the rockshelter site as a culturally significant place, and refers to it as the "Black Top Archaeological Locality" (see Figures 3-119 and 3-120), and the Class II sample survey resulted in the identification of three sites and 16 isolated artifacts.

Indirect impacts along this common segment could include visual impacts to the significant Black Top archaeological locality, which would be within the rail alignment construction right-of-way. This site includes a stratified rockshelter, artifact scatter, and rock alignments, and is noted in the American Indian Resource Document (DIRS 174205-Kane et al. 2005, p. 22) as a culturally significant place. The American Indian Writers Subgroup noted the proximity of Caliente common segment 2 to the Quinn Canyon Range and, specifically, to Quinn Canyon itself, where there were historical events important to American Indians. At the west end of Caliente common segment 2, construction and operation of the proposed railroad could constitute a visual intrusion for the unrecorded historic Cedar Pipeline Ranch, which is part of the larger Reveille Valley historic ranching cultural landscape. It is also in this area that the rail alignment would intersect the 1854 John C. Fremont exploration trail. However, no physical manifestations of this trail or associated features have been identified on the ground surface.

Direct and indirect impacts to American Indian trail systems and a potential historic sheep ranching cultural landscape would be possible. The BLM Ely office has suggested that because of the proximity of ranches and grazing areas in Garden Valley, there could be a potential sheep ranching cultural landscape in the northern part of the valley.

Sample inventory indicates that approximately 27 resources could be present within the Level I region of influence.

4.2.13.2.1.5 South Reveille Alternative Segments. Because the Level II region of influence for the South Reveille alternative segments (Figure 3-120) overlap, they are discussed jointly for the Class I site-file search and the Class II survey. The Class I site-file search revealed the presence of three cultural resources along these segments. These resources include two recorded prehistoric lithic scatter sites and one historic mine prospect. Also in this vicinity are the Reveille Valley rock-art panels. This location was identified in the American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) as a culturally important site for American Indian people.

DOE examined two sample units for each of these alternative segments during the Class II field survey, a total of 1.6 kilometers (1 mile) or 8.5 percent of the segments. Only a single isolate was encountered along South Reveille 2. The Class II survey also recorded the rock-art site noted above.

Both South Reveille alternative segments 2 and 3 would pass within 0.8 kilometer (0.5 mile) of a National Register of Historic Places-eligible rock-art site. Based on limited observations, the American Indian Resource Document (DIRS 174205-Kane et al. 2005, p. 20) also associated a high level of American Indian cultural significance with this property. Construction and operation of the proposed railroad could represent a long-term indirect impact on this important place.

There are two potential quarry locations (NN-9A and NN-9B) along South Reveille alternative segments 2 and 3. The northernmost location (NN-9A) would be within 366 meters (1,200 feet) of a significant rock-art site. Development of the quarry could result in indirect aesthetic, visual, and noise impacts to that site. Potential quarry NN-9B would occupy a long, narrow sandy ridge with frequent rocky outcrops. Preliminary archaeological reconnaissance of this location indicates that development of this quarry would not result in direct impacts to known sites.

Sample archaeological inventory did not indicate the presence of any archaeological sites within the Level I region of influence for these segments.

4.2.13.2.1.6 Caliente Common Segment 3 (Stone Cabin Valley Area). The Class I site-file search identified 35 cultural resources along Caliente common segment 3 (see Figure 3-120), including seven within the Level I region of influence. These resources include 29 prehistoric sites and six historic sites. The Class II survey examined 22 sample units, a total of 18 kilometers (11 miles) or 16 percent of the segment. Three prehistoric sites are evaluated as eligible for listing on the National Register of Historic Places, including two lithic scatters within the Level I region of influence and a rock-art site within the Level II region of influence. Several potentially important cultural resources are found along Caliente common segment 3, although most are just outside the Level II region of influence.

Caliente common segment 3 would cross nearly all of Reveille Valley, Stone Cabin Valley, and the southern part of Ralston Valley, and it would pass close to many archaeological and historical places, and several potential cultural landscapes that could be eligible for listing on the *National Register of Historic Places* (see Section 3.2.13.3.4 for a list of individual sites and cultural landscapes). There could be direct and indirect impacts at one National Register-eligible archaeological site recorded during the Class II inventory. Based on the prevalence of known but largely unrecorded cultural resources in these valleys, it can be anticipated that a Class III inventory of the construction right-of-way would encounter additional cultural resources that could be subject to direct impacts from construction activities.

Based on available information, the greatest potential for impacts would be of the indirect visual-intrusion type, with the rail line intersecting possible ethnographic and historic ranching and mining cultural landscapes, and passing in full view of other possible historic properties.

Sample inventory indicates that approximately 45 resources could be present within the Level I region of influence.

4.2.13.2.1.7 Goldfield Alternative Segments.

Goldfield Alternative Segment 1 The Class I site-file search identified four cultural resources along Goldfield alternative segment 1, all within the Level II region of influence. These resources include two prehistoric lithic scatters and two historic sites (a trash scatter and a campsite). The Class II survey examined six sample units along this segment, a total of 4.8 kilometers (3 miles) or 10 percent of the segment; 52 isolated artifacts were recorded. No sites within the Goldfield alternative segment 1 are considered as eligible for listing on the *National Register of Historic Places*.

Construction of Goldfield alternative segment 1 could result in direct impacts to several important cultural resources close to the construction right-of-way, including a rockshelter and rock art in the vicinity of Mud Lake and early Western Shoshone camps east of Goldfield. None of these sites would be within the construction right-of-way, but they could be subject to indirect impacts during construction, and in the longer term, by a potential visual intrusion to the cultural landscape.

Construction of Goldfield alternative segment 1 could result in additional direct and indirect impacts to the five prehistoric sites within the region of influence, including three campsites, a lithic scatter, and an historic habitation, none of which is eligible for listing on the *National Register of Historic Places*. The American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) identifies the campsites, which occur at springs east of Goldfield, as possible Western Shoshone camps, with one of them (Willow Springs), having been identified as such in the literature. The American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) also notes the Lowe rockshelter site as having a high level of cultural significance. There are also rock-art panels at this location. The Lowe site would be east of Goldfield alternative segment 1.

Sample archaeological inventory did not indicate the presence of any archaeological sites within the Level I region of influence for this segment.

Goldfield Alternative Segment 3 The Class I site-file search identified three previously recorded cultural resources along Goldfield alternative segment 3, including one within the Level I region of influence and two within the Level II region of influence. These resources include two rockshelters and a prehistoric campsite. The Class II survey covered 2.4 kilometers (1.5 miles) or 5 percent of the segment, and 13 isolated artifacts were recorded. The campsite is the same possible group of Western Shoshone winter camps discussed in the preceding section. The American Indian Resource Document discussion from Goldfield alternative segment 1 also applies to this segment.

A potential quarry site NS-3A would be along the northern portion of this alternative segment. Limited archaeological reconnaissance of this location indicates that development of this quarry would not result in direct impacts to known sites; DOE has not evaluated potential indirect effects.

Sample inventory indicates that approximately 21 resources could be present within the Level I region of influence.

Goldfield Alternative Segment 4 The Class I site-file search revealed 154 previously recorded cultural resources along Goldfield alternative segment 4 (see Figure 3-121), including 35 within the Level I region of influence and 119 within the Level II region of influence. The Class II field effort examined eight sample units along this segment, totaling 6.4 kilometers (4 miles) or 12 percent of the segment, resulting in the identification of 69 isolates.

Sites that are evaluated as being *National Register of Historic Places*-eligible include the downtown section of Goldfield itself, which is National Register listed. Goldfield 4 would pass through the National Register-eligible historic Goldfield town dump area and two mining sites. Rail line construction could result in direct or indirect impacts to these resources.

Other eligible sites outside the Level I region of influence include two town-related features, three mining sites, and three lithic scatters. In addition, several unrecorded prehistoric and historic sites are known to exist in the region of influence (see Section 3.2.13.1), based on literature reviews and field reconnaissance, along with an unmarked historic cemetery.

The American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) commented on the known presence of numerous American Indian resources in the vicinity of Goldfield alternative segment 4. American Indian Writers Subgroup field reconnaissance noted the presence of several rockshelters, a boulder with rock art, and several unrecorded lithic scatters. Additionally, a grave marker in the paupers section of the historic Goldfield Cemetery indicates that an American Indian woman was buried there in 1908.

A potential quarry ES-7 would be near Goldfield alternative segment 4, west of Goldfield. No cultural materials or other evidence of prehistoric or historic activities were noted during preliminary archaeological reconnaissance of the quarry area. Access to this quarry from Goldfield would pass through recent and historic mining areas, but neither the quarry location nor the access road would directly overlay the historic mining areas.

Sample inventory indicates that approximately 289 resources may be present within the Level I region of influence.

4.2.13.2.1.8 Caliente Common Segment 4 (Stonewall Flat Area). In Stonewall Flat, Caliente common segment 4 would generally follow an abandoned historic rail line for much of its length to a place in Lida Valley. The Class I site-file search identified one previously recorded but unevaluated rockshelter site along this segment. The Class II survey examined four sample units, a total of 3.2 kilometers (2 miles) or 29 percent of the segment. Eight isolates were recorded.

The American Indian Resource Document does not note any specific areas of importance to American Indians. In the Stonewall Flat area, the rail line construction right-of-way would create a direct impact for the unrecorded and unevaluated trail stop of Ralston, where there could be buried historical archaeological features and remains.

Sample inventory indicates that approximately 4 resources could be present within Level I region of influence.

4.2.13.2.1.9 Bonnie Claire Alternative Segments.

Bonnie Claire Alternative Segment 2 The Class I site-file search identified one cultural resource in the Level I region of influence. The site includes both prehistoric and historic components (a lithic scatter and mining prospects and debris). The prehistoric component was evaluated as being eligible for listing on the *National Register of Historic Places*.

The Class II sample survey examined five sample units, a total of 4 kilometers (2.5 miles) or 19 percent of the segment. Two sites and five isolates were recorded. The sites include a prehistoric campsite with a lithic and ground stone scatter, evaluated as being eligible for listing on the *National Register of Historic Places*, and a lithic scatter for which eligibility is under review.

Potential direct and indirect impacts along this alternative segment include the National Register-eligible prehistoric lithic and ground stone scatter identified during the Class II survey. This area also reveals the potential for the existence of prehistoric lithic scatters, obsidian nodule source areas, and rockshelters that, if present, would be directly affected by the construction of this alternative segment. The American Indian Resource Document (DIRS 174205-Kane et al. 2005, all) does not identify any known areas of importance to American Indians along this alternative segment.

The sample inventory indicates that approximately 10 resources could be present within the Level I region of influence.

Bonnie Claire Alternative Segment 3 The Class I site-file search identified four cultural resources within the Level I region of influence. These resources include four previously recorded but unevaluated prehistoric sites. One of these is a rockshelter, and the other three are extractive sites located in areas of obsidian cobble occurrences.

The Class II survey inspected four sample units along this segment, a total of 3.2 kilometers (2 miles) or 17 percent of the segment. One site and 24 isolates were recorded. The site is an historic rail line construction camp along the abandoned combined Bullfrog and Goldfield/Las Vegas and Tonopah rail bed, recommended as eligible for listing on the *National Register of Historic Places*. The American Indian Resource Document (DIRS 174205-Kane et al. 2005, all) does not identify specific resources for this alternative segment.

Construction along this alternative segment could result in direct and indirect impacts to the historic railroad camp along the abandoned Bullfrog and Goldfield/Las Vegas and Tonopah Railroad.

Sample inventory indicates that approximately 12 resources could be present within the Level I region of influence.

4.2.13.2.1.10 Common Segment 5 (Sarcobatus Flat Area). The Class I site-file search identified 33 cultural resources along common segment 5, including seven within the Level I region of influence and 26 within the Level II region of influence. These resources include 20 prehistoric sites (14 lithic scatters and six quarry extractive sites), four historic sites (a Tolicha mining district campsite, two debris scatters, and a railroad segment), seven isolates, and two unknown sites. Of these sites, one lithic scatter has been recommended as eligible for listing on the *National Register of Historic Places*, 11 are not eligible, and 14 remain unevaluated.

DOE surveyed 10 sample units along this segment for the Class II effort, a total of 8 kilometers (5 miles) or 20 percent of the segment. Four prehistoric sites (three lithic scatters and one campsite) and 33 isolates were recorded. Of these sites, the campsite was recommended as eligible for listing on the *National Register of Historic Places*, and the tree lithic scatters are not eligible. Common segment 5 would pass about 2.4 kilometers (1.5 miles) east of the Timbisha Shoshone Trust Lands at Scottys Junction. However, no specific cultural resource properties are identified on those lands that would be indirectly affected by construction of the proposed railroad. There is a high probability for direct and indirect impacts along common segment 5. Previous cultural resources inventories in the Sarcobatus Flat area indicate a relatively high potential for lithic scatters and extractive quarries (obsidian nodules). The sample inventory indicates that approximately 15 resources could be present within the Level I region of influence.

4.2.13.2.1.11 Oasis Valley Alternative Segments. The Class I site-file search identified three cultural resources along Oasis Valley alternative segments 1 and 3, within the Level II region of influence. These resources include one prehistoric campsite (recommended as eligible for nomination to the *National Register of Historic Places*) and two sites with both prehistoric and historic components (unevaluated ethnographic village sites).

Oasis Valley Alternative Segment 1 The Class II survey looked at three sample units along Oasis Valley 1, a total of 2.4 kilometers (1.5 miles) or 25 percent of the segment. Two prehistoric sites (lithic scatters) and one historic mine site were recorded, all recommended not eligible for nomination to the *National Register of Historic Places*.

This alternative segment would cross the culturally sensitive Oasis Valley, where potential ethnographic and historic ranching cultural landscapes are present. There could be direct and indirect impacts to sites in the Oasis Valley, particularly the unrecorded historic Beatty Cattle Company Ranch and an unevaluated Western Shoshone winter camp.

The American Indian Resource Document notes the presence of the early Western Shoshone camp and also states that, because of its abundant water supply and large variety of culturally important plants and animals, American Indian people extensively used the entire valley (DIRS 174205-Kane et al. 2005, Section 2.3). Recent ethnographic studies on the nearby Nevada Test and Training Range revealed cultural links to Oasis Valley. The Oasis Valley area is both a potential ethnographic and historic ranching cultural landscape. In later historic times, these landscapes overlapped, as American Indian people collocated and supplied labor for the ranches.

Rail line construction could directly and indirectly affect sites in the Oasis Valley, particularly the historic Beatty Cattle Company Ranch and a known Western Shoshone winter camp.

The sample inventory indicates that approximately 20 resources could be present within the Level I region of influence.

Oasis Valley Alternative Segment 3 The Class II sample survey inspected four sample units, a total of 3.2 kilometers (2 miles) or 22 percent of the segment; five sites and 28 isolated artifacts were recorded. These resources include five prehistoric sites (four lithic scatters and one campsite with a lithic scatter and cleared rock rings). The campsite has been determined eligible for listing on the *National Register of Historic Places.*

Oasis Valley 3 also would cross the culturally sensitive Oasis Valley. It would pass just east of another historic ranch, the Colson or Indian Camp Ranch, which also has an early Western Shoshone winter camp adjacent to the ranch buildings. While both the ranch and Western Shoshone camp are unevaluated, rock lines (geoglyphs) were observed at the Indian camp area during field reconnaissance. These resources would be additional components of the potential Oasis Valley ethnographic and historic ranching cultural landscapes. Construction of the alternative segment could result in a visual intrusion to these cultural landscapes.

The sample inventory indicates that approximately 23 resources could be present within the Level I region of influence.

4.2.13.2.1.12 Common Segment 6 (Yucca Mountain Approach). The Yucca Mountain area has been heavily analyzed in conjunction with repository ***site characterization*** studies. Intensive cultural resource studies related to the development of the repository site have been completed. Consequently, a large number of archaeological sites have been found along common segment 6. This is due more to the intensive nature of past studies than actual site density characteristics.

A Class I site-file search identified 204 cultural resources along common segment 6. These resources include 152 prehistoric sites, 3 historic sites, one site with both prehistoric and historic components, and 49 isolates. Prehistoric sites include eight rockshelters (four eligible), two eligible rock-art sites, 13 campsites (five eligible), six quarry sites (two eligible), four rock features and two rock rings, and 117 lithic scatters (one eligible). Historic sites include two debris scatters and one rail segment.

The Class II survey for common segment 6 did not extend inside the Yucca Mountain Site boundary. DOE inspected 13 sample units, a total of 11 kilometers (7 miles) or 22 percent of the segment. Seven sites (two prehistoric lithic scatters, four eligible sites with both prehistoric and historic components, and one historic debris scatter) and 52 isolates were recorded.

To provide additional information on cultural resources along common segment 6 within the Yucca Mountain Site boundary, Desert Research Institute conducted a Class III supplementary field survey along the section of proposed rail alignment inside the Yucca Mountain Site boundary. This survey investigated a 150-meter (500-foot)-wide corridor centered on the rail alignment for an approximate length of 5.9 kilometers (3.7 miles). This land comprised acreage that was previously surveyed during repository site characterization activities. Desert Research Institute identified eight cultural resources (two prehistoric sites, five isolates, and one historic site) during the Class III survey. All were evaluated as ineligible for National Register listing.

Given the large number of resources in the area, construction of common segment 6 could result in direct and indirect impacts to prehistoric and historic sites. Three National Register-eligible prehistoric quarry sites are in this area within the Level I region of influence. The Beatty Wash Petroglyphs Site, listed on the National Register, is in the vicinity of a proposed bridge over Beatty Wash. Direct and indirect impacts from construction activities would include vibration of the rock matrix exhibiting the rock-art panels, and a potential for inadvertent or deliberate adverse impacts due to increased access and worker presence. The site holds important cultural value for American Indians. Over the long term, American Indians would likely view the bridge and operating trains as a visual and noise impact to the rock-art cultural landscape site.

After common segment 6 crossed onto the Yucca Mountain Site, it would cross an area that has undergone earlier intensive archaeological inventory and has been the subject of previous American Indian studies during repository characterization. As discussed in Section 4.2.13.1, DOE would consider identification, evaluation, and mitigation of potential impacts to these resources under a separate programmatic agreement with those along the proposed rail alignment.

Based primarily on previous ethnographic studies, the American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) identifies several areas of cultural significance for American Indians along this common segment. Several of these fall inside the Yucca Mountain Site boundary, including the Busted Butte rock-art site, Fortymile Wash, and Alice Hill. The American Indian Writers Subgroup also notes the cultural importance of the Beatty area rock-art site and Crater Flat, specifically the Black Cone geological feature in Crater Flat, which would be within 0.8 kilometer (0.5 mile) of common segment 6.

The sample inventory of the segment outside the Yucca Mountain Site boundary indicates that approximately 32 sites could be present within Level I region of influence.

4.2.13.2.2 Railroad Operations Impacts

After the construction phase, there would be no additional direct or indirect impacts at cultural resource sites, other than the potential visual intrusion of operating trains on the character of potential cultural landscapes. American Indians would continue to view operation of the rail line as an intrusion on their holy lands.

4.2.13.3 Impacts under the Shared-Use Option

Impacts under the Shared-Use Option would be the same as those under the Proposed Action without shared use. Although under the Shared-Use Option there would be a slight increase in train traffic from the addition of commercial users, construction and operation of the proposed railroad would not differ and the slight increase in train traffic under the Shared-Use Option would not result in additional impacts. Construction of any additional commercial-use sidings would have the potential to impact cultural resources.

4.2.13.4 Summary

DOE would be obligated to complete intensive cultural resource inventories of the Caliente rail alignment alternative segments and common segments. Because of the length of the rail alignment and the complexity associated with engineering a feasible alignment, the Department is using a phased cultural resource identification and evaluation approach, described in 36 CFR 800.4(b)2, to identify specific cultural resources. Under this approach, the Department would complete an inventory of the construction right-of-way, evaluate all recorded resources in accordance with criteria established for listing on the *National Register of Historic Places*, assess adverse impacts, and apply mitigation measures for identified impacts before it started any ground-disturbing construction activities.

Table 4-144 summarizes the potential for impacts to cultural resources within the region of influence for each Caliente rail alignment alternative segment and common segment. At present, DOE cannot fully characterize potential effects on cultural resources and the magnitude of those impacts. The potential for impacts is based primarily on the relationship between the frequency of cultural resource sites associated with each alternative segment and common segment (that is, the greater the likely frequency of sites along a particular alternative segment or common segment, the higher the potential of affecting one or more of these sites). Sample inventory indicates that approximately 545 archaeological sites could be present within the Caliente rail alignment Level I region of influence. Based on this sample, DOE expects that most of these sites will be characterized as prehistoric sites (65 percent), primarily lithic scatters, followed by historic sites (20 percent) and sites with both prehistoric and historic components (15 percent). Data currently available indicate that many of these sites (78 percent or more) will not meet eligibility criteria for listing in the *National Register of Historic Places*.

Based on preliminary information and sample surveys conducted to date, the magnitude of these impacts would likely range from small to moderate because there would be an extensive effort to avoid or mitigate impacts in accordance with the regulatory framework and with the terms of the cultural resources programmatic agreement (see Appendix M). To the extent feasible, cultural resources identified within the construction areas will be avoided. Where appropriate, temporary barriers will be used to isolate resources during construction. Monitoring and data recovery through excavation will also be used where necessary to mitigate impacts to archaeological sites. If the additional future inventory work described above indicated the presence of National Register-eligible sites, the magnitude of impacts could be greater.

Table 4-144. Summary of potential impacts to cultural resources – Caliente rail alignment (page 1 of 3).

Location	Construction impacts[a]	Operations impacts[b]
Rail line segment		
Caliente alternative segment (Lincoln County)	Potential direct and indirect impacts at two known National Register-eligible sites, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Eccles alternative segment (Lincoln County)	Potential direct and indirect impacts at two known prehistoric rockshelters, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Caliente common segment 1 (Lincoln County and Nye County)	Construction activities could result in impacts to the early Mormon colonization cultural landscape, the Pioche-Hiko silver mining community route, 1849 emigrant campsites, National Register-eligible prehistoric sites in the vicinity of Black Rock Springs, and to other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Garden Valley alternative segments 1, 2, 3, and 8 (Lincoln County and Nye County)	Construction of Garden Valley alternative segments could result in direct and indirect impacts to American Indian trail systems and to other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Caliente common segment 2 (Lincoln County and Nye County)	Potential indirect impacts include visual impacts to the Black Top archaeological locality; potential direct and indirect impacts to American Indian trail systems and a potential historic ranching cultural landscape, and to other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
South Reveille alternative segments 2 and 3 (Nye County)	Rail line construction could represent a long-term indirect impact on a National Register-eligible rock-art site, and potential direct and indirect impacts at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Caliente common segment 3 (Nye County)	Potential direct and indirect impacts at one known National Register-eligible archaeological site, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Goldfield alternative segments 1 and 4 (Nye County and Esmeralda County) Goldfield alternative segment 3 (Nye County)	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.

Table 4-144. Summary of potential impacts to cultural resources – Caliente rail alignment (page 2 of 3).

Location	Construction impacts[a]	Operations impacts[b]
Rail line segment (continued)		
Caliente common segment 4 (Nye County and Esmeralda County)	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Bonnie Claire alternative segments 2 and 3 (Nye County)	Potential direct and indirect impacts at two National Register-eligible archaeological sites, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Common segment 5 (Nye County)	Potential direct and indirect impacts at two National Register-eligible archaeological sites, 20 additional resources that have been recorded within the region of influence, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Oasis Valley alternative segments 1 and 3 (Nye County)	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Common segment 6 (Nye County)	Potential direct and indirect impacts at archaeological sites recorded in region of influence, including three National Register-eligible resources, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Proposed facilities		
Access roads (including alignment access roads) (Lincoln, Nye, and Esmeralda Counties)	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Facilities at the Interface with the Union Pacific Railroad Mainline (including the Interchange Yard and the Staging Yard) (Lincoln County)	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.

Table 4-144. Summary of potential impacts to cultural resources – Caliente rail alignment (page 3 of 3).

Location	Construction impacts[a]	Operations impacts[b]
Proposed facilities (continued)		
Maintenance-of-Way Facilities (includes Maintenance-of-Way Headquarters Facility, Maintenance-of-Way Trackside Facility, Satellite Maintenance-of-Way Facility); Rail Equipment Maintenance Yard; Cask Maintenance Facility; and Nevada Railroad Control Center and National Transportation Operations Center (Lincoln, Nye, and Esmeralda Counties)	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Construction camps (Lincoln, Nye, and Esmeralda Counties)	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Wells (Lincoln, Nye, and Esmeralda Counties)	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Quarries		
Potential quarry CA-8B (Lincoln County)	No impacts.	No additional direct or indirect impacts.
Potential quarries NA-9A and NA-9B (Nye County)	No direct impacts; indirect impacts to a National Register-eligible rock-art site would be likely.	Utilization of quarries in this area could represent a long-term indirect impact on a National Register-eligible rock-art site.
Potential quarry ES-7 (Nye County)	No impacts.	No additional direct or indirect impacts.
Potential quarry NS-3A (Esmeralda County)	No impacts.	No additional direct or indirect impacts.

a. Impact assessment based on sample inventory only; actual impacts would not be identified until completion of field studies.
b. After the construction phase, no additional direct or indirect impacts would be anticipated at archaeological, historical, and cultural sites, other than the potential visual intrusion of operating trains on the character of potential cultural landscapes.

4.2.14 PALEONTOLOGICAL RESOURCES

This section describes potential impacts to paleontological resources (fossils) from constructing and operating the proposed railroad along the Caliente rail alignment. Section 4.2.14.1 describes the methodology DOE used to assess impacts to such resources; Section 4.2.14.2 describes potential impacts during the construction phase; Section 4.2.14.3 describes potential impacts during the operations phase; Section 4.2.14.4 describes impacts under the Shared-Use Option; and Section 4.2.14.5 summarizes potential impacts.

Section 3.2.14.1 describes the region of influence for paleontological resources along the Caliente rail alignment.

4.2.14.1 Impact Assessment Methodology

Any project activity involving land disturbance could have an adverse impact on the physical environment that could contain paleontological resources. Paleontological resources could be disturbed or destroyed by ground excavation, cuts and fills, surface-disturbing activities such as road building and blasting, or vandalism or theft of the resources.

DOE used the BLM system (DIRS 176084-BLM 1998, all; DIRS 176085-BLM 1998, all) to identify and classify paleontological resource areas along the Caliente rail alignment according to their potential for containing vertebrate (animals with backbones) fossils or noteworthy occurrences of invertebrate or plant fossils. The BLM uses these paleontological resource classifications (***Condition 1***, ***Condition 2***, and ***Condition 3***; see the text box in Section 3.2.14) to identify areas that might warrant special management or special designation for paleontological resources.

The BLM steps to evaluate the potential for impacts to fossil resources are outlined in *General Procedural Guidance for Paleontological Resource Management* (DIRS 176084-BLM 1998, Chapter III), and include identification by a qualified paleontologist and protection of any paleontological area uncovered during field surveys. Educating the public about the value of paleontological resources is also an important part of BLM resource management.

To assess potential impacts to paleontological resources along the Caliente rail alignment, DOE considered whether unique or scientifically important vertebrate, invertebrate, or plant fossils could be damaged, destroyed, or removed during construction and operation of the proposed railroad, quarries, water wells, and access roads.

4.2.14.2 Construction Impacts

There is a Condition 1 paleontological resource site in an area known as Ruin Wash approximately 4.8 to 8 kilometers (3 to 5 miles) south of where Caliente common segment 1 would cross Bennett Pass (DIRS 174204-Palmer 1998, all; DIRS 173841-Shannon & Wilson 2005, pp. 108 and 109; DIRS 174509-Russ 2005, all). Because of its distance from the rail alignment, DOE would expect no impacts to the site as a result of rail line construction.

While other areas within the Caliente rail alignment region of influence could contain paleontological resources, none of the remaining areas of alternative segments or common segments are known to contain or have a strong potential to contain important paleontological resources. Therefore, DOE would expect no impacts to paleontological resources in any of those areas.

None of the proposed railroad construction and operations support facilities would be at or near known or likely fossil beds. Therefore, DOE would expect no impacts to paleontological resources from these facilities.

In addition to known locations of paleontological resources near Caliente common segment 1, DOE could encounter unknown paleontological resources during the construction phase. The BLM would continue to manage all identified paleontological resources in accordance with its management plans, and if DOE discovered new paleontological resources during the construction phase, the BLM would take appropriate action.

4.2.14.3 Operations Impacts

The most likely source of potential impacts to paleontological resources would be from land disturbance during the construction phase, as discussed in Section 4.2.14.2. DOE expects there would be no impacts to paleontological resources resulting from railroad operations.

4.2.14.4 Construction and Operations Impacts under the Shared-Use Option

As for the Proposed Action without shared use (see Sections 4.2.14.2 and 4.2.14.3), DOE expects there would be no impacts to paleontological resources along the Caliente rail alignment under the Shared-Use Option.

4.2.14.5 Summary

DOE expects there would be no impacts to known paleontological resources along Caliente rail alignment common segment 1. There are no known paleontological resources along any of the other Caliente rail alignment alternative segments and common segments or at the proposed locations of railroad construction and operations support facilities. While there could be a potential to uncover previously unknown fossils during the construction phase, DOE would consult with the BLM to develop appropriate measures to minimize damage to any paleontological resources discovered during the construction phase.

Chapter 7, Best Management Practices and Mitigation, describes the best management practices DOE would implement as part of the Proposed Action and the mitigation measures the Department would consider to reduce or eliminate the potential for impacts to paleontological resources.

4.2.15 ENVIRONMENTAL JUSTICE

This section describes the DOE analysis of ***environmental justice*** (the potential for impacts to be ***disproportionately high and adverse*** to ***minority*** or ***low-income populations***) under the Proposed Action along the Caliente rail alignment. Section 4.2.15.1 describes the DOE methodology for analyzing environmental justice; Section 4.2.15.2 describes the assessment of impacts to environmental resources; Section 4.2.15.3 describes the potential for disproportionately high and adverse impacts; and Section 4.2.15.4 summarizes any environmental justice impacts.

Section 3.2.15.1 describes the region of influence for environmental justice.

4.2.15.1 Impact Assessment Methodology

For this analysis, DOE uses the terms minority and low-income in the context of environmental justice (DIRS 155970-DOE 2002, Section 3.1.13.1; DIRS 174625-Bureau of Census 2005, all).

DOE performed the analysis of potential environmental justice impacts in accordance with Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, and Council on Environmental Quality guidance (DIRS 103162-CEQ 1997, all). Using information from Sections 4.2.1 through 4.2.14, this section assesses whether any high and adverse impacts could fall disproportionately on minority or low-income populations.

As a starting point, DOE determined whether there would be minority or low-income populations in the Caliente rail alignment region of influence for environmental justice. Next, DOE determined whether there would be any potential for high and adverse impacts to environmental resources as evaluated in Sections 4.2.1 through 4.2.14. Finally, DOE determined whether any potential high and adverse impacts would fall disproportionately on minority or low-income populations.

According to the Council on Environmental Quality, a minority population exists where either (a) the minority population of the affected area exceeds 50 percent; this calculation includes federally recognized American Indian lands, because American Indians are included in the definition of minority populations; or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis.
In addition to the 50-percent threshold, DOE used both the United States and the State of Nevada minority populations as bases for comparison.

The Council on Environmental Quality defines low-income by using the annual statistical poverty thresholds from the U.S. Census Bureau. A low-income community exists when the low-income population percentage in the area of interest is meaningfully greater than the low-income population in the general population. For purposes of the analysis of low-income communities, DOE used both the United States and the State of Nevada low-income populations as the bases for comparison. DOE assumed a 20-percent threshold above state low-income percentages in accordance with U.S. Nuclear Regulatory Commission guidance.

DOE also considered whether minority or low-income populations would be affected by an alternative in different ways than the general population, such as through unique ***exposure pathways*** or rates of exposure, special sensitivities, or different uses of natural resources.

If there would be no high and adverse impacts to environmental resource areas, or if any identified high and adverse impacts would not fall disproportionately on minority or low-income populations, then there would be no environmental justice impacts.

4.2.15.2 Assessment of Impacts to Environmental Resources

Results of the impacts analyses described in Sections 4.2.1 through 4.2.14 indicate that there would be moderate to large impacts in the following environmental resource areas:

- Land use. Construction and operation of the proposed railroad along the Caliente rail alignment would result in general impacts to land use and ownership along the entire alignment. Specifically there would be changes in land uses on private land within the rail line construction and operations rights-of-way and impacts to unpatented mining claims.

- Aesthetic resources. There would be small to large impacts as a result of construction along all portions of the Caliente rail alignment. There would be small to large, but temporary, impacts as a result of construction along Garden Valley alternative segments 1, 2, 3, and 8. There would be moderate, but temporary, impacts from construction of the Staging Yard at Caliente-Indian Cove and moderate impacts from construction at potential quarry CA-8B. There would be small to moderate impacts from railroad operations along all segments of the Caliente rail alignment. There would be small to large impacts from railroad operations along Garden Valley alternative segments 1, 2, 3, and 8. There would be moderate impacts from Staging Yard operations at Caliente-Indian Cove.

- Air quality. Air pollutant concentrations would not exceed the National Ambient Air Quality Standards for construction or operation of the railroad or any associated facilities, with the exception of the 24-hour standards for PM_{10} that could be exceeded during quarry operations at South Reveille Valley during the construction phase.

- Surface water. The Staging Yard at Caliente-Indian Cove would be in a meadow that is a floodplain of Meadow Valley Wash on the east side of U.S. Highway 93, roughly midway between the City of Caliente and Indian Cove. Construction of the Staging Yard at Indian Cove would require the wetland meadow area to be drained and built up above the level of the floodplain. It might also require an active drainage system and a channel around the site to keep the area dry and in a stable condition. The Staging Yard at Indian Cove would require filling an area of wetlands and the associated plant and animal habitat (see Section 4.2.7 for a discussion of impacts to biological resources). Construction of the Staging Yard in this area would result in the loss of approximately 0.12 square kilometer (30 acres) of wetlands.

- Biological resources. There would be impacts to wetlands and riparian habitats from construction of the Caliente alternative segment and either of the potential Staging Yard locations (Indian Cove or Uplands), the Eccles alternative segment, and the Interchange Yard. There could be impacts to wetlands in the vicinity of Caliente common segment 1 and Oasis Valley alternative segment 1 from rail line construction. Potential adverse impacts related to noxious and ***invasive species*** would include increased risk of these species becoming established in disturbed areas and encroaching on adjacent undisturbed habitat. There would be the potential for impacts to threatened or endangered species during the construction phase. Habitat for several special status species would be disturbed and individuals of several of the species could be disturbed, injured, or killed from construction and operation of the proposed railroad. Direct impacts to wildlife and wild horses and burros from railroad operations would consist of potential collisions of wildlife with trains and temporary disruption of activities (such as foraging, nesting, and resting) due to the disturbance from noise caused by passing trains and from noise and the presence of humans at railroad facilities and potential contamination of forage, prey species, nesting, and spawning habitat, and sources of drinking water in the rare event of train derailment and associated spill of diesel fuel. Indirect impacts could include possible changes to predator/prey interactions due to the construction of towers and other structures that would provide new perch habitat for raptors and other predatory birds.

Although there are many historic and archaeological sites along the Caliente rail alignment (see Section 3.2.13), and construction and operation of the proposed railroad could directly and indirectly affect those resources (see Section 4.2.13), that analysis did not determine that potential impacts to cultural resources would be high and adverse.

4.2.15.3 Potential for Disproportionately High and Adverse Impacts

To determine whether potential environmental impacts identified in Sections 4.2.1 through 4.2.14 could be disproportionately high and adverse to minority or low-income populations, DOE considered the following factors:

- Whether there would be an impact on the natural or physical environment that would adversely affect a minority population, low-income population, or American Indian tribe (such effects could include ecological, cultural, human health, economic, or social impacts on minority communities, low-income communities, or American Indian tribes when those impacts are interrelated with impacts on the natural or physical environment)
- Whether environmental effects could have an adverse impact on minority populations, low-income populations, or American Indian tribes that would be meaningfully greater than or be likely to be meaningfully greater than the impact on the general population or other appropriate comparison group
- Whether minority or low-income populations would be affected by an alternative in different ways than the general population, such as through unique exposure pathways or rates of exposure, special sensitivities, or different uses of natural resources
- Whether the environmental effects could occur in a minority population, low-income population, or American Indian tribe affected by cumulative or multiple adverse exposures from environmental hazards

Based on these factors, DOE identified the following potential impacts to land use, aesthetic resources, air quality, surface-water resources, and biological resources.

- Land use. DOE would need to gain access to some private land, the amount of which would be very small (about 1 percent) compared to the total amount of land that would be required for the project. Additionally, there would be unpatented mining claims along some rail line segments where they would fall within the construction right-of-way, some of which could be extinguished. There is also the possibility that the rail line could be affected by or affect underground mining tunnels or shafts. During the final design phase, DOE would need to perform a survey for these underground features to avoid adverse impacts.

  These impacts would be in census blocks that do not meet the 50-percent threshold for impacts to minority populations, and, because of the low population density, the census units are generally too large in land area to efficiently illustrate distributions of minority populations. Therefore, impacts to land use would not fall disproportionately on minority populations. These impacts would also be in census block groups that do not exceed the 31 percent threshold (20 percent above the state average of 11 percent) established by the Nuclear Regulatory Commission and the Council on Environmental Quality and used for analysis of potential impacts to low-income populations in this Rail Alignment EIS. Thus, land-use impacts would not fall disproportionately on low-income populations located mostly in Caliente.
- Aesthetic resources. There would be small to large impacts from construction as a result of weak to strong contrast in the short term from visible construction equipment either operating or in storage, and from scars on soil and vegetated landscape from cuts, fills, and well pads; and weak to strong

contrast in the long term from scars on rock from cuts, and from access roads along the entire Caliente rail alignment. There would be small to large, but temporary, impacts from construction as a result of weak to strong contrast in the short term, along Garden Valley alternative segments 1, 2, and 8, which would not meet BLM management objectives for Class II visual resources. There would be moderate, but temporary, impacts from construction as a result of moderate contrast during construction of the Staging Yard Caliente-Indian Cove consistent with surrounding non-BLM lands treated as Class III, but inconsistent with BLM management objectives for Class II visual resources on the BLM lands at the north end of the yard. There would be moderate impacts from construction as a result of moderate contrast in the short term from installation and use of the conveyor from the quarry across U.S. Highway 93, consistent with surrounding non-BLM lands treated as Class III.

There would be small to moderate impacts from railroad operations as a result of no to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads along the entire Caliente rail alignment. There would be small to large impacts from railroad operations as a result of track on some parts of Garden Valley alternative segments 1, 2, 3, and 8 that would create a new linear feature that would not meet BLM Class II management objectives. There would be moderate impacts from railroad operations as a result of moderate contrast in the Class III non-BLM lands, and weak contrast from the track on BLM Class II lands at the north end.

These impacts would be in census blocks that do not meet the 50-percent threshold for impacts to minority populations, and because of the low population density, the census units are generally too large in land area to efficiently illustrate distributions of minority populations. Therefore, impacts to aesthetic resources would not fall disproportionately on minority populations. These impacts would also be in census block groups that do not exceed the 31 percent threshold (20 percent above the state average of 11 percent) established by the Nuclear Regulatory Commission and the Council on Environmental Quality and used for analysis of potential impacts to low-income populations in this Rail Alignment EIS. Thus, the potentially moderate and large impacts to aesthetic resources would not fall disproportionately on low-income populations located mostly in Caliente.

- Air quality. Emissions for all air pollutants projected to be released during the construction phase would be greater than during the operations phase. Projected ambient concentrations of all air pollutants would be below the National Ambient Air Quality Standards, except for quarry operations in South Reveille Valley. Therefore, the projected impacts throughout the region of influence, during both construction and operations, would be small, except in the vicinity of the South Reveille quarries. Under the Shared-Use Option, there would be an increase in emissions over those of the Proposed Action without shared use, but impacts to air quality would still be small.

  These impacts would be in census blocks that do not meet the 50-percent threshold for impacts to minority populations, and, because of the low population density, the census units are generally too large in land area to efficiently illustrate distributions of minority populations. Therefore, impacts to air quality would not fall disproportionately on minority populations. These impacts would also be in census block groups that do not exceed the 31 percent threshold (20 percent above the state average of 11 percent) established by the Nuclear Regulatory Commission and the Council on Environmental Quality and used for analysis of potential impacts to low-income populations in this Rail Alignment EIS. Thus, the potentially moderate and large impacts to air quality resources would not fall disproportionately on low-income populations located mostly in Caliente.

- Surface-water resources. There are two options for siting the Staging Yard along the Caliente alternative segment: one approximately 1.6 kilometers (1 mile) northeast of Caliente (the Indian Cove option); the other 6.4 kilometers (4 miles) northeast of Caliente (the Upland option). The Indian Cove option would be in a meadow that is a floodplain of Meadow Valley Wash on the east side of U.S. Highway 93, roughly midway between the City of Caliente and Indian Cove.

Construction of the Staging Yard at Indian Cove would require the wetland meadow area to be drained and built up above the level of the floodplain. It might also require an active drainage system and a channel around the site to keep the area dry and in a stable condition. Meadow Valley Wash drainage through the site is from north to south toward the City of Caliente. Drainage of the site would be accomplished by constructing a channel along the eastern edge of the facility. The channel around the site would be approximately 1,700 meters (5,500 feet) long. The Department would determine final channel dimensions during final design of the Staging Yard. It is very likely that a system of drains would have to be constructed under the Staging Yard tracks. Fill could be needed to elevate portions of the site out of the floodplain. These actions would require permits from the U.S. Army Corps of Engineers, and compliance with Section 404 of the Clean Water Act for stormwater runoff control measures.

The Staging Yard at Indian Cove would require filling an area of wetlands and the associated plant and animal habitat (see Section 4.2.7 for a discussion of impacts to biological resources). Construction of the Staging Yard in this area would result in the loss of approximately 0.12 square kilometer (30 acres) of wetlands. DOE prepared this estimate by intersecting the wetland areas identified during the field survey in support of this Rail Alignment EIS with the perimeter of the Staging Yard fenceline. This facility would also impact the ability of the valley to handle floodwaters. Although the Federal Emergency Management Agency has not mapped floodplains this far north, development in Meadow Valley would make it reasonable to follow Agency criteria for construction in floodplains. The flow path for floodwaters would be constricted through this area, potentially causing the elevation of the floodwaters to increase upstream of the Staging Yard. DOE would incorporate hydraulic modeling into the engineering design process to ensure that adverse impacts to floodplains from elevated floodwaters were kept to an acceptable level (as determined through modeling).

These impacts would be in census blocks that do not meet the 50-percent threshold for impacts to minority populations, and because of the low population density, the census units are generally too large in land area to efficiently illustrate distributions of minority populations. Therefore, impacts to aesthetic resources would not fall disproportionately on minority populations. These impacts would also be in census block groups that do not exceed the 31 percent threshold (20 percent above the state average of 11 percent) established by the Nuclear Regulatory Commission and the Council on Environmental Quality and used for analysis of potential impacts to low-income populations in the Rail Alignment EIS. Thus, impacts to surface-water resources would not fall disproportionately on low-income populations located mostly in Caliente.

Lincoln, Esmeralda, and Nye Counties and the county subdivisions within them have been identified as having a higher percentage of low-income residents than the State of Nevada overall. However, these census block groups do not meet the 20-percent threshold over the state threshold (11 percent) established by the Nuclear Regulatory Commission and the Council on Environmental Quality and used for analysis of potential impacts to low-income populations in this Rail Alignment EIS. There are no minority populations along the Caliente rail alignment that meet the 50 percent threshold. Thus, the potentially large impacts to surface-water resources would not fall disproportionately on low-income or minority populations located mostly in Caliente.

- Biological resources. There would be impacts to wetlands and riparian habitats from construction of the Caliente alternative segment and either of the potential Staging Yard locations (Indian Cove or Upland), the Eccles alternative segment, and the Interchange Yard. There could be impacts to wetlands in the vicinity of common segment 1 and Oasis Valley alternative segment 1 from rail line construction. However, during final design, DOE would make slight adjustments to minimize such impacts. Potential adverse impacts related to noxious and invasive species would include increased risk of these species becoming established in disturbed areas and encroaching on adjacent undisturbed habitat. DOE would implement best management practices (see Chapter 7) and BLM-prescribed and approved methods to prevent the establishment of noxious weeds or invasive plant species. There would be the potential for impacts to threatened or endangered species during rail line construction. Habitat for several special status species would be disturbed and individuals of several of the species could be disturbed, injured, or killed from construction and operation of the proposed railroad and associated facilities. Potential impacts to federally listed species would likely require consultation with the U.S. Fish and Wildlife Service in accordance with Section 7 of the Endangered Species Act. Direct impacts to wildlife and wild horses and burros during the operations phase would consist of potential collisions of wildlife with trains; temporary disruption of activities (such as foraging, nesting, and resting) due to the disturbance from noise caused by passing trains and from noise and presence of humans at railroad facilities; and potential contamination of forage, prey species, nesting, and spawning habitat, and sources of drinking water in the rare event of train derailment and associated spill of diesel fuel. Indirect impacts could include possible changes to predator/prey interactions due to the construction of towers and other structures that would provide new perch habitat for raptors and other predatory birds.

These impacts would be in census blocks that do not meet the 50-percent threshold for impacts to minority populations, and because of the low population density, the census units are generally too large in land area to efficiently illustrate distributions of minority populations. Therefore, impacts to biological resources would not fall disproportionately on minority populations. These impacts would also be in census block groups that do not exceed the 31 percent threshold (20 percent above the state average of 11 percent) established by the Nuclear Regulatory Commission and the Council on Environmental Quality and used for analysis of potential impacts to low-income populations in this Rail Alignment EIS. Thus, the potentially moderate and large impacts to biological resources would not fall disproportionately on low-income populations located mostly in Caliente.

Seventeen tribes and organizations have formed the Consolidated Group of Tribes and Organizations, which is a forum consisting of tribally approved representatives who are responsible for presenting their respective tribal concerns and perspectives to DOE. The Consolidated Group of Tribes and Organizations has provided DOE with valuable insights into American Indian cultural and religious values and beliefs.

Section 3.4 summarizes the interests and concerns expressed by various American Indian tribes and organizations within or near the Caliente and Mina rail alignment regions of influence. Sections 3.2.13 and 3.3.13, Cultural Resources, provide additional information on American Indian cultural resources. Perceptions about the types and magnitudes of potential impacts to American Indian interests along the Caliente and Mina rail alignments vary among the various stakeholders with interests in the proposed railroad because of different beliefs, goals, responsibilities, and values. American Indians are concerned that the proposed railroad could cause substantial and high adverse effects to a number of American Indian interests within and adjacent to the Caliente rail alignment region of influence. DOE acknowledges the concerns of the American Indians and has consulted with the tribes. The Department would continue to consult with the Consolidated Group of Tribes and Organizations throughout the life of the project. If DOE implemented Proposed Action, the Department would work closely with American Indians to ensure that a mitigation action plan was developed and to ensure compliance with Section 106 of the National Historic Preservation Act.

The environmental justice analysis for the Shared-Use Option is the same as that described for the Proposed Action without shared use.

4.2.15.4 Conclusion

Constructing and operating the proposed railroad along the Caliente rail alignment would not result in any high and adverse impacts. No special pathways were identified; therefore, DOE concluded that there would be no disproportionately high and adverse impacts to minority or low-income populations.

4.3 Mina Rail Alignment

4.3.1 PHYSICAL SETTING

This section describes potential impacts to physical setting from constructing and operating the proposed railroad along the Mina rail alignment. Section 4.3.1.1 describes the method DOE used to assess potential impacts to physical setting; Section 4.3.1.2 describes potential impacts of constructing the railroad; Section 4.3.1.3 describes potential impacts of operating the proposed railroad; Section 4.3.1.4 describes potential impacts under the Shared-Use Option; and Section 4.3.1.5 summarizes potential impacts to physical setting.

As described in Section 3.3.1, physical setting includes physiography, geology, and soils. Section 3.3.1.1 describes the ***region of influence*** for physical setting along the Mina rail alignment.

4.3.1.1 Impact Assessment Methodology

To assess potential impacts to physical setting along the Mina rail alignment, DOE considered whether railroad construction and operations would:

- Result in soil erosion or loss of topsoil
- Result in the direct conversion of ***prime farmland*** to nonagricultural uses
- Result in the loss of availability of a known mineral resource that would be of value to the region or residents of Nevada
- Generate unstable slope conditions that could result in an on-site or off-site landslide or collapse
- Expose construction workers, DOE personnel, and structures to amplified or unique adverse effects from ***seismic*** activity

If possible, DOE quantified impacts using data from Nevada soils surveys, geological maps, ***earthquake fault*** maps and records, and the total area of disturbance that would result from construction and operation of the proposed railroad.

The total area of disturbance would be the sum of disturbed areas within the nominal width of the rail line construction right-of-way and areas outside the nominal width of the construction right-of-way (railroad operations support facilities, quarry sites, some water-well sites, and access roads). The nominal width of the construction right-of-way would encompass the rail line, alignment access roads, some wells, ***construction camps***, and ***cuts*** and ***fills*** required to attain an appropriate ***grade***. While the nominal width of the construction right-of-way would be 300 meters (1,000 feet) across BLM lands, the width could vary in certain locations along the rail alignment. For example, it could be wider to accommodate additional earthwork, or narrower to avoid a sensitive environmental resource. Section 4.3.1.2.3 describes potential impacts from constructing the railroad operations support facilities; the number and size of those facilities would not vary among alternative segments.

Some potential impacts to physical setting along the Mina rail alignment are more specifically addressed under other ***environmental resource areas***. Section 4.3.2, Land Use and Ownership, describes potential impacts to ***mining districts*** and mineral and energy resources; Section 4.3.4, Air Quality and Climate, describes soil loss from ***fugitive dust*** emissions; Section 4.3.5, Surface-Water Resources, describes potential erosion due to surface-water flow; and Section 4.3.10, Occupational and Public Health and Safety, describes impacts to worker safety from geologic hazards.

4.3.1.2 Construction Impacts

Direct impacts to physical setting along the Mina rail alignment would occur primarily during the construction phase. Section 4.3.1.2.1 describes potential construction impacts common to the entire rail alignment. Section 4.3.1.2.2 describes impacts specific to alternative segments and common segments. Tables in Section 4.3.1.2.2 list the key information DOE used to analyze potential impacts to physical setting for the common and alternative segments.

4.3.1.2.1 Construction Impacts Common to the Entire Mina Rail Alignment

4.3.1.2.1.1 Physiography. To the extent practicable, the Mina rail alignment would avoid uneven topography and rugged terrain by following valleys and skirting mountain ranges, as described in Section 3.3.1.2.1 and illustrated in Figure 3-124. Where it is necessary to cross mountain ranges, the rail line would be located in gaps and passes. The rugged natural terrain surrounding the mountain ranges would, however, contribute to the potential for impacts to topography and soils. The ruggedness of an area is represented by the "rise and fall" calculation, which is the absolute elevation change measured at a fixed distance along the alignment. The rise and fall calculation provides a context for determining the amount of disturbance that would be required to establish appropriate grades.

Depending on the combination of alternative segments and common segments along the Mina rail alignment, the total area that would be disturbed during the construction phase would range from 40 to 48 square kilometers (9,900 to 12,000 acres) (DIRS 180874-Nevada Rail Partners 2007, p. B-3). Construction impacts to physical setting would be centered along the rail alignment and would decrease with distance from the alignment.

Cuts and fills would be required to level steep slopes and provide a suitable grade for the rail ***roadbed***. The estimated volume of cuts along the Mina rail alignment is 10.9 million to 18.8 million cubic meters (14.3 million to 24.6 million cubic yards), and the estimated volume of fill is 15.9 million to 25.7 million cubic meters (20.8 million to 33.6 million cubic yards) (DIRS 180872-Nevada Rail Partners 2007, Appendix D). Cut and fill activities would occur within the construction right-of-way. DOE would use the material excavated from the cuts to supply a portion of the required fill. The Montezuma alternative segments, especially Montezuma alternative segment 1, would require the most earthwork (see Section 4.3.1.2.2.7). There also would be major cut, fill, and other earthwork processes around the Calico Hills and Terrill Mountains, the Goldfield Hills, Beatty, and Yucca Mountain.

DOE would build up to 10 construction camps along the rail alignment. Each camp would include housing, support facilities, office space, utilities, contractor work areas, roadways, and parking, and would disturb approximately 0.10 square kilometer (25 acres) inside the nominal width of the construction right-of-way (DIRS 176172-Nevada Rail Partners 2006, p. 4-1).

There are five potential quarry sites along the Mina rail alignment, of which DOE would develop up to two. Each site would be expected to disturb an area from 0.97 to 2.7 square kilometers (240 to 660 acres) outside the nominal width of the construction right-of-way (DIRS 176172-Nevada Rail Partners 2006, pp. 3-1 and 3-2).

Construction of the ***Staging Yard*** at Hawthorne could disturb a total of 0.20 square kilometer (50 acres). Construction of the Maintenance-of-Way Facility would disturb 0.061 square kilometer (15 acres), and the ***Rail Equipment Maintenance Yard*** would disturb the largest area (0.41 square kilometer [100 acres]) (DIRS 180874-Nevada Rail Partners 2007, p. A-5).

Construction activities that would disturb topsoil include, but are not limited to, cut excavation; quarry-pit excavation and borrow-pit stockpiles; placement of compacted fill, ***ballast***, and ***subballast***; road development and grading; and building facility foundations. During the construction phase, the soil column would be disturbed and topsoil would be removed. The areas with disturbed soils would have an increased potential for erosion by wind and water. DOE would implement best management practices (see Chapter 7) to control erosion, minimize soil loss, and conserve topsoil for grading after construction was completed. After construction was completed, disturbed areas away from the rail line would be leveled to a grade that would blend with the terrain, covered with reserved topsoil, and to the extent practicable, revegetated.

4.3.1.2.1.2 Geology.

Faulting and Seismic Activity Seismic-related hazards in the project area include ground shaking, rock falls and landslides, soil liquefaction, and fault displacement. The northern portion of the Mina rail alignment would cross through an area with more earthquakes; however, seismic activity in this area is consistent with the rest of southern Nevada, as shown on Figure 3-127. Construction activities would not induce earthquakes or reactivate any faults. The Mina rail alignment would generally cross Quaternary fault traces at a perpendicular angle, which would minimize the contact between the rail alignment and the linear range-bounding faults. At a minimum, DOE would design and operate the proposed railroad to be consistent with American Railway Engineering and Maintenance-of-Way Association seismic guidelines (DIRS 162040-AREMA 2001, Chapter 9) and could decide to implement additional, more stringent standards.

During the construction and operations phases, DOE would monitor earthquake activity using U.S. Department of the Interior, Geological Survey, and Yucca Mountain seismic networks. The response level of the maintenance-of-way authority would depend on the earthquake magnitude and distance to the rail line (see Table 4-145). DOE would develop an inspection protocol that would outline the procedures that would be used to inspect the track, rail roadbed, bridges, and other structures along the rail line. If required after a seismic event, construction would halt, trains would run at reduced speeds, and qualified inspectors would verify the safety of the track.

The rail line and transportation casks would be constructed to be consistent with the American Railway Engineering and Maintenance-of-Way Association seismic guidelines. The inspection protocol and acceptance of the seismic guidelines would ensure that the risks associated with operating in a seismically active area would be minimized. Section 4.3.10, Occupational and Public Health and Safety, describes potential impacts to transportation safety and worker and public health and safety from seismic hazards.

Rock-Slope Hazards Several sections of the Mina rail alignment would pass through steep and rugged terrain where unstable rock slopes would be a hazard (DIRS 180878-Shannon & Wilson 2007, pp. 41 and 42, and Table 6). Rock-slope failures typically occur where rock discontinuities (such as joints, bedding, foliation, and faults) are adversely oriented in relation to natural or constructed slope faces. Slope stability could be further reduced by natural weathering processes, which contribute to the mechanical breakdown of the rock mass within the rock ***matrix*** and along the discontinuities (DIRS 180878-Shannon & Wilson 2007, p. 41).

Rail line construction activities such as blasting and other cut procedures would have the potential to induce rock falls and landslides. Blasting could be required to excavate bedrock and would occur in strict compliance with existing regulations. Impacts resulting from construction and construction-related blasting are expected to be small, due to safety measures DOE would employ during blasting activities.

Table 4-145. American Railways Engineering and Maintenance-of-Way Association seismic guidelines.[a]

Earthquake magnitude (Richter scale)	Response radii (kilometers)[b]	Response level[c]	Response protocol
0.0 to 4.9	d	I	Resume maximum operating speed. The need for the continuation of inspections will be determined by the proper maintenance-of-way authority.
5.0 to 5.9	160	II	All trains and engines will run at restricted speed within a specified radius of the epicenter until inspections have been made and appropriate speeds established by proper authority.
6.0 to 6.9	320	III	All trains and engines within the specified radius of the epicenter must stop and may not proceed until inspections have been performed and appropriate speed restrictions established by proper authority.
	480	II	All trains and engines will run at restricted speed within a specified radius of the epicenter until inspections have been made and appropriate speeds established by proper authority.
7.0 or greater	As directed, but not less than for 6.0 to 6.9	III	All trains and engines within the specified radius of the epicenter must stop and may not proceed until inspections have been performed and appropriate speed restrictions established by proper authority. The radius shall not be less than that specified for earthquakes between magnitudes 6.0 and 6.9.
		II	All trains and engines will run at restricted speed within a specified radius of the epicenter until inspections have been made and appropriate speeds established by proper authority. The radius shall not be less than that specified for earthquakes between magnitudes 6.0 and 6.9.

c. Response level as defined by America Railway Engineering and Maintenance-of-Way Association.
d. Radii not applicable.

Debris Flows Debris flows are rapidly moving mixtures of water, soil, rock, and organic material. A debris flow can begin during or after heavy precipitation, and is especially dangerous if the debris dams a stream channel. If the dam fails, the saturated debris can travel downslope for several miles in a confined channel. Debris flows lose their energy and begin to deposit material when the stream gradient flattens or when the channel widens (DIRS 180878-Shannon & Wilson 2007, pp. 45 and 46).

There would be a potential for debris flows along portions of the rail alignment during the construction and operations phases. Such flows would be most common where there is evidence of prior activity, specifically in steep areas and channels of ***alluvial fans*** (DIRS 180878-Shannon & Wilson 2007, pp. 45 and 46). Debris flows could bury the rail line in sediment, destroy portions of the line, or weaken bridge pylons as a result of excessive erosion. It would not be possible to completely avoid debris flows in the area around the rail alignment.

Mineral and Energy Resources The rail line could cross surface or subsurface mineral or energy resources not part of identified mining districts or mineral leases. During construction, previously unknown resources could be identified in areas with large cuts. The area surrounding the Mina rail alignment has an extensive history of ***mining claims*** and commercial operations. For this analysis, DOE used the existence of historical commercial mining as an indicator of mineral potential.

During the construction phase, some minerals could be rendered inaccessible because they would be within the construction right-of-way. However, the ***operations right-of-way*** would be smaller than the construction right-of-way, so these restricted areas would become available during the operations phase. The Mina rail alignment would not cross any known mineral deposits unique to the region. Any impacts related to restricted access of mineral resources would be temporary and limited to the construction phase. Sections 4.3.1.2.2.1 through 4.3.1.2.2.12 provide more information on potential impacts to individual mineral and energy resources along Mina rail alignment alternative segments and common segments. Section 4.3.2, Land Use and Ownership, describes potential impacts to local mining districts.

Local Sources of Construction Materials Construction of the rail line along the Mina rail alignment would require from 2.49 to 2.73 million metric tons (2.74 to 3.01 million tons) of crushed-rock ballast and from 2.18 to 2.39 million metric tons (2.40 to 2.64 million tons) of subballast for rail roadbed construction (DIRS 180874-Nevada Rail Partners 2007, p. A-5). Soil and rock excavated from construction cuts would not be suitable for ballast; DOE would use this material for subballast and embankment fill (DIRS 176034-Shannon & Wilson 2006, pp. 15, 19 and 20). The amount of cut material excavated during construction would not be sufficient to supply the necessary fill. Additional borrow sites would be opened to supplement the cut material. These sites would be excavated from alluvial gravels and sands approximately every 16 kilometers (10 miles) within the construction right-of-way. Where possible, these sites would be within or adjacent to existing Nevada Department of Transportation gravel pits. Additional subballast requirements would also be supplemented with bedrock extracted from the ballast quarries.

DOE has identified five potential ballast quarry sites along the Mina rail alignment in the Garfield Hills, Gabbs Range, and Goldfield areas (DIRS 180875-Nevada Rail Partners 2007, Figure 3-C). Of these potential locations, DOE would develop two to supply rock for ballast and subballast during the construction phase. Each quarry would be approximately 24 meters (80 feet) deep, with an anticipated ***footprint*** of approximately 0.04 square kilometer (10 acres). However, depending on the number of open quarries, and the quality of the mineral materials, a quarry pit footprint could be as large as 1 square kilometer (260 acres). A waste-rock pile at each quarry site would disturb approximately 0.06 square kilometer (14 acres). ***Overburden*** material and rock not suitable for ballast or subballast gravel would be stored at this location until the end of quarry operations. A railroad ***siding*** to accommodate the ballast cars would be included in the total quarry disturbance area (DIRS 176172-Nevada Rail Partners 2006, pp. 3-1 and 3-2). When adding all of the maximum areas of the quarry site that could be disturbed during construction (quarry pit, production plant, ballast storage, and waste pile), and including a temporary construction buffer area, a quarry site could disturb between 0.97 and 2.7 square kilometers (240 to 660 acres). These quarry-site values are considered to be maximum calculations, in the event of irregular topography and poor-quality excavated mineral materials. Section 4.3.1.2.4 describes potential impacts from the quarry facilities in more detail. The quarries would remain open through the construction phase. Afterward, DOE would reclaim disturbed areas in accordance with the post-construction and maintenance best management practices described in Chapter 7. Such practices would include grading the disturbed area, reshaping quarry-pit walls to stabilized slopes, replacing reserved topsoil, and revegetating.

DOE could use other local materials for rail line construction. Subballast would be generated from borrow sites on certain ***alluvial fans*** and crushed quarry rock. Blasted bedrock from slope cuts and excess ballast rock would be suitable for use to protect rail roadbed embankments from erosion. Some natural sand and gravel excavated from cuts and crushed rock from the quarries could be used to make concrete aggregate (DIRS 176034-Shannon & Wilson 2006, pp. 24 to 26). DOE would determine the prime sand and gravel deposits to be used before beginning construction.

Using local materials for ballast, subballast, and concrete aggregate would result in the consumption of construction resources (such as rock, sand, and gravel) often used for other construction projects in the area. However, alluvial deposits are plentiful in the region, and their use to construct the rail line would not substantially reduce the area supply of these resources. Because the potential impact to sand and gravel resources would be small along the entire alignment, this resource is not discussed further in Sections 4.3.1.2.2.1 through 4.3.1.2.2.12. Section 4.3.11, Utilities, Energy, and Materials, describes impacts to regional supply chains for other construction materials.

4.3.1.2.1.3 Soils. This section describes potential impacts to soils, including the removal of prime farmland from productive use. Rock excavation and land clearing would cause soil loss, surface erosion, and disruption of soil structure on previously undisturbed land.

During the construction phase, most soils would be excavated using conventional earthmoving equipment such as bulldozers, scrapers, rubber-tired backhoes, and track-mounted excavators. Solid rock encountered along the rail alignment would require drilling and blasting (DIRS 180878-Shannon & Wilson 2007, pp. 48 and 49).

Soil Loss and Erosion There would be soil loss and erosion at all places where construction activities disturbed the ground surface. The severity of soil loss would depend on the extent of the disturbance, the erodibility of the soil, and the steepness of the terrain.

Land disturbed along the rail alignment would be most susceptible to soil loss and erosion during heavy rains and high winds. Areas where fine-textured soil and sand (such as on alluvial fans, lake-bed terraces, valleys, and flats) and where soils exhibit the ***erodes easily*** or ***blowing soil*** characteristic would be most susceptible to erosion. The Mina rail alignment would be in an area with an ***arid*** climate that has variable rainfall events across the region. The northern portion of the Mina rail alignment occasionally experiences low-intensity, long period events (DIRS 180885-Parsons Brinckerhoff 2007, pp. 13 and 14). Once the ground is saturated, a brief increase in rainfall intensity can initiate surface flooding. South of the Goldfield Hills, rainfall is typically brief, but can be very intense and form washouts in low-lying areas. Elevated water velocities during rain events would increase erosion and scouring in areas where there is no vegetation, in areas dominated by sandy soils on steep slopes, along channel banks, and at bridge crossings (DIRS 176184-Shannon & Wilson 2006, p. 51). Construction of the proposed railroad would result in the loss of some topsoil and soil erosion. During and after construction, DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion. In areas of temporary surface disturbance, the topsoil would be reserved and replaced, where practicable.

Disturbed soils would also be susceptible to wind erosion, because wind speeds greater than 19 kilometers (12 miles) per hour are sufficient to move sand grains (DIRS 176184-Shannon & Wilson 2006, p. 53). Disturbed soils with the blowing soil characteristic tend to generate sand dunes, increase fugitive dust in the air, and contribute to the loss of topsoil. Wind and water erosion could also impact ***air quality***, surface-water quality, and biological resources, as discussed in Sections 4.3.4, 4.3.5, and 4.3.7, respectively.

Prime Farmland The Farmland Protection Policy Act (7 U.S.C. 4201 *et seq*.) seeks to minimize the extent to which federal programs contribute to the unnecessary and irreversible conversion of farmlands to nonagricultural uses. As discussed in Section 3.3.1.2.3, less than 0.1 percent of soils along the Mina rail alignment are classified as prime farmlands. The Schurz alternative segments would cross prime farmland soils around the Walker River on the Walker River Paiute Reservation (see Figure 3-129). DOE calculated the amount of potentially disturbed prime farmland soils by multiplying the total area of disturbance by the calculated percentage of prime farmland that would be within the rail line construction right-of-way. On the Reservation, there is 0.011 square kilometer (2.7 acres) of prime farmland along

Schurz alternative segment 1, 0.012 square kilometer (3 acres) along Schurz alternative segment 4, and 0.014 square kilometer (3.5 acres) along each of Schurz alternative segments 5 and 6.

Along these alternative segments, DOE would limit the disturbance within the construction right-of-way to minimize potential impacts to private lands and thus minimize impacts to farmland. All of the Schurz alternative segments would cross the prime farmland soils around the Walker River on the eastern side of Sunshine Flat. At present, these soils are not farmed. The Walker River Paiute Reservation contains approximately 5.5 square kilometers (1,400 acres) of prime farmland soils; thus, the proposed railroad would temporarily disturb 2.6 percent of the prime farmland soils on the Reservation.

In addition to using the Nevada soil survey database classification, DOE also requested assistance from the Nevada Natural Resources Conservation Service office to identify prime, unique statewide, or locally important farmland along the Mina rail alignment (DIRS 181388-Arcaya 2007, all). The Conservation Service analysis determined that the Mina rail alignment would not cross prime, unique statewide, or locally important farmland.

Soil Stability Excavation and grading activities would disturb the natural structure of the soil by breaking plant roots and natural mineral cements that bind soils. Soils disturbed along cut slopes would have a higher risk of becoming unstable and creating mudflows or landslides in steep topography because water-bearing properties would have changed, and the soil structure would have been altered. However, DOE would revegetate or otherwise stabilize these areas and would reclaim them to the extent practicable, which would reduce the potential for increased erosion (see Chapter 7).

DOE would erect up to 10 construction camps along the rail alignment to house workers. Although the camps would be temporary and used only during the construction phase, soil could become compacted at these sites. After construction was complete, DOE would grade the terrain and revegetate these areas with ***native plant*** species (see Chapter 7), which would minimize the effects of soil compaction.

Studies have shown that, if left to natural ***soil recovery***, the return of soil to pre-disturbed conditions and natural succession of vegetation in the Yucca Mountain area could take decades or more, creating an increased potential for erosion, landslides, and mudslides (DIRS 104837-DOE 1989, p. 17). Impacts due to soil disruption would be large within the construction right-of-way and immediate region of influence until new vegetation was established and the natural succession was reestablished. DOE would reduce the impacts related to the increased potential for erosion, landslides, and mudslides through the implementation of best management practices, such as revegetating disturbed sites, establishing proper roadbed grades, and using stormwater erosion control measures (see Chapter 7).

4.3.1.2.2 Construction Impacts along Alternative Segments and Common Segments

4.3.1.2.2.1 Department of Defense Branchline North (Wabuska to the boundary of the Walker River Paiute Reservation). DOE would construct a rail siding along the existing rail line within the existing operations right-of-way. This siding would be constructed on previously disturbed land. Otherwise, DOE would not perform any ground-disturbing activities along this portion of the Mina rail alignment. Therefore, there would be no impacts to physical setting along this existing branchline.

4.3.1.2.2.2 Department of Defense Branchline through Schurz. This branchline would not be part of the Mina rail alignment. Rather, as part of the Proposed Action, DOE would remove the track and ballast from this branchline, leaving only the rail roadbed, subballast, and structures such as bridges and culverts. The use of rail removal equipment (such as hydraulic spike pullers, fork-lifts, and front-end loaders) to help dismantle the rail line would cause temporary soil disruption and increased soil erosion. However, this would be confined to the previously disturbed area and would not affect undisturbed resources.

4.3.1.2.2.3 Department of Defense Branchline South. DOE would construct a rail siding along the existing rail line within the existing operations right-of-way. This siding would be constructed on previously disturbed land. Otherwise, DOE would not perform any ground-disturbing activities along this portion of the Mina rail alignment. Therefore, there would be no impacts to physical setting along this existing branchline.

4.3.1.2.2.4 Schurz Alternative Segments. The Schurz alternative segments would travel around or through several mountain ranges and valleys in the Walker River Basin. To maintain a rail grade of less than 2 percent, DOE would excavate and level high points along the alignment and, to the extent practicable, use this material to raise the low points. Table 4-146 lists the anticipated cut and fill requirements and other important information used in the impact analysis for the Schurz alternative segments. The cut and fill requirements would be greatest where an alternative segment would cross mountain passes, specifically between the Calico Hills and Terrill Mountains (Schurz alternative segments 4 and 5), and through an unnamed pass in the Terrill Mountains (Schurz alternative segment 6). Schurz alternative segments 5 and 6 would require the greatest ground disturbance (6.9 and 6.5 square kilometers [1,700 and 1,600 acres], respectively). Schurz alternative segment 1 would primarily travel along alluvial fans along Sunshine Flat and in Campbell Valley, and would therefore involve the least amount of ground disturbance (4.6 square kilometers [1,100 acres]). Construction activities required to achieve the appropriate grade could contribute to the loss of topsoil and local erosion; however, DOE would reduce impacts by regrading and revegetating the disturbed areas (see Chapter 7).

The Schurz alternative segments would cross faults associated with the Wassuk Range fault sequence. Schurz alternative segment 6 would also cross a fault near the Terrill Mountains. Since the U.S. Geological Survey began keeping seismic records, there have been a few earthquakes larger than 4.0 around the town of Schurz. The largest was a magnitude 6.3 earthquake in 1959 (DIRS 180878-Shannon & Wilson 2007, p. 17). The seismic activity in this area is suggested to be part of the extension of the Walker Lane structural belt. DOE would monitor the seismic activity along the Mina rail alignment, and follow procedures outlined in Table 4-145 in the event of an earthquake.

There is a high ***probability*** for metallic minerals in the mountains the Schurz alternative segments would bypass. Gold, silver, and copper historically have been mined in the Calico Hills and Terrill Mountains (DIRS 180882-Shannon & Wilson 2007, pp. 19, 20, 28 and 29). Nonmetallic minerals, such as soda and halite, are identified in the lowland area of Double Springs Marsh (DIRS 180882-Shannon & Wilson 2007, pp. 33 and 34). Each of the Schurz alternative segments is expected to have little or no impact on metallic and nonmetallic minerals in the area because they would be in the lowlands and would not disturb known commercial-grade deposits.

Less than 1 percent of the Schurz alternative segments would traverse prime farmland soils. Depending on alternative segment, 0.011 to 0.014 square kilometer (2.7 to 3.5 acres) of prime farmland soils would be disturbed (see Table 4-146). Prime farmland soils along the Schurz alternative segments only occur in the immediate vicinity of the Walker River.

All of the Schurz alternative segments would contain a high percentage of soils with blowing soil characteristics. Schurz alternative segment 1 would cross a higher percentage of blowing soils than the other Schurz alternative segments. In addition, southwest of Red Ridge, the southern portion of all the Schurz alternative segments would cross an area with a high percentage of blowing soils (see Figure 3-128). Soils with the blowing soils characteristic easily form sand dunes. Schurz alternative segments 1 and 4 would cross a higher percentage of erodes easily soils, but the alternative segments would disturb only about 0.19 to 0.29 square kilometer (47 to 72 acres) of this soil type. As a ***mitigation*** measure (see Chapter 7), DOE might need to install fencing around the rail alignment in this area to stabilize existing sand dunes that would be disturbed during rail line construction. DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion.

Table 4-146. Summary of key information for assessing impacts from constructing Schurz alternative segment 1, 4, 5, or 6.

Attribute	Schurz 1	Schurz 4	Schurz 5	Schurz 6
Length (kilometers)[a,b]	52	64	71	72

4.3.1.2.2.5 Department of Defense Branchline South (end of Schurz Alternative Segments to beginning of Mina Common Segment 1). DOE would develop construction camp number 17 on the southern portion of Department of Defense Branchline South near its junction with Mina common segment 1 (see Figure 2-14). The construction camp would disturb approximately 0.10 square kilometer (25 acres), which would result in topsoil loss and increased erosion. In addition, approximately 39 percent of the area that would be disturbed contains soils with the blowing soil characteristic. DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion. Other than construction of this camp, the Department does not anticipate any other surface-disturbing activities in this area; therefore, there would be no other impacts associated with this portion of the Mina rail alignment. DOE would build the Staging Yard directly north of the junction between Department of Defense Branchline South and Mina common segment 1. Section 4.3.1.2.3.1 describes potential impacts associated with the Staging Yard.

4.3.1.2.2.6 Mina Common Segment 1. Mina common segment 1 would generally travel within valleys flanked by expansive mountain ranges. Most of the required earthwork would be used to fill topographic variations on alluvial fans. Table 4-147 summarizes the key information DOE considered to assess impacts to physical setting from construction of Mina common segment 1. The rail line would disturb a total of 12 square kilometers (3,000 acres). Surface disturbance from construction activities would remove topsoil and increase the potential for erosion around the rail alignment. DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion.

Mina common segment 1 would cross some Quaternary faults. The Soda Spring Valley has experienced several earthquakes in the last 150 years (see Figure 3-126). However, most of these earthquakes had magnitudes below human detection. DOE would adopt the American Railway Engineering and Maintenance-of-Way Association guidelines to reduce the hazards to people and structures from earthquakes greater than magnitude 4.0 (see Chapter 7).

Mina common segment 1 would cross multiple mining districts, which are centered around the bounding mountains. Metallic minerals such as copper, gold, and silver have been identified and occasionally mined within these districts. Impacts to commercial minerals along Mina common segment 1 would be small because, although Mina common segment 1 would approach mining districts with claims, the segment would be restricted to valley locations and would not disturb subsurface mineral deposits.

4.3.1.2.2.7 Montezuma Alternative Segments. The Montezuma alternative segments would travel in valleys and passes as much as possible; however, all of these alternative segments would need to cross some mountain ranges, including the Montezuma Range and Goldfield Hills. Montezuma alternative segment 1 would require the greatest amount of fill material, while Montezuma alternative segment 3 would require the greatest amount of cuts. Table 4-148 summarizes the key information DOE considered to assess impacts to physical setting from construction of any of the Montezuma alternative segments.

Surface disturbance related to construction of the rail line, quarries, water wells, and access roads would range from 11 square kilometers (2,700 acres) along Montezuma alternative segment 2 to 17 square kilometers (4,200 acres) along Montezuma alternative segment 3. Cuts and fills associated with construction of any of the Montezuma alternative segments would result in the loss of topsoil and an increased potential for erosion.

l. Soil area calculated by multiplying total disturbed area by the percent soil characteristic.

Construction of the Montezuma alternative segments would disturb between 1.4 square kilometers (350 acres) and 2.3 square kilometers (570 acres) of erodes easily soils. More soils along Montezuma alternative segments 2 and 3, in the Big Smoky Valley and Montezuma Valley, have the blowing soils characteristic. These soils would have additional potential to be easily displaced by wind. Section 4.3.4, Air Quality and Climate, includes more discussion of impacts related to blowing soils and fugitive dust emissions. DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion.

Montezuma alternative segments 1, 2, and 3 would cross some Quaternary faults, specifically as they approach mountain foothills. There has been one magnitude 5.3 earthquake recorded to the west of Lone Mountain. However, there have been very few earthquakes above magnitude 3.0 in the area (see Figure 3-126). The potential exposure of people or structures to seismic hazards would be small.

There are multiple mining districts in the area surrounding the Montezuma alternative segments. There is an operating lithium evaporate mine immediately east of Silver Peak, and the Goldfield Hills contain multiple mining claims for metallic minerals (DIRS 180882-Shannon & Wilson 2007, pp. 104 to 106). There are also multiple metallic and nonmetallic minerals found within the Monte Cristo and Montezuma Ranges, and at Lone Mountain. However, there would be a small potential for impacts to mineral resources in this area, because ground disturbances would be limited to the rail line construction right-of-way. Construction would not require drilling into the deep saline aquifers Chemetall Foote Corporation uses for its lithium operations.

There is also a high potential for the mineral zeolite around the southern end of Montezuma alternative segment 2. Zeolite can be used as an antimicrobial agent and forms when saline ***groundwater*** reacts with certain volcanic deposits (DIRS 173841-Shannon & Wilson 2005, pp. 31 and 32). The potential impacts to local mineral resources would be small because rail line construction activities would be limited to the nominal width of the construction right-of-way. Section 4.3.2, Land Use and Ownership, also addresses impacts to the mining district from constructing and operating the proposed railroad along the Mina rail segment.

4.3.1.2.2.8 Mina Common Segment 2 (Stonewall Flat Area). Crossing the Stonewall Flat area, Mina common segment 2 would have relatively low rise and fall amounts and low cut and fill requirements (see Table 4-147).

Mina common segment 2 would cross the southern portion of the Stonewall Flat faults. However, within the past 150 years, there have been few earthquakes in the area (see Figure 3-126). There is a high potential for metallic minerals within the central portion of Mina common segment 2. Gold and silver deposits historically have been mined from the Stonewall and Cuprite Mining Districts (DIRS 173841-Shannon & Wilson 2005, pp. 56 to 59). However, impacts to these areas resulting from construction of the proposed rail line would be expected to be small and temporary because the minerals have not been found within the nominal width of the construction right-of-way. There are also geothermal wells near Mina common segment 2. DOE would avoid these wells during rail line construction, thereby reducing potential impacts. Section 4.3.2, Land Use and Ownership, describes land-use impacts regarding access to and use of mineral and energy resources.

Mina common segment 2 would disturb approximately 0.28 square kilometer (69 acres), which would include construction of the rail line, water wells, and access roads. The surface-area disruption would result in a loss of topsoil and the potential for increased erosion. Approximately 0.28 square kilometer (69 acres) of soils along Mina common segment 2 have the blowing soil characteristic and would be especially susceptible to wind erosion during construction.

There are also soils characterized as ***soft soils*** in ***playa*** deposits present along Mina common segment 2. The saline conditions of these soils limit the chemical and physical potentials of the soil and could have negative effects on the vegetation-bearing capacity of the soil. Reclamation of these soils following construction would be more difficult than on non-saline soils, and would require more maintenance and care than on more productive soils. These soils would have a higher potential for erosion until revegetation was complete. DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion.

4.3.1.2.2.9 Bonnie Claire Alternative Segments. The two Bonnie Claire alternative segments would pass through Lida Valley and Sarcobatus Flat. The alternative segments would require similar amounts of fill, but Bonnie Claire alternative segment 2 would require excavation of twice as much cut material as Bonnie Claire alternative segment 3. Table 4-149 summarizes the key information DOE considered to assess impacts to physical setting from construction of either of the Bonnie Claire alternative segments.

Each alternative segment would result in a total land disturbance of 1.9 square kilometers (470 acres) (see Table 4-149). Areas disturbed during construction would result in a loss of topsoil and increase the potential for erosion. However, these impacts would be temporary and would be reduced through the implementation of best management practices (see Chapter 7).

Although the alternative segments would pass through areas that have experienced recent low-level ***seismicity*** (magnitude 3.0 to 3.9) events, neither Bonnie Claire 2 nor Bonnie Claire 3 would cross known Quaternary fault traces. The primary seismic activity within the past 150 years occurred in 1999, when a magnitude 5.3 earthquake triggered many aftershocks over a series of days. Since then, earthquakes in the immediate vicinity of the Bonnie Claire alternative segments have been below magnitude 3.0 (DIRS 176184-Shannon & Wilson 2006, Plate 4). Seismic hazards in this area are considered consistent with the rest of southern Nevada.

There is a potential for metallic mineral deposits along both Bonnie Claire alternative segments. Each segment would travel around the Wagner Mining District, which has produced low-tonnage mixed oxide and sulfide copper ore (DIRS 173841-Shannon & Wilson 2005, p. 54). DOE would position the rail alignment to avoid the mining district and to reduce the potential for impacts to mineral deposits. Section 4.3.2, Land Use and Ownership, addresses potential impacts to the Wagner Mining District. The rail alignment would travel along the low sections of Stonewall Flat; therefore, impacts to metallic mineral deposits would be small.

About 0.48 to 0.51 square kilometer (120 to 130 acres) of the soils along Bonnie Claire 3 and Bonnie Claire 2, respectively, have the erodes easily characteristic (see Table 4-149). Thus, there would be a high potential for erosion along these alternative segments. DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion. Overall, the potential impacts from constructing a rail line along either Bonnie Claire alternative segment 2 or Bonnie Claire alternative segment 3 would be similar.

4.3.1.2.2.10 Common Segment 5 (Sarcobatus Flat Area). Passing through Sarcobatus Flat, common segment 5 would have a low rise and fall. Table 4-147 summarizes the key information DOE considered to assess impacts to physical setting from construction of common segment 5.

The potential to expose people or structures to seismic hazards would be small because common segment 5 would not cross any known Quaternary fault traces, and would travel over relatively level terrain.

Table 4-149. Summary of key information for assessing impacts from constructing Bonnie Claire alternative segments 2 or 3.

Key information	Bonnie Claire 2	Bonnie Claire 3

There is a high potential for metallic mineral resources where common segment 5 would pass near the Clarkdale Mining District. Small gold and silver deposits have been mined in Clarkdale, and are hypothesized to extend below portions of common segment 5 (DIRS 173841-Shannon & Wilson 2005, Table 1). However, construction activities would not uncover the bedrock and disturb the mineral resources. The area of common segment 5 also has a generally high potential for geothermal resources; there are several thermal springs near U.S. Highway 95 that would be parallel to the rail line (DIRS 173841-Shannon & Wilson 2005, p. 23). However, because DOE would avoid these resources during rail line construction, the potential for impacts would be small.

Construction of this common segment would disturb a total of 3.1 square kilometers (770 acres) of land. Surface disturbance related to construction activities would remove topsoil and increase the potential for erosion along the rail alignment. These impacts would be temporary and would be reduced through the use of best management practices (see Chapter 7).

Approximately 0.081 square kilometer (20 acres) of common segment 5 has the blowing soils characteristic, which would increase the potential for soil loss from wind. DOE would implement best management practices to minimize any additional soil loss from erosion. Section 4.3.4, Air Quality and Climate, addresses impacts related to construction-generated fugitive dust emissions.

4.3.1.2.2.11 Oasis Valley Alternative Segments. Oasis Valley alternative segments 1 and 3 would have a similar profile throughout the valley. Table 4-150 summarizes the key information DOE considered to assess impacts to physical setting from construction of either Oasis Valley alternative segment.

The Oasis Valley alternative segments would not cross known fault traces. Within the past 150 years of seismic records, there has been generally low earthquake activity in the area, so the potential seismic-related impacts to humans and structures would be small.

There is a low potential for commercial metallic, nonmetallic, and oil resources in the area of the Oasis Valley alternative segments (DIRS 182762-Shannon & Wilson 2005, Appendix E). The minerals present in the area around the alternative segments are found in small veins in the surrounding hills. There would be small impacts to such resources because the rail alignment would remain in the valley, away from mineral-bearing ***outcrops***. There is a high potential for geothermal deposits in the area; however, neither Oasis Valley alternative segment would approach any known hot springs or wells.

Oasis Valley alternative segment 3 would require more earthwork than Oasis Valley alternative segment 1 to obtain the appropriate grade (see Table 4-150) and would disturb 0.3 square kilometer (74 acres) more land area than Oasis Valley alternative segment 1. Construction activities would remove topsoil in the area and increase the potential for erosion along the rail alignment. Oasis Valley 1 also contains about twice as much blowing soils as Oasis Valley 3. DOE would implement best management practices (see Chapter 7) to reduce the potential for additional soil loss due to erosion.

Overall, potential impacts along either Oasis Valley alternative segment would be small. Oasis Valley 3 would be longer and would require more land disturbance than Oasis Valley 1, and Oasis Valley 1 would contain more soils with a high potential for erosion.

4.3.1.2.2.12 Common Segment 6 (Yucca Mountain Approach). Approaching Yucca Mountain, common segment 6 would pass through rugged terrain and along fault blocks. To achieve an appropriate grade, 15-meter (49-foot) cuts and fills would be required with up to 42-meter (140-foot) cuts and fills in some areas (see Table 4-147). Some of the fill would be required to build the bridge over Beatty Wash.

Table 4-150. Summary of key information for assessing impacts from constructing Oasis Valley alternative segment 1 or 3.

j. Source: DIRS 176781-MO0603GSCSSGEO.000, all.
k. Soil area calculated by multiplying total disturbed area by the percent soil characteristic.

There is a low potential for ground rupture associated with the eastern and western Yucca Fault systems (DIRS 176184-Shannon & Wilson 2006, Table 6). In areas with high topographic relief, construction of this common segment would also result in an increased potential for rock-slope failure and landslides (DIRS 176184-Shannon & Wilson 2006, Table 6). DOE would incorporate appropriate engineering features (see Chapter 2) during construction to stabilize these areas and prevent rock-slope failure and landslides. Construction activities would not be expected to result in off-site rock falls and landslides.

There is a high potential for the occurrence of some metallic and nonmetallic minerals along common segment 6. The rail alignment would cross the northeastern portion of the Bare Mountain Mining District, which has produced a variety of commodities over its period of operation, including fluorspar, silica, limestone, and trace amounts of gold and mercury (DIRS 173841-Shannon & Wilson 2006, p. 39). Construction impacts to mineral resources in this area would be small because the width of the construction right-of-way would allow for the extraction of the mining district's resources. Section 4.2.2, Land Use and Ownership, further describes impacts to the Bare Mountain Mining District.

There is a potential for geothermal resources in the northern portions of common segment 6. There are several warm and hot springs around Beatty, some of which are used as warm bathing pools. The rail alignment would bypass the springs; therefore, there would be no impact to local geothermal resources (DIRS 182762-Shannon & Wilson 2005, p. 31).

Construction activities along common segment 6 would disturb an estimated 5.5 square kilometers (1,400 acres). These activities could cause topsoil loss and an increase erosion potential. DOE would implement best management practices (see Chapter 7) to minimize these impacts. There are no special soil characteristics along this common segment.

4.3.1.2.3 Facilities

4.3.1.2.3.1 Staging Yard. DOE would build the Staging Yard northeast of Hawthorne near the end of Department of Defense Branchline South. The Staging Yard would disturb approximately 0.20 square kilometer (50 acres) and consist of a 610-square-meter (6,600-square-foot) office, a 560-square-meter (6,600-square-foot) Satellite Maintenance-of-Way Facility, and a paved access road (DIRS 180919-Nevada Rail Partners 2007, p. 3-1; DIRS 176168-Nevada Rail Partners 2006, p. 5-2). Construction of this facility would result in removal of topsoil and an increased potential for erosion within the disturbed areas. There would be a permanent loss of topsoil in the areas under buildings and paved roads.

4.3.1.2.3.2 Maintenance-of-Way Facility. There are two potential locations for the Maintenance-of-Way Facility along the Mina rail alignment, depending on the alternative segment. The Montezuma alternative segment 1 site would be approximately 1.6 kilometers (1 mile) south of Silver Peak. The site along Montezuma alternative segment 2 or 3 would be 2.9 kilometers (1.8 miles) west of U.S. Highway 95 between Tonopah and Goldfield (DIRS 180919-Nevada Rail Partners 2007, p. 4-4). Construction of this facility would disturb 0.061 square kilometer (15 acres) (DIRS 176170-Nevada Rail Partners 2006, Appendix B). The disturbed area would have the potential for topsoil loss and increased erosion.

4.3.1.2.3.3 Rail Equipment Maintenance Yard. Construction of the Rail Equipment Maintenance Yard would disturb approximately 0.41 square kilometer (100 acres) (DIRS 176170-Nevada Rail Partners 2006, p. A-5). This area would include the ***Cask Maintenance Facility***, and ***escort-car*** and locomotive-light-repair garages. It could also house the ***Nevada Railroad Control Center*** and National Transportation Operations Center. Construction of these facilities would result in topsoil loss and increased erosion potential. DOE would implement best management practices (see Chapter 7) to minimize potential erosion impacts. During construction, the topsoil would be sequestered and stabilized to prevent its permanent loss.

4.3.1.2.3.4 Cask Maintenance Facility. The Cask Maintenance Facility would be used to house the transportation casks, and would process them during routine inspections, cleaning, and repair.
The facility would disturb 0.081 square kilometer (20 acres), which would include buildings, a rail yard, and track siding (DIRS 176168-Nevada Rail Partners 2006, p. 1-3). The facility could be in one of three locations: collocated with the Rail Equipment Maintenance Yard inside the ***Yucca Mountain Site*** boundary, along one of the rail alignment segments outside the ***Yucca Mountain Site boundary***, or at a currently undetermined location outside Nevada.

4.3.1.2.4 Quarries

DOE would develop two of five potential quarry sites along the Mina rail alignment. Each quarry site would contain an operations plant, quarry and production area, access roads, and a railroad siding with loading facility, and could contain a conveyor belt (see Figure 2-33). The operations plant would include administrative offices, a parking area, sanitary facilities, and an equipment fueling and service area. The quarry and production area would include the pit, which would vary in size depending on quarry location, a waste-rock pile with a rectangular footprint of 0.057 square kilometer (14 acres), a ballast stockpile, settling ponds, a water well, and emergency generators.

The maximum disturbance area for each quarry was calculated from the areas that would be disturbed from excavating the quarry pit and building the associated plant facilities, roads, railroad siding, and conveyor belts. The area for a temporary construction buffer was also included, which would be reclaimed once construction was completed. The quarry pit would create the largest disturbance area, so depending on the quality of the bedrock and the quantity of required ballast and subballast, the total disturbance area for the quarry site would most likely be much smaller. Depending on the topography, the relative positions of the facilities, the quality and amount of the extracted rock, the total area of disturbance from a quarry site would be 0.97 to 2.7 square kilometers (240 to 660 acres).

Construction and operation of quarries would modify the physical setting in multiple ways. Construction of the buildings, access roads, and conveyer belts would disturb topsoil. During quarry operation, rock extraction would require the removal of the thin soil overburden. The result would be some topsoil loss during quarry construction and operation. Construction and operation of the quarries would also increase the potential for erosion. These impacts would be temporary, limited to the area around the quarry facilities, and DOE would implement best management practices (see Chapter 7) to reduce the impacts. Where practicable, the topsoil would be reserved for reclamation and revegetation. Excavation of bedrock from the pit would result in permanent loss of the mineral resources and change the local topography. However, the quarries would be in areas with abundant mineral resources, so impacts to overall availability of minerals suitable for quarrying would be small.

After construction, DOE would implement reclamation activities to reduce permanent impacts (see Chapter 7). The Department would demolish quarry access roads by removing the roadway materials and regrading the area. Terrain restoration around the quarry facility and pit would include restoring quarry-pit walls to more stable slopes, grading and replacing topsoil, and revegetating the area (DIRS 176172-Nevada Rail Partners 2006, p. 3-4). Reclamation activities would reduce the direct and indirect topsoil loss and increased erosion impacts caused by quarry construction and operation.

Sections 4.3.1.2.4.1 through 4.3.1.2.4.5 describe potential impacts related to each potential quarry site along the Mina rail alignment.

4.3.1.2.4.1 Garfield Hills Quarry. The potential Garfield Hills quarry would be in low hills south of Mina common segment 1. The quarry pit (see Figure 2-28) would be mined from the southwest side of a mesa, extracting basalt from two 30-meter (100-foot) hills. At most, this quarry pit could occupy an area of 0.30 square kilometer (74 acres) with an average depth of 22 meters (71 feet), which would produce 38.1 million metric tons (42 million tons) of ballast (DIRS 180875-Nevada Rail Partners 2007, p. A-4). Actual quarry dimensions would likely be much smaller – approximately 0.04 square kilometer (10 acres) (DIRS 176172-Nevada Rail Partners 2006, p. 3-2). The ballast produced from this quarry could supply a portion of the 2.49 to 2.73 million metric tons (2.74 to 3.01 million tons) required for railroad construction and maintenance (DIRS 180875-Nevada Rail Partners 2007, p. 3-1).

Access to the Garfield Hills quarry site would be by existing and new roads (DIRS 180875-Nevada Rail Partners 2007, Appendix H). To connect the quarry pit to the facilities, the Mina common segment 1 siding, and U.S. Highway 95, DOE would construct 3.1 kilometers (1.9 miles) of new roadway and would improve 3.2 kilometers (2 miles) of existing roadway (DIRS 180875-Nevada Rail Partners 2007, Table4-6). The Department would update existing roads with grading and a gravel roadbed. Excavated ballast would be trucked to the quarry plant site, which would be on an alluvial fan to the north of the quarry site. Once the ballast was separated, it would be transported to the rail alignment via conveyer belt. This conveyer belt would need to cross U.S. Highway 95 to reach the siding. The conveyer belt and service road would travel approximately 1.6 kilometers (1 mile) and disturb a 15-meter (50-foot)-wide path from the processing plant to the rail loading facility. The entire quarry footprint, including pit, facilities, and associated transportation routes would disturb a maximum of 1.4 square kilometers (350 acres).

4.3.1.2.4.2 Gabbs Range Quarry. The potential Gabbs Range quarry and its facilities would be northeast of Mina common segment 1, shown on Figure 2-29. When operational, this quarry could supply a portion of the 2.49 to 2.73 million metric tons (2.74 to 3.01 million tons) of ballast required for railroad construction and maintenance (DIRS 180875-Nevada Rail Partners 2007, p. 3-1). The southern edge of a 120-meter (400-foot)-high ridge would be mined for granite. The quarry pit would be able to produce a maximum of 13 million metric tons (14.3 million tons) of ballast excavated out of a 0.21-square-kilometer (52-acre) pit on average 23 meters (77 feet) deep. The potential plant facility would be to the southwest of the quarry pit and adjacent to the rail alignment. Ballast would be trucked along a modified off-road vehicle trail to the loading facility along Mina common segment 1. For the Gabbs Range quarry, DOE would upgrade 8.9 kilometers (5.5 miles) of existing roads, and create 0.81 kilometer (0.50 mile) of new roads (DIRS 180875-Nevada Rail Partners 2007, Table 4-6). The Gabbs Range quarry footprint would disturb about 0.97 kilometer (240 acres).

4.3.1.2.4.3 North Clayton Quarry. The potential North Clayton quarry would be north of Montezuma alternative segment 3 and east of Montezuma alternative segment 1 north of the Montezuma Mountains. The quarry pit would be on granite hills north of the Montezuma Range and Clayton Ridge. The plant site and waste-rock pile would be on alluvial fans to the west and east of the rail alignment, respectively (see Figure 2-30). The quarry would be able to produce a maximum of 12.3 million metric tons (13.6 million tons) of granite rock from a pit totaling 0.35 square kilometer (86 acres) with a bench height of 15 meters (50 feet). Construction requirements for ballast for the rail alignment would be 2.49 to 2.73 million metric tons (2.74 to 3.01 million tons) (DIRS 180875-Nevada Rail Partners 2007, p. 3-1). The ballast would be trucked from the quarry pit to the quarry plant facility, and then trucked to the rail alignment along new and existing roads. DOE would construct 3.1 kilometers (1.9 miles) of new road and use 5.8 kilometers (3.6 miles) of existing roads to connect the quarry pit to the plant facilities and the rail alignment. The entire quarry footprint would disturb a maximum of 1.8 square kilometers (440 acres).

4.3.1.2.4.4 Malpais Mesa Quarry. The potential Malpais Mesa quarry would be in the area between Montezuma alternative segments 1, 2, and 3, shown on Figure 2-32. ***Basalt*** rock would be excavated from the side of a 61-meter (200-foot)-high bowl-shaped cliff. The waste-rock pile and plant facilities would be to the southwest at the base of the cliff. A maximum of 11.9 million metric tons (13.1 million tons) of ballast could be extracted from the 1-square-kilometer (260-acre) pit with a depth of 21 meters (70 feet). Depending on the percentage of the required 2.49 to 2.73 million metric tons (2.74 to 3.01 million tons) of ballast the quarry would supply, the final quarry footprint would likely be smaller (DIRS 180875-Nevada Rail Partners 2007, p. 3-1).

Access to the quarry pit and production plant would be via 5.3 kilometers (3.3 miles) of updated off-road vehicle trails off U.S. Highway 95, with 6.8 kilometers (4.2 miles) of new roadway construction to connect the quarry site to the rail alignment, waste-rock pile, and plant facility (DIRS 180875-Nevada Rail Partners 2007, Table 4-6). A conveyer belt would carry the ballast from the production facility to the rail siding. The width of the conveyer belt and correlating service road would be 15 meters (50 feet). The Malpais Mesa quarry footprint would disturb about 2.7 square kilometers (660 acres).

4.3.1.2.4.5 Quarry ES-7. Potential quarry ES-7 would be west of Montezuma alternative segment 2 or 3 shown on Figure 2-31. The quarry pit and plant facilities would be on a 49-meter (160-foot)-high mesa with access to two basalt deposits. DOE could extract a maximum of 8.49 million metric tons (9.36 million tons) of basalt ballast from the 0.11-square-kilometer (27-acre) pit with a depth of 30 meters (100 feet). Depending on the amount of ballast required, the footprint of this quarry would likely be smaller. There could also be a secondary quarry of variable-quality rock in the area. It would be able to produce a maximum of 2.9 million metric tons (3.2 million tons) of ballast from a 37,000-square-meter (9.2-acre) pit 30 meters deep. However, the final dimensions of this secondary quarry would likely be smaller. This quarry could supply a portion of the required 2.49 to 2.73 million metric tons (2.74 to 3.01 million tons) of ballast (DIRS 180875-Nevada Rail Partners 2007, p. 3-1).

Access to the quarry pit and production plant would be via an existing road off U.S. Highway 95, with new roadway construction to extend into the quarry site (DIRS 176172-Nevada Rail Partners 2006, Appendix I). DOE would construct approximately 6.6 kilometers (4.1 miles) of new roadway and would improve 8.4 kilometers (5.2 miles) of existing roadway to access the quarry pit and facilities (DIRS 176172-Nevada Rail Partners 2006, Table 4-7). A conveyer belt would carry the ballast from the production facility to the rail siding. The conveyer belt and correlating service road would be 15 meters (50 feet) wide. The total disturbance area of the quarry footprint would be 1.5 square kilometers (370 acres).

4.3.1.3 Operations Impacts

The proposed railroad would operate for up to 50 years (DIRS 176173-Nevada Rail Partners 2006, p. 4-1). The operations right-of-way would be nominally 61 meters (200 feet) on either side of the centerline of the rail line. By definition, the operations right-of-way would be within the construction right-of-way; therefore, use of the completed rail line to Yucca Mountain would have no additional impact to physical setting beyond the permanent alterations resulting from construction.

Rail line maintenance would require periodic inspections to verify the condition of the track, drainage structures, and rock-wall surfaces. When necessary, rock faces on cuts would be repaired to minimize the potential for rockfall or landslide. Areas along the rail line would also be monitored for evidence of erosion, particularly where there is a high percentage of soils classified as erodes easily (Schurz alternative segment 1 [31 percent], Schurz alternative segment 5 [36 percent], Schurz alternative segment 6 [49 percent], and Mina common segment 2 [100 percent]).

Eroded areas encroaching on the track bed would be repaired, which could include replacement of ballast and subballast to reduce erosion of exposed soils. Although there would be a potential for erosion and landslides along the rail line, the potential would be substantially similar to baseline conditions, and would be attributed to natural occurrences after construction was completed, not due to train operations. In addition, DOE would use appropriate slope-stabilizing engineering practices (see Chapter 2) during the construction phase that would reduce hazards from rockfalls and landslides during the operations phase. Section 4.2.8, Noise and Vibration, discusses potential impacts from vibration in more detail.

During the operations phase, DOE would continue to monitor seismic activity in the region. DOE would also continue to follow the procedures based on the American Railways Engineering and Maintenance-of-Way Association seismic guidelines adopted during the construction phase (see Section 4.3.1.2.1.2 and Table 4-145). These measures, also outlined in Chapter 7, would reduce the potential for structural damage and human exposure to seismic hazards.

4.3.1.4 Impacts under the Shared-Use Option

The Shared-Use Option would include the construction and operations activities described in Sections 4.3.1.2 and 4.3.1.3, and private companies would use the rail line for shipment of general freight. Under the Shared-Use Option, potential construction and operations impacts would be very similar to those identified in Sections 4.3.1.2 and 4.3.1.3 for the Proposed Action without shared use.

The Shared-Use Option would require the construction of more rail sidings within the rail line construction right-of-way in areas of relatively flat terrain. A commercial-use interchange facility at the beginning of the line and a facility at the commercial-use termination point to support the Shared-Use Option would also be constructed within the construction right-of-way. Implementation of the Shared-Use Option would increase the area of surface disturbance by less than 0.1 percent (see Chapter 2). There would be a potential for topsoil loss and increased erosion in this area.

Under the Shared-Use Option, the rail line would likely be in use for more than 50 years, compared to the railroad operations life under the Proposed Action without shared use. Shared use of the proposed rail line would add no impacts to physical setting beyond the permanent alterations already described.

4.3.1.5 Summary

Table 4-151 summarizes potential impacts to physical setting from constructing and operating the proposed railroad along the Mina rail alignment. With the exception of topsoil loss, overall impacts would be small because of the best management practices or mitigation procedures DOE would implement (see Chapter 7). There would be a potential for increased erosion because relatively undisturbed land would be extensively graded. Impacts related to soil erosion or loss of topsoil would be small because implementation of best management practices would effectively reduce the potential for increased erosion and sedimentation that could occur during construction activities. In addition, soil disturbance would be distributed through several counties, reducing the concentration of increased soil erosion.

The Mina rail alignment would cross faults in Nevada, a seismically active area. However, DOE would adopt the American Railway Engineering and Maintenance-of-Way Association seismic guidelines. Additional seismic monitoring procedures would also be implemented during the construction and operations phases. Construction of the rail line would avoid known commercial mineral deposits, and would not remove them from permanent use. The quarries and borrow sites that would be developed and used for supplying the ballast and subballast would remove mineral resources from the area. However, construction would consume only a small percentage of the total available supply over several counties. There would be no additional impacts to the physical setting from railroad operations under the Proposed Action or the Shared-Use Option.

Table 4-151. Summary of impacts to physical setting from constructing and operating the proposed railroad along the Mina rail alignment[a] (page 1 of 4).

Rail line segment/ facilities (county)	Construction impacts	Operations impacts
Rail line segment		
Department of Defense Branchline North (Lyon County)	Total surface disturbance: 0.16 square kilometer, would result in topsoil loss and increased potential for erosion.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.

Table 4-151. Summary of impacts to physical setting from constructing and operating the proposed railroad along the Mina rail alignment[a] (page 2 of 4).

Rail line segment (continued)		
Schurz alternative segments 1, 4, 5, and 6 (Lyon, Churchill, and Mineral Counties including Walker River Paiute Reservation)	Total surface disturbance would result in topsoil loss and increased potential for erosion: Schurz 1 = 4.6 square kilometers Schurz 4 = 6.1 square kilometers Schurz 5 = 6.9 square kilometers Schurz 6 = 6.5 square kilometers Loss of prime farmland soils: Schurz 1 = 0.011 square kilometer Schurz 4 = 0.012 square kilometer Schurz 5 = 0.014 square kilometer Schurz 6 = 0.014 square kilometer Each segment would cross 2.6 percent of the prime farmland soils of the Walker River Paiute Reservation. Small impact to local mineral resources due to metallic minerals historically mined in local mountains.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Department of Defense Branchline South (Mineral County)	Total surface disturbance: 0.26 square kilometer, would result in topsoil loss and increased potential for erosion.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Mina common segment 1 (Mineral and Esmeralda Counties)	Total surface disturbance: 12 square kilometers, would result in topsoil loss and increased potential for erosion.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Montezuma alternative segments 1, 2, and 3 (Esmeralda and Nye Counties)	Total surface disturbance would result in topsoil loss and increased potential for erosion: Montezuma 1 = 16 square kilometers Montezuma 2 = 11 square kilometers Montezuma 3 = 17 square kilometers Potential impacts to metallic and nonmetallic resources would be small.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Mina common segment 2 (Esmeralda and Nye Counties)	Total surface disturbance: 0.28 square kilometer, would result in topsoil loss and increased potential for erosion. Small impacts to metallic and geothermal resources.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.

Table 4-151. Summary of impacts to physical setting from constructing and operating the proposed railroad along the Mina rail alignment[a] (page 3 of 4).

Rail line segment/ facilities (county)	Construction impacts	Operations impacts
Rail line segment (continued)		
Bonnie Claire alternative segments 2 and 3 (Nye County)	Total surface disturbance, would result in topsoil loss and increased potential for erosion: Bonnie Claire 2 = 1.9 square kilometers Bonnie Claire 3 = 1.9 square kilometers Small impacts to metallic mineral resources.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Common segment 5 (Nye County)	Total surface disturbance: 3.1 square kilometers, would result in topsoil loss and increased potential for erosion. Small impact to metallic mineral and geothermal resources.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Oasis Valley alternative segments 1 and 3 (Nye County)	Total surface disturbance would result in topsoil loss and increased potential for erosion: Oasis Valley 1 = 1 square kilometer; Oasis Valley 3 = 1.3 square kilometers Small impacts to mineral resources.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Common segment 6 (Nye County)	Total surface disturbance: 5.5 square kilometers, would result in topsoil loss and increased potential for erosion. Small impacts to mineral and geothermal resources.	Potential for soil erosion in localized areas along the rail roadbed; implementation of erosion prevention methods would reduce impacts.
Facilities		
Access roads (included in total surface disturbance in individual segments) (Mineral, Esmeralda, and Nye Counties)	Total surface disturbance: 1.5 square kilometers, would result in topsoil loss and increased potential for erosion.	Potential for soil erosion in localized areas around the facility; implementation of erosion prevention methods would reduce impacts.
Staging Yard at Hawthorne (includes the Satellite Maintenance-of-Way Facility) (Mineral County)	Total surface disturbance: 0.2 square kilometer, would result in topsoil loss and increased potential for erosion.	Potential for soil erosion in localized areas around the facility; implementation of erosion prevention methods would reduce impacts.
Maintenance-of-Way Facility (includes Maintenance-of-Way Headquarters Facility and Maintenance-of-Way Trackside Facility) (Esmeralda County)	Total surface disturbance: 0.061 square kilometer, would result in topsoil loss and increased potential for erosion.	Potential for soil erosion in localized areas around the facility; implementation of erosion prevention methods would reduce impacts.
Rail Equipment Maintenance Yard (includes Cask Maintenance Facility)(Nye County)	Total surface disturbance: 0.41 square kilometer, would result in topsoil loss and increased potential for erosion.	Potential for soil erosion in localized areas around the facility; implementation of erosion prevention methods would reduce impacts.

Table 4-151. Summary of impacts to physical setting from constructing and operating the proposed railroad along the Mina rail alignment[a] (page 4 of 4).

Rail line segment/ facilities (county)	Construction impacts	Operations impacts
Facilities (continued)		
Construction camps (Esmeralda, Nye, and Mineral Counties including the Walker River Paiute Reservation)	Total surface disturbance: 1 square kilometer would result in topsoil loss and increased potential for erosion. Construction camps would be within the nominal width of the construction right-of-way.	Potential for soil erosion in localized areas around the construction camps; implementation of erosion prevention methods would reduce impacts.
Water wells (Lyon, Mineral, Churchill including Walker River Paiute Reservation, Nye, and Esmeralda Counties)	Total surface disturbance: 0.17 square kilometer, would result in topsoil loss and increased potential for erosion. (105 potential well sites with 130 potential wells; 76 well sites would be within the nominal width of the construction right-of-way; 29 well sites would be outside the nominal width of the construction right-of-way, at 0.0057 square kilometer surface disturbance at each well site)	Potential for soil erosion in localized areas around the well sites; implementation of erosion prevention methods would reduce impacts.
Quarries		
Potential Garfield Hills quarry (Mineral County)	Total surface disturbance: 1.4 square kilometers, would result in topsoil loss and increased potential for erosion. Extraction of all 38.1 million metric tons of rock would reduce the availability of local construction mineral materials.	Potential for soil erosion in localized areas around the quarry; implementation of erosion prevention methods would reduce impacts.
Potential North Clayton quarry (Esmeralda County)	Surface disturbance: 1.8 square kilometers, would result in topsoil loss and increased potential for erosion. Extraction of all 12.3 million metric tons would reduce the availability of local construction mineral materials.	Potential for soil erosion in localized areas around the quarry; implementation of erosion prevention methods would reduce impacts.
Potential Malpais Mesa quarry (Esmeralda County)	Surface disturbance: 2.7 square kilometers, would result in topsoil loss and increased potential for erosion. Extraction of all 11.9 million metric tons would reduce the availability of local construction mineral materials.	Potential for soil erosion in localized areas around the quarry; implementation of erosion prevention methods would reduce impacts.
Potential quarry ES-7 (Nye County)	Total surface disturbance: 1.5 square kilometers, would result in topsoil loss and increased potential for erosion. Extraction of all 11.4 million metric tons from two pits would reduce the availability of local construction mineral materials.	Potential for soil erosion in localized areas around the quarry; implementation of erosion prevention methods would reduce impacts.

a. To convert square kilometers to acres, multiply by 247.10; to convert metric tons to tons, multiply by 1.1023.

4.3.2 LAND USE AND OWNERSHIP

This section describes potential impacts to land use and ownership from constructing and operating the proposed railroad along the Mina rail alignment. Section 4.3.2.1 describes the methods DOE used to assess potential impacts; Section 4.3.2.2 describes potential impacts to land use during the construction phase; Section 4.3.2.3 describes potential railroad operations impacts; Section 4.3.2.4 describes potential impacts under the Shared-Use Option; and Section 4.3.2.5 summarizes potential impacts to land use and ownership.

Section 3.3.2.1 describes the region of influence for land use and ownership.

4.3.2.1 Impact Assessment Methodology

Table 4-152 lists factors DOE considered to determine potential impacts to land use and ownership from project-related construction and operations activities.

Table 4-152. Impact assessment considerations for land use and ownership.

Land use	Potential for impact
General	Nonconformance with applicable general and regional plans and approved or adopted policies, goals, or operations of communities or governmental agencies
Private land	Change in current land use
	Displacement of existing, developing, or approved urban/industrial buildings or activities (residential, commercial, industrial, governmental, or institutional)
	Loss of ownership or title to private land
American Indian land	Conflict with existing land-use plans or cause incompatible land uses
Department of Defense land	Conflict with existing land-use plans or cause incompatible land uses
Livestock grazing lands	Loss of grazing land and associated ***animal unit months***
	Alteration of livestock operations or disruption of livestock movement
	Change to the amount or distribution of existing stockwater sources
	Potential human disturbance to livestock (such as loss of livestock due to collisions with trains)
Mineral and energy resources	Potential to preclude mining operations or the extraction of oil, gas, and geothermal resources within the rail line construction right-of-way
	Disturbance to existing or proposed mining operations with an approved mining plan
	Potential to cause the collapse of active underground mines, tunnels, or shafts
Recreational areas and access to public or private lands	Potential disturbance to federal, state, local, or private land designated as recreational sites
	Potential alteration of routes for large, recurring organized off-highway vehicle events and races
	Restricted or altered access to federal, state, local, or private recreational sites or public land
	Restricted or altered access to private land
Utility and transportation corridors and rights-of-way	Interference with an existing or planned utility or transportation right-of-way
	Need for a new right-of-way within a BLM-designated right-of-way avoidance area, such as an Area of Critical Environmental Concern

DOE assessed potential impacts to land use and ownership along the rail line based on the nominal width of the construction right-of-way. The Union Pacific Railroad Hazen Branchline and Department of Defense Branchlines North and South are existing rail lines where there would be no new construction outside of the existing railroad right-of-way under the DOE Proposed Action. Therefore, there would be no changes to land use, ownership, or access associated with those segments.

For railroad construction and operations support facilities, this section describes potential impacts to land use and ownership in conjunction with each facility's nearest segment, based on the current land use at the site. Table 4-153 describes the required support facilities and the current land uses at their proposed locations. Chapter 2 describes the facilities and their locations in more detail.

Table 4-153. Land use associated with proposed construction and operations support facilities.

Facilities	Number of facilities under the Proposed Action[a,b]	Within the nominal width of the construction right-of-way	Land ownership
Construction camps	Up to 10	Yes	BLM-administered public land and the Hawthorne Army Depot
Construction wells	Maximum: 74 well sites needed Area of disturbance for each well outside the construction right-of-way would be 0.0057 square kilometer	All but 9	Construction wells outside the nominal width of the construction right-of-way would be on BLM-administered public land and Walker River Paiute Reservation land
Quarries	Up to two needed out of five potential sites	No	All would be on BLM-administered public land except for the potential Garfield Hills quarry, which would be partially on the Hawthorne Army Depot
Staging Yard	One required Area of disturbance would be approximately 0.2 square kilometer	No	BLM-administered public land and the Hawthorne Army Depot
Maintenance-of-Way Facility	One required	Yes	BLM-administered public land
Rail Equipment Maintenance Yard	Includes the Satellite Maintenance-of-Way Facility, possibly the Nevada Railroad Control Center and National Transportation Operations Center	No	DOE-managed land –Yucca Mountain Site[c]
Cask Maintenance Facility	One This facility has three location options: (1) collocated with the Rail Equipment Maintenance Yard, (2) anywhere along the rail line outside the Yucca Mountain Site boundary, or (3) anywhere outside Nevada	No	For purposes of analysis, collocated with the Rail Equipment Maintenance Yard

a. To convert square meters to square feet, multiply by 10.76.
b. To convert square kilometers to acres, multiply by 247.10.
c. DOE would implement the Proposed Action only after the proposed public land withdrawal for the Yucca Mountain Site was completed, when land ownership would be transferred to DOE.

Because the basis for rail line impacts is the construction right-of-way, impacts from construction camps, some construction wells, and some facilities that fall within the construction right-of-way are already accounted for, and those impacts are not addressed separately. Although not all the well locations identified would be used for the project, for purposes of analysis and to conservatively estimate impacts to land use and ownership, DOE assumes that it would develop all the well locations outside the rail line construction right-of-way and ***footprints*** of the quarry sites.

4.3.2.2 Construction Impacts to Land Use and Ownership

Sections 4.3.2.2.1 through 4.3.2.2.8 discuss potential land-use impacts during the construction phase. Because potential impacts to land use would occur primarily from the presence of the rail line, the construction timeframe (which could range from 4 to 10 years) would have little effect on the resulting land-use impacts, other than to provide greater lead time to implement mitigation measures, establish land-use agreements, and revise ***grazing allotment*** permits where applicable. Therefore, DOE did not assess potential land-use impacts for different construction timeframes.

Table 4-154 provides an overview of the land ownership within the proposed construction right-of-way and locations of support facilities.

Table 4-154. Land ownership by common or alternative segment within the proposed construction right-of-way and facilities outside the construction right-of-way[a] (page 1 of 2).

Rail line segment or facility	Land ownership	Area (square kilometers)[b]	Area (acres)[b]
Staging Yard at Hawthorne	Public (BLM-administered)	0.25	63
	Hawthorne Army Depot	1.1	270
Construction camp 17	Hawthorne Army Depot	0.08	20
Schurz alternative segment 1	Walker River Paiute Reservation	3.5	850
	Public (BLM-administered)	0.53	130
Schurz alternative segment 4	Walker River Paiute Reservation	4.7	1,170
	Public (BLM-administered)	0.53	130
Schurz alternative segment 5	Walker River Paiute Reservation	5.0	1,240
	Public (BLM-administered)	2.0	490

	Public (DOE)	4.1	1,020

a. Source: DIRS 181617-Hopkins 2007, all.
b. Land area values are rounded to two significant figures, except for values over 1,000, which are rounded to the nearest 10.

4.3.2.2.1 Private Land

4.3.2.2.1.1 County and Local Land-Use Plans. In general, DOE developed the Mina rail alignment to avoid private land. There would be no land-use conflicts in terms of county land use, projects, or planning.

- *Nye County Comprehensive Plan* (DIRS 147994-McRae 1994, all)

  This plan addresses the proposed Yucca Mountain ***Repository*** and states that the repository could affect the county's future economy and the quality of life of its residents. The plan does not address the proposed railroad. However, DOE has determined that a rail line along the Mina rail alignment would not substantially alter current land uses or impact future land-use plans in Nye County.

- *Esmeralda County Master Plan* (DIRS 176770-Duval et. al. 1976, all)

  This plan predates plans for a repository at Yucca Mountain; therefore, it does not address the project. The plan states that the county must be consulted on all proposed federal projects. DOE continues to consult with Esmeralda County on the Proposed Action. DOE has determined that a rail line along the Mina rail alignment would not substantially alter current land uses or impact future land-use plans in Esmeralda County. The only private land that would be impacted within an established town in Esmeralda County would be along Montezuma alternative segment 2 near Goldfield.

Although there is no zoning designation in the community of Goldfield, the designation of its historic district is a consideration for determining potential adverse impacts to land use. The historic district would be approximately 0.6 kilometer (0.4 mile) from Montezuma alternative segment 2 construction right-of-way. Goldfield has been historically linked with both mining and railroad activity. Therefore, a new rail line adjacent to the town would not be a wholly incompatible feature with its historic characteristics. The BLM, DOE, and the Surface Transportation Board (STB) signed a Programmatic Agreement regarding the Yucca Mountain rail alignment project with the Nevada State Historic Preservation Office on April 17, 2006, to formalize the consultation process (DIRS 176912-Wenker et. al. 2006, all). As for any other potential cultural resources along the rail alignment, DOE would consult with the State Historic Preservation Office to determine potential impacts and possible mitigation measures (see discussion in Section 4.3.13, Cultural Resources).

4.3.2.2.1.2 Private Parcels. DOE would need to gain access to private land that falls within the Mina rail alignment construction right-of-way and the locations of support facilities. Segments that would cross private lands include Mina common segment 1, Montezuma alternative segments 2 and 3, and Oasis Valley alternative segment 1. None of the other segments would cross private land. Table 4-155 lists private lands the Mina rail alignment could affect. No residences or other privately owned structures would lie within the Mina rail alignment construction right-of-way.

Table 4-155. Uses of private land along the Mina rail alignment.

Segment and land use	Number of parcels within the construction right-of-way	Area of parcels within the construction right-of-way (square meters)[a]
Mina common segment 1		
Vacant	1	213,000
Montezuma alternative segment 2		
Vacant	28	177,000
Residential	1	470
Commercial	1	65
Utilities	4	9,500
Patented mining claims	4	137,000
Montezuma alternative segment 3		
Vacant	1	99,000
Oasis Valley alternative segment 1		
Commercial	1	40,000

a. To convert square meters to acres, multiply by 0.000247.

Mina common segment 1 would cross approximately 0.21 square kilometer (52.6 acres) of private land (Figure 3-138) just east of the Hawthorne Army Depot. DOE would need to gain access to this land.

Montezuma alternative segments 2 and 3 would cross 0.1 square kilometer (24.4 acres) of private vacant land at Millers (Figure 3-140). DOE would need to gain access to this land, which would cause a change of land use.

Montezuma alternative segment 2 would pass to the immediate west and south of the community of Goldfield, which is clustered along U.S. Highway 95. The Montezuma alternative segment 2 construction right-of-way would intersect 37 privately owned parcels with at least 20 individual landowners (0.24 square kilometer [58 acres]) (see Table 4-154 and Figure 3-140). Esmeralda County owns 12 of the 37 parcels (including 4 patented ***mining claims***), and the Nevada Department of Highways owns one parcel (while state and county entities own 13 parcels, they are non-federal lands and still considered private land in this Rail Alignment EIS). If DOE selected Montezuma alternative segment 2, DOE would gain access to portions of privately owned land, resulting in changes of land use.

The Oasis Valley alternative segment 1 construction right-of-way would cross one parcel owned by a cattle company (see Figure 3-143), impacting 0.04 square kilometer (9.9 acres) of land. DOE would need to gain access to this land, causing a change to land use.

4.3.2.2.2 American Indian Land

4.3.2.2.2.1 Walker River Paiute Reservation. There are no land-use plans for the Walker River Paiute Reservation. However, DOE developed the Schurz alternative segments in consultation with the Tribe to avoid Schurz and other populated areas on the Reservation.

While the nominal width of the construction right-of-way for most of the Mina rail alignment is 300 meters (1,000 feet), DOE has reduced the proposed width along the Schurz alternative segments to 61 meters (200 feet) to minimize disturbance to the Reservation. The construction right-of-way of the Schurz alternative segments would occupy between 3.5 and 5.3 square kilometers (850 and 1,300 acres) of land on the Reservation. This represents a very small area in relation to the entire Reservation, ranging from 0.3 and 0.5 percent of the land area. Because most of the Reservation is rangeland, the rail line could cause a small reduction of land available for grazing and farming. There would also be construction well sites located outside the construction right-of-way on Reservation land: one along Schurz alternative segments 4 and 5, or two along Schurz alternative segment 6. Each well would disturb an additional 5,800 square meters (1.4 acres) of land.

DOE developed the Schurz alternative segments to comply with the Walker River Paiute Tribe’s wish to ultimately remove the Department of Defense Branchline through Schurz, which runs directly through Schurz, where most of the Tribe resides. The Tribe based this request on safety concerns related to the current rail shipments of Army munitions through their town. Therefore, as part of the Mina rail alignment, DOE would remove the Department of Defense Branchline through Schurz once the selected Schurz alternative segment was constructed. Removal of the existing rail line would provide a perceived benefit to the town’s existing residential land uses and the remaining rail roadbed could become a recreational trail for the Walker River Paiute Tribe.

In April 2007, the Walker River Paiute Tribe Tribal Council passed a resolution removing the Tribe from the DOE EIS process and will not allow ***nuclear waste*** to be transported by rail through the Reservation.

If the Mina rail alignment was selected, DOE would seek to obtain a right-of-way across the Reservation in accordance with 25 CFR 169 (Bureau of Indian Affairs, Department of Interior, Part 169, Right of Way Over Indian Lands), the provisions of which restrict the width of new rights-of-way to 30 meters (9100 feet). Under this regulation (169.3(a)), “No right-of-way shall be granted over and across any tribal land, nor shall any permission to survey be issued with respect to any such lands, without the prior written consent of the tribe.”

4.3.2.2.2.2 Timbisha Shoshone Trust Land. During the scoping period for this Rail Alignment EIS in 2004, DOE received comments from the Western Shoshone Nation indicating that a rail line crossing Timbisha Shoshone Trust Land would be incompatible with current and planned land uses. The opposition was based, in part, on treaty issues involving land in the vicinity of the Caliente rail alignment (see Section 3.4). The Department subsequently eliminated Bonnie Claire alternative segment 1, which would have crossed onto Timbisha Shoshone Trust Land, from analysis in this Rail Alignment EIS.

4.3.2.2.3 BLM-Administered Public Land

4.3.2.2.3.1 Consistency with BLM Resource Management Plans. Some portions of the Mina rail alignment would cross federal land the BLM has identified for potential disposal (sale). The ***withdrawal*** of these lands along the rail alignment for other federal use would take precedence over potential land disposals. While this federal use would not pose a conflict with BLM ***resource management plans***, the community or public would lose the ability to use affected land for future economic or private development.

- *Carson City Field Office, Consolidated Resource Management Plan* (Carson City Consolidated Resource Management Plan; DIRS 179560-BLM 2001, all)

  The northernmost segments of the Mina rail alignment (the Union Pacific Railroad Hazen Branchline, Department of Defense Branchline North, the Schurz alternative segments, Department of Defense Branchline South, and most of Mina common segment 1) would pass through ***public lands*** covered by the Carson City Consolidated Resource Management Plan. Under that plan, future right-of-way corridors will be evaluated on a case-by-case basis, but should be as consistent as possible with the Western Regional Corridor Study and existing roads and trails should be used whenever possible during construction. The Mina rail alignment would be collocated with existing powerline rights-of-way near U.S. Highway 95 and would also generally follow the former Tonopah and Tidewater railroad route. The Mina rail alignment would not cross any right-of-way avoidance areas. Therefore, the Mina rail alignment would not conflict with Carson City Consolidated Resource Management Plan right-of-way provisions. Mina common segment 1 would intersect the western edge of land disposal areas near Mina and Sodaville. Because DOE has withdrawn the land for study and there are no active disposal actions underway, this rail segment would not conflict with the land disposal provisions of the Carson City Consolidated Resource Management Plan. New segments would cross several grazing allotments in the Carson District. Therefore, if DOE selects the Mina rail alignment, the BLM would need to adjust applicable livestock permits to reflect decreases in public land forage available in accordance with the resource management plan.

- *Tonopah Resource Management Plan and* ***Record of Decision*** (Tonopah Resource Management Plan; DIRS 173224-BLM 1997, all)

  The Tonopah Resource Management Plan designates 1,075 kilometers (668 miles) for transportation and utility corridors (DIRS 173224-BLM 1997, p. 2). It also allows rights-of-way on more than 600 square kilometers (149,000 acres) if the land use is compatible with existing land values.
  The Tonopah Resource Management Plan identifies areas for potential disposal at Coaldale Junction, Blair Junction, Silver Peak, Millers, Goldfield, Scottys Junction, and Beatty. The plan does not specifically address the portions of land released from withdrawal in 1999 adjacent to (on the western border of) the Nevada Test and Training Range. Because withdrawal for other federal use has precedence over potential land disposals, there would be no conflict with the Tonopah Resource Management Plan.

- *Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement* (Las Vegas Resource Management Plan; DIRS 176043-BLM 1998, all)

  The Las Vegas Resource Management Plan designates corridors within its planning area to avoid ***Areas of Critical Environmental Concern***. The proposed rail alignment would not pass through or near any right-of-way avoidance areas, such as Areas of Critical Environmental Concern. The portion of the rail alignment (common segment 6) that would pass through this district would be on land for which DOE already has a temporary right-of-way and is slated for future land withdrawal for the Yucca Mountain Project. Therefore, there would be no conflict with the Las Vegas Resource Management Plan.

BLM-administered lands encompassing the Mina rail alignment have been withdrawn from surface and mineral entry to avoid land-use conflicts in the near term (70 *FR* 76854, December 28, 2005). Furthermore, this withdrawal takes precedence over potential land disposals that might be planned in and around the rail alignment. Under the terms of the BLM land-disposal policy, identification of the lands for another federal purpose, such as the proposed railroad, would disqualify the land for disposal for other uses. Therefore, there would be no conflict with BLM land-use plans or policies.

4.3.2.2.3.2 Construction Impacts to BLM Grazing Allotments. Construction of the rail line and support facilities would result in surface disturbances across a number of grazing allotments. Wherever the rail line would cross a grazing allotment, DOE quantified the amount of forage loss in animal unit months.

DOE calculated potential loss of animal unit months as the proportion of land within each grazing allotment that would be crossed by the footprints of the rail line construction right-of-way and support facilities. The Department did not consider site-specific allotment characteristics. The BLM would determine actual loss of animal unit months for each affected allotment in association with the issuance of a ***right-of-way grant***. For this analysis, DOE conservatively assumed that all the area within the rail line construction right-of-way would be unavailable for forage. Section 4.3.9, Socioeconomics, describes the economic consequences of reductions in permitted animal unit months.

The presence of a rail line could require livestock on some allotments to adjust to new routes to access water and forage. Generally, livestock could learn these new routes and acclimate to and cross the rail line in most areas. The rail line could pose additional risk to ranching operations in that livestock may be struck by passing trains. DOE or the commercial operator (under the Shared-Use Option) would reimburse ranchers for such losses, as appropriate. The rail line could intersect existing fences on active grazing allotments. The BLM and DOE would review with the affected allotment permittees the need to restore fences.

The Mina rail alignment would cross one stockwater pipeline on an active grazing allotment (Mina common segment 1 crossing of the Pilot-Table Mountain Allotment) and one or more on the inactive Montezuma Allotment. During the construction phase, the Department would sleeve these pipelines within a casing pipe under the rail roadbed to protect them and keep them operational. The casing pipe would be capable of withstanding the load of the roadbed, track, and rail traffic.

There would also be a number of new construction wells on grazing allotments outside the construction right-of-way. The well footprints would be small (approximately 0.0057 square kilometer [1.4 acres] each) and would not affect grazing patterns except for the presence of human activity during the construction phase.

<u>Union Pacific Railroad Hazen Branchline and Department of Defense Branchline North</u>
DOE would use the existing rail line along the Union Pacific Railroad Hazen Branchline and the Department of Defense Branchline North. Because there would be no new construction outside of the existing right-of-way, there would be no impacts to the use of the land for grazing along these segments, although increased train traffic along these lines could increase the possibility of livestock being struck by trains.

<u>Schurz Alternative Segments</u> The Schurz alternative segments would begin within the Parker Butte Allotment (see Figure 3-146). However, most of the length of these segments would be on the Walker River Paiute Reservation. Although information on current grazing operations on the Reservation is not available, years of drought have put farming and ranching on hold (DIRS 180701-National American Indian Housing Council 2004, p. 30). Therefore, impacts to grazing land from the Schurz alternative segments would be small.

Department of Defense Branchline South DOE would use existing rail line along Department of Defense Branchline South. Because there would be no new construction outside of the existing right-of-way, there would be no impacts to the use of the land for grazing along these segments, although increased train traffic along these lines could increase the possibility of livestock being struck by trains.

Mina Common Segment 1 Mina common segment 1 would pass through three active grazing allotments (Pilot-Table Mountain, Bellville, and Monte Cristo) and one closed grazing allotment (Columbus Salt Marsh) (see Figures 3-147 and 3-148). DOE estimates that this segment could reduce animal unit months across all the active allotments by 104. Table 4-156 lists reductions in animal unit months per grazing allotment. There could be one construction well outside the Mina common segment 1 construction right-of-way that would disturb an additional 0.0057 square kilometer (1.4 acres) of land on the Columbus Salt Marsh Allotment. The land disturbance for this well would not impact grazing operations because the Columbus Salt Marsh Allotment is inactive. However, if DOE decided to leave some wells in place after the construction phase, the Department could make those wells available to ranchers in the future, which would provide additional sources of stockwater.

There are two potential quarry sites along Mina common segment 1. The potential Garfield Hills quarry would impact both the Garfield Flat and Pilot-Table Mountain Allotments, reducing their animal unit months by 4 and 1, respectively. The potential Gabbs Range quarry would impact the Pilot-Table Mountain Allotment, reducing its animal unit months by 4 (see Table 4-156).

Table 4-156. Potential loss of animal unit months associated with Mina common segment 1.

Allotment	Construction right-of-way area or impact area (square kilometers)[a]	Current animal unit months (maximum) and allotment area[b]	Potential loss of animal unit months (as a direct correlation with land area removed)	Percent loss of animal unit months
Pilot-Table Mountain	19	7,900 on 2,020 square kilometers	74	0.9
Bellville	0.90	303 on 630 square kilometers	1	0.3
Monte Cristo	6.34	9,352 on 2,010 square kilometers	29	0.3
Columbus Salt Marsh		None		
Totals	26	17,555 animal unit months	1,044	0.6
Garfield Flat (potential Garfield Hills quarry)	0.99	3,516 on 890 square kilometers	4	0.1
Pilot-Table Mountain (potential Garfield Hills quarry)	0.09	7,900 on 2,020 square kilometers	1	0.01
Pilot-Table Mountain (potential Gabbs Range quarry)	0.97	7,900 on 2,020 square kilometers	4	0.2

a. Source: Refer to Table 3-85 for source information.
b. To convert square kilometers to acres, multiply by 247.10.

Montezuma Alternative Segment 1 Montezuma alternative segment 1 would pass through the Columbus Salt Marsh, Silver Peak, Sheep Mountain, Yellow Hills, Montezuma, and Magruder Mountain Allotments (see Figures 3-149 and 3-150). All but Columbus Salt Marsh and Montezuma are active allotments. This segment would pass through the West Pasture of the Montezuma Allotment (near the Yellow Hills Allotment). At present, there is one temporary grazing permit (1 year for 600 animal unit months) for the West Pasture, but that permit will expire in March 2008. DOE estimates that this alternative segment could reduce animal unit months across all the active allotments by 117. See Table 4-157 for reductions in animal unit months per grazing allotment.

Table 4-157. Potential loss of animal unit months associated with Montezuma alternative segment 1.

Allotment	Construction right-of-way area or impact area (square kilometers)[a]	Current animal unit months (maximum) and allotment area[b]	Potential loss of animal unit months (as a direct correlation with land area removed)	Percent loss of animal unit months
Columbus Salt Marsh	23	None		
Silver Peak	8.1	436 on 1,430 square kilometers	3	0.7
Sheep Mountain	1.9	1,740 on 360 square kilometers	9	0.5
Yellow Hills	4.8	1,212 on 20 square kilometers	23	1.9
Montezuma	14	None		
Magruder Mountain	3.5	6,300 on 267.92 square kilometers	82	1.3
Totals	55	9,688 animal unit months	117	1.2
Montezuma (potential North Clayton quarry)	1.8	None		
Montezuma (potential Malpais Mesa quarry)	2.7	None		

a. Source: Refer to Table 3-85 for source information.
b. To convert square kilometers to acres, multiply by 247.10.

There are two potential quarry sites along Montezuma alternative segment 1: North Clayton and Malpais Mesa. Both would be on the inactive Montezuma Allotment and neither would have an impact on grazing operations.

Montezuma Alternative Segment 2 Montezuma alternative segment 2 would pass through the Columbus Salt Marsh, Monte Cristo, and Montezuma Allotments (see Figures 3-149 through 3-151). Only the Monte Cristo Allotment is active. DOE estimates that Montezuma alternative segment 2 could reduce animal unit months within the Monte Cristo Allotment by 47 (see Table 4-158).

There is one potential 1.5 square kilometer (360 acre) quarry site along the alternative segment, ES-7, which would be on the inactive Montezuma Allotment and would not have an affect on grazing operations.

Table 4-158. Potential loss of animal unit months associated with Montezuma alternative segment 2.

Allotment	Construction right-of-way area or impact area (square kilometers)[a]	Current animal unit months (maximum) and allotment area[b]	Potential loss of animal unit months (as a direct correlation with land area removed)	Percent loss of animal unit months
Columbus Salt Marsh	2.2	None		
Monte Cristo	10	9,352 on 2010 square kilometers	47	0.5
Montezuma	14	None		
Totals	26	9,352 animal unit months	47	0.5
Montezuma (potential ES-7 quarry)	1.5	None		

a. Source: Refer to Table 3-85 for source information.
b. To convert square kilometers to acres, multiply by 247.10.

Montezuma Alternative Segment 3 Montezuma alternative segment 3 would pass through the Columbus Salt Marsh, Monte Cristo, Montezuma, and Magruder Mountain Allotments (see Figures 3-149 through 3-151). Only the Monte Cristo and Magruder Mountain Allotment are active. This segment would pass through the West Pasture of the Montezuma Allotment (near the Yellow Hills Allotment). At present, there is one temporary grazing permit (1 year for 600 animal unit months) for the West Pasture, but that permit will expire in March 2008. DOE estimates that this alternative segment could reduce animal unit months in the affected grazing allotments by 129 (see Table 4-159).

Table 4-159. Potential loss of animal unit months associated with Montezuma alternative segment 3.

Allotment	Construction right-of-way area or impact area (square kilometers)[a]	Current animal unit months (maximum) and allotment area[b]	Potential loss of animal unit months (as a direct correlation with land area removed)	Percent loss of animal unit months
Columbus Salt Marsh	2.2	None		
Monte Cristo	10	9,352 on 2,010 square kilometers	47	0.5
Montezuma	26	None		
Magruder Mountain	3.5	6,300 on 270 square kilometers	82	1.3
Totals	42	15,652 animal unit months	129	0.8
Montezuma (potential North Clayton quarry)	1.8	None		
Montezuma (potential Malpais Mesa quarry)	2.7	None		

a. Source: Refer to Table 3-85 for source information.
b. To convert square kilometers to acres, multiply by 247.10.

There are two potential quarry sites along the Montezuma alternative segment 3: North Clayton and Malpais Mesa. Both would be on the inactive Montezuma Allotment and neither would have an impact on grazing operations.

Mina Common Segment 2 Mina common segment 2 would cross a narrow stretch of the inactive Montezuma Allotment west of the Nevada Test and Training Range and east of the Magruder Mountain Allotment (see Figure 3-151). Because the Montezuma Allotment is inactive, there would be no impacts to grazing activities or stockwater resources during rail line construction along this segment.

Bonnie Claire Alternative Segments The Bonnie Claire alternative segments would cross a narrow stretch of the inactive Montezuma Allotment west of the Nevada Test and Training Range and east of the Magruder Mountain Allotment (see Figure 3-151). Because the Montezuma Allotment is inactive, there would be no impacts to grazing activities or stockwater resources during rail line construction along either of the Bonnie Claire alternative segments.

Common Segment 5 (Sarcobatus Flat Area) Common segment 5 would pass through the southern portion of the inactive Montezuma Allotment near the southwestern boundary of the Nevada Test and Training Range (see Figures 3-151 and 3-152). Because the Montezuma Allotment is inactive, rail line construction along common segment 5 would not impact grazing activities or stockwater resources.

Oasis Valley Alternative Segments The Oasis Valley alternative segments would cross the inactive Montezuma Allotment and the active Razorback Allotment (see Figure 3-152). The Razorback Allotment has one permittee. Oasis Valley alternative segment 1 would pass near the northeastern corner of the small Springdale 2 Allotment, but the construction right-of-way would not fall within the allotment. There are no stockwater features within the construction right-of-way of either of the Oasis Valley alternative segments.

Oasis Valley alternative segments 1 and 3 could result in the loss of 8 or 13 animal unit months, respectively, within the Razorback Allotment (see Table 4-160).

Table 4-160. Potential loss of animal unit months associated with the Oasis Valley alternative segments.

Alternative segment/allotment	Construction right-of-way area or impact area (square kilometers)[a]	Current animal unit months (maximum) and allotment area[b]	Potential loss of animal unit months (as a direct correlation with land area removed)	Percent loss of animal unit months
Oasis Valley 1 – Razorback	2.3	959 animal unit months on 290 square kilometers	8	0.8
Oasis Valley 3 – Razorback	3.8	959 animal unit months on 290 square kilometers	13	1.4

a. Source: DIRS 173224-BLM 1997, p. A-14.
b. To convert square kilometers to acres, multiply by 247.10.

Common Segment 6 (Yucca Mountain Approach) Common segment 6 would cross a corner of the inactive Montezuma Allotment near the beginning of the common segment. At present, there are no permittees on this allotment (DIRS 176942-Metscher 2006, all). Common segment 6 would also pass through the Razorback Allotment (see Figure 3-152) and encompass approximately 5.3 square kilometers (1,300 acres) of the allotment. This would correspond to a potential loss of 18 animal unit months (1.9 percent loss of the grazing allotment) (see Table 4-161).

Table 4-161. Potential loss of animal unit months associated with common segment 6.

Allotment	Construction right-of-way area or impact area (square kilometers)[a,b]	Current animal unit months (maximum) and allotment area	Potential loss of animal unit months (as a direct correlation with land area removed)	Percent loss of animal unit months
Razorback	5.3	959 animal unit months on 290 square kilometers	18	1.9

a. Source: DIRS 173224-BLM 1997, p. A-14.
b. To convert square kilometers to acres, multiply by 247.10.

4.3.2.2.4 Department of Defense-Managed Land

The Mina rail alignment would use portions of the existing Department of Defense Branchlines and DOE would construct a new rail line across the Hawthorne Army Depot (Mina common segment 1). The Staging Yard would also be on the Depot. All new construction would occur within the active military area, near existing rail lines. The Army has concurred with the proposed location of the Mina rail line and facilities. One land-use compatibility concern would be meeting the Explosive Quantity Safety Distance between the ammunition storage areas and Army rail line to the planned Staging Yard, which would be occupied by personnel. Section 4.3.10, Occupational and Public Health and Safety, addresses these safety aspects.

The Department of Defense provided comments during the first scoping period for this Rail Alignment EIS in 2004, which resulted in DOE modifying Bonnie Claire alternative segment 2 and proposing Bonnie Claire alternative segment 3 as a new alternative segment to avoid crossing the Nevada Test and Training Range. These rail segment changes were carried through for the Mina rail alignment when it was added as an alternative. Specifically, the Air Force commented that the earlier proposed rail segments were "within the weapons safety footprint for test and training munitions" and that the rail line would "impinge on Range testing and training activities."

The closest segment to the Range would be Bonnie Claire alternative segment 2, the centerline of which would be approximately 100 meters (330 feet) from the Range boundary. The construction right-of-way for this segment has been reduced to specifically avoid entering Range land. Other segments closest to the Range and the distances of the edge of the construction right-of-way from the boundary include Montezuma alternative segment 2 (200 meters [660 feet]), common segment 5 (560 meters [1,800 feet]), and Oasis Valley alternative segment 3 (280 meters [920 feet]). While the Mina rail alignment would not directly affect land use on the Nevada Test and Training Range, portions of the Bonnie Claire alternative segment 2 and common segment 5 would cross land formerly within the western border of the Range. The land released by the Range now falls under the BLM Tonopah planning area. Portions of the rail line (common segment 5 and common segment 6) would be beneath restricted air space associated with the Range. However, testing and training activities within the restricted air spaces would generally not exceed the western boundary of the range and the Department of Defense would institute controls so that activities within related air spaces would not pose harm to the rail line. The proposed railroad would not interfere with Range activities and would not conflict with the Range's Resource and Management Plan.

4.3.2.2.5 DOE-Managed Land

The Rail Equipment Maintenance Yard, Cask Maintenance Facility, and a portion of common segment 6 would be within the Yucca Mountain Site boundary. These proposed maintenance facilities would be on land that is currently part of the Nevada Test Site, and used for Yucca Mountain Project characterization. Because the proposed railroad project would proceed only after control of the proposed Yucca Mountain Site was transferred to DOE, the Rail Equipment Maintenance Yard and Cask Maintenance Facility and portions of common segment 6 proposed within the Yucca Mountain Site boundary would not conflict with future land uses on the Nevada Test Site.

4.3.2.2.6 Construction Impacts to Mineral and Energy Resources (Public and Private Land)

Because of the relatively high mineral and energy potential of lands along the Mina rail alignment, DOE evaluated the potential impacts to these resources. Rail line construction would require that DOE gain access to lands that contain patented or ***unpatented mining claims*** or have active energy leases (oil, gas, or geothermal). Rail line construction would also require substantial quantities of ballast and subballast that would be obtained from existing or new quarry and ***borrow sites*** (see Sections 2.2.2.3.2 and 2.2.2.3.3). Section 4.2.11, Utilities, Energy, and Materials, describes the impact of the removal of material from the proposed quarries and ballast sites on regional material availability.

The land encompassing the Mina rail corridor was withdrawn through a ***public land order*** (see Chapter 1) from surface and mineral entry through December 2015 so DOE could evaluate the land for the possible location of a rail line. If the BLM granted DOE a right-of-way for the rail line before the public land orders expire, then surface and mineral entry prohibitions would be removed from lands not part of the right-of-way. Therefore, the BLM could issue new unpatented mining claims and energy leases on lands near the rail line during the construction and operations phases of the project. While the presence of the line would not necessarily preclude non-surface resource extraction activities, the applicant would be required to work closely with the BLM and DOE to ensure they would not interfere with the safe operation of the railroad. Engineering solutions for the safe extraction of mineral and energy resources near or beneath the rail line could include directional (lateral) drilling of wells or ensuring all mining shafts or tunnels were sufficiently deep and reinforced to prevent subsidence.

4.3.2.2.6.1 Union Pacific Railroad Hazen Branchline and Department of Defense Branchline North. DOE would use the existing rail line along the Union Pacific Railroad Hazen Branchline and the Department of Defense Branchline North. Because there would be no new construction outside of the existing right-of-way, there would be no land-use impacts to mineral or energy resources along these segments.

4.3.2.2.6.2 Schurz Alternative Segments. The Schurz alternative segments would cross one or more mining districts. However, none of the districts (Calico Hills, Double Springs Marsh, Buckley, Benway, or Holy Cross) have active mining operations (see Figure 3-155). There are no patented or unpatented mining claims within the construction right-of-way of these segments. There are also no active geothermal, oil, or gas leases near the Schurz alternative segments. Therefore, there would be no land-use impacts to mineral or energy resources along these segments.

4.3.2.2.6.3 Department of Defense Branchline South. DOE would use the existing rail line along the Department of Defense Branchline South. Because there would be no new construction outside of the existing right-of-way, there would be no land-use impacts to mineral or energy resources along this segment.

4.3.2.2.6.4 Mina Common Segment 1. Mina common segment 1 would cross six mining districts, although only two of these have active mining or claims that would be impacted by the rail line (see Figures 3-156 through 3-158). The segment would bisect active mining claims in the New York Canyon area east of Luning and cross the Redlich claim block in the northern part of the Rock Hill District. Overall, the Mina common segment 1 construction right-of-way would intersect 20 sections that contain up to 388 unpatented mining claims. Because data on unpatented mining claims are provided by Township and Range Section, the actual number of mining claims within the construction right-of-way would likely be much less. DOE would negotiate surface rights across affected unpatented mining claims with the claim holders.

There are no active oil and gas leases within Mina common segment 1 construction right-of-way. However, it would cross the northeastern-most section of a geothermal lease block (Figure 3-157).

4.3.2.2.6.5 Montezuma Alternative Segments.

Montezuma Alternative Segment 1 Montezuma alternative segment 1 would cross the southwestern portion of Silver Peak Marsh Mining District where production of lithium is ongoing. This alternative segment would cross the Montezuma Mining District but would not intersect historically mined areas near Montezuma, Nevada. It would also cross the northeastern portion of the Cuprite Mining District where there is evidence of recent mining claims and trenching and drilling. Although there are no patented mining claims within the construction right-of-way, there are 17 sections containing up to 202 unpatented mining claims that intersect the construction right-of-way. These include one section southwest of the Alum Mining District; four sections on the western edge of the Silver Peak Marsh Mining District; seven sections south of the Montezuma Mining District; and five sections along U.S. Highway 95 near the Cuprite Mining District. Montezuma alternative segment 1 would cross several geothermal leases near the Alum Mining District and Silver Peak Marsh Mining District (see Figure 3-158).

Montezuma Alternative Segment 2 Montezuma alternative segment 2 would cross the Goldfield and Stonewall Mining Districts. Most of the mining in the Goldfield district occurs to the east of Montezuma alternative segment 2, although the segment's construction right-of-way would intersect four patented mining claims within the district. At present, there is exploration in the Stonewall Mining District 5 kilometers (3 miles) east of the alternative segment. The construction right-of-way would intersect 24 sections containing up to 655 unpatented mining claims. Two of the sections are approximately 10 kilometers (6 miles) east-northeast of Blair Junction. Four sections are approximately 6 to 8 kilometers (4 to 5 miles) north of Goldfield, and one section is to the west of the Stonewall Mining District. There are no geothermal or energy leases along this alternative segment, although there are geothermal occurrences near the segment in the vicinity of Ralston (see Figure 3-159).

Montezuma Alternative Segment 3 Montezuma alternative segment 3 would cross the Montezuma and Cuprite Mining Districts. The segment would be well north of historically mined areas near Montezuma, Nevada. It would also cross the northeastern portion of the Cuprite Mining District where there is evidence of recent mining claims and trenching and drilling. There are 19 sections containing up to 249 unpatented mining claims that would intersect the construction right-of-way. These include two sections south of the Gilbert Mining District along U.S. Highway 6; four sections approximately 8 kilometers north of Goldfield; one section within the northern portion of the Montezuma Mining District; seven sections south of the Montezuma Mining District; and five sections along U.S. Highway 95 near the Cuprite Mining District. There are no geothermal or energy leases along this alternative segment, although there are geothermal occurrences near the segment in the vicinity of Ralston (see Figure 3-159).

DOE would negotiate surface rights across affected unpatented mining claims with the claim holders and surface rights across geothermal lease areas with lease holders.

There are three underground mines or tunnels/shafts within the Montezuma alternative segments construction rights-of-way (see Figures 3-158 and 3-159). There is one underground mine near Millers along Montezuma alternative segments 2 and 3. There is one tunnel/shaft near Goldfield along Montezuma alternative segment 2 and one tunnel/shaft on the southern end of the Montezuma Mining District along Montezuma alternative segments 1 and 3. As discussed in Chapter 2, DOE would conduct further investigations, including drilling ***boreholes***, the use of ground penetrating radar or seismic analysis, to determine the extent of nearby underground features. The Department would then develop appropriate engineered solutions to address underground features.

4.3.2.2.6.6 Bonnie Claire Alternative Segments. The Wagner Mining District would lie between the two Bonnie Claire alternative segments, just to the west of Bonnie Claire alternative segment 3 (see Figure 3-160). There are patented mining claims in this district, but they would all be outside the construction right-of-way of each segment. There are no geothermal or oil and gas leases within the construction right-of-way of either segment. Therefore, there would be no direct impacts to mining or energy resource extraction along either alternative segment. Section 4.3.2.2.7.5 describes potential impacts associated with road access to the patented mining claims in the Wagner Mining District.

4.3.2.2.6.7 Common Segment 5 (Sarcobatus Flat Area). The southwestern portion of the Clarkdale Mining District would be approximately 0.8 kilometer (0.5 mile) northeast of common segment 5, outside the construction right-of-way (see Figure 3-160). Almost two-thirds of the Clarkdale Mining District is on the Nevada Test and Training Range, and the historically mined areas of the district are far enough away from common segment 5 that there would be no impacts to mining activities as a result of rail line construction (DIRS 173841-Shannon & Wilson 2005, pp. 50 to 52).

There are geothermal resources along U.S. Highway 95 in Sarcobatus Valley, but none would be within the rail line construction right-of-way. There is one warm spring that would be approximately 0.8 kilometer (0.5 mile) northeast of common segment 5, and a hot well that would be approximately 0.4 kilometer (0.25 mile) northeast (DIRS 173841-Shannon & Wilson 2005, p. 50). There are no identified uses of these geothermal resources, and they would be far enough away from common segment 5 that they would not be affected by the rail line. The common segment 5 construction right-of-way would not cross any oil or gas lease areas.

4.3.2.2.6.8 Oasis Valley Alternative Segments. The Oasis Valley alternative segments would intersect two sections containing 14 unpatented mining claims (DIRS 173841-Shannon & Wilson 2005, pp. 48 and 49); DOE would negotiate surface rights across affected unpatented mining claims with the claim holders for either alternative segment. There are oil and gas leases north of Beatty along the southwest flank of Pahute Mesa in southern Nye County (see Figure 3-161). Oasis Valley alternative segments 1 and 3 would cross portions of this oil and gas lease block (DIRS 173837-Sweeney 2005, pp. 49 and 50). At present, the lease is not in production, and records show that there has been no exploration in these areas since the 1970s. Therefore, the Oasis Valley alternative segments would not affect ongoing operations associated with this oil and gas lease.

4.3.2.2.6.9 Common Segment 6 (Yucca Mountain Approach). Common segment 6 would cross the northern section of the Bare Mountain Mining District (see Figure 3-161). Most past mining activity in the district occurred more than 3 kilometers (2 miles) south of the common segment (see Figure 3-153). There are recently active gold mining operations within the district, approximately 6 to 8 kilometers (4 to 5 miles) from common segment 6. The Silicon Mine and Thompson Quicksilver Mine would be north of common segment 6. The Silicon Mine would be approximately 800 meters (2,500 feet) and the Thompson Quicksilver Mine would be approximately 1,400 meters (4,500 feet) outside the construction right-of-way. Recent mining activity in these areas would be outside the rail line construction right-of-way, and would not be directly affected by common segment 6. The common segment 6 construction right-of-way would intersect four sections containing 34 unpatented mining claims. DOE would negotiate the surface rights across unpatented mining claims with the claim holders. There are no energy leases (oil, gas, or geothermal) within the common segment 6 construction right-of-way.

4.3.2.2.7 Construction Impacts to Recreation and Access (Public and Private Lands)

DOE developed the Mina rail alignment alternative segments and common segments to avoid crossing sensitive areas, such as Wilderness Areas, ***Wilderness Study Areas***, state and national forests and parks, and other prominent recreational and scenic areas. DOE would maintain access for all existing roads the rail line would cross at or near their current location by constructing ***at-grade crossings*** (the road and the rail line would cross paths at the same elevation) or ***grade-separated crossings*** (the road and the rail line would cross paths via an overpass or an underpass), as appropriate, resulting in no long-term adverse impacts to traffic patterns and land access. However, there could be temporary small impacts to access to these areas during rail line construction due to temporary road closures and detours.

At locations where there would be several road crossings close to one another (generally over a distance of 0.8 kilometer [0.5 mile] or less), there could be some minor rerouting and consolidation of crossings but those would not prevent crossing the rail line. The regulatory authority to make decisions regarding roads, road closures, and rail line crossings rests with the BLM and county and local governments. DOE would work in close consultation with these groups to ensure access would be maintained.

Although many undeveloped recreation opportunities exist over much of the public lands surrounding the rail alignment (such as off-highway vehicle use and dispersed hunting), descriptions of potential impacts in Sections 4.2.2.2.7.1 through 4.2.2.2.7.3 are limited to defined recreation areas. While impacts to non-designated recreation areas are not specifically addressed, individuals might have to alter their access routes to particular recreation areas near the rail line. Construction of the rail line might also cause some dispersed recreationists (such as hunters) who use non-designated areas nearby to temporarily relocate. Future Special Recreation Permits issued by applicable BLM offices would take the presence of the rail line into consideration to minimize impacts to both the applicant and the construction and operation of the railroad. Most organized off-highway vehicle events with previously approved race routes are on existing roads and trails, and access across the rail line for these events would not be compromised. However, some previously permitted routes that the rail line would cross might need to alter their crossing locations in areas where crossing are consolidated.

4.3.2.2.7.1 Churchill County. DOE would use existing rail line along the rail segments in Churchill County. Therefore, there would be no impacts to recreation or access along segments in this county.

4.3.2.2.7.2 Lyon County. DOE would use existing rail line along the rail segments in Lyon County. Therefore, there would be no impacts to recreation or access along segments in this county.

4.3.2.2.7.3 Walker River Paiute Reservation. Common and alternative segments crossing through the Walker River Paiute Reservation would intersect a number of roads that provide access to nearby tribal and private lands.

DOE would remove the Department of Defense Branchline through Schurz, and DOE would transfer ownership of the rail roadbed and remaining structures to the Walker River Paiute Tribe. The Tribe would then have the option to convert the railbed to a recreational trail, potentially resulting in a positive impact to recreation on the Reservation. DOE would remove the ties, track, and ballast under the Mina Implementing Alternative.

The Weber Reservoir on the Walker River, which the Walker River Paiute Tribe manages, lies west of the Schurz alternative segments. Access to the reservoir is primarily via a light duty road that runs west-east between Alternate U.S. Highway 95 and U.S. Highway 95. Schurz alternative segments 1 and 4 would intersect this road east of the reservoir. If DOE selected either of these alternative segments, the Department would maintain access to the reservoir from U.S. Highway 95 with an at-grade-crossing of the rail line; access to the reservoir via this unpaved Reservation road from Alternate U.S. Highway 95 would not be affected.

In addition to U.S. Highway 95, which would intersect all of the alternative segments, the Schurz alternative segments would intersect a number of smaller roads and trails (see Figure 3164 and Table 3-89).

There are a number of private properties west of the alternative segments along the Walker River. Because these parcels would lie between the Schurz alternative segments and U.S. Highway 95, access to these areas would not be affected. There are no patented or unpatented mining claims and no active energy leases near any of the Schurz alternative segments.

4.3.2.2.7.4 Mineral County. Common and alternative segments crossing through Mineral County would intersect a number of roads that provide access to nearby public and private lands.

Recreational use along the rail alignment region of influence in Mineral County is generally dispersed, and DOE would maintain access across the rail line to recreation areas. However, access to the dispersed recreation areas east of Walker Lake and east of Mina, Nevada, could be temporarily affected due to construction of Mina common segment 1 at intersections with primary access roads and rail line construction through the extreme western portion of the recreation area near Mina. No impacts to the Gabbs Valley Range Wilderness Study Area or other recreation areas in Mineral County would occur.

The portion of Mina common segment 1 located in Mineral County would intersect a number of roads and trails (see Figures 3-165 through 3-197, and Table 3-89). Because this portion of Mina common segment 1 would essentially follow the route of U.S. Highway 95, there could be small impacts to private-land access east of the rail line during the construction phase. At the intersection of common segment 1 and State Route 361, which provides access to the unimproved roads to the Gabbs Valley Range Wilderness Study Area and several private parcels north of the common segment, a grade-separated crossing would be used to maintain access. Private parcels accessed via roads from U.S. Highway 95 that would be bisected by Mina common segment 1 include an area east of Hawthorne, Nevada, and another east of Mina. Additional private property along the common segment would be located west of U.S. Highway 95; therefore, access would not be affected.

Of the two actively mined claims Mina common segment 1 would bisect, the common segment would only intersect the primary access to the New York Canyon mine.

4.3.2.2.7.5 Nye County. Rail line common and alternative segments crossing through Nye County would intersect a number of roads that provide access to nearby public and private lands. There are no designated recreation areas in the immediate vicinity of rail segments in Nye County.

Bonnie Claire 2 and 3 and Mina common segment 2 would cross a limited number of roads and trails (see Figure 3-169 and Table 3-89). There is no active grazing of the land surrounding these segments. However, there are patented mining claims east of Bonnie Claire alternative segment 3 and west of Bonnie Claire alternative segment 2 (within the Wagner Mining District) (see Figure 3-169). If DOE selected Bonnie Claire alternative segment 3, the rail line would cross one access road to these mining claims.

There are more than a dozen privately owned properties that would be west of common segment 5 clustered at Scottys Junction. These properties lie on either side of U.S. Highway 95. Because the rail line would be to the east of these properties and not interfere with access from U.S. Highway 95, it would not impact access to land near Scottys Junction. Common segment 5 would cross one road that provides primary access from U.S. Highway 95 to oil and gas leases that would be north of the rail line and provides access to the Nevada Test and Training Range. DOE proposes an active at-grade crossing for this location (DIRS 176165-Nevada Rail Partners 2006, pp. D-1 and D-2).

Each of the Oasis Valley alternative segments would cross three roads (see Figure 3-170). Roads in this area provide access to private property owned by a cattle company; the northern portion of the Razorback Allotment; oil and gas leases; and the Nevada Test and Training Range. Oasis Valley alternative segment 3 would pose minimal restriction to road access from U.S. Highway 95 to the oil and gas leases and privately owned land, and access within the Razorback Allotment because it would be farthest away from these established areas.

Common segment 6 would cross roads that provide access to the Nevada Test and Training Range and the northern portion of the Razorback Allotment (see Figure 3-170). The only privately owned properties in the vicinity of common segment 6 are west of the rail alignment at its northernmost point. These properties are adjacent to U.S. Highway 95 and the rail line would not impact access thereto.

4.3.2.2.7.6 Esmeralda County. Rail line common and alternative segments crossing through Esmeralda County would intersect a number of roads that provide access to nearby public and private lands.

Recreation along the proposed rail alignment in Esmeralda County is generally dispersed, and there are no developed BLM recreation areas within the region of influence. Mina common segment 1 would cross a small portion of the proposed site for the Monte Cristo State Park directly adjacent to U.S. Highways 95 and 96. The common segment would not approach the geologic features cited by park proponents as the basis for designation, because it would not enter the Monte Cristo Range, and thus would not affect the area or its unique attributes. Additionally, the common segment would not cross the existing access road to the area. There would be no impacts to the Silver Peak Wilderness Study Area, Clayton Valley Special Recreation Management Area, or other designated recreation features in Esmeralda County.

Private property along Mina common segment 1 would be primarily located west of U.S. Highway 95; and therefore, access to these areas would not be affected.

In addition to U.S. Highway 95 (grade-separated crossing), the Montezuma alternative segments would cross a number of roads and trails (see Figures 3-167 and 3-168, and Table 3-89).

Access to private land near Montezuma, Nevada, from Silver Peak Road is via Montezuma Wells Road, which Montezuma alternative segment 1 would cross twice; access to private land north of Silver Peak from State Route 265 is via Paymaster Canyon Road, which the alternative segment would cross once. Montezuma alternative segment 1 would intersect Silver Peak Road, the primary access to the active lithium mining area near Silver Peak, but DOE would maintain access with a passive road crossing. The alternative segment would also bisect East Railroad Springs Road and several unnamed off-road vehicle trails, which provide access from U.S. Highway 95 to areas of the Montezuma Range and Goldfield Hills that contain numerous unpatented mining claims (see Figure 3-168).

Montezuma alternative segment 2 would cross through or near numerous unpatented and patented mining claims, resulting in small temporary impacts to access during rail line construction. Access to claims near Goldfield is from U.S. Highway 95 and Silver Peak Road via a series of unpaved roads and off-road vehicle trails. The alternative segment would intersect Silver Peak Road (at-grade passive crossing) and a number of minor roads and off-road vehicle trails in this area (see Figure 3-168). Montezuma alternative segment 2 would also intersect additional roads and trails that provide access from U.S. Highway 95 to the active ***mining areas*** near Stonewall Flats (see Figure 3-168).

Access to private parcels near Montezuma alternative segment 2 in Goldfield and Millers, Nevada, could experience temporary impacts during rail line construction. Access to the private parcels near Millers from U.S. Highway 95 is via two unnamed roads, both of which would intersect the alternative segment; access to private parcels just west of U.S. Highway 95 in Goldfield is via several roads and off-road vehicle trails that would intersect the segment.

Montezuma alternative segment 3 would bisect East Railroad Springs Road and several unnamed jeep trails that provide access from U.S. Highway 95 to areas of the Montezuma Range and Goldfield Hills containing unpatented mining claims. Access to private parcels near Montezuma alternative segment 3 in the historic towns of Millers and Montezuma could suffer temporary small impacts due to rail line construction where the alternative segment and primary access roads intersect. Access to private parcels near Millers is from U.S. Highway 95 via two unnamed roads; access to private land near the town of Montezuma from Silver Peak Road is via Montezuma Wells Road.

4.3.2.2.8 Land-Use Conflicts with Utility Corridors and Rights-of-Way

Where the rail line would cross an existing utility right-of-way, DOE would take precautions to minimize disturbance and disruption of the utilities. Section 4.3.11, Utilities, Energy, and Materials, describes measures the Department would implement to protect existing utilities.

Of the 367 kilometers (228 miles) of new rail line proposed under the longest possible alignment, 161 kilometers (100 miles), or 44 percent, would fall within corridors designated by applicable resource management plans (this does not include use of existing rail line or rail line through the Walker River Paiute Reservation). However, the resource management plans allow for transportation rights-of-way outside these designated corridors if no other option is feasible and the right-of-way would not substantially conflict with other land-use goals and designations. No parts of the rail line common segments or alternative segments would cross right-of-way avoidance areas. DOE would perform field verifications of utility right-of-way locations and would incorporate the information into the final rail line design.

Because final engineering design for utility connections is still underway, the exact tie-in locations for electricity along the rail alignment are unknown. While it is expected that transmission lines could be tapped where they currently cross the rail line, there is a possibility that the project could require additional utility rights-of-way for small feeder lines.

4.3.2.3 Operations Impacts

Land-use and ownership impacts would occur before or during the railroad construction phase. The operations right-of-way would be generally narrower than the construction right-of-way along most of the rail alignment, and some of the land could therefore be returned to its previous uses.

Topics related to the quality-of-life aspects of land use include visual quality, air quality, and noise and vibration, as described in other sections of this Rail Alignment EIS (see Section 4.3.3, Aesthetic Resources; Section 4.3.4, Air Quality and Climate; and Section 4.3.8, Noise and Vibration).

Railroad operations could affect the use of grazing land. For example, the presence of a rail line could require livestock on some allotments to adjust to new routes to access water and forage. Generally, livestock could learn these new routes after construction of the rail line was complete. The noise and presence of people along the rail alignment during construction activities could cause livestock to avoid nearby areas at first, although they could become accustomed to the presence of people over time (DIRS 176920-Metscher 2005, p. 4).

Nevada is an open-range state, where it is the responsibility of private landowners to fence their properties to prevent livestock from damaging their property and where ranchers could be compensated for the loss of their livestock killed by vehicles and trains. If DOE trains struck and killed livestock, DOE or the commercial carrier (under the Shared-Use Option) would reimburse ranchers for such losses, as appropriate.

As discussed in 4.3.2.2.6, the BLM could issue new unpatented mining claims and energy leases on lands near the rail line during the construction and operations phases. While the presence of the rail line would not necessarily preclude non-surface resource extraction activities, the applicant would be required to work closely with the BLM and DOE to ensure they would not interfere with the safe operation of the railroad. Engineering solutions for the safe extraction of mineral and energy resources near or beneath the rail line could include directional (lateral) drilling of wells or ensuring all mining shafts or tunnels were sufficiently deep and reinforced to prevent subsidence.

The parallel rail alignment access roads (unpaved) could improve land access along most of the rail alignment. While most of the rail alignment would follow or be within a few kilometers of existing unpaved roads and trails that are currently open for public use, the new access roads could be of better quality in some areas than nearby existing roads, increasing the likelihood of use. Off-road vehicle use, hunting intensity, and other recreational activities could increase along the rail alignment access roads. Improved human and vehicle access to surrounding areas could result in indirect impacts to vegetation and wildlife, as described in Section 4.3.7, Biological Resources. Recreational use of public land along the access roads (as with other similar roads on public land) would be monitored by the BLM to ensure compliance with its land management goals, as stated in applicable BLM resource management plans. It is important to note that DOE would not maintain the access roads as public roads, except in locations where they would be used for rerouting to consolidate rail line crossings, and the Department would post signs indicating potential users would proceed on the roads at their own risk.

Lastly, future Special Recreation Permits issued by applicable BLM offices would take the presence of the rail line into consideration to minimize impacts to both the applicant and operation of the rail line. This may require new routes to minimize or avoid crossing the rail line and greater manpower to implement and monitor these new routes during recreation events.

4.3.2.4 Impacts under the Shared-Use Option

Impacts to land use and ownership under the Shared-Use Option would be similar to those described for the Proposed Action without shared use, with a small addition of impacts from the construction and operation of commercial sidings. Under the Shared-Use Option, commercial trains would haul a range of products to and from businesses, including stone and other nonmetallic minerals, oil and petroleum products, and nonradioactive waste materials (see Section 2.2.6.3). DOE cannot predict the exact locations of these possible commercial-use sidings, but locations could include Luning, Mina, the Goldfield area, Silver Peak, and the Beatty/Oasis Valley area. The sidings would likely be constructed within the operations right-of-way; if so, there would be no additional impacts to land use and ownership (see Figure 2-55). Because only approximately 0.5 percent (approximately 0.5 square kilometer [121 acres]) of land within the rail line construction right-of-way is privately owned, any commercial sidings or commercial facilities that would be outside the construction right-of-way would likely be on BLM-administered land, and implemented under a separate BLM-issued right-of-way.

Implementation of the Shared-Use Option could facilitate the expansion or introduction of industrial (mining) or commercial operations in the region. This could have future, ***long-term impacts*** on land use, such as new or revised land-use zoning plans to accommodate industrial and commercial land uses in the vicinity of the rail line. The expansion of industrial or commercial activity from shared use of the rail line could also indirectly result in land-use changes in relation to additional residential development. Increased rail traffic could also increase the likelihood of livestock mortality along the rail line within active grazing allotments.

4.3.2.5 Summary

The Mina rail alignment construction right-of-way would occupy between 102 and 125 square kilometers (25,200 to 30,900 acres) of land. Most of this would be public land, although DOE would need to gain access to up to 0.5 square kilometer (121 acres) of private land along the rail alignment. This amount of private land would be very small (about 0.5 percent) compared to the total amount of land that would be required for the project. The Mina rail alignment would not displace existing or planned land uses over a substantial area, nor would it substantially conflict with applicable land-use plans or goals. The area with the highest density of private land the rail alignment would cross is Goldfield (Montezuma alternative segment 2). These lands include private yet vacant land, including patented mining claims and state and county land.

The Schurz alternative segments would cross the Walker River Paiute Reservation, utilizing between 0.3 and 0.5 percent of the Reservation's land (up to 5.3 square kilometers [1,300 acres]), depending on segment. At present, the Walker River Paiute Tribe does not support routes over their Reservation and their concurrence would be necessary to secure a right-of-way for the rail line. Under the Mina Implementing Alternative, DOE would remove existing Department of Defense rail line through Schurz, providing a perceived benefit to the town's existing residential land uses; the Tribe could also use the existing roadbed as a recreational trail. DOE developed the Bonnie Claire alternative segments to avoid American Indian lands. The closest segment, common segment 5, would be approximately 3 kilometers (2 miles) east of the Timbisha Shoshone Trust Land.

The Mina rail alignment would use up to 113.3 square kilometers (28,000 acres) of BLM-administered land. Some of the rail line segments would pass through lands the BLM has identified for potential disposal (sale). However, the land withdrawals already in place for the rail alignment and the potential use by another federal agency would take precedence over disposal actions that could affect the project.

The Mina rail alignment would cross 4.6 square kilometers (1,145 acres) of land within the Hawthorne Army Depot near its northern border where it would not pose a conflict with the base's mission or land uses.

Where the rail segments and facilities would cross active grazing allotments on BLM-administered land, some grazing land would be lost. Because the land would be restored after the construction phase and the operations right-of-way would be smaller than the construction right-of-way, long-term impacts to grazing allotments would be small. In total, the Mina rail alignment would result in less than a 2-percent loss of animal unit months across all affected allotments. The presence of a rail line could require livestock on some allotments to adjust to new routes to access water and forage. Generally, livestock could learn these new routes and acclimate to and cross the rail line in most areas. The rail line could affect ranching operations because livestock could be struck by passing trains. DOE or the railroad's commercial operator (under the Shared-Use Option) would reimburse ranchers for such losses, as appropriate. DOE would consult with the BLM during the final design phase to determine if any of the rail line would need to be fenced.

Construction wells located on grazing allotments outside the construction right-of-way would have small and temporary impacts in terms of loss of grazing area. Once each well was drilled, DOE would reclaim the site in accordance with DOE and BLM requirements. The Department would construct a 10- to 15-centimeter (4- to 6-inch)-diameter temporary pipeline on top of the ground along access roads to transport water to the construction right-of-way. Wells not needed for railroad operations would be properly abandoned in compliance with State of Nevada regulations and sites and access roads would be reclaimed (DIRS 176172-Nevada Rail Partners 2006, p. 4-12).

Most of the local mining activity would be outside the rail line construction right-of-way. DOE would need to negotiate the surface rights to cross the few affected unpatented mining claims the rail line would cross. The Mina rail alignment would cross potentially up to half the number of unpatented mining claims than the Caliente rail alignment. Mina common segment 1 would cross sections with 388 unpatented mining claims and the Montezuma alternative segments would cross sections with 202 and

655 unpatented mining claims. The rail line could be affected by or affect underground mining tunnels or shafts. During the final engineering design phase of the project, DOE would perform a survey to verify the locations of tunnels and shafts to avoid adverse impacts.

DOE developed the Mina rail alignment to avoid Wilderness Areas and other scenic and recreational areas. Road crossings would be constructed to prevent the rail line from obstructing access to private and public land. While there could be temporary road closures or detours during the rail line construction phase, there would be no impact to land access during the operations phase. In addition, organized off-highway vehicle events permitted in the past by BLM might need to alter their routes to avoid the rail line.

Depending on the alternative segments selected, the rail line would cross between 22 and 29 known utility lines. DOE would negotiate crossing agreements with the right-of-way holders and the BLM to determine the duration of use, access needs, mitigation, and compensation, as applicable. DOE would protect existing utilities from damage so that disruption to utility service or damage to lines would be at most small and temporary. The project would require a new BLM right-of-way outside the existing planning corridors, which would be outside of right-of-way avoidance areas. Under the longest potential route, approximately 40 percent of the Mina rail alignment would fall within existing BLM planning corridors (not including existing Department of Defense Branchlines and alternative segments with the Walker River Paiute Reservation).

In addition, to avoid the proliferation of new rights-of-way, the BLM may elect to ***grant*** future rights-of-way for new utilities adjacent to the proposed rail line.

Construction and operation of a railroad along the Mina rail alignment could result in the following general impacts to land use and ownership along the entire alignment:

- Changes in land uses on private and public lands within the construction and operations rights-of-way
- Possible increase in livestock mortality (collisions with trains)
- Reduced animal unit months on affected grazing allotments as determined by the BLM
- Reduction in land available for BLM disposal
- Alteration of past routes for BLM-permitted off-highway vehicle events
- Possible expansion of mining, manufacturing, industrial, or commercial land uses under the Shared-Use Option

Tables 4-162 through 4-167 summarize potential impacts to land use and ownership for each rail line segment and construction and operations support facility.

Table 4-162. Summary of potential impacts to land use and ownership – Schurz alternative segments (Walker River Paiute Reservation).

Construction impacts	Schurz 1	Schurz 4	Schurz 5	Schurz 6
Private parcels the alignment would cross (construction right-of-way)	0	0	0	0

Table 4-167. Summary of potential impacts to land use and ownership – railroad construction and operations support facilities (Mineral, Esmeralda, and Nye Counties).

Potential quarries	Construction impacts
Garfield Hills	This quarry would result in the loss of 0.99 square kilometer[a] of grazing land on the Garfield Flat Allotment and 0.09 square kilometer on the Pilot-Table Mountain Allotment, reducing overall animal unit months by five. The quarry would also impact 0.42 square kilometer of land on the Hawthorne Army Depot.
Gabbs Range	This quarry would result in the loss of 0.97 square kilometer of grazing land on the Pilot-Table Mountain Allotment, and the loss of four animal unit months.
North Clayton	This quarry would be on 1.78 square kilometers of public land within an inactive grazing allotment.
ES-7	This quarry would be located on 1.46 square kilometers of public land within an inactive grazing allotment.
Malpais Mesa	This quarry would be on 2.67 square kilometers of public land within an inactive grazing allotment.
Facility	**Construction impacts**
Staging Yard	Yard would be on 1.1 square kilometers on the Hawthorne Army Depot and 0.25 square kilometer on BLM-administered grazing land.
Maintenance-of-Way Facility	The facility would be on approximately 0.02 square kilometer within the rail alignment construction right-of-way. If located at Silver Peak (Montezuma alternative segment 1), it would be on the active Silver Peak Allotment. If located at Klondike (Montezuma alternative segments 2 and 3), it would be on the inactive Montezuma Allotment.
Rail Equipment Maintenance Yard, Cask Maintenance Facility, Nevada Railroad Control Center and National Transportation Operations Center	These facilities would be entirely on the Nevada Test Site. There would be no charge in land use or ownership.

a. To convert square kilometers to acres, multiply by 247.10

4.3.3 AESTHETIC RESOURCES

This section describes potential impacts to aesthetic (visual) resources from constructing and operating the proposed railroad along the Mina rail alignment. Section 4.3.3.1 describes the methods DOE used to assess potential impacts; Section 4.3.3.2 describes potential impacts during the construction phase; Section 4.3.3.3 describes potential impacts during the operations phase; Section 4.3.3.4 describes potential impacts under the Shared-Use Option; and Section 4.3.3.5 summarizes potential impacts to aesthetic resources.

Section 3.3.3.1 describes the region of influence for aesthetic resources along the Mina rail alignment.

4.3.3.1 Impact Assessment Methodology

4.3.3.1.1 Approach

Most of the lands along the Mina rail alignment are BLM-administered public lands. For this reason, DOE used BLM methods to evaluate potential impacts to visual resources.

The BLM uses a process to rate visual resource contrast and evaluate the magnitude of a project's impact on existing visual resources (DIRS 173053-BLM 1986, all). The BLM evaluates the contrast between existing conditions and conditions expected during a project, drawing on information from the BLM visual resource management inventory, which the BLM uses to classify the aesthetic value of BLM-administered lands (DIRS 101505-BLM 1986, all). BLM management objectives allow different levels of project-related contrast for each visual resource management class (DIRS 101505-BLM 1986, Section VB). Figure 4-23 shows the visual resource management classes for lands surrounding the Mina rail alignment. DOE used the BLM methodology to assign visual resource management classes to non-BLM public and private land.

To identify potential impacts to aesthetic resources, DOE applied the process for rating visual resource contrast specified in BLM Manual Handbook 8431-1 (DIRS 173053-BLM 1986, all). This process involved comparing the existing aesthetic conditions to conditions that would exist during proposed railroad construction and operations in relation to:

- Landform attributes, vegetative features, and structural features (such as existing and proposed rail roadbeds, power distribution lines, buildings, and communications towers)
- Form, line, color, and texture
- Other factors including distance, angle of observation, how long the project feature would be visible, relative size or scale, season of use, light conditions, recovery time for vegetation after construction, spatial relationships, and atmospheric conditions

DOE developed contrast ratings using the methodology in BLM Manual Handbook 8410-1 (DIRS 101505-BLM 1986, all) from the key observation points identified in Section 3.3.3 (see Figure 3-176). DOE prepared simulations to illustrate the expected project-related contrast at some key observation points. Appendix D, Aesthetics, Section D.2, provides baseline photographs and simulations for the Mina rail alignment.

4.3.3.1.2 Criteria for Determining Impacts

DOE used the criteria listed in Table 4-168 to rank the contrast between existing conditions and conditions expected during the railroad construction and operations phases at each key observation point.

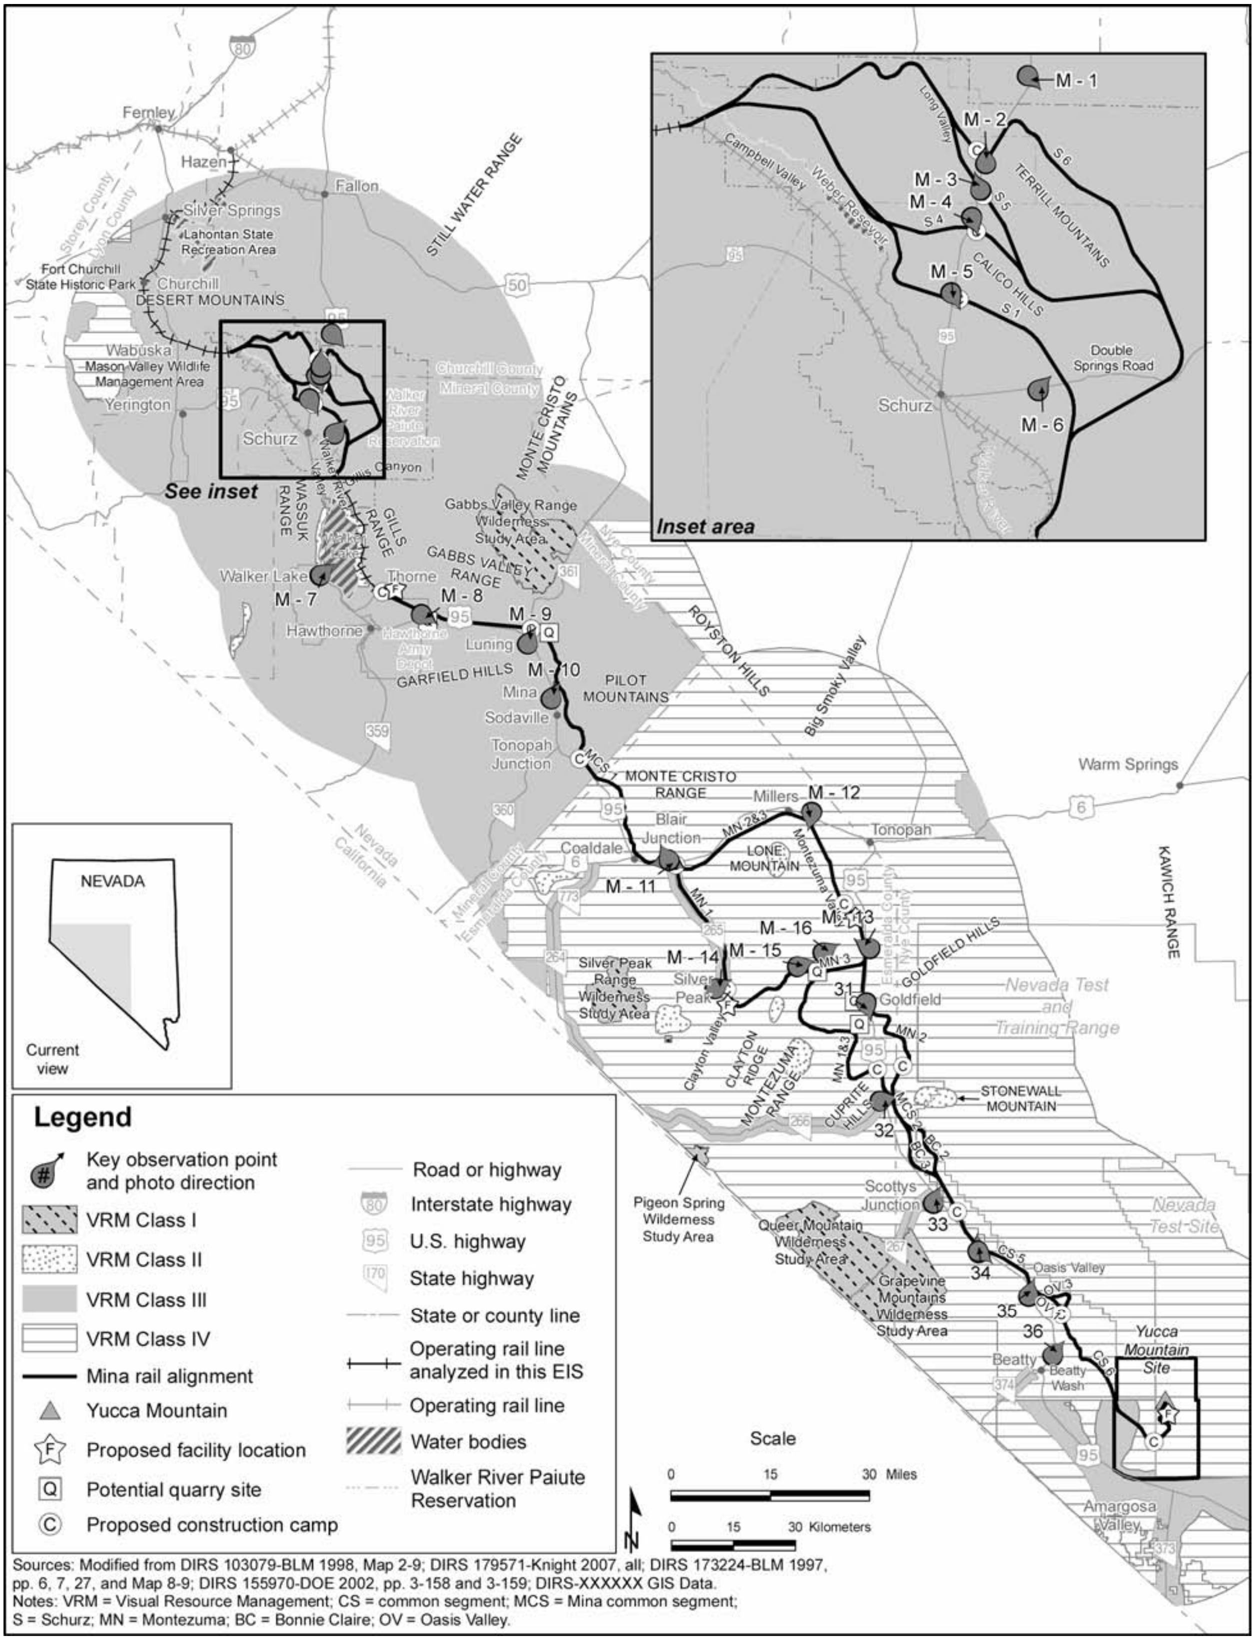

Figure 4-23. Visual resource management classifications and key observation points along the Mina rail alignment.

Table 4-168. Criteria for determining degree of visual contrast.[a]

Degree of contrast	Criteria
None	The element contrast is not visible or perceived.
Weak	The element contrast can be seen but does not attract attention.
Moderate	The element contrast begins to attract attention and begins to dominate the characteristic landscape.
Strong	The element contrast demands attention, will not be overlooked, and is dominant in the landscape.

a. Source: DIRS 173053-BLM 1986, Section III.D.2.a.

DOE then considered contrast ratings against the BLM visual resource management objectives listed in Table 4.-169, where applicable. In general, the BLM manages areas of high visual value (Classes I and II) to minimize contrast, while allowing more contrast in areas of lower visual value (Classes III and IV).

Table 4-169. BLM visual resource management classes and objectives.[a]

Visual resource class	Objective	Acceptable changes to land
Class I	Preserve the existing character of the landscape.	Provides for natural ecological changes but does not preclude limited management activity. Changes to the land must be small and must not attract attention.
Class II	Retain the existing character of the landscape.	Management activities may be seen but should not attract the attention of the casual observer. Changes must repeat the basic elements of form, line, color, and texture of the predominant natural features of the characteristic landscape.
Class III	Partially retain the existing character of the landscape.	Management activities may attract attention but may not dominate the view of the casual observer. Changes should repeat the basic elements in the predominant natural features of the characteristic landscape.
Class IV	Provides for management activities that require major modifications of the existing character of the landscape.	Management activities may dominate the view and be the major focus of viewer attention. An attempt should be made to minimize the impact of activities through location, minimal disturbance, and repeating the basic elements.

a. Source: DIRS 101505-BLM 1986, Section V.B.

In this analysis, the primary basis for identifying potential adverse impacts to aesthetic resources is inconsistency with BLM management objectives for a ***viewshed***. This includes consideration of effects on the visual values of parks, recreation areas, and other scenic resources (recognized at the national, state, or local level) and visual intrusions or contrasts affecting the quality of landscapes. Along much of the Mina rail alignment, where the landscape is sparsely populated and undeveloped, the visual impact of equipment, facilities, and activities could create a weak or moderate contrast, according to the criteria listed in Table 4-168. That is, from key observation points that are within a few miles, equipment, facilities, and activities could be seen (weak contrast) or would begin to attract attention and begin to dominate the viewshed (moderate contrast). However, as noted in BLM guidance, distance and duration of project activities affect perceptions of contrast (DIRS 173053-BLM 1986, Section III.D.2.b).

Distance of an observer from project activities and facilities would greatly affect the observer's perception of project-related contrasts with the landscape. The likelihood that activities or facilities would divert an observer's attention away from the landscape would decrease as distance increased. Thus, views from observation points where the project would appear in the foreground or middleground would usually be affected more than views from observation points where the project was in the background.

Duration of activities also affects conclusions about a project's consistency with BLM visual resource management objectives in a particular location. For example, visible construction activities over 18 months could cause a moderate degree of contrast and be inconsistent with Class II objectives. Such activities would be recognized as a moderate adverse impact of construction in Class II areas, although BLM methodology recognizes that "few projects meet the VRM [visual resource management] management objectives during construction" (DIRS 173053-BLM 1986, Section III.D.2.b.7). In contrast, passage of a train on a track more than approximately 1.6 kilometers (1 mile) from observers for a few minutes three times a day for up to 50 years might comply with Class II objectives if the track itself did not attract attention or dominate the view of a casual viewer, thus creating only a weak degree of contrast. In such a case, presence of the proposed rail line would be recognized as a small adverse impact of operation.

4.3.3.2 Construction Impacts

Table 4-170 lists contrast ratings for views from each key observation point along the Mina rail alignment and consideration of project consistency with BLM management objectives. In cases where construction and operations activities would cause different levels of contrast, the table identifies the phase for each rating; otherwise, a single rating applies to both construction and operations. Figure 4-23 is the same as Figure 3-177 in Section 3.3.3, showing visual resource management classifications of lands around each key observation point. It is a useful reference when reading impact discussions in this section. Appendix D, Section D.2, provides photographs of views from each key observation point and simulations of views including the track, trains, or other features.

4.3.3.2.1 Construction Impacts Common to the Entire Mina Rail Alignment

Construction-related equipment, facilities, and activities would be potential sources of short-term (temporary) impacts to visual resources during the construction phase. Most of the equipment, facilities, and activities would be within the ***nominal*** width of the ***construction right-of-way***. From some viewpoints, the presence of workers, vehicles, equipment, supply trains, ***borrow pits***, quarries, laydown yards, well pads, construction camps, and electric distribution lines, and the generation of dust and vehicle exhaust, might be seen or might attract the attention of a casual observer during construction. These would result in small impacts to visual setting except in areas discussed in Section 4.3.3.2.2.

Newly constructed ***cut*** and ***fill*** slopes could temporarily result in a weak to strong contrast with adjacent soils and vegetation. The short-term level of impact to the visual setting from this contrast would be small to large, and would decrease with the reestablishment of vegetation. Cuts in virgin rock would initially show a weak to strong contrast between freshly exposed rock and previously weathered rock. Without mitigation, this contrast would result in long-term small to large impacts to the visual setting.

Construction supply trains consisting of 8 to 20 cars would pass eight times per day, at most (loaded on the trip out, empty on the return), along rail line segments under active construction. Construction trains would likely be visible for 5 to 20 minutes from a single vantage point, depending on train speed and terrain.

Table 4-170. Contrast ratings along the Mina rail alignment and consistency with BLM objectives (page 1 of 5).

Key observation point	Location	Visual resource management classes in viewshed[a]	Contrast rating[b]	Consistent with visual resource management class rail line would cross?[c]	Impact level[d]	Notes
M-1	U.S. Highway 95, view over Rawhide Flats toward Schurz alternative segment 6 against hills	Surrounding lands (III)	Weak	Yes	Small	None
M-2[e]	U.S. Highway 95 view of Schurz alternative segment 6 rail-over-road crossing	Surrounding lands (III)	Construction: strong	No	Construction: moderate to large	Extensive earthworks would be required for approach to the rail-over-road crossing.
			Operations: moderate	Yes	Operations: small to moderate	
M-3[e]	U.S. Highway 95 in Long Valley, views of Schurz alternative segment 5 and road-over-rail crossing	Surrounding lands (III)	Construction: moderate Operations: weak	Yes	Construction: moderate Operations: small	Typical road-over-rail highway crossing.
M-4[e]	U.S. Highway 95 at intersection with Weber Dam Road, view of Schurz alternative segment 4 and road-over-rail crossing	Surrounding lands (III)	Construction: moderate Operations: weak	Yes	Construction: moderate Operations: small	Typical road-over-rail highway crossing.
M-5[e]	U.S. Highway 95, view of Schurz alternative segment 1 and road-over-rail crossing	Surrounding lands (III)	Construction: moderate Operations: weak	Yes	Construction: moderate Operations: small	Typical road-over-rail highway crossing.
M-6[e]	Double Springs Road, view of Schurz alternative segment 1 and at-grade crossing	Surrounding lands (III)	Weak	Yes	Small	At-grade crossing of dirt road, typical of crossing of this type.

Table 4-170. Contrast ratings along the Mina rail alignment and consistency with BLM objectives (page 2 of 5).

Key observation point	Location	Visual resource management classes in viewshed[a]	Contrast rating[b]	Consistent with visual resource management class rail line would cross?[c]	Impact level[d]	Notes
M-7	Town of Walker Lake, view across lake to Department of Defense Branchline South	Surrounding lands (II and III), western and eastern perimeters of Walker Lake (II)	None	Yes	Small	Existing rail line.
M-8	U.S. Highway 95 just west of Hawthorne, view of potential Garfield Hills quarry facilities	Surrounding lands (III)	Construction: moderate Operations: weak to none	Yes	Construction: moderate Operations: small	Conveyor and support facilities associated with quarry would be visible. DOE would dismantle the quarry conveyor system and facilities after construction was complete.
M-9	Town of Luning, view of potential Gabbs Range quarry site	Surrounding lands (III)	Construction: weak to moderate Operations: none	Yes	Construction: Small to moderate Operations: small	DOE would dismantle the facilities after construction was complete.
M-10	Town of Mina, view of Mina common segment 1	Surrounding lands (III)	Weak	Yes	Small	Buildings and vegetation might shield segment from most homes.

Table 4-170. Contrast ratings along the Mina rail alignment and consistency with BLM objectives (page 3 of 5).

Key observation point	Location	Visual resource management classes in viewshed[a]	Contrast rating[b]	Consistent with visual resource management class rail line would cross? [c]	Impact level[d]	Notes
M-11	Near intersection of State Route 265 and U.S. Highway 95 (Blair Junction), views of Mina common segment 1 toward Monte Cristo Range; south/southeast over State Route 265 to Montezuma alternative segment 1; west over Mina common segment 1	Surrounding lands (III and IV), State Route 265 (III), Monte Cristo Range (IV)	Construction of Mina common segment 1: moderate	Yes	Moderate	None
			Construction of Montezuma alternative segment 1: moderate	Yes	Moderate	None
			Operation of Mina common segment 1: weak to moderate	Yes	Small	View west might not show rail line due to topography.
			Operation of Montezuma alternative segment 1: weak	Yes	Small	None
M-12	U.S. Highway 95 in Montezuma Valley, view south across Montezuma alternative segment 2 toward Lone Mountain	Surrounding lands (IV)	Weak	Yes	Small	Follows existing rail bed.

Table 4-170. Contrast ratings along the Mina rail alignment and consistency with BLM objectives (page 4 of 5).

Key observation point	Location	Visual resource management classes in viewshed[a]	Contrast rating[b]	Consistent with visual resource management class rail line would cross?[c]	Impact level[d]	Notes
M-13	U.S. Highway 95, view toward Montezuma alternative segment 2 and proposed Maintenance-of-Way Facility	Surrounding lands (IV)	Weak to none	Yes	Small	None
M-14	Main Street in Silver Peak (just past the Chemetall Foote Corporation processing plant), view east over Montezuma alternative segment 1	Surrounding lands (IV), State Route 265 (III)	Weak to moderate	Yes	Small to Moderate	Buildings and vegetation would shield segment from most viewers.
M-15	Silver Peak Road, view toward Montezuma alternative segment 1 and potential North Clayton quarry	Surrounding lands (IV)	Weak	Yes	Small	None
M-16	Silver Peak Road intersection with road to Klondike, views over Montezuma alternative segment 2	Surrounding lands (IV)	Weak to none	Yes	Small	Rail line would barely be visible in background.
31	Rail line crossing U.S. Highway 95 south of Goldfield, view south-southeast toward Montezuma alternative segment 2	Surrounding lands (IV)	Weak	Yes	Small	Typical highway crossing structure would not draw attention.
32	U.S. Highway 95 at State Route 266, view east to Montezuma alternative segments	Surrounding lands (IV), State Route 266 (III), Stonewall Mountain (II)	Weak	Yes	Small	Montezuma alternative segment 2 would be distant from Class II feature, which would be in background; Class III lands would not be visible in views from highway over the rail line.

Table 4-170. Contrast ratings along the Mina rail alignment and consistency with BLM objectives (page 5 of 5).

Key observation point	Location	Visual resource management classes in viewshed[a]	Contrast rating[b]	Consistent with visual resource management class rail line would cross?[c]	Impact level[d]	Notes
33	U.S. Highway 95 at State Route 267, view north-northeast over common segment 5	Surrounding lands (IV), State Route 267 (III)	Weak	Yes	Small	None
34	U.S. Highway 95 (typical cut), view toward common segment 5 hill cuts	Surrounding lands (IV)	Strong to moderate	Yes	Large to moderate	None
35	U.S. Highway 95 north of Oasis Valley (typical landscape)	Surrounding lands (IV)	Weak	Yes	Small	Rail line would be visible but would not attract attention away from topography in background.
36	U.S. Highway 95 and Beatty Wash access road, view northeast to construction access road	Surrounding lands (IV)	None to weak	Yes	Small	Rail line would not be visible from key observation point; increased traffic along access road would be visible but would not attract attention.

b. Contrast rating definitions from DIRS 173053-BLM 1986, Section III.D.2.a; see Table 4.4-1.
c. BLM methodology recognizes that "few projects meet the VRM [visual resource management] management objectives during construction" (DIRS 173053-BLM 1986, Section III.D.2.b.7).
d. Impact level definitions from Section 4.1.
e. Key observation point is located on the Walker River Paiute Reservation.

In addition, small pieces of equipment such as track tampers, ballast regulators, tie handlers, rail clip applicators, and ballast consolidators would pass two to eight times per day (DIRS 180874-Nevada Rail Partners 2007, Appendix A). The level of impact to visual resources would be small.

Activities associated with three of the potential quarry sites (see Figure 2-23) would be visible from towns, highways, or county roads. At the potential Garfield Hills quarry just south of the Hawthorne Army Depot, the plant, a conveyor and a siding would be visible from U.S. Highway 95. This site would be entirely within Class III land and would present a moderate degree of contrast from the highway (see Appendix D, Figure D-102). The potential Gabbs Range quarry, 4 kilometers (2.5 miles) east of Luning, would be in a Class III area visible from U.S. Highway 95 and Luning. Viewers in Luning and on the highway would see a weak to moderate contrast from the quarry and associated facilities (see Appendix D, Figure D-104). Moderate levels of contrast are compatible with BLM Class III management objectives. The potential North Clayton quarry would be in Class IV land and the plant site, siding, and waste dump areas would be visible from Silver Peak Road, though the quarry itself would not be visible from any frequently traveled roads. A weak to moderate degree of contrast would result from the quarry facilities. The potential Malpais Mesa quarry would not be visible from U.S. Highway 95, but would be visible from Railroad Springs Road. Viewers passing on Railroad Springs Road would encounter a moderate to strong contrast from the quarry and associated facilities. A moderate or strong contrast is compatible with BLM Class IV management objectives. Potential quarry site ES-7 west of Goldfield would not be visible from highways or county roads.

In situations where water wells could not be constructed within the nominal width of the construction right-of-way (see Figure 2-3), they would lie within a 23-square-meter (250-square-foot) drilling area connected to the construction right-of-way by small pipelines feeding temporary 9.3-square-meter (100-square-foot) reservoirs. These would cause localized short-term weak-to-moderate contrast, compatible with BLM management objectives in surrounding lands.

There would be up to 10 temporary construction camps along the rail alignment at intervals of approximately 50 kilometers (30 miles) (see Figure 2-23). The camps, which would each average 0.1 square kilometer (25 acres) in size, would have a long and narrow layout of approximately 730 meters by 120 meters (2,400 feet by 400 feet) and would be within the nominal width of the rail line construction right-of-way as close as possible to intersections of existing public roads and the rail alignment access roads. Each camp would consist of single-story housing, offices, support facilities (commissary, kitchen, cafeteria, recreation facilities, service station, fueling area, and medical facilities), utilities (power lines, water- and wastewater-treatment facilities, and trash storage), a contractor work area (sections for maintenance and parts and materials storage), and parking (DIRS 180875-Nevada Rail Partners 2007, Chapter 4). The most visible structures at each construction camp would be the housing facilities. The camps would contrast weakly against the landscape as observed by passing motorists, resulting in short-term small impacts to the visual setting. See Figure 4-24 for a simulation showing a construction camp along the Caliente rail alignment, with camp layout and design identical to that planned for camps along the Mina rail alignment.

Electricity distribution lines would be buried within the operations right-of-way over the length of the rail line (see Section 4.3.11, Utilities, Energy, and Materials). Where the lines connected to the commercial power grid, an electrical substation and a line of power poles extending from the substation to the rail line would be visible. Temporary electrical distribution poles would be visible carrying power to facilities within construction camps, contributing to short-term small impacts to the visual setting around the camps.

Construction duration at most individual locations along the rail line would be a period of weeks or a few months under a 4-year construction schedule. Under a 10-year schedule, there would be multiple phases

Figure 4-24. Simulation of a typical construction camp.

of work (of weeks or a few months) separated by years of inactivity. Active construction would be longer at locations of major structures, such as bridges and railroad operations support facilities, but nowhere would construction of earthworks and rail line be expected to exceed 18 continuous months except at the bridge over Beatty Wash, which DOE expects would take 2 years to construct. DOE would withdraw construction camps from service and keep them in reserve during periods of construction inactivity, and would close camps and reclaim the land as sections of the rail line were completed. Thus, a longer construction schedule would not increase the level of visual impact because inactivity would minimize the visual contrast at individual locations where construction was halted, although the impact of disturbed soil and vegetation would be prolonged. Under either construction schedule, DOE would consider requests by local governments to leave individual construction camp sites (the cleared and hardened site the camp occupied) in place after permanent closure of the facility for possible use by these governments or their designees. The visual impacts from these sites would likely be small because the Department would remove equipment and structures prior to transfer, and rail line-related construction activities would cease.

Considering the effects of distance and duration, construction activities or facilities would either not be visible or would be noticeable during the construction phase but would not dominate the attention of a viewer. That is, they would create no contrast or a weak degree of contrast at key observation points, with the exception of those discussed in Section 4.3.3.2.2. A weak degree of contrast, even where Class I and II lands are present in the viewshed, is compatible with BLM management objectives for all classes of land. Thus, there would be small, temporary project-related impacts to the visual setting during construction of any of the Mina rail alignment alternative segments and common segments, except as described in Section 4.3.3.2.2. As noted in Section 4.3.3.1.2, BLM methodology recognizes that "few projects meet the VRM [visual resource management] management objectives during construction" (DIRS 173053-BLM 1986, Section III.D.2.b.7).

The section of Department of Defense rail line currently in operation on the Walker River Paiute Reservation (Department of Defense Branchline Schurz) would be decommissioned, and the ballast and rail would be removed, with the selection of any of the Schurz alternative segments. Removal of the rail and ballast material would result in a small decrease in the contrast with the surrounding landscape, though the linear feature of the railbed would remain. A weaker contrast would likely result in a small positive impact to the visual setting near the site of this existing rail line. Department of Defense Branchline Schurz as it currently appears from Alternate U.S. Highway 95 north of the town of Schurz is shown in Figure 4-25.

4.3.3.2.2 Construction Impacts along Alternative Segments and Common Segments

The aesthetic resources impact analysis identified moderate or strong contrast ratings associated with rail line construction along three portions of the Mina rail alignment, as described in Sections 4.3.3.2.2.1 through 4.3.3.2.2.3.

4.3.3.2.2.1 Schurz Alternative Segments (Walker River Paiute Reservation). The Schurz alternative segments would cross through non-BLM-administered lands treated in this analysis as Class III. The construction of several of the crossings of U.S. Highway 95 could present a moderate to strong contrast to passing motorists due to topography, cuts and fills, and installation of crossing structures. Construction activities for the crossing of Schurz alternative segment 6 over U.S. Highway 95 near the crest of the hills between Long Valley and Rawhide Flats would begin to dominate the viewscape of drivers approaching key observation point M-2 from the south due to the large amount of earthworks required for the long approach and the type and span of the crossing structure. The construction of this crossing would not be compatible with BLM Class III management objectives, as it would represent a strong degree of contrast. Construction of the Schurz alternative segments 1, 4, and 5 road-over-rail

Figure 4-25. View south from key observation point M-4 toward typical road-over-rail crossing structure.

crossing structures of U.S. Highway 95, seen from key observation points M-3, 4, and 5 (see Appendix D, Figures D-91 through D-96), would result in a moderate degree of contrast due to hill cuts and the construction of the crossing structures and rail line. A moderate contrast rating would meet BLM management objectives for the Class III lands in the area of these crossings.

4.3.3.2.2.2 Mina Common Segment 1 (Hawthorne Army Ammunition Depot to Blair Junction). Mina common segment 1 would cross exclusively through Class III land in the Carson City BLM District and Class IV land in the Battle Mountain BLM District. From key observation point M-8 on U.S. Highway 95 overlooking the potential Garfield Hills quarry site (see Appendix D, Figure D-101), ballast production facilities and a conveyor crossing the highway would cause a moderate degree of contrast. Similarly, development and use of the potential Gabbs Range quarry site (see Appendix D, Figure D-101) would cause a weak to moderate contrast when viewed from key observation point M-9 at U.S. Highway 95 and Luning. Either quarry would be in Class III areas, where a moderate contrast would be consistent with BLM management objectives.

4.3.3.2.2.3 Montezuma Alternative Segments. The Montezuma alternative segments would cross Class III and Class IV lands as they head south. Because of the close proximity of Montezuma alternative segment 1 to the Class III area surrounding State Route 265, and the unobstructed view of the segment viewers would have from this highway, the contrast due to construction would be moderate as seen from key observation point M-11. For viewers at key observation point M-14 in Silver Peak, construction of the rail line through the Class IV Clayton Valley would cause a moderate contrast due to the color disparity between the ballast and playa bottom, although topography and structures and vegetation in Silver Peak would screen the construction from most viewers in Silver Peak. A moderate degree of contrast is compatible with BLM Class III and IV management objectives.

4.3.3.3 Operations Impacts

4.3.3.3.1 Operations Impacts Common to the Entire Mina Rail Alignment

Sources of potential impacts to the visual setting during the operations phase would be the presence of the rail line and operations support facilities in the landscape, and the passage of trains to and from the repository. For sections of new rail line, there would be less impact to the visual setting during the operations phase than during the construction phase, because there would be less activity (fewer, shorter trains and equipment, and fewer people), the operations right-of-way (nominally 61 meters [200 feet] on either side of the centerline of the rail line) would be narrower in some areas, and disturbed areas outside the operations right-of-way would be reclaimed (see Chapter 7 for a discussion of best management practices). For existing sections of rail line, operations impacts to the visual setting would be less noticeable than during construction because there would be comparatively fewer and shorter trains.
The decommissioning and removal of Department of Defense Branchline Schurz would result in a small positive impact to viewers near the current rail line, which runs directly through the town of Schurz, as all traffic would cease.

The primary visual impact of railroad operations would be the existence of the linear track for up to 571 kilometers (355 miles) (of which 112 kilometers [70 miles] would be existing rail line), with ***wayside signals*** and communications towers visible from short distances. No new linear feature would be created along some sections of rail line, as portions of some common and alternative segments would follow existing, abandoned rail beds (Mina common segment 1, Montezuma alternative segments 2 and 3, and a small portion of Schurz alternative segments 4, 5, and 6). Additionally, the electrical distribution line currently located along U.S. Highway 95 creates a linear feature between this commonly traveled route and the potential location of Mina common segment 1.

In addition to the impact of the track itself, the passage of a train would attract the attention of a casual observer, both because of the sound associated with the train and its appearance on the track, but this would be an infrequent, short-duration visual distraction. Travel along the rail line is expected to peak at 17 one-way train trips per week (DIRS 180874-Nevada Rail Partners 2007, Appendix C). This would average fewer than three one-way trips per day. Trains would be up to 19 cars long, and would likely be visible for between 5 and 20 minutes from a single vantage point, depending on train speed and terrain. Passage of these trains would create a small impact to the visual setting.

Along the rail alignment, DOE would install 4.6-meter (15-foot)-tall wayside signals to control train movements at intervals sufficient to connect each by line-of-sight. DOE would place 23-to-30-meter (75-to-100 foot)-tall radio communications towers at the beginning and the end of the line and at intervals along the rail line as needed to ensure signal transmission (DIRS 180923-Nevada Rail Partners 2007, Chapter 6). See Figure D-27 and D-33 in Appendix D for simulations showing signals and communications towers along the Caliente rail alignment, which would utilize designs identical to those along the Mina alignment. The substations and distribution lines that connect the buried power lines to the grid would remain during the operations phase. The wayside signals, radio communication towers, substations, and distribution lines all would create small impacts to the visual setting unless placed in visually sensitive areas close to observers, where impacts could be moderate or large.

DOE established contrast ratings at key observation points considering the view of the rail line or operations support facilities and the nature and extent of operations activities that would be visible. The Department compared ratings with BLM visual resource management objectives for the lands in the viewshed. Contrast ratings at key observation points confirmed that the presence of the rail line and associated crossing structures, while noticeable in some cases, would not dominate a viewer's attention and would result in a weak level of contrast (see Figure 4-26), except in some cases where the rail line would be close to the viewer and at some grade-separated crossings. In some instances where the rail line would run close to the viewer, the linear track would cause a moderate contrast (see Section 4.3.3.3.2). Ratings from key observation points with views of road crossings (all of which would be in Class III and IV lands) found contrasts would range from moderate to none. A weak level of contrast is compatible with BLM management objectives for all classes of land, a moderate level of contrast is compatible with BLM management objectives for Class III and IV lands but not for Class II lands, and a strong level of contrast is sometimes compatible with BLM Class IV objectives but not with Class III objectives.

Contrast ratings confirmed that the level of contrast between a passing train and the landscape would be strong (demanding a viewer's attention) or moderate (beginning to attract attention) where the rail line would fall in the foreground or middleground of the viewshed. Contrast between the landscape and a passing train would be less where the rail line would be in the background. In such cases, the level of contrast would be moderate or weak, where the passing of a train could be noticeable but would not demand attention (see Figure 4-27). The extremely short duration of the passage would diminish the effect, so that management objectives would be met for Class II, III, and IV lands, even if the rail line were to fall in the foreground or middleground of the viewshed, as long as it would not create a linear feature across the landscape that would attract attention or would begin to dominate the landscape.

4.3.3.3.2 Operations Impacts along Alternative Segments and Common Segments

The analysis of impacts to aesthetic resources identified moderate contrast ratings associated with railroad operations along two portions of the Mina rail alignment, as discussed in Sections 4.3.3.3.2.1 and 4.3.3.3.2.2.

4.3.3.3.2.1 Schurz Alternative Segments (Walker River Paiute Reservation). The Schurz alternative segments would cross through non-BLM-administered lands treated in this analysis as Class III. Because it would cross directly over U.S. Highway 95 near where the road crests the hills between

Figure 4-26. View east from key observation point M-10 in the town of Mina showing passage of a train in background.

Figure 4-27. View of Department of Defense Branchline Schurz from Alternate U.S. Highway 95 on the Walker River Paiute Reservation north of the town of Schurz.

Long Valley and Rawhide Flats, the Schurz alternative segment 6 rail-over-road grade-separated crossing seen in Appendix D, Figures D-89 and D-90, would likely draw the attention of viewers. This structure would cause a moderate degree of contrast compatible with BLM management objectives for the Class III lands in the area.

4.3.3.3.2.2 Montezuma Alternative Segments. The Montezuma alternative segments would cross Class III and Class IV lands as they head south. From key observation point M-14 (Appendix D, Figure D-116) in Silver Peak, Montezuma alternative segment 1 running through the Class IV Clayton Valley would be clearly evident due to the color discrepancy between the ballast and playa bottom, causing a moderate contrast where visible (though topography and structures and vegetation would screen the rail line from most viewers in Silver Peak). A moderate level of contrast is compatible with BLM management objectives for Class III and IV lands.

4.3.3.4 Impacts under the Shared-Use Option

Impacts to aesthetic resources during the construction phase under the Shared-Use Option would be the same as those under the Proposed Action without shared use (see Section 4.3.3.2.1). Construction of additional sidings or short spurs would create small impacts to the visual setting because of the short duration of construction.

Impacts to the visual setting during the operations phase under the Shared-Use Option would be the same as those under the Proposed Action without shared use (see Section 4.3.3.3.1). Under the Shared-Use Option, there would be an additional five round-trip trains per week on rail line sections south of Hawthorne and nine round trips on the sections north of Hawthorne (DIRS 180694-Ang-Olson and Gallivan 2007, p. 3). These additional trains would not substantially increase the assumed three one-way trips per day DOE used to establish visual contrast ratings under the Proposed Action without shared use.

4.3.3.5 Summary

Table 4-171 summarizes potential impacts to aesthetic resources from constructing and operating the proposed railroad along the Mina rail alignment.

Table 4-171. Summary of potential impacts to aesthetic resources – Mina rail alignment[a] (page 1 of 2).

Location (county)	Construction impacts[b]	Operations impacts
Rail alignment		
Impacts common to all portions of the Mina rail alignment	Small impact. Weak to moderate contrast in the short term from dust and exhaust; lighting, temporary power poles, construction camps, and material laydowns; operation of supply trains. Small to large impact. Weak to strong contrast in the short term from visible construction equipment either operating or in storage, and from scars on soil and vegetated landscape from cuts, fills, and well pads. Small to large impact. Weak to strong contrast in the long term from scars on rock from cuts, and from access roads.	Small to moderate impact. No to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads. Small impact. No to strong contrast in the short term from passing trains.

Table 4-171. Summary of potential impacts to aesthetic resources – Mina rail alignment[a] (page 2 of 2).

Location (county)	Construction impacts[b]	Operations impacts
Rail alignment (continued)		
Schurz alternative alignments 1, 4, 5, and 6 (Churchill County and Mineral County)	Small to large, but temporary, impact. Moderate to strong contrast in the short term for rail-over-road crossing of U.S. Highway 95 by Schurz 6, which would not meet BLM Class III management objectives. Weak to moderate contrast in the short term for other rail line sections and structures, which would meet Class III objectives.	Small to moderate impact. Weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives.
Montezuma alternative segment 1 (Esmeralda County)	Moderate impact. Moderate contrast due to proximity to viewers on State Route 265 and in some parts of town of Silver Peak; would meet BLM Class III and IV management objectives.	Small to moderate impact. Weak contrast from new linear feature adjacent to State Route 265 and weak to moderate contrast in Clayton Valley; would meet BLM Class III and IV management objectives.
Quarries		
Potential Garfield Hill quarry (Mineral County)	Moderate impact. Moderate contrast in the short term from quarrying, ballast production facilities, and conveyor close to viewers that would be compatible with BLM Class III management objectives.	Small to no impact. Production facilities and conveyor would be removed and quarried areas restored after closure of quarry at end of construction phase.
Potential Gabbs Range quarry (Mineral County)	Small to moderate impact. Weak to moderate contrast in the short term from ballast production facilities close to viewers that would be compatible with BLM Class III management objectives.	Small to no impact. Production facilities would be removed after closure of quarry at end of construction phase.
Potential North Clayton quarry (Esmeralda County)	Small to moderate impact. Moderate contrast in the short term from production facilities close to viewers that would be compatible with BLM Class IV management objectives.	Small to no impact. Production facilities would be removed and waste dumps restored after closure of quarry at end of construction phase.

a. Impacts under the Shared-Use Option would be similar to those under the Proposed Action without shared use.
b. BLM methodology recognizes that "few projects meet the VRM [visual resource management] management objectives during construction" (DIRS 173053-BLM 1986, Section III.D.2.b.7).

4.3.4 AIR QUALITY AND CLIMATE

This section describes potential impacts to ***air quality*** from constructing and operating a railroad along the Mina rail alignment. Section 4.3.4.1 describes the methodology DOE used to assess potential impacts; Section 4.3.4.2 discusses conformity with the appropriate State Implementation Plan(s); Section 4.3.4.3 describes potential construction and operations impacts; Section 4.3.4.4 describes potential impacts under the Shared-Use Option; and Section 4.3.4.5 summarizes potential impacts to air quality.

Section 3.3.4.1 describes the region of influence for the air quality impacts analysis.

4.3.4.1 Impact Assessment Methodology

DOE calculated project-related emissions and examined county emissions inventories to determine county-level increases in air pollutant emissions, and performed air quality simulations to determine potential changes in air pollutant concentrations at specific receptors (population centers). Appendix E, Air Quality Assessment Methodology, provides a detailed description of the approach DOE used to perform the air quality assessment.

For areas along the Mina rail alignment for which no local air quality data are available, DOE compared projected emissions under the Proposed Action with the U.S. Environmental Protection Agency county-level emissions data in the National Emission Inventory database (DIRS 177709-MO0607NEI2002D.000). DOE compared emissions from proposed railroad construction and operations in Churchill, Lyon, Mineral, Esmeralda, and Nye Counties to existing emissions in three categories: highway emissions, off-highway emissions, and all county sources. Section 4.3.4.3.1 describes projected emissions associated with construction of the proposed railroad and Section 4.3.4.3.2 describes emissions from railroad operations.

To assess potential impacts to air quality in the region of influence, DOE modeled air quality where there are population centers that would be relatively close to the proposed railroad: Schurz, Hawthorne, and Mina in Mineral County; and Silver Peak and Goldfield in Esmeralda County. In each case, DOE compared the modeling results to the Nevada and National ***Ambient Air Quality Standards*** (NAAQS). These two standards are nearly identical (Section 3.2.4 explains differences), but DOE primarily references the NAAQS in this section with noted exceptions. DOE also modeled air quality and assessed impacts for construction and operations of associated railroad facilities: the Staging Yard at Hawthorne and for construction-related activities at the northern potential quarry site of Garfield Hills and the southerly potential quarry site of Malpais Mesa. Appendix E provides a detailed description of the air quality modeling methodology and assumptions.

There would be an adverse impact to air quality if the Proposed Action:

- Would conflict with or obstruct implementation of a state or regional air quality management plan
- Would violate a NAAQS primary standard or contribute to existing or projected violations

4.3.4.2 The Conformity Rule

Section 176(c) of the Clean Air Act (42 U.S.C. 7401 *et seq.*) requires that federal actions conform to the appropriate State Implementation Plan. The final rule for "Determining Conformity of General Federal Actions to State or Federal Implementation Plans" (called the Conformity Rule) is codified in 40 CFR Parts 6, 51, and 93. This Conformity Rule established the conformity criteria and procedures necessary to ensure that federal actions conform to the State Implementation Plans and meet the provisions of the Clean Air Act. In general, this rule ensures that all emissions of ***criteria air pollutants*** and ***volatile***

organic compounds are specifically identified and accounted for in the State Implementation Plan's attainment or maintenance demonstration, and conform to the State Implementation Plan's purpose of eliminating or reducing the severity and number of violations of the NAAQS and achieving expeditious attainment of such standards.

The provisions of the Conformity Rule apply only where the action is undertaken in a federally classified ***nonattainment*** or maintenance area. Apart from Clark and Washoe Counties, the rest of the State of Nevada is classified as ***in attainment*** for all criteria air pollutants. There are no nonattainment or maintenance areas in the proposed rail alignment's host counties of Churchill, Lyon, Mineral, Esmeralda and Nye. Hence, the provisions of the Conformity Rule do not apply to the Proposed Action.

4.3.4.3 Impacts to Air Quality

4.3.4.3.1 Construction Impacts

Potential impacts to air quality from construction of a rail line and railroad construction and operations support facilities along the Mina rail alignment would include (1) exhaust emissions from construction equipment and (2) fugitive dust ***particulate matter*** emissions resulting from construction activities. These impacts would be small, except in the vicinity of the potential Garfield Hills quarry, the Staging Yard at Hawthorne, and near the rail line construction right-of-way in the vicinity of Mina and Schurz.

Appendix E describes the modeling approach and methodology DOE used to estimate emissions and air quality impacts that would result from these activities.

DOE evaluated emissions and air quality impacts by county because the most complete and comprehensive annual emissions data available from the U.S. Environmental Protection Agency National Emission Inventory are at the county level (DIRS 177709-MO0607NEI2002D.000). DOE assessed emissions impacts by comparing construction emissions with 2002 annual county-wide emissions for ***nitrogen oxides*** (NO_x), particulate matter with aerodynamic diameters equal to or less than 10 micrometers (***PM_{10}***) and 2.5 micrometers (***$PM_{2.5}$***), ***sulfur dioxide*** (SO_2), ***carbon monoxide*** (CO), and volatile organic compounds (VOCs). DOE assessed air quality impacts by comparing resulting concentrations of these air pollutants against the NAAQS.

Churchill, Lyon, Mineral, Esmeralda, and Nye Counties are all in attainment for ***ozone(O_3)***. Ozone is generally recognized as a regional-scale air quality problem. The potential increase in the emissions of VOCs (a precursor to ozone formation) associated with rail line construction would be small in relation to the existing regional emissions of VOCs. Thus, the impact on ozone formation would not be anticipated to cause a violation of the ozone standard.

Sections 4.3.4.3.1.1 through 4.3.4.3.1.5 describe potential exhaust emissions and air quality impacts from constructing the proposed rail line and railroad construction and operations support facilities along the Mina rail alignment in Churchill, Lyon, Mineral, Esmeralda, and Nye Counties.

4.3.4.3.1.1 Churchill County.

Emissions Appendix E describes the methodology DOE used to determine construction-related emissions. In Churchill County, the Mina rail alignment is anticipated to use the existing Union Pacific Railroad Hazen Branchline. Hence, the only construction emissions in Churchill County would be from the operation of construction materials trains through the county. Appendix E, Section E.3.1.2.1, provides additional detail on the Churchill County emissions inventory.

Table 4-172 compares the highest modeled annual total emissions under a 4-year construction schedule in Churchill County to the county's 2002 emissions estimates in the National Emission Inventory (DIRS 177709-MO0607NEI2002D.000). The table lists potential project-related emissions as a maximum and minimum range according to the possible lengths of the existing Union Pacific Railroad Hazen Branchline and new construction of rail line through the county, and increased equipment activity that would be necessary when construction was in rugged terrain.

Simulated construction-related emissions for VOCs, CO, NO_x, PM_{10}, $PM_{2.5}$, and SO_2 would be small fractions of the county's 2002 annual emissions for these air pollutants. Given that these emissions would be distributed over the entire length of the existing Union Pacific Railroad Hazen Branchline in Churchill County, 17 to 31 kilometers (11 to 20 miles), exceedance of any air quality standards is not likely.

As shown in Table 4-172, fugitive dust would be the principal source of particulate matter emissions. More than half of these fugitive dust emissions would be directly associated with rail line construction of Schurz alternative segment 6. Access roads (including the alignment access roads) fugitive dust emissions would contribute about 39 percent (or 100 metric tons [110 tons] per year).

4.3.4.3.1.2 Lyon County.

Emissions Appendix E describes the methodology DOE used to determine construction-related emissions. Section E.3.1.3.1 provides additional detail on the Lyon County emissions inventory.

Table 4-173 compares the highest annual total emissions under a 4-year construction schedule in Lyon County to the county's 2002 emissions estimates in the National Emission Inventory database (DIRS 177709-MO0607NEI2002D.000 2006). The table lists potential project-related emissions as a maximum and minimum range according to the possible lengths of the existing and proposed rail line through the county, and increased equipment activity that would be necessary when construction was in rugged terrain.

Simulated construction-related emissions for VOCs, CO, NOx, PM_{10}, $PM_{2.5}$, and SO_2 would be small fractions of the county's 2002 annual emissions for these air pollutants. Given that these emissions would be distributed over the entire length of the rail alignment in Lyon County, 61 to approximately 81 kilometers (38 to 51 miles), exceedance of any air quality standards is not likely.

As shown in Table 4-173, fugitive dust would be the principal source of particulate matter emissions. More than half of these fugitive dust emissions would be directly associated with rail line construction. Access roads (including the alignment access roads) fugitive dust emissions would contribute about 39 percent (or 260 metric tons [290 tons] per year) of this amount; construction camp 18C or 18D would contribute about 1 percent.

4.3.4.3.1.3 Mineral County.

Emissions Appendix E describes the methodology DOE used to determine construction-related emissions. Section E.3.1.4.1 provides additional detail on the Mineral County emissions inventory.

Table 4-174 compares the highest annual total emissions under a 4-year construction schedule in Mineral County to the county's 2002 emissions estimates in the National Emission Inventory database (DIRS 177709-MO0607NEI2002D.000). The table lists potential project-related emissions as a maximum and minimum range according to the possible lengths of the existing and proposed rail line through the county, and increased equipment activity that would be necessary when construction was in rugged terrain.

Table 4-172. Maximum and minimum peak annual emissions anticipated from construction of a railroad along the Mina rail alignment through Churchill County, Nevada, compared to 2002 existing county emissions.

Emissions source	Total emissions (metric tons per year)[a,b]											
	VOCs		CO		NO_x		PM_{10}		$PM_{2.5}$		SO_2	
	Max. length[c]	Min. length[d]	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length
Construction exhaust	70	40	540	290	650	350	40	20	40	20	-	-

Totals	420	380	3,110	2,810	3,700	3,430	2,780	2,620	700	650	-	-
Off highway (2002)[e]	258		872		54		9		9		4	
Highway vehicles (2002)[e]	221		2,069		172		5		4		5	
All county sources (2002)[e]	1,260		3,093		248		1,636		436		23	

a. To convert metric tons to tons, multiply by 1.1023.
b. CO = carbon monoxide; NO_x = nitrogen oxides; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO_2 = sulfur dioxide; VOCs = volatile organic compounds.
c. Maximum (Max.) length of rail alignment in Mineral County would be 171 kilometers (100 miles). (The maximum and minimum lengths along the complete rail alignment are not equal to the sum of the possible maxima or the minima in individual counties.)
d. Minimum (Min.) length of rail alignment in Mineral County would be 153 kilometers (95 miles).
e. Only includes anthropogenic (the influence of humans on the environment) source of emissions (DIRS 177709-MO0607NEI2002D.000).

Simulated construction-related emissions for VOCs, CO, PM_{10}, and $PM_{2.5}$ would be comparable to the county's 2002 annual emissions for these air pollutants. NO_x emissions would be 3,500 metric tons (3,800 tons) per year greater than the 2002 county-wide emissions. However, these emissions would be distributed over the entire length of the rail line in Mineral County, 153 to 171 kilometers (95 to 106 miles), and would not lead to a localized problem.

As shown in Table 4-174, fugitive dust would be the principal source of particulate matter emissions. More than half of these fugitive dust emissions would be directly associated with rail line construction. Access roads (including the alignment access roads) fugitive dust emissions would contribute about 39 percent (or 1,000 metric tons [1,100 tons] per year) of this amount; while construction of the Staging Yard would contribute about 1 percent, construction camps 15,16, and 17, about 1 percent each, and all wells about 4 percent.

Air Quality Impacts, Construction Activities DOE modeled air quality to determine how construction of the proposed railroad would be likely to impact air pollutant concentrations near Mina, Hawthorne, and Schurz, in Mineral County. In addition to the rail line, the air quality modeling included the impact from constructing the Staging Yard at Hawthorne. Appendix E, Section E.3.1.4.2, summarizes the modeling methodology DOE used to assess construction-related air quality impacts in Mineral County.

Table 4-175 shows the maximum modeled concentrations at any receptor point within the construction right-of-way of criteria air pollutants that could be emitted during the construction phase near Mina. Tables 4-176 and 4-177 show the maximum modeled concentrations at any receptor point during the construction phase near Hawthorne and Schurz, respectively. In each case, DOE modeled a 3-year period using 3 years of actual meteorological data from 2004 through 2006. The following tables also list the highest background concentration (see Section 3.3.4 for the basis of the background concentration) and the relevant NAAQS for each air pollutant, and the maximum resulting concentration as a fraction of the NAAQS.

Table 4-175. Maximum air pollutant concentrations in the construction right-of-way from construction of the proposed railroad near Mina, Nevada.

Averaging period	Air pollutant[a]		Background concentration[b]	Maximum project impact[c]	Maximum resulting concentration	NAAQS[d]	Maximum concentration (percent of standard)

	PM_{10}	$\mu g/m^3$	23	29	52	50[f]	103
	$PM_{2.5}$	$\mu g/m^3$	5.4	6.6	12	15	80
	SO_2	ppm	0.002	< 0.0001	0.002	0.03	7

a. CO = carbon monoxide; NO_2 = nitrogen dioxide; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; ppm = parts per million; SO_2 = sulfur dioxide; $\mu g/m^3$ = micrograms per cubic meter.
b. Sources: DIRS 182287-Hoelscher 2007, all for CO, SO_2, and NO_2; 40 CFR 50.4 through 50.11; DIRS 180073-Tribal Environmental Exchange Network 2007, all.
c. < = less than.
d. NAAQS = National Ambient Air Quality Standards.
e. For comparison to the air quality standard, the 3-year average of the 98^{th} percentile is 16 micrograms per cubic meter.
f. The Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 *FR* 60853, October 17, 2006), but the Nevada annual average PM_{10} standard remains in effect.

At Hawthorne, the maximum concentrations from construction of the proposed rail line would be below the NAAQS for all air pollutants and all averaging periods. For rail line construction at Mina and Schurz, under current, conservative estimates of emissions and dispersion from the associated activities, PM_{10} would exceed the 24-hour average NAAQS levels, while for Schurz the 24-hour $PM_{2.5}$ concentrations would also be above the NAAQS levels. However, each of these exceedances would apply only at the edge of the construction right-of-way and would only occur during the relatively short time of construction activities (less than 6 months). Air quality disposition modeling for Schurz shows that the highest simulated 24-hour PM_{10} and $PM_{2.5}$ concentrations in town, including background concentration, would be 105 and 25 micrograms per cubic meter, respectively, both of which would be well below the NAAQS levels. Similarly, air quality modeling in the town of Mina, showed that the simulated maximum 24-hour PM_{10} and $PM_{2.5}$ concentrations, including background concentration, would be 128 and 28 micrograms per cubic meter, respectively, also below the NAAQS levels.

Table 4-178 shows the maximum concentrations at any modeled receptor point of criteria air pollutants that would be emitted over the 3-year modeling period as a result of construction of the proposed Staging Yard at Hawthorne. The table also shows the highest background concentration (second highest for 24-hour PM_{10}) of each air pollutant (see Section 3.3.4 for the basis of the background concentration) and the relevant NAAQS for each air pollutant, and the maximum resulting concentration as a fraction of the NAAQS. Figure 4-28 shows the predicted second highest 24-hour PM_{10} concentration near the proposed site of the Staging Yard at Hawthorne to illustrate the construction-related air pollutant concentrations relative to the form of the NAAQS in this area.

Table 4-178. Maximum air pollutant concentrations at the facility fence line from construction of the proposed Staging Yard at Hawthorne, Nevada.

Averaging period	Air pollutant[a]		Background concentration[b]	Maximum project impact[c]	Maximum resulting concentration	NAAQS[d]	Maximum concentration (percent of standard)
1-hour	CO	ppm	1.8	4.9	6.7	35	19

Annual	NO_2	ppm	0.004	0.005	0.009	0.053	18
	PM_{10}	μg/m^3	23	28	51	50[f]	102
	$PM_{2.5}$	μg/m^3	5.4	5.7	11	15	74
	SO_2	ppm	0.002	< 0.0001	0.002	0.03	7

a. CO = carbon monoxide; NO_2 = nitrogen dioxide; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; ppm = parts per million; SO_2 = sulfur dioxide; μg/m^3 = micrograms per cubic meter.
b. Sources: DIRS 182287-Hoelscher 2007, all for CO, SO_2, and NO_2; 40 CFR 50.4 through 50.11; DIRS 180073-Tribal Environmental Exchange Network 2007, all.
c. < = less than.
d. NAAQS = National Ambient Air Quality Standards.
e. For comparison to the air quality standard, the 3-year average of the 98th percentile is 16 micrograms per cubic meter.
f. The Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 *FR* 60853, October 17, 2006), but the Nevada annual average PM_{10} standard remains in effect.

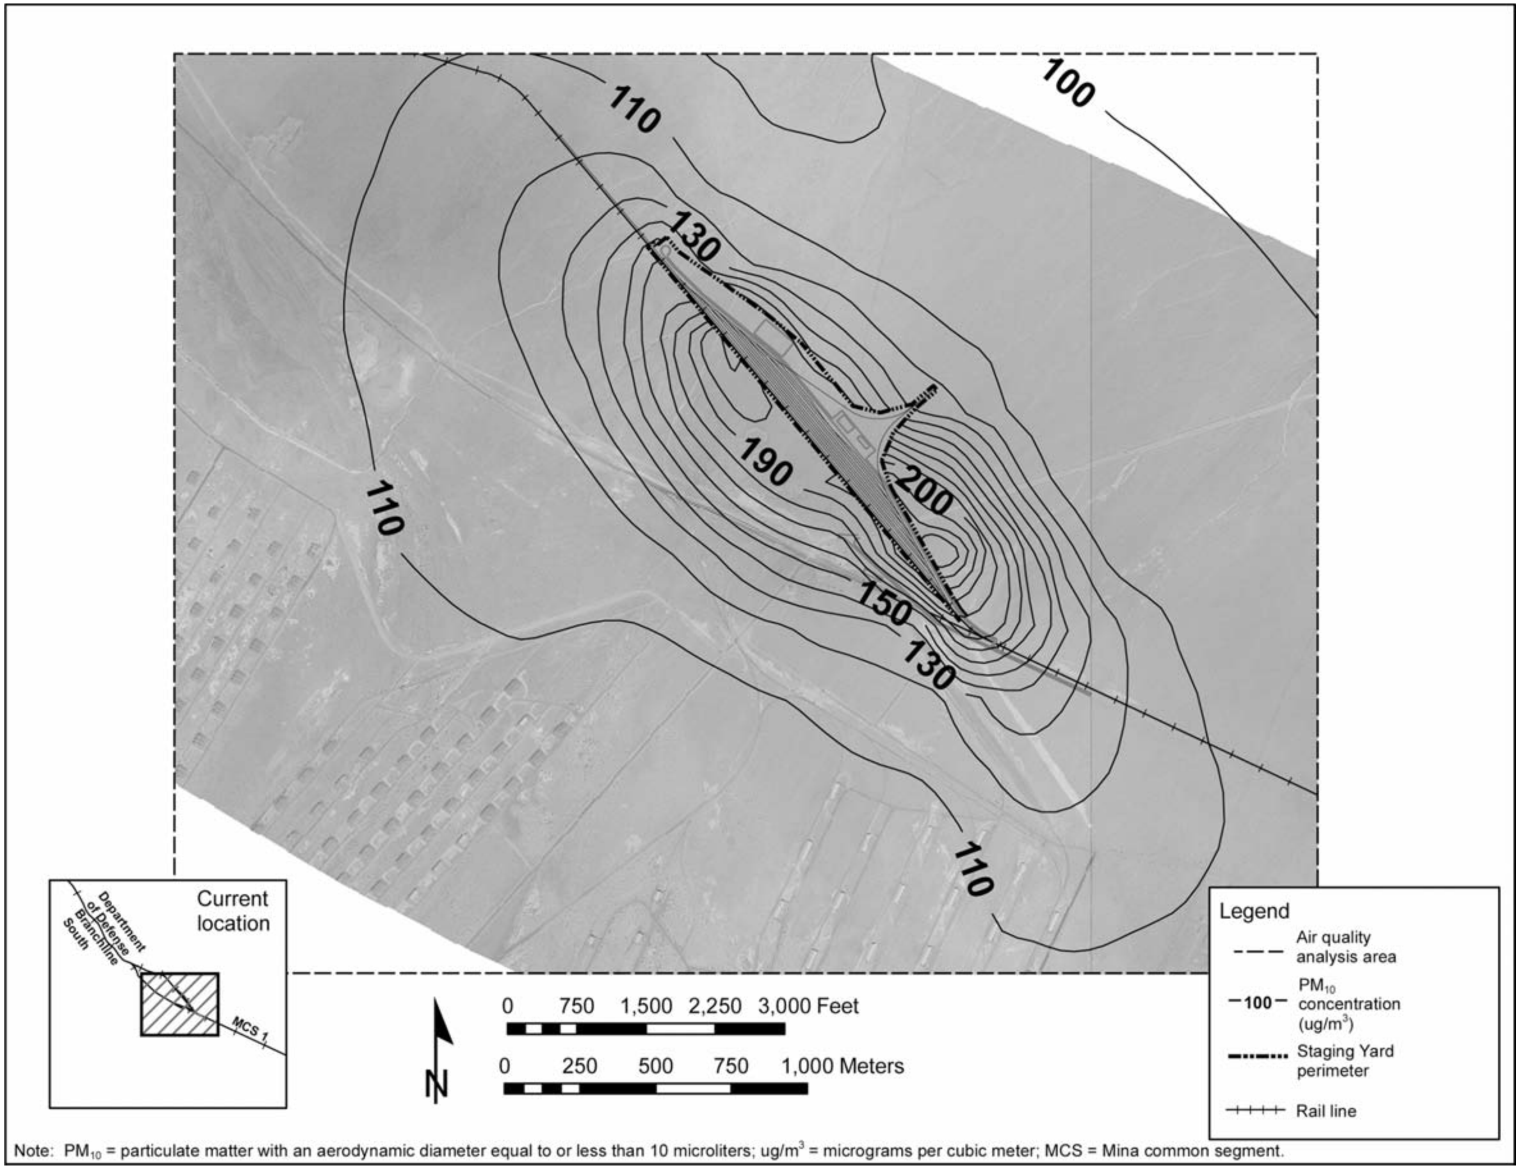

Figure 4-28. Simulated maximum modeled 24-hour PM_{10} concentrations, including background, from construction of the proposed Staging Yard near Hawthorne, Nevada.

The maximum concentrations from construction of the Staging Yard at Hawthorne would be below NAAQS for all air pollutants except for the 24-hour PM_{10} and $PM_{2.5}$ concentration at the facility fence line under the conservative modeling approach DOE employed here, and would only occur during the 12-month construction period. Also, as shown in Figure 4-28, air pollutant concentrations in the population centers farther from the facility than the fence line would have lower concentrations, below all applicable air quality standards.

In addition, under Nevada Administrative Code 445B.22037, DOE would be required to obtain a Surface Area Disturbance Permit Dust Control Plan, which would address in detail the best types of fugitive dust control methods to be used. Specifics as to the best control methods would depend on the specific layout, operation, and activity level at the Staging Yard. These details are not fully available at this time, but would be when DOE filed the Surface Disturbance Permit Dust Control Plan with the State of Nevada. More than one method to control fugitive dust could be necessary to prevent fugitive dust generation, and use of multiple methods to control fugitive dust must be addressed, if needed. The Permit Plan could require such measures as paving roads, cessation of operations when winds make control of fugitive dust difficult, and limitations on the areas worked per day. DOE anticipates that these measures would reduce the PM_{10} emissions, making an exceedance of the 24-hour PM_{10} NAAQS unlikely. Further, DOE could reduce this concern by acquiring additional land and moving public access (the fence line) farther away from the Staging Yard.

Air Quality Impacts, Quarry Activities DOE also performed simulations to determine potential impacts to air quality associated with activity at the potential Garfield Hills quarry near the town of Hawthorne (DIRS 180919-Nevada Rail Partners 2007, Appendixes A and B; DIRS 180881-Shannon & Wilson 2007, pp. 24 to 27). Appendix E, Section E.3.1.4.2.2, describes the methodology DOE used to simulate quarry-related impacts to air quality.

Table 4-179 shows the maximum concentrations at any modeled receptor point of criteria air pollutants that could be emitted from quarry-related activities over the 3-year period. The table also shows the highest background concentration of each air pollutant (see Section 3.3.4 for the basis of the background concentration) and the relevant NAAQS for each air pollutant, and the maximum resulting concentration as a fraction of the NAAQS.

The maximum concentrations from operation of the potential Garfield Hills quarry would be during the quarry construction, for which the results shows that concentrations would be below the NAAQS for all air pollutants except the 24-hour PM_{10} and $PM_{2.5}$ concentration at the facility fence line under the conservative modeling approach DOE employed here. However, air pollutant concentrations in the population centers farther from the facility than the fence line would have much lower concentrations. In developing the quarry, under Nevada Administrative Code 445B.22037, DOE would be required to obtain a Surface Area Disturbance Permit Dust Control Plan, which would address in detail the best types of fugitive dust control methods to be used. Specifics as to the best control methods would depend on the specific layout, operation, and activity level at the quarry. These details are not fully available at this time, but would be when DOE filed the Surface Disturbance Permit Dust Control Plan with the State of Nevada. More than one method to control fugitive dust could be necessary to prevent fugitive dust generation, and use of multiple methods to control fugitive dust must be addressed, if needed. The Permit Plan could require such measures as paving roads and cessation of operations when winds make control of fugitive dust difficult, the use of wet suppression during rock crushing, screening, and conveyor transfer. DOE anticipates that these measures would reduce the PM_{10} emissions, making an exceedance of the 24-hour PM_{10} NAAQS unlikely. During quarry operations, PM_{10} emissions would be more than 80 percent lower than during quarry construction and no exceedance of the 24-hour PM_{10} NAAQS would be expected. Further, DOE could reduce this concern by acquiring additional land and moving public access (the fence line) farther away from the quarry (see Chapter 7, Best Management Practices and Mitigation).

Table 4-179. Maximum pollutant concentration at the facility fence line from operation of the potential Garfield Hills quarry during the construction phase.

Averaging period	Air pollutant[a]		Background concentration[b]	Maximum project impact[c]	Maximum resulting concentration	NAAQS[d]	Maximum concentration (percent of standard)
1-hour	CO	ppm	1.8	1.7	3.5	35	10
3-hours	SO_2	ppm	0.072	0.001	0.07	0.5	14
8-hours	CO	ppm	1.4	0.34	1.74	9	15
24-hours	PM_{10}	$\mu g/m^3$	99	201.	300	150	200
	$PM_{2.5}$	$\mu g/m^3$	16[e]	17.4	33.4	35	95
	SO_2	ppm	0.025	< 0.0001	0.03	0.14	18
Annual	NO_2	ppm	0.004	0.001	0.005	0.053	10
	PM_{10}	$\mu g/m^3$	23	23	46	50[f]	93
	$PM_{2.5}$	$\mu g/m^3$	5.4	2.9	8.3	15	55
	SO_2	ppm	0.002	< 0.0001	0.002	0.03	7

a. CO = carbon monoxide; NO_2 = nitrogen dioxide; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; ppm = parts per million; SO_2 = sulfur dioxide; $\mu g/m^3$ = micrograms per cubic meter.
b. Sources: DIRS 182287-Hoelscher 2007, all for CO, SO_2, and NO_2; 40 CFR 50.4 through 50.11; DIRS 180073-Tribal Environmental Exchange Network 2007, all.
c. < = less than.
d. NAAQS = National Ambient Air Quality Standards.
e. For comparison to the air quality standard, the 3-year average of the 98th percentile is 16 micrograms per cubic meter.
f. The Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 *FR* 60853, October 17, 2006), but the Nevada annual average PM_{10} standard remains in effect.

DOE did not model other construction activities (at access roads, construction camps, and wells) because emissions from those construction activities would be smaller than emissions during rail line construction and would be expected to show even lower concentrations during the operations phase; therefore, emissions would be well below NAAQS for all air pollutants.

4.3.4.3.1.4 Esmeralda County.

Emissions Appendix E describes the methodology DOE used to determine construction-related emissions. Section E.3.1.5.1 provides additional detail on the Esmeralda County emissions inventory.

Table 4-180 compares the highest annual total emissions under a 4-year construction schedule in Esmeralda County to the county's 2002 emissions estimates in the National Emission Inventory database (DIRS 177709-MO0607NEI2002D.000). The table lists potential project-related emissions as a maximum and minimum range according to the possible lengths of the rail line through the county, and increased equipment activity that would be necessary when construction was in rugged terrain.

Simulated construction-related emissions for VOCs, CO, NOx, PM_{10}, and $PM_{2.5}$ would be much larger than the county's 2002 annual emissions for these air pollutants. The emissions of NO_x during rail line construction could increase emissions by 3,570 metric tons (3,940 tons) per year over the county's 2002 annual emissions. Similarly, emissions of PM_{10} and $PM_{2.5}$ could increase by as much as 1,370 and 480 metric tons (1,500 and 530 tons) per year, respectively, over the 2002 county annual emission values. VOCs and CO would increase by 180 and 1,750 metric tons (198 and 1,930 tons) per year, respectively, over the 2002 county annual emissions. However, these emissions would be distributed over the entire length of the rail alignment in Esmeralda County (134 to 175 kilometers [83 to 109 miles]), greatly reducing any air quality impacts and would not lead to a localized problem; thus, no air quality standard would be exceeded during the construction phase in Esmeralda County, as shown in Table 4-181 for Silver Peak.

Table 4-180. Maximum and minimum peak annual emissions anticipated from construction of a railroad along the Mina rail alignment through Esmeralda County, Nevada, compared to 2002 existing county emissions.

	Total emissions (metric tons per year)[a,b]											
	VOCs		CO		NO_x		PM_{10}		$PM_{2.5}$		SO_2	
Emissions source	Max. length[c]	Min. length[d]	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length
Construction exhaust	420	330	3,100	2,400	3,720	2,860	220	170	210	170	-	-
Construction fugitive dust	-	-	-	-	-	-	2,470	2,210	460	390	-	-
Totals	420	330	3,100	2,400	3,720	2,860	2,690	2,290	670	560	-	-
Off highway (2002)[e]	9		68		26		3		3		3	
Highway vehicles (2002)[e]	131		1,247		107		3		3		3	
All county sources (2002)[e]	240		1,352		149		1,105		194		55	

a. To convert metric tons to tons, multiply by 1.1023.
b. CO = carbon monoxide; HC = hydrocarbons; NO_x = nitrogen oxides; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO_2 = sulfur dioxide; VOCs = volatile organic compounds.
c. Maximum (Max.) length of rail alignment in Esmeralda County would be 175 kilometers (109 miles). (The maximum and minimum lengths along the complete rail alignment are not equal to the sum of the possible maxima or the minima in individual counties.)
d. Minimum (Min.) length of rail alignment in Esmeralda County would be 134 kilometers (83 miles).
e. Only includes anthropogenic (the influence of humans on the environment) source of emissions (DIRS 177709-MO0607NEI2002D.000).

As shown in Table 4-180, fugitive dust would be the principal source of particulate matter emissions. More than half of these fugitive dust emissions would be directly associated rail line construction. Access roads (including the alignment access roads) fugitive dust emissions would contribute about 39 percent (or 960 metric tons [1,060 tons] per year) of this amount; while construction of the Maintenance-of-Way Facility would contribute less than 1 percent, construction camps 9 or 9A, 13A or 13B, and 14 would contribute about 1 percent each, and the wells would contribute about 4 percent.

Air Quality Impacts, Construction Activities DOE modeled air quality to determine how construction of the proposed rail line would be likely to impact air pollutant concentrations near Silver Peak, in Esmeralda County. Appendix E, Section 3.1.5.2.1 summarizes the modeling methodology DOE used to assess construction-related air quality impacts in Esmeralda County.

Table 4-181 lists the maximum concentrations at any receptor point within the modeled domain of criteria air pollutants that could be emitted during the construction phase near Silver Peak. DOE modeled the effects near Silver Peak for a 3-year period using 3 years of actual meteorological data from 2004 through 2006. The table also lists the highest background concentration of each air pollutant (see Section 3.3.4 for the basis of the background concentration) since 1991 and the relevant NAAQS for each air pollutant, and the maximum resulting concentration as a fraction of the NAAQS.

Under the conservative modeling approach DOE employed, PM_{10} concentrations were the closest to the standard at 63 percent of the NAAQS, while all other pollutants were lower. Additionally, for any distance greater than immediately at the fence line where populations are likely to be, concentrations would be below the standard. Modeling results for the central area of Silver Peak show the highest 24-hour PM_{10} and $PM_{2.5}$ concentrations, including peak background concentration, are 94 and 19 $\mu g/m^3$ (micrograms per cubic meter), respectively, both of which are below the NAAQS levels.

Air Quality Impacts, Quarry Activities DOE also performed simulations to determine potential impacts to air quality associated with activity at the potential Malpais Mesa quarry near the town of Goldfield (DIRS 180919-Nevada Rail Partners 2007, Appendixes A and B; DIRS 180881-Shannon & Wilson 2007, pp. 24 to 27). Appendix E, Section E.3.1.5.2.2, describes the methodology DOE used to simulate quarry-related impacts to air quality.

Table 4-182 shows the maximum concentrations at any receptor point of criteria air pollutants that would be emitted over the 3-year period and that would result from quarry-related activities. The table also shows the highest background concentration of each air pollutant (see Section 3.2.4 for the basis of the background concentration) since 1991 and the relevant NAAQS for each air pollutant, and the maximum resulting concentration as a fraction of the NAAQS. Modeling results show that the highest 24-hour PM_{10} and $PM_{2.5}$ concentrations, including peak background concentration, would be 71 and 15 $\mu g/m^3$, respectively, both of which are below the NAAQS levels.

DOE did not model other construction activities (access roads, construction camps, and wells) because their emissions would smaller than emissions during rail line construction and would be expected to show even lower concentrations; therefore, these emissions would be well below NAAQS for all air pollutants.

4.3.4.3.1.5 Nye County.

Emissions Appendix E describes the methodology DOE used to determine construction-related emissions. Section E.3.1.6.1 provides additional detail on the Nye County emissions inventory.

Table 4-183 compares the highest annual total emissions under a 4-year construction schedule in Nye County to the county's 2002 emissions estimates in the National Emission Inventory database (DIRS 177709-MO0607NEI2002D.000).

Table 4-181. Maximum pollutant concentrations in the construction right-of-way from construction of the proposed railroad near Silver Peak, Nevada.

Averaging period	Air pollutant[a]		Background concentration[b]	Maximum project impact[c]	Maximum resulting concentration	NAAQS[d]	Maximum concentration (percent of standard)
1-hour	CO	ppm	0.2	2.5	2.7	35	8
3-hours	SO_2	ppm	0.002	< 0.0001	0.002	0.5	< 1
8-hours	CO	ppm	0.2	0.45	0.65	9	7
24-hours	PM_{10}	$\mu g/m^3$	39	55	94	150	63
	$PM_{2.5}$	$\mu g/m^3$	12	6.5	19	35	54
	SO_2	ppm	0.002	< 0.0001	0.002	0.14	14
Annual	NO_2	ppm	0.002	0.002	0.004	0.053	7.5
	PM_{10}	$\mu g/m^3$	12	7.4	19.4	50[e]	39
	$PM_{2.5}$	$\mu g/m^3$	3.6	1.6	5.2	15	35
	SO_2	ppm	0.002	< 0.0001	0.002	0.03	7

a. CO = carbon monoxide; NO_2 = nitrogen dioxide; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; ppm = parts per million; SO_2 = sulfur dioxide; $\mu g/m^3$ = micrograms per cubic meter.

	SO_2	ppm	0.002	0.00001	0.002	0.14	1
Annual	NO_2	ppm	0.002	0.0001	0.0021	0.053	4
	PM_{10}	$\mu g/m^3$	12	3.2	15.2	50[e]	30
	$PM_{2.5}$	$\mu g/m^3$	3.6	0.4	4	15	27
	SO_2	ppm	0.002	< 0.0001	0.002	0.03	7

a. CO = carbon monoxide; NO_2 = nitrogen dioxide; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; ppm = parts per million; SO_2 = sulfur dioxide; $\mu g/m^3$ = micrograms per cubic meter.
b. Sources: DIRS 182287-Hoelscher 2007, all; DIRS 179933-State of Nevada 2007; 40 CFR 50.4 through 50.11; DIRS 180073-Tribal Environmental Exchange Network 2007, all.
c. < = less than.
d. NAAQS = National Ambient Air Quality Standards.
e. The Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 *FR* 60853, October 17, 2006), but the Nevada annual average PM_{10} standard remains in effect.

The table lists potential project-related emissions as a maximum and minimum range according to the possible lengths of the proposed rail alignment through the county, and increased equipment activity that would be necessary when construction was in rugged terrain.

Simulated construction-related emissions for VOCs, SOx, CO, PM_{10}, and $PM_{2.5}$ would be less than the county's 2002 annual emissions for these air pollutants. The emissions of NO_x during the construction phase could increase emissions by 2,300 metric tons (2,500 tons) per year over the county's 2002 annual emissions. Given that these emissions would be distributed over the entire length of the rail line in Nye County (126 to 148 kilometers [78 to 92 miles]), no air quality standards would be exceeded.

As shown in Table 4-183, fugitive dust would the principal source of particulate matter emissions. More than half of these fugitive dust emissions would be directly associated with rail line construction. Access roads (including the alignment access roads) fugitive dust emissions would contribute about 39 percent (or 780 metric tons [860 tons] per year) of this amount; while construction camps 9 or 9A, 10, 11 and 12 would contribute about 1 percent each, and all wells would contribute about 4 percent.

DOE did not model other construction activities (at access roads, construction camps, and wells) because emissions from those construction activities would be smaller than emissions during rail line construction and would be expected to show even lower concentrations; therefore, those emissions would be well below NAAQS for all air pollutants.

4.3.4.3.2 Operations Impacts

Exhaust emissions during the railroad operations phase would impact air quality, but these impacts would be small.

Appendix E describes the modeling approach and methodology DOE used to estimate operations exhaust emissions and impacts to air quality.

DOE evaluated exhaust emissions and impacts to air quality by county because the most complete and comprehensive emissions data are available only at the county level. To assess emissions impacts, DOE compared modeled operations emissions with 2002 annual county-wide emissions for NO_x, $PM_{10,}$ $PM_{2.5}$, SO_2, CO, and VOCs. To assess impacts to air quality, DOE compared resulting concentrations of these air pollutants to the NAAQS. Churchill, Lyon, Mineral, Esmeralda, and Nye Counties are all in attainment for ozone. Ozone is generally recognized as a regional-scale air quality problem.
The potential increase in the emissions of VOCs (a precursor to ozone formation) associated with the operations phase would be small in relation to the existing regional emissions of VOCs. Thus, the impact on ozone formation would not cause a violation of the ozone standard.

Sections 4.3.4.3.2.1 through 4.3.4.3.2.5 detail the potential emissions and air quality impacts during the railroad operations phase in Churchill, Lyon, Mineral, Esmeralda, and Nye Counties.

4.3.4.3.2.1 Churchill County.

<u>Emissions</u> Appendix E describes the methodology DOE used to assess operations-related emissions. Section E.3.2.2.1 provides additional detail on the Churchill County emissions inventory.

Table 4-184 compares the modeled highest annual total emissions during operation of the rail line in Churchill County to the county's 2002 National Emission Inventory database emissions estimates (DIRS 177709-MO0607NEI2002D.000). The table lists project-related emissions as a maximum and minimum range according to the possible lengths of the rail alignment through Churchill County.

Table 4-183. Maximum and minimum peak annual emissions anticipated from construction of a railroad along the Mina rail alignment through Nye County, Nevada, compared to 2002 existing county emissions.

	Total emissions (metric tons per year)[a,b]											
	VOCs		CO		NO_x		PM_{10}		$PM_{2.5}$		SO_x	
Emissions source	Max. length[c]	Min. length[d]	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length
Construction[f] exhaust	370	320	2,700	2,320	3,200	2,750	190	160	180	160	< 1	< 1
Construction fugitive dust	0	0	0	0	0	0	1,990	1,820	400	360	0	0
Totals	370	320	2,700	2,320	3,720	2,860	2,180	1,980	580	520	< 1	< 1
Off highway (2002)[e]	338		1,788		199		27		25		22	
Highway vehicles (2002)[e]	1,335		13,977		1,050		32		25		28	
All county sources (2002)[e]	2,279		17,071		1,436		3,324		650		237	

a. To convert metric tons to tons, multiply by 1.1023.
b. CO = carbon monoxide; NO_x = nitrogen oxides; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO_2 = sulfur dioxide; VOCs = volatile organic compounds.
c. Maximum (Max.) length of rail alignment in Nye County would be 148 kilometers (92 miles). (The maximum and minimum lengths along the complete rail alignment are not equal to the sum of the possible maxima or the minima in individual counties.)
d. Minimum (Min.) length of rail alignment in Nye County would be 126 kilometers (78 miles).
e. Only includes anthropogenic (the influence of humans on the environment) source of emissions (DIRS 177709-MO0607NEI2002D.000).
f. < = less than.

Table 4-184. Maximum and minimum peak annual emissions anticipated from operation of a railroad along the Mina rail alignment through Churchill County, Nevada, compared to 2002 existing county emissions.

Emissions source	Total emissions (metric tons per year)[a,b]											
	VOCs		CO		NO_x		PM_{10}		$PM_{2.5}$		SO_x	
	Max. length[c]	Min. length[d]	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length	Max. length	Min. length
Operations exhaust	-	-	2	1	9	5	-	-	-	-	-	-
Off highway (2002)[e]	748		2,431		527		35		33		36	
Highway vehicles (2002)[e]	1,782		19,067		1,796		50		39		45	
All county sources (2002)[e]	4,353		27,556		2,524		5,248		1,138		280	
Percent increase[f] (projected emission/county emission × 100)	< 0.1	< 0.1	< 0.1	< 0.1	0	0	< 0.1	< 0.1	< 0.1	< 0.1	< 0.1	< 0.1

a. To convert metric tons to tons, multiply by 1.1023.
b. CO = carbon monoxide; NO_x = nitrogen oxides; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO_2 = sulfur dioxide; VOCs = volatile organic compounds.
c. Maximum (Max.) length of rail alignment in Churchill County would be 17 kilometers (11 miles). (The maximum and minimum lengths along the complete rail alignment are not equal to the sum of the possible maxima or the minima in individual counties.)
d. Minimum (Min.) length of rail alignment in Churchill County would be 31 kilometers (20 miles).
e. Only includes anthropogenic (the influence of humans on the environment) source of emissions (DIRS 177709-MO0607NEI2002D.000).
f. < = less than.

The projected operations-related emissions for all air pollutants considered in this analysis would be much less than the county's 2002 annual emissions for these air pollutants. These emissions would be distributed over the entire length of the rail alignment through Churchill County (17 to 31 kilometers [11 to 20 miles]); thus, no air quality standard would be exceeded.

4.3.4.3.2.2 Lyon County.

Emissions Appendix E describes the methodology DOE used to assess operations-related emissions. Section E.3.2.3.1 provides additional detail on the Lyon County emissions inventory.

Table 4-185 compares the modeled highest annual total emissions during operation of the rail line in Lyon County to the county's 2002 National Emission Inventory database emissions estimates (DIRS 177709-MO0607NEI2002D.000). The table lists project-related emissions as a maximum and minimum range according to the possible lengths of the rail alignment through Lyon County.

The projected operations-related emissions for all air pollutants considered in this analysis would be much less than the county's 2002 annual emissions for these air pollutants. These emissions would be distributed over the entire length of the rail alignment through Lyon County (61 to 81 kilometers [38 to 51 miles]); thus, no air quality standard would be exceeded.

4.3.4.3.2.3 Mineral County.

Emissions Appendix E describes the methodology DOE used to assess operations-related emissions. Section E.3.2.4.1 provides additional detail on the Mineral County emissions inventory.

Table 4-186 compares the modeled highest annual total emissions during operation of the rail line in Mineral County to the county's 2002 National Emission Inventory database emissions estimates (DIRS 177709-MO0607NEI2002D.000). The table lists project-related emissions as a maximum and minimum range according to the possible lengths of the rail alignment through the county.

The projected operations-related emissions for all air pollutants considered in this analysis would be much less than the county's 2002 annual emissions for these air pollutants. These emissions would be distributed over the entire length of the rail alignment through Mineral County (153 to 171 kilometers [95 to 106 miles]); thus, no air quality standard would be exceeded.

Air Quality Impacts DOE modeled air quality to determine how railroad operations would be likely to impact air pollutant concentrations near the towns of Mina, Hawthorne, and Schurz, and the Staging Yard at Hawthorne. Appendix E, Section E.3.2.4.2, summarizes the modeling methodology DOE used to assess operations-related impacts to air quality in Mineral County.

Table 4-187 lists the maximum concentrations at any modeled receptor point of the criteria air pollutants that would result from operation of the proposed rail line near Mina. DOE modeled a 3-year period using 3 years of actual meteorological data from 2004 through 2006. The table also lists the highest background concentration of each air pollutant (see Section 3.3.4 for the basis of the background concentration) since 1991 and the relevant NAAQS for each air pollutant, and the maximum resulting concentration as a fraction of the NAAQS. Similarly, Tables 4-188 and 4-189 list the maximum concentrations for Hawthorne and Schurz, respectively. In each case, the maximum concentrations from operation of the proposed rail line would be below the NAAQS for all air pollutants. The maximum fraction of the NAAQS modeled at each location was for the 24-hour PM_{10} concentration with 66 percent at Mina, 66 percent at Hawthorne, and 67 percent at Schurz. Table 4-190 lists the maximum concentrations for operation of the Staging Yard at Hawthorne. Figure 4-29 shows the predicted second highest 24-hour PM_{10} concentration near the proposed site of the Staging Yard near Hawthorne to illustrate the operations-related air pollutant concentrations, in the form of the NAAQS, in the vicinity of the Yard.

Table 4-185. Maximum and minimum peak annual emissions anticipated from operation of a railroad along the Mina rail alignment through Lyon County, Nevada, compared to 2002 existing county emissions.

Emissions source	Total emissions (metric tons per year)[a,b]

d. NAAQS = National Ambient Air Quality Standards.
e. For comparison to the air quality standard, the 3-year average of the 98th percentile is 16 micrograms per cubic meter.
f. The Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 *FR* 60853, October 17, 2006), but the Nevada annual average PM_{10} standard remains in effect.

Table 4-190. Maximum pollutant concentrations from operation of the proposed Staging Yard at Hawthorne, Nevada.

Averaging period	Air pollutant[a]		Background concentration[b]	Maximum project impact[c]	Maximum resulting concentration	NAAQS[d]	Maximum concentration (percent of standard)
1-hour	CO	ppm	1.8	1.1	2.9	35	8
3-hours	SO_2	ppm	0.07	< 0.001	0.07	0.5	15
8-hours	CO	ppm	1.4	0.04	1.44	9	16
24-hours	PM_{10}	μg/m^3	99	16.3	115	150	77
	$PM_{2.5}$	μg/m^3	16[e]	11	27	35	77
	SO_2	ppm	0.03	0.0002	0.03	0.14	18
Annual	NO_2	ppm	0.004	0.02	0.024	0.05	48
	PM_{10}	μg/m^3	23	5.3	28.3	50[f]	59
	$PM_{2.5}$	μg/m^3	5.4	4.8	10.2	15	68
	SO_2	ppm	0.002	< 0.0001	0.002	0.03	7

a. CO = carbon monoxide; NO_2 = nitrogen dioxide; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; ppm = parts per million; SO_2 = sulfur dioxide; μg/m^3 = micrograms per cubic meter.
b. Sources: DIRS 182287-Hoelscher 2007, all for CO, SO_2, and NO_2; 40 CFR 50.4 through 50.11; DIRS 180073-Tribal Environmental Exchange Network 2007, all.
c. < = less than.
d. NAAQS = National Ambient Air Quality Standards.
e. For comparison to the air quality standard, the 3-year average of the 98th percentile is 16 micrograms per cubic meter.
f. The Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 *FR* 60853, October 17, 2006), but the Nevada annual average PM_{10} standard remains in effect.

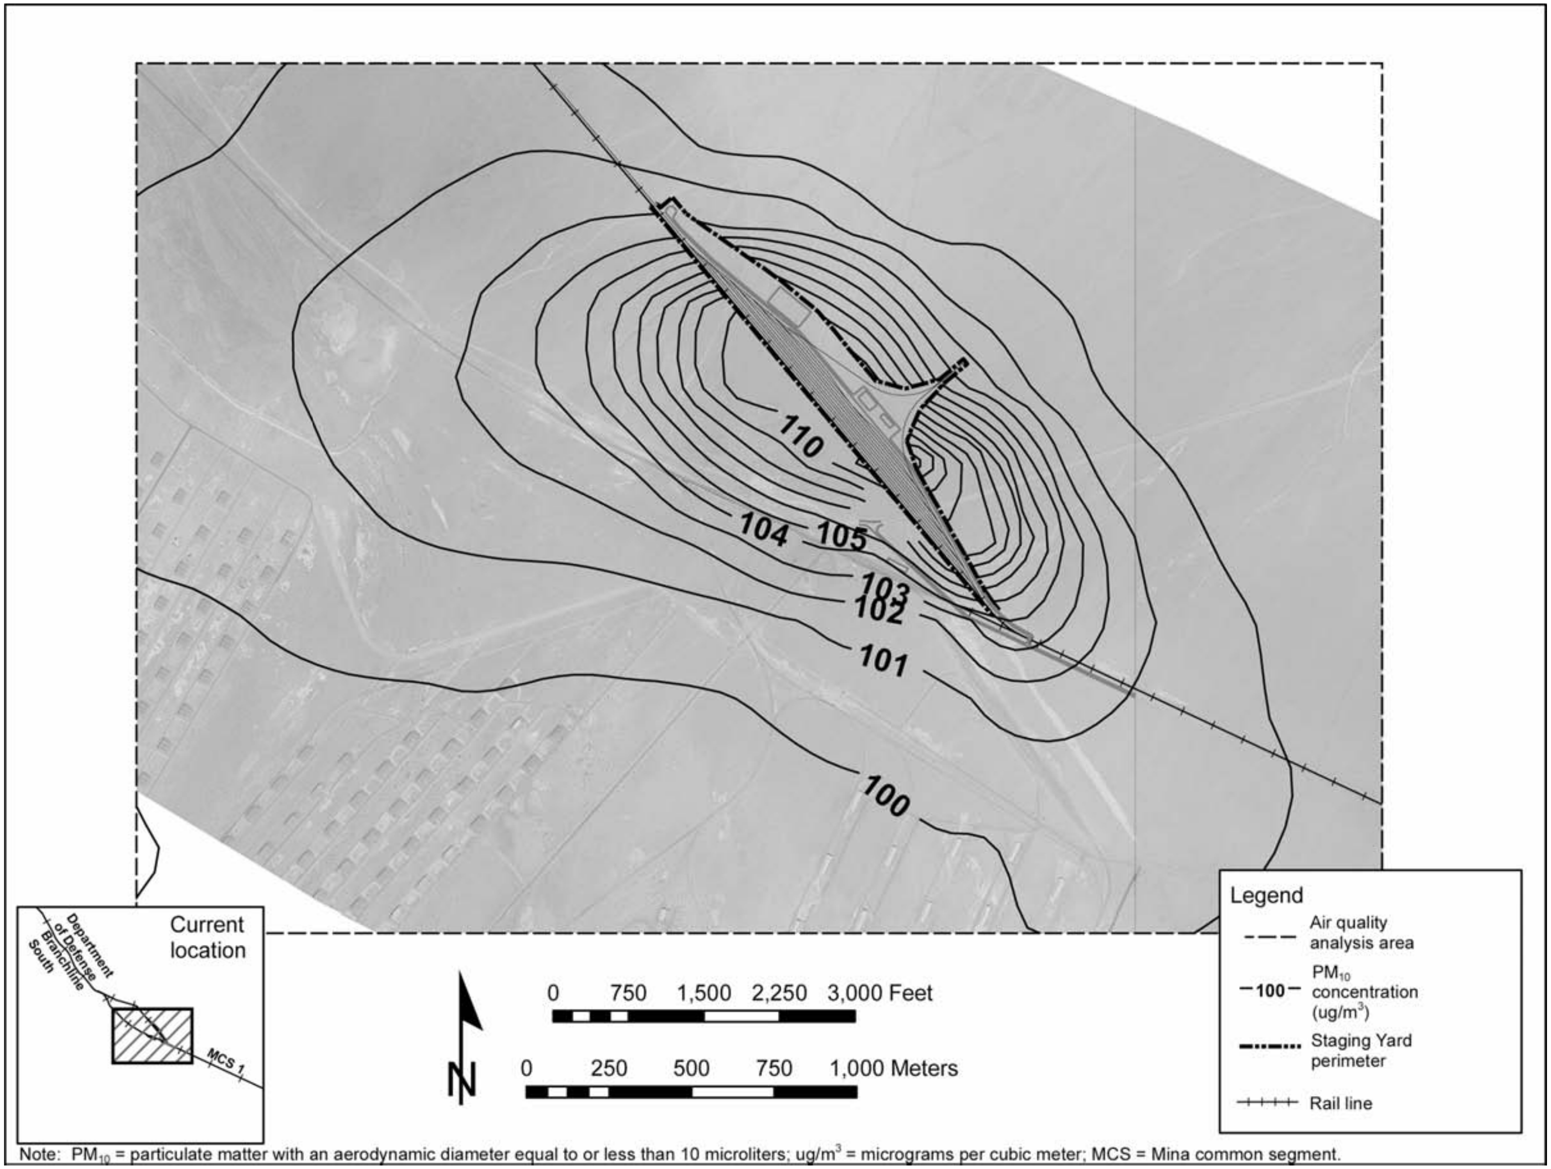

Figure 4-29. Simulated maximum modeled 24-hour PM_{10} concentrations, including background, from operation of the proposed Staging Yard at Hawthorne, Nevada.

The maximum fraction of the NAAQS at the Staging Yard would be 77 percent for 24-hour $PM_{2.5}$ (DIRS 177709-MO0607NEI2002D.000). The table lists potential project-related emissions as a maximum and minimum range according to the possible lengths of the rail alignment through the county.

The projected operations-related emissions for all air pollutants considered in this analysis would be much less than the county's 2002 annual emissions for these air pollutants. These emissions would be distributed over the entire length of the rail alignment through Mineral County (153 to 171 kilometers [95 to 106 miles]); thus, no air quality standard would be exceeded.

4.3.4.3.2.4 Esmeralda County.

Emissions Appendix E describes the methodology DOE used to assess operations-related emissions. Section E.3.2.5.1 provides additional detail on the Esmeralda County emissions inventory.

Table 4-191 compares the modeled highest annual total emissions during the railroad operations phase in Esmeralda County to the county's 2002 National Emission Inventory database emissions estimates (DIRS 177709-MO0607NEI2002D.000). The table lists project-related emissions as a maximum and minimum range according to the possible lengths of the rail alignment through the county.

The projected operations-related emissions for all air pollutants considered in this analysis would be much less than the county's 2002 annual emissions for these air pollutants. These emissions would be distributed over the entire length of the rail alignment through Esmeralda County (134 to 175 kilometers [83 to 109 miles]); thus, no air quality standard would be exceeded.

Air Quality Impacts DOE modeled air quality to determine how the operations phase would be likely to impact air pollutant concentrations near Silver Peak. Appendix E, Section E.3.2.5.2, summarizes the modeling methodology DOE used to assess operations-related impacts to air quality in Esmeralda County.

Table 4-192 lists the maximum concentrations at any modeled receptor point of the criteria air pollutants that would result from operation of the proposed rail line near Silver Peak. DOE modeled a 3-year period using 3 years of actual meteorological data from 2004 through 2006. The table also lists the highest background concentration of each air pollutant since 1991 (see Section 3.3.4 for the basis of the background concentration) and the relevant NAAQS for each air pollutant, and the maximum resulting concentration as a fraction of the NAAQS. The maximum concentrations from railroad operations near Silver Peak would be 34 percent for the 24-hour $PM_{2.5}$ standard which is well below the NAAQS.

4.3.4.3.2.5 Nye County.

Emissions Appendix E describes the methodology DOE used to assess operations-related emissions. Section E.3.2.6.1 provides additional detail on the Nye County emissions inventory.

Table 4-193 compares the modeled highest annual total emissions during operation of the rail line in Nye County to the county's 2002 National Emission Inventory database emissions estimates (DIRS 177709-MO0607NEI2002D.000). The table lists project-related emissions as a maximum and minimum range according to the possible lengths of the rail alignment through the county.

The projected operations-related emissions for all air pollutants considered in this analysis would be much less than the county's 2002 annual emissions for these air pollutants. These emissions would be primarily from operation of the rail line, Cask Maintenance Facility, and Rail Equipment Maintenance Yard, with the bulk of the emissions associated with the operation of the Cask Maintenance Facility and Rail Equipment Maintenance Yard. The rail line emissions would be distributed over the entire length of the rail alignment through Nye County (126 to 148 kilometers [78 to 92 miles]); thus, no air quality standard

Table 4-191. Maximum and minimum peak annual emissions anticipated from operation a railroad along the Mina rail alignment through Esmeralda County, Nevada, compared to 2002 existing county emissions.

b. Sources: DIRS 182287-Hoelscher 2007, all; DIRS 179933-State of Nevada 2007; DIRS 180073-Tribal Environmental Exchange Network 2007, all.
c. < = less than.
d. NAAQS = National Ambient Air Quality Standards.
e. The Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 *FR* 60853, October 17, 2006), but the Nevada annual average PM_{10} standard remains in effect.

would be exceeded. Similarly, no air quality problems would be anticipated from operation of the Cask Maintenance Facility and Rail Equipment Maintenance Yard inside the Yucca Mountain Site boundary because the distance from those facilities to the nearest point of public access would be more than 11 kilometers (7 miles). At that distance, there would be no or small impacts on air quality from operation of the facilities.

4.3.4.4 Shared-Use Option

Impacts to air quality along the Mina rail alignment under the Shared-Use Option would be similar to those under the Proposed Action without shared use.

Under the Shared-Use Option, commercial entities could construct additional sidings of 300 meters (980 feet) in length at a number of locations along the rail alignment. Operationally, the Shared-Use Option would consist of up to 60 railcars pulled by three or four locomotives at a frequency of up to 18 additional one-way trips per week along the Mina rail alignment north of Schurz and ten additional one-way trips south of Schurz.

The additional sidings would be placed parallel to track within the construction right-of-way and would not require additional rail roadbed foundation, only additional laying of track. Overall, additional construction-related emissions would be very small. Appendix E, Section E.3.3, describes the rationale for not conducting additional emissions inventory calculations or air quality simulations to assess construction-related impacts under the Shared-Use Option.

Table 4-193. Maximum and minimum peak annual emissions anticipated from operation of a railroad along the Mina rail alignment through Nye County, Nevada, compared to 2002 existing county emissions.

Emissions source	Total emissions (metric tons per year)[a,b]											
	VOCs		CO		NO_x		PM_{10}		$PM_{2.5}$		SO_x

Percent increase (projected emission/county emission × 100)	2	2	1	1	30	30	0	0	2	2	0	0

a. To convert metric tons to tons, multiply by 1.1023.
b. CO = carbon monoxide; NO_x = nitrogen oxides; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO_2 = sulfur dioxide; VOCs = volatile organic compounds.
c. Maximum (Max.) length of rail alignment in Nye County would be 148 kilometers (92 miles). (The maximum and minimum lengths along the complete rail alignment are not equal to the sum of the possible maxima or the minima in individual counties.)
d. Minimum (Min.) length of rail alignment in Nye County would be 126 kilometers (78 miles).
e. Only includes anthropogenic (the influence of humans on the environment) source of emissions (DIRS 177709-MO0607NEI2002D.000).

Appendix E, Section E.3.3, also describes the methodology DOE used to calculate potential emissions that would result from the five additional round trips per week of commercial train activity associated with the Shared-Use Option south of Schurz and nine round trips north of Schurz. For Churchill, Lyon, Mineral, Esmeralda, and Nye Counties, Tables 4-194 to 4-198 compare the minimum and maximum annual incremental emissions expected from operation of commercial trains under the Shared-Use Option with each county's 2002 National Emission Inventory database emissions (DIRS 177709-MO0607NEI2002D.000), based on the shortest and longest routes through the counties. Also shown is the range of peak county-wide emissions that would result from the Proposed Action, as discussed in Section 4.3.4.3, and the resulting range of peak emissions totals by county.

As shown in Tables 4-194 through 4-198, under the Shared-Use Option, total emissions would be increased marginally (as discussed above) beyond those associated with railroad operations under the Proposed Action. Likewise, the maximum air pollutant concentrations expected under the Shared-Use Option would be marginally increased. These levels have been shown to be low (see Tables 4-187, 4-188, 4-189 and 4-192). Therefore, DOE did not perform additional and separate air quality modeling of air pollutant concentrations for the Shared-Use Option.

4.3.4.5 Summary

Potential impacts to air quality from construction and operation of the proposed railroad along the Mina rail alignment would be as follows:

- The project would not cause conflicts with state or regional air quality management plans.
- The highest increase in air emissions from railroad operations would occur in the vicinity of the operations support facilities.
- The highest increase in air pollutant emissions would occur during the construction phase.
- Air pollutant concentrations would not exceed the NAAQS during the construction or operations phase, with the exception of the 24-hour NAAQS for both PM_{10} and $PM_{2.5}$ that could be exceeded near the construction right-of-way at Mina and Schurz during the relatively short (less than 6 months) construction period, at the Staging Yard at Hawthorne, and at the potential Garfield Hills quarry. However, DOE would be required to obtain a Surface Area Disturbance Permit Dust Control Plan prior to quarry and Staging Yard development, and it is likely that requirements in the plan would reduce fugitive dust emissions, thus reducing the possibility of NAAQS exceedances.
- The highest increase in emissions would be for NO_x in Esmeralda County during the construction phase, where emissions could be 3,570 metric tons (3,940 tons) per year higher than the county's 2002 annual NO_x emissions.
- The Shared-Use Option would result in a slightly higher increase in air pollutant emissions and air pollutant concentrations than under the Proposed Action without shared use.

Annualized emissions for all air pollutants projected to be released during the construction phase would be greater than during the operations phase. Projected ambient concentrations of all air pollutants would be below the NAAQS, except for particulate matter during the construction phase, which could exceed the 24-hour NAAQS under some conditions. Therefore, the projected impacts throughout the region of influence, during both the construction and operations phases, would be small, except possibly in the vicinity of the potential Garfield Hills quarry, the Staging Yard at Hawthorne, and segments of the rail line (only during construction). Under the Shared-Use Option, there would be in an increase in emissions over those of the Proposed Action without shared use, but impacts to air quality would still be small. Table 4-199 summarizes impacts to air quality.

Table 4-194. Maximum and minimum peak annual incremental emissions anticipated from operation of commercial trains along the Mina rail alignment under the Shared-Use Option through Churchill County, Nevada, and county-wide total railroad operations emissions compared to 2002 existing county emissions.

a. To convert metric tons to tons, multiply by 1.1023.
b. CO = carbon monoxide; NOx = nitrogen oxides; PM10 = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; PM2.5 = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO2 = sulfur dioxide; VOCs = volatile organic compounds.
c. Maximum (Max.) length of rail alignment in Nye County would be 148 kilometers (92 miles). (The maximum and minimum lengths along the complete rail alignment are not equal to the sum of the possible maxima or the minima in individual counties.)
d. Minimum (Min.) length of rail alignment in Nye County would be 126 kilometers (78 miles).
e. Only includes anthropogenic (the influence of humans on the environment) source of emissions (DIRS 177709-MO0607NEI2002D.000).
f. < = less than.

Table 4-199. Summary of potential impacts to air quality – Mina rail alignment[a,b] (page 1 of 4).

County/rail line segment/facility	Construction impacts	Operations impacts
Rail line		
Churchill County		
Union Pacific Railroad Hazen Branchline; Schurz alternative segment 6	Construction activities would add less than the 2002 county-wide burden of SO_2, CO, NO_x, $PM_{2.5}$, PM_{10}, and VOCs. In addition, these emissions would be distributed over the length of the rail line in the county; thus, no air quality standard would be exceeded.	Operations activities would add less than about 1 percent to the 2002 county-wide burden of all criteria air pollutants and would not lead to a violation of air quality standards.
Lyon County		
Union Pacific Railroad Hazen Branchline; Department of Defense Branchline North; Schurz alternative segments 1, 4, 5, and 6	Construction activities would add less than the 2002 county-wide burden of SO_2, CO, NO_x, $PM_{2.5}$, PM_{10}, and VOCs. In addition, these emissions would be distributed over the length of the rail line in the county; thus, no air quality standard would be exceeded.	Operations activities would add less than about 1 percent to the 2002 county-wide burden of all criteria air pollutants and would not lead to a violation of air quality standards.
Mineral County		
Schurz alternative segments 1, 4, 5, and 6; Department of Defense Branchline South; Mina common segment 1	Construction activities would add less than the 2002 county-wide burden of SO_2 and VOCs. CO, $PM_{2.5}$, PM_{10}, and NO_x would each have an increase greater than the 2002 county-wide burden. However, these emissions would be distributed over the entire length of the rail line in the county; thus, no air quality standard would be exceeded.	Operations activities would add less than about 2 percent to the 2002 county-wide emissions for SO_2, CO, $PM_{2.5}$, PM_{10}, and VOCs, and about 80 percent for NOx emissions; however, these increases should not lead to a violation of air quality standards.
	Modeling of emissions from construction of the rail line near Mina showed there is potential for the 24-hour PM_{10} NAAQS to be exceeded in the immediate vicinity of the rail line under some conditions. Within the town of Mina, concentrations would be below the NAAQS.	Modeling of emissions from operation of the rail line near Mina showed no air pollutant would exceed 70 percent of the NAAQS for any averaging period.
	Modeling of emissions from construction of the rail line near Hawthorne showed that no air pollutant would exceed the NAAQS.	Modeling of emissions from operation of the rail line near Hawthorne showed no air pollutant would exceed 70 percent of the NAAQS for any averaging period.
	Modeling of emissions during construction of the rail line near Schurz showed there is potential for the 24-hour PM_{10} and $PM_{2.5}$ NAAQS to be exceeded in the immediate vicinity of the rail line under some conditions. Within the town of Schurz, concentrations would be below the NAAQS.	Modeling of emissions from operation of the rail line near Schurz showed no air pollutant would exceed 70 percent of the NAAQS for any averaging period.

Table 4-199. Summary of potential impacts to air quality – Mina rail alignment[a,b] (page 2 of 4).

County/rail line segment/facility	Construction impacts	Operations impacts
Esmeralda County		
Mina common segment 1; Montezuma alternative segments 1, 2, and 3; Mina common segment 2	Construction activities would add less than the 2002 county-wide burden of SO_2. CO, VOCs, $PM_{2.5}$, PM_{10}, and NO_x would each have an increase greater than the 2002 county-wide burden. However, these emissions would be distributed over the entire length of the rail line in the county; thus, no air quality standard would be exceeded.	Operations activities would add less than 35 percent to the 2002 county-wide burden of all criteria air pollutants and would not lead to a violation of air quality standards.
	Modeling of emissions from construction of the rail line near Silver Peak showed no air pollutant would exceed 70 percent of the NAAQS for any averaging period.	Modeling of emissions from operation of the rail line near Silver Peak showed no air pollutant would exceed 35 percent of the NAAQS for any averaging period.
Nye County		
Montezuma common segments 1 and 3; Mina common segment 2; Bonnie Claire alternative segments 2 and 3; common segment 5; Oasis Valley alternative segments 1 and 3; common segment 6	Construction activities would add less than the 2002 county-wide burden of SO_2, CO, PM_{10}, $PM_{2.5}$, and VOCs. NO_x would have an increase greater than the 2002 county-wide burden. However, emissions would be distributed over the entire length of the rail line in the county; thus, no air quality standard would be exceeded.	Operations activities would add less than about 35 percent to the 2002 county-wide burden of all criteria air pollutants and would not lead to a violation of air quality standards.
Construction and operations support facilities		
Churchill County		
Access roads (including the alignment access road) Schurz alternative segment 6	About 39 percent of PM_{10} construction fugitive dust emissions would be from access roads. In no case would this be expected to lead to an exceedance of any air quality standards.	Operations would result in very small emissions from access roads.
Lyon County		
Access roads (including the alignment access road)	About 39 percent of PM_{10} construction fugitive dust emissions would be from access roads. In no case would this be expected to lead to an exceedance of any air quality standards.	Operations would result in very small emissions from access roads.
Construction camp 18C or 18D	Only about 1 percent of the fugitive dust emissions would be due to construction of the construction camp. In no case would construction camp emissions be expected to cause an exceedance of any air quality standards.	Construction camp would be reclaimed following the construction phase and would have no emissions during the operations phase.

Table 4-199. Summary of potential impacts to air quality – Mina rail alignment[a,b] (page 3 of 4).

County/rail line segment/facility	Construction impacts	Operations impacts
Mineral County		
Access roads (including the alignment access road)	About 39 percent of PM_{10} construction fugitive dust emissions would be from access roads. In no case would this be expected to lead to an exceedance of any air quality standards.	Operations would result in very small emissions from access roads.
Staging Yard at Hawthorne	Modeling of emissions from construction of the Staging Yard at Hawthorne found that the 24-hour PM_{10} and $PM_{2.5}$ NAAQS could be exceeded in the immediate vicinity of the Staging Yard under some conditions.	Modeling of emissions from operation of the Staging Yard at Hawthorne showed no air pollutant would exceed 80 percent of the NAAQS for any averaging period.
Quarry	Modeling of emissions from the potential Garfield Hills quarry indicates that the 24-hour PM_{10} and $PM_{2.5}$ NAAQS could be exceeded. However, the required Surface Disturbance Permit would greatly reduce PM_{10} and $PM_{2.5}$ emissions, making an exceedance of the NAAQS unlikely.	Quarries would be reclaimed following rail line construction and would have no emissions during the operations phase.
Construction camps 15, 16, and 17	Only about 3 percent of the fugitive dust emissions would be due to construction of the construction camps. In no case would construction camp emissions be expected to cause an exceedance of any air quality standards.	Construction camps would be reclaimed following the construction phase and would have no emissions during the operations phase.
Wells	Well construction would be responsible for about 4 percent of the fugitive PM_{10} emissions. In no case would the construction of the wells be expected to cause an exceedance of any air quality standards.	Operation of the wells would result in very small emissions because only a few wells would continue to operate after the completion of construction to serve as the water source for facility operations.
Esmeralda County		
Access roads (including alignment access road)	About 39 percent of PM_{10} construction fugitive dust emissions would be from access roads. In no case would this be expected to lead to an exceedance of any air quality standards.	Operations would result in very small emissions from access roads.
Maintenance-of-Way Facility	Construction of the Maintenance-of-Way Facility would account for less than 1 percent of construction fugitive dust emissions. In no case would this be expected to cause an exceedance of any air quality standards.	The Maintenance-of-Way Facility would be responsible for less than 1 percent of the operations emissions in Esmeralda County and would not lead to a violation of air quality standards.
Quarries	Modeling of emissions from the operation of the potential quarry at Malpais Mesa during construction of the rail line shows no air pollutant would exceed 60 percent of the NAAQS for any averaging period.	Quarries would be reclaimed following the construction phase and have no emissions during the operations phase.

Table 4-199. Summary of potential impacts to air quality – Mina rail alignment[a,b] (page 4 of 4).

County/rail line segment/facility	Construction impacts	Operations impacts
Construction camp		
14, 13A or 13B	Only about 3 percent of the fugitive dust emissions would be due to construction of the construction camps. In no case would construction camp emissions be expected to cause an exceedance of any air quality standards.	Construction camps would be reclaimed following the construction phase and have no emissions during the operations phase.
Wells	Well construction would be responsible for about 4 percent of the fugitive PM_{10} emissions. In no case would the construction of the wells be expected to cause an exceedance of any air quality standards.	Operation of the wells would result in very small emissions because only a few wells would continue to operate after the completion of the construction phase to serve as the water source for facility operations.
Nye County		
Access roads (including alignment access road)	About 39 percent of PM_{10} construction fugitive dust emissions would be from access roads. In no case would this be expected to lead to an exceedance of any air quality standards.	Operations would result in very small emissions from access roads.
Construction camps 10, 11 and 12	Only about 4 percent of the fugitive dust emissions would be due to construction of the construction camps. In no case would construction camp emissions be expected to cause an exceedance of any air quality standards.	Construction camps would be reclaimed following the construction phase and have no emissions during the operations phase.
Wells	Well construction would be responsible for about 4 percent of fugitive PM_{10} emissions. In no case would the construction of the wells be expected to cause an exceedance of any air quality standards.	Operation of the wells would result in very small emissions because only a few wells would continue to operate after the completion of the construction phase to serve as the water source for facility operations.
Rail Equipment Maintenance Yard and Cask Maintenance Facility	Combined, construction of the Rail Equipment Maintenance Yard and Cask Maintenance Facility would account for less than 2 percent of fugitive dust emissions. In no case would these emissions be expected to cause an exceedance of any air quality standards.	Combined, the Rail Equipment Maintenance Yard and Cask Maintenance Facilities would be responsible for about 93 percent of the operations emissions in Nye County.
Nevada Railroad Control Center and National Transportation Operations Center	Construction dust and exhaust emissions would be very small.	Operation of the Nevada Railroad Control Facility would result in very small emissions.

a. Impacts to air quality under the Shared-Use Option would be similar to those under the Proposed Action without shared use.
b. CO = carbon monoxide; NO_x = nitrogen oxides; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO2 = sulfur dioxide; NAAQS = National Ambient Air Quality Standards; VOCs = volatile organic compounds.

4.3.5 SURFACE-WATER RESOURCES

This section describes potential impacts to surface-water resources (***washes***, playas, ***floodplains***, and ***wetland*** areas) from constructing and operating the proposed railroad along the Mina rail alignment. Section 4.3.5.1 describes the methodology DOE used to analyze potential impacts; Section 4.3.5.2 describes potential construction impacts; Section 4.3.5.3 describes potential operations impacts; Section 4.3.5.4 describes potential impacts under the Shared-Use Option; and Section 4.3.5.5 summarizes potential impacts to surface-water resources.

4.3.5.1 Impact Assessment Methodology

As described in Section 3.3.5.1, the region of influence for surface-water resources would be limited in most cases to the nominal width of the rail line construction right-of-way. In some cases the region of influence would extend beyond the construction right-of-way. Construction and operations activities along the rail alignment could impact a larger distance from the rail line in cases where surface-water drainages could carry pollutants (such as petroleum-based lubricants and fuels) and eroded soil downstream of the rail line or in cases where floodwaters backed up on the upstream side of the rail line.

DOE evaluated potential impacts to surface-water resources based on a series of criteria, as listed in Table 4-200. There would be an impact if construction and operations would cause any of the conditions listed in Table 4-200. To avoid or limit adverse impacts to surface-water resources, the Department would comply with applicable laws, regulations, policies, standards, and directives, and implement best management practices (see Chapter 7). Most importantly, careful pre-planning of construction and operations activities would allow the Department to assess and minimize potential impacts before they occurred (see Section 2.1).

Table 4-200. Impact assessment criteria for surface-water resources (page 1 of 2).

Resource criteria	Basis for assessing adverse impact
Stormwater drainage	Would railroad construction or operations: • Alter stormwater discharges, which could adversely affect drainage patterns, flooding, and/or erosion and sedimentation • Alter infiltration rates, which could adversely affect (increase or decrease) the volume of surface water that flows downstream • Conflict with applicable stormwater management plans or ordinances
Surface-water quality	Would railroad construction or operations: • Contaminate public water supplies and other surface waters, exceeding water quality criteria or standards established in accordance with the Clean Water Act, state regulations, or permits • Conflict with regional water quality management plans or goals
Surface-water availability and uses	Would railroad construction or operations: • Alter the capacity of available surface-water resources such that human health, the environment, or personal property would be adversely affected • Conflict with established water rights or regulations protecting surface water resources for future beneficial uses
Wetlands and waters of the United States	Would railroad construction or operations: • Cause filling of wetlands or otherwise alter drainage patterns such that wetlands or waters would be adversely affected

Table 4-200. Impact assessment criteria for surface-water resources (page 2 of 2).

Resource criteria	Basis for assessing adverse impact
Floodplains and floodwaters	Would railroad construction or operations: • Alter floodway or floodplain or otherwise impede or redirect flows such that human health, the environment, or personal property would be adversely affected • Conflict with applicable flood management plans or ordinances
Springs	Would railroad construction or operations: • Reduce or eliminate access to springs such that human health, the environment, or personal property would be adversely affected

The areas where surface-water impacts would be greatest and where DOE would implement direct controls (such as erosion and sedimentation controls) would be within the construction right-of-way. The Department expects that the numbers and types of surface-water features within the construction right-of-way would have a direct relationship to the degree of impacts within this area. To evaluate potential impacts to surface water, the Department identified areas where there are drainage channels, floodplains, springs, and wetlands along the rail alignment (including those it would cross or cover) and identified the activities associated with construction or operations that would have the potential to impact these surface-water resources.

4.3.5.2 Construction Impacts

Section 3.3.5 describes surface-water resources along the Mina rail alignment. Table 4-201 lists the numbers of surface-water features within the nominal width of the rail line construction right-of-way and support facilities. The table includes estimates of the number of drainage channels the Mina rail alignment alternative segments and common segments would cross. DOE identified drainage channels using the National Hydrological Dataset, a U.S. Geological Survey dataset of hydrologic features. The table also identifies two subsets of the total number of drainage channel crossings. The first is the notable channels described in Section 3.3.5.2.1. The second subset is the washes DOE classified as ***waters of the United States*** during field studies in support of this Rail Alignment EIS.

This section also addresses impacts to surface-water quality, and water availability and usage. Springs are also evaluated because they are a significant source of surface water within and near the Mina rail alignment region of influence.

Floodplains and wetlands are two other important surface-water features the Department evaluated as part of this analysis. Appendix F, Floodplain and Wetlands Assessment, provides additional information on wetlands and floodplains the Mina rail alignment could encounter. Appendix F includes figures showing the locations of these surface-water features and provides more detail on their characteristics.

4.3.5.2.1 Impacts Common to the Entire Rail Alignment

The following sections describe common impacts identified and assessed for activities associated with construction of the proposed railroad along the Mina rail alignment. DOE would minimize impacts through the engineering design (see Chapter 2.2) and the implementation of best management practices (see Chapter 7).

4.3.5.2.1.1 Stormwater Drainage. Construction of the proposed railroad could result in both direct and indirect impacts to surface-water resources. Direct impacts would result from the temporary or permanent grading, dredging, rerouting, or filling of e***phemeral*** or ***intermittent streambeds***.

Table 4-201. Summary of drainages the rail line and support facilities would cross – Mina rail alignment.

Rail line segments/facilities	Total[a]	Notable drainages[b]	Waters of the United States[c]
Schurz alternative segment 1	21	9	4
Schurz alternative segment 4	42	18	6
Schurz alternative segment 5	61	21	1
Schurz alternative segment 6	67	28	1
Mina common segment 1	141	123	0
Staging Yard at Hawthorne	3	0	0
Potential Gabbs Range quarry	2	0	0
Montezuma alternative segment 1	187	93	0
Maintenance-of-Way Facility (Silver Peak option)	0	0	0
Montezuma alternative segment 2	85	42	0
Maintenance-of-Way Facility (Klondike option)	2	1	0
Montezuma alternative segment 3	148	60	0
Mina common segment 2	3	0	0
Bonnie Claire alternative segment 2	31	11	0
Bonnie Claire alternative segment 3	23	9	0
Common segment 5	124	84	0
Oasis Valley alternative segment 1	24	15	2
Oasis Valley alternative segment 3	28	11	1
Common segment 6	43	20	14
Rail Equipment Maintenance Yard	1	0	0

a. All drainages identified in National Hydrologic Dataset (DIRS 177714-MO0607NHDFLM06.000).
b. Only includes drainages with stream order equal to or greater than two from the National Hydrologic Dataset (DIRS 177714-MO0607NHDFLM06.000).
c. Source: DIRS 180889-PBS&J 2007, Figures 3A through 3C.

Indirect impacts would include increases in ***nonpoint source pollution*** resulting from runoff from construction areas where surface grades and characteristics had been changed (such as the rail roadbed, support facilities, and access roads).

Cut and fill operations during rail line construction would cause the alteration of natural drainage patterns and runoff rates in some areas could affect downgradient resources. Construction activities that could temporarily block surface drainage channels include moving large amounts of soil and rock to develop the track platform and constructing temporary access roads to reach construction initiation points and major structures, such as bridges, and movement of equipment to the construction initiation points. Depending on site conditions, construction could include regrading so that a number of minor drainage channels would collect in a single ***culvert*** or pass under a single bridge, resulting in water flowing from a single location on the downstream side rather than across a broader area. As a result, there would be some localized changes in drainage patterns.

Regrading and rerouting washes through channelization, including the installation of culverts and stabilization of existing stream banks, could increase the flow rate in relation to natural flow conditions. Culverts and improved channels would provide less resistance to flow so that the flow rate of runoff could increase as it passed through such a structure. The speed by which water flows through a drainage structure (a culvert, a bridge, or a stream channel) affects the erosive potential of the flow; therefore, the design of drainage structures must account for the potential for scour and erosion and incorporate outlet protection and velocity-dissipating devices that calm the flow and lessen its erosive potential. Without such protective measures, scour might occur, especially around bridge piers and abutments, where water flowing past a pier or abutment could erode the supporting soil and sediment around these structures. As the speed of flow increased, the chances for the entire streambed and bank to be exposed to scour and erosion would increase.

Subgrade elevation of the rail line is the elevation of the top of the ***subballast***.

Subballast is a layer of crushed gravel that is used to separate the ***ballast*** and roadbed for the purpose of load distribution and drainage.

Ballast is crushed stone used to support the railroad ties and provide drainage.

DOE would incorporate hydraulic modeling into the final design process to ensure that crossings are properly engineered so that they would not contribute to erosion and sediment pollution, and impacts to surface-water resources downstream of the rail line would be greatly minimized. Therefore, impacts associated with surface-water drainage patterns from rail line construction would be small.

DOE would employ standard engineering design practices to size and place culverts to move runoff water from one side of the track to the other. These culverts or other means of runoff control would be put in place as part of subgrade construction to prevent water from backing up. Preliminary rail line design includes various structures to accommodate drainage features the rail line would cross (DIRS 176166-Nevada Rail Partners 2006, all). These structures include slab bridges with multiple piers spaced at 4-meter (13-foot) intervals; double cell bridges with multiple piers spaced at 10-meter (33-foot) intervals; shaft-supported bridge structures with spans between end shafts of 14 to 24 meters (45 to 80 feet); precast reinforced concrete box culverts with a maximum cross-section size of 3.7 meters by 3.7 meters (12 feet by 12 feet); and corrugated metal pipe culverts of various diameters.

Except in areas where drainage structures would cross a Federal Emergency Management Agency-designated 100-year floodplain, hydraulic design would be based on typical Class 1 freight railroad standard design criteria. Floodplain crossings are described in Section 4.3.5.2.1.6. Class 1 freight railroad standard criteria require that the ***50-year flood*** should not come into contact with the top (crown) of the culvert or the lowest point of the bridge, whichever is applicable. For the ***100-year flood***, these criteria require that the floodwaters should not rise above the ***subgrade elevation*** at the structure. To conform to these standards, DOE would use circular culverts where flow rates would be small (less than 4 cubic meters per second [140 cubic feet per second]). For larger flows (up to 28 cubic meters per second [1,000 cubic feet per second]), DOE would use box culverts. The Department would construct bridges where flows were larger and where the rail surface would not be tall enough to accommodate a sufficiently sized culvert, and would install the culverts with ***riprap*** around the exposed ends to protect the fill material from erosion (DIRS 176166-Nevada Rail Partners 2006, p. ii). Bridge abutments and piers would be similarly protected. In some places, training dikes or ***berms*** would be required to redirect flow and ensure that the flow would be conveyed through the structure. In places, channel improvements might be necessary for a short distance upstream and downstream of the rail line to intercept and effectively redirect flows through drainage structures.

50-year flood is a flood that has a 2-percent chance of being equaled or exceeded in any given year.

100-year flood is a flood that has a 1-percent chance of being equaled or exceeded in any given year. A base flood may also be referred to as a 100-year storm and the area inundated during the base flood is sometimes called the 100-year floodplain.

500-year flood is a flood that has a 0.2-percent chance of being equaled or exceeded in any given year.

DOE would analyze crossings on a case-by-case basis and propose culverts whenever feasible. Where there would be very wide and shallow depths of flow during a 100-year flood, or the flow would be divided into multiple natural channels that would cross the rail line, the Department would use a series of multiple culverts, potentially in concert with small bridges to span the main flow channel. In locations where there were very high fill conditions, it would be more economical to use multiple culverts than to construct a bridge (DIRS 176166-Nevada Rail Partners 2006, p. ii). Because DOE would design stormwater conveyance systems to safely convey design floods (50-year and 100-year) and would minimize concentration of flow to the greatest extent practicable, impacts on stormwater conveyance associated with construction of the rail line would be small.

Construction activities that disturbed the land surface, such as grading, excavation, or stockpiling, would have the potential to alter the rate at which water could infiltrate the disturbed areas. Depending on the type of disturbance, the ***infiltration*** rate could increase (for example, in areas with loosened soil) or decrease (for example, in areas where construction activities had compacted the soil or involved the installation of impermeable surfaces like asphalt pads, concrete surfaces, or buildings). Most of the land disturbance during the construction phase would result in surfaces with lower infiltration rates; that is, the surfaces would be less ***permeable*** than natural soil conditions and would cause an increase in runoff. The change in the amount of runoff that would actually reach the drainage channels would be minor, because construction would affect a small amount of the overall natural drainage area (DIRS 155970-DOE 2002, p. 4-24). Therefore, impacts associated with changes in stormwater infiltration and runoff rates would be small.

DOE would construct two access roads (each up to 7.3 meters [24 feet] wide) along most of the rail line within the rail line construction right-of-way (one on each side of the rail line) to support operations. Additional access roads could be needed to provide access to the construction support facilities, such as construction camps, wells, and quarries. DOE would improve all access roads, as necessary, in accordance with the parameters for rural roads as defined by the Nevada Department of Transportation and the American Association of State Highway and Transportation Officials (DIRS 180922-Nevada Rail Partners 2007, p. 4-20). The Department would excavate roadside ditches on both sides of the roadway as necessary to direct stormwater to drainage features and washes. Most access roads would likely have gravel surfaces, except for those to wells. Dip sections (depressions in a road that allow stormwater to flow across the road surface) would be used to convey ephemeral flows across the road surfaces (DIRS 180922-Nevada Rail Partners 2007, p. 4-20).

DOE would locate most wells along the two alignment access roads or adjacent to existing roads; however, construction of new access roads to distant wells might be required in four cases (total distance of less than 5.5 kilometers [3.5 miles]). These roads would be needed to reach the well sites and to accommodate temporary pipelines constructed to convey water to the construction right-of-way. DOE would construct temporary pipelines on top of the ground next to an existing road or a new access road (DIRS 176172-Nevada Rail Partners 2006, p. 4-11). The Department would position the temporary pipelines so they would not obstruct or redirect surface runoff or natural drainage channels. Therefore, there would be no adverse impacts to surface-water resources from construction of temporary pipelines.

Water would be required for compaction of fill material to construct the embankment areas of the rail roadbed. Compaction of fill would require approximately 6.4 billion liters (1.7 billion gallons) of water (DIRS 180857-Nevada Rail Partners 2007, p. 4-4). To stay within the plastic limits of the soil, fill would not be completely saturated, and runoff would be intentionally avoided. DOE would use standard erosion-control practices during compaction activities. Water would also be required for dust control along roads used to access the rail alignment during construction activities. Approximately 250 million liters (65 million gallons) of water would be required for dust control over a 3-year period. DOE would use standard construction dust-control measures. Water used for dust suppression in these areas would not be expected to result in runoff.

DOE would minimize construction impacts to stormwater drainage through engineering design (see Section 2.2) and implementation of best management practices (see Chapter 7). A National Pollutant Discharge Elimination System General Construction Permit would be required for construction activities. In accordance with this permit, construction contractors would be required to prepare and submit a Stormwater Pollution Prevention Plan, which would be prepared consistent with state and federal standards for construction activities and would detail the best management practices that would be employed to minimize soil loss and degradation to nearby water resources. Design of the best management practices program would be based on practices listed in the *Best Management Practices Handbook* developed by the Nevada Division of Environmental Protection and the Nevada Division of Conservation Districts (DIRS 176309-NDEP 1994, all) and the *Storm Water Quality Manuals Construction Site Best Management Practices Manual* developed by the Nevada Department of Transportation (DIRS 176307-NDOT 2004, all).

Best management practices are structural and nonstructural controls that would be used to control non-point source pollution such as sedimentation and stormwater runoff. Structural controls are those best management practices that need to be constructed (such as detention or retention basins). Nonstructural controls refer to best management practices that typically do not require construction, such as planning, education, revegetation, or other similar measures. Sedimentation and stormwater runoff are typically addressed through the use of temporary and permanent best management practices, including techniques such as grading that would induce positive drainage; silt fences; and revegetation to minimize or prevent soil exposed during construction from becoming sediment to be carried offsite. Best management practices would be implemented, inspected, and maintained to minimize the potential for adverse impacts to downstream water quality. Chapter 7 describes best management practices in more detail.

4.3.5.2.1.2 Surface-Water Quality. Construction activities could adversely impact surface-water quality due to increased sedimentation because rail line construction activities would result in the potential for erosion and sediment during precipitation events. Sediment would generally be contained onsite through the use of best management practices, including erosion- and sedimentation-control measures. For the areas of the Mina rail alignment near surface-water bodies, ***contaminants*** could be released directly to surface water. The Mina rail alignment would encounter a wide variety of surface drainage features. As described in Section 3.3.5.2.1.1, the Carson River and the Walker River appear on the Nevada 303(d) list of impaired waters. Suspended solids are pollutants of concern in these areas. DOE would implement direct controls (such as erosion and sedimentation controls) within the construction right-of-way to minimize surface-water impacts (DIRS 180120-NDEP 2005, Appendix A).

Water quality impacts are also possible from potential release and spread of contaminants (materials potentially harmful to human health or the environment), which could be released through an accidental spill or discharge. These types of releases could be localized if there was a small spill or widespread if precipitation or intermittent runoff carried contaminants away from the site of the spill. For the areas of the Mina rail alignment near surface-water bodies, contaminants could be released directly to surface water; however, there are only a few places where there are surface-water bodies along the rail alignment.

Section 4.3.12, Hazardous Materials and Waste, describes construction materials that could be mishandled (spilled), including petroleum products (such fuels and lubricants) and coolants (such as antifreeze). Incidental spills could also include solvents used for cleaning or for degreasing equipment. The construction camps would include some bulk storage of hazardous materials, and supply trucks would routinely bring new materials and remove used materials and wastes (such as lubricants and coolants) from the construction sites (see Section 4.3.12). These activities would present some potential for incidental spills and releases, the significance of which would depend largely on the nature and volume of the material spilled and its location. A release or spill of pollutants to a stream or river, or stormwater runoff carrying pollutants to such receptors, would have the greatest potential to adversely impact surface-water quality.

The potential for such impacts during the construction phase would be small because the environment along the Mina rail alignment is arid and there is little flowing water. Also, construction contractors would be required to comply with regulatory requirements for spill-prevention measures, reporting and remediating spills, and properly disposing of or recycling used materials (as described in Chapter 7). Common stormwater pollution control practices mandate that hazardous materials be stored inside facilities or have secondary containment or other protective devices and that spill control and containment equipment be stationed close to hazardous material (for example, fuel) storage.

Sanitary sewage generated at construction camps would be treated onsite or collected and trucked to a ***wastewater treatment*** plant. A portable wastewater treatment facility could be installed at each construction camp. As a water conservation measure, the Department could use treated wastewater effluent (***gray water***) produced at the camps for dust suppression and soil compaction. These water conservation measures would help reduce the demands placed on groundwater wells. The portable wastewater treatment plants would be designed and operated so that generated effluent would not adversely impact the quality of surface water with which it comes in contact; therefore, impacts to surface-water quality from wastewater treatment operations during the construction phase would be small. There would be no on-site discharges of industrial wastewater during the construction phase.

The wastewater treatment process would result in the production of biosolids (sludge). DOE would store biosolids on the sites and allowed them to dry until the conditions specified in federal regulations (40 CFR Part 503) and state regulations are met. DOE would dispose of biosolids at a licensed facility in accordance with all applicable state and federal laws (DIRS 176172-Nevada Rail Partners 2006, p. 4-6).

4.3.5.2.1.3 Surface-Water Availability and Uses. See Section 4.3.2, Land Use and Ownership, for a discussion of impacts to manmade water systems.

4.3.5.2.1.4 Waters of the United States. Jurisdictional waters of the United States subject to Section 404 of the Clean Water Act include interstate waters and intrastate waters with a connection to interstate commerce, tributaries to such waters, and wetlands that are adjacent to waters of the United States. The Section 404 permitting program prohibits discharge of dredged or fill material into jurisdictional waters if a practicable alternative exists that would be less damaging to the aquatic environment, or if the Nation's waters would be significantly degraded. In other words, it must be demonstrated that, to the extent practicable, steps have been taken to avoid impacts and that potential impacts to waters of the United States have been minimized and mitigation is provided for any remaining unavoidable impacts (if required). See Chapter 6, Statutory, Regulatory, and Other Applicable Requirements, for further discussion of the Clean Water Act Section 404 permitting requirements.

The U.S. Army Corps of Engineers is responsible for determining whether drainages and wetlands along the rail alignment are regulated under Section 404; therefore, all conclusions in this analysis about the classification of washes and wetlands as waters of the United States are tentative. On June 5, 2007, the U.S. Environmental Protection Agency and U.S. Army Corps of Engineers released interim guidance that addresses jurisdiction over waters of the United States under the Clean Water Act. Based on this guidance, it is likely that many of the drainages along the rail alignment that DOE currently considers to be waters of the United States might not be considered as such according to the new guidance. If DOE selected the Mina rail alignment for construction of the proposed railroad, the Department would request that the U.S. Army Corps of Engineers determine the limits of jurisdiction under Section 404 along the rail alignment before beginning construction.

Estimates for potential fill area and quantity of fill are provided in this section to support Section 404 permitting requirements (see Table 4-202). These estimates were calculated based on the depth and width of the water body that would be crossed and the type of engineered structure planned for each crossing. For crossings with culverts, DOE assumed that culverts would be extended 12 meters (40 feet) on either side of the cut/fill boundary for the rail roadbed. For bridges over waters of the United States having a width of less than 3 meters (10 feet), DOE assumed that no fill would be placed in the channel. For bridges over wider channels, DOE assumed that there would be one bridge pier every 6 meters (20 feet) and that each pier would cover a surface area of 1.9 square meters (20 square feet). Fill estimates calculated for these crossings depend on channel depths. These fill estimates represent an upper bound estimate, because many of the drainages currently identified during this analysis as waters of the United States might not be considered waters of the United States under the new U.S. Army Corps of Engineers guidance.

If DOE constructed the railroad along the Mina rail alignment there would be no practicable alternative to crossing some ***ephemeral streams*** that are waters of the United States. There are numerous ephemeral waters of the United States that flow perpendicular to the general direction of the rail line and the rail line would have to cross them. DOE would construct bridges across many of the ephemeral waters of the United States along the rail line and very little or no fill in regulated stream channels would be required for those crossings. The Department would place culverts in the smaller ephemeral streams. Because the size of these regulated channels is generally less than 1 to 2 meters (3.3 to 6.6 feet), the area filled per crossing would typically be less than about 100 square meters (0.03 acre). The crossings would be designed so that they would not alter stream flow and best management practices (see Chapter 7) would be implemented to minimize sedimentation during and after construction.

Impacts to drainages classified as waters of the United States would be the same as impacts described in Section 4.3.5.2.1.1.

4.3.5.2.1.5 Wetlands. Executive Order 11990, *Protection of Wetlands*, requires that federal agencies "…take action to minimize the destruction, loss, or degradation of wetlands…" The Executive Order requires consideration of all wetlands regardless of whether they are regulated under Section 404 of the Clean Water Act. DOE regulations at 10 CFR Part 1022 direct that impacts to wetlands be avoided wherever possible and minimized to the extent practicable during construction projects. In accordance with Executive Order 11990 and 10 CFR Part 1022, this Rail Alignment EIS examines impacts to all wetlands regardless of whether they are considered jurisdictional under Section 404 of the Clean Water Act.

Under 10 CFR 1022, the Department is required to preserve and enhance the natural and beneficial values of wetlands. The values of wetlands are a function of the importance or worth of the functions that wetlands serve to society. Functions of wetlands include storage of water (floodwater protection), water filtration (wetlands can trap nutrients, sediment, and pollutants), and biological productivity (plant and animal ***habitat***). Impacts to these functions can eliminate or diminish the value of wetlands (DIRS 176797-USEPA 2001, p. 1). Temporary or permanent filling or draining of wetlands would result in direct impacts to those resources.

Actions in and around wetlands could result in indirect impacts, such as potential degradation of water quality and disruption of water flow. To meet the requirements of 10 CFR Part 1022, Appendix F, Floodplain and Wetlands Assessment, includes a detailed analysis of wetlands and wetland functions. Specifically, this appendix includes a more detailed presentation of the data sources the Department used to identify wetlands and floodplains along the Mina rail alignment, a discussion of potential impacts (repeated in this section), and an alternatives analysis. The discussion of impacts in this section and Appendix F is limited to the water storage and filtration functions of wetlands. Section 4.3.7, Biological Resources, addresses impacts to the biological-productivity functions of wetlands.

Table 4-202. Summary of waters of the United States – Mina rail alignment.[a]

Rail line segments/facilities	Crossings[b]	Fill area (square meters)[c]	Fill volume (cubic meters)[d]
Schurz alternative segment 1	4	420	18
Schurz alternative segment 4	6	510	19
Schurz alternative segment 5	1	1.9	1.7
Schurz alternative segment 6	1	1.9	1.7
Oasis Valley alternative segment 1	2 (bridged)	0	0
Oasis Valley alternative segment 3	1 (bridged)	0	0
Common segment 6	14	560	37

a. Source: DIRS 180889-PBS&J 2007, Figure 3A through 3C.
b. Any water of the United States within 12 meters (40 feet) of the construction footprint is considered to be crossed.
c. To convert square meters to acres, multiply by 2.4711.
d. To convert cubic meters to cubic feet, multiply by 35.314.

DOE would minimize filling of wetlands by keeping the rail line footprint to a minimum and incorporating avoidance into rail line engineering and design to the extent practicable. DOE would mitigate loss of wetlands, as required under Section 404 of the Clean Water Act, by enhancing existing wetlands adjacent to or near the rail line that have been degraded by grazing and other impacts, or by creating new wetlands adjacent to or near the rail line. The exact acreage of wetlands to be enhanced or created would be determined in coordination with the U.S. Army Corps of Engineers and the U.S. Environmental Protection Agency and would be based in part on the amount of wetlands that would have to be filled to construct the rail line, the function and quality of the wetlands that would be lost, and the likelihood of success of the methods used to enhance or replace wetlands. This section describes impacts to wetlands in the segment-specific sections.

4.3.5.2.1.6 Floodplains and Floodwaters. DOE has prepared a floodplain assessment (see Appendix F) for the area along the Mina rail alignment in accordance with the requirements of 10 CFR Part 1022. Appendix F includes figures that show the Federal Emergency Management Agency floodplain maps that cover the Mina rail alignment region of influence. DOE obtained floodplain data from the Agency, which has published Flood Insurance Rate Maps that, depending on the combination of alternative segments, cover only 20 percent of the Mina rail alignment (see Appendix F, Table F-2). The Agency has not mapped areas that are uninhabited. These floodplain maps depict, as applicable, the lateral boundaries or spread of water that could be expected in drainage channels or around collection basins from a 100-year and a ***500-year flood***.

DOE overlaid a map of the Mina rail alignment on the available floodplain maps and estimated the crossing distances for each alternative segment and common segment. Table 4-203 lists the crossing distances and the percentage of the area for which floodplain map coverage is available. Areas with little or no floodplain map coverage could contain floodplains not listed in the table. Appendix F discusses floodplains in more detail.

Construction activities would affect floodplains, either through direct alteration of the stream-channel cross section that would affect the flow pattern of the stream, or through indirect changes in the amount of impervious surfaces and additional water volume added to the floodplain. Based on Federal Emergency Management Agency floodplain maps and flood studies completed in the area of the Yucca Mountain Site, the Mina rail alignment would cross more than six floodplains.

Construction impacts associated with these floodplains would be similar to any other identified drainage areas (the alteration of natural drainage patterns and possible changes in erosion and sedimentation rates or locations). Construction in washes or other flood-prone areas could reduce the area through which floodwaters would naturally flow, which could cause water levels to rise on the upstream side of crossings.

Table 4-203. 100-year floodplains the Mina rail alignment would cross.

Rail line segment	Percent covered by FEMA[b] floodplain maps	Floodplain crossing distance (kilometers)[a]		Floodplain description
		Mapped	Additional estimated	
Schurz alternative segment 1	0	0	0	No floodplains mapped.
Schurz alternative segment 4	0	0	0	No floodplains mapped.
Schurz alternative segment 5	0	0	0	No floodplains mapped.
Schurz alternative segment 6	0	0	0	No floodplains mapped.
Mina common segment 1	0	0	0	No floodplains mapped.
Montezuma alternative segment 1	0.1	0.01	0	The very southern end of Montezuma alternative segment 1 would cross a very small section of FEMA floodplains just before it joined with Mina common segment 2.
Montezuma alternative segment 2	10	2	0	The floodplain is located between the Stonewall Mountains and Cuprite Hills and is associated with Stonewall Flat.
Montezuma alternative segment 3	0.1	0.01	0	The very southern end of Montezuma alternative segment 3 would cross a very small section of FEMA floodplains just before it joined with Mina common segment 2.
Mina common segment 2	100	1.3	0	Floodplain extends downgradient of Stonewall Flat Playa to the Lida Valley Alkali Flat Playa.
Bonnie Claire alternative segment 2	30	0	0	No floodplains identified.
Bonnie Claire alternative segment 3	78	1.9	0	Floodplains extending up tributaries of the Lida Valley Alkali Flat Playa and up the Stonewall Pass wash from the Bonnie Claire Flat area of Sarcobatus Flat.
Common segment 5	74	0.3	0	Floodplain extending from Sarcobatus Flat up to Tolicha Wash.
Oasis Valley alternative segment 1	100	1.1	0	Floodplain of the Amargosa River within Thirsty Canyon.
Oasis Valley alternative segment 3	100	0.4	0	Floodplain of the Amargosa River within Thirsty Canyon.
Common segment 6	55	0.1	0	Beatty Wash floodplain extending from Amargosa River Floodplain.
		0.23[c]		Busted Butte Wash draining east side of Yucca Mountain to Fortymile Wash (rail line would cross wash and tributaries).

a. To convert kilometers to miles, multiply by 0.62137.
b. FEMA = Federal Emergency Management Agency.
c. There are no FEMA floodplain maps covering Busted Butte Wash on the eastern slope of Yucca Mountain. Estimates of floodplain crossings in this area are from DIRS 155970-DOE 2002, Figure 3-12 floodplain mapping efforts.

Sedimentation would be likely to occur on the upstream side of crossings in areas where the flow of water was restricted enough to cause ponding. DOE would manage sedimentation of this type under a regular maintenance program (DIRS 155970-DOE 2002, p. 6-79). Therefore, impacts to floodplains from construction of the rail line that result in restrictions in flow and sedimentation would be small.

Construction within floodplains would cause direct impacts to floodplains. The Mina rail alignment would be in a region where flash flooding is the primary concern. Although such flooding can be violent and hazardous, it is generally limited in its extent and duration, limiting the potential for impacts associated with the proposed railroad; that is, any damage would be expected to be confined to a small portion of the rail line.

Although DOE would generally design rail line features to accommodate 100-year floods, based on typical Class 1 freight railroad standard design criteria (see Section 4.3.5.2.1.1), the final design process could also consider a range of flood frequencies and include a cost-benefit analysis in the selection of a design frequency in accordance with standard rail line design guidelines and practices (DIRS 106860-AREA 1997, Volume 1, Section 3.3.2.2 c). In areas where drainage structures would cross a Federal Emergency Management Agency-designated 100-year floodplain, DOE would design the bridge to comply with Agency standards and appropriate county regulations. Federal Emergency Management Agency standards require that floodway surcharge (the difference between the 100-year flood elevation and the actual flood surface elevation) not exceed 0.3 meter (1 foot) at any location. These standards are designed to limit the impacts of floodwater to structures built in or adjacent to floodplains (DIRS 176166-Nevada Rail Partners 2006, p. ii). By adhering to these standards, the Department would substantially limit the potential for adverse impacts to the population and resources located adjacent to floodplains.

Bridge constructing usually involves placing a portion of the bridge abutment in the floodplain (called encroachment). For this reason, the abutment can have some impact on the height of floodwaters upstream of the bridge. Excessive encroachment can result in increased scour potential at the abutments, piers, and the stream bottom through the bridge opening due to increases in flow velocities. Based on the conceptual design for the Mina rail alignment, there could be encroachments up to 30 percent of the floodplain width, which could result in an approximately 0.3-meter (1-foot) increase in water surface elevation at the upstream side of the bridge where the floodplain is wide and shallow (DIRS 176166-Nevada Rail Partners 2006, p. ii).

DOE would reduce impacts to floodplains and the resources close to the floodplains by adhering to the design standards that limit the degree to which floodwaters would be allowed to rise. The Department would incorporate hydraulic modeling into the engineering design process to ensure that all crossings were designed to limit impacts to nearby populations and resources.

4.3.5.2.1.7 Springs. DOE designed the rail line to avoid springs and other surface-water resources whenever practicable. In the few cases where there would be springs within the construction right-of-way, the Department would incorporate avoidance into final engineering and design of the rail line to the extent practicable. To minimize temporary impacts, springs would be marked prior to construction and avoided where possible. Section 4.3.6, Groundwater Resources, addresses impacts to springs from a groundwater-supply perspective.

4.3.5.2.2 Impacts along Alternative Segments and Common Segments

4.3.5.2.2.1 Union Pacific Railroad Hazen Branchline (Hazen to Wabuska). DOE would not perform any construction activities along this portion of the Mina rail alignment. Therefore, there would be no impacts to surface-water resources along the existing Union Pacific Railroad Hazen Branchline.

4.3.5.2.2.2 Department of Defense Branchline North (Wabuska to the boundary of the Walker River Paiute Reservation). DOE would construct a passing siding within the existing right-of-way and no new land would be disturbed. DOE would not perform any additional construction activities along the existing branchline. The construction of the passing siding would not affect current drainage patterns. Therefore, there would be no impacts to surface-water resources along the existing Department of Defense Branchline North.

4.3.5.2.2.3 Department of Defense Branchline through Schurz. DOE would remove track, timber ties, and ballast, and grade the ballast section to a smooth surface along this branchline. This removal activity would not involve land disturbance outside the existing rail line right-of-way because these actions would be performed using equipment designed to move along the track. Impacts resulting from grading would be the same as those described in Section 4.3.5.2.1.1 and are expected to be limited to the existing right-of-way because of best management practices that would be used to control nonpoint source pollution, such as sedimentation and stormwater runoff.

4.3.5.2.2.4 Schurz Alternative Segments. The Schurz alternative segments would cross waters of the United States as summarized in Table 4-201, including the Walker River and tributaries to Walker River. Of the four waters of the United States that Schurz alternative segment 1 would cross, the amount of fill would range from 1.7 cubic meters (60 cubic feet) for the smallest drainage to 8.6 cubic meters (300 cubic feet) for the largest drainage. Of the six waters of the United States that Schurz alternative segment 4 would cross, the amount of fill would range from 1.7 cubic meters (60 cubic feet) for the smallest drainage to 10 cubic meters (360 cubic feet) for the largest drainage. Both Schurz alternative segments 5 and 6 would cross only one water of the United States, therefore the total amount of fill for this drainage would be 1.7 cubic meters (60 cubic feet). The total amount of fill for waters of the United States crossed by Schurz alternative segment 1 would cross would be 18 cubic meters (630 cubic feet) and 19 cubic meters (670 cubic feet) for Schurz alternative segment 4. Section 4.3.5.2.1.4 addresses common impacts to waters of the United States.

Suspended solids have been identified as a contributing factor in the failure of the Walker River to meet water quality standards. Section 4.3.5.2.1.2 addresses common impacts to surface-water quality.

To reduce impacts to the Walker River and the associated floodplain, a bridge would be constructed at the Walker River crossing. The proposed dimensions are 300 meters (1,000 feet) long and 12 meters (40 feet) high (DIRS 180872-Nevada Rail Partners 2007, p. E-1). To construct a bridge over the Walker River, an approximately 18-meter (60-foot)-wide work area would be cleared of trees and other large vegetation along the alignment on both sides of the river. This would result in the temporary disturbance of about 0.002 square kilometer (0.55 acre) of wetlands for Schurz alternative segments 1 and 4, and 0.003 square kilometer (0.73 acre) of wetlands for Schurz alternative segments 5 and 6. DOE would place mats on all wetlands and moist soils within this work area to protect those soils from heavy equipment. The boundaries of the work area would be fenced, flagged, or otherwise marked to minimize disturbances in wetlands. The Department would locate all staging areas and equipment yards in uplands. DOE would revegetate wetlands and other disturbed areas after completion of the bridge. Placement of piers and construction of the bridge in the active stream would occur during low flow (generally September through April). To provide access for cranes and other heavy equipment to the stream channel, which is about 12 meters wide in this area, DOE would sink heavy mats made of wood or other solid material into the stream. There would be sufficient gaps between the mats to allow flow of water. DOE would not place any sand, gravel, or other loose fill in the stream channel. The Department would remove the mats from the channel after the bridge pilings were driven into ground and the concrete bridge sections were erected over the channel. Using these methods, the only permanent fill or loss of wetlands would be a total of about 20 square meters (0.005 acre) for ***emplacement*** of about 10 piers in wetlands for Schurz alternative segments 1 and 4, or 28 square meters (0.007 acre) for emplacement of about 14 piers for Schurz alternative segments 5 and 6. Appendix F, Floodplain and Wetlands Assessment, provides additional information on construction of the bridge on wetlands. Section 4.3.5.2.1.5 addresses common impacts to wetlands.

Although the Federal Emergency Management Agency has not mapped this area, the Schurz alternative segments cross areas with ***ephemeral washes*** and playas where the potential for flash flooding exists. The Department would construct appropriate drainage structures (including box culverts along Schurz alternative segment 6 and a plate girder along Schurz alternative segment 1, 4, 5, or 6). DOE anticipates impacts from construction of the rail line in floodplains would be small (DIRS 180872-Nevada Rail Partners 2007, pp. 3-2 and 3-3). Section 4.3.5.2.1.6 addresses common impacts to floodplains and floodwaters.

The two springs identified along Schurz alternative segment 1, Double Spring and an unnamed spring, lie within the region of influence but outside the construction right-of-way. Section 4.3.5.2.1.7 addresses common impacts to springs.

Construction camps 18A, 18B, 18C, and 18D, as described in Section 3.3.5.3.4, would be within the construction right-of-way. Construction camp 18C, which would be adjacent to Schurz alternative segment 5, would overlie one small ephemeral wash, and construction camp 18D, which would be adjacent to Schurz alternative segment 6, would overlie two small ephemeral washes. The camps would not cross any waters of the United States or wetlands. Construction camp 18A, which would be adjacent to Schurz alternative segment 1, and construction camp 18B, which would be adjacent to Schurz alternative segment 4, do not overlie any surface-water features. Section 4.3.5.2.1.1 addresses common impacts to surface-water crossings.

4.3.5.2.2.5 Department of Defense Branchline South (Hawthorne to Common Segment 1). DOE would use the existing rail line along the Department of Defense Branchline South for operations along the Mina rail alignment. With the exception of a new siding that would be constructed within the existing right-of-way and the construction of construction camp 17 along the southern portion of the segment, DOE does not anticipate any other construction activities. Construction camp 17 would be 0.3 kilometer (0.2 mile) northeast of Hawthorne and 0.93 kilometer (0.57 mile) northeast of the rail segment. The construction camp would be on the Hawthorne Army Depot and would not require additional road construction. Construction camp 17 would overlie one notable wash. Aside from construction of this camp and the siding, DOE does not anticipate any other surface disturbances along this portion of the Mina rail alignment.

4.3.5.2.2.6 Mina Common Segment 1 (Gillis Canyon to Blair Junction). Mina common segment 1 would cross several notable drainages but no waters of the United States, as summarized in Table 4-201. These drainages are described in Section 3.3.5.3.6 as ephemeral washes and playas. Notably, this segment crosses a large playa in Soda Spring Valley. Section 4.3.5.2.1.1 addresses common impacts to drainages.

There are no waters of the United States identified along Mina common segment 1 (DIRS 180889-PBS&J 2007, p. 7).

The National Wetland Inventory dataset identifies the playas in Soda Spring Valley and Alkali Flat as wetlands; however, DOE field studies in support of this Rail Alignment EIS confirmed no wetlands in these areas and therefore, no impact is anticipated (DIRS 180889-PBS&J 2007, Figure 4).

The Federal Emergency Management Agency has not mapped the area near Mina common segment 1; however, there are areas such as the Soda Springs playa where the potential for flash flooding exists. Section 4.3.5.2.1.6 addresses common impacts to floodplains and floodwaters.

The two springs identified along Mina common segment 1, Kinkaid Spring and an unnamed spring, would lie within the Mina rail alignment region of influence but outside the construction right-of-way. Section 4.3.5.2.1.7 addresses common impacts to springs.

Construction camps 14, 15, and 16, as described in Section 3.3.5.3.6, would be within the construction right-of-way of Mina common segment 1. Construction camp 16 would overlie one small ephemeral wash and one notable drainage, and construction camp 14 would overlie one small ephemeral wash and one notable drainage. The camps would not cross any waters of the United States or wetlands. Construction camp 15 would not overlie any surface water. Section 4.3.5.2.1.1 addresses common impacts to surface-water crossings.

4.3.5.2.2.7 Montezuma Alternative Segments. The Montezuma alternative segments would cross over several drainage features, including Jackson Wash and China Wash (Montezuma alternative segment 1) and Big Wash (Montezuma alternative segments 2 and 3). As shown in Table 4-201, the Montezuma alternative segments would cross numerous drainage channels. These drainages are described in Section 3.3.5.3.7 as ephemeral washes and playas. Notably, Montezuma alternative segments 2 and 3 would cross a large playa in Big Smoky Valley. Section 4.3.5.2.1.1 addresses common impacts to drainages.

There are no waters of the United States identified along the Montezuma alternative segments (DIRS 180889-PBS&J 2007, p. 7).

The National Wetland Inventory dataset identifies the playas in Big Smoky Valley (Montezuma alternative segments 2 and 3) and Stonewall Flat (Montezuma alternative segment 2) as wetlands; however, DOE field studies in support of this Rail Alignment EIS confirmed no wetlands in these areas and therefore, no impact is anticipated (DIRS 180889-PBS&J 2007, Figure 4).

Federal Emergency Management Agency flood maps only cover a small portion of the Montezuma alternative segments, near their southern termination. However, there are areas such as Big Smoky Valley, Clayton Valley, Stonewall Flat, and Montezuma Valley where the potential for flash flooding exists. Section 4.3.5.2.1.6 addresses common impacts to floodplains and floodwaters.

There are three springs identified along the Montezuma alternative segments – Hot Spring (Montezuma alternative segment 1), Slaughterhouse Spring (Montezuma alternative segment 2), and Rabbit Spring (Montezuma alternative segment 2). All three springs are within the Mina rail alignment region of influence but outside the construction right-of-way. Section 4.3.5.2.1.7 addresses common impacts to springs.

Construction camps 9, 9A, 13A, and 13B, as described in Section 3.3.5.3.7, would be within the construction right-of-way of the Montezuma alternative segments. Construction camp 9A would overlie one small ephemeral wash, and construction camp 13B would overlie one small ephemeral wash. The camps would not cross any waters of the United States or wetlands. Construction camps 9 and 13A would not overlie any surface water. Section 4.3.5.2.1.1 addresses common impacts to surface-water crossings.

4.3.5.2.2.8 Mina Common Segment 2. Mina common segment 2 would skirt two playas – Stonewall Flat Playa to the east and Alkali Flat Playa to the southwest. Mina common segment 2 would cross a drainage path that connects these two playas. These features are described in Section 3.3.5.3.8. Section 4.3.5.2.1.1 addresses common impacts to drainages.

There are no waters of the United States or wetlands along Mina common segment 2 (DIRS 180889-PBS&J 2007, pp. 7 and 9).

Federal Emergency Management Agency floodplain maps show a floodplain associated with the drainage path that connects Stonewall Flat Playa and Alkali Flat Playa, as indicated in Table 4-203. Where the Mina common segment would cross the floodplain, a drainage structure would be required that does not result in more than a 0.3-meter (1-foot) increase in water-surface elevations upstream of the crossing. Because of the engineering design process DOE would use and the regulatory requirements DOE would meet, impacts to surface-water drainage patterns would be small. Section 4.3.5.2.1.6 addresses common impacts to floodplains and floodwaters.

There are no springs identified or construction camps planned along Mina common segment 2.

4.3.5.2.2.9 Bonnie Claire Alternative Segments. Both of the Bonnie Claire alternative segments would cross an unnamed drainage channel that drains the area of Stonewall Mountain. Bonnie Claire alternative segment 3, the southwestern alternative segment, would also cross Alkali Flat Playa. These features are described in Section 3.3.5.3.9. Common impacts to drainages are addressed in Section 4.3.5.2.1.1.

There are no waters of the United States or wetlands identified along the Bonnie Claire alternative segments (DIRS 180889-PBS&J 2007, pp. 7 and 9).

Floodplain maps of the area show floodplains associated with the unnamed drainage channel that drains the area of Stonewall Mountain and Alkali Flat Playa; however, map coverage of the unnamed wash terminates just downstream (southwest) of Bonnie Claire alternative segment 3. The coverage stops at an old boundary of the Nevada Test and Training Range, but is close enough to the alternative segment that a reasonable estimate of the crossing distance could be made and included in Table 4-203. The area where Bonnie Claire alternative segment 2, the northeastern alternative segment, would cross the unnamed wash is far enough away from the limit of the floodplain map coverage that a crossing distance was difficult to estimate, which is why no value is shown in Table 4-203. Common impacts to floodplains and floodwaters are addressed in Section 4.3.5.2.1.6.

There are no springs identified or construction camps planned along the Bonnie Claire alternative segments.

4.3.5.2.2.10 Common Segment 5 (Sarcobatus Flat Area). Common segment 5 would cross numerous drainage channels, including Tolicha Wash and several unnamed washes, and would skirt playa areas of Sarcobatus Flat. These features are described in Section 3.3.5.3.10. Common impacts to drainages are addressed in Section 4.3.5.2.1.1.

There are no waters of the United States or wetlands identified along common segment 5 (DIRS 180889-PBS&J 2007, pp. 7 and 9).

Where common segment 5 would cross the floodplain associated with Tolicha Wash, a drainage structure would be required that would not result in more than a 0.3-meter (1-foot) increase in water-surface elevations upstream of the crossing. Playa areas near common segment 5 would be subject to occasional flooding and standing water, but the Federal Emergency Management Agency floodplain maps do not show that 100-year flood levels would reach this rail line segment. Common impacts to floodplains and floodwaters are addressed in Section 4.3.5.2.1.6.

There are no springs identified along common segment 5.

Construction camp 10, as described in Section 3.3.5.3.10, would be within the construction right-of-way and would overlie two small ephemeral washes and three notable drainages. The camp would not cross any waters of the United States or wetlands. Common impacts to surface-water crossings are addressed in Section 4.3.5.2.1.1.

4.3.5.2.2.11 Oasis Valley Alternative Segments. The Oasis Valley alternative segments would cross several washes and both would cross the Amargosa River, which is an ephemeral stream in this area. The northeastern alternative segment, Oasis Valley 3, would run within approximately 0.24 kilometer (0.15 mile) from Colson Pond. These features are described in Section 3.3.5.3.11. Common impacts to drainages are addressed in Section 4.3.5.2.1.1.

DOE field surveys of these areas identified two drainage channels along Oasis Valley alternative segment 1 and one drainage channel along Oasis Valley alternative segment 3 that would qualify as waters of the United States (DIRS 180889-PBS&J2007, p. 7 and Figure 3B). Crossings of waters of the United States are summarized in Table 4-201. However, DOE would likely use bridges for these crossings. Therefore, the total amount of fill for waters of the United States the Oasis Valley alternative segments would cross would be very small. Common impacts to waters of the United States are addressed in Section 4.3.5.2.1.4.

DOE field surveys also identified a small isolated wetland, WT-15 (74 square meters [800 square feet]), that would be just outside the construction right-of-way, approximately 160 meters (530 feet) north of Oasis Valley alternative segment 1 (DIRS 180914-PBS&J 2006, p. 13 and Figure 4T). There would be no direct impacts to this wetland during the construction phase because it would be outside the construction right-of-way and would be fenced or flagged. Indirect impacts such as sedimentation, erosion, and incidental spills would still be possible. Common impacts to wetlands are addressed in Section 4.3.5.2.1.5.

As shown in Table 4-203, both of these alternative segments would cross floodplains associated with Thirsty Canyon. Common impacts to floodplains and floodwaters are addressed in Section 4.3.5.2.1.6.

There are 25 springs within the region of influence of the Oasis Valley alternative segments, all of which would be outside the construction right-of-way. Oasis Valley alternative segment 3 would run within 200 to 520 meters (640 to 1,700 feet) of two unnamed springs. Oasis Valley alternative segment 1 would run within 480 to 610 meters (1,600 to 2,000 feet) of seven springs. Because the springs would be downstream of the rail line, there would be the potential for impacts from erosion and sedimentation during the construction phase. Common impacts to springs are addressed in Section 4.3.5.2.1.7.

Construction camp 11, as described in Section 3.3.5.3.11, would be within the Oasis Valley 1 construction right-of-way and would overlie one small ephemeral wash and two notable drainages. The camp would not cross any waters of the United States or wetlands. Common impacts to surface-water crossings are addressed in Section 4.3.5.2.1.1.

4.3.5.2.2.12 Common Segment 6 (Yucca Mountain Approach). Common segment 6 would cross several drainage features, including Beatty Wash, Tates Wash, Windy Wash, Busted Butte Wash (also known as Dune Wash), and unnamed tributaries of the Amargosa River, Busted Butte Wash, and Drill Hole Wash. These features are described in Section 3.3.5.3.12. Common impacts to drainages are addressed in Section 4.2.5.2.1.1.

Common segment 6 would cross 14 channels that qualify as waters of the United States, including two tributaries of the Amargosa River, Beatty Wash, seven tributaries to Beatty Wash, and four tributaries to Fortymile Wash. Of the 14 waters of the United States that common segment 6 would cross, the amount of fill would range from none for the smallest drainage to 9.9 cubic meters (350 cubic feet) for the largest drainage. The total amount of fill for waters of the United States that common segment 6 would cross would be 37 cubic meters (1,300 cubic feet).

There are no wetlands identified along common segment 6 (DIRS 180889-PBS&J 2007, p. 7).

Federal Emergency Management Agency floodplain maps provide coverage for the western portion of common segment 6, but the coverage terminates at approximately the point where the rail line would reach the Yucca Mountain Site boundary. In the areas covered by floodplain maps, the only floodplain along common segment 6 is one associated with Beatty Wash. The maps also show a floodplain associated with the unnamed wash from Crater Flat, but it does not extend up the wash as far as where common segment 6 would cross. DOE would build a large (370-meter [1,200-foot]-long) special-condition railroad bridge across Beatty Wash. Although the floodplain maps do not provide coverage for the area of the repository site on the east side of Yucca Mountain, there have been flood studies performed on several washes in that area, as described in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Figure 3-12 and pp. 3-38 and 3-39). If the Mina rail alignment is overlain on the figure of the floodplains in the Yucca Mountain FEIS (see Figure F-15 in Appendix F of this Rail Alignment EIS), it can be seen that common segment 6 would cross short stretches of 100-year floodplains associated with Busted Butte Wash and Drill Hole Wash before it terminated just prior to crossing a floodplain associated with Midway Valley Wash (also known as Sever Wash). Table 4-208 lists the estimated crossing distances for Beatty Wash, Busted Butte Wash, and Drill Hole Wash. Common impacts to floodplains and floodwaters are addressed in Section 4.3.5.2.1.6.

There are no springs identified along common segment 6.

Construction camp 12, as described in Section 3.3.5.3.12, would be within the common segment 6 construction right-of-way and would overlie one small ephemeral wash. The camp would not cross any waters of the United States or wetlands. Common impacts to surface-water crossings are addressed in Section 4.3.5.2.1.1.

4.3.5.2.3 Impacts from Constructing Facilities

4.3.5.2.3.1 Staging Yard. The Staging Yard would be constructed to the east of Hawthorne along Mina common segment 1. The disturbance area of the Staging Yard would be approximately 0.20 square kilometer (50 acres) and would include a 350-square-meter (3,800-square-foot) office, a 560-square-meter (6,000-square-foot) Satellite Maintenance-of-Way Facility, and a paved access road (DIRS 180872-Nevada Rail Partners 2007, p. 3-1 and 3-2). The facility would overlie one notable wash; however, impacts to surface-water features would be small. Impacts to surface waters are summarized in Table 4-204.

4.3.5.2.3.2 Maintenance-of-Way Facility. There are two potential locations for the Maintenance-of-Way Facility along the Mina rail alignment, depending on the selected alternative segment. The Silver Peak option along Montezuma alternative segment 1 would be approximately 1.6 kilometers (1 mile) south of Silver Peak. The Klondike option along Montezuma alternative segment 2 or 3 would be 2.9 kilometers (1.8 miles) west of U.S. Highway 95 between Tonopah and Goldfield (DIRS 180872-Nevada Rail Partners 2007, p. 4-4). The disturbance area of either potential location would be approximately 61,000 square meters (15 acres). There are no surface-water features in the area of either Maintenance-of-Way Facility option; therefore, there are no impacts to surface-water features.

4.3.5.2.3.3 Rail Equipment Maintenance Yard. Because there are no perennial surface waters in the area where the rail line would end at Yucca Mountain, potential impacts to surface-water features from the construction of rail line facilities in that area would be small (similar to the common impacts already described in Section 4.3.5.2.1.1). The Rail Equipment Maintenance Yard would overlie one ephemeral wash, but would not cross any waters of the United States. The Yard construction disturbance area, approximately 0.41 square kilometer (100 acres), would also include the train crew quarters, and could be the location for the Nevada Railroad Control Center and National Transportation Operations Center, and the Cask Maintenance Facility. Construction of the operations support facilities would include stormwater runoff control, as necessary, which would minimize the potential for contaminated runoff to reach any of the washes in the area; therefore, impacts related to construction of the Rail Equipment Maintenance Yard would be small.

4.3.5.2.4 Quarries

Each quarry facility would be comprised of three primary components: an operations plant, the quarry and production area, and possibly a railroad siding. The operations plant would include an office and administration complex, parking areas, services for fueling and maintenance, and sanitary facilities. Portable sanitary systems would be provided onsite; no water supply or wastewater treatment facilities would be provided at the quarry sites. The quarries would be close enough to construction camps that on-site residential facilities would not be necessary.

Ballast quarry operations would require the use of water, primarily to wash excavated rock during crushing and screening operations. Water usage quantities would vary depending on the specific quarry process selected to wash the rock during these operations. It is estimated that approximately 140,000 liters (38,000 gallons) of water would be needed per operational day at each quarry site (DIRS 180875-Nevada Rail Partners 2007, p. 3-1). Water used during these activities would also be used for dust suppression in these quarry areas. The wash water would be contained and recirculated through settling ponds. Relatively small quantities of water would also be used for dust suppression during drilling and blasting, truck loading and unloading, ballast stockpile and waste rock pile operations, and along access roads and in the quarry pit to suppress dust from truck and heavy equipment operations. Water used for dust suppression in these areas would not be expected to result in runoff from the quarry operational areas.

Overburden and waste rock removed from quarry areas would be stockpiled and later used for reclamation of the quarry sites. These piles would be stabilized or, if necessary, covered (for example, with mulch, netting, or synthetic stabilizer) to reduce the potential for erosion and runoff of sediments from these areas. Other best management practices that would be implemented include filter berms, straw bail barriers, fences, or revegetation, as necessary. The change in the amount of runoff that would actually reach drainage channels would be minor, because construction would affect a small amount of the overall natural drainage areas.

Three separate programs established by the Clean Water Act are significant when reviewing activities associated with potential quarries. These include the establishment of water quality standards pursuant to Section 303(c) of the Clean Water Act, National Pollutant Discharge Elimination System permit requirements set forth in Section 402 of the Clean Water Act, and dredge and fill permit requirements set forth in Section 404 of the Clean Water Act. General National Pollutant Discharge Elimination System permits would require that best management practices (including inventorying, assessment, prioritization, and identification and implementation of best management practices) be employed to meet water quality standards. It is expected that any discharges associated with quarry operations would be managed with appropriate stormwater control systems that would effectively minimize off-site impacts from stormwater drainage. Thus, impacts to surface-water features associated with quarry operations would be small.

4.3.5.3 Railroad Operations Impacts

Potential impacts during the operations phase are addressed in relation to the impact assessment standards for surface-water resources identified in Table 4-200, including stormwater drainage and surface-water quality. Section 4.3.5.2.1 addresses surface-water availability, and floodplains and wetlands.

4.3.5.3.1 Operations Impacts Common to the Entire Rail Alignment

Operation of the proposed railroad would result in a small impact to surface waters beyond the permanent drainage alterations from construction. The rail roadbed would be expected to have runoff rates different from those of the natural terrain but, given the small size of the potentially affected areas within the overall drainage system, the impact on overall runoff quantities would be small. Thus, impacts related to stormwater increases would be limited to those localized areas where drainage patterns would be altered to convey storm flows.

Rail line maintenance would require periodic inspections of flood-prone areas (particularly after flood events) to verify the condition of the track and drainage structures. When necessary, sediment accumulating in these areas would be removed and disposed of appropriately. Similarly, eroded areas encroaching on the rail roadbed would be repaired. If the eroded areas had to be repaired often, that would be an indication that flow patterns had been changed and sediment was being moved as the water was cutting out a new channel. Regular inspection and maintenance of the rail line would help ensure that erosion and sedimentation problems were identified and addressed in a timely manner so that they did not contribute to upstream or downstream impacts. Therefore, impacts during the operations phase from sediment buildup and floodwater activity would be small.

The primary sources of potential surface-water ***contamination*** during the operations phase would be fuels (diesel and gasoline) and lubricants (oils and greases) required for equipment operation and maintenance. DOE would minimize the potential for contamination by managing spills and implementing best management practices.

4.3.5.3.2 Facility Operations

Activities at the facilities (including quarries) would adhere to a Spill Prevention, Control, and Countermeasures Plan to comply with environmental regulations and would also include a number of best management practices. The plan would describe the actions the Department would take to prevent, control, and remediate spills of fuel or lubricants. It would also describe the reporting requirements that would accompany the identification of a spill (DIRS 155970-DOE 2002, p. 4-23). Therefore, impacts to surface waters from facilities operations would be small.

Sanitary sewage generated at facilities would be contained and removed, sent to treatment facilities, or in some cases, disposed of through on-site septic systems. No industrial wastewater discharges would be expected from the operation of facilities. All wastewater collection and transfer systems would be designed and operated such that untreated wastewater would not be released to the environment; therefore, impacts to surface-water resources from facilities operations would be small.

4.3.5.3.3 Quarry Operations

Quarries would be reclaimed following the construction phase and would not be used during the operations phase. Therefore, there would be no impacts from quarry operations.

4.3.5.4 Shared-Use Option

Construction impacts to surface-water resources under the Shared-Use Option would be similar to those identified for the Proposed Action without shared use. The Shared-Use Option would involve the construction of additional sidings, which would be approximately 300 meters (980 feet) long and would be aligned parallel to the rail line within the construction right-of-way. Construction of these additional sidings would involve the same types of land disturbance as for the Proposed Action without shared use, but with minor additive impacts. As for the Proposed Action without shared use, potential impacts would be the release and spread of contaminants by precipitation or intermittent runoff events or, for portions of the rail line near surface-water bodies, possible release to the surface water; the alteration of natural drainage patterns or runoff rates that could affect downgradient resources; and the need for dredging or filling of perennial or ephemeral streams. However, the adverse impacts to surface-water resources from constructing additional sidings under the Shared-Use Option would add little to potential impacts described for the Proposed Action without shared use, because the same control measures would be in effect. Because construction of these additional sidings would not be a DOE action and there are uncertainties regarding the exact locations of needed commercial-use facilities, specific impacts of the Shared-Use Option to surface-water features were not analyzed.

Operations impacts under the Shared-Use Option would be similar to those identified for the Proposed Action without shared use. Use of a completed rail line from Mina to Yucca Mountain, including additional sidings, would result in small impacts to surface waters beyond the permanent drainage alterations that would result from construction. The rail roadbed would likely have runoff rates different from those of the natural terrain but, given the small size of the potentially affected areas in a single drainage system, the impact from shared-use operations on overall runoff quantities would be small.

Maintenance of the rail line and shared-use sidings would require periodic inspections of flood-prone areas (particularly after floods) to verify the condition of the track and drainage structures. When necessary, sediment accumulating in these areas would be removed and disposed of appropriately. Similarly, eroded areas encroaching on the rail roadbed would be repaired. Therefore, impacts from maintenance of the rail line related to sedimentation and erosion under the Shared-Use Option would be small.

General freight shipped on the proposed railroad could include mineral products, petroleum, agricultural products, or other commodities shipped or received by private companies. Spills of oil or hazardous substances carried on the rail line as general freight could affect surface-water resources. If a spill occurred, the potential for contamination to enter flowing surface water would present the greatest risk of a large contaminant migration until spills were contained and remediated. If there was no routinely flowing surface water, as is the condition for most areas along the Mina rail alignment, it is expected that released materials would not travel far or affect critical resources before corrective action could be taken. Compliance with regulatory requirements on reporting and remediating spills would result in a small probability of spills and, with specific regard to rail line operations, the overall risk of a transportation ***accident*** that could result in a release of a hazardous substance is considered to be small, as discussed in Section 4.3.10, Occupational and Public Health and Safety. Therefore, impacts to surface-water resources from potential accidental releases of contaminants from commercial rail shipments during operations under the Shared-Use Option would be small.

4.3.5.5 Summary

4.3.5.5.1 Common Impacts

Construction and operation of a railroad along the Mina rail alignment could result in both direct and indirect impacts to surface-water resources (see Table 4-204). Direct impacts would include temporary or permanent grading, dredging, rerouting, or filling of surface-water resources. Indirect impacts would potentially increase or impede surface flow. Also, nonpoint source pollution could result from runoff from areas where surface grades and characteristics would be changed (such as the rail roadbed and access roads). Overall, impacts to surface-water resources from railroad construction and operations would be small.

To evaluate potential impacts to surface-water resources, DOE identified areas where there are surface-water resources along the rail alignment (including those that would be crossed, filled, or covered) and identified the activities associated with construction or operations that would have the potential to affect these surface-water resources. Because of their importance in influencing the types and magnitude of potential impacts, Table 4-201 summarizes the numbers of surface-water features the Mina rail alignment would encounter. The table includes estimates of the total number of surface-water features the rail line, facilities, and quarries would cross. Such features include drainage channels, floodplains, and wetlands. The table also identifies two subsets of the total number of drainage channel crossings. The first is the notable channels described in Section 3.3.5.2.1, and the second includes drainage channels that would be classified as waters of the United States.

In all instances where the alignment would cross or come close to a surface-water feature, that feature could be affected to some degree by railroad construction and operation; however, impacts would be substantially minimized through the engineering design process and the implementation of best management practices prior to, during, and after construction. DOE would incorporate hydraulic modeling into the engineering design process to ensure that crossings were properly engineered so they would not contribute to erosion and sediment pollution. The design of drainage structures would account for scour and erosion and incorporate outlet protection and velocity-dissipating devices that would calm the flow and diminish its erosive potential. Because conveyance systems would be designed to safely convey increased flows during storm events (50-year and 100-year) and would minimize concentration of flow to the greatest extent practicable, impacts on stormwater drainage conveyance from construction of the rail line would be small.

DOE would minimize impacts to surface-water resources through the implementation of engineering design standards (as described above) and best management practices (see Chapter 7). Best management practices would include erosion control measures, such as the use of silt fences and flow-control devices to reduce flow velocities and minimize erosion. Further, the Department would minimize filling of surface-water resources by incorporating avoidance into final engineering and design of the rail line, to the extent practicable. DOE would use a minimum-width rail line footprint whenever possible.

4.3.5.5.2 Alternative Segment-Specific Impacts

The Mina alternative segments are adjacent to wetlands and some wetland fill would be unavoidable. DOE would construct a bridge at the Walker River crossing in part to minimize filling wetlands. Of the 0.07 square kilometer (17 acres) of wetlands delineated along the rail alignment, only about 20 square meters (0.005 acre) for Schurz alternative segments 1 and 4, or 28 square meters (0.007 acre) for Schurz alternative segments 5 and 6 would be permanently filled or lost to construct the alternative segment.

Table 4-204. Summary of impacts to surface-water resources – Mina rail alignment (page 1 of 2).

Rail line segment/facility (county)	Proposed Action[a]	
	Construction impacts[b,c]	Operations impacts
Existing branchlines (Lyon and Mineral Counties)	Not applicable	No additional surface-water impacts are anticipated due to increased rail traffic.
All alternative segments and common segments (Lyon, Mineral, Churchill, Esmeralda, and Nye Counties)	Potential for increases in nonpoint source pollution, alteration of natural drainage patterns and runoff rates, temporary blockage of surface drainage channels, localized changes in drainage patterns, and increases in the flow rate in relation to natural flow conditions. Potential for release and spread of contaminants through an accidental spill or discharge. Potential impact from erosion and sediment loading and reduction of floodwater area flow.	Potential for fuel spills or release of contaminants. Drainage crossings (culverts and bridges) might cause floodwaters to back up.
Staging Yard at Hawthorne and Maintenance-of-Way Facility (Mineral and Esmeralda Counties)	Potential impact from erosion and sediment loading.	Potential for fuel spills or release of contaminants.
Potential quarries (Mineral and Esmeralda Counties)	Potential impact from erosion and sediment loading.	Potential impact from erosion and sediment loading.

Table 4-204. Summary of impacts to surface-water resources – Mina rail alignment (page 2 of 2).

Rail line segment/facility (county)	Proposed Action[a]	
	Construction impacts[b,c]	Operations impacts
Rail Equipment Maintenance Yard; Cask Maintenance Facility; Nevada Railroad Control Center and National Transportation Operations Center (Nye County)	Potential impact from erosion and sediment loading.	Potential for fuel spills during fueling; fuel transfer; or storage tank failure. Drainage crossings (culverts and bridges) might cause floodwaters to back up.
Schurz alternative segment 1 (Lyon and Mineral Counties)	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 20 square meters (220 square feet) would be permanently filled to construct the bridge. Potential short-term impacts to wetlands from construction of the bridge over Walker River.	Permanent loss of wetlands.
Schurz alternative segment 4 (Lyon and Mineral Counties)	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 20 square meters (220 square feet) would be permanently filled to construct the bridge. Potential short-term impacts to wetlands from construction of the bridge over Walker River.	Permanent loss of wetlands.
Schurz alternative segment 5 (Lyon and Mineral Counties)	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 28 square meters (300 square feet) would be permanently filled to construct the bridge. Potential short-term impacts to wetlands from construction of the bridge over Walker River.	Permanent loss of wetlands.
Schurz alternative segment 6 (Lyon, Mineral, and Churchill Counties)	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 28 square meters (300 square feet) would be permanently filled to construct the bridge. Potential short-term impacts to wetlands from construction of the bridge over Walker River.	Permanent loss of wetlands.
Common segment 1 (Mineral and Esmeralda Counties)	Potential for impacts from erosion and sedimentation to spring.	No additional surface-water impacts are anticipated.
Montezuma alternative segment 1 (Esmeralda County)	Potential for impacts from erosion and sedimentation to spring.	No additional surface-water impacts are anticipated.
Montezuma alternative segment 2 (Esmeralda and Nye Counties)	Potential for impacts from erosion and sedimentation to springs.	No additional surface-water impacts are anticipated.
Oasis Valley alternative segment 1 (Nye County)	Indirect impacts such as sedimentation, erosion and incidental spills possible to small wetland along Oasis Valley 1. Potential for impacts from erosion and sedimentation to springs downstream of the rail line.	No additional surface-water impacts are anticipated.
Oasis Valley alternative segment 3 (Nye County)	Potential for impacts from erosion and sedimentation to springs downstream of the rail line.	No additional surface-water impacts are anticipated.

a. Impacts under the Shared-Use Option would be similar to those under the Proposed Action without shared use.
b. Wetland filling estimates are based on the assumption that the construction right-of-way would be 30 meters (100 feet) wide.
c. Floodplain crossing distance is presented as a range. The minimum crossing distance is represented by the length of the rail line crossing Federal Emergency Management Agency mapped floodplains. The maximum value represents the minimum value in addition to the estimated crossing distance over floodplains that have not been mapped.

4.3.6 GROUNDWATER RESOURCES

This section describes potential impacts to groundwater resources from constructing and operating the proposed railroad along the Mina rail alignment. To analyze potential impacts, DOE considered whether constructing and operating the railroad would result in:

- Possible damage to existing wells as a result of construction work
- Possible declines in groundwater levels or groundwater production rates at existing groundwater production wells
- Possible changes in discharge rates at existing springs
- Possible changes in infiltration rates in disturbed areas
- Possible changes in groundwater quality at wells, springs, or in shallow groundwater
- Possible subsidence of the ground surface

Section 4.3.6.1 and Appendix G describe the methods DOE used to assess potential impacts to existing groundwater resources; Section 4.3.6.2 describes potential construction impacts; Section 4.3.6.3 describes potential impacts of operating the railroad along the Mina rail alignment under the Proposed Action; Section 4.3.6.4 describes potential impacts of operating the railroad along the Mina rail alignment under the Shared-Use Option; and Section 4.3.6.5 summarizes potential impacts to groundwater resources.

Section 3.3.6.1 describes the region of influence for groundwater resources for the Mina rail alignment. The section includes a discussion of existing wells and springs that fall within the Mina rail alignment region of influence that could be affected by new wells that would be installed and used to obtain water to support construction and operation of the proposed rail line.

4.3.6.1 Impact Assessment Methodology

DOE considered a variety of methods for obtaining water that would be needed to support construction and operation of the proposed rail line and railroad construction and operations support facilities along the Mina rail alignment. These methods include, but are not limited to, construction of new water wells; purchasing water from municipalities or other existing water-rights holders; or importing water from other groundwater ***hydrographic areas***. A combination of such methods could reduce potential impacts to groundwater resources. However, acquiring all required water from new wells would place the greatest amount of increased water ***demand*** on existing groundwater resources. Therefore, to develop a conservative or upper bound estimate analysis of potential impacts to groundwater resources, DOE assumed that it would obtain all water required for construction and operation of the Mina rail line and Mina railroad construction and operations support facilities from newly constructed wells. This EIS does not analyze the impacts of obtaining water through other methods.

In this section, DOE evaluates the potential impacts associated with the following types of new water wells that would be installed and utilized to obtain water required for construction and operation of the proposed Mina rail line and associated facilities:

- Construction water wells – These temporary wells (DIRS 180888-Converse Consultants 2007, Section 2.1 and Table 2-2) would furnish approximately 87 percent of the total project water demand. The remaining 13 percent of total water demand would be provided by wells for quarries or permanent wells. Wells in this category include wells that would provide water for earthwork compaction during rail roadbed construction and wells that would supply water for temporary construction camps. Nearly all water obtained from wells to support rail roadbed construction within each hydrographic area would be pumped within a 1-year period. The average groundwater withdrawal (usage) rate for these wells would vary according to location. Water wells at construction camps would have production rates of 76 liters (20 gallons) per minute.

- Quarry water wells – These wells would supply water to support start-up and operation of quarry operations, with each quarry being in operation over an estimated period of about 2 years, following an initial start-up period. The average withdrawal rate for these wells would be approximately 91 liters (24 gallons) per minute.
- Permanent water wells – These wells would supply water to meet water requirements for rail sidings and railroad operations facilities and provide water for fire protection purposes. Average withdrawal rates for these wells would be very low (less than 3.8 liters [1 gallon] to approximately 16 liters [4.2 gallons] per minute). DOE would use these new wells during the 50 years of railroad operations.

DOE would install most of the new water wells adjacent to new access roads that would be constructed on either side of the rail roadbed and within the rail line construction right-of-way. DOE assumes that if it could not obtain adequate volumes of water from some of these new wells because of limited ***aquifer*** productivity (less than the required productivity for that location based on the water demand at the associated construction location), it would obtain the additional water required at those locations from other new wells proposed for installation either within the typical maximum 300-meter (1,000-foot)-wide construction right-of-way or from one or more of the proposed new wells simulated outside of that right-of-way. In these cases, the water would either be transported by truck or pumped through a temporary above-ground pipe within the construction right-of-way. Wells installed outside of the construction right-of-way would be installed as near as reasonably possible, based on hydrogeologic criteria, to the right-of-way, except for wells installed at the proposed quarry sites, which might or might not be at more remote locations.

DOE considered a number of factors to evaluate potential adverse impacts to groundwater resources. There could be an adverse impact if construction and operation of the Mina rail line and railroad construction and operations support facilities would cause any of the conditions listed in Table 4-205.

Table 4-205. Impact assessment considerations for groundwater resources.

Resource criteria	Basis for assessing adverse impact
Groundwater availability and uses	• Adversely affect an existing aquifer. Adverse effects would include substantial depletion of groundwater supplies on a scale that would affect available capacity of a groundwater source for use by existing water-rights holders within the hydrographic area where groundwater withdrawal would occur or in any downgradient hydrographic area, interfere with groundwater recharge, or reduce discharge rates to existing springs or seeps. • Conflict with established water rights, allotments, or regulations protecting groundwater resources.
Ground subsidence	• Cause subsidence of the ground surface (as a result of groundwater withdrawals).
Groundwater quality	• Contaminate a public water-supply aquifer and exceed federal, state, or local water-quality criteria.

To evaluate potential impacts to groundwater resources DOE considered:

- Potential changes to infiltration rates, with consequent changes to percolation rates of surface water to the groundwater system that could be caused by the same disturbances evaluated in the surface-water impact analysis (also see Section 4.3.5, Surface-Water Resources).
- Potential changes to groundwater quality due to groundwater withdrawals or from accidental spills or releases.

- Potential impacts to aquifer users and uses resulting from withdrawal of groundwater from new wells to support water needs for construction and operation of the Mina rail line and railroad construction and operations support facilities. DOE focused the impact analysis on aquifers and the existing groundwater users who withdraw water from the groundwater hydrographic areas that would serve as sources of water for construction and operation of the rail line. DOE compared the amount of water that would be required for construction and operation of a railroad along the Mina rail alignment and existing uses of groundwater in those groundwater hydrographic areas. Existing groundwater resources addressed in these evaluations include existing wells, springs, and groundwater seeps. DOE considered potential impacts resulting from the following actions: (1) pumping from new wells to obtain water needed for rail roadbed construction (including water needed for earthwork, dust control, and construction camps), and (2) pumping from new wells installed to support quarry operations, rail sidings, and other railroad facilities.
- Potential for damage to existing wells from construction activities or potential ground subsidence as a result of the proposed groundwater withdrawals.

4.3.6.2 Construction Impacts

4.3.6.2.1 Construction Impacts Common to the Entire Rail Alignment

Impacts to groundwater or the land surface during construction of the Mina rail line could include: (1) potential changes in infiltration rates in disturbed areas with resulting changes in rates of percolation to groundwater (addressed in Section 4.3.5, Surface-Water Resources); (2) reduced flow to springs or seeps or a reduction in available flow rates to one or more existing wells within the ***radius of influence*** of, or the radius of the ***cone of depression*** surrounding, purposed new wells; (3) possible damage to, or loss of, use of existing wells within the construction right-of-way; (4) degradation of groundwater quality resulting from groundwater withdrawals; or (5) potential ground subsidence.

As described in Section 4.3.5, construction of the rail line and railroad construction and operations support facilities would result in land-surface disturbance, such as grading, excavating, or stockpiling, that would alter the rate at which water could infiltrate the disturbed areas. Construction activities would disturb and temporarily loosen the ground, which could produce temporarily higher near-surface infiltration rates (see Section 4.3.5). This situation would typically be short-lived; rail roadbed materials and disturbed areas associated with railroad facilities and ballast areas would become compacted and less porous, with most of the land disturbance during railroad and facilities construction likely resulting in surfaces with lower infiltration rates causing an increase in runoff. Even in the short term, localized changes in infiltration would likely cause no large-scale change in the amount of groundwater percolation (***recharge***) because the disturbed areas would be a very small percentage of the overall surface area of a hydrographic area (see Section 4.3.5). Therefore, changes to infiltration rates in the regions where construction would take place would be small, and adverse impacts associated with changes in stormwater infiltration rates would be small.

Most recharge to aquifers in the region is derived from precipitation falling in the higher parts of the inter-basin mountain ranges (see, for example, DIRS 103136-Prudic, Harrill, and Burbey 1993, pp. 2, 58, 84, and 88; DIRS 180759-Van Denburgh and Rush 1970, Table 6). The climate in the region through which DOE would construct a railroad along the Mina rail alignment is generally arid. These factors combine to produce a deficit of shallow groundwater beneath many parts of the rail alignment, such as several valley floors it would cross. Estimated depths to groundwater beneath most of the hydrographic areas the rail line would cross range from approximately 15 to 150 meters (50 to 490 feet) or more below ground, with some localized areas where shallower groundwater occurs, at depths ranging between 3 and less than 15 meters (10 and less than 50 feet) below ground. Areas of such shallower groundwater occurrence include portions of the Mason Valley, Walker Lake Valley (Schurz Subarea), Rhodes Salt

Marsh, Columbus Salt Marsh, Clayton Valley, and Oasis Valley hydrographic areas (DIRS 180887-Converse Consultants 2007, Plates 4-1 to 4-10; DIRS 180888-Converse Consultants 2007, Appendix B). However, with the exception of one portion of one alternative segment (Montezuma alternative segment 1) in the Clayton Valley hydrographic area (area 143) and a portion of Department of Defense Branchline North in the Mason Valley hydrographic area (area 108), areas of known shallower groundwater occurrence lie outside of the proposed rail alignment construction right-of-way (DIRS 180887-Converse Consultants 2007, Plates 4-1 to 4-10). Available hydrogeologic information suggests that shallow groundwater would occur infrequently, and on a localized basis, beneath the Mina rail alignment.

Other potential impacts include degradation of groundwater quality due to new sources of contamination that could come into direct contact with, or migrate to, groundwater. Construction-related materials that would be used in this arid environment, that could contaminate groundwater if spilled, include petroleum products (such as fuels and lubricants) and coolants (such as antifreeze) necessary to operate construction equipment. The infrequent occurrence of shallow groundwater beneath the Mina rail alignment (see Section 3.3.6) beneath the vast majority of the proposed Mina rail alignment indicates that the probability of contaminants reaching underlying groundwater would be low; therefore, DOE would not expect impacts to groundwater quality resulting from spills of hazardous or nonhazardous materials.

As discussed in Section 4.3.11, Utilities, Energy, and Materials, ***sanitary wastes*** from the construction camps would be disposed of in accordance with all applicable regulatory requirements. By complying with regulatory requirements, it is expected that wastewater-related impacts to groundwater resources in these areas would be minimized.

Railroad construction activities might occur near one or more existing wells. However, based on the available data, DOE does not anticipate that construction would disturb any existing wells. In the unlikely event that wells are identified prior to rail roadbed construction that could be disturbed by construction activities, DOE would take steps to minimize impacts to those wells, such as advising well owners of planned activities and discussing with the owners measures needed to protect the well head (the portion of the well above the ground surface) during construction. An estimated total of approximately 7.34 million cubic meters (5,950 ***acre-feet***) of water could be required to construct a railroad along the Mina rail alignment (DIRS 180875-Nevada Rail Partners 2007, p. 4-4). The actual amount of water required would depend on the specific combination of alternative rail segments that would be selected for construction (see Table 3-114). DOE would use water for earthwork compaction, control of excavation dust, workforce needs, and ballast production (DIRS 180875-Nevada Rail Partners 2007, p. 4-4). DOE has assumed that it would obtain all water from new wells. Over 87 percent of the total required project water demand is needed to support rail roadbed construction (DIRS 180875-Nevada Rail Partners 2007, Section 4.4.2). These construction water wells would be temporary wells and DOE assumes they would be used for up to a year (DIRS 180888-Converse Consultants 2007, Section 2.1 and Table 2-2). As discussed in Chapter 2, Proposed Action and Alternatives, DOE is considering a 4- to 10-year rail construction schedule. The typical groundwater pumping scenario for rail roadbed construction wells assumes a 9-month effective pumping period with 3 months of lost production for each construction well because of adverse weather conditions or other factors such as equipment repairs. This provides for a conservative scenario, or upper bound estimate of groundwater withdrawal rates that would result in the largest potential impacts (greatest amounts of drawdown) to groundwater resources (and existing groundwater users potentially situated within the region of influence of the proposed water wells). If the construction schedule were lengthened (for example, up to 10 years), less water would be required to support construction activities in any given year, thereby resulting in the same or reduced groundwater withdrawal rates and the same or reducing impacts to groundwater resources and existing groundwater users. Section 4.3.6.2.2 further describes the approach and methods DOE used to quantitatively evaluate potential site-specific impacts to groundwater resources. Table 4-206 lists the proposed Mina rail alignment alternative segments and common segments and summarizes the estimated total construction-related water requirements (demands) within each hydrographic area. The table lists a range of water demand values for hydrographic areas associated with more than one alternative segment or common segments. The range of values consists of the minimum water demand and the maximum water demands based on the various possible combinations of alternative rail segments that could be constructed, for the 18 hydrographic areas that would be crossed by the Mina rail alignment. Figure 4-30 depicts the proposed Mina rail alignment, hydrographic areas the alignment would cross, and the range of estimated total water demand associated with railroad construction within each hydrographic area.

As described in Section 3.3.6, Table 3-113 identifies hydrographic areas that are considered to be ***designated groundwater basins***, and lists information about total annual committed resources and ***pending annual duty*** amounts in the listed hydrographic areas. Seven of the 18 hydrographic areas that could be crossed by the alignment are designated groundwater basins.

Comparison of the information presented in Tables 4-206 indicates that, depending on the specific combination of alternative segments selected for construction, where applicable, total water withdrawals could exceed annual ***perennial yield*** values for hydrographic areas 123, 144, and 229, and could be as high as 48 percent, 57 percent, 82 percent, 87 percent, and 99 percent of the annual perennial yield in hydrographic areas 145, 228, 110A, 121B, 227A, respectively. Water withdrawals would typically range from less than 1 percent to as high as approximately 28 percent of the annual perennial yield value for the remaining areas for the various possible theoretical combinations of alignment segments. It should be noted that, for all hydrographic areas crossed, approximately 87 percent of the groundwater withdrawals would be temporary withdrawals, occurring within 1 year or less, rather than long-term withdrawals. For evaluating potential impacts from the proposed groundwater withdrawals, it is also noteworthy that although available groundwater resources in some hydrographic areas might be deemed to be currently "overcommitted" as a whole (hydrographic areas 146, 228, and 229), one or more particular aquifers within a hydrographic area might not be overcommitted. Additionally, all water-rights appropriations might not be in service simultaneously.

The information in Tables 3-113 and 4-206 suggests that the selection of one alternative segment over another or different possible combinations of alignment segments over others would make no notable difference in the amount of water needed to support construction when compared to the annual committed resources for each hydrographic area, with the following exceptions:

- Construction of the Schurz alternative segment 1/Department of Defense Branchline South combination for construction through hydrographic area 110A (Walker Lake-Schurz Subarea) would result in the lowest ratios of groundwater demand to perennial yield and groundwater demand to committed resources for this area, representing approximately 32 percent, and 75 percent, respectively, of the estimated annual perennial yield and the total annual committed resources of the hydrographic area. By comparison, construction of the Schurz alternative segment 4/Department of Defense Branchline South combination through hydrographic area 110A would result in the highest ratios of groundwater demand to perennial yield and groundwater demand to committed resources for this area (approximately 82 percent, and 190 percent, respectively, of the estimated annual perennial yield and the total annual committed resources of the hydrographic area). Construction of either the Schurz alternative segment 5/Department of Defense Branchline South or the Schurz alternative segment 6/Department of Defense Branchline South alternative segment combinations through area 110A would represent ratios of groundwater demand to perennial yield and groundwater demand to committed resources that are intermediate between those for these two options.

Table 4-206. Estimated water requirements for railroad construction by hydrographic area – Mina rail alignment (page 1 of 3).

Hydrographic area[a] number and name	Perennial yield for hydrographic area (acre-feet)[b,c]	Total annual committed resources/pending annual duties for hydrographic area (acre-feet)[c,d]	Rail line segment or rail line segment combination[e]	Estimated water demand or possible range of water demand values within hydrographic area (acre-feet)[f]
108 – Mason Valley*	25,000	179,696/ 25,269	Department of Defense Branchline North	22

227A – Fortymile Canyon, Jackass Flats	580[g]	58[g] / 5	Common segment 6	572
Estimated lowest total water demand value (acre-feet) based on possible combinations of rail line segments				Approximately 5,750
Estimated highest total water demand value (acre-feet) based on possible combinations of rail line segments				Approximately 8,200
Current estimate of total water demand (acre-feet) – current best estimate (see text)				Approximately 5,950

a. Source: DIRS 106094-Harrill, Gates, and Thomas et al. 1988, Summary, Figure 3, with the proposed rail alignment map overlay. An asterisk (*) indicates that the State of Nevada considers the hydrographic area a designated groundwater basin (DIRS 177741-State of Nevada 2005, all).

b. Source: DIRS 103406-Nevada Division of Water Planning 1992, Regions 10, 13, and 14, except hydrographic areas 227A, 228, and 229, for which the source is DIRS 147766-Thiel Engineering Consultants 1999, pp. 6 to 12. The perennial yield value shown for area 228 is the lowest value in range of estimated values (1,000 to 2,000 acre-feet per year) presented by Thiel Engineering Consultants 1999.

c. To convert acre-feet to cubic meters, multiply by 1,233.49. To convert acre-feet to gallons, multiply by 3.259×10^5.

d. Data for committed groundwater resources and pending annual duties are current as of the dates described in Section 3.3.6. Pending duties include underground duties but do not include duties for streams or springs. All values have been rounded to the nearest acre-foot.

e. Figures 3.3.6-4 through 3.3.6-10 show the locations of the Mina rail alignment alternative segments and common segments.

f. Water demand estimates are from DIRS 180888-Converse Consultants 2007, Table 2-3 and DIRS 180875-Nevada Rail Partners 2007, Table 4-3. All demand values rounded to the nearest acre-foot.

g. Based on a 1979 Designation Order by the State Engineer; there are no committed resources in area 227A. However, water-rights information from the NDWR indicates there are 58 acre-feet in committed resources for this area. The discrepancy appears to be related to the location of the boundary between areas 227A and 230 (Amargosa Desert) (DIRS 176600-Converse Consultants 2005, page 29 and Table 4-45). The perennial-yield value shown for area 227A is the lowest estimated value presented in *Data Assessment & Water Rights/Resource Analysis of: Hydrographic Region #14 Death Valley Basin* (DIRS 147766-Thiel Engineering Consultants 1999, p. 8), for the entirety of hydrographic area 227A. The perennial yield estimate for area 277A is broken down into 300 acre-feet for the eastern third of the area and 580 acre-feet for the western two-thirds of the area.

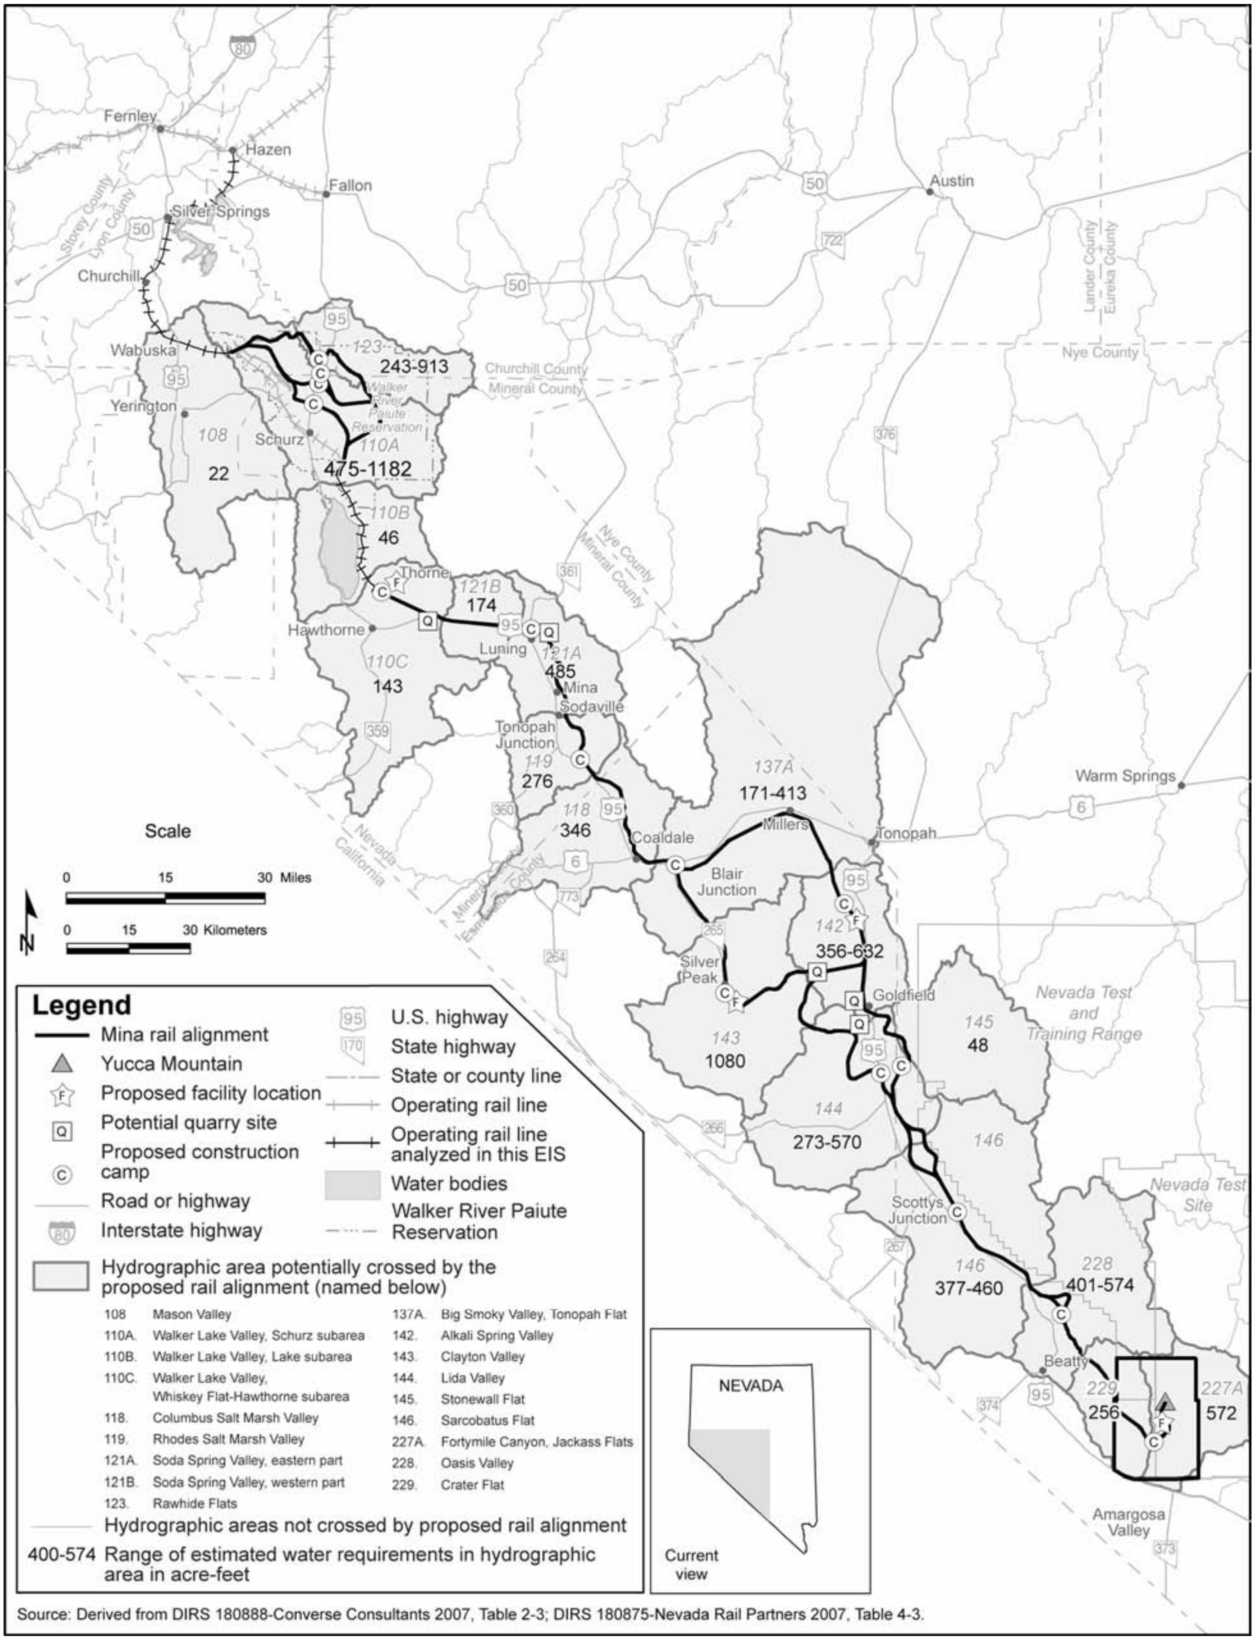

Figure 4-30. Estimated water requirements along the Mina rail alignment.

- Construction of Schurz alternative segment 5 within hydrographic area 123 (Rawhide Flats) would result in a groundwater demand representing approximately 49 percent of the estimated annual perennial yield and approximately 210 percent the total committed resources of the hydrographic area, whereas constructing the Schurz alternative segment 6 within hydrographic area 123 would result in a groundwater demand representing approximately 183 percent of the estimated annual perennial yield and approximately 790 percent of the total committed resources of the hydrographic area.

- Construction of the Montezuma alternative segment 2/Mina common segment 2/Bonnie Claire alternative segment 3 combination for construction through hydrographic area 144 (Lida Valley) would result in the lowest ratios of groundwater demand to perennial yield and groundwater demand to committed resources for this area, representing approximately 78 percent, and 380 percent, respectively, of the estimated annual perennial yield and the total annual committed resources of the hydrographic area. By comparison, construction of the Montezuma alternative segment 1/Mina common segment 2/Bonnie Claire alternative segment 2 combination through hydrographic area 144 would result in the highest ratios of groundwater demand to perennial yield and groundwater demand to committed resources for this area (approximately 160 percent, and 790 percent, respectively, of the estimated annual perennial yield and the total annual committed resources of the hydrographic area). Construction of either the Montezuma alternative segment 2/Mina common segment 1/Bonnie Claire alternative segment 2 combination or the Montezuma alternative segment 2/Mina common segment 2/Bonnie Claire alternative segment 3 combination through area 144 would represent ratios of groundwater demand to perennial yield and groundwater demand to committed resources that are intermediate between those for these two options.

- Construction of the Mina common segment 1/Montezuma alternative segment 2 combination within hydrographic area 137A (Big Smoky Valley-Tonopah Flat) would result in a groundwater demand representing approximately 7 percent of the estimated annual perennial yield and approximately 3 percent of the total committed resources of the hydrographic area, whereas constructing the Mina common segment 1/Montezuma alternative segment 2 combination within hydrographic area 137A would result in somewhat lower ratios of groundwater demand to perennial yield and groundwater demand to committed resources for this area (approximately 21 percent of the estimated annual perennial yield and approximately 9 percent of the total committed resources of the hydrographic area).

As described previously in Section 4.2.6, construction of Oasis Valley alternative segment 1 and common segments 5 and 6 within hydrographic area 128 (Oasis Valley) would result in a groundwater demand equaling approximately 41 percent of the estimated annual perennial yield and approximately 31 percent of the total annual committed resources of the hydrographic area. Construction of Oasis Valley alternative segment 3 and common segments 5 and 6 through hydrographic area 128 would result in a groundwater demand equaling approximately 57 percent of the estimated annual perennial yield and approximately 44 percent of the total annual committed resources of this hydrographic area.

DOE evaluated potential impacts to existing groundwater resources assuming that it would apply for permits to appropriate water from 77 to 110 new water wells, including from 3 to 5 new quarry water wells, to furnish all the water required to support rail construction, construction camps, quarry operations, and operation of railroad operations support facilities, including sidings (DIRS 180888-Converse Consultants 2007, Table 2-1; DIRS 180875-Nevada Rail Partners 2007, Table 4-5). Each construction camp would need one new well.

Depending on location along the rail alignment, each well serving a construction camp would furnish water to just that camp, furnish water for construction of the rail roadbed, or furnish water for both construction of the rail line roadbed and operation of a proposed facility (DIRS 180888-Converse Consultants 2007, Appendixes A and C). The actual total number of wells required would depend on the specific alternative segments selected and flow rates achieved in completed wells.

New multiple-use wells would be installed in each hydrographic area along the Mina rail alignment, with the exception of area 227A, and used as sources of water supply. DOE assumed that each of the wells used to support rail roadbed construction would be pumped for a period not to exceed 1 year (for purposes of quantitative analysis, DOE assumed 9 months) (DIRS 180888-Converse Consultants 2007, Section 2.1). These wells would have the highest required water withdrawal rates. DOE could use quarry water wells, which would have lower production rates of approximately 91 liters (24 gallons) per minute, for up to 2 years. Wells to supply water for construction camps would be temporary and would have average production rates less than 76 liters (20 gallons) per minute. Wells supplying water for railroad operations support facilities and sidings would have the lowest average withdrawal rates (less than 3.8 liters [1 gallon] per minute to approximately 16 liters [4.2 gallons] per minute); these would be permanent wells (DIRS 180873-Nevada Rail Partners 2007, Table 2-2; DIRS 180888-Converse Consultants 2007, Section 2.1).

DOE would construct, and plans to subsequently decommission, all new water wells in accordance with applicable State of Nevada well-construction standards. After DOE completed construction of the rail line, some wells would remain in operation to supply water to railroad operations support facilities located near sidings, rail yards, or other locations along the rail line during the operations phase. As was the case for wells that could be installed to support the Caliente rail alignment construction, DOE currently plans that wells not needed for operation of the Mina rail line or for quarries would be properly abandoned in compliance with State of Nevada regulations, and the well sites and temporary access roads would be reclaimed (DIRS 180875-Nevada Rail Partners 2007, Section 4.4.4; DIRS 180922-Nevada Rail Partners 2007, Section 4.4.4) in accordance with applicable requirements.

DOE assumed that proposed new well sites outside the typical maximum 300-meter (1,000-foot)-wide rail alignment construction right-of-way would consist of a drilling pad approximately 5,700-square-meter (1.4-acre) or smaller in area (DIRS 180888-Converse Consultants 2007, Section 3.4). On the basis of analysis of available data on hydrogeologic characteristics along the proposed alignment, DOE assumed that one new well would be installed at each drilling pad (DIRS 180888-Converse Consultants 2007, Appendix A). Areas identified as potential locations for such well sites would be adjacent to documented existing land disturbances, including existing improved or unimproved roadways. If necessary, DOE would construct temporary access roads to accommodate 0.10- to 0.15-meter (4- to 6-inch)-diameter temporary aboveground pipelines that would transport water from these wells to the area of the construction right-of-way. Impacts that might result from the construction and temporary use of such water transfer pipelines are evaluated in the sections of this Rail Alignment EIS that address applicable resources or media (such as Biological Resources, Cultural Resources, and Land Use and Ownership). After construction of the rail line was complete, some wells would remain in operation to supply water to railroad operations support facilities near sidings, rail yards, or other locations along the rail alignment during the operations phase.

Well water would be piped through the temporary aboveground pipelines to temporary in-ground storage basins (reservoirs), inflatable bladders (“pillow tanks”), or rigid storage tanks within the construction right-of-way to provide storage capacity to meet daily construction needs. For planning purposes, DOE assumed that temporary water-storage reservoirs, if used, would be approximately 30 by 30 meters (100 feet by 100 feet) wide and approximately 3 meters (10 feet) deep, and would be used to store the daily water production from wells. Storage tanks or inflatable bladders, if used, could vary in their storage capacity up to approximately 190,000 liters (50,000 gallons) or more, depending on water demands and water withdrawal rates required for specific locations along the construction right-of-way. Open storage basins or reservoirs, if used, would be surrounded by a fence to mitigate the potential to attract wildlife (Section 4.3.7).

In determining the quantity of water that can be appropriated from a specific hydrographic area, requirements contained in the applicable State of Nevada statutes are considered. This authority includes the ability to grant appropriation requests in hydrographic areas that are designated groundwater basins or in cases where such appropriations would cause an exceedance of an area's estimated perennial yield.

DOE evaluated the potential impacts to groundwater resources as a result of withdrawal of groundwater from the proposed new water wells. For analysis purposes, each new well was assumed to be pumped, with one exception, at an average withdrawal rate of up to approximately 850 liters (225 gallons) per minute, or approximately 0.5 cubic foot per second (DIRS 180888-Converse Consultants 2007, Appendix A). Actual groundwater withdrawal rates at several of the proposed new wells could likely be less than 0.5 cubic foot per second, based on hydrogeologic limitations associated with the specific aquifers involved; however, DOE considered the effects of groundwater withdrawals at this production rate in order to help assess the degree of flexibility available for possibly utilizing some proposed new wells at the 0.5-cubic-foot-per-second withdrawal rate more than, or in lieu of, other proposed wells, based on potential differences in well productivity that might occur between the new wells. At one proposed new well location, due to existing groundwater quality conditions in areas surrounding the proposed well location, it is assumed that the average withdrawal rate could be as high as 1,300 liters (350 gallons) per minute, or approximately 0.78 cubic foot per second. An analysis of potential impacts due to groundwater withdrawal at this well location is described in Section 4.3.6.2.2).

Any groundwater withdrawal would decrease the availability of water in a portion of the aquifer within the cone of depression induced within the aquifer surrounding a groundwater-production well. However, as described previously, DOE would obtain approximately 87 percent of all the water required for construction of the proposed rail line along the Mina rail alignment from new temporary rail roadbed construction wells. The withdrawal of groundwater from new wells to support railroad construction would not be likely to result in long-term adverse impacts to the groundwater aquifers that are targeted for meeting project water demands for the following reasons:

- For the proposed new groundwater withdrawals, hydrogeologic impact analysis results (see Section 4.3.6.2.2 and Appendix G) show that short-term direct impacts on groundwater availability in aquifers resulting from proposed groundwater withdrawals where the new wells would be pumped at the withdrawal rate of 852 liters (225 gallons) per minute, approximately 0.5 cubic foot per second, would be limited in aerial extent. Analytical results indicate that the maximum calculated lateral extent of the drawdown feature (the cone of depression) that would be induced at any location within the host aquifers from the proposed groundwater withdrawals would be approximately 0.8 kilometer (0.5 mile), and in most cases less at the proposed well locations. With the exception of three locations in the Oasis Valley hydrographic area (see Section 4.3.6.2.2.11) and one location in the Clayton Valley hydrographic area (see Section 4.3.6.2.2.5), withdrawals of groundwater from the proposed new water wells at the 0.5-cubic-foot-per-second withdrawal rate would not be expected to impact existing groundwater users (owners of active pumping wells) or impact discharge rates or groundwater quality at nearby springs. Sections 4.3.6.2.2.5 and 4.3.6.2.2.11 describe one or more mitigation approaches that could be implemented to avoid potential impacts at these otherwise affected locations.

- For areas where proposed new water wells would be installed near the boundary between adjacent hydrographic areas, groundwater withdrawals would not be likely to affect downgradient hydrographic areas because: (1) there are no identified existing well users in downgradient groundwater basins that are within 1.6 kilometers (1 mile) of any of these proposed well water withdrawal locations (see Figures 3-190 through 3-196), or (2) available hydrogeologic information indicates either that no significant inter-basin groundwater (under) flow is inferred to be occurring in the areas downgradient of the proposed well locations (see Figure 3-188) or, in three cases (proposed well locations Ssa-3, BSa-4a, and LV7 on Figures 3-192, 3-193, and 3-195, respectively) where the proposed well locations are located near such a boundary and in the general vicinity of such inferred underflow areas, the wells are located at least 2.3 to 4 kilometers (1.4 to 2.5 miles) upgradient of the hydrographic area boundary. Because the distances of these well locations from the hydrographic area boundary in these two cases are significantly greater than the maximum range (0.8 kilometer to 1 kilometer [0.5 to 0.6 mile]) of pumping-induced radii of influence surrounding the proposed well locations, pumping at these locations should have a negligible effect on existing inter-basin underflow patterns or flow rates and thus would have a very small effect on groundwater resources in downgradient hydrographic areas.
- Long-term direct impacts to groundwater resources would not be likely because most of the total project water demand would be used over a short period to support railroad construction. Most water demands within any given hydrographic area would occur over approximately 9 months under an assumed 4-year railroad construction schedule; therefore, long-term impacts resulting from their use would be small.
- Direct impacts to downgradient groundwater resources would be unlikely for the reasons stated above; indirect impacts to groundwater resources in adjacent downgradient hydrographic areas also would not be likely.

New wells that are proposed to be installed outside of the construction of right-of-way of some alignment segments to support railroad construction or quarries would be located on either grazing land, on Walker River Paiute Reservation land, or, for one proposed quarry, partly on BLM-managed grazing land and partly on Hawthorne Army Depot property (see Section 4.3.2). Direct or indirect impacts to private property owners from construction and use of such wells are expected to be small and capable of being minimized through the use of appropriate planning and mitigation measures as required (Section 4.3.2).

Several of the proposed railroad operations support facilities and sidings would overlie hydrographic areas that are designated by the Nevada State Engineer as designated groundwater basins. Construction-water demand for these facilities would be low compared to the amount of water required for railroad construction. These facilities include the Staging Yard at Hawthorne in hydrographic area 110C, the Maintenance-of-Way Facility at either Silver Peak in hydrographic area 143 or Klondike in hydrographic area 142, the Rail Equipment Maintenance Yard in hydrographic area 227A, and proposed sidings in several hydrographic areas (Figures 3-191, 3-193, 3-194, and 3-196). DOE assumed that water demand for constructing these railroad facilities and sidings would be met by installing new wells.

Details on the water requirements activity and groundwater impacts at the railroad operations facilities and sidings are provided in the *Facilities Design Analysis Report Mina Rail Corridor, Task 10: Facilities, Rev. 00* (DIRS 180873-Nevada Rail Partners 2007, Sections 2.1.5 and 3.6) and in the *Repository Surface Design Engineering Files Report* (DIRS 104508-CRWMS M&O 1999, Tables III-1 and II-2). The Staging Yard at Hawthorne, Maintenance-of-Way Facility, and Rail Equipment Maintenance Yard would require only limited amounts of water, with water required for operations estimated to range from approximately 11,000 to 23,000 liters (3,000 to 6,000 gallons) per day at the facilities, which is equivalent to 7.9 to 16 liters (2.1 to 4.2 gallons) per minute. Sidings would require less than 625 liters (165 gallons) per day, which is equivalent to less than 3.8 liters (1 gallon) per minute

(DIRS 180873-Nevada Rail Partners 2007, Table 2-2). DOE derived operations water requirements from estimated staffing and shift projections, a 190-liter (50-gallon) per day per capita use ratio, estimated shop process needs, and a multiplier of 1.5 to account for miscellaneous water needs (DIRS 180873-Nevada Rail Partners 2007, Section 2.1.5). Water needed for meeting emergency water storage capacity requirements (for fire safety) are estimated to range from 420,000 to 830,000 liters (110,000 to 220,000 gallons). Water needs for meeting water storage requirements at each facility could be readily met using a new small production-rate well. The water demand for operation of the Cask Maintenance Facility is estimated at approximately 40,000 liters (10,500 gallons) per day, which is equivalent to approximately 26 liters (7 gallons) per minute (DIRS 104508-CRWMS M&O 1999, Table III-1). Owing to the very small required well production rates for wells supporting operations of these facilities and sidings, the magnitude of short-term or long-term impacts on the host aquifer for the individual facility water wells would be small. For this reason, DOE did not perform quantitative impact analyses for water wells that would support facilities operations or sidings.

Water consumption rates during the period of use of construction camps during the peak output year have been estimated at approximately 76 liters (20 gallons) per minute, which is equivalent to approximately 110,000 liters (29,000 gallons) per day (DIRS 180888-Converse Consultants 2007, Table 2-1). Water consumption rates during the period of use of quarries have been estimated at approximately 91 liters (24 gallons) per minute, which is equivalent to 131,000 liters (34,560 gallons) per day (DIRS 180888-Converse Consultants 2007, Table 2-4). New wells proposed for supplying water to support construction camp and quarry operations were considered when performing the quantitative impact analyses.

Construction of the Cask Maintenance Facility would require approximately 4,400 cubic meters (approximately 3.6 acre-feet, or 1.176 million gallons) of water, with construction estimated to occur over approximately 2 years (DIRS 104508-CRWMS M&O 1999, Table III-2). The amount of water needed to construct the other railroad facilities (Staging Yard at Hawthorne, Maintenance-of-Way Facility, and Rail Equipment Maintenance Yard) would range from approximately 14,000 to 200,000 cubic meters, which is equivalent to 11.5 to 161.1 acre-feet, or 3.75 to 52.5 million gallons (DIRS 180873-Nevada Rail Partners 2007, Table 2-2). No water is required for constructing the rail sidings (DIRS 180873-Nevada Rail Partners 2007, Table 2-2). When compared to the total annual ***committed groundwater resources*** listed in Table 4-206, the direct short-term impacts to groundwater resources in the respective hydrographic areas due to water withdrawals associated with construction of railroad facilities and sidings would be small, and long-term direct and indirect impacts on groundwater resources also would be small.

DOE also assessed the potential for the proposed groundwater withdrawals to cause ground subsidence in areas of the proposed withdrawals. Groundwater pumping-induced ground subsidence has been observed at some locations in the western United States, including the Las Vegas Valley of Nevada, the Santa Clara Valley and San Joaquin Valley areas of California, and other selected locations in Texas, New Mexico, and Arizona, and selected other locations overseas. The subsidence that has occurred is primarily related to prolonged groundwater withdrawal at rates that exceed the estimated annual recharge to the affected groundwater system. The estimated annual recharge to the aquifer systems in each of these localities is often less than approximately 50 percent of the total average annual groundwater pumped from these aquifers. In the Las Vegas Valley, groundwater withdrawals between 1955 and 1990 ranged from approximately 49.4 to 108.5 million cubic meters (40,080 to over 88,000 acre-feet) per year, with the maximum groundwater withdrawal occurring in 1968 (108.9 million cubic meters [88,290 acre-feet]) (DIRS 181390-Bell et al. 2002, p. 156). Estimates of annual ***recharge*** rate to the Las Vegas Valley aquifer system range from approximately 30.6 to 72.2 million cubic meters (25,000 to 59,000 acre-feet) per year, indicating that groundwater withdrawal rates in the Las Vegas Valley have typically exceeded, sometimes by a factor of more than two, natural recharge rates over a period of decades (DIRS 181390-Bell et al. 2002, p. 156). Groundwater withdrawals of over 12.1 billion cubic meters (9.8 million acre-feet) per year in the San Joaquin Valley resulted in withdrawal overdrafts of at least 4.93 billion cubic meters (4 million acre-feet) per year during the 1950s and 1960s (DIRS 181392-USGS 1984, p. 264). Annual groundwater pumping rates in each of these areas have exceeded their respective annual groundwater recharge rates between the mid-1940s to 1950s and the 1990s.

Interbedded fine- and coarse-grained sediments underlie each of these areas. Where impermeable caliche horizons occur within ***alluvial fan*** deposits or poorly permeable clay horizons occur within fine-grained material, groundwater is under confined or partially confined conditions, frequently exhibiting artesian flow conditions (for example, DIRS 181390-Bell et al. 2002, p. 56). Continued groundwater pumping in excess of the yearly recharge has reduced the artesian pressures in these aquifer systems resulting in an increase in vertical loads, or effective stresses. The increased effective stresses result in the compaction of the underlying sediments and corresponding ground subsidence.

An evaluation of the proposed new groundwater withdrawal wells for the Mina rail alignment indicates that most of the wells would be developed in unconsolidated alluvia sediments, with a few completed in consolidated bedrock aquifers. Subsidence is not expected to be an issue in consolidated bedrock aquifers because these aquifers are not susceptible to compaction during pumping.

Of the wells developed in unconsolidated alluvial sediments, a relatively small percentage would be developed in confined alluvial sediments. In general, subsidence is not expected to be an issue for pumping unconfined alluvial aquifers, because the major reported cases of land subsidence due to groundwater withdrawals involve pumping from confined aquifers.

Groundwater withdrawals from confined alluvial aquifers, at the withdrawal rates expected for this project, and if they exceeded recharge rates, could, in theory, result in some small amount of subsidence within the radius of influence associated with each pumping well. However, no known subsidence effects have been documented for preexisting pumping wells in these hydrographic areas, many of which are being pumped at rates much higher than the range of pumping rates proposed for this project. In addition, the area of disturbance within the radius of influence surrounding each well represents an extremely small percentage of the total area of the host aquifer within hydrographic area. Finally, the duration of pumping for approximately 90 percent of the proposed total groundwater withdrawals would be on the order of 1 year or less within each hydrographic area crossed by the alignment. The pumping rates required, the total volume of groundwater that would be withdrawn from each hydrographic area, and the pumping timeframes involved are much smaller than the pumping rates, water volumes removed, and the prolonged periods of pumping that were involved at locations where ground subsidence has been observed, such as the Las Vegas Valley, Santa Clara Valley, and San Joaquin Valley. For these reasons, the potential for ground subsidence to occur as a result of the construction and operation a railroad along the Mina rail alignment would be small.

4.3.6.2.2 Construction Impacts for Specific Alternative Segments and Common Segments

DOE evaluated potential site-specific impacts to groundwater resources from constructing and operating a rail line along the Mina rail alignment. This section summarizes the approach and methodologies DOE used to quantitatively evaluate the extent of potential hydrogeologic impacts from withdrawing groundwater to support construction of the rail line and railroad construction and operations support facilities. Appendix G provides a more detailed description of the approach and methodology. Section 3.3.6 summarizes the existing groundwater resources along each of the alternative segments and common segments.

To evaluate potential impacts of proposed groundwater withdrawals from new water wells on existing wells and springs, DOE reviewed proposed well locations, well construction details, estimated groundwater depths, and proposed groundwater withdrawal rates and timeframes (DIRS 176189-

Converse Consultants 2006, all; DIRS 180888-Converse Consultants 2007, all). Unless otherwise noted, the sources for all spring and well data in this section are as follows:

- DIRS 176600-Converse Consultants 2006, all; DIRS 180887-Converse Consultants 2007, all
- The Nevada Division of Water Resources (NDWR) water-rights database and water-well log databases, and other datasets (DIRS 182288-NDWR 2007, all ; DIRS 182759-Converse Consultants 2007, all; DIRS 182899-NDWR 2007, all; DIRS 182900-NDWR 2007, all)
- Data from the U.S. Geological Survey (USGS) National Water Information System (NWIS) database (DIRS 176325-USGS 2006, all; DIRS 177294-MO0607USGSWNVD.000, all)
- The U.S. Geological Survey (USGS) National Hydrographic Datasets (DIRS 177712-MO0607NHDPOINT.000, all; DIRS 177710-MO0607NHDWBDYD.000, all)
- Geographic Names Information Systems databases on springs in Nevada (DIRS 176979-MO0605GISGNISN.000, all)

For initial screening purposes, if DOE identified an existing well or a spring within a 1.6-kilometer (1-mile) radius (buffer distance) of a proposed new water well, DOE selected that proposed well location as a candidate for conducting a groundwater hydrogeologic impacts evaluation. When DOE found no spring or existing well in this initial search radius, it extended the search distance outward from the proposed well location to identify the nearest spring or existing well within a 2.4-kilometer (1.5-mile) radius (buffer distance) of the proposed new well and determined its hydrogeologic and construction characteristics. In addition to the above screening processes, and before completing impacts analyses, for a selected set of new groundwater withdrawal well locations where the well was specifically targeted for installation within a fault zone or an extensive ***fracture*** zone, the locations of existing wells and springs up to 9.7 kilometers (6 miles) away from each such proposed well were identified. These larger search distances were considered to: (1) allow evaluation of potential simultaneous drawdown effects involving individual private wells having higher pumping rates that might be located in the general vicinity; and (2) assess the potential for a fault zone or extensive fracture zone present at the proposed new well location to act as a conduit for groundwater flow (possibly resulting in a groundwater drawdown effect over a larger distance).

DOE then searched the NDWR water-rights database and well-log databases to confirm the identity, use, water-rights status, and appropriated annual ***duty*** and diversion rate, if any, associated with each existing well located within these buffer distances. DOE included domestic wells and considered the appropriated annual duty and diversion rate for each well with a water right in hydrogeologic impacts analyses to estimate potential hydrogeologic impacts from groundwater withdrawals at the proposed well location. In some cases, using the available information, DOE could not positively correlate wells listed in the USGS NWIS database to any well listed in the NDWR water-rights database or the NDWR well-log database. For such wells, DOE did not perform quantitative impacts analyses for these wells. For impacts analysis purposes, DOE considered the locations of known domestic wells with respect to the proposed alignment and relative to proposed new well locations. Figures 3-190 through 3-196 show the approximate locations of existing wells, including domestic wells, and springs within the 1.6-kilometer (1-mile) screening level region of influence.

DOE reviewed available geologic and hydrogeologic information to confirm the hydrogeologic characteristics of known and potential aquifers in areas near proposed wells. Appendix G provides a detailed list of published geologic and hydrogeologic reports and maps and water resource appraisal reports that were reviewed prior to completing the groundwater resource impacts analysis calculations. Where applicable, for the closest existing well having a water right, DOE identified water appropriations information (annual appropriated groundwater duty, well use period, and authorized groundwater diversion rate) and documented the information for subsequent use in analysis.

DOE used the information obtained from the geologic and hydrogeologic data reviews to identify an appropriate analytical method or methods to determine the magnitude of drawdown that would be created in the aquifer as a result of the proposed groundwater withdrawals and determine the amount of simultaneous drawdown created, where applicable, due to groundwater pumping from the nearest existing pumping well. For purposes of analysis, fractured consolidated rock aquifers were treated as homogeneous, ***isotropic***, equivalent porous media. For a selected set of new groundwater withdrawal well locations where the well was determined to be located in the vicinity of faults or extensive fracture systems or specifically targeted for installation within a major fault zone or an extensive fracture zone (DIRS 180888-Converse Consultants 2007, Appendix B), additional evaluations of hydrogeologic data and/or additional analyses were performed.

In cases where a proposed well was determined to be oriented lateral to a mapped fault or fracture zone, the fault or fracture zone was treated as a potential no-flow ***barrier*** if it was located sufficiently close to the proposed new well to be within the region of influence from pumping at that well location. In such cases, the calculations included a specific method (image well method) to simulate the potential effects of the fault or fracture zone on groundwater flow behavior.

Hydraulic tests performed in faulted and fractured consolidated rock aquifers at a few wells in the region of the Nevada Test Site indicate that when a pumping well pumps groundwater from a high-***permeability*** zone associated with a fault that fault zone might act as a conduit for transmitting hydraulic responses from the pumping well over larger-scale (on the order of kilometers) distances. Results from pump tests conducted at these wells often indicate that very complex hydrogeologic conditions, including heterogeneous hydraulic rock properties, the presence of complex structural systems controlling flow, and other non-isotropic conditions, exist at these test sites. For these reasons, where a proposed new well was identified as targeting a specific fault or fracture system that could act as a high-permeability conduit, DOE identified the locations of existing wells and springs up to 9.7 kilometers (6 miles) away from each such proposed well. In these cases, DOE reviewed available data on existing wells and springs and locations of known (mapped) faults and fracture zones within the 9.7-kilometer radius surrounding each new well location and compared these with the locations of the proposed well to estimate the likelihood of a hydraulic connection occurring between the proposed well and existing wells and springs beyond a distance of 2.4 km (1.5 miles) but within the approximately 10-kilometer (6-mile) distance. Additional details regarding the treatment of faults and extensive fracture systems as conduits (or barriers) to flow in the impacts analyses are described in Appendix G.

DOE calculated a region of influence for each well and determined how far from the well the aquifer would be affected by the drawdown. For analysis purposes, DOE assumed that (1) it would obtain all water for railroad construction from new groundwater wells, and (2) groundwater might be pumped at the nearest existing well with a water right simultaneously to groundwater withdrawal at the new well or wells. If existing wells were found to be farther away from the proposed new well than the sum of the radii of influence associated with both wells, DOE concluded that there would be no impacts to the nearest existing well. If the nearest spring was found to beyond the calculated radius of influence of the proposed new well, DOE concluded that there would be no impacts to the spring.

For each analysis completed, with the exception of one proposed new well location (Cl-1a in Clayton Valley, as described in Section 4.3.6.2.2.5), DOE assessed the potential impacts to existing wells with water rights from imposing a pumping rate of 852 liters (225 gallons) per minute at each proposed well, considering the possibility of intersecting cones of depression from the simultaneous pumping of the nearest existing well with a water right and the proposed new well. The pumping rate assumed for the nearest well in nearly all cases was the average withdrawal rate required to realize the total appropriated annual or seasonal duty value for that well, if that well had a formal appropriated water right, over the authorized period of use. The exceptions included existing wells for which the average pumping rate calculated based on the total appropriated duty value was very low and much smaller than the authorized (short-term) diversion rate for that well, and those existing wells for which NDWR-issued certificates list only a diversion rate but do not specify an authorized annual duty. In those cases, to conservatively bound impact analysis results, DOE used the diversion rate to calculate the well's radius of influence.

Sections 4.3.6.2.2.1 through 4.3.6.2.2.12 describe potential impacts to existing springs or groundwater wells. Table 4-206 lists information about the hydrographic areas the rail line would cross and the estimated volume of water DOE would need to construct each set of Mina rail alignment alternative and/or common segments across each hydrographic area.

Figures 3-190 through 3-196 show the approximate locations of the proposed new water wells. DOE assumed that appropriation applications for new water wells represent a viable mechanism for obtaining the water required to support construction and operation of the Mina rail line and the Shared-Use Option. This approach does not predispose the final outcome of decisions regarding the approval or denial of such appropriation applications; however, the analysis assumes that such applications would, in theory, be accepted, and that groundwater withdrawal would occur at the proposed new well as designed. This analysis approach provides a conservative framework for estimating potential impacts to groundwater resources resulting from groundwater withdrawals within the respective hydrographic areas crossed by the rail alignment.

4.3.6.2.2.1 Department of Defense Branchline North. Department of Defense Branchline North begins at a new siding to be installed along the Union Pacific Hazen Branchline near Wabuska. Most of Department of Defense Branchline North segment overlies hydrographic area 108.

One new well is proposed within hydrographic area 108 to support water needs associated with operation of a new rail siding. Due to the anticipated small required withdrawal rate for this well (likely to be less than 3.8 liters [1 gallon] per minute), impacts to existing groundwater resources from this well would be small. Therefore, the new well proposed to support construction of the new siding at the beginning of Department of Defense Branchline North is not likely to have an adverse impact on the local groundwater uses or users.

4.3.6.2.2.2 Schurz Alternative Segments (Walker River Paiute Reservation). The Schurz alternative segments would cross hydrographic areas 110A (Walker Lake Valley-Schurz Subarea) and/or 123 (Rawhide Flats). New wells in these hydrographic areas could be between 15 and 230 meters (50 and 750 feet) deep (DIRS 180888-Converse Consultants 2007, Appendix A). The target aquifer for proposed wells would be alluvial valley-fill or alluvial fan deposits (DIRS 180888-Converse Consultants 2007, Appendix B).

Figures 3-190 and 3-191 show the approximate locations of USGS NWIS wells and known existing NDWR wells, existing springs, and proposed new wells along the Schurz alternative segments. Assuming that a proposed average groundwater withdrawal rate of 852 liters (225 gallons) per minute could be applied at each proposed new right-of-way well location and each well location outside of the construction right-of-way that would be used within the Walker River Paiute Reservation, analysis results (Table 4-207) indicate that there would be no impacts to existing wells and springs near the proposed Schurz alternative segments from pumping at the proposed well locations. Where the closest existing well or spring to a proposed new well was found to be located more than 2.4 kilometers (1.5 miles) away from that proposed new well location, no quantitative impacts analysis calculations were completed.

As noted in Sections 3.3.6.3.1 and 3.3.6.3.2, land the Schurz alternative segments would cross includes lands occupied by the Walker River Paiute Reservation. As described in Sections 3.3.6.3.1 and 3.3.6.3.2, the Nevada Division of Water Resources Well Log and Water Rights Databases are incomplete with respect to existing wells present in hydrographic areas 110A and 123.

Table 4-207. Summary of calculated radii of influence for proposed new wells for the Mina rail alignment – Schurz alternative segments.

Well number	Distance to nearest well or nearest spring (kilometers)[a,b]	Radius of influence at base-case pumping rate (kilometers)	Radius of influence at 852 liters[c] per minute pumping rate (kilometers)
WLa-3a	> 1.60 (spring)	Not applicable [d]	0.38

a. To convert kilometers to miles, multiply by 0.62137.
b. > = greater than.
c. To convert liters to gallons, multiply by 0.26418.
d. No calculation was completed for reasons stated in text.

Therefore, DOE does not have a complete record of the total groundwater usage on the reservation. In accordance with Council on Environmental Quality NEPA implementing regulations (Section 1502.22), DOE has used the resources that are available to evaluate potential adverse impacts to groundwater usage on the Walker River Paiute Reservation.

A new well (see Figure 3-190) might be installed in area 110A (Well Wla-1c) in the same general area where several mapped faults exist. Several northeast-striking faults are mapped on the south edge of the Desert Mountains and might pass through the general area of this proposed well location (DIRS 180888-Converse Consultants 2007, Appendix B). There are no known existing wells or springs within approximately 9.7 kilometers (6 miles) of this proposed well location that are known to be associated with the same fault system or potentially related major fault zones.

4.3.6.2.2.3 Department of Defense Branchline South Segment (Walker Lake Valley Area). Department of Defense Branchline South would overlie the southern part of hydrographic area 110A and would continue southward across area 110B (Walker Lake Valley-Lake Subarea). One new well (at location WLa-5a) is proposed within hydrographic area 110A for supplying water to support water needs associated with railroad construction and operation of a new rail siding. Figures 3-191 and 3-192 show the approximate location of this proposed new water well. The target aquifer for this proposed well would be an alluvial fan deposit (DIRS 180888-Converse Consultants 2007, Appendix B).

There are no existing springs, no existing USGS NWIS wells, and no existing NDWR water wells within 1.6 kilometers (1 mile) of proposed well location WLa-5a. Withdrawal of groundwater from proposed well location WLa-5a would therefore not be expected to impact existing springs or existing water wells in area 110A. Additionally, the proposed well at WLa-5a is located approximately 1.6 kilometers north of the southern boundary of hydrographic area 110A, which is significantly greater than the maximum 0.8 kilometer (0.5 mile) radius of the pumping-induced cone of depression that would surround this proposed well location. For this reason, and because the area south of location WLa-5a is also not an area where inter-basin groundwater flow is inferred to be occurring (Figure 3-188), pumping at this location should have a very small effect on existing groundwater resources in area 110A and on groundwater resources in the adjacent hydrographic area (area 110B).

4.3.6.2.2.4 Mina Common Segment 1. Mina common segment 1 would overlie most of hydrographic area 110C (Walker Lake Valley-Whiskey Flat-Hawthorne Subarea), would continue southeastward across hydrographic areas 121B (Soda Spring Valley-Western Part), 121A (Soda Spring Valley-Eastern Part), 119 (Rhodes Salt Marsh Valley), and 118 (Columbus Salt Marsh Valley), and continue into the western portion of hydrographic area 137A (Big Smoky Valley-Tonopah Flat). Beginning at a point northeast of Luning, Mina common segment 1 would change its direction from eastward-to-southeastward to more southward-to-southeastward. Figures 3-191 through 3-193 show Mina common segment 1 and the approximate locations of new wells DOE could install to meet construction-water demands and locations of existing wells and existing springs in the vicinity of Mina common segment 1.

Assuming that a proposed average groundwater withdrawal rate of 852 liters (225 gallons) per minute was to be applied at each proposed new right-of-way well location and well location outside of the nominal 300-meter (1,000-foot)-wide construction right-of-way, analysis results (Table 4-208) indicate that, with one possible exception (CSM-2a, described below), no impacts would be expected to occur to existing wells or springs near Mina common segment 1 from pumping at the proposed new well locations along Mina common segment 1.

Table 4-208. Summary of calculated radii of influence for proposed new wells for the Mina rail alignment – Mina common segment 1.

Well number	Distance to nearest well or nearest spring (kilometers)[a,b]	Radius of influence at base-case pumping rate (kilometers)	Radius of influence at 852 liters[c] per minute pumping rate (kilometers)
WLa-3a	> 1.60 (spring)	Not applicable[d]	0.38
WLc-2a	1.42 (well)	Not applicable[d]	0.72
SSb-2	0.73 (spring)	Not applicable[d]	0.48
SSa-4	> 1.60 (well)	Not applicable[d]	0.80
SSa-2	> 1.60 (well)	Not applicable[d]	0.80
SSa-3	> 1.60 (well)	Not applicable[d]	0.80
CSM-3a	1.24 (well)	Not applicable[d]	0.48
CSM-2a	0.37 (spring)[e]	Not applicable[d]	0.89
CMS-2a	> 1.60 (well)	Not applicable[d]	0.89

a. To convert kilometers to miles, multiply by 0.62137.
b. > = greater than.
c. To convert liters to gallons, multiply by 0.26418.
d. No calculation was completed for reasons stated in text.
e. Spring might no longer be discharging (see text).

One new well is proposed at location CSM-2a in the Columbus Salt Marsh Valley (hydrographic area [area 118]), as shown on Figure 3-193. North-trending faults lie along the western front of the Monte Cristo Range in this area. The presence of a nearby spring might be related to the Eastern Columbus fault zone (DIRS 180888-Converse Consultants 2007, Appendix B). Based on the best available information, it cannot be conclusively demonstrated that the proposed well at location CSM-2a would be installed in a fault zone. Therefore, it is not possible to infer a direct hydraulic connection between any existing wells and springs located within 10 kilometers of the proposed well at location CSM-2a.

The proposed withdrawal rate in this new well is approximately 852 liters (225 gallons) per minute or less. The closest spring, or existing well, appears to be a spring. This spring is described in a water resources appraisal report published in 1970 (DIRS 180759-Van Denburgh and Glancy, 1970, Plate 1 and Table 16) as “Spring 8aaa,” located approximately 370 meters (1,230 feet) north-northwest of the site (see Figure 3-193). It should be noted that this spring is not part of the GNIS Nevada springs database (DIRS 176979- DTNMO0605GISGNIS.000, all), nor is it included in the USGS National Hydrologic Point Data Database (DIRS 177712-DTNMO0607NHDPOINT.000, all), or the NDWR water-rights database (DIRS 182759-Converse Consultants 2007, all). Analysis results indicate that, for a scenario where the spring is assumed to be present and be in direct hydraulic connection with the water-producing zone in the proposed well at location CSM-2a, the spring would not be affected by groundwater withdrawal at site CSM-2a if the average withdrawal rate at site CSM-2a is limited to approximately 150 liters (40 gallons) per minute or less. This potential spring was included as a possible existing hydrogeologic feature in the impact analysis calculations to represent a very conservative scenario. The spring was reported to have a very low rate of discharge of 1.9 liters (0.5 gallon) per minute in the 1970 report, and, given that this spring is not included in the other springs databases described above, it is considered likely that the spring no longer exists today (that is, there is no groundwater discharge occurring at this location). In the unlikely event that this spring might still exist, impacts to that spring could be eliminated by reducing the average withdrawal rate at location CSM-2a to approximately 150 liters per minute or less. In this case, the remaining balance of make-up water required could be obtained at another proposed well location, provided that well was sufficiently far away from known existing springs and active pumping wells. Alternatively, additional water could be obtained from an existing water-rights holder or proposed well CSM-2a could be moved to a point sufficiently distant from the spring, if present, to preclude the cone of depression from the well from reaching the spring.

If Spring 8aaa no longer exists, the potential impact on the next closest existing groundwater resource, a Nevada Division of Water Resources (NDWR) well was also evaluated. Analysis results indicate that this well would not be impacted by the proposed groundwater withdrawal activity at location CSM-2a.

4.3.6.2.2.5 Montezuma Alternative Segment 1. Montezuma alternative segment 1 would cross a portion of hydrographic area 137A (Big Smoky Valley-Tonopah Flat), and then cross hydrographic area 143 (Clayton Valley), then proceed into and then exit hydrographic area 142 (Alkali Spring Valley), after which it would re-enter hydrographic area 143, then cross hydrographic area 144 (Lida Valley). Figures 3-193 and 3-194 show the approximate locations of existing wells, existing springs, and proposed new wells within the typical maximum 300-meter (1,000-foot)-wide rail line construction right-of-way to meet water demands along Montezuma alternative segment 1. As of March 31, 2007, there were no pending annual duties assigned to hydrographic areas 137A, 142, 143, or 144 (see Table 4-206).

DOE could install one new well at proposed well location Cl-1a southwest of the community of Silver Peak in the hydrographic area 143 (Clayton Valley). This well location (see Figure 3-194) would be southwest of an existing well field that services Silver Peak. The proposed production rate in the new well installed at this location is approximately 1,300 liters (350 gallons) per minute or less. This withdrawal rate is higher than the anticipated withdrawal rate for other proposed new wells along the Mina alternative ***rail route*** because groundwater underlying much of Clayton Valley is too brackish for human consumption (DIRS 180760-Albers and Stewart 1981, p. 2). Therefore sources of better-quality groundwater for use in the rail roadbed construction and for supplying water for a proposed construction camp are very limited in this area.

The nearest existing spring, domestic well, or well with a known water right is a municipal well (DIRS 182759-Converse Consultants 2007, all; DIRS 182899-NDWR Water Rights Data 2007, all) approximately 980 meters (3,206 feet) northwest of location Cl-1a (see Figure 3-194). Under a scenario where both wells are assumed to be pumped simultaneously, the cones of depression from the two wells would likely intersect each other, and as a result, groundwater pumping at location Cl-1a at the 1,300 liters (350 gallons) per minute production rate would be expected to impact pumping at the existing municipal well. Analysis results (see Table 4-209) indicate that if the average pumping rate in the proposed well at location Cl-1a does not exceed approximately 1,000 liters (266 gallons) per minute, the cones of depression from the two wells would therefore not be expected to intersect each other, and groundwater pumping at either of the two wells would not be expected to impact the availability of groundwater for pumping at the other well. Alternatively, the location of proposed well Cl-1a could be moved to a point sufficiently distant from the existing well with the water right to preclude the cones of depression from the two wells from intersecting each other.

With the exception of proposed well location Cl-1a, there are no known existing wells or springs within 1.6 kilometers (1 mile) or within the potential radius of influence of these proposed alternative well locations.

Table 4-209. Summary of calculated radii of influence for proposed new wells for the Mina rail alignment – Montezuma alternative 1 segment.

Well number	Distance to nearest well or nearest spring (kilometers)[a,b]	Radius of influence at base-case pumping rate (kilometers)	Radius of influence at 852 liters[c] per minute pumping rate (kilometers)
CL-1a	0.98 (well)	Not applicable[d]	0.87 (1,325 liters [350 gallons] per minute)
CL-8a	> 1.60 (well)	Not applicable[d]	0.50
Cl-9a	> 1.60 (well)	Not applicable[d]	0.50
Li-3a	> 1.60 (well)	Not applicable[d]	1.0

a. To convert kilometers to miles, multiply by 0.62137.
b. > = greater than.
c. To convert liters to gallons, multiply by 0.26418.
d. No calculation was completed for reasons stated in text.

A proposed alternate well location (Li-5a) in Lida Valley, if used in lieu of proposed well location Li-1a (see Figure 3-194), could require construction of a separate access road whereas no separate access road would be required for a well at location Li-1a (DIRS 180875-Nevada Rail Partners 2007, Figure G-14). There are no existing wells or existing springs within 1.6 kilometers of the proposed Li-5a well location. The potential for impacts to occur to groundwater resources from such an access road would be small, for the reasons previously described in Section 4.3.6.2.1.

Two proposed new locations (As-2a and As-3a) are situated in an area (Figure 3-195) where several northeast-striking faults exist in bedrock to the southwest of these well locations. The possibility exists that these faults might project through the general vicinity of these proposed well locations (DIRS 180888-Converse Consultants 2007, Appendix B). However, based on the best available information, it cannot be conclusively demonstrated that the proposed well at locations As-2a and As-3a would be installed in a fault zone. Therefore, it is not possible to infer a direct hydraulic connection between any existing wells and springs located within 9.7 kilometers (6 miles) of the proposed wells at the As-2a and As-3a locations.

4.3.6.2.2.6 Montezuma Alternative Segment 2. Montezuma alternative segment 2 would cross a portion of hydrographic area 137A (Big Smoky Valley-Tonopah Flat Valley), then continue on through Area 142 (Alkali Spring Valley), and finally end in hydrographic area 144 (Lida Valley). Figures 3-193 and 3-194 show the approximate locations of existing wells, existing springs, and proposed new wells within the rail line construction right-of-way to meet water demands along Montezuma alternative segment 2.

DOE proposes to install up to 15 new wells to support the construction of Montezuma alternative segment 2. Groundwater impacts analyses were conducted for the proposed new wells for which existing wells or existing springs are present within the potential region of influence. Results of the analyses (Table 4-210) indicate that application of the withdrawal rate of approximately 852 liters (225 gallons) per minute at these proposed new well locations would not impact existing users and uses of groundwater resources in any of the hydrographic areas Montezuma alternative segment 2 would cross.

A new well (BSa-3a) might be installed in area 137A (see Figure 3-193) between prominent fault zones. Both north-south fault zones might promote enhanced groundwater flow within stratified ***colluvium***/alluvium in this general area (DIRS 180888-Converse Consultants 2007, Appendix B). Based on the best available information, it cannot be conclusively demonstrated that the proposed well at location BSa-3a would be installed in a fault zone. Therefore, it is not possible to infer a direct hydraulic connection between any existing wells and springs located within 9.7 kilometers (6 miles) of the proposed well at location BSa-3a.

Table 4-210. Summary of calculated radii of influence for proposed new wells for the Mina rail alignment – Montezuma alternative segment 2.

Well number	Distance to nearest well or nearest spring (kilometers)[a,b]	Radius of influence at base-case pumping rate (kilometers)	Radius of influence at 852 liters[c] per minute pumping rate (kilometers)
Bsa-1a	1.10 (well)	Not applicable[d]	0.80
Bsa-2a	1.40 (spring)	Not applicable[d]	0.54
Bsa-3a	> 1.60 (well)	Not applicable[d]	0.86
As-1b	> 1.60 (well)	Not applicable[d]	0.84
As-2b	> 1.60 (well)	Not applicable[d]	0.83

a. To convert kilometers to miles, multiply by 0.62137.
b. > = greater than.
c. To convert liters to gallons, multiply by 0.26418.
d. No calculation was completed for reasons stated in text.

4.3.6.2.2.7 Montezuma Alternative Segment 3. Montezuma alternative segment 3 would begin in the western part of hydrographic area 137A, then travel south through the middle of hydrographic area 142, then proceed westward to briefly enter hydrographic area 143, then proceed in an eastward direction where it would end in the southeastern portion of hydrographic area 144. Figures 3-193 and 3-194 show the approximate locations of existing wells, existing springs, and proposed new wells within the rail line construction right-of-way to meet water demands along Montezuma alternative segment 3. DOE proposes to install a total of up to 14 new wells to support the construction of Montezuma alternative segment 3. Groundwater impacts analyses were conducted for the proposed new wells for which existing wells or existing springs are present within the potential region of influence. Results of the groundwater impacts evaluation show that imposing an average pumping rate of 852 liters (225 gallons) per minute at these 14 proposed new wells would not impact the local groundwater users and uses in any of the hydrographic areas that Montezuma alternative segment 3 would cross.

Assuming proposed base-case average and sensitivity analysis groundwater production rates at each new well location, the impacts assessment results indicate that existing wells and springs near Montezuma alternative segment 3 would be outside the radius of influence of the proposed new water wells. For this reason, no quantitative impacts analysis calculations were completed for new well locations proposed for this portion of the Mina rail alignment.

4.3.6.2.2.8 Mina Common Segment 2. Mina common segment 2 would be entirely in hydrographic area 144 and would be approximately 5 kilometers (3.1 miles) long, proceeding from the northwest to the southeast. Figures 3-194 and 3-195 show a map view of Mina common segment 2.

There are no proposed wells, no existing USGS NWIS wells, no existing NDWR wells and no existing springs within 1.6 kilometers (1 mile) of the centerline of Mina common segment 2. Proposed wells from Montezuma alternative segments 1, 2, or 3 would be used for obtaining water needed to support the construction of Mina common segment 2. Therefore, groundwater impacts resulting from construction of Mina common segment 2 are presented in Sections 4.3.6.2.2.5, 4.3.6.2.2.6, and 4.3.6.2.2.7.

4.3.6.2.2.9 Bonnie Claire Alternative Segments. Figures 3-194 and 3-195 show the approximate locations of proposed new water wells DOE could use to support construction of these alternative segments. Evaluation of proposed new wells and information regarding existing groundwater wells and springs in the area where the Bonnie Claire alternative segments would cross indicate, for cases where groundwater pumping is assumed at the projected base-case average required withdrawal rates and where the hypothetical maximum withdrawal rate of 852 liters (225 gallons) per minute is assumed at each location, that known existing wells and springs along Bonnie Claire alternative segments 2 and 3 would be outside the radius of influence of proposed water wells along this portion of the Mina rail alignment. There are no existing USGS NWIS wells, no existing NDWR wells, and no springs within 1.6 kilometers (1 mile) of the centerlines of Bonnie Claire alternative segment 2 or 3 (see Figure 3-195). For this reason, no quantitative impacts analysis calculations were completed for new well locations proposed for this portion of the Mina rail alignment.

4.3.6.2.2.10 Common Segment 5 (Sarcobatus Flat Area). Figures 3-195 and 3-81 show the approximate locations of proposed new wells that DOE could use to support construction of common segment 5.

Assuming proposed base-case average and sensitivity analysis groundwater withdrawal rates at each new well location, the impacts assessment results (Table 4-211) indicate that existing wells and springs near common segment 5 would be outside the radius of influence of the proposed new water wells. Where the closest existing well or spring to a proposed new well was found to be located more than 2.4 kilometers (1.5 miles) away from that proposed new well location, no quantitative impacts analysis calculations were completed.

Table 4-211. Summary of calculated radii of influence for proposed new wells for the Mina rail alignment – common segment 5.

Well number	Distance to nearest well or nearest spring (kilometers)[a,b]	Radius of influence at base-case pumping rate (kilometers)	Radius of influence at 852 liters[c] per minute pumping rate (kilometers)
SaF1/2/3	0.14 (well)	0.35	0.56
SaF4	> 1.60 (well)	0.48	0.81
SaF5/9	> 1.60 (well)	Not applicable[d]	0.68
SaF7/11	1.21 (well)	0.36	0.63
OV24/25/26	> 1.60 (well)	0.31	0.38

a. To convert kilometers to miles, multiply by 0.62137.
b. > = greater than.
c. To convert liters to gallons, multiply by 0.26418.
d. No calculation was completed for reasons stated in text.

4.3.6.2.2.11 Oasis Valley Alternative Segments. A potential concern in this area is that shallow groundwater, if used for meeting ***potable water*** needs at a rail siding, construction camp, or quarry, could have elevated fluoride levels. However, deeper groundwater northeast of Beatty could be of higher quality.

Figure 3-195 shows the approximate locations of proposed new water wells within the Oasis Valley alternative segments 1 and 3 construction right-of-way. Specific siting and use considerations for new wells that would be installed along this portion of the rail alignment are summarized below. Impacts to existing springs in this area (Section 3.3.6.3.11) could be eliminated by employing the following mitigation strategies:

- For Oasis Valley alternative segment 1, up to three proposed new wells at locations OV3 and OV4, and up to two new wells at location OV5, sited within valley-fill alluvial materials, could be used to obtain water needed to support rail line construction. Alternatively, or in combination with these wells, a series of alternate wells approximately 7.2 kilometers (4.5 miles) northwest of proposed well location OV4 (at locations OV24, OV25, and OV26 on Figure 3-196), would also be used to supply water, for the same purpose, to a rail alignment water-demand location in the vicinity of proposed well locations OV3, OV4, and OV5. Locations OV24 through OV26 would be within the proposed rail alignment construction right-of-way, and in valley-fill alluvium. A series of springs on the Upper Oasis Valley Ranch (DIRS 169384-Reiner et al. 2002, Figure 7; DIRS 181909-Fridrich et al. 2007, all) are within approximately 1 kilometer (0.6 mile) of proposed well locations OV3, OV4, and OV5. Section 3.3.5, Surface-Water Resources, discusses other springs in this area. Wells at locations OV3, OV4, and OV5 would be between approximately 15 and 30 meters (50 and 100 feet) deep, while wells at locations OV24, OV25, and OV26 would be between approximately 30 and 46 meters (100 and 150 feet) deep (DIRS 176189-Converse Consultants 2006, Appendix B). For a 4-year construction schedule, the total combined average withdrawal rate for wells at locations OV3 and OV4, taken together with that for alternative wells at locations OV24 and OV25, would be approximately 410 liters (approximately 109 gallons) per minute (DIRS 176189-Converse Consultants 2006, Appendix A). For the same schedule, the total combined withdrawal rate for wells at locations OV5, together with that for alternative wells at location OV26, would be approximately 150 liters (approximately 40 gallons) per minute. The total required water withdrawal would be divided between these well locations (Figure 3-195).

- For Oasis Valley alternative segment 3, up to two proposed new wells at locations OV13, sited at the same location as OV5 under Oasis Valley alternative segment 1, could be used to obtain water needed to support railroad construction. Alternatively, or in combination with these wells, up to two alternate wells at location OV24, sited at the same location as OV24 under the Oasis Valley alternative segment 1 (see Figure 3-195), would also be used to supply water to a rail alignment water-demand location in the vicinity of proposed well location OV13. Wells at these locations would have the same depth as the corresponding wells at these locations under Oasis Valley alternative segment 1. For a 4-year construction schedule, the total combined withdrawal rate for wells at location OV13, taken together with that for alternative wells at location OV24, would be approximately 340 liters (approximately 89 gallons) per minute ([DIRS 176189-Converse Consultants 2006, Appendix A). The total required water withdrawal would be divided between these well locations (see Figure 3-196).

- Analysis results (Table 4-212) indicate that pumping groundwater from wells at locations OV3, OV4, and OV5, under Oasis Valley alternative segment 1, and pumping from wells at location OV13, under the Oasis Valley alternative segment 3, would need to be limited to a total of approximately 76 liters (approximately 20 gallons) per minute or less at each location, under each alternative segment, to preclude possible reductions in discharge rates and water quality at the Upper Oasis Valley Ranch springs. The remaining water needed to support construction activities in this portion of the rail alignment would be obtained from proposed alternate well locations OV24, OV25, and/or OV26. For Oasis Valley alternative segment 1, the total combined net withdrawal that would be met through the use of wells at alternate well locations would be approximately 340 liters (89 [109 + 40 − 20 − 20 − 20] gallons) per minute. For Oasis Valley alternative segment 3, the total combined net production from wells at location OV24 would be approximately 261 liters (69 [89 – 20]) gallons) per minute.

Table 4-212. Summary of calculated radii of influence for proposed new wells for the Mina rail alignment – Oasis Valley alternative segments.

Well number	Distance to nearest well or nearest spring (kilometers)[a]	Radius of influence at base-case pumping rate (kilometers)	Radius of influence at 852 liters[b] per minute pumping rate (kilometers)
OV3/4/5	0.64 (spring)	0.28	Not applicable[c]
OV9	1.50 (spring)	0.18	0.64
OV12/18/19/20/21	0.96 (spring)	0.56	0.61
OV6/8/14/16	1.32 (spring)	0.49	0.64

a. To convert kilometers to miles, multiply by 0.62137.
b. To convert liters to gallons, multiply by 0.26418.
c. No calculation was completed for reasons stated in text.

Evaluation of the effects of proposed groundwater withdrawals from proposed wells at locations OV9, OV12, OV17, OV18, OV19, and OV20 for Oasis Valley alternative segment 3 indicate that there would be no expected impact to known existing springs or wells in the Oasis Valley area.

Existing USGS NWIS wells (OVU-Dune Well, OVU-Middle ET Well, OVU-Lower ET Well, and Well ER-OV2) within approximately 0.32 to 0.48 kilometer (0.2 to 0.3 mile) of the proposed new wells at locations OV3, OV4, and OV5 on Oasis Valley alternative segment 1 (see Section 3.3.6.3.11) are shallow groundwater monitoring wells owned and installed by the U.S. Geological Survey. All of these wells have no current or projected beneficial use and are used solely for monitoring purposes. An existing well cluster of USGS NWIS wells (ER-OV-01, ER-OV-06a, and ER-OV-6a2) is approximately 1.9 kilometers (1.2 miles) northeast of the proposed new wells at location OV20/OV21 on Oasis Valley alternative segment 3. These are also shallow groundwater monitoring wells owned and installed by the U.S. Geological Survey. These wells have no current or projected beneficial use and are used solely for monitoring purposes.

Alternatively, for Oasis Valley alternative segment 1, up to four proposed new wells could be installed at proposed alternative well locations OV6 and OV8 west of the Amargosa River in the Oasis Valley area (see Section 3.3.6.3.11 and Figure 3-195). For Oasis Valley alternative segment 3, these alternate well locations are designated OV14 and OV16 but the wells would have the same characteristics and same required production rates. These alternate wells would support earthwork construction and would be between 30 and 46 meters (100 and 150 feet) deep. The total combined required withdrawal rate for this set of wells would be approximately 510 liters (136 gallons) per minute (DIRS 176189-Converse Consultants 2006, Appendix A). Analysis results (Table 4-212) indicate that pumping groundwater from these wells at the required base-case withdrawal rates would not be expected to impact discharge rates and/or water quality at a group of springs (identified in records as Ute Springs and Manley Springs) approximately 0.64 kilometer (0.4 mile) to 0.97 kilometer (0.6 mile) east of the OV14 and OV16 locations.

For two proposed new well locations associated with the Oasis Valley alternative segments, the targeted water zone is a possibly water-bearing detachment fault system (DIRS 176189-Converse Consultants 2006, Appendixes A and B and Maps 14a and 14b). A proposed well location (well location OV5 or OV15, depending on alternative segment) could be installed in the southern portion of hydrographic area 228, within the typical maximum 300-meter (1,000-foot)-wide construction right-of-way of common segment 6 (see Figure 3-195). A new well (see Section 3.3.6.3.11 and Figure 3-195) might be installed in the southern part of the Oasis Valley hydrographic area near the area boundary, approximately 0.8 kilometer (0.5 mile) west of common segment 6 (well location OV22 or OV23, depending on alternative segment). The target water source at this location would be a possibly water-bearing detachment fault system (DIRS 176189-Converse Consultants 2006, Appendix B). There are no known existing wells or springs within approximately 9.7 kilometers (6 miles) of either of these proposed well locations that are known to be associated with the same fault system as, or with potentially related major fault zones in either of these proposed well locations, should these wells be used for obtaining water required at corresponding rail alignment water-demand stations.

4.3.6.2.2.12 Common Segment 6 (Yucca Mountain Approach). Figure 3-195 shows the approximate locations of proposed new wells along this common segment. There are 1.41 million cubic meters (1,147 acre-feet) and 72,000 cubic meters (58 acre-feet) of annual committed groundwater resources in hydrographic areas 229 and 227A, respectively. There are 101,000 cubic meters (82 acre-feet) of documented pending annual duties in area 229 and approximately 6,170 cubic meters (5 acre-feet) of documented pending annual duties in area 227A. Tables 3-113 and 4-206 indicate that water withdrawal required within hydrographic area 229 for construction of common segment 6 would exceed the estimated annual perennial yield for that hydrographic area. However, except for smaller-magnitude water requirements (on the order of 3.8 liters [1 gallon] per minute) associated with a proposed rail siding

(DIRS 176189-Converse Consultants 2006, Table 2-1) and a proposed construction camp (approximately 76 liters [20 gallons] per minute), water requirements for common segment 6 would be required for only 9 months (DIRS 176189-Converse Consultants 2006, Appendix A).

There are 14 existing USGS NWIS wells, no NDWR wells with water rights, no NDWR domestic wells, and no springs located within approximately 1.6 kilometers (1 mile) of the centerline of common segment 6. Up to two new water wells are proposed at location CF4. These wells would furnish water for earthwork compaction and would be between approximately 370 and 460 meters (1,200 and 1,500 feet) deep. Although there is one USGS NWIS well approximately 1.5 kilometers (0.9 mile) northeast of this location, that well is a groundwater test/monitoring well (NC-EWDP-18P) installed to test subsurface characteristics and monitor groundwater conditions downgradient of the Yucca Mountain repository site. This well has no current or projected beneficial use, and is used only for monitoring purposes (DIRS 176600-Converse Consultants 2005, Plate 4-2 and Appendix A; DIRS 176808-Nye County Nuclear Waste Repository Project Office 2002, all).

As shown in Table 3-113, the perennial yield for the western two-thirds of hydrographic area 227A is approximately 720,000 cubic meters (580 acre-feet) and committed groundwater resources are very low. Appropriations for new wells could be pursued in this area to meet railroad construction-water needs and water demands for rail line construction and for the railroad operations support facilities near the end of the rail line at Yucca Mountain.

Water required for railroad construction and operations through area 227A would be acquired as part of the water inventory of approximately 530,000 cubic meters (430 acre-feet) per year proposed for appropriation in area 227A to support construction and operation of a repository at Yucca Mountain. The total estimated water demand for construction of the portion of common segment 6 within area 227A is approximately 710,000 cubic meters (572 acre-feet). Water requirements associated with the construction and operation of proposed rail facilities in area 227A are described in Section 4.3.6.2.1. If the amount of water required to support rail construction and operations exceeds the current amount proposed for appropriation, the schedule for railroad construction or for water acquisition could be modified to reduce peak water demands or an additional temporary water appropriation for rail construction could be sought (DIRS 176189-Converse Consultants 2006, p. 15).

Assuming proposed base-case average and sensitivity analysis groundwater withdrawal rates at each new well location, the impacts assessment results indicate that existing wells and springs near common segment 6 would be outside the radius of influence of the proposed water wells. For this reason, no quantitative impacts analysis calculations were completed for new well locations proposed for this portion of the Mina rail alignment.

4.3.6.3 Operations Impacts

Overall, potential impacts to groundwater resources from operating the proposed railroad along the Mina rail alignment under the Proposed Action or under the Shared-Use Option would be small.

Rail line operations facilities would need water for daily operation. However, other than relatively limited water quantities required for maintaining fire-protection water-tank reserves at rail sidings and meeting relatively low water needs for operations personnel at selected facility locations along the rail line, there would be no continued need for any large-scale pumping wells once construction of the railroad is completed. Possible changes to recharge characteristics, and resulting changes in percolation rates to groundwater, if any, in the areas of railroad operations facilities would be the same as those at the completion of construction of the rail line.

By complying with applicable regulations, it is expected that impacts to groundwater resources from disposal of wastewater would be minimized (see Section 4.3.11, Utilities, Energy, and Materials).

4.3.6.4 Impacts under the Shared-Use Option

Impacts to groundwater under the Shared-Use Option would be similar to those identified for the Proposed Action without shared use. Under the Shared-Use Option, additional commercial rail sidings would be constructed as a third track alongside passing sidings (see Figure 2-55). The total length of commercial rail sidings would be relatively small compared to the total length of the rail line. Under the Shared-Use Option, water needs for construction of the rail line would increase only by approximately 150,000 cubic meters (119 acre-feet).

For purposes of analysis, DOE assumed that the commercial sidings would be in the same hydrographic areas as analyzed for the Proposed Action without shared use. Impacts would be similar to those described for the Proposed Action without shared use; additional impacts to groundwater resources in these areas would be small.

The commercial-only facilities that would be constructed under the Shared-Use Option would likely be close to DOE-owned and -operated rail facilities and would likely overlie the same hydrographic areas identified for the Proposed Action without shared use. Overall, the impacts would be similar to those described for the Proposed Action without shared use and would be small.

Impacts to groundwater under Shared-Use Option operations would be similar to those identified for operations under the Proposed Action without shared use (Section 4.2.6.2). Use of the completed rail line from Wabuska to Yucca Mountain, including any additional sidings, would have a small impact on groundwater resources. There would be no continued need for water along the additional sidings, and possible changes to recharge, if any, would be the same as those at the completion of construction.

The commercial-only facilities would require water for daily operation. Water demand to operate these facilities has not been determined, but DOE assumes this demand would be small. Therefore, the additional impacts to groundwater resources would likely be small and overall would be similar to those described for the Proposed Action without shared use.

4.3.6.5 Summary

This section summarizes and characterizes potential impacts to groundwater resources from constructing and operating the proposed rail line and railroad construction and operations support facilities along the Mina rail alignment. The potential for impacts to groundwater resources resulting from physical disturbance of the ground surface during the construction phase would be small. Proposed groundwater withdrawals would locally affect groundwater flow patterns and groundwater availability. Impacts on downgradient groundwater basins (hydrographic areas) due to the proposed groundwater withdrawals would be very small. Impacts on groundwater resources due to groundwater withdrawals at proposed quarry locations and rail facility locations would also be very small. As discussed in Section 4.1, DOE would implement best management practices as part of the Proposed Action to avoid, minimize, or otherwise reduce impacts to groundwater resources. Chapter 7 describes best management practices and mitigation measures.

For the case of groundwater withdrawals from proposed wells to support a 4-year rail construction schedule, analysis results indicate that, based on anticipated hydrogeologic conditions, existing known wells or springs are not expected to fall within the radius of influence of the proposed new wells, except for location Cl-1a in Clayton valley, possibly location CSM-2a in Columbus Salt Marsh Valley, and selected proposed new well locations in the Oasis Valley area (if the restrictions and use limitations discussed for these well locations as described below were not followed). The proposed groundwater withdrawal at each new production well would create a drawdown feature in the portion of the ***saturated zone*** immediately surrounding that well, locally affecting groundwater flow patterns and water availability in the portion of the aquifer immediately surrounding the well. The effects in each case where projected average production rates are assumed to occur at the proposed well locations would be limited in extent to a maximum horizontal distance of approximately 0.8 to 1 kilometer (approximately 0.5 to 0.6 mile) or less in a few instances and generally a much smaller distance.

As noted above, impacts analysis results indicate at two proposed well locations along the portion of the proposed Mina rail alignment that would be unique to the alignment (that is, distinct from the rail line segments that would be common to both the Mina and Caliente rail alignments as described in Section 4.2.6), proposed groundwater withdrawals, if unmitigated, could impact existing groundwater resources and/or an existing groundwater user. The following is a summary of these potential impacts:

- Location CSM-2a – There is potentially a spring located within the calculated region of influence of this pumping location. It should be noted that available information suggests that this spring, noted in a report from 1970 as having a very small flow rate, might no longer exist (that is, no longer discharge). If this potential spring location was excluded from consideration in the impact analysis calculations, there would be no impact to nearby groundwater uses or users due to the pumping at location CSM-2a. In the unlikely event that this spring might still exist, impacts to that spring could be eliminated by reducing the average withdrawal rate at location CSM-2a to approximately 150 liters (40 gallons) per minute or less. In this case, the remaining balance of make-up water required could be obtained at another proposed well location provided that well is sufficiently far away from known existing springs and active pumping wells. Alternatively, the location of proposed well CSM-2a could be moved to a point located sufficiently distant from the spring, if present, to preclude the cone of depression from the well from reaching the spring.

- Location Cl-1a – This well location would be southwest of an existing groundwater well field that services the community of Silver Peak. The proposed production rate in the new well installed at this location would be approximately 1,300 liters (350 gallons) per minute (gpm) or less. This withdrawal rate is higher than the anticipated production rate for other proposed new wells along the Mina rail alignment because groundwater underlying much of Clayton Valley is very brackish in nature. Therefore, possible target areas for obtaining better-quality groundwater for use in the rail line roadbed construction and for supplying water for a proposed construction camp are very limited in this area. Analysis indicates that if the average pumping rate in the proposed well at location Cl-1A were maintained at approximately 1,000 liters (265 gallons) per minute or less, the cone of depression developed around this proposed well would not be expected to intersect the cone of depression surrounding the nearest existing well with a known water right (a municipal water well), under the scenario where both wells are assumed to be pumped simultaneously. In this case, the remaining balance of make-up water required could be obtained at another proposed well location provided that well is sufficiently far away from known existing springs and active pumping wells. Alternatively, the location of proposed well Cl-1a could be moved to a point sufficiently distant from the existing well with the water right to preclude the cones of depression from the two wells from intersecting each other.

Analysis results (see Tables 4-207 through 4-212) for the rail line segments that would be common to both the Mina and Caliente rail alignments indicate that certain restrictions or use prohibitions would need to be factored into the final siting and use of some specific proposed new groundwater well locations (mostly with respect to potential higher well-productivity scenarios) at selected locations in the Oasis Valley hydrographic area (proposed well locations OV3, OV4, OV5/OV13 in order to preclude impacts on existing groundwater resources. The resources that could be affected if such restriction for use prohibitions were not followed include springs (locations OV3, OV4, and OV5/13) or existing wells (location Cl-1a).

Wells having the largest withdrawal rates would be expected to be those that are designed for use as supply wells for earthwork compaction; groundwater withdrawals from these wells would occur over a period of less than 1 year (typically over a 9-month pumping period). For a longer rail construction schedule (up to 10 years), groundwater withdrawal rates from new wells could be the same or reduced for most well locations compared to those described in this section. For this longer schedule, the magnitude of potential impacts to existing groundwater users from groundwater withdrawals would be equal to or less than that determined for the 4-year railroad construction schedule.

Collectively, the impacts analysis results indicate that the effects of groundwater withdrawals from the proposed new wells at the range of production rates that may be required for this project would be localized in nature and extent. The impacts caused by the majority of water withdrawals and the wells having the highest production rates (those associated with construction of the rail line roadbed) would be short term in duration. Additionally, for those areas where proposed new water wells would be near a boundary between adjacent hydrographic areas, downgradient hydrographic areas would not be likely to be affected by the proposed groundwater withdrawals because (1) there are no identified existing groundwater users associated with the downgradient groundwater basins within 1.6 kilometers (1 mile) of any of these proposed well-water withdrawal locations, and (2) available hydrogeologic information indicates that significant inter-basin groundwater (under) flow is not occurring in the areas downgradient of the proposed well locations.

DOE compared hydrogeologic conditions occurring at the proposed withdrawal well locations and required groundwater withdrawal durations and proposed groundwater withdrawal rates for new wells to hydrogeologic conditions and groundwater withdrawal rates and pumping durations that have occurred at certain locations in the western United States where ground subsidence has been observed as a result of prolonged, large-scale groundwater withdrawals. Comparison results indicate that the potential for ground subsidence to occur as a result of proposed groundwater withdrawals in the hydrographic areas crossed by the Mina rail alignment is small, both during the construction and operations phases.

Table 4-213 summarizes potential impacts to groundwater resources from constructing and operating the proposed railroad along the entire Mina rail alignment.

Table 4-213. Summary of potential impacts to groundwater resources – Mina rail alignment.

Resource	Proposed Action
Groundwater availability and uses	*Construction* - Analysis results indicate that proposed groundwater withdrawals would locally affect groundwater flow patterns and water availability in the portion of the aquifer immediately surrounding each new withdrawal well. The effects resulting from application of assumed withdrawal rates of 852 liters (225 gallons) per minute at proposed well locations, and an initially proposed withdrawal rate of 1,300 liters (350 gallons) per minute at one proposed well location (Cl-1a), would be limited in extent. Analysis results indicate that the radius of influence of the cone of depression created in the aquifer in each case averages approximately 0.64 kilometer (0.4 mile) for the proposed new well locations, with a maximum horizontal distance of approximately 0.97 kilometer (0.6 mile) indicated at one proposed well location. Hydrogeologic effects resulting from use of the proposed new wells for supporting rail line roadbed construction would be temporary in nature. Proposed groundwater withdrawals at a proposed well location Cl-1a in the Clayton Valley hydrographic area (Cl-1a) and at selected proposed well locations in the Oasis Valley hydrographic areas (OV3, OV4, and OV5/13), could, if unmitigated, likely impact existing groundwater users or existing groundwater resources during the construction of a railroad along the Mina rail alignment. Proposed groundwater withdrawals from proposed well CSM-2a in the Columbus Salt Marsh Valley hydrographic area, could, depending on whether a small-discharge rate spring might still exist in the nearby vicinity, impact discharge rates at that spring. One or more specific mitigation measures described earlier in this section, as needed, and if implemented at these locations, would effectively avoid such potential impacts. *Construction and Operations* - Physical impacts to existing groundwater resource features such as existing wells or springs resulting from rail line construction and operations would be small. *Operations* - Owing to the very small groundwater withdrawal rates needed to support railroad operations, potential impacts to groundwater resources from operating the rail line from Wabuska to Yucca Mountain under the Proposed Action would be small.
Ground subsidence	*Construction* - The temporary duration of the vast majority (approximately 87 percent) of the total groundwater withdrawals required for railroad construction indicates that the potential for the proposed groundwater withdrawals to cause subsidence of the ground surface is small. *Operations* - Owing to the very small groundwater withdrawal rates needed to support railroad operations, the potential for the groundwater withdrawals needed to support railroad operations to cause subsidence of the ground surface is small.
Groundwater quality	*Construction and Operations* - The impact to groundwater resources of contaminants that might be released by construction equipment during rail line construction or during rail system operation would be small because of generally deep groundwater depths beneath most of the alignment. *Construction and Operations* - The impact of proposed groundwater withdrawals on groundwater quality would be small to negligible. The proposed withdrawals would not conflict with water-quality standards protecting groundwater resources.

4.3.7 BIOLOGICAL RESOURCES

This section describes potential impacts to biological resources (vegetation, wildlife, special-status species, State of Nevada game species, and wild horses and burros) from constructing and operating the proposed railroad along the Mina rail alignment. Potential impacts are reported and described as either direct or indirect, and either long-term or short-term.

There could be short-term impacts to biological resources in the rail line construction right-of-way during the construction phase. These impacts would be short term because DOE would restore disturbed lands not required for railroad operations with appropriate vegetation immediately after construction was complete.

There would be long-term impacts to biological resources in areas where there would be unavoidable impacts that would result in a change in the natural setting that could last beyond the 50-year operations phase. These areas would include the rail roadbed, along access roads, and in facility and quarry footprints. For biological resources, such impacts are identified for areas of the maximum edge of cut and toe of slope for fill (see Section 2.2.2.5).

Section 4.3.7.1 describes the methods DOE used to assess potential impacts to biological resources; Section 4.3.7.2 describes impacts under the Proposed Action; Section 4.3.7.3 describes impacts under the Shared-Use Option; and Section 4.3.7.4 summarizes impacts. Section 6.2.7 summarizes laws and regulations governing the protection of biological resources. Appendix H provides more detail on the methods DOE used to assess potential impacts to biological resources.

4.3.7.1 Impact Assessment Methodology

For this analysis, DOE calculated potential direct long-term impacts to biological resources based on the footprint of the rail roadbed. The footprint would be within the nominal width of the construction right-of-way, and is the area that would involve clearing of vegetation, excavation, and filling to support the rail line. The width of the footprint would fluctuate along the alignment due to topography, cut and fill requirements, land use, and to avoid or minimize impacts to other resources (such as water and structures). This area would experience direct, long-term impacts.

DOE coordinated with personnel from pertinent federal, state, and local agencies to identify potential impacts to biological resources. Where possible, the Department has quantified potential impacts (such as habitat loss due to construction and operations activities).

Although the Department would minimize the use of the area between the edge of the construction footprint and the outside edge of the construction right-of-way, DOE took a conservative approach and analyzed the short-term impacts to biological resources within this area. This approach overstates impacts as DOE would likely not disturb a large portion of this area.

For facilities that would be outside the nominal width of the construction right-of-way (such as quarries and railroad operations support facilities), the area DOE assessed for potential impacts was the maximum construction footprint of each facility. In order to assess potential impacts, the Department performed a spatial Geographical Information System analysis to compare the footprints of these facilities with biological resources information.

Where possible, this section reports potential impacts to biological resources quantitatively. Potential species-specific impacts are reported qualitatively as either small, moderate, or large, as defined in Section 4.1. DOE estimated impacts based on the amount of change to or loss of the resource from the baseline conditions described in Section 3.3.7, and considered the following criteria for determining the level of change in conditions:

- Direct effects would be-
  - Long-term loss of vegetation (land-cover types)
  - Short-term disturbance to habitat and vegetation
  - Long-term and short-term species displacement or alteration of access to important year-round or seasonal habitat during the construction and operations phases (including watering areas and other key areas)
  - Long-term loss of potential habitat (species-specific land-cover types)
  - Short-term disturbance to habitat and vegetation
  - The risk of trains colliding with wildlife
- Indirect effects would be-
  - Changes in land use that could effect movement patterns and migratory patterns
  - Displacement of species after construction that could add additional stress to other areas and habitat

The assessment of impacts to biological resources considers the potential for continued engineering and site evaluation and planning efforts (see Chapter 2), compliance with applicable requirements (see Chapter 6), and implementation of best management practices (see Chapter 7) to minimize or avoid impacts. This section reports potential direct impacts for the entire rail alignment and specific rail line segments.

DOE expects that there would be small indirect impacts, if any, to biological resources from changes in land use and post-construction displacement, because of the large expanses of land in the area and the types of current uses that tend to be less intrusive than normal development and rural or urban expansion.

DOE concluded from the groundwater impact analysis that project-related groundwater withdrawals would not result in changes to water levels at springs; therefore, there would be no impacts to vegetation, wildlife, special status species, state of Nevada game species, wild horses or burros associated with those springs (see Section 4.2.5, Surface-Water Resources).

4.3.7.1.1 Vegetation

DOE began the assessment of impacts to vegetation resources quantitatively and qualitatively by reviewing available resource data and field surveys. The Department considered the potential direct impacts to land-cover types from railroad construction and operations activities. To assess potential direct impacts from the loss or disturbance of most land-cover types, DOE compared the area of a land-cover type that could be disturbed during the construction and operations phase to the land-cover types present within the affected mapping zones. For ecologically important and relatively uncommon land-cover types within the entire mapping zone, such as ***riparian*** and marsh habitats, DOE compared the area of a land-cover type that would be disturbed (within the construction right-of-way and facilities footprints) to the land-cover type present within the study area, as defined in Section 3.3.7.1.2. The Department used this information to quantitatively estimate the potential loss of habitat and to determine qualitatively whether the loss of habitat would result in a small, moderate, or large impact.

DOE also evaluated potential impacts from noxious or invasive plant species based on the potential for railroad construction or operations activities to introduce or spread noxious or ***invasive species***.

4.3.7.1.2 Wildlife

DOE assessed potential impacts to wildlife communities qualitatively by reviewing the land-cover types that could be affected during railroad construction and operations and identifying the wildlife species likely to be present within those areas. Habitat loss with these communities would be the primary driver of impacts to wildlife and is the focus of this analysis. The Department also evaluated potential impacts from railroad operations on wildlife.

4.3.7.1.3 Special Status Species

DOE assessed potential impacts to special status species (threatened and endangered species; BLM-designated sensitive species; and State of Nevada-designated sensitive and protected species) qualitatively by reviewing the potential for a species to occur within the study area and the region of influence; species habitat that would be affected; and the potential mechanisms for impact. The primary impact would be from the loss of habitat, which is the focus of this analysis. DOE also evaluated impacts from railroad operations on special status species.

4.3.7.1.4 State of Nevada Game Species

DOE assessed potential impacts to State of Nevada Game Species, as defined in Section 3.3.7.2.4, based on the potential for loss of important foraging habitat, the potential for loss of important water sources, the potential displacement of game, and the potential disruption of movement patterns.

4.3.7.1.5 Wild Horses and Burros

DOE assessed potential adverse impacts to wild horses and burros based on the potential for loss of important foraging habitat, the potential for loss of important watering areas, and the potential for impacts to individual ***herd management areas***.

4.3.7.2 Environmental Impacts

This section describes potential impacts to biological resources from construction and operation of a railroad along the Mina rail alignment under the Proposed Action. To minimize redundancy and provide clear and concise reporting of potential impacts, Section 4.3.7.2.1 describes impacts common to all rail line segments and construction and operations support facilities and how each biological resource could be affected. Section 4.3.7.2.2 describes rail line segment- and facility-specific impacts. Tables list the amount of departure from baseline conditions (see Section 3.3.7) based on the indicators described above.

4.3.7.2.1 Environmental Impacts Common to the Entire Mina Rail Alignment

This section describes potential short-term and long-term impacts to each biological resource that could result from rail line construction along the Mina rail alignment.

4.3.7.2.1.1 Vegetation Construction of the rail line and facilities along the Mina rail alignment would directly impact a diverse mix of vegetation communities and land-cover types. Tables 4-214, 4-215, 4-216, and 4-217 list the land-cover types associated with the Mina rail alignment common segments, alternative segments, quarries, and operations support facilities that would be affected during the construction phase. The primary construction-related impacts to vegetation communities during the construction phase would be the physical short-term or long-term removal of vegetation and compaction of the soil.

c. Totals might differ from sum of values due to rounding.

Areas where there could be short-term impacts to vegetation include the area from the outer edge of the construction right-of-way to the toe of slope of the rail roadbed, construction camps, and material lay-down areas. Disturbance to vegetation associated with these areas would result in relatively small impacts compared to the amount of available specific land-cover types within the Great Basin and Mojave Deserts. Impacts in the area between the outer edge of the roadbed footprint and the outer edge of the construction right-of-way would be short-term because DOE would implement best management practices. These practices would minimize disturbance and promote effective restoration efforts, including stockpiling and replacing topsoil, reseeding of native species, monitoring for success, and in most cases the eventual return of a native vegetation community.

Areas where there could be long-term impacts include the rail line construction right-of-way and the footprints of facilities. The amount of vegetation loss under the rail line and facility footprints would be relatively small compared to the amount of available specific land-cover types within the Great Basin and Mojave Deserts. The removal of vegetation for the rail line would be linear and for part of its length, would be adjacent to an existing state highway and other roadways. Therefore, impacts related to fragmentation of vegetation communities would be relatively small and would not be expected to disrupt the dispersal of seeds across the rail bed.

Clearing vegetation and disturbing soil during construction activities could create habitat suitable for potential colonization by ***noxious weeds*** and invasive plant species. In addition, linear disturbances such as the rail line and access roads that cross relatively undisturbed regions have the potential to increase the spread of noxious weeds and invasive plant species, with the increase in traffic or human activity. If noxious weeds and invasive species were to become established along the rail alignment, they could spread to adjacent areas and affect intact plant communities beyond the initial area of disturbance.

DOE would implement best management practices during and after the construction phase to prevent the establishment of noxious weeds and invasive species. Such practices would include limiting the grading of surfaces and surface disturbance to the immediate area of construction; planting stockpiles of topsoil retained for more than a year; establishing staging areas in previously disturbed areas when practicable; applying approved herbicides; and revegetating disturbed areas not needed for the operations phase (see Chapter 7). As a result, potential impacts from the spread of noxious weeds and invasive species would be minimized or avoided, and would be small.

Additionally, the watering of land surfaces during construction activities for such purposes as soil stabilization, ballast cleaning, vehicle washing, and dust suppression could encourage the growth of noxious weeds and invasive species. However, watering would primarily occur on road surfaces where weeds would not become established. DOE would implement best management practices to limit the watering of land surfaces to the extent practicable (see Chapter 7). Short-term impacts from introduction and spread of noxious weeds and invasive species would be very small during the construction phase; long-term impacts would be small over the entire length of the rail alignment.

4.3.7.2.1.2 Wildlife. Potential impacts to wildlife during the construction phase would consist of the loss of suitable habitat (land-cover types), disturbance to habitat, displacement of or limited access to important year-round or seasonal habitat during the construction phase, change in movement patterns, and the potential increase in the risk of wildlife collisions with vehicles along access roads. Reduced vegetation could limit forage for wildlife, such as big game or bird species, and could reduce or limit habitat for ground dwelling mammals in the area. These impacts are reported as direct short- or long-term losses of land-cover types or habitat. To reduce redundancy, direct impacts from habitat disturbance and displacement and changes in wildlife movement and potential collisions with trains and automobiles are described in segment- and facility-specific sections. Wildlife collisions with trains would be minimal over most of the alignment due to the amount of sight distance, low speeds of trains, and area for escape beside the tracks.

Wildlife species that use underground habitats and were present within the construction right-of-way could be crushed or smothered during rail line construction. However, DOE would implement best management practices (such as conducting clearance surveys for the presence of sensitive species and their habitat) before and during the construction phase to minimize adverse impacts to wildlife. The more mobile wildlife species, such as kit fox, badgers, mountain lions, and rabbits would be less likely to incur mortality, as they would be able to avoid the construction area, resulting in a short-term impact to these species due displacement or avoidance of the area.

Cuts into steep hillsides, depending on design, could encourage wildlife to congregate in the cut areas, resulting in a potential increase of collision with trains and possible fatalities. Access roads adjacent to the rail line would allow animals to move off the tracks to avoid oncoming trains. Therefore, the potential for mortality of animals congregating in cut areas would be small. Additionally, sight distance and the slow speeds of the trains would help minimize potential collisions. Cuts would also have the potential to slightly disrupt movement patterns of some wildlife species. However, this impact would be small because animals would be able to travel around cuts to move up or down the hillsides.

Construction of additional access roads and the improvement of existing access roads could increase traffic during the construction phase and in the short term could increase wildlife fatality from vehicle collisions and potentially disturb wildlife habitat from the increase in off-road vehicle traffic. However, the degree and magnitude of impacts would be species-specific and would depend on the existing habitat range of the species.

The generation of solid waste at construction camps could increase the occurrence of coyotes and ravens, indirectly increasing the death rate of the prey of these two species. As part of the worker education program, all personnel would be trained on the proper way to dispose of waste. Therefore, this potential indirect impact would be small.

Draw-down of ground-fed springs and seeps and the consequent reduction in associated riparian habitat due to the use of groundwater during construction activities, could indirectly impact wildlife species that depend on riparian habitat. However, DOE has proposed the placement of wells such that there should be no impact to groundwater from the use of the wells during the construction phase. (See Sections 3.3.6 and 4.3.6, Groundwater Resources, for the analysis of wells and groundwater use.) There could be impacts to aquatic species in streams and springs in the construction area due to sedimentation and erosion, but such impacts would be small because DOE would implement best management practices to prevent sedimentation and erosion throughout the construction phase (see Chapter 7).

The Migratory Bird Treaty Act (16 U.S.C. 703 through 712) protects migratory birds, their eggs, and occupied nests, but it does not protect their habitat. Therefore, long-term impacts to migratory bird species as a result of the proposed project could result from loss of suitable nesting and foraging habitat where large amounts of vegetation (for example, junipers and pinyon pines) are removed or where rock outcrops or cliffs are disturbed for construction purposes (see Appendix H, Table H-4 for a list of all bird species that could occur in construction right-of-way). Short-term impacts could include birds avoiding the area during construction activities. However, to avoid or minimize adverse impacts to migratory birds during the construction phase, DOE would implement best management practices, including minimizing groundbreaking activities in nesting habitat during the critical nesting period, which the BLM defines as May 1 through July 15 (see Chapter 7). If groundbreaking or land-clearing activities had to be conducted during the bird nesting season, DOE would conduct surveys for the nests of migratory bird before beginning those activities. All activities that would harm nesting birds or result in nest abandonment would be prohibited.

4.3.7.2.1.3 Special Status Species. A review of the Nevada Natural Heritage Program database for the 16-kilometer (10-mile)-wide study area, which extends 8 kilometers (5 miles) on either side of the centerline of the rail alignment (see Section 3.3.7.1.2), documented 54 special status species that have the potential to occur within the study area. Potential impacts to special status wildlife species would include loss of and disturbance to potential foraging and nesting habitat, avoidance of the area that could change movement patterns, and disturbance from the increase of noise.

The loggerhead shrike is known to occur along the entire Mina rail alignment where suitable habitat is present. There could be small, short-term impacts this species from increased human activity and noise during construction of sidings along existing rail line and construction of new rail line. Loggerhead shrikes occupy a wide range of habitat; therefore, there would be no long-term impacts to the population or viability of this species.

The western burrowing owl potentially occurs along the entire Mina rail alignment where suitable habitat is present. There could be small, short-term impacts to this species from increased human activity and noise during construction of sidings along existing rail line and construction of new rail line. Burrowing owls occupy a wide range of habitat; therefore, there would be no long-term impacts to the population or viability of this species.

It is possible that some individual cacti and yucca plants would be removed during the construction phase, resulting in a small impact to individual plants. However, construction activities would not threaten cacti or yucca populations.

4.3.7.2.1.4 State of Nevada Game Species. The rail line would cross areas recognized by the BLM and the Nevada Department of Wildlife as habitat for game species (see Figures 3-215 through 3-218). Direct impacts to game species during rail line construction would include loss of foraging habitat, disturbance from noise, potential fatality from collisions with trains, and a short-term avoidance of year-round or seasonal habitat, migratory corridors and water sources during construction activities. Because of the relatively low density of game animals in the study area, their mobility, and the presence of humans and machines, such impacts would be small. Potential impacts to game species would be greatest in the areas under active construction. After sections of the rail line were completed, potential impacts would be related to trains crossing the area to move workers and materials to active construction locations. It is possible that individual game animals could collide with moving trains and be injured or killed. However, the likelihood of such collisions would be low, because most game animals would likely avoid oncoming trains whenever possible.

During rail line construction there would be a potential for short-term impacts from the potential for disruption of movement patterns of game species within an area or along migratory corridors, which could disturb individuals or groups of animals and cause animals to avoid the construction areas. Game species are large, mobile animals and would be able to avoid contact with humans at construction sites and would likely move temporarily to other areas during construction activities. These changes in movement or habitat-use patterns would affect relatively low numbers of individuals at any one time; therefore, changes in utilization of the water or forage resources in the region would be small.

There could be direct impacts to the various game populations if animals avoid water sources close to construction activities. Water sources are found only along certain portions of the Mina rail alignment and there could be small, short-term impacts to individuals and groups of animals if they are unable to reach those water sources. There would be no impact on the overall populations of State of Nevada game species due to avoidance of adjacent water resources during construction. Other potential impacts to State of Nevada game species would be similar to those described for wildlife, and would be small.

4.3.7.2.1.5 Wild Horses and Burros. This section identifies the magnitude of potential adverse impacts to wild horses and burros due to potential displacement and loss of their habitat or vegetation for grazing.

Construction activities within herd management areas would result in a long-term loss of forage, potential for collisions with trains, the short-term loss of year-round or seasonal habitat, and the potential to disrupt wild horse and burro movement patterns. Appendix H describes specific herd management areas that could be affected during the construction phase.

The removal of vegetation during the construction phase would result in a long-term loss of potential forage for wild horses and burros. However, the amount of vegetation permanently removed in the rail line, facility, and quarry footprints would be relatively small compared to the available forage within the affected herd management area. Vegetation removal would likely result in an overall small impact to the associated herd management area. Tables in segment- and facility-specific sections list the potential loss of forage due to construction of the proposed railroad.

The potential changes in movement or habitat-use patterns would affect relatively low numbers of individuals at any one time due to the localized nature of the construction; therefore, changes in utilization of the water or forage resources in the region would be small. Generally, wild horses and burros avoid contact with humans and therefore would likely move temporarily to other areas during construction activities. DOE would also minimize impacts to herd management areas by fencing off temporary ponds or reservoirs that are used during construction activities to prevent herds from utilizing those water sources, which could otherwise change herd movement patterns. The loss of potential forage and habitat and the temporary short-term loss of access due to construction activities and noise would be similar for each affected herd management area.

4.3.7.2.2 Segment-Specific Construction Impacts

Sections 4.3.7.2.2.1 through 4.3.7.2.2.18 describe potential short- and long-term direct impacts to biological resources from the construction of specific alternative segments and common segments, quarries, and facilities along the Mina rail alignment. The discussion in Section 4.3.7.2.1 for the impacts to biological resources common to all of the segments is not repeated. Rather, tables provide information necessary to report direct impacts to the specific biological resources associated with each alternative segment, common segment, quarry, and facility. Where DOE would utilize existing rail lines, a brief discussion of the impacts is provided; any operations impacts are reported in Section 4.3.7.2.3.

4.3.7.2.2.1 Union Pacific Hazen Branchline (Hazen to Wabuska), Existing Rail. DOE would not perform any ground-disturbing activities along this portion of the Mina rail alignment. Therefore, there would be no construction-related impacts to biological resources along this existing rail line. (See Section 4.3.7.2.3 for a description of potential impacts during the operations phase.)

4**.3.7.2.2.2 Department of Defense Branchline North (Wabuska to the Boundary of the Walker River Paiute Reservation), Existing Rail Line.** This segment is an existing rail line that connects to the Union Pacific Railroad Hazen Branchline just east of Wabuska and would connect to one of the Schurz alternative segments near the Walker River. DOE would construct a siding within the construction right-of-way of this existing rail line, which would result in some small short-term construction-related impacts.

<u>Special Status Species</u>

Threatened and Endangered Species: There are no federally threatened, endangered, candidate or proposed species known to occur within the study area of the Department of Defense Branchline North, therefore there would be no impact.

BLM- and State of Nevada-designated Sensitive/Protected Species: There are no species that are known to occur within the study area of the Department of Defense Branchline South, except the loggerhead shrike and western burrowing owl which potentially occur within the study area of the entire Mina rail alignment. These potential impacts would be small and short-term due to avoidance of the area during construction of the siding; however, the area has been previously disturbed and these species do not likely nest within the footprint of the siding, therefore there would be no loss of habitat.

State of Nevada Game Species The existing rail line occurs within designated yearlong habitat for both mule deer and pronghorn antelope. Potential impacts would be small and short-term due to temporary avoidance of the area during the construction of the siding. Any potential impacts from operation of the rail line are discussed in Section 4.3.7.2.3.

Wild Horses and Burros There are no designated herd management areas that occur within the study area of the Department of Defense Branchline North. Therefore, there would be no impacts on wild horse and burros as a result of construction of the siding.

Table 4-218 summarizes potential impacts to biological resources that have the potential to occur within or near the existing Department of Defense Branchline North. Section 4.3.7.2.3 describes potential impacts during the operations phase.

Table 4-218. Summary of potential impacts to biological resources from constructing a siding along Department of Defense Branchline North.

Resource/impact type	Extent of impact
Wildlife	
Noise and human activity	Small impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Loggerhead shrike (*Lanius ludovicianus*)	Small impact due to avoidance
Western burrowing owl (*Athenes cunicularia*)	Small impact due to avoidance
State of Nevada game species	
Pronghorn antelope	Small impact due to avoidance
Mule deer	Small impact due to avoidance
Wild horses and burros	No impact

4.3.7.2.2.3 Schurz Alternative Segments, Rail Line Construction.

Vegetation The Schurz alternative segments, located primarily on the Walker River Paiute Reservation, would pass through several land-cover types. The dominant land-cover type that would be affected along all the Schurz alternative segments would be Inter-Mountain Basins Mixed Salt Desert Scrub, followed by Inter-Mountain Basins Greasewood Flat. Playas and sand dunes are common in this area, and some would likely be affected by the Schurz alternative segments. Sites of this type, depending on annual precipitation levels, support special status plants such as the Dune sunflower, oryctes, and Wassuk beardtongue. However, the areas through which the alternative segments would pass are disturbed and occupied (in some areas dominated) by noxious and invasive weeds such as halogeton *(Halogeton glomeratus),* Russian thistle *(Salsola kali),* and cheatgrass *(Bromus tectorum*). The extent of noxious and invasive weed colonizations in these areas makes it unlikely that special plant species would be present.

However, potential suitable habitat for special status plant species could be affected during construction along any of the Schurz alternative segments.

Schurz alternative segment 1 would result in a long-term impact to 1.03 square kilometers (254 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub and 0.18 square kilometer (44 acres) of Inter-Mountain Basins Greasewood Flat (see Table 4-215). The overall impact from the loss of this vegetation would be small because these are the predominant land-cover types and are abundant in the region.

Schurz alternative segment 4 would result in a long-term impact to 1.82 square kilometer (450 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub and 0.08 square kilometer (20 acres) of Inter-Mountain Basins Greasewood Flat (see Table 4-215). The impact from the loss of this vegetation would be small because these are the predominant land-cover types and are abundant in the region.

Schurz alternative segment 5 would pass on the south side of the Terrill Mountains and to the north of the Calico Hills through a narrow valley. There would be a long-term impact to 2.17 square kilometers (536 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub and 0.07 square kilometer (17 acres) of Inter-Mountain Basins Greasewood Flat (see Table 4-215). This would result in an overall small impact, if any, to the land-cover types given the current condition of the affected vegetative communities and the relatively small percentage of these land-cover types that would be affected within the Nellis mapping zone.

Schurz alternative segment 6 would result in a long-term impact to 2.34 square kilometers (578 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub and 0.07 square kilometer (17 acres) of Inter-Mountain Basins Greasewood Flat (see Table 4-215). This alternative segment would pass on the northwest side of the Terrill Mountains, which also supports some scattered patches of winterfat communities. Potential impact from the loss of this vegetation would be small to moderate due to the quality and value of the plant communities in that area.

Schurz alternative segments 1, 4, 5, 6, and a bridge over the Walker River could affect riparian and wetland vegetation communities. Schurz alternative segments 1 and 4 would run parallel to the Walker River for about 10 kilometers (6 miles) and would cause a long-term impact to less than 0.01 square kilometer (about 0.31 acre) of Great Basin Foothill and Lower Montane Riparian Woodland and Shrubland and would temporarily impact another 0.03 kilometers (6.4 acres [see Table 4-215]). DOE would use best management practices, comply with the requirements of the Clean Water Act, and reduce the construction footprint to as little as 8 to 20 meters (6 to 65 feet) within identified wetlands to minimize adverse impacts to riparian habitat. Rail line construction would not alter the natural flow or stream channel of the Walker River.

Wildlife Because of the potential impacts to riparian and wetland habitats described above, Schurz alternative segments 1 and 4 could result in direct impacts to various wildlife populations if wildlife avoided riparian or aquatic habitats close to construction activities. Most of the impact would be short-term (see Table 4-215) because construction would not alter the natural flow or stream channel characteristics of the Walker River. These potential impacts would be small. Other impacts to wildlife species would be similar to those described in Section 4.3.7.2.1.2.

Special Status Species

Threatened and Endangered Species: The Lahontan cutthroat trout has been documented in the Walker River downstream of the Weber Dam and in areas outside the rail line construction right-of-way. The species has been absent from areas upstream from the dam because it obstructs their seasonal migration. There is suitable habitat for Lahontan cutthroat trout upstream of the Weber Dam, which would be within the construction right-of-way for all of the Schurz alternative segments where they would cross the

Walker River. However, the species has been absent from this area for years because the dam obstructs upstream seasonal migration. Weber Dam is currently being renovated and will include a fish ladder that will enable Lahontan cutthroat trout to migrate north of the dam. Should this species return to the area upstream of the Weber Dam, there would be direct impacts to this threatened fish as a result of bridge construction across the Walker River. Short-term impacts would include pile-driving, the presence of timber mats in parts of the stream, and in-water work. This would cause turbidity and sedimentation downstream where potential Lahontan trout would migrate if the new fish ladder was in operation. DOE would apply appropriate best management practices and timing restrictions to minimize impacts to any Lahontan trout during bridge construction. These impacts would be small and short-term, and Lahontan cutthroat trout would be expected to recover within 3 years after the end of construction activities.

There is potential marginal foraging and roosting habitat for the southwestern willow flycatcher within the construction right-of-way along Schurz alternative segments 1 and 4 where they would parallel the Walker River. No occurrences of this species have been documented within the study area for these segments, but there is marginal habitat within the construction right-of-way. There would be direct impacts to the willow flycatcher due to the restriction of the habitat. There could be direct impacts in the form of noise disturbances to transient southwestern willow flycatchers during construction activities if the birds used habitat within the vicinity of active construction areas. Any noise disturbance impacts would be small given that there are no recorded occurrences for the southwestern willow flycatcher within the construction right-of-way for any of the Schurz alternative segments.

Habitat for the western yellow-billed cuckoo, a ***candidate species***, is similar to the habitat of the southwestern willow flycatcher. Potentially suitable habitat for this species is present along Schurz alternative segments 1 and 4 where they would parallel the Walker River. However, there are no documented occurrences of the western yellow-billed cuckoo within the construction right-of-way for any of the Schurz alternative segments. Therefore, there would be no direct impacts to the western yellow-billed cuckoo due to the destruction of habitat. There could be direct impacts in the form of noise disturbances to migratory western yellow-billed cuckoos during construction activities if the birds used habitat in the vicinity of active construction areas. However, these impacts would be small given that there are no recorded occurrences of the western yellow-billed cuckoo within the construction right-of-way for any of the Schurz alternative segments.

Potentially suitable nesting or winter roosting habitat for the bald eagle is present within the study area for Schurz alternative segments 1 and 4 where they would parallel the Walker River. However, there are no documented nest sites within the construction right-of-way of the Schurz alternative segments. Areas up and down river of Weber Dam, which is approximately 0.8 kilometer (0.5 mile) west of the Schurz alternative segments, have been reported to provide winter habitat for this species (DIRS 182302-Miller Ecological Consultants 2005, p. 3-35). If wintering or migrating eagles were in the area during construction activities, increased noise and human activity would likely deter them from using the area or would cause them to leave the area of disturbance. Any noise impacts are expected to be small and short-term, and would not affect the population of bald eagles in Nevada because this species does not nest or roost in the study area.

BLM- and State of Nevada-designated Sensitive/Protected Species: The western burrowing owl potentially occurs along the entire Mina rail alignment where suitable habitat is present. However, no burrowing owl nests have been documented within the study area. Potential impacts to this species from construction of the Schurz alternative segments would result from burrows used by nesting owls being covered over or collapsing during rail line construction. Burrowing owls occupy a wide range of habitat; therefore, any potential impact would be small and short-term.

White-faced ibis have been observed in the study area of Schurz alternative segments 1 and 4 below the Weber Dam on the Walker River. There could be direct impacts in the form of noise disturbances to white-faced ibis during construction activities if the birds used habitat in the vicinity during these activities. However, these impacts would be small given that there are no recorded occurrences of the ibis within the construction right-of-way for any of the Schurz alternative segments.

Swainson's hawks have been reported flying and roosting in the area around Weber Reservoir and Weber Dam (DIRS 182302-Miller Ecological Consultants 2005, p. 3-31) outside of the construction right-of-way of the Schurz alternative segments. No evidence of nesting was reported. There could be direct impacts in the form of noise disturbances to Swainson's hawks during construction activities if the birds used habitat in the vicinity of active construction areas. However, these impacts would be small and short-term given that this species would only be present as a transient and there are no recorded occurrences of the Swainson's hawk within the construction right-of-way for any of the Schurz alternative segments.

The loggerhead shrike is known to occur along the entire Mina rail alignment where suitable habitat is present. However, nest sites for this species have not been documented within the study area or construction right-of-way of the Schurz alternative segments. There could be direct impacts to this species as a result of increased noise and human activity or long-term removal of suitable habitat during construction of the Schurz alternative segments. These impacts would be small and short-term. Loggerhead shrikes occupy a wide range of habitat; therefore, there would be no long-term impacts to the population or viability of this species.

The river otter might occur in the Walker River or Weber Reservoir. There could be direct impacts to this species as a result of increased noise and human activity during rail line construction. These impacts would be small and short-term given that there are no reported occurrences of this species in the construction right-of-way and DOE does not expect to alter aquatic habitats.

There could be potential impacts to several bat species, listed in Table 3-133, during rail line construction as a result of a temporary increase of noise and human activity. However, these impacts would be small and short-term. No bats have been documented roosting within the construction right-of-way of the Schurz alternative segments.

Wassuk beardtongue has been observed on the east side of the Wassuk Range; but the Walker River and U.S. Highway 95 would be between the rail line and this population; thus, there would be no impact on this species population.

The nearest population of Orcytes is approximately 1.4 kilometers (0.8 mile) east of the southern terminus of Department of Defense Branchline South; there would be a small impact, if any, to this species population due to the potential loss of individual plants and suitable habitat during construction.

The dune sunflower has been observed 1.8 kilometers (1.1 miles) north of Schurz alternative segment 6, near U.S. Highway 95. However, impacts to suitable habitat would not be likely; therefore, there would be no impact on this species as result of construction of Schurz alternative segment 6. There is a documented occurrence of the dune sunflower about 0.8 kilometer (0.5 mile) from Schurz alternative segment 1. Potential habitat could be adversely affected, resulting in a small impact from construction of Schurz alternative segment 1; however, there would likely be no impact to occupied habitat.

There is potential habitat for Cima milkvetch in the Calico Hills and Terrill Mountains. This species typically occurs on slopes. Because the rail line would be constructed in the valley, impacts to this species would not be likely.

State of Nevada Game Species The Schurz alternative segments would not cross any documented game habitat.

Wild Horses and Burros The Horse Mountain Herd Management Area would be north of and adjacent to Schurz alternative segment 6. There are currently no wild horses or burros within this Herd Management Area due to recent modifications in the primary water source once used by herds (DIRS 181843-Axtell 2007, all). Therefore, there would be no impacts to wild horse and burros.

Table 4-219 summarizes potential impacts to biological resources that have the potential to occur within or near the Schurz alternative segments. Section 4.3.7.2 describes impacts during the railroad operations phase.

4.3.7.2.2.4 Department of Defense Branchline South (end of Schurz Alternative Segments to Mina Common Segment 1). This existing rail line would connect the Schurz alternative segments with Mina common segment 1. DOE would construct a siding along this existing branchline within the existing right-of-way, which would result in some small short-term construction-related impacts. However, most impacts would be a result of railroad operations and are described in Section 4.3.7.2.3.

Vegetation There would be no construction impacts to vegetation associated with this existing rail line. Operations impacts are described in Section 4.3.7.2.3.1.

Wildlife There would be direct impacts to various wildlife populations if wildlife avoided the area close to construction activities. These potential impacts would be small and short-term, because the area has been previously disturbed and the surrounding habitat provides habitat primarily for a suite of disturbance-tolerant species. Other impacts to wildlife species would be similar to those described in Section 4.3.7.2.1.2. Operations impacts are described in Section 4.3.7.2.3.2.

Special Status Species There would be no construction impacts to special status plants, because none are documented to occur in the construction right-of-way.

Threatened and Endangered Species There are no documented occurrences of federally listed plants or wildlife within the construction right-of-way; therefore, there would be no impacts to listed species within or near Department of Defense Branchline South.

BLM- and State of Nevada-Designated Sensitive and Protected Species The loggerhead shrike is known to occur along the entire Mina rail alignment where suitable habitat is present. Potential impacts to this species from the construction of a siding along this branchline would be small and short-term due to noise and the increase in human activity during construction. However, loggerhead shrikes occupy a wide range of habitat; therefore, there would be no long-term impacts to the population or viability of this species.

The western burrowing owl potentially occurs along the entire Mina rail alignment where suitable habitat is present. Potential impacts to this species from the construction of a siding along this branchline would be small and short-term due to noise and the increase in human activity during construction. However, burrowing owls occupy a wide range of habitat; therefore, there would be no long-term impact to the population or viability of this species.

Oryctes has previously been found 1.39 kilometers (0.86 mile) from the existing rail line; however, there were no observations of this species during the 2006 survey. No other BLM- or State of Nevada-designated species are documented to occur within the area. There would be no impact to this species as a result of construction of the siding. Any potential impacts to oryctes along Department of Defense Branchline South would occur from operation of the rail line (see Section 4.3.7.2.3.1).

Table 4-219. Summary of potential impacts to biological resources from rail line construction along the Schurz alternative segments.

Resource/impact type	Extent of impact, Schurz 1	Extent of impact, Schurz 4	Extent of impact, Schurz 5	Extent of impact, Schurz 6
Wildlife				
Loss of vegetation or land-cover type (long-term)	1.24 square kilometers[a]	1.92 square kilometers	2.27 square kilometers	2.45 square kilometers
Construction related disturbance vegetation or land cover type (short-term)	2.41	4.84 square kilometers	4.10 square kilometers	4.52 square kilometers
Loss of riparian and water related habitats (long-term)[b]	<0.01 square kilometer	<0.01 square kilometer	0	0
Construction related disturbance to riparian habitats (short-term)[b]	0.01 square kilometer	0.01 square kilometer	0.02 square kilometer	0.01 square kilometer

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined; < = less than.

State of Nevada Game Species There would be direct impacts to pronghorn antelope and mule deer if they avoided the area close to construction activities due to temporarily increased noise and visual disturbances. These potential impacts would be small and short-term. Operations impacts are described in Section 4.3.7.2.3.4.

Wild Horses and Burros There are no designated herd management areas adjacent to or intersecting Department of Defense Branchline South. Therefore, there would be no impacts to wild horses and burros associated with construction of a siding along this existing rail line.

Table 4-220 summarizes potential impacts to biological resources that have the potential to occur within or near the existing Department of Defense Branchline North.

4.3.7.2.2.5 Hawthorne Staging Yard, Facility Construction.

Vegetation Construction of the Staging Yard at Hawthorne would not result in any long-term impacts to vegetation. There would be a short-term impact to 2.2 square kilometers (544 acres) of Inter Mountain Basins Mixed Salt Desert Scrub and a long-term loss of 1.0 square kilometer (254 acres) of Inter Mountain Basins Mixed Salt Desert Scrub. The overall impact would be small because most of the land where DOE would construct the Staging Yard is currently disturbed.

Wildlife There would be direct impacts to various wildlife populations if wildlife avoided the area close to construction activities due to temporarily increased noise and human activity or the long-term loss of 1.0 square kilometer (254 acres) of salt desert scrub habitat. These potential impacts would be small and short-term, because the area has been previously disturbed and likely supports a disturbance-tolerant wildlife community. Other impacts to wildlife species would be similar to those described in Section 4.3.7.2.1.2. Operations impacts are described in Section 4.3.7.2.3.2.

Special Status Species

Threatened and Endangered Species: There are no documented occurrences of federally listed plants or wildlife within the study area; therefore, there would be no impacts to listed species within or near the Hawthorne Staging Yard.

Table 4-220. Summary of potential impacts to biological resources from constructing a siding along Department of Defense Branchline South.

Resource/impact type	Extent of impact
Wildlife	
Noise and human activity	Small impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM and State of Nevada-designated sensitive/protected species	
Loggerhead shrike (*Lanius ludovicianus*)	Small impact due to avoidance
Western burrowing owl (*Athenes cunicularia*)	Small impact due to avoidance
Oryctes *(Oryctes nevadensis)*	No impact
State of Nevada game species	
Pronghorn antelope	Small impact due to avoidance
Mule deer	Small impact due to avoidance
Wild horses and burros	No impact

BLM- and State of Nevada-Designated Sensitive or Protected Species: Potential impacts to loggerhead shrike and the western burrowing owl would be small and short-term due to the loss of potential habitat and potential displacement. Potential occupied and suitable habitat for oryctes could be affected as a result of constructing the Staging Yard. There are no other documented occurrences of BLM- or State of Nevada-designated sensitive or protected species.

State of Nevada Game Species There would be direct impacts to pronghorn antelope if they avoided the area close to construction activities due to temporarily increased noise and visual disturbances. These potential impacts would be small and short-term. Operations impacts are described in Section 4.3.7.2.3.4.

Wild Horses and Burros There are no designated herd management areas at or near the proposed Staging Yard location; therefore, there would be no impact to wild horses and burros.

Table 4-221 summarizes potential impacts to biological resources that have the potential to occur within or near the proposed Staging Yard location at Hawthorne.

4.3.7.2.2.6 Mina Common Segment 1, Rail Line Construction.

Vegetation Mina common segment 1 would result in a long-term impact to 2.45 square kilometers (605 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub. This land-cover type is typical of sandy and alkaline soils and is common throughout the Nellis mapping zone. A small amount of Inter-Mountain Basins Greasewood Flat (0.05 square kilometer [12 acres]) and Inter-Mountain Basins Semi-Desert Shrub Steppe vegetation (0.05 square kilometer) would also be affected in the long term. The proposed rail line would parallel U.S. Highway 95 and would be constructed on top of an historic rail roadbed in some areas. Overall impacts to the existing land-cover types would be small because the highway corridor currently fragments the vegetation, and DOE would reduce impacts to vegetation by utilizing the existing historic rail roadbed.

Mina common segment 1 would pass through Soda Spring Valley, which supports wetlands identified by the National Wetlands Inventory dataset, including the Alkali Flat and Soda Spring Valley playas. However, DOE field surveys did not identify these as wetlands. This area supports three separate locations of the Great Basin Foothill and Lower Montane Riparian Woodland and Shrubland land-cover type. It is highly unlikely that these land-cover types would be affected by rail line construction along Mina common segment 1, because they are not present within the construction right-of-way. Any potential impact to the associated playas would be short-term and occur within the ephemeral washes. DOE would minimize such impacts by incorporating appropriate drainage structures into the engineering design.

Wildlife Construction of Mina common segment 1 would create a long-term impact to 2.61 square kilometers (645 acres) of potential wildlife habitat, predominantly Inter-Mountain Basins Mixed Salt Desert Scrub land-cover type. However, much of the vegetation within this area is already disturbed. The disturbed habitat is of relatively low value to wildlife because it parallels U.S. 95 and lies adjacent to the Hawthorne Army Depot. Because species that use this habitat are likely disturbance-tolerant, impacts to wildlife from construction of Mina common segment 1 would be small, but long-term. The aquatic habitat at Soda Spring is of relatively high value because water is scarce in this part of the study area. Impacts to this habitat are expected to be moderate and long-term.

Special Status Species

Threatened and Endangered Species: The Railroad Valley spring fish, a ***threatened species***, has been documented to occur within the springs near Sodaville (Figure 3-213). However, the spring does not

Table 4-221. Summary of potential impacts to biological resources from construction of the Staging Yard at Hawthorne.

Resource/impact type	Extent of impacts
Wildlife	
Loss of vegetation or land cover type (long-term)	0.27 square kilometers[a]
Construction related disturbance vegetation or land cover type (short-term)	1.07 square kilometers
Loss of riparian and water related habitats (long-term)[b]	0
Construction related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Loggerhead shrike (*Lanius ludovicianus*)	Small impact to potential habitat
Western burrowing owl (*Athenes cunicularia*)	Small impact to potential habitat
Oryctes *(Oryctes nevadensis)*	Small impact to suitable habitat
State of Nevada game species	
Pronghorn antelope	Small impact
Wild horses and burros	No impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands/seeps/streams/and riparian combined.

occur within the construction right-of-way, therefore, there would be no impact on this species as a result of construction of Mina common segment 1.

BLM- and State of Nevada-Designated Sensitive or Protected Species: Common loons have been documented to occur on Walker Lake (DIRS 182302-Miller Ecological Consultants 2005 p. 3-32). Large numbers of loons stop at Walker Lake during the spring and fall migration (DIRS 182895-Boise State University 2007). Construction activities would not impact Walker Lake; therefore, there would be no impacts to common loons.

The Western snowy plover has been documented to occur within the study area near Walker Lake and the Hawthorne Army Depot. Because of the lack of specificity of some Nevada Natural Heritage Program data, it is not clear how close this observation was to the Mina common segment 1 construction right-of-way, but it might have been in the construction right-of-way or as far away as 2.8 kilometers (1.75 miles). This species is not federally listed in this part of its range. There could be direct impacts to the western snowy plover due to the destruction of habitat or the short-term increase of noise and human activity during construction if the birds used habitat in the vicinity during these activities. These impacts could be small and short-term to long-term depending on the level of use by this species in the construction right-of-way.

The western burrowing owl potentially occurs throughout the entire Mina rail alignment where suitable habitat is present. However, no burrowing owl nests have been documented within the study area. Potential impacts to this species from construction of Mina common segment 1 would result from burrows used by nesting owls being covered over or collapsing during rail line construction. Burrowing owls occupy a wide range of habitat. Therefore, there would be no long-term impacts to the population or viability of this species.

White-faced ibis likely occur at Walker Lake in Mina common segment 1 study area, although they have not been documented to breed there. There could be direct impacts in the form of noise disturbances to white-faced ibis during construction if the birds used habitat in the vicinity during these activities. However, these impacts would be small given that there are no recorded occurrences of the ibis within the construction right-of-way for Mina common segment 1 and construction would have no effect on Walker Lake.

The loggerhead shrike is known to occur throughout the entire Mina rail alignment where suitable habitat is present. Nest sites for this species have not been documented within the Mina common segment 1 study area or construction right-of-way. There could be direct impacts to this species as a result of increased noise and human activity or long-term removal of suitable habitat during rail line construction along Mina common segment 1. These impacts would be small and short-term; 2.61 square kilometers (645 acres) of potentially suitable habitat for this species would be removed. Loggerhead shrikes occupy a wide range of habitat; therefore, there would be no long-term impact to the population or viability of this species.

There could be potential impacts to several bat species, listed in Table 3-133, during rail line construction as a result of temporarily increased noise and human activity. However, these impacts would be small and short-term. No bats have been documented nesting or roosting within the Mina common segment construction right-of-way.

Tiehm buckwheat has been found in the vicinity of Mina common segment 1. However, it is highly unlikely individuals or any potential habitat for this species would be affected and there would be no impact.

Sodaville milkvetch is known to occur near Sodaville, 2.5 kilometers (1.5 mile) from Mina common segment 1. It is a wetland-dependent species and is likely associated with Soda Spring, which would not be affected by the rail line construction along Mina common segment 1. Therefore, there would be no impacts to this species.

Oryctes has been observed within the Soda Spring Valley north of Mina, 0.5 kilometer (0.3 mile) from Mina common segment 1. Occupied and suitable habitat could be altered or destroyed as a result of rail line construction along Mina common segment 1, resulting in a small impact to the population of this species. The alignment would impact less than 0.01 square kilometer (0.17 acre) of the Inter-Mountain Basins Active and Stabilized Dune land-cover type and would have a small impact on potential habitat for this species. There would be no impact on the viability of the population of this species.

State of Nevada Game Species There would be direct impacts to pronghorn antelope and mule deer if they avoided the area close to construction activities due to temporarily increased noise and visual disturbances. These potential impacts would be small and short-term. Operations impacts are described in Section 4.3.7.2.3.4.

Wild Horses and Burros Mina common segment 1 would run adjacent to the Pilot Mountain Herd Management Area (Figure 3-214). The rail line would not intersect designated wild horse and burro habitat, but the increased human activity during construction could cause herds to avoid the low-elevation areas associated with the proposed alignment. Given that the Pilot Mountain Herd Management Area encompasses about 1,937 square kilometers (477,985 acres), there would be small, if any, short-term impacts due to potential avoidance of the area during construction.

Table 4-222 summarizes the potential impacts to biological resources that have the potential to occur within or near Mina common segment 1.

Table 4-222. Summary of potential impacts to biological resources from construction of Mina common segment 1.

Resource/impact type	Extent of impact, Mina common segment 1
Wildlife	
Loss of vegetation or land cover type (long-term)	2.60 square kilometers[a]
Construction related disturbance vegetation or land cover type (short-term)	31.05 square kilometers
Loss of riparian and water related habitats (long-term)[b].	0
Construction related disturbance to riparian habitats (short-term)[b].	0
Wildlife water resources	Small
Special status species	
Threatened and endangered species and habitat	
Railroad Valley springfish (*Crenichthys nevadae*)	No impact
BLM- and State of Nevada-designated sensitive/protected species	
Bat species (see Table 3-133)	Small impact
Common loon (*Gavia immer*)	No impact
Western snowy plover *(Charadrius alexandrinus nivosus)*	Small impact
White-faced ibis *(Plegadis chihi)*	Small impact
Western burrowing owl (*Athenes pallidus*)	Small impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact
Sodaville milkvetch *(Astragalus lentiginosus var. sesquimetralis)*	No impact
Tiehm buckwheat *(Eriogonum tiehmii)*	No impact
Oryctes (Oryctes nevadensis)	Small impact
State of Nevada game species	
Pronghorn antelope	Small impact
Mule deer	Small impact
Wild horses and burros	Small to no impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands/seeps/streams/and riparian combined.

4.3.7.2.2.7 Garfield Hills Quarry, Quarry Construction.

Vegetation The proposed Garfield Hills quarry would result in a long-term impact to 0.99 square kilometer (245 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub. However, this area is sparsely vegetated and the overall impacts on vegetation would be small.

The quarry pit would be constructed within a series of ephemeral washes. There is no riparian vegetation within the washes. However, any ephemeral flows could be altered as a result of construction.

Wildlife Construction of the Garfield Hills quarry would remove approximately 0.99 square kilometer (245 acres) of potential wildlife habitat in the long-term, primarily Inter-Mountain Basins Mixed Salt Desert Scrub and a small percentage of Inter-Mountain Basins Big Sagebrush Shrubland. This habitat is sparsely vegetated and likely supports a disturbance-tolerant suite of wildlife species. Therefore, impacts from development of the quarry would be small, but long-term.

Special Status Species

Threatened and Endangered Species: There are no documented occurrences of federally listed plants or wildlife within the study area; therefore, there would be no construction impacts to listed species within or near the proposed Garfield Hills quarry. Operations impacts are described in Section 4.3.7.2.3.3.

BLM Special Status and State of Nevada Protected Species: The western burrowing owl potentially occurs throughout the entire Mina rail alignment where suitable habitat is present. However, no burrowing owl nests have been documented within the study area. Potential impacts to this species from construction of a quarry at Garfield Hills would result from burrows used by nesting owls being covered over or collapsing during quarry construction. Burrowing owls occupy a wide range of habitat; therefore, there would be no long-term impact to the population or viability of this species.

The loggerhead shrike is known to occur throughout the entire Mina rail alignment where suitable habitat is present. However, nest sites for this species have not been documented within the quarry footprint. There could be direct impacts to this species as a result of increased noise and human activity or long-term removal of suitable habitat during construction of a quarry at Garfield Hills. These impacts would be small and short-term because 0.99 square kilometer (244 acres) of potentially suitable habitat for this species would be removed. Loggerhead shrikes occupy a wide range of habitat; therefore, there would be no long-term impact to the population or viability of this species.

There could be potential impacts to several bat species, listed in Table 3-133, during construction of the proposed quarry as a result of temporarily increased noise and human activity, and long-term removal or modification of potential roosting habitat. However, these impacts would be small and short-term. No bats have been documented roosting within the quarry footprint.

There is good potential habitat for Wassuk beardtongue within the series of washes at the potential quarry site. However, the closest recorded occurrence of this species is outside the quarry study area. Therefore, it is unlikely that any individual plants would be affected, and this species has a wide distribution range. Thus there would be no impacts on this species population.

State of Nevada Game Species There would be no impacts to State of Nevada game species, as the Garfield Hills quarry would not cross any documented game habitat.

Wild Horses and Burros The proposed Garfield Hills quarry does not occur within any designated wild horse and burro management area. The closest Herd Management Area is the Garfield Herd Management Area to the south approximately 11 kilometers (7 miles). Therefore there would be no impact to wild horses and burros as a result of the construction and operation of the Garfield Hills Quarry.

Table 4-223 summarizes the potential impacts to biological resources that have the potential to occur within or near the proposed quarry. Operations impacts are discussed in Section 4.3.7.2.3.

Table 4-223. Summary of potential impacts to biological resources from construction of a quarry at Garfield Hills.

Resource/impact type	Extent of impact
Wildlife	
Loss of vegetation or land-cover type (long-term)	0.99 square kilometers[a]
Construction-related disturbance vegetation or land-cover type (short-term)	0.39 square kilometers
Loss of riparian and water-related habitats (long-term)[b]	0
Construction-related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Bat species (see Table 3-133)	Small impact
Western burrowing owl (*Athenes pallidus*)	Small impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact
Wassuk beardtongue (*Penstemon rubicundus*)	No impact
State of Nevada Game species	No designated game habitat within study area of quarry
Wild horses and burros	No impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands/seeps/streams/and riparian combined.

4.3.7.2.2.8 Gabbs Range Quarry, Quarry Construction.

Vegetation Construction of the potential Gabbs Range quarry would result in a long-term impact to 0.66 square kilometer (163 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub. There are also some scattered patches of winterfat that occur within and surrounding the proposed site. Potential impacts from the loss of a portion of the Inter-Mountain Basins Mixed Salt Desert Scrub land-cover type would be small. However, the loss of any winterfat community could result in a moderate impact because this vegetative cover is uncommon in the Nellis mapping zone and is considered highly valuable for wildlife.

There is no riparian or wetland vegetation present within the study area of the quarry, therefore, there would be no impact on riparian or wetland vegetation as a result of construction of the quarry site.

Special Status Species

Threatened and Endangered Species: There are no documented occurrences of federally listed plants or wildlife within the study area; therefore, there would be no construction impacts to listed species within or near the potential Gabbs Range quarry.

BLM- and State of Nevada-Designated Sensitive or Protected Species: Potential impacts to loggerhead shrike and western burrowing owl would be the same as those described in previous section for Garfield Hills Quarry.

Potential habitat for the Wassuk beardtongue occurs within and near the proposed quarry site; however, there are no known occurrences in the vicinity. There would be no impact on this species.

There could be potential impacts to several bat species, listed in Table 3-133, during construction of the proposed quarry as a result of a temporary increase of noise and human activity, and long-term removal or modification of potential roosting habitat. However, these impacts would be small and short-term. No bats have been documented roosting within the quarry footprint.

State of Nevada Game Species There would be direct impacts to pronghorn antelope if they avoided the area close to construction activities due to temporarily increased noise and visual disturbances. These potential impacts would be small and short-term because the area has been previously disturbed and provides habitat primarily for a suite of disturbance-tolerant species. Operations impacts are described in Section 4.3.7.2.3.4.

Wild Horses and Burros The potential Gabbs Range quarry site is within the Pilot Mountain Herd Management Area. Any potential impacts to wild horses and burros would be short-term as a result of the increase in human activity in the area, which could cause herds to avoid the area during construction and operations activities. The loss of vegetation from the quarry construction would not be likely affect available forage for herds, given that the Pilot Mountain Herd Management Area is relatively large, encompassing 1,937 square kilometers (477,985 acres) of higher-elevation shrub-steppe. There are several ***wildlife guzzlers*** in the area, but most occur northeast to east of the quarry site. The quarry would not interfere with any potential conduits to and from guzzlers within the herd management area.

Table 4-224 summarizes the impacts to biological resources that have the potential to occur within or near the potential quarry site. Operations impacts are described in Section 4.3.7.2.3.

4.3.7.2.2.9 Montezuma Alternative Segments, Rail Line Construction.

Vegetation Several different land-cover types would be affected as a result of the Montezuma alternative segments (Table 4-215).

Construction of Montezuma alternative segment 1 could result in long-term impacts to 2.42 square kilometers (598 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub, 0.21 square kilometer (52 acres) of Inter-Mountain Basins Playa, 0.3 square kilometer (74 acres) of Inter-Mountain Basins Big Sagebrush Shrubland, and 0.28 square kilometer (69 acres) of Great Basin xeric Mixed Sagebrush Shrubland (see Table 4-215); resulting in a small impact. This segment would parallel U.S. Highway 265 to Silver Peak, then parallel an alkali lake and existing road, which is surrounded by disturbed lands. Therefore, there would be minimal fragmentation of vegetation across the landscape, which would result in an overall small impact. There are also some patches of winterfat communities within the Montezuma Range (below the pinyon-juniper zone). Potential loss of this community type would result in a moderate impact given its infrequency and high value to wildlife within the Nellis mapping zone.

Construction of Montezuma alternative segment 2 could result in a long-term impact 2.29 square kilometers (566 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub, 23.58 square kilometers (350 acres) of Inter-Mountain Basins Greasewood Flat, and 0.33 square kilometer (82 acres) of Inter-Mountain Basins Big Sagebrush Shrubland (see Table 4-215). The overall impact as a result of construction would be small given the amount of these land-cover types within the Nellis mapping zone. This portion of the rail alignment would parallel U.S. Highway 95 and would leave the highway corridor,

Table 4-224. Summary of potential impacts to biological resources from constructing the potential Gabbs Range quarry.

Resource/impact type	Extent of impact
Wildlife	
Loss of vegetation or land cover type (long-term)	0.66 square kilometers[a]
Construction related disturbance vegetation or land cover type (short-term)	0.30 square kilometers
Loss of riparian and water related habitats (long-term)[b]	0
Construction related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Bat species (see Table 3-133)	Small impact
Western burrowing owl (*Athenes pallidus*)	Small impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact
Wassuk beardtongue (*Penstemon rubicundus*)	No impact
Greater sage-grouse	Small impact
State of Nevada game species	
Pronghorn antelope	Small impact
Wild horses and burros	Small impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

intersect the Montezuma Valley, and follow an abandoned rail roadbed, which would minimize potential adverse impacts from fragmentation. However, there is a large winterfat community in the Montezuma Valley; therefore, the overall impact from the construction of this segment in this area would be moderate due to the loss of vegetative community type.

Construction of Montezuma alternative segment 3 would create a long-term impact to 2.29 square kilometers (566 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub, 0.33 square kilometer (82 acres) of Inter-Mountain Basins Greasewood Flat, 0.90 square kilometer (222 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub, 0.14 square kilometer (35 acres) of Great Basin xeric Mixed Sagebrush Shrubland, and 2.08 square kilometers (514 acres) of Inter-Mountain Basins Big Sagebrush Shrubland (see Table 4-215). This portion of the rail alignment would parallel U.S. Highway 95 for 35 kilometers (22 miles) and would leave the highway corridor, intersect the Montezuma Valley, and follow an abandoned rail roadbed, which would minimize potential adverse impacts from fragmentation. However, there is a large winterfat community within the Montezuma Valley; therefore, the overall impact from the construction of this segment in this area would be moderate due to the loss of vegetative community type.

There is no riparian or wetland vegetation present within the study area therefore, there would be no impact on riparian or wetland vegetation as a result of construction of Montezuma alternative segments 1, 2, and 3.

Special Status Species

Threatened and Endangered Species: There are no threatened, endangered, candidate or proposed species known to occur within the study area of the Montezuma alternative alignments. Therefore, there would be no impact as a result of construction of any of the alternative segments.

BLM- and State of Nevada-Designated Sensitive or Protected Species: There is potentially suitable habitat for the pygmy rabbit within the study area of the Montezuma alternative segments including Inter-Mountain Basins Mixed Salt Desert Scrub and Inter-Mountain Basins Big Sagebrush Shrubland land-cover types. However, there are no known occurrences of this species within the study area. Construction of Montezuma alternative segments 1, 3 and 5 would result in a small, long-term impact due to the loss of potentially suitable habitat.

Potential long-term impacts to the pale kangaroo mouse and the dark kangaroo mouse would be small and due to the loss of potential suitable habitat from the construction of the Montezuma alternative segment 1, 2 and 3. Short-term impacts would result from avoidance of the active construction areas due to the temporary increase in noise and human presence in the area.

The ferruginous hawk has been observed near Montezuma alternative segments 2 and 3. Potential impact to this species would be small and short-term due to the increase in noise and human presence during construction. However, there would be no long-term impact because less than 0.01 square kilometer of pinyon-juniper habitat would be removed for construction of Montezuma alternative segment 1.

Potentially suitable habitat for the northern goshawk is present along Montezuma alternative segments 1 and 3 where they would intersect pinyon-juniper habitat. However, this species has not been documented in the study area. Potential impacts would result from removal of potential nesting or roosting habitat (trees) during rail line construction. However, it is likely that there would be no impact considering the amount of pinyon-juniper that would be removed compared to the amount within the area.

There could be potential impacts to several bat species, listed in Table 3-133, during construction of the Montezuma alternative segment 1, 2 and 3, as a result of a temporary increase of noise and human activity and long-term removal or modification of potential roosting or nesting habitat. However, these impacts would be small and short-term. No bats have been documented nesting or roosting within the construction right-of-way; however, there is ample suitable habitat for bats within the study area of all alternative segments and it is highly likely that bats occupy the area.

The long-term loss of Inter-Mountain Basins Big Sagebrush Shrubland and Great Basin Xeric Mixed Sagebrush Shrubland could adversely affect sagebrush dependant species such as Brewer's sparrow and sage thrasher. Overall impact would be small and short-term due to possible displacement, but potential impacts would also be long-term due to the loss of habitat.

Eastwood milkweed has been historically observed west of Tonopah about 8 kilometers (5 miles) from Montezuma alternative segments 2 and 3. It is possible that rail line construction could impact occupied and suitable Eastwood milkweed habitat. This would result in an overall small impact to this species due to reduced suitable habitat, potential loss of individuals, and the reduced opportunity for this species to expand its range.

There is potential habitat for Cima milkvetch within the southeast facing side of the Montezuma Range where there are multi-colored clay hills. Construction of either Montezuma alternative segment 1 or Montezuma alternative segment 3 could result in the loss of some potential habitat; however, there would likely be no impact on this species.

Pahute Mesa beardtongue has been documented within the Montezuma Range 5.5 kilometers (3.4 miles) from Montezuma alternative segments 2 and 3. It is possible that individual plants and suitable habitat for this species would be adversely affected as a result of rail line construction along Montezuma alternative segments 2 and 3. However, the overall impact would be small and would not affect the viability of this species because there is ample suitable habitat in the area.

There is potential habitat for Nevada dune beardtongue near Montezuma alternative segments 2 and 3 along the portion from Blair Junction to Lone Mountain. There are some patches of vegetated dunes along this route. There would likely be no impact on this species because there are no known occurrences in the construction right-of-way and no occurrences in the study area.

State of Nevada Game Species Short-term direct impacts to pronghorn antelope and mule deer would result due to construction activities and the temporary increased noise and visual disturbance. In addition, there would be a loss of foraging habitat. However, these impacts would be small as a result of constructing all alternative segments considering these land-cover types relative to the amount within the entire Nellis mapping zone. Montezuma alternative segment 1 would cross some greater sage grouse habitat. The impact from construction would be small.

Wild Horses and Burros Montezuma alternative segment 1 would run to the east of and adjacent to the Silver Peak Herd Management Area. The Montezuma alternative segments would be within and adjacent to the Montezuma Peak Herd Management Area. Due to current starvation and genetics issues, all horses were removed from the Silver Peak Herd Management Area. Therefore, impacts to wild horses and burros would be negligible..

Table 4-225 summarizes potential impacts to biological resources that have the potential to occur within or near the alternative segments. Operations impacts are described in Section 4.3.7.2.3.5.

4.3.7.2.2.10 Klondike Option - Maintenance-of-Way Facility, Facility Construction.

Impacts to biological resources associated with development of the Klondike option for the Maintenance-of-Way Facility would be similar to those discussed above for Montezuma alternative segments 2 and 3. Refer to Table 4-217 for short-term and long-term impacts to land-cover types from construction of this facility.

4.3.7.2.2.11 North Clayton Quarry, Quarry Construction.

Vegetation Construction of the potential North Clayton quarry would have a long-term impact on 0.95 square kilometer (235 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub and 0.28 square kilometer (69 acres) of Inter-Mountain Basins Big Sagebrush Shrubland.

This land-cover type and its existing good condition in the area of the potential quarry site support wildlife habitat and wild horse and burro habitat. Therefore, the overall impact would be moderate due to the loss of this vegetative cover and fragmentation.

There is no riparian or wetland vegetation present within the study area of the quarry.

Table 4-225. Summary of potential impacts to biological resources from rail line construction along the Montezuma alternative segments.

Resource/impact type	Extent of impact, Montezuma 1	Extent of impact, Montezuma 2	Extent of impact, Montezuma 3
Wildlife			
Loss of vegetation or land-cover type (long-term)	3.23 square kilometers[a]	2.32 square kilometers	2.96 square kilometers
Construction-related disturbance vegetation or land cover type (short-term)	31.61 square kilometers	31.50 square kilometers	41.57 square kilometers

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

Special Status Species

Threatened and Endangered Species: There are no documented occurrences of federally listed plants or wildlife within the study area.

BLM- and State of Nevada-Designated Sensitive or Protected Species: Potentially suitable habitat for the ferruginous hawk may occur within the footprint of the potential quarry. Potential impacts to this species would be small and short-term due to the removal of 1.39 square kilometers (343 acres) of potential foraging habitat.

Potentially suitable habitat for the northern goshawk is present along Montezuma alternative segments 1 and 3 where it intersects with Great Basin Pinyon-Juniper Woodland habitat. However, this species has not been documented in the study area. Potential impacts would result from removal of potential foraging habitat during construction of the quarry. This impact would be small because this species is dependent on woodland habitats, which are not within the footprint of the proposed quarry site.

There could be potential impacts to several bat species, listed in Table 3-133, during construction of the quarry as a result of a temporary increase of noise and human activity and long-term removal or modification of potential roosting habitat. However, these impacts would be small and short-term. No bats have been documented roosting within the quarry footprint; however, there is ample suitable habitat for bats within the study area and it is highly likely that bats occupy the area.

State of Nevada Game Species There would be short-term direct impacts to pronghorn antelope and mule deer if they avoided the area close to construction activities due to the temporary increased noise and visual disturbances. In addition, there would be a long-term impact due to a loss of potential forage habitat. However, these impacts would be small considering the amount of land-cover type affected in relation to the amount within the entire Nellis mapping zone. Operations impacts are addressed in Section 4.3.7.2.3.4.

Wild Horses and Burros The potential North Clayton quarry would be constructed within the Montezuma Peak Herd Management Area. A 2006 BLM census flight located 58 wild horses and 18 burros in the herd management area. Construction of this quarry could result in a small impact due to the small loss of available forage and the short-term avoidance of the area during construction and operations activity.

Table 4-226 summarizes potential impacts to biological resources that have the potential to occur within or near the potential North Clayton quarry. Operations impacts are described in Section 4.3.7.2.3.

4.3.7.2.2.12 Silver Peak Option - Maintenance-of-Way Facility, Facility Construction.

Impacts to biological resources associated with construction of the Maintenance-of-Way Facility at Silver Peak would be similar to those discussed above for Montezuma alternative segment 1. Refer to Table 4-217 for a quantification of short-term and long-term impacts to land-cover types from construction of this facility.

4.3.7.2.2.13 Malpais Mesa Quarry, Quarry Construction.

Vegetation Construction of the potential Malpais Mesa quarry would result in a long-term impact to 1.16 square kilometers (287 acres) of Inter-Mountain Basins Big Sagebrush Shrubland and 0.73 square kilometer (180 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub. The overall impact would be moderate due to the loss of this vegetative cover and fragmentation of habitat.

There is no riparian or wetland vegetation present within the study area of the quarry; therefore, there would be no impact on riparian or wetland vegetation as a result of constructing a quarry at this site.

Table 4-226. Summary of potential impacts to biological resources from construction of the North Clayton quarry.

Resource/impact type	Extent of impact
Wildlife	
Loss of vegetation or land cover type (long-term)	1.39 square kilometers[a]
Construction related disturbance vegetation or land cover type (short-term)	0.39 square kilometer
Loss of riparian and water related habitats (long-term)[b].	0
Construction related disturbance to riparian habitats (short-term)[b].	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Bat species (see Table 3-133)	Small impact
Western burrowing owl (*Athenes pallidus*)	Small impact
Northern goshawk (*Accipiter gentiles*)	Small impact
Ferruginous hawk *(Buteo regalis)*	Small impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact
State of Nevada game species	
Pronghorn antelope	Small impact
Mule deer	Small impact
Wild horses and burros	Small impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

Special Status Species

Threatened and Endangered Species: There are no documented occurrences or suitable habitat for any federally listed or candidate species within the study area of the proposed quarry site.

BLM- and State of Nevada-Designated Sensitive or Protected Species: Potential impacts to bat species would result from disturbance or alteration of mineshafts, caves, talus slopes with cracks, crevices, and cliff faces during cut and fill or quarry operations. The overall impact on bats would be short-term and small due to temporary avoidance during construction activities.

State of Nevada Game Species There is no designated habitat for State of Nevada game species within the proposed quarry footprint. However, designated mule deer yearlong habitat occurs adjacent to the proposed quarry site, and designated pronghorn antelope yearlong habitat occurs to the north approximately 8 kilometers (5 miles) (Figures 3-222 and 3-223). Potential impacts would be due to avoidance of the area because of an increase in noise during construction activity.

Wild Horses and Burros Impacts on wild horses and burros would be the same as described in Section 4.3.7.2.2.11 for the North Clayton Quarry.

Table 4-227 summarizes potential impacts to biological resources that have the potential to occur within or near the potential Malpais Mesa quarry. Operation impacts are discussed in Section 4.3.7.2.3.

Table 4-227. Summary of potential impacts to biological resources from construction of the Malpais Mesa quarry

Resource/impact type	Extent of impacts
Wildlife	
Loss of vegetation or land-cover type (long-term)	2.09 square kilometers[a]
Construction-related disturbance vegetation or land-cover type (short-term)	0.54 square kilometers
Loss of riparian and water-related habitats (long-term)[b]	0
Construction related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Bat species (see Table 3-133)	Small impact
Western burrowing owl (*Athenes pallidus*)	Small impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact
State of Nevada game species	
Pronghorn antelope	Small impact due to avoidance
Mule deer	Small impact due to avoidance
Wild horses and burros	No impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands/seeps/streams/and riparian combined.

4.3.7.2.2.14 ES-7 Quarry, Quarry Construction.

Vegetation Construction of potential quarry ES-7 would result in a long-term impact to 0.55 square kilometer (136 acres) of Inter-Mountain Basins Big Sagebrush Shrubland, 0.34 square kilometer (84 acres) of Great Basin Xeric Mixed Sagebrush Shrubland, and 0.24 square kilometer (59 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub. Sagebrush communities are highly valuable within the Nellis mapping zone; therefore, the overall impact would be moderate due to the loss of this vegetative cover and fragmentation of habitat.

There is no riparian or wetland vegetation present within the study area of the quarry; therefore, there would be no impact on riparian or wetland vegetation as a result of construction of the quarry site.

Special Status Species

Threatened and Endangered Species: There are no documented occurrences or suitable habitat for any federally listed or candidate species within the study area of the proposed quarry site.

BLM- and State of Nevada-Designated Sensitive or Protected Species: There could be potential impacts to bat species from constructing the proposed Goldfield Quarry which would include the disturbance or alteration of mineshafts, caves, talus slopes with cracks, crevices, and cliff faces during cut and fill or quarry operations. Potential impacts to bat habitats from construction activities would be small.

Potential impacts to the loggerhead shrike would result from the long-term loss of potential suitable habitat. The impact would be small since this species would be temporarily displaced, and there is ample suitable habitat throughout the region.

Potential impacts to the Western burrowing owl would result from loss of potential suitable habitat and possible crushing of burrows. Potential impact would be small since this species occupies various land-cover types throughout the region.

There would be a loss of potential suitable habitat for the dark kangaroo mouse and the pale kangaroo mouse; however, there are no documented occurrences of this species within the construction right-of-way therefore potential impact would be small.

State of Nevada Game Species The proposed quarry ES-7 would cross year-round mule deer habitat (see Figure 3-222). Potential impacts to this species would include long-term loss of habitat and increased noise and human activity. However, these impacts would be expected to be small because year-round mule deer habitat is abundant in the area, and the quarry would affect only a small portion of this habitat.

Wild Horses and Burros Impacts on wild horses and burros would be the same as described in Section 4.3.7.2.2.11 for the North Clayton quarry.

Table 4-228 summarizes potential impacts to biological resources that have the potential to occur within or near potential quarry ES-7.

4.3.7.2.2.15 Mina Common Segment 2 (Stonewall Flat Area), Rail Construction.

Vegetation Mina common segment 2 would pass primarily through Inter-Mountain Basins Mixed Salt Desert Scrub, creating a long-term impact to 0.06 square kilometer (15 acres) of this land-cover type. It would pass through a small portion of Inter-Mountain Basins Big Sagebrush Shrubland (less than 0.01 square kilometer), which is relatively common in the area and could provide habitat for various sagebrush community-obligate species. The amount of vegetation loss in these land-cover types associated with construction of Mina common segment 2 would be small in relation to the amount of these land-cover types that exist within the mapping zone. Therefore, the potential impacts of this loss of vegetative communities would be small. Construction of Mina common segment 2 would not impact any riparian or wetland vegetation.

Wildlife There would be direct impacts to various wildlife populations if wildlife avoided habitats close to construction activities. Any potential impact would be small and short-term. Other impacts to wildlife species would be similar to those described in Section 4.3.7.2.1.2.

Special Status Species

Threatened and Endangered Species: There are no documented occurrences of federally listed plants or wildlife within the study area; therefore, there would be no impacts to listed species within or near Mina common segment 2.

BLM- and State of Nevada-Designated Sensitive or Protected Species: Although there are no documented occurrences of special status species in the common segment 2 study area, there is a potential for some to be present, and thus affected by, rail line construction along Mina common segment 2. These are summarized in Table 4-229.

State of Nevada Game Species There would be no impacts to State of Nevada game species because Mina common segment 2 would not cross any designated game habitat.

Table 4-228. Summary of potential impacts to biological resources from construction of potential quarry ES-7.

Resource/impact type	Extent of impact
Wildlife	
Loss of vegetation or land-cover type (long-term)	1.13 square kilometers[a]
Construction-related disturbance vegetation or land-cover type (short-term)	0.32 square kilometers
Loss of riparian and water related habitats (long-term)[b]	0
Construction related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Bat species (see Table 3-133)	Small impact to potential habitat
Western burrowing owl (*Athenes pallidus*)	Small impact to potential habitat
Loggerhead shrike (*Lanius ludovicianus*)	Small impact to potential habitat
Pale kangaroo mouse *(Microdipidops pallidus)*	Small impact to potential habitat
Dark kangaroo mouse *(Microdipidops megacephalus albiventer)*	Small impact to potential habitat
State of Nevada game species	
Mule deer	Small impact to potential habitat
Pronghorn antelope	Small impact to potential habitat
Wild horses and burros	Small impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

Wild Horses and Burros Mina common segment 2 would pass through the Stonewall Herd Management Area. Potential impacts to burros in the Stonewall Herd Management Area would be similar to those described in Section 4.3.7.2.1.5, but would occur in a different area. Burro population estimates indicate that as many as 34 resident burros could be affected.

Table 4-229 summarizes impacts to biological resources along Mina common segment 2.

4.3.7.2.2.16 Bonnie Claire Alternative Segments, Rail Line Construction. Table 4-230 summarizes potential direct impacts to biological resources from rail line construction along the Bonnie Claire alternative segments.

Vegetation The area of the Bonnie Claire alternative segments represents a transition in vegetative communities. Sagebrush communities occur less frequently as the rail alignment progresses south to southeast into the Mojave mapping zone.

Table 4-229. Summary of potential impacts to biological resources from rail line construction along Mina common segment 2.

Resource/impact type	Extent of impact
Wildlife habitat	
Loss of vegetation or land-cover type (long-term)	0.06 square kilometers[a]
Construction-related disturbance vegetation or land-cover type (short-term)	0.99 square kilometers
Loss of riparian and water related habitats (long-term)[b]	0
Construction related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat present
BLM- and State of Nevada-designated sensitive/protected species	
Bat species (see Table 3-133)	Small impact
Western burrowing owl (*Athenes pallidus*)	Small impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact
State of Nevada game species	No impact
Wild horses and burros	Small impact

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps/streams, and riparian areas combined.

Construction of the Bonnie Claire alternative segment 2 could result in long-term impacts to 0.02 square kilometers (5 acres) of Inter-Mountain Basins Big Sagebrush Shrubland 0.20 square kilometers (49 acres) of Inter-Mountain Basins Mixed Salt Desert Scrub, .06 square kilometers (15 acres) of Inter-Mountain Basins Semi-Desert Shrub Steppe, 0.15 square kilometers (37 acres) of Mojave Mid-Elevation Mixed Desert Scrub, 0.05 square kilometers (12 acres) of Sonora-Mojave Creosotebush-White Bursage Desert Scrub, and 0.02 square kilometers (5 acres) of Sonora-Mojave Mixed Salt Desert Scrub. Construction of the Bonnie Claire alternative segment 3 could result in long-term impacts to less than 0.01 square kilometers (2 acres) of Inter-Mountain Basins Big Sagebrush Shrubland, 0.14 square kilometers (35 acres) of Inter-Mountain Basin Mixed Salt Desert Scrub, .07 square kilometers (17 acres) of Inter-Mountain Basin Semi-Desert Shrub Steppe, 0.13 square kilometers (32 acres) of Mojave Mid-Elevation Mixed Desert Scrub, 0.13 square kilometers (32 acres) of Sonora-Mojave Creosotebush-White Bursage Desert Scrub, and less than .01 square kilometers (2 acres) of Sonora-Mojave Mixed Salt Desert Scrub (see Section 3.3.7 and Table 4-215).

Rail line construction along the Bonnie Claire alternative segments would not impact any riparian or wetland vegetation.

Table 4-230. Summary of potential impacts to biological resources from rail line construction along the Bonnie Claire alternative segments.

Resource/impact type	Extent of impact, Bonnie Claire 2	Extent of impact, Bonnie Claire 3
Wildlife		
Loss of vegetation or land-cover type (long-term)	0.51 square kilometers[a]	0.49 square kilometers
Construction-related disturbance to habitat (short-term)	5.65 square kilometers	5.59 square kilometers
Loss of riparian and water-related habitats (long-term)[b]	0	0
Construction-related disturbance to riparian habitats (short-term)[b]	0	0
Wildlife water resources	No impact	No impact
Special status species		
Threatened and endangered species and habitat	No species or habitat occurrence	No species or habitat occurrence
BLM- and State of Nevada-designated sensitive/protected species		
Loggerhead shrike (*Lanius ludovicianus*)	Small impact to potential habitat	Small impact to potential habitat
Western burrowing owl (*Athenes cunicularia*)	Small impact to potential habitat	Small impact to potential habitat
Bat species (see Table 3-133)	Small impact to potential habitat	Small impact to potential habitat
Nevada Game Species		
Mule deer	Small impact	Small impact
Pronghorn antelope	Small impact	Small impact
Wild horses and burros	Small impact to potential habitat	Small impact to potential habitat

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

Special Status Species

Threatened and Endangered Species: There are no threatened, endangered, candidate or proposed species that occur within the study area of the Bonnie Claire alternative segments.

BLM- and State of Nevada-Designated Sensitive or Protected Species: As summarized in Table 4-230, there would be small impacts to BLM- and State of Nevada-designated sensitive and protected species from rail line construction along the Bonnie Claire alternative segments.

State of Nevada Game Species As summarized in Table 4-230, there would be small potential impacts to game species along the Bonnie Claire alternative segments.

Wild Horses and Burros The Bonnie Claire alternative segments would pass through the Stonewall Herd Management Area. Potential impacts to the herd management area and the wild horses and burros would be a small loss of vegetation for foraging.

4.3.7.2.2.17 Common Segment 5 (Sarcobatus Flat Area), Rail Line Construction. Table 4-231 summarizes potential direct impacts to biological resources from rail line construction along common segment 5.

Vegetation As discussed in Section 3.3.7 and shown in Table 4-214, common segment 5 would pass through a small area of Great Basin Juniper Woodland, which would be temporarily affected during rail line construction activities. This land-cover type is relatively common on the lower mountain slopes in the area and likely provides roosting and nesting habitat for some raptors. Construction of common segment 5 could result in long-term impacts to 0.04 square kilometers (10 acres) of Inter-Mountain Basins Semi-Desert Shrub Steppe, 0.09 square kilometers (22 acres) of Mojave Mid-Elevation Mixed Desert Scrub, 0.23 square kilometers (57 acres) of Sonora-Mojave Creosotebush-White Bursage Desert Scrub, and 0.44 square kilometers (109 acres) of Sonora-Mojave Mixed Salt Desert Scrub. The potential impacts on these land-cover types would be small because the amount of vegetation loss associated with rail line construction along common segment 5 would be small in relation to the amount of these land-cover types within the mapping zone. Common segment 5 would affect a small portion of Inter-Mountain Basins Big Sagebrush Shrubland, which provides habitat for various sagebrush community-obligate species.

Rail line construction along common segment 5 would not impact any riparian or wetland vegetation.

Special Status Species

Threatened and Endangered Species: There are no threatened, endangered, candidate or proposed species that occur within the study area of common segment 5.

BLM- and State of Nevada-Designated Sensitive or Protected Species: As summarized in Table 4-231, there would be small impacts to BLM- and State of Nevada-designated sensitive and protected species from rail line construction along common segment 5. Habitat for burrowing owl and loggerhead shrike are present along common segment 5 and are discussed in section 4.3.7.2.1, Environmental Impacts Common to the Entire Mina Rail Alignment. Some isolated sand dunes provide habitat for the Nevada dune breadtonge (*Penstemon arenarius*). Rail line construction would create a small impact to the habitat. Occasional stands of pinion juniper provide habitat for the ferruginous hawk (Buteo regalis). Impacts to this species would be small and short-term. Habitat for the Oasis Valley speckled dace is confined to streams in southern Nye County. Impacts to potential habitat for this species would be small and short-term due to the proposed construction of a bridge across Oasis Valley speckled dace is confined to steams in southern Nye County. Impact to potential habitat for this species would be small and short-term due to the proposed construction of a bridge across Oasis Valley that would temporarily increase turbidity in the stream. After construction, the impact would be minimal.

State of Nevada Game Species There is designated pronghorn antelope yearlong habitat to the north of the rail alignment in the Gold Flat area (see Figure 3-223). Potential impacts, if any, to antelope as a result of rail line construction along common segment 5 would be small. Common segment 5 would pass near desert bighorn sheep and mule deer yearlong habitat. It is possible that desert bighorn sheep and mule deer would pass through the area of the rail line, which along common segment 5 would be adjacent to an existing transportation corridor (U.S. Highway 95). Although it is likely that desert bighorn sheep and mule deer use this area during migration, there are no designated game ***movement corridors*** along or near common segment 5. Thus, impacts to these species would be small and short-term, primarily from avoidance of the area during construction activities.

Table 4-231. Summary of potential impacts to biological resources from rail line construction along common segment 5.

Resource/impact type	Extent of impact, common segment 5
Wildlife[a]	
Loss of vegetation or land-cover type (long-term)	0.81 square kilometer[a]
Construction-related disturbance to habitat (short-term)	11.12 square kilometers
Loss of riparian and water-related habitats (long-term)[b]	0
Construction-related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	No species or habitat occurrence
BLM- and State of Nevada-designated sensitive/protected species	
Loggerhead shrike (*Lanius ludovicianus*)	Small impact to potential habitat
Western burrowing owl (*Athenes cunicularia*)	Small impact to potential habitat
Ferruginous hawk (*Buteo regalis*)	Small impact to potential habitat
Bat species (see Table 3-133)	Small impact to potential habitat
Nevada dune beardtongue (*Penstemon arenarius*)	Small impact to potential habitat
Oasis Valley speckled dace (*Rhinichthys osculus* ssp. 6)	Small impact to potential habitat
State of Nevada game species	
Pronghorn antelope	Small impact due to avoidance
Bighorn sheep	Small impact due to avoidance
Mule deer	Small impact due to avoidance
Wild horses and burros	Small impact to potential habitat

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

Wild Horses and Burros Common segment 5 would not pass through any wild horse and burro herd management areas. However, burro activity in the region is likely based on local utilization patterns. Potential impacts to wild horses and burros would be small.

4.3.7.2.2.18 Oasis Valley Alternative Segments, Rail Line Construction. Table 4-232 summarizes potential direct impacts to biological resources from rail line construction along the Oasis Valley alternative segments.

Vegetation There is wetland and riparian habitat present within the study area of the Oasis Valley alternative segments. Oasis Valley alternative segments 1 and 3 would cross the Thirsty Canyon/Oasis

Table 4-232. Summary of potential impacts on biological resources from rail line construction along the Oasis Valley alternative segments.

Resource/impact type	Extent of impacts, Oasis Valley 1	Extent of impacts, Oasis Valley 3
Wildlife		
Loss of vegetation or land-cover type (long-term)	0.31 square kilometer[a]	0.43 square kilometer
Construction-related disturbance to habitat (short-term)	2.62 square kilometer	3.95 square kilometer
Loss of riparian and water-related habitats (long-term)[b]	0	0
Construction-related disturbance to riparian habitats (short-term)[b]	0	0.02
Wildlife water resources	No impact	No impact
Special status species		
Threatened and endangered species and habitat	No species or habitat occurrence	No species or habitat occurrence
BLM- and State of Nevada-designated sensitive/protected species		
Black woollypod (*Astragalus funereus*)	Small impact to species and potential habitat	Small impact to species and potential habitat
Loggerhead shrike (*Lanius ludovicianus*)	Small impact to potential habitat	Small impact to potential habitat
Western burrowing owl (*Athenes cunicularia*)	Small impact to potential habitat	Small impact to potential habitat
Oasis Valley speckled dace (*Rhinichthys osculus* spp. [unnamed])	No impact	No impact
Oasis Valley pyrg (*Pyrgulopsis micrococcus*)	No impact	No impact
Amargosa toad (*Bufo nelsoni*)	No Impact	No impact
Bat species (see Table 3-133)	Small impact to potential habitat	Small impact to potential habitat
State of Nevada game species		
Mule deer	Small impact	Small impact
Desert bighorn sheep	Small impact	Small impact
Wild horses and burros	Small impact to potential habitat	Small impact to potential habitat

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

Valley Wash area. Oasis Valley alternative segment 3 would run within 0.7 kilometer (0.4 mile) of Colson Pond and across the Amargosa River drainage (see Section 3.3.5.3.11).

The Amargosa River receives ephemeral flows during high precipitation events; it does not carry water most of the year. There would be no impacts to Colson Pond and engineering design would include appropriate structures (a culvert and bridge) to reduce impacts to the Amargosa River drainage. Within the Oasis Valley alternative segment 3 construction right-of-way, construction activities would temporarily impact 0.02 square kilometer (4.67 acres) of the North American Warm Desert Lower Montane Riparian Woodland and Shrubland land-cover type.

Potential impacts would be short-term from rail line construction along this Oasis Valley alternative segment 3, which would only cross this land-cover type. Given the small amount of this land-cover type within the mapping zone and its high value for wildlife, the impacts on riparian and wetland vegetation would be moderate, but short-term. However, DOE would use drainage structures and best management practices to minimize erosion, runoff, and the subsequent impacts to riparian vegetation along the Oasis Valley alternative segments.

Construction of Oasis Valley alternative segment 1 could result in long-term impacts to 0.02 square kilometers (5 acres) of Inter- Mountain Basis Semi-Desert Shrub Steppe, 0.01 square kilometers (2 acres) of Mojave Mid-Elevation Mixed Desert Scrub, 0.02 square kilometers (5 acres) of North American Warm Desert Playa, 0.22 square kilometers (54 acres) of Sonora-Mojave Creosotebush-White Bursage Desert Scrub, 0.22 square kilometers (7 acres) of Sonora-Mojave Mixed Salt Desert Scrub. Construction of Oasis Valley alternative segment 3 could result in long-term impacts to 0.02 square kilometers (5 acres) of Mojave Mid-Elevation Mixed Desert Scrub, less than 0.01 square kilometers (2 acres) of North American Warm Desert Playa, 0.31 square kilometers (22 acres) of Sonora-Mojave Mixed Salt Desert Scrub.

Special Status Species

Threatened and Endangered Species: There are no threatened, endangered, candidate or proposed species that occur within the study area of the Oasis Valley alternative segments.

BLM- and State of Nevada-Designated Sensitive or Protected Species: The black woollypod, a ***BLM-designated sensitive*** plant ***species***, is known to occur along the Beatty Wash section of common segment 6. The closest known occurrence of this species is 0.3 kilometer (0.2 mile) from common segment 6. Construction of the Oasis Valley alternative segments could result in small impacts due to loss of suitable habitat and possible individuals present during construction.

However, black woollypod appears to adapt well to disturbed areas, thus, anticipated impacts to this species habitat and population would be small from rail line construction along the Oasis Valley alternative segments. The Oasis Valley speckled dace occurs in the Amargosa River drainage and Fleur de Lis Spring near the towns of Springdale and Beatty, less than 1.6 kilometers (1 mile) southwest from Oasis Valley alternative segment 1. This subspecies has a very limited range and is only known from this watershed in Oasis Valley. Specific distribution of this fish varies with available water. Because of the distance of this habitat from construction activities, there should be no impacts to this to the Oasis Valley speckled dace during rail line construction.

The Oasis Valley pyrg is an ***endemic*** snail of the springs found in Oasis Valley. This species has not been documented closer than 4 kilometers (2.5 miles) from the rail alignment and suitable habitat for this species would not occur within the construction right-of-way. Therefore, rail line construction would not impact this species.

The Amargosa toad occurs along the Amargosa River drainage and has been recorded in Oasis Valley, 1.4 kilometers (0.84 mile) from Oasis Valley alternative segment 1 and 1.9 kilometers (1.2 miles) from Oasis Valley alternative segment 3. Typical habitat for this species is near open water, such as springs, seeps and ponds, and the riparian vegetation generally associated with wet areas. In these instances, the presence of moist soil might be sufficient for suitable habitat. There are no open waters that would be within the construction right-of-way, and all seeps and springs within Oasis Valley and Thirsty Canyon would be outside and down gradient of the construction right-of-way. Therefore, it is unlikely that the Amargosa toad would occur within the construction right-of-way.

State of Nevada Game Species The Oasis Valley alternative segments would pass within mule deer limited range (see Figure 3-222) and would be near designated desert bighorn sheep yearlong habitat (see Figure 3-221). Oasis Valley supports riparian vegetation and ephemeral flows that are highly valuable as a potential water source and for forage. Colson Pond, which also provides a potential water source for these species, is 0.7 kilometer (0.4 mile) from Oasis Valley alternative segment 3. However, impacts from rail line construction along the Oasis Valley alternative segments would be very small and very short-term.

Wild Horses and Burros The Oasis Valley alternative segments would pass through northern portions of the Bullfrog Herd Management Area. Potential impacts to the herd management area and the wild horses and burros would be small losses of vegetation for foraging and grazing.

4.3.7.2.2.19 Common Segment 6 (Yucca Mountain Approach), Rail Line Construction.

Table 4-233 summarizes potential direct impacts to biological resources (vegetation, threatened and ***endangered species***, special status species, State of Nevada big game, and wild horses and burros) from rail line construction along common segment 6.

Vegetation As discussed in Section 3.3.7 and shown in Table 4-214, common segment 6 would pass through mostly Sonora-Mojave Creosotebush-White Bursage Desert Scrub and Mojave Mid-Elevation Mixed Desert Scrub. Construction of common segment 5 could result in long-term impacts to 0.24 square kilometers (59 acres) of Inter-Mountain Basin Semi-Desert Shrub Steppe, 0.38 square kilometers (94 acres) of Mojave Mid-Elevation Mixed Desert Scrub, less than .01 square kilometers (2 acres) of North American Warm Desert Bedrock Cliff and Outcrop, less than .01 square kilometer (about 1 acre) of North American Warm Desert Playa, 1 square kilometer (247 acres) of Sonora-Mojave Creosotebush-White Bursage Desert Scrub, and less than 0.01 square kilometers (2 acres) of Sonora-Mojave Mixed Salt Desert Scrub.

Rail line construction along common segment 6 would not impact wetland vegetation.

Special Status Species

Threatened and Endangered Species: Common segment 6 would be in an area of low-density desert tortoise habitat (the northernmost extent of the desert tortoise range), and the extent of habitat loss would result in small impacts.

The potential for desert tortoise to occur or be encountered in the common segment 6 construction right-or-way would be low. The overall impact on the desert tortoise as a result of constructing a rail line and facilities along common segment 6 would be small.

Construction of the proposed rail line, well sites, and construction camps along common segment 6 would result in the potential for species fragmentation, potential species loss, and disturbance of desert tortoise habitat along the southwestern section of common segment 6 from Beatty south to Yucca Mountain (see Figure 3-213). The rail line would not cross any areas of U.S. Fish and Wildlife Service-designated critical habitat. Potential direct impacts to desert tortoises during construction activities could include tortoise injury or mortality from being buried in their burrows or being crushed by construction equipment or other vehicles on access roads. Although these losses would cause a small decrease in the number of individual tortoises in the vicinity of the rail line, there would be no long-term impacts to the survival of this species. Indirect impacts would result from the fragmentation of habitat. A total of 5.61 square kilometers (1,387 acres) of desert tortoise habitat would be disturbed by rail line and facilities construction along common segment 6 (see Table 4-234).

Table 4-233. Summary of potential impacts on biological resources from rail line construction along common segment 6.

Resource/impact type	Extent of impacts, common segment 6
Wildlife	
Loss of vegetation or land-cover type (long-term)	1.63 square kilometers[a]
Construction-related disturbance to habitat (short-term).	13.24 square kilometers
Loss of riparian and water-related habitats (long-term)[b]	0
Construction-related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	
Desert tortoise (*Gopherus agassizii*)	Small impact to species and habitat
BLM- and State of Nevada-designated sensitive/protected species	
Black woollypod (*Astragalus funereus*)	Small impact to species and habitat
Rock purpusia (*Ivesia arizonica* var. *saxosa*)	No impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact to habitat
Western burrowing owl (*Athenes cunicularia*)	Small impact to habitat
Oasis Valley speckled dace (*Rhinichthys osculus* spp. [unnamed])	No impact
Oasis Valley pyrg (*Pyrgulopsis micrococcus*)	No impact
Amargosa toad (*Bufo nelsoni*)	No impact
Chuckwalla (*Sauromalus ater*)	Small impact to habitat
Bat species (see Table 3-133)	Small impact to habitat
Impacts to State of Nevada game species	
Desert bighorn sheep (*Ovis canadensis*)	Moderate, short-term impact to migration corridor
Mule deer	Small impact to habitat
Wild horses and burros	Small impact to forage habitat and avoidance

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

BLM- and State of Nevada-designated Sensitive/Protection Species: The black woollypod, a BLM-designated sensitive plant species, is known to occur along the Beatty Wash portion of common segment 6. The closest known occurrence of this species is 0.3 kilometer (0.2 mile) from common segment 6. Rail line construction along common segment 6 could result in small impacts from the loss of suitable habitat and individual plants. However, black woollypod appears to adapt well to disturbed areas; thus anticipated impacts to this species habitat and population would be small. In addition, DOE would implement best management practices (see Chapter 7) to avoid or minimize plant mortality.

Table 4-234. Amount of desert tortoise habitat that would be disturbed during construction of the rail line and facilities along common segment 6.

Source of disturbance	Amount of habitat disturbed (square kilometers)[a,b]
Rail roadbed and adjacent access roads	4.45
Access road to Beatty Wash bridge and well site 14	0.04
Access road to well site 15	<0.01
Construction camp 12	0.10
Access road to construction camp 12	0.20
Rail Equipment Maintenance Yard	0.81
Total	5.61

a. To convert square kilometers to acres, multiply by 247.10.
b. < = less than.

Rock purpusia has been documented approximately 13 kilometers (8 miles) from common segment 6. The loss of a small percentage (less than 0.01 square kilometer [about 1 acre]) of the North American Warm Desert Bedrock Cliff and Outcrop land-cover type would be a long-term impact as a result of rail line construction along common segment 6. There would be possible loss of suitable habitat (rock crevices and cliffs); however, there would be no impact on this species.

There is suitable habitat for the Amargosa toad in Oasis Valley west of common segment 6. This common segment would not cross any suitable habitat; thus, impacts to this species would be highly unlikely. However, any potential impact to this species would be limited to the northern portion of common segment 6 where it would connect to the Oasis Valley alternative segments (see Section 4.3.7.2.2.16).

Habitat for the Oasis Valley speckled dace is found in the neighboring Oasis Valley. It is unlikely that speckled dace exist in the area that would be crossed by common segment 6 due to lack of persistent streams of ponds. Therefore, no impacts to speckled dace would occur. The Oasis Valley pyrg requires habitat similar to the speckled dace and no impact is expected for this segment.

Chuckwalla have been documented in the southeastern foothills of Yucca Mountain adjacent to common segment 6. This area represents the chuckwalla's northern-most range in southern Nevada. Construction activities in this area could result in the loss of habitat for this species and possible loss of individuals. This would be a small overall impact to this species.

State of Nevada Game Species Common segment 6 would intersect a designated desert bighorn sheep migratory corridor near Beatty Wash (see Figure 3-221). There is also yearlong desert bighorn sheep habitat southwest of common segment 6. Impacts would be moderate, but mostly short-term, due to possible displacement from the designated migratory corridor during construction activities. There is also mule deer habitat along common segment 6 (see Figure 3-222). Impacts to mule deer habitat would be small.

Wild Horses and Burros Common segment 6 would pass through central portions of the Bullfrog Herd Management Area. Impacts to the herd management area and any wild horses and burros in the area would be similar – a small loss of vegetation for grazing. Burro activity south of Beatty Wash and in the Crater Flat area would likely shift temporarily to other locations farther away from the disturbance of human activity. Burro population estimates for this area suggest that 34 burros could be affected. There are no known populations of wild horses along common segment 6.

4.3.7.2.2.20 Common Segment 6 (Yucca Mountain Approach), Facilities Construction. Table 4-235 summarizes potential direct impacts to biological resources (vegetation, threatened and endangered species, special status species, State of Nevada big game, and wild horses and burros) from construction of facilities along common segment 6.

Vegetation The Rail Equipment Maintenance Yard would occupy an area of 0.41 square kilometer (100 acres). There are several different land-cover types in the area, but most of the land cover is Sonora-Mojave Creosotebush-White Bursage Desert Scrub. Construction of the Rail Equipment Maintenance Yard would impact 0.24 square kilometer (60 acres) in the long term and 0.44 square kilometer (108 acres) in the short term.

Special Status Species

Threatened and Endangered Species: Potential impacts to the desert tortoise would be similar to those described in Section 4.3.7.2.2.17. Construction of the Rail Equipment Maintenance Yard would result in a loss of tortoise habitat (see Table 4-234); however, areas of critical habitat would not be affected. The increase in human activity in the area would increase the risk of vehicle collisions with tortoise on access roads. Although these losses would cause a small decrease in the number of individual tortoises in the vicinity of this facility, there would be no impacts to the long-term survival of this species. Therefore, potential impacts to the desert tortoise as a result of the facility would be small.

Potential impacts to special status species would be similar to the impacts described in Section 4.3.7.2.2.17.

State of Nevada Game Species The Rail Equipment Maintenance Yard would be within mule deer limited range (see Figure 3-222). Potential impacts would be similar as those described in Section 4.3.7.2.1.5. Potential impacts would be small due to the infrequent occurrence of mule deer in the area. However, any existing mule deer would likely avoid the area due to increased human activity and noise.

Wild Horses and Burros Potential impacts to wild horses and burros would be similar to the impacts described in Section 4.3.7.2.2.17.

4.3.7.2.3 Operations Impacts Common to the Entire Mina Rail Alignment

4.3.7.2.3.1 Vegetation. DOE would expect activities during the railroad operations to remain within the operations right-of-way or disturbed areas after construction was complete; therefore, there would be no ongoing operations impacts to land-cover types. There could be long-term impacts in the form of a changed use of the land-cover types from construction of the rail roadbed, access roads, and all associated facilities, as described above in Section 4.3.7.2.1.1.

Wetland/Riparian Habitat DOE would not expect railroad operations activities to result in continuing land-disturbing activities outside of areas disturbed and developed during the construction phase. For this reason, DOE would expect no additional direct loss of wetland or riparian habitat during operations activities. However, wetlands and riparian habitat adjacent to the proposed rail line or associated facilities could be affected in the event of a train derailment resulting in the spill of diesel fuel into these habitats. The likelihood of and the severity of impacts from such spills would be small because DOE would implement best management practices to help prevent such occurrences (see Chapter 7).

Noxious Weeds and Invasive Species DOE would not anticipate additional direct habitat disturbances during railroad operations. However, continued use of the rail line, facilities, and the associated access roads would continue to provide a mechanism for dispersal of seeds and rootable fragments of invasive and noxious plant species.

Table 4-235. Summary of potential impacts on biological resources from constructing facilities along common segment 6.

Resource/impact type	Extent of impact
Wildlife	
Loss of vegetation or land-cover type (long-term)	0.30 square kilometer[a]
Construction-related disturbance to habitat (short-term)	0.61 square kilometer
Loss of riparian and water-related habitats (long-term)[b]	0
Construction-related disturbance to riparian habitats (short-term)[b]	0
Wildlife water resources	No impact
Special status species	
Threatened and endangered species and habitat	
Desert tortoise (*Gopherus agassizii*)	Small impact to species and habitat
BLM- and State of Nevada-designated sensitive/protected species	
Black woollypod (*Astragalus funereus*)	Small impact to species and potential habitat
Rock purpusia (*Ivesia arizonica* var. *saxosa*)	No impact
Loggerhead shrike (*Lanius ludovicianus*)	Small impact to habitat
Western burrowing owl (*Athenes cunicularia*)	Small impact to habitat
Oasis Valley speckled dace (*Rhinichthys osculus* spp. [unnamed])	No impact
Oasis Valley pyrg (*Pyrgulopsis micrococcus*)	No impact
Amargosa toad (*Bufo nelsoni*)	No impact
Chuckwalla (*Sauromalus ater*)	Small impact to habitat
Bat species (see Table 3-133)	Small impact to habitat
State of Nevada game species	
Desert bighorn sheep (*Ovis canadensis*)	Small impact to habitat
Mule deer	Small impact to habitat
Wild horses and burros	Small impact to forage habitat

a. To convert square kilometers to acres, multiply by 247.10.
b. Total includes wetlands, seeps, streams, and riparian areas combined.

Similar to best practices utilized in the construction phase, during the operations phase DOE would implement best management practices and BLM-prescribed and -approved methods to prevent the establishment of noxious weeds or invasive plant species (see Chapter 7).

4.3.7.2.3.2 Wildlife. Potential direct impacts to wildlife from railroad operations collisions with trains could occur during the operations phase. DOE estimates that approximately 17 one-way trains per week would utilize the track during the operations phase. While some individual animals could be lost from collisions with trains, the impact on wildlife communities would be small. Because some wildlife species in the area are often more active at night, nighttime collisions with trains would be possible if the trains were to operate during the night. Again, DOE would expect small impacts to the nocturnal wildlife communities.

Construction of communication towers, bridges, or any other structures that would provide raptors, crows (*Corvus brachyrhynchos*), and ravens (*Corvus corax*) with additional perches would increase predation pressure on the local small animal populations such as reptiles, rodents, and small birds. This could result in a potential negative indirect impact on the small animals, but a positive indirect impact on the predatory species. Some long-term structures, such as bridges, if designed to include bat roosting and hibernation sites, could provide additional habitat resulting in positive indirect impact to bat species.

Noise from trains would disturb wildlife species close to the rail line throughout the operations phase of the project. However, this disturbance would diminish with distance from the track and over time because some wildlife species would become acclimated to daily disturbances from passing trains. Noise from the trains and human presence at facilities associated with the rail line could cause wildlife species to move away from the tracks during the period of disturbance (short-term avoidance) and possibly cause changes in migratory patterns (long-term displacement).

Wildlife habitat and associated species adjacent to the proposed rail line or facilities could be affected in the event of a train derailment resulting in the spill of diesel fuel into these habitats. Forage, prey species, nesting and spawning habitat, and sources of drinking water could become contaminated. This potential impact would have greater ramifications for aquatic species. The likelihood of and the severity of impacts from such spills would be small because DOE would implement best management practices to help prevent such occurrences (see Chapter 7).

4.3.7.2.3.3 Special Status Species.

Threatened and Endangered Species General impacts to vegetation and wildlife from railroad operations addressed above under Sections 4.3.7.2.3.1 and 4.3.7.2.3.2 also apply to the threatened and endangered species described below.

Railroad operations would result in potential short-term impacts to southwestern willow flycatchers and western yellow-billed cuckoos in the form of noise from passing trains and human activities if these species used habitat within the vicinity during these activities. However, these impacts would be small given that there are no recorded occurrences and only marginal suitable migratory habitat for the flycatcher and cuckoo along the Mina rail alignment. Further, the area where potentially suitable habitat for these species occurs is near the existing Union Pacific Hazen Branchline and existing roads, and therefore, these species would likely already be acclimated to such disturbances.

Railroad operations would result in potential short-term and long-term disturbances to bald eagles. If bald eagles were present in the vicinity of the rail line when a train passed through or in the vicinity of facilities when people were present, the noise and presence of humans could startle the eagles or deter them from using the area for the duration of the disturbance; however, these impacts would be expected to be very small.

No impacts are expected to the Railroad Valley springfish during the operations phase because habitat for this species is far from the operations right-of-way and would not be disturbed.

Potential impacts to desert tortoises from habitat fragmentation would be small. Although there is no available documentation of tortoise behavior related to rail lines, it is possible that desert tortoises could use culverts installed within washes under the rail line to cross from one side of the rail line to the other.

Utility lines, buildings, or communication towers installed to support railroad operations might provide additional nesting and perching sites for the common raven, a frequent predator of juvenile tortoises. Therefore, the presence of these structures could increase juvenile tortoise mortality.

BLM- and State of Nevada-Designated Sensitive and Protected Species Potential impacts to vegetation and special status plants associated with railroad operations would be from the possible introduction of invasive plant species by trains or maintenance vehicles. Invasive species could take hold in disturbed areas and essentially out-compete native species for resources. Potential impacts to vegetation could also result in the event of train derailment and possible associated spill of diesel fuel. The likelihood of and the severity of impacts from such spills would be small because DOE would implement best management practices to help prevent such occurrences (see Chapter 7).

Any active sage-grouse mating and nesting areas located close to the Mina rail alignment would be adversely affected by noise and vibration from the daily operations and maintenance activities during the breeding season. This could result in reduced nesting success especially during the incubation period when birds would be frightened from their nests, exposing the eggs to predation. However, only one historic sage-grouse lek was identified in the construction right-of-way. DOE surveyed the area on May 13, 2005, for signs of recent use or individual birds, but there was no evidence that sage grouse still occupy the area even though suitable habitat was present at the time. Therefore, there would be no impacts on sage-grouse breeding and nesting areas during the operations phase, unless sage grouse were to occupy this area in the future.

In general, passing trains would initially disturb BLM special status and state protected wildlife close to the rail line. However, this disturbance would diminish with distance from the track and over time as animals became acclimated to daily disturbances. Individual animals could occasionally be killed or injured in collisions with trains. Nevertheless, impacts to animals near the rail line would be small because of the infrequency of trains using the rail line.

Operation of facilities associated with the rail line would create a potential disturbance to BLM special status and state protected wildlife species due to the presence of humans and associated noise. This could result in short-term avoidance of an area or lead to long-term displacement, depending on the degree of disturbance.

Habitat for BLM special status and state protected wildlife species and associated species adjacent to the proposed rail line or associated facilities could be affected in the event of train derailment resulting in the spill of diesel fuel into these habitats. Forage, prey species, nesting and spawning habitat, and sources of drinking water could become contaminated. This potential impact would have greater ramifications for aquatic species. The likelihood of and the severity of impacts from such spills would be small because DOE would implement best management practices to help prevent such occurrences (see Chapter 7).

Nevada State Protected Cacti, Yucca, and Conifers There would be no impacts to cacti, yucca, or conifers as a result of railroad operations.

Migratory Birds Impacts to migratory bird species during the operations phase would be limited to potential disturbances from passing trains (noise and vibration), facility operations, and maintenance activities. Impacts such as altered behavior and nest abandonment could occur initially. However, noise and vibration disturbances would diminish with distance from the track, and over time, birds could become acclimated to daily disturbances.

In the event of a train derailment resulting in the spill of diesel fuel into surrounding vegetation, foraging habitat, prey species, and water sources for migratory birds could be adversely affected. The likelihood of and the severity of impacts from such spills would be small because DOE would implement best management practices to help prevent such occurrences (see Chapter 7).

4.3.7.2.3.4 State of Nevada Protected Game Species. Direct impacts to game species during the operations phase would consist of long-term habitat loss within the construction right-of-way. Game species habitat would be affected in the long-term in areas where DOE would construct the proposed rail line and associated roads and facilities. Direct impacts to game species in the form of collisions with trains would also occur during the operations phase. It is estimated that approximately 17 one-way trains per week would utilize the track during the operations phase. Again, mortality rates from collisions would not be expected to be sizeable because game animals are fairly agile and would usually be able to move out of the way of oncoming trains. While some individual animals could be lost from collisions with trains, the impact on game communities would be small. Noise from trains would disturb game species close to the rail line throughout the operations phase of the project; however, this disturbance would diminish with distance from the track and over time as the game species became acclimated to daily disturbances from passing trains. Noise from the trains could cause game species to move away from the tracks and possibly cause changes in migratory patterns before game species became acclimated to the noise. The rail roadbed itself would represent an attractive nuisance to antelope, because they prefer a vantage point from which to survey the surrounding areas for predators. However, as noted above, antelope are agile and would usually be able to avoid oncoming trains. The finished rail line would bisect game habitat and movement corridors. However, because the rail line would not be fenced, once the animals became acclimated to the presence of the rail line they would be able to move freely across the rail line and impacts to game movements would be small.

Operation of support facilities would create a potential disturbance to game species due to the presence of humans and associated noise. This could result in short-term avoidance or long-term displacement of game species from the area.

In the rare event of a possible train derailment resulting in the spill of diesel fuel into surrounding vegetation, foraging habitat, and sources of drinking water could become contaminated. The likelihood of and the severity of impacts from such spills would be small because DOE would implement best management practices to help prevent such occurrences (see Chapter 7).

4.3.7.2.3.5 Wild Horses and Burros. Direct impacts to wild horses and burros during the operations phase would consist of long-term habitat loss where the footprints of the rail line and associated maintenance roads would intersect herd management areas. There would also be potential direct impacts to wild horses and burros in the form of collisions with trains. DOE estimates that approximately 17 one-way trains per week would utilize the rail line during the operations phase. Again, death rates from collisions are not expected to be sizeable because wild horses and burros are fairly agile and would usually be able to move out of the way of oncoming trains. While some individual animals could be lost from collisions with trains, the impact on wild horse and burro communities would be small. Noise from trains could disturb wild horses and burros close to the rail line throughout the operations phase of the project; however, this disturbance would diminish with distance from the track and over time the wild horses and burros would become acclimated to daily disturbances from passing trains. Noise from the trains could cause wild horses and burros to move away from the tracks and possibly cause changes in migratory patterns. However, because the rail line would not be fenced, once the animals became acclimated to its presence they would be able to move freely across the rail line. Therefore, potential impacts to wild horse and burro movements, as discussed in Section 4.3.7.2.3.5, would be small.

4.3.7.3 Impacts under the Shared-Use Option – Mina Rail Alignment

The Shared-Use Option would require construction of commercial sidings and facilities. All such construction would be immediately adjacent to the rail line and would have impacts similar to those under the Proposed Action without shared use. The Shared-Use Option would mean an increase in train traffic. Therefore, DOE would expect special status species, State of Nevada game species, and wild horse and burro interactions with train traffic (collisions, change in movement patterns, altered behavior, and nest abandonment) to be slightly larger than those interactions with rail traffic under the Proposed Action without shared use. This slight increase in train traffic would result in small impacts to the wildlife communities.

4.3.7.4 Summary

Table 4-236 summarizes potential impacts to biological resources from constructing and operating the proposed rail line along the Mina rail alignment.

Adverse impacts to vegetation communities would be small in relation to the abundance of the vegetation communities in the region, with minimal loss of unique or particularly sensitive communities. There would be impacts to wetlands and riparian habitats from construction of Schurz alternative segments 1 and 6; however, impacts would be mostly short-term during construction of a bridge across the Walker River. There could be impacts to wetlands in the vicinity of Mina common segment 1 and Oasis Valley alternative segment 1 from rail line construction. However, during rail line final design, DOE would make slight adjustments to minimize such impacts. Potential adverse impacts related to noxious and invasive species would include increased risk of these species becoming established in disturbed areas and encroaching on adjacent undisturbed habitat. DOE would implement best management practices (see Chapter 7) and BLM-prescribed and -approved methods to prevent the establishment of noxious weeds or invasive plant species.

Although impacts to wildlife habitats and individual populations could occur as a result of the rail line construction, impacts would be small and would not impact the continued existence of any wildlife species.

There would be the potential for impacts to threatened or endangered species during rail line construction. Potential impacts to desert tortoise would be small. DOE would implement best management practices to protect this species (see Chapter 7).

Localized and minor loss of roosting and foraging habitat for the southwestern willow flycatcher and western yellow-billed cuckoo could occur as a result of the Proposed Action. However, since these species do not nest along the rail alignment, impacts would be small and limited to transient individuals.

Habitat for several special status species would be disturbed and individuals of several of the species could be disturbed, injured, or killed from the construction and operation of the proposed rail line and associated facilities. Potential impacts to federally listed species would likely require consultation with the U.S. Fish and Wildlife Service in accordance with Section 7 of the Endangered Species Act.

Overall, there would be a loss of conifer habitat and individual conifer trees. There would also likely be a net loss of cacti and yucca along the proposed rail line.

Table 4-236. Summary of potential impacts to biological resources from constructing and operating the railroad along the Mina rail alignment (page 1 of 6).

Segment/ facility	Land cover (square kilometers)		Introduction/ proliferation of noxious/ invasive weeds		Wetlands/ riparian habitat (square kilometers)[a]		Threatened and endangered species		Special status species		Herd management areas/ Nevada game species

a. To convert square kilometers to acres, multiply by 247.10.

Overall, potential impacts to migratory birds would be short-term noise disturbances during construction and long-term habitat loss during the operations phase. These impacts would not have an adverse impact on migratory birds.

Although there would be impacts to game habitats and potential impacts to individuals or populations from constructing the proposed rail line, impacts would be small and would not significantly impact the continued existence of game species.

Although there would be impacts to herd management areas and potential impacts to individuals or wild horse and burro populations from constructing the proposed rail line along the Mina rail alignment, impacts would be small and would not significantly impact the management strategies utilized within the herd management areas.

Direct impacts to wildlife, wild horses and burros from the operation of the rail line would consist of potential collisions of wildlife with trains and short-term disruption of activities (such as foraging, nesting, and resting) due to the disturbance from noise caused by passing trains and from noise and presence of humans at rail facilities. Direct impacts would also include potential contamination of forage, prey species, nesting and spawning habitat, and sources of drinking water in the rare event of train derailment and associated spill of diesel fuel. Indirect impacts could include possible changes to predator/prey interactions due to the construction of towers and other structures that would provide new perch habitat for raptors and other predatory birds.

4.3.8 NOISE AND VIBRATION

This section describes potential noise and vibration impacts from constructing and operating a railroad along the Mina rail alignment. Section 4.3.8.1 describes the methodology DOE used to assess potential impacts; Section 4.3.8.2 describes potential construction impacts. Section 4.3.8.3 describes potential operations impacts; Section 4.3.8.4 describes potential impacts under the Shared-Use Option. Section 4.3.8.5 summarizes potential impacts from noise and vibration.

Section 3.3.8.1 describes the region of influence for the analysis of noise and vibration impacts along the Mina rail alignment. Appendix I, Noise and Vibration Impact Assessment Methodology, provides more information on the fundamentals of analyzing noise.

4.3.8.1 Impact Assessment Methodology

The approach for analyzing potential noise impacts is based on measurements of current ***ambient noise*** levels (see Section 3.3.8.2), noise modeling for future activities (proposed railroad construction and operations), and identification of changes in noise levels that receptors within the region of influence would experience.

To establish a baseline for determining if there would be an increase in noise, DOE measured ambient noise in the study area at five representative locations along the rail alignment: Silver Springs, Schurz, Mina, Silver Peak, and Goldfield (see Section 3.3.8.2). DOE chose these locations because they are representative of the few populated areas near the existing Union Pacific Railroad Hazen Branchline and the Mina rail alignment.

DOE used several criteria to determine the level of potential impacts from noise and vibration along the rail alignment. For noise impacts from construction activities, DOE used U.S. Department of Transportation, Federal Transit Administration, methods (DIRS 177297-Hanson, Towers, and Meister 2006, all) and construction noise guidelines listed in Table 4-237.

Table 4-237. Federal Transit Administration construction noise guidelines.[a,b]

Land use	8-hour L_{eq} (dBA) Day	8-hour L_{eq} (dBA) Night	30-day average DNL (dBA)
Residential	80	70	75[c]
Commercial	85	85	80[d]
Industrial	90	90	85[d]

a. Source: DIRS 177297-Hanson, Towers, and Meister 2006, p. 12-8.
b. dBA = A-weighted decibels; DNL = ***day-night average noise level***; L_{eq} = equivalent sound level.
c. In urban areas with very high ambient noise levels (DNL greater than 65 dBA), DNL from construction projects should not exceed existing ambient + 10 dBA.
d. Twenty-four hour L_{eq}, not DNL.

For operation of trains during the construction and operations phases, DOE analyzed noise impacts under established STB criteria. The STB has environmental review regulations for noise analysis (49 CFR 1105.7e(6)), with the following criteria:

- An increase in noise exposure as measured by DNL of 3 dBA or more
- An increase to a noise level of 65 DNL or greater

If the estimated noise-level increase at a location would exceed either criterion, the STB then estimates the number of affected noise-***sensitive receptors*** (such as schools, libraries, residences, retirement communities, and nursing homes). The two components (3 dBA increase, 65 DNL) of the STB criteria are implemented separately to determine an upper bound of the area of potential noise impact. However, current noise research indicates that both criteria must be met to cause an adverse noise impact (DIRS 173225-STB 2003, p. 4-82). That is, noise levels would have to be greater than or equal to 65 DNL and increase by 3 dBA or more for an adverse noise impact to occur.

The approach for analyzing potential vibration impacts is based on estimates of project-generated vibration and measurements of current ambient vibration conditions (see Section 3.3.8). To evaluate potential vibration impacts from construction and operation activities, DOE used Federal Transit Administration building vibration damage and human annoyance criteria. Under these criteria, if vibration levels exceeded 80 VdB (human annoyance criterion for infrequent events) or if the vibration levels (measured as ***peak particle velocity***) exceeded 0.20 inch per second for fragile buildings or 0.12 inches per second for extremely fragile historic buildings, then there could be a vibration impact (DIRS 177297-Hanson, Towers, and Meister 2006, all). Appendix I provides more information on the vibration metrics used in this study.

Day-night average noise level (DNL): The energy average of A-weighted decibels (dBA) sound level over 24 hours; includes an adjustment factor for noise between 10 p.m. and 7 a.m. to account for the greater sensitivity of most people to noise during the night. The effect of nighttime adjustment is that one nighttime event, such as a train passing by between 10 p.m. and 7 a.m., is equivalent to 10 similar events during the day.

A-weighted decibels (dBA): A measure of noise level used to compare noise from various sources. A-weighting approximates the frequency response of the human ear.

To establish a baseline for determining if there would be an increase in vibration, DOE measured ambient vibration in the study area at five representative locations: Silver Springs, Schurz, Mina, Silver Peak, and Goldfield (see Section 3.3.8).

4.3.8.2 Construction Impacts

Noise and vibration levels created by construction equipment vary greatly depending on such factors as the type of equipment, the specific model, the operation being performed, and the condition of the equipment. In addition, the proximity of the equipment to noise- and vibration-sensitive locations, duration of the activity, and time of day will influence the effects of construction noise and vibration. The results of this assessment reflect the ***uncertainty*** about the exact details of construction activities that would be required. However, the analysis assumes extreme combinations of equipment and operations known at this time that conservatively estimate upper-bound construction noise and vibration levels.

4.3.8.2.1 Construction Noise

The Federal Transit Administration construction noise analysis method suggests using the two noisiest pieces of equipment to estimate noise levels at sensitive locations (DIRS 177297-Hanson, Towers, and Meister 2006, p. 12-7). For this analysis, DOE used heavy trucks and bulldozers as the two noisiest pieces of equipment, based on the types of construction equipment that would be needed (DIRS 176170-Nevada Rail Partners 2006, Appendix B). There would be no pile driving near populated areas, so no pile-driving noise analysis is required.

DOE developed 8-hour construction noise-level estimates by assuming that a bulldozer (with a noise emission level of 85 dBA at 15 meters [50 feet]) would be at full operation for 8 hours at a given location along a common segment or alternative segment at the approximate minimum distance to the nearest residential receptor anywhere along the Mina rail alignment. Tables 4-238 and 4-239 list estimated construction noise levels for Mina, Silver Peak, and Goldfield. In addition, based on the construction schedule, the analysis conservatively assumed that 15 bulldozers would be operating simultaneously in the same general area. DOE also assumed that trucks (with a noise emission level of 88 dBA at 15 meters) would be at full power at the same general area for 8 hours per day. Based on the construction schedule, DOE conservatively assumed that 27 trucks would be operating simultaneously in the same general area. These analyses assume that there would be no construction activities during the night.

Table 4-238. Estimated construction noise levels along the Mina rail alignment (8-hour L_{eq}).[a]

Location (segment)	Approximate distance to nearest receptor (meters)[b]	8-hour bulldozer L_{eq}	8-hour truck L_{eq}	Total 8-hour L_{eq} (dBA)[a]
Mina (Mina common segment 1)	834	62	67	69
Silver Peak (Montezuma alternative segment 1)	442	67	73	74
Goldfield (Montezuma alternative segment 2)	250	72	78	79

a. dBA = A-weighted decibels; L_{eq} = equivalent sound level.
b. To convert meters to feet, multiply by 3.2808.

Table 4-239. Estimated construction noise levels along the Mina rail alignment (30-day DNL).[a]

Location (segment)	Approximate distance to nearest receptor (meters)[b]	30-day bulldozer DNL	30-day truck DNL	Total 30-day DNL (dBA)
Mina (Mina common segment 1)	834	47	53	54
Silver Peak (Montezuma alternative segment 1)	442	53	58	59
Goldfield (Montezuma alternative segment 2)	250	58	63	64

a. dBA = A-weighted decibels; DNL = day-night average noise level.
b. To convert meters to feet, multiply by 3.2808.

The distances from construction activities to the nearest receptors would be great; therefore, construction noise levels would be below the Federal Transit Administration noise guidelines listed in Table 4-237.

There would be construction noise associated with removal of the existing Department of Defense track through Schurz, but this noise would be temporary and no adverse impact would be expected.

The Maintenance-of-Way Facility would be the only railroad operations support facility within the general vicinity of a populated area. However, this facility would be much farther from Silver Peak than the proposed rail line and, consequently, construction of the facility would produce lower noise levels. Therefore, there would be no adverse noise impacts from construction of associated rail facilities.

4.3.8.2.2 Construction Vibration

DOE based the construction vibration analysis on Federal Transit Administration methods (DIRS 177297-Hanson, Towers, and Meister 2006, all). Construction vibration should be assessed in cases where there is a significant potential for impact from construction activities. Such activities include blasting, pile driving, drilling, or excavation close to ***sensitive structures***. No pile driving is planned near populated areas, so pile driving vibration analysis is not required.

Based on the proposed construction equipment and Federal Transit Administration vibration data, DOE estimated potential ground-borne vibration levels due to construction activity. Table 4-240 lists estimated vibration levels associated with potential bulldozer activity.

Table 4-240. Estimated construction vibration levels along the Mina rail alignment.

Location (segment)	Approximate distance to nearest receptor (meters)[a]	Peak particle velocity (inches per second)
Mina (Mina common segment 1)	834	0.000078
Silver Peak (Montezuma alternative segment 1)	442	0.000201
Goldfield (Montezuma alternative segment 2)	250	0.0005

a. To convert meters to feet, multiply by 3.2808.

The vibration levels listed in Table 4-240 are below Federal Transit Administration building vibration damage criteria (0.20 inch per second for fragile buildings, and 0.12 inch per second for extremely fragile historic buildings). Therefore, DOE would expect no damage to buildings due to vibration during construction. In addition, because of relatively low vibration levels and the temporary nature of construction, human annoyance due to construction vibration would be low.

Blasting operations could be required as part of the excavation process to accommodate the rail roadbed in hilly areas. Uncertainty about the need for and the exact locations of blasting operations is typical at this phase of the proposed project. If blasting were needed and would occur near populated areas, DOE would assess potential blasting noise and vibration and take measures to minimize these temporary impacts, if any.

None of the railroad operations support facilities would be near receptors; therefore, there would be no adverse vibration impacts from construction of these facilities.

4.3.8.2.3 Construction-Train Noise

As the rail roadbed, track, and bridges were completed, construction trains would be employed to move railroad ties, ballast, and other rail-construction equipment to other construction areas. Up to 16 one-way trains per day could pass by certain receptor locations, such as those in Mina and Silver Peak, during a 4-year construction phase. Up to eight trains per day could pass by certain receptor locations on the Union Pacific Railroad Hazen Branchline in Silver Springs during the construction period. If the construction period was extended up to 10 years, the same total amount of construction trains would operate, but at a lower average number of trains per day. This analysis conservatively uses the higher number of 16 trains per day for Mina and Silver Peak and 8 trains per day for Silver Springs. As with operations trains, locomotive horn sounding at grade crossings would be the dominant noise source.

Using the equations in Appendix I, Section I.2.1, and analytical methods described in that appendix, DOE generated construction-train noise contours for Silver Springs (on the Union Pacific Railroad Hazen Branchline) and for two other populated areas near the Mina rail alignment: Mina and Silver Peak. Figures 4-31 through Figures 4-34 show 65 DNL noise contours for construction-train activity in these areas.

DOE estimates that 34 receptors would be included within the construction-train 65 DNL contours in Silver Springs, and 7 receptors would be included within the 65 DNL contours in Wabuska. These noise impacts would not be considered adverse because the construction phase would be temporary. There would be no receptors within the construction-train 65 DNL contours in Mina and Silver Peak. DOE estimates that 713 receptors would be included within the construction-train 3 dBA increase contours in Silver Springs (see Figure 4-35), and 15 receptors would be included within the 3 dBA increase contours in Wabuska (see Figure 4-36). There would be no receptors within the 3 dBA increase contour in Mina as shown in Figure 4-37. However, as shown in Figure 4-38, approximately 12 receptors would be included within the 3 dBA increase contour in Silver Peak. DOE estimates that 190 receptors would be included within the 3 dBA increase contour in Goldfield.

There would be no adverse noise impacts associated with these receptors because they would not experience a 3 dBA increase and also be exposed to 65 DNL or greater noise levels. The purpose of the 3 dBA increase component of STB noise guidelines is to identify potential impact areas and areas where train noise would be particularly audible. However, because transportation noise sources are audible throughout the United States, the audibility of train noise itself does not constitute an adverse noise impact.

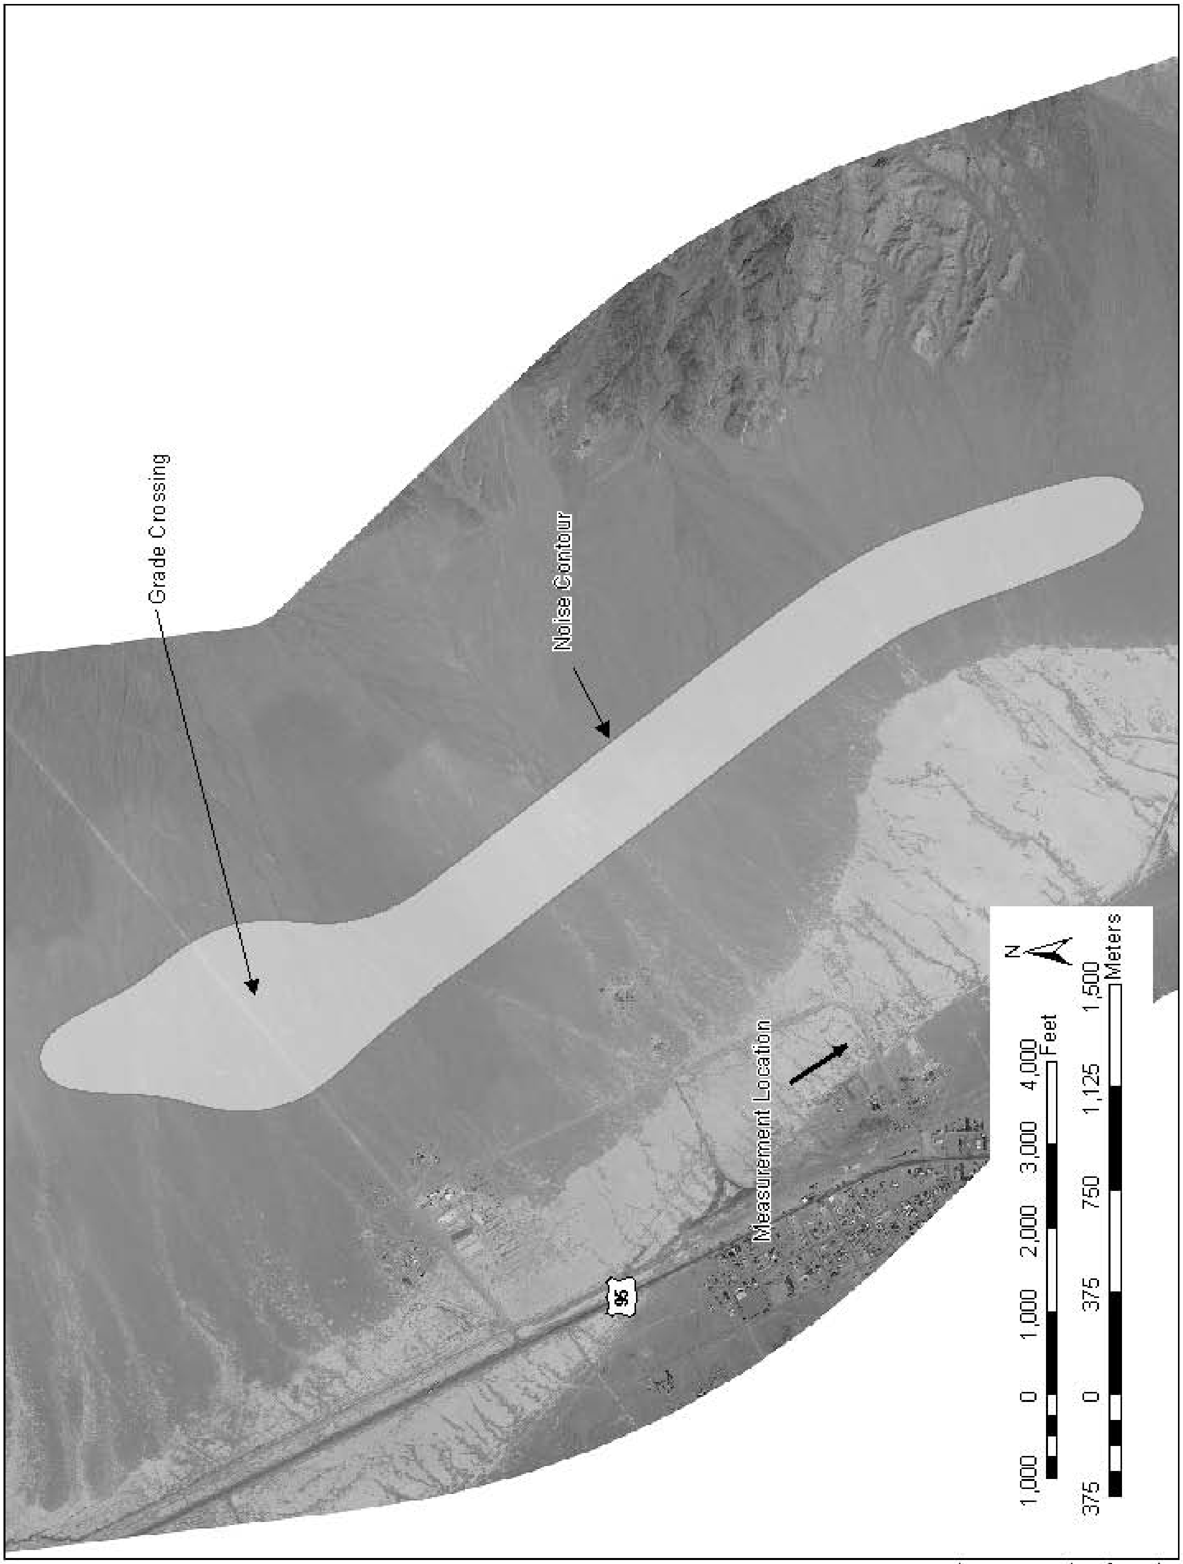

Figure 4-37. Construction train 3 dBA increase contour, Mina, Nevada.

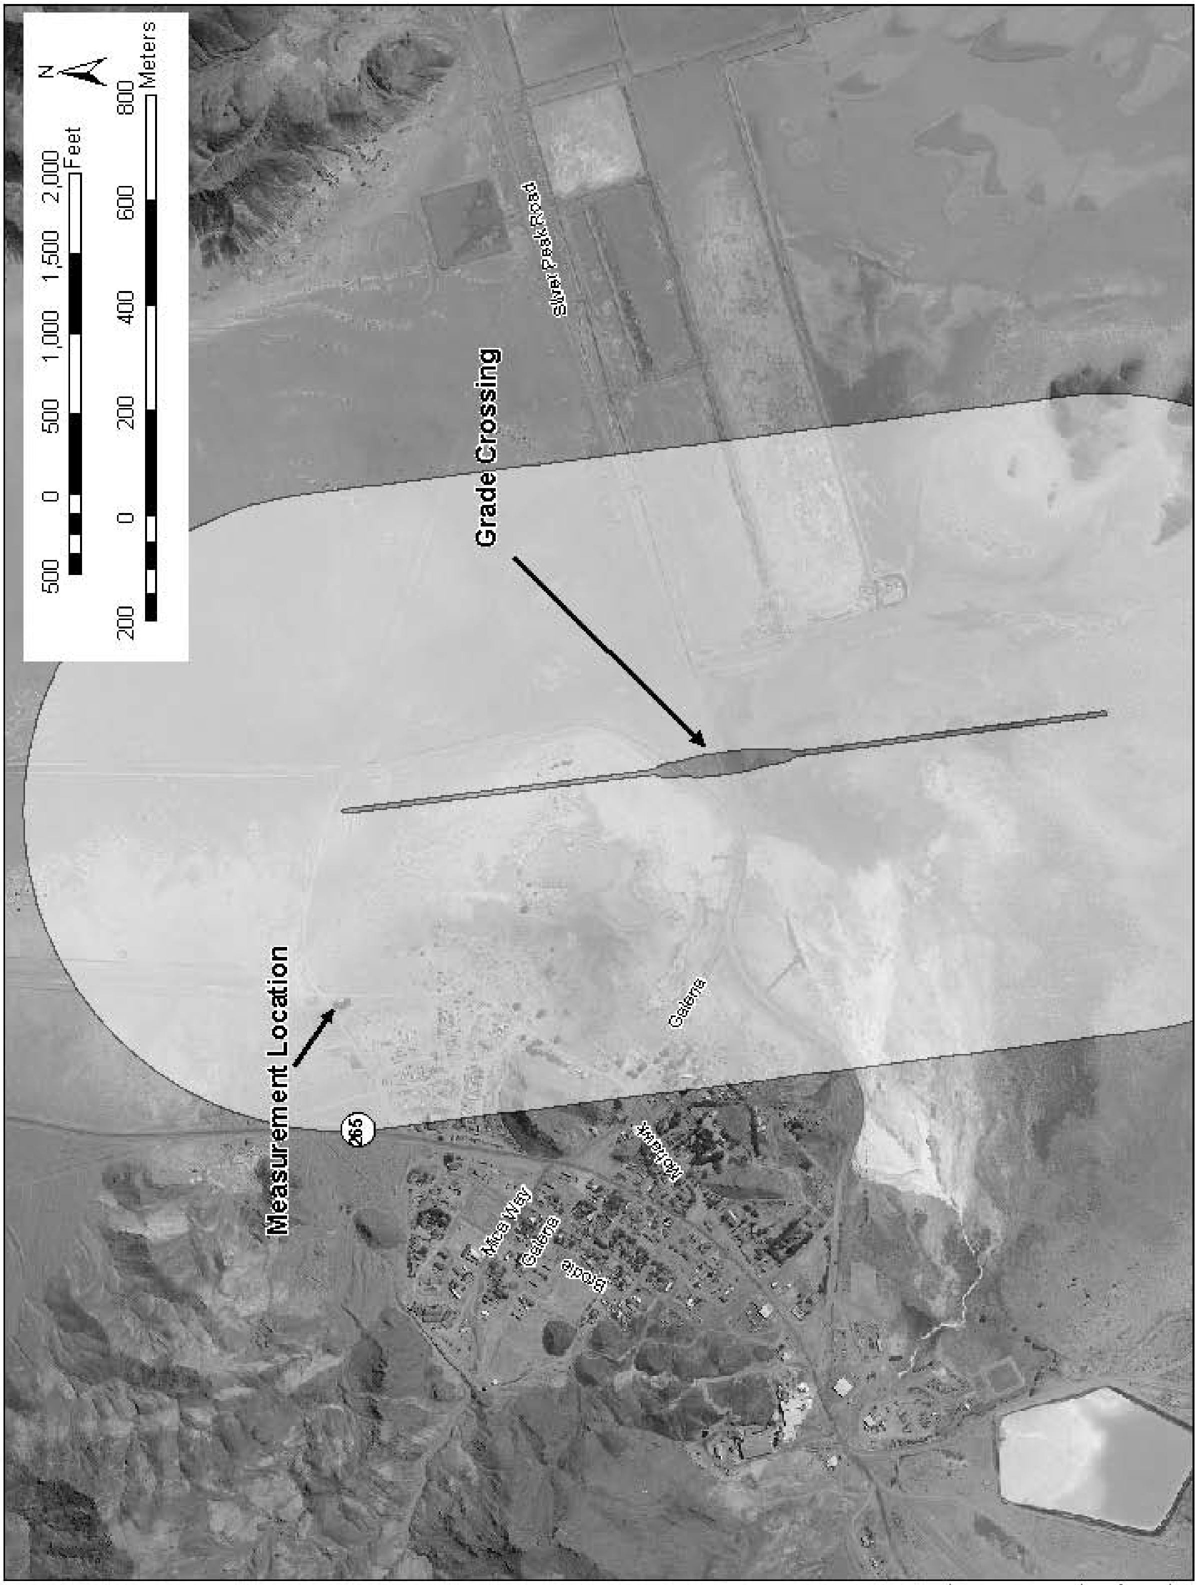

Figure 4-38. Construction-train 3 dBA increase contour, Silver Peak, Nevada.

4.3.8.2.4 Construction-Train Vibration

Construction trains would travel at lower speeds than operations trains. Because vibration is a function of train speed, construction-train vibration would be lower than operations-train vibration (see Section 4.3.8.3.4). Freight trains operating at 80 kilometers (50 miles) per hour would produce an annoyance-based vibration contour extending approximately 24 meters (80 feet) from the tracks (DIRS 177297-Hanson, Towers, and Meister 2006, p. 10-3). There are no buildings within approximately 24 meters of the Mina rail alignment, so operations trains would produce no adverse vibration impacts; therefore, there would be no adverse vibration impacts from construction trains.

Construction-train cars carrying ballast could weigh more than operations-train cars; therefore, those cars could produce higher levels of vibration. The locomotive itself would be considered representative of heavier cars. However, typically the locomotive produces the highest vibration level during a train passby, which would determine the maximum passby vibration level. Because operations-train and construction-train locomotives would be similar, the higher-speed operations locomotive would generate the highest level of vibration.

4.3.8.2.5 Quarry-Site Noise

Noise sources associated with potential quarry operations during the construction phase include blasting, rock crushing, heavy-equipment operation, and truck traffic. There are no receptors in the immediate vicinity of the potential Garfield Hills, Gabbs Range, North Clayton, and Malpais Mesa quarry sites. Therefore, there would be no noise impacts associated with operation of these quarries during rail line construction.

At potential quarry ES-7 west of Goldfield, there would be blasting and rock-crushing activities at least 1,500 meters (5,000 feet) away from receptors in west Goldfield. While quarry noise would likely be audible in west Goldfield, this distance and the intervening topography, which would act as a barrier to and would attenuate noise, would make it unlikely that there would be adverse noise impacts from this quarry.

4.3.8.2.6 Quarry-Site Vibration

Vibration sources associated with operations at potential quarries during the construction phase include blasting, rock crushing, heavy-equipment operation, and truck traffic. Peak overpressures and ground-borne vibration associated with blasting can be an issue in relation to the structural integrity of buildings close to blasting activities.

There are no receptors in the immediate vicinity of the potential Garfield Hills, Gabbs Range, North Clayton, and Malpais Mesa Quarry sites. Therefore, there would be no vibration impacts associated with operation of these quarries during the construction phase.

At potential quarry ES-7 west of Goldfield, there would be blasting and rock-crushing activities at least 1,500 meters (5,000 feet) away from receptors in west Goldfield. Because of this large distance between quarry activities and receptors, it is unlikely that ground-borne vibration would be perceptible at receptor locations; therefore, there would be no adverse vibration impacts.

4.3.8.3 Operations Impacts

The primary sources of noise considered in the analysis for railroad operations were wayside train noise and horn noise. Wayside noise refers collectively to all train-related operations noise adjacent to the operations right-of-way, excluding locomotive warning-horn noise. Wayside noise results from steel train wheels contacting steel rails (wheel-rail noise) and from locomotive exhaust and engine noise. The amount of noise created by the wheels on the rails would depend on train speed; the amount of engine noise created by the locomotive would depend on the throttle setting. Wheel squeal can sometimes occur on curved sections of track where the radius of curvature of the track is small. There would be horn noise in the vicinity of grade crossings to warn motorists and pedestrians of approaching trains; this noise is assessed separately from wayside noise.

Operation of any of the Schurz alternative segments would eliminate future noise from operation of the Department of Defense Branchline through Schurz.

4.3.8.3.1 Wayside Noise

Appendix I describes the methodology DOE used to estimate wayside noise during the operations phase. Wheel-rail noise would vary as a function of speed and could increase by as much as 15 dBA if wheels or rails were in poor condition (DIRS 174623-Kaiser 1998, all). One of the most common causes of additional noise from wheels is the formation of flat surfaces on wheels caused by wheels sliding during hard braking.

The main components of locomotive noise are the exhaust of the diesel engines, cooling fans, general engine noise, and the wheel-rail interaction. Noise associated with the engine exhaust and cooling fans usually dominates; this noise would depend on the throttle setting (most locomotives have eight throttle settings), not on locomotive speed. Tests have shown that locomotive noise levels change by about 2 dBA for each step change in throttle setting, meaning that noise levels increase by about 16 dBA as the locomotive throttle is moved from notch one to notch eight (DIRS 174623-Kaiser 1998, all). Because locomotive engineers constantly adjust throttle settings as necessary, only rough estimates of throttle settings are usually available for noise projections. Numerous field measurements of freight train operations indicate that locomotive noise can be projected with reasonable accuracy by assuming a base condition of throttle position six and adjusting noise levels when better information about typical throttle position is known.

Given the maximum train passby noise level of freight cars and a locomotive under a specific set of reference conditions, the noise models allow estimation of the maximum train passby noise level, the noise exposure level, the DNL, and other noise metrics for varying distances from the track, varying train speeds, and varying schedules.

The spent nuclear fuel and high-level radioactive waste train used to model noise impacts for this analysis would consist of two to three locomotives and four to eight railcars (one to five ***cask cars***, two ***buffer cars***, and one escort car). The average length of the cars would be about 18 to 27 meters (59 to 89 feet), and the length of the locomotives would be 23 meters (75 feet), for a total train length ranging from 118 to 285 meters (390 to 940 feet).

Trains would operate along the rail line at a top speed of 80 kilometers (50 miles) per hour. Because train speed has a direct correlation to noise generated, DOE used the top train speed to conservatively estimate potential noise levels. Table 4-241 lists distances to the wayside 65 DNL noise contour along the Mina rail alignment, assuming an average of 2.4 trains per day (based on 17 one-way trips per week). The average of 2.4 trains per day includes ***cask*** trains, maintenance-of-way trains, and repository supply and construction trains.

Table 4-241. Summary of distances to 65 dBA DNL along the Mina rail alignment.

Area	Speed in kilometers per hour[a]	Distance in meters[b] to 65 dBA DNL contour[c]		Noise level increase (dBA)[c]
		Wayside	Horn	
Silver Springs	80[d]	17	75	0 to 12
Mina	80	17	75	0
Silver Peak	80	17	75	0 to 6
Goldfield	80	17	75	0 to 10

a. To convert kilometers per hour to miles per hour, multiply by 0.62137.
b. To convert meters to feet, multiply by 3.2808.
c. dBA = A-weighted decibels; DNL = day-night average noise level.
d. Actual speeds would be lower.

4.3.8.3.2 Horn Noise

The key components in projecting noise exposure from horn noise are the horn sound level, the duration of the horn noise, the distance of the receptor from the tracks, and the number of trains running during daytime and nighttime hours.

For safety reasons, the Federal Railroad Administration requires train engineers to sound horns when approaching most grade crossings unless a Quiet Zone has been established. Horn sounding is generally not required at private crossings. Federal Railroad Administration regulations at 49 CFR 229.129 require all lead locomotives to have an audible warning device that produces a minimum sound level of 96 dBA at a distance of 30 meters (100 feet) in front of the locomotive.

Most freight train audible warning devices are air horns. The maximum sound level of the air horns can usually be adjusted to some degree by adjusting the air pressure. Maximum sound levels are typically 105 to 110 dBA at 30 meters (100 feet) in front of the trains, well above the 96 dBA value required by the Federal Railroad Administration. Additional noise sources associated with grade crossings would be the grade crossing bells that would start sounding just before the gates were lowered, and idling road traffic that must wait at the crossing. Because train horns create high noise levels, noise exposure would be dominated by horn noise near any grade crossing where sounding horns is required. The analysis assumes that trains would be equally likely to occur at any hour of the day or night. Table 4-241 does not include adjustments for building or terrain shielding. At distances beyond approximately 30 meters, obstructions such as buildings or terrain could act as a partial acoustic shield, causing a noise reduction of approximately 5 to 10 dBA. As one of the final steps in the noise modeling process, where appropriate, DOE included adjustments for building shielding, based on International Organization for Standardization standard number ISO 9613-2 *Acoustics – Attenuation of Sound During Propagation Outdoors – Part 2: General Method of Calculation* (DIRS 176684-ISO 1996, all).

4.3.8.3.3 Railroad Operations Noise Impacts

Table 4-241 lists approximate distances to the wayside for train noise without horns and horn-noise contours from the centerline of the rail alignment in Silver Springs, Mina, Silver Peak, and Goldfield. These distances do not include the effects of building shielding. Also shown are potential increases in noise in relation to ambient noise conditions, which would vary between and within the areas where DOE took ambient noise measurements. Ambient noise refers to existing conditions in the region of influence. At present, there is no train activity in Mina, Silver Peak, or Goldfield, but there is train activity in Silver Springs.

Figures 4-39 through 4-43 show modeled 65 DNL contours in Silver Springs, Wabuska, Mina, Silver Peak, and Goldfield. DOE counted receptors that would be included in the contours in accordance with STB procedures (DIRS 173225-STB 2003, all). These figures show that eight receptors would be included in the 65 DNL contours in Silver Springs and one receptor would be included in Wabuska. These nine receptors would experience an adverse noise impact because they would be exposed to 65 DNL and a 3 dBA increase. Should the Mina rail alignment (currently a nonpreferred alternative) be selected, DOE would investigate mitigation methods for these nine receptors. Mitigation methods, where reasonable and feasible, could include building sound insulation or the development of a Quiet Zone. Alternatively, DOE could provide sound insulation for houses near grade crossings

Figures 4-44 through 4-48 show 3 dBA increase contours in Silver Springs, Wabuska, Mina, Silver Peak, and Goldfield. Table 4-242 shows the number of receptors included in the noise contours.

Table 4-242. Mina Implementing Alternative receptor counts.[a]

	Silver Springs	Wabuska	Mina	Silver Peak	Goldfield
Greater than or equal to 65 DNL + 3 dBA[b]	8	1	0	0	0
Less than 65 DNL + 3 dBA[c]	567	20	0	8	87

a. dBA = A-weighted decibels; DNL = day-night average noise level.
b. Adverse noise impact.
c. No adverse noise impact. The purpose of the 3 dBA-increase criterion is to identify potential impact areas where train noise would be particularly audible.

4.3.8.3.4 Railroad Operations Vibration Impacts

At certain times, such as when a locomotive is idling near a residential building, trains can produce low-frequency airborne noise, which in turn can cause structural vibrations. However, trains generally do not produce enough airborne noise or ground-borne vibrational energy to cause building damage.

DOE evaluated the potential impacts from vibration during railroad operations by using train-induced vibration levels as a function of distance from a rail line, along with vibration levels likely to result in building damage or annoyance, in combination with information on the location of residences or other buildings in relation to the rail line.

Unlike noise, vibration impacts are evaluated on the basis of maximum level. A freight train traveling at 80 kilometers (50 miles) per hour will generate a vibration velocity level of 95 decibels with respect to 1 micro-inch per second (VdB), measured 3 meters (10 feet) from the tracks (DIRS 177297-Hanson, Towers, and Meister 2006, p. 10-3). This level of vibration is substantially lower than levels that can cause cosmetic building damage (0.20 inch per second), nominally a vibration velocity of 106 VdB, or 100 VdB, assuming a crest factor of 2 (DIRS 176857-Martin 1980, all). This level of vibration is even lower than that which can cause structural damage (126 VdB) (DIRS 175495-Nicholls, Johnson, and Duvall 1971, all). There are no buildings within 3 meters of the Mina rail alignment, so there would be no adverse vibration impacts to buildings.

According to the Federal Transit Administration, a vibration velocity of 80 VdB or above constitutes an impact in terms of human annoyance for infrequent train events (that is, fewer than 70 events per day). For a freight train traveling 80 kilometers (50 miles) per hour, this annoyance impact distance extends approximately 24 meters (80 feet) from the tracks (DIRS 177297-Hanson, Towers, and Meister 2006, p. 10-3). There are no residential buildings within this distance of the Mina alignment; therefore, DOE expects no adverse vibration impacts related to annoyance.

Operation of any of the Schurz alternative segments would eliminate future vibration from operation of the Department of Defense Branchline through Schurz.

4.3.8.4 Impacts of the Shared-Use Option

The Shared-Use Option could result in increased train operations because DOE would allow commercial shippers to use the rail line. Such increased operations could result in increased noise impacts because DNL is a function of the number of train events per day. Increased train operations would not affect vibration impacts because vibration is evaluated on a maximum-level basis only.

The typical train under the Shared-Use Option would consist of three to four locomotives and up to 60 railcars. The average length of a car would be 18 meters (60 feet) for a total length (railcars only) of

1,100 meters (3,600 feet). Trains would operate along the rail line at a top speed of 80 kilometers (50 miles) per hour. Table 4-243 shows distances to the wayside 65 DNL noise contour, assuming an average of 5 trains per day (the Proposed Action plus Shared-Use Option train volumes).

Table 4-243. Summary of distances to 65 dBA DNL under the Mina rail alignment Shared-Use Option in Silver Springs, Mina, Silver Peak, and Goldfield.[a]

Area	Train speed in kilometers[b] per hour	Distance in meters[c] to 65 dBA DNL contour		Noise level increase (dBA)
		Wayside	Horn	
Silver Springs	80	20	90	0 to 13
Mina	80	20	90	0
Silver Peak	80	20	90	0 to 6
Goldfield	80	20	90	0 to 10

a. dBA = A-weighted decibels and DNL = day-night average noise level.
b. To convert kilometers to miles, multiply by 0.62137.
c. To convert meters to feet, multiply by 3.2808.

The shared-use 65 DNL contours include eight receptors in Silver Springs and one receptor in Wabuska. These nine receptors would experience an adverse noise impact because they would be exposed to 65 DNL and a 3 dBA increase. If DOE selected the Mina rail alignment (currently a non-preferred alternative), DOE would investigate mitigation methods for these nine receptors. Mitigation methods, where reasonable and feasible, could include building sound insulation or the development of a Quiet Zone. There would be no receptors included in the shared-use 65 DNL contours for Mina, Silver Peak, or Goldfield.

DOE estimates that 722 receptors would be included in the shared-use 3 dBA increase contour in Silver Springs, 24 receptors in Wabuska, no receptors in Mina, and 12 receptors in Silver Peak. DOE estimates that 37 receptors would be within the shared-use 3 dBA increase contour in Goldfield. The total estimated number of receptors included within the shared-use 3 dBA increase contour would be 795.

4.3.8.5 Summary

Table 4-244 lists potential noise and vibration impacts related to construction and operation of the proposed railroad along the Mina rail alignment.

During the construction phase, noise levels along the Mina rail alignment would be lower than adverse impact criteria (see Table 4-237). During the operations phase, estimated noise levels at nine receptor locations would be higher than impact criteria (65 DNL, with a 3 dBA or greater increase from the baseline); therefore, there would be adverse noise impacts associated with railroad operations at those locations. Under the Mina Implementing Alternative, DOE would investigate mitigation methods for these nine receptors. Mitigation methods, where reasonable and feasible, could include building sound insulation or the development of a Quiet Zone.

During the construction and operations phase, vibration levels would not exceed the Federal Transit Administration damage criteria of 0.20 inch per second for fragile buildings, and 0.12 inch per second for extremely fragile historic buildings (see Table 4-240); therefore, DOE would expect no building damage due to vibration. In addition, train-generated vibration levels would be lower than Federal Transit Administration human annoyance criterion.

Table 4-244. Summary of potential impacts from noise and vibration as a result of constructing and operating the proposed railroad along the Mina rail alignment[a].

Location (county)	Construction impacts	Operations impacts
Silver Springs (Lyon County)	There would be no impact from vibration, which would fall below Federal Transit Administration criteria. DOE estimates that 34 receptors would be included within the construction-train 65 DNL contours in Silver Springs, and 7 receptors would be included within the 65 DNL contours in Wabuska. These noise impacts would be considered temporary adverse impacts. There would be no adverse impact from vibration, which would fall below Federal Transportation Administration criteria.	There would be adverse noise impacts at eight receptors in Silver Springs and one receptor in Wabuska. There would be no adverse impact from vibration, which would fall below Federal Transit Administration criteria.
Mina (Mineral County)	There would be no adverse construction noise or vibration impacts. There would be no adverse impact from the operation of construction trains. No receptors would fall within the 3 dBA increase contour or the 65 DNL contours.	There would be no adverse impacts from noise from the operation of trains along the rail alignment. There would be no adverse impact from vibration, which would fall below Federal Transit Administration criteria.
Silver Peak (Esmeralda County)	There would be no adverse construction noise or vibration impacts. There would be no adverse impact from the operation of construction trains.	There would be no adverse impacts from noise from the operation of trains along the rail alignment. There would be no adverse impact from vibration, which would fall below Federal Transit Administration criteria.
Goldfield (Montezuma alternative segment 2) (Esmeralda County)	Noise from construction activities would fall below Federal Transit Administration guidelines. There would be no adverse impact from vibration, which would fall below Federal Transit Administration criteria. There would be no adverse impact from the operation of construction trains. No receptors within the 65 DNL contours.	There would be no adverse impacts from the operation of trains along the rail alignment. No receptors would fall within the 65 DNL contours. There would be no adverse impact from vibration, which would fall below Federal Transit Administration criteria.
Quarries		
Railroad quarry ES-7 (Esmeralda County)	The nearest receptor would be approximately 1,500 meters[b] away from ES-7; therefore, potential impacts would be small.	The nearest receptor would be approximately 1,500 meters[b] away from ES-7; therefore, potential impacts would be small.
Rail line construction and operations support facilities	No impact. There would be no receptors near these facilities.	No impact. There would be no receptors near these facilities.

a. Adverse impacts under the Shared-Use Option would be the same as those under the Proposed Action without shared use.
b. To convert meters to feet, multiply by 3.2808.

4.3.9 SOCIOECONOMICS

This section describes potential impacts to socioeconomic conditions (employment and income, population and housing, public services, and transportation) from constructing and operating the proposed railroad along the Mina rail alignment. This section does not attribute socioeconomic impacts to the rail line alternative segments; rather, it describes impacts of the Proposed Action as a whole on the region of influence. Section 4.3.9.1 describes the methodology DOE used to assess potential impacts; Section 4.3.9.2 describes potential construction impacts; Section 4.3.9.3 describes potential operations impacts; Section 4.3.9.4 describes potential impacts under the Shared-Use Option; and Section 4.3.9.5 summarizes potential impacts.

Section 3.3.9.1 describes the region of influence for the socioeconomic analysis.

4.3.9.1 Impact Assessment Methodology

DOE analyzed socioeconomic impacts by comparing projected conditions in the region of influence during the construction and operations phases with projected baseline conditions (without the project) described in Section 3.3.9. Sections 4.3.9.1.1 through 4.3.9.1.4 describe the methods DOE used to estimate impacts to socioeconomic conditions.

4.3.9.1.1 Employment and Income

Both the projections of baseline employment and income conditions (without the project) and projections of conditions during the construction and operations phases came from the Regional Economic Models, Inc., *Policy Insight* model (DIRS 182251-REMI 2007, all; DIRS 179558-Bland 2007, all; DIRS 180690-Bland 2007, all; DIRS 180689-Bland 2007, all) described in Section 3.3.9 and Appendix J, Socioeconomics. Impacts are stated in terms of the number of jobs, ***gross regional product***, ***real disposable income***, and state and local government spending. Direct economic effects are the changes in jobs, gross regional product, and income in sectors that would supply directly needed goods and services, such as heavy-duty equipment, during railroad construction and operations. Indirect or secondary economic effects are the changes in sectors that would supply goods and services to the direct sectors (such as the production of construction material components). Secondary effects also would include the spending of income earned from the project (known as indirect effects). The extent to which a local economy could supply goods and services to the proposed project would be constrained by its level of economic development. DOE has assessed adverse impacts qualitatively in terms of disruption of economic activity, particularly for mining and agricultural operations.

> **Gross regional product** is the value of all final goods and services produced in a specified region.
>
> **Real disposable income** is the value of total after-tax income received; it is the income available for spending or saving.

DOE used runs of the *Policy Insight* model to estimate construction impacts over 5 years and operations impacts over 52 years (DIRS 182251-REMI 2007, all; DIRS 179558-Bland 2007, all; DIRS 180690-Bland 2007, all; DIRS 180689-Bland 2007, all). The actual construction phase would range from 4 to 10 years. DOE expects the construction phase to last a minimum of 4 years and 6 months, so the Department modeled a fifth year. Because impacts, described in this analysis as peak changes from the baseline (without the project), would be strongest and most concentrated under a shorter construction schedule, DOE modeled only the 5-year construction phase. Construction-related impacts under a 10-year schedule would be bounded by the analysis described. Noteworthy impacts associated with a longer construction phase are identified, as appropriate. For the operations phase, this analysis assumes that the first 2 years represent a transition period. During these 2 years (2015 and 2016), the railroad support facilities would be operational. Starting in 2017, DOE would begin shipping spent nuclear fuel and high-level radioactive waste to Yucca Mountain; the shipping campaign would span up to 50 years, with up to 50 years of active shipping.

Because the socioeconomic impacts would vary depending on the county in which DOE placed the Nevada Railroad Control Center and National Transportation Operations Center, DOE modeled two different scenarios for both the construction and operation phases. Scenario 1 has the Nevada Railroad Control Center and National Transportation Operations Center in Mineral County near the beginning of the proposed rail line; Scenario 2 has these facilities in Nye County near the end of the rail line.

4.3.9.1.2 Population and Housing

DOE estimated population impacts by comparing project-related increases or decreases at the county level against the projected population figures without the project. These estimates came from the same *Policy Insight* model runs used to estimate employment and income. Population changes are related to changes in employment; as employment increases in an area, permanent population could also increase, although increases in population typically lag behind increases in employment. DOE assessed impacts on housing by evaluating worker and permanent population increases associated with railroad construction and operation against county and community housing-capacity information.

4.3.9.1.3 Public Services

DOE assessed impacts to public services as changes to the county or community baseline capacity (assuming no railroad), as described in Section 3.3.9. There would be positive impacts when there were project-related enhancements that the community could also access. Adverse impacts would occur when increased demand exceeded the capacities of public services or hastened the deterioration of a particular public service, resulting in a lower ***level of service*** to community users.

4.3.9.1.4 Transportation Infrastructure

There could be an adverse impact on roadways within the region of influence if construction or operation of the proposed railroad would degrade the level of service of a roadway to unacceptable levels (below a level of service of C) as a result of project-related traffic. Section 3.3.9.3.5.1 includes a definition of level of service. As discussed in Section 3.3.9, existing annual average daily traffic data for the major roadways within the Mina rail alignment region of influence were provided by the Nevada Department of Transportation. Baseline levels of service of the roadways were then projected using the Highway Capacity Manual guidelines. To assess the impacts the railroad would have on the roadways, DOE added potential project-related vehicles to baseline traffic volumes and then estimated new levels of service. Because rail line operations along the Mina rail alignment would require operating trains along the existing Union Pacific Railroad Hazen Branchline and Department of Defense Branchlines, DOE compared new rail traffic volumes on the proposed rail line to baseline rail conditions. The Department estimated road-traffic delay at highway-rail grade crossings based on the additional rail traffic along the existing rail segments between Hazen and Thorne. All roads that would cross the new rail segments at grade have very low traffic, and DOE did not estimate delay at grade crossings for these segments. Section 4.3.10, Occupational and Public Health and Safety, provides the safety analysis (traffic accidents and fatalities) for the proposed railroad along the Mina rail alignment.

4.3.9.2 Rail Line Construction Impacts

The Mina Implementing Alternative includes construction and operation of the rail line and its associated construction and operations support facilities. Inputs to the analysis using the *Policy Insight* model (DIRS 182251-REMI 2007, all; DIRS 179558-Bland 2007, all; DIRS 180690-Bland 2007, all; DIRS

180689-Bland 2007, all) included construction and operations costs, or labor needs, or both when available. The inputs also accounted for the differences between expected project-related wages and average wages, by county and economic sector, contained in the *Policy Insight* model. Project-related wages would generally be higher than the average wages embedded in the model.

The common social and economic activities and changes associated with the construction of the proposed railroad would include:

- A period of brief, intense elevation in project-related employment
- Population increases
- A slightly slower rate of growth in the level of employment as the economy moved from the construction phase to the operations phase
- Some effects on public services (such as health care), particularly where construction activities were concentrated near communities
- Some effects on transportation resources

The equivalent of 1,100 full-time workers would be required during the grading phase of the construction phase, but fewer workers would be required as construction activities moved toward completion (this number reflects full-time work over a typical annual work year of approximately 2,000 hours [accounting for weekends, holidays, and vacation and sick days], and a construction phase of 54 months). More than 1,100 people would be performing this work, because not all employees would work full time. DOE used *Policy Insight* population projections to assess population-related impacts (for example, impacts to housing stock, ***infrastructure***, public services) related to the total number of actual employees resulting from the project. DOE would establish up to 10 temporary construction camps along the rail alignment to house workers.

Construction impacts for employment, income, and population are drawn from model runs of *Policy Insight* (DIRS 182251-REMI 2007, all; DIRS 179558-Bland 2007, all; DIRS 180690-Bland 2007, all; DIRS 180689-Bland 2007, all), which used a 5-year modeling period. As mentioned above, the actual construction phase would range from 4 to 10 years; impacts associated with the longer construction phase are noted as appropriate; however, levels of impacts would be higher and more concentrated under the modeled 5-year schedule.

4.3.9.2.1 Employment and Income

Direct employment and income impacts would stem from the hiring of construction workers and their spending of wages. Workers would have the option of shopping in towns near the construction camps, or relying on the cafeterias, drug stores, and non-perishables markets at the construction-camp commissaries (DIRS 174087-Nevada Rail Partners 2005, p. 4-5). Indirect impacts could result from employment of workers by businesses that supply goods and services in support of construction work, including the construction and operation of construction camps, where services such as catering, utility supply, and waste disposal would be needed. For purposes of this analysis, and consistent with the methodology established in the Yucca Mountain FEIS, DOE assumes that most construction workers would live in Clark County (DIRS 155970-DOE 2002, Section 4.1.6.2.1), and reside in construction camps. DOE makes this assumption because the construction sectors in Lyon, Mineral, Nye, and Esmeralda Counties are not large enough to provide enough workers for the construction activities. This section also considers an alternative analysis, which assumes that half of the construction workers for the Mina rail alignment reside in the combined Washoe County-Carson City area, and the other half reside in Clark County. The analysis considers this second scenario because Washoe County and Carson City may be more likely than Clark County to supply construction workers for the northern portions of the Mina rail alignment. Therefore, for the purposes of this second scenario, the analysis presents socioeconomic impacts for the combined area of Washoe County-Carson City.

Table 4-245 lists potential changes in economic measures during the construction phase for the two modeled scenarios. Appendix J describes the analysis in more detail. Each scenario includes the impact of constructing the proposed rail line and railroad construction and operations support facilities. DOE modeled employment of construction workers and some support workers as beginning in 2010 and ending in 2014. All construction-related economic impact values are presented in 2006 dollars. Table 4-245 lists the estimated changes to current trends (without construction of the railroad) in employment and income for each year of the construction phase. The discussion of the data in the table attempts to identify and address the largest deviations (“peak” changes) from the current trends without the railroad as a way to show the upper bounds of potential impacts.

In all five counties, changes to the baseline (conditions without the proposed railroad) would be similar under the two scenarios. In Lyon County, the increase in peak employment would represent 0.02 percent of the total projected employment levels in Lyon County in the absence of the project. The peak construction-related impact to real disposable income would be 0.03 percent above the baseline, gross regional product would be 0.04 percent above the baseline, and state and local government spending would be 0.01 percent above the baseline.

In Mineral County, the increase in peak employment would represent 6.1 percent of the total projected employment levels in Mineral County in the absence of the project. The peak construction-related impact to real disposable income would be 4.5 percent above the baseline, gross regional product would be 14.1 percent above the baseline, and state and local government spending would be 1.8 percent above the baseline. Residents would likely feel the peak changes to employment and gross regional product.

DOE also considered construction-related impacts to the Walker River Paiute Reservation. If one of the four construction camps proposed in Mineral County is instead placed on the Walker River Paiute Reservation, the Reservation would benefit from increased employment, gross regional product, and real disposable income. The increase in peak employment would be up to 20 additional jobs. The peak construction-related impact to gross regional product would be up to $1.4 million, and the impact to real disposable income would be up to $386,000 (DIRS 180691-Bland 2007, all).

In Nye County, the project-related increase in employment at peak would correspond to 0.6 percent of the total projected employment levels in Nye County without the project. The peak construction-related impact to real disposable income would be a 0.4-percent increase above the baseline, gross regional product would be 1 percent above the baseline, and state and local government spending would correspond to a 0.2-percent increase above the baseline.

In Esmeralda County, the project-related increase in employment at peak would correspond to 13.9 percent of the total projected employment levels without the project. The peak construction-related impact to real disposable income would be a 27-percent increase above the baseline, gross regional product would be 57 percent above the baseline, and state and local government spending would correspond to a 4.6-percent increase above the baseline.

In Clark County, the peak increase in real disposable income, gross regional product, and ***total employment*** would correspond to an increase of one-tenth of 1 percent of the baseline in Clark County. The peak construction-related impacts to state and local government spending would correspond to less than one tenth of 1 percent above the respective baseline, meaning that all impacts, if any, would be small in such a large economy.

Table 4-245. Estimated changes in economic measures during the construction phase – Mina rail alignment (page 1 of 3).[a,b]

	Construction year				
County/scenario/measure	2010	2011	2012	2013	2014
Lyon County

b. Model does not discriminate non-county regions, such as the Walker River Paiute Reservation.

If half of the construction workers come from the Washoe County-Carson City area, then there would be construction-related socioeconomic impacts to this region. These results are presented in Table 4-246 as a sensitivity analysis. The peak increase in real disposable income, gross regional product, and total employment would correspond to an increase of less than three-tenths of 1 percent of the baseline. The peak construction-related impacts to state and local government spending would correspond to less than one-tenth of 1 percent above the respective baseline, meaning that all impacts, if any, would be small in such a large economy.

The major economic activities that could be adversely affected by construction of the proposed railroad along the Mina rail alignment are mining and grazing interests. Economic activities could be disrupted during the construction phase, which could range from 4 to 10 years. Impacts on private lands (other than patented mining claims) would be small, because as discussed in Section 3.3.2, the Mina rail alignment would lie mostly within BLM-administered public land. DOE would anticipate impacts to private land mainly in the Goldfield area.

There also could be limited disruption of economic activity from construction impacts on the transportation infrastructure as the movement of construction equipment and supplies temporarily disrupted traffic flow along local road systems. Under the construction schedule, DOE traffic modeling predicts that construction of the rail line itself would not affect traffic volume on local roads, but that construction of facilities might. Construction of the Maintenance-of-Way Facility and the Staging Yard would affect traffic on U.S. Highway 95 in the vicinity of Tonopah and Hawthorne; however, the level of service would remain the same in both locations. DOE would limit the impact of these disruptions by measures such as limiting road closures to low-traffic periods. Construction of the facilities inside the Yucca Mountain Site boundary near the repository (the Rail Equipment Maintenance Yard, the Cask Maintenance Facility, and possibly the Nevada Railroad Control Center and National Transportation Operations Center) would affect traffic on U.S. Highway 95 at the entrance to the Yucca Mountain Site, resulting in a drop in level of service from a B to a C at peak times during the construction phase.

Table 4-246. Alternative analysis for estimated changes in economic measures in Washoe County-Carson City during the construction phase – Mina rail alignment.[a]

	Construction year				
County/scenario/measure	2010	2011	2012	2013	2014
Washoe County-Carson City[b]					
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County					
Employment	809	824	798	268	159
State and local government spending	$690,016	$1,271,038	$1,757,619	$1,718,730	$1,626,718
Real disposable income	$45,080,673	$46,549,836	$46,325,305	$17,239,105	$11,966,869
Gross Regional Product	$56,693,801	$59,920,164	$60,034,931	$21,979,836	$13,866,185
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County					
Employment	809	824	798	268	159
State and local government spending	$689,598	$1,270,620	$1,757,340	$1,718,451	$1,626,300
Real disposable income	$45,068,400	$46,554,300	$46,332,000	$17,245,800	$11,969,100
Gross Regional Product	$56,651,400	$59,915,700	$60,037,164	$21,988,764	$13,850,569

a. This table does not list data for Clark County, but under the alternative analysis, Clark County impacts would be approximately half of the Clark County impacts identified in Table 4-245.
b. Source: DIRS 181590-Bland 2007, all.

There would be fewer such impacts under a 10-year construction schedule, because worker trips and materials shipments would be spread over a longer period. As discussed in Section 4.3.11, the supplies needed for construction would not create shortages at a local, regional, or national level. Primary materials include steel for rails and concrete for rail ties, bridges, and drainage structures. These materials are available regionally and nationally; purchasing would not be expected to create demand and supply impacts, and there should be no harmful price effects.

There could be some reductions in mining- and agriculture-related employment and income because of construction-related land disturbances. The nominal width of the rail line construction right-of-way would include land upon which there are grazing and mining activities. The construction right-of-way might be narrower in certain locations to minimize impacts to lands with mining claims, or wider in other places (such as cut and fill areas and bridges) that could affect parcels adjoining the construction right-of-way where mining and agricultural activities take place.

As discussed in Section 4.3.2.2.1.2, the only mining claims that would be within the rail line construction right-of-way are associated with Mina common segment 1 and Montezuma alternative segments 1, 2, and 3. Although DOE would reduce the area of disturbance to minimize impacts to these claims, Mina common segment 1 would intersect 388 mining claims, Montezuma alternative segment 1 would intersect 202 claims, Montezuma alternative segment 2 would intersect 153, and Montezuma alternative segment 3 would intersect up to 249 (see Section 4.3.2.2.6).

Should parties with existing mining claims have plans to explore, develop, or produce minerals on claims within the construction right-of-way, these plans might require accommodations to allow for both railroad construction and mining activities to proceed. Such accommodations might have economic consequences. DOE recognizes that mineral exploration and development is strongly tied to the price of mineral commodities. However, foreseeable impacts to mining from railroad construction would be very small because the mineral production in affected districts is only a small percentage of overall mineral production in Nevada. Further, construction would only temporarily affect the filing of new claims. However, individuals and localized areas could feel the impacts more severely.

As described in Section 4.3.2.2.3.2, wherever the rail line would cross a grazing allotment, DOE quantified the amount of forage loss in animal unit months in accordance with BLM standards. Factors that influence the determination of permitted animal unit months include quantity and quality of forage; type of forage; season in which the forage will be grazed; kind and mix of grazing animals; presence of water; topography; soil, climate, and disturbance regimes; wildlife cover; proper use factor; and management objectives. In 2001, the State of Nevada Department of Agriculture commissioned a report, *Nevada Grazing Statistics Report and Economic Analysis for Federal Lands in Nevada*, in which one animal unit month was assigned a value of $53.40 in direct and indirect contributions to the economy (DIRS 176949-Resource Concepts 2001, p. 47). DOE used this value to estimate economic losses due to impacts to grazing. Section 4.3.2, Land Use and Ownership, describes, for each potentially affected grazing allotment, the potential impacts to grazing activities from a land-use perspective.

Grazing allotments within the Mina rail alignment construction right-of-way would be affected in Mineral, Esmeralda, and Nye Counties for a total potential loss of up to 326 animal unit months and $17,400 to the local economy during each year of construction activity. This is a conservative estimate, because it assumes DOE would select only the most disruptive alternative segments. Table 4-247 summarizes animal unit month loss information presented in Section 4.3.2 and the corresponding economic impact. Table 4-247 only lists portions of the Mina rail alignment that would result in a loss (for example, the Bonnie Claire alternative segments are not included because none would affect animal unit months on nearby allotments). DOE calculated the totals to two significant figures by adding common segments and the most conservative alternative segment losses (shown in bold type).

Of the totals, about 133 of the animal unit months and $7,100 would be lost in Mineral County, 164 animal unit months and $8,800 would be lost in Esmeralda County, and 29 animal unit months and $1550 would be lost in Nye County. As presented in Table 3-140, Mineral, Esmeralda, and Nye Counties were projected to have gross regional products of $131 million, $25.7 million, and $1.16 billion, respectively, in 2007. In economies of these scales, the overall impacts of grazing losses would be small. However, individuals and localized areas could feel the impacts more severely. The BLM could elect to redraw the boundaries of grazing allotments to address these effects.

Table 4-247. Segment-specific annual economic impacts to grazing allotments during construction of the proposed rail line – Mina rail alignment.

Rail line segment	Animal unit months lost[a,b]	Value ($)
Mina common segment 1	133	7,100
Montezuma alternative segment 1	117	6,200
Montezuma alternative segment 2	82	4,400
Montezuma alternative segment 3	164	8,800
Oasis Valley alternative segment 1	8	400
Oasis Valley alternative segment 3	12	600
Common segment 6	17	900
Totals[c]	326	17,400

a. Figures for animal unit months lost for the Facilities at the Interface with the Union Pacific Railroad Mainline include impacts from associated quarries and the Staging Yard.
b. The values shown are worst-case values of the animal unit months that would be lost for 1 year (per year during proposed railroad construction and operations). The table lists only those portions of the rail alignment that would result in a loss.
c. Totals might differ from sums of values due to rounding.

During the construction phase, there could be an additional impact from construction trains colliding with cattle. DOE would compensate ranchers for any such losses of cattle in accordance with Nevada Revised Statutes 705.150 to 705.200.

The potential economic impacts to prime farmland areas are described in relation to employment and lost market value of crops. As discussed in Section 4.3.1.2.1.3, some portion of the 37,000 square meters (9.2 acres) of prime farmland soils would be lost under the Mina Implementing Alternative. This calculated amount of prime farmland is based on the total disturbed area, and is therefore an upper-bound measurement. Table 4-248 lists the estimated impacts to prime farmland.

Table 4-248. Potential impacts to prime farmland – Mina rail alignment.

Rail line segment	Number of acres affected	Market value of crops per acre ($)	Workers per acre	Market value lost ($)	Employment lost
Schurz alternative segment 1					
Lyon County	2.7	510	0.01	1,380	0.03
Schurz alternative segment 4					
Lyon County	3	510	0.01	1,530	0.03
Schurz alternative segments 5 and 6					
Lyon County	3.5	510	0.01	1,780	0.04

a. Source: DIRS 173571-USDA 2004, Tables 1 and 7.

Based on data from Nevada's Census of Agriculture, DOE estimated the market value of crops lost as less than $2,000 in Lyon County regardless of the Schurz alternative segment selected. DOE also estimates that less than one job would be lost in Lyon County under the Mina Implementing Alternative. The other counties in the Mina rail alignment region of influence would not experience any impacts because the rail line would not cross prime farmland in these counties.

4.3.9.2.2 Population and Housing

Population changes are related to changes in employment. DOE modeled employment of construction workers and some support workers as beginning in 2010 and ending in 2014, and estimated population impacts for the same period. Table 4-249 lists the estimated changes to population during the construction phase for each of the modeled scenarios. Appendix J describes the analysis in more detail. In Esmeralda and Lyon Counties and Washoe County-Carson City, population changes would be identical under either scenario. The peak population increases would be largely due to indirect employment effects.

In Lyon County, the peak estimated population change attributed to railroad construction along the Mina rail alignment would be an increase of eight people, which would correspond to a 0.01-percent increase in the Lyon County projected 2014 population level without the project. Two of these people would be school-aged children, according to the age distribution of Lyon County published by the Bureau of Census (DIRS 181384-Bureau of Census).

In Mineral County, the peak estimated population change attributed to railroad construction along the Mina rail alignment would be an increase of 64 people, which would correspond to a 1.4-percent increase in the Mineral County projected 2013 population level without the project. Twelve of these people would be school-aged children, according to the age distribution of Mineral County published by the Bureau of Census (DIRS 181384-U.S. Census Bureau [n.d.]).

Table 4-249. Estimated changes to population during railroad construction – Mina rail alignment.[a,b]

Location	2010	2011	2012	2013	2014
Lyon County	2	4	7	8	8
Mineral County					
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	35	51	64	64	63
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	34	50	64	64	60
Nye County					
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	23	27	51	83	86
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	23	51	84	89	88
Esmeralda County	5	8	18	27	33
Clark County					
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	387	717	1,024	1,057	1,011
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	385	714	1,023	1,059	1,015

a. Sources: DIRS 179558-Bland 2007, all; DIRS 180690-Bland 2007, all; DIRS 180689-Bland 2007, all.
b. Model does not discriminate non-county regions, such as the Walker River Paiute Reservation.

In Esmeralda County, the peak population gain of 33 people would translate to approximately five additional school-aged children, according to the age distribution of Esmeralda County published by the Bureau of Census (DIRS 175922-Census Bureau 2000, all). The *Policy Insight*-estimated population gain attributed to railroad construction along the Mina rail alignment represents a 3.1-percent increase in the projected 2014 population level for Esmeralda County without the project.

In Nye County, the peak population increase would be 89 people, about 16 of whom would be school-aged children, according to the age distribution of Nye County published by the Bureau of Census (DIRS 181384-U.S. Census Bureau [n.d.]). The estimated population gain attributed to construction of the proposed railroad along the Mina rail alignment would be less than a 1-percent increase over Nye County's projected population level without the project for all construction years.

In Clark County, the peak population increase would be 1,059 people. Of this increase, about 191 people would be school-aged children, according to the age distribution of Clark County published by the Bureau of the Census (DIRS 171297-Census Bureau 2004, all). The estimated population increase attributed to construction of the proposed railroad along the Mina rail alignment would represent less than a 1-percent increase over Clark County's projected population level without the project for all construction years.

If half of the construction workers for the project come from Washoe County-Carson City, then the peak population increase would be 384 people (Table 4-250). The estimated population increase attributed to construction of the proposed railroad along the Mina rail alignment would represent less than a 1-percent increase over the region's projected population level without the project for all construction years.

Table 4-250. Alternative analysis for estimated changes to population in Washoe County-Carson City during railroad construction – Mina rail alignment.[a]

Location	2010	2011	2012	2013	2014
Washoe County-Carson City[b]	160	291	397	384	359

a. This table does not list data for Clark County, but under the alternative analysis, Clark County impacts would be approximately half of the Clark County impacts identified in Table 4-249.
b. Source: DIRS 181590-Bland 2007, all.

Impacts on housing infrastructure would be small during the construction phase because most construction workers would be housed in construction camps at strategic locations along the rail alignment, rather than in nearby communities. If construction workers elected not to stay in the camps, motels or recreational vehicle parks could substitute as housing options. As discussed in Section 3.3.9.3.3, lodging is available along U.S. Highway 95 and 95A in and around Yerington, Hawthorne, Walker Lake, Mina, Goldfield, Beatty, and Town of Amargosa Valley. These towns offer 21 motels with a total of 733 rooms, and 13 recreational vehicle parks with a total of 412 spaces. These lodging options could not accommodate all workers and completely substitute for construction camps.

Some contractors could elect to use commercially available facilities to house construction personnel, such as those in Yerington, Hawthorne, Walker Lake, Mina, Goldfield, Beatty, and Town of Amargosa Valley. As indicated in Section 3.3.9.3.3, it appears there would be sufficient vacant housing stock in these areas to meet the needs of construction personnel.

4.3.9.2.3 Public Services

Impacts to public services at the county level would likely be small because the population projections with the project show very limited increases in overall counts. An additional demand on local health-care capacity would be the primary impact on public services. The area that is likely to experience the greatest impact is southern Nye County, where the Rail Equipment Maintenance Yard, the Cask Maintenance Facility, and the Nevada Railroad Control Center and National Transportation Operations Center would be.

4.3.9.2.3.1 Health Care. As presented in Section 4.3.10, Occupational and Public Health and Safety, during the construction phase, DOE expects approximately 620 total recordable and ***lost workday cases*** among involved and noninvolved workers; that is, approximately 120 per year. Construction workers would be served by one of the health services centers at each construction camp to be staffed by four medical personnel who would rotate shifts (DIRS 174087-Nevada Rail Partners 2005, p. 4-5). In addition, Nevada Test Site personnel could provide medical services for construction workers along common segment 6 as they do at present for workers at the Yucca Mountain Site. As is the practice at both the Nevada Test Site and the Yucca Mountain Site, medical evacuation services from Las Vegas would transport cases to facilities in Clark County or in Utah as needed.

Nevertheless, to conservatively estimate potential impacts to health-care capacity in the region of influence, DOE assumed that all of the accident and injury cases would be treated at existing facilities in Nye County. This addition of approximately 120 cases per year (related to the less than 1 percent increase in population attributable to the construction effort) could have a small adverse impact on the existing health-care capacity in Nye County. As described in Section 3.3.9.3.4, Nye County is considered medically underserved. The Nye Regional Medical Center in Tonopah has ambulance services, but lacks surgical facilities. The new hospital in Pahrump increased the county capacity to respond to routine and emergency and surgical needs, but the 25-bed increase in capacity might not be sufficient to meet current needs. Thus, any additional number of cases could affect the capacity of Nye County to address the health care needs of local users.

4.3.9.2.3.2 Education. Although there are only 39 schools in Lyon, Mineral, Nye, and Esmeralda Counties, it is unlikely that the capacities of these schools would be affected by railroad construction. DOE would not expect workers to be accompanied by their families and children because the availability of work camps and the use of 1- to 2-week work shifts would encourage workers to work from camps and return home on their weeks off to established residences in these counties, Clark County, or other Nevada counties. Any small increase in the number of children could be accommodated by the school systems, which have student-to-teacher ratios that are comparable to the national average.

4.3.9.2.3.3 Fire Protection. As discussed in Section 3.3.9.3.4, Lyon, Mineral, Nye, and Esmeralda Counties all meet fire-suppression needs with volunteers, with the exception of Pahrump, which has a paid fire department. In addition, three of the four fire districts in Lyon County are part of a quad-county partnership with Douglas County, Storey County, and Carson City. Although most communities characterized in the region of influence are currently able to provide adequate protection (except for Pahrump, which is currently underserved), any increased demand would move them closer to the limit that existing resources (personnel and equipment) could address. However, each construction camp would have personnel dedicated to fire response, and water wells and a water-tank trailer that would be used to respond to fire emergencies at the camps and construction areas. Because of this and low population increases expected for volunteer-reliant Lyon, Mineral, and Esmeralda Counties, construction-phase activities would not have an adverse impact on fire-protection capacity in the region of influence.

4.3.9.2.3.4 Law Enforcement. Because workers would be dispersed along the rail alignment, and given the low crime rate in the counties that would be directly affected (Lyon, Mineral, Nye, and Esmeralda) (particularly in comparison to the substantially higher Clark County and national crime rates), it is unlikely that the incidence of crime would increase to the extent that existing law enforcement services became inadequate. In other words, project-related increases in crime would be unlikely to overwhelm existing services. Additionally, construction camps would be staffed with security personnel (DIRS 174087-Nevada Rail Partners 2005, pp. 4-4 to 4-7). Accommodations could be made to decrease the possibility of adverse impacts to local law enforcement capacity. Although civil or domestic issues requiring law enforcement interface would be handled by the appropriate authorities, there have been no detailed discussions on protocols and working relationships.

4.3.9.2.4 Transportation Infrastructure

4.3.9.2.4.1 Traffic Impacts. The increased traffic required to support proposed railroad construction would have some additional impacts on existing roadways. Key roads likely to be affected are portions of U.S. Highway 95. At present, these roads are mainly operating at levels of service A or B as defined in Section 3.3.9.3.5, except for a stretch south of U.S. Highway 6 in Tonopah that is currently operating at level of service C. There could be impacts along these routes, particularly in communities that are near construction sites for the railroad operations support facilities. Areas where local road systems could be most affected are Hawthorne in Mineral County; Tonopah, Beatty, Town of Amargosa Valley, and at the entrance to the Yucca Mountain Site in Nye County; and Goldfield and Coaldale in Esmeralda County. The busiest roads within the transportation region of influence, in the Hazen, Silver Springs, and Wabuska areas, would not be affected by railroad construction or operations because no new rail lines or facilities are proposed in these areas.

Railroad construction would generate vehicle trips during facilities construction, both from the movement of materials and from workers traveling to and from the work sites. Truck traffic would be highest at the beginning and end of the construction phase while equipment was brought in and taken away, and could therefore adversely impact traffic conditions during specific weeks. However, trucks could be directed to move during off-peak hours to minimize their impacts on local traffic. Additionally, most construction materials for the Staging Yard and Maintenance-of-Way Facility would be transported by rail; therefore, there would be limited truck trips associated with the movement of materials for these facilities. For both reasons, the analysis does not account for transportation of materials, focusing instead on the transportation of workers to and from the work sites.

Construction of the rail line itself would not be likely to adversely affect traffic volumes on local roads, because much of the construction material would be transported by rail. Additionally, workers would be housed in construction camps close to work sites, so transportation of construction workers along local roads would be minimal. This would place only limited pressure on the transportation infrastructure, mainly at the end of a work week and possibly over the weekend when travel to local towns might increase. Therefore, the analysis of impacts to levels of service focuses on construction of the railroad operations support facilities.

The level of service analysis evaluates the additional traffic volume in terms of the "peak hour," which is the hour with the highest volume of traffic during a study period, usually a peak period. For example, DOE estimated that the movement of employees for the Rail Equipment Maintenance Yard and the Cask Maintenance Facility would require approximately 600 trips per day and 300 trips during the peak hour at the height of construction activities. The traffic analysis assumes that each employee would generate two vehicle trips per day, one of which would be during the peak hour.

The level of service analysis in this section is conservative because it assumes construction activities during a peak period when all workers are working simultaneously. DOE estimated the number of workers assigned to each facility (DIRS 180874-Nevada Rail Partners 2007, Appendix D, Table 2; DIRS 181425-Cask Maintenance Facility Technical Report, March 2007, p. 5). Table 4-251 lists the estimated number of vehicle trips during the construction phase.

Based on the estimated increases in traffic volumes listed in Table 4-251, DOE calculated the effect on the level of service of the affected roadways during peak hour traffic for construction of the three key facilities. All affected roadways were assumed to be configured as two-lane, non-divided paved highways.

The Staging Yard would be near Hawthorne along Mina common segment 1, potentially affecting traffic levels along U.S. Highway 95 and State Route 359. Construction of the Staging Yard would not degrade the level of service on either road, which would remain at C and A, respectively.

The Maintenance-of-Way Facility would be approximately 1.6 kilometers (1 mile) south of Silver Peak (Montezuma alternative segment 1) or near Klondike, about 2.9 kilometers (1.8 miles) west of U.S. Highway 95 between Tonopah and Goldfield (Montezuma alternative segment 2 or 3). Its construction could affect traffic levels on local roads, including U.S. Highway 95 between Tonopah and Goldfield. The analysis assumes that all traffic is channeled through U.S. Highway 95, which is the most heavily traveled road in the region. Construction of the Maintenance-of-Way Facility would not degrade the level of service, which would remain at B.

Table 4-251. Estimated highway trips during construction of the railroad operations support facilities – Mina rail alignment.[a]

Facility	Number of daily vehicle trips	Number of peak hour vehicle trips
Employees for construction of the Staging Yard	220	110
Employees for construction of the Maintenance-of-Way Facility	120	60
Employees for construction of the Rail Equipment Maintenance Yard and Cask Maintenance Facility	600	300

a. Sources: DIRS 180874-Nevada Rail Partners 2007, Appendix D, Table 2; DIRS 181425-Cask Maintenance Facility Technical Report, March 2007, p. 5.

Construction of the Rail Equipment Maintenance Yard, the Cask Maintenance Facility, and possibly the Nevada Railroad Control Center and National Transportation Operations Center would affect traffic on U.S. Highway 95 near the entrance to the Yucca Mountain Site, degrading its level of service from B to C during the peak hour. Level C would still represent stable traffic flow, but would mark the beginning of the range of flow that would become affected by interactions with others in the traffic stream.

4.3.9.2.4.2 Traffic Delay at Grade Crossings. DOE examined the potential for delays at grade crossings along existing rail lines in the region of influence and along the proposed rail line. Rail-highway crossings can be a source of delay to motorists because trains have movement priority. The delay analysis at grade crossings concentrates on the existing rail line between Hazen and Thorne because grade separation is not planned for any of these existing rail-highway intersections. DOE did not estimate delay at grade crossings for new rail segments because all major roads (U.S. Highways 95 and 6, and State Route 361) would be grade separated, and all roads that would cross the new rail segments at grade have very low traffic.

DOE estimated road traffic delay at rail-highway grade crossings based on the additional rail traffic from construction trains along the existing rail segments between Hazen and Thorne. Over the 4-year construction period, DOE estimated that eight one-way trains per day would be necessary (DIRS 180874-Nevada Rail Partners 2007, Appendix A, p. A-9). This estimate does not account for ballast trains, since they would not originate in Hazen, but at quarries along the rail alignment.

DOE calculated blocked crossing time per train according to the speed and length of trains, and determined crossing delay per stopped vehicle based on blocked crossing time, road arrival, and road departure rates. The Department calculated the total number of vehicles delayed per day as a function of the number of daily trains, average daily road traffic volume, and blocked crossing time. Total delay per day is the product of crossing delay per stopped vehicle and total number of vehicles delayed per day. Appendix J includes a detailed description of the methodology DOE used to calculate delay at grade crossings.

Table 4-252 summarizes total daily delay at each grade crossing analyzed. The maximum average delay per vehicle would be 1.7 seconds, up from 0.36 second without the additional construction rail traffic. Therefore, the maximum average delay at grade crossings caused by the additional rail traffic under the Proposed Action would be 1.3 seconds per vehicle, which represents a very small impact. The level of service on any of the analyzed intersections would not be degraded due to delay at grade crossings from additional rail traffic. Vehicles traveling on U.S. Highway 50A in Hazen, which currently has the lowest level of service (C) in the transportation region of influence, would experience an average delay of 0.6 second. The number of vehicles delayed in a day would increase from 10 to 89, and each stopped vehicle would be delayed by an average of 0.89 minute. Even though the number of vehicles affected would increase substantially, the average daily traffic at this intersection is about 7,900 vehicles. Therefore, less than one percent of vehicles traveling along U.S. Highway 50A would incur a delay of less than one minute.

4.3.9.2.4.3 Impacts to Existing Rail Lines. DOE examined the impacts of additional construction rail traffic to existing rail traffic along the Union Pacific Railroad Hazen Branchline and Department of Defense Branchlines. At present, these existing branchlines operate a few trains per week that would continue after construction of the proposed railroad. From Hazen to Wabuska, there are approximately two Union Pacific Railroad trains per week that operate on the Hazen Branchline. For purposes of analysis in this EIS, DOE estimated that approximately two Union Pacific Railroad trains en route to Wabuska and two Department of Defense trains en route to the Hawthorne Army Depot would run from Hazen to Hawthorne per week. During the construction phase, there would be five additional trains per day, which would be a substantial increase in the number of existing trains.

Table 4-252. Delay at highway-rail grade crossings during the construction phase – Mina rail alignment.

Federal Railroad Administration Crossing ID Number	Road name	County/ Reservation	Number of vehicles delayed per day		Average delay per vehicle (seconds)		Total delay per day (vehicle-minutes)	
			Existing	With proposed rail line	Existing	With proposed rail line	Existing	With proposed rail line
740905S	U.S. Highway 50A	Churchill	10	89	0.04	0.60	5.00	80.00
740906Y	Bango Road	Churchill	0	0	0.03	0.41	0.01	0.18
740907F	City Street	Churchill	0	0	0.03	0.41	0.00	0.01

Because there is very little traffic currently operating along the existing rail segments, DOE would not expect that existing trains would experience long delays, especially because train traffic would be coordinated to avoid delays. Therefore, impacts of new construction rail traffic on existing rail traffic would be moderate.

4.3.9.3 Railroad Operations Impacts

The common social and economic activities and changes associated with the operations phase would include:

- Increases in project-related employment, particularly associated with railroad operations support facilities
- Slight population increases associated with employment increases
- Some pressure on housing in southern Nye County where the Cask Maintenance Facility, Rail Equipment Maintenance Yard, and possibly the Nevada Railroad Control Center and National Transportation Operations Center would be
- Continued effects on mining and agriculture
- Possible effects on public services (health and education)
- Possible effects on transportation infrastructure

4.3.9.3.1 Employment and Income

Local impacts during the operations phase would be linked to the location of facilities, size of the workforce, and the extent to which the community would provide goods and services to facilities and workers. Table 4-253 lists the estimated number of full-time-equivalent workers that would be required for each railroad operations support facility. DOE used these employment figures as input to the *Policy Insight* model.

Table 4-253. Estimated average employment by railroad operations support facility – Mina rail alignment.[a]

Facility	Location	Workforce (full-time equivalent)
Staging Yard	Hawthorne	40
Cask Maintenance Facility	Inside the Yucca Mountain Site boundary near the repository	30
Nevada Railroad Control Center/National Transportation Operations Center	Mineral County or collocated with the Rail Equipment Maintenance Yard	15
Maintenance-of-Way Facility	Esmeralda County	40
Rail Equipment Maintenance Yard	Inside the Yucca Mountain Site boundary near the repository	25

a. Sources: DIRS 180873-Nevada Rail Partners 2007, Table 2-1; DIRS 180874-Nevada Rail Partners 2007, Table 3.

As it did for railroad construction, DOE modeled two scenarios for railroad operations – one with the Railroad Control Center and National Transportation Operations Center in Mineral County (Scenario 1) and the other with these facilities in Nye County (Scenario 2).

DOE modeled employment of operations workers and some support workers as beginning in 2015 and ending in 2067. Table 4-254 lists the economic impacts of both scenarios during the operations phase. All operations-related economic impact values are given in 2006 dollars.

The employment impacts on the Walker River Paiute Reservation are included in the estimates for Mineral County. The economic forecasting model is unable to discriminate impacts for the Reservation.

Table 4-254. Estimated changes in average annual economic measures during the operations phase – Mina rail alignment.[a]

Location/scenario	Total employment	Real disposable income	Gross regional product	State and local government expenditures
Lyon County				
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	1	$207,887	$107,280	$46,680
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	1	$155,125	$74,945	$35,205
Mineral County				
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	58	$3.6 million	$4.2 million	$599,000
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	38	$2.3 million	$3.3 million	$344,000
Nye County				
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	22	$2.2 million	$3.7 million	$419,000
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	27	$2.6 million	$4.6 million	$479,000
Esmeralda County				
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	62	$4.6 million	$11.2 million	$776,000
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	62	$4.6 million	$11.2 million	$776,000
Clark County				
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	85	$11.4 million	$12.8 million	$1.3 million
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	98	$12.7 million	$14.8 million	$1.4 million

a. Sources: DIRS 179558-Bland 2007, all; DIRS 180690-Bland 2007, all; DIRS 180689-Bland 2007, all.

In Lyon County, increases in economic measures would be similar under the two scenarios; however, the larger increases would be under Scenario 1, with the Nevada Railroad Control Center and National Transportation Operations Center in Mineral County. However, all increases would represent less than a 1-percent average annual increase over the projected annual average without the project. See Table 3-136 for baseline population data.

In Mineral County, the greater increases would be under Scenario 1, with the Nevada Railroad Control Center and National Transportation Operations Center in Mineral County. The total increased employment in Mineral County would average about 58 jobs annually over the operations phase. This would represent a 2.6-percent increase above the projected annual average employment level without the project. The peak operations-related impact to real disposable income, gross regional product, and state and local government spending would correspond to 2.8-, 1.9-, and 1.5-percent increases, respectively, above the projected levels for each measure without the project.

In Nye County, the greater increases in economic measures would be for Scenario 2, with the Nevada Railroad Control Center and National Transportation Operations Center in Nye County. However, all increases would represent less than a 1-percent average annual increase over the projected annual average without the project.

In Esmeralda County, changes in economic measures during the operations phase would be nearly identical under the two scenarios. The annual average change in employment would be an average increase of 62 jobs over the baseline during the operations phase. This peak impact would represent a 14-percent increase above the projected level without the project. The average increases in economic indicators would be $4.6 million above the baseline for real disposable income, $11.2 million above the baseline for gross regional product, and $776,000 above the baseline for state and local government spending. These impacts represent 10-, 24-, and 10-percent increases, respectively, above the projected levels for each measure without the project.

In Clark County, the greater increases in economic measures would be observed under Scenario 2, with the Nevada Railroad Control Center and National Transportation Operations Center in Nye County. However, all increases would represent less than a one-tenth of 1-percent average annual increase over the projected annual average without the project.

If half of the construction workers come from the combined area of Washoe County and Carson City, then there will be socioeconomic impacts that linger into the operations phase of the Proposed Action. The greater increases in economic measures would be observed under Scenario 1, with the Nevada Railroad Control Center and National Transportation Operations Center in Mineral County (see Table 4-255). However, all increases would represent less than a one-tenth of 1-percent average annual increase over the projected annual average without the project.

Section 4.3.11, Utilities, Energy, and Materials, describes impacts related to the use of construction materials and fossil fuel during the construction and operations phases.

The small economic impacts to mining and agriculture identified for the construction phase would continue during the operations phase. As for the construction phase, there would be a risk of trains colliding with cattle. DOE would compensate ranchers for any loss of cattle during railroad operations in accordance with Nevada Revised Statutes 705.150 to 705.200. Train and track inspection and maintenance activities would be confined to areas disturbed by construction activities, so there would be no additional disturbances to the physical environment. There could be some areas that were disturbed during construction activities that would not be affected during operations (for example, staging areas), and on which agricultural and mining activities could be resumed. Areas disturbed during construction but not needed for operations would be reclaimed in accordance with BLM guidance.

Table 4-255. Alternative analysis for estimated changes in average annual economic measures in Washoe County-Carson City during the operations phase – Mina rail alignment.[a]

Location/scenario	Total employment	Real disposable income	Gross regional product	State and local government expenditures
Washoe County-Carson City[b]				
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	28	$3.6 million	$3.8 million	$405,000
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	27	$3.6 million	$3.6 million	$393,000

a. This table does not list data for Clark County, but under the alternative analysis, Clark County impacts would be approximately half of the Clark County impacts identified in Table 4-254.
b. Source: DIRS 181590-Bland 2007, all.

4.3.9.3.2 Population and Housing

Population changes would be related to changes in employment. DOE modeled employment of railroad operations workers and some support workers as beginning in 2015 and ending in 2067. Population impacts are estimated for the same period. Table 4-256 lists estimated population changes for the two modeled scenarios during the operations phase.

Table 4-256. Estimated changes to population during the operations phase – Mina rail alignment (page 1 of 2).[a]

Location	Average change in population
Lyon County	
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	9

Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	76

Table 4-256. Estimated changes to population during the operations phase – Mina rail alignment (page 2 of 2).[a]

Location	Average change in population
Clark County	
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	280
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	310

a. Sources: DIRS 179558-Bland 2007, all; DIRS 180690-Bland 2007, all; DIRS 180689-Bland 2007, all.

The population impacts on the Walker River Paiute Reservation are included in the estimates for Mineral County. The economic forecasting model is unable to discriminate impacts for the Reservation.

In Lyon County, Scenario 1 would result in an average gain of 9 people annually above the projected levels without the project. Of this increase, about 2 people would be school-aged children, according to the age distribution of Lyon County published by the Bureau of the Census (DIRS 181384-U.S. Census Bureau [n.d.], all). The estimated average annual population increase attributed to the operations phase would be less than 1 percent above Lyon County's projected population annual average without the project.

At the county level, Lyon County would be able to absorb the increased demand for housing. At present, there are 1,272 vacant housing units in Lyon County (see Table 3-141).

In Mineral County, Scenario 1 would result in an average gain of 66 people annually above the projected levels without the project. Of this increase, about 13 people would be school-aged children, according to the age distribution of Mineral County published by the Bureau of the Census (DIRS 181384-U.S. Census Bureau [n.d.], all). The estimated average annual population increase attributed to the operations phase would be 1.6 percent above Mineral County's projected population annual average without the project.

At the county level, Mineral County might be able to absorb the increased demand for housing. At present there are 669 vacant housing units in Mineral County (see Table 3-141).

In Nye County, the greater average increase in population would be under Scenario 2, with an average gain of 98 people annually above the projected levels without the project. Of this increase, about 17 would be school-aged children, according to the age distribution of Nye County published by the Bureau of the Census (DIRS 181384-U.S. Census Bureau [n.d.], all). The estimated average annual population increase attributed to the operations phase would be less than 1 percent above Nye County's population projected annual average level without the project.

At the county level, Nye County, with 2,625 vacant housing units, would likely be able to absorb the increased demand for housing. Within the county, workers would likely choose to live in southern Nye County, where the Cask Maintenance Facility, Rail Equipment Maintenance Yard, and possibly the Nevada Railroad Control Center and National Transportation Operations Center would be. The 1,058 vacant housing units in Pahrump could accommodate increased demand, though it should be noted that Pahrump has been undergoing a substantial population increase recently (more than 25 percent between 2000 and 2004). Future increases in population are expected, which will place additional demand on the current housing stock. Therefore, project-worker demand for housing in the community would have the potential to create small impacts on the supply of available housing. No impact is expected on housing availability in the Tonopah area; the number of operations workers residing in that community would likely be small, and there would be adequate vacant housing available in the community to accommodate this increase, as discussed in Section 3.3.9.

In Esmeralda County, the average increase in population would be the same under either scenario, with an average gain of 76 people annually above the projected levels without the project. Of this increase, about 12 would be school-aged children, according to the age distribution of Esmeralda County published by the Bureau of the Census (DIRS 175922-Census Bureau 2000, all). The estimated average annual population increase attributed to the operations phase is 7 percent above the baseline.

At the county level, Esmeralda County, with 378 vacant housing units, would likely be able to absorb the increased demand for housing. At the local level, no impact is expected on housing availability in Goldfield or Tonopah, which are both close to Klondike and Silver Peak, the two alternative locations for where the Maintenance-of-Way Facility would be. The number of operations workers residing in either community would likely be small, and there would be adequate vacant housing available, as discussed in Section 3.3.9.3.3.

In Clark County, the greater average increase in population would be under Scenario 2, with an average gain of 310 people annually above the projected levels without the project. Of this increase, about 56 would be school-aged children, according to the age distribution of Clark County published by the Bureau of the Census (DIRS 171297-Bureau of Census 2004, all). The estimated average annual population increase attributed to the operations phase would be a less than one-tenth of 1-percent increase above Clark County's projected population annual average level without the project.

If half of the construction workers came from Washoe County and Carson City, then there would be population impacts that linger into the operations phase. The greater average increase in population for this combined region would be under Scenario 1, with an average gain of 81 people annually above the projected levels without the project (see Table 4-257). The estimated average annual population increase would be less than one-tenth of 1-percent increase above the combined region's projected population annual average level without the project.

Table 4-257. Alternative analysis for estimated changes to population in Washoe County-Carson City during the operations phase – Mina rail alignment.[a]

Location	Average change in population
Washoe County-Carson City[b]	
Scenario 1: Nevada Railroad Control Center/National Transportation Operations Center in Mineral County	81
Scenario 2: Nevada Railroad Control Center/National Transportation Operations Center in Nye County	79

a. This table does not list data for Clark County, but under the alternative analysis, Clark County impacts would be approximately half of the Clark County impacts identified in Table 4-256.
b. Source: DIRS 181590- Bland 2007, all.

4.3.9.3.3 Public Services

Railroad operations along the Mina rail alignment would result in small impacts to health-care capacity in Lyon, Mineral, Nye, and Esmeralda Counties and on education infrastructure in southern Nye County (Pahrump). The exact extent of impacts to other public services would depend on the total number of workers and their residential locations, and operations activities in relation to existing system capacity. However, workers could create small to moderate impacts in the form of additional demand for fire-protection services in Lyon, Mineral, Nye, and Esmeralda Counties.

4.3.9.3.3.1 Health Care. The increased demand for health care associated with the railroad operations support facilities could result in small adverse impacts to the existing health service capacity. As discussed in Section 3.3.9.3.4, Lyon, Mineral, Nye, and Esmeralda Counties are all considered medically underserved. This analysis assumes that there will be no health-care support for the project on the Walker River Paiute Reservation.

In particular, population impacts associated with facilities in southern Nye County could place increased demand on the health-care system in the county. The peak average increase in Nye County's permanent population would be 98 people (0.22 percent above the projected population without the project, or less than one-quarter of 1 percent), and it is assumed that many of these people would reside in or near Pahrump. Pahrump does have preventive care clinics and a new hospital although, as noted in Section 4.3.9.2.3.1, it is not clear whether the hospital is able to serve the routine and emergency health-care needs of the local population. Increased demand related to project increases in workers and permanent population, however small, could adversely affect the capacity of Pahrump's health-care system to meet local needs. If the Nevada Railroad Control Center and National Transportation Operations Center were in Mineral County instead of Nye County, the impacts to the health-care system in Nye County would be slightly less. Under this scenario, Nye County's permanent population would increase by 86 people, which would represent a 0.19-percent average increase.

4.3.9.3.3.2 Education. As indicated in Section 4.3.9.2.3.2, the annual impact to schools in Lyon, Mineral, Nye, and Esmeralda Counties that would result from the increase in population would average about 2, 13, 17, and 12 additional pupils, respectively. The operations phase workforce could place limited strains on the education system in Mineral and Nye Counties, resulting in small, if any, impact. The exact extent of this impact would depend on the final location of railroad operations support facilities, where workers choose to reside, whether workers relocated families and children, the ages of children, and the capacities of particular schools in 2015 and later.

In Nye County, DOE estimates a peak average annual increase of 132 people above the county's projected population without the project in 2066. The addition of these workers and permanent population to the county would have the potential to increase the number of children in the school system by 23.

The location of railroad facilities at the end of the line could result in many workers and their families residing in Pahrump. As noted in Section 3.3.9, independent of the proposed railroad, Pahrump is experiencing a fairly rapid increase in its population, and all schools are functioning at or above maximum design capacity. Further baseline population increases are predicted, meaning that even without project-related impacts, school capacity would become strained in the future. While any additional increases to the projected baseline population would increase the need for school capacity, the estimated additional 23 students associated with the proposed railroad would be a small incremental increase in relation to the school population increases Pahrump is experiencing at present. Therefore, the projected project-related impact would be small in comparison with the impact related to other factors.

Impacts in Esmeralda County would be limited because the number of resident workers at the Maintenance-of-Way Facility would be small; the elementary school system in Esmeralda County can accommodate an additional 100 students (DIRS 174970-Arcaya 2005, all); and students can attend high school in Tonopah, where there are elementary, middle, and high school facilities. The influx of operations-phase workers to Tonopah or Goldfield would not adversely affect school capabilities.

4.3.9.3.3.3 Fire Protection. As discussed in Section 4.3.9.2.3.3, Lyon, Mineral, Nye, and Esmeralda Counties all meet fire suppression needs with volunteers, with the exception of Pahrump's paid fire department. At present, most communities characterized in the region of influence are able to provide adequate protection (except for Pahrump, which is currently underserved), but increased demand on these services could move them closer to the limit that existing resources (personnel and equipment) could address. Increases to permanent county populations could result in small to moderate impacts in Lyon, Mineral, Nye, and Esmeralda Counties, and particularly in Pahrump, where, as noted in Section 3.3.9, fire-protection capabilities are already overextended. With the Cask Maintenance Facility collocated with the Rail Equipment Maintenance Yard, and most workers and their families residing in Pahrump, these additional demands on the fire-protection capabilities of Pahrump could affect the system's ability to meet the community's needs.

4.3.9.3.3.4 Law Enforcement. Given the low crime rates in Lyon, Mineral, Nye, and Esmeralda Counties, it is not likely that population increases would increase the incidence of crime to the extent that the existing level of law enforcement services would become inadequate to meet the demand.

4.3.9.3.4 Transportation Infrastructure

4.3.9.3.4.1 Traffic Impacts. There would be fewer road traffic impacts during the operations phase than during the construction phase because there would be considerably fewer workers during the operations phase. DOE estimates that a total of 150 employees would be needed to operate the railroad operations support facilities. A total of 70 employees would be working at the Nevada Railroad Control Center and National Transportation Operations Center, Rail Equipment Maintenance Yard, and Cask Maintenance Facility. Additionally, 40 employees would work at the Staging Yard, and 40 would work at the Maintenance-of-Way Facility (DIRS 180874-Nevada Rail Partners 2007, Appendix D, Table 4). Table 4-258 summarizes the projected number of vehicle trips that would be generated during the operations phase, assuming that each of these employees would generate two trips per day, one of them during the peak hour. The affected road segments would be the same as the ones considered in the analysis for the construction phase (see Section 4.3.9.2.4.1).

Table 4-258. Projected highway trips during operation of the railroad operations support facilities – Mina rail alignment.[a]

Facility	Number of daily vehicle trips	Number of peak hour vehicle trips
Employees for operations of the Staging Yard	80	40
Employees for operations of the Maintenance-of-Way Facility	80	40
Employees for operations of the facilities inside the Yucca Mountain Site boundary near the repository	140	70

a. Source: DIRS 180874-Nevada Rail Partners 2007, Appendix D, Table 4.

DOE determined that the projected trips listed in Table 4-258 for the three key areas could result in the following impacts to traffic:

- Operations at the Staging Yard would have a small impact on traffic along U.S. Highway 95 and State Route 359, and levels of service would remain at C and A, respectively (no degradation in level of service).
- Operations at the Maintenance-of-Way Facility would have a small impact on traffic along U.S. Highway 95 between Tonopah and Goldfield, and level of service would remain at B (no degradation in level of service).
- Operations at the facilities inside the Yucca Mountain Site boundary near the repository would affect traffic along U.S. Highway 95 near the entrance to the Yucca Mountain Site, which would degrade the level of service from B to C.

4.3.9.3.4.2 Traffic Delay at Grade Crossings. As in Section 4.3.9.2.4.2, DOE examined the effects of the Mina Implementing Alternative on delay at grade crossings along existing rail lines in the region of influence and along the proposed rail line. Rail-highway crossings can be a source of delay to motorists because trains have movement priority. The delay analysis at grade crossings concentrates on the existing rail line between Hazen and Thorne because grade separation is not planned for any existing rail-highway intersections. Delay at grade crossings was not estimated for new rail segments because all major roads (U.S. Highways 95 and 6, and State Route 361) would be grade separated, and all roads that would cross the new rail line at grade have very low traffic.

DOE estimated road traffic delay at rail-highway grade crossings based on the additional rail traffic at the existing rail segments between Hazen and Thorne. Over the 50-year operations phase, there would be a maximum of 17 one-way trains per week, including cask trains, maintenance-of-way trains, and repository supply trains (DIRS 180874-Nevada Rail Partners 2007, Appendix A, p. A-9). To provide a conservative estimate, DOE assumed that all trains would originate in Hazen. Assuming that trains would only travel on weekdays, an average of approximately 3.4 trains per day would be expected.

DOE calculated blocked crossing time per train according to the speed and length of trains, and determined crossing delay per stopped vehicle based on blocked crossing time, road arrival, and road departure rates. The Department calculated the total number of vehicles delayed per day as a function of the number of daily trains, average daily road traffic volume, and blocked crossing time. Total delay per day is the product of crossing delay per stopped vehicle and total number of vehicles delayed per day. Appendix J includes a detailed description of the methodology DOE used to calculate delay at grade crossings.

Table 4-259 summarizes total daily delay at each grade crossing analyzed. The maximum average delay per vehicle would be 0.48 second, up from 0.36 second without the additional rail traffic. Therefore, the maximum average delay at grade crossings caused by the additional rail traffic under the Proposed Action would be 0.12 second per vehicle, which would represent a very small impact. The level of service on any of the analyzed intersections would not be degraded due to delay at grade crossings from additional rail traffic. Vehicles traveling on U.S. Highway 50A in Hazen, which currently has the lowest level of service (C) in the transportation region of influence, would experience an average delay of 0.1 second. The number of vehicles delayed in a day would increase from 10 to 27, and all stopped vehicles would be delayed by an average of 0.5 minute. Even though the number of vehicles affected would increase substantially, the average daily traffic at this intersection is about 7,900 vehicles per day. Therefore, less than one percent of vehicles traveling along U.S. Highway 50A would incur a delay of 0.5 minute.

4.3.9.3.4.3 Impacts to Existing Rail Traffic. DOE examined the impacts of additional rail traffic to existing rail traffic along the Union Pacific Railroad Hazen Branchline and Department of Defense Branchlines. These existing branchlines currently operate a few trains per week that would continue after the proposed railroad was constructed. From Hazen to Wabuska, there are approximately two Union Pacific Railroad trains per week that operate on the Hazen Branchline. For purposes of analysis in this EIS, DOE estimated that approximately two Union Pacific Railroad trains en route to Wabuska and two Department of Defense trains en route to the Hawthorne Army Depot would run from Hazen to Hawthorne per week. During the operations phase, there would be between three and four additional trains per day, which is a significant increase to the number of existing trains. Because there is very little traffic currently operating along the existing rail segments, it is not expected that existing trains would face long delays, especially because train traffic would be coordinated to avoid delays. Therefore, impacts of new rail traffic on existing rail traffic would be moderate.

Table 4-259. Delay at highway-rail grade crossings during the operations phase – Mina rail alignment.

Federal Railroad Administration Crossing ID Number	Road name	County/ Reservation	Number of vehicles delayed per day		Average delay per vehicle (seconds)		Total delay per day (vehicle-minutes)	
			Existing	With proposed rail line	Existing	With proposed rail line	Existing	With proposed rail line

4.3.9.4 Impacts under the Shared-Use Option

The Shared-Use Option could result in additional facilities to support commercial use of the DOE rail line. Shared-use facilities could include access sidings in any of the following areas: Hawthorne, Luning, Mina, Goldfield, Silver Peak, and the Beatty area. Consideration of the Shared-Use Option addresses only those impacts that are reasonably foreseeable based on existing conditions in the affected communities.

4.3.9.4.1 Construction Impacts under the Shared-Use Option

Because commercial entities or local government would build commercial sidings at the locations of selected passing sidings (to the extent practicable), the incremental effort to construct the commercial sidings would be reduced. While there would be a need for some additional materials and labor, the increase over that needed under the Proposed Action without shared use would be small. As discussed in the following sections, DOE would expect impacts on population and housing; employment and income; public services; and transportation resources to be small under the Shared-Use Option, and similar to those under the Proposed Action without shared use.

4.3.9.4.1.1 Population and Housing. Given the minimal increase in economic activity that would be associated with railroad construction under the Shared-Use Option, there would be no to low population changes and attendant pressures on the available housing stock.

4.3.9.4.1.2 Employment and Income. There could be very limited increases in employment and income associated with construction under the Shared-Use Option. These increases would be similar to the changes in employment and income associated with construction under the Proposed Action without shared use. There could be limited loss of economic activity associated with land acquisition for the commercial-siding and parking-area rights-of-way, but DOE would expect such impacts, if any, to be small.

4.3.9.4.1.3 Public Services. Railroad construction under the Shared-Use Option would impact existing public services similar to the Proposed Action without shared use. Given the minimal incremental change in labor and population under the Shared-Use Option, impacts to health care, education, law enforcement, and fire-protection services would be small.

4.3.9.4.1.4 Transportation Infrastructure. The volume of daily and peak-hour trips that would be generated during railroad construction under the Shared-Use Option would be consistent with the volumes generated under the Proposed Action without shared use. For purposes of this analysis, DOE assumed that commercial access sidings and facilities would be constructed at the same time as the rail line, although it could also occur at a later date. There would be little increased traffic volume beyond that described for the Proposed Action without shared use.

The construction approach under the Shared-Use Option would be the same as that described for the Proposed Action without shared use, with construction being phased and best management practices implemented. Because, to the extent practicable, commercial sidings would be built at the locations of selected passing sidings, the incremental effort to construct commercial-use sidings would be minimized. There would be no need for additional construction camps and no need for new roads because the temporary access roads would also be used for commercial siding construction. Therefore, although there would be a need for some additional materials and labor under the Shared-Use Option, there would be little increase beyond that described for the Proposed Action without shared use. Based on the lengths of track involved under the Shared-Use Option, the incremental impacts to traffic from constructing the additional sidings would be a small fraction of the overall impacts for railroad construction under the Proposed Action without shared use. Thus, impacts to the transportation infrastructure under the Shared-Use Option would be small.

Traffic delay impacts at highway-rail grade crossings from construction trains would be consistent with the delay impacts under the Proposed Action without shared use.

4.3.9.4.2 Operations Impacts under the Shared-Use Option

The impact assessment for railroad operations under the Shared-Use Option draws on information from a DOE analysis (DIRS 180694-Ang-Olson and Gallivan 2007, all), as described in Section 2.2.6. In the near term, commercial shippers using the DOE rail line would be existing nearby companies that currently transport materials and goods by truck.

4.3.9.4.2.1 Population and Housing. It is not likely that there would be noticeable increases in population associated with railroad operations under the Shared-Use Option. Increases in economic activity and associated indicators, particularly in terms of employment, would likely be limited and therefore would not generate substantial changes in permanent population. Therefore, DOE would expect no impacts on housing under the Shared-Use Option.

4.3.9.4.2.2 Employment and Income. Shared use of the DOE rail line could allow business activity to develop and expand in the region of influence, which would result in some employment and income benefits. For some companies, especially those involved in the shipment of heavy or bulk products, the rail line could allow firms to access new markets and to ship greater quantities of products to existing and new markets.

Based on the DOE analysis (DIRS 180694-Ang-Olson and Gallivan 2007, all), and as described in Section 2.2.6, overall potential commercial shipments are estimated at 2,465,000 metric tons (2,711,000 tons) or 27,110 carloads annually, with shipments of stone estimated at 878,000 metric tons (966,000 tons) or 9,660 carloads (consisting primarily of outgoing decorative rock); nonmetallic minerals at 251,000 metric tons (276,000 tons) or 2,760 carloads (consisting primarily of pozzolan); and petroleum products at 13,000 metric tons (14,000 tons) or 140 carloads (consisting of incoming crude oil).

Therefore, access to commercial rail service could support business expansion and revenue increases for firms in Mineral and Nye Counties. These increases in revenue might generate small direct and indirect employment and income impacts. However, there are a number of factors, such as a firm's overall business objectives and planning decisions, which would influence the extent to which revenue translated into increased hiring or increased income.

Railroad operation under the Shared-Use Option would generate limited employment and income impacts. It is expected that a crew of three people would be needed to operate the commercial train service. As discussed in Section 2.2.4.1, depending on the total travel time for the commercial train, a crew change point might be needed. Train crews would use local commercial facilities for sleeping and provision needs, causing some small, but positive, impacts to employment and income. There might also be small economic benefits associated with maintenance of the commercial rail facilities by a commercial contractor.

4.3.9.4.2.3 Public Services. Because the impacts to population and employment would be so small in Lyon, Mineral, Esmeralda, Nye, and Clark Counties, impacts to public services under the Shared-Use Option would be unlikely in any of these counties.

4.3.9.4.2.4 Transportation Infrastructure. Under the Shared-Use Option, commercial rail service would begin after the completion of construction. During railroad operations, trains carrying casks would have priority over trains carrying commercial shipments in terms of time in transit. Up to 18 one-way commercial trains per week would run along the rail line (DIRS 180694-Ang-Olson and Gallivan 2007, all). For comparison, an average total of 17 one-way trains would run between Hazen and the repository per week carrying casks and other materials for ***maintenance-of-way activities*** (DIRS 175036-BSC 2005, Table 4.2). The commercial trains (not including the locomotives) would consist of up to 60 cars and would be approximately 1,100 meters (3,600 feet) long. Depending on the weight of the train, three or four locomotives would be required (DIRS 176756-Ang-Olson and Khan 2005, all).

Commercial trains would haul a range of products to and from businesses, including stone and other nonmetallic minerals, oil and petroleum products, and nonradioactive waste materials. DOE expects the operating characteristics of these trains to be similar to those typical of freight train operations. The Nevada Railroad Control Center would control and coordinate commercial rail service movements and would therefore maintain overall safety of operations along the rail line.

The volume of daily and peak-hour vehicle trips that would be generated during operations under the Shared-Use Option would be consistent with operations under the Proposed Action without shared-use. There would be little increase in traffic volumes beyond those described in Section 4.3.9.2.4.1.

During operation of commercial service on the rail line, there would be an increase in truck traffic to and from the commercial sidings as compared to the Proposed Action without shared use. DOE assumed that under the Proposed Action without shared use, private companies near the rail line would continue to ship and receive freight using truck-only transport. Under the Shared-Use Option, some of those shipments would be diverted to rail, with trucks accessing the commercial sidings. The reduced number of truck shipments that would result from rail shipment would offset the adverse impacts due to additional increase in number of trucks under the Shared-Use Option. Therefore, DOE would anticipate little increase in adverse impacts to the traffic levels of service of nearby roadways.

Road traffic delay impacts at highway-rail grade crossings would be higher than under the Proposed Action without shared use because of the additional commercial trains. Over the 50-year operations phase, there would be up to 18 one-way commercial trains per week (DIRS 180694-Ang-Olson and Gallivan 2007, all). To provide a conservative estimate, DOE assumed all trains would originate in Hazen. Assuming that trains would only travel on weekdays, an average of approximately 3.6 commercial trains per day would be expected. Even though the train length could vary based on the number of railcars, DOE used the maximum train length (with 60 railcars and four locomotives) in this analysis. Because there would be approximately 3.4 trains per day operating along the rail line (including cask trains, maintenance-of-way trains, and repository supply/construction trains), DOE considered a total of 7 trains per day in the analysis.

Table 4-260 summarizes total daily delay at each grade crossing analyzed. The maximum average delay per vehicle would be 4.4 seconds, up from 0.36 second without the additional rail traffic. Therefore, the maximum average delay at grade crossings caused by the additional rail traffic under the Proposed Action would be about 4 seconds per vehicle, which would represent a very small impact. The level of service on any of the analyzed intersections would not be degraded due to delay at grade crossings from additional rail traffic. Vehicles traveling on U.S. Highway 50A in Hazen, which currently has the lowest level of service (C) in the transportation region of influence, would experience an average delay of 1.8 seconds. The number of vehicles delayed in a day would increase from 10 to 169, and each stopped vehicle would be delayed by an average of 1.36 minutes. Even though the number of vehicles affected would increase substantially, the average daily traffic at this intersection is about 7,900 vehicles per day. Therefore, about two percent of vehicles traveling along U.S. Highway 50A would incur a delay of just above 1 minute.

4.3.9.4.2.5 Impacts to Existing Rail Traffic. DOE examined the impacts of additional rail traffic (including commercial trains) on existing rail traffic along the Union Pacific Railroad Hazen Branchline and Department of Defense Branchlines. These existing branchlines currently operate a few trains per week that would continue after the proposed railroad was constructed. From Hazen to Wabuska, there are approximately two Union Pacific Railroad trains per week that operate on the Hazen Branchline. For purposes of analysis in this Rail Alignment EIS, DOE estimated that approximately two Union Pacific Railroad trains en route to Wabuska and two Department of Defense trains en route to the Hawthorne Army Depot would run from Hazen to Hawthorne per week. During the operations phase, there could be about seven additional trains per day, which is a significant increase in the number of existing trains. Because there is very little traffic currently operating along the existing rail segments, DOE does not expect that existing trains would face long delays, especially because train traffic would be coordinated to avoid delays. Therefore, impacts of new rail traffic on existing rail traffic would be moderate.

Table 4-260. Delay at highway-rail grade crossings during the operations phase – Mina rail alignment Shared-Use Option.

Federal Railroad Administration Crossing ID Number	Road name	County/ Reservation	Number of vehicles delayed per day		Average delay per vehicle (seconds)		Total delay per day (vehicle-minutes)

4.3.9.5 Summary

Table 4-261 summarizes the potential socioeconomic impacts of constructing and operating the proposed railroad along the Mina rail alignment. Impacts under the Shared-Use Option would be the same as those under the Proposed Action without shared use; however, DOE recognizes the speculative potential for increased economic development.

Potential socioeconomic impacts from construction and operation of the proposed railroad along the Mina rail alignment include the following:

- Population increases in all of the counties in the region of influence during the construction phase. The greatest percentage increase in population would be in Esmeralda County (3.1 percent) and Mineral County (1.4 percent).
- Population increases in all of the counties in the region of influence during the operations phase. The greatest percentage increase in population would be in Esmeralda County (7 percent) and Mineral County (1.6 percent).

- Employment increases in all of the counties in the region of influence during the construction phase. The greatest percentage increase in employment would be in Esmeralda County (14 percent) and Mineral County (6.1 percent).
- Employment increases in all of the counties in the region of influence during the operations phase. The greatest percentage increase in employment would be in Esmeralda County (14 percent) and Mineral County (2.6 percent).
- Real disposable income increases in all of the counties in the region of influence during the construction phase. The greatest percentage increase in real disposable income would be in Esmeralda County (27 percent) and Mineral County (4.5 percent).
- Real disposable income increases in all of the counties in the region of influence during the operations phase. The greatest percentage increase in real disposable income would be in Esmeralda County (10 percent) and Mineral County (2.8 percent).
- Gross regional product increases in all of the counties in the region of influence during the construction phase. The greatest percentage increase in gross regional product would be in Esmeralda County (57 percent) and Mineral County (14 percent).
- Gross regional product increases in all of the counties in the region of influence during the operations phase. The greatest percentage increase in gross regional product would be in Esmeralda County (24 percent) and Mineral County (1.9 percent).
- State and local government spending increases in all of the counties in the region of influence during the construction phase. The greatest percentage increase in state and local government spending would be in Esmeralda County (4.6 percent) and Mineral County (1.8 percent).
- State and local government spending increases in all of the counties in the region of influence during the operations phase. The greatest percentage increase in state and local government spending would be in Esmeralda County (9.9 percent) and Mineral County (1.5 percent).
- There would be no noticeable impacts to public services during the construction phase.
- There would be small to moderate impacts to some public services during the operations phase (see Table 4-261 for details).
- There would be some impacts to transportation during the construction phase (see Table 4-261 for details).
- There would be some impacts to transportation during the operations phase (see Table 4-261 for details).

4.3.10 OCCUPATIONAL AND PUBLIC HEALTH AND SAFETY

This section describes potential nonradiological and radiological health and safety impacts to workers and the public from construction and operation of the proposed railroad along the Mina rail alignment, including ***incident-free transportation*** and transportation accident scenarios. Section 4.3.10.1 describes the impact assessment methodology, Section 4.3.10.2 describes potential impacts associated with the Proposed Action, Section 4.3.10.3 describes potential impacts associated with the Shared-Use Option, and Section 4.3.10.4 summarizes potential impacts.

Incident-free transportation: Routine transportation in which cargo travels from origin to destination without being involved in an accident.

Accident: An unplanned sequence of events that leads to undesirable consequences.

Section 4.3.10.1 describes the region of influence for nonradiological and radiological impacts.

Appendix K, Radiological Health and Safety, describes the methods and data DOE used to assess radiological impacts for this Rail Alignment EIS.

4.3.10.1 Impact Assessment Methodology

4.3.10.1.1 Nonradiological Impact Assessment Methodology

Nonradiological impacts to occupational health and safety would include impacts to workers from exposure to physical hazards and nonradioactive ***hazardous chemicals*** during construction and operation of the proposed rail line and associated facilities. DOE estimated such impacts using occupational incident rates for total ***recordable cases***, lost workday cases, and fatalities. Total recordable cases are defined as the total number of work-related injuries or illnesses that resulted in fatalities, days away from work, job transfer or restriction, or other cases as identified in Occupational Safety and Health Administration (OSHA) Form 300, Log of Work-Related Injuries and Illnesses (DIRS 175488-OSHA [n.d.], all). Recordable cases of work-related injury or illness include fatality; loss of consciousness; injury or illness resulting in one or more days away from work; administration of medical treatment other than first aid; and other workplace injury or illness diagnosed by a physician or other health-care professional. OSHA defines lost workday cases as injuries or illnesses resulting in loss of 1 or more work days, not including the day the injury or illness occurred.

This section also discusses potential exposure of workers to physical (nonradiological) hazards related to transportation accidents and cask-handling accidents. Impacts to occupational and public health and safety from exposures to hazards associated with other resource areas are also discussed separately in this section. These include air quality hazards (potential occupational exposures to criteria and ***toxic air pollutants***, including diesel particulate matter and carbon monoxide, and to nonradiological ***hazardous air pollutants***) and noise hazards (potential occupational exposure to noise). Public exposure to air pollutants and noise are discussed in more detail in Section 4.3.4, Air Quality and Climate, and Section 4.3.8, Noise and Vibration. Hazards associated with other specific resource areas discussed in this section include biological hazards and dust and soils hazards.

DOE estimated nonradiological occupational impacts by multiplying the number of labor hours worked by involved and noninvolved construction workers and operations workers by workplace health and safety incident rates in units of number of occurrences per hour worked for involved workers and noninvolved workers. The workplace incident rates DOE used for this analysis are U.S. Department of Labor, Bureau of Labor Statistics, data for 2005 (DIRS 179129-BLS 2007, all; DIRS 179131-BLS 2006, all).

The nonradiological occupational health and safety impact analysis is based on health and safety incident statistics defined as follows (DIRS 155970-DOE 2002, p. F-17):

- Fatalities, regardless of the time between the injury and death, or the length of the illness
- Lost workday cases, other than fatalities, that result in lost workdays
- Nonfatal cases without lost workdays that result in transfer to another job, termination of employment, medical treatment (other than first aid), loss of consciousness, or restriction of work or motion

DOE estimated the frequency of occurrence of such incidents based on the specific activity (construction or operations) and the number of activity-specific worker labor hours.

Table 4-262 cites U.S. Department of Labor, Bureau of Labor Statistics, incident rate data DOE used to estimate total recordable cases, lost workday cases, and fatalities for involved and noninvolved workers during construction and operation of the proposed railroad. Involved workers are defined for the purposes of this analysis as personnel who would be directly involved in construction or operations activities. Noninvolved workers are defined for the purposes of this analysis as personnel who would be involved in management, administration, and security. The Bureau of Labor Statistics compiled the health and safety statistics by employment sector, including the Heavy and Civil Engineering Construction Sector; Management of Companies and Enterprises Sector; Transportation and Warehousing: Rail Transportation Sector; Support Activities for Transportation Sector; Non-Metallic Mineral Manufacturing (Batch Plant Construction and Operation); and Mining and Support Activities for Mining (Quarry Construction and Operation involved and noninvolved workers). Fatality incident statistics are compiled by employment sector, including Construction; Professional and Business Services; Transportation and Warehousing; Mining (Quarry Construction and Operation); and Manufacturing (Batch Plant Construction and Operation.)

The U.S. Department of Labor Mine Safety and Health Administration reports occupational nonfatal incident and fatality incident data for stone, quarry, and mill operations (surface mining). In 2005, a total of nine fatalities were reported in sand and gravel surface mining for 37,258 full-time-equivalent workers and a total of five fatalities were reported in stone surface mining for 34,744 full-time-equivalent workers. This corresponds to a total fatal incident rate of 20.3 fatalities per 100,000 full-time-equivalent workers. This is lower than the fatality incident rate of 25.6 fatalities per 100,000 full-time-equivalent workers reported by the Bureau of Labor Statistics for all mining activities. DOE used the Bureau of Labor Statistics fatality incident rate to estimate the fatalities associated with quarry and ballast site construction, operation, and reclamation for the purposes of maintaining consistency with the Bureau of Labor Statistics incident rate data for other rail line and facilities construction and operations activities (DIRS 178746-MSHA 2006, all; DIRS 178747-MSHA 2006, all; DIRS 178748-MSHA 2006, all).

The statistics for recordable cases and lost workday cases for rail line and associated facility construction for involved workers are applicable to the Heavy and Civil Engineering Construction Sector, and statistics for noninvolved workers are applicable to the Management of Companies and Enterprises Sector. The statistics for total recordable cases and lost workday cases for rail line operations for involved workers are applicable to the Transportation and Warehousing: Rail Transportation Sector. The statistics for rail line facility operations for involved workers are applicable to the Support Activities for Transportation Sector. The statistics for noninvolved workers are applicable to the Management of Companies and Enterprises Sector. Statistics for fatalities are applicable to the Construction Sector and Transportation and Warehousing Sector for involved workers and to the Professional and Business Services Sector for noninvolved workers.

Table 4-262. U.S. Department of Labor, Bureau of Labor Statistics, incident rate data for estimating industrial safety impacts common to the workplace.[a]

	Total recordable cases incidents per 100 FTEs[b]		Lost workday cases per 100 FTEs[b]		Fatalities per 100,000 FTEs[b]	
Activity	Involved	Noninvolved	Involved	Noninvolved	Involved	Noninvolved
Construction						
Rail line	5.6	2.4	3.1	1.3	11	3.5
Facilities	5.6	2.4	3.1	1.3	11	3.5
Quarry/ballast site construction and operation	4.1	3.9	2.7	2.2	25.6	3.5
Batch plant construction and operation	9.1		3.8		2.4	
Operations						
Rail line	2.5	2.4	1.9	1.3	17.6	3.5
Facilities	5.5	2.4	3.4	1.3	17.6	3.5

a. Sources: DIRS 179129-BLS 2007, Table 1. Incidence rates (1) of nonfatal occupational injuries and illnesses by selected industries and case types, 2005; DIRS 179131-BLS 2006, Number of fatal work injuries, 1992-2005, Number and rate of fatal occupational injuries by major occupation groups, 2005.
b. One full-time-equivalent worker is defined as 2,000 labor hours worked.

All Bureau of Labor Statistics data used in this Rail Alignment EIS are for 2005. These statistics are summarized in Table 4-262 and are applied to estimate the total recordable cases, lost workday cases, and fatalities for the construction and operation of the rail line and associated facilities.

DOE performed the following steps as part of the nonradiological occupational health and safety impact calculations:

1. DOE obtained full-time-equivalent data for each phase of construction and operation of the proposed rail line and associated facilities from the following documents: The numbers of full-time-equivalent worker years for each rail line construction and operations activity were obtained from Appendix D of the *Air Quality Emissions Factors and Socioeconomic Input Mina Rail Corridor*, Rev 00, April 20, 2007 (DIRS 180874-Nevada Rail Partners 2007), and the Personnel Breakdown Per Camp shown as Table 4-2 and the schedule shown as Figure 7-A, MRC Construction Schedule, from the Construction Plan, Rev 00, April 30, 2007 (DIRS 180875-Nevada Rail Partners 2007). The numbers of full-time-equivalent worker years for each rail line facility construction and operations activity were obtained from Appendix D of the *Air Quality Emissions Factors and Socioeconomic Input – Mina Rail Corridor*, Rev 00, April 20, 2007 (DIRS 180874-Nevada Rail Partners 2007). A "full-time-equivalent" is defined as 2,000 labor hours worked per year. It is not necessarily the case that all 2,000 hours of an annual full-time-equivalent would be worked by the same individual. For example, train engineers operate on a crew schedule based on the number of train trips. Therefore the 2,000 hours per year worked for one full-time-equivalent for the labor category "train engineer" may comprise several individual train engineers.

2. DOE categorized full-time-equivalent workers for construction and operations workers as either "involved" workers or "noninvolved" workers depending on the specific activity of the worker identified. For purposes of this analysis, involved workers are defined as workers directly involved in construction or operations activities. Noninvolved workers are defined as workers performing management, administration, or security functions.

   The incident statistics used in the calculation are reported by the Bureau of Labor Statistics for calendar year 2005 (DIRS 179129-BLS 2007, all; DIRS 179131-BLS 2006, all).

   Incident rate statistics for total recordable cases, lost workday cases, and fatalities differ for involved and noninvolved workers.

   - All rail line workers are categorized as involved workers.
   - Facilities operations workers in job categories including "management," "administration," "clerical," and "security" are categorized as "noninvolved" workers.
   - Facilities operations workers in other job categories are categorized as "involved" workers.

   The Bureau of Labor Statistics compiles health and safety statistics by employment sector, including the Heavy and Civil Engineering Construction Sector; Management of Companies and Enterprises Sector; Transportation and Warehousing: Rail Transportation Sector; and Support Activities for Transportation Sector. The statistics for total recordable cases and lost workday cases for rail line and associated facilities construction for involved workers are applicable to the Heavy and Civil Engineering Construction Sector, and statistics for noninvolved workers are applicable to the Management of Companies and Enterprises Sector. The statistics for total recordable cases and lost workday cases for rail line operations for involved workers are applicable to the Transportation and Warehousing: Rail Transportation Sector, statistics for railroad facility operations for involved workers are applicable to the Support Activities for Transportation Sector, and statistics for noninvolved workers are applicable to the Management of Companies and Enterprises Sector. Statistics for fatalities are applicable to the Construction Sector and Transportation and Warehousing Sector for involved workers and to the Professional and Business Services Sector for noninvolved workers. All Bureau of Labor Statistics data used in this Rail Alignment EIS are for 2005.

3. Full-time-equivalent workers for construction of the rail line include the following activities.

   - Rail line construction

4. Full-time-equivalent workers for construction of railroad facilities include the following facilities.

   - Concrete batch plant construction
   - Concrete batch plant operation
   - Water-well drilling
   - Construction camp construction
   - Construction camp operation
   - Quarry construction
   - Quarry operation
   - Staging Yard
   - Maintenance-of-Way Facility
   - Nevada Railroad Control Center and National Transportation Operations Center

- Cask Maintenance Facility
- Rail Equipment Maintenance Yard
- Facility access roads

5. Full-time-equivalent workers for operation of the railroad facilities include the following facilities.

    - Staging Yard
    - Maintenance-of-Way Facility
    - Nevada Railroad Control Center and National Transportation Operations Center
    - Cask Maintenance Facility
    - Rail Equipment Maintenance Yard

6. DOE identified construction full-time-equivalent workers for each year of the construction schedule for the rail line and each facility. The full-time-equivalent workers for each year are summed to calculate the total involved full-time-equivalent workers and total noninvolved full-time-equivalent workers for the rail line and each facility.

7. Full-time-equivalent worker data for involved workers and noninvolved workers are multiplied by incident rates published by the U.S. Department of Labor, Bureau of Labor Statistics, for various employment sector categories applied to involved and noninvolved construction workers and operations workers to estimate the number of incidents for construction and operation of the rail line and associated facilities for the Proposed Action and Shared-Use Option. Employment sector categories for the Bureau of Labor Statistics incident rate data applied to involved and noninvolved workers are described above in Step 2.

Sections 4.3.10.2 and 4.3.10.3 discuss nonradiological impacts to the public from construction and operation of the proposed rail line and associated facilities under the Proposed Action and the Shared-Use Option. These nonradiological impacts include air quality impacts, noise impacts, and transportation (traffic accident and fatality) impacts. The methodologies for estimating these impacts from specific resource areas are described in the respective sections of this Rail Alignment EIS. Potential impacts from occupational exposure to workplace dust and noise during construction and operation of the Proposed Action and the Shared-Use Option are also discussed in Sections 4.3.10.2 and 4.3.10.3.

4.3.10.1.2 Radiological Impact Assessment Methodology

Radiation is the emission and propagation of energy through space or through a material in the form of waves or bundles of energy called photons, or in the form of high-energy subatomic particles. Radiation generally results from atomic or subatomic processes that occur naturally. The most common kind of radiation is electromagnetic radiation, which is transmitted as photons. Electromagnetic radiation is emitted over a range of wavelengths and energies. Humans are most commonly aware of visible light, which is part of the spectrum of electromagnetic radiation. Radiation of longer wavelengths and lower energy includes infrared radiation (which heats material when the material and the radiation interact), and radio waves. Electromagnetic radiation of shorter wavelengths and higher energy (more penetrating) includes ultraviolet radiation (which causes sunburn), X-rays, and gamma radiation.

Ionizing radiation is radiation that has sufficient energy to displace ***electrons*** from atoms or molecules to create ions. It can be electromagnetic (for example, X-rays or gamma radiation) or subatomic particles (for example, alpha, beta, or ***neutron*** radiation). The ions have the ability to interact with other atoms or molecules; in biological systems, this interaction can cause damage in the tissue or organism.

Radioactivity is the property or characteristic of an unstable atom to undergo spontaneous transformation (to disintegrate or decay) with the emission of energy as radiation. Usually the emitted radiation is ionizing radiation. The result of the process, called ***radioactive decay***, is the transformation of an unstable atom (a ***radionuclide***) into a different atom, accompanied by the release of energy (as radiation) as the atom reaches a more stable, lower energy configuration.

Radioactive decay produces three main types of ionizing radiation—***alpha particles***, **beta particles**, and ***gamma*** or ***X-rays***. Neutrons emitted during nuclear fission are another type of ionic radiation. These types of ionizing radiation can have different characteristics and levels of energy and, thus, varying abilities to penetrate and interact with atoms in the human body. Because each type has different characteristics, each requires different amounts of material to stop (shield) the radiation. Alpha particles are the least penetrating and can be stopped by a thin layer of material such as a single sheet of paper. However, if radioactive atoms (radionuclides) emit alpha particles in the body when they decay, there is a concentrated deposition of energy near the point where the radioactive decay occurs. Shielding beta particles requires thicker layers of material such as several reams of paper or several inches of wood or water. Shielding from gamma rays, which are highly penetrating, requires very thick material such as several inches to several feet of heavy material (for example, concrete or lead). Deposition of the energy by gamma rays is dispersed across the body in contrast to the local energy deposition by an alpha particle. Some gamma radiation will pass through the body without interacting with it. Shielding from neutrons, which are also highly penetrating, requires materials that contain light elements such as hydrogen.

In a nuclear ***reactor***, heavy atoms such as uranium and plutonium can undergo another process, called ***fission***, after the absorption of a subatomic particle (usually a neutron). In fission, a heavy atom splits into two lighter atoms and releases energy in the form of radiation and the kinetic energy of the two new lighter atoms. The new lighter atoms are called ***fission products***. The fission products are usually unstable and undergo radioactive decay to reach a more stable state.

Some of the heavy atoms might not fission after absorbing a subatomic particle. Rather, a new nucleus is formed that tends to be unstable (like fission products) and undergo radioactive decay.

The radioactive decay of fission products and unstable heavy atoms is the source of the radiation from spent nuclear fuel and high-level radioactive waste that makes these materials hazardous in terms of potential human health impacts.

Radiation that originates outside of an individual's body is called external or direct radiation. Such radiation can come from an X-ray machine or from radioactive materials that directly emit radiation, such as radioactive waste or radionuclides in soil. ***Exposure*** to direct radiation can be mitigated by placing shielding, such as lead, between the source of the radiation and the exposed individual. Internal radiation originates inside a person's body following intake of radioactive material or radionuclides through ingestion or inhalation. Once in the body, the ***fate*** of a radioactive material is determined by its chemical behavior and how it is metabolized. If the material is soluble, it might be dissolved in bodily fluids and transported to and deposited in various body organs; if it is insoluble, it might move rapidly through the gastrointestinal tract or be deposited in the lungs.

Exposure to ionizing radiation is expressed in terms of ***absorbed dose***, which is the amount of energy imparted to matter per unit mass. Often simply called ***dose***, it is a fundamental concept in measuring and quantifying the effects of exposure to radiation. The unit of absorbed dose is the ***rad***. The different types of radiation mentioned above have different effects in damaging the cells of biological systems. ***Dose equivalent*** is a concept that considers the absorbed dose and the relative effectiveness of the type of ionizing radiation in damaging biological systems, using a radiation-specific quality factor. The unit of dose equivalent is the ***rem***. In quantifying the effects of radiation on humans, other types of concepts are also used. The concept of ***effective dose equivalent*** is used to quantify effects of radionuclides in the body.

It involves estimating the susceptibility of the different tissue in the body to radiation to produce a tissue-specific weighting factor. The weighting factor is based on the susceptibility of that tissue to cancer. The sum of the products of each affected tissue's estimated dose equivalent multiplied by its specific weighting factor is the effective dose equivalent. The potential effects from a one-time ingestion or inhalation of radioactive material are calculated over a period of 50 years to account for radionuclides that have long ***half-lives*** and long residence time in the body. The result is called the committed effective dose equivalent. The unit of effective dose equivalent is the rem. Total effective dose equivalent is the sum of the committed effective dose equivalent from radionuclides in the body plus the dose equivalent from radiation sources external to the body (also in rem). All estimates of radiation dose in this Rail Alignment EIS, unless specifically noted otherwise, are total effective dose equivalents, which are quantified in terms of rem or millirem (mrem).

More detailed information on the concepts of radiation dose and dose equivalent are in publications of the National Council on Radiation Protection and Measurements (DIRS 101857-NCRP 1993, all) and the International Commission on Radiological Protection (DIRS 101836-ICRP 1991, all).

The factors used to convert estimates of radionuclide intake (by inhalation or ingestion) or external exposure to radionuclides (by ***groundshine*** or ***cloudshine*** [immersion]) to radiation dose are called dose conversion factors or dose coefficients. The International Commission on Radiological Protection and federal agencies such as the U.S. Environmental Protection Agency (EPA) publish these factors (DIRS 172935-ICRP 2001, all; DIRS 175544-EPA 2002, all). They are based on original recommendations of the International Commission on Radiological Protection (DIRS 101836-ICRP 1991, all).

The radiation dose to an individual or to a group of people can be expressed as the total dose received or as a ***dose rate***, which is dose per unit time (usually an hour or a year). ***Collective dose*** is the total dose to an exposed population. ***Person-rem*** is the unit of collective dose. Collective dose is calculated by summing the individual dose to each member of a population. For example, if 100 workers each received 0.1 rem, the collective dose would be 10 person-rem (100 persons × 0.1 rem).

Exposures to radiation or radionuclides are often characterized as being acute or chronic. Acute exposures occur over a short period, typically 24 hours or less. Chronic exposures occur over longer periods (months to years); they are usually assumed to be continuous over a period, even though the dose rate might vary. For a given dose of radiation, chronic radiation exposure is usually less harmful than acute exposure because the dose rate (dose per unit time, such as rem per hour) is lower, providing more opportunity for the body to repair damaged cells.

The radiation dose estimates discussed in this Rail Alignment EIS are associated with exposure to radiation at low dose rates. Such exposures can be chronic (continuous or nearly continuous), such as those to workers who are security escorts. In some instances, exposures to low levels of radiation would be intermittent (for example, infrequent exposures to an individual from radiation emitted from ***shipping casks*** as they are transported). ***Cancer*** induction is the principal potential risk to human health from exposure to low levels of radiation. However, this cancer induction is a statistical process because exposure to radiation conveys only a chance of developing cancer, not a certainty. Furthermore, other causes, such as exposure to chemical agents, can induce cancer in individuals.

Cancer is the principal potential risk to human health from exposure to low or chronic levels of radiation. Radiological health impacts are expressed as the incremental changes in the number of expected fatal cancers (referred to as ***latent cancer fatalities***) for populations and as the incremental increases in lifetime probabilities of contracting a fatal cancer for an individual. The estimates are based on the dose received and on dose-to-health effect conversion factors recommended by the Interagency Steering Committee on Radiation Standards (DIRS 174559-Lawrence 2002, all). The Interagency Steering Committee on Radiation Standards is comprised of eight federal agencies (the Environmental Protection Agency, the

Nuclear Regulatory Commission, DOE, the Department of Defense, the Department of Homeland Security, the Department of Transportation, the Occupational Safety and Health Administration, and the Department of Health and Human Services), three federal observer agencies (the Office of Science and Technology Policy, the Office of Management and Budget, and the Defense Nuclear Facilities Safety Board), and two state observer agencies (Illinois and Pennsylvania). The Committee estimated that, for the general population and workers, a collective dose of 1 person-rem would yield 6×10^{-4} excess latent cancer fatalities.

Sometimes, calculations of the number of latent cancer fatalities associated with radiation dose do not yield whole numbers, and, especially in environmental applications, can yield numbers less than 1.0. For example, if each individual in a population of 100,000 received a total radiation dose of 0.001 rem, the collective radiation dose would be 100 person-rem and the corresponding estimated number of latent cancer fatalities would be 0.06 (100,000 persons × 0.001 rem × 0.0006 latent cancer fatalities per person-rem). How should one interpret a nonintegral number of latent cancer fatalities, such as 0.06? The answer is to interpret the result as a statistical estimate. That is, 0.06 is the average number of latent cancer fatalities that would result if the same exposure situation were applied to many different groups of 100,000 people. For most groups, no one would incur a latent cancer fatality from the 0.001 rem radiation dose each member would have received. In a small fraction of the groups (about 6 percent), 1 latent cancer fatality would result; in exceptionally few groups, 2 or more latent cancer fatalities would occur. The average number of latent cancer fatalities over all of the groups would be 0.06. The most likely outcome for any single group is 0 latent cancer fatalities.

DOE estimated radiological impacts for incident-free transportation, transportation accident risks and the consequences of severe transportation accidents, and transportation sabotage events.

The analysis of potential radiological occupational and public health and safety impacts in this Rail Alignment EIS includes all of those potentially exposed individuals discussed in Section 3.3.10 of this Rail Alignment EIS. No construction-related radiation dose is anticipated to workers or the public during respository construction activities.

The U.S. Department of Energy (DOE) Department of Environment Safety and Health guidance in *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements*, Second Edition, December 2004 (DIRS 178579-DOE 2004, all), requires that radiological impacts be estimated, no matter how small the population. Therefore, the radiological impact analyses in this Rail Alignment EIS are applied to various populations of potentially exposed individuals.

4.3.10.1.3 Transportation Impact Assessment Methodology

DOE based the transportation impact analysis on guidelines from the American Institute of Chemical Engineers with respect to chemical transportation risk analyses (DIRS 182284-Center for Chemical Process Safety 1995, all). The methodology presented in this section uses both qualitative and quantitative components. The number of fatalities and accidents resulting from vehicular and train travel were based on fatality and accident rates provided by Federal Railroad Administration and Nevada Department of Transportation statistics. The rates were used in combination with the specifics of an operation (for example, total distance traveled, route length, and number of trips) to estimate the likelihood of accidents and fatalities. The estimated number of potential vehicular traffic fatalities was based on assuming a total distance traveled from workers commuting during both the construction and operations phases. The estimates for potential rail traffic fatalities and accidents were also based on assuming total distances traveled from material/equipment transport during construction and shipment during operations. Traffic accidents under the Shared-Use Option were qualitatively analyzed based on a proportional comparison to the Proposed Action. Rail line fatalities associated with the Shared-Use Option were evaluated by revising the analyses for the additional rail traffic levels.

4.3.10.2 Proposed Action

4.3.10.2.1 Nonradiological Impacts

Nonradiological health and safety addresses potential exposure of construction and operations workers to physical hazards, and nonradioactive chemical hazards generated from construction and operations. This section also summarizes impacts associated with nonradiological occupational health and safety from specific resource areas, including biological hazards, dust and soils hazards, air quality hazards, and noise hazards.

4.3.10.2.1.1 Workers. Tables 4-263 and 4-264 summarize nonradiological impacts to workers from industrial hazards associated with construction and operation of the proposed rail line and associated facilities under the Proposed Action. Table 4-263 summarizes impacts for construction and operation of the rail line. Table 4-264 summarizes impacts for construction and operation of facilities. In general, rail line construction would create hazards that are common to heavy construction and earthmoving operations. Accidents that commonly occur at construction workplaces are:

- Trip and fall
- Object falls on worker
- Electrocution
- Asphyxiation (confined space or other)
- Penetrating wounds
- Dermal exposure skin injury
- Jobsite vehicle accident injury
- Hearing injury
- Object in eye
- Welding or laser eye injury
- Injury from trench or slope collapse
- Injury from explosion

Similar types of workplace accidents can occur during operation and maintenance of the proposed rail line and facilities. Workplace incidents also include incidents such as heat stress and workplace exposure to hazardous chemicals. These types of workplace accidents and incidents are included in the Bureau of Labor Statistics incident rate for total recordable cases, lost workday cases, and fatalities summarized in Table 4-262.

DOE would adopt a rigorous safety program that would enable workers to avoid most common accidents as required by DOE Order O 440.1A, *Worker Protection Management for DOE Federal and Contractor Employees*, as codified in 10 CFR Part 851. Chapter 7 of this Rail Alignment EIS describes mitigation measures and safety management practices to address workplace hazards. In accordance with 10 CFR Part 851 DOE would also be required to comply with applicable regulations under 29 CFR Part 1910 *Occupational Health and Safety Standards*, 29 CFR Part 1926, *Safety and Health Regulations for Construction*, and 29 CFR Part 1960, *Basic Program Elements for Federal Employee Occupational Safety and Health Programs and Related Matters* (Section 11.4, Table 11-4, pp. 1 to 3). Code of Federal Regulations 29 Part 1926 applies to DOE contractors; 29 CFR 1960 (Basic Elements for Federal Employees OSHA) applies to DOE employees; 10 CFR 851.23 also requires DOE to apply American Council of Government Industrial Hygienist Threshold Limit Values for Chemical Substances and Physical Agents and Biological Exposure Indices when the Threshold Limit Values are lower (more protective) than permissible exposure limits in 29 CFR 1910.

Table 4-263 includes nonradiological impacts from proposed railroad construction and operations, but does not include facilities construction and operations. Construction impacts are estimated for activities occurring during the minimum 4.5-year construction phase, including construction of the rail line

Table 4-263. Estimated impacts to workers from nonradiological industrial hazards during proposed railroad construction and railroad operations under the Proposed Action.[a,b]

Group and industrial hazard category	Construction			Operations		
	FTEs[c]	Labor hours worked	Incidents	FTEs[c]	Labor hours worked	Incidents
Involved workers	5,233	10.5 million		1,471	2.9 million	
Total recordable cases[d]			292			37
Lost workday cases			162			28
Fatalities			0.60			0.26
Noninvolved workers	1,290	2.6 million		0	0	
Total recordable cases[d]			32			0
Lost workday cases			18			0
Fatalities			0.05			0
Totals[e]	6,523	13.0 million		1,471	2.9 million	
Total recordable cases[d]			324			37
Lost workday cases			179			28
Fatalities			0.65			0.26

a. Calculations are based on U.S. Department of Labor, Bureau of Labor Statistics, incident rates in Table 4-262 and full-time-equivalent worker year data from Appendix D of the *Air Quality Emissions Factors and Socioeconomic Input-Mina Rail Corridor*, Rev 0, April 20, 2007 (DIRS 180874-Nevada Rail Partners 2007) and Table 4-2 and Figure 7-A, MRC Construction Schedule, from the Construction Plan- Rev 0, April 30, 2007 (DIRS 180875-Nevada Rail Partners 2007). All rail line construction workers are considered to be involved workers with the exception of construction camp operating workers.
b. Totals include rail line construction, quarry construction and operation, concrete batch plant construction and operation, construction camp construction and operation, construction train operation, and water-well construction and operation. Totals do not include construction or operation of rail line facilities.
c. FTE = full-time-equivalent worker; one FTE is defined as 2,000 labor hours worked. FTE and labor hours worked values are calculated over the minimum 4.5-year construction phase and 50-year operations phase of the Proposed Action.
d. Total recordable cases include injury and illness.
e. Totals might differ from sums of values due to rounding.

Rail line operations impacts include impacts to train crews and escort and security personnel.
The numbers of full-time equivalent workers for each rail line construction and operations activity, summarized in Table 4-263, were obtained from Appendix D of the *Air Quality Emissions Factors and Socioeconomic Input-Mina Rail Corridor*, Rev 00, April 20, 2007 (DIRS 180874-Nevada Rail Partners 2007, Appendix D) and the schedule shown as Figure 7-A, MRC Construction Schedule, from the Construction Plan, Rev 00, April 30, 2007 (DIRS 180875-Nevada Rail Partners 2007, Figure 7-A).

Rail line construction support facilities include:

- Construction of the construction camps
- Operation of the construction camps
- Construction of ballast quarries
- Operation of ballast quarries
- Construction of water wells
- Operation of water wells
- Construction of concrete batch plants
- Operation of concrete batch plants

Table 4-264. Estimated impacts to workers from nonradiological industrial hazards during facility construction and facility operations under the Proposed Action.[a,b]

Group and industrial hazard category	Construction			Operations		
	FTEs[c]	Labor hours worked	Incidents	FTEs[c]	Labor hours worked	Incidents
Involved workers	1,340	2.7 million		5,850	11.7 million	
Total recordable cases[d]			75			322
Lost workday cases			41			199
Fatalities			0.01			1.03
Noninvolved workers	0	0		1,650	3.3 million	
Total recordable cases[d]			0			40
Lost workday cases			0			21
Fatalities			0			0.06
Totals[e]	1,340	2.7 million		7,500	15.0 million	
Total recordable cases[d]			75			361
Lost workday cases			41			220
Fatalities			0.01			1.09

a. Source: Calculation based on U.S. Department of Labor, Bureau of Labor Statistics, incident rates in Table 4.3.10-1 and full-time- equivalent worker year data in Appendix D of the *Air Quality Emissions Factors and Socioeconomic Input-Mina Rail Corridor*, Rev 0, April 20, 2007 (DIRS 180874-Nevada Rail Partners 2007, Appendix D).
b. Totals include construction and operation of the Staging Yard, Maintenance-of-Way Facility, Cask Maintenance Facility, Nevada Railroad Control Center and National Transportation Operations Center, and Rail Equipment Maintenance Yard. Totals do not include construction or operation of the rail line.
c. FTE = full-time-equivalent worker; one FTE is defined as 2,000 labor hours worked. FTE and labor hours worked values are calculated over the minimum 4.5-year construction phase and 50-year operations phase of the Proposed Action.
d Total recordable cases include injury and illness.
e. Totals might differ from sums of values due to rounding.

Facility construction and operations impacts include impacts to facility construction workers and facility operations workers during the minimum 4.5-year construction phase and 50-year operations phase for the facilities. Table 4-264 summarizes the nonradiological impacts of constructing and operating rail line construction support facilities and rail line operations support facilities under the Proposed Action, including the Rail Equipment Maintenance Yard, the Staging Yard, the Nevada Railroad Control Center and National Transportation Operations Center, the Maintenance-of-Way Facility, and the Cask Maintenance Facility. The numbers of full-time-equivalent worker years for each rail line facility construction and operations activity were obtained from Appendix D of the *Air Quality Emissions Factors and Socioeconomic Input-Mina Rail Corridor*, Rev 00, April 20, 2007 (DIRS 180874-Nevada Rail Partners 2007, Appendix D).

Construction and operations workers under the Proposed Action could potentially be exposed to nonradiological hazardous chemicals related to operation and maintenance of construction equipment and facility equipment, including maintenance-of-way and management of fleet. Such activities are anticipated to include welding, metal degreasing, painting, and related activities. Occupational health and safety impacts could also result from worker exposure to fuels, lubricants, and other materials used in construction, operation, and maintenance of the proposed rail line and facilities.

Rail Line Construction Construction of the proposed rail line would involve 13.0 million labor hours corresponding to a total of 6,527 full-time-equivalent construction workers.

For the purposes of this Rail Alignment EIS, nonradiological impacts associated with construction of the proposed rail line are reported separately from the nonradiological impacts associated with construction of the facilities. Table 4-263 summarizes nonradiological occupational health and safety impacts associated with construction of the proposed rail line, not including the Rail Equipment Maintenance Yard, Staging Yard, or other facilities.

Facilities Construction Construction of railroad construction support facilities and railroad operations support facilities, including the Staging Yard, Nevada Railroad Control Center and National Transportation Operations Center, Maintenance-of-Way Facility, Cask Maintenance Facility, and Rail Equipment Maintenance Yard, would involve approximately 1,335 full-time-equivalent construction workers corresponding to approximately 2.7 million labor hours. Table 4-264 summarizes the nonradiological impacts of construction of the rail line facilities under the Proposed Action.

Rail Line Operations Operation of the proposed rail line would take place over a period of 50 years and involve approximately 50 rail line operations personnel, corresponding to approximately 2.9 million labor hours.

For the purposes of this Rail Alignment EIS, nonradiological impacts associated with operation of the proposed rail line are reported separately from the nonradiological impacts associated with operation of the facilities. Table 4-263 lists nonradiological occupational health and safety impacts associated with operation of the proposed rail line, not including the Rail Equipment Maintenance Yard or Staging Yard, or other facilities.

Overall railroad operations including cask trains, maintenance-of-way trains, and repository construction and supply trains correspond to approximately 8,200,000 train-kilometers over the 50 year period of operation for the 570-kilometer (354-mile) Mina rail alignment based on transporting 9,495 casks and an additional two maintenance-of-way trains and one repository construction and supply train per week. The 37 total recordable cases and 28 lost-workday cases over the 50-year operations phase (Table 4-263) correspond to 4.5 total recordable cases and 3.4 lost-workday cases per million train-kilometers traveled.

Rail Line Facilities Operations Operation of the rail line facilities under the Proposed Action, including the Staging Yard, Nevada Railroad Control Center and National Transportation Operations Center, Maintenance-of-Way Facility, Cask Maintenance Facility, and the Rail Equipment Maintenance Yard would take place over a period of 50 years and involve approximately 150 full-time-equivalent operations workers per year of operation, corresponding to approximately 15.0 million labor hours over the 50-year operations phase (DIRS 180874-Nevada Rail Partners 2007; DIRS 180875-Nevada Rail Partners 2007). Table 4-264 summarizes the nonradiological impacts of operation of the facilities under the Proposed Action. The 361 total recordable cases and 220 lost-workday cases over the 50-year operations phase (Table 4-264) correspond to 44 total recordable cases and 27 lost-workday cases per train-kilometer traveled.

Impacts from Specific Resource Areas Workers constructing the proposed rail line and associated facilities could be exposed to a variety of hazards associated with specific resource areas. These include biological hazards, dust and soils hazards, air-quality hazards, transportation accidents, and noise hazards. Transportation hazards include wild horses and burros, and free-range livestock. Biological hazards include potential human health effects from rodent-borne diseases, soil-borne diseases, insect-borne diseases, and venomous animals. Dust and soils hazards include potential human health effects from exposure to inhalable soils and dusts containing hazardous constituents and potential occupational encounters with unexploded ordnance. Construction workers could also be exposed to air-quality hazards, including potential human health effects of exposure to fugitive dust, diesel engine exhaust, and other air emissions associated with construction activities. Workers could also be exposed to noise hazards from operation of equipment. Operations workers, in particular maintenance-of-way workers, could also be exposed to similar hazards. Impacts associated with specific resource areas are discussed in the paragraphs that follow.

Biological Hazards Biological hazards are any virus, bacteria, fungus, parasite, or other living organism that can cause a disease or otherwise harm human beings. Biological hazards that may be encountered by workers constructing and operating the proposed rail line and associated facilities include disease-causing organisms and venomous animals. Diseases potentially encountered when performing construction activities include West Nile Virus, Valley Fever, Hantavirus, and rabies. Venomous animals potentially encountered include spiders, snakes, scorpions, bees, wasps, and other insects. These biological hazards are described in the following sections. The recorded incidence rates of these biological hazards in the region of influence in Nevada are small, according to statistics published by state and federal agencies including the U.S. Centers for Disease Control and the Nevada State Health Division, as cited below. Therefore, DOE would expect small impacts to construction or operations workers from these biological hazards.

- **Venomous Animals –** Nevada is home to five venomous snake species: Sidewinder, Mohave, Speckled, Western Diamondback and Great Basin rattlesnakes (*Crotalus* spp.). These types of rattlesnakes may inhabit the open grasslands and desert habitat in the construction and operations areas. The Gila Monster, a venomous lizard, also occurs in southern Nevada. There are several types of scorpions (such as *paruroctonus* spp.) native to Nevada that may occur in construction and operations areas. Scorpions are venomous and are most active at night. A scorpion sting would require medical treatment, but for the species of scorpions found in Nevada, would not be fatal. Black widow spiders (*Latrodectus mactans*) and brown recluse spiders (*Loxosceles recluse*) may also occur in construction areas. Bites from these spiders would require medical treatment and are potentially fatal if untreated. Other types of spider bites are generally harmless to most people. Spider bites usually occur when someone is reaching into dark, out-of-the way places. Bees, including Africanized Swarming Bees, and wasps also occur in southern Nevada.

- **West Nile Virus –** West Nile virus is a mosquito-borne virus that can cause illness in humans, including meningitis or arboviral encephalitis, a brain inflammation. Mosquitoes acquire the virus from birds and pass it on to other birds, and occasionally to humans. Mosquitoes spread this virus after they feed on infected birds and then bite other birds, people, or certain domestic animals. The virus is not spread by person-to-person contact. West Nile virus occurs primarily in the late summer or early autumn, although the mosquito season is generally April through October. About 80 percent of people who are infected with West Nile virus exhibit no symptoms, or at most, experience symptoms similar to the flu. People with mild infections, referred to as West Nile fever, may experience fever, headache, body ache, skin rash, and swollen lymph glands. More severe infection can result in more serious symptoms, including high fever, headache, disorientation, coma, tremors, occasional convulsions, and paralysis. This form is referred to as West Nile meningitis or encephalitis. In 2004, a total of 44 cases of West Nile virus were reported in Nevada, including 23 cases in Clark County, 15 cases in Churchill County, and one case in Lyon County. Of the 44 West Nile virus cases, 19 involved West Nile fever. In 2005, 31 cases of West Nile virus were reported in Nevada, including eight cases in Clark County and three cases in Nye County (DIRS 177618-USGS 2006, all). No human cases of West Nile virus were reported in Nye, Esmeralda, Mineral, or Storey Counties in 2004 (DIRS 175028-USGS 2005, all; DIRS 175026-Nevada State Health Division 2005, all). In 2006 there were a total of 123 reported cases of West Nile virus, including 12 cases in Churchill County, 16 cases in Lyon County, two cases in Nye County, and three cases in Clark County (DIRS 178696-USGS 2007, all). Incident rates of West Nile Virus are affected by the population density and availability of water.

- **Valley Fever –** The technical name for Valley Fever is *Coccidioidomycosis*. It is caused by *Coddidioides immitis*, a fungus that lives in soil. Fungus spores become wind-borne and may be inhaled into the lungs, where infection can occur. Valley Fever is not contagious from person to person. It appears that after one exposure, the body develops immunity. The Valley Fever fungus is established in the Southern Nevada region of influence. Infection rates, as reflected by positive skin tests, are 2 to 3 percent per year in highly endemic regions, and activities associated with heavy dust exposure (such as excavation, agricultural labor) increase infection rates (DIRS 175021-Barnato, Sanders, and Owens 2001, p. 1). About 60 percent of people who breathe the spores do not develop any symptoms. About one out of every 200 persons infected with Valley Fever develops the disseminated form, in which the disease spreads beyond the lungs through the bloodstream causing meningitis. Meningitis is a potentially fatal inflammation of the membrane around the brain and the spinal cord.

- **Hantavirus –** A 1993 outbreak of fatal respiratory illness on an Indian Reservation in the Four Corners area (where the states of Arizona, New Mexico, Colorado, and Utah meet) led to the identification of Hantavirus as the causative agent. Hantavirus is a rodent-borne disease. The route of exposure is believed to be inhalation of aerosolized virus, and/or ingestion of rodent excreta through contaminated food or water. Rodent bites and direct contact with broken skin or mucous membranes are also potential sources of infection. Symptoms include pneumonia, fever, and other flu-like symptoms. In 24 to 48 hours after symptoms appear, potentially fatal respiratory failure may occur. As of March 2007, there have been 465 recorded cases of Hantavirus in the United States, with 18 of the cases recorded in Nevada (DIRS 181391-CDC 2007, all). DOE has implemented procedures for decontamination of any rodent excreta encountered by construction workers during construction activities at the Yucca Mountain Site to prevent Hantavirus infection of workers.

- **Rabies –** Rabies may be a hazard to construction and operations workers through accidental contact with mammalian species in construction and operations areas. The route of exposure is a bite or scratch from an infected animal, or non-bite exposure through inhalation of aerosolized rabies virus. Rabies has been reported in Nevada in bats but not in terrestrial animals (DIRS 177449-Krebs et al. 2005, p. 1917). The incubation period of rabies is variable, ranging from less than 10 days to greater than 6 years, and post exposure treatment is necessary following true exposure unless the subject has been vaccinated. Absent post exposure treatment, the first symptoms may be noted within 30 to 90 days of exposure. Once symptoms occur, death may occur in less than one week following the development of initial symptoms, usually as a result of respiratory failure. No human cases of rabies were reported in Nevada between January 2000 and September 2005, the latest period for which data are available (DIRS 177449-Krebs et al. 2005, p. 1920).

Dust and Soils Hazards Dust and soils hazards include potential occupational exposure to hazardous inhalable soils and dust, including the minerals crystalline silica, cristobalite, and ***erionite***, and potential occupational encounters with unexploded ordnance. These hazards are discussed below.

- **Inhalable Dust –** Construction activities such as blasting, scarifying, and excavating create dust that can be inhaled by workers.

Some types of rock and associated soils may contain hazardous minerals such as crystalline silica, cristobalite, and erionite. It is unlikely that any fugitive particulates generated in the construction areas would contain a concentration of crystalline silica, eronite, or cristobalite that would result in exceedance of occupational exposure limits for these materials. Inhaling dust originating from these types of rock and containing these minerals can lead to disease such as silicosis if adequate precautions are not taken when working in dusty areas. However, DOE recognizes the potential for exposure to crystalline silica, cristobalite, or erionite during the development of quarries for production of hard rock ballast, in ballast placement, rock cuts, and other types of excavation. Of the three mineral dust hazards mentioned above, crystalline silica is the most common in hard rock ballast because it is a material of relative abundance in granite and quartz. DOE would be required to comply with Occupational Safety and Health Administration workplace guidance for mineral dusts (29 CFR 1910-1000, Table Z-3, Mineral Dusts).

DOE would therefore conduct routine monitoring of occupational dust exposure during quarry construction and operation and during rail alignment construction activities, such as ballast placement, with the potential for such exposure. DOE would apply best management practices and engineering controls such as application of water for dust suppression and washing the ballast before placement in order to minimize the potential for occupational exposure to dust, and an industrial hygienist would take mineral dust measurements to identify if any potential exposure hazards are present. In the event that these monitoring activities identify potential occupational exposure at levels exceeding Occupational Safety and Health Administration occupational exposure standards for silica, DOE would implement additional processing and engineering controls to mitigate, prevent, or reduce exposures to silica to below occupational exposure standards. Therefore, impacts associated with occupational exposure to these materials are anticipated to be small.

- **Unexploded Ordnance –** Portions of the construction area may have unexploded ordnance in surface or in subsurface locations. The potential areas of concern for unexploded ordnance are sections west of the Nevada Test and Training Range and within the Nevada Test Site. These include areas south of Goldfield and north of Beatty Wash and the area between the southeastern shore of Walker Lake and the Hawthorne Depot. Unexploded ordnance may include shell casings, projectiles, or fragments, and may include live small arms ammunition, bombs, and rockets. These types of unexploded ordnance may have been generated from historical Air Force and other military training activities in the region. Sections of rail alignment and associated facility locations north and east of Goldfield are considered clear of unexploded ordnance at this time. An unexploded-ordnance specialist would develop a plan, including evaluation of types of unexploded ordnance possible, depths, etc. Unexploded-ordnance technicians would be present and screen ahead of the construction crew in areas where there is potential for unexploded ordnance.

DOE would coordinate with the U.S. Air Force, Army, and Navy concerning proposed construction activities and would follow standard and established procedures for unexploded ordnance.

Air Quality Hazards Construction workers could be exposed to air quality hazards, including potential human health effects of occupational exposure to stationary and area source emissions associated with construction activities. Operations workers, in particular maintenance-of-way workers, could also be exposed to similar air-quality hazards.

Stationary and area source emissions associated with the construction phase include exhaust emissions from on-site vehicles and heavy construction equipment, and fugitive dust from excavation and construction activities. Stationary and area source emissions associated with the operations phase would include emissions from locomotive fueling stations and locomotive rail line maintenance operations. Section 4.3.4, Air Quality and Climate, describes stationary source and area source emissions associated with construction and operation of the rail line and associated facilities.

Exposure of construction and operations workers to vehicle exhaust emissions and other air emissions would be subject to exposure standards, including standards established under 10 CFR Part 851. Threshold Limit Values established by the Occupational Safety and Health Administration and American Council of Government Industrial Hygienists would apply to occupational exposure to vehicle exhaust emissions and other air emissions. DOE would apply administrative controls and conduct workplace monitoring to control exposure to below applicable standards.

Noise Hazards Workers conducting construction and operations activities under the Proposed Action could be exposed to noise from operation of heavy construction equipment, operation of locomotives, or from conducting blasting operations. Potential sources of occupational noise exposure, applicable noise exposure standards, and requirements for controlling noise exposure are described in this section and further described in Section 4.3.8.

- **Roadbed/Track Structure Construction Noise Exposure –** DOE would require employers of construction workers exposed to heavy equipment noise to comply with Occupational Safety and Health Administration regulation 29 CFR 1910.95 to avoid effects of excessive noise exposure. Hearing damage is related to absolute noise level and duration of exposure. Table 4-265 shows Occupational Safety and Health Administration noise level limits that would require hearing protection. Code of Federal Regulations 10 Part 851 requires DOE to use American Conference of Governmental Industrial Hygienists Threshold Limit Values as occupational exposure standards. Table 4-265 also shows the Threshold Limit Values.

Table 4-265. Occupational noise exposure limits.[a]

Duration per day, hours	Sound level (decibels slow response)	ACGIH[b] Threshold Limit Value
8	90	85
6	92	86
4	95	88
3	97	89
2	100	91
1.5	102	92
1	105	94
0.5	110	97
0.25 or less	115	100

a. Sources: 29 CFR 1910.95, 30 CFR 62.130, and 10 CFR 851.
b. ACGIH = American Conference of Governmental Industrial Hygienists.

DOE would be required to administer a continuing, effective hearing conservation program whenever employees would be exposed to noise equal to or exceeding an 8-hour time-weighted average sound level of 85 A-weighted decibels.

- **Railroad Worker Noise Exposure –** Railroad operators are required to comply with Federal Railroad Administration Regulation 49 CFR 229.121 for worker exposure to locomotive cab noise. Applicable noise levels, the exceedance of which would require hearing protection, are shown in Table 4-265.

- **Ballast Quarry Noise Exposure –** Employers of quarry workers supplying ballast for the rail bed would be required to comply with Mine Safety and Health Administration Regulation 30 CFR 62. Applicable Mine Safety and Health Administration noise levels, the exceedance of which would require hearing protection, are shown in Table 4-265. Noise levels above 115 dBA are not permitted under the regulation (30 CFR 62.130).

4.3.10.2.2 Radiological Impacts

For the portion of the Mina rail corridor that originates at Hazen and terminates at the repository, the radiological impacts from incident-free transportation for members of the public were estimated to be 8.2×10^{-4} latent cancer fatality. For workers, these impacts were estimated to be 0.33 latent cancer fatality. The radiological accident risks for this portion of the Mina rail corridor were estimated to be 7.4×10^{-6} latent cancer fatality.

4.3.10.2.2.1 Workers.

Rail Line and Facilities Construction DOE does not anticipate that there would be any radiological occupational health and safety impacts associated with construction of the proposed rail line or facilities for the Proposed Action.

Rail Line and Facilities Operations Occupational radiological impacts associated with incident-free operation of the rail line and rail line facilities are described below. Occupational radiological impacts are quantified in terms of latent cancer fatalities. Occupational radiation doses (effective dose equivalent) are also reported.

Incident-Free Transportation During the shipment of spent nuclear fuel and high-level radioactive waste from Hazen to the Staging Yard at Hawthorne to the repository, workers would be exposed to direct radiation from 9,495 shipping casks. These workers would include rail transportation crew members, security escorts, workers exposed when trains with loaded shipping casks passed the Maintenance-of-Way Facility, and workers exposed when trains with loaded shipping casks passed trains with unloaded casks or other materials at sidings. The methods and data used to estimate the radiation doses for these workers are described in Appendix K. Workers not exposed to shipping casks would not be exposed to radiation in excess of background.

As discussed in Chapter 2, there are a number of possible combinations of common segments and alternative segments that could make up the rail alignment from Hazen to the Staging Yard at Hawthorne to the Rail Equipment Maintenance Yard. For the radiological impacts analyses, four specific alignments were evaluated: 1) the alignment with the highest exposed population, 2) the shortest alignment, 3) the longest alignment, and 4) the alignment with the lowest exposed population. These alignments are described in Table 3-146.

Table 4-266 lists the radiation doses and impacts for these workers along these four alignments. The collective radiation dose for these workers is estimated to be 310 to 320 person-rem. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.18 to 0.20.

Table 4-266. Estimated radiological impacts for workers along the proposed rail alignment.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker [annual]	0.50 rem per year	0.00030
Maximally exposed worker [50-year operation]	25[a] rem	0.015[a,b]
Worker population	310 – 340 person-rem	0.18 – 0.20[c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

> **Risk Terms**
>
> A risk value of 1×10^{-4} is equivalent to 1 in 10,000.
> A risk value of 1×10^{-6} is equivalent to 1 in 1,000,000.
> A risk value of 1×10^{-8} is equivalent to 1 in 100,000,000.

The maximally exposed worker would be a security escort. This worker is estimated to receive a radiation dose of 25 rem over the entire operations phase, based on a 0.5 rem per year administrative dose limit for repository facilities (DIRS 174942-BSC 2005, Section 4.9.3.3) and assuming that a person could work for up to 50 years escorting shipments. The probability of a latent cancer fatality for this worker is estimated to be 0.015. Security escort workers and other rail line workers would be subject to a radiation protection program. Workers, including security escort workers, would not be exposed to radiation in excess of the administrative dose limit for repository facilities of 0.5 rem per year. This requirement may in some cases limit the number of hours per year that workers are permitted to work as security escorts to less than 2,000 hours per year.

- **Staging Yard at Hawthorne, Rail Workers, Inspectors, and Escorts –** When shipping casks arrived at the Staging Yard, the railcars containing the shipping casks would be removed from the train, an inspection would be conducted, and the railcars would be transferred to the train for transport to the Rail Equipment Maintenance Yard. The escorts that had accompanied the shipping cask from its origin would also be present during this inspection. These rail workers, inspectors, and escorts would be exposed to direct radiation from 9,495 shipping casks over the entire shipping campaign. The methods and data used to estimate the radiation doses for these workers are described in Appendix K.

Table 4-267 lists the radiation doses and impacts for the workers involved with these activities. The analysis assumed that noninvolved workers would also be exposed to direct radiation during these activities.

Table 4-267. Estimated radiological impacts for rail workers, inspectors, and escorts at the Staging Yard.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.50 rem per year	0.00030
Maximally exposed worker (50-year operation)	25[a] rem	0.015[a,b]
Worker population (involved workers)	240 person-rem	0.14[c]
Worker population (noninvolved workers)	10 person-rem	0.0063
Worker population (total)	250 person-rem	0.15

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

The collective radiation dose for involved and noninvolved workers is estimated to be 250 person-rem. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.15. The maximally exposed worker is estimated to receive a radiation dose of 25 rem over the 50 years of operation, based on a 0.5 rem per year administrative dose limit for repository facilities (DIRS 174942-BSC 2005, Section 4.9.3.3) and assuming that a person could work for up to 50 years at the Staging Yard. The probability of a latent cancer fatality for this worker is estimated to be 0.015. Staging Yard workers and other facilities workers would be subject to a radiation protection program. Workers, including Staging Yard workers, would not be exposed to radiation in excess of the administrative dose limit for repository facilities of 0.5 rem per year. This requirement may in some cases limit the number of hours per year that workers are permitted to work at the Staging Yard to less than 2,000 hours per year.

- **Rail Equipment Maintenance Yard –** Under the Proposed Action, a Rail Equipment Maintenance Yard would be constructed and operated to transfer cask cars to the repository. The workers at this facility would be exposed to direct radiation from handling 9,495 shipping casks over 50 years of shipping. The radiation doses for these workers would be similar to the radiation doses for handling dedicated rail shipments at other rail yards and are described in Neuhauser et al. (2000) (DIRS 155430-Neuhauser, Kanipe, and Weiner, Section 3.5.2).

Table 4-268 summarizes the radiation doses and impacts for workers involved in these activities. The collective radiation dose for these workers is estimated to be 16 person-rem. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.0096.

Table 4-268. Estimated radiological impacts for workers at the Rail Equipment Maintenance Yard.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.013 rem per year	7.6×10^{-6}[c]
Maximally exposed worker (50 years)	0.64[a] rem	0.00038[b]
Worker population	16[a] person-rem	0.0096[c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

The individual radiation dose for workers at this facility was estimated to be 0.013 rem per year. The probability of a latent cancer fatality for this worker is estimated to be 7.6×10^{-6}. If this individual worked at the facility for 50 years, their radiation dose would be 0.64 rem. The probability of a latent cancer fatality for this worker is estimated to be 0.00038.

- **Cask Maintenance Facility –** Under the Proposed Action, Cask Maintenance Facility operations would include testing, inspection, certification, incidental repair, and minor decontamination and modification of the transportation casks. Impacts to workers from activities at the Cask Maintenance Facility were based on the impacts for a similar facility, the Alaron Regional Service Facility, located in Wampum, PA. This facility provides treatment, decontamination, compaction, and repackaging services for generators of radioactively contaminated materials. One of the services provided by Alaron is the decontamination of spent nuclear fuel casks, which is similar to the activities that would occur at the Cask Maintenance Facility. The activities at Alaron are discussed in DIRS 181886-NRC 1989, all and DIRS 151227-Blasing et al. 1998, all.

Radiation dose from cask handling and maintenance activities at the Cask Maintenance Facility could result in radiation dose to workers, primarily as a result of exposure to "crud." Crud is the term used to describe contamination on the outside of spent nuclear fuel and would consist of the radionuclides Co-60, Mn-54, Fe-55, and Zn-65. Crud may be present in reactor spent nuclear fuel pools and may contaminate the inside of the cask during loading, even if the spent nuclear fuel has been placed in canisters. For the radionuclides contained in crud, average radionuclide inventories at the Alaron Regional Service Facility would consist of about 4.7 Ci of Co-60, 0.32 Ci of Mn-54, 7.6 Ci of Fe-55, and 0.061 Ci of Zn-65. Not all of this radionuclide inventory would be from the decontamination of spent nuclear fuel casks; some of the radionuclide inventory would be as a result of other services provided at the Alaron Regional Service Facility.

Workers at Alaron were estimated to receive an individual radiation dose of 0.04 rem per month. Over the course of a year, a worker would receive a radiation dose of 0.480 rem. This radiation dose was used to estimate the radiation dose to a worker at the Cask Maintenance Facility. The probability of a latent cancer fatality for this worker is estimated to be 0.00029.

Based on the total number of workers at the Cask Maintenance Facility, the collective radiation dose at the Cask Maintenance Facility would be 14 person-rem per year. In the exposed population of workers, the probability of a latent cancer fatality is estimated to be 0.0086. Table 4-269 summarizes these impacts and also presents impacts for the entire duration of operations.

- **Other Rail Line Facility Operations –** Under the Proposed Action, other rail line facilities would be constructed and operated, including the Maintenance-of-Way Facility, and Nevada Railroad Control Center and National Transportation Operations Center. Radiological health impacts to workers operating these facilities are anticipated to be minimal, as casks would not be loaded or unloaded at these facilities.

Table 4-269. Estimated radiological impacts for rail workers, inspectors, and escorts at the Cask Maintenance Facility.

Group	Radiation dose	Latent cancer fatality
Maximally exposed worker (annual)	0.48 rem per year	0.00029[c]
Maximally exposed worker (50-year operation)	24[a] rem	0.014[b,c]
Worker population (annual)	14 person-rem per year	0.0086[c]
Worker population (50 years)	720[a] person-rem	0.43[a,c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual worker.
c. The estimated number of latent cancer fatalities in an exposed worker population.

Note that the dose calculations for rail facility operations workers in Table 4-269 above include radiological exposure to workers at the Maintenance-of-Way Facility and at sidings who would be exposed when the cask train passes by.

4.3.10.2.2.2 Public.

Construction DOE does not anticipate that there would be any radiological public health and safety impacts associated with construction of the proposed rail line or associated facilities under the Proposed Action.

Operations

Incident-free Rail Transportation

- **Public along the Proposed Rail Line –** During the shipment of spent nuclear fuel and high-level radioactive waste from Hazen to the Staging Yard at Hawthorne to the Rail Equipment Maintenance Yard, people along the proposed rail line could be exposed to direct radiation from 9,495 shipping casks. These people would include people along the transportation route. Because shipments would be made using ***dedicated trains***, there would be no exposures of members of the public sharing the transportation route or members of the public at stops along the route. The methods and data used to estimate the impacts from direct radiation for these people are described in Appendix K.

As discussed in Chapter 2, there are a number of possible combinations of common segments and alternative segments that could make up the rail alignment from Hazen to the Staging Yard at Hawthorne to the Rail Equipment Maintenance Yard. For the radiological impacts analyses, four specific alignments were evaluated. These alignments are described in Table 3-146.

Table 4-270 lists the radiation impacts for these people. The collective radiation dose for members of the public is estimated to be 1.4 person-rem. In the exposed population, the probability of a latent cancer fatality is estimated to be 8.1×10^{-4} to 8.5×10^{-4}.

Table 4-270. Estimated radiological impacts for the public along the proposed rail line.

Group	Radiation dose	Latent cancer fatality
Maximally exposed individual (annual)	0.00016 rem	9.4×10^{-8}[a]
Maximally exposed individual (50-year operation)	0.0078[a] rem	4.7×10^{-6}[a]
Population	1.4 person-rem	$8.1 \times 10^{-5} – 8.5 \times 10^{-4}$[b]

a. The estimated probability of a latent cancer fatality for an exposed individual.
b. The estimated number of latent cancer fatalities in an exposed population.

- **Public Near the Staging Yard –** The public surrounding the Staging Yard location at Hawthorne could be exposed to direct radiation from 9,495 shipping casks over the entire shipping campaign.

The methods and data used to estimate the radiation doses for members of the public are described in Appendix K.

Table 4-271 lists the radiation doses and impacts for these people. Based on 2000 Census data, there are no people who reside within 800 meters (2,623 feet) of the Hawthorne Staging Yard. There is, however, a business located 660 meters (2,165 feet) from the Staging Yard. The radiation dose for a person at this business is estimated to be 0.00018, assuming that an individual was exposed to each of the 9,495 shipping casks for a period of 2 hours per cask. The probability of a latent cancer fatality for this individual is estimated to be 1.1×10^{-7}.

Table 4-271. Estimated radiological impacts for the public at the Staging Yard at Hawthorne.

Group	Radiation dose	Latent cancer fatality
Maximally exposed individual	0.00018 rem[a]	1.1×10^{-7} [b]
Population[c]		

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual.
c. According to 2000 Census data, there are no people residing within 800 meters (2,623 feet) of the Staging Yard.

- **Cask Maintenance Facility –** Under the Proposed Action, Cask Maintenance Facility operations would include testing, inspection, certification, incidental repair, and minor decontamination and modification of the transportation casks. Impacts to members of the public from activities at the Cask Maintenance Facility were based on the impacts for a similar facility, the Alaron Regional Service Facility, located in Wampum, PA. This facility provides treatment, decontamination, compaction, and repackaging services for generators of radioactively contaminated materials. One of the services provided by Alaron is the decontamination of spent nuclear fuel casks, which is similar to the activities that would occur at the Cask Maintenance Facility. The activities at Alaron are discussed in DIRS 181886-NRC 1989, all and DIRS 151227-Blasing et al. 1998, all.

At the Alaron Regional Service Facility, the maximally exposed member of the public was located 300 meters (984 feet) from the facility. The radiation dose for this individual from emissions through all environmental pathways was estimated to be 2.0×10^{-9} rem per year. The probability of a latent cancer fatality for this individual is estimated to be 1.2×10^{-12}. The radiation dose and latent cancer fatality risk for members of the public from emissions from the Cask Maintenance Facility would be much lower, because the public is located much further from the facility. For example, the nearest site boundary is 11 kilometers (7 miles) from the repository, while at Alaron, the maximally exposed member of the public was located 300 meters (984 feet) from the facility.

The total population within 84 kilometers (52 miles) of the Cask Maintenance Facility is estimated to be about 118,000 people in the year 2067. If all of these people were exposed at the same level as the maximally exposed member of the public, the resulting collective radiation dose would be 0.00023 person-rem per year. In this exposed population, the probability of a latent cancer fatality is estimated to be 1.4×10^{-7}. Table 4-272 summarizes these impacts and also presents impacts for the entire duration of operations.

Accidents To quantify the potential radiological impacts of transportation accidents, two types of analyses were performed. The first analysis provided an estimate of the radiological accident risks associated with transporting spent nuclear fuel and high-level radioactive waste along the Mina rail alignment. The analysis of radiological accident risks takes into account a spectrum of accidents ranging from higher-probability accidents of low severity to hypothetical high-severity accidents that have a correspondingly low probability of occurrence. Included are accidents in which no release of radioactive material occurred, but where there was a deformation of shielding because of lead shield displacement, and accidents in which radioactive material was released from the shipping cask.

Table 4-272. Estimated radiological impacts for the public from the Cask Maintenance Facility.

Group	Radiation dose	Latent cancer fatality
Individual member of the public (annual)	2.0×10^{-9} rem per year	1.2×10^{-12}[b]
Individual member of the public (50 years)	1.0×10^{-7}[a]	6.0×10^{-11}[a,b]
Collective members of the public (annual)	0.00023 person rem per year	1.4×10^{-7}[c]
Collective members of the public (50 years)	0.012[a] person-rem	7.0×10^{-6}[a,c]

a. Total for 50 years of operation.
b. The estimated probability of a latent cancer fatality for an exposed individual.
c. The estimated number of latent cancer fatalities in an exposed population.

Radiological accident risks were defined as the probability of occurrence of an accident multiplied by the consequences of the accident, summed over a complete spectrum of accidents. This quantity is known as "***dose risk***."

The second analysis provided an estimate of the consequences of severe transportation accidents, known as maximum reasonably foreseeable transportation accidents. Historically, maximum reasonably foreseeable transportation accidents were defined as transportation accidents with a frequency of about 1×10^{-7} per year. However, in this analysis, the consequences of severe transportation accidents with frequencies as low as 3×10^{-18} per year are presented.

Accidents in which no release of radioactive material and no deformation of shielding occurred are discussed in Section 4.3.10.2.3 below.

- **Accident Risks –** The methods and data used to estimate radiological accident risks are discussed in Appendix K. The impacts from these accidents are listed in Table 4-273. The risks from accidents where a release of radioactive material or shielding deformation occurred are estimated to be 7.4×10^{-6} to 7.6×10^{-6} latent cancer fatality.

Table 4-273. Estimated radiological accident risks from potential transportation accidents along the proposed rail line.

Risk	Accident dose risk[a]	Latent cancer fatality[a]
Radiological accident risk	$1.2 \times 10^{-2} – 1.3 \times 10^{-2}$	$7.4 \times 10^{-6} – 7.7 \times 10^{-6}$

a. Radiological accident dose risk is the sum of the products of the probabilities and consequences in person-rem of all potential transportation accidents. This sum is converted to latent cancer fatalities using the conversion factor of 0.0006 latent cancer fatality per person–rem.

- **Severe Accidents –** Severe accidents having a frequency of about 1×10^{-7} per year are known as maximum reasonably foreseeable accidents. Accidents with frequencies below 1×10^{-7} per year are generally not reasonably foreseeable. In this Rail Alignment EIS, the maximum reasonably foreseeable transportation accident has a frequency of about 7×10^{-7} per year. This accident involves a long duration, high-temperature fire that would engulf a cask. The methods and data used to estimate the impacts of this accident are discussed in Appendix K.

For the four evaluated rail alignments described in Table 3-146, there were no urban areas as defined in U.S. Census Bureau population data. However, there were suburban areas and rural areas. Suburban areas are defined as areas with a population density between 139 and 3,326 people per square mile. Rural areas were defined as areas with a population density less than 139 people per square mile. Using alignment-specific 2000 census population data escalated to the year 2067, the average population density in suburban areas along the alignments was 589 people per square kilometer (1,525 people per square mile), near Silver Springs, Nevada. The average population density along rural areas, escalated to the year 2067, ranged from 4.19 to 4.33 people per square kilometer (10.9 to 11.2 people per square mile).

Table 4-274 presents estimates of the impacts of this severe accident. If the maximum reasonably foreseeable accident were to occur in a suburban area, the population radiation dose would be 2,000 person-rem. In the exposed population, it is estimated that there could be 1.2 latent cancer fatalities. If the maximum reasonably foreseeable accident were to occur in a rural area, the collective radiation dose would be 15 person rem. The probability of a latent cancer fatality in the exposed population is estimated to be 8.9×10^{-3}.

Table 4-274. Estimated radiological impacts from the maximum reasonably foreseeable transportation accident scenarios for suburban and rural areas.[a,b]

Impact	Suburban area[c]	Rural area[c]
Impacts to population		
Population dose (person-rem)	2,000	15
Latent cancer fatalities	1.2	8.9×10^{-3}
Impacts to maximally exposed individuals		
Maximally exposed individual dose (rem)	34	34
Probability of a latent cancer fatality	0.020	0.020
Impacts to first responder		
Maximally exposed responder dose (rem)	0.14 – 2.0	0.14 – 2.0
Probability of a latent cancer fatality	8.2×10^{-5} – 0.0012	8.2×10^{-5} – 0.0012

a. There are no urban areas for the four specific alignments.
b. Accident frequency is estimated to be 7 × 10-7 per year.
c. Radiological impacts were based on low wind speeds and stable atmospheric conditions. These were defined as Class F stability and a wind speed of 0.89 meters per second.

In either a suburban area or rural area, the radiation dose from the maximum reasonably foreseeable transportation accident for the maximally exposed individual located 330 meters (1,083 feet) from the accident would be 34 rem. The probability of a latent cancer fatality for that individual is estimated to be 0.020.

The radiation dose to a first responder would range from 0.14 to 2.0 rem. The probability of a latent cancer fatality for this first responder is estimated to range from 8.2×10^{-5} to 0.0012.

- **Accidents at the Cask Maintenance Facility –** Under the Proposed Action, Cask Maintenance Facility operations would include testing, inspection, certification, incidental repair, and minor decontamination and modification of the transportation casks. Impacts to members of the public from Regional Service Facility, located in Wampum, PA. This facility provides treatment, decontamination, compaction, and repackaging services for generators of radioactively contaminated materials. One of the services provided by Alaron is the decontamination of spent nuclear fuel casks, which is similar to the activities that would occur at the Cask Maintenance Facility. The activities at Alaron are discussed in DIRS 181886-NRC 1989, all and DIRS 151227-Blasing et al. 1998, all.

A fire at the Alaron Regional Service Facility was estimated to result in a radiation dose of 0.00045 rem to a member of the public at a distance of 50 meters (164 feet) from the facility and a radiation dose of 0.000011 rem to a member of the public at a distance of 300 meters (984 feet) from the facility. The probability of a latent cancer fatality for these individuals is estimated to be 2.7×10^{-7} and 6.5×10^{-9}, respectively.

SEVERE TRANSPORTATION ACCIDENTS: AN OPPOSING VIEWPOINT

The State of Nevada has provided analyses that indicate that the consequences of severe transportation accidents would be much higher than those in this Rail Alignment EIS. For example, the state has estimated that the long-term consequences of a rail accident in a rural area could result in 7 to 614 latent cancer fatalities in the exposed population (DIRS 181756-Lamb et al. 2001, Table 41), while DOE estimates that about 1 latent cancer fatality would occur in the exposed population.

The state estimated these consequences using computer programs that DOE developed and uses. However, the state's analysis used values for parameters that would be at or near their maximum values. DOE guidance for the evaluation of accidents in environmental impact statements (DIRS 172283-DOE 2002, p. 6) specifically cautions against the evaluation of scenarios for which conservative (or bounding) values are selected for multiple parameters because the approach yields unrealistically high results.

DOE's approach to accident analysis estimates the consequences of severe accidents having frequencies as low as 1×10^{-7} per year (1 in 10 million) (DIRS 172283-DOE 2002, p. 9) using realistic yet cautious methods and data. DOE believes that the State of Nevada estimates are unrealistic and that they do not represent the reasonably foreseeable consequences of severe transportation accidents.

For a similar fire at the Cask Maintenance Facility, the impacts would be much lower, because the public is located much further from the facility, about 11 kilometers (7 miles), as opposed to 50 to 300 meters at Alaron.

The total population within 84 kilometers (52 miles) of the Cask Maintenance Facility is estimated to be about 118,000 people in the year 2067. If all of these people were exposed at the same level as the member of the public located 300 meters (984 feet) from the facility, the resulting collective radiation dose would be 1.3 person-rem. The probability of a latent cancer fatality in the exposed population is estimated to be 7.6×10^{-4}.

- **Sabotage –** In response to the terrorist attacks of September 11, 2001, and to intelligence information that has been obtained since then, the United States Government has initiated nationwide measures to reduce the threat of sabotage. These measures include security enhancements to prevent terrorists from gaining control of commercial aircraft, such as (1) more stringent screening of airline passengers and baggage by the Transportation Security Administration, (2) increased presence of federal air marshals on many flights, (3) improved training of flight crews, and (4) hardening of aircraft cockpits. Additional measures have been imposed on foreign passenger carriers and domestic and foreign cargo carriers, as well as charter aircraft.

Beyond these measures to reduce the potential for terrorists to gain control of an aircraft, DOE has adopted an approach that focuses on ensuring that safety and security requirements are adequate and effective in countering and mitigating the effects of sabotage events that involve transportation casks. The Federal Government has greatly improved the sharing of intelligence information and the coordination of response actions among federal, state, and local agencies. DOE has been an active participant in these efforts; it now has regular and frequent communications with other federal, state, and local government agencies and industry representatives to discuss and evaluate the current threat environment, to assess the adequacy of security measures at DOE facilities and, when necessary, to recommend additional actions. In addition to its domestic efforts, DOE is a member of the International Working Group on Sabotage for Transport and Storage Casks, which is investigating the consequences of sabotage events and exploring opportunities to enhance the physical protection of casks.

In addition, the Nuclear Regulatory Commission NRC has promulgated rules (10 CFR 73.37) and interim compensatory measures (67 *FR* 63167, October 10, 2002) specifically to protect the public from harm that could result from sabotage of spent nuclear fuel casks. The purposes of these security measures are to minimize the possibility of sabotage and to facilitate recovery of spent nuclear fuel shipments that could come under the control of unauthorized persons. These measures include the use of armed escorts to accompany all shipments, safeguarding of the detailed shipping schedule information, monitoring of shipments through satellite tracking and a communication center with 24-hour staffing, and coordination of logistics with state and local law enforcement agencies, all of which would contribute to shipment security. The Department has committed to following these rules and measures (see 69 *FR* 18557, April 8, 2004).

The Department, as required by the NWPA, would use Nuclear Regulatory Commission-certified shipping casks. Each cask design must meet stringent requirements for structural, thermal, shielding, and criticality performance and confinement integrity for routine (incident-free) and accident events. Spent nuclear fuel is protected by the robust metal structure of the shipping cask, and by cladding that surrounds the fuel pellets in each fuel rod of an assembly. Further, the fuel pellets in each fuel rod of an assembly, and the fuel is in a solid form, which would tend to reduce dispersion of radioactive particulates beyond the immediate vicinity of the cask, even if a sabotage event were to result in a breach of the multiple layers of protection.

Based on this knowledge, the Department has analyzed plausible threat scenarios, required enhanced security measures to protect against these threats, and developed emergency planning requirements that would mitigate potential consequences for certain scenarios. DOE would continue to modify its approach to ensuring safe and secure shipments of spent nuclear fuel and high-level radioactive waste, as appropriate, between now and the time of shipments.

For the reasons stated above, DOE believes that under general credible threat conditions the probability of a sabotage event that would result in a major radiological release would be low. Nevertheless, because of the uncertainty inherent in the assessment of the likelihood of a sabotage event, DOE has evaluated events in which a military jet or commercial airliner would crash into a spent nuclear fuel cask or a modern weapon (high energy density device or) would penetrate a spent nuclear fuel cask.

In the Yucca Mountain FEIS (Appendix J, Section J.3.3.1), DOE evaluated the ability of large aircraft parts to penetrate shipping casks. In that analysis, DOE determined that the parts having the highest probability of penetrating a cask are jet engines and jet engine shafts. Accordingly, DOE undertook a penetration analysis using these parts from military aircraft (F-15/16) and from a commercial airliner (B-767), which found that neither the engines nor the shafts would penetrate a cask and cause a release of radiological materials if an aircraft were to crash into a spent nuclear fuel cask.

To estimate the potential consequences of a sabotage event in which an high energy density device penetrates a rail or truck cask, DOE, in the Yucca Mountain FEIS, referred to *Projected Source Terms for Potential Sabotage Events Related to Spent Fuel Shipments* to obtain estimates of the fraction of spent nuclear fuel materials that would be released (release fractions) (DIRS 104918-Luna et al. 1999, all). In this Rail Alignment EIS, the Department used the more recent release fraction estimates from *Release Fractions from Multi-element Spent Fuel Casks Resulting from HEDD* [high energy density device] *Attack* (DIRS 181279-Luna 2006, all) to estimate the consequences of such events involving spent nuclear fuel in truck or rail casks. These more recent estimates of release fractions (DIRS 181279-Luna 2006, all) are based on the release fractions estimated in 1999 from *Projected Source Terms for Potential Sabotage Events Related to Spent Fuel Shipments* (DIRS 104918-Luna et al. 1999, all), but they also incorporate data from additional tests sponsored by *Gesellschaft für Anlagen - und Reaktorsicherheit* in Germany and conducted in France in 1994 that were not available for the 1999 report.

The potential impacts of sabotage were assessed for rail shipments from Hazen to the Hawthorne Staging Yard to the Rail Equipment Maintenance Yard. As with the maximum reasonably foreseeable accidents discussed in the Accidents section, four specific rail alignments were evaluated. The methods and data used to estimate the impacts of potential sabotage events are described in Appendix K.

For the four specific alignments there were no urban areas, as defined in U.S. Census Bureau population data. However, there were suburban areas and rural areas. Using alignment-specific 2000 census population data escalated to the year 2067, the average population density in suburban areas along the alignments was 589 people per square kilometer (1,525 people per square mile) near Silver Springs, Nevada. The average population density along rural areas, escalated to the year 2067, ranged from 4.19 to 4.33 people per square kilometer (10.9 to 11.2 people per square mile).

The impacts of potential sabotage events are listed in Table 4-275. If a sabotage event occurred in a suburban area, the collective radiation dose is estimated to be 4,700 person-rem. The total latent cancer fatalities for people exposed during a sabotage event is estimated to be 2.8. If a sabotage event occurred in a rural area, the collective radiation dose is estimated to be 35 person-rem. The total latent cancer fatalities for people exposed during this sabotage event is estimated to be 0.021.

Table 4-275. Estimated radiological impacts for a sabotage event involving a rail shipping cask for suburban and rural areas.[a]

Impact	Suburban area[b]	Rural area[b]
Impacts to populations		
Population dose (person-rem)	4,700	35
Latent cancer fatalities	2.8	0.021
Impacts to maximally exposed individuals		
Maximally exposed individual dose (rem)	27	27
Probability of a latent cancer fatality	0.016	0.016

a. There are no urban areas for the four specific alignments.
b. Based on neutral atmospheric conditions and moderate wind speeds. These were defined as Class D stability class and a wind speed of 4.47 meters per second.

In either a suburban area or rural area, the maximally exposed individual would be located 100 meters (330 feet) from the sabotage event. The radiation dose for the maximally exposed individual is estimated to be 27 rem. The probability of a latent cancer fatality for the maximally exposed individual is estimated to be 0.016.

4.3.10.2.3 Transportation Impacts

4.3.10.2.3.1 Construction Impacts.

Nonradiological Roadway Accidents During construction, personnel and equipment would be moved initially by truck and other vehicles, and could be moved by rail once portions of the rail line were completed. Such movements of equipment and personnel could lead to roadway accidents.

DOE estimates that the construction phase would involve approximately 2,160 full-time-equivalent workers during the first three years, 750 full-time-equivalent workers in the fourth year, and 370 full-time-equivalent workers in the last year for a total of 7,600 full-time-equivalent workers, not including the Cask Maintenance Facility (DIRS 174083-WPI 2003, all; DIRS 180874-Nevada Rail Partners 2007, Appendix D, Tables 1 and 2). The construction phase would take a minimum of 4 years and 6 months. The Cask Maintenance Facility construction would involve additional 150 workers for 88 weeks.

In total, this suggests that there would be 7,600 full-time workers involved in the construction of the rail line and associated facilities over the minimum 4.5-year construction project and an additional 260 full-time-equivalent workers for construction of the Cask Maintenance Facility. The exact distribution over time is not significant for the traffic safety calculations, which are aggregated over the total construction

TRANSPORTATION SABOTAGE: AN OPPOSING VIEWPOINT

The State of Nevada has provided analyses that assert a sabotage event using a high-energy density device such as an antitank missile would completely penetrate a spent nuclear fuel cask, which would result in consequences 10 times higher than those DOE estimated (DIRS 181892-Lamb, Hintermann, and Resnikoff 2002, p. 19).

Because of DOE classification policy requirements, the Department cannot state specifically the devices that the analyses in Luna, Neuhauser, and Vigil (DIRS 104918-1999, all) and Luna (DIRS 181279-2006, all) considered. However, the analyses encompassed the damage that modern weapons could produce in an optimally successful sabotage event. The assertion that modern weapons can produce full penetration of both cask walls is not confirmed by calculations from Luna, Neuhauser, and Vigil (DIRS 104918-Luna, Neuhauser, and Vigil 1999, all).

In addition, in scoping comments, the State of Nevada recommended that the sabotage analysis address factors such as attacks that involve multiple weapons, attacks that use combinations of weapons designed to maximize release and dispersal of radioactive materials, attacks that involve large groups of well-trained adversaries, suicide attacks, attacks that involve the infiltration of trucking and railroad companies, and attacks at locations with high symbolic value.

Because DOE assumed that the sabotage event would be optimally successful, most of the factors listed by the State could affect the chances of success but not the outcome of the sabotage event. In addition, even though attacks that use multiple weapons and combinations of weapons designed to maximize release and dispersal of radioactive materials are possible, DOE believes that the sabotage event it analyzed encompasses the damage that modern weapons might produce in an optimally successful sabotage event.

time. In other words, if the construction phase were assumed to take place over a 10-year period, this would only mean that fewer workers would be making more trips; this would result in a similar total number of trips as the minimum 4.5-year construction phase.

For each year, it is assumed that each worker would make two trips per day over five days a week for 50 weeks a year (that is 2,000 hours per year full-time-equivalent workers). To provide a conservative upper bound estimate of roadway accidents, DOE assumed that all workers would individually make daily vehicle trips on roadways, even though it is likely that many rail line construction workers would reside in construction camps linked to work sites by access roads. Each trip is assumed to be 80 kilometers (50 miles) in length, which translates to approximately 40,000 kilometers (25,000 miles) per year per worker. While the distances involved for portions of this construction project are obviously much greater, a worker might travel hundreds of miles each way every one to two weeks and stay in the construction camps between these longer trips. This travel pattern would result in approximately the same distance traveled per worker. Collectively, the total number of miles driven by all workers would be approximately 315 million kilometers (190 million miles).

Based on a fatal accident rate of 1.65 fatalities per 100 million vehicle-kilometers (2.66 per 100 million vehicle-miles) (DIRS 180484-FHWA 2006, p. 1, Section V, Tables FI-20 and VM-2) traveled for light trucks or passenger cars in rural areas in Nevada, approximately six fatalities could occur due to the movement of workers during construction of the rail line and facilities.

These estimates would not vary among the proposed specific alignments, because the number of potential fatalities is based on the total distance traveled and is not dependent on the minor difference in the length or location of the alternative segments. Therefore, the predicted accident rates are the same for each specific alignment.

Nonradiological Rail Line Accidents During the construction phase, there are expected to be up to 368 loaded trains servicing the Schurz area, 1,116 for the Mina common segment 1 and Montezuma areas, and 1,260 for the Mina common segment 2 area (DIRS 180874-Nevada Rail Partners 2007, Appendix A) as the portions of the rail line that had already been completed were used to bring critical materials to the various staging areas (the length of line constructed from a particular staging area would influence the number of trains used on each segment of the partially completed rail line). A shorter construction phase would result in more trains per day, and a more extended construction phase would likely experience the lower end of the range of expected train volume.

Given the variability in the number of trains per day or year, this analysis focuses on the total number of inbound loaded and outbound unloaded construction trains, which is predicted to be 5,488 ([368 + 1,116 + 1,260] × 2). These trains would travel at speeds between 24 and 64 kilometers (15 and 40 miles) per hour depending on both the load carried and the area in which they operate. It is assumed that each train would travel one-half of the total route length (accounting for only new rail segments), or approximately 230 kilometers (144 miles) on average. Therefore, the total number of train-kilometers would be approximately 1.3 million kilometers (787 thousand miles). The total expected number of loaded railcars (including locomotives) during the construction phase are 8,240 for the Schurz area, 25,020 for the Mina common segment 1 and Montezuma areas, and 30,540 for the Mina common segment 2 area. The total number of inbound loaded and outbound unloaded construction rail cars is predicted to be 127,600 ([8,240 + 25,020 + 30,540] × 2), resulting in approximately 29 million railcar-kilometers (18 million railcar-miles).

The transportation safety impacts of concern during construction focus on rail-related accidents and worker and public fatalities. Based on the same rail accident rates described in the operations phase (Section 4.3.10.2.3.2), accidents associated with train-kilometers and railcar-kilometers are calculated. A total of two rail accidents would be expected to occur for the entire set of estimated train and railcar movements during construction.

Based on Federal Railroad Administration statistics, the fatality rate for workers is 3.46×10^{-10} fatality per railcar-kilometer traveled, and the rate for occupants of other vehicles and pedestrians is 1.11×10^{-8} fatality per railcar-kilometer traveled (DIRS 178016-DOT 2005, Chapter 1, all). Rates were derived by considering fatalities associated with freight train operations only (fatalities associated with passenger train operations were omitted for more applicable rates). As a result, the worker category considers worker-on-duty, worker-not-on-duty, contractor-on-duty, and contractor-other. Public fatalities include both trespassers and nontrespassers. Because passenger operations are not relevant to the Proposed Action, there is no consideration of the passengers-on-train category.

Based on these fatality rates, a total of 0.4 fatality (that is, not more than one) would be expected to occur for the entire set of estimated railcar movements during construction. No detectable difference is expected for the specific alignments, as the total variation in route lengths is small (greatest difference would be between Schurz alternative segments 6 and 1, which is a 20-kilometer [13-mile] difference).

Many movements of rail-mounted construction equipment are also anticipated. This equipment would travel fairly short distances each day to conduct such activities as setting out railroad ties or preparing the ballast. These movements have not been included in the count of train-kilometers as they would occur in controlled work areas and in very small increments, rather than at any measurable speed in a publicly accessible area.

4.3.10.2.3.2 Operations Impacts.

Nonradiological Roadway Accidents The assessment of impacts to transportation safety begins with accidents, such as may be experienced by any vehicle, independent of cargo. These accidents typically result in injuries or fatalities to drivers or operators, other motorists, or pedestrians, and could result from the movement of cargo.

Approximately 210 workers would be involved in the operation of the rail line and the facilities. Each year it is assumed that each worker would make two trips per day, over five days a week, for 50 weeks a year. It is assumed that each trip would be 80 kilometers (50 miles). This would result in 40,000 kilometers (25,000 miles) per year per worker. Collectively, over the 50-year operations phase, the total number of kilometers driven by workers would be approximately 420 million kilometers (263 million miles).

Based on a fatal accident rate of 1.65 fatalities per 100 million vehicle-kilometers (2.66 per 100 million vehicle-miles) traveled for light trucks or passenger cars in rural areas in Nevada (DIRS 180484-FHWA 2006, p. 1, Section V, Tables FI-20 and VM-2), approximately seven fatalities would be expected due to the movement of workers during operation of the rail line and facilities over 50 years of operation. These estimates are not specific to the specific alignments, because the small variations in length and location of the alternative segments would not significantly affect the total distance traveled.

Nonradiological Rail Line Accidents The rail transportation safety analysis for the operations phase of the Proposed Action assesses the impacts of transportation, rail facilities, and grade crossings.

Rail Alignment: The proposed rail line would range from 521 to 571 kilometers (approximately 255 to 285 miles) in length, depending on which alternative segments are chosen. Given the similarities in the lengths of the alternative segments, the longest specific alignment has been selected to conservatively estimate the overall accident risks for the rail line.

This analysis includes both dedicated railcar cask trains and other trains not involving casks from the Staging Yard to the Rail Equipment Maintenance Yard. A typical spent nuclear fuel or high-level radioactive waste train would have two to three locomotives, followed by a buffer car, one to five cask cars, another buffer car, and an escort car. two engines, followed by a buffer car, three cask cars, another buffer car, and an escort car. The actual number of casks per train could vary from one to five, while the number of locomotives could vary from two to three. The total number of casks that would be moved by rail is 9,495. Based on TSM (Total System Model) runs, there would be 2,833 trains carrying loaded casks and an equal number carrying empty casks. Therefore, to determine the impacts of moving cask cars, the analysis considers 5,666 trains (2,833 × 2) involving cask cars. The TSM runs also give the total number of railcars involved in cask trains, with an average of 8.54 cars per train (3.35 cask cars, 2.19 locomotives, two buffer cars, and one escort car). Over the 50-year operations phase, there would be approximately 48,408 railcars associated with cask trains.

In addition to trains involving cask cars, there are also other types of trains that would be operating along the rail line, including maintenance-of-way trains (two one-way trains per week), and repository supply and construction trains (seven one-way trains per week). The total number of trains not involving casks would be 23,400 over 50 years of operation. The total number of railcars not carrying casks would be 58,338, accounting for both loaded and unloaded cars (DIRS 180876-Nevada Rail Partners 2007, Section 4.0, Table 1).

The total number of railcars (all kinds) moved under the Proposed Action would be approximately 106,746 (48,408 + 58,338), considering both directions of travel. Based on the same fatality rates used in the construction analysis, namely 3.46×10^{-10} fatalities per worker per railcar-kilometer, and 1.11×10^{-8} fatalities per pedestrian per railcar-kilometer, 0.7 fatality (that is not more than one) would be expected to occur for the entire set of estimated railcar movements during operation.

The interchange tracks at the Staging Yard would operate like a typical large siding or other similar types of rail yards, so the hazards associated with its operation would be the potential for transport accidents.

However, because the buffer cars, cask cars, and escort car would be separated as a unit from the trains used to transport the casks from their origins, there would be limited changes for derailments involving the cask cars on the Staging Yard tracks. Accidents in yards typically occur as individual cars are handled, not with complete sets of cars. Accidents during the handling of railcars also occur at very low speeds, further limiting the chance of an accident. Because the trains are expected to enter the interchange track from the branchline at normal track speed, the accident rate for the interchange tracks at the Staging Yard would be based on mainline accident rates rather than yard accident rates.

Accident rates for rail transportation are generally presented as either accidents per train-kilometers or a combination of accident rates based on both train-kilometers and railcar-kilometers, considering these two classes of accident causes separately. Review of Federal Railroad Administration statistics and industry data on the distribution of track classes produced the accident rates given in Table 4-276 for Track Class 3 (DIRS 180220-Bendixen and Facanha 2007, all). These rates include derailments and collisions from a variety of causes, including track failures resulting from geological hazards. These accident rates reflect railroad operations involving general freight service. Dedicated train service, which would be used to move cask railcars to the Rail Equipment Maintenance Yard, would follow stringent safety regulations. Additionally, dedicated train service has increased control and command capabilities, since shorter trains allow better visual monitoring from the locomotive and the escort car.

Table 4-276. Estimated rail accident rates.[a]

Accident location	Accident rate per train-kilometer	Accident rate per car-kilometer	Combined accident rate per train-kilometer for 8-car train
Mainline track	7.50×10^{-7}	0.17×10^{-7}	8.95×10^{-7}

a. Source: DIRS 180220-Bendixen and Facanha 2007, all.

Therefore, the accident rates here included provide a conservative estimate of the number of accidents involved in the operations of the rail line.

While not all accidents would lead to derailments of any railcars, any accident is likely to require the train to be inspected and other precautions to be taken. Hence, this analysis conservatively considers all accidents involving cask cars. In addition, a number of design and operating changes for dedicated trains have been predicted to reduce accident rates for dedicated trains, but to maintain conservatism, these potential benefits are not considered here.

Based on the lengths of each alternative segment and common segment, and the combined accident rate for an 8.54-car train (that is, 8.95×10^{-7} accident per train kilometer), the predicted accident counts are given in Table 4-277 for the full set of cask shipments expected during the entire operations phase (that is, the analysis considers the 5,666 trains involving cask cars, which includes both directions). For accidents not involving cask trains, the total number of accidents was calculated by adding the accidents associated with the number of trains and the accidents associated with the number of rail cars. For purposes of this analysis, DOE used the longest specific alignment. Because the upper bound of the accident rate is so small for the specific alignments, there would be no discernable difference.

As shown in Table 4-277, a total of approximately three accidents involving cask trains could occur over the 50-year operations phase. While potential consequences could involve environmental damage, evacuation costs, and human health impacts, the focus of the frequency analysis is on scenarios that could lead to human health impacts as discussed in greater detail elsewhere in this section. The total number of accidents involving trains that do not carry casks would be approximately 11 for 50 years of operation. Therefore, the total number of predicted rail accidents would be approximately 14.

Rail Facilities: The analysis of potential incidents at rail facilities was based on the types of activities and operations that are expected to be carried out at such facilities. The scenarios of concern relate primarily to transportation accidents at the Staging Yard. The likelihoods of accidents are based on both available failure and accident rates, and on the number of switchovers that would need to be made. The results for accident potential at the Staging Yard are included within the calculations for Table 4-277.

The Rail Equipment Maintenance Yard and the geologic repository operations area interface are essentially rail yards in terms of the operations that would occur there: train make-up and car switching. Casks would be removed from the railcars at the geologic repository operations area and empty casks would be placed back onto railcars at the Rail Equipment Maintenance Yard. The results for accident potential at the Rail Equipment Maintenance Yard and the geologic repository operations area interface are also included within the calculations for Table 4-277 (common segment 6).

Table 4-277. Estimated number of predicted rail accidents.[a]

Rail alignment segment	Segment length (longest alternative segment, in kilometers)[b]	Predicted number of accidents	
		Involving cask trains	Not involving cask trains
Union Pacific Hazen Branchline	69	0.35	1.28
Department of Defense Branchline North	8.1	0.04	0.15
Schurz alternative segments	72	0.37	1.34
Department of Defense Branchline South	35	0.18	0.65
Mina common segment 1	120	0.61	2.22
Montezuma alternative segments	140	0.71	2.60
Mina common segment 2	3.4	0.02	0.06
Bonnie Claire alternative segments	21	0.11	0.39
Common segment 5	40	0.20	0.74
Oasis Valley alternative segments	14	0.07	0.26
Common segment 6 (including Rail Equipment Maintenance Yard)	51	0.26	0.95
Total	573	2.91	10.63

a. During 50-year operation.
b. To convert kilometers to miles, multiply by 0.62137.

Grade Crossings: DOE also examined the consequences of the Proposed Action on delay and safety conditions for at-grade crossings along the proposed rail alignment. Delay considerations are discussed in Section 4.3.9. The examination of grade-crossing safety typically considers the expected number and locations of grade crossings, the volume of both vehicle and rail traffic at crossings, the nature of road traffic (for example, trucks versus passenger vehicles), the design and safety features of the crossings, and train and vehicle speeds in the vicinity of any crossings.

Grade-crossing collisions reported as train accidents are included in the number of rail accidents estimated in Table 4-277. Accidents at grade crossings are accounted for in the rail accident estimates included in this analysis.

Grade-crossing safety is influenced by the type of protection installed at each crossing. Most of the crossings for this project would involve very low-usage unpaved roads that would mainly involve passive warning systems (such as cross-bucks and stop signs), or paved roads that might have active warning systems (such as flashing lights and gates). The exception is the existing rail segment between Hazen and Wabuska, which crosses public roads with moderate traffic (that is U.S. Highway 50A in Hazen, U.S. Highway 50 in Silver Springs, and U.S. Highway 95A in Churchill and Wabuska). Even with the additional rail traffic generated by the Proposed Action, these grade crossings would not meet any of the conditions established by the U.S. Department of Transportation to be considered for grade separation (such as maximum highway and train speed, average daily road and rail traffic, crossing exposure, vehicle delay) (DIRS 180695-DOT 2002, all). Although grade-separated crossings are not mandatory for this project, DOE would be providing up to five grade-separated crossings on state and federal highways as identified in Chapter 2. The numbers of crossings with each type of protection are listed in Table 4-278 for each rail line alternative segment and common segment. Table 2-23 provides a detailed list of grade crossings.

Table 4-278. Number of grade crossings with primary roads.[a]

Rail alignment segment	Passive protection	Active protection	Grade separation
Union Pacific Hazen Branchline[b]	7	7	None
Schurz alternative segments	None	None	1
Department of Defense Branchlines	1	None	None
Mina common segment 1	None	None	2
Montezuma alternative segments	None-1[c]	None-1[c]	None-1[c]
Mina common segment 2	None	None	None
Bonnie Claire alternative segments	None	None	None
Common segment 5	None	1	None
Oasis Valley alternative segments	1	None	None
Common segment 6	None	None	None
Totals	9/10	8/9	3/4

a. This list does not include all grade crossings.
b. The Union Pacific Railroad Hazen Branchline is part of the region of influence for the purposes of the transportation impact assessment; however, it is not part of the Mina rail alignment.
c. This depends on the specific alternative segment.

4.3.10.2.3.3 Transportation of Munitions. Under the Mina Implementing Alternative, any of the Schurz alternative segments would route existing rail traffic, including munitions shipments and other shipments to and from the Hawthorne Army Depot, around the town of Schurz, and the existing Department of Defense Branchline through Schurz would no longer be used. A safe distance would be maintained between munitions trains and cask trains at all times at the Staging Yard. Therefore, munitions trains would not represent a hazard to cask trains.

U.S. Army quantity-distance calculations provide an assessment of the distance to public traffic routes and distance to inhabited buildings for storage or transportation of munitions. Public traffic route distances consider the transient nature of the exposure and are calculated as 60 percent of the inhabited building distance (DIRS 181032-Dillingham 2007, all).

According to Department of the Army Pamphlet 385-64, Table 5-1, a distance to public traffic route of 725 meters (2,380 feet) and a distance to inhabited building of 1,210 meters (3,970 feet) apply to munitions shipments of the types made along the existing rail line. The Army has indicated that there should be an easement of at least 725 meters on either side of the tracks (no building) along the entire route. This is based on 60 percent of the inhabited building distance of 1,210 meters (DIRS 181032-Dillingham 2007, all). There are no inhabited buildings identified within this distance for any of the

Schurz alternative segments, as shown in Figure 4-49. As the figure shows, the closest point along any of the four Schurz alternative segments to the town of Schurz is 6.1 kilometers (3.8 miles) for Schurz alternative segment 1, 10.5 kilometers (6.6 miles) for Schurz alternative segment 4, 10.6 kilometers (6.6 miles) for Schurz alternative segment 5, and 12.1 kilometers (7.6 miles) for Schurz alternative segment 6. As also shown in the figure, there are only four grade crossings for Schurz alternative segments 1, 4, and 5, and only three grade crossings for Schurz alternative segment 6, compared with the nine grade crossings in the town of Schurz along the existing Department of Defense Branchline.

4.3.10.3 Shared-Use Option

4.3.10.3.1 Nonradiological Impacts

4.3.10.3.1.1 Impacts to Workers. Rail line construction and operations nonradiological occupational health and safety impacts for the Shared-Use Option would be approximately the same as for the Proposed Action, based on the construction and operation of the proposed rail line. It is assumed that construction of the proposed rail line for the Shared-Use Option would require approximately the same number of workers and labor hours, and approximately the same amount of construction materials and equipment as would construction of the proposed rail line for the Proposed Action.

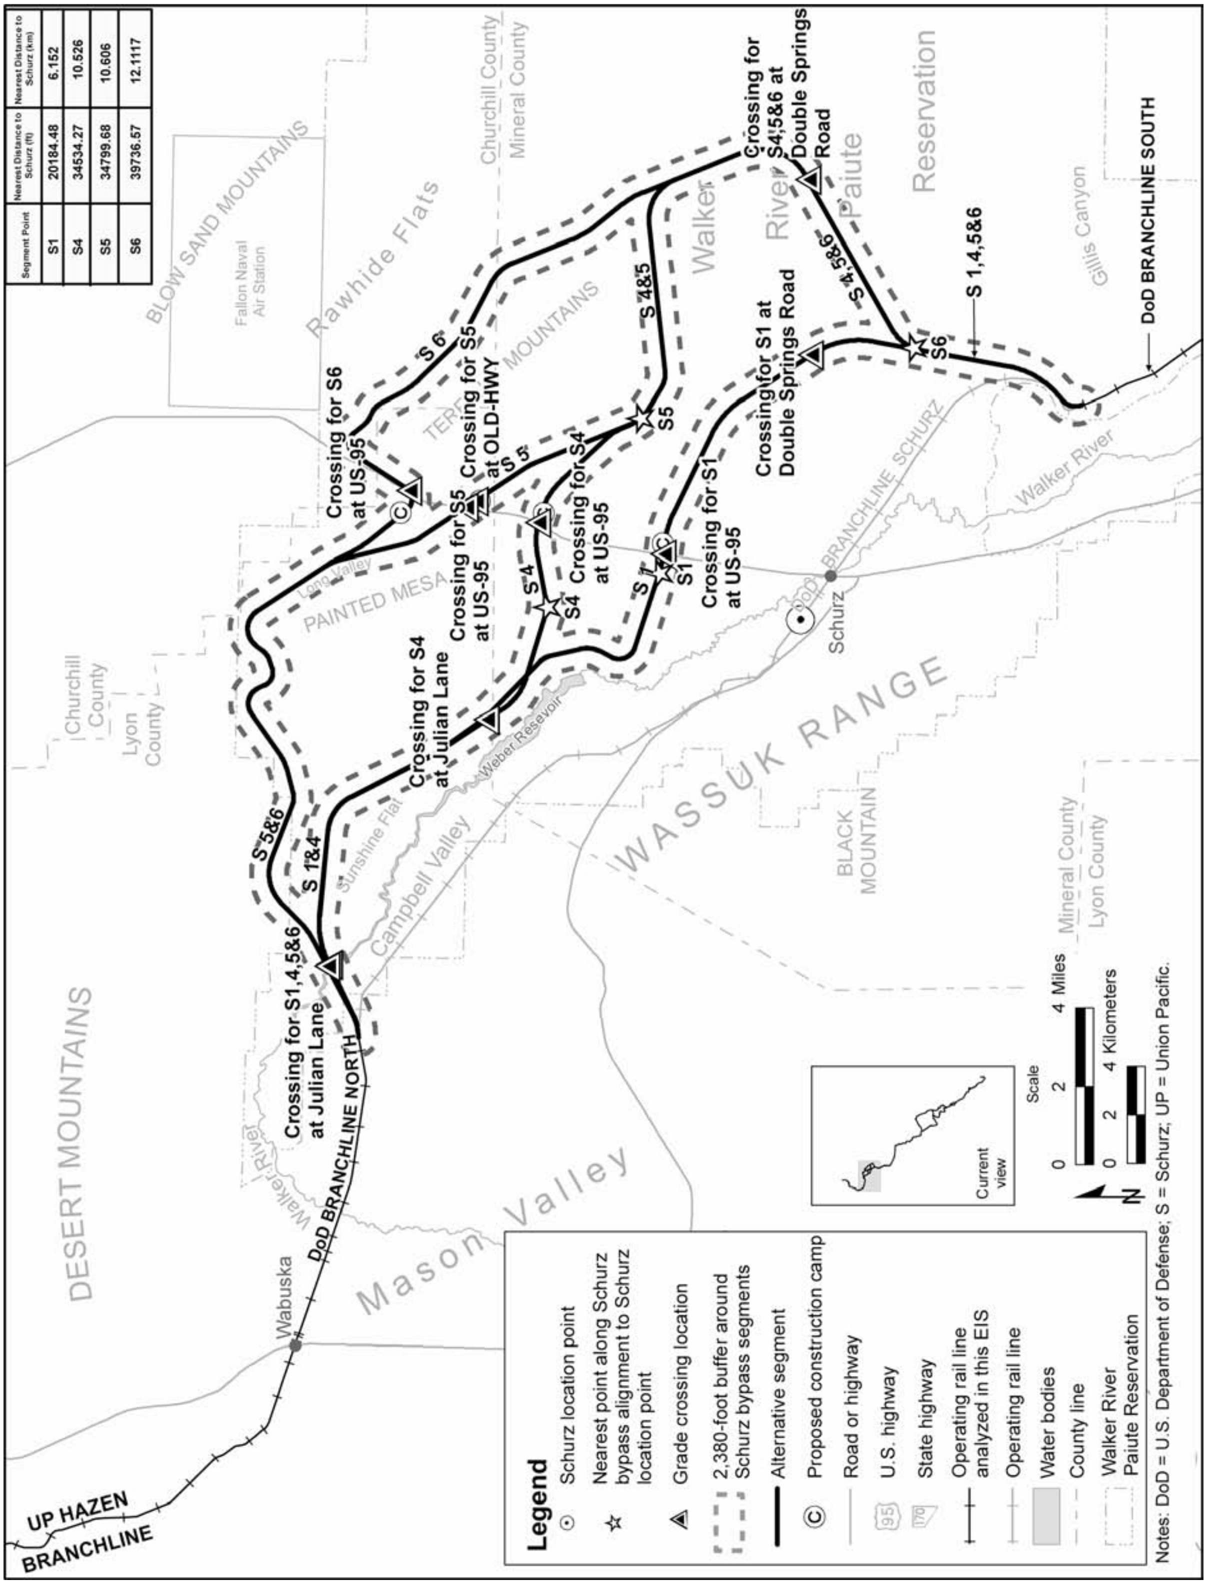
Rail line facility construction and operations nonradiological occupational health and safety impacts for the Shared-Use Option would be approximately the same as for the Proposed Action, based on the construction and operation of the proposed rail line and associated facilities. It is assumed that the construction of the railroad facilities under the Shared-Use Option would require approximately the same number of workers and labor hours, and approximately the same amount of construction materials and equipment as would construction of the facilities under the Proposed Action, and that the configuration and operation of the facilities, including emergency response systems, would be the same for both the Proposed Action and Shared-Use Option.

4.3.10.3.1.2 Impacts from Specific Resource Areas. Rail line construction and operations nonradiological occupational health and safety impacts related to the specific resource areas discussed in Section 4.3.10.2.1.1 would be approximately the same for the Shared-Use Option as for the Proposed Action, based on the construction and operation of the proposed rail line.

4.3.10.3.2 Radiological Impacts

4.3.10.3.2.1 Impacts to Workers. It is anticipated that worker health and safety impacts from the Shared-Use Option are similar to those for the Proposed Action, with the exception of radiological occupational exposure impacts. One difference would be the number of times a loaded cask train would pass workers at sidings. For the Proposed Action, there could be up to about 30 passes involving loaded cask trains and other trains over the life of the rail shipping campaign. A cask train could pass more than one shared-use train between the Staging Yard and the Yucca Mountain Site boundary (DIRS 180876-Nevada Rail Partners 2007, all). This would result in a collective radiation dose of 0.0013 person-rem for these workers. This is equivalent to a probability of a latent cancer fatality of 7.7×10^{-7}. For the Shared-Use Option, there could be up to about 60 passes involving loaded cask trains and other trains over the life of the rail shipping campaign. A cask train could pass more than one shared-use train between the Staging Yard and the Yucca Mountain Site boundary. This would result in a collective radiation dose of 0.0028 person-rem for these workers. This is equivalent to a probability of a latent cancer fatality of 1.7×10^{-6}.

4.3.10.3.2.2 Impacts to the Public. It is anticipated that radiological health and safety impacts for the Shared-Use Option would be similar to those for the Proposed Action with the exception of radiological occupational exposure impacts.



Segment Point	Nearest Distance to Schurz (ft)	Nearest Distance to Schurz (km)
S1	20184.48	6.152
S4	34534.27	10.526
S5	34799.68	10.606
S6	39736.57	12.1117

Figure 4-49. Inhabited building distance for Schurz bypass segments.

The additional trains that would be operated for the Shared-Use Option would not involve transportation of radioactive materials and therefore there would be no additional exposure to the public.

4.3.10.3.3 Transportation Impacts

4.3.10.3.3.1 Construction Impacts.

<u>Nonradiological Roadway Accidents</u> Under the Shared-Use Option, any increase beyond what is described under the Proposed Action for roadway accidents and fatalities would be minimal. The collective impact would be expected to be less than one percent of the overall risk calculated for construction of the Proposed Action rail line. Therefore, impacts are considered to be the same as those identified for the Proposed Action.

<u>Nonradiological Rail Line Accidents</u> No commercial rail transports would be conducted during construction of the Shared-Use Option. Under the Shared-Use Option, any increase beyond what is described under the Proposed Action for rail line accidents and fatalities would be minimal. The collective impact would be expected to be less than one percent of the overall risk calculated for construction of the Proposed Action rail line. Therefore, impacts are considered to be the same as those identified for the Proposed Action.

4.3.10.3.3.2 Operations Impacts.

<u>Nonradiological Roadway Accidents</u> Under Shared-Use Option operations, any increase beyond what is described under the Proposed Action for roadway accidents and fatalities would be minimal. Impacts are considered to be the same as those identified for the Proposed Action.

<u>Nonradiological Rail Line Accidents</u> The rail transportation safety analysis for the operations phase of the Shared-Use Option assesses the impacts of transportation, rail facilities, and grade crossings.

Rail Alignment: The Shared-Use Option differs from the Proposed Action only in the amount and type of traffic that would use different portions of the proposed rail line and the composition of some of the trains in terms of both length and materials categories. Up to ten commercial train trips (five round trips) a week would expected along the entire alignment, and up to eight commercial train trips (four round trips) a week would be expected from Hazen to the Schurz area. Each train would consist of up to four locomotives and up to 60 railcars (DIRS 180694-Ang-Olson and Gallivan 2007, all). For comparison, an average total of 17 one-way trains would run between the Staging Yard and the geologic repository per week carrying casks, repository construction and supplies materials, and other materials for Maintenance-of-Way activities. It is anticipated that the trains would travel at 64 kilometers per hour (40 miles per hour). The addition of the commercial trains would have a small impact on the potential for an accident involving a cask car, as operational procedures and controls regarding both scheduling and the use of sidings would restrict the interactions of the two types of trains. Trains carrying cask cars would take precedent. The overall density of trains on the proposed rail line would still be considered low, even with the commercial trains added in, so additional risk of an accident involving cask cars due to increased traffic densities would be minimal.

During the peak level of transportation operations along the rail line, there could be 17 trains servicing the repository each week (8 cask trains, 7 repository construction and supplies trains, and 2 maintenance-of-way trains, or 17 one-way trips), and 18 commercial trains (9 round trips). During these peak years, the transportation safety impacts associated with nonradiological risks might increase by approximately 100 percent. Over the full 50-year operating lifetime of the rail line, the Shared-Use Option could result in an additional 20,800 trains, considering each direction separately (eight one-way trains per week). Assuming that ten trains would travel the full length of the rail line and eight trains would travel from Hazen to Schurz, an additional 17.9 million train-kilometers would be generated over 50 years. Based on a list of potential shippers, demand estimates were developed (DIRS 180694-Ang-Olson and Gallivan

2007, all). A total of 524 weekly carloads are expected to be shipped along different portions of the rail line. According to the location and demand of each potential shipper, it was estimated that each loaded car would travel an average of 188 kilometers (117 miles). Considering both directions of travel, this would result in approximately 512 million car-kilometers over 50 years (524 cars × 52 weeks × 50 years × 188 kilometers × 2). Assuming the same rail fatality and accident rates included in Sections 4.3.10.2.3.1 and 4.3.10.2.3.2, respectively, a total of six additional fatalities and 22 additional accidents would be expected to occur for the entire set of estimated railcar movements during Shared-Use Option operations. Rail accidents are not allocated to specific rail line segments due to the uncertainty of where those accidents will occur.

In general, the operating characteristics of these commercial trains are unknown at this time; therefore, the travel times and operational movements of these trains cannot be described. However, the Nevada Railroad Control Center described under the Proposed Action would control and coordinate commercial rail service movements and would therefore maintain overall safety of operations along the rail line to minimize potential rail accidents.

Rail Facilities: The Rail Equipment Maintenance Yard and the geologic repository operations area interface would not be affected by any shared use of the proposed rail line because commercial shippers would not use the DOE Rail Equipment Maintenance Yard. Many of the commercial railcars would be dropped off along the way at intermittent commercial facilities. As a result, the commercial service end-of-line facility would have significantly less car handling than the Rail Equipment Maintenance Yard, and operations at the commercial facility would have no impact on the number of accidents involving the cask cars.

Grade Crossings: The increased number of trains under the Shared-Use Option would slightly increase the potential for accidents because of the increased number of trains crossing each at-grade crossing (with a maximum of nine round trips per week). However, because this volume of commercial traffic would be low, adverse impacts would be small. Delay considerations were included in Section 4.3.9. Even with the additional rail traffic from the Shared-Use Option, the grade crossings would still not meet any of the conditions established by the U.S. Department of Transportation to be considered for grade separation (DIRS 180695-DOT 2002, all).

4.3.10.4 Summary

This section summarizes nonradiological occupational health and safety impacts, public and occupational radiological impacts, and nonradiological transportation impacts under the Proposed Action and the Shared-Use Option for the Mina rail alignment.

Alignment segments and facility locations are not relevant to the nonradiological transportation impacts analysis or to the nonradiological occupational health and safety impacts analysis. Nonradiological occupational health and safety impacts depend on the number of construction and operations full-time-equivalent workers. Nonradiological transportation impacts depend on the number of construction and operations full-time-equivalent workers and the number of casks transported. Therefore, there are no important differences among alignments or facility locations in relation to nonradiological transportation impacts or nonradiological occupational health and safety impacts.

Radiological impacts for the Mina rail alignment are estimated based on the longest-distance alignment, the shortest-distance alignment, the alignment with the highest population density, and the alignment with the lowest population density. There are no important differences among alignments with respect to radiological impacts for the Mina rail alignment.

All nonradiological transportation impacts for construction and operation, including vehicle-related fatalities, rail-related accidents, and rail-related fatalities, are considered to be long-term impacts. Nonradiological occupational health and safety incidents for construction and operation could be either short term (such as lost workday cases involving short-term disability) or long term (such as lost workday cases involving long-term disability). However, because there is no way to distinguish the duration of a specific lost workday case, for example, all nonradiological occupational health and safety impacts are deemed to be long-term impacts. All radiological impacts from railroad and facility operations are considered long-term impacts because such impacts would be experienced over the 50-year operating life of the railroad. Nonradiological transportation impacts, nonradiological occupational health and safety impacts, and radiological impacts would be direct impacts.

4.3.10.4.1 Nonradiological Impacts

Tables 4-279 and 4-280 summarize nonradiological impacts to workers from industrial hazards associated with railroad construction and operations under the Proposed Action. Impacts to involved workers and noninvolved workers and total impacts are shown in Table 4-263 for rail line construction and operations and in Table 4-264 for associated facility construction and operations. No construction or operations activities would occur under the No-Action Alternative. Therefore, there would be no occupational or public health and safety impacts associated with the No-Action Alternative.

Table 4-279. Estimated impacts to workers from nonradiological industrial hazards during rail line construction and operations under the Proposed Action.

	Construction		Operations	
	Labor hours worked	Incidents	Labor hours worked	Incidents
	13.0 million		2.9 million	
Total recordable cases		325		37
Lost workday cases		180		28
Fatalities		0.65		0.26

Table 4-280. Estimated impacts to workers from nonradiological industrial hazards during rail line facility construction and operations under the Proposed Action.

Group and industrial hazard category	Construction		Operations	
	Labor hours worked	Incidents	Labor hours worked	Incidents
	2.7 million		15.0 million	
Total recordable cases		75		361
Lost workday cases		42		220
Fatalities		0.01		1.09

Table 4-279 includes nonradiological impacts of construction and operation of the rail line under the Proposed Action including construction of the rail line, construction and operation of the construction work camps, construction and operation of quarries to produce ballast for construction activities, construction and operation of wells to produce water for construction activities, operation of construction trains, and construction and operation of batch plants to produce concrete for construction activities. Operations impacts include impacts to train crews and escort and security personnel. Table 4-281 summarizes the nonradiological impacts of construction and operation of rail line facilities under the Proposed Action, including the Rail Equipment Maintenance Yard, Staging Yard, Nevada Railroad Control Center and National Transportation Operations Center, Maintenance-of-Way Facilities, and Cask Maintenance Facility.

Table 4-281. Estimated impacts to workers from nonradiological industrial hazards during rail line and facility construction and operations under the Proposed Action.

Group and industrial hazard category	Construction		Operations	
	Labor hours worked	Incidents	Labor hours worked	Incidents
	15.7 million		17.9 million	
Total recordable cases		400		398
Lost workday cases		221		248
Fatalities		0.65		1.35

4.3.10.4.1.1 Workers. Nonradiological occupational health and safety impacts from railroad construction and operations under the Proposed Action involve approximately 800 recordable incidents, approximately 470 lost-workday accidents, and approximately two fatalities. Rail line construction and operation nonradiological occupational health and safety impacts for the Shared-Use Option would be approximately the same as for the Proposed Action, based on the construction and operation of the proposed rail line. It is assumed that construction of the proposed rail line for the Shared-Use Option would require approximately the same number of workers and labor hours, and approximately the same amount of construction materials and equipment as would construction of the proposed rail line for the Proposed Action.

Construction and operations workers under the Proposed Action and Shared-Use Option could potentially be exposed to nonradiological hazardous chemicals related to operation and maintenance of construction equipment and rail line facility equipment, including maintenance-of-way and maintenance of casks. Such activities are anticipated to include welding, metal degreasing, painting, and related activities. Occupational health and safety impacts could also result from worker exposure to fuels, lubricants, and other materials used in construction, operation, and maintenance of the proposed rail line and associated facilities. The recorded incident rates of these exposure hazards during construction work at the Yucca Mountain site has been small and is anticipated to be small for construction and operation of the rail alignment and facilities under the Proposed Action.

Dust and soils hazards include potential occupational exposure to hazardous inhalable dust, including the minerals crystalline silica, cristobalite, and erionite, and potential occupational encounters with unexploded ordnance. It is unlikely that any fugitive particulate generated in the construction areas would contain a concentration of crystalline silica, erionite, or cristobalite that would result in exceedance of occupational exposure limits for these materials. Therefore, impacts associated with occupational exposure to these materials are not anticipated from construction and operation of the railroad and facilities under the Proposed Action.

Impacts to construction or operations workers from unexploded ordnance would be small due to implementation of inspection procedures and mitigation measures if necessary.

Workers may also be exposed to biological hazards including infectious diseases (such as Hantavirus, West Nile Virus) and other biological hazards (such as venomous animals). The recorded incidence rates of these biological hazards in the region of influence in Nevada are small, according to statistics published by state and federal agencies including the U.S. Centers for Disease Control and the Nevada State Health Division, and the recorded incident rates of these biological hazards during construction work at the Yucca Mountain site has also been small. Therefore, DOE would expect small impacts to construction or operations workers from these biological hazards.

4.3.10.4.1.2 Public. Nonradiological impacts to the public from the construction and operation of the rail line and facilities (other than impacts from transportation accidents) are presented in the air quality section and noise section of this Rail Alignment EIS and are therefore not further discussed in Section 4.3.10.

Impacts to the public from transportation accidents (those transportation accidents not involving release of radiation) are discussed in Section 4.3.10.4.3.

4.3.10.4.2 Radiological Impacts

Occupational and public radiological impacts and accident risk of rail line and associated facility operations for the Proposed Action and Shared-Use Option are summarized in Table 4-282. For the radiological impacts analyses, the four specific alignments described in Table 3-146 were evaluated. Table 4-282 summarizes the radiation doses and impacts for these workers along these four alignments.

Table 4-282. Summary of occupational and public estimated radiological impacts for the Proposed Action (expressed as latent cancer fatality units).[a]

Case	Staging Yard	Workers	Public	Accident Risk	Total
Highest population	Hawthorne	0.3	8.5×10^{-4}	7.7×10^{-6}	0.3
Shortest distance	Hawthorne	0.33	8.2×10^{-4}	7×10^{-6}	0.33
Longest distance	Hawthorne	0.35	8.34×10^{-4}	7.6×10^{-6}	0.35
Lowest population	Hawthorne	0.35	8.1×10^{-4}	7×10^{-6}	0.35

a. Radiation doses modeled from the point where the proposed railroad would meet the existing Union Pacific rail line at Hazen.

Radiological occupational and public health and safety impacts to workers and the public for the Shared-Use Option would be approximately the same as those for the Proposed Action, as the additional trains that would be operated for the Shared-Use Option would not involve transportation of radioactive materials that would result in additional occupational or public exposure to radiation.

4.3.10.4.2.1 Workers. For workers, the radiological impacts of the Proposed Action and Shared-Use Option are estimated to result in less than one latent cancer fatality.

4.3.10.4.2.2 Public. Radiological impacts of the Proposed Action and Shared-Use Option are estimated to result in less than one latent cancer fatality.

4.3.10.4.2.3 Accidents. Radiological impacts of the Proposed Action and Shared-Use Option are estimated to result in less than one latent cancer fatality.

4.3.10.4.3 Transportation Impacts

Table 4-283 summarizes impacts from nonradiological transportation accidents, including vehicular-related accidents and rail-related accidents, from construction and operation of the Proposed Action and Shared Use Option. Impacts for the Shared Use Option are considered to be the same as those identified for the Proposed Action for the construction phase.

Table 4-283. Summary of estimated transportation accident impacts.

	Construction	Operations	
	Proposed Action and Shared-Use Option	Proposed Action	Shared-Use Option
Vehicular-related fatalities	6	7	7
Rail-related fatalities	0.4	0.7	7
Rail-related accidents	2	14	36
Rail-related accidents involving cask trains	Not applicable	3	3

4.3.11 UTILITIES, ENERGY, AND MATERIALS

This section describes potential impacts to utilities, energy, and materials from constructing and operating the proposed railroad along the Mina rail alignment. Section 4.3.11.1 describes the methodology DOE used to assess potential impacts to utilities, energy, and materials; Section 4.3.11.2 describes potential impacts; Section 4.3.11.3 describes the potential impacts under the Shared-Use Option; and Section 4.3.11.4 summarizes potential impacts.

Section 3.3.11.1 describes the regions of influence for utilities, energy, and materials. To aid reader understanding, the regions of influence are repeated throughout Section 4.3.11 where appropriate.

4.3.11.1 Impact Assessment Methodology

The utilities, energy, and materials impacts analysis considered whether construction and operation of the proposed railroad along the Mina rail alignment would:

- Cause utility service outages as a result of construction activities
- Affect the capacity of ***public water systems***, directly or indirectly
- Require extension of water mains involving off-site construction for connection to a public water source
- Impact water-supply capacity needed for fire suppression
- Affect the capacities of public wastewater treatment facilities, directly or indirectly
- Require extension of sewer mains involving off-site construction for connection with a public wastewater treatment system
- Require extensive expansion of telecommunications systems involving off-site construction for connections with the network (including construction of communications towers)
- Affect the capacity and distribution capabilities of local and regional suppliers of fossil fuel
- Cause new sources of construction materials and operations supplies to be built, such as new mining areas, processing plants, or fabrication plants
- Affect the capacity of existing materials suppliers and industries in the region

4.3.11.2 Construction and Operations Impacts

This section describes potential impacts to utilities, energy, and materials resources from constructing and operating the proposed railroad along the Mina rail alignment. The analysis of impacts to existing utilities considers:

- Potential impacts of constructing the rail line in or near existing utility lines or rights-of-way
- Potential impacts on the capacities of public utilities
- Potential impacts on the availability of fossil fuels (the focus of the energy analysis)
- Potential impacts on the availability of construction materials

4.3.11.2.1 Construction Impacts

4.3.11.2.1.1 Potential Interfaces with Public Utility Corridors and Rights-of-Way. Potential utility conflicts would arise if construction activities could interfere with a public utility's ability to continue service or could prevent future expansion of that utility or its use of a right-of-way. Conflicts could arise in areas where the rail line and its construction and operations support facilities would either cross or overlap an existing utility corridor or right-of-way.

Utility crossings are common to linear projects such as roads, railroads, and pipelines, and they can be accomplished with minimal impact using standard engineering procedures and appropriate design specifications (see Chapter 2).

Utilities that would require the construction of crossings either above or beneath the rail line (new grade crossings) might be subject to temporary interruption as the switch is made from the existing infrastructure to the new routing. Service interruptions for electrical and telephone service, if necessary, could be limited to the time required to throw a transfer switch or to disconnect and reconnect. Service interruptions to pipelines might be longer, but to the greatest extent practicable, would be limited to a few hours.

4.3.11.2.1.2 Public Utility Systems. Potential impacts to public utility systems during the construction phase would be related to the demands on these systems to support construction activity and sustain construction workers. DOE would establish 10 temporary construction camps along the rail alignment within the construction right-of-way to house construction workers, and would fully operate a maximum of six camps at any one time (DIRS 180874-Nevada Rail Partners 2007, Section 2.3). DOE estimates that 2,160 construction personnel would be employed full-time. Each construction camp would have the capacity to house 360 people (254 construction workers and 106 support staff) for such functions as construction administration, utilities, emergency services, and other support. The personnel at each camp would comprise 40 professional staff, 20 clerical staff, and 300 craftsmen (DIRS 180874-Nevada Rail Partners 2007, Table D-1). The utilities sector of each construction camp would include areas dedicated to power, wastewater treatment, water treatment, and trash disposal. DOE expects that most construction workers would live in and spend most of their time in these camps, thereby reducing the impacts that these individuals would have on public water and wastewater systems and the use of fuel for travel.

As described in Section 4.3.9, Socioeconomics, population changes are related to changes in employment. DOE expects that most of the full-time construction workers would live in the construction camps, but the Department estimates 40 construction workers might live in Mineral County, 5 in Esmeralda County, and 15 in Nye County (DIRS 180874 Nevada Rail Partners 2007, Table D-1). There would be some population increases in nearby towns attributable to construction workers and indirect support workers. Because increases in population affect future demand on public utilities in a community, the utilities impacts analysis uses the basic assumptions and expectations regarding population change during the construction phase, as described below.

For purposes of this analysis, and consistent with the methodology described in Section 4.3.9 of this Rail Alignment EIS, DOE assumes that most construction workers would come from outside the region of influence rather than the sparsely populated Lyon, Mineral, Esmeralda, and Nye Counties. Any changes in the populations of Lyon, Mineral, Esmeralda, Nye, and Clark Counties and towns within those counties would be small (see Section 4.3.9). Therefore, associated infrastructure impacts at the county and local levels during the construction phase would be small.

Public Water Systems The region of influence for public water systems is Lyon, Mineral, Esmeralda, and Nye Counties, and communities within those counties, and the Walker River Paiute Reservation, the bulk of which lies within Mineral County with smaller portions in Lyon and Churchill Counties. However, water requirements for the project during the construction phase would be met by new wells.

Because DOE does not plan to rely on public water systems as primary sources of water during the construction phase, direct impacts to public water systems would be those related to permanent population increases within the region of influence attributable to the construction phase.

Because, as previously discussed in Section 4.3.9, permanent population increases would be expected to be minor for most areas during the construction phase, DOE expects that existing public water systems in the region of influence could accommodate the increased demand within existing system capacities without adverse impacts.

As discussed in Section 3.3.11, Lyon and Mineral Counties can adequately meet current and future demands for water. Given the level of demand and limited capacity of groundwater in Nye County, further demands could strain the water-supply system. However, future population growth that might occur in Nye County during the railroad construction phase would be less than 1 percent. Goldfield, in Esmeralda County, has the water and infrastructure to triple the number of users served by its water-supply system, and can meet increased demands for water. Section 4.3.6, Groundwater Resources, discusses water requirements by hydrologic basin and indirect impacts associated with groundwater withdrawals.

Wastewater Treatment Systems The region of influence for wastewater transported offsite for treatment and disposal is the existing permitted treatment facilities in Lyon, Mineral, Esmeralda, and Nye Counties, and communities within those counties, and the Walker River Paiute Reservation, the bulk of which lies within Mineral County with smaller portions in Lyon and Churchill Counties.

DOE estimated that up to 609,000 liters (161,000 gallons) per day of sanitary wastewater could be generated during the construction phase, as summarized in Table 4-284. However, because construction activities would be phased, actual daily maximums would be less. The Department estimates that the amount of sanitary wastewater that would be generated at each construction camp would peak at 95,000 liters (25,000 gallons) per day. Most of this wastewater would be generated from flush toilets and showers. Sanitary sewage generated at the construction camps would be treated onsite using portable wastewater treatment facilities, and treated wastewater would be recycled and used for construction purposes (such as soil compaction and dust suppression). DOE would recycle about 90 percent of all construction-generated wastewater. Therefore, there would be no impacts to existing wastewater treatment capacity in the region of influence.

Commercial vendors would provide portable restroom facilities where needed and would transport wastewater offsite for treatment, which could include the use of permitted wastewater treatment facilities in the region of influence. As shown in Table 3-284, permitted wastewater treatment facilities in the region of influence have adequate capacity. Therefore, any impacts to those wastewater treatment facilities during the construction phase would be small.

DOE expects permanent population increases would be small for most areas during the construction phase (see Section 4.3.9); therefore, existing publicly owned wastewater treatment works in the region of influence could accommodate the increased wastewater within existing system capacities without adverse impacts.

Telecommunications Systems The region of influence for telephone and fiber-optic telecommunications systems is the southern Nevada region serviced by Nevada Bell Telephone Company (AT&T Nevada), Citizens Telecommunications Company of Nevada, and Verizon.

During preliminary grading, construction communications would be provided via short-wave radio and satellite telephone (DIRS 180875-Nevada Rail Partners, Section 2.5). Communications systems during construction would be designed to not interfere with other licensed services operating in the same

Table 4-284. Wastewater generation during the construction phase – Mina rail alignment.

Facility	Number of personnel (maximum)	Wastewater generation (liters per day per person)[a,b]	Total wastewater (liters per day)[c]
Construction camps[d]	2,160[e]	265	570,000
Staging Yard at Hawthorne	110[e]	76	8,400
Maintenance-of-Way Facility (Silver Peak or Klondike)	60[e]	76	4,600
Rail Equipment Maintenance Yard	150[e]	76	11,400
Cask Maintenance Facility	150[f]	76	11,400
Concrete batch plant	10[e]	76	800
Total			609,000

a. Sources: Daily wastewater generation rates from DIRS 180921-Nevada Rail Partners 2007, Section 4.4.2; Nevada Administrative Code 444.8312 as an estimated per person wastewater flow from an office (for other facilities).
b. To convert liters to gallons, multiply by 0.26418.
c. Numbers in column are rounded to three significant figures.
d. Six construction camps of a total of 10 would be in operation at one time.

geographic areas and would remain in place until the communications systems for railroad operations were in place and commissioned. Little or no landline telecommunications service would be required during the construction phase. The installation and use of telecommunications systems would have a small impact on local telecommunications utilities.

Electricity The region of influence for electric power includes areas serviced by the southern Nevada electrical grid operated by Nevada Power Company, Sierra Pacific Power Company, and Valley Electric Association, Inc. Electric energy demand for initial construction activities would be satisfied with portable generators until electrical connections were established. This section discusses energy needs that would be satisfied through the use of existing electrical utilities.

During the construction phase, DOE proposes to lay an underground 25-kilovolt distribution line under the rail roadbed (DIRS 180875-Nevada Rail Partners 2007, Section 4.1.2). The primary purpose of the distribution line would be to provide electric power to facilities and equipment needed for routine railroad operations (such as signals, switches, and radio communication towers), and to be able to provide the capacity to meet expected power needs for support facilities; a secondary purpose would be to provide an alternative to diesel-powered generators or local power sources.

Although power might be required during construction or operations only in specific areas along the rail alignment (such as at sidings, radio communication towers, construction camps, and quarries), for purposes of analysis DOE assumed that an underground 25-kilovolt distribution line would be laid in a trench in an uninterrupted length of approximately 452 kilometers (281 miles) which would include the nominal 409 kilometers (254 miles) of new rail construction, and the approximately 43 kilometers (27 miles) of Department of Defense Branchline between the southern end of the Schurz bypass and Hawthorne (Department of Defense Branchline South). Chapter 2 fully describes these rail segments and explains that different combinations of alternative segments and common segments would produce a rail line of different lengths. At the same time the Department was laying the power distribution line, it would also lay the fiber-optic cable to be used as part of a telecommunications system (encased in a polyvinyl-chloride [commonly referred to as PVC] duct), and would place it in the same trench as the 25-kilovolt distribution line. Once the cables were placed, the trench would be back-filled to grade.

Based on initial planning studies, power to the distribution system would be fed from locations where the rail line would intersect existing high-voltage transmission lines (DIRS 180875-Nevada Rail Partners 2007, Section 4.1.2). At this stage of the design process, DOE has not identified specific locations. DOE would construct substations within the nominal width of the construction right-of-way to feed the 25-kilovolt distribution line from the higher-voltage transmission lines at such intersections. At locations along the rail line where lower-voltage power was required for railroad systems, DOE would place step-down transformers from the 25-kilovolt distribution line on the trackside.

Construction camps would be powered one of three ways: (1) from existing transmission or distribution lines where they run alongside the camp sites, (2) from the 25-kilovolt distribution line, or (3) from diesel-powered generators. Option (1) would require access to pre-existing nearby transmission or distribution lines at construction-camp sites and their contracted use. Option (2) would depend on the availability of an energized 25-kilovolt distribution line during the period in which a construction camp would be operated. For options (1) and (2), DOE would place a substation at the construction camp. If neither option (1) nor (2) was available, DOE would select option (3). In addition, for options (1) and (2), the Department would use backup diesel-powered generators at each camp during unexpected power outages. Energy use at each camp during the peak output year would approach 54,000 kilowatt-hours per day, or 20 million kilovolt-hours per year.

Quarry sites would require electric power for conveyor belts, machinery, lighting, and support services. That need would be met by either of three options: (1) from nearby transmission or distribution lines if available, (2) from diesel-powered generators, or (3) from the 25-kilovolt distribution line. DOE would build a substation at each quarry site. Temporary power lines would distribute power at the quarry facility. If DOE selected option (1) or (3), diesel-powered backup generators would always be available at each quarry site for emergencies. Each quarry would be expected to use 27,600 kilowatt-hours of power per day. Energy use at each quarry site during the peak output years would approach 10 million kilowatt-hours per year (DIRS 180875-Nevada Rail Partners 2007, Section 3.1.3).

DOE plans to have 24-meter (80-foot)-long rails delivered by rail from manufacturing plants to Hawthorne. DOE would set up a portable welding plant at Hawthorne and would later relocate the plant along the rail alignment at 80- to 160-kilometer (50- to 100-mile) increments to weld 24-meter-long rail into 438-meter (1,440-foot)-long strings to be distributed along the rail alignment by dedicated welding trains (DIRS 180875-Nevada Rail Partners 2007, Section 3.3). Typically, such welding units are powered by diesel generators generating 375 kilowatts of electrical power. DOE might build a substation connected to existing transmission lines to supply this need at Hawthorne, but this is conceptual at this stage of design. Yard and siding areas would be likely candidate relocation sites. At these sites, the Department would use portable diesel-powered generators, or conceptually, the 25-kilovolt distribution line if available and energized. (Alternatively, off-line welding of the rail would be possible, but would require dedicated welding trains to support track construction activities.)

The major electrical providers in the project region, including Nevada Power Company, Sierra Pacific Power Company, and Valley Electric Association, Inc., would have adequate generating capacity or power-purchase capabilities (see Section 3.3.11) to supply the project during peak demand without disrupting service to the providers' respective coverage areas. As discussed in Section 3.3.11, demand is expected to remain relatively stable in the serviced areas, increasing at about 1 to 2 percent annually, and is not expected to impact the capacity of service providers. In cooperation with the affected utilities, DOE would perform electrical-capacity analyses to ensure adequate capacity exists, including evaluation of the conditions of existing electric facilities and determination of appropriate interface equipment to meet the needs of both parties, prior to any connection to a transmission or distribution line; therefore, any impact on electric services would be small.

For purposes of analysis, DOE assumed that electricity requirements for construction of the railroad operations support facilities would be met with portable generating equipment, but could later be met through substations connected to the 25-kilovolt distribution line when it was completed. As described in Chapter 2, these facilities would include the Staging Yard at Hawthorne, which would incorporate a Satellite Maintenance-of-Way Facility and possibly the Nevada Railroad Control Center and National Transportation Operations Center, and where designated tracks would serve as interchange tracks for Union Pacific Railroad trains; the Maintenance-of-Way Facility located either in the vicinity of Silver Peak or Klondike; and the Rail Equipment Maintenance Yard, which would incorporate a Satellite Maintenance-of-Way Facility, the Cask Maintenance Facility, and possibly the Nevada Railroad Control Center and National Transportation Operations Center.

4.3.11.2.1.3 Fossil Fuels. At this point in project planning, DOE has not identified specific providers of fossil fuels. However, for purposes of analysis, DOE expects that regional supply systems and suppliers could economically supply the project.

Fossil-fuel consumption during the construction phase would primarily consist of diesel fuel for construction equipment and vehicles. Heavy construction equipment would be diesel-powered, as would electric generators. Fuel would be transported by truck and stored at the hazardous materials storage areas at the construction camps. These materials would be stored in accordance with applicable state and federal regulations (DIRS 180875-Nevada Rail Partners 2007, Section 6.2). DOE estimated that annual consumption of diesel fuel would be 109 million liters (28.8 million gallons) (DIRS 180874-Nevada Rail Partners 2007, Appendix D, Table 5b). The annual consumption of diesel fuel for the region of influence, as represented by the State of Nevada, is approximately 1.8 billion liters (480 million gallons) (DIRS 176397-EIA 2005, Table 4, 2004 data). Construction fuel consumption would represent 6 percent of diesel fuel used annually in Nevada, and could be met by existing regional supply systems and suppliers.

Construction of the proposed railroad would have a small impact on the capacity of regional suppliers or the availability of fuel resources. The fuel supply system is such that it can flexibly respond to changes in demand. Fuel consumption for construction of the railroad operations support facilities would be lower; therefore, fuel consumption during construction of those facilities would have a small impact on the capacity of regional suppliers or the availability of fuel resources.

4.3.11.2.1.4 Materials. As described in Section 3.3.11, the region of influence for necessary raw materials is limited to the distribution networks and suppliers that can economically service the general project area. For cast-in-place concrete, ballast, and subballast, the region of influence is limited to the State of Nevada. DOE would need a ***free-use permit*** from the BLM to use common varieties of sand, stone, and gravel from BLM-administered public lands during the construction phase, pursuant to the regulations implementing the Materials Act of 1947 (30 U.S.C. 601 through 603) as codified in 43 CFR Part 3600. As described in Chapter 2, the Department could obtain ballast materials from two of the five potential quarry sites within Nevada that would be close to the Mina rail alignment construction right-of-way. Therefore, the region of influence for obtaining ballast would be limited to the immediate area in Nevada. Other materials, including steel, steel rail, concrete ties, and other precast concrete could be procured and shipped on a national level. Therefore, the region of influence for these materials is considered to be national.

Material needs for construction of the proposed rail line along the Mina rail alignment would vary among the alternative segments roughly in proportion to their lengths. The primary materials that would be consumed during rail line construction include steel; concrete, principally for rail ties, bridges, and drainage structures; and rock for ballast and subballast. Table 4-285 lists the rail line construction material requirements and current production rates within the respective regions of influence.

Table 4-285. Rail line construction material requirements – Mina rail alignment.

Material	Total requirements	Annual requirements over a 4- to 10- year construction period	Region of influence	Region of influence annual production	Percent of region of influence production
Steel rail	63,000 metric tons[a]	16,000 to 6,000 metric tons	U.S. (all steel)	86,000,000 metric tons	0.02 to 0.007
			U.S. (steel rail)	518,000 metric tons	3.4 to 1.4
Concrete, cast-in-place	120,000 metric tons	30,000 to 12,000 metric tons	Nevada	16,000,000 metric tons[d]	0.2 to 0.08
Concrete, precast (including concrete ties)	373,000 metric tons	94,000 to 37,000 metric tons	U.S.	15,000,000 metric tons[d]	0.6 to 0.02
Concrete ties	776,000 ties	194,000 to 77,600 ties	U.S.	1,000,000 ties	19 to 7.6
Ballast	2.5 million metric tons	625,000 to 250,000 metric tons	Nevada	24,000,000 metric tons [b,c,d]	2.6 to 1.0
Subballast	2.2 million metric tons	550,000 to 220,000 metric tons	Nevada	9,200,000 metric tons [b,c,d]	6.0 to 2.4

a. To convert metric tons to tons, multiply by 1.1023.
b. Based on use of concrete ties only.
c. Includes granite and traprock production only, 2003 data. Some data withheld to avoid disclosing company proprietary information (DIRS 173393-Tepordei 2003, Table 9).
d. Includes crushed stone of all types, 2003 data (DIRS 173393-Tepordei 2003, Table 6).

Steel DOE has calculated that construction of the proposed rail line along the nominal 409 kilometers (254 miles) of the Mina rail alignment, including sidings and yard tracks, would require 2,176 strings of ***136 RE*** welded rail, each string being 439 meters (1,440 feet) long (DIRS 180875-Nevada Rail Partners 2007, Section 3.3). This would correspond to a requirement for 63,000 metric tons (69,000 tons) of steel over an estimated construction period of 4 to 10 years. DOE would acquire the sections of rail from national commercial sources.

Because DOE would purchase steel rail from national suppliers in staggered preordered phases over a 2- to 3-year period, the impact on availability of steel rail would be small.

DOE would need additional steel for rail hardware, bridges, and facility structures. Existing commercial fabricators would supply the steel required for the bridges. The designs of bridges and rail facilities are not sufficiently advanced to tabulate materials needs; however, the quantities required would be much less than required for rail line construction.

Concrete DOE has estimated that 50,000 cubic meters (65,000 cubic yards) of cast-in-place concrete would be required for Mina rail alignment structures (DIRS 180874-Nevada Rail Partners 2007, p. B-19). Concrete weighs approximately 2.4 metric tons per cubic meter (145 pounds per square foot) and 50,000 cubic meters would translate to an approximate requirement of 120,000 metric tons (132,000 tons) over the 4- to 10-year construction phase. Cast-in-place concrete for the Mina rail alignment would be required primarily for bridge abutments. As described in Chapter 2, DOE would obtain concrete for site placement activities at proposed bridges and other structures from a portable batch plant set up near the construction sites. DOE would truck all aggregate and cement from the portable batch plant to the construction sites. Annual production of cast-in-place concrete in Nevada equals approximately 16 million metric tons (18 million tons) per year (DIRS 173400-NRMCA 2004, p. 2).

The primary use of precast concrete would be for concrete ties. Concrete ties would be placed at 0.61-meter (2-foot) intervals along the constructed rail line (DIRS 180875-Nevada Rail Partners 2007, Section 3.2). DOE estimates that approximately 776,000 concrete ties would be required for the nominal 409 kilometers (254 miles) of new rail line construction, and an additional 64 kilometers (40 miles) of track at sidings, the Staging Yard at Hawthorne, and the Rail Equipment Maintenance Yard. Using 318-kilogram (700-pound) ties would require 247,000 metric tons (272,000 tons) of concrete to produce the ties. Precast concrete ties would either be supplied through national manufacturers or potentially through a dedicated tie production facility a commercial manufacturer would establish in Hawthorne or another area. Additional precast concrete requirements would include manufactured elements such as culverts, bridge beams, and overpass components. These precast concrete elements would be obtained from commercial sources nationally. At this stage of the design process, DOE has extrapolated that these additional precast concrete requirements would be broadly similar to an estimate documented in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Section 6.3.2.1.10) of approximately 126,000 metric tons (139,000 tons) for the rail line along the Caliente corridor. DOE has estimated that total precast concrete requirements (that include concrete ties) for the Mina rail alignment would be approximately 373,000 metric tons (411,000 tons) over a 4-year construction period.

Annual national production of concrete railway ties has been increasing from about 620,000 ties in 2000 (DIRS 173572-RTA 2000, p. 22) to about 720,000 ties in 2004, and is projected to grow to about 1.2 million ties in 2007 (DIRS 173573-Gauntt 2004, p. 17). The 247,000 metric tons (272,000 tons) of concrete ties that would be required to construct the rail line along the Mina rail alignment represent 19 percent of the annual national production of concrete ties. Although this might seem like a significant requirement, the national production volume for concrete ties does not reflect manufacturing capacity. Concrete tie production is a very scaleable industry, and recent data suggests that, if needed, the industry has the capacity to increase concrete tie production rapidly (DIRS 173573-Gauntt 2004, p. 17). For example, the current national production of concrete ties represents only approximately 0.3 percent of all manufactured (precast) concrete production, which is 15 million metric tons (17 million tons) per year (DIRS 173392-van Oss 2003, Table 15). Because DOE would purchase precast concrete components from national suppliers in staggered preordered phases, and because construction would involve a small amount of cast-in-place concrete via the use of an onsite batch plant, the impact on availability of concrete would be small.

Ballast and Subballast Ballast and subballast are essentially crushed rock such as that required for the development of the rail roadbed. DOE has estimated that a total of approximately 2.5 million metric tons (2.8 million tons) of rail roadbed ballast would be required for track construction along the Mina rail alignment (DIRS 180875-Nevada Rail Partners 2007, Section 3.1.2). As discussed in Chapter 2, the Department has identified five potential quarry sites along the Mina rail alignment and would develop only two on an as-needed basis. Each of the potential quarries could produce approximately 3,100 metric tons (3,400 tons) of useable ballast per day. Therefore, the impact to availability of ballast from constructing the rail line along the Mina rail alignment would be small.

> **Ballast:** Gravel or broken stone laid in a rail roadbed to distribute train weight uniformly across the bed.
>
> **Subballast:** Gravel or broken stone that does not have to meet the ballast specifications, layered beneath the ballast as a transition between the ballast and the compacted subgrade.

DOE has estimated that a total of approximately 2.2 million metric tons (2.4 million tons) of subballast would be required for track construction along the Mina rail alignment (DIRS 180875-Nevada Rail Partners 2007, Section 3.1.2). Some of the remaining material from each ballast quarry might be suitable for subballast. Remaining subballast requirements would be obtained either from cuts made for constructing the roadbed or from existing borrow sites and quarries along the alignment. The Mina rail alignment would not incorporate enough cut sections to generate the required 2.2 million metric tons of subballast; therefore, DOE would develop sources approximately 16 kilometers (10 miles) apart along the alignment during construction. Approximately 55 surplus borrow-site locations are available adjacent to Nevada Department of Transportation materials sources and additional nearby sites could be developed (DIRS 180875-Nevada Rail Partners 2007, Section 3.1.2). Impacts on the availability of subballast materials would be small.

DOE would construct 7.3-meter (24-foot)-wide gravel access roads parallel to the rail line and within the construction right-of-way. The rail line and the alignment access roads would be accessed via existing public roads where the rail line would cross an existing roadway. DOE would construct additional access roads to reach features like wells and quarries that are not immediately accessible to the rail alignment. The quarry sites identified would be within 3 kilometers (2 miles) of the alignment, thereby minimizing access-road construction requirements.

Materials for access-road construction or improvement would be obtained primarily from locally available materials such as stone, and gravel resulting from cuts and fills along the alignment and overburden at quarries. Access roads would likely have gravel surfaces. The native material would be supplemented by crushed rock screenings as necessary to provide a serviceable roadway surface.

Sand and Gravel There is a high likelihood DOE would find sand and gravel on the alluvial fans along cuts for the rail line that would be suitable for construction purposes and road making. Sand and gravel also would be generated from overburden at quarry and borrow sites. Approximately 55 surplus pit locations are available adjacent to Nevada Department of Transportation materials sources and additional nearby sites could be developed. DOE would use some natural sand and gravel excavated from cuts and crushed rock from the quarries to make concrete aggregate (DIRS 180881-Shannon & Wilson 2007, pp. 20, 21, 25, 26, 30, 31, 36, 41, and 42). The Department would determine the prime sand and gravel deposits needed before beginning construction. Using locally available sand and gravel would result in the consumption of a nonrenewable resource that could be used as a supply of construction materials for other construction projects in the area. However, alluvial deposits of sand and gravel are commonplace in the Mina rail alignment region of influence, and their use to construct the rail line would not substantially reduce the area's resources. Therefore, impacts would be small.

Other Materials Requirements In addition to the aforementioned materials needed for the rail line, DOE would also need construction materials for railroad operations support facilities. An estimated total of approximately 9,300 square meters (100,000 square feet) of building space would be required for operations support facilities (DIRS 180873-Nevada Rail Partners 2007, Sections 3, 4, and 5); DIRS 181425-MTS 2007, p. 1). By comparison, the Las Vegas market alone had over 186,000 square meters (2 million square feet) of industrial space under construction in 2004 (DIRS 173390-Colliers International Partnership 2004, p. 1) and 160,000 square meters (1.7 million square feet) of office space completed in the 12-month period ending in March 2004 (DIRS 173391-Colliers International Partnership 2004, p. 1). Materials for the construction of rail yards at the operations support facilities are included in the rail line material estimates described in this section. Materials requirements for buildings would not be substantial in comparison to regional demand and would have a small impact on the regional supply system.

4.3.11.2.2 Operations Impacts

4.3.11.2.2.1 Utility Systems. None of the potential utility interfaces identified in Section 4.3.11.2.1.1 would prevent the future expansion of a utility service area. Impacts on infrastructure at the county level associated with railroad operations would be small because regional population projections anticipate modest growth (see Section 4.3.9.3.2). However, there could be some impacts on infrastructure in towns near the proposed railroad operations support facilities. Areas that would be likely to experience the greatest impacts include:

- Hawthorne (Mineral County), where the Staging Yard, the Maintenance-of-Way Satellite Facility, train crew quarters, and possibly the Nevada Railroad Control Center and National Transportation Operations Center would be located
- Tonopah (Nye County) and Goldfield (Esmeralda County), the towns that would be closest to the Maintenance-of-Way Facility located either at Silver Peak or Klondike
- Southern Nye County, the location of the Rail Equipment Maintenance Yard, Cask Maintenance Facility, train crew quarters, and possibly the Nevada Railroad Control Center and National Transportation Operations Center

Public Water Systems DOE would need water for railroad operations, particularly at operations support facilities. Because they would be reclaimed after the construction phase was completed, there would be no water demands associated with the quarries.

DOE estimates water consumption at the Rail Equipment Maintenance Yard would be about 23,000 liters (6,000 gallons) per day for personnel and an additional 11,000 liters (3,000 gallons) per day for building and rail yard uses, including irrigation and vehicle washing. At the Rail Equipment Maintenance Yard, water needs would be met by using the repository's well system, which would eliminate the need for service by any local public water system. DOE estimates water consumption at the Maintenance-of-Way Facility that would be located either in the vicinity of Silver Peak or Klondike would be about 11,000 liters (3,000 gallons) per day, and 21,000 liters (5,500 gallons) per day at the Staging Yard at Hawthorne, where water would be obtained from locally drilled wells (DIRS 180873-Nevada Rail Partners 2007, Table 2-2, Section 3.6, and Section 4.6).

Public water systems in Lyon, Mineral, Esmeralda, and Nye Counties could be affected by incremental changes in population attributable to railroad operations. As discussed in Section 3.3.11, Lyon and Mineral Counties are able to meet current and future demands for water. Goldfield, in Esmeralda County, has the groundwater resources and infrastructure available to triple the number of users served by its public water system and thus has the potential to meet increased demand for water by additional residential and commercial users.

In Nye County, given the level of demand and the limited capacity of groundwater resources (particularly in the Pahrump Valley hydrographic area), water needs could strain supply. Although the Cask Maintenance Facility would be collocated with the Rail Equipment Maintenance Yard and the geologic repository operations area interface in Nye County, the estimates for population increase attributable to the employees at the Yucca Mountain Site (see Section 4.3.9.3.2) would represent a small incremental increase. Therefore, impacts to the public water systems in Nye County from the demands associated with these potential new residents would be small.

Wastewater Treatment Facilities DOE would dispose of sanitary wastewater in accordance with State of Nevada regulations. Under the Statutory Authority of Nevada Revised Statutes (NRS) 445A.300 through 445A.730, and pursuant to the Nevada Administrative Codes (NAC) 445A.810 through

445A.925, and NAC 444.750 through 444.828, the Nevada Division of Environmental Protection, Bureau of Water Pollution Control, issues wastewater discharge permits, administers loans to publicly owned treatment works, and oversees the certification program for sewer-treatment plant employees. In most cases, DOE would construct onsite sanitary wastewater treatment systems within the railroad operations right-of-way and they would be permitted by the State of Nevada. These would likely be ***package plants***, as described in Section 3.3.11.2.3. If access to nearby existing permitted wastewater treatment facility capacity was available to any on-site facilities, DOE would discharge sanitary waste to those existing facilities. Impacts to existing wastewater treatment capacities of jurisdictions in the region of influence during the operations phase would be small.

Table 4-286 lists the rates of wastewater generation that would be associated with railroad facilities during the operations phase.

Table 4-286. Wastewater generation during the operations phase – Mina rail alignment.

Facility	Number of personnel (maximum)	Total wastewater generation (liters per day)[b]
Staging Yard at Hawthorne	40[b]	21,000
Maintenance-of-Way Facility	40[b]	11,000
Rail Equipment Maintenance Yard, including the Nevada Railroad Control Center and National Transportation Operations Center	70[b,c]	23,000
Totals	150	55,000

a. To convert liters to gallons, multiply by 0.26418.
b. Source: DIRS 180873-Nevada Rail Partners 2007, Section 2.1.3.
c. Source: DIRS 181425-MTS 2007, p. 1.

Wastewater from the Staging Yard at Hawthorne would be disposed of at the permitted wastewater treatment facility in Hawthorne, the capacity of which is approximately 1.5 million liters (0.6 million gallons per day (see Table 3-152) (DIRS 180873-Nevada Rail Partners 2007, Section 4.6). The Rail Equipment Maintenance Yard would provide a staging area for delivery of loaded cask cars to the repository, construction materials, and fuel. The facility would include office space, and train crew and escort personnel quarters, all of which would generate sanitary wastewater. Sanitary wastewater disposal at this facility would consist of septic systems or wastewater treatment facilities at the Yucca Mountain Site (DIRS 180919-Nevada Rail Partners 2007, p. 3-5).

The numbers of employees projected to reside in the communities near railroad operations support facilities would represent small fractions of the existing populations (see Section 4.3.9). Also, as shown in Table 3-152, most of the existing wastewater treatment facilities are operating well below their capacities, and these facilities would be capable of accommodating any increases in wastewater attributable to railroad facility employees. Goldfield has recently been awarded a Water Resource Development Act grant of approximately $3 million for renovations and upgrades. Therefore, the impact to public wastewater systems from operating railroad support facilities would be small.

Telecommunications Systems The communication system required to support railroad operations would utilize four distinct communication technologies: synchronous optical network fiber-optic backbone, very high frequency (VHF) land mobile radio, geosynchronous satellite dispatch radio, and possibly satellite telephone service (DIRS 180876-Nevada Rail Partners 2007, Section 6). The fiber-optic cable laid along the length of the nominal 409 kilometers (254 miles) of DOE-constructed rail line and the approximately 43 kilometers (27 miles) of Department of Defense Branchline South (between the southern end of the Schurz bypass and Hawthorne) would allow the installation of a VHF land mobile radio system consisting of a series of base stations located at points approximately 16 to 32 kilometers (10 to 20 miles) apart along the rail alignment to provide full radio coverage communications with locomotive and maintenance crews. Base stations would consist of an equipment room that would house the radio and fiber-optic electronics and a monopole radio tower to mount an elevated VHF antenna. The Nevada Railroad Control Center would also have a private branch exchange telephone system. In the event of a failure of all or part of the primary VHF radio system, operations would continue via a geosynchronous satellite dispatch radio system. As a backup, DOE could utilize satellite telephone hand sets.

At the Nevada Railroad Control Center, the system would be configured to allow the dispatcher easy access to all of the various communication modes available, including the ability to patch communication modes together if required. However, for external communications, the Staging Yard at Hawthorne, the Nevada Railroad Control Center and National Transportation Operations Center, the Maintenance-of-Way Facility, the Cask Maintenance Facility, and the Rail Equipment Maintenance Yard would each require digital subscriber line and telephone service. The Rail Equipment Maintenance Yard would require the greatest telecommunications capacity, with approximately 75 conventional telephone lines, 50 broadband internet connections, five secure telephone lines, a fiber-optic line for closed-circuit television and data communication, and radio communications for railroad operations in conjunction with the centralized traffic control rail signal system (DIRS 180919-Nevada Rail Partners 2007, Section 6.6). The radio communication systems would be designed not to interfere with other licensed systems operating in the same area. The radio communication systems would be designed not to interfere with other licensed systems operating in the same area. The levels of commercially provided service would be small, and would not adversely affect the capacities of commercial telecommunications providers.

Electricity Impacts associated with the underground 25-kilovolt distribution line would be related to utility interfaces, as discussed in Section 4.3.11.2.1.1, and in Section 4.3.2, Land Use and Ownership.

Operation of the proposed railroad would require electricity for buildings, signaling, communications, and control. Twelve-kilovolt electrical service would be required for each facility. Depending on the distance from available power sources, larger distribution lines and intermediate substations might be needed. In addition to commercial sources, electric power could be supplied from the installed power distribution system. Each facility site would require a 12-kilovolt/480-volt transformer with a 480-volt distribution system to power industrial equipment and feed each building where a 480-volt/120-volt transformer would supply the building power (DIRS 180873-Nevada Rail Partners 2007, Section 2.1.5). Additional transformers could be required for other site requirements such as site lighting, power to yard switches and signals, or power for communications equipment. Each site would require a diesel-powered emergency generator to supply electrical power in case of an outage.

DOE estimates that the Staging Yard at Hawthorne would have a normal power demand of 386 kilowatts with the Nevada Railroad Control Center and National Transportation Operations Center (or 290 kilowatts without) (DIRS 180873-Nevada Rail Partners 2007, Section 3.6). DOE would build a substation connected to existing transmission lines to service this power need or make use of the 25-kilovolt distribution line. Diesel-powered generators would provide backup power.

DOE estimates that the Maintenance-of-Way Facility would have a normal power demand of 484 kilowatts (DIRS 180873-Nevada Rail Partners 2007, Section 4.6). DOE has made separate estimates of power demand at the Rail Equipment Maintenance Yard that range between 722 and 815 kilowatts (DIRS 180919-Nevada Rail Partners 2007, p. 6-20). The Department has established an 8-megawatt power requirement (which includes a 30-percent reserve) for the Rail Equipment Maintenance Yard and Cask Maintenance Facility (DIRS 181033-Hamilton-Ray, 2007, all). DOE could obtain power from a newly constructed substation connected to the existing transmission line providing power to the Yucca

Mountain Site, or from a new 138-kilovolt transmission line DOE plans to build to the geological repository operations area.

The 2003 peak load for the Nevada Power Company was 4,808 megawatts (DIRS 172302-Nevada Power Company 2004, all), whereas there would be approximately a 3-megawatt demand to operate the proposed railroad. The Department would perform an electrical capacity analysis before connecting into local transmission or distribution lines, and consistent with the demonstration of available capacity. Therefore, impacts to other regional needs for electric power during the railroad operations phase would be small.

4.3.11.2.2.2 Fossil Fuels. DOE has estimated that 119 million liters (31.5 million gallons) of diesel fuel would be consumed over an anticipated 50-year operations phase, and that the annual consumption rate would peak at 4.3 million liters (1.1 million gallons) (DIRS 180874-Nevada Rail Partners 2007, Appendix D, Table 5a), a rate that would be less than 0.25 percent of the current annual vehicular diesel fuel usage in Nevada. Therefore, potential impacts to capacities of national and regional fuel producers and distributors during the operations phase would be small.

4.3.11.2.2.3 Materials. Materials use during the operations phase would be limited to materials for repair and maintenance of the railroad, including the locomotives, railcars, casks, and operations support facilities. The annual rate of material use over the 50-year operations phase would be substantially less than during the construction phase, and materials requirements would be expected to remain well below available capacity.

DOE would reclaim the quarries developed during the construction phase and would not use them during operations. Therefore, the relatively minor amounts of ballast required for repairs and replacements during the operations phase would be met through existing commercial sources that at this stage of the design process have been identified as quarries in Milford, Utah, and Oroville, California, as described in Section 3.3.11.4. The impacts to available supplies of ballast at these quarries would be small.

4.3.11.3 Impacts under the Shared-Use Option

Railroad construction under the Shared-Use Option would include all of the features described in Section 4.3.11.2, but would include the construction of commercial sidings and support facilities. All such construction would occur on lands immediately adjacent to the rail alignment within the rail line construction right-of-way and would have impacts related to interfaces with utility corridors and rights-of-way similar to those under the Proposed Action without shared use.

The incremental demands on public water systems, wastewater systems, telecommunications systems, electric power systems, fossil fuels, and materials for construction of commercial sidings and support facilities would be sufficiently small that the anticipated impacts on these resources would be effectively the same as for the Proposed Action without shared use. Therefore, potential impacts to local, regional, or national suppliers of such resources under the Shared-Use Option would be small.

Railroad operations under the Shared-Use Option would be the same as described in Section 4.3.11.2 for the Proposed Action without shared use, but commercial shippers would add to traffic on the rail line.

The incremental demands on public water systems, wastewater systems, telecommunications systems, electric power systems, and materials for the operation and maintenance of commercial sidings and support facilities would be sufficiently small that the anticipated impacts on these resources would be effectively the same as those for the Proposed Action without shared use. Therefore, potential impacts to local, regional, or national suppliers of such resources under the Shared-Use Option would be small.

Fossil-fuel requirements for transporting general freight under the Shared-Use Option would depend on the volume and distance of shared-use traffic. DOE estimated that the incremental annual diesel consumption for commercial shared-use traffic would be 4.6 million liters (1.2 million gallons), a rate that is less than 0.3 percent of current annual diesel fuel usage in Nevada (DIRS 180874-Nevada Rail Partners 2007, Appendix D, Table 5a). Most, if not all, of this fuel consumption would be offset by diesel fuel that would otherwise be used if the goods or materials were shipped by truck. Therefore, impacts to the capacities of national and regional fuel producers and distributors with shared used would be small.

4.3.11.4 Summary

Table 4-287 summarizes potential impacts to utilities, energy, and materials from constructing and operating the proposed railroad along the Mina rail alignment. DOE determined that those impacts would be small.

Table 4-287. Summary of potential impacts to utilities, energy, and material resources – Mina rail alignment.[a]

Resource	Construction impacts	Operations impacts
Utility interfaces	Potential for short-term interruption of service. No permanent or long-term loss of service or prevention of future service-area expansions.	None.
Public water systems	Most water would be supplied by new wells; small effect on public water systems from population increase attributable to construction employees.	Most water for operations would be supplied by new wells; small effect on public water systems from population increase attributable to operations employees.
Wastewater treatment systems	Dedicated treatment systems would be provided at construction camps; small impact on public systems from population increase attributable to construction employees.	Dedicated treatment systems would be provided at operations facilities; small impact on public systems from population increase attributable to operations employees.
Telecommunications systems	Dedicated systems; minimal reliance on communications providers.	Dedicated system along rail line; minimal reliance on communications providers.
Electricity	Peak demand would be within capacity of regional providers.	Peak demand would be within capacity of regional providers.
Fossil fuels	Demand would be approximately 6 percent of statewide use and can be met by existing regional supply systems and suppliers. Under the Shared-Use Option, demand would be less than 0.3 percent of statewide use during operations. Demand would be met by existing regional supply.	Demand would be less than 0.25 percent of statewide use.
Materials	Requirements generally would be very small in relation to supply capacity.	Requirements would be very small in relation to supply capacity.

a. Impacts under the Shared-Use Option would be similar to those under the Proposed Action without shared use, except as noted for fossil fuels.

4.3.12 HAZARDOUS MATERIALS AND WASTES

This section describes potential impacts of the use of hazardous materials and the management of nonhazardous wastes, ***hazardous wastes***, and ***low-level radioactive wastes*** that would be generated during construction and operation of the proposed railroad along the Mina rail alignment. The section identifies the types of hazardous materials DOE would use and the hazardous, nonhazardous, and low-level radioactive wastes that would be generated during the construction and operations phases. The applicable guidelines, regulations, and available methods for treatment or ***disposal*** are identified for each waste. DOE evaluated the potential impacts of hazardous materials, hazardous wastes, nonhazardous wastes, and low-level radioactive wastes based on this information.

Section 4.3.12.1 describes the methodology DOE used to assess potential impacts; Section 4.3.12.2 describes potential construction impacts; Section 4.3.12.3 describes potential operations impacts; Section 4.3.12.4 describes potential impacts under the Shared-Use Option; and Section 4.3.12.5 summarizes potential impacts related to the use of hazardous materials and the generation of wastes.

DOE could purchase hazardous materials necessary for railroad construction and operations, such as engine coolant and solvents, through the federal supply chain or through local vendors. The Department anticipates local distributors in Nevada would supply propane and natural gas. The required hazardous materials would consist primarily of products consumers could purchase at most hardware, building-supply, or home-improvement stores. Therefore, DOE does not expect the supply of such products to be limited. As a consequence of using hazardous materials, associated hazardous wastes would be generated.

Section 3.3.12.1 describes the region of influence for hazardous materials and wastes.

4.3.12.1 Impact Assessment Methodology

DOE developed a list of anticipated types of hazardous materials and wastes to evaluate potential impacts from the use of hazardous materials or generation of wastes (see Table 4-288). To avoid or limit adverse impacts, DOE emphasizes adhering to applicable laws, regulations, policies, standards, and directives. The ***storage*** and disposal of hazardous and nonhazardous wastes is largely governed by the Resource Conservation and Recovery Act of 1976 (42 U.S.C. 6901 *et seq.*) and State of Nevada waste regulations (see Chapter 6, Statutory, Regulatory, and Other Applicable Requirements).

4.3.12.2 Construction Impacts

This section summarizes the types of hazardous materials DOE would use and the wastes that would be generated during construction of the proposed railroad. DOE would handle all wastes in accordance with applicable federal, state, and local environmental, occupational safety, and public health and safety requirements to minimize the possibility of adverse impacts to plants, animals, soils, and water resources inside or outside the region of influence. Because DOE would manage the use of hazardous materials and the disposal of wastes in accordance with applicable regulations and would implement best management practices (see Chapter 7), adverse impacts to environmental resources would be small.

4.3.12.2.1 Nonhazardous Waste

A total of approximately 2,300 metric tons (2,500 tons) per year of ***solid waste*** (such as general trash from kitchens and dormitories) would be generated during the construction phase, for a daily rate of

Table 4-288. General considerations for assessing potential impacts from the use of hazardous materials and the generation of hazardous and nonhazardous wastes.

Material	Basis for assessing adverse impacts
Hazardous materials	Determine if the use of hazardous materials would create reasonably foreseeable conditions that would significantly increase the risk of a release of hazardous materials resulting from not adhering to storage and use standards set in applicable guidelines and regulations.
Hazardous waste	Determine if the quantity of hazardous wastes generated would adversely affect the capacity of hazardous-waste collection and disposal services.
Nonhazardous waste	Determine if the volume of solid and industrial and special wastes generated would adversely affect the capacity of solid-waste collection service and landfills.
Low-level radioactive waste	Determine if the quantity of low-level radioactive wastes generated would adversely affect the capacity of available disposal facilities.

approximately 6.3 metric tons (6.9 tons). Most of the solid waste would be generated at construction camps. DOE would dispose of all solid waste in permitted landfills. Table 4-289 summarizes the solid waste generation rate during the construction phase.

Construction activities would generate approximately 12,000 metric tons (13,100 tons) of ***industrial and special wastes*** (such as construction debris, used tires, and other materials with specific management requirements) per year, for an approximate daily rate of 33 metric tons (36 tons) (DIRS 180875-Nevada Rail Partners 2007, p. 6-3). (This estimate includes rail, ballast, and rail tie materials from the dismantling of the Department of Defense Branchline through Schurz, which would either be reused for the new rail line or recycled.) DOE would minimize the amount of these wastes as much as possible by ordering construction materials in correct sizes and amounts, reusing leftover materials, and recycling appropriate types of materials (DIRS 152540-Hoganson 2000, all).

Almost 1.8 million metric tons (2 million tons) of industrial and special wastes were disposed of in Nevada in 2002, which was 90 percent of the total solid waste (all categories) generated state-wide (DIRS 174663-State of Nevada 2005, slide 8). Nevada has 23 operating municipal landfills that combined accept more than 12,700 metric tons (14,000 tons) of waste per day (DIRS 174663-State of Nevada 2005, slide 5; DIRS 181625-Simpson 2007, all). However, most of this capacity is available through the Apex Landfill, which serves the Las Vegas Valley, and receives an average of 8,000 metric tons (8,800 tons) per day (DIRS 174041-State of Nevada 2004, pp. 6 and 7). Some of the landfills in Mineral, Esmeralda, and Nye Counties are quite small by comparison, and receive less than 2.7 metric tons (3 tons) of waste per day (DIRS 174041-State of Nevada 2004, p. 6).

It is likely that while some of the larger landfills would not see an appreciable change in the amount of waste received if they were utilized, some of the smaller landfills might see a substantial, although manageable, change in daily receipt of solid and industrial and special wastes if utilized during the construction phase.

As shown in Table 3-154, landfills in Mineral, Nye, Esmeralda, and Clark Counties accept more than 8,100 metric tons (9,000 tons) of waste per day combined. The addition of about 6.3 metric tons (6.9 tons) per day of solid waste anticipated during the construction phase (see Table 4-289) would raise the total amount disposed of in the four-county area by approximately 0.077 percent. DOE anticipates that about 33 metric tons (36 tons) per day of industrial and special wastes would need to be disposed of due to construction activities, which would result in an increase of approximately 0.41 percent in waste receipt to local landfills (DIRS 180875-Nevada Rail Partners 2007, p. 6-3). Therefore, impacts to local

Table 4-289. Solid waste generation during the construction phase – Mina rail alignment.

	Number of personnel (maximum)	Solid-waste generation (kilograms per day per person)[a,b]	Total solid waste (metric tons per day)[c,d]	Total solid waste (metric tons per year)[d]
Workforce	2,160[e]	2.9	6.3	2,300

a. Source: DIRS 174041-State of Nevada 2004, p. 13.
b. To convert kilograms to pounds, multiply by 2.2046.
c. To convert metric tons to tons, multiply by 1.1023.
d. Numbers are not exact due to rounding.
e. Source: DIRS 180874-Nevada Rail Partners 2007, Appendix D.

landfills from the disposal of solid and industrial and special wastes would be small (for the relatively large Apex Landfill) to moderate (for the smaller landfills).

The geotechnical exploration program would include drilling approximately 2,100 boreholes at depths of 15 to 60 meters (50 to 200 feet). These borings would generate more than 1,000 cubic meters (1,300 cubic yards) of drill cuttings (DIRS 181867-Holder 2007, all). DOE would not dispose of these drill cuttings in landfills, but would dispose of them through land application, which would involve spreading the drill cuttings on the land surface. All drilling fluids would meet the requirements for standard land disposal. Therefore, there would be no impacts to waste treatment or disposal facilities as a result of the generation of drill cuttings.

Construction activities would include dismantling the existing Department of Defense Branchline through Schurz, which would involve the removal of 44 kilometers (27 miles) of rail, ballast, and rail ties (DIRS 180875-Nevada Rail Partners 2007, p. 2-3). Culverts, bridges, and the roadbed would be left in place. The rail, ballast, and rail tie materials from the Department of Defense Branchline through Schurz would either be reused for the proposed new rail line or recycled to the extent practicable.

Construction activities would include some clearing of land. Wastes generated from this activity, including soil and plant material, would be used to construct fill slopes and contours within the rail line construction right-of-way; therefore, no waste would need to be disposed of and there would be no impacts to local waste disposal facilities from clearing of land (DIRS 180875-Nevada Rail Partners 2007, p. 6-1).

Earthwork fill requirements for rail line construction would be expected to outweigh cut requirements (DIRS 180872-Nevada Rail Partners 2007, Appendix D). In the event that more cut material was generated than would be needed as fill, DOE would use the excess to strengthen access roads and rail embankments. Therefore, no excess cut material would need to be disposed of and there would be no impacts to disposal facilities from the generation of excess cut material.

4.3.12.2.2 Hazardous-Materials Use and Hazardous-Waste Generation

DOE would store and use hazardous materials such as oil, gasoline, diesel fuel, and solvents during the construction phase primarily for the operation and maintenance of equipment and cleaning of equipment and facilities. The Department would implement an Environmental Management System and a Pollution Prevention/Waste Minimization Program during the construction and operations phases, which would include an evaluation of alternatives to eliminate, reduce, or minimize the amounts of hazardous materials used and hazardous wastes generated. As part of the Environmental Management System, DOE would regularly perform assessments to identify opportunities to reduce the generation of waste (DIRS 182385-Burns 2007, all). The Department would formulate and implement Spill Prevention Control and Countermeasures plans, including the use of secondary containment, to prevent releases of hazardous materials, such as diesel fuel, to the environment.

Table 4-290 lists the anticipated hazardous materials and the waste types that could be generated. The Department expects some materials (such as diesel fuel, lubricants, and hydrocarbons) would be used at each of the construction support facilities. However, most materials used and wastes generated would be specific to certain activities and facilities.

Hazardous wastes, such as used lubricants and solvents, would be accumulated, shipped, and disposed of in accordance with Resource Conservation and Recovery Act regulations. Hazardous wastes would be shipped in accordance with 49 CFR Parts 171 and 172 and U.S. Department of Transportation Hazardous Materials 215D regulations. The disposal capacity for hazardous wastes in western states has been estimated at 50 times the demand for landfills and 7 times the demand for incineration until at least 2013 (DIRS 103245-EPA 1996, pp. 32, 33, 36, 46, 47, and 50); thus, there would be ample capacity available to dispose of any hazardous wastes. Through compliance with applicable state and federal regulations, adverse impacts from the use of hazardous materials, generation of hazardous waste, and the disposal of hazardous waste would be small.

DOE could use explosives during quarry, access-road, and rail line construction, and would develop a safety program specifically for the storage, transportation, and handling of these materials. The Department would adhere to the requirements of DOE Order 440.1A, *Worker Protection Management for DOE Federal and Contractor Employees* (as described in Chapter 6), which specifies that explosives operations must comply with the DOE Explosives Safety Manual (DOE M 440.1-1A). The manual provides guidance on the storage and transportation of explosives and refers to Occupational Safety and Health Administration safety requirements for routine construction and tunnel-blasting operations.

There could be impacts if hazardous materials, such as fuels, lubricants, and antifreeze, were released and spread. DOE would store such materials at construction camps, and supply trucks would routinely bring new materials and remove used lubricants and coolants from the construction sites. These activities could result in local spills and releases of contaminants. DOE would immediately remediate any areas affected by such spills in accordance with applicable regulations (see Chapter 6).

4.3.12.2.3 Low-Level Radioactive Waste

No low-level radioactive waste would be generated during the construction phase.

4.3.12.3 Operations Impacts

DOE would purchase hazardous and nonhazardous products and materials during the operations phase. The use of hazardous materials and products would lead to the generation of hazardous wastes. Table 4-290 lists the anticipated hazardous materials and the waste types that could be generated during the railroad operations phase.

4.3.12.3.1 Nonhazardous Waste

Railroad operations would generate solid wastes, which DOE would dispose of at facilities along the rail line. Amounts of such wastes would be very small and would not impact disposal capacity in Clark, Esmeralda, Nye, and Mineral Counties.

Amounts of industrial and special wastes generated during maintenance of fixed equipment such as signals and rail crossings would be very small (DIRS 155560-Hoganson 2001, all). Crossties, ballast, rails, and bridges would not be likely to require replacement before 2033 (DIRS 152540-Hoganson 2000, all). However, when these materials do require maintenance or replacement, they would be reused wherever possible or recycled if reuse was not an option. Therefore, no impacts to local landfills would be anticipated from the disposal of industrial and special wastes during the operations phase.

Table 4-290. Summary of anticipated types of hazardous materials that would be used and wastes that would be generated during railroad construction and operations – Mina rail alignment.[a,b]

	Railroad construction	Construction camps	Concrete batch plants	Asphalt plants	Railroad operations[c]
Materials

b. An X indicates that the listed material would be used or the listed waste would be generated during that specific activity or at that specific facility; a dash indicates that the listed material would not be used or the listed waste would not be generated during that specific activity or at that specific facility.
c. Includes only the proposed railroad activities; does not include DOE facilities at the Yucca Mountain Repository.

The anticipated quantity of solid waste generated at all railroad operations support facilities is 170 metric tons (190 tons) per year or 0.45 metric ton (0.5 ton) per day (Table 4-291). DOE would transport solid waste to permitted solid-waste landfills. As shown in Table 3-154, landfills in Mineral, Nye, Esmeralda, and Clark Counties accept more than 8,100 metric tons (9,000 tons) of waste per day combined. The addition of about 0.45 metric ton (0.5 ton) of solid waste anticipated during the operations phase (Table 4-291) would raise the total amount disposed of in the four-county area by less than 0.01 percent. Nevada has enough landfill capacity to accommodate this additional solid waste; therefore impacts to landfill capacities would be small.

Table 4-291. Solid waste generation at proposed railroad operations support facilities – Mina rail alignment.

Facility	Number of personnel (maximum)	Solid waste generation (kilograms[a] per day per person)[b]	Total solid waste (metric tons per day)[c]	Total solid waste(metric tons per year)

f. The Nevada Railroad Control Center could be at either the Rail Equipment Maintenance Yard or the Staging Yard at Hawthorne and the National Transportation Operations Center could be anywhere in the continental United States; for purposes of analysis, DOE assumed these centers would be at the Rail Equipment Maintenance Yard.
g. Totals might not equal sums of values due to rounding.

4.3.12.3.2 Hazardous-Materials Use and Hazardous-Waste Generation

Maintenance of rolling and stationary railroad equipment and track would generate some hazardous wastes, including: lubricants from equipment and machinery, solvents, paint, and other hazardous materials typical of railroad operations.

The Staging Yard at Hawthorne, including the collocated Interchange Yard, would use limited quantities of hazardous materials, such as oils, solvents, and lubricants, and associated wastes would be generated. An off-site contractor would perform diesel fueling at the Staging Yard using a tank truck to service the yard switcher locomotive. DOE would also store propane and natural gas at the Staging Yard in tanks (DIRS 180873-Nevada Rail Partners 2007, pp. 3-1 and 3-2).

The Maintenance-of-Way Facility would include maintenance work areas, office space, and a material-storage area. Limited quantities of hazardous materials such as lubricants, solvents, and possibly pesticides (for example, herbicides and rodenticides), would be stored and used there, and associated wastes would be generated. DOE would also store propane or natural gas onsite in tanks (DIRS 180873-Nevada Rail Partners 2007, pp. 4-1, 4-4, and 4-7).

DOE would store and use hazardous materials, including diesel fuel, gasoline, propane, oils, paints, and solvents, at the Cask Maintenance Facility and associated hazardous wastes (such as oily rags and solvent wastes) would be generated (DIRS 174083-WPI 2003, pp. 30, 39, and 52). Compressed flammable gas and oxygen would also be stored at the Cask Maintenance Facility.

The Nevada Railroad Control Center could be at either the Rail Equipment Maintenance Yard or the Staging Yard and the National Transportation Operations Center could be anywhere in the continental United States, although for purposes of analysis, DOE assumed these Centers would be at the Rail Equipment Maintenance Yard. The Centers would consist primarily of office space (DIRS 180873-Nevada Rail Partners 2007, p. 5-1). DOE would store general cleaning supplies at these facilities.

There would be a diesel fuel storage tank with a 190,000-liter (50,000-gallon) capacity (a 1-month reserve) and a diesel fueling depot at the Rail Equipment Maintenance Yard (DIRS 181033-Hamilton-Ray 2007, all). There would also be a staging area where fuel oil and construction materials could be delivered to the repository. DOE would store and use hazardous materials, including lubricating oil, diesel fuel, natural gas or propane, and solvents, at the Rail Equipment Maintenance Yard and associated hazardous wastes would be generated (DIRS 180873-Nevada Rail Partners 2007, p. 5-1). Locomotive maintenance activities would generate approximately 420 liters (110 gallons) of used oil for each locomotive maintained (DIRS 155970-DOE 2002, p. 6-89). During peak operations, a maximum of 442 locomotives would travel on the rail line each year (DIRS 175036-BSC 2005, Table 4.2), which would generate approximately 190,000 liters (50,000 gallons) per year of used oil from locomotive maintenance. The used oil would be reclaimed rather than disposed of (DIRS 155970-DOE 2002, p. 6-89).

There could be small spills of hazardous materials such as oils and fuel along the rail line during the operations phase. DOE would immediately remediate any areas affected by such spills in accordance with applicable regulations (See Chapter 6).

DOE would manage the use of hazardous materials and would follow all federal, state, and local regulations, and would transport hazardous wastes to appropriately permitted disposal facilities that have ample capacities to receive such wastes, as discussed in Section 4.3.12.2.2. Therefore, impacts from the use of hazardous materials and the disposal of hazardous waste during the operations phase would be small.

4.3.12.3.3 Low-Level Radioactive Waste

Activities at the Cask Maintenance Facility would generate from 3,200 to 7,900 cubic meters (113,000 to 280,000 cubic feet) of Class A low-level radioactive waste throughout the operations phase (DIRS 181425-MTS 2007, p. 6). The Department would control and dispose of site-generated low-level radioactive waste in a DOE low-level waste disposal site, a site in an ***Agreement State***, or in a U.S. Nuclear Regulatory Commission-licensed site.

The Nevada Test Site accepts low-level radioactive waste for disposal and has an estimated disposal capacity of 3.7 million cubic meters (130 million cubic feet). DOE has estimated that approximately 1.1 million cubic meters (39 million cubic feet) of low-level radioactive wastes will be disposed of at the Nevada Test Site by 2070 from all potential sources, but not including Cask Maintenance Facility-generated wastes (DIRS 155970-DOE 2002, Section 3.1.12.4). Commercial disposal capacity for low-level radioactive wastes is currently available in the United States.

Relatively small amounts of low-level radioactive wastes would be generated and the aforementioned potential disposal options would have ample capacities to accept these wastes; therefore, impacts to low-level radioactive waste disposal facilities would be small.

4.3.12.4 Impacts under the Shared-Use Option

Impacts under the Shared-Use Option would be similar to those described for the Proposed Action without shared use. The only difference would be the construction and operation of additional sidings and a slight increase in overall rail traffic. Waste characteristics, generation rates, and disposal requirements would vary only slightly. Therefore, any additional adverse impacts associated with the Shared-Use Option would be small.

4.3.12.5 Summary

Table 4-292 summarizes potential impacts related to the use of hazardous materials and the generation of waste from constructing and operating the proposed railroad along the Mina rail alignment. Chapter 7 describes mitigation measures DOE could employ to reduce impacts.

Impacts from nonhazardous waste (solid and industrial and special waste) disposal listed in Table 4-292 represent the degree to which potentially affected landfills could be affected by increased waste receipt rates as a result of railroad construction and operation along the Mina rail alignment. Construction of the proposed railroad along the Mina rail alignment would raise the disposal rate of nonhazardous waste to landfills in the region of influence by about 0.49 percent. Overall, impacts during the construction phase would be small, for the relatively large Apex Landfill, to moderate for smaller landfills. During the operations phase, impacts to landfills would be small.

Impacts from the use of hazardous materials listed in Table 4-292 represent the likelihood that railroad construction and operation along the Mina rail alignment would create reasonably foreseeable conditions that would significantly increase the risk of a release of hazardous material. Overall, impacts during the construction and operations phases would be small, considering that DOE would implement proper planning measures in relation to the storage and handling of hazardous materials and would adhere to all applicable regulations.

Impacts from hazardous-waste disposal listed in Table 4-292 represent the degree to which potentially affected hazardous-waste disposal facilities could be affected by increased waste receipt rates as a result of railroad construction and operation along the Mina rail alignment. Overall, impacts during the construction and operations phases would be small because adequate disposal capacity would be available.

Impacts from the disposal of low-level radioactive waste disposal listed in Table 4-292 represent the degree to which potentially affected low-level radioactive waste disposal facilities could be affected by increased waste receipt rates as a result of railroad construction and operation along the Mina rail alignment. No low-level radioactive waste would be generated during the construction phase. During the operations phase, low-level radioactive wastes would be generated during cask maintenance activities at the Cask Maintenance Facility. Impacts to low-level radioactive waste disposal facilities during the operations phase would be small because adequate disposal capacity would be available.

Table 4-292. Summary of potential impacts related to the use of hazardous materials and the generation of waste from constructing and operating the proposed railroad – Mina rail alignment (page 1 of 2).[a]

Rail line segment/facilities(county)	Construction impacts	Operations impacts
Common to all alternative segments and common segments (Mineral, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste dispos	Small impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.

Table 4-292. Summary of potential impacts related to the use of hazardous materials and the generation of waste from constructing and operating the proposed railroad – Mina rail alignment (page 2 of 2).[a]

Staging Yard at Hawthorne (Mineral County)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste dispos	Small impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.
Maintenance-of-Way Facility; Rail Equipment Maintenance Yard; Cask Maintenance Facility; and Nevada Railroad Control Center and National Transportation Operations Center at the Rail Equipment Maintenance Yard (Mineral, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	Small impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal. Small impacts from low-level radioactive waste disposal for wastes that would be generated at the Cask Maintenance Facility.
Construction camps (Mineral, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	No impact. There would be no construction camps during railroad operations.
Access roads (including alignment access roads) (Mineral, Nye, and Esmeralda Counties)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	No impact. Use of access roads during railroad operations would not involve the use of hazardous materials or the generation of wastes.
Quarries (common to all potential quarry locations)	Small (Apex Landfill) to moderate (smaller landfills) impacts from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials. Small impacts from hazardous-waste disposal.	No impact. DOE would not operate quarries after the end of the construction phase.

a. Impacts under the Shared-Use Option would be similar to those under the Proposed Action without shared use.

4.3.13 CULTURAL RESOURCES

This section describes potential impacts to cultural resources from constructing and operating the proposed railroad along the Mina rail alignment. Section 4.3.13.1 describes the methods DOE used to assess potential impacts; Section 4.3.13.2 describes potential construction and operations impacts; Section 4.3.13.3 describes potential impacts under the Shared-Use Option; and Section 4.3.13.4 summarizes potential impacts to cultural resources. This section also incorporates American Indian perspectives to assess the potential direct and indirect impacts to important American Indian prehistoric and historic resources.

Section 3.3.13.1 describes the region of influence for cultural resources. Unless specified otherwise, this section describes impacts within 3.2-kilometer (2-mile)-wide area centered on the rail alignment.

4.3.13.1 Impact Assessment Methodology

Because of the length of the proposed rail line along the Mina rail alignment, DOE is using a phased cultural resource identification and evaluation approach, as described in 36 CFR 800.4(b) 2, to identify specific cultural resources along the alignment. Under this approach, DOE would defer final field surveys (an intensive BLM ***Class III inventory***) of the actual construction right-of-way, as provided in the programmatic agreement between DOE, the BLM, the STB, and the Nevada State Historic Preservation Office (see Appendix M).

> A **Class II inventory** is a sample-oriented field inventory designed to locate and record, from surface and exposed profile indications, all cultural resource sites within a portion of a defined area to make possible an objective estimate of the nature and distribution of cultural resources in the entire defined area.
>
> A **Class III inventory** is an intensive field survey designed to locate and record all cultural resource sites within a specified area. Upon completion of such an inventory, no further cultural resource inventory work is normally needed in the area.

The programmatic agreement states that an appropriate level of field investigation – including on-the-ground intensive surveys; evaluations of all recorded resources listed on the *National Register of Historic Places*; assessments of adverse effects; and applicable mitigation of identified impacts – be completed before any ground-disturbing construction activities could begin. This programmatic agreement also stipulates that there be proper tribal consultation activities, and treatment (mitigation) guidelines and measures designed to cover unanticipated discoveries and impacts during the construction and operations phases. The BLM administers most of the potentially affected land along the Mina rail alignment. Relevant provisions of another programmatic agreement between the BLM, the State of Nevada, and the Nevada State Historic Preservation Office (DIRS 174690-Abbey & Baldrica 2005, all) would apply, along with cultural resources procedures outlined in the BLM *Cultural Resource Inventory Guidelines* (DIRS 174691-BLM 1990, all).

The region of influence for the Class III inventory would include all potential direct and indirect effects to cultural resources and all properties of traditional religious and cultural importance from any construction activities associated with the proposed railroad. Before beginning any ground-disturbing activities, DOE would conduct a Class III inventory for the following specific region of influence for project activities (DIRS 176912-Wenker et al. 2006, p. 2):

> The APE [Area of Potential Effect, referred to in this Rail Alignment EIS as the region of influence] for the rail line will be 200 feet [61 meters] from the centerline of the alignment or the actual ROW [right-of-way] application submitted to BLM, whichever is greater. The APE for access roads outside of the alignment will be a minimum of 100 feet [30.5 meters] wide with at

least 50 feet [15 meters] on either side of centerline. The minimum APE for any construction areas or other temporary use areas, outside of the alignment, will be the footprint of the area plus 100 feet outward in all directions from the perimeter of each area. The APE for assessing indirect effects on historic properties outside of the rail line alignment will extend at least one mile in all directions from the perimeter of the direct effects APE.

Cultural resource requirements for the portion of Mina rail alignment within the Yucca Mountain Site boundary and at the Rail Equipment Maintenance Yard would be covered by a separate programmatic agreement prepared to address development of a geologic repository at Yucca Mountain, Nevada, underway between the DOE Office of Civilian Radioactive Waste Management, the Advisory Council on Historic Preservation, and the Nevada State Historic Preservation Office.

The present evaluation of impacts depends on a comprehensive review of existing literature and site-file databases, sample archaeological inventory, and discussions with responsible federal agencies, State of Nevada agencies, and American Indian groups, which have identified many known and potential archaeological, historical, and American Indian sites and features along the Mina rail alignment. Section 3.3.13.3 provides pertinent baseline information. DOE acquired additional information for potential cultural resources during ***Class II*** (sample-oriented) field surveys of the Mina rail alignment. American Indian viewpoints for potential impacts to sites and resources important to regional tribes and organizations in the southern portion of the Mina rail alignment are expressed in *American Indian Perspectives on the Proposed Rail Alignment Environmental Impact Statement for the U.S. Department of Energy's Yucca Mountain Project* (the American Indian Resource Document) (DIRS 174205-Kane et al. 2005, all). However, the American Indian Writers Subgroup prepared that document to address the Caliente rail alignment; therefore, it does not necessarily fully capture the views of the Walker River Paiute Tribe and other Northern Paiute groups.

4.3.13.2 Railroad Construction and Operations Impacts

Nearly all potential direct physical impacts to cultural resources, including those that would physically damage, alter, or disturb a historic property, would occur during the construction phase, specifically within the designated rail construction right-of-way. There could be additional construction-related ground disturbances at quarry sites, road crossings, temporary access roads, borrow sites, ***spoils areas*** or piles, and temporary construction camps. Each camp would have a construction footprint of about 0.1 square kilometer (25 acres). There would be other ground disturbances at the locations of the railroad operations support facilities, including the Staging Yard at Hawthorne (0.2 square kilometer [50 acres]); the Maintenance-of-Way Facility (0.06 square kilometer [15 acres]), which would be near Goldfield; the Rail Equipment Maintenance Yard (about 0.41 square kilometer [101 acres]), which would be within the Yucca Mountain Site boundary; and the Cask Maintenance Facility, which would be collocated with the Rail Equipment Maintenance Yard.

There could be various forms of indirect impacts during both the construction and operations phases, such as visual intrusions or increased access and visitation. During construction, large numbers of workers in the vicinity of the construction camps could increase the potential for both intentional and unintentional impacts to nearby cultural resources. Excavation and other construction-related ground-disturbing activities could unearth additional cultural materials that, based on previous archaeological surveys, were either thought to occur only at the surface or were previously undetected because they were completely buried. Improved access to remote areas could also increase the likelihood of looting or other damage to archaeological properties during the construction and operations phases.

Another indirect impact that would be unavoidable from construction in remote areas would be visual intrusion effects to a variety of resources designated as potential cultural resource landscapes. These resources include potential ***ethnographic landscapes***, rural historic landscapes, and historic mining landscapes, and incorporate geographic areas, including both cultural and natural resources associated with historic events or activities. In some instances, the literature reviews, known-site file searches, and the Class II inventory conducted for this Rail Alignment EIS have identified potential areas of specific impacts for some of the alternative segments and common segments. In addition, the American Indian Resource Document (DIRS 174205-Kane et al. 2005, all) provides other relevant information.

4.3.13.2.1 Construction Impacts along Mina Rail Alignment Alternative Segments and Common Segments

The following sections outline both the direct and indirect construction-related impacts within each of the Mina rail alignment alternative segments and common segments. Each section begins with a discussion of the direct impacts to cultural resources, which is followed by a discussion of the indirect impacts. These sites include those listed on the *National Register of Historic Places*, those eligible for listing on the National Register, and those known to have cultural significance but are not listed on the National Register.

4.3.13.2.1.1 Union Pacific Railroad Hazen Branchline. The Class I site-file search identified 21 previously recorded cultural resources within the Level I region of influence of the existing Union Pacific Railroad Hazen Branchline. These resources include seven prehistoric sites, 10 historic sites, one site with both prehistoric and historic components, and three unknown site types. Six of the cultural properties are considered eligible or probably eligible for the National Register of Historic Places, including several that are part of the National Register-listed Lahontan Dam historic district (DIRS 182290-Desert Research Institute 2007, all). Eligible or potentially eligible resources include a large prehistoric residential base camp, a portion of the Overland Stage Road, the Newlands Waterworks at Lahontan City, a Lahontan City construction townsite and railroad station, a railroad ***berm*** and debris scatter, and a multi-component site with eligible historic elements including a telephone line and debris scatter. In addition, the existing rail line passes through Fort Churchill State Historic Park, site of an important 1860-1869 U.S. Army post. No direct or indirect impacts to these resources are anticipated due to the lack of planned construction activities.

The presence of 21 archaeological sites indicates a known site frequency of 0.5 site per mile within the Level I region of influence for this segment.

4.3.13.2.1.2 Department of Defense Branchline North. The Class I site-file search did not identify any cultural resources recorded within the Level I region of influence. No Class II survey has been conducted. No direct or indirect impacts to these resources are anticipated due to the lack of planned construction activities.

Previous archaeological studies do not indicate the presence of any archaeological sites within the Level I region of influence for this segment.

4.3.13.2.1.3 Schurz Alternative Segments. The Class I site-file search revealed that five cultural resources are recorded along Schurz alternative segment 1, including two within the Level I region of influence and three within the Level II region of influence. Previously recorded sites include one prehistoric site, three historic sites, and one multi-component prehistoric and historic site. None of the five resources has been evaluated for eligibility to the *National Register of Historic Places*.

DOE surveyed 15 sample units during the Class II effort, totaling 12 kilometers (7.5 miles) or 23 percent of the segment. Eight resources were recorded, including five prehistoric sites, all characterized by ***lithic scatters***, and three historic sites, including two railroads and one trash deposit. One prehistoric lithic scatter and one historic railroad are potentially eligible for listing on the *National Register of Historic Places*. The other six resources appear ineligible for listing. Construction activities along this segment could result in direct and indirect impacts to these eligible or potentially eligible prehistoric and historic resources. Sample inventory indicates that approximately 34 resources could be present within the Level I region of influence.

The Class I site-file search revealed that one historic cultural resource, the Rawhide Western Railroad grade, has been recorded along Schurz alternative segment 4, within the Level I region of influence. National Register-eligibility of this resource has not been determined. Construction activities along this segment could result in direct and indirect impacts to this grade.

DOE surveyed four sample units during the Class II effort along Schurz alternative segment 4, totaling 3.2 kilometers (2 miles) or 5 percent of the segment. Eight prehistoric resources were recorded, including lithic and groundstone scatters, and a quarry. Three of the sites are considered potentially eligible for listing on the *National Register of Historic Places*, two are considered not eligible, and three of the sites have not been evaluated. Construction activities along this segment could result in direct and indirect impacts to these eligible or potentially eligible prehistoric and historic resources. Sample inventory indicates that approximately 160 resources could be present within the Level I region of influence.

The Class I site-file search revealed that four cultural resources are recorded along Schurz alternative segment 5, including two within the Level I region of influence and two within the Level II region of influence. These include three historic sites and one multi-component prehistoric and historic site. The multi-component site, Double Spring, is considered eligible for listing on the *National Register of Historic Places* and is in the Level II region of influence; the historic sites have not been evaluated.

DOE surveyed 10 sample units during the Class II effort along Schurz alternative segment 5, totaling 8 kilometers (5 miles) or 11 percent of the segment. Four resources were recorded, including three prehistoric lithic scatters, all unevaluated for eligibility, and one historic site, a trash deposit that is recommended not eligible for listing on the *National Register of Historic Places*. Construction activities along this segment could result in direct and indirect impacts to these eligible or potentially eligible prehistoric and historic resources. The National Register-eligible Double Spring, located outside of the Level I region of influence, would not be directly impacted. Sample inventory indicates that approximately 35 resources could be present within the Level I region of influence.

The Class I site-file search revealed that nine cultural resources are recorded along Schurz alternative segment 6, including five within the Level I region of influence and four within the Level II region of influence. Of these nine, seven are prehistoric or have a prehistoric component, and two are historic resources. Prehistoric resources include one isolate, two lithic scatters, one rock alignment with possible burials, one ***petroglyph*** site, and one site considered eligible for listing on the *National Register of Historic Places* that has a medicine rock, cairns, hunting blinds, and petroglyphs. The isolate and one of the lithic scatters are considered not eligible; eligibility status of the remaining prehistoric sites has not been determined. The sites within the Level I region of influence include a lithic scatter, the isolate, and the rock alignment. The two historic sites that would fall along Schurz alternative segment 6 are found within the Level I region of influence and include the Rawhide Western Railroad grade and the Reese River Road stage route. Eligibility status of these resources has not been determined.

DOE surveyed two sample units during the Class II effort, totaling 1.6 kilometers (1 mile) or 2 percent of the segment. One resource, a prehistoric lithic scatter, was recorded. This site has not been evaluated for listing on the *National Register of Historic Places*. Construction activities along this segment could result in direct and indirect impacts to the eligible or potentially eligible prehistoric and historic resources. Sample inventory indicates that approximately 45 resources could be present within the Level I region of influence.

4.3.13.2.1.4 Department of Defense Branchline South. The Class I site-file search revealed that three cultural resources are recorded within 152 meters (500 feet) of the existing rail line, including an historic pier piling, the historic Nolan Station rail siding, and a boulder containing cupule-style rock art (DIRS 182290-Desert Research Institute 2007, all). The historic pier piling is considered not eligible, and the other two sites have not been evaluated for eligibility. No direct or indirect impacts to these resources are anticipated due to the lack of planned construction activities.

4.3.13.2.1.5 Mina Common Segment 1 (Soda Spring Valley Area). The Class I site-file search revealed that 56 cultural resources are recorded along Mina common segment 1, including 18 within the Level I region of influence and 38 within the Level II region of influence. Within the Level I region of influence, previously recorded resources include two prehistoric lithic scatters (one site is considered not eligible, one site has not been evaluated), 14 historic sites (five sites are considered eligible, two sites are considered not eligible, and seven sites have not been evaluated), and two multi-component sites (one site is not eligible, one site has not been evaluated). Types of eligible resources falling within the Level I region of influence include the Sodaville to Tonopah Freight Road, railroad workers' camps, and a railroad grade. Within the Level II region of influence, there are 24 prehistoric sites (15 sites are considered not eligible, and nine have not been evaluated), and 14 historic sites (four are considered eligible, six are considered not eligible, and four have not been evaluated). The prehistoric sites consist of a rockshelter, lithic scatters, and isolates. Most of the historic sites are associated with railroad construction and operation, including camps, stations, and grades. Mining sites and the townsites of Redlich and Mina also fall within the region of influence of Mina common segment 1.

DOE surveyed 29 sample units during the Class II effort, totaling 23 kilometers (15 miles) or 20 percent of the segment. A total of 19 resources were recorded, including 14 prehistoric sites (13 lithic scatters and one quarry), three historic trash deposits, and two historic railroads. One historic railroad and the prehistoric quarry site are both considered eligible for listing on the *National Register of Historic Places*. Seven of the prehistoric lithic scatters are considered not eligible, and six have not been evaluated for eligibility. The three historic trash deposits and the additional historic railroad are considered not eligible. Given the high density of resources along this segment, construction activities could result in direct and indirect impacts to the eligible or potentially eligible prehistoric and historic resources.

Sample inventory indicates that approximately 94 resources could be present within the Level I region of influence.

4.3.13.2.1.6 Montezuma Alternative Segments.

<u>Montezuma Alternative Segment 1</u> The Class I site-file search revealed that 43 cultural resources are recorded along Montezuma alternative segment 1, including five within the Level I region of influence and 38 within the Level II region of influence. Within the Level I region of influence, two prehistoric sites, including a quarry site of unknown eligibility status and a small lithic scatter that is considered not eligible, and three historic sites (two sites, a railroad grade and telephone line, are considered eligible and one site, a trash dump, has not been evaluated) are present.

Within the Level II region of influence, previously recorded resources include 27 prehistoric sites (one site is considered eligible, 17 sites are considered not eligible, and nine have not been evaluated), 10 historic sites (three are considered eligible, four are considered not eligible, and three have not been evaluated), and one multi-component site that is considered not eligible. The majority of the prehistoric sites consist of lithic scatters and isolates, though cave and quarry sites are also present; historic sites include railroad grades, a dump, a wagon road, mining sites, and the townsite of Blair.

DOE surveyed 25 sample units during the Class II effort, totaling 20 kilometers (13 miles) or 17 percent of the segment. Twenty resources were recorded, including 17 prehistoric lithic scatters, two historic trash deposits, and one historic mining site. One lithic scatter is considered eligible for listing on the

National Register of Historic Places; three scatters are considered not eligible, and the remaining 13 prehistoric sites have not been evaluated for eligibility. Of the historic sites, one trash deposit and the mining site are considered not eligible; the other trash deposit has not been evaluated. Construction activities along this segment could result in direct and indirect impacts to the eligible or potentially eligible prehistoric and historic resources.

Sample inventory indicates that approximately 117 resources could be present within the Level I region of influence.

Montezuma Alternative Segment 2 The Class I site-file search revealed that 226 cultural resources are recorded along Montezuma alternative segment 2, including 39 within the Level I region of influence and 187 within the Level II region of influence. Within the Level I region of influence, previously recorded resources include 11 prehistoric sites (10 are considered not eligible, one has not been evaluated), 17 historic sites (one site, the townsite of Goldfield, is listed on the *National Register of Historic Places*, nine sites are considered eligible, and seven are considered not eligible), and 11 multi-component sites (one site is considered eligible, nine are considered not eligible, and one has not been evaluated). Eligible site types include railroad grades, Millers townsite, a mining camp and miner's cabin, the Goldfield Junction Station and Goldfield Dump, a feed lot with corrals, and a multi-component site having mining structures and rock art. An unrecorded American Indian settlement is also reported along Montezuma alternative segment 2.

Within the Level II region of influence, recorded resources include 112 prehistoric sites (four sites are considered eligible, 73 are considered not eligible, and 35 have not been evaluated), 58 historic sites (14 sites are considered eligible, 42 are considered not eligible, and two have not been evaluated), and 17 multi-component sites (14 are considered not eligible, and three have not been evaluated). The majority of the prehistoric sites consist of small lithic scatters and isolates; a variety of historic sites is found, primarily associated with mining and railroad activities. Historic sites also include the townsite of Millers, cemeteries, historic dumps, and military encampments, as well as sites and features potentially contributing to the *National Register of Historic Places*-listed Goldfield townsite.

DOE surveyed 24 sample units during the Class II effort, totaling 19 kilometers (12 miles) or 16 percent of the segment. A total of 39 resources were recorded, including 28 prehistoric lithic scatters and one quarry, four historic trash deposits, three historic railroad sites, one historic homestead site, one historic mining site, and one multi-component site.

Two of the lithic scatters are considered eligible for listing on the *National Register of Historic Places*, and seven are considered not eligible; 19 lithic scatters and the quarry have not been evaluated for eligibility. The four historic trash deposits, two of the railroads, and the mining site are considered not eligible; one railroad, the homestead, and the multi-component site have not been evaluated. Given the high density of resources along this segment, construction activities could result in direct and indirect impacts to the eligible or potentially eligible prehistoric and historic resources.

Sample inventory indicates that approximately 241 resources could be present within the Level I region of influence.

Montezuma Alternative Segment 3 The Class I site-file search revealed that 84 cultural resources are recorded along Montezuma alternative segment 3, including eight within the Level I region of influence and 76 within the Level II region of influence. Within the Level I region of influence, there is one prehistoric site (considered not eligible) and seven historic sites (six are considered eligible, and one is considered not eligible). The eligible resources include two railroad grades, Millers townsite, the Goldfield Junction Station, a mining camp, and a feed lot with corrals.

Within the Level II region of influence, previously recorded resources include 55 prehistoric sites (35 sites are considered not eligible, and 20 have not been evaluated), 18 historic sites (four sites are considered eligible, 12 are considered not eligible, and two have not been evaluated), and three multi-component sites that are considered not eligible. The majority of the prehistoric sites consist of small lithic scatters and isolates; a rockshelter is also present. Historic sites are primarily associated with mining and railroad activities, and include camps, dumps, mining features, and railroad grades and stations.

DOE surveyed 30 sample units during the Class II effort, totaling 24 kilometers (15 miles) or 17 percent of the segment. A total of 46 resources were recorded, including 36 prehistoric lithic scatters and one quarry, three historic trash deposits, three historic railroad sites, one historic homestead site, one historic mining site, and one multi-component site.

Two of the lithic scatters are considered eligible for listing on the *National Register of Historic Places*, and eight are considered not eligible; 26 lithic scatters and the quarry have not been evaluated for eligibility. The three historic trash deposits, two of the railroads, and the mining site are considered not eligible; one railroad, the homestead, and the multi-component site have not been evaluated. Given the high density of resources along this segment, construction activities could result in direct and indirect impacts to the eligible or potentially eligible prehistoric and historic resources.

Sample inventory indicates that approximately 270 resources could be present within the Level I region of influence.

4.3.13.2.1.7 Mina Common Segment 2 (Lida Junction Area). The Class I site-file search revealed that one prehistoric cultural resource, the Twin Buttes Rockshelters, is recorded along Mina common segment 2 within the Level II region of influence. This site has not been formally evaluated for eligibility, but is likely to be considered eligible. No cultural resources are previously identified within the Level I region of influence.

No Class II effort has been conducted along this short segment, which is between regular sample intervals; archaeological site distribution can be anticipated to reflect that noted along adjoining segments. The Twin Buttes Rockshelters would not be affected by construction of this segment.

4.3.13.2.1.8 Bonnie Claire Alternative Segments.

Bonnie Claire Alternative Segment 2 The Class I site-file search identified one cultural resource in the Level I region of influence. The site includes both prehistoric and historic components (a lithic scatter and mining prospects and debris). The prehistoric component was evaluated as being eligible for listing on the *National Register of Historic Places*.

The Class II sample survey examined five sample units, a total of 4 kilometers (2.5 miles) or 19 percent of the segment. Two sites and five isolates were recorded. The sites include a prehistoric campsite with a lithic and ground stone scatter, evaluated as being eligible for listing on the *National Register of Historic Places*, and a lithic scatter for which eligibility is under review.

Potential direct and indirect impacts along this alternative segment include the National Register-eligible prehistoric lithic and ground stone scatter identified during the Class II survey. This area also reveals the potential for the existence of prehistoric lithic scatters, obsidian nodule source areas, and rockshelters that, if present, would be directly affected by the construction of this alternative segment. The American Indian Resource Document (DIRS 174205-Kane et al. 2005, all) does not identify any known areas of importance to American Indians along this alternative segment.

The sample inventory indicates that approximately 10 resources could be present within the Level I region of influence.

Bonnie Claire Alternative Segment 3 The Class I site-file search identified four cultural resources within the Level I region of influence. These resources include four previously recorded but unevaluated prehistoric sites. One of these is a rockshelter, and the other three are extractive sites located in areas of obsidian cobble occurrences.

The Class II survey inspected four sample units along this segment, a total of 3.2 kilometers (2 miles) or 17 percent of the segment. One site and 24 isolates were recorded. The site is an historic rail line construction camp along the abandoned combined Bullfrog and Goldfield/Las Vegas and Tonopah rail bed, recommended as eligible for listing on the *National Register of Historic Places*. The American Indian Resource Document (DIRS 174205-Kane et al. 2005, all) does not identify specific resources for this alternative segment.

Construction along this alternative segment could result in direct and indirect impacts to the historic railroad camp along the abandoned Bullfrog and Goldfield/Las Vegas and Tonopah Railroad.

Sample inventory indicates that approximately 6 resources could be present within the Level I region of influence.

4.3.13.2.1.9 Common Segment 5 (Sarcobatus Flat Area). The Class I site-file search identified 33 cultural resources along common segment 5, including seven within the Level I region of influence and 26 within the Level II region of influence. These resources include 20 prehistoric sites (14 lithic scatters and six quarry extractive sites), four historic sites (a Tolicha mining district campsite, two debris scatters, and a railroad segment), seven isolates, and two unknown sites. Of these sites, one lithic scatter has been recommended as eligible for listing on the *National Register of Historic Places*, 11 are not eligible, and 14 remain unevaluated.

DOE surveyed 10 sample units along this segment for the Class II effort, a total of 8 kilometers (5 miles) or 20 percent of the segment. Four prehistoric sites (three lithic scatters and one campsite) and 33 isolates were recorded. Of these sites, the campsite was recommended as eligible for listing on the *National Register of Historic Places*, and the tree lithic scatters are not eligible.

Common segment 5 would pass about 2.4 kilometers (1.5 miles) east of the Timbisha Shoshone Trust Lands at Scottys Junction. However, no specific cultural resource properties are identified on those lands that would be indirectly affected by construction of the proposed railroad. There is a high probability for direct and indirect impacts along common segment 5. Previous cultural resources inventories in the Sarcobatus Flat area indicate a relatively high potential for lithic scatters and extractive quarries (obsidian nodules). The sample inventory indicates that approximately 15 resources could be present within the Level I region of influence.

4.3.13.2.1.10 Oasis Valley Alternative Segments. The Class I site-file search identified three cultural resources along Oasis Valley alternative segments 1 and 3, within the Level II region of influence. These resources include one prehistoric campsite (recommended as eligible for nomination to the *National Register of Historic Places*) and two sites with both prehistoric and historic components (unevaluated ethnographic village sites).

Oasis Valley Alternative Segment 1 The Class II survey looked at three sample units along Oasis Valley 1, a total of 2.4 kilometers (1.5 miles) or 25 percent of the segment. Two prehistoric sites (lithic scatters) and one historic mine site were recorded, all recommended not eligible for nomination to the *National Register of Historic Places*.

This alternative segment would cross the culturally sensitive Oasis Valley, where potential ethnographic and historic ranching cultural landscapes are present. There could be direct and indirect impacts to sites in the Oasis Valley, particularly the unrecorded historic Beatty Cattle Company Ranch and an unevaluated Western Shoshone winter camp.

The American Indian Resource Document notes the presence of the early Western Shoshone camp and also states that, because of its abundant water supply and large variety of culturally important plants and animals, American Indian people extensively used the entire valley (DIRS 174205-Kane et al. 2005, Section 2.3). Recent ethnographic studies on the nearby Nevada Test and Training Range revealed cultural links to Oasis Valley. The Oasis Valley area is both a potential ethnographic and historic ranching cultural landscape. In later historic times, these landscapes overlapped, as American Indian people collocated and supplied labor for the ranches.

Rail line construction could directly and indirectly affect sites in the Oasis Valley, particularly the historic Beatty Cattle Company Ranch and a known Western Shoshone winter camp.

The sample inventory indicates that approximately 20 resources could be present within the Level I region of influence.

Oasis Valley Alternative Segment 3 The Class II sample survey inspected four sample units, a total of 3.2 kilometers (2 miles) or 22 percent of the segment; five sites and 28 isolated artifacts were recorded. These resources include five prehistoric sites (four lithic scatters and one campsite with a lithic scatter and cleared rock rings). The campsite has been determined eligible for listing on the *National Register of Historic Places.*

Oasis Valley 3 also would cross the culturally sensitive Oasis Valley. It would pass just east of another historic ranch, the Colson or Indian Camp Ranch, which also has an early Western Shoshone winter camp adjacent to the ranch buildings. While both the ranch and Western Shoshone camp are unevaluated, rock lines (geoglyphs) were observed at the Indian camp area during field reconnaissance. These resources would be additional components of the potential Oasis Valley ethnographic and historic ranching cultural landscapes. Construction of the alternative segment could result in a visual intrusion to these cultural landscapes.

The sample inventory indicates that approximately 23 resources could be present within the Level I region of influence.

4.3.13.2.1.11 Common Segment 6 (Yucca Mountain Approach). The Yucca Mountain area has been heavily analyzed in conjunction with repository ***site characterization*** studies. Intensive cultural resource studies related to the development of the repository site have been completed. Consequently, a large number of archaeological sites have been found along common segment 6. This is due more to the intensive nature of past studies than actual site density characteristics.

A Class I site-file search identified 204 cultural resources along common segment 6. These resources include 152 prehistoric sites, three historic sites, one site with both prehistoric and historic components, and 49 isolates. Prehistoric sites include eight rockshelters (four eligible), two eligible rock-art sites, 13 campsites (five eligible), six quarry sites (two eligible), four rock features and two rock rings, and 117 lithic scatters (one eligible). Historic sites include two debris scatters and one rail segment.

The Class II survey for common segment 6 did not extend inside the Yucca Mountain Site boundary. DOE inspected 13 sample units, a total of 11 kilometers (7 miles) or 22 percent of the segment. Seven sites (two prehistoric lithic scatters, four eligible sites with both prehistoric and historic components, and one historic debris scatter) and 52 isolates were recorded.

To provide additional information on cultural resources along common segment 6 within the Yucca Mountain Site boundary, Desert Research Institute conducted a Class III supplementary field survey along the section of proposed rail alignment inside the Yucca Mountain Site boundary. This survey investigated a 150-meter (500-foot)-wide corridor centered on the rail alignment for an approximate length of 5.9 kilometers (3.7 miles). This land comprised acreage that was previously surveyed during repository site characterization activities. Desert Research Institute identified eight cultural resources (two prehistoric sites, five isolates, and one historic site) during the Class III survey. All were evaluated as ineligible for National Register listing.

Given the large number of resources in the area, construction of common segment 6 could result in direct and indirect impacts to prehistoric and historic sites. Three National Register-eligible prehistoric quarry sites are in this area within the Level I region of influence. The Beatty Wash Petroglyphs Site, listed on the National Register, is in the vicinity of a proposed bridge over Beatty Wash. Direct and indirect impacts from construction activities would include vibration of the rock matrix exhibiting the rock-art panels, and a potential for inadvertent or deliberate adverse impacts due to increased access and worker presence. The site holds important cultural value for American Indians. Over the long term, American Indians would likely view the bridge and operating trains as a visual and noise impact to the rock-art cultural landscape site.

After common segment 6 crossed onto the Yucca Mountain Site, it would cross an area that has undergone earlier intensive archaeological inventory and has been the subject of previous American Indian studies during repository characterization. As discussed in Section 4.2.13.1, DOE would consider identification, evaluation, and mitigation of potential impacts to these resources under a separate programmatic agreement with those along the proposed rail alignment.

Based primarily on previous ethnographic studies, the American Indian Resource Document (DIRS 174205-Kane et al. 2005, Section 2.3) identifies several areas of cultural significance for American Indians along this common segment. Several of these fall inside the Yucca Mountain Site boundary, including the Busted Butte rock-art site, Fortymile Wash, and Alice Hill. The American Indian Writers Subgroup also notes the cultural importance of the Beatty area rock-art site and Crater Flat, specifically the Black Cone geological feature in Crater Flat, which would be within 0.8 kilometer (0.5 mile) of common segment 6.

The sample inventory of the segment outside the Yucca Mountain Site boundary indicates that approximately 32 sites could be present within the Level I region of influence.

4.3.13.2.2 Railroad Operations Impacts

After the construction phase, there would be no additional direct or indirect impacts at cultural resource sites, other than the potential visual intrusion of operating trains on the character of potential cultural landscapes. American Indians would continue to view operation of the rail line as an intrusion on their holy lands.

4.3.13.3 Impacts under the Shared-Use Option

Impacts under the Shared-Use Option would be the same as those under the Proposed Action without shared use. Although under the Shared-Use Option there would be a slight increase in train traffic from the addition of commercial users, construction and operation of the proposed railroad would not differ and the slight increase in train traffic under the Shared-Use Option would not result in additional impacts. Construction of any additional commercial-use sidings would have the potential to impact cultural resources.

4.3.13.4 Summary

DOE would be obligated to complete intensive cultural resource inventories of the Mina rail alignment alternative segments and common segments. Because of the length of the rail alignment and the complexity associated with engineering a feasible alignment, DOE is using a phased cultural resource identification and evaluation approach, described in 36 CFR 800.4(b)2, to identify specific cultural resources. Under this approach, DOE would complete an inventory of the construction right-of-way, evaluate all recorded resources in accordance with criteria established for listing on the *National Register of Historic Places*, assess adverse impacts, and apply mitigation measures for identified impacts before it started any ground-disturbing construction activities.

Table 4-293 summarizes the potential for impacts to cultural resources within the region of influence for each Mina rail alignment alternative segment and common segment. At present, DOE cannot fully characterize potential effects on cultural resources and the magnitude of those impacts. The potential for impacts is based primarily on the relationship between the density of cultural resource sites associated with each alternative segment and common segment (that is, the greater the likely density of sites along a particular alternative segment or common segment, the higher the potential of affecting one or more of these sites). Sample inventory indicates that approximately 527 archaeological sites could be present within the Mina rail alignment Level I region of influence. Based on this sample, DOE expects that most of these sites will be characterized as prehistoric sites (77 percent), primarily lithic scatters, followed by historic sites (20 percent) and sites with both prehistoric and historic components (3 percent). Data currently available indicate that many of these sites (43 percent or more) will not meet eligibility criteria for listing on the *National Register of Historic Places*.

Based on preliminary information and sample surveys conducted to date, the magnitude of these impacts would likely range from small to moderate due to the extensive effort to avoid or mitigate impacts in accordance with the regulatory framework and with the terms of the cultural resources programmatic agreement (see Appendix M). To the extent feasible, DOE would avoid cultural resources identified within the construction areas. Where appropriate, temporary barriers would be used to isolate resources during construction. Monitoring and data recovery through excavation would also be used where necessary to mitigate impacts to archaeological sites. If the additional future inventory work described above indicated the presence of National Register-eligible sites, the magnitude of impacts could be greater.

Table 4-293. Summary of impacts to cultural resources – Mina rail alignment (page 1 of 2).

Location	Construction impacts[a]	Operations impacts[b]
Rail line segment		
Union Pacific Railroad Hazen Branchline	No potential for impacts.	No additional direct or indirect impacts.
Department of Defense Branchline North	No potential for impacts.	No additional direct or indirect impacts.
Schurz alternative segments	Potential direct and indirect impacts at archaeological sites identified along segments of alignments subject to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Department of Defense Branchline South	No potential for impacts.	No additional direct or indirect impacts.
Mina common segment 1	Potential direct and indirect impacts at archaeological sites identified along segments of alignments subject to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Montezuma alternative segments	Potential direct and indirect impacts at archaeological sites identified along segments of alignments subject to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Mina common segment 2	Potential direct and indirect impacts at archaeological sites identified along segments of alignments subject to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Bonnie Claire alternative segments 2 and 3 (Nye County)	Potential direct and indirect impacts at two National Register-eligible archaeological sites and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Common segment 5 (Nye County)	Potential direct and indirect impacts at two National Register-eligible archaeological sites and 20 additional resources recorded within the region of influence.	No additional direct or indirect impacts.
Oasis Valley alternative segments 1 and 3 (Nye County)	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	No additional direct or indirect impacts.
Common segment 6 (Nye County)	Potential direct and indirect impacts at archaeological sites recorded in the region of influence, including three National Register-eligible resources.	No additional direct or indirect impacts.

Table 4-293. Summary of impacts to cultural resources – Mina rail alignment (page 2 of 2).

Location	Construction impacts[a]	Operations impacts[b]
Proposed facilities		
Access roads (including alignment access roads)	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Staging Yard at Hawthorne	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Maintenance-of-Way Facility; Rail Equipment Maintenance Facility; Cask Maintenance Facility; and Railroad Control Center and National Transportation Operations Center	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Construction camps	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Wells	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Potential quarries		
Malpais Mesa	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
North Clayton Valley	Potential direct and indirect impacts at sites that might be identified during the complete survey. Significant resources likely avoidable.	No additional direct or indirect impacts.
Gabbs Valley	Small potential for impacts; significant resources likely avoidable.	No additional direct or indirect impacts.
Garfield Hills	Possible obsidian source; impacts would require mitigation.	No additional direct or indirect impacts.

a. Impact assessment based on sample inventory only; actual impacts cannot be identified until completion of field studies.
b. After the proposed rail line was constructed, no additional direct or indirect impacts would be anticipated at archaeological, historical, and cultural sites, other than the potential visual intrusion of operating trains on the character of potential cultural landscapes.

4.3.14 PALEONTOLOGICAL RESOURCES

This section describes potential impacts to paleontological resources ***fossils*** from constructing and operating the proposed railroad along the Mina rail alignment. Section 4.3.14.1 describes the methodology DOE used to assess impacts to such resources; Section 4.3.14.2 describes potential impacts during the construction phase; Section 4.3.14.3 describes potential impacts during the operations phase; Section 4.3.14.4 describes impacts under the Shared-Use Option; and Section 4.3.14.5 summarizes potential impacts.

Section 3.3.14.1 describes the region of influence for paleontological resources along the Mina rail alignment.

4.3.14.1 Impact Assessment Methodology

Any project activity involving land disturbance could have an adverse impact on the physical environment that could contain paleontological resources. Paleontological resources could be disturbed or destroyed by ground excavation, cuts and fills, surface-disturbing activities such as road building and blasting, or vandalism or theft of the resources.

DOE used the BLM system (DIRS 176084-BLM 1998, all; DIRS 176085-BLM 1998, all) to identify and classify paleontological resource areas along the Mina rail alignment according to their potential for containing vertebrate (animals with backbones) fossils or noteworthy occurrences of invertebrate or plant fossils. The BLM uses these paleontological resource classifications (***Condition 1***, ***Condition 2***, and ***Condition 3***; see the text box in Section 3.3.14) to identify areas that might warrant special management or special designation for paleontological resources.

The BLM steps to evaluate the potential for impacts to fossil resources are outlined in *General Procedural Guidance for Paleontological Resource Management* (DIRS 176084-BLM 1998, Chapter III), and include identification by a qualified paleontologist and protection of any paleontological area uncovered during field surveys. Educating the public about the value of paleontological resources is also an important part of BLM resource management.

To assess potential impacts to paleontological resources along the Mina rail alignment, DOE considered whether unique or scientifically important vertebrate, invertebrate, or plant fossils could be damaged, destroyed, or removed during construction and operation of the proposed railroad, quarries, water wells, and access roads.

4.3.14.2 Construction Impacts

Neither the rail line nor its construction and operations support facilities would be constructed at or near known or likely fossil beds. There is a known vertebrate bed between Hawthorne and Luning in the Garfield Hills area, just south of existing rail line along Mina common segment 1, but there would be no new construction in this area. Therefore, DOE would expect no impacts to paleontological resources during the construction phase.

However, the Department could encounter currently unknown paleontological resources during the construction phase. The BLM would continue to manage all identified paleontological resources in accordance with its management plans, and if DOE discovered new paleontological resources during the construction phase, the BLM would take appropriate action (DIRS 179560-BLM 2001, p. CUL-5).

4.3.14.3 Operations Impacts

The most likely source of potential impacts to paleontological resources would be from land disturbance during the construction phase, as discussed in Section 4.3.14.2. DOE expects there would be no impacts to paleontological resources resulting from railroad operations.

4.3.14.4 Construction and Operations Impacts under the Shared-Use Option

As for the Proposed Action without shared use (see Sections 4.3.14.2 and 4.3.14.3), DOE expects there would be no impacts to paleontological resources along the Mina rail alignment under the Shared-Use Option.

4.3.14.5 Summary

Although DOE could discover currently unknown paleontological resources along the Mina rail alignment during the construction phase, at present there are no known resources. The Department would expect impacts to paleontological resources during construction and operation of the proposed railroad to be small. Though there could be a potential to uncover previously unknown fossils during the construction phase, if paleontological resources were uncovered, DOE would consult with the BLM to develop appropriate measures to minimize damage to these resources.

Chapter 7, Best Management Practices and Mitigation, describes the best management practices DOE would implement as part of the Proposed Action and the mitigation measures the Department would consider to reduce or eliminate the potential for impacts to paleontological resources.

4.3.15 ENVIRONMENTAL JUSTICE

This section describes the DOE analysis of ***environmental justice*** (the potential for impacts to be ***disproportionately high and adverse*** to ***minority*** or ***low-income populations***) under the Proposed Action along the Mina rail alignment. Section 4.3.15.1 describes the DOE methodology for analyzing environmental justice; Section 4.3.15.2 describes the assessment of impacts to environmental resources; Section 4.3.15.3 describes the potential for disproportionately high and adverse impacts; and Section 4.3.15.4 summarizes any environmental justice impacts.

Section 3.3.15.1 describes the region of influence for environmental justice.

4.3.15.1 Impact Assessment Methodology

For this analysis, DOE uses the terms minority and low-income in the context of environmental justice (DIRS 155970-DOE 2002, Section 3.1.13.1; DIRS 174625-Bureau of Census 2005, all).

DOE performed the analysis of potential environmental justice impacts in accordance with Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, and Council on Environmental Quality guidance (DIRS 103162-Council on Environmental Quality 1997, all). Using information from Sections 4.3.1 through 4.3.14, this section assesses whether any high and adverse impacts could fall disproportionately on minority or low-income populations.

As a starting point, DOE determined whether there would be minority or low-income populations in the Mina rail alignment region of influence for environmental justice. Next, DOE determined whether there would be any potential for high and adverse impacts to environmental resources as evaluated in Sections 4.3.1 through 4.3.14. Finally, DOE determined whether any potential high and adverse impacts would fall disproportionately on minority or low-income populations.

According to the Council on Environmental Quality, a minority population exists where either (a) the minority population of the affected area exceeds 50 percent; this calculation includes federally recognized American Indian lands, because American Indians are included in the definition of minority populations; or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. In addition to the 50-percent threshold, DOE used both the United States and the State of Nevada minority populations as bases for comparison.

The Council on Environmental Quality defines low-income by using the annual statistical poverty thresholds from the U.S. Census Bureau. A low-income community exists when the low-income population percentage in the area of interest is "meaningfully greater" than the low-income population in the general population. For purposes of the analysis of low-income communities, DOE used both the United States and the State of Nevada low-income populations as the bases for comparison. DOE assumed a 20-percent threshold above state low-income percentages in accordance with U.S. Nuclear Regulatory Commission guidance.

DOE also considered whether minority or low-income populations would be affected by an alternative in different ways than the general population, such as through unique exposure pathways or rates of exposure, special sensitivities, or different uses of natural resources.

If there would be no high and adverse impacts to environmental resource areas, or if any identified high and adverse impacts would not fall disproportionately on minority or low-income populations, then there would be no environmental justice impacts.

4.3.15.2 Assessment of Impacts to Environmental Resources

Results of the impacts analyses described in Sections 4.3.1 through 4.3.14 indicate that there would be moderate to large impacts in the following environmental resource areas:

- Land use. Construction and operation of the proposed railroad along the Mina rail alignment would result in impacts to land use and ownership along the entire alignment. There would be changes in land uses on public lands within the operations right-of-way and impacts to patented mining claims.
- Aesthetic resources. During the construction phase, there would be small to large impacts with weak to strong contrasts in the short term from visible construction equipment, either operating or in storage, and from scars on soil and vegetated landscape from cuts, fills, and well pads along all segments of the Mina rail alignment. There would be small to large, but temporary, impacts from moderate to strong contrast in the short term for rail-over-road crossing of U.S. Highway 95 by Schurz alternative segment 6, which would not meet BLM Class III management objectives, and weak to moderate contrast in the short term for other rail line sections and structures, which would meet Class III objectives. There would also be moderate impacts from moderate contrast due to proximity to viewers on State Route 265 and in some parts of the town of Silver Peak that would meet BLM Class III and IV management objectives, and impacts from moderate contrast in the short term from quarrying, ballast production facilities, and a conveyor close to viewers that would be compatible with BLM Class III management objectives.

  During the operations phase there would be small to moderate impacts as a result of no to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads along the entire Mina rail alignment. There would also be small to moderate impacts from weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives. There would be moderate impacts from moderate contrast from a new linear feature adjacent to State Route 265 and in Clayton Valley that would meet BLM Class III and IV management objectives.
- Air quality. Air pollutant concentrations would not exceed the National Ambient Air Quality Standards for construction or operation of the railroad or any associated facilities, with the exception of the 24-hour standards for both PM_{10} and $PM_{2.5}$ that could be exceeded near the construction right-of-way at Mina and Schurz during the relatively short construction period, and at the Staging Yard at Hawthorne and the potential Garfield Hills quarry. The highest increase in emissions would be for NO_x emissions in Esmeralda County during the construction phase, where emissions could be as high as 25 times greater than 2002 county-wide NO_x emissions. The Shared-Use Option impact would result in a slightly higher increase in air pollutant emissions and air pollutant concentrations than would the Proposed Action without shared use.
- Noise and vibration. Eight receptors (individuals who could be affected) would be included in the 65 ***day-night average noise level*** contours in Silver Springs and one receptor would be included in Wabuska. These nine receptors would experience an adverse noise impact because they would be exposed to 65 DNL and a 3 dBA increase.
- Biological resources. There would be potential adverse impacts related to noxious and invasive species, which would include increased risk of these species becoming established in disturbed areas and encroaching on adjacent undisturbed habitat. There would be the potential for impacts to threatened or endangered species during the construction phase. Habitat for several special status species would be disturbed and individuals of several of the species could be disturbed, injured, or killed from construction and operation of the proposed railroad. Direct impacts to wildlife and wild horses and burros from railroad operations would consist of potential collisions of wildlife with trains

and temporary disruption of activities (such as foraging, nesting, and resting) due to the disturbance from noise caused by passing trains and from noise and presence of humans at facilities and potential contamination of forage, prey species, nesting, and spawning habitat, and sources of drinking water in the rare event of train derailment and associated spill of diesel fuel. Indirect impacts could include possible changes to predator/prey interactions due to the construction of towers and other structures that would provide new perch habitat for raptors and other predatory birds.

Although there are many historic and archaeological sites along the Mina rail alignment (see Section 3.3.13), and construction and operation of the proposed railroad could directly and indirectly affect those resources (see Section 4.3.13), that analysis did not determine that potential impacts to cultural resources would be high and adverse.

4.3.15.3 Potential for Disproportionately High and Adverse Impacts

To determine whether potential environmental impacts identified in Sections 4.3.1 through 4.3.14 could be disproportionately high and adverse to minority or low-income populations, DOE considered the following factors:

- Whether there would be an impact on the natural or physical environment that would adversely affect a minority population, low-income population, or American Indian tribe (such effects could include ecological, cultural, human health, economic, or social impacts on minority communities, low-income communities, or an American Indian tribe when those impacts are interrelated with impacts on the natural or physical environment)
- Whether environmental effects could have an adverse impact on minority populations, low-income populations, or an American Indian tribe that would be meaningfully greater than or be likely to be meaningfully greater than the impact on the general population or other appropriate comparison group
- Whether minority or low-income populations would be affected by an alternative in different ways than the general population, such as through unique exposure pathways or rates of exposure, special sensitivities, or different uses of natural resources
- Whether the environmental effects could occur in a minority population, low-income population, or American Indian tribe affected by cumulative or multiple adverse exposures from environmental hazards

Based on these factors, DOE identified the following potential impacts to land use, aesthetic resources, air quality, biological resources and from noise and vibration:

- Land use. To implement the Proposed Action along the Mina rail alignment, DOE would need to gain access to some private land, the amount of which would be very small (about 0.2 percent) compared to the total land required for the project. The Schurz alternative segments would cross the Walker River Paiute Reservation, utilizing between 0.3 and 0.5 percent of the Reservation's land, depending on the segment. The Tribe's concurrence would be necessary to secure a right-of-way for the rail line. However, the Tribe's current position (as stated in an April 29, 2007 [DIRS 181604-Williams 2007, all] letter from the Tribal Council) is that the Tribe will not allow nuclear waste to be transported across their Reservation. Under the Mina Implementing Alternative, DOE would remove the existing Department of Defense rail line through Schurz, providing a perceived benefit to the town's residential land uses; the Tribe could use the existing roadbed as a recreational trail. Most of the local mining activity is outside the rail-line construction right-of-way. However, Montezuma alternative segment 2 would intersect some patented mining claims and DOE would need to acquire access to this land. Mina common segment 1, all the Montezuma alternative segments, the Oasis Valley alternative segments, and common segment 6 would cross several Township and Range

Sections that contain many unpatented mining claims. The actual number of claims that would intersect the construction right-of-way would need to be determined through additional record searches and field verification. Nevertheless, there would be moderate impacts to patented and unpatented mining claims along these segments where they would fall within the construction right-of-way. There is also the possibility that the rail line could be affected by or affect underground mining tunnels or shafts. During the final engineering design phase, DOE would need to survey these underground features to avoid adverse impacts.

Although the Schurz population center and the Walker River ***Census County Division*** exceed the minority population threshold of 50 percent and the Walker River Census County Division exceeds the low-income threshold of 20 percent over the state average of 11 percent established by the Nuclear Regulatory Commission and the Council on Environmental Quality, the impacts to land use that would be felt on the Walker River Paiute Reservation are not large or adverse. The moderate impacts to patented and unpatented mining claims would be felt all along the Mina rail alignment and not just in the areas where the minority population threshold of 50 percent or the low-income threshold of 20 percent over the state average of 11 percent is exceeded. DOE has concluded that low-income and minority populations in these areas would not be disproportionately affected.

- Aesthetic resources. During the construction phase, there would be small to large impacts with weak to strong contrast in the short term from visible construction equipment either operating or in storage, and from scars on soil and vegetated landscape from cuts, fills, and well pads. There would be small to large impacts with weak to strong contrast in the long term from scars on rock from cuts, and from access roads along the entire Mina rail alignment. Also, there would be small to large, but temporary, impacts with a moderate to strong contrast in the short term for the Schurz alternative segment 6 rail-over-road crossing of U.S. Highway 95, which would not meet BLM Class III management objectives. There would be weak to moderate contrasts in the short term for other rail line sections and structures, which would meet Class III objectives.

  Along the Mina rail alignment, the Schurz population center and the Walker River Census County Division, both in Mineral County, are the two extreme cases with the widest percentage difference of 89-percent and 80-percent minority populations, respectively, compared to a 30-percent minority population for Mineral County as a whole. These two areas exceed the 50-percent threshold described in section 3.3.15.2. Also, there is one Census County Division with a poverty rate of more than 20 percent above the state average of 11 percent – the Walker River Census County Division, with a 32-percent poverty rate.

  Although the Schurz population center and the Walker River Census County Division exceed the minority population threshold of 50 percent and the Walker River Census County Division exceeds the low-income threshold of 20 percent over the state average of 11 percent established by the Nuclear Regulatory Commission and the Council on Environmental Quality, the large, permanent impacts to aesthetic resources would be felt all along the Mina rail alignment and not just in these areas. DOE has concluded that low-income and minority populations in these areas would not be disproportionately affected.

- Air quality. Annualized emissions for all air pollutants projected to be released during the construction phase would be greater than during the operations phase. Projected ambient concentrations of all air pollutants would be below the National Ambient Air Quality Standards, except for particulate matter during the construction phase, which could exceed the 24-hour standard under some conditions. Therefore, the projected impacts throughout the region of influence, during both construction and operation, would be small, except immediately adjacent to the potential Garfield Hills quarry and the Staging Yard at Hawthorne, and segments of the rail line during construction. Under the Shared-Use Option, there would be in an increase in emissions over those of the Proposed Action without shared use, but impacts to air quality would still be small.

Along the Mina rail alignment, the Schurz population center and the Walker River Census County Division, both in Mineral County, are the two extreme cases with the widest percentage difference of 89-percent and 80-percent minority populations, respectively, compared to a 30-percent minority population for Mineral County as a whole. These two areas exceed the 50-percent threshold described in section 3.3.15.2. Also, there is one Census County Division with a poverty rate of more than 20 percent above the state average of 11 percent – the Walker River Census County Division, with a 32-percent poverty rate.

Although the Schurz population center and the Walker River Census County Division exceed the minority population threshold of 50 percent and the Walker River Census County Division exceeds the low-income threshold of 20 percent over the state average of 11 percent established by the Nuclear Regulatory Commission and the Council on Environmental Quality, the impacts to air quality would be felt all along the Mina rail alignment and not just in these areas. DOE has concluded that low-income and minority populations in these areas would not be disproportionately affected.

- Biological resources. Potential adverse impacts related to noxious and invasive species would include increased risk of these species becoming established in disturbed areas and encroaching on adjacent undisturbed habitat. DOE would implement best management practices (see Chapter 7) and BLM-prescribed and -approved methods to prevent the establishment of noxious weeds or invasive plant species. There would be the potential for impacts to threatened or endangered species during rail line construction. Habitat for several special status species would be disturbed and individuals of several of the species could be disturbed, injured, or killed from the construction and operation of the proposed railroad and associated facilities. Potential impacts to federally listed species would likely require consultation with the U.S. Fish and Wildlife Service in accordance with Section 7 of the Endangered Species Act. Direct impacts to wildlife and wild horses and burros during the operations phase would consist of potential collisions of wildlife with trains; temporary disruption of activities (foraging, nesting, resting, etc.) due to the disturbance from noise caused by passing trains and from noise and presence of humans at railroad facilities; and potential contamination of forage, prey species, nesting, and spawning habitat, and sources of drinking water in the rare event of train derailment and associated spill of diesel fuel. Indirect impacts could include possible changes to predator/prey interactions due to the construction of towers and other structures that would provide new perch habitat for raptors and other predatory birds.

  Along the Mina rail alignment, the Schurz population center and the Walker River Census County Division, both in Mineral County, are the two extreme cases with the widest percentage difference of 89-percent and 80-percent minority populations, respectively, compared to a 30-percent minority population for Mineral County as a whole. These two areas exceed the 50-percent threshold described in section 3.3.15.2. Also, there is one Census County Division with a poverty rate of more than 20 percent above the state average of 11 percent – the Walker River Census County Division, with a 32-percent poverty rate.

  Although the Schurz population center and the Walker River Census County Division exceed the minority population threshold of 50 percent and the Walker River Census County Division exceeds the low-income threshold of 20 percent over the state average of 11 percent established by the Nuclear Regulatory Commission and the Council on Environmental Quality, the impacts to biological resources would be felt all along the Mina rail alignment and not just in these areas. DOE has concluded that low-income and minority populations in these areas would not be disproportionately affected.

- Noise and Vibration. There would be eight receptors included in the 65 DNL contours in Silver Springs and one receptor in Wabuska. There would be no receptors included in the 65 DNL contours for Mina, Silver Peak, or Goldfield. These nine receptors would experience an adverse noise impact because they would be exposed to 65 DNL and a 3 dBA increase. These impacts would not occur within the Schurz population center or the Walker River Census County Division. The Schurz population center and the Walker River Census County Division are the only locations along the Mina rail alignment where the minority populations exceed the threshold of 50 percent, and the Walker River Census County Division is the only location along the Mina rail alignment where the low-income population exceeds the threshold of 20 percent over the state average of 11 percent established by the Nuclear Regulatory Commission and the Council on Environmental Quality. DOE has concluded that low-income and minority populations in these areas would not be disproportionately affected.

Seventeen tribes and organizations have formed the Consolidated Group of Tribes and Organizations, which is a forum consisting of tribally approved representatives who are responsible for presenting their respective tribal concerns and perspectives to DOE. The Consolidated Group of Tribes and Organizations has provided DOE with valuable insights into American Indian cultural and religious values and beliefs.

Section 3.4 summarizes the interests and concerns expressed by various American Indian tribes and organizations within or near the Mina rail alignment region of influence. Sections 3.2.13 and 3.3.13, Cultural Resources, provide additional information on American Indian cultural resources. Perceptions about the types and magnitudes of potential impacts to American Indian interests along the Mina rail alignment vary among the various stakeholders with interests in the proposed railroad because of different beliefs, goals, responsibilities, and values. American Indians are concerned that the proposed railroad could cause substantial and high adverse effects to a number of American Indian interests within and adjacent to the Mina rail alignment region of influence. DOE acknowledges the concerns of the American Indians and has consulted with the tribes. The Department would continue to consult with the Consolidated Group of Tribes and Organizations throughout the life of the project. Under the Mina Implementing Alternative, DOE would work closely with the American Indians to develop a mitigation action plan and ensure compliance with Section 106 of the National Historic Preservation Act (16 U.S.C. 470).)

The environmental justice analysis for the Shared-Use Option is the same as that described for the Proposed Action without shared use.

4.3.15.4 Conclusion

The Schurz population center and the Walker River Census County Division are the only locations along the Mina rail alignment where the minority populations exceed the threshold of 50 percent, and the Walker River Census County Division is the only location along the Mina rail alignment where the low-income population exceeds the threshold of 20 percent over the state average of 11 percent established by the Nuclear Regulatory Commission and the Council on Environmental Quality. Because there are no large and adverse impacts in these areas, DOE concluded that low-income and minority populations in these areas would not be disproportionately affected. Constructing and operating the proposed railroad along the Mina rail alignment would not result in high and adverse impacts to minority or low-income populations and no special pathways were identified. DOE has concluded that there would be no disproportionately high and adverse impacts to minority or low-income populations.

5. CUMULATIVE IMPACTS

This chapter presents the results of the DOE analysis of potential cumulative impacts under the Proposed Action for the Caliente rail alignment and the Mina rail alignment. The analysis considers impacts associated with past, present, and reasonably foreseeable future and continuing actions along with potential impacts from each of the rail alignments.

Glossary terms are shown in ***bold italics***.

5.1 Introduction

Cumulative Impact: The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7).

The U.S. Department of Energy (DOE or the Department) combined potential ***impacts*** reported in Chapter 4 of this Rail Alignment EIS with the potential impacts of other relevant past, present, and ***reasonably foreseeable future actions*** in the ***region of influence*** for each rail alignment. These combined impacts are called ***cumulative impacts***. Council on Environmental Quality (CEQ) regulations (40 Code of Federal Regulations [CFR] 1500 to 1508) that implement the procedural requirements of the National Environmental Policy Act (42 United States Code [U.S.C] 4321 *et seq.*) (NEPA) require a cumulative impacts analysis as part of the environmental impact statement (EIS) process. In conducting this analysis, DOE followed the guidelines in CEQ handbook *Considering Cumulative Effects Under the National Environmental Policy Act* (DIRS 103162-CEQ 1997, all).

5.1.1 REGIONS OF INFLUENCE

The regions of influence for this cumulative impacts analysis encompass the potentially affected areas specific to the Caliente and Mina rail alignments. For the cumulative impacts analysis, the resource-specific regions of influence would generally be the same as those for the resource areas described in Chapter 3 and used for impact analysis reported in Chapter 4 of this Rail Alignment EIS. Table 3-1 and Table 3-78 list the regions of influence for each resource area within the Caliente and Mina rail alignment areas, respectively. The Caliente and Mina rail alignments share the same region of influence between Goldfield and the Yucca Mountain Repository, in Esmeralda and Nye Counties. The Caliente rail alignment region of influence also includes Lincoln County, while the region of influence for the Mina rail alignment also includes the Walker River Paiute Reservation and Lyon and Mineral Counties. Clark County, Churchill County, and Washoe County are generally excluded from the cumulative impacts regions of influence except as needed to maintain consistency with individual resource analyses, such as socioeconomics or air quality. Because the Caliente and Mina rail alignment regions of influence are different for much of their routes, some of the past, present, and reasonably foreseeable activities and projects affecting cumulative impacts for each rail alignment are also different, as described in this chapter.

5.1.2 APPROACH AND ANALYTICAL PERSPECTIVE

DOE used the following approach, analytical perspective, and considerations to perform this cumulative impacts analysis:

- Where analysis indicated a potential for cumulative impacts, information is quantified to the extent feasible (for example, land disturbance and water demand); however, the analysis is primarily ***qualitative***.
- The analysis considers federal, state and local government, and private activities.
- Projects included in the analysis have potential interaction in time (the foreseeable future) or space with the effects from implementation of the ***Proposed Action*** or the ***Shared-Use Option***.
- Effects from past and existing projects and activities are primarily considered in the Chapter 3 and Chapter 4 discussions for each resource area (such as mining and grazing).
- DOE considers reasonably foreseeable actions as those future actions for which there is a reasonable expectation that the action could occur, such as a Proposed Action under analysis, a project that has already started, or a future action that has obligated funding.
- Assessment of whether potential impacts would be beneficial or adverse would in many cases depend on individual and group values, beliefs, and goals, and would vary from location to location within the cumulative impacts regions of influence.

DOE has assessed potential cumulative impacts under the Proposed Action qualitatively and quantitatively to the extent available information allows. Not all quantitative information is additive because of different methodologies or conflicting regions of influence.

DOE identified activities relevant to the cumulative impacts analysis from reviews of information available from government agencies, such as environmental impact statements, land-use and natural resource management plans, and from private organizations. DOE reviewed this information for relevance to this cumulative impacts analysis based on potential geographical and temporal relationships with construction and operation of the proposed rail line along either the Caliente or Mina rail alignment. Not all actions identified in this analysis would have cumulative impacts on all resource areas.

This section describes some future actions only in general terms because the projects are in an early stage of planning or development, or they are broad concepts of activity (for example, BLM resource management planning). This analysis focuses more on geographic interaction of projects than timing of interactions because the actual timeframes for many of the reasonably foreseeable future actions are uncertain.

The approach taken for this cumulative impact analysis is consistent with the intent of CEQ regulations at 40 CFR 1502.22, *Incomplete or Unavailable Information*. This regulation directs agencies how to proceed when evaluating reasonably foreseeable significant adverse effects on the human environment in an environmental impact statement and there is incomplete or unavailable information. While information describing the characteristics and potential effects of other projects and activities within the regions of influence is primarily qualitative and, in some cases is incomplete or unavailable, there is sufficient information to complete a fair disclosure and hard look at potential cumulative impacts in the Caliente and Mina regions of influence.

5.1.3 RELATIONSHIP OF THIS ANALYSIS TO THE YUCCA MOUNTAIN REPOSITORY CUMULATIVE IMPACTS ANALYSIS

The Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (the Yucca Mountain FEIS) (DIRS 155970-DOE 2002, all) provided an analysis of potential cumulative impacts associated with construction and operation of a repository at Yucca Mountain. The portion of that analysis relevant and still valid to the Caliente and Mina rail alignments (DIRS 155970-DOE 2002) is incorporated in this cumulative impacts analysis for the proposed railroad, as appropriate.

To evaluate the potential environmental impacts, including cumulative impacts, of the revised repository design and operational plans, DOE has prepared *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F-S1) (Repository SEIS), which includes an analysis of cumulative impacts as they relate to the Yucca Mountain Repository. Sections 5.2.1.2.1 and 5.3.1.2.1 include a description of the repository, as currently proposed, and additional context about the repository as a reasonably foreseeable action. This Rail Alignment EIS cumulative impacts analysis incorporates updated cumulative impacts information from the Repository SEIS, as appropriate.

5.1.4 RESPONSIBILITY FOR MITIGATION OF CUMULATIVE IMPACTS

DOE is responsible for impacts associated with activities for which it is the project proponent. The Department would plan and design the Caliente and Mina rail alignments to avoid sensitive and regionally important resources like Wilderness Areas and Wilderness Study Areas and to avoid or minimize impacts to sensitive environmental areas (such as wetlands) and to private property. In addition, the Department would construct and operate the proposed railroad in compliance with all applicable requirements. Actions undertaken by other proponents are subject to a variety of environmental requirements to avoid, minimize, or otherwise reduce adverse impacts on the environment.

To help comply with requirements and to eliminate or reduce potential environmental impacts, the Department would implement a variety of engineering, site planning actions, and ***best management practices,*** all of which are parts of the Proposed Action (see Chapters 2 and 7). The DOE best management practices include the practices, techniques, methods, processes, and activities commonly accepted and used throughout the construction and railroad industries that facilitate compliance with applicable requirements and that provide an effective and practicable means of preventing or minimizing the environmental impacts of an action. Such practices would avoid, minimize, or otherwise reduce the direct and indirect environmental impacts of the DOE Proposed Action, thereby avoiding or minimizing contributions to direct, indirect, and cumulative environmental impacts along either the Caliente or Mina rail alignment cumulative impacts region of influence.

To the extent the Proposed Action would contribute cumulatively to impacts to regional resources, or to other activities such as BLM land management activities, DOE could take additional actions to reduce any identified impacts associated with its Proposed Action, as practicable (see Chapter 7). DOE continues to coordinate with public- and private-sector project proponents to foster adequate consideration of cumulative environmental issues. As part of its NEPA responsibilities, the Department would perform additional NEPA analysis related to the proposed railroad, if required.

5.1.5 ORGANIZATION OF THE ANALYSIS

Section 5.2 summarizes potential cumulative impacts associated with implementing the Proposed Action along the Caliente rail alignment. Section 5.3 summarizes potential cumulative impacts associated with implementing the Proposed Action along the Mina rail alignment. Section 5.4 summarizes combined repository and Nevada rail transportation impacts.

5.2 Caliente Rail Alignment

Sections 5.2.1 and 5.2.2 summarize the projects and activities considered in the Caliente rail alignment cumulative impacts analysis. Figure 5-1 shows the locations of these major projects and activities, including:

1. Southwest Intertie Project
2. Southern Nevada Water Authority Groundwater Development Project
3. Nevada Test and Training Range
4. Timbisha Shoshone Trust Land
5. Yucca Mountain Geologic Repository
6. Nevada Test Site
7. Coyote Springs Development Project
8. Union Pacific Railroad Operations
9. Toquop Energy Project
10. BLM Disposal of Public Land – Lincoln County Land Sales

This section also considers other relevant projects and actions that are not depicted on the map, such as:

- BLM planning and management actions – There are a variety of BLM past, present, and reasonably foreseeable actions within the three BLM management areas (Ely, Battle Mountain, and Las Vegas) relevant to the Caliente rail alignment.
- Various rights-of-way – Many future utility or other right-of-way corridors are not depicted in Figure 5-1 because specific routes are not known. For example, DOE and the BLM are preparing a programmatic environmental impact statement for potential designation of energy corridors on federal land in western states (70 *Federal Register* [*FR*] 56647, September 28, 2005).
- Energy and mineral development activities.
- Other regional economic development plans and activities within Lincoln, Nye, and Esmeralda Counties.

The Caliente rail alignment ranges in length from about 528 to 541 kilometers (328 to 336 miles), depending on the alternative segments considered. As a linear project, land disturbance and other direct impacts would be most likely to occur within the relatively narrow ***construction right-of-way*** and the narrower ***operations rights-of-way***. However, other direct and indirect impacts for some resources could occur outside of these rights-of-way.

To evaluate the potential for cumulative impacts, DOE identified and reviewed public and private actions in the Caliente rail alignment region of influence to determine if the impacts associated with these actions could coincide in time or space with potential impacts from construction and operation of the proposed Caliente rail alignment. Only those projects and activities DOE believes would have the potential for cumulative impacts are identified herein. In some cases, similar actions have been grouped together and listed by category of action.

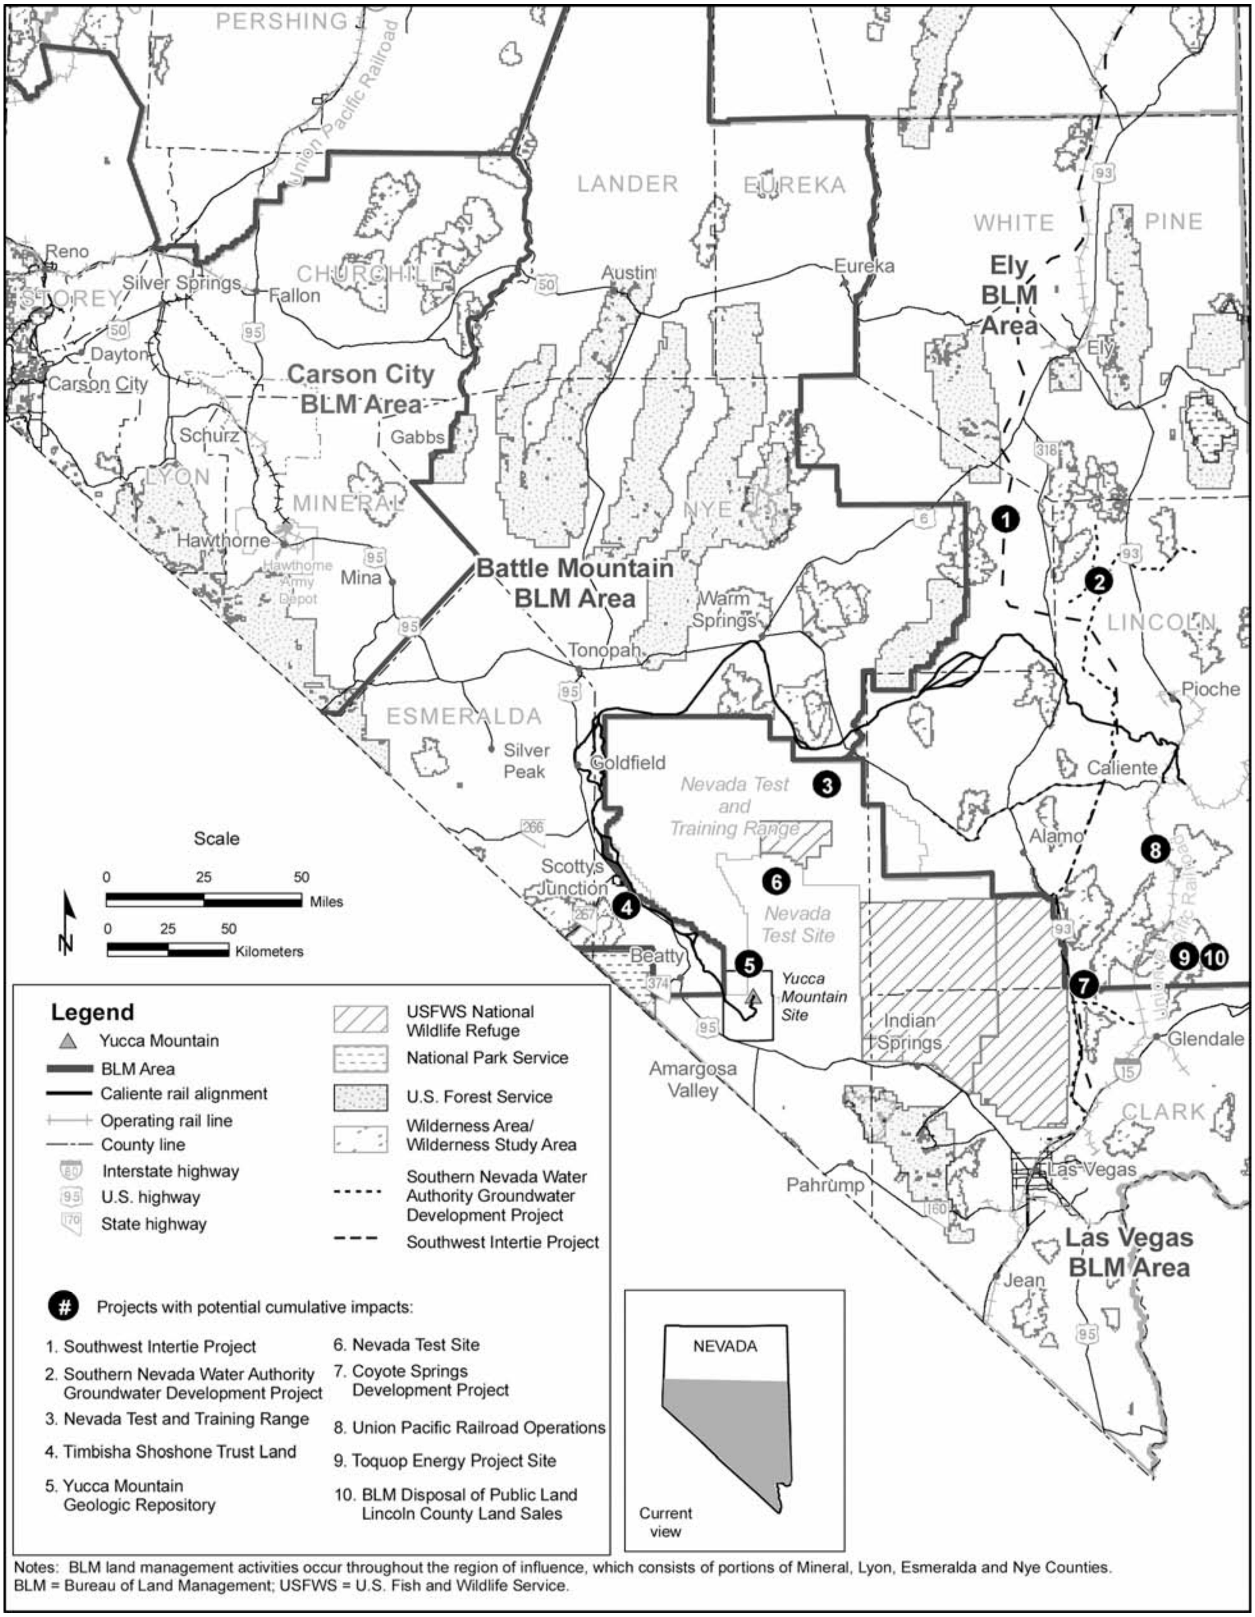

Figure 5-1. Major reasonably foreseeable future actions and continuing activities in the Caliente rail alignment cumulative impacts region of influence.

5.2.1 PROJECTS AND ACTIVITIES INCLUDED IN THE CUMULATIVE IMPACTS ANALYSIS – CALIENTE RAIL ALIGNMENT

5.2.1.1 Past and Present Actions

The descriptions of existing (baseline) environmental conditions (Chapter 3) and impacts (Chapter 4) associated with the various environmental resource regions of influence for the Caliente rail alignment considered in this Rail Alignment EIS include the relationships between proposed railroad construction, operation, abandonment, and past and present actions such as:

- Operations at major federal facilities such as the Yucca Mountain Geologic Repository, Nevada Test and Training Range, and Nevada Test Site
- BLM resource management planning and land management uses
- Traditional land uses such as regional ranching, mining, and recreation
- Military operations
- Residential, commercial, and industrial development activities associated with growth in the Caliente rail alignment cumulative impacts region of influence

Reasonably foreseeable future actions and the continuation of existing actions in the Caliente rail alignment cumulative impacts region of influence were also considered. Figure 5-1 shows the locations of individual projects and activities.

5.2.1.2 Reasonably Foreseeable Future and Continuing Federal Actions

Sections 5.2.1.2.1 through 5.2.1.2.6 describe reasonably foreseeable future and continuing federal agency actions that could result in cumulative impacts when combined with the potential impacts of constructing and operating the proposed railroad along the Caliente rail alignment.

5.2.1.2.1 Yucca Mountain Geologic Repository

The Proposed Action in this Rail Alignment EIS is directly related to the proposed geologic repository at Yucca Mountain, which is a reasonably foreseeable project that would have potential cumulative impacts in the Caliente rail alignment region of influence (see Figure 5-1, Project #5). In the Yucca Mountain FEIS (DIRS 155970-DOE 2002, all) and the *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (the Repository SEIS; DOE/EIS-0250F-S1 DOE proposes to construct, operate and monitor, and eventually close a ***geologic repository*** for the ***disposal*** of 70,000 metric tons (77,000 tons) of heavy metal of ***spent nuclear fuel*** and ***high-level radioactive waste*** at Yucca Mountain in Nye County, Nevada. DOE proposed to dispose of spent nuclear fuel and high-level radioactive waste in the repository using the natural geologic features of the mountain and engineered barriers as a total system to help ensure long-term ***isolation*** of the materials from the accessible environment. As analyzed in the Repository SEIS, the repository design and associated construction and operation plans require the following:

- DOE spent nuclear fuel and high-level radioactive waste would be placed in disposable canisters at the DOE sites, and as much as 90 percent of the commercial spent nuclear fuel would be placed in ***transportation, aging, and disposal*** (TAD) canisters at the commercial sites prior to shipment. This is the preferred method of receipt. The remaining commercial spent nuclear fuel (about 10 percent) would be transported to the repository in ***dual-purpose canisters*** (canisters suitable for storage and transportation), or would be uncanistered.

- Most spent nuclear fuel and high-level radioactive waste would be transported from 72 commercial and four DOE sites to the repository in Nuclear Regulatory Commission-certified transportation casks placed on trains dedicated only to these shipments. Some shipments, however, would be transported to the repository by truck over the Nation's highways.
- At the repository, DOE would conduct waste handling activities to manage thermal output of the commercial spent nuclear fuel and to package the spent nuclear fuel into TAD canisters. The disposable canisters and TAD canisters would be placed into ***waste packages*** for disposal in the repository. A waste package is a container that consists of the barrier materials and internal components in which DOE would place the canisters that contained spent nuclear fuel and high-level radioactive waste.
- DOE would place approximately 11,000 waste packages, containing no more than a total of 70,000 metric tons (77,000 tons) of heavy metal, spent nuclear fuel, and high-level radioactive waste in the repository at Yucca Mountain.
- When authorized by the Nuclear Regulatory Commission, the repository would be closed permanently. The design for construction would allow for phased construction of the surface and subsurface facilities that would be compatible with constrained funding.
- The surface and subsurface facilities and associated infrastructure, such as the onsite road and water distribution networks and emergency response facilities, would be constructed in phases to accommodate the expected receipt rates of spent nuclear fuel and high-level radioactive waste.
- DOE also would construct a four-lane access road that would extend from U.S. Highway 95 to the existing access road at Gate 510. This access road might be constructed using a phased approach, with initial construction of two lanes, and the road being widened later. The Department would also build a suitable intersection at U.S. Highway 95.
- DOE assumes that the following facilities would be constructed outside the repository land withdrawal area: a training facility near Yucca Mountain to support the Project Prototype Testing and the Operator Training and Qualification programs; temporary accommodations for construction workers; a proposed Sample Management Facility to consolidate, upgrade, and improve storage and warehousing for scientific samples and materials, perhaps near the Town of Amargosa Valley; and a marshalling yard and warehouse, a proposed leased facility that would consolidate material shipment and receipt into a 0.2-square-kilometer (50-acre) facility to allow for off-site receipt, transfer, and staging of materials required to perform construction activities at the Yucca Mountain site.

The Nuclear Regulatory Commission, through its licensing process, would regulate repository construction, operation and monitoring, and closure. Repository operations would only begin after the Commission granted DOE a license to receive and possess spent nuclear fuel and high-level radioactive waste. DOE is currently preparing an application for construction authorization.

The Yucca Mountain FEIS and the Repository SEIS evaluate the cumulative impacts of two additional inventories (Modules 1 and 2), which include spent nuclear fuel and high-level radioactive waste in addition to that of the Proposed Action inventory, and other radioactive wastes generally considered unsuitable for near-surface disposal. Inventory Module 1 or 2 could have cumulative impacts on the operation of the proposed railroad. Regarding potential cumulative impacts from Inventory Module 1 or 2, there would be no cumulative construction impacts because the need for a new railroad would not change; that is, whichever rail alignment DOE selected in which to build the proposed railroad to serve the Yucca Mountain FEIS Proposed Action would also serve Module 1 or 2. In addition, because the planned annual shipment rate of spent nuclear fuel and high-level radioactive waste to the Yucca Mountain Repository would be about the same for Module 1 or 2 and the FEIS Proposed Action, the only cumulative operations impacts would result because of the annual increase of shipments for Module 1 or 2. Because Modules 1 and 2 exceed the NWPA disposal limit of 70,000 metric tons (77,000 tons) of heavy metal considered in the Repository SEIS, the emplacement of any such waste at Yucca Mountain would require legislative action by Congress unless a second licensed repository was in operation. The 70,000 metric tons of heavy metal limit is comprised of 63,000 metric tons (69,000 tons) of heavy metal from commercial utilities and 7,000 metric tons (7,000 tons) of heavy metal from DOE.

DOE is preparing the *Disposal of Greater-Than-Class-C Low-Level Radioactive Waste Environmental Impact Statement* (DOE/EIS-0375) (72 *FR* 40135, July 23, 2007). That EIS will address the disposal of wastes with concentrations greater than Class C, as defined in U.S. Nuclear Regulatory Commission regulations at 10 CFR Part 61, and DOE Low-Level Radioactive Waste and ***transuranic*** waste having characteristics similar to Greater-Than-Class-C waste and that otherwise do not have a path to disposal. DOE proposes to evaluate alternatives for Greater-Than-Class-C low-level waste disposal in a geologic repository; in intermediate depth boreholes; and in enhanced near surface facilities. Candidate locations for these disposal facilities are the Idaho National Laboratory; the Los Alamos National Laboratory and Waste Isolation Pilot Plant in New Mexico; the Nevada Test Site and the proposed Yucca Mountain Repository; the Savannah River Site in South Carolina; the Oak Ridge Reservation in Tennessee; and the Hanford Site in Washington. DOE will also evaluate disposal at generic commercial facilities in arid and humid locations. The Draft Yucca Mountain SEIS evaluates the potential cumulative impacts of disposal of these wastes at Yucca Mountain as a reasonably foreseeable action, which are included in Inventory Module 2. Current repository design plans do not accommodate disposal of Greater-Than-Class-C low-level radioactive waste.

DOE is preparing the *Programmatic Environmental Impact Statement for the Global Nuclear Energy Partnership* (DOE/EIS-0396). Global Nuclear Energy Partnership (GNEP) would encourage expansion of domestic and international nuclear energy production while reducing nuclear proliferation risks, and reduce the volume, thermal output, and ***radiotoxicity*** of spent nuclear fuel before disposal in a geologic repository. DOE anticipates that its Programmatic EIS will evaluate a range of alternatives, including a proposal to recycle spent nuclear fuel and separate many of the high-heat ***fission products*** and the uranium and transuranic components. The full implementation of GNEP would involve the construction and operation of advanced reactors, which would be designed to generate energy while destroying the transuranic elements. DOE also anticipates evaluating project-specific proposals to construct and operate an advanced fuel-cycle research facility at one or more DOE sites.

The United States uses a "once through" fuel cycle in which a nuclear power reactor uses nuclear fuel only once, and then the utility places the spent nuclear fuel in storage while awaiting disposal. GNEP would establish a fuel cycle where the uranium and transuranic materials would be separated from the spent nuclear fuel and reused in thermal and/or advanced nuclear reactors. GNEP would not diminish in any way the need for the nuclear waste disposal program at Yucca Mountain, because under any fuel recycle scenario, high-level radioactive waste will continue to be produced and require disposal.

DOE anticipates that by about 2020 the commercial utilities will have produced about 86,000 metric tons (95,000 tons) of heavy metal of spent nuclear fuel, which exceeds the DOE disposal limit of 63,000 metric tons (69,000 tons) of heavy metal of commercial spent nuclear fuel at the Yucca Mountain Repository. If DOE were to decide, in a GNEP Record of Decision, to proceed with its proposal to recycle spent nuclear fuel, the Department anticipates that the necessary facilities would not commence operations until 2020 or later. Although the spent nuclear fuel-recycling concept has not yet been implemented and the capacity of a separations facility has not been determined, one or more separations facilities could be designed with a total capacity sufficient to recycle the spent nuclear fuel discharged by commercial utilities. Consequently, the Department believes there would be no change in the spent nuclear fuel and high-level radioactive waste inventory, and therefore the number of casks of spent nuclear fuel and high-level radioactive waste shipped to the Yucca Mountain repository analyzed under the Proposed Action in this Rail Alignment EIS would remain unchanged (that is, the shipment of approximately 9,500 casks containing spent nuclear fuel and high-level radioactive waste).

Overall, development of a GNEP fuel cycle has the potential to decrease the amount (number of assemblies) of spent nuclear fuel that would require geologic disposal, but would increase the number of casks of high-level radioactive waste requiring disposal in a geologic repository in the long term. Consequently, recycling of commercial spent nuclear fuel could affect the nature of the inventory that represents the balance of Inventory Module 1 (that is, commercial spent nuclear fuel in amounts greater than 63,000 metric tons [69,000 tons] of heavy metal). Nevertheless, given the uncertainties inherent at this time in estimating the amount of spent nuclear fuel and high-level radioactive waste that would result from full or partial implementation of the GNEP closed fuel cycle, this Rail Alignment EIS analyzes rail transportation within Nevada of approximately 9,500 casks of spent nuclear fuel and high-level radioactive waste.

5.2.1.2.2 Nevada Test Site (Continuation of Activities)

The Nevada Test Site, adjacent to the Nevada Test and Training Range, engages in a number of defense-related material and management activities, waste management, environmental restoration, and non-defense research and development (see Figure 5-1, Project #6). The Nevada Test Site was established in 1951 as the Nation's proving ground for developing and testing nuclear weapons. The site is on land administratively held by the BLM, but the Nevada Test Site land was withdrawn for use by the Atomic Energy Commission and its successors (including DOE). At present, the DOE National Nuclear Security Administration manages the site. It consists of about 3,200 square kilometers (800,000 acres) of land.

The *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996, all) described existing and projected future actions at the Nevada Test Site. That EIS was followed by a *Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 162638-DOE 2002, all). DOE activities at the Nevada Test Site include stockpile stewardship and management (helping ensure the U.S. nuclear weapon stockpile is safe, secure, and reliable), materials disposition (removal of nuclear materials in a safe and timely manner), and nuclear emergency response. Activities at the Nevada Test Site since the 1996 EIS and 2002 supplement analysis have continued to support these missions in accordance with federal law, DOE policies and missions, and NEPA requirements. There are a number of other programmatic DOE waste management initiatives that can affect current and potential future operations at the Nevada Test Site, many of which require NEPA analyses. The Nevada Test Site also produces annual environmental reports that describe program activities and related environmental issues and activities.

DOE is currently preparing the *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement–Complex 2030* (Complex Transformation Supplemental PEIS [formerly known as the Complex 2030 SEIS]; DOE/EIS-0236-S4). That SEIS will analyze the environmental impacts of the continued transformation of the United States nuclear weapons complex by implementing the National Nuclear Security Administration's vision of the complex as it would exist in 2030, and alternatives to that action. Part of the proposed action in that SEIS is to identify one or more sites for conducting National Nuclear Security Administration flight test operations. Existing Department of Defense and DOE test ranges (for example, the White Sands Missile Range in New Mexico and the Nevada Test Site in Nevada) would be considered as alternatives to the continued operation of the Tonopah Test Range in Nevada.

Another part of the proposed action in the Complex Transformation Supplemental PEIS is to accelerate dismantlement activities. The DOE sites that will be considered as potential locations for the consolidated plutonium centers and consolidation of Category I (high strategic significance) and II (moderate strategic significance) special nuclear materials include Los Alamos National Laboratory, the Nevada Test Site, the Pantex Plant, the Y-12 National Security Complex, and the Savannah River Site.

DOE manages several types of radioactive and hazardous waste (***low-level radioactive waste***, ***mixed low-level waste*** [referred to as mixed waste], transuranic waste, high-level radioactive waste, and ***hazardous waste***) generated by past and present nuclear defense research activities at many DOE sites across the United States, including the Nevada Test Site. The Department manages each of those waste types separately because they have different components, levels of radioactivity, and regulatory requirements. DOE needs facilities like the Nevada Test Site to manage its radioactive and hazardous wastes to maintain safe, efficient, and cost-effective control of these wastes; comply with applicable federal and state laws; and protect public health and safety and the environment. In *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DIRS 101816-DOE 1997, all) DOE evaluated the environmental impacts of managing the five waste types. The Nevada Test Site will continue to be a major facility involved in DOE waste management programs, including serving as a disposal site for certain waste types generated off the site, and for on-site wastes primarily from environmental restoration and remediation activities.

The Nevada Test Site is a candidate disposal location for Greater-Than-Class-C Low-Level Radioactive Waste which is currently being examined in the *Disposal of Greater-Than-Class-C Low-Level Radioactive* Waste *Environmental Impact Statement* (DOE/EIS-0375). That DOE EIS will address the disposal of wastes with concentrations greater than Class C, as defined in Nuclear Regulatory Commission regulations at 10 CFR Part 61, and DOE low-level radioactive waste and transuranic waste having characteristics similar to Greater-Than-Class-C low-level waste and that might not have an identified path to disposal. DOE proposes to evaluate alternatives for Greater-Than-Class-C low level waste disposal in a geologic repository; in intermediate-depth boreholes; and in enhanced near-surface facilities.

Table 5-1 lists and briefly describes recent environmental assessments that describe Nevada Test Site operations.

Table 5-1. Recent environmental assessments describing Nevada Test Site operations.

Title	Description
Environmental Assessment for Relocation of Technical Area 18 capabilities and materials from the Los Alamos National Laboratory to the Nevada Test Site (DIRS 162639-DOE 2002, all)	DOE completed relocation of Technical Area 18 operational capabilities and materials from the Los Alamos National Laboratory to the Nevada Test Site in November 2005. Relocation included the transport of about 2.4 metric tons (2.6 tons) of special nuclear material and approximately 10 metric tons (11 tons) of natural and depleted uranium and thorium, as well as support equipment, some of which would have radioactive contamination, associated with the operations. A Finding of No Significant Impact was issued.
Environmental Assessment for Defense Logistics Agency Transfer of Waste to DOE and Finding of No Significant Impact (DIRS 172280-DLA 2003, all; DIRS 172281-DOD 2003, all)	The Defense Logistics Agency of the Department of Defense issued an environmental assessment of its proposal to transfer thorium nitrate from the Defense National Stockpile Center to DOE for disposal as a low-level radioactive waste at the Nevada Test Site. The Agency issued a Finding of No Significant Impact in November 2003 (DIRS 172281-DOD 2003, all). The Defense Logistics Agency made eight shipments of low-level thorium waste (about 310 cubic yards [10,800 cubic feet]) in 2004 (DIRS 182346-DOE 2005, all).

5.2.1.2.3 BLM Resource Planning and Management

The presence of BLM-administered public land is a very important factor affecting how and where activities occur within Caliente rail alignment regions of influence. Many private and federal projects, including the proposed ***railroad***, would involve use of BLM-administered public land. Therefore, these projects would require BLM-issued ***right-of-way grants*** before they could proceed. Right-of-way grants have two general forms: linear (applicable to such projects as transmission lines, railroads, and pipelines), and nonlinear (applicable to projects at one specific location). Rights-of-way on BLM-administered land are extensive in the region. These rights-of-way vary tremendously in size and scope of activity.

The BLM administers most of the land through which the Caliente rail alignment would pass. The BLM manages these lands through a multiple-use concept (which means managing public lands and their various resource values so that they are utilized in the combination that will best meet the present and future needs of the American people) in accordance with the Federal Lands Policy and Management Act of 1976 (43 U.S.C. 1732, *et seq*.) and other federal legislation. The management framework for each BLM planning area is documented in a resource management plan. The Caliente rail alignment would cross three BLM planning areas (Ely, Battle Mountain, and Las Vegas). The Battle Mountain and Las Vegas planning areas are operating under resource management plans adopted in 1998 and 1997, respectively (DIRS 176043-BLM 1998, all; DIRS 173224-BLM 1997, all). The Ely planning area is currently operating under terms of the Schell and Caliente Management Framework Plans approved in 1983 and 1981, respectively, and the Egan Resource Management Plan approved in 1987. The Caliente rail alignment would pass through areas outlined in the Schell and Caliente Management Framework Plan. The Ely Field Office issued a Draft Resource Management Plan in 2005 (DIRS 174518-BLM, 2005, all), which when finalized, will replace the existing plans within the Ely planning area. Because the Ely Resource Management Plan is still in draft form and has not yet been adopted by the BLM, the Schell, Caliente, and Egan land-use plans provide the basis for planning activities in the Ely planning area.

The BLM manages public lands in accordance with the existing management goals and objectives in applicable plans, and takes various specific actions on the affected public lands. There are many land uses on BLM-administered land in the region of influence; livestock grazing is a major use. The BLM activities to plan for and manage the public lands it administers have a major role in balancing competing needs and resources, and in determining the scope and locations of public and private activities on public lands.

5.2.1.2.4 BLM Disposal of Public Land – Lincoln County Land Sales

Based on the terms of federal legislation, the BLM is implementing the following laws that authorize disposing of (selling) public lands in southern Nevada (See Figure 5-1, Project #10). These land disposals are driven by two primary legislative initiatives, as follows:

- Lincoln County Land Act of 2000 – This Act (Public Law 106-298) identified approximately 53square kilometers (13,000 acres) in the southeastern corner of Lincoln County near Mesquite, Nevada, for sale. In February 2005, the BLM sold this acreage to private interests for $47.5 million. Ten percent of the proceeds of this sale go to Lincoln County, and the remainder is earmarked for archaeological preservation and development of a multi-species habitat conservation plan in Lincoln County.
- Lincoln County Conservation, Recreation and Development Act of 2004 – This Act (Public Law 108-424) provides for the sale of up to 360 square kilometers (90,000 acres) in Lincoln County.

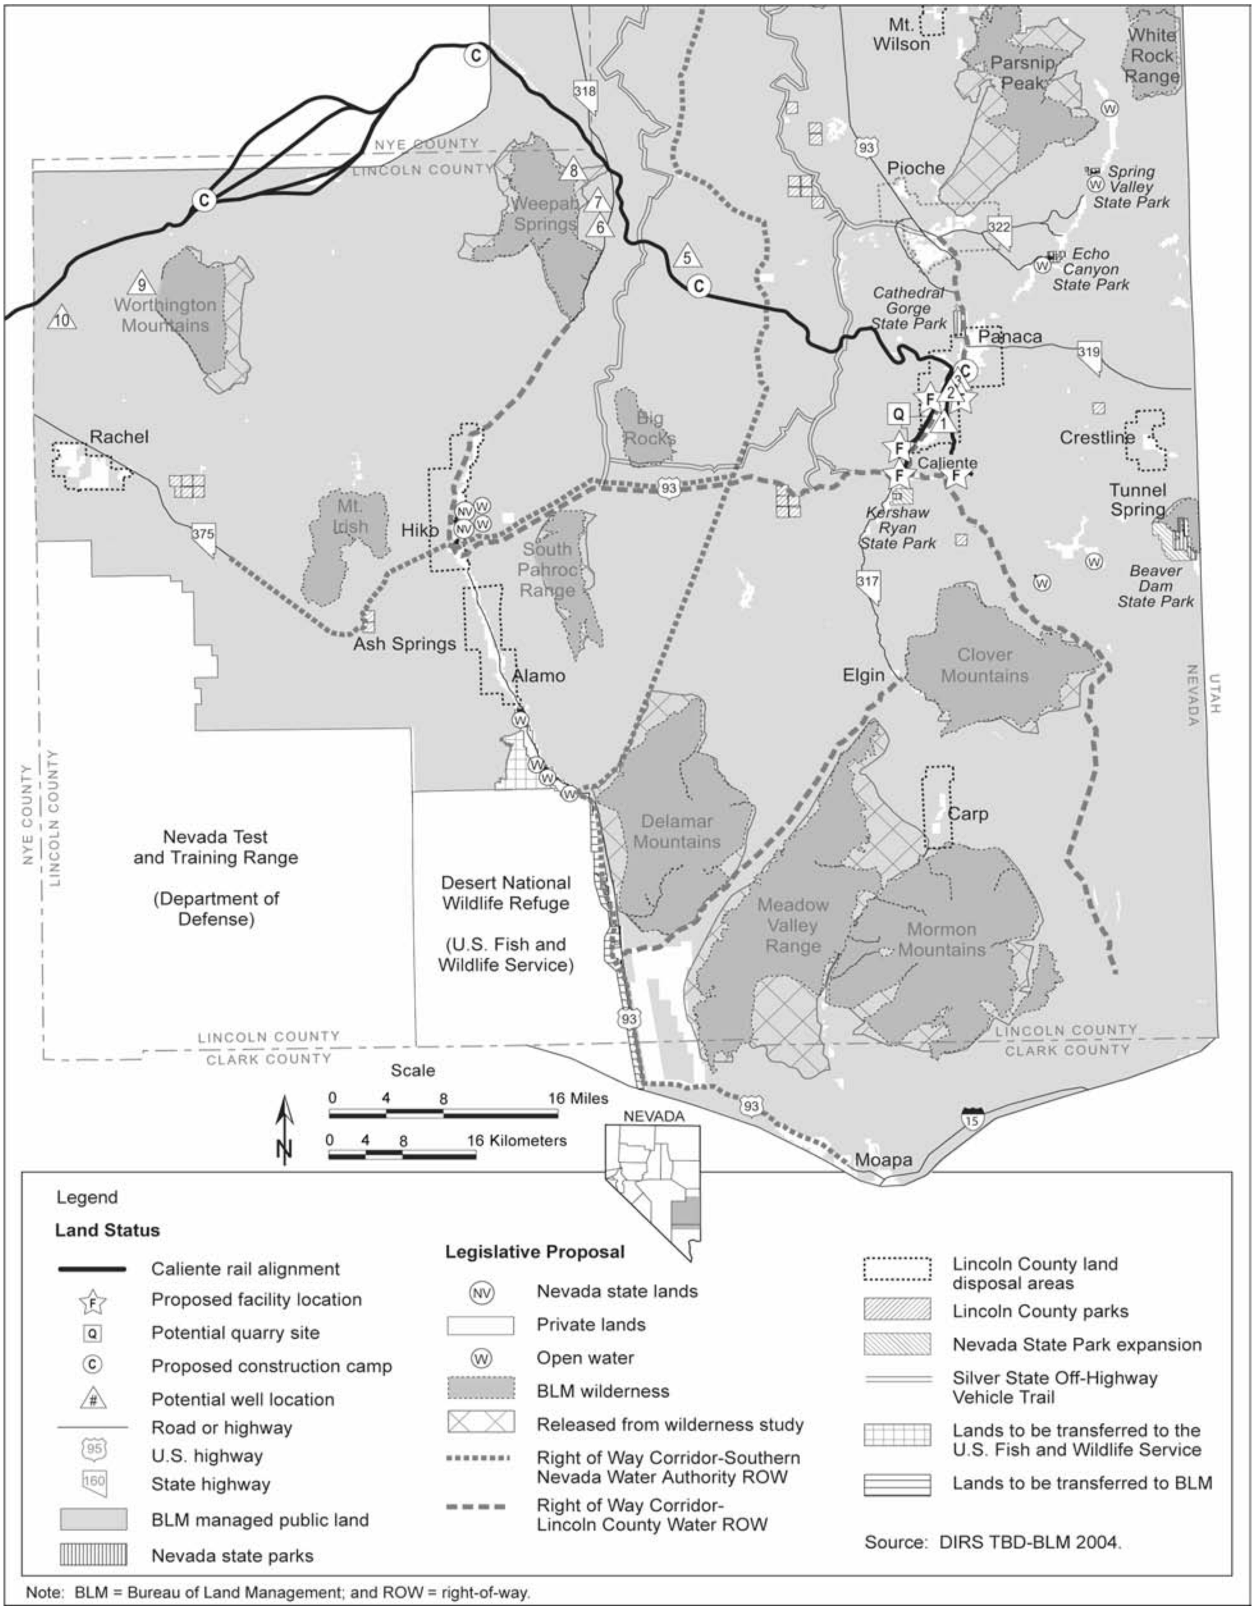

Figure 5-2. Lincoln County Conservation, Recreation, and Development Act activities.

The lands that would be eligible for sale will be identified in the Final Ely Resource Management Plan, which is currently being prepared by the BLM and is scheduled for completion in 2007. The Act will affect the growth and development in the Caliente rail alignment region of influence. See Figure 5-2 for the locations of activities and projects related to this Act. In addition to the planned BLM land disposals, the Act provides for:

- Designation of 14 new wilderness areas (consisting of 3,100 square kilometers [770,000 acres]) of BLM-administered land in Lincoln County, and release of 1,000 square kilometers (250,000 acres) of land from the BLM wilderness study area status.
- Establishment of nonexclusive utility corridors for the Southern Nevada Water Authority and the Lincoln County Water District/Vidler Water Company totaling 740 kilometers (460 miles) as rights-of-way for water pipelines and associated facilities to convey water in Clark and Lincoln Counties.
- Movement of an undeveloped right-of-way from the east side of U.S. Highway 93 to an existing utility corridor on the west side of the highway. Coyote Springs Investment will pay the Federal Government for the appreciated value of the property due to adding the right-of-way to their property.
- Establishment of a 420-kilometer (260-mile) Silver State Off-Highway Vehicle Trail along a series of existing backcountry roads that are currently open and used by off-highway vehicle enthusiasts, subject to the BLM preparation of a management plan for this trail.
- Transfer of about 35 square kilometers (8,500 acres) of BLM-administered land to the Desert National Wildlife Range, and transfer of about 34 square kilometers (8,400 acres) of Desert National Wildlife Range land to the BLM to facilitate the utility corridor for the Coyote Spring Investment development.
- Conveyance of up to 61 square kilometers (15,000 acres) of BLM-administered land to Lincoln County for conservation of natural resources or for public parks, with specific lands to be identified based on consultation between the county and the BLM.

In addition to the disposals required by the federal legislation described above, about 92 square kilometers (22,622 acres) have been identified for potential disposal in the vicinity of Goldfield, about 23 square kilometers (5,765 acres) have been identified for potential disposal near Scottys Junction, and 160 square kilometers (39,432 acres) have been identified for potential disposal near Beatty.

5.2.1.2.5 Nevada Test and Training Range (Continuation of Activities)

The U.S. Air Force operates the Nevada Test and Training Range in south-central Nevada (see Figure 5-1, Project #3), a national test and training facility for military equipment and personnel consisting of approximately 12 million square kilometers (3 million acres). Military training maneuvers and jet aircraft are commonly visible in the Caliente rail alignment cumulative impacts region of influence. In 2005, the U.S. Air Force designated the Indian Springs Air Force Auxiliary Airfield to Creech Air Force Base and expanded its mission and infrastructure to play a major role in the war on terrorism. The base is home to two key military operations: the MQ-1 unmanned aerial vehicle and the Unmanned Aerial Vehicle Battle laboratory.

The 1,600-square-kilometer (390,000-acre) BLM-administered National Wild Horse Management Area is within the boundary of the Nevada Test and Training Range. More than 3,200 square kilometers (800,000 acres) of the Nevada Test and Training Range comprise the Desert National Wildlife Range. The U.S. Air Force and the U.S. Fish and Wildlife Service jointly manage this area.

In *Renewal of the Nellis Air Force Range Land Withdrawal: Legislative Environmental Impact Statement* (DIRS 103472-USAF 1999, all) the U.S. Air Force addressed potential environmental consequences of extending the land withdrawal in order to continue using the Nevada Test and Training Range lands for military use. Activities at the Nevada Test and Training Range change, as necessary, to meet military test and training needs.

In 2004, the BLM prepared a resource management plan for about 8,900 square kilometers (2.2 million acres) of withdrawn public lands within the Nevada Test and Training Range (DIRS 178102-BLM 2004, all). The plan guides the management of the affected Nevada Test and Training Range natural resources 20 years into the future (2024). The decisions, directions, allocations, and guidelines in the plan are based on the primary use of the withdrawn area for military training and testing purposes.

Table 5-2 lists and briefly describes recent environmental assessments that describe Nevada Test and Training Range operations.

Table 5-2. Recent environmental assessments describing Nevada Test and Training Range operations.

Title	Description
Final Environmental Assessment for Increased Depleted Uranium Use on Target 63-10, Nevada Test and Training Range (DIRS 181607-USAF 2006, all)	The proposed action was to increase the use of depleted uranium ammunition at the Nevada Test and Training Range to meet ongoing test and training requirements for A-10 aircraft. The Air Force was to increase the number of depleted uranium rounds authorized to be fired on Target 63-10 from 7,900 to 19,000 annually. The environmental assessment evaluated five resource areas—air quality, soils and water resources, health and safety, hazardous and radioactive materials and waste, and biological resources—in detail to identify potential environmental consequences. The Air Force issued a Finding of No Significant Impact.
Final Environmental Assessment for Predator Force Structure Changes at Indian Springs Air Force Auxiliary Field, Nevada (DIRS 172314-USAF 2003, all)	The proposed action included changes to personnel assignments, upgrades to existing facilities, construction of new facilities, and extension of a runway by 120 meters (400 feet). The Air Force completed facilities for the Predator unmanned aerial vehicles in 2006. The Air Force issued a Finding of No Significant Impact.
Expeditionary Readiness Training Course Expansion, Final Environmental Assessment, Creech AFB (DIRS 182838-USAF 2006, all)	Environmental assessment to increase the number of Security Forces personnel trained at the Regional Training Center at Silver Flag Alpha and Creech AFB, Nevada, from an existing 2,520 to 6,000 students per year. The Air Force issued a Finding of No Significant Impact.
Wing Infrastructure Development Outlook, Final Environmental Assessment, Nellis AFB (DIRS 182839-USAF 2006, all)	The proposed action consists of 630 Wing Infrastructure and Development Outlook projects in 11 categories as classified under 32 CFR Part 989, *Air Force EIAP*. A total of 18 new construction and demolition projects are proposed for Creech Air Force Base. On the Nevada Test and Training Range, the proposed action would implement four new construction projects at four locations. At Tonopah Test Range, three new construction projects are planned along with the demolition of 10 buildings. The Air Force issued a Finding of No Significant Impact.
Draft Range 74 Target Complexes Environmental Assessment Nevada Test and Training Range, Nevada (DIRS 182840-USAF 2007, all)	The proposed action is to construct and operate three target complexes in mountainous terrain in Range 74 of the Nevada Test and Training Range at Saucer Mesa, Limestone Ridge, and Cliff Springs. The Saucer Mesa target array would employ both large-scale live and inert munitions; the Limestone Ridge sites would employ large-scale inert munitions; both target sites would employ small-scale live munitions. The Cliff Springs target complex would be laser and simulated attack targets and no munitions would be used. The Air Force issued a Finding of No Significant Impact.
A Final Base Realignment and Closure Environmental Assessment for Realignment of Nellis Air Force Base (DIRS 181492-USAF 2007, all)	The proposed action would affect the Nevada Test and Training Range by adding 1,400 F-16 sorties flown from Nellis Air Force Base, although they would not cause total annual sortie operations to exceed the current maximum of 300,000 at the Nevada Test and Training Range. The environmental assessment evaluated noise, air quality, socioeconomics and infrastructure, water and soil resources, biological resources, cultural resources, and hazardous materials and waste. The Air Force issued a Finding of No Significant Impact.

5.2.1.2.6 Timbisha Shoshone Trust Land (Federal Action)

The Secretary of the Interior issued a draft report to Congress (DIRS 103470-Timbisha Shoshone Tribe [n.d.], all) describing a plan to establish trust lands for people of the Timbisha Shoshone Tribe in portions of the Mojave Desert in eastern California and southwestern Nevada (see Figure 5-1, Project #4). On November 1, 2000, the President signed the Timbisha Shoshone Homeland Act (Public Law 106-423) to provide a permanent land base for the Timbisha Shoshone Tribe within its ancestral homeland in five separate parcels. Lands in the designated area for tribal purposes were then identified, including land parcels containing water rights. The parcel near Scottys Junction (about 11 square kilometers [2,800 acres]) is approximately 3.2 kilometers (2 miles) from the proposed Caliente rail alignment. The Timbisha Shoshone Tribe is actively evaluating economic development opportunities on this Scottys Junction parcel. The locations and nature of these future development opportunities are not known and are not considered to be reasonably foreseeable for the purpose of this analysis.

5.2.1.3 Reasonably Foreseeable Future Non-Federal Actions

Non-federal and private actions in the Caliente rail alignment region of influence primarily consist of energy development, infrastructure development, groundwater development projects, continued Union Pacific railroad operations, residential development, and general economic development initiatives and efforts. As noted above, many of these privately sponsored projects would interact with the BLM land management policies and procedures because of a need to acquire right-of-way grants to initiate proposed activities on BLM-administered land.

5.2.1.3.1 Power Plants, Transmission Lines, Pipelines, and Other Infrastructure

Various power companies and public utilities have proposed locations for new power plants in southern Nevada due to substantial population and economic growth in southern California, Arizona, and southern Nevada. Much of this recent and proposed development is in Clark County. In addition to the power plants, regional infrastructure developments include natural gas pipelines and transmission lines that provide fuel and transmit electricity. Recently completed projects or reasonably foreseeable projects that could result in cumulative impacts near the proposed Caliente rail alignment and associated facilities are listed below. It is likely that other power plants, transmission lines, pipelines, and other infrastructure would be built in the proposed Caliente rail alignment region of influence in the future, but the locations and timing of other future projects are not known at this time. Additionally, the region holds the potential for wind, solar, and geothermal energy development, although the magnitude and specific locations of these energy development projects are not known.

- <u>Southwest Intertie Project</u> (see Figure 5-1, Project #1) – LS Power Associates acquired the right-of-way, which is approximately 870 kilometers (540 miles) long, originally granted by the BLM in 1994 for a transmission line that would run from near Twin Falls, Idaho, to the Dry Lake Valley northeast of Las Vegas. The power line would connect the Nevada Power Company and Sierra Pacific Power Company electrical generation and transmissions systems.
- <u>Toquop Energy Power Project</u> (see Figure 5-1, Project #9) – This proposed power plant would be near Mesquite in Lincoln County, about 160 kilometers (100 miles) northeast of Las Vegas, on BLM-administered lands. In September 2003, the BLM issued to the proponent, Toquop Energy, Inc., a right-of-way to build the proposed 1,100-megawatt natural-gas fired power plant and associated facilities. However, since then, the project plan has changed to a 750-megawatt coal-fired power plant, in the same location as originally proposed. The BLM has determined that the proposed changes warrant the preparation of a new NEPA analysis and has initiated an environmental impact statement on the revised project concept (71 *FR* 8869, February 21, 2006).

In addition to the power plant itself, the project would require an approximate 50-kilometer (30-mile) rail spur, transmission lines, water, and a new access road.

- Various utilities in the Caliente rail alignment cumulative impacts region of influence have recently been constructed and are being planned, including new cable lines (for example, fiber optic lines) and other facilities (such as wireless towers) that would require BLM right-of-way grants or use of private land in the area. The BLM has designated certain corridors in the area that should be used for most utility purposes; however, use of other BLM-administered land requiring new right-of-way grants has traditionally been considered on a case-by-case basis. To identify appropriate right-of-way corridors throughout the western United States, including Nevada, DOE and the BLM are preparing a programmatic EIS (*Designation of Energy Corridors on Federal Land in the 11 Western States*; 70 *FR* 56647, September 28, 2005). This effort could include changes to the rights-of-way in the Caliente rail alignment cumulative impacts region of influence in future years but any such changes are unknown at this time.

5.2.1.3.2 Groundwater Development Projects

As part of its effort to augment future water supplies, the Southern Nevada Water Authority has initiated plans to develop groundwater for which it holds rights and applications in Clark, Lincoln, and White Pine Counties (see Figure 5-1, Project #2). The groundwater proposed for development involves seven hydrographic areas. These hydrographic areas generally lie along the east side of the state from an area north of the Las Vegas Valley, north into Lincoln County, and then extending into White Pine County. One of the hydrographic areas involved in the plan is hydrographic area 181 (Dry Lake Valley), which is west of the City of Caliente. The proposed Caliente rail alignment would pass through hydrographic area 181. The proposed project would develop and convey about 250 million cubic meters (204,000 acre-feet) per year of groundwater through a series of water wells, pipelines, and other infrastructure. The groundwater planned for development includes both existing and future permitted water rights, as permitted by the Nevada State Engineer. Of the total annual water planned for development, the Southern Nevada Water Authority would produce about 210 million cubic meters (170,000 acre-feet) per year for use by its purveyor members in the Las Vegas Valley, and about 44 million cubic meters (36,000 acre-feet) per year for conveyance to the Lincoln County Water District under terms of a February 2006 cooperative agreement between the two entities (DIRS 178053-Southern Nevada Water Authority 2006, all). The project would also involve electricity substations, transmission lines, pumping stations, a water storage facility, and a water treatment facility.

Final locations for individual well fields, and the number of wells in each valley, have not yet been determined, but preliminary exploratory areas have been identified, and water rights applications have been submitted for some proposed new wells at some specific locations (described below) that could lie within the region of influence used for groundwater resources as determined through the impacts analysis. In August 2004, the Southern Nevada Water Authority filed an application with the BLM to obtain necessary rights-of-way for the proposed system of regional water supply facilities associated with the project. The BLM has begun development of an EIS (70 *FR* 18043, April 8, 2005) to identify and disclose the environmental effects associated with this project. Scoping for the project was originally conducted in 2005; however, because of refinements in project plans, scoping for the project was reopened in July 2006.

As described in Section 3.2.6.2, applications have been filed for a proposed irrigation well that would be within approximately 1.7 kilometers (1.1 miles) of a DOE-proposed well location in Dry Lake Valley (hydrographic area 181), and an application has been filed for a proposed municipal well that would be located within approximately 1.7 kilometers of a DOE-proposed new well location in Pahroc Valley (hydrographic area 208). Each application gives 5 years as the minimum time period required for the construction of works and an estimated time required to complete the application of water to beneficial use of 10 years, as of the date the application was submitted (either December 1998 or October 2005). Applications have also been submitted for proposed municipal wells that would be approximately 1.5 kilometers (0.9 mile) northeast of another DOE-proposed new well location in area hydrographic 208, and approximately 1 kilometer (0.6 mile) northeast of another DOE-proposed well location in hydrographic area 208, respectively (Section 3.2.6.2). Both applications are under request-for-proposal status and according to the applications, the minimum time for construction of works (pumping station, pipelines, reservoirs, and distribution system) is 20 years for each proposed well. Section 5.2.2.6 evaluates the potential for cumulative impacts if these proposed well applications were to be approved and the wells installed and pumped contemporaneously with the DOE-proposed groundwater withdrawals.

The Lincoln County Land Act Groundwater Development and Utility Right of Way Project would include a projected 8 production water wells in the Tule Desert hydrographic basin and up to 10 production water wells in the Clover Valley hydrographic basin, cumulatively producing over 28 million cubic meters (23,000 acre-feet) of groundwater per year. A system of pipelines would collect the pumped water for conveyance through a main transmission pipeline southeast to the Lincoln County Land Act development area near Mesquite. Associated facilities would include power distribution and transmission and communications lines to be placed in the utility right-of-way to provide power and communication for the project facilities. A natural gas pipeline would parallel the water pipeline from the existing Kern River Natural Gas pipeline. The BLM initiated an EIS on this project (71 *FR* 16340, March 31, 2006) to evaluate potential impacts associated with this project.

As described in Section 3.2.6.3.3 of this Rail Alignment EIS, an application has been filed for a proposed municipal well that would be approximately 1.2 kilometers (0.8 mile) southwest of a DOE-proposed new well location in Garden Valley (hydrographic area 172). The municipal well would have a proposed production rate of up to 10,200 liters (2,690 gallons) per minute and would operate year round. The application lists an estimated time to construct this new well of 5 years and lists the estimated time required to complete the application of water to beneficial use as 10 years, as of the date the application was submitted (October 2005). The current status of this well is listed by the Nevada Division of Water Resources as “Ready for Action.” Section 5.2.2.6 evaluates the potential for cumulative impacts if these proposed well applications were to be approved and the wells installed and pumped contemporaneously with the DOE-proposed groundwater withdrawals.

The Kane Springs Valley Groundwater Development Project would consist of up to seven water production wells along Kane Springs Road north of the Coyote Springs development site. The project is being proposed by the Lincoln County Water District, and would result in the groundwater withdrawal of about 6.17 million cubic meters (5,000 acre-feet) of groundwater per year. Ancillary facilities would include lateral pipelines, power distribution and communications lines, and access roads. The BLM initiated an EIS on this project to evaluate potential impacts associated with this project (71 *FR* 16340, March 31, 2006).

As with the other BLM EIS processes under way, BLM could not issue the necessary right-of-way grants for any of the water development projects, and the projects could not be initiated, until the EIS process was complete and the BLM decision was to allow the developments. In addition, the Nevada State Engineer must approve any proposed water production and grant approval for the use of groundwater for any project in Nevada (Nevada Revised Statutes, Chapters 532 through 538). The proposed rights-of-way for the proposed groundwater development projects are all based on terms of the Lincoln County Conservation, Recreation and Development Act of 2004 (see Section 5.2.2.6).

5.2.1.3.3 Union Pacific Railroad Operations

Under the Caliente Implementing Alternative evaluated in this Rail Alignment EIS, rail transportation of spent nuclear fuel and high-level radioactive waste would originate in or near the City of Caliente from the Union Pacific Railroad mainline track (see Figure 5-1, Project #8). The existing relevant portion of the Union Pacific Railroad track enters Nevada from Utah, with the track generally trending southwest into the Caliente area. From Caliente, the track continues southwest into Las Vegas. Union Pacific Railroad operations are well established in the area, and as of 2005, approximately 25 trains pass through Caliente each day on the Union Pacific Railroad track.

5.2.1.3.4 Coyote Springs Development Project

As outlined in Section 5.2.1.2.4, the BLM sold approximately 53 square kilometers (13,000 acres) of land in Lincoln County to a private entity, Coyote Springs Investment, LLC, which is in the process of turning the land into a housing development. The Coyote Springs Development Project would be a planned community about 80 kilometers (50 miles) north of Las Vegas (see Figure 5-1, Project #7). The planned development area consists of about 170 square kilometers (43,000 acres) in the Coyote Spring Valley. About one-third of the land held by Coyote Springs Investment, LLC, is in Clark County and two-thirds is in Lincoln County. As envisioned, the community would consist of a series of neighborhoods and villages located among open space corridors. Initially, the community focus would be on second-home development and development of a destination resort concept centering on golf courses. Over time, there would be more traditional community development, with ultimate development occurring over 40 years. Development would begin in the Clark County portion of the land, with plans for about 47,500 residential units, together with commercial and recreational facilities. The BLM stated that public services such as water, roads, law enforcement, emergency services, sewer, and power, must be established before home construction could begin on the land. Water for the potential new housing developments on the land might come from the Tule Springs area of Lincoln County. In addition, a new road from Caliente to Mesquite might be built to provide additional land access to these areas. The road would be about 130 kilometers (80 miles) long with a 30-meter (100-foot)-wide construction right-of-way. Coyote Springs Development, LLC, has not yet obtained water rights to provide for full build-out, and this could be a limiting factor for the development.

5.2.1.3.5 Other Regional Economic Development

Cumulative impacts issues associated with regional economic development actions include socioeconomic effects and overall growth in the region of influence. All of the counties and cities in the Caliente rail alignment region of influence have expressed a desire for economic development. The Lincoln County government is preparing for extensive growth (for example, Coyote Springs and population growth through BLM land disposals) with expansion of the county planning department, development of a Strategic Tourism Plan, and refinement of economic development strategies. Examples of Lincoln County economic development include the Meadow Valley Industrial Park and the Alamo Industrial Park (that would use land obtained through a BLM land disposal).

Nye and Esmeralda Counties also are pursuing growth and development opportunities. Economic development plans and tourism enhancement concepts have also been developed in those areas. Pahrump will continue to grow and urbanize with its proximity to Las Vegas. A perceived need for support to the Nevada Test Site has led to designation of the Nevada Science and Technology Corridor by the Economic Development Authority for Nye County. The Science and Technology Corridor extends from Indian Springs in Clark County in the south to Tonopah in the north, passing through the Pahrump Valley, Mercury (entrance to the Nevada Test Site), Amargosa Valley, Beatty and Goldfield, with industrial park and technology initiatives associated with the Tonopah Aeronautics and Technology Park, the Nevada Science and Technology Park in Amargosa Valley, and the Pahrump Center for Technology Training and

Development. The continuing BLM land sales and other development in the area indicate an increasing trend toward and desire for economic development, especially in Lincoln County. The locations and nature of specific future development opportunities are not known and are not considered to be reasonably foreseeable for the purpose of this analysis.

Nye County has completed a Yucca Mountain Project Gateway Area Concept Plan with proposed activities for the area around the entrance to the proposed repository site (DIRS 182345-Giampaoli 2007, all). This plan presents Nye County's conceptual, multi-phased land-use guidance for communities adjacent to and near the site entrance area. Nye County proposed this plan with the objective that land development occurs in an orderly and consistent manner and to increase opportunities for industrial and commercial development beneficial to the repository program. Nye County views this plan as a starting point for development of the infrastructure, institutional capacity, and facilities to support the proposed repository. The county developed the plan to use and manage existing initiatives while expanding and improving the area.

5.2.2 POTENTIAL CUMULATIVE IMPACTS – CALIENTE RAIL ALIGNMENT

Located in portions of Lincoln, Esmeralda, and Nye Counties, the Caliente rail alignment cumulative impacts region of influence covers millions of acres of land, most of which is BLM-administered public land. Most of the land in the Caliente rail alignment region of influence is undeveloped, although much of it has been affected by human activity such as ranching, mining, and recreation.

Potential cumulative impacts are often discussed herein within the context of the existing regulatory framework (primarily federal and state laws and regulations) and the BLM resource management planning goals and objectives. For example, the existing regulatory frameworks for water and air consider a regional and cumulative impacts perspective, in that regulatory decisions consider the potential effects from other projects and a proposed action. As the primary regional land manager, BLM planning and management actions consider the cumulative effects for many resources through stated planning goals and objectives, which often are based on quantitative criteria.

The following analysis of the cumulative impacts associated with the Caliente rail alignment is organized by resource area, with Sections 5.2.2.1 through 5.2.2.15 summarizing potential cumulative impacts in the same order of resource discussions in Chapter 4.

5.2.2.1 Physical Setting

5.2.2.1.1 Disturbance of Physical Resources

Physical resources consist of resources, conditions, and characteristics such as physiography, soils, and geology. As construction of any project in the area occurs, there would be a potential for changes to the physical setting because land would be disturbed through activities such as cuts and fills, and constructing new structures such as buildings and bridges. The proposed railroad would be one of many new sources of change to physical resources that would continue the trend of increasing land disturbance and modifications of the natural physical environment. In large-scale projects that involve substantial ground disturbance, natural features are considered in project design, construction, operations, and potential abandonment plans, which would tend to limit direct, indirect, and cumulative impacts. The proposed railroad would disturb only a small percentage of land in the Caliente rail alignment cumulative impacts region of influence.

Given the large amount of land potentially available for development of existing and reasonably foreseeable projects, and the small percentage of potentially available land required for the proposed railroad, overall cumulative impacts to physical setting in the Caliente rail alignment region of influence would be small.

5.2.2.1.2 Known or Potentially Contaminated Soils

The major sources of existing soil contamination in the Caliente rail alignment region of influence include mining and the Nevada Test Site. Mining activities in the region have occurred for many years, with mining wastes still remaining from older operations before the regulatory framework required waste management and clean-up. Nevada Test Site contamination has been described in recent NEPA documentation (DIRS 101811-DOE 1996, all; DIRS 162638-DOE 2002, all). Historic contamination of soils resources at the Nevada Test Site resulted primarily from radioactive-waste management sites and nuclear testing activities. Environmental restoration and remediation is occurring at contaminated Nevada Test Site locations in accordance with the facility's Environmental Restoration Program. For most of the contaminated soils within the Nevada Test Site boundary, DOE is planning a characterization and long-term monitoring program. Contaminated areas on the Nevada Test Site are generally defined and access is restricted for safety and security reasons. Spills of hazardous materials are possible from the projects described in this section; however, the current regulatory framework to manage and control hazardous materials and wastes ensures that actions are in place to minimize any impacts.

While any potential impacts associated with hazardous materials and wastes from current and future mining operations in the region are controlled through the existing regulatory framework, mining wastes from past mining extraction and processing activities, especially in the Goldfield area, remain a concern related to soil contamination.

The proposed railroad could result in very localized contamination of soils through occasional spills (such as fuel, oil, and solvents). However, such incidents would be minor in scope and quickly mitigated in accordance with plans and regulations. All existing and foreseeable projects would be subject to the same regulations. Cumulative impacts related to contamination of soils would likely be small.

5.2.2.2 Land Use and Ownership

5.2.2.2.1 Land Use Changes

Many of the past, present, and reasonably foreseeable future actions in the Caliente rail alignment region of influence result in land use changes. Changes in land uses can also alter land ownership, land management responsibilities, and preclude future activities from these areas. More than 97 percent of the land the proposed Caliente rail alignment and associated facilities would disturb is on BLM-administered land in Lincoln, Nye, and Esmeralda Counties. The BLM manages more than 55,700 square kilometers (13.7 million acres) in those three counties. One of the primary land uses in and around the proposed Caliente rail alignment on those BLM-administered lands is grazing. Regional grazing activities are often affected by BLM land management plans and activities.

Other existing and reasonably foreseeable major land uses in the Caliente rail alignment region of influence include:

- Yucca Mountain Repository – About 6.3 square kilometers (1,600 acres) of land disturbance, most of which would be on the Nevada Test Site (already withdrawn for Nevada Test Site activities).
- Nevada Test and Training Range – About 12,000 square kilometers (3 million acres) of land the U.S. Air Force has withdrawn for special-purpose use, with about 530 square kilometers (130,000 acres) of that land disturbed by Air Force tactical target complexes and associated infrastructure.

- Nevada Test Site – About 3,200 square kilometers (800,000 acres) of land DOE has withdrawn for special-purpose use (about 4.12 square kilometers [1,020 acres]) of this land would be used by the proposed Yucca Mountain railroad).
- Coyote Springs Development Project – About 170 square kilometers (43,000 acres) of land.
- Lincoln County Land Act of 2000 – Completed disposal of about 53 square kilometers (13,000 acres) of BLM-administered land.
- Lincoln County Conservation, Recreation, and Development Act of 2004 – Approved disposal of up to 360 square kilometers (90,000 acres) of BLM-administered land in Lincoln County (specific locations to be determined as part of the BLM Ely Resource Management Plan process; the Draft Ely Resource Management Plan (DIRS 174518-BLM 2005, all), includes alternatives and assessment for disposal of about 140 square kilometers (34,000 acres), with various linear rights-of-way of about 61 square kilometers (15,000 acres).
- Rights-of-way corridors that may be established when DOE and the BLM complete the Energy Corridor programmatic EIS (70 *FR* 56647, September 28, 2005).

The proposed Caliente rail alignment would disturb up to 165 square kilometers (40,000 acres) of BLM land, most of which would be within the construction right-of-way. Therefore, the proposed Caliente rail alignment would directly affect about 0.3 percent of the BLM-administered land in the three counties. This disturbance would include construction and operation of the proposed rail line, facilities, quarries, water wells, construction camps, and access roads. While the amount of disturbed land would be relatively small compared to the total amount of BLM-administered land, this disturbance could also result in indirect effects beyond the direct disturbance area.

Considering both the proposed railroad and existing and reasonably foreseeable land uses and land ownership, cumulative impacts from land-use changes would be small.

5.2.2.2.2 Existing or Potential Land-Use Conflicts

The Federal Government administers most of this land in the Caliente rail alignment cumulative impacts region of influence, with the BLM, DOE, and the U.S. Air Force acting as the major federal land managers. Private land holdings are small, and generally associated with the towns in the Caliente rail alignment region of influence. Traditional land uses in most of the Caliente rail alignment region of influence that would be directly and indirectly affected include grazing and wildlife management. Much of this land is not extensively disturbed, although it has been modified through activity such as grazing.

Over time, human activity in the area, while relatively minor, has begun to change the natural and traditional conditions, and land-use conflicts occasionally result from this human activity. The Nevada Test Site and Nevada Test and Training Range lands have been withdrawn for special purpose and use. Both of these areas are inaccessible to the general public and land use is that of "dominant use," in which the specific DOE and U.S. Air Force missions, respectively, for these lands have ultimate priority over all other potential land uses. However, around these primary regional land uses are other uses, including mineral development, recreation, urban development, and rights-of-way for various infrastructure. All of these activities and land uses result from a much more intensive land usage involving human activity.

BLM land management goals allow for management of the land for special purposes (protection of cultural resources, wilderness designations or study areas, protection of wildlife habitat, or visual resource management), but with increasing development in the Caliente rail alignment region of influence there are more occurrences of land-use conflicts. As noted in Chapter 4 of this Rail Alignment EIS, construction and operation of a railroad along the Caliente rail alignment would have potential direct and indirect conflicts with grazing uses, access to grazing infrastructure, access to mineral resources, recreational resources, other linear rights-of-way (for example, utility corridors), and wildlife movement patterns in some locations. Potential land-use conflicts resulting from a railroad along the Caliente rail alignment would be similar in scope to some of the other linear rights-of-way proposed in the region of influence (such as water pipelines and transmission lines) but more extensive in scope compared to many of the other projects, which are generally smaller on a linear scale or at a specific location. Even with the existing and reasonably foreseeable land-use changes, the region as a whole would continue its traditional ways, with grazing and wildlife habitat as major land uses, and cumulative impacts related to land-use conflicts would be small.

5.2.2.2.3 Energy and Mineral Development

Existing and potential future energy and mineral development occurs in various locations throughout the Caliente rail alignment cumulative impacts region of influence. In addition to the traditional energy and mineral development (primarily hard-rock mining, industrial mineral development, and limited oil and gas development), more recently, this development includes geothermal resources and wind energy. The BLM administers energy and mineral development on public lands. Today's energy development environment includes a mix of old and new, involving both non-renewable and renewable resource development. Wind-energy development on the BLM-administered lands could be one of the biggest changes in the future landscape, because wind-energy opportunities are growing and the BLM-administered land is valued for possible wind-energy locations. Depending on the number and size of each new proposed wind-energy site, land requirements for development of this resource could be substantial.

Because of the scope and extent of typical mining operations, mineral resources that become actual operating mines could result in environmental and land-use issues. Within the Caliente rail alignment region of influence, most mining and energy-development activities would occur on federal lands, and the BLM will have a major role in mitigating and monitoring potential effects through its mining and reclamation requirements, NEPA, and other elements of the regulatory framework. Mineral exploration will continue to occur in many parts of the Caliente rail alignment region of influence, and some level of conflict from mining exploration and development with other land uses could be unavoidable.

Any potential conflict of the proposed railroad with energy and mineral development would be small in scope and occur in localized areas, and the effects of any such conflicts would be mitigated through the existing regulatory framework and BLM policies and plans. All existing and foreseeable projects would be subject to regulatory requirements and BLM policies and plans related to energy and mineral development. Therefore, cumulative impacts resulting in land-use conflicts related to energy and mineral development along the Caliente rail alignment would be small.

5.2.2.2.4 BLM Land Sales and Other Disposals

The BLM has identified a number of land parcels in the Caliente rail alignment region of influence that have been or will be removed from government ownership and disposed of through auctions or agreements with local governments. These BLM land disposals will continue, and will either directly or indirectly, enhance the potential for growth and urbanization in the Caliente rail alignment region of influence, as the land is changed from generally undeveloped to private lands available for residential or other development, or to government lands available for utility corridors, airports, or parks.

In many cases, these BLM land disposals would result in permanent land-use changes. With private land at a premium in the area, private-sector developer interest in the BLM land disposals will likely continue. These changes in land use could cause increasing urbanization and economic development in the Caliente rail alignment cumulative impacts region of influence.

While the proposed railroad would operate within the regional context of BLM land disposal efforts and any related implications and effects, it would have no affect on, nor would it be affected by, BLM land disposal efforts.

5.2.2.2.5 Recreational Land Use

Public lands in the Caliente rail alignment region of influence provide a number of diverse recreation opportunities, and the BLM has designated certain lands as recreation management areas. Demand for recreation is increasing as more people move to and recreate in the Caliente rail alignment cumulative impacts region of influence. Dispersed recreation, the principal opportunities available within the Caliente rail alignment region of influence, requires a variety of sites but needs no special facilities. These opportunities include caving, photography, automobile touring, backpacking, bird watching, hunting, primitive camping, hiking, rock climbing, and competitive and non-competitive off-highway vehicle events. Water-based recreation in the Caliente rail alignment region of influence is extremely limited. Increased demand for off-highway vehicle use from the increasing regional population, including the Las Vegas area, has been noted and is expected to continue. Many areas of BLM-administered land in Clark County previously used for off-highway vehicle recreation have been closed, causing a shift in use into the BLM Ely District. As growth and development occur in the Caliente rail alignment cumulative impacts region of influence, recreational resources will continue to be in demand, but the potential for conflict with recreational resources also will increase. Recreational resource locations, quality, and availability will evolve as the Caliente rail alignment region of influence changes.

The Lincoln County Conservation, Recreation, and Development Act of 2004 (Public Law 108-424) included such recreation initiatives as the designation of wilderness areas and the Silver State Off-Highway Vehicle Trail. Table 5-3 lists the wilderness designations, and the amount of land designated as wilderness area in Lincoln County. The wilderness-area designations provide wilderness characteristics such as solitude, primitive conditions, and unconfined recreation in these areas. DOE has sited the proposed Caliente rail alignment to avoid wilderness areas.

Table 5-3. Lincoln County wilderness designations from Public Law 108-424.

Wilderness Area	Designated as wilderness (square kilometers)[a]
Weepah Springs	210
Worthington Mountains	130
Big Rock	57
Mt. Irish	130
South Pahroc Range	100

a. To convert square kilometers to square miles, multiply by 0.38610.

The BLM has a major role in recreation opportunities in the Caliente rail alignment region of influence. BLM field offices are evaluating opportunities for new Areas of Critical Environmental Concern and Special Recreation Management Areas that would provide both passively and actively managed recreation opportunities. There are substantial management efforts to focus off-highway recreation opportunities to appropriate designated areas. For example, the Silver State Off-Highway-Vehicle Trail is a 420-kilometer (260-mile) combination of existing backcountry roads that are currently open and being used by off-highway vehicle enthusiasts. The Lincoln County Conservation, Recreation, and Development Act of 2004 provided for the creation of a Silver State Trail Management Plan to minimize impacts on natural resources and to protect cultural and archaeological resources. The Act also provides for the temporary closure of the Trail in the event that there are unintended adverse impacts on resources associated with the Trail. The proposed Caliente rail alignment would intersect the Silver State Off-Highway-Vehicle Trail in three places; however, the BLM and DOE could effectively manage those intersections.

Cumulative impacts to access to and use of recreational resources along the Caliente rail alignment would be small.

5.2.2.2.6 BLM Rights-of-Way

As urbanization and other development occurs in the Caliente rail alignment region of influence, the need for utility and other rights-of-way will increase. This has already begun to occur and will likely continue in the future in various parts of the Caliente rail alignment cumulative impacts region of influence. The BLM has developed certain preferred corridors over federal lands that it uses to the maximum extent possible for linear rights-of-way, such as for utilities. This keeps many right-of-way purposes together in one location instead of spreading them out over more dispersed areas. However, the BLM also acknowledges the need for exceptions to these standard rights-of-way locations. *Approved Caliente Management Framework Plan Amendment and Record of Decision for the Management of the Desert Tortoise* (DIRS 174200-BLM 2000, p. 27) states that the BLM would "[g]rant power distribution lines 69 kilovolt or less, local telephone, water distribution pipelines and facilities, local fiber optic loops and cable lines outside of designated corridors on a case-by-case basis." Proposed other future projects involving pipelines, railroads, transmission lines, etc., would all change land uses along a linear route if approved through the BLM right-of-way approval process. The BLM also has seen increasing demand for nonlinear rights-of-way, and will continue to grant rights-of-way for these nonlinear projects such as power plants, construction camps, and communication-tower sites.

The land use changes authorized by a BLM right-of-way grant would also have the potential to impact other resource areas as those land-use changes occur. Before approval of right-of-way applications, the BLM will evaluate the impacts of the projects through appropriate NEPA evaluation. Use of land for right-of-way purposes is consistent with BLM regulations and planning processes, and any land-use changes or disturbances associated with those rights-of-way are mitigated to the extent possible and according to BLM policies. As required for the issuance of rights-of-way, the project proponent would prepare and submit to the BLM a Plan of Development for each proposed right-of-way. The Plan of Development would describe the methods and procedures to be used to construct the proposed action on the right-of-way, including site-specific stipulations, terms, and conditions to satisfy all BLM requirements. Certain rights-of-way are long-term in nature and result in unavoidable impacts through land disturbance and the exclusion of other land uses now or in the future.

Utility and other right-of-way crossings are common to linear projects such as roads, railroads, and pipelines. Land areas for the Caliente rail alignment, construction camps, quarries, and access roads would cross or overlap up to 34 existing or proposed utility rights-of-way. Land areas for the proposed railroad facilities could also overlap existing or proposed utility rights-of-way. This situation would be typical for other linear rights-of-way. The crossings would be accomplished with small impact using standard engineering procedures and appropriate design details.

Cumulative impacts to BLM rights-of-way and right-of-way holders would be small.

5.2.2.2.7 Other BLM Land-Management Actions

The Federal Land Policy Management Act of 1976 (Public Law 94-579) mandates the BLM to manage its public lands from a multiple-use perspective. The Federal Land Policy Management Act specifically mentions balancing renewable and non-renewable resources, including but not limited to recreation, range, timber, minerals, watershed, wildlife, fish, natural, scenic, scientific, and historic values. Therefore, the BLM mission to manage the lands to meet multiple-use objectives is challenging, because many of the resources and associated values often conflict.

Within the context of the Caliente rail alignment cumulative impacts region of influence, the BLM planning process and management goals and objectives within their plans are key determinants of the compatibility of the proposed Caliente rail alignment with other projects in the Caliente rail alignment region of influence. Because the BLM is and will remain the major land manager in and around the Caliente rail alignment region of influence, BLM land-management goals, objectives, and subsequent land-management actions will largely determine if and how new projects and activities occur.

BLM objectives and goals within the resource management plans can serve to encourage or restrict activities in certain locations. Areas needing special management attention (such as Areas of Critical Environmental Concern) are also identified in the planning process to protect and prevent irreparable damage to important historical, cultural, or scenic values, fish and wildlife resources, or other natural systems or processes, or to protect life and safety from natural hazards. Multiple-use management goals and objectives become more challenging as cumulative development and land-use changes encroach on open land in the Caliente rail alignment region of influence.

The proposed Caliente rail alignment would cross several BLM planning areas. The Las Vegas and Tonopah Resource Management Plans and the Schell and Caliente Management Framework Plans (within the Ely planning district) would be applicable to the proposed location of the Caliente rail alignment. The Ely BLM Field Office is currently preparing an updated Resource Management Plan, which would replace the Schell and Caliente Management Framework Plans when formally adopted. When finalized, the Ely District Resource Management Plan will serve as the initial effort to implement the Eastern Nevada Landscape Restoration Project, which is eastern Nevada's regional program to put into practice the national BLM priority to revitalize the ecological condition of the Great Basin through the Great Basin Restoration Initiative.

These programs and resource management plans require a number of public and private partnerships and a collaborative approach to land management and planning. Grazing operations are a major BLM land-management program in the Caliente rail alignment region of influence. Grazing results in both direct and indirect cumulative impacts to vegetation, habitats, and wildlife in the Caliente rail alignment region of influence. The environmental impacts associated with grazing operations are a function of the location, timing, intensity, duration, and frequency of grazing. Grazing animals directly affect plant communities through trampling and nutrient redistribution. The most noticeable impacts occur around waters, salt blocks, fence lines, and other areas where animals concentrate. With proper grazing management, these concentration areas are limited in extent and mitigated regularly through management procedures such as movement of salt blocks and water hauls. While grazing can stimulate growth of some plants and provide other benefits, it can also reduce plant abundance, density, and vigor, especially in sandy soils.

Ultimately, BLM land management efforts and content of the resource management plans will play a major role in the magnitude, location, and extent of direct, indirect, and cumulative impacts in the Caliente rail alignment region of influence, and in the relative balance among multiple uses and resource values chosen for the public lands. DOE recognizes the importance of these land management actions and encourages readers to review specific resource management plans for more detailed information.

5.2.2.2.8 Urbanization and Economic Development Initiatives

Even without the increased urbanization and economic development caused by the BLM land disposals or expansion of the Las Vegas metropolitan complex northward into the Caliente rail alignment cumulative impacts region of influence, the urbanized areas in the Caliente rail alignment region of influence have generally planned for and solicited ways to grow and increase urbanization. Concepts such as industrial-park development, airport expansion, increased retail opportunities, and housing are prominent goals of the public and private sectors in the Caliente rail alignment region of influence.

The Coyote Springs development and the Toquop Township (24 kilometers [15 miles] northwest of Mesquite in southern Lincoln County) are examples of major potential community development sites. The Coyote Springs development has entered its initial development phase and is planned to include a full suite of homes, zoning regulations, services, and infrastructure in direct association with the BLM land sales of the 53 square kilometers (13,000 acres) of public land resulting from the Lincoln County Land Act of 2000. This trend is likely to continue, with land-use and ownership changes and potential land-use conflicts becoming an increasing issue and challenge for the future.

With or without the proposed railroad, urbanization and economic development activities, while increasing, would not generally change the overall undeveloped character of the Caliente rail alignment region of influence.

5.2.2.3 Aesthetic Resources

Cumulative impacts to aesthetic resources from the proposed railroad and other regional activities would primarily result from modifications to natural ***viewsheds***. The natural setting of the Caliente rail alignment region of influence includes vast and expansive viewsheds typical of much of the western United States. The open spaces and wide vistas offer interesting cloud, weather, and landscape interactions. Human activity disturbs the natural viewsheds with land disturbances such as buildings, roads, removal of vegetation, power lines, equipment, and vehicles. Any activity that disturbs substantial areas of land can result in visual impacts from fugitive dust and ground scars. Additionally, most man-made structures are designed and built for their functionality and safety, not for their visual appeal. For example, projects with construction-related equipment, facilities, and activities can include the presence of workers, camps, vehicles, machinery, lay-down yards, and dust.

The presence of the railroad would be an identifiable change to the regional viewsheds from some observation points and provide a noticeable contrast with natural visual attributes. The passage of a train would attract the attention of an observer, both because of the noise associated with the train and the change in the landscape, especially if the train were to fall in the foreground or middle ground of the viewshed. Visual impacts of passing trains would be temporary, but visual impacts of the track would be long-term.

Visual resources within the region of influence have been considered through application of the BLM Visual Resource Management System (see Sections 3.2.3 and 4.2.3 and Appendix D of this Rail Alignment EIS). This system identifies and classifies the BLM-administered lands within established visual resource objectives, and proposed activities are evaluated within the visual resource management framework to consider consistency with the visual resource objectives. Without restoration and reclamation efforts, ground disturbances in the regional environment would last for long periods. The magnitude and extent of potential visual impacts vary based on the number of viewers affected, distance and atmospheric conditions of viewing, degree of visual contrast compared to existing visual attributes, viewer sensitivity to the visual changes, and compatibility with existing land uses. BLM generally requires ground disturbances to be restored and reclaimed as part of project approval.

For the Caliente rail alignment, analysis using the BLM Visual Resource Management System indicated that the proposed railroad could be inconsistent with visual resource management objectives in the areas of the Caliente-Indian Cove Staging Yard during construction, in Garden Valley during railroad construction and operations, and in some other sites of rock cuts and fills during construction and operations. As shown in Appendix D, lands that have potential restrictive visual resource objectives (Classes I and II) are not prevalent in the region of influence.

There would be no known interactions of the proposed railroad with other reasonably foreseeable activities that would affect a Class I or Class II area in the Caliente region of influence.

5.2.2.4 Air Quality and Climate

Emissions of concern in the Caliente rail alignment region of influence include ***fugitive dust*** and emissions resulting from the operation of machinery and equipment. Construction activities such as surface disturbance and use of haul trucks in the Caliente rail alignment region of influence would generate fugitive dust. Fugitive dust is a type of nonpoint source air pollution (small airborne particles that do not originate from a specific point). These ***particulate matter*** emissions are regulated according to their size (aerodynamic diameter equal to or less than 2.5 micrometers [$PM_{2.5}$] and 10 micrometers or less [PM_{10}]). Fugitive dust is generally controlled through the application of water, or in some cases, application of a chemical compound designed to minimize dust emissions. Most of the projects and activities identified in this analysis would generate some level of fugitive dust. The plumes associated with fugitive dust generation are often localized to the area being disturbed and are temporary. In arid areas such as the Caliente rail alignment cumulative impacts region of influence, generation and control of fugitive dust will always be a concern. Exhaust emissions from the operation of machinery and equipment include sulfur dioxide, oxides of nitrogen, volatile organic compounds, and carbon monoxide.

There is a comprehensive air quality permitting system in Nevada to evaluate and approve only those projects that are allowable within quantitative air quality thresholds. The Nevada Division of Environmental Control, Bureau of Air Pollution Control, has established and implemented air pollution control requirements in Nevada Revised Statutes 445B.100 through 445B.825, inclusive, and Nevada Revised Statutes 486A.010 through 486A.180, inclusive. The Bureau of Air Pollution Control has jurisdiction over air quality programs in all counties in the state except Washoe and Clark. The Bureau of Air Pollution Control also has jurisdiction over all fossil fuel-fired units in the state that generate steam for electrical production. The Caliente rail alignment would be subject to the permitting requirements noted above, and would occur in air basins that are either in attainment or unclassifiable. The State of Nevada will not grant permits for activities that cannot show compliance with the applicable federal and state regulations will not be permitted.

The air quality impact analysis for the Caliente rail alignment assessed potential impacts through several means including air quality modeling of maximum concentrations relevant to National Ambient Air Quality Standards. The analysis concluded that emissions during construction or operation of the rail line or any associated facilities would be in conformance with applicable standards with the possible exception of the 24-hour National Ambient Air Quality Standards for PM_{10}, which could be exceeded from quarry operations at South Reveille Valley during the construction phase. DOE would be required to prepare an application for a Dust Control Permit and a Surface Area Disturbance Permit Dust Control Plan and submit them to the Nevada Division of Environmental Protection Bureau of Air Pollution Control prior to quarry development. It is likely that the requirements of the plan would greatly reduce fugitive dust particulate matter emissions, thus reducing the possibility of exceeding National Ambient Air Quality Standards.

Potential cumulative impacts to air quality from construction and operation of the proposed railroad along the Caliente rail alignment would be small, but could approach moderate if the potential violation of the National Ambient Air Quality Standards noted above occurred.

5.2.2.5 Surface-Water Resources

5.2.2.5.1 Changes in Drainage, Infiltration Rates, and Flood Control

Construction of major projects in previously undeveloped areas often results in changes to natural drainage. Construction could include regrading that would allow runoff from a number of minor drainage channels to collect in a single culvert or pass under a single bridge, which would result in water flowing from a single location on the downstream side rather than across a broader area. This would cause some localized changes in drainage patterns, but this probably would occur only in areas where natural drainage channels are small. Compaction of soil during construction could reduce water infiltration rates and change natural runoff and drainage patterns. However, some activities would disturb and loosen the ground for some time, which could cause higher infiltration rates.

Construction in washes or other flood-prone areas probably would reduce the area through which floodwaters naturally flow. This could result in water building up, or ponding, on the upstream side of crossings during flood events, and then slowly draining through the culverts or bridges. These alterations to natural drainage, sedimentation, and erosion would be unlikely to increase future flood damage, increase the impact of floods on human health and safety, or cause significant harm to the natural and beneficial values of the floodplains.

One special area of drainage/flooding concern, however, involves the Meadow Valley Wash area near the City of Caliente. The Caliente alternative segment would start next to Meadow Valley Wash in an area where the wash is joined by Clover Creek, and travel up Meadow Valley alternatively running adjacent to, or crossing the wash. The Federal Emergency Management Agency has studied Meadow Valley Wash, Antelope Canyon Wash, and Clover Creek Wash for flooding potential within the corporate limits of the City of Caliente and for some portions of Lincoln County. One-hundred-year water surface elevations and regulatory floodways have been established for these watercourses within the area studied. Encroachment into the floodway is prohibited unless it can be determined that such an encroachment into the floodway portion of the floodplain does not cause any increase in the water surface elevations for these watercourses. The area has a history of flooding events that can affect the roads, trails, and Union Pacific rail lines. In January 2005, a substantial flooding event occurred in the Meadow Valley Wash area. The BLM is currently involved in a multi-agency evaluation of remedial actions to avoid drainage/flooding issues in the area. The presence of the proposed railroad in this area has raised concerns about the potential interaction of railroad operations with future flooding events; these concerns and issues are currently being evaluated through the multi-agency evaluation and appropriate measures to reduce direct, indirect, or cumulative impacts would be identified through that process.

Overall effects would generally be localized to each specific project, and these concerns and potential impacts are factored into project design considerations as standard engineering and construction operating procedures. While cumulative impacts would be small, the risks and localized impacts from a flood event such as that experienced in the Meadow Valley Wash area in 2005 cannot be totally eliminated.

As a long linear project of up to 541 kilometers (336 miles) long (DIRS 180916-Nevada Rail Partners 2007, Table E-2), a rail line along the Caliente rail alignment would pose new surface drainage challenges because of the existing characteristics of terrain, topography, soils, and physical features. Construction activities that could temporarily block surface drainage channels include moving large amounts of soil and rock to develop the rail roadbed (subgrade) and constructing temporary access roads to reach construction initiation points and major structures, such as bridges, and to allow movement of equipment to the construction initiation points.

Project planning and best management practices would help avoid or reduce potential impacts from the proposed railroad or other ongoing or reasonably foreseeable future actions. Potential cumulative impacts due to changes in drainage, infiltration rates, and flood control would be very small and localized.

5.2.2.5.2 Spill and Contamination Potential

Major construction activities and other projects in the region of influence would use materials including petroleum products (fuels and lubricants) and coolants (antifreeze) necessary to operate construction equipment, and could include solvents used in cleaning or degreasing actions. A release or spill of contaminants to a stream or river would have the greatest potential for adverse environmental impacts; a release of contaminants to dry impermeable soil would have the least potential for adverse impacts. Spill-control and management plans (and standard operating procedures for the construction industry) would reduce the likelihood of spills. Railroad construction and operation along the Caliente rail alignment would be typical of major activities that use materials that could cause contamination through spills.

While the risk of a spill and associated water contamination cannot be totally eliminated, risks can be managed through regulatory controls so that the resulting cumulative impacts would be small.

5.2.2.6 Groundwater Resources

Increasing urbanization and other development in the Caliente region of influence presents the challenge of matching water supply with water demand. Because water availability is a potential resource constraint in the Caliente rail alignment region of influence over time, water demand can be both competitive among potential users and controversial among users and the general public. To allocate water uses, the State of Nevada uses a water permit application process coordinated by the State Engineer. Once granted, water rights in Nevada have the standing of both real and personal property. It is possible to buy or sell water rights and change the water's point of diversion, manner of use, and place of use by filing the appropriate application with the State Engineer. Overall, because the water permitting and allocation process considers the broad range of factors noted above, the process serves as a way to manage potential cumulative impacts of water demand and use within each basin.

Representative existing and reasonably foreseeable water users in the Caliente rail alignment region of influence include:

- Agriculture, which consumes the most water in the Caliente rail alignment region of influence. Based on groundwater usage data compiled by the U.S. Geological Survey, during calendar year 2000, approximately 46 percent of groundwater withdrawals in the State of Nevada were for irrigation, about 26 percent were for mining purposes, and the remainder were for drinking-water systems, geothermal production, and other uses.
- The Toquop power plant, the FEIS for which (DIRS 174208-BLM 2003, all) estimates future water needs associated with a portion of recent BLM land dispositions and the Coyote Springs residential development (at build out) to be roughly 140 million cubic meters (115,000 acre-feet) per year.
- The Clark, Lincoln, and White Pine Groundwater Development Project (Southern Nevada Water Authority) (DIRS 175909-Hafen et al. 2003, all), which would result in water withdrawal and transfer of up to 250 million cubic meters (200,000 acre-feet) per year.
- The combined effects of the Lincoln County Land Act Groundwater Development Project and the Kane Springs Valley Groundwater Development Project (DIRS 175909-Hafen et al. 2003, all), which would produce more than 35 million cubic meters (28,000 acre-feet) of water per year for conveyance to other locations.

- Groundwater withdrawals, which if approved, would be associated with the specific water-rights applications that have been submitted for proposed new municipal or irrigation wells in hydrographic areas 181, 208, and 172 (see Section 5.2.1.3.2).
- Recently constructed or planned power plants (water-cooled) in the Apex and Moapa areas, which require about 8 million to 9 million cubic meters (6,500 to 7,000 acre-feet) of water per year. The air-cooled power plants in those areas require less than 123,000 cubic meters (100 acre-feet) of water per year.
- The Nevada Test Site, which uses about 830,000 cubic meters (673 acre-feet) of water per year.
- Grazing activity in the 38 allotments around the proposed Caliente rail alignment, which demands about 600,000 cubic meters (500 acre-feet) of water per year.
- The Yucca Mountain Repository, which would have demands ranging from about 218,000 to 527,000 cubic meters (176 to 427 acre-feet) of water per year between calendar years 2010 and 2013 (this represents the period of the highest water demand for the proposed railroad project). The Repository would use approximately 76,700 to 397,000 cubic meters (62 to 322 acre-feet) of water per year in calendar year 2014 through completion of operation.

Excluding the large agricultural water use in the Caliente rail alignment region of influence, cumulative water use for the projects described above could total more than 430 million cubic meters (350,000 acre-feet) per year. Overall, the share of water that would be committed to construction and operation of the proposed railroad would represent a small portion of water use in the Caliente rail alignment region of influence, which would still be dominated by agriculture. Committed groundwater resources already exceed annual perennial yield values (a measure of available groundwater supply replenished each year through recharge) within some of the groundwater basins (hydrographic areas) that would be affected by the proposed railroad. Based on the proposed locations of new wells in specific hydrographic areas along the Caliente rail alignment, additional groundwater appropriations would be needed in 19 hydrographic areas. However, committed (cumulative) groundwater resources currently exceed estimated perennial yields in eight of these hydrographic areas (146, 149, 170, 173A, 203, 204, 228, and 229). One of these eight hydrographic areas (229) and two other hydrographic areas (144 and 145) the rail would cross have low perennial yields. Five of these areas are State of Nevada-designated groundwater basins. While designated groundwater basins are not considered closed to additional appropriations, the State Engineer could impose additional restrictions and preferred uses of the water in these designated basins.

A number of scenarios have been developed to assess the potential effects of the proposed Caliente rail alignment's contribution to cumulative water demand in the Caliente rail alignment cumulative impacts region of influence. The assumption used for developing these scenarios is that proposed railroad construction and operation and associated quarry and rail facility construction and operation water demands would be met through installing and withdrawing groundwater from new wells. Pumping in individual wells would occur primarily over 9 months to support construction, over 2 to 3 years at quarry sites, and over the rail system operational period for the rail facilities. Total water withdrawals associated with the proposed railroad could substantially exceed annual perennial yield values for hydrographic areas 145 and 229, and could represent approximately 99 percent of the annual perennial yield in hydrographic area 227A. In other areas, water withdrawals associated with the railroad could range from less than 1 percent to as high as 57 percent of the annual perennial yield value.

A proposed new irrigation well in Dry Lake Valley would have an average pumping rate of approximately 17,000 liters (4,488 gallons) per minute and the would operate year round This application is currently under protest. If this well application were to be approved and the well installed and used contemporaneously with a nearby proposed well location (location DLV3), analysis results indicate that the proposed new DLV3 well location would lie within the radius of influence of this irrigation well and the DLV3 well location would therefore not be viable. In that event, DOE could obtain the water required from one or more alternative proposed well locations from which the simultaneous pumping from that well location or locations and the proposed municipal well would not impact each other's operation, water could be obtained from an existing water rights holder, or one or more other best management practices could be implemented to preclude cumulative impacts from occurring.

The proposed new municipal well that would be northeast of a DOE-proposed new well location (PahV9) in Pahroc Valley would have an average pumping rate of up to 10,200 liters (2,690 gallons) per minute, and would operate year round. If this municipal well application were to be approved and the well installed and used contemporaneously with the DOE-proposed well(s) at location PahV9, analysis results indicate that, depending on the transmissivity (hydraulic conductivity) of the host consolidated rock unit aquifers involved, withdrawal of groundwater at a rate of up to approximately 920 liters (244 gallons) per minute from an equivalent single well at the PahV9 could either not, or might, impact pumping operations at the proposed new municipal well location, and vice versa. The 920-liter-per-minute pumping rate used in the analysis comprises the total withdrawal rate required for well locations PahV7, PahV8, and PahV9 combined and, therefore, represents a very conservative assumption. If hydraulic conductivities of the host aquifers are similar to values estimated in some published reports (such as DIRS 176852-Drici et al. 1993, p. 56), the proposed municipal well and the DOE-proposed well(s) at location PahV9 would not be expected to impact each other's operations if the two well locations were to be pumped simultaneously and the average pumping rate at location PahV9 were as high as 924 liters (244 gallons) per minute. Alternatively, if host aquifer hydraulic conductivity values were lower, if necessary, the average pumping rate imposed at location PahV9 could be restricted to a sufficiently low value (with the remainder of the required water acquired from locations PahV7 and/or PahV8), some of the required amount of water could be obtained from an existing water rights holder, if needed, or one or more other best management practices could be implemented to preclude potential impacts resulting from simultaneous groundwater withdrawals from the PahV9 location and the proposed new municipal well location.

Water rights applications have been submitted for two proposed municipal wells that would be approximately 1.5 kilometers (0.9 mile) northeast of, and approximately 1 kilometer (0.6 mile) northeast of, two DOE-proposed new well locations in hydrographic area 208, respectively. These water rights have not yet been granted and given the relatively long timeframes (20 years) estimated for completing the infrastructure components required for these wells, even if the applications were approved, these wells would likely be placed into use at a time beyond the proposed railroad projected 4- to 10-year construction phase. Therefore, DOE did not evaluate potential cumulative impacts from these proposed future municipal supply wells.

A water rights application has been submitted for a proposed municipal well that would be approximately 1.2 kilometers (0.8 mile) southwest of a DOE-proposed new well location (GV10) in Garden Valley (hydrographic area 172). At present, the Nevada Department of Water Resources lists the status of this well as "Ready for Action." The well has an estimated time to construct of 10 years. If this well application were to be approved and the well installed and used contemporaneously with the DOE-proposed GV10 well(s), the GV10 well location would lie within the radius of influence of this municipal well; therefore, the GV10 well location would not be viable. In that event, the Department could (1) obtain the required water from one or more alternative DOE-proposed wells from which the simultaneous pumping from that well(s) and the proposed municipal well would not impact each other's operation; (2) obtain water from an existing water rights holder; or (3) or implement one or more other best management practices to preclude cumulative impacts.

By utilizing one or more specific approaches or a combination of approaches for obtaining groundwater for construction of the proposed railroad (including approaches that are tailored to a hydrographic area's unique groundwater conditions), potential cumulative impacts to groundwater resources would be minimized. New groundwater withdrawals could, depending on the withdrawal rate; the hydrogeologic conditions present at the proposed pumping location and in the surrounding area; and the location and characteristics of nearby groundwater resource features, cause some decrease in the amount of water that might be available to an existing well having an associated water right, to an existing spring discharge, or to a downgradient groundwater basin.

Overall, the needs of the proposed railroad would represent a small portion of the current cumulative water usage within the Caliente rail alignment region of influence, which in some locations would continue to exceed perennial yield values.

5.2.2.7 Biological Resources

5.2.2.7.1 Habitat Loss and Fragmentation

The past, present, and reasonably foreseeable future actions in the Caliente rail alignment cumulative impacts region of influence would result in noticeable cumulative land disturbance. Existing activities such as the Nevada Test and Training Range and the Nevada Test Site have already resulted in land disturbance, and projects such as the various proposed rights-of-way and the Coyote Springs development would continue this trend. Such land disturbances result in altered natural biological and ecological conditions, and directly serve to reduce the amount of natural land available as habitat and open space.

The primary adverse construction-related impacts to vegetation communities from ground disturbance are the physical destruction or removal of the vegetation, and the permanent or temporary removal or compaction of the topsoil or other growing medium for the plants. These effects would occur with any major activity resulting in ground disturbance, including the proposed railroad. As more activity occurs, the cumulative loss of vegetative communities and associated habitats would increase. Management of these effects would typically be considered in project planning and mitigation, including projects on BLM-administered land. Much of the emphasis in land management in the Caliente rail alignment region of influence concerns the maintenance or reconstruction of healthy habitats.

Habitat destruction leads to direct impacts such as wildlife injury and mortality, alteration of behavior and movement patterns, and the indirect impacts of reduced vegetative health, reduced biological diversity, and locally degraded ecological function. When extensive habitat fragmentation occurs, the individuals or populations of particular species may have difficulty surviving. Habitat destruction arises from a number of sources, including projects that involve land disturbance, land management actions including wild horse and burro management. Though any project that causes disturbance of vegetation contributes to habitat fragmentation, linear projects that impose any degree of impediment to movements, like the proposed railroad, amplify the potential effects. A number of utility and water rights-of-way are anticipated in the eastern portion of the proposed Caliente rail alignment, with many of these crossing the Caliente rail alignment.

Measures to avoid, minimize or otherwise reduce impacts are typically implemented by project proponents and encouraged by government agencies and generally include actions to reduce or avoid habitat fragmentation and loss. Such actions would include minimizing land disturbance, using existing roads, interim reclamation, combined roads/utility rights-of-way for pipelines and cables, noise reduction, centralization of facilities, and employee training and education.

In areas proposed for railroad operational purposes, the impacts to vegetation would typically be moderate in scope, and cumulatively add to habitat loss and fragmentation. However, in areas slated for short-term use during construction, such as construction camps, revegetation and reclamation efforts would result in replacement of topsoil, reseeding of native species, monitoring for success, and eventual return of a native vegetation community somewhat comparable to predisturbance conditions.

Cumulative impacts due to habitat loss and fragmentation would be small to moderate through the construction and operations phases throughout the Caliente rail alignment region of influence.

5.2.2.7.2 Invasive Species and Noxious Weeds

Invasive species and noxious weeds naturally move into new areas over time, but this occurrence has been accelerated in many areas through human activity, either intentionally or by accident. In many cases these plants have been moved into North America from another continent. They have been accidentally introduced through contaminated grain or hay, or sometimes intentionally introduced for erosion control or as ornamentals. In addition, livestock and vehicles can cause invasive species and noxious weeds to spread, birds could carry seed, or the species can be brought in with contaminated fill dirt. Regardless of how they were introduced, invasive species and noxious weeds possess characteristics that allow them to compete aggressively with native vegetation. Invasive species and noxious weeds impact native plants, animals, and natural ecosystems by:

- Reducing biodiversity
- Altering hydrologic conditions
- Altering soil characteristics
- Altering fire intensity and frequency
- Interfering with natural succession
- Competing for pollinators
- Displacing rare plant species
- Replacing complex communities with single-species monocultures

From a cumulative impacts perspective, any time land is disturbed and native vegetation is lost there is an opportunity for noxious weeds to replace the native vegetation. While the BLM and other land owners/managers in the area have implemented programs to minimize this potential, invasion of noxious weeds cannot always be prevented. Therefore, coordinated multi-agency management actions and efforts are needed to mitigate the effects from cumulative land disturbance. Management of noxious and invasive weeds is essential for restoration of native plant community health and resiliency. If noxious and invasive weeds were not managed, they would continue to gradually replace more desirable native species throughout the Caliente rail alignment region of influence.

Linear disturbances such as pipelines, roads, utility corridors, or rail alignments that cross relatively undisturbed land have the potential to exacerbate the spread of these species into areas not previously affected. As the invasive or noxious weeds become established along the linear features they spread to adjacent areas, affecting the plant and animal communities beyond the actual disturbance, and are able to out-compete native species by responding more rapidly to the infrequent availability of water.

These impacts could occur as a result of railroad construction and operation and from existing or foreseeable projects, but strict adherence to best management practices would reduce the potential for impacts. Cumulative impacts due to the introduction and spread of invasive species and noxious weeds would be small.

5.2.2.7.3 Special-Status Species

Habitat for several special-status species would be disturbed and individuals of several of the species could be killed or injured during construction and operation of the proposed Caliente rail alignment. Implementation of best management practices, making minor adjustments to site locations during final design, and conducting pre-construction clearance surveys would substantially reduce these potential impacts. Through the NEPA and permitting processes, each proposed project and land management planning effort in the Caliente rail alignment region of influence will face challenges for the protection of various special-status species. There are a number of special-status species that could be affected by cumulative impacts in the Caliente rail alignment region of influence. Recent attention has focused on several specific species, including the desert tortoise and greater sage grouse, as discussed below.

The Mojave population of the desert tortoise (*Gopherus agassizii*) is listed as threatened under the Endangered Species Act of 1973 (16 U.S.C. 1531 to 1544). It is found within the proposed Caliente rail alignment only in the southwestern-most 48 kilometers (30 miles), from the Beatty Wash area to Yucca Mountain (DIRS 101830-Bury et al. 1994, pp. 55 to 72). The desert tortoise is found in southern California, parts of southern Utah, and in the southern portions of Nevada, with the tortoises potentially affected by railroad construction and operation at the extreme northern extent of their range. While relative abundance of the tortoise is low in much of the Caliente rail alignment region of influence, every action that could disturb soil or vegetation within the tortoise's range has potential cumulative impacts of loss or fragmentation of the species' habitat or the direct mortality of individual desert tortoises,

The BLM resource management plans sometimes place restrictions on other activities (such as grazing, wild horse and burro abundance, off-road vehicle use, mineral activities) so that desert tortoise or other special status species habitat can be protected. However, off-road vehicle use, shooting, and collecting of individuals continue to affect tortoise populations. Habitat protection efforts for the desert tortoise are coordinated among a number of federal, state, and local governmental agencies, with the cumulative impact perspective a major factor in determining allowable impacts to the tortoise. Restoration plans and habitat conservation plans also affect the required mitigation measures, best management practices, and standard operating procedures for the protection of the desert tortoise or other special-status species.

In early 2005, the U.S. Fish and Wildlife Service completed its status review of the greater sage-grouse (*Centrocercus urophasianus*) throughout its range and determined that the species does not warrant protection under the Endangered Species Act at this time. The BLM would maintain habitats used by the greater sage-grouse in consideration of the priorities identified in the BLM National Sage-Grouse Conservation Strategy. This strategy considers that the greater sage-grouse has been substantially affected throughout the Great Basin by habitat loss due to residential development and the associated infrastructure; habitat degradation from heavy grazing, drought, and invasive and noxious weeds; habitat fragmentation from development of roads and other rights-of-way; and other activities throughout the Caliente rail alignment region of influence. A number of projects within the Caliente rail alignment region of influence, including the potential for wind-energy projects and associated infrastructure, have the potential to directly affect this species in a number of areas. The proposed Caliente rail alignment could pass near a small portion of previously used sage-grouse habitat, but it is not expected that the project would have direct, indirect, or cumulative impacts on this species.

Private landowners, corporations, state or local governments, or other non-federal landowners who wish to conduct activities on their land that might incidentally harm (or "take") wildlife listed as endangered or threatened must first obtain an incidental take permit from the U.S. Fish and Wildlife Service. To obtain a permit, the applicant must develop a Habitat Conservation Plan designed to offset any harmful effects the proposed activity might have on the species. Multi-species Habitat Conservation Plans are underway in two places in the Caliente rail alignment region of influence: (1) the Coyote Springs area and (2) in southern Lincoln County in the area of the recent BLM land disposal. Additionally, there is a single species (desert tortoise) Habitat Conservation Plan being developed in the Pahrump area of Nye County. These plans would support development of private lands while accounting for the potentially affected species.

No major effects on special status species are projected to result from construction and operation of the proposed railroad along the Caliente rail alignment. DOE would conduct any required consultation with the U.S. Fish and Wildlife Service in accordance with the Endangered Species Act. There is a substantial regulatory framework, to which all projects are subject, that serves to evaluate and protect special status species. Therefore, cumulative impacts to special status species would be small.

5.2.2.7.4 Wildfires

Wildfires are a major environmental concern throughout the Caliente rail alignment region of influence due to the generally dry climate and the increasing presence of invasive plant species. When they occur, wildfires have a significant and long-term impact on vegetation, wildlife, other natural resources, and human safety. The most important biological effects of fires include:

- Loss of native plant communities
- Decreased stability of watershed and soils
- Decreased or degraded wildlife habitat
- Increase in potential for invasive species spread
- Overall disruptions to ecological function

Sources of regional wildfires are both natural (for example, lightning) and human caused. With increased activity in the Caliente rail alignment region of influence, the potential for future human-caused fires increases. Because the BLM administers most of the land in the Caliente rail alignment region of influence, the BLM has primary fire-avoidance and fire-fighting responsibilities in the Caliente rail alignment region of influence.

Both the proposed railroad project and other reasonably foreseeable future actions would likely implement appropriate fire-avoidance strategies in consultation with the BLM. Potential cumulative impacts from wildfires would be small.

5.2.2.8 Noise and Vibration

5.2.2.8.1 Railroad Noise

The Union Pacific Railroad is the predominant ***Class I commercial railroad*** in Nevada and has operated in the state for many years. Noise associated with Union Pacific Railroad operations is part of the existing environment, specifically in the area of Caliente where the presence of the railroad is very evident. The sounds associated with the Union Pacific Railroad in and near the City of Caliente include wayside noise (noise generated by the cars and locomotives) and horn sounding. The individual operating rules of each railroad require train engineers to sound horns when approaching most grade crossings. Horn sounding is generally not required at private crossings. Wayside noise and horn sounding are common in Caliente and other portions of the existing Union Pacific Railroad routes.

The Toquop Energy Project could involve a new short rail spur of about 50 kilometers (30 miles) in an isolated part of Lincoln County south of Caliente. This spur would connect with the Union Pacific Railroad system but would be in an area that would not have any identifiable noise receptors.

Transportation of spent nuclear fuel and high-level radioactive waste casks along the Caliente rail alignment would result in as many as eight one-way trips per week. Train activity associated with supply and maintenance of the Yucca Mountain Repository is also proposed (as many as seven one-way trips per week), as is Caliente rail alignment maintenance activity (about two one-way trips per week), for a total of about 17 one-way trips per week. During construction, the completed portions of the rail line could also be used to deliver ballast to construction areas.

Potential noise impacts (as evaluated through noise modeling near Caliente, in Garden Valley, and in Goldfield) would be expected to be small. Construction and operation of a railroad along the Caliente rail alignment would introduce railroad noise into areas of the Caliente rail alignment region of influence that previously had none. This could result in annoyance for some people.

5.2.2.8.2 Urban Noise

As the population increases in Lincoln, Nye, and Esmeralda Counties, existing towns will grow and new residential areas will develop characteristics of more urban areas. Urban noise includes automobiles, construction activities, barking dogs, and other human activities generally within an identifiable community. At present, urban noise in the Caliente rail alignment region of influence is limited because there are only a few cities and communities. However, with economic development and growth goals throughout the Caliente rail alignment region of influence, the number and scope of urbanized areas is expected to increase. Urban noise is generally localized and is differentiated from aircraft and railroad noise sources, which move with the source from one location to another, while urban noise is within identifiable geographic borders associated with the locations of populations.

The proposed railroad would have a very small effect on urbanization in the area, and its effect on urban noise in the Caliente rail alignment region of influence would be small. Cumulative impacts related to urban noise would be small.

5.2.2.8.3 Aircraft Noise

Noise from aircraft engines and sonic booms is common throughout most of the Caliente rail alignment cumulative impacts region of influence, and can cause "startle" and annoyance effects. The noise associated with military aircraft is consistent with the "dominant use" of the area for military and defense-related activities at the Nevada Test and Training Range. Any noise effects associated with Nevada Test and Training Range missions would be considered necessary and unavoidable. Commercial air traffic also contributes to noise impacts in the region of influence.

The proposed railroad project would not contribute to cumulative aircraft noise.

5.2.2.8.4 Vibration

Vibration can be perceived on land surfaces and within buildings with certain types of activities. Construction activity is one of the more common sources of vibration, but railroad construction vibration would be very localized and typically minor in scope and duration. In the Caliente rail alignment cumulative impacts region of influence, other possible sources of vibration include occasional testing activities at the Nevada Test and Training Range and sonic booms from aircraft-related military activities in the airspace above the region of influence. These events would also tend to be short term and localized.

Cumulative impacts from vibration would be small.

5.2.2.9 Socioeconomics

The economy in the Caliente rail alignment cumulative impacts region of influence has traditionally been based on mineral development and livestock grazing. However, the economy in the region of influence is changing, just as land uses are changing. New economic drivers include services, retirement communities, and tourism, including recreation opportunities.

While the proposed railroad would be a major development in the Caliente rail alignment region of influence, its long-term economic development potential would be limited and would primarily be related to construction activities. This pattern of larger magnitude, short-term construction impacts followed by relatively small, long-term operations impacts for linear projects (for example, pipelines and transmission lines) is not uncommon in the Caliente rail alignment region of influence. If the Shared-Use Option were chosen and implemented, there would be greater potential for positive economic development benefits compared to the Proposed Action.

Population growth in the Caliente rail alignment cumulative impacts region of influence is projected to occur in existing residential areas such as Caliente and Tonopah, but also in new areas such as Coyote Springs and the BLM land-disposal areas in Lincoln County. It is uncertain if there is sufficient economic development growth potential in these areas to support all of the desired growth. It is possible that some areas would grow at the expense of other areas, or that recently developed plans for growth turn out to be unrealistic. Provision of housing to meet market demand is a private-sector activity, with the private-housing sector assumed to build to the needed level to meet housing demand at the appropriate locations. One of the factors that will affect how and where growth occurs is the availability of infrastructure to support the growth. Beyond the traditional infrastructure needs like roads, sewer, water, and public buildings, modern infrastructure such as the availability of fiber optic lines might also affect growth patterns. For example, the availability of fiber-optic lines or other high-technology infrastructure is likely to be a substantial growth discriminator for both businesses and individuals. The locations of and extent to which factors such as fiber-optic lines would ultimately affect growth cannot be projected at this time.

The recent and potential future BLM land disposals have the potential to provide land for private sector projects such as housing, industrial or commercial facilities, or other developments. In addition to the growth opportunities presented by the BLM land disposals, the proposed Coyote Springs community would be comprised of about 170 square kilometers (43,000 acres), about two-thirds of which would be in Lincoln County and one-third of which would be in Clark County). As envisioned, the development would be a series of neighborhoods with villages nestled between open-space corridors. It is planned to consist of both second-home residents and commuters to Las Vegas (about 80 kilometers [50 miles] away), with initial plans to focus on a role as a destination vacation location. At final build-out, the development could provide about 47,500 residential housing units. However, the development has not procured sufficient water rights for build-out, and the ability to reach its build-out objectives is primarily dependent on water availability.

As part of the Shared-Use Option analysis for this Rail Alignment EIS, the existing decisionmakers for Lincoln, Nye, and Esmeralda Counties, and the City of Caliente clearly stated their objective to grow and develop with additional business enterprises. Esmeralda County is working on a plan to relocate the Goldfield airport to a point west of the community, and develop a light industrial/manufacturing complex adjacent to the airport. The City of Caliente is working on the redevelopment of a 0.24 square kilometer (60-acre) industrial park south of the city, and Lincoln County is working aggressively to attract new business from Southern California and Las Vegas to the area.

The State of Nevada has developed population projections for the Caliente rail alignment cumulative impacts region of influence (DIRS 178807-Hardcastel 2006, all) as follows:

- Esmeralda County is projected to have a small decrease in population from 2005 to 2026
- Lincoln County is projected to add only about 2,000 persons from 2005 to 2026
- Nye County is projected to add more than 32,000 persons from 2005 to 2026

The Nevada State Demographer develops population projections for Nevada counties, which are always subject to change with new information. For example, the full potential growth from Coyote Springs and the BLM land disposals in Lincoln County over the next 20 years would increase population growth beyond the State Demographer's projections for Lincoln County.

Nye County's projected growth continues a recent trend, with growth in Pahrump very evident over the past several years. Growth in Pahrump is being driven by low-cost land, proximity to the Las Vegas metropolitan area, and relocation of retirees to the area. Growth in Nye County is also linked directly to existing and future Yucca Mountain Site operations.

As discussed in Section 4.2.9 of this Rail Alignment EIS, DOE used an economic model to estimate potential socioeconomic impacts of the proposed rail line (DIRS 182251-REMI 2007, all). The model includes consideration of construction and operation employment and wages, project-related spending, and other parameters that could affect the socioeconomic environment. The model included a future baseline of socioeconomic parameters that would represent a cumulative impacts baseline without the proposed railroad (see Table 3-61 of this Rail Alignment EIS).

Consistent with the methodology established in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, p. 4-43), most of the construction workers for the proposed railroad are assumed to be residents of Clark County. This assumption is made because the construction sectors in Nye, Lincoln, and Esmeralda Counties are not large enough to provide enough workers for construction activities. Therefore, it is not surprising that Clark County is projected to attain the largest levels of construction-related employment, income, and spending effects from the proposed project, followed by Nye, Lincoln, and Esmeralda Counties. Lincoln County would experience the largest employment percentage increase during construction with an estimated increase of about 6 percent above baseline conditions.

Employee locations for the operations phase would follow the same general pattern and relative magnitude of the construction phase, but there would be fewer operations jobs than construction jobs. Gains in employment during the operations phase would be felt most strongly in Lincoln County, where the peak percentage change in average annual employment is projected to be 4 percent above baseline conditions during full operations. Esmeralda County is the only other county in the region of influence projected to experience more than a 1-percent change in average annual employment at any point during the operations phase (3-percent change).

Population changes that would result from railroad construction and operations are also projected to generally follow this pattern. During the construction phase, the upper bound of increase to population would be about 2 percent or less of the future cumulative population baseline in all four counties. The operations phase population change would have the largest percentage increase compared to the cumulative baseline in Lincoln County (about a 3-percent average annual increase over the baseline).

Strains on housing infrastructure during the construction phase would not be anticipated, because most construction workers could be housed in construction camps at strategic locations along the proposed Caliente rail alignment, rather than in nearby communities. Contractors might elect to use commercially available facilities for housing construction personnel at locations such as Caliente, Tonopah, Goldfield, Beatty, and Pahrump. There would be enough vacant housing in these locations to absorb both construction and operations personnel.

Some infrastructure impacts would be expected where construction activities or operating facilities were near communities. For example, construction workers, including those from the proposed railroad, could strain the existing health care service capacity in the Caliente rail alignment region of influence, particularly in Caliente, Goldfield, and Tonopah. The operations-related population gains could also result in identifiable effects on health and education-related services.

The road network in the Caliente rail alignment region of influence consists generally of two-lane highways and unpaved roads. In rural, less populated parts of the Caliente rail alignment cumulative impacts region of influence, roads are adequate to handle existing and projected future traffic flow. However, the array of new and proposed activities throughout the Caliente rail alignment cumulative impacts region of influence would have the potential to strain parts of the existing roadway infrastructure.

Railroad project-related road traffic would result in small increases in some areas but construction of the proposed railroad itself would not materially affect traffic volumes on local roads because most construction materials would be transported using rail, and most construction employees and contractors would be housed in construction camps linked to the work site by access roads. Cumulative traffic levels in the region would likely continue to increase as overall regional growth and development occurs.

Any road improvement and maintenance responsibilities in the region of influence are handled by the Nevada Department of Transportation through a Statewide Transportation Plan and a Statewide Transportation Improvement Program. The Statewide Transportation Improvement Program includes a 3-year list of federally funded and regionally important non-federally funded transportation projects and programs consistent with the goals and strategies of the Statewide Transportation Plan. Routine highway improvements and maintenance projects for the period 2006 through 2015 have been identified for Lincoln, Nye, and Esmeralda Counties as part of the Nevada Department of Transportation planning processes. The level of cumulative traffic changes would generally not be sufficient for major upgrades of regional roads.

Overall, the proposed railroad project would have a small impact on economic development and growth, housing and community infrastructure, and traffic in the Caliente rail alignment region of influence. While there is some limited potential for induced growth impacts, the specific locations and scope of these actions is unknown at this time, and any such actions are projected to be small. Cumulative impacts to socioeconomics in the Caliente rail alignment region of influence would be small.

5.2.2.10 Occupational and Public Health and Safety

5.2.2.10.1 Nonradiological Health and Safety

Throughout the Caliente rail alignment region of influence, continuing and reasonably foreseeable activities have the potential to result in occupational injuries or fatalities including, but not necessarily limited to sources such as tripping, being cut on equipment or material, dropping heavy objects, and catching clothing in moving machine parts, and other types of accidents. Other occupational risks include biological hazards, dust and soils hazards, air quality hazards, transportation accidents, and noise hazards. Biological hazards include potential human health effects from rodent-borne diseases, soil-borne diseases, insect-borne diseases, and venomous animals. Dust and soils hazards include potential human health effects from exposure to inhalable soils and dusts containing hazardous constituents, and potential occupational encounters with unexploded ordnance.

While occupational injuries or fatalities are unavoidable with human activity, the public and private facilities within the Caliente rail alignment region of influence cumulative activity area are highly regulated. There is a substantial regulatory framework for occupational health and safety, with the Occupational Safety and Health Administration programs and regulations forming the basis for protection of workers. Through DOE Order 440.1A, *Worker Protection Management for DOE Federal and Contractor Employees*, the Department has prescribed the Occupational Safety and Health Act Standards that contractors are to meet in their work at government-owned, contractor-operated facilities. The Department of Labor, Bureau of Labor Statistics, measures occupational incident rates, including total recordable cases, lost workday cases, and fatalities, associated with the work environment.

There are no data on injury/illness incident rates for the Caliente rail alignment cumulative impacts region of influence, but injury/illness incidence rates in Nevada are generally higher than those in the United States as a whole. The economic segments with the highest injury/illness incidence rates in Nevada are construction and goods-producing industries.

Additional traffic is a concern with the construction phases of reasonably foreseeable projects. The construction phase of a project not only brings construction workers to the work sites, but also means an increase in slow-moving and bulky traffic involving the transportation of construction equipment. Use of trucks for hauling hazardous or other dangerous materials is also an increasing concern as traffic increases on the road network. To minimize traffic impacts at the entrance to the Yucca Mountain Site, a new interchange with U.S. Highway 95 at the site entrance has been proposed for both traffic flow and safety reasons. Increased traffic would not necessarily mean an increase in the rate of traffic accidents, but the number of accidents would increase if the rate of traffic accidents stayed the same and traffic increased. Therefore, transportation safety concerns would increase and there could be an increased workload for traffic-accident responders in the Caliente rail alignment region of influence with the cumulative growth in traffic.

An estimated 9,500 casks would be transported to the repository by rail along the Caliente rail alignment. Nonradiological occupational health and safety impacts are projected as follows:

- Construction and operations activities for the Caliente rail alignment are projected to result in approximately 880 recordable incidents, approximately 520 lost-workday accidents, and approximately three fatalities.
- Vehicular-related fatalities related to worker commuting are projected to result in an estimated 14 vehicular-related fatalities for the Caliente rail alignment.
- Rail-related accidents and rail-related fatalities related to the movement of cask trains, maintenance trains, and supply trains are projected to result in 16 rail-related accidents and two rail-related fatalities for the Caliente alignment.

Under Module 1, approximately 22,000 casks would be transported to the repository by rail and under Module 2, approximately 24,000 casks would be transported to the repository by rail. To estimate the cumulative health and safety impacts of Module 1 and Module 2, the impacts of the Proposed Action were increased by the ratio of the number of casks transported in Module 1 or Module 2 versus the Proposed Action. For Module 1, the nonradiological health and safety impacts noted above would increase by a factor of approximately 2.3 over the impacts under the Proposed Action. For Module 2, nonradiological safety impacts would increase by a factor of approximately 2.4 over the impacts under the Proposed Action.

Other regional activities would also cumulatively add to the totals beyond the railroad-related impacts, but cumulative nonradiological health and safety impacts in the Caliente rail alignment region of influence would be small within the context of the overall region of influence.

5.2.2.10.2 Radiological Health and Safety

Existing and reasonably foreseeable future activity (such as the Nevada Test Site and Yucca Mountain Repository activity managed by DOE) in the Caliente rail alignment region of influence involves the storage, handling, transportation, use, and disposal of radioactive materials and wastes. There is an extensive regulatory framework associated with transportation safety, and the proposed railroad would operate in compliance with these laws and regulations. For example, DOE complies with U.S. Department of Transportation regulations regarding the transportation of radioactive materials. DOE also uses U.S. Environmental Protection Agency protective action guides (identifying projected dose levels at which specified actions should be taken) and actions designed to limit doses and impacts in the event of a transportation accident resulting in releases of radioactive material. The regulatory framework and implementation of appropriate standard operating procedures would reduce the potential for accidents. Coordination of plans for proposed railroad construction and operation with local emergency response providers would be important to limit the potential for accidents, and for an effective response to an accident should one occur.

There is a small risk of radiological impacts to workers and the general public from external radiation exposure during normal operations and incident-free transportation. Staff at the Nevada Test Site and the Yucca Mountain Repository would be separate, and it is not anticipated that there would be cumulative exposures to workers from both operations. The modes of transportation of radioactive wastes for the Nevada Test Site (shipment by truck) and the Yucca Mountain Repository (shipment by rail) would differ. Radiological impacts associated with rail operations would be higher under Repository SEIS Module 1 or 2 operations compared to the Repository SEIS Proposed Action level of transportation. The radiological risk relationships among the repository, the proposed Caliente rail alignment, and Nevada Test Site operations is summarized below.

As part of the Repository SEIS process, DOE estimated that 9 to 28 latent cancer fatalities for members of the public would result from Yucca Mountain Repository construction, operations, monitoring, and closure for the population within the 80-kilometer (50-mile) repository region of influence. The estimated latent cancer fatalities correspond to a total collective dose of 15,000 to 46,000 person-rem, and the projected population within the repository region of influence is 120,000 persons. The region of influence for the Yucca Mountain Repository extends 80 kilometers (50 miles) to the northwest from the repository site boundary along the rail corridor, approximately to Scottys Junction; the remainder of the Caliente rail alignment is outside of the Yucca Mountain Repository region of influence. Population within the area where the rail alignment region of influence and the Yucca Mountain Repository region of influence coincide (between the repository boundary and the Scottys Junction area) would receive radiation dose from both the repository and from the railroad operations. Members of the public along the rail line but outside of the region of influence of the Yucca Mountain Repository would receive a negligible radiation dose from the repository.

For members of the public along the rail line, DOE estimated that there could be up to 1.3×10^{-4} latent cancer fatalities, corresponding to a collective population dose of 0.2 person-rem for the Caliente alignment. Therefore, for members of the public situated along the rail alignment, the radiological impacts of operation of the Caliente rail line would be a very small contribution to the overall radiological impacts of the Yucca Mountain Repository.

The estimated radiological dose to members of the public from Nevada Test Site operations in 2005 was 0.2 mrem per year; the maximum radiation dose was 2.3 mrem per year at the northwest corner of the Nevada Test Site boundary. Dose at off-site populated locations between 20 kilometers and 80 kilometers (12 to 50 miles) from this location would experience much lower radiation doses due to wind dispersion (*Nevada Test Site Environmental Report 2005,* DIRS 182285-Wills 2006, Table 8-4, p. 8-2.) The collective population dose from Nevada Test Site operations was below 0.6 person-rem in 2004 (*Nevada Test Site Environmental Report 2005,* DIRS 182285-Wills 2006, Table 8-3, p. 8-8.) Radiation dose from Nevada Test Site operations would be a very small contribution to the overall radiological impacts of the Yucca Mountain repository.

Operation of the proposed railroad along the Caliente rail alignment under the Proposed Action would result in a small contribution to cumulative radiological health and safety impacts. Cumulative radiological impacts in the Caliente rail alignment region of influence would be small.

5.2.2.11 Utilities, Energy, and Materials

5.2.2.11.1 Utilities

From a cumulative impacts perspective within the Caliente alignment region of influence, utility crossings are and will continue to be commonplace, with little impact other than minor ground disturbance. The proposed railroad project would contribute to regional utility and other right-of-way crossings, which are common to linear projects such as roads, railroads, and pipelines. Land areas for the rail line, construction camps, quarries, and access roads would cross or encroach upon existing or proposed utility rights-of-way in a variety of locations. Land areas for railroad operations support facilities could also encroach upon existing or proposed utility rights-of-way. This situation would be typical for other rights-of-way in the region, meaning that the cumulative region of influence would have hundreds of utility and other right-of-way crossings for the various existing and reasonably foreseeable projects in the region. The crossings would be accomplished with small impacts using standard engineering procedures and appropriate design details.

Many regional activities, including the proposed railroad, would increase demands on public water systems, wastewater systems, telecommunications systems, electric power systems, and other utilities. However, regional service providers are projected to be able to adjust to any increasing demand, and overall cumulative impacts to utilities would be small.

5.2.2.11.2 Energy and Materials Usage

Large projects such as pipelines, transmission lines, and power plants that could occur within the Caliente rail alignment cumulative impacts region of influence require materials and energy to construct and operate. Energy and material resources necessary for construction or operation of these projects are often obtained within regional or, in some cases, national markets.

For this Rail Alignment EIS, DOE analyzed cumulative energy and materials supply and demand from a regional perspective. Energy and materials (for example, steel and concrete) that would be needed for construction and operation of the proposed railroad are not constrained in regional markets, and proposed railroad needs would represent a small percentage of the cumulative annual materials use within the Caliente rail alignment cumulative impacts region of influence.

While the regional markets for various construction-related materials and energy sources will continue to grow as the region develops, there is no evidence of potential limits to growth from constrained material or energy supplies. Cumulative impacts from energy and materials usage in the Caliente rail alignment region of influence would be small.

5.2.2.12 Hazardous Materials and Waste

5.2.2.12.1 DOE Waste-Management Activities

DOE has had existing waste-management programs at the Nevada Test Site for several decades. While Site missions have changed over time (with an emerging focus on national security, energy, and environmental issues), waste management and disposal at the Site has been one of the primary long-term land uses. There are two active waste-management and disposal sites on the Nevada Test Site:

- Area 5 occupies 2.9 square kilometers (720 acres) and is in Frenchman Flat north of Mercury, Nevada.
- Area 3 occupies 0.53 square kilometer (130 acres) north of Mercury in Yucca Flat.

Environmental restoration efforts are under way at various locations throughout the Nevada Test Site. The Nevada Test Site waste-management program currently includes management and disposal operations for hazardous waste, mixed waste, and low-level radioactive waste. Transportation of the waste is accomplished by truck from both on-site and off-site sources. There are no plans for Nevada Test Site activities to include use of the proposed Caliente rail alignment for shipment of wastes.

The proposed railroad would not contribute to cumulative impacts associated with DOE waste-management activities on the Nevada Test Site.

At present, Yucca Mountain Repository-development efforts are focused on preparing an application to the U.S. Nuclear Regulatory Commission for authorization to construct the repository for spent nuclear fuel and high-level radioactive waste. Proposed operations at the Yucca Mountain Site are discussed in detail in the Yucca Mountain FEIS and the Repository SEIS.

5.2.2.12.2 Sanitary and Construction Wastes

As the populated areas in the Caliente rail alignment cumulative impacts region of influence expand, the volume of sanitary waste generated will also expand. Project proponents are legally required to dispose of nonhazardous and nonradiological construction and other solid waste in appropriately permitted solid waste landfills. Nevada has 24 operating municipal landfills with a combined capacity to accept more than 11,000 metric tons (12,000 tons) of waste per day. However, the number of operating landfills has decreased substantially over the past 15 years, and while there is sufficient capacity to accept waste for the state of Nevada as a whole, there are some areas, such as Pahrump, that have limited capacity for future years.

Construction- and operations-related waste that would be associated with the proposed railroad would add only a fraction of a percent to the total waste stream in the state. If there were a constraint to landfill capacity at some future time, additional land would be needed to expand or open a new landfill. Because of the scarcity of private land in the Caliente rail alignment region of influence, any land used for this purpose might need to come from BLM-administered federal land. As an alternative to local government landfill provision, private companies can also be expected to seek business opportunities to provide solid- and hazardous-waste management, transportation, and disposal.

DOE would store and use hazardous materials (such as oil, gasoline and solvents) during the construction phase, and would control and manage these materials in accordance with the extensive federal and state regulatory framework. Other major projects would have similar waste streams, and project plans and requirements would call for disposal of such wastes in permitted facilities and materials management according to accepted industry practices.

The proposed railroad's contribution to impacts from the generation and management of sanitary and construction wastes would be small. Cumulative impacts to waste disposal facilities in the Caliente rail alignment region of influence would be small.

5.2.2.13 Cultural Resources

Cultural resources include historic and archeological sites, buildings, structures, landscapes, and objects. Most reasonably foreseeable projects in the Caliente rail alignment cultural resources region of influence will involve at least some ground disturbance. With that ground disturbance, cultural resources could be destroyed, damaged, or discovered for recovery or mitigation. As part of the evaluation of proposed projects on federal land, the existing regulatory framework requires that cultural resources be identified and protected. With information on the location of a proposed project, and the estimated extent of ground disturbance, cultural resource specialists can be called on to perform appropriate surveys and inventories of cultural resources in the potentially disturbed area. Once discovered, the sites of cultural resources are kept confidential to reduce the potential for vandalism or theft of the resources.

Because cultural resources are typically on or below the ground, they can be damaged by other activities such as off-highway vehicle use. As the major land manager in the Caliente rail alignment region of influence, the BLM has an extensive cultural resource management program and manages federal land with protection of cultural resources as a key management objective. Once ground is disturbed and facilities are constructed on the land, the opportunity for identification of cultural resources is usually lost. Therefore, the BLM and other land managers in the area (like DOE on the Nevada Test Site and the U.S. Air Force on the Nevada Test and Training Range) employ cultural resource specialists and involve tribal representatives, as appropriate. Commonly, mitigation for any ground disturbance in the Caliente rail alignment region of influence includes the involvement of these cultural resource specialists as potential cultural resources are discovered. Other activities occurring on federal land, such as off-road vehicle use and rock collecting, can cause unintended adverse impacts to cultural resources. Mission activities occurring at the Nevada Test Site, the Nevada Test and Training Range, and the Yucca Mountain Repository also can cause unintended adverse impacts to cultural resources.

The problem of vandalism to and theft of cultural resources is prevalent throughout the western United States. The Draft Ely District Resource Management Plan (DIRS 174518-BLM 2005, p. 3.9-5) notes that the trend of degradation to cultural resource sites is increasing at a rapid rate as the population increases in the Caliente rail alignment region of influence. Land-management agencies such as the BLM make extensive attempts to protect cultural resource locations, but the areas to be managed are often so vast that patrols by law enforcement are not effective in protecting these sites. DOE, the BLM, and other federal agencies in the Caliente rail alignment region of influence are committed to public education and employee training regarding the protection of cultural resources.

Visitors could also be drawn to the area for purposes of curiosity and sight-seeing. Based on the extent of cultural resource site finds within BLM-administered land and the Nevada Test Site, and data collected to date on the Caliente rail alignment, there could be a large number of cultural resources in the Caliente rail alignment region of influence. For example, the Draft Ely District Resource Management Plan (DIRS 174518-BLM 2005, p. 3.9-1) notes that approximately 12,000 cultural resource sites covering a time span of more than 10,000 years have been identified within the Ely District. It is likely that only a portion of any currently undiscovered sites would ultimately be found eligible for the *National Register of Historic Places*.

The railroad would be a major new construction project introduced into a remote area. Beyond the implications of ground disturbance and permanent and temporary use areas, railroad construction and operations would bring employees, visitors, and equipment into an area where prior access was limited. If right-of-way roads remain open to the public, there could be an increase in off-road vehicles traveling along newly constructed roads and illegal use of lands. As the number of visitors increases, so does the potential for vandalism and damage to cultural resources. There is an extensive regulatory framework to manage and protect cultural resources.

Impacts to cultural resources in the Caliente rail alignment region of influence would be small because the Department would conduct intensive field surveys and implement mitigation measures, including avoidance. Other project proponents would be subject to the same regulatory framework and BLM policies and procedures. Cumulative impacts to cultural resources in the Caliente rail alignment region of influence would be small.

5.2.2.14 Paleontological Resources

Regional protection, management, and impact issues in relation to paleontological resources are similar to those for cultural resources. Any type of ground disturbance could disturb or destroy known or yet identified paleontological resources. Impacts to paleontological resources would generally be measured by physical damage to fossil-bearing formations through excavation or surface disturbance. The primary cumulative impact mechanisms that could affect paleontological resources include excavations or surface disturbances associated with approval and implementation of BLM rights-of-way, off-highway vehicle use, minerals development, land disposals, and special designations. Many BLM management activities, however, serve to protect and mitigate impacts to paleontological resources. As noted in the Draft Ely District Resource Management Plan (DIRS 174518-BLM 2005, p. 4.10-1), knowledge of the outcrop pattern of geologic units, and the kinds and quality of the fossils produced by such units, is a critical management tool for land-use decisionmaking where fossils might be involved. Potential effects on paleontological resources from ground disturbance would continue to be a major regional concern for the BLM from both resource management planning and rights-of-way evaluation perspectives.

Paleontological resources are considered valuable and are collected in the Caliente rail alignment region of influence for their cultural, scientific, and recreational values. Therefore, these resources are sometimes removed from federal lands. While common invertebrate fossils such as plants, mollusks, and trilobites can be collected for personal use in reasonable quantities, the lack of regular site monitoring and public education about fossil collecting has led to increased illegal commercial taking of paleontological resources. Paleontological resources are also vulnerable to intentional or unintentional vandalism. The specific locations of some identified paleontological resources are kept confidential to avoid vandalism or theft.

The most likely locations of currently unknown paleontological resources can be identified based on geological characteristics, and potential impacts can be avoided or minimized through careful project planning and implementation. Most formations the rail line would cross are volcanic and would not contain paleontological resources. Therefore, the proposed railroad project would not contribute to cumulative impacts to paleontological resources.

5.2.2.15 Environmental Justice

5.2.2.15.1 Potential Effects to Low-Income or Minority Populations

Environmental justice impacts result when high and adverse human health or environmental impacts fall disproportionately on low-income and minority populations. If high and adverse impacts are found to have disproportionate impacts on environmental justice populations as compared to the general population in the area, the impacts would be mitigated to the extent practicable by the federal agencies involved in the proposed action.

Based on individual and group values, beliefs, and goals among stakeholders and other interested parties, there are different perspectives on the potential effects of activities in the Caliente rail alignment region of influence on low-income or minority populations. The American Indian Resource Document (DIRS 174205-Kane et al. 2005) discusses cultural resources, American Indian values and their relationship to environmental justice, and broader American Indian values. DOE considers the American Indian Writers Subgroup conclusions to be responsible opposing viewpoints for purposes of its environmental justice responsibilities.

DOE has concluded that there are no identifiable human health or environmental impacts associated with the proposed railroad that would disproportionately affect low-income or minority populations, nor has the Department identified any special pathways for impacts (such as subsistence hunting and gathering) in the Caliente region of influence.

Cumulative impacts to low-income or minority populations along the Caliente rail alignment would be would be small, if any.

5.2.2.15.2 Economic Opportunity

Existing and reasonably foreseeable projects and activities in the Caliente rail alignment region of influence would present economic opportunities for some people in the area. Economic opportunities include employment, wages, revenue from business operation, and other economic stimuli associated with growth and development. DOE and other project proponents in the Caliente rail alignment region of influence have a legally mandated equal opportunity approach to these economic opportunities. Any potential for economic gain would be distributed equally to people or businesses in the area that seek employment or business opportunity.

While not all people would gain economically from the cumulative group of projects and activities, the opportunity for gain does not favor one population group or another based on minority or income status.

5.3 Mina Rail Alignment

Sections 5.3.1 to 5.3.2 summarize the projects and activities considered in the cumulative impacts analysis for the Mina rail alignment. Figure 5-3 shows the locations of these major projects and activities, including the:

1. Naval Air Station Fallon
2. Federal actions on the Walker River Paiute Reservation
3. Hawthorne Army Depot
4. Walker River Basin Restoration
5. Monte Cristo's Castle (proposed state park)
6. Timbisha Shoshone Trust Land (federal land transfer)
7. Yucca Mountain Geologic Repository
8. Nevada Test Site
9. Nevada Test and Training Range

This section also considers other relevant projects and actions that are not depicted on the map, such as:

- BLM planning and management actions – A variety of BLM past, present, and reasonably foreseeable actions are located within the three BLM management areas (Carson City, Battle Mountain, and Las Vegas) relevant to the Mina rail alignment.
- Various rights-of-way – Many future utility or other rights-of-way corridors are not depicted in Figure 5-3 because specific routes are not known. For example, DOE and the BLM are preparing a programmatic environmental impact statement for potential designation of energy corridors on federal land in western states (70 *FR* 56647, September 28, 2005).
- Energy and mineral development activities.
- Other regional economic development plans and activities within Nye, Esmeralda, Lyon, and Mineral Counties.

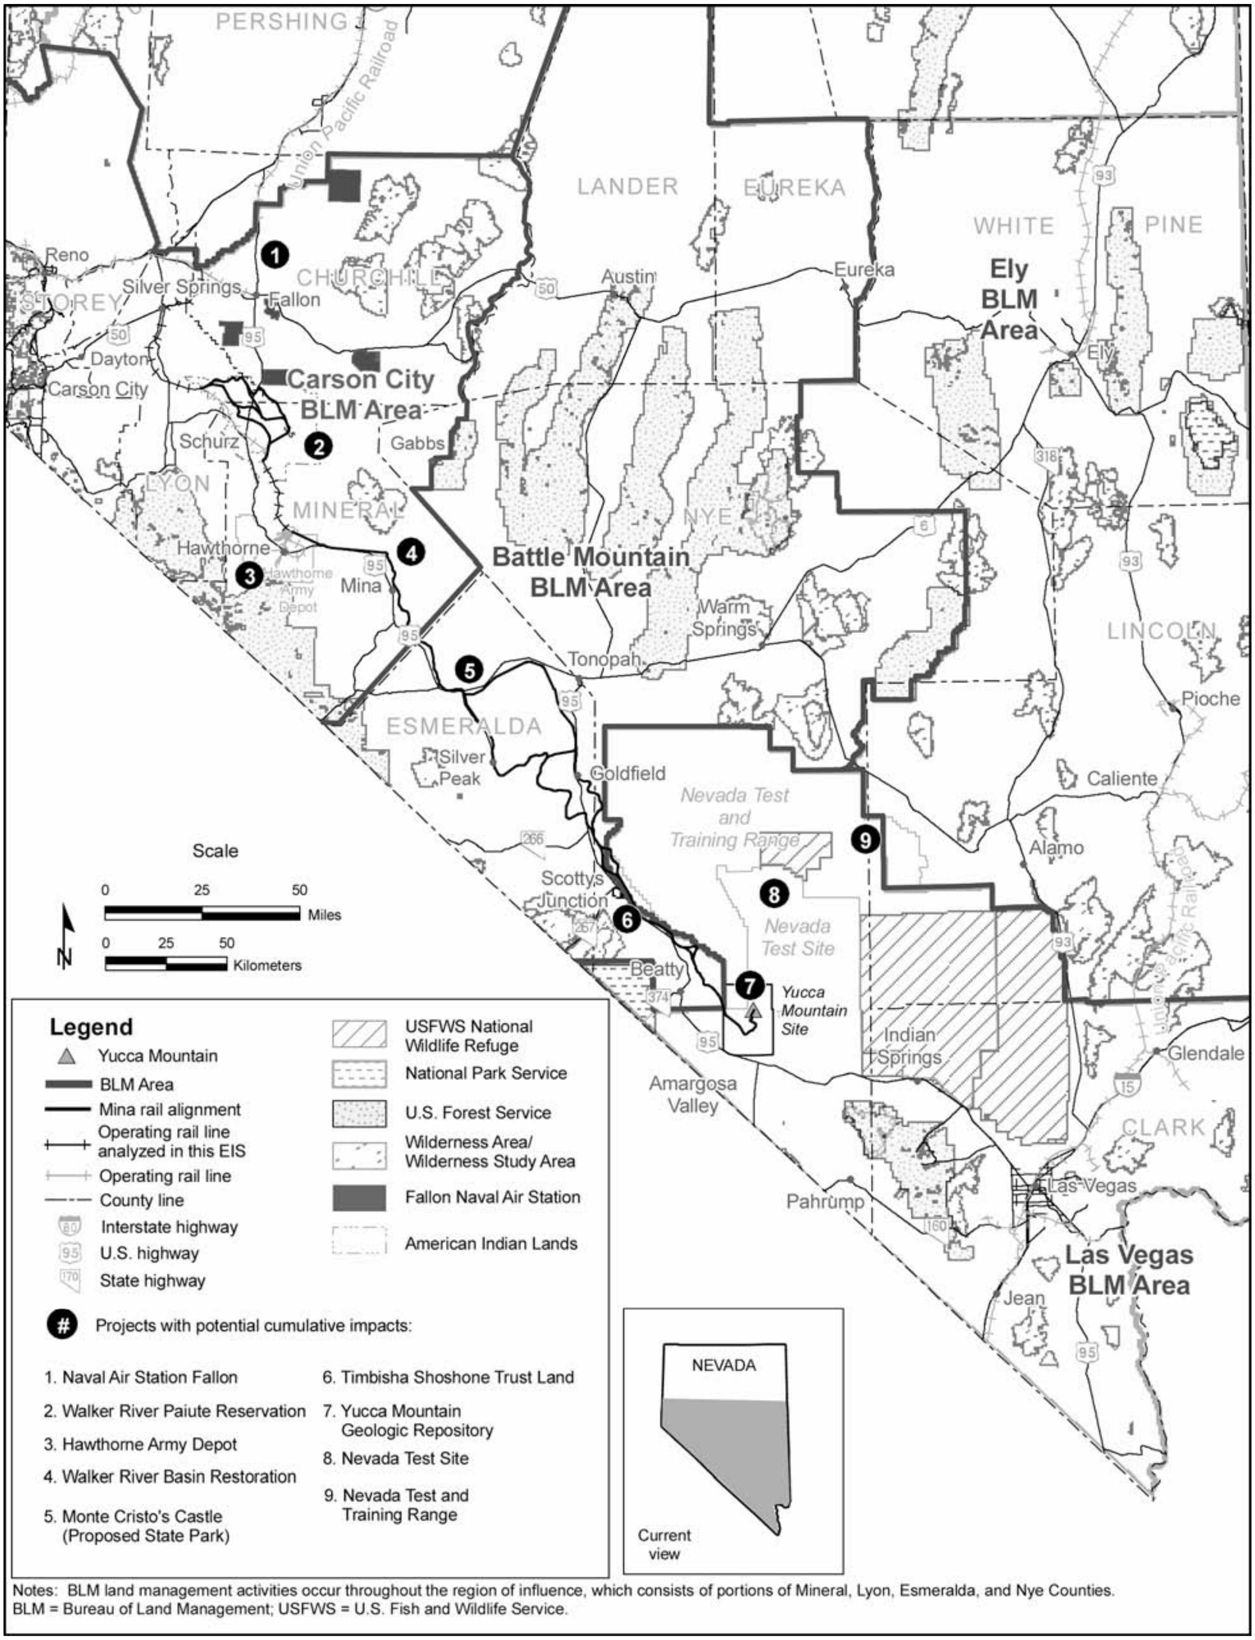

Figure 5-3. Major reasonably foreseeable future actions and continuing activities in the Mina rail alignment cumulative impacts region of influence.

The Mina rail alignment ranges in length from about 469 to 502 kilometers (281 to 312 miles), depending on the alternative segments considered. As a linear project, land disturbance and other direct impacts would be most likely to occur within the relatively narrow construction and operations rights-of-way. However, there could be other direct and indirect impacts for some resources outside the rights-of-way.

To evaluate the potential for cumulative impacts, DOE identified and reviewed public and private actions in the Mina rail alignment region of influence to determine if the impacts associated with these actions could coincide in time or space with potential impacts from railroad construction and operations along the Mina rail alignment. Only those projects and activities DOE believes would have the potential for cumulative impacts are identified herein. In some cases, similar actions have been grouped together and listed by category of action.

5.3.1 PROJECTS AND ACTIVITIES INCLUDED IN THE CUMULATIVE IMPACTS ANALYSIS – MINA RAIL ALIGNMENT

5.3.1.1 Past and Present Actions

The descriptions of existing (baseline) environmental conditions (Chapter 3) and impacts (Chapter 4) associated with the various environmental resource regions of influence for the Mina rail alignment considered in this Rail Alignment EIS include the relationships between proposed railroad construction, operation, and abandonment and past and present actions such as:

- Operations at major federal facilities such as the Yucca Mountain Geologic Repository, Nevada Test and Training Range, Nevada Test Site, Hawthorne Army Depot, and Naval Air Station Fallon
- BLM resource management planning and land management uses
- Traditional land uses such as regional ranching, mining, and recreation
- Military operations
- Walker River Basin restoration activities
- Residential, commercial, and industrial development activities associated with growth in the Mina rail alignment cumulative impacts region of influence; including the Pahrump area and the Reno-Carson City area adjacent to the northern portion of the Mina rail alignment region of influence.

Reasonably foreseeable future actions and the continuation of existing actions in the Mina rail alignment cumulative impacts region of influence were also considered. Figure 5-3 shows the locations of individual projects and activities.

5.3.1.2 Reasonably Foreseeable Future and Continuing Federal Actions

Sections 5.3.1.2.1 through 5.3.1.2.8 describe reasonably foreseeable future and continuing federal agency actions that could result in cumulative impacts when combined with the impacts of constructing and operating a railroad along the Mina rail alignment.

5.3.1.2.1 Yucca Mountain Geologic Repository

The Proposed Action in this Rail Alignment EIS is directly related to the proposed geologic repository at Yucca Mountain, which is a reasonably foreseeable project that would have potential cumulative impacts in the Mina rail alignment region of influence (see Figure 5-3, Project #7). In the Yucca Mountain FEIS

(DIRS 155970-DOE 2002, all) and the *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (the Repository SEIS; DOE/EIS-0250F-S1 DOE proposes to construct, operate and monitor, and eventually close a geologic repository for the disposal of 70,000 metric tons (77,000 tons) of heavy metal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain in Nye County, Nevada. DOE proposed to dispose of spent nuclear fuel and high-level radioactive waste in the repository using the natural geologic features of the mountain and engineered barriers as a total system to help ensure long-term isolation of the materials from the accessible environment. As analyzed in the Repository SEIS, the repository design and associated construction and operation plans require the following:

- DOE spent nuclear fuel and high-level radioactive waste would be placed in disposable canisters at the DOE sites, and as much as 90 percent of the commercial spent nuclear fuel would be placed in transportation, aging, and disposal (TAD) canisters at the commercial sites prior to shipment. The remaining commercial spent nuclear fuel (about 10 percent) would be transported to the repository in dual-purpose canisters (canisters suitable for storage and transportation), or would be uncanistered.
- Most spent nuclear fuel and high-level radioactive waste would be transported from 72 commercial and four DOE sites to the repository in Nuclear Regulatory Commission-certified transportation casks placed on trains dedicated only to these shipments. Some shipments, however, would be transported to the repository by truck over the Nation's highways.
- At the repository, DOE would conduct waste handling activities to manage thermal output of the commercial spent nuclear fuel and to package the spent nuclear fuel into TAD canisters. The disposable canisters and TAD canisters would be placed into waste packages for disposal in the repository. A waste package is a container that consists of the barrier materials and internal components in which DOE would place the canisters that contained spent nuclear fuel and high-level radioactive waste.
- DOE would place approximately 11,000 waste packages, containing no more than a total of 70,000 metric tons (77,000 tons) of heavy metal, of spent nuclear fuel and high-level radioactive waste in the repository at Yucca Mountain.
- When authorized by the Nuclear Regulatory Commission, the repository would be closed permanently. The design for construction would allow for phased construction of the surface and subsurface facilities that would be compatible with constrained funding.
- The surface and subsurface facilities and associated infrastructure, such as the onsite road and water distribution networks and emergency response facilities, would be constructed in phases to accommodate the expected receipt rates of spent nuclear fuel and high-level radioactive waste.
- DOE also would construct a four-lane access road that would extend from U.S. Highway 95 to the existing access road at Gate 510. This access road might be constructed using a phased approach, with initial construction of two lanes, and the road being widened later. The Department would also build a suitable intersection at U.S. Highway 95.
- DOE assumes that the following facilities would be constructed outside the repository land withdrawal area: a training facility near Yucca Mountain to support the Project Prototype Testing and the Operator Training and Qualification programs; temporary accommodations for construction workers; a proposed Sample Management Facility to consolidate, upgrade, and improve storage and warehousing for scientific samples and materials, perhaps near the Town of Amargosa Valley; and a marshalling yard and warehouse, a proposed leased facility that would consolidate material shipment and receipt into a 0.2-square-kilometer (50-acre) facility to allow

for offsite receipt, transfer, and staging of materials required to perform construction activities at the Yucca Mountain site.

The Nuclear Regulatory Commission, through its licensing process, would regulate repository construction, operation and monitoring, and closure. Repository operations would only begin after the Commission granted DOE a license to receive and possess spent nuclear fuel and high-level radioactive waste. DOE is currently preparing an application for construction authorization.

The Yucca Mountain FEIS and the Repository SEIS evaluate the cumulative impacts of two additional inventories (Modules 1 and 2), which include spent nuclear fuel and high-level radioactive waste in addition to that of the Proposed Action inventory, and other radioactive wastes generally considered unsuitable for near-surface disposal. Inventory Module 1 or 2 could have cumulative impacts on the operation of the proposed railroad. Regarding potential cumulative impacts from Inventory Module 1 or 2, there would be no cumulative construction impacts because the need for a new railroad would not change; that is, whichever rail alignment DOE selected in which to build the proposed railroad to serve the Yucca Mountain FEIS Proposed Action would also serve Module 1 or 2. In addition, because the planned annual shipment rate of spent nuclear fuel and high-level radioactive waste to the Yucca Mountain Repository would be about the same for Module 1 or 2 and the FEIS Proposed Action, the only cumulative operations impacts would result because of the annual increase of shipments for Module 1 or 2. Because Modules 1 and 2 exceed the NWPA disposal limit of 70,000 metric tons (77,000 tons) of heavy metal considered in the Repository SEIS, the emplacement of any such waste at Yucca Mountain would require legislative action by Congress unless a second licensed repository was in operation. The 70,000 metric tons of heavy metal limit is comprised of 63,000 metric tons (69,000 tons) of heavy metal from commercial utilities and 7,000 metric tons (7,000 tons) of heavy metal from DOE.

DOE is preparing the *Disposal of Greater-Than-Class-C Low-Level Radioactive Waste Environmental Impact Statement* (DOE/EIS-0375) (72 *FR* 40135, July 23, 2007). That EIS will address the disposal of wastes with concentrations greater than Class C, as defined in U.S. Nuclear Regulatory Commission regulations at 10 CFR Part 61, and DOE Low-Level Radioactive Waste and transuranic waste having characteristics similar to Greater-Than-Class-C waste and that otherwise do not have a path to disposal. DOE proposes to evaluate alternatives for Greater-Than-Class-C low-level waste disposal in a geologic repository; in intermediate depth boreholes; and in enhanced near surface facilities. Candidate locations for these disposal facilities are the Idaho National Laboratory; the Los Alamos National Laboratory and Waste Isolation Pilot Plant in New Mexico; the Nevada Test Site and the proposed Yucca Mountain Repository; the Savannah River Site in South Carolina; the Oak Ridge Reservation in Tennessee; and the Hanford Site in Washington. DOE will also evaluate disposal at generic commercial facilities in arid and humid locations. The Draft Yucca Mountain SEIS evaluates the potential cumulative impacts of disposal of these wastes at Yucca Mountain as a reasonably foreseeable action, which are included in Inventory Module 2. Current repository design plans do not accommodate disposal of Greater-Than-Class-C low-level radioactive waste.

DOE is preparing the *Programmatic Environmental Impact Statement for the Global Nuclear Energy Partnership* (DOE/EIS-0396). Global Nuclear Energy Partnership (GNEP) would encourage expansion of domestic and international nuclear energy production while reducing nuclear proliferation risks, and reduce the volume, thermal output, and radiotoxicity of spent nuclear fuel before disposal in a geologic repository. DOE anticipates that its Programmatic EIS will evaluate a range of alternatives, including a proposal to recycle spent nuclear fuel and separate many of the high-heat fission products and the uranium and transuranic components. The full implementation of GNEP would involve the construction and operation of advanced reactors, which would be designed to generate energy while destroying the transuranic elements. DOE also anticipates evaluating project-specific proposals to construct and operate an advanced fuel-cycle research facility at one or more DOE sites.

The United States uses a "once through" fuel cycle in which a nuclear power reactor uses nuclear fuel only once, and then the utility places the spent nuclear fuel in storage while awaiting disposal. GNEP would establish a fuel cycle where the uranium and transuranic materials would be separated from the spent nuclear fuel and reused in thermal and/or advanced nuclear reactors. GNEP would not diminish in any way the need for the nuclear waste disposal program at Yucca Mountain, because under any fuel recycle scenario, high-level radioactive waste will continue to be produced and require disposal.

DOE anticipates that by about 2020 the commercial utilities will have produced about 86,000 metric tons 995,000 tons) of heavy metal of spent nuclear fuel, which exceeds the DOE disposal limit of 63,000 metric tons (69,000 tons) of heavy metal of commercial spent nuclear fuel at the Yucca Mountain Repository. If DOE were to decide, in a GNEP Record of Decision, to proceed with its proposal to recycle spent nuclear fuel, the Department anticipates that the necessary facilities would not commence operations until 2020 or later. Although the spent nuclear fuel-recycling concept has not yet been implemented and the capacity of a separations facility has not been determined, one or more separations facilities could be designed with a total capacity sufficient to recycle the spent nuclear fuel discharged by commercial utilities. Consequently, the Department believes there would be no change in the spent nuclear fuel and high-level radioactive waste inventory, and therefore the number of casks of spent nuclear fuel and high-level radioactive waste shipped to the Yucca Mountain repository analyzed under the Proposed Action in this Rail Alignment EIS would remain unchanged (that is, the shipment of approximately 9,500 casks containing spent nuclear fuel and high-level radioactive waste).

Overall, development of a GNEP fuel cycle has the potential to decrease the amount (number of assemblies) of spent nuclear fuel that would require geologic disposal, but would increase the number of casks of high-level radioactive waste requiring disposal in a geologic repository in the long term. Consequently, recycling of commercial spent nuclear fuel could affect the nature of the inventory that represents the balance of Inventory Module 1 (that is, commercial spent nuclear fuel in amounts greater than 63,000 metric tons [69,000 tons] of heavy metal). Nevertheless, given the uncertainties inherent at this time in estimating the amount of spent nuclear fuel and high-level radioactive waste that would result from a full or partial implementation of the GNEP closed fuel cycle, this Rail Alignment EIS analyzes rail transportation within Nevada of approximately 9,500 casks of spent nuclear fuel and high-level radioactive waste.

5.3.1.2.2 Nevada Test Site (Continuation of Activities)

The Nevada Test Site, adjacent to the Nevada Test and Training Range, engages in a number of defense-related material and management activities, waste management, environmental restoration, and non-defense research and development (see Figure 5-3, Project #8). The Nevada Test Site was established in 1951 as the Nation's proving ground for developing and testing nuclear weapons. The site is on land administratively held by the BLM, but the Nevada Test Site land was withdrawn for use by the Atomic Energy Commission and its successors (including DOE). At present, the DOE National Nuclear Security Administration manages the site. It consists of about 3,200 square kilometers (800,000 acres) of land.

The *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996, all) described existing and projected future actions at the Nevada Test Site. That EIS was followed by a *Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 162638-DOE 2002, all). DOE activities at the Nevada Test Site include stockpile stewardship and management (helping ensure the U.S. nuclear weapon stockpile is safe, secure, and reliable), materials disposition (removal of nuclear materials in a safe and timely manner), and nuclear emergency response. Activities at the Nevada Test Site since the 1996 EIS and 2002 supplement analysis have continued to support these missions in accordance with federal law, DOE policies and missions, and NEPA requirements. There are a number of other programmatic DOE waste management initiatives that can affect current and potential future operations at the Nevada Test Site, many of which require NEPA analyses. The Nevada Test Site also produces annual environmental reports that describe program activities and related environmental issues and activities.

DOE is currently preparing the *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement–Complex 2030* (Complex Transformation Supplemental PEIS [formerly known as the Complex 2030 SEIS]; DOE/EIS-0236-S4). That SEIS will analyze the environmental impacts of the continued transformation of the United States nuclear weapons complex by implementing the National Nuclear Security Administration's vision of the complex as it would exist in 2030, and alternatives to that action. Part of the proposed action in that SEIS is to identify one or more sites for conducting National Nuclear Security Administration flight test operations. Existing Department of Defense and DOE test ranges (for example, the White Sands Missile Range in New Mexico and the Nevada Test Site in Nevada) would be considered as alternatives to the continued operation of the Tonopah Test Range in Nevada.

Another part of the proposed action in the Complex Transformation Supplemental PEIS is to accelerate dismantlement activities. The DOE sites that will be considered as potential locations for the consolidated plutonium centers and consolidation of Category I (high strategic significance) and II (moderate strategic significance) special nuclear materials include Los Alamos National Laboratory, the Nevada Test Site, the Pantex Plant, the Y-12 National Security Complex, and the Savannah River site.

DOE manages several types of radioactive and hazardous waste (***low-level radioactive waste***, ***mixed low-level waste*** [referred to as mixed waste], transuranic waste, high-level radioactive waste, and ***hazardous waste***) generated by past and present nuclear defense research activities at many DOE sites across the United States, including the Nevada Test Site. The Department manages each of those waste types separately because they have different components, levels of radioactivity, and regulatory requirements. DOE needs facilities like the Nevada Test Site to manage its radioactive and hazardous wastes to maintain safe, efficient, and cost-effective control of these wastes; comply with applicable federal and state laws; and protect public health and safety and the environment. In *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DIRS 101816-DOE 1997, all) DOE evaluated the environmental impacts of managing the five waste types. The Nevada Test Site will continue to be a major facility involved in DOE waste-management programs, including serving as a disposal site for certain waste types generated off the site, and for on-site wastes primarily from environmental restoration and remediation activities.

The Nevada Test Site is a candidate disposal location for Greater-Than-Class-C Low-Level Radioactive Waste which is currently being examined in the *Disposal of Greater-Than-Class-C Low-Level Radioactive* Waste *Environmental Impact Statement* (DOE/EIS-0375). That DOE EIS will address the disposal of wastes with concentrations greater than Class C, as defined in Nuclear Regulatory Commission regulations at 10 CFR Part 61, and DOE low-level radioactive waste and transuranic waste having characteristics similar to Greater-Than-Class-C low-level waste and that might not have an identified path to disposal. DOE proposes to evaluate alternatives for Greater-Than-Class-C low level waste disposal in a geologic repository; in intermediate-depth boreholes; and in enhanced near-surface facilities.

Table 5-1 lists and briefly describes recent environmental assessments that describe Nevada Test Site operations.

5.3.1.2.3 BLM Resource Planning and Management

The presence of public land administered by the BLM is a very important factor affecting how and where activities occur within the region of influence. Many private and federal projects in the regions of influence, including the proposed railroad, would involve use of BLM-administered federal land. Therefore, these projects would require BLM-issued right-of-way grants before they could proceed. Right-of-way grants have two general forms: linear (applicable to such projects as transmission lines, railroads, and pipelines), and non-linear (applicable to projects at one specific location). Rights-of-way on BLM-administered land are extensive in the region. These rights-of-way vary tremendously in size and scope of activity.

Similar to the Caliente rail alignment, the BLM also administers most of the public lands along the proposed Mina rail alignment. The BLM manages these lands through a multiple-use concept (which means managing public lands and their various resource values so that they are utilized in the combination that will best meet the present and future needs of the American people) in accordance with the Federal Lands Policy and Management Act of 1976 (43 U.S.C. 1732, et seq.) and other federal legislation. The proposed Mina rail alignment would cross three BLM planning areas (Carson City, Battle Mountain, and Las Vegas). The Carson City Field Office manages its federal lands through a Consolidated Resource Management Plan developed in 2001. The Carson City Field Office was previously divided into eight planning units, all of which were consolidated into the 2001 Carson City Resource Management Plan. The Battle Mountain and Las Vegas planning areas are operating under resource management plans adopted in 1998 and 1997, respectively (DIRS 176043-BLM 1998, all; DIRS 173224-BLM 1997, all). There are many land uses on BLM-administered federal land in the region of influence, with grazing use being a major source of activity.

As directed by Federal legislation, the BLM Carson City Field Office may issue leases for geothermal resources located in multiple areas within the Mina rail alignment cumulative impacts region of influence. The development of any geothermal resources would be guided by BLM land and resource management policies and procedures established in the applicable resource management plans.

5.3.1.2.4 Walker River Paiute Reservation (Federal Actions)

The Walker River Paiute Reservation consists of more 130 square kilometers (323,000 acres) of land between Yerington, Nevada, and Walker Lake (See Figure 5-3, Project #2). Although the Reservation is recognized as a sovereign entity under the non-federal actions discussion below, federal agencies could also be taking actions on the reservation. The Bureau of Indian Affairs operates the Weber Dam and Weber Reservoir, which impounds water from the Walker River just north of the community of Schurz for use on the Reservation. Constructed in the 1930's, the dam needs several repairs and modifications to address a number of deficiencies identified as a result of inspections and a safety analysis conducted in the 1980s under the Bureau of Indian Affairs Dam Safety Maintenance and Repair Program, created as part of the Indian Dams Safety Act. Additionally, the U.S. Fish and Wildlife Service is involved in recovery efforts for the threatened Lahontan cutthroat trout (*Oncorhynchus clarki henshawi*). Lahontan cutthroat trout are stocked in Walker Lake and occur in the Walker River upstream to Weber Reservoir. Weber Dam currently blocks movement further upstream, and prevents spawning by cutthroat trout; however, in the near future a fish ladder might be developed at that dam to allow fish movement. Re-establishment of a self-sustaining population of Lahontan cutthroat trout in the Walker River system is a prerequisite for recovery of this species (see also Sections 5.3.1.3.1 and 5.3.1.3.4 below).

5.3.1.2.5 Nevada Test and Training Range (Continuation of Activities)

The U.S. Air Force operates the Nevada Test and Training Range in south-central Nevada (see Figure 5-3, Project #9), a national test and training facility for military equipment and personnel consisting of approximately 12 million square kilometers (3 million acres). Military training maneuvers and jet aircraft are commonly visible in the Mina rail alignment cumulative impacts region of influence. In 2005, the U.S. Air Force designated the Indian Springs Air Force Auxiliary Airfield to Creech Air Force Base and expanded its mission and infrastructure to play a major role in the war on terrorism. The base is home to two key military operations: the MQ-1 unmanned aerial vehicle and the Unmanned Aerial Vehicle Battle laboratory.

The 1,600-square-kilometer (390,000-acre) BLM-administered National Wild Horse Management Area is within the boundary of the Nevada Test and Training Range. More than 3,200 square kilometers (800,000 acres) of the Nevada Test and Training Range comprise the Desert National Wildlife Range. The U.S. Air Force and the U.S. Fish and Wildlife Service jointly manage this area.

In *Renewal of the Nellis Air Force Range Land Withdrawal: Legislative Environmental Impact Statement* (DIRS 103472-USAF 1999, all), the U.S. Air Force addressed potential environmental consequences of extending the land withdrawal in order to continue using the Nevada Test and Training Range lands for military use. Activities at the Nevada Test and Training Range change, as necessary, to meet military test and training needs.

In 2004, the BLM prepared a resource management plan for about 8,900 square kilometers (2.2 million acres) of withdrawn public lands within the Nevada Test and Training Range (DIRS 178102-BLM 2004, all). The plan guides the management of the affected Nevada Test and Training Range natural resources 20 years into the future (2024). The decisions, directions, allocations, and guidelines in the plan are based on the primary use of the withdrawn area for military training and testing purposes.

See Table 5-2 for a list and brief description of recent environmental assessments that describe Nevada Test and Training Range operations.

5.3.1.2.6 Hawthorne Army Depot

The Hawthorne Army Depot occupies approximately 590 square kilometers (147,000 acres) in Mineral County, Nevada (see Figure 5-3, Project #3). Hawthorne Army Depot was commissioned in 1930 as a Naval Ammunition Depot, transferred to the Army in October 1977, and renamed Hawthorne Army Ammunition Plant. It was converted to a government-owned, contactor-operated installation in December 1980. In 1994, the name changed back to the Hawthorne Army Depot. Control of Hawthorne Army Depot is maintained by the U.S. Army, which is responsible for the plans, installation, operation, and equipment of the Depot. The mission of Hawthorne Army Depot is to support the Army, Air Force, and Navy. It also has the capabilities to receive, maintain, store, and issue ammunition and explosive ordnance items. The Hawthorne Army Depot also has the responsibility to renovate, recover, or dispose of unserviceable ammunition and explosives. These latter operations are referred to as demilitarization activities.

The primary ordnance areas at Hawthorne Army Depot extend over 400 square kilometers (100,000 acres) that cross U.S. Highway 95. This area is surrounded on its northeast, east, south, and west sides by fencing and on its north and northwest sides by a boundary line that includes a portion of Walker Lake. The southern one-third of Walker Lake is within the ordnance area. The Mount Grant watershed is in the northwest part of the installation. This watershed consists of about 180 square kilometers (45,000 acres), and is a resource that Hawthorne Army Depot maintains to supply its primary potable water needs. Hawthorne Army Depot has 2,572 buildings and structures, which are comprised of offices, production buildings, ammunition storage magazines, and warehouses. The Depot is bordered by public grazing lands administered by the BLM, and the installation completely surrounds the town of Hawthorne. Hawthorne Army Depot is planning to construct a rail siding, known as the Wabuska Spur, which would increase the Depot’s outloading capacity.

5.3.1.2.7 Naval Air Station Fallon

Naval Air Station Fallon is in the Lahontan Valley of west-central Nevada, approximately 113 kilometers (70 miles) east of Reno and 10 kilometers (6 miles) southeast of the city of Fallon (See Figure 5-3, Project #1). Naval Air Station Fallon administers approximately 32 square kilometers (7,900 acres) of withdrawn and acquired land associated with the air station and approximately 95 square kilometers (234,000 acres) of land associated with the Fallon Range Training Complex. The Fallon Range Training Complex airspace overlies portions of Washoe, Lyon, Churchill, Pershing, Mineral, Nye, Lander, and Eureka Counties, most of which is BLM-administered public land.

In January of 2000, the Navy and BLM issued the *Final Environmental Impact Statement: Proposed Fallon Range Training Complex Requirements Naval Air Station Fallon, Nevada* (DIRS 182891-Department of the Navy, BLM 2000, all). The Naval Strike and Air Warfare Center at Naval Air Station Fallon proposes to implement changes at the Fallon Range Training Complex to meet Chief of Naval Operations mandated training requirements resulting from the real world threat environment. The proposed changes would allow the Navy to update and consolidate Navy training on public and Navy-administered lands and to update existing airspace overlying these lands. The changes evaluated in the EIS include developing new fixed and mobile electronic warfare sites, developing new tracking instrumentation subsystem sites, developing additional targets at two of its training ranges, laying fiber optic cable to two training ranges, utilizing Navy-administered lands in Dixie Valley for close-air-support training, performing Hellfire missile and high altitude weapons delivery training at two of its training ranges, and changes to special-use airspace. The EIS provided a comprehensive evaluation of the environmental impacts, including cumulative impacts, associated with the Navy's proposed changes.

5.3.1.2.8 Timbisha Shoshone Trust Land (Federal Action)

The Secretary of the Interior issued a draft report to Congress (DIRS 103470-Timbisha Shoshone Tribe [n.d.], all) describing a plan to establish trust lands for people of the Timbisha Shoshone Tribe in portions of the Mojave Desert in eastern California and southwestern Nevada (See Figure 5-3, Project #6). On November 1, 2000, the President signed Bill S. 2102 (Public Law 106-423) to provide a permanent land base for the Timbisha Shoshone Tribe within its ancestral homeland in five separate parcels. Lands in the designated area for tribal purposes were then identified, including land parcels containing water rights. The parcel near Scottys Junction (about 11 square kilometers [2,800 acres]) is approximately 3.2 kilometers (2 miles) from the proposed Mina rail alignment. The Timbisha Shoshone Tribe is actively evaluating economic development opportunities on this Scottys Junction parcel. The locations and nature of these future development opportunities are not known and are not considered to be reasonably foreseeable for the purpose of this analysis.

5.3.1.3 REASONABLY FORESEEABLE FUTURE NON-FEDERAL ACTIONS

Non-federal and private actions in the Mina rail alignment cumulative impacts region of influence primarily involve mineral resource development projects, Walker River Paiute Tribal activities, and some residential and general economic development initiatives and efforts. As previously noted, many of these privately sponsored projects would interact with the BLM land management policies and procedures through the need to acquire right-of-way grants to initiate proposed activities on BLM-administered land.

5.3.1.3.1 Walker River Paiute Reservation

The Walker River Paiute Reservation consists of over 130 square kilometers (323,000 acres) of land between Yerington, Nevada and Walker Lake (see Figure 5-3, Project #2). The 2000 census reported a population of 853 people residing on the Reservation. The rural community of Schurz is the only community within the boundaries of the Reservation. Land use on the Reservation consists primarily of open range used for cattle grazing or other agricultural activities. The Department of Defense Branchline from Wabuska extends south through the Reservation to its termination point at the Hawthorne Army Depot.

5.3.1.3.2 Power Plants, Transmission Lines, Pipelines, and Other Infrastructure

There are transmission lines, pipelines, and telecommunications infrastructure within the Mina rail alignment cumulative impacts region of influence, which holds the potential for wind, solar, and geothermal energy development, although the magnitude and specific locations of these energy development projects are not known. As indicated in Section 5.3.1.2.6, the BLM may issue geothermal leases within the Mina rail alignment region of influence. The approval of any leases and subsequent development of geothermal resources would be subject to environmental review and would be guided by BLM resource management plans.

The BLM has designated certain corridors in the area that should be used for most utility purposes; however, use of other BLM-administered land requiring new right-of-way grants has traditionally been considered on a case-by-case basis. As previously noted, the DOE and BLM Energy Corridor programmatic EIS (70 *FR* 56647, September 28, 2005) is an attempt to identify appropriate right-of-way corridors throughout the western United States, including Nevada. This effort could influence the location of rights-of-way in the Mina rail alignment cumulative impacts region of influence in future years.

5.3.1.3.3 Mining

The Mina rail alignment cumulative impacts region of influence contains a variety of mineral resources, with mining claims filed in accordance with BLM requirements and several operating mines. Establishment of mining claims on federal land do not necessarily ever lead to actual development of mining operations on those sites. Major cumulative impact issues involving mining projects include potential land-use conflicts and wastes from operations. Mineral resource locations of note within the region of influence include:

- Nevada Western Silica Corporation holds mining claims for a large, high grade silica deposit near Lida Junction, south of Goldfield in Esmeralda County. There are at least 24 million cubic meters (32 million cubic yards) of silica on site. Both the Caliente and Mina rail alignments pass within 2.4 kilometers (1.5 miles) of the claims.

- Chemetall Foote Corporation runs an operation in Silver Peak, Nevada, that mines lithium carbonate. The company pumps lithium-rich groundwater to the ground surface and then collects the lithium powder as the water evaporates. Chemetall Foote Corporation pumps the groundwater on to dry lake beds in the Clayton Valley to facilitate the evaporation process. Once removed from the water, the raw lithium material is processed in an on-site plant into market-ready, lithium containing products.

- Metallic Ventures Gold holds mining claims near Goldfield in an historic district that produces high-grade gold. The project is currently in the pre-feasibility stage of development.

Mining activities are expected to continue within the Mina rail alignment cumulative impacts region of influence. Mining activities are heavily regulated and must comply with all applicable environmental laws, rules, and regulations. The BLM has an extensive regulatory framework for mineral resource development on federal lands that strives to balance mining activities and mineral extraction with other resource management goals.

5.3.1.3.4 Walker River Basin Restoration

The decline in water quality throughout the Walker River Basin, particularly in Walker Lake, and concerns related to the Lahontan cutthroat trout, have resulted in organized restoration efforts throughout the basin (See Figure 5-3, Project #4). Walker Lake water levels have dropped substantially since the late 1800s. In addition to the declining water level, levels of total suspended solids have also increased in Walker Lake. The increasing total dissolved solid levels along with other physical, biological, and chemical conditions in the watershed and lake have stressed fisheries and other aquatic life in the lake changing the resident fish population. The Walker Lake Working Group is a nonprofit organization building public support for developing a long-term solution to protect the lake without jeopardizing the upstream community. The Group has developed a restoration strategy focused on three objectives: (1) reestablishment of spawning runs of the Lahontan cutthroat trout; (2) providing sufficient water so that levels of total dissolved solids are low enough to support the Walker Lake ecosystem; and (3) acquiring and transferring water rights for environmental and recreational purposes.

5.3.1.3.5 Monte Cristo's Castle (Proposed State Park)

In 2005, a new state park was proposed near Blair Junction (See Figure 5-3, Project #5). If approved, the park would be known as Monte Cristo's Castle and would highlight the unique geology of the area. As proposed, the park would include approximately 23 square kilometers (5,800 acres) of land located just north of the intersection of U.S. 95 and State Route 265 at Blair Junction. As currently envisioned, the proposed park would include hiking areas and interpretive trails with displays about the unique geologic formations in the area. The Nevada State Legislature in June 2007 provided for establishment of the State Park, which would be on land currently administered by the BLM. To transfer the land to the State of Nevada for establishment of the State Park, the BLM would conduct an environmental assessment and other work required as part of the Recreation and Public Purpose Lease process.

5.3.1.3.6 Other Regional Economic Development

Cumulative impacts issues associated with regional economic development actions include socioeconomic effects and overall growth in the region of influence. South and east of the Carson City/Reno area, several regional economic development initiatives are on-going or planned in the northern portion of the Mina rail alignment cumulative impacts region of influence. For example, a county-owned airport near the community of Silver Springs, Nevada, plans to expands its operations, pave its runway, and promote the development of nearby industrial parks totaling approximately 3.8 square kilometers (950 acres). Western Nevada Rail Park is approximately 56 kilometers (35 miles) east of Reno along Alternate U.S. Highway 50. When complete, the rail park would include roughly 1 square kilometer (240 acres) of industrial park serviced by the Union Pacific Railroad mainline. A master-planned community is being developed near the community of Dayton, Nevada. The development contains approximately 12 square kilometers (2,900 acres) consisting of approximately 2,300 single family homes, 0.02 square kilometer (4 acres) of multi-family units, 0.11 square kilometer (27 acres) of commercial land, 1 square kilometer (240 acres) of industrial land, and 0.08 square kilometer (20 acres) for a resort/casino and an improved airstrip that is approximately 1,600 meters (5,400 feet) long. Infrastructure, including new elementary, middle and high schools, fire station, municipal water and wastewater utilities, community center and a health and fitness center, is already in place to support this development. Industrial parks in the Hazen area are also being developed, including a 9.3-square-kilometer (2,300-acre) development along the existing Union Pacific Railroad mainline. As the Reno and Carson City metropolitan areas continue to grow and expand, additional privately sponsored developments can be expected within the northern portion of the Mina rail alignment cumulative impacts region of influence.

Additionally, major transportation corridors such as U.S. Highway 95 through the region of influence into both the Reno and Las Vegas areas will continue to grow and expand, and present additional regional economic development opportunities. A perceived need for support to the Nevada Test Site has led to designation of the Nevada Science and Technology Corridor by the Economic Development Authority for Nye County. The Science and Technology Corridor extends from Indian Springs in Clark County in the south to Tonopah in the north, passing through the Pahrump Valley, Mercury (an entrance to the Nevada Test Site), Amargosa Valley, Beatty and Goldfield, with industrial park and technology initiatives associated with the Tonopah Aeronautics and Technology Park, the Nevada Science and Technology Park in Amargosa Valley, and the Pahrump Center for Technology Training and Development. The locations and nature of specific future development opportunities are not known and are not considered to be reasonably foreseeable for the purposes of this analysis.

Nye County has completed a Yucca Mountain Project Gateway Area Concept Plan with proposed activities for the area around the entrance to the proposed repository site (DIRS 182345-Giampaoli 2007, all). This plan presents Nye County's conceptual, multi-phased land-use guidance for communities adjacent to and near the site entrance area. Nye County proposed this plan with the objective that land development occurs in an orderly and consistent manner and to increase opportunities for industrial and commercial development beneficial to the repository program. Nye County views this plan as a starting point for development of the infrastructure, institutional capacity, and facilities to support the proposed repository. The county developed the plan to use and manage existing initiatives while expanding and improving the area.

5.3.2 POTENTIAL CUMULATIVE IMPACTS – MINA RAIL ALIGNMENT

Located primarily in portions of Esmeralda, Nye, Lyon, and Mineral Counties, the Mina rail alignment cumulative impacts region of influence covers millions of acres of land, most of which is federally managed public land. Most of the land in the Mina rail alignment cumulative impacts region of influence is undeveloped, although much of it has been affected by human activity such as ranching and mining.

Potential cumulative impacts are often discussed herein within the context of the existing regulatory framework (primarily federal and state laws and regulations) and the BLM resource management planning goals and objectives. For example, the existing regulatory frameworks for water and air consider a regional and cumulative impacts perspective, in that regulatory decisions consider the potential effects from other projects as well as a proposed action. As the primary regional land manager, BLM planning and management actions consider the cumulative effects for many resources through stated planning goals and objectives, which often are based on quantitative criteria.

The following analysis of the cumulative impacts associated with the Mina rail alignment is organized by resource area, with Sections 5.3.2.1 through 5.3.2.15 summarizing potential cumulative impacts in the same order of resource discussions in Chapters 3 and 4 of this Rail Alignment EIS.

5.3.2.1 Physical Setting

5.3.2.1.1 Disturbance of Physical Resources

Physical resources consist of resources, conditions, and characteristics such as physiography, soils, and geology. As construction of any project in the area occurs, there would be a potential for changes to the physical setting because land would be disturbed through activities such as cuts and fills and construction of new structures such as buildings and bridges. The proposed railroad would be one of many new sources of change to physical resources that would continue the trend of increasing land disturbance and modifications of the natural physical environment. In large-scale projects that involve substantial ground disturbance, natural features are considered in project design, construction, operations, and potential abandonment plans, which would tend to limit direct, indirect, and cumulative impacts. The proposed railroad would disturb only a small percentage of land in the Mina rail alignment cumulative impacts region of influence.

Given the large amount of land potentially available for development of existing and reasonably foreseeable projects, and the small percentage of potentially available land required for the proposed railroad, overall cumulative impacts to physical setting in the Mina rail alignment region of influence would be small.

5.3.2.1.2 Known or Potentially Contaminated Soils

The major sources of existing soil contamination problems in the Mina rail alignment region of influence are mining, the Nevada Test Site, and the Hawthorne Army Depot. Mining activities in the region have occurred for many years, with mining wastes still remaining from older operations before the regulatory framework required waste management and cleanup. The problems associated with the Nevada Test Site have been described in recent NEPA documentation (DIRS 101811-DOE 1996, all; DIRS 162638-DOE 2002, all). Historic contamination of soils resources on the Nevada Test Site is primarily from radioactive-waste management sites and past nuclear testing activities. Environmental restoration and remediation is occurring at contaminated Nevada Test Site locations in accordance with the facility's Environmental Restoration Program, but much of the contamination is long-term and the land and soil are not restorable to useful condition. For most of the contaminated soils within the Nevada Test Site boundary, DOE is planning only a characterization and long-term monitoring program. Contaminated areas on the Nevada Test Site are generally defined and access is restricted for reasons of safety and security. Spills of any hazardous materials are possible with regional activities, but the current regulatory framework to manage and control hazardous materials and wastes ensures that actions are in place to minimize any impacts.

The Hawthorne Army Depot has an Installation Restoration Program that outlines proposed future investigations and remedial actions at each Solid Waste Management Unit at the installation and other areas of concern. A total of 123 Defense Site Environmental Tracking System sites have been identified on Hawthorne Army Depot property. Soil and groundwater contamination issues exist with the primary contaminants of concern being compounds associated with explosives and heavy metals. Environmental restoration and remediation is ongoing at a number of sites. Other sites have achieved the status of "no further remedial action planned." Contaminated areas on the Hawthorne Army Depot are generally defined and access is restricted for reasons of safety and security.

Contaminated soils or spills can affect other resources such as water resources, biological resources, and land use. Spills of any hazardous materials are possible with regional activities, but the current regulatory framework to manage and control hazardous materials and wastes ensures that actions are in place to minimize any impacts. While any potential impacts associated with hazardous materials and wastes from current and future mining operations in the region are controlled through the existing regulatory framework, mining wastes from old mining extraction and processing activities, especially in the Goldfield area, remain a concern related to soil contamination.

The proposed railroad could result in very localized contamination of soils through occasional spills (such as fuel, oil, and solvents). However, such incidents would be minor in scope and quickly mitigated in accordance with plans and regulations. All existing and foreseeable projects would be subject to the same regulations. Cumulative impacts related to contamination of soils would likely be small.

5.3.2.2 Land Use and Ownership

5.3.2.2.1 Land Use Changes

Many of the past, present, and reasonably foreseeable future actions in the Mina rail alignment region of influence result in land use changes. Land use change can also alter land ownership, land management responsibilities, and preclude future activities from these areas. The vast majority of the land used for the proposed Mina rail alignment and associated facilities would be on BLM-administered land in Lyon, Mineral, Esmeralda, and Nye Counties. The BLM manages more than 45,000 square kilometers (11 million acres) in those four counties. One of the primary land uses in and around the proposed Mina rail alignment on those BLM-administered lands is grazing. Regional grazing activities are often affected by BLM land management plans and activities.

Other existing and reasonably foreseeable major land uses in the Mina rail alignment region of influence include:

- Yucca Mountain Repository – About 6.3 square kilometers (1,600 acres) of land disturbance, most of which would be on the Nevada Test Site (already withdrawn for Nevada Test Site activities).
- Nevada Test and Training Range – About 12,000 square kilometers (3 million acres) of land the U.S. Air Force has withdrawn for special-purpose use, with about 530 square kilometers (130,000 acres) of that land disturbed by Air Force tactical target complexes and associated infrastructure.
- Nevada Test Site – About 3,200 square kilometers (800,000 acres) of land DOE has withdrawn for special-purpose use.
- Naval Air Station Fallon and the Fallon Range Training Complex – Naval Air Station Fallon administers approximately 30 square kilometers (8,000 acres) of withdrawn and acquired land associated with the air station and 950 square kilometers (234,000 acres) of land associated with the Fallon Range Training Complex.
- Walker River Paiute Reservation – Approximately 1,300 square kilometers (323,000 acres) of land managed by the Walker River Paiute Tribal Council.
- Hawthorne Army Depot – Approximately 600 square kilometers (147,000 acres) of land managed by the Army for purposes of receiving, issuing, storing, renovating, inspecting, demilitarizing, and disposing of conventional ammunition. The Army is in the preliminary planning stages regarding an offer from a private firm of 40 square kilometers (10,000 acres) to expand the Army's military training and other missions.
- Reno and Carson City Expansion – A minimum of approximately 25 square kilometers (6,300 acres) of industrial, commercial, and residential developments associated with growth and expansion of the Reno and Carson City Metropolitan areas into the northern portion of the Mina rail alignment cumulative impacts region of influence.
- Hazen industrial parks – Two industrial parks are being developed at Hazen. The Great Basin Industrial Park, a 9.3-square-kilometer (2,300-acre) industrial and residential project is being developed alongside the existing Union Pacific Railroad mainline. Churchill County has already approved this project. The Rail Park, the Union Pacific Railroad mainline from the Great Basin Industrial Park, spans approximately 1.9 square kilometers (480 acres) and is currently in the planning stage.

- Right-of-way corridors that might be established when the DOE West-Wide Energy Corridor programmatic EIS (70 *FR* 56647, September 28, 2005) is completed.

The proposed Mina rail alignment would disturb up to 140 square kilometers (35,000 acres) of land, most of which would be within the construction right-of-way. Therefore, the proposed Mina rail alignment would directly affect about 0.25 percent of the BLM-administered land in the four counties. This disturbance would include construction and operation of the rail line, facilities, quarries, water wells, construction camps, and access roads. The Mina rail alignment would cross up to 15 separate grazing allotments. These 15 grazing allotments constitute about 11,700 square kilometers (2.9 million acres) of BLM-administered land. The approximate disturbance area associated with the proposed Mina rail alignment would constitute less than 1 percent of the land within those 15 grazing allotments. Within this regional perspective of nearby existing and reasonably foreseeable land uses and land ownership, the commitment of land for the proposed Mina rail alignment and associated facilities would constitute a small proportion of overall cumulative land commitment. Use of private land for the proposed rail line would be small, and the rail line would not displace existing or planned land uses on private lands over a substantial area, nor would it substantially conflict with applicable land use plans or goals.

Considering both the proposed railroad and existing and reasonably foreseeable land uses and land ownership, cumulative impacts from land-use changes would be small.

5.3.2.2.2 Existing or Potential Land-Use Conflicts

The Federal Government administers most of the land in the Mina rail alignment region of influence, with the BLM, DOE, and the Department of Defense (Air Force and Army) acting as the major federal land managers. The Mina rail alignment region of influence also includes Walker River Paiute Reservation lands. Private land holdings are small, and generally associated with Chemetall Foote Corporation's Lithium mine near Silver Peak and other towns in the Mina rail alignment region of influence. Traditional land uses in most of the Mina rail alignment region of influence that would be directly and indirectly affected include grazing, mining, and wildlife management. Much of this land is not extensively disturbed, although it has been modified through activity such as grazing and mining.

Over time, human activity in the area, while relatively minor on a regional basis, has begun to change the natural and traditional conditions, and land-use conflicts occasionally result from this human activity. The Nevada Test Site and Nevada Test and Training Range lands have been withdrawn for special purpose and use. Both of these areas are inaccessible to the general public and land use is that of "dominant use," in which the specific DOE and U.S. Air Force missions, respectively, for these lands have ultimate priority over all other potential land uses. Hawthorne Army Depot and Naval Air Station Fallon lands were also withdrawn for special use, are inaccessible to the general public, and land use is that of "dominant use" in which the specific Army and Navy missions, respectively, for these lands have ultimate priority over all other potential land uses. Walker River Paiute Reservation lands are managed by a sovereign tribal government and used by reservation inhabitants accordingly. Around these primary regional land uses are other uses, including mineral development, recreation, urban development, and rights-of-way for various infrastructure. All of these activities and land uses result from a much more intensive land usage involving human activity.

Railroad construction and operation along the Mina rail alignment could have direct and indirect conflicts with grazing uses, access to grazing infrastructure, access to mineral resources, recreational resources, other linear rights-of-way (for example, utility corridors), and wildlife movement patterns in some locations.

Even with the existing and reasonably foreseeable land-use changes, the region as a whole would continue its traditional ways, with grazing and wildlife habitat as major land uses, and cumulative impacts related to land-use conflicts would be small.

5.3.2.2.3 Energy and Mineral Development

Existing and potential future energy and mineral development occurs in various locations throughout the Mina rail alignment cumulative impacts region of influence. In addition to the traditional energy and mineral development (primarily hard-rock mining and industrial mineral development), more recently this development includes geothermal and wind resources. The BLM administers energy and mineral development, evaluates and approves various proposed mineral development operations, and evaluates and approves geothermal energy development projects on federal lands proposed by private companies. Today's energy development environment includes a mix of old and new, involving both nonrenewable and renewable energy resource development.

Because of the scope and extent of typical mining operations, mineral resources that become actual operating mines could result in environmental and land-use issues. Within the Mina rail alignment region of influence, most mining and energy-development activities would occur on federal lands, and the BLM will have a major role in mitigating and monitoring potential effects through its mining and reclamation requirements, NEPA, and other elements of the regulatory framework. Mineral exploration will continue to occur in many parts of the Mina rail alignment region of influence, and some level of conflict from mining exploration and development with other land uses could be unavoidable.

Any potential conflict of the proposed railroad with energy and mineral development would be small in scope and occur in localized areas, and the effects of any such conflicts would be mitigated through the existing regulatory framework and BLM policies and plans. All existing and foreseeable projects would be subject to regulatory requirements and BLM policies and plans related to energy and mineral development. Therefore, cumulative impacts resulting in land-use conflicts related to energy and mineral development along the Mina rail alignment would be small.

5.3.2.2.4 BLM Land Sales and Other Disposals

While specific initiatives for land disposals in the Mina rail alignment region of influence have not yet been developed, BLM has plans to designate for potential future disposal approximately 750 square kilometers (185,000 acres) of public lands in the area including: lands that are difficult and uneconomic to manage (for example, scattered parcels south of Hawthorne and in Smith and Mason Valleys, checkerboard lands near Fernley, Silver Springs and the Carson sink); land that would support community expansion (such as land west of Yerington, land surrounding the towns of Luning, Mina, Sodaville, Fallon, Gabbs, Reno, Verdi, and lands east of Montgomery Pass, near Honey Lake Valley and Dixie Valley); lands with possible agricultural potential (for example, Smith Valley, Mason Valley, Honey Lake Valley, and Edwards Creek); lands along the East Walker River identified for exchange to benefit Bureau programs.

Approximately 92 square kilometers (22,622 acres) have been identified for potential disposal in the vicinity of Goldfield, about 23 square kilometers (5,765 acres) have been identified for potential disposal near Scottys Junction, and 160 square kilometers (39,432 acres) have been identified for potential disposal near Beatty. Land disposal areas have also been identified near Coaldale Junction, Blair Junction, Silver Peak, and Millers.

While the proposed railroad would operate within the regional context of BLM land disposal efforts and any related implications and effects, the railroad would have no affect on, nor would it be affected by, BLM land disposal efforts.

5.3.2.2.5 Recreational Land Use

Public lands in the Mina rail alignment region of influence provide a number of diverse recreation opportunities, and the BLM has designated certain lands as recreation management areas. Demand for recreation is increasing as more people move to and recreate in the Mina rail alignment cumulative impacts region of influence. Dispersed recreation, the principal opportunities available within the Mina rail alignment region of influence, requires a variety of sites but needs no special facilities. These opportunities include caving, photography, automobile touring, backpacking, bird watching, fishing, hunting, primitive camping, hiking, rock climbing, and competitive and noncompetitive off-highway vehicle events. An example of increasing interest in recreation areas is the proposal for the Monte Cristo's Castle as a State Park near Blair Junction; this Park would highlight the unique geology of the area and include hiking areas and interpretive trails with displays about the geologic formations in the area.

The BLM has a major role in recreation opportunities in the Mina rail alignment region of influence. BLM field offices regularly evaluate new opportunities for recreational resources that would provide both passively and actively managed recreation opportunities. There are many such areas that BLM has designated for recreational use, such as a campground and other day-use facilities at Walker Lake, attracting about 35,000 visitors per year. Other forms of dispersed recreation in the region of influence include hunting, camping, and off-highway vehicle use. Increased demand for off-highway vehicle use from the increasing regional population, including the Las Vegas and Reno-Carson City areas, is expected to continue. Many areas of BLM-administered land in Clark County previously used for off-highway vehicle recreation have been closed, causing a shift in use into other BLM areas. As growth and development occur in the Mina rail alignment cumulative impacts region of influence, recreational resources will continue to be in demand, but the potential for conflict with recreational resources also will increase. Recreational resource locations, quality, and availability will evolve as the Mina rail alignment region of influence changes.

The Pahrump area is growing very rapidly for a variety of reasons. Both developed and undeveloped recreational opportunities in the area are abundant, with very easy access to public lands for activities such as hiking, camping, sightseeing, and rockhounding. The town of Pahrump is planning for development of approximately 6 square kilometers (1,500 acres) to be called the Last Chance Park on lands currently managed by the BLM and already used for various types of recreation. The plans include construction of access roads, restrooms, parking areas, and turn-outs, as well as the placing of signs, bike racks, benches, a pole-and-cable fence, trash cans and picnic tables. Much of the park would be dedicated to equestrian, hiking and biking paths, with the remainder allotted to all-terrain vehicle motorized use. Potential environmental impacts and issues will be identified and assessed through the NEPA process.

DOE has sited the proposed Mina rail alignment to avoid wilderness areas and other major recreational resources to the maximum extent practicable. Given the limited effects on regional population, the existence of vast regional recreational opportunities, and limited direct interaction of the railroad with recreational resources, cumulative impacts to access to and use of recreational resources in the Mina rail alignment region of influence would be small.

5.3.2.2.6 BLM Rights-of-Way

As urbanization and other development occur in the Mina rail alignment region of influence, the need for utility and other rights-of-way will increase. The BLM has developed certain preferred corridors over federal lands that it uses to the maximum extent possible for linear rights-of-way, such as for utilities. This keeps many right-of-way purposes together in one location instead of spreading them out over more dispersed areas.

The land-use changes authorized by a BLM right-of-way grant would also have the potential to impact other resource areas as those land-use changes occur. Before approval of right-of-way applications, the BLM will evaluate the impacts of the projects through appropriate NEPA evaluation. Use of land for right-of-way purposes is consistent with BLM regulations and planning processes, and any land-use changes or disturbances associated with those rights-of-way are mitigated to the extent possible and according to BLM policies. As required for the issuance of rights-of-way, the project proponent would prepare and submit to the BLM a Plan of Development for each proposed right-of-way. The Plan of Development would describe the methods and procedures to be used to construct the proposed action on the right-of-way, including site-specific stipulations, terms, and conditions to satisfy all BLM requirements. Certain rights-of-way are long-term in nature and result in unavoidable impacts through land disturbance and the exclusion of other land uses now or in the future.

Utility and other right-of-way crossings are common to linear projects such as roads, railroads, and pipelines. Land areas for the Mina rail alignment, construction camps, quarries, and access roads would cross or overlap existing or proposed utility rights-of-way in approximately 22 to 29 locations. Land areas for railroad operations support facilities could also overlap existing or proposed utility rights-of-way. This situation would be typical for other linear rights-of-way. The crossings would be accomplished with small impact using standard engineering procedures and appropriate design details.

Cumulative impacts to BLM rights-of-way and right-of-way holders would be small.

5.3.2.2.7 Other BLM Land-Management Actions

The Federal Land Policy Management Act of 1976 (Public Law 94-579) mandates the BLM to manage its public lands from a multiple-use perspective. The Federal Land Policy Management Act specifically mentions balancing renewable and nonrenewable resources, including but not limited to recreation, range, timber, minerals, watershed, wildlife, fish, natural, scenic, scientific, and historic values. Therefore, the BLM mission to manage the lands to meet multiple-use objectives is challenging, because many of the resources and associated values often conflict.

Within the context of the Mina rail alignment cumulative impacts region of influence, the BLM planning process and management goals and objectives within their plans are key determinants of the compatibility of the proposed railroad with other projects in the region of influence. As noted in Section 5.3.1, there are many continuing and reasonably foreseeable activities that involve the BLM. Because the BLM is and will remain the major land manager in and around the Mina rail alignment region of influence, BLM land-management goals, objectives, and subsequent land-management actions will largely determine if and how new projects and activities occur.

BLM objectives and goals within the resource management plans can serve to encourage or restrict activities in certain locations. Areas needing special management attention (such as Areas of Critical Environmental Concern) are also identified in the planning process to protect and prevent irreparable damage to important historical, cultural, or scenic values, fish and wildlife resources, or other natural systems or processes, or to protect life and safety from natural hazards. Multiple-use management goals and objectives become more challenging as cumulative development and land-use changes encroach on open land in the Mina rail alignment region of influence.

The Mina rail alignment would cross three BLM planning areas (Carson City, Battle Mountain, and Las Vegas). Each BLM Field Office manages lands within its administrative boundaries according to one or more Management Framework Plans or Resource Management Plans. The Carson City, Battle Mountain, and Las Vegas plans would be applicable to the Mina rail alignment. These programs and resource management plans require a number of public and private partnerships and a collaborative approach to land management and planning.

Grazing operations are a major BLM land-management program in the Mina rail alignment region of influence. Grazing results in both direct and indirect cumulative impacts to vegetation, habitats, and wildlife. Environmental impacts associated with grazing operations are a function of the location, timing, intensity, duration, and frequency of grazing. Grazing animals directly affect plant communities through trampling and nutrient redistribution. The most noticeable impacts occur around waters, salt blocks, fence lines, and other areas where animals concentrate. With proper grazing management, these concentration areas are limited in extent and mitigated regularly through management procedures such as movement of salt blocks and water hauls. While grazing can stimulate growth of some plants and provide other benefits, it can also reduce plant abundance, density, and vigor, especially in sandy soils.

Ultimately, BLM land-management efforts and the content of resource management plans will play a major role in the magnitude, location, and extent of direct, indirect, and cumulative impacts in the Mina rail alignment region of influence, and in the relative balance among multiple uses and resource values chosen for the public lands. DOE recognizes the importance of these land-management actions and encourages readers to review specific resource management plans for more detailed information. As discussed in Chapter 2 of this Rail Alignment EIS, the proposed railroad would be subject to BLM decisions and approval, and any effects of the railroad on BLM resource management planning, land-management activities, and BLM-managed natural resources would be implemented by BLM as appropriate. The proposed railroad's contribution to cumulative impacts to BLM land-management planning and actions in the Mina rail alignment region of influence would be small.

5.3.2.2.8 Urbanization and Economic Development Initiatives

In response to increased economic development goals in the region of influence, the urbanized areas in the Mina rail alignment region of influence have generally planned for and solicited ways to grow and develop. Concepts such as industrial-park development, airport expansion, increased retail opportunities, and housing are prominent goals of the public and private sectors in the Mina rail alignment region of influence. Several regional economic development initiatives are on-going or planned in the northern portion of the Mina rail alignment cumulative impacts region of influence. This trend is likely to continue, with land-use and ownership changes and potential land-use conflicts becoming an increasing issue and challenge for the future. However, it is likely that the rural nature of the overall Mina rail alignment cumulative impacts region of influence will remain largely in tact.

With or without the proposed railroad, urbanization and economic development activities, while increasing, would not generally change the overall undeveloped character of the Mina rail alignment region of influence.

5.3.2.3 Aesthetic Resources

Cumulative impacts to aesthetic resources from construction and operation of a railroad along the Mina rail alignment and other regional activities would primarily result from modifications to natural viewsheds. The natural setting of the Mina rail alignment region of influence includes vast and expansive viewsheds typical of much of the western United States. The open spaces and wide vistas offer interesting cloud, weather, and landscape interactions. Human activity disturbs the natural viewsheds with views of land disturbances such as buildings, roads, removal of vegetation, power lines, equipment, and vehicles. Any activity that disturbs substantial areas of land can result in visual impacts from fugitive dust and ground scars that create a contrast with the surrounding environment and draw the viewer's attention. Additionally, most man-made structures are designed and built for their functionality and safety, not for their visual appeal or compatibility with the visual character of the landscape. For example, projects with construction-related equipment, facilities, and activities can include the presence of workers, camps, vehicles, and machinery, lay-down yards, and dust. The likely addition of explosives bunkers at the Hawthorne Army Depot and projected wind-energy development are examples of other long-term visual changes that are reasonably foreseeable. Each type of project has its unique visual features, but generally, new projects would not be consolidated into any specific location within the region of influence.

While the area has a history of railroad use, the presence of a railroad and associated train traffic would be an identifiable change to the regional viewsheds from some observation points and provide a noticeable contrast with natural visual attributes. The passage of a train would attract the attention of an observer, both because of the noise associated with the train and the contrast with the landscape, especially if the train were to fall in the foreground or middle ground of the viewshed. Visual impacts of passing trains would be temporary, but visual impacts of the track would be long term.

Visual resources within the region of influence have been considered through application of the BLM Visual Resource Management System (see Sections 3.3.3 and 4.3.3 and Appendix D of this Rail Alignment EIS). This system identifies and classifies the BLM-administered lands within established visual resource objectives, and proposed activities are evaluated within the visual resource management framework to consider consistency with the visual resource objectives. Without restoration and reclamation efforts, ground disturbances in the regional environment would last for long periods. The magnitude and extent of potential visual impacts vary based on the number of viewers affected, distance and atmospheric conditions of viewing, degree of visual contrast compared to existing visual attributes, viewer sensitivity to the visual changes, and compatibility with existing land uses. The BLM generally requires ground disturbances to be restored and reclaimed as part of project approval.

For the Mina alignment, analysis using the Visual Resource Management System indicated that the proposed railroad would potentially be inconsistent with visual resource management objectives in the areas of the Schurz crossing of U.S. Highway 95 (construction), and some cuts and fills (during construction and operations). As shown in Appendix D, lands that have potentially restrictive visual resource objectives (such Classes I and II) are not prevalent in the region of influence.

There would be no known interactions of the proposed railroad with other reasonably foreseeable activities that would affect a Class I or Class II area in the Mina rail alignment region of influence.

5.3.2.4 Air Quality and Climate

Emissions of concern in the Mina rail alignment region of influence include fugitive dust and emissions resulting from the operation of machinery and equipment. Construction activities such as surface disturbance and use of haul trucks in the Caliente rail alignment region of influence would generate fugitive dust. Fugitive dust is a type of nonpoint source air pollution (small airborne particles that do not originate from a specific point). These particulate matter emissions are regulated according to their size (aerodynamic diameter equal to or less than 2.5 micrometers [$PM_{2.5}$] and 10 micrometers or less [PM_{10}]). Fugitive dust is generally controlled through the application of water, or in some cases, application of a chemical compound designed to minimize dust emissions. Most of the projects and activities identified in this analysis would generate some level of fugitive dust. The plumes associated with fugitive dust generation are often localized to the area being disturbed and are temporary. In arid areas such as the Mina rail alignment cumulative impacts region of influence, generation and control of fugitive dust will always be a concern. Exhaust emissions from the operation of machinery and equipment include sulfur dioxide, oxides of nitrogen, volatile organic compounds, and carbon monoxide.

There is a comprehensive air quality permitting system in Nevada to evaluate and approve only those projects that are allowable within quantitative air quality thresholds. The Nevada Division of Environmental Control, Bureau of Air Pollution Control, has established and implemented air pollution control requirements in Nevada Revised Statutes 445B.100 through 445B.825, inclusive, and Nevada Revised Statutes 486A.010 through 486A.180, inclusive. The Bureau of Air Pollution Control has jurisdiction over air quality programs in all counties in the state except Washoe and Clark. The Bureau of Air Pollution Control also has jurisdiction over all fossil fuel-fired units in the state that generate steam for electrical production. The Mina rail alignment would be subject to the permitting requirements noted above, and would occur in air basins that are either in attainment or unclassifiable. The State of Nevada will not grant permits for activities that cannot show compliance with the applicable federal and state regulations.

The air quality impact analysis for the Mina rail alignment assessed potential impacts through several means, including air quality modeling of maximum concentrations relevant to National Ambient Air Quality Standards. The analysis concluded the emissions during construction or operation of the rail line or any associated facilities would be in conformance with applicable standards, with the exception of the 24-hour standard for both PM_{10} and $PM_{2.5}$ near the construction right-of-way at Mina and Schurz during the relatively short construction period, and at the Staging Yard at Hawthorne and the potential Garfield Hills quarry. DOE would be required to prepare an application for a Dust Control Permit and a Surface Area Disturbance Permit Dust Control Plan and submit them to the Nevada Division of Environmental Protection Bureau of Air Pollution Control prior to the quarry and Staging Yard development. It is likely that the requirements of the plan would reduce fugitive dust emissions, thus reducing the possibility of exceeding National Ambient Air Quality Standards.

Potential cumulative impacts to air quality from construction and operation of the proposed railroad along the Mina rail alignment would be small, but could approach moderate if the potential violation of the National Ambient Air Quality Standards noted above occurred.

5.3.2.5 Surface-Water Resources

5.3.2.5.1 Changes in Drainage, Infiltration Rates, and Flood Control

Construction of major projects in previously undeveloped areas often results in changes to natural drainage. Construction could include regrading that would allow runoff from a number of minor drainage channels to collect in a single culvert or pass under a single bridge, which would result in water flowing from a single location on the downstream side rather than across a broader area. This would cause some localized changes in drainage patterns, but this probably would occur only in areas where natural drainage channels are small. Compaction of soil during construction could reduce water infiltration rates and change natural runoff and drainage patterns. However, some activities would disturb and loosen the ground for some time, which could cause higher infiltration rates.

Construction in washes or other flood-prone areas probably would reduce the area through which floodwaters naturally flow. This could result in water building up, or ponding, on the upstream side of crossings during flood events, and then slowly draining through the culverts or bridges. These alterations to natural drainage, sedimentation, and erosion would be unlikely to increase future flood damage, increase the impact of floods on human health and safety, or cause significant harm to the natural and beneficial values of the floodplains.

Insufficient inflow from the Walker River into Walker Lake would continue to jeopardize Walker Lake's future as a viable fishery, with or without the proposed railroad. If developed, the proposed railroad would not result in further inflow reductions into Walker Lake. Mitigation measures that could be implemented by the U.S. Fish and Wildlife Service or other entities could improve the chances for a viable fishery in the lake in future years.

As a long linear project of up to 502 kilometers (312 miles) long, the proposed Mina rail alignment would pose new surface drainage challenges because of the existing characteristics of terrain, topography, soils, and physical features. Construction activities that could temporarily block surface drainage channels include moving large amounts of soil and rock to develop the rail roadbed (subgrade) and constructing temporary access roads to reach construction initiation points and major structures, such as bridges, and to allow movement of equipment to the construction initiation points.

Project planning and best management practices would help avoid or reduce potential impacts from the proposed railroad or other ongoing or reasonably foreseeable future actions. Potential cumulative impacts due to changes in drainage, infiltration rates, and flood control would be very small and localized.

5.3.2.5.2 Spill and Contamination Potential

Major construction activities and other projects in the region of influence would use materials including petroleum products (fuels and lubricants) and coolants (antifreeze) necessary to operate construction equipment, and could include solvents used in cleaning or degreasing actions. A release or spill of contaminants to a stream or river would have the greatest potential for adverse environmental impacts; a release of contaminants to dry impermeable soil would have the least potential for adverse impacts. Other projects would face similar situations. Spill-control and -management plans (and standard operating procedures for the construction industry) would reduce the likelihood of spills. Construction and operation of the proposed railroad would be typical of major activities that use materials that could cause contamination through spills.

While the risk of a spill and associated water contamination cannot be totally eliminated, risks can be managed through regulatory controls so that the resulting cumulative impacts would be small.

5.3.2.6 Groundwater Resources

Existing and proposed future development within the Mina alignment region of influence presents the challenge of matching water supply with water demand. Because water availability is a potential resource constraint in the Mina rail alignment region of influence over time, water demand can be both competitive among potential users and controversial among users and the general public. To allocate water uses, the State of Nevada uses a water permit application process coordinated by the State Engineer. Once granted, water rights in Nevada have the standing of both real and personal property. It is possible to buy or sell water rights and change the water's point of diversion, manner of use, and place of use by filing the appropriate application with the State Engineer. Overall, because the water permitting and allocation process considers the broad range of factors noted above, the process serves as a way to manage potential cumulative impacts of water demand and use within each basin.

Representative existing and reasonably foreseeable water uses in the Mina rail alignment region of influence include:

- Public-supply/municipal, agricultural (stock watering), and mining uses collectively comprise approximately 87 percent of groundwater use within the Mina rail alignment region of influence.
- The Nevada Test Site uses about 830,000 cubic meters (673 acre-feet) of water per year.
- The Yucca Mountain Repository demands would range from about 218,000 to 527,000 cubic meters (176 to 427 acre-feet) of water per year between calendar years 2010 and 2013, which represents the period of the highest water demand for the Mina rail alignment project. The Repository would use approximately 76,700 to 397,000 cubic meters (62 to 322 acre-feet) of water per year in calendar year 2014 through completion of operation.

It is estimated that rail construction along the Mina rail alignment would use up to about 7.34 million cubic meters (5,950 acre-feet) of water, with about 80 percent of that water use occurring in the first 2 years of construction. About 23,000 cubic meters (17 acre-feet) of water would be needed annually during the operations phase. DOE would obtain water for construction and operation of the railroad from proposed new wells installed in various water basins along the Mina rail alignment.

Committed groundwater resources in the Mina rail alignment region of influence already exceed annual perennial yield values (a measure of available groundwater supply replenished each year through recharge) within some of the groundwater basins (hydrographic areas) that would be affected by the proposed railroad. Based on the proposed locations of new wells in specific hydrographic areas along the proposed Mina rail alignment, additional groundwater appropriations would be needed in 19 hydrographic areas. However, committed (cumulative) groundwater resources currently exceed estimated perennial yields in eight of these hydrographic areas (146, 149, 170, 173A, 203, 204, 228, and 229). One of these eight hydrographic areas (229) and two other hydrographic areas (144 and 145) that the Mina rail alignment would cross have low perennial yields. Five of these areas are State of Nevada-designated groundwater basins. While designated groundwater basins are not considered closed to additional appropriations, the State Engineer could impose additional restrictions and preferred uses of the water in these designated basins.

A number of scenarios have been developed to assess the potential effects of the Mina rail alignment's contribution to cumulative water demand in the cumulative impacts region of influence. Groundwater would need to be appropriated in 18 hydrographic areas. The assumption used for developing these scenarios is that water demands for railroad construction and operations along the Mina rail alignment would be met through installing and withdrawing groundwater from new wells, with pumping in individual wells at a constant rate occurring primarily over 9 months to support all rail-line construction water needs, over 2 to 3 years at quarry sites, and over the railroad operations period for facilities. Depending on the specific combination of alternative segments, total water withdrawals associated with the proposed railroad could exceed annual perennial yield values for hydrographic areas 123, 144, and 229, and could be as high as 48 percent, 57 percent, 82 percent, 87 percent, and 99 percent of the annual perennial yield in hydrographic areas 145, 228, 110A, 121B, 227A, respectively. In other areas, water withdrawals associated with the railroad would range from less than 1 percent to as high as approximately 28 percent of the annual perennial yield value.

By utilizing a combination of one or more specific approaches or methods to obtain water for construction (including methods that are tailored to a hydrographic area's unique groundwater condition), potential cumulative impacts to groundwater resources would be minimized. New groundwater withdrawals could, depending on the withdrawal rate; hydrogeologic conditions present at the proposed pumping location and in the surrounding area; and the location and characteristics of nearby groundwater resource features, cause some decrease in the amount of water that might be available to an existing well having an associated water right, to an existing spring discharge, or to a downgradient groundwater basin.

Overall, the needs of the proposed railroad would represent a small portion of the current cumulative water usage within the Mina rail alignment region of influence, which in some locations would continue to exceed perennial yield values.

5.3.2.7 Biological Resources

5.3.2.7.1 Habitat Loss and Fragmentation

Past, present, and reasonably foreseeable future actions in the Mina rail alignment cumulative impacts region of influence would result in noticeable cumulative land disturbance. Existing activities such as the

Nevada Test and Training Range, the Nevada Test Site, Naval Air Station Fallon and the Hawthorne Army Depot have already resulted in land disturbance and substantial changes to existing biological resources, and projects such as the various proposed industrial parks and master-planned communities in the northern portion of the Mina rail alignment cumulative impacts region of influence would continue this trend. Such land disturbances result in altered natural biological and ecological conditions, and directly serve to reduce the amount of natural land available as habitat and open space.

The primary adverse construction-related impacts on vegetation communities from ground disturbance would be the physical destruction or removal of vegetation, and the permanent or temporary removal or compaction of topsoil or other growing medium for the plants. These effects would occur with any major activity resulting in ground disturbance, including the proposed railroad. As more activity occurred, the cumulative loss of vegetative communities and associated habitats would increase. Management of these effects would typically be considered in project planning and mitigation, including projects on BLM-administered land. Much of the emphasis in land management in the Mina rail alignment region of influence concerns the maintenance or reconstruction of healthy habitats.

Habitat destruction would lead to direct impacts such as wildlife injury and mortality, alteration of behavior and movement patterns, and the indirect impacts of reduced vegetative health, reduced biological diversity, and locally degraded ecological function. When extensive habitat fragmentation occurs, the individuals or populations of particular species could have difficulty surviving. Habitat destruction arises from a number of sources, including projects that involve land disturbance, and land management actions including wild horse and burro management. Though any project that causes disturbance of vegetation contributes to habitat fragmentation, linear projects that impose any degree of impediment to movements, like the proposed railroad, amplify the potential effects.

Measures to avoid, minimize or otherwise reduce impacts are typically implemented by project proponents and encouraged by government agencies and generally include actions to reduce or avoid habitat fragmentation and loss. Such actions would include minimizing land disturbance, using existing roads, interim reclamation, combined roads/utility rights-of-way for pipelines and cables, noise reduction, centralization of facilities, and employee training and education.

The Hawthorne Army Depot has an Integrated Natural Resources Management Plan (DIRS 181899-USAF 2007, all), which is being used to ensure that natural resource conservation and Army mission activities are integrated and are consistent with federal stewardship requirements on mission lands. The plan describes an ecosystem-management approach that provides guidance to avoid the impacts of habitat loss and fragmentation, conserve biodiversity, and improve and enhance natural resource integrity while supporting sustainable economies and communities.

In areas proposed for railroad operations purposes, the impacts to vegetation would typically be moderate in scope, and cumulatively add to habitat loss and fragmentation. However, in areas slated for short-term use during the construction phase, such as construction camps, revegetation and reclamation efforts would result in replacement of topsoil, reseeding of native species, monitoring for success, and eventual return of a native vegetation community to conditions comparable to predisturbance conditions.

Cumulative impacts due to habitat loss and fragmentation would be small to moderate through the construction and operations phases throughout the Mina rail alignment region of influence.

5.3.2.7.2 Invasive Species and Noxious Weeds

Invasive species and noxious weeds naturally move into new areas over time, but this occurrence has been accelerated in many areas through human activity, either intentionally or unintentionally. In many cases, these plants have been moved into North America from another continent. They have been accidentally introduced through contaminated grain or hay, or sometimes intentionally introduced for erosion control or as ornamentals. In addition, livestock and vehicles can cause invasive species and noxious weeds to spread, birds could carry seed, or the species can be brought in with contaminated fill dirt. Regardless of how they were introduced, invasive species and noxious weeds possess characteristics that allow them to compete aggressively with native vegetation. Invasive species and noxious weeds impact native plants, animals, and natural ecosystems by:

- Reducing biodiversity
- Altering hydrologic conditions
- Altering soil characteristics
- Altering fire intensity and frequency
- Interfering with natural succession
- Competing for pollinators
- Displacing rare plant species
- Replacing complex communities with single-species monocultures

From a cumulative impacts perspective, any time land is disturbed and native vegetation is lost there is an opportunity for noxious weeds to replace the native vegetation. While the BLM and other land owners/ managers in the area have implemented programs to minimize this potential, invasion of noxious weeds cannot always be prevented. Therefore, coordinated multi-agency management actions and efforts are needed to mitigate the effects from cumulative land disturbance. Management of noxious and invasive weeds is essential for restoration of native plant community health and resiliency. If noxious and invasive weeds were not managed, they would continue to gradually replace more desirable native species throughout the Mina rail alignment region of influence.

Linear disturbances such as pipelines, roads, utility corridors, or rail alignments that cross relatively undisturbed land have the potential to exacerbate the spread of these species into areas not previously affected. As the invasive or noxious weeds become established along the linear features they spread to adjacent areas, affecting the plant and animal communities beyond the actual disturbance, and are able to outcompete native species by responding more rapidly to the infrequent availability of water.

These impacts could occur as a result of railroad construction and operation and from existing or foreseeable projects, but strict adherence to best management practices should reduce the potential for impacts. Cumulative impacts due to the introduction and spread of invasive species and noxious weeds would be small.

5.3.2.7.3 Special-Status Species

Habitat for several special-status species would be disturbed, and individual mortality of several of those special status species could occur during railroad construction and operations along the Mina rail alignment. Through the NEPA and permitting processes, each proposed project and land-management planning effort in the Mina rail alignment region of influence will face challenges for the protection of various special-status species. There are a number of special-status species that could be affected by cumulative impacts in the Mina rail alignment region of influence. Recent attention has focused on several specific species, including the desert tortoise and Lahontan cutthroat trout, as discussed below.

The Mojave population of the desert tortoise (*Gopherus agassizii*) is listed as threatened under the Endangered Species Act of 1973 (16 U.S.C. 1531 to 1544). It is found within the proposed Mina rail alignment only in the southwestern-most 48 kilometers (30 miles), from the Beatty Wash area to Yucca Mountain (DIRS 101830-Bury et al. 1994, pp. 55 to 72). The desert tortoise is found in southern California, parts of southern Utah, and in the southern portions of Nevada, with the tortoises potentially affected by railroad construction and operation at the extreme northern extent of their range. While relative abundance of the tortoise is low in much of the Mina rail alignment region of influence, every action that could disturb soil or vegetation within the tortoise's range has potential cumulative impacts of loss or fragmentation of the species' habitat or the direct mortality of individual desert tortoises

The threatened Lahontan cutthroat trout (*Oncorhynchus clarki henshawi*) is stocked in Walker Lake and occurs upstream to Weber Reservoir. Weber Dam currently blocks movement further upstream, and prevents spawning by cutthroat trout. However, in the near future, a fish ladder might be developed at that dam to allow fish movement. Reestablishment of a self-sustaining population of Lahontan cutthroat trout in the Walker River system is a prerequisite for recovery of this species. With mitigation, the construction activities along the Mina rail alignment would have minimal effects on the trout, but the existing problem with Weber Dam blocking movement of the trout further upstream would remain.

The BLM resource management plans sometimes place restrictions on other activities (such as grazing, wild horse and burro abundance, off-road vehicle use, mineral activities) so that desert tortoise or other special status species habitat can be protected. However, off-road vehicle use, shooting, and collecting of individuals continue to affect tortoise populations. Habitat protection efforts for the desert tortoise are coordinated among a number of federal, state, and local governmental agencies, with the cumulative impact perspective a major factor in determining allowable impacts to the tortoise. Restoration plans and habitat conservation plans also affect the required mitigation measures, best management practices, and standard operating procedures for the protection of the desert tortoise or other special-status species.

Private landowners, corporations, state or local governments, or other non-federal landowners who wish to conduct activities on their land that might incidentally harm (or "take") wildlife listed as endangered or threatened must first obtain an incidental take permit from the U.S. Fish and Wildlife Service. To obtain a permit, the applicant must develop a Habitat Conservation Plan, designed to offset any harmful effects the proposed activity might have on the species. Multi-species Habitat Conservation Plans are underway in two places in the Caliente rail alignment region of influence: (1) the Coyote Springs area and (2) in southern Lincoln County in the area of the recent BLM land disposal. Additionally, there is a single species (desert tortoise) Habitat Conservation Plan being developed in the Pahrump area of Nye County. These plans would support development of private lands while accounting for the potentially affected species.

No major effects on special status species are projected to result from construction and operation of the proposed railroad along the Mina rail alignment. DOE would conduct any required consultation with the U.S. Fish and Wildlife Service in accordance with the Endangered Species Act. There is a substantial regulatory framework, to which all projects are subject, that serves to evaluate and protect special status species. Therefore, cumulative impacts to special status species would be small.

5.3.2.7.4 Wildfires

Wildfires are a major environmental concern throughout the Mina rail alignment region of influence due to the generally dry climate and the increasing presence of invasive plant species. When they occur, wildfires have a significant and long-term impact on vegetation, wildlife, other natural resources, and human safety. The most important biological effects of fires include:

- Loss of native plant communities
- Decreased stability of watershed and soils
- Decreased or degraded wildlife habitat
- Increase in potential for invasive species spread
- Overall disruptions to ecological function

Sources of regional wildfires are both natural (for example, lightning) and human caused. With increased activity in the Mina rail alignment region of influence, the potential for future human-caused fires increases. Because the BLM administers most of the land in the Mina rail alignment region of influence, the BLM has primary fire-avoidance and fire-fighting responsibilities in the Mina rail alignment region of influence.

Both the proposed railroad project and other reasonably foreseeable future actions would likely implement appropriate fire-avoidance strategies in consultation with the BLM. Potential cumulative impacts from wildfires would be small.

5.3.2.8 Noise and Vibration

5.3.2.8.1 Railroad Noise

In the Mina rail alignment cumulative impacts region of influence, there is an existing branchline extending from Hazen, Nevada, to the Hawthorne Army Depot. The noise associated with railroad operations is part of the existing environment, specifically in the Schurz area where the railroad's presence is very evident. The sounds associated with the existing branchline include wayside noise (noise generated by the cars and locomotives), and horn sounding. The individual operating rules of each railroad require train engineers to sound horns when approaching most grade crossings. Horn sounding is generally not required at private crossings. Wayside noise and horn sounding are common in Schurz and along other portions of the existing branchline.

Hawthorne Army Depot is planning to construct a rail siding, known as the Wabuska Spur, which would increase the Depot's outloading capacity. Increased rail capacity could cause increases in overall rail traffic on the existing branchline and could result in more wayside noise and horn sounding events more frequently near Hawthorne within the Mina rail alignment cumulative impact region of influence.

Transportation of spent nuclear fuel and high-level radioactive waste casks would result in as many as eight one-way trips per week along the Mina rail alignment. Train activity associated with supply and maintenance of the Yucca Mountain Repository is also proposed along the completed railroad (as many as seven one-way trips per week), as is rail line maintenance activity (about two one-way trips per week), for a total of about 17 one-way trips per week. During the construction phase, completed portions of the rail line would also be used to deliver ballast to construction areas.

Potential impacts from noise along the Mina rail alignment would be expected to be small. However, the proposed railroad would introduce or expand noise sources into areas of the Mina rail alignment region of influence that previously had very limited railroad noise. This could result in incremental annoyance effects for some people.

While adverse noise effects could increase for some people in the Mina rail alignment region of influence, railroad construction and operations along the Mina rail alignment would substantially reduce noise impacts for people in Schurz, because the existing rail line through Schurz would be eliminated and replaced by one of Schurz alternative segments. This would provide a substantial reduction in annoyance effects for people in Schurz.

5.3.2.8.2 Urban Noise

Urban noise includes automobiles, construction activities, barking dogs, and other human activities generally within an identifiable community. At present, urban noise in the Mina rail alignment region of influence is limited because there are only a few cities and communities. However, with economic development and growth goals throughout the region of influence, the number and scope of urbanized areas is expected to increase. Urban noise is generally localized and is differentiated from the aircraft and railroad noise sources, which move with the source from one location to another, while urban noise is within identifiable geographic borders associated with the locations of populations.

The proposed railroad would have a very small effect on urbanization in the area, and its effect on urban noise in the Mina rail alignment region of influence would be small. Cumulative impacts related to urban noise would be small.

5.3.2.8.3 Aircraft Noise

Aircraft-related noise from engines and sonic booms is common throughout the Mina rail alignment cumulative impact region of influence, and can cause “startle” and annoyance effects. The noise associated with military aircraft is consistent with the “dominant use” of the area for military and defense-related activities at the Nevada Test and Training Range and Naval Air Station Fallon. Any noise effects associated with the missions for the Nevada Test and Training Range or Naval Air Station Fallow would be considered necessary and unavoidable. Commercial air traffic also contributes to noise impacts in the region of influence.

The proposed railroad would not contribute to cumulative aircraft noise.

5.3.2.8.4 Vibration

Vibration can be perceived on land surfaces and within buildings with certain types of activities. Construction activity is one of the more common sources of vibration, but construction vibration would be very localized and typically minor in scope and duration. In the Mina rail alignment cumulative impacts region of influence, other possible sources of vibration include occasional testing activities at the Nevada Test and Training Range and sonic booms from aircraft-related military activities in the airspace above the region of influence. These events would also tend to be short-term and localized.

Cumulative impacts from vibration would be small.

5.3.2.9 Socioeconomics

The economic roots of the Mina rail alignment cumulative impacts region of influence have traditionally been based on mineral development, military operations and support, and livestock grazing. These activities will continue to be the primary economic drivers in the Mina rail alignment cumulative impacts region of influence. Additionally, the expansion of the Reno-Carson City metropolitan area in the northern reaches of the Mina rail alignment cumulative impacts region of influence will continue to occur, providing additional economic inputs. While a railroad in the Mina rail alignment would be a major development in the region of influence, its long-term economic development potential would be limited and would primarily be related to construction activities. If the Shared-Use Option were chosen and implemented, there would be greater potential for positive economic development benefits compared to the Proposed Action.

Population growth in the Mina rail alignment cumulative impacts region of influence has generally been stagnant in much of the area. However, growth and development is desired by many in the region. It is uncertain if there is sufficient economic development growth potential in these areas to support the desired growth. It is possible that some areas would grow at the expense of other areas, or that recently developed plans for growth turn out to be unrealistic. Provision of housing to meet market demand is a private-sector activity, with the private housing sector assumed to build to the needed level to meet housing demand at the appropriate locations. One of the factors that will affect how and where growth occurs is the availability of infrastructure to support the growth. Beyond the traditional infrastructure needs like roads, sewer, water, and public buildings, modern infrastructure such as the availability of fiber-optic lines might also affect growth patterns. For example, the availability of fiber-optic lines or other high-technology infrastructure is likely to be a substantial growth discriminator for both businesses and individuals. The locations of and extent to which factors such as fiber-optic lines would ultimately affect growth cannot be predicted at this time.

The potential future BLM land disposals identified in Section 5.3.2.2.4, if implemented, could have the potential to provide land for private-sector projects such as housing, industrial or commercial facilities, or other developments. In contrast to specific developments proposed on BLM land disposals in the Caliente rail alignment region of influence, such growth in the Mina rail alignment region of influence is not currently planned and the market for this type of developmental stimulus is uncertain.

The State of Nevada has developed population projections for the Mina rail alignment cumulative impacts region of influence (DIRS 178807-Hardcastle 2006, all) as follows:

- Esmeralda County is projected to have a small decrease in population from 2005 to 2026.
- Nye County is projected to add mover than 32,000 persons from 2005 to 2026.
- Lyon County is projected to add more than 41,000 persons from 2005 to 2026.
- Mineral County is projected to have a small decrease in population from 2005 to 2026.

The Nevada State Demographer develops population projections for Nevada counties, which are always subject to change with new information.

Nye County's projected growth continues a recent trend, with growth in Pahrump very evident over the past several years. Growth in Pahrump is being driven by low-cost land, proximity to the Las Vegas metropolitan area, and relocation of retirees to the area. Growth in Nye County is also linked directly to existing and future Yucca Mountain Site operations. Growth in Lyon County is due largely to its proximity to Carson City and Reno.

As discussed in Section 4.3.9, Socioeconomics, DOE used an economic model to estimate potential socioeconomic impacts of the proposed railroad (DIRS 182251-REMI 2007, all). The model includes consideration of construction and operations employment and wages, project-related spending, and other parameters that could affect the socioeconomic environment. The model included a future baseline of socioeconomic parameters that would represent a cumulative impacts baseline without the proposed railroad.

Consistent with the methodology established in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, p. 4-43), most of the construction workers for the proposed Mina rail alignment are assumed to be residents of Clark County. This assumption is made because the construction sectors in Nye, Esmeralda, Lyon and Mineral Counties are not large enough to provide sufficient workers for the construction activities. Under this scenario, Clark County is projected to attain the largest levels of construction-related employment, income, and spending effects from the proposed project, followed by Mineral, Nye, Esmeralda, and Lyon Counties. Mineral County would experience the largest employment percentage increase during construction with an estimated increase of about 6 percent above baseline conditions.

The socioeconomic analysis also considers a second scenario, which assumes that half of the construction workers for the Mina rail alignment reside in the combined Washoe County-Carson City area, and the other half reside in Clark County. This second scenario is considered because Washoe County and Carson City might be more likely than Clark County to supply construction workers for the northern portions of the Mina rail alignment. With this second scenario, the beneficial economic effects on Clark County would obviously be reduced, while the Washoe County-Carson City area would gain some of these beneficial aspects of proposed railroad project. In any case, the overall effects of the proposed railroad along the Mina rail alignment on the Clark County or Washoe County economies would still be relatively small.

Employee locations for the operations phase would follow the same general pattern and relative magnitude of the construction phase, but there would be fewer operations jobs than construction jobs. Gains in employment during the operations phase would be felt most strongly in Esmeralda County, where the peak percentage change in average annual employment is projected to be 6.3 percent above baseline conditions during full operations. Mineral County is the only other county in the region of influence projected to experience more than a 1 percent change in average annual employment at any point during the operations phase (2.6 percent).

Population changes that would result from construction and operation of the proposed Mina rail alignment are also projected to generally follow this pattern. During the construction phase, the upper bound of increase to population would be about 3 percent or less of the future cumulative population baseline in all four counties. The operations phase population change would have the largest percentage increase compared to the cumulative baseline in Esmeralda County (about 7-percent average annual increase over the baseline). There are no projected impacts to population on the Walker River Paiute Reservation.

Strains on housing infrastructure during the construction phase would not be anticipated because most construction workers could be housed in construction camps at strategic locations along the proposed Mina rail alignment, rather than in nearby communities. Contractors might elect to use commercially available facilities for housing construction personnel at locations such as Hawthorne, Tonopah, Goldfield, Beatty, and Pahrump. There would be enough vacant housing stock in these locations to absorb both construction and operations personnel.

Some infrastructure impacts would be expected where construction activities or operating facilities were near communities. For example, construction workers, including those from the proposed Mina rail alignment, could strain the existing health care service capacity in the Mina rail alignment region of influence, and particularly in Hawthorne, Goldfield, and Tonopah. The operations-related population gains could also result in identifiable effects on health and education-related services.

The road network in the Mina rail alignment region of influence consists generally of two-lane highways and unpaved roads. U.S. Highway 95 is the major north-south highway in the region of influence. In rural, less populated parts of the Mina rail alignment cumulative impacts region of influence, roads are adequate to handle existing and projected future traffic flow. However, the array of new and proposed activities throughout the Mina rail alignment region of influence would have the potential to strain parts of the existing roadway infrastructure.

Railroad project-related road traffic would result in small increases in some areas but railroad construction would not materially affect traffic volumes on local roads because most construction materials would be transported using rail, and most construction employees and contractors would be housed in construction camps linked to the work site by access roads. There could be some traffic delays at existing rail-highway grade crossings, and grade separation might be necessary for some crossings in Churchill, Lyon, and Mineral counties. However, cumulative traffic levels in the region would likely continue to increase as overall regional growth and development occurs.

Any road improvement and maintenance responsibilities in the region of influence are handled by the Nevada Department of Transportation through a Statewide Transportation Plan and a Statewide Transportation Improvement Program. The Statewide Transportation Improvement Program includes a 3-year list of federally funded and regionally important non-federally funded transportation projects and programs consistent with the goals and strategies of the Statewide Transportation Plan. Routine highway improvements and maintenance projects for the period 2006 through 2015 have been identified for Lyon, Mineral, Esmeralda, and Nye Counties as part of the Nevada Department of Transportation planning processes. The level of cumulative traffic changes would generally not be sufficient for major upgrades of regional roads.

Overall, the proposed railroad project would have a small impact on economic development and growth, housing and community infrastructure, and traffic in the Mina rail alignment region of influence. While there is some limited potential for induced growth impacts, the specific locations and scope of these actions is unknown at this time, and any such actions are projected to be small. Cumulative impacts to socioeconomics in the Mina rail alignment region of influence would be small.

5.3.2.10 Occupational and Public Health and Safety

5.3.2.10.1 Nonradiological Health and Safety

Throughout the Mina rail alignment region of influence, continuing and reasonably foreseeable activities have the potential to result in occupational injuries or fatalities including, but not necessarily limited to sources such as tripping, being cut on equipment or material, dropping heavy objects, and catching clothing in moving machine parts, and other types of accidents. Other occupational risks include biological hazards, dust and soils hazards, air quality hazards, transportation accidents, and noise hazards. Biological hazards include potential human health effects from rodent-borne diseases, soil-borne diseases, insect-borne diseases, and venomous animals. Dust and soils hazards include potential human health effects from exposure to inhalable soils and dusts containing hazardous constituents, and potential occupational encounters with unexploded ordnance.

While occupational injuries or fatalities are unavoidable with human activity, public and private facilities within the Mina rail alignment cumulative activity area are highly regulated. There is a substantial regulatory framework for occupational health and safety, with the Occupational Safety and Health Administration programs and regulations forming the basis for protection of workers. Through DOE Order 440.1A, *Worker Protection Management for DOE Federal and Contractor Employees*, the Department has prescribed the Occupational Safety and Health Act Standards that contractors are to meet in their work at government-owned, contractor-operated facilities. The Department of Labor, Bureau of Labor Statistics, measures occupational incident rates, including total recordable cases, lost workday cases, and fatalities, associated with the work environment.

There are no data on injury/illness incident rates for the Mina rail alignment cumulative impacts region of influence; however, injury/illness incidence rates in Nevada generally run higher than those in the United States as a whole. The economic segments with the highest injury/illness incidence rates in Nevada are construction and goods-producing industries.

Additional traffic is especially a concern with the construction phases of reasonably foreseeable projects. The construction phase of a project not only brings construction workers to the work sites, but also means an increase in slow-moving and bulky traffic involving the transportation of construction equipment. Use of trucks for hauling hazardous or other dangerous materials is also an increasing concern as traffic increases on the road network. To minimize traffic impacts at the entrance to the Yucca Mountain Site, a new interchange with U.S. Highway 95 at the site entrance been proposed for both traffic flow and safety reasons. Increased traffic would not necessarily mean an increase in the rate of traffic accidents, but the number of accidents would increase if the rate of traffic accidents stayed the same and traffic increased. Therefore, transportation safety concerns would increase and there could be an increased workload for traffic-accident responders in the Mina rail alignment region of influence with the cumulative growth in traffic.

From a transportation safety standpoint, railcars loaded with live munitions and ordnance currently travel between Wabuska and the Hawthorne Army Depot. A railroad along the Mina rail alignment would reduce health and safety risks associated with accidents involving existing rail traffic because the trains would be routed away from the populated community of Schurz via one of the Schurz alternative segments.

An estimated 9,500 casks would be transported to the repository by rail using the Mina alignment. Nonradiological occupational health and safety impacts are projected as follows:

- Construction and operations activities for the Mina rail alignment are projected to result in approximately 800 recordable incidents, approximately 470 lost-workday accidents, and approximately two fatalities.
- Vehicular-related fatalities related to worker commuting are projected to result in an estimated 13 vehicular-related fatalities for the Mina rail alignment.
- Rail-related accidents and rail-related fatalities related to the movement of cask trains, maintenance trains, and supply trains are projected to result in 16 rail-related accidents and one rail-related fatality for the Mina rail alignment.

Under Module 1, approximately 21,900 casks would be transported to the repository by rail, and under Module 2, approximately 22,600 casks would be transported to the repository by rail. To estimate the cumulative health and safety impacts of Module 1 and Module 2, the impacts of the Proposed Action were increased by the ratio of the number of casks transported in Module 1 or Module 2 versus the Proposed Action. For Module 1, the nonradiological health and safety impacts noted above would increase by a factor of approximately 2.3 over the impacts under the Proposed Action. For Module 2, nonradiological safety impacts would increase by a factor of approximately 2.4 over the impacts of under Proposed Action.

Other regional activities would also cumulatively add to the totals beyond the railroad-related impacts, but cumulative nonradiological health and safety in the Mina rail alignment region of influence would be small within the context of the overall region of influence.

5.3.2.10.2 Radiological Health and Safety

Existing and reasonably foreseeable future activity (such as the Nevada Test Site and Yucca Mountain Repository activity managed by DOE) in the Mina rail alignment region of influence involves the storage, handling, transportation, use, and disposal of radioactive materials and wastes. There is an extensive regulatory framework associated with transportation safety, and the proposed railroad would operate in compliance with these laws and regulations. For example, DOE complies with U.S. Department of Transportation regulations regarding the transportation of radioactive materials. DOE also uses U.S. Environmental Protection Agency protective action guides (identifying projected dose levels at which specified actions should be taken) and actions designed to limit doses and impacts in the event of a transportation accident resulting in releases of radioactive material. The regulatory framework and implementation of appropriate standard operating procedures would reduce the potential for accidents. Coordination of plans for proposed railroad construction and operations with local emergency response providers would be important to limit the potential for accidents, and for an effective response to an accident should one occur.

There is a small risk of radiological impacts to workers and the general public from external radiation exposure during normal operations and incident-free transportation. Staff at the Nevada Test Site and the Yucca Mountain Repository would be separate, and it is not anticipated that there would be cumulative exposures to workers from both operations. The modes of transportation of radioactive wastes for the

Nevada Test Site (shipment by truck) and the Yucca Mountain Repository (shipment by rail) would differ. Radiological impacts associated with rail operations would be higher under Yucca Mountain FEIS Modules 1 or 2 operations compared to the Repository SEIS Proposed Action level of transportation. The radiological risk relationships among the repository, the proposed Mina rail alignment, and Nevada Test Site operations are summarized below.

As part of the Repository SEIS process, DOE estimated that 9 to 28 latent cancer fatalities for members of the public would result from Yucca Mountain Repository construction, operations, monitoring, and closure for the population within the 80-kilometer (50-mile) region of influence of the repository site. The estimated latent cancer fatalities correspond to a total collective dose of 15,000 to 46,000 person-rem, and the projected population within the repository region of influence is 120,000 persons. The region of influence for the Yucca Mountain Repository extends 80 kilometers (50 miles) to the northwest from the repository site boundary along the rail corridor, approximately to Scottys Junction; the remainder of the Mina rail alignment is outside of the Yucca Mountain Repository region of influence. Population within the area where the rail alignment region of influence and the Yucca Mountain repository region of influence coincide (between the repository boundary and the Scottys Junction area) would receive radiation dose from both the repository and from the Mina rail line operation. Members of the public situated along the rail alignment but outside of the region of influence of the Yucca Mountain Repository would receive a negligible radiation dose from the repository.

For members of the public along the rail line, DOE estimated that there could be up to 8.5×10^{-4} latent cancer fatality, corresponding to a collective population dose of 1.4 person-rem, for the Mina rail alignment. Therefore, for members of the public situated along the rail alignment, the radiological impacts of railroad operations would be a very small contribution to the overall radiological impacts of the Yucca Mountain Repository.

The estimated radiological dose to members of the public from Nevada Test Site operations in 2005 was 0.2 mrem per year; the maximum radiation dose was 2.3 mrem per year at the northwest corner of the Nevada Test Site boundary. Dose at off-site populated locations between 20 kilometers and 80 kilometers (12 to 50 miles) from this location would experience much lower radiation doses due to wind dispersion (*Nevada Test Site Environmental Report 2005,* DIRS 182285-Wills 2006, Table 8-4, p. 8-2). The collective population dose from Nevada Test Site operations was below 0.6 person-rem in 2004 (*Nevada Test Site Environmental Report 2005,* DIRS 182285-Wills 2006, Table 8-3, p. 8-8.) Radiation dose from Nevada Test Site operations would be a very small contribution to the overall radiological impacts of the Yucca Mountain repository.

Operation of the proposed railroad along the Mina rail alignment under the Proposed Action would result in a small contribution to cumulative radiological health and safety impacts. Cumulative radiological impacts in the Mina rail alignment region of influence would be small.

5.3.2.11 Utilities, Energy, and Materials

5.3.2.11.1 Utilities

From a cumulative impacts perspective within the Mina rail alignment region of influence, utility crossings are and will continue to be commonplace with little impact other than minor ground disturbance. Utility and other right-of-way crossings are common to linear projects such as roads, railroads, and pipelines. Land areas for the proposed rail alignment, construction camps, quarries, and access roads would cross or encroach upon existing or proposed utility rights-of-way in a variety of locations. Land areas for operations support facilities could also encroach upon existing or proposed utility rights-of-way. This situation would be typical for other rights-of-way in the region. The crossings would be accomplished with small impact using standard engineering procedures and appropriate design details.

Many regional activities, including the proposed railroad, would increase demands on public water systems, wastewater systems, telecommunications systems, electric power systems, and other utilities. However, regional service providers are projected to be able to adjust to any increasing demand, and overall cumulative impacts to utilities would be small.

5.3.2.11.2 Energy and Materials Usage

Large projects such as pipelines, transmission lines, and power plants, that could occur within the Mina rail alignment cumulative impacts region of influence require materials and energy to construct and operate. Energy and material resources necessary for construction or operation of these projects are often obtained within regional or, in some cases, national markets.

For this Rail Alignment EIS, DOE analyzed cumulative energy and materials supply and demand from a regional perspective. Energy and materials (for example, steel and concrete) that would be needed for railroad construction and operations are not constrained in regional markets, and railroad needs would represent a small percentage of the cumulative annual materials use within the Mina rail alignment cumulative impacts region of influence.

While the regional markets for various construction-related materials and energy sources will continue to grow as the region develops, there is no evidence of potential limits to growth from constrained material or energy supplies. Cumulative impacts from energy and materials usage in the Mina rail alignment region of influence would be small.

5.3.2.12 Hazardous Materials and Waste

5.3.2.12.1 DOE Waste-Management Activities

DOE has had existing waste management programs at the Nevada Test Site for several decades. While the Site missions have changed over time (with an emerging focus on national security, energy, and environmental issues), waste management and disposal at the Site has been one of the primary long-term land uses. There are two active waste management and disposal sites on the Nevada Test Site:

- Area 5 occupies 2.9 square kilometers (720 acres) and is in Frenchman Flat north of Mercury, Nevada.
- Area 3 occupies 0.53 square kilometer (130 acres) north of Mercury in Yucca Flat.

Environmental restoration efforts are under way at various locations throughout the Nevada Test Site. The Nevada Test Site waste-management program currently includes management and disposal operations for hazardous waste, mixed waste, and low-level radioactive waste. Transportation of the waste is accomplished by truck from both on-site and off-site sources. There are no plans for Nevada Test Site activities to include use of the proposed Mina rail alignment for shipment of wastes.

The proposed railroad’s contribution to cumulative impacts associated with DOE waste-management activities on the Nevada Test Site would be small.

At present, Yucca Mountain Repository-development efforts are focused on preparing an application to the U.S. Nuclear Regulatory Commission for a authorization to construct the repository for spent nuclear fuel and high-level radioactive waste. The Yucca Mountain FEIS (DIRS 155970-DOE 2002, all) and the

Repository SEIS (DOE/EIS-0250F-S1, all) describe proposed operations at the Yucca Mountain Site in detail.

5.3.2.12.2 Sanitary and Construction Wastes

As the populated areas in the Mina rail alignment cumulative impacts region of influence expand and grow, the volume of sanitary waste generated will also expand. Project proponents are legally required to dispose of nonhazardous and nonradiological construction and other solid waste in appropriately permitted solid waste landfills. Nevada has 24 operating municipal landfills with a combined capacity to accept more than 11,000 metric tons (12,000 tons) of waste per day. However, the number of operating landfills has decreased substantially over the past 15 years, and while there is sufficient capacity to accept waste for the State of Nevada as a whole, there are some areas such as Pahrump that have limited capacity for future years.

Construction- and operations-related waste that would be associated with the proposed Mina rail alignment would add only a fraction of a percent to the total waste stream in the state. If there were a constraint to landfill capacity at some future time, additional land would be needed to expand or open a new landfill. Because of the relative scarcity of private land in the Mina rail alignment region of influence, any land used for this purpose might need to come from BLM-administered federal land. As an alternative to local government landfill provisions, private companies can also be expected to seek business opportunities to provide solid-and hazardous-waste management, transportation, and disposal.

DOE would store and use hazardous materials (such as oil, gasoline and solvents) during the Mina rail alignment construction, and would control and manage these materials in accordance with the extensive federal and state regulatory framework. Other major projects would have similar waste streams, and project plans and requirements would call for disposal of such wastes in permitted facilities and materials management according to accepted industry practices.

The proposed railroad's contribution to impacts from the generation and management of sanitary and construction wastes would be small. Cumulative impacts to waste disposal facilities in the Mina rail alignment region of influence would be small.

5.3.2.13 Cultural Resources

Cultural resources include historic and archeological sites, buildings, structures, landscapes, and objects. Most reasonably foreseeable projects in the Mina rail alignment cultural resources region of influence will involve at least some ground disturbance. With that ground disturbance, cultural resources could be destroyed, damaged, or discovered for recovery or mitigation. As part of the evaluation of proposed projects on federal land, the existing regulatory framework requires that cultural resources be identified and protected. With information on the location of a proposed project and the estimated extent of ground disturbance, cultural resource specialists can be called on to perform appropriate surveys and inventories of cultural resources in the potentially disturbed area. Once discovered, the sites of cultural resources are kept confidential to reduce the potential for vandalism or theft of the resources.

Because cultural resources are typically on or below the ground, they can be damaged by other activities such as off-highway vehicle use. As the major land manager in the Mina rail alignment region of influence, the BLM has an extensive cultural resource management program and manages federal land with protection of cultural resources as a key management objective. Once ground is disturbed and facilities are constructed on the land, the opportunity for identification of cultural resources is usually lost. Therefore, the BLM and other land managers in the area (for example, DOE on the Nevada Test Site and the U.S. Air Force on the Nevada Test and Training Range) employ cultural resource specialists and involve tribal representatives, as appropriate. Commonly, mitigation for any ground disturbance in the

Mina rail alignment region of influence includes the involvement of these cultural resource specialists as potential cultural resources are discovered. Other activities occurring on federal land, such as off-road vehicle use and rock collecting, can cause unintended adverse impacts to cultural resources. Mission activities occurring at the Nevada Test Site, the Nevada Test and Training Range, and the Yucca Mountain Repository also could cause unintended adverse impacts to cultural resources.

The problem of vandalism to and theft of cultural resources is prevalent throughout the western United States. Land-management agencies such as the BLM make extensive attempts to protect locations of cultural resources, but the areas to be managed are often so vast that patrols by law enforcement are not effective in protecting these sites. DOE, the BLM, and other federal agencies in the Mina rail alignment region of influence are committed to public education and employee training regarding the protection of cultural resources.

Visitors may also be drawn to the area for purposes of curiosity and sight-seeing. Based on the extent of cultural resource site finds on BLM-administered land and on the Nevada Test Site, and data collected to date on the proposed Mina rail alignment, there could be a large number of cultural resources in the Mina rail alignment region of influence. Also, it is likely that only a portion of any currently undiscovered sites would ultimately be found eligible for the *National Register of Historic Places*.

The railroad would be a major new construction project introduced into a remote area. Beyond the implications of ground disturbance and permanent and temporary use areas, railroad construction and operations would bring employees, visitors, and equipment into an area where prior access was limited. If right-of-way roads remain open to the public, there could be an increase in off-road vehicles traveling along newly constructed roads and illegal use of lands. As the number of visitors increases, so does the potential for vandalism and damage to cultural resources. There is an extensive regulatory framework to manage and protect cultural resources.

Impacts to cultural resources in the Mina rail alignment region of influence would be small because the Department would conduct intensive field surveys and implement mitigation measures, including avoidance. Other project proponents would be subject to the same regulatory framework and BLM policies and procedures. Cumulative impacts to cultural resources in the Mina rail alignment region of influence would be small.

5.3.2.14 Paleontological Resources

Regional protection, management, and impact issues relative to paleontological resources are similar to those of cultural resources. Any type of ground disturbance could disturb or destroy known or unknown paleontological resources. Impacts to paleontological resources would generally be measured by physical damage to fossil-bearing formations through excavation or surface disturbance. The primary cumulative impact mechanisms that could affect paleontological resources include excavations or surface disturbances associated with approval and implementation of BLM rights-of-way, off-highway vehicle use, minerals development, land disposals, and special designations. Many BLM management activities, however, serve to protect and mitigate impacts to paleontological resources. Knowledge of the outcrop pattern of geologic units, and the kinds and quality of the fossils produced by such units, is a critical management tool for land-use decision-making where fossils might be involved. Potential effects on paleontological resources from ground disturbance would continue to be a major regional concern of BLM from both resource management planning and rights-of-way evaluation perspectives. Most formations the rail line would cross are volcanic and would not contain paleontological resources.

Any paleontological resources are considered valuable and are often collected for their cultural, scientific, and recreational values. Therefore, these resources are sometimes removed from federal lands. While common invertebrate fossils such as plants, mollusks, and trilobites can be collected for personal use in reasonable quantities, the lack of regular site monitoring and public education about fossil collecting has led to increased illegal commercial taking of paleontological resources. Paleontological resources are also vulnerable to intentional or unintentional vandalism. The specific locations of some identified paleontological resources are kept confidential to avoid vandalism or theft.

The most likely locations of currently unknown paleontological resources can be identified based on geological characteristics, and potential impacts can be avoided or minimized through careful project planning and implementation. Most formations the rail line would cross are volcanic and would not contain paleontological resources. Therefore, the proposed railroad project would not contribute to cumulative impacts to paleontological resources.

5.3.2.15 Environmental Justice

5.3.2.15.1 Potential Effects to Low-Income and Minority Populations

Environmental justice impacts result when high and adverse human health or environmental impacts fall disproportionately on low-income and minority populations. If high and adverse impacts are found to have disproportionate impacts on environmental justice populations as compared to the general population of the area, the impacts would be mitigated to the extent practicable by the federal agencies involved in the proposed action.

Based on individual and group values, beliefs, and goals, there is a difference in perspective as to the potential effects of activities in the Mina rail alignment region of influence on low-income and/or minority populations among the different stakeholders and other interested parties. The American Indian Resource Document (DIRS 174205-Kane et al. 2005) discusses cultural resources, American Indian values and their relationship to environmental justice, and broader American Indian values. DOE considers the American Indian Writers Subgroup conclusions to be responsible opposing viewpoints for purposes of its environmental justice responsibilities. DOE has concluded that there are no identifiable environmental or human health impacts associated with the proposed railroad that would disproportionately affect low-income or minority populations. Additionally, there are no identified effects to special pathways (such as subsistence hunting and gathering) in the Mina rail alignment region of influence.

The largest concentration of low-income or minority populations along the Mina rail corridor occurs in Mineral County and on the Walker River Paiute Reservation. The corridor would cross American Indian tribal lands, with the four Schurz alternative segments almost entirely on the Walker River Paiute Reservation (DIRS 180222-BSC 2006). There are approximately 1.4 square kilometers (350 acres) of reservation lands in the corridor (DIRS 180222-BSC 2006). The population of the reservation, estimated to be 853 persons in 2000, is low-income and consists mainly of American Indians, a minority population. The poverty rate in Mineral County is 15 percent, which exceeds the rate of poverty (11 percent) in the State of Nevada, while the poverty rate of Walker River Paiute Reservation residents is 32 percent, nearly three times the rate of poverty in the state. The only moderate or large impacts that were identified relate to noise impacts from construction. These impacts would not occur on the Walker River Paiute Reservation; therefore, there would be no large and adverse effects that would disproportionately affect a low income or minority community and there are no special pathways that would result in disproportionately large and adverse effects to low income or minority communities.

DOE has concluded that there are no identifiable human health or environmental impacts associated with the proposed railroad that would disproportionately affect low-income or minority populations, nor has the Department identified any special pathways for impacts (such as subsistence hunting and gathering) in the Caliente region of influence.

Cumulative impacts to low-income or minority populations along the Caliente rail alignment would be would be small, if any.

5.3.2.15.2 Economic Opportunity

Existing and reasonably foreseeable projects and activities in the Mina rail alignment region of influence would present economic opportunities for some persons in the area. Economic opportunities include employment, wages, revenue from business operation, and other economic stimuli associated with growth and development. DOE and other project proponents in the Mina rail alignment region of influence have a legally mandated equal opportunity approach to these economic opportunities. Any potential for economic gain would be distributed equally to persons or businesses in the area that seek employment or business opportunity. While not all persons would gain economically from the cumulative group of projects and activities, the opportunity for gain does not favor one population group or another based on minority or income status.

Because there would be small changes in long-term population attributable to activities in the corridor, impacts or stresses to the housing stock, infrastructure systems, or social services would be unlikely. Socioeconomic impacts from railroad construction and operations along the Mina rail corridor would be small overall and would be unlikely to adversely or disproportionately affect the low-income or minority populations along the corridor.

5.4 Combined Repository and Nevada Rail Transportation Impacts

This section presents the total estimated environmental impacts for the proposed construction, operation, monitoring, and closure of the repository combined with the environmental impacts from the proposed Nevada transportation activities. As construction along the rail alignment approached the physical location of the repository and its surface facilities, the potential for impacts to overlap would increase.

Table 5-4 provides an overview of the total combined impacts of the proposed repository and railroad in Nevada within overlapping regions of influence. In most instances, DOE evaluated the potential impacts qualitatively and judged them to be small. However, there are several air quality and groundwater impacts from the repository and the railroad actions that DOE was able to sum and quantify:

- Air Quality. The air quality impacts from simultaneous construction of the proposed repository and of the railroad and associated rail facilities would not produce criteria air pollutant concentrations that exceeded the regulatory limit at the boundary of the analyzed repository land withdrawal area.
- Groundwater. Groundwater withdrawals would occur for both the repository and railroad actions from the same hydrographic area, specifically Area 227A, Jackass Flats. DOE has analyzed water demand from both actions to gauge overall impacts to groundwater resources in the Jackass Flats area. The highest combined annual water demand for railroad and repository activities would be below the Nevada State Engineer's ruling of perennial yield (the amount that can be withdrawn annually without depleting reserves) for the Jackass Flats hydrographic area. The combined demand would also be lower than the lowest estimated perennial yield for the western two-thirds of this hydrographic area. Coupled with the demand for Nevada Test Site activities in Jackass Flats, the total annual water demand would exceed the lowest estimated value of perennial yield for the western two-thirds of the hydrographic area during only one year. However, this estimated total combined water demand would still be below estimated values of perennial yield for the entire hydrographic area for all years. The combined repository and railroad actions would withdraw groundwater that would

Table 5-4. Summary of combined repository and Nevada railroad impacts (page 1 of 3).

Resource area	Summary of repository and Nevada rail transportation impacts that occur within overlapping regions of influence
Land use and ownership	About 12 square kilometers of disturbed land; 600 square kilometers of land withdrawn from public use.
Air quality	Nye County is the only location where Nevada rail transportation impacts would overlap the repository region of influence. The Nevada rail transportation emissions would be distributed over the entire county and only the southern portion of the emissions from Nye County would be within the repository region of influence. Modeled concentrations of criteria pollutants at the boundary of the repository land withdrawal area would not exceed regulatory limits during simultaneous construction of the repository and railroad. Concentrations of all criteria air pollutants except for particulate matter would be less than 6 percent of the regulatory limit. Concentrations of $PM_{2.5}$ would not exceed 37 percent, and concentrations of PM_{10} would not exceed 84 percent of the regulatory limit. The simultaneous operation of the repository and railroad would not exceed regulatory limits.
Hydrology	
Surface water	At least two of the drainage channels and floodplains (Busted Butte Wash and Drill Hole Wash) the rail line would cross would also be affected by construction of repository surface facilities.
Groundwater	Water identified for rail line construction includes 572 acre-feet (over 4 years) plus 6 acre-feet per year for operations, all from the same groundwater basin as for repository activities. A peak annual water demand of 530 acre-feet would result from the combined Nevada rail transportation and repository needs, but this high level would last only 1 year. The average annual water demand for the combined construction period would be 400 acre-feet. All of the combined water demand levels would be below the lowest estimate of the groundwater basin's perennial yield (580 acre-feet). The year of highest water demand would not result in a well drawdown that could affect the nearest public or private wells. Modeling for the Yucca Mountain FEIS showed small to moderate impacts from the Proposed Action groundwater withdrawals that are still applicable. The model's assumed withdrawal rate of 430 acre-feet per year is lower than the peak water demand, but over the life of the project, is still conservatively high.
Biological resources and soils	Loss of up to 12 square kilometers of desert soil, habitat, and vegetation, but no loss of rare or unique habitat or vegetation; adverse impacts to individual threatened desert tortoises and loss of a small amount of low-density tortoise habitat, but no adverse impacts to the species as a whole; reasonable and prudent measures would minimize impacts.
Cultural resources	Small potential for impacts; including three National Register-eligible prehistoric sites; opposing American Indian viewpoint.

Table 5-4. Summary of combined repository and Nevada railroad impacts (page 2 of 3).

Resource area	Summary of repository and Nevada rail transportation impacts in overlapping regions of influence
Socioeconomics	
New jobs (percent of workforce in affected counties	Peak increases would be small, less than 1 percent in the region, Clark County, and Nye County when construction of repository and the railroad overlap.
Peak real disposable income (million dollars)	For repository: In Clark County (2034), $58.3 million; in Nye County (2035) $27.5 million. For railroad: In Clark County (2011) $100.6 million; in Nye County (2012) $9.6 million.
Peak incremental gross regional product (million dollars)	For repository: In Clark County (2034), $98.7 million; in Nye County (2034) $68.9 million. For railroad: In Clark County (2012), $154.5 million; in Nye County (2012), $42.8 million.
Occupational and public health and safety	
Public, radiological	
Maximally exposure individual (probability of a latent cancer fatality)	Not applicable
Population (latent cancer fatalities)	Not applicable
Public, nonradiological	
Fatalities due to emissions	Not applicable
Workers (involved and noninvolved)	
Radiological (latent cancer fatalities)	Not applicable
Nonradiological fatalities (includes commuting traffic fatalities)	Not applicable
Accidents	
Public, Radiological	
Maximally exposed individual (probability of a latent cancer fatality)	Not applicable
Population (latent cancer fatalities)	Not applicable
Workers	Not applicable
Noise and vibration	Impacts to public would be small due to large distances from the repository to residences; workers exposed to elevated noise levels; controls and protection would be used as necessary.
Aesthetics	The exhaust ventilation stacks on the crest of Yucca Mountain could be an aesthetic aggravation to American Indians. If the Federal Aviation Administration required beacons atop the stacks, they could be visible for a great distance, especially west of Yucca Mountain.

Table 5-4. Summary of combined repository and Nevada railroad impacts (page 3 of 3).

Resource area	Summary of repository and Nevada rail transportation impacts in overlapping regions of influence
Utilities, energy, materials, and site services	Use of materials would be small in comparison to regional use; some effect on public water systems and public wastewater treatment facilities due to population growth from construction and operations employment; annual fossil-fuel use would be less than 7 percent of state-wide use during construction and less than 2 percent of state-wide use during operation; electric power delivery system to the Yucca Mountain site would have to be enhanced.
Waste and hazardous materials	Small impacts from nonhazardous waste (solid and industrial waste) disposal to disposal capacities of local solid waste facilities near Yucca Mountain in Nye, Esmeralda, Clark, and Lincoln counties.
Environmental justice	No high and adverse impact to population as a whole; no specific pathways for minority populations; therefore no high and adverse impacts to minorities and low income populations; opposing American Indian viewpoint.
Manufacturing repository components	Not applicable.
Airspace restrictions	Small impacts to airspace use; airspace restriction could be lifted once operations have been completed.

otherwise move into aquifers of the Amargosa Desert, but the combined water demand for the railroad, the repository, and Nevada Test Site activities in Jackass Flats would have, at most, small impacts on the availability of groundwater in the Amargosa Desert area in comparison with the quantities of water already being withdrawn there.

6. STATUTORY, REGULATORY, AND OTHER APPLICABLE REQUIREMENTS

This chapter identifies the permits and approvals, Federal Government and State of Nevada regulations, and Executive and DOE Orders that could apply to construction and operation of the proposed railroad.

Glossary terms are shown in ***bold italics***.

During proposed ***railroad*** construction and operations, the U.S. Department of Energy (DOE or the Department) would comply with applicable requirements, and has developed and is implementing a comprehensive approach to the permitting and approval processes that would ensure compliance.

As illustrated in Figure 6-1, compliance with regulatory requirements is the second step in the DOE approach to avoiding, minimizing or reducing environmental ***impacts***.

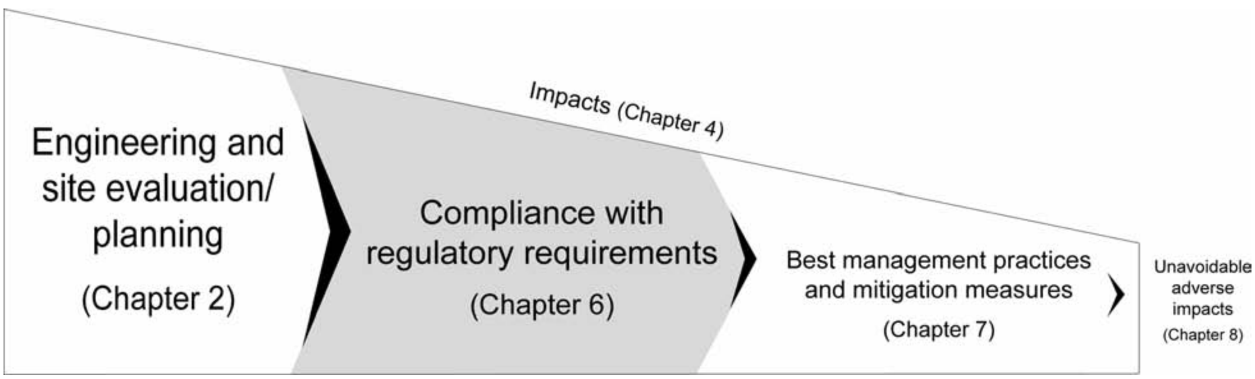

Figure 6-1. Multi-step approach to avoid, minimize, or reduce environmental impacts.

The chapter is organized as follows:

- Section 6.1 summarizes statutes and regulations that establish or affect DOE authority to construct and operate the proposed railroad.
- Section 6.2 identifies Surface Transportation Board (STB) requirements.
- Section 6.3 summarizes statutes and regulations that establish environmental protection requirements that could apply to construction and operation of the railroad.
- Section 6.4 identifies potentially applicable DOE Orders.
- Section 6.5 identifies U.S. Department of the Interior, Bureau of Indian Affairs, requirements.
- Section 6.6 identifies U.S. Department of the Interior, Bureau of Land Management (BLM), requirements.
- Section 6.7 identifies U.S. Army requirements.

Appendix A provides copies of the applicable *Federal Register* (*FR*) notices. Appendix B describes interagency and intergovernmental interactions.

6.1 Statutes and Regulations Establishing or Relating to DOE Authority to Propose, Construct, and Operate a Railroad in Nevada for Shipment of Spent Nuclear Fuel and High-Level Radioactive Waste to the Repository at Yucca Mountain

This section summarizes the statutes and regulations that establish or affect DOE authority to propose, construct, and operate the proposed railroad.

6.1.1 NUCLEAR WASTE POLICY ACT, AS AMENDED (42 UNITED STATES CODE [U.S.C.] 10101 *et seq.*)

The Nuclear Waste Policy Act, as amended (NWPA), establishes the Federal Government's responsibility for the ***disposal*** of ***spent nuclear fuel*** and ***high-level radioactive waste*** and generators' responsibility to bear the costs of disposal. The NWPA identified the ***Yucca Mountain Site*** in Nye County, Nevada, as the only site to be studied as a potential location for a ***geologic repository***. As part of its obligations under the NWPA, DOE is responsible for developing a system to transport spent nuclear fuel and high-level ***radioactive*** waste to the repository. On April 8, 2004, DOE published *Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV* (69 *FR* 18557) announcing the selection, both nationally and in the State of Nevada, of the mostly rail scenario analyzed in the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* 155970 (DIRS 155970-DOE 2002, all) as the mode of transportation for shipping spent nuclear fuel and high-level radioactive waste to Yucca Mountain and selected the Caliente ***rail corridor*** to evaluate alignments for a ***rail line***.

6.1.2 YUCCA MOUNTAIN DEVELOPMENT ACT OF 2002 (PUBLIC LAW 107-200)

On February 15, 2002, President George W. Bush approved the Secretary of Energy's recommendation of Yucca Mountain as the site for the development of a repository for the disposal of spent nuclear fuel and high-level radioactive waste. The House of Representatives approved the Yucca Mountain Site on May 8, 2002, as did the Senate on July 9, 2002. This approval of the site at Yucca Mountain became known as the Yucca Mountain Development Act, which the President signed into law on July 23, 2002. This Act is a joint resolution of the House of Representatives and Senate approving the site at Yucca Mountain, Nevada, for the development of a repository for the disposal of spent nuclear fuel and high-level radioactive waste, pursuant to the Nuclear Waste Policy Act of 1982, as amended.

6.1.3 ATOMIC ENERGY ACT, AS AMENDED (42 U.S.C. 2011 *et seq.*)

The Atomic Energy Act of 1954, as amended, provides fundamental jurisdictional authority to DOE and the U.S. Nuclear Regulatory Commission (NRC) over governmental and commercial use of nuclear materials. This Atomic Energy Act ensures proper management, production, possession, and use of radioactive materials. In accordance with the Atomic Energy Act, DOE established a system of requirements issued as DOE Orders.

The Atomic Energy Act gives the Nuclear Regulatory Commission specific authority to regulate the possession, transfer, ***storage***, and disposal of nuclear materials, and aspects of transportation packaging design for radioactive materials, including testing for packaging certification. Nuclear Regulatory Commission regulations applicable to the transportation of radioactive materials (10 Code of Federal Regulations [CFR] Parts 71 and 73) require that shipping ***casks*** meet specified performance criteria under both normal transport and hypothetical ***accident*** conditions. DOE and Nuclear Regulatory Commission regulations applicable to protection against ***radiation*** (10 CFR Parts 20 and 835) address occupational ***dose*** limits, public dose limits, survey and monitoring procedures, ***exposure*** controls, respiratory protection and controls, precautionary procedures, and related topics. DOE would comply with all applicable radiation protection regulations during operation of the proposed railroad.

6.2 Surface Transportation Board Requirements

If DOE selected the ***Shared-Use Option*** as part of the ***Proposed Action***, DOE would have to apply to the STB for a license to construct and operate the proposed rail line (known as a "certificate of public convenience and necessity"). If DOE did not select the Shared-Use Option, the STB would have no regulatory authority related to the Proposed Action. The Shared-Use Option involves operating the proposed railroad as a common-carrier railroad – one that holds itself out to the public for service and has an obligation to provide rail service to any and all shippers that request service along that line.

The STB has exclusive jurisdiction over the construction, acquisition, and operation of common-carrier railroads pursuant to the Interstate Commerce Act (as amended by the ICC Termination Act of 1995 [Public Law 104-88, 109 Stat. 803 (1995)]). To operate the proposed railroad under the Shared-Use Option, DOE would have to apply for a "license of public convenience and necessity" issued under 49 U.S.C. 10901 or under 49 U.S.C. 10502. The regulations prescribing how to apply for a license to construct and operate a rail line are provided in 49 CFR Part 1150. If the Department sought a license from the STB, the STB would subject the proposal to a careful review, including preparation of the environmental documentation required to meet STB obligations under the National Environmental Policy Act (NEPA), as provided in 49 CFR Part 1105.

The STB has jurisdiction over common-carrier rail lines that are part of the interstate rail network. This jurisdiction includes facilities and structures that are an integral part of rail transportation [49 U.S.C. 10501(b); 49 U.S.C. 10102(9)]. Section 10501(b) also states that "the remedies provided under this part are exclusive and preempt the remedies provided under federal and state law." The purpose of Section 10501(b) is to prevent a patchwork of local regulation from unreasonably interfering with interstate commerce. Thus, Section 10501(b) does not permit dual state and federal regulation of railroads or activities related to rail transportation at railroad facilities. This statutory framework, with supporting case law, supports the STB broad preemption authority.

The STB preemption authority applies to state or local regulation of matters directly related to the STB, and state or local pre-clearance or permitting requirements – such as zoning ordinances and environmental and land-use permitting requirements – that could be used to deny or defeat a railroad's ability to conduct its operations. Thus, a local or state body cannot deny a carrier the right to construct, develop, and maintain facilities or conduct operations, because this denial would create irreconcilable conflict with the STB's exclusive jurisdiction over such facilities and operations.

While exempt from traditional permitting, zoning, and land-use processes for railroad operations, railroads such as the one DOE proposes are not necessarily exempt from other applicable laws. The states retain the police powers reserved by the 10th Amendment of the U.S. Constitution. Pursuant to the Commerce Clause, Article I, Section 8 of the U.S. Constitution, states can take appropriate actions to protect public health and safety so long as their actions do not regulate operations or unreasonably interfere with interstate commerce.

STB environmental regulations are set forth in 49 CFR Part 1105. These rules require consideration of various environmental statutes, including NEPA, the National Historic Preservation Act of 1966, as amended (16 U.S.C. 470 *et seq*.), and the Energy Policy and Conservation Act (42 U.S.C. 6361; Public Law 94-163). These rules combine the STB's former environmental and energy regulations; revise and clarify environmental and historic requirements; require service of environmental reports on certain state, federal, and local agencies; and reclassify and clarify the types of actions for which environmental and other historic reports and analyses are required. For railroads providing service to commercial interests, these regulations enable applicants, interested parties, and STB environmental staff to better identify and more expeditiously resolve environmental concerns associated with proposed actions. If DOE implemented the Shared-Use Option, this Rail Alignment EIS is intended to satisfy the STB environmental analysis requirements provided for in 49 CFR Parts 1105 and 1150.

6.3 Potential Statutes, Regulations, and Executive Orders Regarding Environmental Protection Requirements

This section summarizes, according to environmental topic, the statutes, regulations, and Executive Orders that set environmental protection requirements that could apply to construction and operation of the proposed railroad.

Table 6-1 is organized by environmental topic and is a comprehensive summary of the regulatory actions DOE could take for construction and operation of the proposed railroad. This table lists the permits, licenses, approvals, statutes or regulations, and agency associated with each regulatory action. Table 6-2 lists applicable federal codified regulations, Executive Orders, and other documents and directives.

Table 6-1. Potential permits, licenses, and approvals necessary for construction and operation of the proposed railroad in the State of Nevada (page 1 of 4).

Regulatory action	Statute or regulation[a]	Agency	Activity
Air Quality			
Air quality operating permit	NAC 445B.287 *et seq.*	Nevada Division of Environmental Protection	Demonstrate control of surface disturbances and emissions of criteria pollutants.
Water Quality and Use			
Stormwater discharge permit and other National Pollutant Discharge Elimination System permits	40 CFR Part 122 NAC 445A.266	U.S. Environmental Protection Agency Nevada Division of Environmental Protection	Control of stormwater discharges and point-source discharges.
Temporary permit to work in waterways (rolling stock permit)	NRS 445A.485 NAC 445A.266 through 445A.272	Nevada Division of Environmental Protection	Work in waterways of the state.
Section 404, permit to discharge dredge or fill materials to waters of the United States	Clean Water Act, Section 404 33 CFR Part 323	U.S. Army Corps of Engineers	Discharge dredge or fill materials into waters of the United States for bridges and culverts in interstate streams, dry washes, and wetlands.

Table 6-1. Potential permits, licenses, and approvals necessary for construction and operation of the proposed railroad in the State of Nevada (page 2 of 4).

Regulatory action	Statute or regulation[a]	Agency	Activity
Water Quality and Use (continued)			
Section 401, water quality certification by State of Nevada	Clean Water Act, Section 401 40 CFR 131	U.S. Army Corps of Engineers Nevada Division of Environmental Protection, Bureau of Water Quality Planning	Section 401 review requires state certification prior to issuance of Section 404 permit to discharge dredge or fill materials to waters of the United States. The request is made by U.S. Army Corps of Engineers to Nevada Division of Environmental Protection, Bureau of Water Quality Planning, to certify that the proposed activity will not violate state or federal water standards.
Water appropriation permit	NRS 533.324 through 533.435	Nevada State Engineer	Drill wells or use existing wells to withdraw groundwater to support rail construction.
Underground water and wells	NAC 534	Nevada State Engineer	Drill wells and use wells to withdraw groundwater to support rail construction.
Septic/sewage disposal permit	40 CFR Part 122 NAC 445A.810 through 445A.925 NAC 444.750 through 444.828	U.S. Environmental Protection Agency Nevada Division of Environmental Protection	Construct and operate temporary or permanent sanitary-sewage collection systems for construction camps and railroad operations facilities.
Hazardous Materials			
Hazardous materials storage permit	NAC 459 NAC 477.323	Nevada State Fire Marshal	Store and use hazardous materials, including explosives, associated with construction and operation of the proposed railroad.
Hazardous waste generation, storage, transportation, and disposal permit	Resource Conservation and Recovery Act (42 U.S.C. 6962), Subtitle C 40 CFR Part 261 40 CFR Part 262 40 CFR Part 263 40 CFR Part 264 40 CFR Part 268 40 CFR Part 270 40 CFR Part 273 40 CFR Part 279 NRS 459.400 to 459.600	U.S. Environmental Protection Agency Nevada Division of Environmental Protection	Transport, handle, treat, store, and dispose of Resource Conservation and Recovery Act hazardous wastes used during rail construction and operation.

Table 6-1. Potential permits, licenses, and approvals necessary for construction and operation of the proposed railroad in the State of Nevada (page 3 of 4).

Regulatory action	Statute or regulation[a]	Agency	Activity
Hazardous Materials (continued)			
Hazardous waste transportation approval, exemption, or permit	Hazardous Materials Transportation Act (49 U.S.C. 1801) 49 CFR Parts 171 to 180	U.S. Department of Transportation	Shipment of hazardous waste, including spent nuclear fuel and high-level radioactive waste.
Type B package approval	10 CFR Part 71	U.S. Nuclear Regulatory Commission	Shipment of spent nuclear fuel and high-level radioactive waste.
Cultural Resources			
Protection of cultural resources and development of programmatic agreement	National Historic Preservation Act (16 U.S.C. 470 *et seq.*) The Archaeological Resources Protection Act (16 U.S.C. 470aa *et seq.*) The Antiquities Act (16 U.S.C. 431 through 433) The American Indian Religious Freedom Act (42 U.S.C. 1996) The Native American Graves Protection and Repatriation Act (25 U.S.C. 3001 *et seq.*) 36 CFR Part 79 36 CFR Part 800	Advisory Council on Historic Preservation Nevada State Historic Preservation Office	Protect cultural resources; applicable to all activities that disturb the land.
Ecology and Habitat			
Endangered species consultation	50 CFR Part 402	U.S. Fish and Wildlife Service	Protect listed threatened and endangered species and designated critical habitat; applicable to all activities that disturb the habitat of threatened and endangered species.
Land and Water Use			
Free-use permit for sand and gravel	43 CFR Part 3600	Bureau of Land Management	Use sand, stone, and gravel from public lands during construction of the rail line.

Table 6-1. Potential permits, licenses, and approvals necessary for construction and operation of the proposed railroad in the State of Nevada (page 4 of 4).

Regulatory Action	Statute or Regulation[a]	Agency	Activity
Land and Water Use (continued)			
Right-of-way reservations	43 CFR Part 2800	Bureau of Land Management	Obtain rights-of-way for access to land that is needed for construction, operation, and access to the rail line, roads, construction camps, borrow pits, and other facilities.
Permit for a ***public water system***	NAC 445A.602 through 445A.612	Nevada Division of Environmental Protection	Construct and operate a public water-supply system at construction camps and some railroad operations facilities.
Construction			
Communication system authorization	Communications Act 47 CFR Part 17 47 CFR Part 24	Federal Communications Commission	Construct and operate a radio system and install fiber optics.
Operating permit for construction/labor camps	NRS 444.130 *et seq.*	Nevada State Health Division	Maintain specified conditions for construction and labor camps in Nevada.
Permit to cross state highways (occupancy permit)	NRS 408.423 NRS 408.423 through 408.427 NAC 703.455	Nevada Department of Transportation Nevada Public Utilities Commission	Construct rail line across a state highway or occupy a highway right-of-way. Applies also to construction of access roads, water pipelines, and other infrastructure that would intersect highway rights-of-way.

a. CFR = Code of Federal Regulations; NAC = Nevada Administrative Code; NRS = Nevada Revised Statutes; RCRA = Resource Conservation and Recovery Act.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 1 of 11).

Regulation/Order	Title	Subject
Regulation[a]		
7 CFR Part 658	Farmland Protection Policy Act	Law minimizes the extent to which federal programs contribute to the unnecessary conversion of farmland to nonagricultural uses.
10 CFR Part 20	Standards for Protection Against Radiation	Standards for protection against ionizing radiation resulting from activities conducted under licenses issued by the Nuclear Regulatory Commission.
10 CFR Part 34	Licenses for Industrial Radiography and Radiation Safety Requirements for Industrial Radiographic Operations	Requirements for the issuance of licenses for the use of sealed sources containing byproduct material and radiation safety requirements for persons using sealed sources in industrial radiography.
10 CFR Part 71	Packaging and Transportation of Radioactive Material	Requirements for packaging, preparation for shipment, and transportation of licensed fissile material.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 2 of 11).

Regulation/Order	Title	Subject
10 CFR Part 73	Physical Protection of Plants and Materials	Requirements for the establishment and maintenance of a physical protection system which have capabilities for the protection of special nuclear material.
10 CFR Part 75	Safeguards on Nuclear Material–Implementation of U.S./International Atomic Energy Agency Agreement	Establishes a system of nuclear material accounting and nuclear material control to implement the agreement between the United States and the International Atomic Energy Agency for the Application of Safeguards in the United States.
10 CFR Part 830	Nuclear Safety Management	Standards for governing the conduct of DOE contractors, DOE personnel, and other persons conducting activities (including providing items and services) that affect the safety of DOE nuclear facilities.
10 CFR Part 835	Occupational Radiation Protection	Radiation protection standards, limits, and program requirements for protecting individuals from ionizing radiation resulting from the conduct of DOE activities.
10 CFR Part 860	Trespassing on Department of Energy Property	Requirements for the protection and security of facilities, installations and real property subject to the jurisdiction or administration, or in the custody of, DOE.
10 CFR Part 1010	Conduct of Employees	Standards for conduct of employees of the Department of Energy, excluding employees of the Federal Energy Regulatory Commission.
10 CFR Part 1021	National Environmental Policy Act Implementing Procedures	Establishes the procedures that the Department of Energy (DOE) shall use to comply with section 102(2) of the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4332(2)) and the Council on Environmental Quality (CEQ) regulations for implementing the procedural provisions of NEPA (40 CFR parts 1500-1508). To be used in conjunction with the CEQ Regulations.
10 CFR Part 1022	Compliance with Floodplain/Wetland Environmental Review Requirements	Policy and procedures for discharging DOE responsibilities under Executive Order 11988 and Executive Order 11990, including: DOE policy regarding the consideration of floodplain and wetland factors in DOE planning and decisionmaking; and DOE procedures for identifying proposed actions located in a floodplain or wetland, providing opportunity for early public review of such proposed actions, preparing floodplain or wetland assessments, and issuing statements of findings for actions in a floodplain.
25 CFR Part 162	Leases and Permits	Policies and procedures for lease of tribal lands, Bureau of Indian Affairs.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 3 of 11).

Regulation/Order	Title	Subject
25 CFR Part 169	Rights-of-Way Over Indian Lands	Procedures, terms, and conditions under which rights-of-way over and across tribal land, individually owned land, and government-owned land may be granted.
29 CFR Part 1910	Occupational Safety and Health Standards	Standards for industry and business for occupational safety and health.
29 CFR Part 1926	Safety and Health Regulations for Construction	Standards for safety and health for construction activities.
29 CFR Part 1960	Recordkeeping and Reporting	Basic program elements for occupational safety and health programs and related matters for federal employees.
33 CFR Part 323	Permits for Discharges of Dredged or Fill Material into Waters of the United States	Policies, practices, and procedures, to be followed by the Army Corps of Engineers to review of applications for permits to authorize the discharge of dredged or fill material into waters of the United States pursuant to Section 404 of the Clean Water Act.
36 CFR Part 79	Curation of Federally-Owned and Administered Archaeological Collections	Standards, procedures and guidelines to be followed by federal agencies to preserve collections of prehistoric and historic material remains, and associated records, recovered under the authority of the Antiquities Act, the Reservoir Salvage Act, section 110 of the National Historic Preservation, Act or the Archaeological Resources Protection Act.
36 CFR Part 296	Protection of Archaeological Resources: Uniform Regulations	Standards and procedures for federal land managers to provide protection for archaeological resources, located on public lands and Indian lands of the United States.
36 CFR Part 800	Protection of Historic and Cultural Properties	Procedures for federal agencies to meet statutory responsibilities for historic preservation concerns with the needs of historic properties.
40 CFR Part 50	National Primary and Secondary Ambient Air Quality Standards	National primary and secondary ambient air quality standards.
40 CFR Part 60	Standards of Performance for New Stationary Sources	Air standards of performance for new stationary Sources.
40 CFR Part 61	National Emission Standards for Hazardous Air Pollutants	Emission standards for hazardous air pollutants.
40 CFR Part 63	National Emission Standards for Hazardous Air Pollutants for Source Categories	Emission standards for hazardous air pollutants for source categories.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 4 of 11).

Regulation/Order	Title	Subject
40 CFR Part 68	Chemical Accident Prevention Provisions	List of regulated substances and threshold quantities, and accident prevention regulations, the petition process for adding or deleting substances to the list of regulated substances, the requirements for owners or operators of stationary sources concerning the prevention of accidental releases, and the State accidental release prevention programs.
40 CFR Part 112	Oil Pollution Prevention	Procedures, methods, equipment, and other requirements to prevent the discharge of oil from non-transportation-related onshore and offshore facilities into or upon the navigable waters of the United States or adjoining shorelines.
40 CFR Part 122	EPA Administered Permit Programs: The National Pollutant Discharge Elimination System	Permit programs for the National Pollutant Discharge Elimination System that requires permits for the discharge of "pollutants" from any "point source" into "waters of the United States."
40 CFR Part 125	Criteria and Standards for National Pollutant Discharge Elimination System	Criteria and standards for technology-based treatment requirements for permits under the National Pollutant Discharge Elimination System.
40 CFR Part 131	Water Quality Standards	Requirements and procedures for developing, reviewing, revising, and approving water quality standards by the states for Section 404 Permits for Discharges of Dredged or Fill Material into Waters of the United States.
40 CFR Part 136	Guidelines for Establishing Test Procedures for Analysis of Pollutants	Guidelines for test procedures for analysis of pollutants to be used to perform measurements of waste constituents specified for a state having an approved National Pollutant Discharge Elimination System program.
40 CFR Part 141	National Primary Drinking Water Regulations	Primary standards for public drinking water supplies, including maximum contaminant levels, and sampling and analysis, monitoring and reporting, and recordkeeping requirements.
40 CFR Part 142	National Primary Drinking Water Regulations Implementation	Regulations for the implementation and enforcement of the national primary drinking water regulations contained in 40 CFR Part 141.
40 CFR Part 143	National Secondary Drinking Water Regulations	Secondary standards for public drinking water supplies that primarily affect the aesthetic qualities relating to the public acceptance of drinking water.
40 CFR Part 260	Hazardous Waste Management System: General	Definitions of terms, general standards, and overview information applicable to parts 260 through 265 and 268 that sets forth the requirements for hazardous waste generators, transporters, or owners or operators of treatment, storage, or disposal facilities.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 5 of 11).

Regulation/Order	Title	Subject
40 CFR Part 261	Identification and Listing of Hazardous Waste	Standards and criteria for identifying the characteristics of hazardous waste and for listing hazardous waste.
40 CFR Part 262	Standards Applicable to Generators of Hazardous Waste	Standards for generators of hazardous waste.
40 CFR Part 263	Standards Applicable to Transporters of Hazardous Waste	Standards for transporters of hazardous waste.
40 CFR Part 264	Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities	Standards for hazardous waste treatment, storage, and disposal facilities.
40 CFR Part 265	Interim Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities	Interim standards for hazardous waste treatment, storage, and disposal facilities.
40 CFR Part 268	Land Disposal Restrictions	Identifies hazardous wastes that are restricted from land disposal and defines treatment requirements for which an otherwise prohibited waste may be land disposed.
40 CFR Part 270	EPA Administered Permit Programs: The Hazardous Waste Permit Program	Hazardous waste permit requirements, including application requirements, standard permit conditions, and monitoring and reporting requirements.
40 CFR Part 273	Standards for Universal Waste Management	Requirements for managing universal waste, including batteries, pesticides, thermostats, and lamps.
40 CFR Part 279	Standards for the Management of Used Oil	Standards for used oil generators, transporters, transfer facilities, collection centers, and processors and re-refineries.
40 CFR Part 302	Designation, Reportable Quantities, and Notification	Standards for designation, reportable quantities, and notification requirements for hazardous substances.
40 CFR Part 355	Emergency Planning and Notification	Establishes the list of extremely hazardous substances, threshold planning quantities, and facility notification responsibilities necessary for the development and implementation of state and local emergency response plans.
40 CFR Part 370	Hazardous Chemical Reporting: Community Right-to-Know	Reporting requirements that provide the public with important information on the hazardous chemicals in their communities for the purpose of enhancing community awareness of chemical hazards and facilitating development of state and local emergency response plans.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 6 of 11).

Regulation/Order	Title	Subject
40 CFR Part 372	Toxic Release Chemical Reporting: Community Right-to-Know	Requirements for informing the public and the communities surrounding covered facilities about the release of toxic chemicals under Section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986.
40 CFR Part 503	Standards for the Use or Disposal of Sewage Sludge	General requirements, pollutant limits, management practices, and operational standards for the final use or disposal of sewage sludge generated during the treatment of domestic sewage in a treatment works.
40 CFR Parts 1500 through 1508	Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act	Regulations applicable to and binding on all federal agencies for implementing the procedural provisions of the National Environmental Policy Act.
41 CFR Part 101	Federal Property Management Regulations	Introductory material concerning the Federal Property Management Regulations System: its content, types, publication, authority, applicability, numbering, deviation procedure, as well as agency consultation, implementation, and supplementation.
43 CFR Part 3	Preservation of American Antiquities	Permit requirements for the preservation of ruins, archeological sites, historic and prehistoric monuments and structures, objects of antiquity, historic landmarks, and other objects of historic and scientific interest.
43 CFR Part 7	Protection of Archaeological Resources	Implementing provisions of the Archaeological Resources Protection Act of 1979, as amended, by establishing uniform definitions, standards, and procedures to be followed by federal land managers in providing protection for archaeological resources, located on public lands and Indian lands of the United States.
43 CFR Part 1600	Planning, Programming, Budgeting	Establishes a process for the development, approval, maintenance, amendment, and revision of resource management plans, and the use of existing plans for public lands administered by the Bureau of Land Management.
43 CFR Part 2300	Land Withdrawals	Procedures implementing the Secretary of the Interior's authority to process federal land withdrawal applications and, where appropriate, to make, modify, or extend federal land withdrawals.
43 CFR Part 2800	Rights-of-Way, Principles and Procedures; Rights-of-Way Under the Federal Land Policy and Management Act	Grants for necessary transportation or other systems and facilities which are in the public interest and which require the use of public lands for the purposes identified in 43 U.S.C. 1761, and administering, amending, assigning, renewing, and terminating them.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 7 of 11).

Regulation/Order	Title	Subject
43 CFR Part 3600	Mineral Materials Disposal	Procedures for the exploration, development, and disposal of mineral material resources on the public lands, and for the protection of the resources and the environment.
43 CFR Part 3620	Free Use of Petrified Wood	Terms and conditions for persons collecting limited quantities of petrified wood for noncommercial purposes consistent with the preservation of significant deposits as a public recreational resource.
47 CFR Part 17	Construction, Marking, and Lighting of Antenna Structures	Standards for construction, marking, lighting, maintenance, and inspection of antenna structures.
47 CFR Part 24	Personal Communications Services	Conditions under which portions of the radio spectrum are made available and licensed for personal communications.
49 CFR Part 40	Procedures for Transportation Workplace Drug and Alcohol Testing Programs	Procedures for conducting workplace drug and alcohol testing for the federally regulated transportation industry.
49 CFR Part 107	Hazardous Materials Program Procedures	Procedures and permits for the transportation of hazardous materials.
49 CFR Part 171	General Information, Regulations, and Definitions	General information, regulations, and definitions for the safe and secure transportation of hazardous materials in commerce.
49 CFR Part 172	Hazardous Materials Table, Special Provisions, Hazardous Materials Communications, Emergency Response Information, and Training Requirements	Listing and classification of materials that the Department of Transportation has designated as hazardous materials for purposes of transportation and prescribes the requirements for shipping papers, packaging, marking, labeling, and transport vehicle placarding applicable to the shipment and transportation of those materials.
49 CFR Part 173	Shippers-General Requirements for Shipments and Packaging	Requirements for preparing hazardous materials for shipment by air, highway, rail, or water, and inspection, testing, and retesting responsibilities for persons who retest, recondition, maintain, repair, and rebuild containers used or intended for use in the transportation of hazardous materials.
49 CFR Part 174	Carriage By Rail	Handling, loading, and operating requirements for transport of hazardous and radioactive materials by rail.
49 CFR Part 177	Carriage By Public Highway	Requirements for transportation of hazardous materials by private, common, or contract carriers by motor vehicle, including hazardous materials training.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 8 of 11).

Regulation/Order	Title	Subject
49 CFR Part 178	Specifications for Packaging	Manufacturing and testing specifications for packaging and containers used for the transportation of hazardous materials in commerce.
49 CFR Part 179	Specifications for Tank Cars	Specifications for tanks that are mounted on or form part of a tank car and which are to be marked with a Department of Transportation specification.
49 CFR Part 180	Continuing Qualification and Maintenance of Packaging	Requirements for the maintenance, reconditioning, repair, inspection, and testing of packaging, and any other function having an effect on the continuing qualification and use of a packaging.
49 CFR Part 210	Rail Noise Emission Compliance Regulations	Inspection and testing requirements for railcars for compliance with the Railroad Noise Emission Standards established by the Environmental Protection Agency in 40 CFR part 201.
49 CFR Part 213	Track Safety Standards	Minimum safety requirements for railroad track that is part of the general railroad system of transportation.
49 CFR Part 214	Railroad Workplace Safety	Minimum federal safety standards for railroad employees involved in railroad inspection, maintenance, and construction activities.
49 CFR Part 215	Railroad Freight Car Safety Standards	Minimum federal safety standards for railroad freight cars.
49 CFR Part 217	Railroad Operating Rules	Railroad operating rules and practices with respect to trains and other rolling equipment in the railroad industry, and each railroad is required to instruct its employees in operating practices.
49 CFR Part 218	Railroad Operating Practices	Minimum requirements for railroad operating rules and practices. Each railroad may prescribe additional or more stringent requirements in its operating rules, timetables, timetable special instructions, and other special instructions.
49 CFR Part 219	Control of Alcohol and Drug Use	Minimum federal safety standards for control of alcohol and drug use by rail line employees.
49 CFR Part 220	Railroad Communications	Wireless and radio communication procedures for trains and rail line workers.
49 CFR Part 221	Rear End Marking Device–Passenger, Commuter, and Freight Trains	Minimum requirements governing highly visible marking devices for the trailing end of the rear car of all passenger, commuter, and freight trains.
49 CFR Part 223	Safety Glazing Standards–Locomotives, Passenger Cars, and Cabooses	Minimum requirements for glazing materials in order to protect railroad employees and railroad passengers from injury as a result of objects striking the windows of locomotives, cabooses, and passenger cars.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 9 of 11).

Regulation/Order	Title	Subject
Regulation (continued)		
49 CFR Part 225	Railroad Accidents/Incidents: Reports, Classification, and Investigations	Reporting, classification, and investigation procedures for rail line accidents and incidents.
49 CFR Part 228	Hours of Service of Railroad Employees	Records and reporting requirements for railroad employees hours of service and construction of sleeping quarters.
49 CFR Part 229	Railroad Locomotive Safety Standards	Minimum safety requirements for locomotives.
49 CFR Part 231	Railroad Safety Appliance Standards	Safety standards for locomotives and railcars.
49 CFR Part 232	Brake System Safety Standards for Freight and Other Non-passenger Trains and Equipment	Requirements for railroad power brakes and drawbars for freight and other nonpassenger trains.
49 CFR Part 233	Signal Systems Reporting Requirements	Reporting requirements for railroad signal systems.
49 CFR Part 234	Grade Crossing Signal System Safety	Inspection, testing, and maintenance requirements for rail crossing signal systems.
49 CFR Part 235	Instructions Governing Applications for Approval of a Discontinuance or Material Modification of a Signal System or Relief from the Requirements of Part 236	Provides applications for approval to discontinue or materially modify block signal systems, interlockings, traffic control systems, automatic train stop, train control, or cab signal systems, or other similar appliances, devices, methods, or systems.
49 CFR Part 236	Rules, Standards and Instructions Governing the Installation, Inspection, Maintenance, and Repair of Signal and Train Control Systems, Devices, and Appliances	Rules, standards and instructions for the installation, inspection, maintenance, and repair of signal and train control systems, devices, and appliances.
49 CFR Part 240	Qualification and Certification of Locomotive Engineers	Qualification and certification requirements for locomotive engineers.
49 CFR Part 395	Hours of Service of Drivers	Hours of service requirements for drivers of commercial motor vehicles.
49 CFR Part 1005	Principles and Practices for the Investigation and Voluntary Disposition of Loss and Damage Claims and Processing Salvage	Principles and practices for the investigation and voluntary disposition of loss and damage claims and processing salvage.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 10 of 11).

Regulation/Order	Title	Subject
49 CFR Part 1035	Bills of Lading	Requirements for uniform bills of lading.
49 CFR Part 1104	Filing with the Board-Copies-Verification-Service-Pleadings	Requirements for filing of pleading and other documents with the Surface Transportation Board.
49 CFR Part 1105	Procedures for Implementation of Environmental Laws	Procedures for implementation of environmental laws by the Surface Transportation Board.
49 CFR Part 1150	Certificate to Construct, Acquire, or Operate Railroad Lines	Administrative practices and procedures to obtain certification for construction, acquisition, or operation of railroad lines.
50 CFR Part 15	Wild Bird Conservation Act	Standards for the protection of wild birds.
50 CFR Part 17	Endangered and Threatened Wildlife and Plants	Standards for the protection of endangered and threatened wildlife and plants.
50 CFR Part 402	Interagency Cooperation–Endangered Species Act of 1973, as Amended	Interprets and implements the Endangered Species Act of 1973, as amended.
Executive Orders		
Executive Order 11514	*Protection and Enhancement of Environmental Quality*	The federal government shall provide leadership in protecting and enhancing the quality of the Nation's environment to sustain and enrich human life. Federal agencies shall initiate measures needed to direct their policies, plans, and programs so as to meet national environmental goals.
Executive Order 11593	*Protection and Enhancement of the Cultural Environment*	The federal government shall provide leadership in preserving, restoring, and maintaining the historic and cultural environment of the Nation and institute procedures to assure that federal plans and programs contribute to the preservation and enhancement of non-federally owned sites, structures, and objects of historical, architectural or archaeological significance.
Executive Order 11988	*Floodplain Management*	Federal agencies shall provide leadership and take action to reduce the risk of flood loss, to minimize the impact of floods on human safety, health and welfare, and to restore and preserve the natural and beneficial values served by floodplains in carrying out its responsibilities for acquiring, managing, and disposing of federal lands and facilities.
Executive Order 11990	*Protection of Wetlands*	Federal agencies shall provide leadership and shall take action to minimize the destruction, loss or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands in carrying out the agency's responsibilities for acquiring, managing, and disposing of federal lands and facilities.
Executive Order 12088	*Federal Compliance with Pollution Control Standards*	Federal agencies are responsible for compliance with applicable pollution control standards.

Table 6-2. Potentially applicable federal regulations and Executive Orders (page 11 of 11).

Regulation/Order	Title	Subject
Executive Order 12898	*Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*	Federal agencies shall make achieving ***environmental justice*** part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on ***minority populations*** and ***low-income populations***.
Executive Order 13007	*Indian Sacred Sites*	In managing federal lands, each executive branch agency with statutory or administrative responsibility for the management of federal lands shall accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners and avoid adversely affecting the physical integrity of such sacred sites.
Executive Order 13112	*Invasive Species*	Federal agencies shall prevent the introduction of invasive species and provide for their control, and to minimize the economic, ecological, and human health impacts that invasive species cause.
Executive Order 13132	*Federalism*	Establishes policy to guarantee the division of governmental responsibilities between the national government and the states, and to ensure that the principles of federalism guide the executive departments and agencies in the formulation and implementation of policies.
Executive Order 13175	*Consultation and Coordination with Indian Tribal Governments*	Federal agencies shall establish regular and meaningful consultation and collaboration with Indian tribal governments in the development of regulatory practices on federal matters that significantly or uniquely affect their communities; to reduce the imposition of unfunded mandates upon Indian tribal governments; and to streamline the application process for and increase the availability of waivers to Indian tribal governments.
Executive Order 13186	*Responsibilities of Federal Agencies to Protect Migratory Birds*	The United States recognizes that migratory birds are of great ecological and economic value to this country and to other countries. They contribute to biological diversity and bring tremendous enjoyment to millions of Americans who study, watch, feed, or hunt these birds throughout the United States and other countries. The United States has recognized the critical importance of this shared resource by ratifying international, bilateral conventions for the conservation of migratory birds.
Executive Order 13423	*Strengthening Federal Environmental, Energy, and Transportation Management*	Federal agencies must conduct their environmental, transportation, and energy-related activities under the law in support of their respective missions in an environmentally, economically and fiscally sound, integrated, continuously improving, efficient, and sustainable manner.

a. CFR = Code of Federal Regulations.

Table 6-3 lists applicable State of Nevada codes and statutes. Sections 6.3.1 through 6.3.8 are organized by environmental topic and describe the laws, regulations, Executive Orders, State of Nevada codes and statutes, and regulatory actions potentially applicable to construction and operation of the proposed railroad facilities.

Table 6-3. Potentially applicable State of Nevada codes and statutes (page 1 of 3).

Code or statute[a]	Title	Subject
NAC 408	Highways and Roads Installation and Relocation of Facilities and Encroachments	Requirements for design and location, permits, etc.
NAC 444 - Sanitation		
NAC 444.550 through 444.566	Labor Camps	Standards for living and sleeping quarters; cooking and eating, sanitary, and laundry facilities; lighting; and operating permits
NAC 444.8618	Disposal of Hazardous Waste Hazardous Waste Generator Identification Number	Information concerning an application for EPA identification number
NAC 444.850 through 444.8746	Disposal of Hazardous Waste	Standards of practice, variances, and administrative penalties
NAC 445A	Water Controls	Permits, certification of laboratories to analyze substances in water, water pollution control, public water systems, and underground injection control
NAC 445A.226 through 445A.22755	Action Levels for Contaminated Sites	Remediation standards and monitoring requirements for soil, groundwater, and surface-water contamination
NAC 445A.228 through 445A.263	Discharge Permits	Requirements, establishment of effluent limitations, schedules of compliance, inspection, sampling, and monitoring
NAC 445A.266 through 445A.272	General Permits	Requirements for discharge and procedures for application for general permits
NAC 445A.305 through 445A.340	Diffuse Sources	Administration of controls by municipality, determination of new sources of water pollution, state and local handbooks of best management practices, and requirements for permits to construct or grade and forlogging
NAC 445A.345 through 445A.348	Notification of Release of Pollutant	Notice required and use of information in criminal prosecution
NAC 445A.591 through 445A.6731	Drinking Water Systems	Operation of ***community water system*** or nontransient water system; permits to operate privately owned systems; certification of operators; and design, construction, operation, and maintenance
NAC 445A.810 through 445A.925	Underground Injection Control Permits	Permits and construction, operation, monitoring, and abandonment
NAC 445B.001 through 455B.899	Air Pollution Control	Permits, air emissions control program, clean air mercury rule program, and emissions from engines
NAC 445C.010 through 445C.120	Environmental Requirements	Requirements to enter into and contents of an environmental audit agreement
NAC 459	Hazardous Materials	Hazardous materials

Table 6-3. Potentially applicable State of Nevada codes and statutes (page 2 of 3).

Code or statute[a]	Title	Subject
NAC 459.952 through 459.95528	Regulation of Highly Hazardous Substances and Explosives	Requirements, permits, hazard assessments, prevention programs, emergency response programs, and enforcement
NAC 459.975 through 459.991	Transportation of Hazardous Materials on Public Highways	Transportation of hazardous materials on public highways permits
NAC 459.9912 through 459.99184	Planning for and Responding to Discharge of Hazardous Materials	Emergency planning funding for local emergency planning committees, funding for state agencies, and payment of fees
NAC 459.9921 through 459.999	Storage Tanks	Storage tank requirements, registration, monitoring, and corrective action
NAC 472	State Forester Firewarden	Fire retardant roofing materials
NAC 477.010 and 477.290	State Fire Marshal – General Provisions	Definitions and severability
NAC 477.323	Permit to Store Hazardous Material	Permit required; issuance, expiration, renewal, suspension, reinstatement and revocation of permit; fees; criminal investigation; plan for termination
NAC 477.710	Use of Explosives in Blasting	Certificate required; qualifications; exemptions; renewal of certificate; fees
NAC 477.920	Miscellaneous Requirements	Fire suppression systems in buildings in rural areas
NAC 503	Hunting, Fishing, and Trapping Miscellaneous Protective Measures	Classification and taking of wildlife; possession, transportation, importation, exportation, and release of wildlife; hunting and trapping generally; raptors; fishing; depredation; and dredging permits
NAC 504.520	Alteration of a Stream System or Watershed	Approval of Department required to alter stream system or watershed to detriment of wildlife habitat; application for approval
NAC 527	Protection and Preservation of Timbered Lands, Trees, and Flora	Nevada Natural Heritage Program, permits, compliance with plan, revocation of permit, and protection of cacti and yucca
NAC 534	Underground Water and Wells	License to drill well; duties of well drillers; drilling, construction, and plugging of wells and boreholes; waivers; and enforcement
NAC 555	Control of Insects, Pests, and Noxious Weeds	Classification of weeds, weed control districts, regulation of nurseries and nursery stock, custom application of pesticides, certified applicators, and rodent control districts
NAC 586.018	Pesticides	Restricted-use pesticides: Application by or under supervision of certified applicator
NAC 703	Public Utilities Commission of Nevada	Application for privileges, rights, and authority and practice before the public utilities commission
NAC 705	Railroads	Standards and requirements for health and safety and transportation of hazardous materials by rail
NRS 408	Highways, Roads, and Transportation Facilities	Planning; financing highways and roads; improvement of county roads; state highway system; and construction, improvement, and maintenance of highways
NRS 444.130 through 444.200	Sanitation/Construction and Labor Camps	Requirements for conditions

Table 6-3. Potentially applicable State of Nevada codes and statutes (page 3 of 3).

Code or statute[a]	Title	Subject
NRS 444.440 through 444.620	Collection and Disposal of Solid Waste	Collection and disposal of solid waste
NRS 444.570 through 444.650	Disposal of Solid Waste	Disposal of solid waste and sewage
NRS 445A	Water Controls	Concentration of fluoride in water, water pollution control, and public water systems
NRS 445B	Air Pollution	State environmental commission, local hearing board, provisions for enforcement, program for control of air pollution, penalties, and control of emissions from engines
NRS 459.400 through 459.600	Disposal of Hazardous Waste	Disposal of hazardous waste
NRS 533.324 through 533.455	Appropriation of Public Waters: Applications, Permits and Certificates	Environmental permits and transfer of water from county of origin to another county
NRS 704	Regulation of Public Utilities Generally	Rates and schedules, general standards and practices, etc.
NRS 705	Railroads and Monorails	Railroads and monorails

a. NAC = Nevada Administrative Code; NRS = Nevada Revised Statutes.

6.3.1 NATIONAL ENVIRONMENTAL POLICY ACT, AS AMENDED (42 U.S.C. 4321 *et seq.*)

The National Environmental Policy Act (NEPA) of 1969, as amended (42 U.S.C. 4321 *et seq.*), requires federal agencies to integrate environmental values into their decision-making process by considering the environmental impacts of proposed federal actions and reasonable ***alternatives*** to those actions. The Act establishes policy, sets goals (in Section 101), and provides means (in Section 102) for carrying out the policy. Section 102(2) contains action-forcing provisions to ensure that federal agencies follow the letter and spirit of the Act. For major federal actions significantly affecting the quality of the human ***environment***, Section 102(2)(C) of NEPA requires federal agencies to prepare a detailed statement that includes the environmental impacts of the proposed action and other specified information. DOE promulgated regulations (10 CFR Part 1021) and issued DOE Order 451.1B, National Environmental Policy Act Compliance Program, to ensure compliance with Section 102(2) of NEPA.

DOE would construct and operate the proposed railroad in compliance with NEPA and promulgated DOE regulations.

6.3.2 HAZARDOUS MATERIALS PACKAGING, HANDLING, AND TRANSPORTATION (49 CFR PARTS 172 AND 173; 10 CFR PARTS 71 AND 73)

The ***shipment*** of ***nuclear waste*** is highly regulated and subject to the utmost scrutiny. DOE follows the strict U.S. Department of Transportation and U.S. Nuclear Regulatory Commission transportation rules, including the use of Commission-certified transportation casks, advance route approvals and notification, and shipment escorts. The Department also tracks its shipments by satellite 24 hours a day. DOE follows these precautions carefully now and will follow any others that might be required in the future, whether by the U.S. Congress, the Department of Transportation, or the Nuclear Regulatory Commission.

In addition, the Department would follow DOE Order 460.1B, which establishes safety requirements for the proper packaging and transportation of DOE/National Nuclear Security Administration offsite shipments and onsite transfers of hazardous materials and for modal transport.

The Department of Transportation is responsible for developing and implementing transportation-safety standards for hazardous materials, including radioactive materials. The Department of Transportation has established standards and requirements for packaging, transporting, and handling radioactive materials for all modes of transportation (49 CFR Parts 172 and 173). The regulations also specify safety requirements for vehicles and transportation operations, training for personnel who perform handling and transportation of hazardous materials, and liability insurance requirements for carriers. For all spent nuclear fuel and high-level radioactive waste shipments, DOE would comply with the requirements for identification, labeling, packaging, marking, placarding, and preparation of shipping papers set forth by the Department of Transportation in 49 CFR Parts 172 and 173.

The Nuclear Regulatory Commission regulates the packaging- and transportation-related operations of its licensees, including commercial shippers of radioactive materials. It sets design and performance standards for packaging (***shipping casks***) that contain materials with high levels of ***radioactivity***.

The Department of Transportation, by agreement with the Nuclear Regulatory Commission, accepts the Commission standards of 10 CFR Part 71 for packaging. The Commission also establishes safeguards and security regulations to minimize the possibility of theft, diversion, or attack on shipments of radioactive materials (10 CFR Part 73). Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local governments and American Indian tribes through whose jurisdictions DOE plans to transport spent nuclear fuel or high-level radioactive waste.

6.3.2.1 Hazardous Materials Transportation Act, as Amended (49 U.S.C. 1801)

The Hazardous Materials Transportation Act of 1975, as amended (49 U.S.C. 1801), gives the U.S. Department of Transportation authority to regulate the transport of hazardous materials, including radioactive materials. Under these regulations, the Department of Transportation regulates the interstate and intrastate shipment of hazardous materials, including spent nuclear fuel and high-level radioactive waste, by land, air, and navigable water. As outlined in a 1979 memorandum of understanding with the U.S. Nuclear Regulatory Commission (44 *FR* 38690, July 2, 1979), the Department of Transportation specifically regulates carriers of spent nuclear fuel and the conditions of transport such as routing, handling, storage, and vehicle and driver requirements. It also regulates the labeling, classification, and marking of transportation packages for radioactive materials.

Department of Transportation regulations include requirements for carriers, drivers, vehicles, routing, packaging, labeling, marking, placarding of vehicles, shipping papers, training, and emergency response. The requirements specify the maximum ***dose rate*** associated with radioactive material shipments and the maximum allowable levels of radioactive surface ***contamination*** on packages and vehicles. Department of Transportation regulations also include requirements to protect the health and safety of transportation workers.

6.3.2.2 Low-Level Radioactive Waste Policy Act, as Amended (42 U.S.C. 2021b *et seq.*)

In 1980 Congress passed the Low-Level Radioactive Waste Policy Act to establish federal policy on nuclear waste disposal, the foundation of which is the idea that the states are responsible for the disposal of ***low-level radioactive waste*** generated within their borders (except for certain federal waste). The desire to restrict access to disposal facilities was a driving force behind the adoption of the 1980 Act and the subsequent Low-Level Radioactive Waste Policy Act of 1985, as amended (42 U.S.C. 2021b *et seq.*).

The 1985 amendments clarified the right of Congressionally approved compacts to control access to their disposal facilities. This Act gives states the responsibility to dispose of low-level radioactive waste generated within their borders and allows them to form compacts to establish facilities to serve a group of states. The Act provides that the facilities will be regulated by the U.S. Nuclear Regulatory Commission or by states that have entered into agreements with the Commission under Section 274 of the Atomic Energy Act. The Act also requires the Commission to establish standards for determining when ***radionuclides*** are present in waste streams in sufficiently low concentrations or quantities as to be "below regulatory concern." Whereas Congress maintains authority over the disposal of high-level nuclear waste and ***transuranic waste***, states are responsible for low-level radioactive waste, which, unlike spent nuclear reactor fuel or high-level radioactive waste, emits a low level of radiation that decays fairly rapidly. Most low-level radioactive waste (97 percent) does not require special ***shielding*** during handling or transportation for the protection of workers or the surrounding community, and it can include such things as contaminated clothing, tools, or equipment.

6.3.2.3 U.S. Nuclear Regulatory Commission Radioactive Material Packaging and Transportation (10 CFR Parts 71 and 73)

Pursuant to 10 CFR Part 71, the U.S. Nuclear Regulatory Commission regulates the packaging and transport of spent nuclear fuel for its licensees, including commercial shippers of radioactive material and the DOE Office of Civilian Radioactive Waste Management. Under an agreement with the Department of Transportation, the Commission sets standards for packaging of radioactive materials, including spent nuclear fuel and high-level radioactive waste. These wastes must meet Type B packaging standards, which require that packages be designed and built to retain their radioactive contents in both normal and accident conditions.

The demonstration of compliance with these requirements applies a combination of calculation methods, computer modeling techniques, and physical testing to the design features of the package. DOE would present the results of the analyses and tests to the Nuclear Regulatory Commission in a safety analysis report for packaging. The Commission would review the safety analysis report, and if approved, would then issue a certificate of compliance to allow spent nuclear fuel or high-level radioactive waste to be shipped to the repository.

The regulations at 10 CFR Part 73 govern safeguards and physical security during the transit of shipments of spent nuclear fuel and specify requirements for carrier personnel, communications, notification of state governors, escorts, and route planning for such shipments. DOE carefully follows the Department of Transportation and the Nuclear Regulatory Commission transportation rules and will follow or exceed any others that may be established in the future, whether by the U.S. Congress, the Department of Transportation, or the Nuclear Regulatory Commission.

6.3.2.4 Emergency Planning and Community Right-to-Know Act (42 U.S.C. 1001 *et seq.*)

Under Subtitle A of the Emergency Planning and Community Right-to-Know Act of 1986 (42 U.S.C. 1001 *et seq.*), which is also known as the Superfund Amendments and Reauthorization Act, Title III, federal agencies must provide information on hazardous and toxic chemicals to state emergency response commissions, local emergency planning committees, and the U.S. Environmental Protection Agency. The goal of providing this information about inventories of specific chemicals used or stored, and descriptions of releases that could occur at work sites, is to ensure that emergency plans are sufficient to respond to unplanned releases of hazardous substances. The Emergency Planning and Community Right-to-Know Act, codified at 40 CFR Parts 302 through 372, requires agencies to provide reports on material safety data sheets, emergency and ***hazardous chemical*** inventory, and toxic chemical releases to appropriate local, state, and federal agencies. These regulations also require facilities that store, dispense, use, or handle extremely hazardous materials in excess of specified thresholds, to report quantity data to specific agencies and organizations. Nevada Administrative Code, Chapters 459 and 477, establish the permitting requirements for highly hazardous substances and hazardous materials, respectively.

6.3.3 AIR QUALITY

6.3.3.1 Clean Air Act, as Amended (42 U.S.C. 7401 *et seq.*)

The Clean Air Act of 1970, as amended (42 U.S.C. 7401 *et seq.*), is intended to "protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population." The Act requires:

- Federal agencies with jurisdiction over any property or endeavor that might result in the discharge of air pollutants to comply with "all federal, state, interstate, and local requirements" related to the control and abatement of air pollution in accordance with 42 U.S.C. 7401, Section 118.
- The Environmental Protection Agency to establish national ***ambient air quality standards*** to protect public health from any known or anticipated adverse effects of a regulated pollutant (42 U.S.C. 7409).
- The Environmental Protection Agency to establish national standards of performance for new or modified stationary sources of atmospheric pollutants (42 U.S.C. 7411) and the evaluation of specific emission increases to prevent a significant deterioration in ***air quality*** (42 U.S.C. 7470).

6.3.3.2 National Primary and Secondary Ambient Air Quality Standards (40 CFR Part 50)

Under the Clean Air Act, the Environmental Protection Agency has established national ***ambient air*** quality standards at 40 CFR Part 50 to protect the public health and the environment. The national ambient air quality standards identify six pollutant types as criteria pollutants: ***nitrogen dioxide***, ***ozone***, lead, ***carbon monoxide***, ***particulate matter***, and ***sulfur dioxide***. The Environmental Protection Agency calls these "criteria" air pollutants because it regulates them from the development of human health-based and/or environmentally based criteria (science-based guidelines) in setting permissible levels.

The Clean Air Act specifically regulates emissions of hazardous air pollutants, including radionuclides, through the national emission standards for ***hazardous air pollutants*** program (40 CFR Parts 61 and 63).

6.3.3.3 Nevada Revised Statutes: Air Pollution (Title 40, Chapter 445B)

Nevada Revised Statutes, Chapter 445B, Air Pollution, and regulations in the Nevada Administrative Code implement state and federal Clean Air Act provisions, identify the requirements for permits for each air pollution source unless it is specifically exempted, and identify ongoing monitoring requirements. DOE would need operating permits from the Nevada Division of Environmental Protection, Bureau of Air Pollution Control, for the control of gaseous and particulate emissions from construction and operation of the proposed railroad.

6.3.4 WATER QUALITY

6.3.4.1 Clean Water Act, as Amended (33 U.S.C. 1251 *et seq.*)

The Clean Water Act regulates the discharge of pollutants into the Nation's surface waters, including lakes, rivers, streams, ***wetlands***, and coastal areas. Passed in 1972 and amended in 1977 and 1987, the Clean Water Act was originally known as the Federal Water Pollution Control Act. The Clean Water Act is administered by the U.S. Environmental Protection Agency, which sets water quality standards, handles enforcement, and helps state and local governments develop their own pollution control plans. The purpose of the Clean Water Act of 1977 (33 U.S.C. 1251 *et seq.*) is to "restore and maintain the chemical, physical, and biological integrity of the Nation's water." The U.S. Environmental Protection Agency delegated the State of Nevada the authority to implement and enforce most programs in the state under the Clean Water Act; exceptions include those addressed by Section 404 of the Act, which is administered by the U.S. Army Corps of Engineers, and described in this section.

This Act prohibits the "discharge of toxic pollutants in toxic amounts" to navigable ***waters of the United States***. Section 313 of the Act requires all departments and agencies of the Federal Government engaged in any activity that might result in a discharge or runoff of pollutants to surface waters to comply with federal, state, interstate, and local requirements. The Act applies to activities at and along the Caliente ***rail alignment*** and the Mina rail alignment that could affect waterways. Under the Clean Water Act, the State of Nevada sets water quality standards, and the U.S. Environmental Protection Agency and the State of Nevada regulate and issue permits for point-source discharges as part of the National Pollutant Discharge Elimination System permitting program. The Environmental Protection Agency regulations for this program are codified at 40 CFR Part 122, and Nevada rules for this program are codified at Nevada Administrative Code, Chapter 445A. If construction or operation of the proposed railroad in Nevada would result in point-source discharges, DOE would need to obtain a National Pollutant Discharge Elimination System permit from the Nevada Division of Environmental Protection, Bureau of Water Pollution Control.

Section 402(p) of the Clean Water Act requires the Environmental Protection Agency to establish regulations and requires individual states to issue permits for stormwater discharges associated with industrial activity, including construction activities that could disturb 20,000 or more square meters (5 or more acres) (40 CFR Part 122). Stormwater discharge permits are designed to control the degradation of surface water and ***groundwater*** primarily from erosion and sedimentation. Nevada rules for this program are codified at Nevada Administrative Code, Chapter 445A. Stormwater permits issued from the Nevada Bureau of Water Pollution Control regulate the discharge of stormwater from facilities. The Proposed Action includes rail line ***construction and operations support facilities*** that would have discharges of stormwater. DOE would need to obtain permits for these discharges. Additionally, construction and operation of septic and sanitary-sewage collection systems would require permits from the Nevada Bureau of Water Pollution Control.

Jurisdictional waters of the United States are subject to regulation by the U.S. Army Corps of Engineers under Section 404 of the Clean Water Act. Jurisdictional waters of the United States include navigable and interstate waters, intrastate waters with a connection to interstate commerce and tributaries to such waters, and wetlands that are adjacent to waters of the United States. Section 404 of the Clean Water Act established a program to regulate the discharge of dredged or fill material into waters of the United States, including wetlands. Construction activities, such as those for the proposed railroad, that would impact waters of the United States are regulated under this program.

The basic premise of the Section 404 permitting program is that no discharge of dredged or fill material into jurisdictional waters will be permitted if a practicable alternative exists that is less damaging to the aquatic environment, or the Nation's waters would be significantly degraded. In other words, it must be demonstrated that, to the extent practicable, steps have been taken to avoid impacts and that potential impacts on jurisdictional waters have been minimized and compensation is provided for any remaining unavoidable impacts (if required). Proposed activities are regulated through a permit review process.

An evaluation under Section 404(b)(1) of the Clean Water Act would analyze and describe the potential impacts from any proposed discharges of dredged or fill material into jurisdictional waters that would result from construction and operation of the proposed railroad. To complete the 404(b)(1) analysis, DOE would be required to identify the appropriate and applicable steps that would be taken during construction to minimize potential adverse impacts. These steps would include actions taken to reduce the potential for increased erosion and subsequent sedimentation and to ensure that any downstream water would not experience increases in sediment loading or turbidity that would threaten the beneficial use of that stream.

Section 404(r) of the Clean Water Act states that the discharge of dredged or fill material as part of the construction of a federal project specifically authorized by Congress is not prohibited or subject to regulation under Section 404 of the Clean Water Act so long as certain conditions are met. One of those conditions is to publish in an EIS information on the effects of such discharge, including an analysis of alternatives as required by Section 404(b)(1) of the Clean Water Act. If DOE determines that it will comply with Section 404(r), an alternatives analysis that meets the requirements of Sections 404(b)(1) and 404(r) will be published in the Final EIS. Otherwise, DOE would apply to the U.S. Army Corps of Engineers for a permit to fill jurisdictional waters of the United States.

Sections 401 and 405 of the Water Quality Act of 1987 and Public Law 100-4 added Section 402(p) to the Clean Water Act. Section 401 provides states with the opportunity to review and approve, condition, or deny all federal permits or licenses that might result in a discharge to state or tribal waters, including wetlands. The major federal permit subject to Section 401 review is a Section 404 permit. Every applicant for a Section 404 permit must request state certification that the proposed activity will not violate state or federal water quality standards. Construction of the proposed railroad would require the discharge of dredged or fill materials for bridges and culverts into United States waters via interstate streams and dry ***washes***. DOE would follow the requirements of Section 401 in requesting state certification. The proposed construction activities would not exceed State of Nevada water quality standards or otherwise violate a state requirement.

6.3.4.2 Safe Drinking Water Act, as Amended (42 U.S.C. 300 *et seq.*)

The Safe Drinking Water Act of 1974, as amended (42 U.S.C. 300(f) *et seq.*), gives the U.S. Environmental Protection Agency the responsibility and authority to regulate public drinking-water supplies by establishing drinking-water standards, delegating authority for enforcement of drinking-water standards to the states, and protecting ***aquifers*** from pollution hazards. The Nevada Division of Environmental Protection, Bureau of Safe Drinking Water, is the state agency responsible for enforcement. Environmental Protection Agency regulations for this program are codified at 40 CFR Part 141, and Nevada rules for this program are codified at Nevada Administrative Code, Chapter 445A. Operating permits are required for public water distribution systems, which are classified as a public water supply if each serves 15 connections or 25 people for more than 60 days per year. Because public water distribution systems would be located along the rail line at ***construction camps*** and railroad operations support facilities, DOE would have to obtain operating permits for these systems.

6.3.4.3 Nevada Revised Statutes: Water Controls (Title 40, Chapter 445A)

Nevada Revised Statutes, Chapter 445A, Water Controls, classifies the waters of the state, establishes standards for the quality of all waters in the state, and specifies permit and notification provisions for stormwater discharges and for other discharges to the waters of the state according to provisions of the Clean Water Act of 1977 (33 U.S.C. 1251 *et seq.*) and the Safe Drinking Water Act of 1974 (42 U.S.C. 300 *et seq.*). These statutes and regulations in the Nevada Administrative Code set drinking water standards, specifications for certification, and conditions for issuance of variance and exemptions; set standards and requirements for the construction of wells and other water-supply systems; establish the different classes of wells and aquifer exemptions; and establish requirements for well operation and monitoring, plugging, and abandonment activities.

Additionally, the Nevada Division of Environmental Protection, Bureau of Water Pollution Control, requires a temporary permit to work in waterways of the state (that is, a rolling stock permit) before using equipment in waters of the state, including dry washes, that could directly discharge pollutants into waters of the state. Construction of the rail line would require installation of drainage ***culverts*** or bridges to cross some of the washes and streambeds and other construction activities in channels. DOE would have to obtain a permit for such work.

6.3.4.4 Nevada Revised Statutes: Adjudication of Vested Water Rights, Appropriation of Public Waters; Underground Water and Wells (Title 48, Chapters 533 and 534)

Nevada Revised Statutes, Chapters 533 and 534, and accompanying regulations in the Nevada Administrative Code, Chapters 533 and 534, establish permitting procedures for appropriating public waters of the state, including underground waters for beneficial use. The withdrawal of underground water in Nevada requires a permit from the Nevada State Engineer. DOE intends to meet water needs through construction of new wells and would need to apply for water rights with the Nevada State Engineer for construction of wells along the proposed rail alignment.

6.3.4.5 Floodplain Management and Protection of Wetlands (Executive Orders 11988 and 11990)

Executive Order 11988 requires federal agencies to ensure that the agency evaluates the potential effects of any proposed action on ***floodplains***; to ensure that planning programs and budget requests reflect consideration of flood hazards and floodplain management; and to prescribe procedures to implement the policies and requirements of the Order. Federal agencies are required to reduce risk of flood damage; minimize the impact of floods on human safety, health, and welfare; and restore and preserve the natural and beneficial values served by floodplains.

Executive Order 11990 requires that federal agencies "…take action to minimize the destruction, loss, or degradation of wetlands," and to consider wetland protection in decision making. It should be noted that exclusion of isolated (nonjurisdictional) wetlands is not indicated in the Executive Order.

DOE issued regulations that implement these Executive Orders (10 CFR Part 1022, Compliance with Floodplain/Wetlands Environmental Review Requirements). In accordance with this regulation, specifically 10 CFR 1022.11(d), DOE must prepare a floodplain assessment for proposed actions that would take place in floodplains and a wetlands assessment for proposed actions that would take place in wetlands. DOE must also avoid to the extent possible the long- and short-term adverse impacts associated with the destruction of wetlands and the occupancy and modification of floodplains and wetlands, and avoid direct and indirect support of floodplain and wetlands development wherever there is a practicable alternative.

To meet the requirements of 10 CFR Part 1022, Appendix F, Floodplain and Wetlands Assessment, includes a detailed analysis of floodplains and wetlands within the Caliente and Mina rail alignments regions of influence.

6.3.5 POLLUTION PREVENTION AND CONTROL

6.3.5.1 Pollution Prevention Act (42 U.S.C. 13101 *et seq.*)

The Pollution Prevention Act of 1990 (42 U.S.C. 13101 *et seq.*) establishes a national policy for waste management and pollution control that focuses first on source reduction, and then on environmentally safe waste recycling, treatment, and disposal. Executive Order 13423, *Strengthening Federal Environmental, Energy, and Transportation Management,* directs federal agencies to implement sustainable practices for pollution and waste prevention and recycling.

6.3.5.2 Comprehensive Environmental Response, Compensation, and Liability Act, as Amended (42 U.S.C. 9601 *et seq.*)

The Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended by the Superfund Amendments and Reauthorization Act (42 U.S.C. 9601 *et seq.*), authorizes the U.S. Environmental Protection Agency to require responsible site owners, operators, arrangers, and transporters to clean up releases of hazardous substances, including certain radioactive substances. Under this Act, the Environmental Protection Agency has the authority to regulate hazardous substances at rail line construction zones in the event of a release or a “substantial threat of a release.” DOE would report any releases greater than reportable quantities of hazardous substances (as codified in 40 CFR Part 302 under the Comprehensive Environmental Response, Compensation, and Liability Act) to the National Response Center, extremely hazardous substances (as codified in 40 CFR Part 355 under the Emergency Planning and Community Right-to-Know Act) to the State Emergency Response Commission contacts for Nevada, and substances classified as both hazardous and extremely hazardous to both the National Response Center and the State Emergency Response Commission contacts for Nevada. Nevada Administrative Code, Sections 445A.226 through 445A.22755, provide action levels for contaminated sites, including levels for groundwater, surface water, and soil. In the event of a release of hazardous substances during construction and operation of the proposed railroad, DOE would clean up releases in a manner that complies with the Comprehensive Environmental Response, Compensation, and Liability Act, as amended.

6.3.5.3 Resource Conservation and Recovery Act, as Amended (42 U.S.C. 6901 *et seq.*)

The treatment, storage, and disposal of hazardous and nonhazardous waste is regulated by the provisions of the Solid Waste Disposal Act, as amended by the Resource Conservation and Recovery Act of 1976 and the Hazardous and Solid Waste Amendments of 1984 (42 U.S.C. 6901 *et seq.*), and applicable state laws. Environmental Protection Agency regulations implementing the ***hazardous waste*** portions of the Resource Conservation and Recovery Act define hazardous wastes and specify requirements for their transportation, handling, treatment, storage, and disposal (40 CFR Parts 260 through 272). Immediate response actions and cleanup of spills are specified in 40 CFR Part 263.

Subtitle C of the Resource Conservation and Recovery Act requires that Resource Conservation and Recovery Act hazardous wastes be characterized and managed. DOE would track the amount of hazardous wastes that would be generated each month during proposed railroad construction and operations, including a log of materials and weight of all generated hazardous wastes. DOE would monitor waste-generator status and would comply in accordance with the applicable Subtitle C regulations. Nevada Administrative Code, Sections 444.850 to 444.8746, are the governing requirements for wastes generated under Subtitle C.

Subtitle D of the Resource Conservation and Recovery Act sets forth definitions, methods of disposal, and special requirements for solid-waste collection, transportation standards; and classification of landfills. Subtitle D focuses on state and local governments as the primary planning, regulating, and implementing entities for the management of nonhazardous solid waste, such as household garbage and nonhazardous industrial solid waste. The governing requirements for wastes generated in Nevada under Subtitle D are Nevada Revised Statutes, Sections 444.440 to 444.620, and Nevada Administrative Code, Sections 444.570 to 444.7499. DOE plans to dispose of solid waste from railroad construction and operations at commercial or municipal landfill facilities that meet Subtitle D requirements.

6.3.5.4 Federal Insecticide, Fungicide, and Rodenticide Act, as Amended (7 U.S.C. 136 *et seq.*)

The primary focus of the Federal Insecticide, Fungicide, and Rodenticide Act of 1948, as amended (7 U.S.C. 136 *et seq.*), and the Act's implementing regulations (40 CFR Parts 152 through 186), is to provide federal control of pesticide distribution, sale, and use. The Nevada Pesticides Act, Nevada Administrative Code, Chapter 586, and Nevada Revised Statutes, Sections 586.010 through 586.450, also regulate pesticide distribution and use, and require registration with the state. DOE would comply with federal and state laws in the application and storage of pesticides during construction and operation of the proposed railroad.

6.3.5.5 Noise Control Act, as Amended (42 U.S.C. 4901 *et seq.*)

Section 4 of the Noise Control Act of 1972, as amended (42 U.S.C. 4901 *et seq.*), directs federal agencies to carry out programs in their jurisdictions "to the fullest extent within their authority" and in a manner that furthers a national policy of promoting an environment free from noise that jeopardizes health and welfare. This law provides requirements related to noise that would be generated by construction and operations activities associated with the proposed railroad. The STB, a cooperating agency on this Rail Alignment EIS, has environmental review regulations for noise analysis (49 CFR 1105.7e(6)) with the following criteria:

- An increase in noise exposure as measured by day-night average noise level of 3 ***A-weighted decibels*** or more.
- An increase to a noise level of 65 A-weighted decibels ***day-night average noise level*** or greater.

DOE used these environmental review regulations to analyze potential train noise for this Rail Alignment EIS.

6.3.5.6 Strengthening Federal Environmental, Energy, and Transportation Management (Executive Order 13423)

Executive Order 13423 sets goals for federal agencies in the areas of energy efficiency, acquisition, renewable energy, toxics reductions, recycling, renewable energy, sustainable buildings, electronics stewardship, fleets, and water conservation. In addition, this Order requires more widespread use of Environmental Management Systems as the framework in which to manager and continually improve these sustainable practices. DOE would comply with the provisions of this Order during construction and operation of the proposed railroad.

6.3.6 CULTURAL RESOURCES

To meet federal historic preservation laws and regulations and NEPA (40 CFR 1500 through 1508) mandates, DOE would identify and evaluate all cultural resources in the regions of influence along the Caliente rail alignment and the Mina rail alignment, including prehistoric, historic, and American Indian, and assess the potential for adverse impacts during construction and operation of the proposed railroad. The National Historic Preservation Act of 1966, as amended (16 U.S.C. 470 *et seq.*), is the primary source of regulatory requirements for the protection of cultural resources (see Section 6.3.6.1). Sections 6.3.6.2 through 6.3.6.8 describe other sources of regulatory requirements.

6.3.6.1 National Historic Preservation, as Amended (16 U.S.C. 470 *et seq.*)

The National Historic Preservation Act of 1966, as amended (16 U.S.C. 470 *et seq.*), provides for the placement of sites with significant national historic value on the *National Register of Historic Places*. It requires no permits or certifications. In this Rail Alignment EIS, DOE evaluated proposed railroad construction activities that could have a potential effect on historic resources pursuant to a programmatic agreement with the BLM, the STB, and the Nevada State Historic Preservation Office (DIRS 176912-Wenker et al. 2006, all). The programmatic agreement provides that, prior to commencement of any ground-disturbing construction activities, an appropriate level of field investigation including on-the-ground intensive surveys, evaluations of all recorded resources on the *National Register of Historic Places*, assessments of adverse effects, and applicable ***mitigation*** of identified impacts be completed. The BLM manages most of the land over which DOE would construct the proposed railroad; therefore, relevant provisions of the programmatic agreement would apply. Additionally, in cooperation with the BLM and the STB, the programmatic agreement requires DOE to make a good faith effort to consult with tribes and identify affected ethnic groups, to identify properties of traditional religious and cultural importance, inform the consulting parties of the eligibility of properties for listing on the *National Register of Historic Places*, and suggest appropriate treatment to avoid adverse impacts to historic properties. Appendix B of this Rail Alignment EIS describes the consultation process.

6.3.6.2 American Antiquities Act (16 U.S.C. 431 *et seq.*)

The American Antiquities Act of 1906 (16 U.S.C. 431 *et seq.*) protects historic and prehistoric ruins, monuments, and objects of antiquity including vertebrate paleontological resources, on federally owned or controlled lands. If historic or prehistoric ruins or objects were found during construction of the proposed railroad, DOE would follow provisions of this Act to minimize or mitigate adverse effects.

6.3.6.3 Archaeological Resources Protection Act, as Amended (16 U.S.C. 470aa *et seq.*)

The Archaeological Resources Protection Act of 1979, as amended (16 U.S.C. 470aa *et seq.*), requires a permit for excavation or removal of archaeological resources from publicly held or American Indian lands. The Act requires that excavations further archaeological knowledge in the public interest, and that the resources removed remain the property of the United States. Requirements of this Act would apply to any proposed excavation activity that resulted in identification of archaeological resources.

6.3.6.4 Native American Graves Protection and Repatriation Act (25 U.S.C. 3001 *et seq.*)

The Native American Graves Protection and Repatriation Act of 1990 (25 U.S.C. 3001 *et seq.*) directs the Secretary of the Interior to guide the repatriation of federal archaeological collections and collections that are culturally affiliated with American Indian tribes and held by museums that receive federal funding. Actions required by this law include establishing a review committee with monitoring and policy-making responsibilities, developing regulations for repatriation, including procedures for identifying lineal descent or cultural affiliation needed for claims, overseeing museum programs designed to meet the inventory requirements and deadlines of this law, and developing procedures to handle unexpected discoveries of graves or grave artifacts during activities on federal or tribal land. DOE would follow the provisions of this Act if any excavations associated with the proposed railroad construction led to unexpected discoveries of American Indian graves or grave artifacts.

6.3.6.5 American Indian Religious Freedom Act (42 U.S.C. 1996)

The American Indian Religious Freedom Act of 1978 (42 U.S.C. 1996) reaffirms American Indian religious freedom under the First Amendment of the U.S. Constitution, and establishes policy to protect and preserve the inherent and Constitutional right of American Indians to believe, express, and exercise their traditional religions. This law ensures the protection of sacred locations and access of American Indians to those sacred locations and traditional resources that are integral to the practice of their religions. It also establishes requirements that would apply to American Indian sacred locations, traditional resources, or traditional religious practices potentially affected by construction and operation of the proposed railroad.

6.3.6.6 Protection and Enhancement of the Cultural Environment (Executive Order 11593)

Executive Order 11593 directs federal executive agencies to locate, catalog, and nominate properties under their jurisdiction or control to the *National Register of Historic Places*. DOE would follow the provisions of this Order during construction of the proposed railroad.

6.3.6.7 Indian Sacred Sites (Executive Order 13007)

Executive Order 13007 directs federal agencies, to the extent permitted by law and not inconsistent with agency missions, to avoid adverse effects to sacred sites and to provide access to those sites to American Indians for religious practices. The Order directs agencies to plan projects in a manner that allows protection of and access to sacred sites to the extent compatible with the project. DOE would follow the provisions of this Order during construction and operation of the proposed railroad.

6.3.6.8 Consultation and Coordination with Indian Tribal Governments (Executive Order 13175)

Executive Order 13175 directs federal agencies to establish regular and meaningful consultation and collaboration with tribal governments in developing federal policies that have tribal implications, to strengthen U.S. government-to-government relationships with American Indian tribes, and to reduce the imposition of unfunded mandates on tribal governments. DOE has and will continue to follow the provisions of this Order during construction and operation of the proposed railroad through regular consultation with the Consolidated Group of Tribes and Organizations, which consists of officially appointed tribal representatives who are responsible for presenting their respective tribal concerns and perspectives to DOE.

6.3.7 BIOLOGICAL RESOURCES

6.3.7.1 Endangered Species Act, as Amended (16 U.S.C. 1531 *et seq.*)

The Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*), provides for the conservation of ***threatened*** and ***endangered species*** and the ***ecosystems*** upon which those species rely. If construction or operation of the proposed railroad could affect threatened or endangered species, or their designated critical ***habitat***, DOE would be required to assess the potential impact and develop measures to minimize the impact. If there would be potential adverse impacts to a listed species or designated critical habitat, DOE would be required to consult formally with the U.S. Fish and Wildlife Service in compliance with Section 7 of the Act. As part of the Section 7 consultation, DOE would have to prepare a Biological Assessment and provide it to the Fish and Wildlife Service. The Fish and Wildlife Service would then prepare a Biological Opinion making a determination as to whether the Proposed Action would jeopardize the continued existence of the species under consideration. If the Fish and Wildlife Service rendered a non-jeopardy opinion, but a finding that some individuals could be killed or otherwise harmed incidentally by the Proposed Action, the Fish and Wildlife Service could determine that such losses are not prohibited, so long as measures outlined in a permit to incidentally take a listed species were followed. The permit would include limits on the taking of a listed species and its designated critical habitat and mandatory terms and conditions for minimizing the take. Regulations implementing the applicable interagency consultation process of the Endangered Species Act are codified at 50 CFR Part 402.

If the Fish and Wildlife Service determines that the proposed federal action jeopardizes a listed species or adversely modifies its designated critical habitat, the Secretary of the Interior suggests alternatives to the proposed action that would not violate the action. Then federal agencies must decide whether to modify the project as suggested, abandon it, or file an application for an exemption. Regulations that describe the exemption process are found in 50 CFR Parts 450 through 453.

6.3.7.2 Fish and Wildlife Coordination Act, as Amended (16 U.S.C. 661 *et seq.*)

The Fish and Wildlife Coordination Act of 1934, as amended (16 U.S.C. 661 *et seq.*), promotes effectual planning and cooperation between federal, state, public, and private agencies for the conservation and rehabilitation of the Nation's fish and wildlife, and authorizes the U.S. Department of the Interior to provide assistance. The Act requires that when a department or agency of the U.S. Government modifies the waters, or channel of a body of water, the department or agency must consult with the U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, and the state agency that administers wildlife resources in the affected state. DOE consultation with appropriate federal and State of Nevada agencies regarding construction and operation of the proposed railroad would be in compliance with the requirements of this Act.

6.3.7.3 Migratory Bird Treaty Act, as Amended (16 U.S.C. 703 seq.)

The Migratory Bird Treaty Act of 1918, as amended (16 U.S.C. 703 *et seq.*), protects birds that have common migration patterns between the United States, Canada, Mexico, Japan, and Russia. It also regulates the take and harvest of migratory birds. All species of birds found along the proposed rail alignments are protected by the Migratory Bird Treaty Act with the exceptions of European starlings (*Sturnus vulgaris*), rock doves (pigeons; *Columba livia*), and house sparrows (*Passer domesticus*), and any game species having legal harvest seasons set by the Nevada Department of Wildlife. DOE would implement methods during proposed railroad construction and operation, including surveys for nesting birds and restrictions on the timing of construction, to prevent the take of migratory birds.

6.3.7.4 Bald and Golden Eagle Protection Act, as Amended (16 U.S.C. 668 through 668d)

The Bald and Golden Eagle Protection Act of 1940, as amended (16 U.S.C. 668 through 668d), makes it illegal to take, pursue, molest, or disturb bald eagles (American, *Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*), their nests, or their eggs anywhere in the United States (Sections 668 and 668c). The U.S. Department of the Interior regulates activities that might adversely affect bald and golden eagles.

6.3.7.5 The Wild Free-Roaming Horses and Burros Act, as Amended (16 U.S.C. 1331 *et seq.*)

The Wild Free-Roaming Horses and Burros Act of 1971, as amended (16 U.S.C. 1331 *et seq.*), requires the protection, management, and control of wild free-roaming horses and burros on ***public lands***. The Act states that "wild free-roaming horses and burros shall be protected from capture, branding, harassment, or death; and to accomplish this they are to be considered in the area where presently found, as an integral part of the natural system of the public lands." DOE would construct and operate the railroad in compliance with the provisions of this Act.

6.3.7.6 National Wildlife Refuge System Administration Act, as Amended (16 U.S.C. 668dd)

The National Wildlife Refuge System Administration Act of 1966, as amended (16 U.S.C. 668dd), provides guidelines for the administration and management of lands, including "wildlife refuges, areas for the protection and conservation of fish and wildlife that are threatened with extinction, wildlife ranges, game ranges, wildlife management areas, or waterfowl production areas." If use of lands for the proposed railroad could affect lands in the National Wildlife Refuge System, DOE would consult with the U.S. Fish and Wildlife Service. Regulations implementing the Act are codified at 50 CFR Parts 25 and 27 through 29.

6.3.7.7 Nevada Revised Statutes: Protection and Preservation of Timbered Lands, Trees, and Flora (Title 47, Chapter 527)

Nevada Revised Statutes, Chapter 527, specifies protection of the indigenous flora of the State of Nevada. If the state determines that a species or subspecies of native flora is threatened with extinction, that species or subspecies is to be placed on the state list of fully protected species. No member of the species or subspecies may be taken or destroyed unless an authorized state official issues a special permit.

6.3.7.8 Nevada Revised Statutes: Hunting, Fishing, and Trapping; Miscellaneous Protective Measures (Title 45, Chapter 503)

Nevada Revised Statutes, Chapter 503, Hunting, Fishing, and Trapping, Miscellaneous Protective Measures, and Nevada Administrative Code, Chapter 503, Sections 010 through 104, specify procedures for the classification and protection of wildlife. No member of a species classified as protected may be hunted, taken, or possessed without first obtaining a permit or written authorization from the Nevada Department of Wildlife. Nevada Revised Statute, Chapter 527, Protection and Preservation of Timbered

Lands, Trees, and Flora, also applies to the permit requirement. No protected species would be hunted, taken, or possessed during construction or operation of the proposed railroad.

6.3.7.9 Nevada Revised Statutes: Control of Insects, Pests, and Noxious Weeds (Title 49, Chapter 555)

Nevada Revised Statutes, Chapter 555, Control of Insects, Pests, and Noxious Weeds, specifies the laws by which the Nevada Department of Agriculture designates and regulates ***noxious weeds*** and pests. Clearing vegetation and disturbing the soil during construction would create habitat for colonization by noxious weeds present along the rail line. DOE would minimize such impacts, in compliance with the provisions in this Nevada Statute, by developing and implementing a weed management program, which could include reclamation of disturbed areas that would enhance the recovery of native vegetation and reduce colonization by exotic species.

6.3.7.10 Invasive Species (Executive Order 13112)

Executive Order 13112 directs federal agencies to act to prevent the introduction of, or to monitor and control, nonnative or invasive plant species, to provide for restoration of ***native plant species***, to conduct research, to promote educational activities, and to exercise care in taking actions that could promote the introduction or spread of ***invasive species***. DOE would minimize such impacts, in compliance with the provisions in this Executive Order, by developing and implementing a weed management program.

6.3.7.11 Responsibilities of Federal Agencies to Protect Migratory Birds (Executive Order 13186)

Executive Order 13186 requires federal agencies to avoid or minimize the negative impacts of their actions on migratory birds and to take active steps to protect birds and their habitats. The Order directs each federal agency whose action has, or is likely to have, a negative impact on migratory bird populations to develop an agreement with the U.S. Fish and Wildlife Service to conserve those birds. The Order directs agencies to avoid or minimize the impact on migratory bird populations, to take reasonable steps that include restoring and enhancing bird habitats, to prevent or abate pollution that would affect birds, and to incorporate migratory bird conservation into agency planning processes when possible. The Order also requires environmental analyses of federal actions to evaluate effects of those actions on migratory birds, to control the spread and establishment in the wild of exotic animals and plants that could harm migratory birds and their habitats, and either to provide advance notice of actions that could result in the taking of migratory birds or to report annually to the U.S. Fish and Wildlife Service on the numbers of each species taken during the conduct of agency actions. Section 4.12 of this Rail Alignment EIS, Biological Resources, discusses potential impacts to migratory birds. DOE would implement methods during proposed railroad construction and operation, including surveys for nesting birds and restrictions on the timing of construction, to prevent the take of migratory birds.

6.3.8 LAND USE

Land uses that could be affected by the proposed railroad are under the jurisdiction of federal, state, county, and municipal plans and policies. Lincoln, Nye, and Esmeralda Counties have land-use plans (*Lincoln County Master Plan* [DIRS 174520-State of Nevada 2001, all]; *Adoption of the Nye County Comprehensive Plan* [DIRS 147994-McRae 1994, all]; *Master Plan Esmeralda County, Nevada* [DIRS 176770-Duval et al. 1976, all]). Approximately 99 percent of the lands along the Caliente and Mina rail alignments are BLM-administered public lands. The BLM administers the uses of lands along the Caliente rail alignment through ***resource management plans*** including the *Tonopah Resource Management Plan and Record of Decision* (DIRS 173224-BLM 1997, all), the *Draft Ely Resource*

Management Plan (when it is finalized; DIRS 174518-BLM 2005, all), and the *Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement* (DIRS 176043-BLM 1998, all). The BLM administers the uses of lands along the Mina rail alignment through the *Carson City Field Office Consolidated Resource Management Plan* (DIRS 179560-BLM 2001, all), the *Tonopah Resource Management Plan and Record of Decision* (DIRS 173224-BLM 1997, all), and the *Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement* (DIRS 176043-BLM 1998, all).

6.3.8.1 Federal Land Policy and Management Act (43 U.S.C. 1701 *et seq.*)

The Federal Land Policy and Management Act of 1976 (43 U.S.C. 1701 *et seq*.) established procedures for acquiring access to public lands. The regulations regarding withdrawals of public-domain land from public use, as codified in 43 CFR Part 2300, and the establishment of right-of-way reservations, as codified in 43 CFR Part 2800, primarily govern access to, and use of, BLM-administered lands. Section 6.6 describes this Act.

6.3.8.2 Materials Act (30 U.S.C. 601 *et seq.*)

The Materials Act of 1947 (30 U.S.C. 601 *et seq.*) authorizes land management agencies such as the BLM to make common varieties of sand, stone, and gravel from public lands available to federal and state agencies under a ***free-use permit***. Regulations implementing the Materials Act are codified at 43 CFR Part 3600. To use common varieties of sand, stone, and gravel from public lands during construction of the proposed railroad, DOE would obtain free-use permits from the BLM.

6.3.8.3 Taylor Grazing Act, as Amended (43 U.S.C. 315 *et seq.*)

The Taylor Grazing Act of 1943, as amended (43 U.S.C. 315 *et seq.*), establishes processes by which the BLM grants and administers grazing rights. Regulations implementing the Taylor Grazing Act are codified at 43 CFR Parts 2300 and 4100 and include provisions for the agency to consider in administering grazing rights.

6.3.8.4 Farmland Protection Policy Act (7 U.S.C. 4201 *et seq.*)

The Farmland Protection Policy Act of 1981 (7 U.S.C. 4201 *et seq.*) seeks to minimize the extent to which federal programs contribute to the unnecessary and irreversible conversion to nonagricultural uses of farmlands with soils that are identified as prime and unique or of statewide and local importance. To comply with this law, DOE has coordinated with the U.S. Department of Agriculture, Natural Resources Conservation Service, to identify ***prime farmlands*** that could be affected by the proposed action and to evaluate impacts to those lands. Regulations implementing the Farmland Protection Policy Act are codified at 7 CFR Part 658.

6.3.8.5 Uniform Relocation Assistance and Real Property Acquisition Policies Act (42 U.S.C. 4651 *et seq.*)

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (42 U.S.C. 4651 *et seq.*) encourages and expedites the acquisition of real property by agreements with owners; avoids litigation, including condemnation actions where possible, and relieves congestion in the courts; provides for consistent treatment of owners; and promotes public confidence in federal land-acquisition practices. For those portions of the rail line that would cross private land, DOE could negotiate a long-term lease with the landowner or transfer the land to federal ownership in accordance with this Act.

6.3.8.6 General Mining Law, as Amended (30 U.S.C. 22 through 54)

The Mining Law of 1872, as amended (30 U.S.C. 29; 43 CFR 3860) (30 U.S.C. 22 through 54), was one of a number of public land laws passed by Congress in the late 1800s to encourage settlement, development, and private ownership of the public-domain lands in the western United States. The Mining Law of 1872 enables public citizens and the mining industry the right to claim, settle on, develop mineral resources, and acquire title to public lands administered by the BLM and the U.S. Forest Service (an agency of the U.S. Department of Agriculture).

The Mining Law Administration program managed by the BLM involves primarily the last three elements: recordation, maintenance (annual work/surface management), and mineral patents. Surface management on National Forest System lands is administered by the Forest Service.

6.3.9 CONSTRUCTION- AND OPERATIONS-RELATED STATUTES AND REGULATIONS

6.3.9.1 Communications Act, as Amended (47 U.S.C. 308 *et seq.*)

The Communications Act of 1934, as amended by the Telecommunications Act of 1996 (47 U.S.C. 308 *et seq.*), and regulations of the Federal Communications Commission require an agency to obtain Federal Communications Commission permission to construct a private broadcasting system. DOE would need to obtain permission to use an assigned frequency, and the Federal Communications Commission would have to approve the design and location of the system prior to construction. The communication system for the proposed railroad would consist of a fiber optic cable along the length of the line with broadcasting antenna located within the ***operations right-of-way*** at sufficient intervals to allow complete coverage of train-to-dispatch radio communications. DOE would obtain Federal Communications Commission approval to construct and operate this radio system and install a fiber optics line.

6.3.9.2 Construction Camp Permits (Title 40, Chapter 444.130; NAC 444.550 through 444.566)

The Nevada State Health Division specifies conditions and requires permits for construction and labor camps in Nevada (Nevada Revised Statutes, Chapter 444.130 *et seq.*, and Nevada Administration Code, Chapters 444.550 through 444.566). These statutes and regulations are designed to maintain sanitary and healthy conditions at construction and labor camps in Nevada. They would apply to the design and operation of construction camps that DOE would establish during construction of the proposed railroad.

6.3.9.3 Occupancy Permits to Cross State Highways

The Nevada Department of Transportation and the Nevada Public Utilities Commission regulate rail crossings of public highways. The Nevada Department of Transportation requires an occupancy permit to place a facility (including a railway) within a right-of-way of a state highway (Nevada Administrative Code, Section 408.427). The Public Utilities Commission must approve the placement of railroad tracks across public highways prior to construction of the tracks (Nevada Administrative Code, Section 703.455). DOE would have to obtain similar approvals for construction of access roads, water pipelines, and other ***infrastructure*** that would intersect highway rights-of-way.

The STB would regulate the proposed railroad if DOE implemented the Shared-Use Option. In this case, the Federal Railroad Safety Act of 1970, as amended (49 U.S.C. 20106 *et seq.*), could preempt Nevada regulations related to railroad safety. However, DOE would still design and construct highway crossings to address the concerns of Nevada regulatory agencies.

6.4 U.S. Department of Energy Orders

Under the authority of the Atomic Energy Act of 1954, as amended (42 U.S.C. 2011 through 2259), DOE is responsible for establishing a comprehensive health, safety, and environmental program for its activities and facilities. DOE has established a framework for managing its facilities through the promulgation of regulations and the issuance of DOE Orders that set forth policies, programs, and procedures for implementing activities. DOE Orders are a component of DOE Directives that also include Policies, Notices, Manuals, and Guides, all of which are intended to direct, guide, inform, and instruct employees in the performance of their jobs, and enable them to work effectively within the Department and with agencies, contractors, and the public. Table 6-4 lists DOE Orders that could be relevant to construction and operation of the proposed railroad.

Table 6-4. Potentially applicable DOE Orders (page 1 of 2).

Order number and date of last revision	Subject	Description[a]
151.1C 11/02/05	Comprehensive Emergency Management System	Establishes requirements for emergency planning, preparedness, response, recovery, and readiness assurance activities and describes the approach for effectively integrating these activities under a comprehensive, all-emergency concept.
231.1A 06/03/04	Environment, Safety, and Health Reporting	Establishes the requirements procedures for information with environmental protection, safety, or protection significance for DOE operations.
252.1 11/19/99	Technical Standards	Requires that appropriate voluntary consensus standards (codes and standards) be selected, used, and adhered to for the design, testing, etc., of the proposed railroad.
413.3 07/28/06	Project Management	Demonstrates that DOE will support the development of documentation for the critical-decision process.
414.1C 06/17/05	Quality Assurance	Establishes an effective quality assurance management system using the performance requirements of this Order, coupled with technical standards, where appropriate.
420.1B 12/22/05	Facility Safety	Where no specific requirements are specified concerning natural phenomena hazard mitigation, requires model building codes or national consensus industry standards to be used in the design of the proposed railroad facilities.
430.1B 09/24/03	Life-Cycle Asset Management, Building Codes, and Value Engineering	Establishes procedures to follow in all phases of the management of DOE facilities.
430.2A 04/15/02	Energy Management	Requires design for the proposed railroad to be in compliance with the energy management plan, sustainable design, and water efficiency required by this Order.
440.1A 03/27/98	Worker Protection Management for DOE, Federal and Contractor Employees, and Fire Protection	Establishes a comprehensive worker protection program that ensures that DOE and its contractor employees have an effective worker protection program to reduce or prevent injuries, illnesses, and accidental losses by providing DOE, federal, and contractor workers with a safe and healthful workplace.
450.1 01/03/07	Environmental Protection Program	Establishes DOE policy to conduct its operations in an environmentally safe and sound manner and to conduct its activities in compliance with applicable laws and regulations through implementation of environmental management systems at DOE sites.

Table 6-4. Potentially applicable DOE Orders (page 2 of 2).

Order number and date of last revision	Subject	Description[a]
451.1B[b] 09/28/01	NEPA Compliance Program	Establishes DOE requirements and responsibilities for complying with NEPA.
460.1B 4/4/03	Packaging and Transportation Safety	Establishes requirements and assigns responsibilities for the safe transport of hazardous materials, hazardous substances, hazardous wastes, and radioactive materials.
460.2A 12/22/04	Transportation and Packaging Management	Establishes DOE polices and requirements to supplement applicable laws, rules, regulations, and other DOE Orders for materials, transportation and packaging operations.
470.2B 10/31/02	Independent Oversight and Performance Assurance Program	Prescribes the requirements and responsibilities to enhance safeguards and security; cyber security; emergency management; environment, safety, and health programs; and other critical functions by providing an independent evaluation of the adequacy of DOE policy and the effectiveness of line management performance.
470.4 08/26/05	Safeguards and Security System Design	Requires the design of the proposed railroad facilities to provide site-specific safeguards and security protection or to tailor the physical protection elements in a number of areas, as described in the Order.
5400.5 01/07/93	Protection of Public from Radiation Risks	Establishes standards and requirements for operations of DOE and DOE contractors for protection of members of the public and the environment against undue risk from radiation.
5480.19 10/23/01	Conduct of Operations Requirements for DOE Facilities	Provides requirements and guidelines for departments to use in developing directives, plans, and procedures for conducting operations at DOE facilities that should result in improved quality and uniformity of operations.

a. DOE = U.S. Department of Energy; NEPA = National Environmental Policy Act.
b. DOE Order 451.1B was modified by a DOE Notice (DOE N 451.1, 10/6/06).

6.5 Bureau of Indian Affairs Requirements

The regulations at 25 CFR Part 169 prescribe the procedures, terms, and conditions under which the U.S. Department of the Interior, Bureau of Indian Affairs, may grand rights-of-way over and across tribal land, individually owned land, and Federal Government-owned land; subsection 169.23 outlines that rights-of-way for railroads shall not exceed 50 feet in width on each side of the centerline of the railroad, except where there are heavy ***cuts*** and ***fills***, when they shall not exceed 100 feet in width. The regulations at 25 CFR Part 162 identify the conditions and authorities under which the Bureau of Indian Affairs may lease certain interests in Indian land and Federal Government land.

6.6 Bureau of Land Management Requirements

As a cooperating agency, the BLM may adopt this Rail Alignment EIS for the disclosure and analysis of potential environmental impacts, as required by NEPA.

The Federal Land Policy and Management Act of 1976 (43 U.S.C. 1701 *et seq*.) established procedures for acquiring access to public lands. The regulations regarding ***withdrawals*** of public-domain land from public use, as codified at 43 CFR Part 2300, and the establishment of right-of-way reservations, as codified at 43 CFR Part 2800, primarily govern access to, and use of, BLM-administered lands. Construction and operation of a proposed railroad along either the Caliente rail alignment or the Mina rail alignment would require access to BLM-administered lands through application to the BLM for a

right-of-way grant. A right-of-way grant is an instrument issued pursuant to Title V of the Federal Land Policy and Management Act authorizing the use of a right-of-way over, upon, under, or through public lands for construction, operation, maintenance, and termination of a project.

The BLM-authorized officer considers whether the application is in compliance with the purpose for which the public lands are managed and the public interest. The Federal Land Policy and Management Act requires the authorized officer, prior to issuing a right-of-way grant or temporary-use permit, to perform the following tasks:

- Complete an environmental analysis in accordance with NEPA using the Council on Environmental Quality regulatory provisions for implementing NEPA (40 CFR Parts 1500 through 1508) as the review guidelines.
- Determine compliance of the applicant's proposed plan with applicable federal and state laws.
- Consult with all other federal, state, and local agencies having an interest.
- Take any other action necessary to fully evaluate and make a decision to approve or deny the application and prescribe suitable terms and conditions for the grant (reservation) or permit.

The BLM-authorized officer may hold public meetings on an application for a right-of-way grant if it is determined that such meetings are appropriate and that sufficient public interest exists to warrant the time and expense for such meetings.

Requirements of the application for a right-of-way grant are outlined at 43 CFR 2802.3. Requirements include a description of the proposal and a map (aerial photo or equivalent) showing the approximate location of the proposed right-of-way and facilities on public lands and existing improvements adjacent to the proposal. The BLM-authorized officer may require the applicant to submit additional information such as a description of the ***common segments*** and ***alternative segments*** considered; a statement of need and economic feasibility of the proposal; and a statement of the environmental, social, and economic effects of the proposal.

The regulations specify that all right-of-way grants assigned under 43 CFR Part 2800 contain terms, conditions, and stipulations as required by the authorized officer regarding extent, duration, survey, location, construction, operation, maintenance, use, and termination. Stipulations typically include the following requirements:

- Restoration, revegetation, and curtailment of erosion of the surface of the land, or any other rehabilitation measure determined necessary
- Assurance that activities in connection with the grant or permit do not violate applicable air- and water-quality standards or related facility siting standards established by or pursuant to applicable federal or state law
- Controls or prevention of damage to scenic, aesthetic, cultural, and environmental values including damage to fish and wildlife habitat, damage to federal property, and hazards to public health and safety
- Compliance with state standards for public health and safety, environmental protection and siting, construction, operation, and maintenance, when those standards are more stringent than federal standards

The Federal Land Policy and Management Act, by which the government accomplishes most federal land withdrawals, contains a detailed procedure for application, review, and study by the BLM of the withdrawal of public domain land. The BLM submits the application to the Secretary of the Interior for approval of the terms and conditions of withdrawal. Withdrawals accomplished through the Act remain valid for no longer than 20 years unless extended after further review and approval by the Secretary of the Interior.

On December 19, 2003, DOE submitted *Application for Administrative Land Withdrawal for Potential Rail Corridor* (DIRS 177745-Arthur 2003, all) to the BLM, pursuant to Section 204 of the Federal Land Policy and Management Act. The purpose of the application was to withdraw 124.9 square kilometers (308,600 acres) of public land encompassing the Caliente rail corridor from ***surface entry*** and new ***mining claims*** for 20 years to evaluate the land for potential construction and operation of the proposed railroad. On December 29, 2003, the BLM issued a notice in the *Federal Register* of the proposed land withdrawal (*Notice of Proposed Withdrawal and Opportunity for Public Meeting*; *Nevada*, 68 *FR* 74965).

The notice segregated the land from surface entry and mining for a period of up to 2 years to allow a ***case file*** containing various studies and analyses to be prepared to support a final decision on the withdrawal application. The action would not transfer the land to DOE control. The BLM would continue to manage the withdrawal area in compliance with BLM resource management plans. In a May 21, 2004, Notice of Public Meetings, the BLM invited the public to submit written comments and gave notice of two public scoping meetings on the proposed land withdrawal and possible land-use plan amendments (*Notice of Public Meetings; Notice of Intent to Amend the Caliente Management Framework Plan, Schell Management Framework Plan, Tonopah Resource Management Plan, and the Las Vegas Resource Management Plan; Nevada*; 69 *FR* 29323). Separately from this Rail Alignment EIS, DOE prepared and released an environmental assessment in December 2005, *Environmental Assessment for the Proposed Withdrawal of Public Lands Within and Surrounding the Caliente Rail Corridor, Nevada* (DIRS 176452-DOE 2005, all), proposing the continued segregated effect of the land by withdrawing the land for a preferred period of 10 years. On December 28, 2005, the BLM withdrew the requested lands, subject to valid existing rights, from settlement, sale, location, or entry under general land laws, including the United States mining laws (30 U.S.C. Chapter 2), but not from leasing under the mineral leasing laws (for example, the Mineral Leasing Act of 1920, as amended [30 U.S.C. 181 *et seq.*]), for a period of 10 years (70 *FR* 76854).

DOE initiated a further application for land withdrawal and requested that the Secretary of the Interior withdraw a total of 84.19 square kilometers (208,037 acres) of public lands from surface entry and mining through December 27, 2015. Thereby the BLM issued a notice on January 10, 2007 in the *Federal Register* of this application by DOE (*Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada*; 72 *FR* 1235). This notice included an additional 27.78 square kilometers (68,646 acres) of public lands for evaluation along the Caliente rail corridor, and 56.41 square kilometers (139,391 acres) of public lands for the purpose of evaluating the potential construction, operation, and maintenance of a rail line along a suite of alternative segments and common segments referred to by the DOE as the "Mina Route." The expiration date for this proposed withdrawal is the same (December 27, 2015) as in the earlier December 28, 2005 BLM land withdrawal.

Implementation of the Proposed Action along the Caliente rail alignment or the Mina rail alignment would require a BLM right-of-way grant for use and access to BLM-administered lands that would be disturbed for rail line construction and operation. The BLM may issue a right-of-way grant for temporary or long-term use of land, and before issuing a right-of-way grant, must complete an environmental analysis in accordance with the National Environmental Policy Act of 1969. As a cooperating agency in the preparation of this Rail Alignment EIS, the BLM may adopt this document as authorized by 40 CFR 1501 to satisfy the NEPA requirements for the right-of-way application.

6.7 U.S. Army Requirements

The U.S. Army is a consulting agency to DOE in the preparation of this Rail Alignment EIS. Under the Mina Implementing Alternative (the nonpreferred alternative), DOE would need to construct and operate the ***Staging Yard*** on the Hawthorne Army Depot in Mineral County. DOE would do so in conformance with existing permits issued to the Hawthorne Army Depot by the State of Nevada, Division of Environmental Protection. Table 6-5 lists the permits for the main site at the Hawthorne Army Depot.

Table 6-5. Permits for the Hawthorne Army Depot main site at Hawthorne, Nevada, issued by the State of Nevada, Division of Environmental Protection.[a]

Permit	Type	Permit number
Class I, Title V, Main Base	Air	AP9711-0863.01
Class I Construction, hazardous waste generator	Air	AP9711-1145
Class I Construction, Bulk Energetics Demilitarization System	Air	AP9711-1489
Wastewater, Plasma Ordnance Demilitarization System	Groundwater	NEV2003516
Wastewater, Western Area Demilitarization Facility	National Pollutant Discharge Elimination System	NV0021946
Stormwater	Clean Water Act	NVR050000
Treatment storage and disposal system, storage open burn, incineration	Resource Conservation and Recovery Act, C	HW0017
Solid-waste and fill	Resource Conservation and Recovery Act, D	Waiver No. SWMI-09-68
Solid-waste landfill	Resource Conservation and Recovery Act, D	SW-1209702
Drinking water	Solid Waste Disposal Act	MI-0357-12C
Water Treatment Facility	Groundwater	NEV2004524

CHAPTER 7. BEST MANAGEMENT PRACTICES AND MITIGATION

This chapter describes the best management practices DOE would implement to help avoid impacts to environmental resources and the measures the Department would consider to mitigate adverse impacts from constructing and operating the proposed railroad under the Caliente Implementing Alternative or the Mina Implementing Alternative, as appropriate. Mitigation measures include only those actions that would be above and beyond compliance with statutory and regulatory requirements and implementation of best management practices DOE has incorporated into the Proposed Action.

Glossary terms are shown in ***bold italics***.

During planning and design of the proposed railroad, the U.S. Department of Energy (DOE or the Department) used various engineering and site evaluation and planning measures to avoid, minimize, or otherwise reduce environmental ***impacts***. These measures included the elimination of certain ***alternative segments*** as unreasonable and moving the location of specific segments. The Department took many of these actions in response to comments received during the scoping periods for this Rail Alignment EIS. As the environmental analyses have progressed, DOE has refined the Caliente ***rail alignment*** and the Mina rail alignment to avoid certain sensitive environmental features and reduce potential impacts to sensitive areas by limiting the project's ***footprint*** in such areas. Chapter 2 and Appendix C describe this process.

As described in Chapter 2 and shown in Figure 7-1, engineering and site evaluation and planning represent the initial step toward avoiding, minimizing, or otherwise reducing the environmental impacts of the Proposed Action.

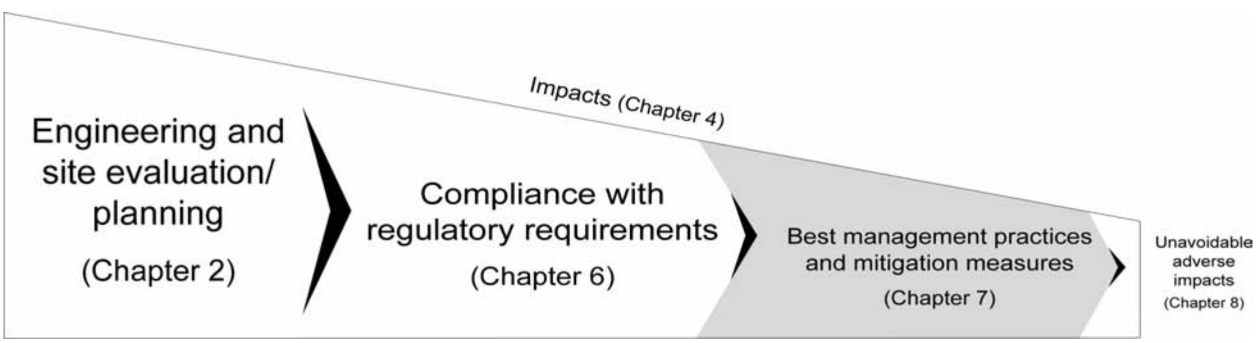

Figure 7-1. Multi-step approach to avoid, minimize, or reduce environmental impacts.

In addition to engineering and site evaluation and planning practices, DOE must also comply with all applicable environmental requirements (see Chapter 6). DOE incorporated a variety of best management practices into the ***Proposed Action*** that relate to these requirements and would further reduce the environmental impacts of constructing and operating the proposed ***railroad***.

After consideration of engineering and site evaluation and planning measures, compliance with environmental requirements, and application of best management practices, DOE would also consider various ***mitigation*** measures to further avoid, minimize, rectify, reduce, or compensate for any remaining adverse environmental impacts. DOE regards mitigation measures as activities or actions that would be above and beyond compliance with statutory and regulatory requirements and the application of the best management practices DOE has incorporated into the Proposed Action.

7.1 Representative Best Management Practices

> **Best Management Practices**
>
> Practices, techniques, methods, processes, and activities commonly accepted and used throughout the construction and railroad industries that DOE would implement as part of the Proposed Action to facilitate compliance with applicable requirements and that provide an effective and practicable means of preventing or minimizing the adverse impacts of an action on human health and the environment.

As part of the Proposed Action, DOE would implement appropriate best management practices to prevent or minimize environmental impacts. Table 7-1 lists, but does not limit, such practices. Some of the representative best management practices listed in Table 7-1 could change depending on the requirements included in permits and ***right-of-way grants*** applicable to construction and operation of the proposed railroad. The table identifies the affected resource area(s) for each best management practice, the requirement(s) the practice would support (see Chapter 6), and the purpose of the practice.

7.2 Mitigation

As the agency responsible for administering the federal lands over which the proposed railroad would cross, the Bureau of Land Management (BLM), an agency of the U.S. Department of the Interior, would have a substantial role in development of any necessary mitigation measures and monitoring requirements on the affected lands.

7.2.1 MITIGATION ACTION PLAN

> **Mitigation** (40 CFR 1508.20) includes:
>
> Avoiding the impact altogether by not taking a certain action or parts of an action.
>
> Minimizing impacts by limiting the degree or magnitude of the action and its implementation.
>
> Rectifying the impact by repairing, rehabilitating, or restoring the affected environment.
>
> Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action.
>
> Compensating for the impact by replacing or providing substitute resources or environments.

DOE regulations at 10 Code of Federal Regulations (CFR) 1021.331 requires the preparation of a mitigation action plan when DOE identifies mitigation commitments in the ***Record of Decision*** for this Rail Alignment EIS. If a mitigation action plan is necessary, it would follow the Record of Decision and would provide details about mitigation commitments and provisions provided in the Record of Decision, if any. DOE must prepare the mitigation action plan before it could take any action authorized by the Record of Decision that would be subject to a mitigation measure or commitment. The Plan would contain:

- An introduction describing the basis, function, and organization of the Plan
- A summary of the impacts to be mitigated
- A description of specific mitigation measures

- A description of the Mitigation Action Plan monitoring and reporting system that DOE would implement to ensure that elements of the Plan were met and were effective
- A schedule for actions and identification of the responsible parties

7.2.2 MONITORING

If DOE implemented the Proposed Action along the Caliente rail alignment or the Mina rail alignment, the Department would implement any mitigation measures and commitments specified in the Record of Decision. As needed, DOE would adapt mitigation measures to accomplish their intended objectives. As required by 40 CFR 1505.2(c), DOE would adopt and summarize a monitoring and enforcement program where applicable for any mitigation.

7.2.3 MITIGATION MEASURES

Table 7-2 summarizes potential mitigation measures for potential impacts along the proposed railroad. Each mitigation measure is linked to an identified potential impact, and is either location specific or global (applicable to the entire appropriate ***region of influence***), depending on the level of knowledge and degree of certainty regarding the extent, duration, and location of the potential impact. Mitigation measures would continue to evolve with project development and could change or become more specific and refined in a mitigation action plan following a Record of Decision for this Rail Alignment EIS (see Section 7.2.1). Consistent with the definition of mitigation described above, the mitigation measures identified in Table 7-2 include only those actions that would be above and beyond compliance with statutory and regulatory requirements and implementation of best management practices DOE has incorporated into the Proposed Action.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 1 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Pre-construction best management practices			
Prior to ground-disturbing activities, collect data to plan for the restoration of disturbed areas and minimize impacts to sensitive ***habitats***. This could include collecting satellite data to identify previously disturbed land, surveying vegetation, and looking for special status species habitat.	Physical Setting Aesthetic Resources Biological Resources	50 CFR Part 402 – Interagency Cooperation Endangered Species Act Of 1973, as Amended	Minimize impacts to sensitive habitats and species. Promote effective restoration efforts.
General employee training for construction personnel would include a desert tortoise education program. Surveys would be conducted prior to clearing vegetation at previously undisturbed sites within the range of the desert tortoise. For areas within the desert tortoise range, a desert tortoise biologist or environmental monitor would be available during construction activities to help ensure that desert tortoises are not inadvertently harmed. Project activities that may endanger desert tortoises would cease if a tortoise is found on a project site and activities would resume only after a biologist or environmental monitor ensures that the tortoise is not in danger or after the tortoise has been moved to a safe area. The worker education program would also include training to prevent the intentional or unintentional take of sensitive or protected plant and animal species, State of Nevada game species, or wild horses and burros.	Biological Resources	Endangered Species Act Of 1973, as Amended	Minimize impacts to desert tortoises.
Minimize groundbreaking or land clearing activities during the critical nesting period for migratory birds, which the BLM defines as May 1 through July 15. If groundbreaking or land-clearing activities must be conducted during the bird nesting season, DOE would conduct surveys for migratory bird nests prior to any of those activities. All activities that would harm nesting birds or result in nest abandonment would be prohibited.	Biological Resources	Migratory Bird Treaty Act	Avoid harm to migratory birds, their nests, and their young.
Coordinate with local Floodplain Administrators to ensure that new project-related stream and ***floodplain*** crossings are appropriately designed to minimize impacts. DOE would incorporate hydraulic modeling into the engineering design process to ensure that all crossings would be designed to limit adverse impacts.	Surface-Water Resources	10 CFR Part 1022 – Compliance with Floodplain/Wetlands Environmental Review Requirements	Minimize risks to streams and floodplains.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 2 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Pre-construction best management practices			
Position temporary pipelines to prevent obstructing or redirecting surface runoff and to prevent obstructing natural drainage channels.	Surface-Water Resources	Clean Water Act of 1977 33 CFR Part 323 NAC 445A – Water Controls	Prevent flooding or surface-water ponding.
Require construction contractors to prepare and submit a stormwater pollution prevention plan. This plan would be prepared consistent with state and federal standards for construction activities and would detail practices that would be employed to minimize soil loss and degradation to nearby water resources. Such practices could include those listed in the *Best Management Practices Handbook* developed by the Nevada Division of Environmental Protection and the Nevada Division of Conservation Districts (DIRS 176309-NDEP 1994, all), and the *Storm Water Quality Manuals Construction Site Best Management Practices Manual* developed by the Nevada Department of Transportation (DIRS 176307-NDOT 2004, all).	Surface-Water Resources	40 CFR Part 122, EPA Administered Permit Programs: The National Pollutant Discharge Elimination System Clean Water Act of 1977 (33 U.S.C. 1251 *et seq.*)	Control site runoff and minimize erosion.
Continue to solicit input from American Indians to identify the potential for impacts to American Indian cultural resources, discuss potential solutions, and avoid adverse impacts. Comply with all regulatory requirements that protect American Indian interests.	Cultural Resources American Indian Interests	Executive Order 13175, *Consultation and Coordination with Indian Tribal Governments*	Minimize impacts to American Indian cultural resources.
Conduct final field surveys (an intensive BLM ***Class III inventory***) of the ***construction right-of-way***, as described in the Programmatic Agreement (see Appendix C) between DOE, the BLM, the Surface Transportation Board, and the Nevada State Historic Preservation Office.	Cultural Resources	National Historic Preservation Act, 36 CFR Part 800 – Protection of Historic Properties	Minimize impacts to cultural resources.
Consult with American Indian tribes and protect their access to ***public lands*** that contain American Indian cultural resources.	Cultural Resources American Indian Interests	American Indian Religious Freedom Act of 1978 Executive Order 13007, *Indian Sacred Sites*	Minimize impacts and allow access to sacred American Indian sites.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 3 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Pre-construction best management practices			
Notify all potentially affected utility owners prior to project-related construction activities and coordinate with the owners to minimize impacts to utilities. Consult with utility owners to design the ***rail line*** so that utilities are protected during project-related construction activities. Contact Nevada Underground Service Alert so they can locate and mark underground facilities to prevent possible damage to underground utility lines, injury, property damage, and service outages.	Land Use and Ownership Utilities, Energy, and Materials Occupational and Public Health and Safety	NAC 455 – Excavations and Demolitions	Prevent damage to utilities, avoid and/or minimize disturbances to utility service, and avoid injuries to workers.
Prior to initiation of construction activities in the area, provide appropriate information regarding construction plans and schedules for the proposed rail line to fire departments and other local emergency planning agencies within the project area. Communicate updates and changes in the construction plans to appropriate parties as needed.	Occupational and Public Health and Safety	40 CFR Part 355 – Emergency Planning and Notification	Facilitate local emergency response planning and community awareness.
Prior to initiating any project-related construction activities, develop a spill prevention plan for petroleum products and other hazardous materials during construction activities. Ensure that equipment is available to respond to spills and identify the location of such equipment. In the event of a reportable spill, comply with the spill prevention plan and applicable federal, state, and local regulations pertaining to spill containment and appropriate cleanup. Make the required notifications to the appropriate federal and state environmental agencies in the event of a reportable hazardous materials release.	Hazardous Materials and Waste Occupational and Public Health and Safety Biological Resources Surface-Water Resources Groundwater Resources	40 CFR Part 112 – Oil Pollution Prevention 40 CFR Part 263 – Standards Applicable to Transporters of Hazardous Waste 40 CFR Part 302 – Designation, Reportable Quantities and Notification	Prevent release of oil and chemicals during construction. Establish effective spill response procedures. Minimize adverse environmental effects of a spill. Ensure appropriate cleanup of spilled material.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 4 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Pre-construction best management practices			
Develop internal emergency response plans for use during proposed rail line construction and operations to ensure that appropriate agencies and individuals are notified in case of an emergency. Provide the emergency response plans to appropriate state and local entities prior to any rail construction activities. Ensure such plans fully delineate the roles and responsibilities of all parties.	Hazardous Materials and Waste Occupational and Public Health and Safety	The Nuclear Waste Policy Act of 1982	Facilitate emergency response planning and enhance emergency response capabilities.
Provide fire departments and local emergency response agencies with a toll-free number for the DOE contact, who will be available to answer questions or attend meetings for the purpose of informing emergency-service providers about the project construction and operations. Revise this information, including changes in construction schedule, as appropriate. Before the start of operations, contact any local emergency response agencies to provide them with information concerning the proposed operations to allow them to incorporate the information into local response plans.	Hazardous Materials and Waste Occupational and Public Health and Safety	40 CFR Part 355 – Emergency Planning and Notification 49 CFR Part 172 – Hazardous Materials Table, Special Provisions, Hazardous Materials Communications, Emergency Response Information, and Training Requirements NAC 705 – Railroads	Facilitate communication to ensure state and local emergency response efforts are up to date. Ensure local response plans are up to date before the start of operations.
Develop and implement an Ordnance and Explosives Safety Construction Support Program applicable to construction activities. Include ordnance and explosives training for all construction personnel working in the areas designated by the U.S. Department of Defense (DoD) as being at risk of containing unexploded ordnance. DOE may employ a full-time unexploded-ordnance technician to oversee construction activities in areas near the Nevada Test and Training Range.	Hazardous Materials and Waste Occupational and Public Health and Safety	DoD Directive 4715.11 – Environmental and Explosives Safety Management on DoD Active and Inactive Ranges Within the U.S. 29 CFR 1910.120 and 1926.65 – Hazardous Waste Operations and Emergency Response Standard	Identify, evaluate, and control safety and health hazards related to unexploded ordnance on DoD property.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 5 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Pre-construction best management practices			
Adopt a rigorous safety program that would enable workers to avoid the most common accidents.	Occupational and Public Health and Safety	DOE Order O 440.1A, Worker Protection Management for DOE Federal and Contractor Employees 29 CFR Part 1926, *S*afety and Health Regulations for Construction 29 CFR Part 1960, Basic Program Elements for Federal Employee Occupational Safety and Health Programs and Related Matters	Ensure health and safety of construction workers during construction.
As appropriate, remove and stockpile topsoil that will be needed later for application during reclamation of disturbed areas. Stabilize topsoil stockpiles to prevent erosion. If the topsoil would remain in a stockpile for more than one year, seed with ***native plant species***. Periodically monitor and maintain the topsoil reserve to keep it stable and minimize erosion until it is used during reclamation efforts.	Physical Setting Biological Resources Surface-Water Resources	43 CFR Part 2800 – Rights-of-Way, Principles and Procedures; Rights-of-Way Under the Federal Land Policy and Management Act and the Mineral Leasing Act 40 CFR Part 122, EPA Administered Permit Programs: The National Pollutant Discharge Elimination System	Re-establish the stability and productivity of land subjected to surface disturbances through proper soils management. Preserve native seed stock contained in topsoil. Minimize erosion and control stormwater runoff to maintain water quality.
Construction best management practices			
Phase construction to the extent practicable. Limit grading activities to the phase immediately under construction and limit ground disturbance to areas necessary for project-related construction activities. Identify limits of disturbance on maps and in the field, and convey to construction personnel. Implement erosion and sediment control measures prior to and during construction.	Physical Setting Surface-Water Resources Groundwater Resources Biological Resources	40 CFR Part 122, EPA Administered Permit Programs: The National Pollutant Discharge Elimination System 10 CFR Part 1022 – Compliance with Floodplain/Wetlands Environmental Review Requirements Clean Water Act of 1977 (33 U.S.C. 1251 *et seq.*)	Minimize and control stormwater runoff to maintain water quality. Minimize ground disturbance and disturbance to vegetation, wetlands, streams, floodplains, and other sensitive environments.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 6 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Construction best management practices			
Establish staging and laydown areas for project-related construction material and equipment away from streams and wetlands and in areas that are not environmentally sensitive. Avoid clearing vegetation between the staging area and the waterway or wetlands. When project-related construction activities, such as ***culvert*** and bridge work, require work in streambeds, conduct these activities, to the extent practicable, during minimum-flow conditions. Maintain current drainage patterns to the greatest extent practicable. Prohibit project-related construction vehicles from driving in or crossing streams and/or ***washes*** at locations other than established crossing points. Place heavy equipment on mats when working in wetlands or use other methods to minimize soil disturbance in wetlands.	Physical Setting Surface-Water Resources Biological Resources	10 CFR Part 1022 – Compliance with Floodplain/Wetlands Environmental Review Requirements Clean Water Act of 1977 (33 U.S.C. 1251 *et seq.*) NAC 445A – Water Controls Fish and Wildlife Coordination Act	Protect surface-water quality and floodplains. Minimize project-related increases in turbidity and impacts to ***waters of the United States***.
During construction, use temporary barricades, fencing, and/or flagging to demarcate sensitive habitats; contain project-related impacts to the area within the construction right-of-way. When practicable, locate staging areas in previously disturbed sites or in construction right-of-way, and avoid sensitive habitat areas. Fence off areas of habitat for sensitive species or other special resources, such as wetlands, prior to ground-disturbing activities. Inform project workers of all resource protection goals.	Physical Setting Surface-Water Resources Biological Resources	Frequently a Clean Water Act of 1977 (33 U.S.C. 1251 *et seq.*) permit condition or a result of Section 7 consultation under the Endangered Species Act Of 1973, as Amended	Minimize impacts to sensitive habitats and species.
Use a minimum-width rail line footprint when practicable. DOE would limit disturbance within the construction right-of-way in the areas where it could not completely avoid wetlands.	Surface-Water Resources Biological Resources	10 CFR Part 1022 – Compliance with Floodplain/Wetlands Environmental Review Requirements Clean Water Act of 1977 (33 U.S.C. 1251 *et seq.*)	Minimize impacts to wetlands.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 7 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Construction best management practices			
Require periodic inspections of equipment for any fuel, lube oil, hydraulic, or antifreeze leaks. If leaks are found, repair the leak or replace the equipment.	Hazardous Materials and Waste Occupational and Public Health and Safety Surface-Water Resources Groundwater Resources Biological Resources	Pollution Prevention Act of 1990 (42 U.S.C. 133)	Avoid accidental discharge of pollutants.
Use storage tanks, ponds (temporary holding reservoirs), or inflatable bladders along the rail alignment to help manage water ***demand***, such as to control ***groundwater*** withdrawal rates and pumping timetables.	Surface-Water Resources Groundwater Resources	NRS 533.324 through 533.435 – Water Appropriation Permit	Maximize water-use efficiency during construction activities.
Use treated wastewater effluent (***gray water***) produced at the camps for dust suppression and soil compaction to reduce the demands placed on groundwater wells.	Groundwater Resources	NAC 534 – Underground Water and Wells NRS 533.324 through 533.435 – Water Appropriation Permit	Reduce ***aquifer*** drawdown.
If determined through impacts analysis to be possibly or likely required to preclude impacts on an existing well or spring, limit pumping rates or eliminate pumping at a proposed new groundwater withdrawal well, obtain (purchase) additional water from existing water-rights holder(s), relocate a proposed new well to an alternative location, or implement one or more other best management practices as necessary. Alternatively, DOE would negotiate with the existing water-rights holder or domestic water-well owner to access and monitor water levels in the existing well or monitor discharge rates to the spring, where appropriate, to verify the effects, if any, of the proposed groundwater withdrawal on those wells or springs.	Groundwater Resources	NAC 534 – Underground Water and Wells NRS 533.324 through 533.435 – Water Appropriation Permit	To preclude a reduction in flow rate to an existing well or a reduction in discharge rate to a spring.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 8 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Construction best management practices			
Provide alternate sources of water or relocate wells if DOE action prevents access to groundwater. Any action to change the location of an existing water diversion would require the approval of the well owner and/or the holder of the water rights associated with that diversion point and would require a permit from the State of Nevada under Nevada Revised Statutes (NRS) 533.325.	Groundwater Resources	NRS 533.325 – Application to State Engineer for Permit	To ensure continued access to wells and groundwater.
Keep disturbance around known areas of underground utilities to a minimum. Ensure that work crossing any buried utility line would not be started until all material and equipment was available for immediate use. Complete work as quickly as possible; keep exposure of existing utilities to a minimum. Install underground utility crossings within protective casings buried in trenches beneath the rail and surround the utility line with appropriate backfill material.	Utilities, Energy, and Materials Occupational and Public Health and Safety Land Use and Ownership	NAC 455 – Excavations and Demolitions NAC 704A – Facilities Placed Underground	Prevent inadvertent disruption to utilities, destruction of property, and injury to DOE contractors. Ensure future functionality and safety of underground utilities.
Implement ***fugitive dust*** suppression per applicable permits, such as spraying water, the use of crusting agents, or other approved measures to minimize fugitive dust emissions created during project-related construction activities, including activities on haul roads and at quarries.	Aesthetic Resources Air Quality Occupational and Public Health and Safety	40 CFR Part 50 – National Primary and Secondary ***Ambient Air Quality Standards*** 29 CFR 1910-1000 – Occupational Health and Safety Standards	Meet ***ambient air*** quality standards during construction.
Maintain construction equipment to ensure that exhaust and muffler systems and other required pollution-control and noise-control devices are in good working condition. Administer a continuing, effective hearing conservation program in accordance with the Occupational Safety and Health Administration standards.	Air Quality Noise and Vibration Occupational and Public Health and Safety	40 CFR Parts 61 and 63 – National Emission Standards for Hazardous Air Pollutants and Noise Control Act of 1972 Federal Railroad Administration Regulation 49 CFR 229.121 Mine Safety and Health Administration Regulation 30 CFR 62	Minimize exhaust, emissions, and noise during construction and operations.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 9 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Construction best management practices			
Implement construction activities with the goal of minimizing, to the extent practicable, construction-related noise disturbances near any residential areas; coordinate and communicate these goals to construction contractors.	Noise and Vibration Occupational and Public Health and Safety	Noise Control Act of 1972 49 CFR Part 210, Rail Noise Emission Compliance Regulations	Minimize rail line construction noise.
Conduct routine monitoring for occupational dust exposure during quarry construction and operations and during rail alignment construction activities that would potentially expose workers, such as ***ballast*** placement. Apply engineering controls such as the application of water for dust suppression and washing the ballast before placement. An industrial hygienist would take mineral dust measurements to identify potential exposure. Implement the use of personal protective equipment, such as respirators, and other measures to reduce occupational exposure to silica in the event aforementioned activities are not effective in reducing such exposure.	Occupational and Public Health and Safety	29 CFR 1910 – Occupational Safety and Health Standards	To prevent exposure to crystalline silica, ***erionite***, or cristobalite.
Reduce packaging wastes by purchasing supplies in bulk; purchase recycled or recyclable goods; and reuse waste paper and Styrofoam™ as packaging materials and fillers (DIRS 182385-Burns 2007, all).	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Eliminate excessive resource use and trash generation.
Dispose of drill cuttings through land application.	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Prevent overburdening local landfill facilities with waste.
Promote the use of environmentally preferable products such as recovered materials (recycled-content products) and ***bio-based products*** (energy, industrial, and consumer products made from renewable biological resources such as wood, agricultural residues, and fiber crops). Purchase materials and equipment designated as long life, energy efficient, and sustainable if they are reasonably cost-effective and available (DIRS 182385-Burns 2007, all).	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Eliminate excessive resource use and trash generation.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 11 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Construction best management practices			
Practice preventive maintenance, use recycled oil, and use oil additives that improve engine and oil performance.	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Increase the number of lubricating-oil changes to reduce leaks and drips and poor engine performance.
Where practicable, use biodegradable water-based solvents, substitute nonhazardous surfactants for hazardous surfactants for equipment cleaning, and reuse spent solvents. Paint only when necessary and use less-toxic, less-volatile paints.	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Reduce the production of ***hazardous wastes***.
Inspect and replace worn or damaged components. Use sealed components (DIRS 155558-Hoganson 2001, all).	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Reduce the production of hazardous wastes.
Establish and implement a centralized procurement and distribution program to purchase, track, distribute, and manage hazardous and toxic materials. Implement a Hazardous Material Management Program to review hazardous and toxic material requisitions and purchases; and to recommend feasible nonhazardous, biodegradable, or less-toxic substitutes, such as nonhazardous solvents, paints, and cleaning materials (DIRS 182385-Burns 2007, all).	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Reduce the production of wastes.
Implement an Environmental Management System and a Pollution Prevention/Waste Minimization Program, which would include an evaluation of alternatives to eliminate, reduce, or minimize the amounts of hazardous materials used and hazardous wastes generated. As part of the Environmental Management System, regularly perform Pollution Prevention Opportunity Assessments (DIRS 182385-Burns 2007, all).	Hazardous Materials and Waste	Executive Order 13101 – *Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions*	Reduce the production of wastes.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 12 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Construction best management practices			
Salvage extra materials not used as ballast for the rail alignment and use for other construction activities or for regrading during quarry reclamation activities (DIRS 176172-Nevada Rail Partners 2006, Section 3.1).	Hazardous Materials and Waste	Executive Order 13101 – Greening the Government through Waste Prevention, Recycling, and Federal Acquisitions	Reduce the generation of wastes and ***contamination*** of environmental media.
Store and dispose of biosolids (sludge), allowing them to dry according to applicable requirements. DOE would dispose of biosolids at a licensed facility in accordance with all applicable requirements (DIRS 176172-Nevada Rail Partners 2006, p. 4-6).	Hazardous Materials and Waste	40 CFR Part 503 – Standard for the Use or Disposal of Sewage Sludge	Ensure proper treatment and disposal of wastes.
Post-construction, operations, and maintenance best management practices			
Control ***noxious weeds***/***invasive species*** using approved herbicides and other pest-management techniques. Select herbicide products that would minimize impacts to water; apply the smallest effective amount of herbicide to reduce the risk of contamination from runoff and leaching. Adhere to herbicide labeling requirements. Plan to treat between weather fronts (calms) and at the appropriate time of day to avoid high winds and to avoid potential stormwater runoff. Establish buffer widths based on herbicide- and site-specific criteria to minimize impacts to water bodies.	Surface-Water Resources Groundwater Resources Biological Resources Occupational and Public Health and Safety	NAC 555 – Control of Insects, Pests, and Noxious Weeds Executive Order 13112, Invasive Species Federal Insecticide, Fungicide, and Rodenticide Act of 1948 (40 CFR Parts 152 through 186)	Prevent introduction of, or minimize impacts from, insects, pests, and noxious weeds. Minimize the risk of adverse effects to non-target species. Minimize the potential for adverse effects on water quality. Protect occupational and public health and safety.
Once construction is complete, revegetate disturbed areas within the right-of-way not required for operation of the rail line with native species or cover with angular rock fragments to prevent erosion. Use weed-free straw and mulch for revegetation and restoration activities. To the extent practicable, return all stream/wash crossing points to their preconstruction contours and reseed or replant the crossing banks with native species immediately following project-related construction. If weather or season precludes the prompt reestablishment of vegetation, employ measures such as mulching or erosion control blankets to prevent erosion until reseeding can be completed.	Physical Setting Aesthetic Resources Biological Resources Surface-Water Resources	43 CFR Part 2800 – Rights-of-Way, Principles and Procedures; Rights-of-Way Under the Federal Land Policy and Management Act and the Mineral Leasing Act The Fish and Wildlife Coordination Act of 1934 (16 U.S.C. 661 *et seq.*) NAC 555 – Control of Insects, Pests, and Noxious Weeds Executive Order 13112, *Invasive Species*	Reduce the visual scope of disturbed areas. Prevent loss of and damage to wildlife resources. Prevent introduction of invasive or exotic species.

Table 7-1. Representative best management practices and their relationships to applicable requirements[a,b] (page 13 of 13).

Best management practice	Related environmental resource area(s)	Associated requirement(s)[c]	Purpose
Post-construction, operations, and maintenance best management practices			
Once construction is complete, eliminate new quarry access roads by removing pavement and regrading road to original contours. Restore quarry walls to a 3-to-1 grade for public safety. Revegetate around quarry.	Physical Setting Biological Resources Surface-Water Resources	NAC 445 – Water Controls NAC 519A – Reclamation of Land Subject to Mining	Restoration of quarry sites. Minimize erosion. Protect public health.
Monitor reclaimed sites to determine whether reclamation success standards are being met.	Physical Setting Biological Resources	43 CFR Part 2800 – Rights-of-Way, Principles and Procedures; Rights-of-Way Under the Federal Land Policy and Management Act and the Mineral Leasing Act	Ensure success of site restoration.
When practical, use proven technologies to reduce idling time of trains.	Air Quality Utilities, Energy, and Materials	40 CFR Parts 61 and 63 – National Emission Standards for Hazardous Air Pollutants	Minimize exhaust emissions during construction and operations and minimize energy required for operations.
Provide training to emergency response units in the vicinity of the proposed rail line on how to respond to incidents potentially involving ***radioactive*** materials.	Hazardous Materials and Waste Occupational and Public Health and Safety	The Nuclear Waste Policy Act Of 1982	Facilitate emergency response planning and enhance emergency response capabilities.

a. Best management practices are the practices, techniques, methods, processes, and activities commonly accepted and used throughout the construction and railroad industries that DOE would implement as part of the Proposed Action to facilitate compliance with applicable requirements and that provide an effective and practicable means of preventing or minimizing the adverse impacts of an action on human health and the environment.

b. Requirements include laws, statutes, codes, regulations, and orders. DOE commits to appropriate best management practices that support implementation of such requirements and specific compliance requirements in project-related activities and approvals.

c. CFR = Code of Federal Regulations; DoD = U.S. Department of Defense; EPA = U.S. Environmental Protection Agency; NAC = Nevada Administrative Code; NRS = Nevada Revised Statutes; U.S.C. = United States Code.

Table 7-2. Potential measures to mitigate potential environmental impacts of constructing and operating the proposed railroad (page 1 of 3).

Environmental resource/project phase	Nature of potential impact	Mitigation measure	Agency jurisdiction	Location
Physical Setting (see Sections 4.2.1 and 4.3.1)				
Construction and operations	Human health risks attributed to ***seismic*** activities	During the construction and operations phases, adopt Railway Engineering and Maintenance-of-Way Association guidelines and implement monitoring procedures to reduce the potential for structural damage and human exposure to seismic hazards. DOE would make use of seismic monitoring with regional networks; early warning systems to identify track disruption; and track inspections immediately before transit of the trains.	DOE[a]	Site-specific as determined through seismic and geotechnical investigations.
Land Use and Ownership (see Sections 4.2.2 and 4.3.2)				
Construction	Land-use conflict	Notify nearby mining lessees/claimants and consult with owners of active local mines and ***mining claims*** to ensure that impacts to mine-related operations are minimized during construction activities.	DOE and BLM[a]	Site-specific dependent upon the locations of mining claims and active mines.
Construction and operations	Segmenting wildlife habitat	Limit fencing on public lands to those areas where safety is a concern, or where it is required for the safety of livestock.	DOE and BLM	Site-specific as determined through coordination with permittees and the BLM.
Construction	Construction schedule	To the extent practicable, minimize the number of road closures due to construction, and limit detours to one mile or less. DOE would inform the public of road closures through various media outlets.	DOE and BLM	Site-specific dependent upon the locations of road closures.
Air Quality and Climate (see Sections 4.2.4 and 4.3.4)				
Operations	Air quality impacts associated with quarries	Acquire additional land and move the public access (fence line) farther away from the quarries.	DOE	Site-specific quarry locations.

Table 7-2. Potential measures to mitigate potential environmental impacts of constructing and operating the proposed railroad (page 2 of 3).

Environmental resource/project phase	Nature of potential impact	Mitigation measure	Agency jurisdiction	Location
Biological Resources (see Sections 4.2.7 and 4.3.7)				
	Growth and/or spreading of noxious weeds and invasive species	Minimize watering of land surfaces for soil stabilization, ballast cleaning, vehicle washing, and dust suppression to the extent possible.	DOE	Various locations as warranted.
	Conifer mortality	Salvage and restore damaged conifers.	DOE	Specific locations as warranted.
	Attract wildlife to areas of active construction	Install a fence around any storage reservoirs. Install removable covers over storage reservoirs or basins as needed.	DOE	Applies to overall project.
Noise and Vibration (see Sections 4.2.8 and 4.3.8)				
	Elevated noise levels resulting from construction activities	Limit major noise producing activities, such as blasting and pile driving, near ***sensitive receptors***.	DOE	Specific locations as warranted.
	Elevated noise levels from operations such as locomotive warning horns	Apply for a Quiet Zone. Install quad gates, or other supplementary safety measures, to provide the level of warning necessary to allow the communities to request a waiver from the Federal Railroad Administration of the requirement to sound the horn at ***at-grade crossings***.	FRA[a]	Specific locations as warranted.
Socioeconomics (see Sections 4.2.9 and 4.3.9)				
	Overextend local law enforcement capacity	Staff ***construction camps*** with security personnel.	DOE	Construction camp sites.
Occupational and Public Health and Safety (see Sections 4.2.10 and 4.3.10)				
	Hantavirus infection of workers	Implement procedures for decontamination of any rodent excreta encountered by construction workers during construction activities.	DOE	Applies to overall project.
	Equipment and property damage and injury	Assign people, a source of water, and a water-tank trailer that would be used to respond to fire emergencies at the camps and construction areas.	DOE	Construction camp sites.

Table 7-2. Potential measures to mitigate potential environmental impacts of constructing and operating the proposed railroad (page 3 of 3).

Environmental resource/project phase	Nature of potential impact	Mitigation measure	Agency jurisdiction	Location
Hazardous Materials and Waste (see Sections 4.2.12 and 4.3.12)				
	Overburdening local landfill facilities with waste	Determine which landfills solid and ***industrial and special wastes*** would be sent to during the construction phase and balance the distribution. Send manageable quantities of ***solid waste*** to local landfills or send the waste to the larger Apex Landfill.	DOE	Applies to construction.
Cultural Resources (see Sections 4.2.13 and 4.3.13)				
	Adverse impacts or disturbances to cultural resources sites	Provide cultural resources training to workers.	DOE and SHPO[a]	Applies to construction and various locations along the rail alignments.
Paleontological Resources (see Sections 4.2.14 and 4.3.14)				
	Disturbance and/or destruction of paleontological resources	Perform pre-disturbance testing of physical resources within the rail line construction right-of-way where there could be a potential for important paleontological resources. Consult with the BLM to develop appropriate measures to minimize damage to paleontological resources during the construction phase if fossils were found.	DOE and BLM	Specific locations along the rail alignments.

a. BLM = Bureau of Land Management; DOE = Department of Energy; FRA = Federal Railroad Administration; SHPO = State Historic Preservation Office.

8. UNAVOIDABLE ADVERSE IMPACTS; SHORT-TERM USES AND LONG-TERM PRODUCTIVITY; IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

In accordance with the National Environmental Policy Act (NEPA), Section 102 (42 U.S.C. 4332), and the Council on Environmental Quality (CEQ) NEPA implementing regulations (40 CFR 1502.16), this chapter addresses:

- Any adverse environmental impacts DOE would not be able to avoid if the Department implemented the Proposed Action along the Caliente rail alignment or the Mina rail alignment.
- The relationship between local short-term uses of the environment within the Caliente rail alignment or Mina rail alignment region of influence and the maintenance and enhancement of long-term productivity.
- Any irreversible and irretrievable commitments of resources if DOE implemented the Proposed Action along the Caliente rail alignment or the Mina rail alignment.

Glossary terms are shown in ***bold italics***.

8.1 Caliente Rail Alignment

During the engineering and site evaluation and planning phase for the proposed ***railroad***, DOE considered many factors to avoid or minimize potential environmental ***impacts*** (see Chapter 2), and would continue to consider these factors during the final design phase. DOE would meet all applicable regulatory requirements during proposed railroad construction and operations along the Caliente ***rail alignment***, and would implement an array of best management practices to ensure compliance with requirements (see Chapter 7, Best Management Practices and Mitigation). Also as described in Chapter 7, DOE could implement measures to mitigate any impacts remaining after final design and compliance with regulatory requirements and implementation of best management practices.

However, there could be unavoidable adverse impacts (adverse impacts are impacts that could be viewed as having disproportionately negative effects); impacts to short-term uses and long-term productivity resources; and/or irreversible and irretrievable commitment of resources, for example:

- DOE could mitigate most potential impacts described in Chapter 4, but there would be some unavoidable impacts, for example, on the use of grazing land.
- Railroad construction would involve ground-disturbing activities that would result in localized ***short-term impacts***

An **irreversible commitment** of resources represents a loss of future options. It applies primarily to nonrenewable resources, such as minerals or cultural resources, and to those factors that are renewable only over long time spans, such as soil productivity.

An **irretrievable commitment** of resources represents opportunities that are foregone for the period of the proposed action. Examples include the loss of production, harvest, or use of renewable resources. The decision to commit the resources is reversible, but the utilization opportunities foregone are irretrievable.

to soil, water use, and ***habitat***. These resources would recover over time, and long-term productivity would not be affected.

- An irreversible commitment of resources such as consumption of fossil fuel, and an irretrievable commitment such as a loss of habitat.

This chapter summarizes and consolidates information from Chapter 4, Environmental Impacts, and Chapter 7, Best Management Practices and Mitigation.

8.1.1 UNAVOIDABLE ADVERSE IMPACTS

Engineering and site evaluation and planning are the first steps in undertaking a ***proposed action***. Next follows compliance with all laws, regulatory requirements, and stipulations and conditions of associated permits to minimize environmental and health-related impacts. Best management practices are implemented to maintain compliance with these requirements. Where analyses identify potential environmental impacts, ***mitigation*** measures are implemented to avoid, minimize, rectify, reduce, or compensate for those impacts. Finally, unavoidable adverse impacts may arise where there are no reasonably practicable mitigation measures to entirely eliminate impacts, and there are no reasonably practicable ***alternatives*** to the proposed project that would meet the purpose and need of the action, eliminate the impact, and not cause other or similar significant adverse impacts. Figure 8-1 illustrates how unavoidable adverse impacts may arise and identifies the chapters of this Rail Alignment ***Environmental Impact Statement*** (EIS) where the topic areas shown are discussed.

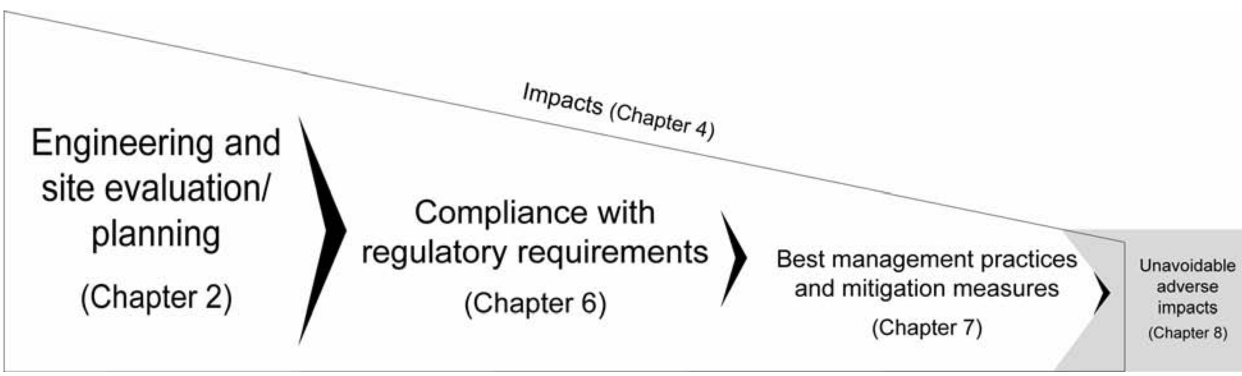

Figure 8-1. How unavoidable adverse impacts might arise.

Unavoidable adverse impacts would not vary substantially among alternative segments along the Caliente rail alignment, or by implementation of the ***Shared-Use Option***. Sections 8.1.1.1 to 8.1.1.15 describe unavoidable adverse impacts, if any, for each environmental resource area evaluated in this Rail Alignment EIS.

8.1.1.1 Physical Setting

Construction of the proposed railroad along the Caliente rail alignment would lead to permanent alterations in topography in the ***rail line construction right-of-way*** as a result of ***cuts*** and ***fills***, and in the locations of potential quarry sites. Cuts and fills would also alter local drainage patterns, and would remain after a possible future abandonment of the railroad. Cuts and fills associated with construction of any of the ***alternative segments*** could result in the loss of topsoil, and an increased potential for erosion. No mineral deposits would be removed; nevertheless, a rail line could unavoidably restrict access to such deposits. The Goldfield alternative segments would cross ***mining areas*** and could displace minerals or limit the boundaries for mining if mineral resources extended under the rail alignment. There would be potential impacts to isolated pockets of unused land classified as ***prime farmland*** along the Caliente or

Eccles alternative segment and Caliente ***common segment*** 1. As required under the Farmland Protection Policy Act (7 United States Code [U.S.C.] 4201 *et seq.*), which directs federal agencies to identify and quantify adverse impacts of federal programs on farmlands, DOE has coordinated with the Natural Resources Conservation Service to minimize any potential conversion of land classified as prime farmland to nonagricultural uses. The 0.22 square kilometer (54 acres) of prime farmland soils along Caliente common segment 1 is in a relatively isolated area in Nye County (see DIRS 182843-Coogan and Bethoney 2007, Part A, plates 107 to 109), and at present is not being farmed. Construction of the proposed railroad along the Caliente rail alignment would result in the loss of a total of 0.43 square kilometer (110 acres) of prime farmland soils. Lincoln and Nye Counties contain approximately 1,500 square kilometers (370,000 acres) of prime farmland soils; thus, the proposed railroad would remove less than 0.1 percent of the prime farmland soils from productive use. Construction activities within the construction right-of-way would result in local soil compaction, which could impact the natural revegetation rate and vegetation types over time.

Any permanent alterations in topography that could not be mitigated could be viewed as unavoidable adverse impacts. As described in Section 4.2.1.2.1, topographic impacts due to major cut and fill and other earthwork processes would primarily occur along the Goldfield alternative segments and common segment 6, and around Bennett Pass, Goldfield Hills, Beatty, and Yucca Mountain. Tables 4-2 to 4-9 in Section 4.2.1 list specific amounts of disturbed surface areas for the Caliente rail alignment alternative segments, common segments, and ***construction and operations support facilities***. Any impacts to physical setting, although unavoidable, would be small.

8.1.1.2 Land Use and Ownership

Use of land along the Caliente rail alignment for construction and operation of the proposed railroad and railroad construction and operations support facilities would involve some long-term changes in land use. The land DOE would use for this project would be managed as a ***right-of-way grant*** obtained from the U.S. Department of the Interior, Bureau of Land Management (BLM). This would not pose a land-use conflict because the rights-of-way would not be in right-of-way avoidance areas. The BLM could establish land management requirements that provide for multiple use, but land used for the proposed railroad and railroad construction and operations support facilities could limit certain other land uses. The multiple-use mandate set forth in the Federal Land Policy and Management Act would continue to apply to the ***public lands*** within the right-of-way, but railroad construction and operations could limit certain future land uses that pose a conflict.

DOE would need to gain access to some private lands. Assuming a ***nominal*** 61-meter (200-foot) right-of-way on either side of the centerline of the rail line, this could result in a loss of about 1 percent of private land compared to the total amount of land that would be required for the project. The parking lot and access road to the Hot Springs Hotel would lie within the Caliente alternative segment construction right-of-way, and the loss of some parking area and the impact of noise during construction and operation of the rail line may cause the hotel to no longer remain viable. If the Caliente alternative segment is selected, DOE would negotiate with the hotel owner to gain access to the land. The Staging Yard at either of the Caliente options (Upland or Indian Cove) would be on private land.

Construction and operation of the proposed railroad along the Caliente rail alignment would directly impact ***grazing allotments*** by transecting parcels and potentially hindering access to forage and water resources. Other potential impacts include allotments being reduced in size and a reduced ability of livestock, wild horses, and burros to range freely across grazing areas. The Eccles-North Staging Yard would be on public land within an active grazing allotment. Even with mitigation, some adverse impacts to the use of grazing land would be unavoidable. Tables 4-23 to 4-30 in Section 4.2.2 summarize potential impacts to land use and ownership for each alternative segment, common segment, and railroad construction and operations support facility.

Construction and operation of the proposed railroad along the Caliente rail alignment would not displace existing or planned land uses over a large area or conflict with land-use plans or goals. Therefore, any impacts to land use and ownership, although unavoidable, would be small.

8.1.1.3 Aesthetic Resources

The ***region of influence*** for aesthetic resources is the ***viewshed*** around all Caliente rail alignment alternative segments, common segments, and railroad construction and operations support facilities, and any additional ***sidings*** that would be added under the Shared-Use Option. Operation of the proposed railroad along the Caliente rail alignment would remain consistent with BLM visual resource management objectives, under which areas of high visual value (Classes I and II) are managed to minimize contrast levels, and areas of lower visual value (Classes III and IV) are allowed higher contrast levels. There would be unavoidable visual changes associated with the proposed rail alignment. Contrast levels that were rated by DOE as none, weak, or moderate would be such that BLM visual resource management objectives would be met. In specific locations such as Garden Valley, which is classified as a more visually sensitive Class II area in the *Draft Ely Resource Management Plan* (DIRS 174518-BLM 2005), BLM visual resource management objectives also would be met.

8.1.1.4 Air Quality

Construction and operation of the proposed railroad along the Caliente rail alignment would cause unavoidable emissions of some ***criteria air pollutants***. Air pollutant concentrations would not exceed the National ***Ambient Air Quality Standards*** during construction and operation of the proposed railroad, with the possible exception of the 24-hour standard for ***particulate matter*** with an aerodynamic diameter less than or equal to 10 micrometers (***PM_{10}***) that DOE modeled as exceeded during quarry operations in South Reveille Valley during rail line construction. However, DOE will be required to obtain a Surface Area Disturbance Permit Dust Control Plan, issued by the State of Nevada, Department of Environmental Protection, prior to quarry development. DOE anticipates that compliance with the requirements of this plan to reduce ***fugitive dust*** emissions would decrease the possibility of exceedance of the ***air quality*** standard—for example, the requirement for cessation of all operations when winds make control of fugitive dust difficult (this was a mitigating attribute not accounted for in the modeling that DOE undertook). DOE could further reduce the possibility of exceeding the 24-hour standards for PM_{10} at a public boundary during quarry operations by acquiring additional land and moving public access farther away.

The highest increase in air pollutant emissions would occur during the construction phase. During the operations phase, the highest increase would occur in the vicinity of the railroad operations support facilities. Fugitive dust emissions from construction-vehicle traffic on unpaved roads, surface disturbance (such as grading, scraping, bulldozing, wind erosion, and quarry excavation activities), and operation of concrete batch plants could cause unavoidable temporary impacts to air quality that, although within permissible limits, could not be completely mitigated. Table 4-53 in Section 4.2.4 summarizes impacts to air quality, which are projected to be small during both construction and operation, with the possible exception in the vicinity of the South Reveille Valley quarry.

Therefore, any impacts to air quality, although unavoidable, would be small.

8.1.1.5 Surface-Water Resources

Regrading, cut and fill activities, and structures such as box ***culverts*** would cause localized changes in drainage patterns throughout the rail line construction right-of-way. Construction of the proposed ***Staging Yard*** and ***Interchange Yard***, whether along the Caliente or Eccles alternative segment, would require channelization of natural drainage surface waters to keep water out of railroad operations support facility sites. Changes in drainage patterns could result in changes in erosion and sedimentation rates or locations. Construction in ***washes*** or other flood-prone areas could reduce the area through which floodwaters naturally flow, resulting in water buildup or ponding on the upstream side of crossings during floods that would slowly drain through the culverts or bridges.

DOE evaluated potential impacts to surface waters by identifying areas where there are drainage channels or water resources. While some changes would be unavoidable, DOE would take steps to ensure the alterations to natural drainage, sedimentation, and erosion would not increase future flood damage, increase the impact of floods on human health and safety, or cause identifiable harm to the functions and values of ***floodplains***. Because hydraulic structures and conveyance systems would be designed to safely convey 50-year or 100-year design storms and minimize concentration of flow, impacts associated with drainage conveyance would be small. The Department would minimize impacts to surface-water resources through the implementation of engineering design standards and best management practices that include erosion control measures. The Caliente alternative segment is adjacent to ***wetlands*** and some wetland fill would be unavoidable. Approximately 0.09 square kilometer (22 acres) of wetlands would be filled to construct the potential quarry siding. Construction of the Staging Yard in Indian Cove would require filling an area of wetlands and in the loss of approximately 0.19 square kilometer (47 acres) of wetland habitat. The Eccles alternative segment Interchange Yard would require portions of Clover Creek to be filled to elevate the site out of the floodplain. The total area to be filled within the confines of Clover Creek would be approximately 0.033 square kilometer (8.2 acres). DOE would minimize adverse impacts to wetlands (and the functions served by wetlands) and other surface-water resources.

8.1.1.6 Groundwater Resources

Withdrawal of ***groundwater*** from multiple wells for construction of the proposed railroad could cause a short-term decrease in groundwater resources resulting from increased ***demand*** on the host ***aquifer*** at each new well location. Groundwater withdrawal could decrease the amount of water available to a nearby existing well or spring discharge, and/or, in theory, decrease the amount of water available for underflow to a downgradient basin. The impacts of groundwater withdrawals from the proposed water-supply wells at the range of production rates that would be required for the railroad would be localized in nature, small in magnitude compared to existing groundwater inventories, and primarily temporary. Impacts analysis results indicate that short-term withdrawal of water from new water wells at the proposed withdrawal rates could, in some instances, if unmitigated, have some unavoidable impact on existing wells or springs. In those instances, mitigation measures are proposed, such as use of a staggered pumping schedule for the new well, or pumping the new well at a reduced rate over a longer time period, in order to minimize or prevent such impacts on existing groundwater users and uses. Over time, because the amount of groundwater withdrawn represents a fractionally small percentage of the available groundwater in storage, and the withdrawals would be limited primarily to the construction phase, DOE anticipated that this water would be replenished through the natural water cycle following the construction phase. Some of the water used for compaction would return to groundwater aquifers. For these reasons, DOE expects that there would be no adverse ***long-term impacts*** to existing groundwater resources.

8.1.1.7 Biological Resources

There could be unavoidable, short-term, adverse impacts to wildlife, special status species, protected game species, and wild horses and burros. There would be the potential for unavoidable impacts to ***threatened or endangered species*** during rail line construction. Potential impacts to desert tortoise would be moderate because of fragmentation of habitat. There could be localized and minor loss of roosting and foraging habitat for the southwestern willow flycatcher and western yellow-billed cuckoo.

DOE determined that there would be unavoidable impacts to wetlands and ***riparian*** habitats from construction of the Caliente alternative segment and either of the potential Staging Yard locations (Indian Cove and Upland), and the Eccles alternative segment. Unavoidable impacts to wildlife and wild horses and burros from the operation of the rail line could result from collisions of wildlife with trains and short-term disruption of activities (such as foraging, nesting, and resting). Although such impacts would be unavoidable, long-term impacts would be small. Other unavoidable impacts could include possible changes to predator/prey interactions due to the construction of towers and other structures that would provide new perch habitat for raptors and other predatory birds.

There could be some unavoidable impacts to special status wildlife or plant species. For example, project activities could result in small but unavoidable adverse impacts to:

- Non-critical habitat for the federally threatened Mojave population of the desert tortoise (*Gopherus agassizii*)
- Habitat for the BLM-designated sensitive southwestern toad (*Bufo microscaphus*) near Caliente and Meadow Valley Wash
- Individual BLM-designated sensitive plants and their habitats, including the Schlesser pincushion (*Sclerocactus schlesseri*) and the White River catseye (*Cryptantha welshii*) along Caliente common segment 1; Eastwood milkweed (*Asclepias eastwoodiana*) near Caliente common segment 3; and the Nevada dune beardtongue (*Penstemon arenarius*) along common segment 5
- Habit for the Chuckwalla lizard (*Sauromalus ater*) documented in the southeastern foothills of Yucca Mountain, adjacent to common segment 6

Nevertheless, DOE has concluded that there would be a small loss of habitats, and potential loss of wildlife from trains and construction traffic would be low. Although such impacts would be unavoidable, long-term impacts would be small.

8.1.1.8 Noise and Vibration

Railroad operations along the Caliente rail alignment would lead to an unavoidable increase in ***ambient noise*** from passing trains in areas of Nevada that are mostly uninhabited. Noise from trains might be noticeable as new noise in residential areas near the rail line in Caliente and Goldfield. Because there is already a substantial amount of train activity in Caliente, additional train noise would be less noticeable there than in other areas where there is no train activity and no train noise at present. DOE estimated noise levels during the operations phase at all sensitive receptor locations along the Caliente rail alignment and found they would be below Surface Transportation Board environmental review criteria for noise analysis. Therefore, DOE has determined that no long-term adverse noise impacts would be expected during railroad operations along the Caliente rail alignment. However, during rail line construction, DOE estimated that noise levels at certain receptor locations near the City of Caliente would be higher than Federal Transit Administration construction noise guidelines. This unavoidable impact would be temporary.

8.1.1.9 Socioeconomics

Construction and operation of the proposed railroad along the Caliente rail alignment would unavoidably impact population, housing, employment, and public services in Lincoln, Nye, Esmeralda, and Clark Counties; traffic; and, to a small extent, local current agriculture, ranching, and mining activities.

Socioeconomic changes during the construction phase would include a brief elevation in project-related employment, temporary population increases, and immediate impact on existing levels of public services (health care, transportation, fire protection, and law enforcement) where construction activities were concentrated near communities. DOE determined that the greatest impacts would be economic, and although unavoidable, would be viewed as beneficial and not adverse. As outlined in Section 4.2.9, Socioeconomics, construction-related impacts in Lincoln, Esmeralda, and Nye Counties would result in small increases in peak employment, increases in ***real disposable income***, and increases in ***gross regional product***. The project would generate vehicle trips during facilities construction, both from the movement of materials and from workers traveling to and from the work sites. DOE analyzed highway ***level of service*** by looking at traffic volume in terms of design hour and peak hour flow during a 4- to 10-year construction phase, and determined that there would be some unavoidable impacts from construction of the ***Rail Equipment Maintenance Yard*** at Yucca Mountain to traffic on U.S. Highway 95 near the entrances to the ***Yucca Mountain Site***. This effect would degrade the level of service during peak traffic hours. However, this level would represent high density but stable traffic flow and constitute a small, but unavoidable, impact. This unavoidable impact would be temporary, lasting only as long as the construction phase (4 to 10 years, with the peak period limited to 2 years).

Impacts to traffic during railroad operations would be considerably lower than construction-related impacts. DOE determined that Rail Equipment Maintenance Yard operations would affect traffic on U.S. Highway 95 near the entrances to the Yucca Mountain Site. However, this level would represent high density but stable traffic flow, and constitute a small, but unavoidable, impact. Elsewhere, there would be no impacts or changes to highway levels of service during the railroad operations phase.

Socioeconomic changes during railroad operations would include increases in project-related employment (particularly associated with railroad operations support facilities); slight long-term population increases; moderate pressure on available housing, and fire-protection and health services in southern Nye County; and continued small impacts on mining, ranching, and agriculture. DOE determined that the greatest economic gains would arise in Lincoln County.

8.1.1.10 Occupational and Public Health and Safety

The possibility of nonradiological industrial hazards (such as exposure to physical hazards, chemicals, dust, and pathogens) causing injury or illness to workers during construction and operations would not be completely unavoidable. However, the potential for such impacts would be very small. DOE has estimated that there could be approximately two fatalities associated with all such hazards during construction and 50 years of railroad operations.

There could be radiological impacts to workers and the public from ***incident-free transportation*** and facility operations. While the impact would be very small, radiological impacts would not be completely unavoidable. DOE estimated that approximately 0.34 ***latent cancer fatality*** would result to workers from incident-free transportation and facility operations, and that approximately 1.4×10^{-4} latent ***cancer*** fatality would result to the public from incident-free transportation and facility operations.

There could be radiological impacts from rail ***accidents*** involving casks. Radiological impacts from accidents are estimated to result in less than one latent cancer fatality.

There could be radiological impacts from sabotage events involving casks. If a sabotage event occurred in a suburban area, the collective ***radiation dose*** to the population is estimated to be 1,800 ***person-rem***. The total latent cancer fatalities for people exposed during a sabotage event is estimated to be one.

By their very nature, roadway accidents are considered unavoidable; however, the projected number of roadway accidents that could be attributed to construction and operation of the proposed railroad would be very small. DOE assessed the potential transportation safety impacts of vehicle traffic on roadways associated with constructing and operating the rail line and facilities. DOE determined that there could be up to six fatalities on roadways for the 335 million vehicle-kilometers (200 million vehicle-miles) traveled over the construction phase, and up to eight fatalities on roadways for the 460 million vehicle-kilometers (288 million vehicle-miles) traveled during the 50-year operations phase.

Also by their nature, rail line accidents are considered unavoidable; however, the projected number of rail accidents that could be attributed to construction and operation of the railroad would be very small. DOE determined that there could be approximately one fatality associated with the construction and operations phases. DOE also assessed the potential transportation safety impacts of rail traffic on the rail line and at ***at-grade crossings*** during the construction and operations phases. The Department estimated that over the construction phase and 50-year operations phase, approximately 16 rail-related accidents could be expected to occur for the entire set of estimated train movements.

8.1.1.11 Utilities, Energy, and Materials

Some interfacing with existing utility rights-of-way, in particular electric utility lines, would be unavoidable. Temporary unavoidable impacts to utilities during the construction phase could include possible short-term service interruptions as service was switched from existing electric-power lines, telecommunication lines, and water pipelines to new lines crossing the proposed railroad, or to lines that were relocated to avoid railroad construction activities.

The two principal electric providers in the project region, Nevada Power Company and Sierra Pacific Power Company, can currently meet peak load demands of 5,800 megawatts and 1,900 megawatts, respectively, through generating capacity or power-purchase capabilities. In 2005, their electricity sales were estimated to be 19 million megawatt-hours and 8.8 million megawatts-hours, respectively. In addition, the smaller Valley Electric Association, Inc. and Lincoln County Power District No. 1 are local area power purchasers and resellers. Over the 4- to 10-year construction phase, the electrical power providers in the project region would have adequate generating capacity or power-purchase capabilities (see Section 3.2.11) to supply the project during peak demand without disrupting service to the providers' respective coverage areas. Therefore, although energy use would be unavoidable, anticipated electricity demand to meet construction and operations needs would be modest and would not adversely impact other regional needs for electric power.

As described in Section 4.2.11.2.1.3, DOE estimated that annual consumption of diesel fuel during the railroad construction phase would be 117 million liters (31 million gallons) (DIRS 182825-Nevada Rail Partners 2007, Appendix D, Table D-5b), which would represent 6.5 percent of diesel fuel used annually in Nevada. As described in Section 4.2.11.2.2.2, DOE estimated that over an anticipated 50-year operations lifecycle, 119 million liters (31.5 million gallons) of diesel fuel would be consumed and the annual consumption rate would peak at 4.3 million liters (1.1 million gallons) (DIRS 182825-Nevada Rail Partners 2007, Appendix D, Table D-5a), a rate which is less than 0.25 percent of the current annual vehicular diesel fuel usage in Nevada. Although the use of fuel would be unavoidable, its use during either construction or operations would not adversely affect the capacity of national and regional fuel producers and distributors.

The need for construction materials, primarily steel, concrete, and aggregate, would be unavoidable, but would represent a small fraction of available materials (see Table 4-135). The regional and national impacts of meeting such needs would be small. Materials needed during the operations phase would be much less than during the construction phase, remaining considerably below available capacity.

8.1.1.12 Hazardous Materials and Waste

The generation of some general ***solid wastes***, special wastes (construction debris, used tires, and other materials with specific management requirements), and hazardous materials would be unavoidable, primarily during the construction phase. DOE would handle all wastes in accordance with applicable regulations, and would implement best management practices and pollution prevention/waste minimization programs. As described in Section 4.2.12, DOE estimated that 2,300 metric tons (2,500 tons) per year of nonhazardous solid waste (for example, general household waste) would be generated during the construction phase, for a daily rate of about 6.3 metric tons (6.9 tons). Nonrecyclable wastes would be disposed of, which would raise the total amount disposed of in the four-county area of Lincoln, Nye, Esmeralda, and Clark by up to approximately 0.077 percent. In addition, DOE estimated that construction activities would generate approximately 4,020 metric tons (4,380 tons) of ***industrial and special wastes*** per year, for an approximate daily rate of 11 metric tons (12 tons), which would result in an increase of approximately 0.13 percent in waste receipt at local landfills.

DOE estimated that 190 metric tons (210 tons) per year or 0.51 metric ton (0.56 ton) per day of nonhazardous solid waste would be generated at railroad operations support facilities, which would raise the total amount disposed of in the four-county area by less than 0.01 percent. There would be ample disposal capacities to accept the small amounts of ***low-level radioactive wastes*** generated from the ***Cask Maintenance Facility*** of 3,200 to 7,900 cubic meters (113,000 to 280,000 cubic feet) over the 30- to 50-year lifetime of this project (DIRS 181425-MTS 2007, all).

Although the use of disposal facilities would be unavoidable, existing disposal facilities have ample capacity to handle all additional wastes.

8.1.1.13 Cultural Resources

Because of the length of the Caliente rail alignment and the complexity associated with engineering a feasible alignment, DOE used a phased cultural resource identification and evaluation approach, as described in 36 Code of Federal Regulations (CFR) 800.4(b)2, to identify specific cultural resources as is fully described in Section 4.2.13. DOE has surveyed approximately 20 percent of the area for cultural resources. Based on cultural resources already identified, it is reasonable to conclude that there may be undiscovered cultural resources in the Caliente region of influence. The number and extent of identified cultural resource sites throughout the Caliente rail alignment region of influence will continue to increase as more surveys and inventories of potentially disturbed land are completed.

Nevertheless, railroad construction could cause unavoidable disturbance or destruction of cultural resources. Disturbance or destruction could occur during ground-disturbing activities along the rail alignment, at quarries, along temporary access roads, at ***borrow sites***, at temporary ***construction camps***, and at railroad operations support facilities. During construction, larger numbers of workers in the vicinity of the construction camps could increase the potential for impacts to nearby cultural resources. Excavation and other construction-related ground-disturbing activities could unearth additional cultural materials that were either thought, based on previous archaeological surveys, to occur only at ground surface, or were previously undetected because they were completely underground.

Railroad construction and operation could also lead to unavoidable changes in cultural landscapes, such as changes to ***ethnographic***, rural historic, and historic viewscapes. Cultural landscapes include historic-period Western Shoshone villages and surrounding use areas in the Oasis Valley, the Goldfield area, and Stone Cabin and Reveille Valleys; early ranching operations in the Stone Cabin and Reveille Valleys, and the Mormon settlement of Meadow Wash Valley; and the Goldfield, Clifford, and Reveille Mining Districts.

DOE would further modify the rail alignment, as necessary, to avoid discovered cultural resources. Based on preliminary information and sample surveys, any impacts would likely range from small to moderate because of an extensive effort to avoid or mitigate them.

8.1.1.14 Paleontological Resources

As described in Section 4.2.14, there is a paleontological resource site approximately 4.8 to 8 kilometers (3 to 5 miles) south of where Caliente common segment 1 would cross Bennett Pass, but because of its distance from the rail line, there would be no impacts to the site. There are no other known paleontological resources at or near the remaining portions of the Caliente rail alignment, nor do these areas have a strong potential to contain important paleontological resources. While there could be a potential to uncover previously unknown ***fossils*** during railroad construction, DOE would consult with the BLM to develop appropriate measures to minimize damage to paleontological resources during project-related construction if fossils were found. DOE has not identified any unavoidable adverse impacts.

8.1.1.15 Environmental Justice

DOE determined that constructing and operating the proposed railroad along the Caliente rail alignment would not result in disproportionately high and adverse human health, environmental, ecological, or cultural impacts on ***minority populations***, low-income communities, or American Indian tribes from construction and operation of a railroad along the Caliente rail alignment. DOE has not identified impacts, unavoidable or otherwise, in the context of ***environmental justice***.

8.1.2 RELATIONSHIP BETWEEN SHORT-TERM USES AND LONG-TERM PRODUCTIVITY

Council on Environmental Quality regulations that implement the procedural requirements of the National Environmental Policy Act (NEPA) require consideration of "the relationship between short-term uses of man's ***environment*** and the maintenance and enhancement of long-term productivity" (40 CFR 1502.16). This includes using " … all practicable means and measures, including financial and technical assistance, in a manner calculated to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generation of Americans" (NEPA, Section 101, 42 U.S.C. 4331).

This section discusses the short-term use of the environment and the maintenance of its long-term productivity. Chapter 4 provides more detailed discussions of the impacts and resource utilization associated with the Proposed Action and the Shared-Use Option. Construction and operation of the proposed railroad would require short-term uses of land and other resources. Any long-term loss of productivity in disturbed areas would be small. The land-cover types along the proposed rail alignment are widely distributed throughout the region of influence and any loss of vegetation in the disturbed area along the rail alignment would have little impact on the regional productivity of plants and animals. Future long-term land uses such as grazing or mining would not be precluded by the short-term use of the land for the proposed rail line. The relationships between short-term uses and long-term productivity would not be meaningfully altered if either the Proposed Action or Shared-Use Option were implemented, or by the selection of alternative segments within the Caliente rail alignment ***implementing alternative***.

Wetlands or waters that would be filled would not recover in the short term and long-term productivity would be lost permanently. To the extent practicable, DOE would minimize such fill by optimizing final engineering and design and use a minimum-width construction right-of-way whenever possible. Construction of the Staging Yard in Indian Cove would require filling an area of wetlands and in the resultant loss of approximately 0.19 square kilometer (47 acres) of wetland habitat. There would be a long-term loss of productivity to riparian habitats from construction of the Caliente alternative segment and either of the potential Staging Yard locations (Indian Cove and Upland), and the Eccles alternative segment. The Eccles alternative segment Interchange Yard would require portions of Clover Creek to be filled to elevate the site out of a floodplain. The total area to be filled within the confines of Clover Creek would be approximately 0.033 square kilometer (8.2 acres).

Productivity loss for soils should be limited to the disturbed areas affected by land clearing, grading, and construction. Most disturbed areas not permanently maintained for railroad operations would recover over time, although recovery and a return to natural productivity could be slow for disturbed biological communities in an ***arid*** environment. DOE would revegetate disturbed areas with appropriate native species. Potentially productive soils characterized as prime farmland along Caliente common segment 1 and the Caliente and Eccles alternative segments are found only in isolated pockets and cannot support farming. Therefore, the minimal loss of these soils would not impact long-term productivity.

The areas used for temporary construction camps would likely recover in the short term because they would be unused after construction activities ceased. DOE would implement restoration activities to encourage natural vegetation to grow on these sites. The Department might eventually abandon the proposed railroad and its operations support facilities, although it is unlikely that the rail ***roadbed*** would ever be completely dismantled. The proposed railroad and these facilities could be turned over to commercial carriers, especially if the Shared-Use Option were selected, and could continue to aid economic productivity in the region. Under the Shared-Use Option, the proposed railroad could increase transportation opportunities and lower transportation costs in the region.

The short-term withdrawal of water from the temporary construction wells could have a small impact on groundwater availability. However, DOE has projected that drawdowns would be sufficiently small to preclude impacts on flow rates or discharge rates at existing productive water-supply wells or springs. There would be no long-term impacts to groundwater resource productivity because the construction wells would only be used for a short time.

8.1.3 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

NEPA Section 102 (42 U.S.C. 4332) and Council on Environmental Quality regulations that implement the procedural requirements of NEPA (40 CFR 1502.16) require that environmental analyses include identification of: "… any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented." An irreversible commitment of resources represents a loss of future options. It applies primarily to nonrenewable resources, such as minerals or cultural resources, and to those factors that are renewable only over long time spans, such as soil productivity, whereas an irretrievable commitment of resources represents opportunities that are foregone for the period of the proposed action. Examples include the loss of production, harvest, or use of renewable resources. The decision to commit the resources is reversible, but the utilization opportunities foregone are irretrievable.

This section describes irreversible and irretrievable commitments of resources associated with implementation of the Proposed Action along the Caliente rail alignment. Sections 8.1.3.1 to 8.1.3.15 discuss resource commitments that could be irreversible and irretrievable. Irreversible and irretrievable commitments of resources would not meaningfully vary among alternative segments along the Caliente rail alignment, or by implementation of the Shared-Use Option.

8.1.3.1 Physical Setting

Construction of the rail line and construction and operations support facilities along the Caliente rail alignment could displace mineral deposits. Perlite is a locally important mineral that occurs in the area of the Caliente and Eccles alternative segments. Although no minerals would be removed, placement of the rail line could displace perlite and reduce its availability for mining, if there was perlite within the construction right-of-way. The Goldfield alternative segments would cross mining areas and could displace minerals or limit the boundaries for mining if mineral resources extend under the rail alignment. If these circumstances occurred and options for future use of minerals were limited, there would be an irreversible commitment of resources.

8.1.3.2 Land Use and Ownership

Construction and operation of the proposed railroad would require the commitment of land for placement of the rail line, construction and operations support facilities, and access roads. If at a future date DOE were to abandon the railroad, although much of the construction material might be removed, it is not likely that all of the natural landscape would be restored, and some of the land commitment would remain irreversible. Following abandonment of the rail line, lands along the Caliente rail alignment would be relinquished back to the BLM. If DOE had to acquire private lands for the Staging Yard at either of the Caliente options (Upland or Indian Cove), the Department would dispose of purchased land pursuant to DOE Order O 430.1B, *Real Property Asset Management*, or would return leased land to the lessee.

8.1.3.3 Aesthetic Resources

DOE determined that the visual impacts of operating trains would range from no visual contrast to strong visual contrast, and that the long-term visual impacts of marks on rock, soil, and vegetated landscape from cuts, fills, well pads, and access roads would range from weak to strong (with mitigation in Garden Valley) (see Section 4.2.3). The railroad would remain consistent with BLM visual resource management objectives where areas of high visual value are managed to minimize contrast levels, and areas of lower visual value are allowed higher contrast levels. Where land commitment was irreversible, aesthetic impacts would sometimes remain irreversible.

8.1.3.4 Air Quality

DOE did not identify any associated irreversible and irretrievable commitments of resources along the Caliente rail alignment.

8.1.3.5 Surface-Water Resources

The Caliente alternative segment is adjacent to wetlands and some wetland fill would be unavoidable. This could result in an irretrievable commitment of resources along the Caliente rail alignment. Approximately 0.09 square kilometer (22 acres) of wetlands would be filled to construct the potential quarry siding. Construction of the Staging Yard in Indian Cove would require filling an area of wetlands and in the resultant loss of approximately 0.19 square kilometer (47 acres) of wetland habitat. The Eccles alternative segment Interchange Yard would require portions of Clover Creek to be filled to elevate the site out of the floodplain. The total area to be filled within the confines of Clover Creek would be approximately 0.033 square kilometer (8.2 acres).

8.1.3.6 Groundwater Resources

DOE estimated that a total of 7.52 billion cubic meters (6,100 ***acre-feet***) of water would be required for railroad construction (DIRS 180875-Nevada Rail Partners 2007, Section 4.4.2, pp. 4 to 10), most of which would be obtained through the construction of new water wells. Over time, because the amount of groundwater withdrawn represents a fractionally small percentage of the available groundwater in storage, and the withdrawals would be limited primarily to the railroad construction period, it is anticipated that this water would be replenished through the natural water cycle following the railroad construction phase. The use of groundwater could be considered as an irretrievable commitment of resources during the construction phase.

8.1.3.7 Biological Resources

The areas that would be occupied by the rail line, railroad construction and operations support facilities, and access roads would be irreversibly removed from natural habitat for the life of the proposed railroad. In addition, the disturbances of the desert soil surfaces in areas of temporary construction activity could result in changes that would be irreversible over the long term. The permanent conversion of vegetation resources and wildlife habitat along the rail line and at construction and operations support facilities could represent an irreversible commitment of biological resources for the life of the proposed railroad and beyond if, following abandonment, DOE did not restore these resources, or if former vegetation cover and composition did not recover. Losses of wildlife during railroad construction and operations would represent an irretrievable commitment of biological resources.

Impacts to wetlands and riparian habitats from construction of the Caliente alternative segment and either of the potential Staging Yard locations (Indian Cove and Upland), the Eccles alternative segment, and the Interchange Yard could represent an irreversible rather than irretrievable commitment of resources if, following abandonment, DOE did not restore these resources. However, during rail line final design, DOE would make adjustments to minimize such impacts.

8.1.3.8 Noise and Vibration

DOE did not identify any associated irreversible and irretrievable commitments of resources along the Caliente rail alignment.

8.1.3.9 Socioeconomics

DOE did not identify any associated irreversible and irretrievable commitments of resources along the Caliente rail alignment.

8.1.3.10 Occupational and Public Health and Safety
