ABSTRACT: The Nevada Rail Corridor SEIS (DOE/EIS-0250F-S2D) analyzes the potential impacts of constructing and operating a railroad to connect the Yucca Mountain repository site to an existing rail line near Wabuska, Nevada (in the Mina rail corridor). The Nevada Rail Corridor SEIS analyzes the Mina rail corridor at a level of detail commensurate with that of the rail corridors analyzed in the Final *Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F). The Nevada Rail Corridor SEIS also updates relevant information regarding other rail corridors previously analyzed in the Yucca Mountain FEIS (Carlin, Jean, and Valley Modified) to identify any significant new circumstances or information relevant to environmental concerns.

The Rail Alignment EIS (DOE/EIS-0369D) analyzes the potential impacts of railroad construction and operation along common segments and alternative segments within the Caliente (selected in a previous Record of Decision, 69 *Federal Register* 18557) and Mina rail corridors for the purpose of determining an alignment for the construction and operation of a railroad for shipments of spent nuclear fuel, high-level radioactive waste, and other materials from an existing rail line in Nevada to a geologic repository at Yucca Mountain. The Rail Alignment EIS also analyzes the potential impacts of constructing and operating support facilities.

COOPERATING AGENCIES: The U.S. Bureau of Land Management, the Surface Transportation Board, and the U.S. Air Force are cooperating agencies in the preparation of the Nevada Rail Corridor SEIS and the Rail Alignment EIS.

PUBLIC COMMENTS: A 90-day comment period on this document begins with the publication of the Environmental Protection Agency Notice of Availability in the *Federal Register*. DOE will consider comments received after the 90-day period to the extent practicable. The Department will hold public hearings to receive comments on the document at the times and locations announced in local media and the DOE Notice of Availability. Written comments may also be submitted by U.S. mail to the U.S. Department of Energy at the above address in Las Vegas, via the Internet at *http://www.ymp.gov*, or by facsimile at 1-800-967-0739. This public comment period and the public hearings coincide with those of the *Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F-S1D).

FOREWORD

The U.S. Department of Energy (DOE or Department) has prepared two draft National Environmental Policy Act (NEPA) documents associated with the proposed disposal of spent nuclear fuel and high-level radioactive waste in a geologic repository at the Yucca Mountain Site in Nye County, Nevada:

Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (DOE/EIS-0250F-S1; the Repository SEIS)

Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada – Nevada Rail Transportation Corridor (Part 1) (DOE/EIS-0250F-S2D; the Nevada Rail Corridor SEIS), and *Draft Environmental Impact Statement for a Rail Alignment for the Construction and Operation of a Railroad in Nevada to a Geologic Repository at Yucca Mountain, Nye County, Nevada* (Part 2) (DOE/EIS-0369D; the Rail Alignment EIS).

The Repository SEIS evaluates the potential environmental impacts of constructing and operating the Yucca Mountain repository under the current repository design and operational plans, the purpose of which is to assist the U.S. Nuclear Regulatory Commission (NRC) in adopting, to the extent practicable, any EIS prepared pursuant to Section 114(f)(4) of the Nuclear Waste Policy Act, as amended (NWPA; 42 United States Code 10101 *et seq.*).

The Nevada Rail Corridor SEIS and the Rail Alignment EIS evaluate the potential environmental impacts of constructing and operating a railroad for shipments of spent nuclear fuel and high-level radioactive waste from an existing rail line in Nevada to the repository at Yucca Mountain, the purpose of which is to help the Department decide whether to construct and operate a railroad, and if so, within which corridor and along which alignment.

Background and Context

The NWPA directs the Secretary of Energy, if the Secretary decides to recommend approval of the Yucca Mountain site for development of a repository, to submit a final EIS with any recommendation to the President. To fulfill that requirement, the Department prepared the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F, February 2002) (Yucca Mountain FEIS).

On February 14, 2002, the Secretary transmitted to the President his recommendation (including the Yucca Mountain FEIS) for approval of the Yucca Mountain site for development of a geologic repository. The President considered the site qualified for application to the NRC for construction authorization and recommended the site to the U.S. Congress. Subsequently, Congress passed a joint resolution of the U.S. House of Representatives and the U.S. Senate designating the Yucca Mountain site for development as a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste. On July 23, 2002, the President signed the joint resolution into law (Public Law 107-200). The Department is now in the process of preparing an application for submittal to the NRC seeking authorization to construct the repository, as required by the NWPA (Section 114(b)).

Since completion of the Yucca Mountain FEIS in 2002, DOE has continued to develop the repository design and associated construction and operational plans. As now proposed, the newly designed surface and subsurface facilities would allow DOE to operate the repository following a primarily canistered approach in which most commercial spent nuclear fuel would be packaged at the reactor sites in transport, aging, and disposal (TAD) canisters. Any commercial spent nuclear fuel arriving at the repository in packages other than TAD canisters would be repackaged by DOE at the repository into TAD canisters. DOE would construct the surface and subsurface facilities over a period of several years (referred to as phased construction) to accommodate an increase in spent nuclear fuel and high-level radioactive waste receipt rates as repository operational capability reaches its design capacity. To address the current repository design and operational plans, the Department announced its intent to prepare a Supplement to the Yucca Mountain FEIS (DOE/EIS-0250F-S1), consistent with NEPA and the NWPA. (*Supplement to the Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV*; 71 *Federal Register* [*FR*] 60490, October 13, 2006). The Repository SEIS supplements the Yucca Mountain FEIS by considering the potential environmental impacts of the construction, operation and closure of the repository under the current repository design and operational plans, and by updating the analysis and potential environmental impacts of transporting spent nuclear fuel and high-level radioactive waste to the repository, consistent with transportation-related decisions the Department made following completion of the Yucca Mountain FEIS.

On April 8, 2004, the Department issued a Record of Decision announcing its selection, both nationally and in the State of Nevada, of the mostly rail scenario analyzed in the Yucca Mountain FEIS as the primary means of transporting spent nuclear fuel and high-level radioactive waste to the repository (*Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV*; 69 *FR* 18557, April 8, 2004). Implementation of the mostly rail scenario ultimately would require the construction of a rail line to connect the repository site at Yucca Mountain to an existing rail line in the State of Nevada. To that end, in the same Record of Decision, the Department also selected the Caliente rail corridor from several corridors considered in the Yucca Mountain FEIS as the corridor in which to study possible alignments for a rail line. On the same day DOE selected the Caliente corridor, it issued a Notice of Intent to prepare an EIS under NEPA to study alternative alignments within the Caliente corridor (the Rail Alignment EIS; DOE/EIS-0369) (*Notice of Intent to Prepare an Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV*; 69 *FR* 18565, April 8, 2004).

During the subsequent public scoping process, DOE received comments suggesting that other rail corridors be considered, in particular, the Mina route. In the Yucca Mountain FEIS, DOE had considered but eliminated the Mina route from detailed study because a rail line within the Mina route could only connect to an existing rail line in Nevada by crossing the Walker River Paiute Reservation, and the Tribe had informed DOE that it would not allow nuclear waste to be transported across the Reservation.

Following review of the scoping comments, DOE held discussions with the Walker River Paiute Tribe and, in May 2006, the Tribal Council informed DOE that it would allow the Department to consider the potential impacts of constructing and operating a railroad to transport spent nuclear fuel and high-level radioactive waste across its reservation. On October 13, 2006, after a preliminary evaluation of the feasibility of the Mina rail corridor, DOE announced its intent to expand the scope of the Rail Alignment EIS to include the Mina corridor (*Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV*; 71 *FR* 60484). Although the expanded NEPA analysis, referred to as the Nevada Rail Corridor SEIS and the Rail Alignment EIS, evaluate the potential environmental impacts associated with the Mina rail corridor, DOE has identified the Mina alternative as nonpreferred because the Tribe has withdrawn its support for the EIS process.

Relationships Among the EISs

The Yucca Mountain FEIS, the Repository SEIS, and the Nevada Rail Corridor SEIS and the Rail Alignment EIS are related in several respects. The Nevada Rail Corridor SEIS supplements the rail corridor analysis of the Yucca Mountain FEIS by analyzing the potential environmental impacts associated with constructing and operating a railroad within the Mina corridor. The Nevada Rail Corridor SEIS analyzes the Mina corridor at a level of detail commensurate with that of the rail corridor analysis in the Yucca Mountain FEIS, and concludes that the Mina corridor warrants further study in the Rail Alignment EIS to identify an alignment for the construction and operation of a railroad.

The Nevada Rail Corridor SEIS also updates relevant information regarding three other rail corridors previously analyzed in the Yucca Mountain FEIS (Carlin, Jean, and Valley Modified). The update demonstrates that there are no significant new circumstances or information relevant to environmental concerns associated with these three rail corridors, and that they do not warrant further consideration in the Rail Alignment EIS. The Caliente-Chalk Mountain rail corridor, which also was included in the Yucca Mountain FEIS, would intersect the Nevada Test and Training Range, and was eliminated from further consideration because of U.S. Air Force concerns that a rail line within the Caliente-Chalk Mountain corridor would interfere with military readiness testing and training activities.

The Rail Alignment EIS tiers from the broader corridor analysis in both the Yucca Mountain FEIS and the Nevada Rail Corridor SEIS, consistent with the Council on Environmental Quality regulations (see 40 Code of Federal Regulations 1508.28). Under the Proposed Action considered in the Rail Alignment EIS, DOE analyzes specific potential impacts of constructing and operating a railroad along common segments and alternative segments within the Caliente and Mina corridors for the purpose of determining an alignment in which to construct and operate a railroad for shipments of spent nuclear fuel and high-level radioactive waste from an existing rail line in Nevada to a geologic repository at Yucca Mountain.

The Repository SEIS includes the potential environmental impacts of national transportation, and the potential impacts from the construction and operation of a rail line along specific alignments in either the Caliente or the Mina corridor, as described in the Rail Alignment EIS, to ensure that the Repository SEIS considers the full scope of potential environmental impacts associated with the proposed construction and operation of the repository. Conversely, the Rail Alignment EIS includes the potential impacts of constructing and operating the repository as a reasonably foreseeable future action in its cumulative impacts analysis. To ensure consistency, the Repository SEIS, the Nevada Rail Corridor SEIS, and the Rail Alignment EIS use the same inventory of spent nuclear fuel and high-level radioactive waste and the same number of rail shipments for analysis. Thus, the associated occupational and public health and safety impacts within the Nevada rail corridors under consideration are the same in both documents. Furthermore, to promote conformity, where appropriate, consistent analytical approaches were used in both documents to evaluate the various resource areas.

The figure that follows summarizes the relationship among the EISs.

Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (DOE/EIS-0250F)

Proposed Action:

- DOE would construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain.
- Repository operations would include transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain nationally and in Nevada by either mostly rail or mostly truck

Record of Decision

- Mostly rail nationally and in Nevada
- Caliente rail corridor to determine a rail alignment

Repository SEIS (DOE/EIS-0250F-S1)

1. Supplements the Yucca Mountain FEIS in its entirety, as modified by:
   - Record of Decision (mostly rail, Caliente rail corridor) (69 *FR* 18557)
   - Outcome of the Nevada Rail Corridor SEIS (Mina rail corridor)
2. Otherwise the Proposed Action remains unchanged:
   - DOE would construct, operate and monitor, and eventually close a repository
   - During repository operations, shipments would occur by mostly rail
   - In Nevada, rail shipments would occur on a railroad to be constructed along an alignment within either the Caliente or the Mina rail corridor
   - Shipments also would arrive at repository by truck
3. To supplement Nevada transportation analysis, Repository SEIS incorporates by reference relevant information from the Rail Alignment EIS:
   - Affected environments for Caliente and Mina rail alignments
   - Environmental impacts from constructing and operating a railroad along Caliente or Mina rail alignment
   - Cumulative impacts associated with Caliente and Mina rail alignments

Nevada Rail Corridor SEIS (Part 1) (DOE/EIS-0250F-S2)

1. Supplements the Nevada transportation analysis of the Yucca Mountain FEIS, as modified by:
   - Record of Decision (mostly rail) (69 *FR* 18557)
   - Proposed consideration of Mina rail corridor
2. Under the Proposed Action, DOE would construct and operate a railroad to connect the Yucca Mountain repository to an existing rail line near Wabuska, Nevada (the Mina rail corridor)
   - Mina corridor information and analyses at a level of detail commensurate with that of the other corridors in the Yucca Mountain FEIS
3. Considers other corridors in the Yucca Mountain FEIS for significant new circumstances or information relevant to environmental concerns
   - Review environmental information available since the Yucca Mountain FEIS
4. Conclusion:
   - Whether the Mina rail corridor warrants further detailed study to determine an alignment based on impact analysis
   - Whether there are significant changes or new information relevant to environmental concerns for the other corridors that would warrant further detailed study to determine an alignment

Rail Alignment EIS (Part 2) (DOE/EIS-0369)

1. Tiers from the Yucca Mountain FEIS and the Nevada Rail Corridor SEIS
2. Proposed Action based on Record of Decision (69 *FR* 18557)
   - Under the Proposed Action, DOE would determine an alignment for the construction and operation of a railroad
     - ⇒ Caliente Implementing Alternative (preferred)
     - ⇒ Mina Implementing Alternative (nonpreferred)

Relationship between the Repository SEIS, the Nevada Rail Corridor SEIS, and the Rail Alignment EIS.

SUMMARY OF NEVADA RAIL CORRIDOR SEIS AND RAIL ALIGNMENT EIS

This document summarizes the Nevada Rail Corridor SEIS and the Rail Alignment EIS. Volumes I, II, III, and IV provide detailed background information; descriptions of existing environments and environmental analyses; analytical methods and assumptions; a list of technical references; a glossary of terms; supporting appendixes, and an index.

S.1 INTRODUCTION

The U.S. Department of Energy (DOE or the Department) has prepared the *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada – Nevada Rail Transportation Corridor* (for brevity, referred to as the Nevada Rail Corridor SEIS) and the *Draft Environmental Impact Statement for a Rail Alignment for the Construction and Operation of a Railroad in Nevada to a Geologic Repository at Yucca Mountain, Nye County, Nevada* (for brevity, referred to as the Rail Alignment EIS) to evaluate the potential environmental impacts of constructing and operating a railroad for shipments of spent nuclear fuel and high-level radioactive waste from an existing rail line in Nevada to a geologic repository at Yucca Mountain. The purpose of the evaluation is to assist the Department in deciding whether to construct and operate a railroad in Nevada, and if so, in which corridor and along which specific alignment within the selected corridor.

Spent nuclear fuel is fuel that has been withdrawn from a reactor following irradiation.

- **Commercial spent nuclear fuel** comes from civilian nuclear power plants that generate electricity.
- **DOE spent nuclear fuel** comes from DOE production reactors (such as defense nuclear material production reactors), naval reactors, and university- and government-owned test and experimental reactors.

High-level radioactive waste is the highly radioactive material that results from the reprocessing of spent nuclear fuel and other highly radioactive material, which the U.S. Nuclear Regulatory Commission determines by rule requires permanent isolation.

The Nevada Rail Corridor SEIS supplements the analysis in the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Yucca Mountain FEIS; DOE/EIS-0250F, February 2002) . The Rail Alignment EIS, analyzes the potential environmental impacts associated with constructing and operating a railroad along specific alignments within the Caliente and Mina rail corridors.

Section S.2 summarizes the Nevada Rail Corridor SEIS. Section S.3 summarizes the Rail Alignment EIS.

Rail corridor: A strip of land 400 meters (0.25 mile) wide within which DOE would determine an alignment for the construction of a rail line.

Rail alignment: An engineered refinement of a rail corridor in which DOE would identify the location of a rail line. A rail alignment is comprised of common segments and alternative segments.

Railroad: A transportation system incorporating the rail line, rail line operations support facilities, rail cars, locomotives, and other related property and infrastructure.

Rail line: An engineered feature incorporating the track, ties, ballast, and subballast at a specific location.

S.1.1 Background

The United States has focused a national effort on siting and developing a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste and on developing systems for transporting these materials from their present locations throughout the country to that repository.

The Nuclear Waste Policy Act of 1982 (Public Law 97-425) acknowledged the Federal Government's responsibility to provide for the disposal of the Nation's spent nuclear fuel and high-level radioactive waste, and initiated a process to select sites for technical study as potential geologic repository locations. In 1987, Congress amended the Nuclear Waste Policy Act. This Act, as amended (42 U.S.C. 10101 *et seq.*), which the Supplemental Nevada Rail Corridor EIS and Rail Alignment EIS refers to as the NWPA, identifies the Yucca Mountain Site in Nye County, Nevada, as the site to be studied as a potential location for a geologic repository.

After completion of site characterization studies at Yucca Mountain, the Secretary of Energy found the site to be scientifically and technically suitable for development of a repository. On February 14, 2002, the Secretary submitted his recommendation, along with a comprehensive statement of the basis for the recommendation, to the President of the United States, George W. Bush, for approval of the Yucca Mountain Site for the development of a nuclear waste repository. As required by the NWPA, the U.S. Department of Energy (DOE) had prepared an EIS, *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Yucca Mountain FEIS), to accompany the Secretary's recommendation to the President.

On February 15, 2002, the President, in accordance with the NWPA, approved the Secretary of Energy's recommendation of the Yucca Mountain Site for development as a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste. On July 23, 2002, the President signed into law a joint resolution of the U.S. House of Representatives and the U.S. Senate designating the Yucca Mountain Site for development as a geologic repository (Yucca Mountain Development Act of 2002, Public Law 107-200).

As part of its obligations under the NWPA, DOE is responsible for developing a system to transport spent nuclear fuel and high-level radioactive waste to the repository. In the Yucca Mountain FEIS, DOE analyzed a proposed action to construct, operate, monitor, and eventually close a geologic repository at Yucca Mountain in southern Nevada for the disposal of spent nuclear fuel and high-level radioactive waste. As part of that action, DOE evaluated various modes of transporting spent nuclear fuel and high-level radioactive waste from 72 commercial sites and five DOE sites nationwide to the Yucca Mountain Site. (Note: DOE now plans to move all spent nuclear fuel from Fort St. Vrain to Idaho National Laboratory prior to packaging for shipment to Yucca Mountain. Therefore, the number of DOE sites is four.)

After the Yucca Mountain Site was designated, DOE initiated preparation of a license application to be submitted to the U.S. Nuclear Regulatory Commission seeking authorization to construct the repository. In addition, to be in a position to transport spent nuclear fuel and high-level radioactive waste to the repository if the Commission granted the Department a construction authorization (and subsequently authorization to receive these materials), DOE proceeded with certain decisions related to transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain.

The Yucca Mountain FEIS examined various national transportation scenarios and Nevada transportation alternatives to evaluate potential transportation impacts to human health and the environment. DOE evaluated two national transportation scenarios, referred to as the "mostly legal-weight truck scenario" and the "mostly rail scenario," and three Nevada transportation scenarios, referred to as the "Nevada mostly legal-weight truck scenario," the "Nevada mostly rail scenario," and the "Nevada mostly heavy-haul truck scenario." Following completion of the Yucca Mountain FEIS, DOE identified the mostly rail scenario as its preferred mode of transportation, both nationally and in Nevada, due in part to lower potential impacts on the health and safety of workers and the public (*Notice of Preferred Nevada Rail Corridor* [68 *Federal Register* {*FR*}74951, December 29, 2003]). In the same *Federal Register* notice, DOE announced its preference for the Caliente rail corridor.

In 2004, DOE announced the selection of the mostly rail scenario analyzed in the Yucca Mountain FEIS for transporting spent nuclear fuel and high-level radioactive waste nationally and within Nevada (*Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV*, 69 *FR* 18557, April 8, 2004). As part of implementing that decision, DOE recognized that it would need to construct a rail line to connect the repository site to an existing rail line in Nevada. DOE also announced in that Record of Decision that it had selected the Caliente rail corridor for further evaluation for the construction and operation of a railroad in Nevada. (Note: The Record of Decision referred to construction and operation of a rail line. However, the Rail Alignment EIS refers to construction and operation of a railroad, which better describes the total transportation system, including the infrastructure required under the Proposed Action.) The Caliente rail alignment is an engineered refinement of the Caliente rail corridor analyzed in the Yucca Mountain FEIS.

At present, there is no rail line to the Yucca Mountain Site. In the Yucca Mountain FEIS, DOE evaluated in detail five potential rail corridors within the State of Nevada in which the Department could construct a rail line to link an existing rail line to Yucca Mountain: Caliente, Carlin, Caliente–Chalk Mountain, Jean, and Valley Modified rail corridors. DOE did not include the Mina rail corridor it the detailed evaluation because a rail line in the Mina rail corridor would need to cross the Walker River Paiute Reservation. In 1995, the Department eliminated the Mina rail corridor from further study because the Walker River Paiute Tribe had stated that it would not allow DOE to transport spent nuclear fuel and high-level radioactive waste across the Walker River Paiute Reservation.

However, the Mina rail corridor became feasible when, in a May 2006 letter, the Walker River Paiute Tribal Council informed DOE that it would allow the Department to consider the potential impacts of constructing and operating a railroad to transport spent nuclear fuel and high-level radioactive waste across its Reservation. DOE prepared a preliminary feasibility study of the Mina rail corridor and announced its intent to expand the scope of the Rail Alignment EIS to incorporate analysis of the potential environmental impacts associated with constructing and operating a railroad along an alignment in the Mina rail corridor (*Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV*, 71 *FR* 60484, October 13, 2006).

Because the Mina rail corridor was not included in the detailed Yucca Mountain FEIS analysis, the Department decided it was appropriate to supplement the Yucca Mountain FEIS with a corridor-level analysis of the Mina rail corridor commensurate with that performed for the other rail corridors analyzed in the FEIS. In addition, the Department decided it was appropriate to update the analyses of the Carlin, Jean, and Valley Modified rail corridors to identify any significant new information or circumstances that could change the range or magnitude of potential environmental impacts described in the Yucca Mountain FEIS. DOE eliminated the Caliente-Chalk Mountain rail corridor, which would cross part of the Nevada Test and Training Range, from further consideration because of U.S. Air Force concerns that a rail line would interfere with military mission activities.

On April 17, 2007, the Tribal Council for the Walker River Paiute Tribe announced a resolution withdrawing support for the Tribe's participation in the EIS process. The Tribal Council based its decision on review of information gathered to that time and input from members of the tribe. The Council's resolution also renewed the Tribe's past objection to the transportation of nuclear waste through the Walker River Paiute Reservation. Accordingly, DOE has identified the Mina rail corridor and the Mina Implementing Alternative as nonpreferred in the Rail Alignment EIS.

S.1.2 Cooperating Agencies

Council on Environmental Quality (CEQ) regulations at 40 Code of Federal Regulations (CFR) 1501.6, emphasize agency cooperation early in the NEPA process and allow a lead agency (in this case, DOE) to request the assistance of other agencies that either have jurisdiction by law or have special expertise regarding issues considered in an EIS. The Bureau of Land Management (BLM or the Bureau), the Surface Transportation Board (STB), and the U.S. Air Force are cooperating agencies in the development of the Supplemental Nevada Rail Corridor EIS and Rail Alignment EIS, pursuant to CEQ regulations, and have participated in its preparation.

Cooperating agencies that could issue decisions concerning the Proposed Action and alternatives to the Proposed Action could adopt the Supplemental Nevada Rail Corridor EIS and Rail Alignment EIS in whole or in part and use it as a basis for their decisions. These agencies have management and regulatory authority over lands and resources that would be crossed by or close to the proposed railroad, or they have special expertise related to the Proposed Action.

S.2 SUMMARY OF NEVADA RAIL CORRIDOR SEIS

S.2.1 Purpose and Need for Agency Action

The Nevada Rail Corridor SEIS has two purposes, as follows:

1. To analyze the Mina rail corridor, which was not previously analyzed in detail, at a level of detail commensurate with that of the rail corridors analyzed in the Yucca Mountain FEIS to determine if it warrants further detailed evaluation at the alignment level
2. To update relevant information regarding the Carlin, Jean, and Valley Modified rail corridors to identify any significant new circumstances or information relevant to environmental concerns associated with these three rail corridors that would warrant their further detailed evaluation at the alignment level

On April 8, 2004, the Department announced that it would ship most spent nuclear fuel and high-level radioactive waste to the repository by rail (train) and announced its selection of the Caliente rail corridor as the preferred corridor (69 *FR* 18557). On October 13, 2006, the Department issued an *Amended Notice of Intent To Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, Nevada* (71 *FR* 60484). In that notice, the Department announced its intent to incorporate analyses for the Mina rail corridor.

DOE did not analyze the Mina rail corridor in the Yucca Mountain FEIS; therefore, the Department has prepared a supplement (DOE/EIS-0250F-S2) to the Yucca Mountain FEIS, which considers the potential environmental impacts of a railroad in the Mina rail corridor at the same level of analysis as that for the Carlin, Jean, and Valley Modified rail corridors in the Yucca Mountain FEIS. Figure S-1 shows the rail corridors analyzed in the Yucca Mountain FEIS and the Mina rail corridor.

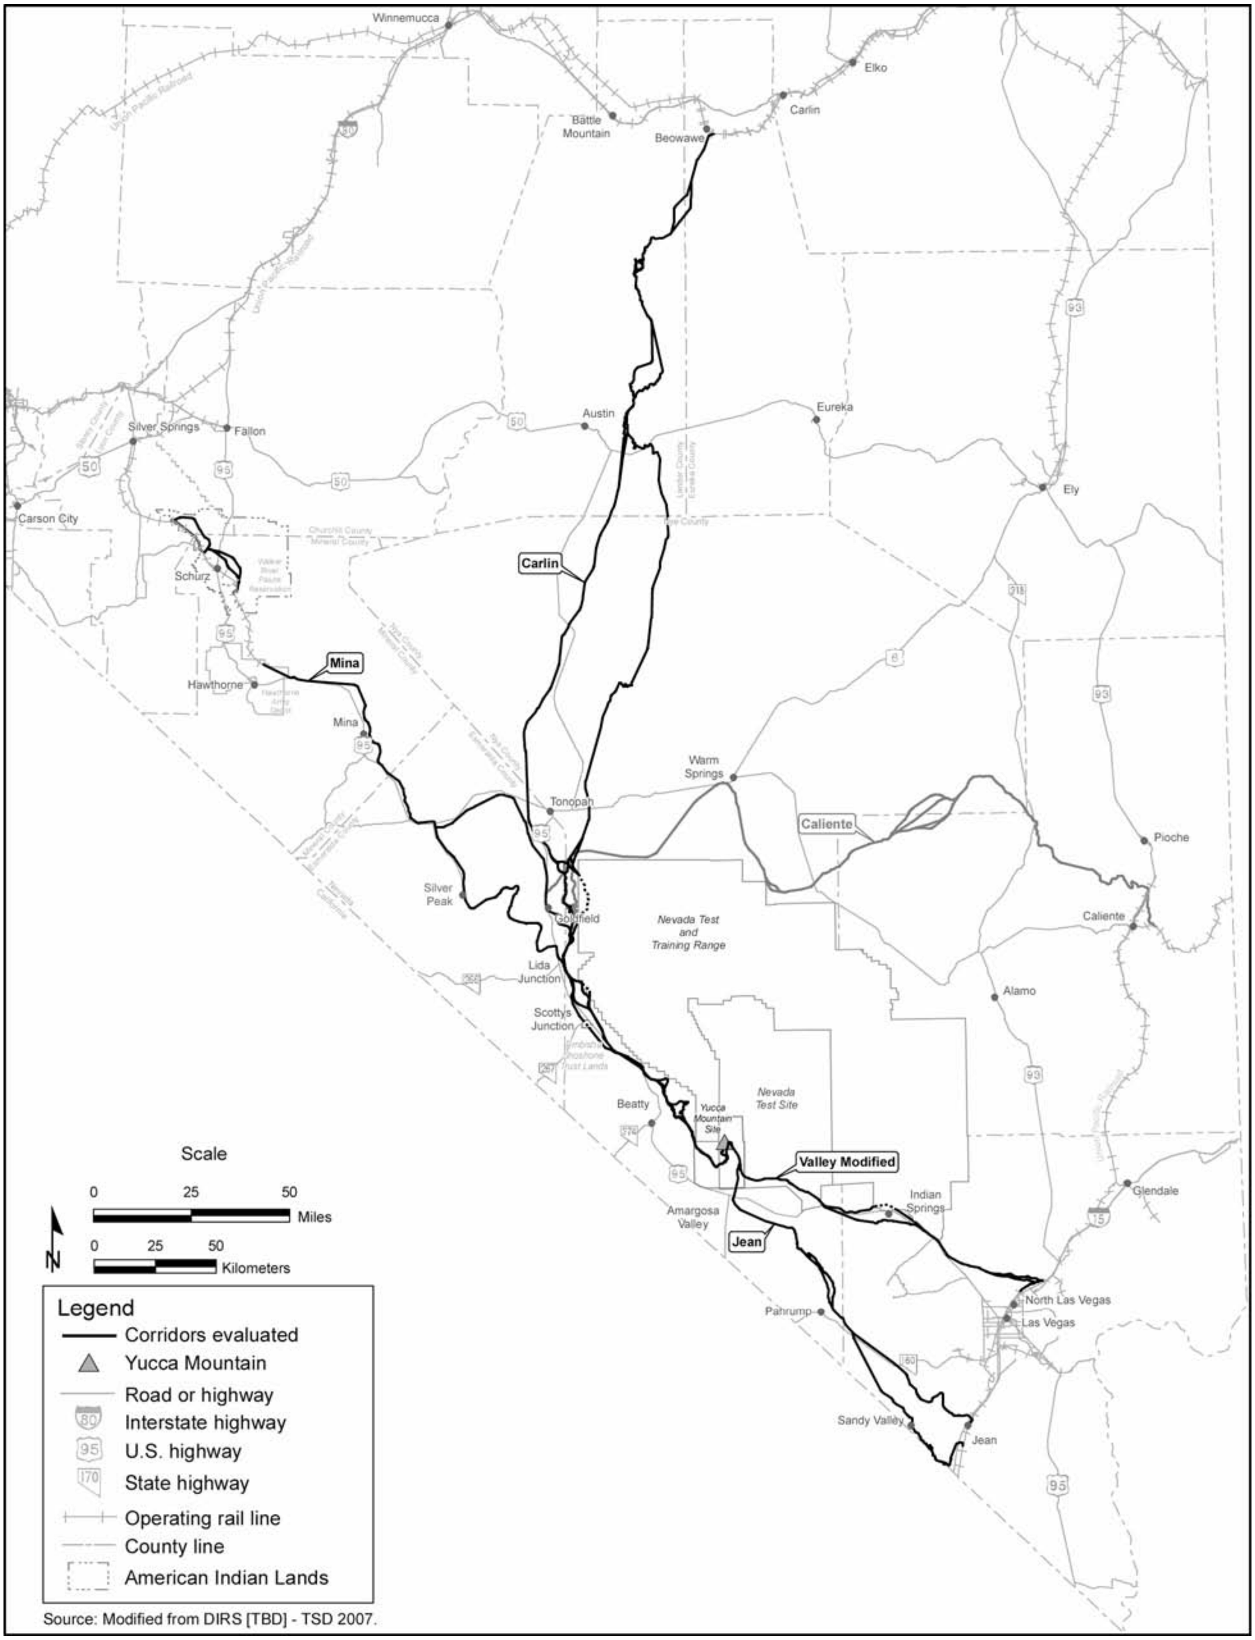

Figure S-1. Carlin, Jean, Valley Modified, Caliente, and Mina rail corridors (pre-scoping, October 2006).

The purpose of the DOE action is to construct and operate a railroad for the transportation of spent nuclear fuel and high-level radioactive waste that connects an existing rail line in the State of Nevada to the Yucca Mountain Site. In this regard, the Department is evaluating the Mina rail corridor so it can determine if the attributes, characteristics, and potential impacts of railroad construction and operation in the Mina rail corridor would be such that DOE should proceed with analyses of specific alignments within the corridor in the Rail Alignment EIS. At the same time, the Department has updated relevant environmental information for the Carlin, Jean, and Valley Modified rail corridors to determine whether there are significant new circumstances or information that would warrant consideration of these three rail corridors at the alignment level.

S.2.2 Proposed Action and Alternatives

The Nevada Rail Corridor SEIS evaluates a Proposed Action and a No-Action Alternative. It supplements the Yucca Mountain FEIS to the extent that it analyzes the potential impacts of the Proposed Action to construct and operate a railroad to connect the Yucca Mountain Site to an existing rail line near Wabuska, Nevada, in the Mina rail corridor. Under the Proposed Action, DOE has analyzed the Mina rail corridor at a level of detail commensurate with that of the rail corridors (Caliente, Caliente-Chalk Mountain, Carlin, Jean, and Valley Modified) analyzed in the Yucca Mountain FEIS.

CEQ and DOE regulations that implement the procedural requirements of NEPA require consideration of the alternative of no action. Under the Nevada Rail Corridor SEIS No-Action Alternative, DOE would not select a rail alignment within the Mina rail corridor for the construction and operation of a railroad. Therefore, the No-Action Alternative provides a basis for comparison to the Proposed Action.

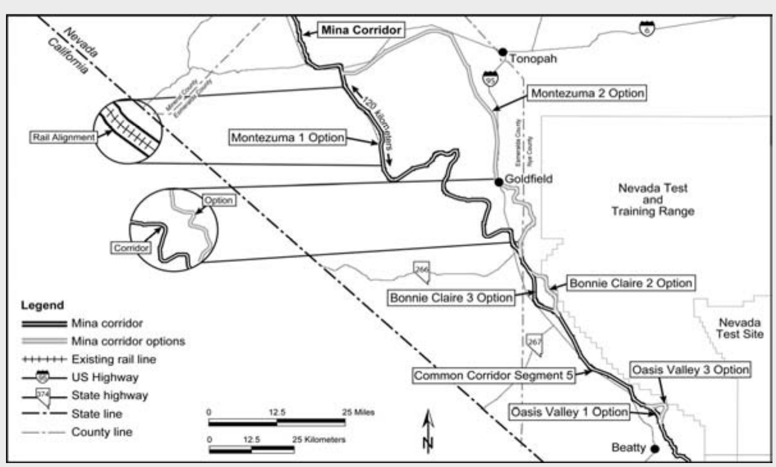
In response to the May 2006 letter from the Walker River Paiute Tribe, DOE initiated a study to consider the feasibility of the Mina rail corridor and to identify a specific corridor and associated preliminary options. The Department completed the feasibility study in October 2006. Based on the information in the feasibility study, DOE expanded the scope of the Rail Alignment EIS (DOE/EIS-0369) to incorporate analysis of the Mina rail corridor as a supplemental EIS.

The Nevada Rail Corridor SEIS also updates relevant information for the corridors already analyzed in the Yucca Mountain FEIS.

The Department identified rail corridor options on the Walker River Paiute Reservation to bypass the town of Schurz (Schurz bypass options), around the Montezuma Range (Montezuma options), north of Scottys Junction (Bonnie Claire options), and in Oasis Valley (Oasis Valley options). Figure S-2 shows the Mina rail corridor and its options.

Option – In the Yucca Mountain FEIS the terms for describing separate routes within a corridor were alternates, variations and options. For the Nevada Rail Corridor SEIS, only option is used and is applied more generally; option refers to a strip of land from one point along a corridor to another point on the same corridor that provides a different route.

Common corridor segment – Geographic region for which a single route has been identified.



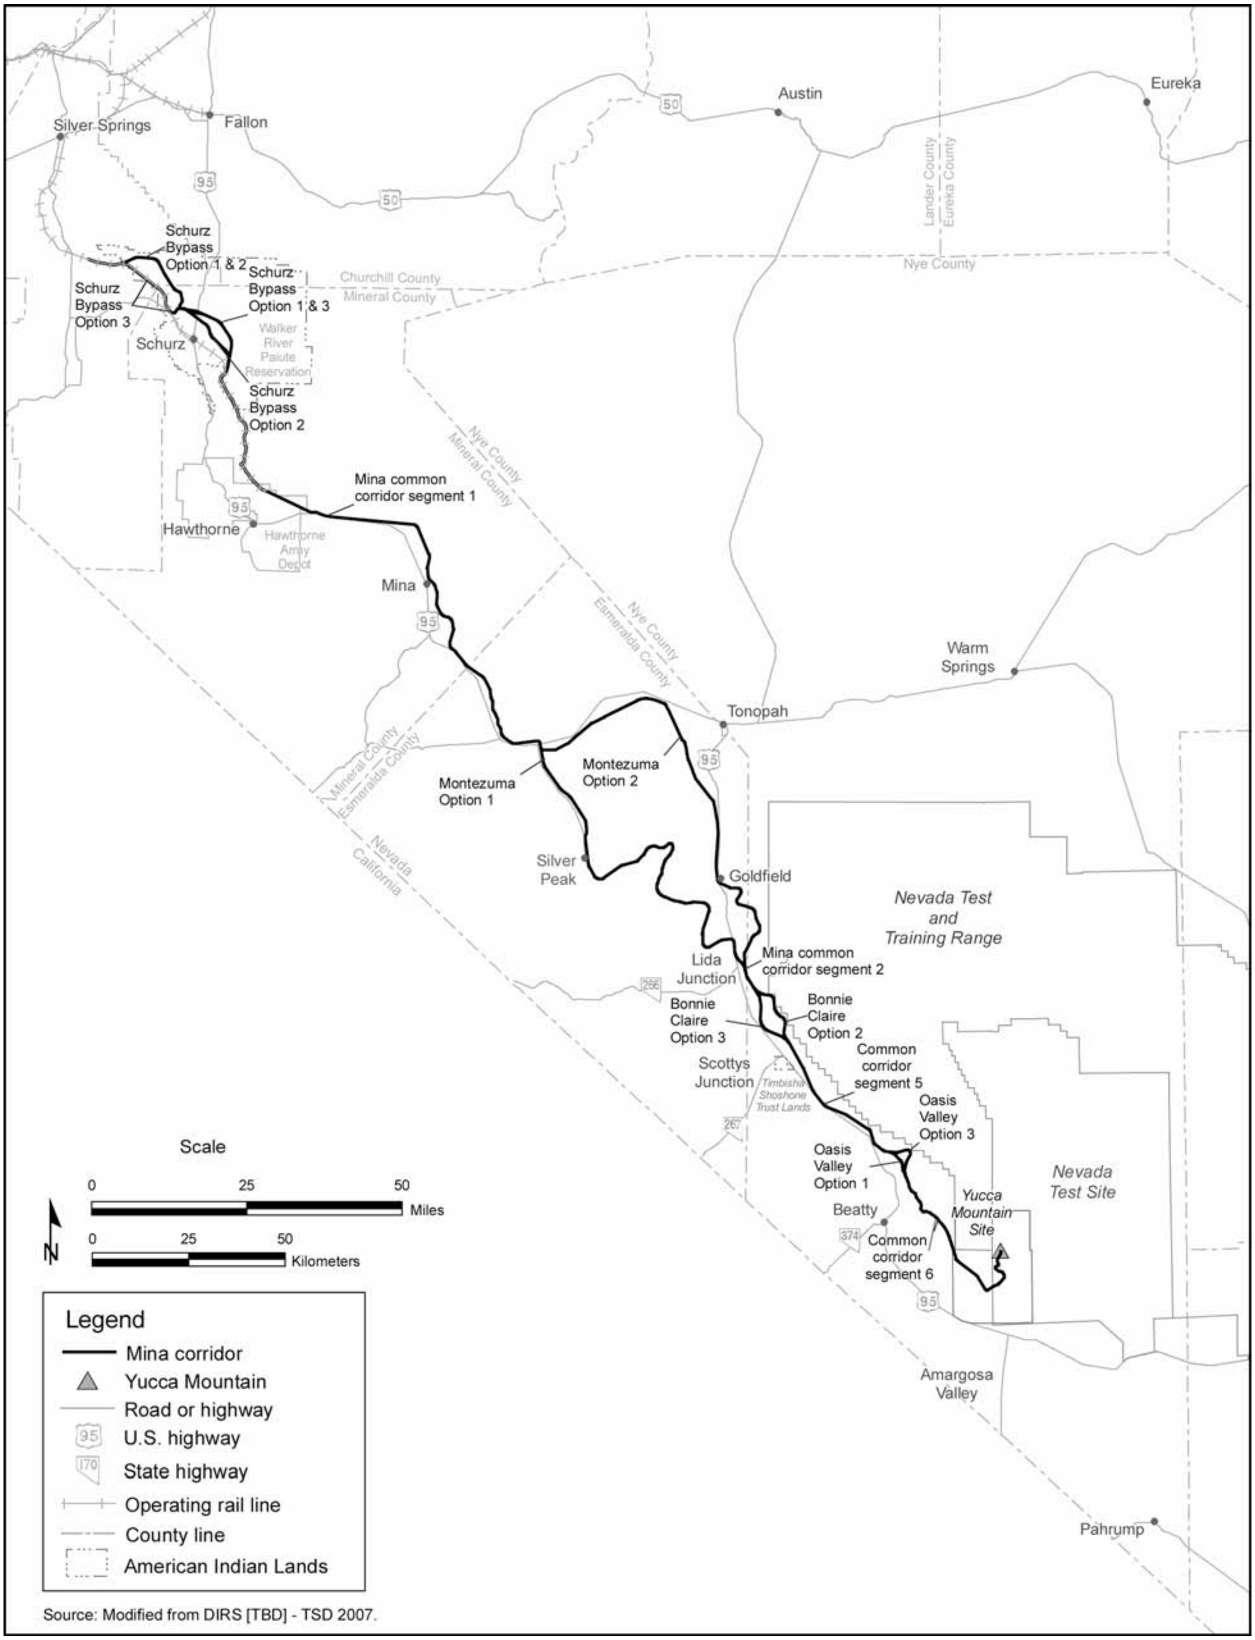


Figure S-2. Mina rail corridor and options (as defined prior to the October 2006 scoping meetings described Section S.2.3.1).

Construction of a rail line in the Mina rail corridor would begin near Wabuska, Nevada, and proceed southeast across the Walker River Paiute Reservation, along one of three options that would bypass the town of Schurz. Mina common corridor segment 1 would begin north of Hawthorne and would trend southeast before turning east at U.S. Highway 95. It would trend east along U.S. Highway 95 through Soda Springs Valley for approximately 40 kilometers (25 miles). Continuing to parallel U.S. Highway 95, the rail line would cross State Route 361 and turn south for approximately 64 kilometers (40 miles). It would pass the towns of Luning and Mina, which are along U.S. Highway 95. The rail line would then turn east before crossing U.S. Highway 95 with a grade-separated crossing in the area of Blair Junction and continue for about 1.5 kilometers (1 mile) before joining one of the Montezuma options. Mina common segment 1 would be approximately 120 kilometers (72 miles) long.

Near Blair Junction, the rail line would follow one of two options that would go around the Montezuma Range, and then move on to Lida Junction. Mina common corridor segment 2 would begin at the end of the selected Montezuma option and run roughly southeast as a single route for about 3.4 kilometers (2.1 miles) before reaching the Bonnie Claire area. At that point the corridor would follow one of two options until forming a single route in the vicinity of Scottys Junction. The corridor would then trend southeast to Oasis Valley, and would follow one of two options through the Oasis Valley before turning north-northeast to Yucca Mountain as a single route. For purposes of analysis, the region of influence for the Mina rail corridor extends to Hazen, Nevada, where shipments to Yucca Mountain would leave the Union Pacific Railroad Mainline.

The Mina rail corridor would be from about 410 to 450 kilometers (255 to 280 miles) long, depending on the combination of options. However, construction of new rail line would range from between about 386 and 400 kilometers (240 and 264 miles) because the corridor would include the existing U.S. Department of Defense Branchline from Wabuska to the Hawthorne Army Depot in Hawthorne, Nevada.

S.2.3 Issues Raised by the Public

S.2.3.1 PUBLIC SCOPING

On April 8, 2004 (69 *FR* 18565), DOE issued a Notice of Intent to prepare an EIS under NEPA for the alignment, construction, and operation of a railroad for shipments of spent nuclear fuel, high-level radioactive waste, and other materials related to the construction and operation of a repository from a site near Caliente, Nevada, to a geologic repository at Yucca Mountain, Nevada (the Rail Alignment EIS; DOE/EIS-0369). DOE received more than 4,100 comments during this first public scoping period for the Rail Alignment EIS, and some after the close of the scoping period. The Department considered the content of all substantive comments in determining the scope of the EIS. During this scoping period, DOE also received comments suggesting that other rail corridors be considered in the Rail Alignment EIS, in particular the Mina rail corridor. Public comments provided compelling arguments that the Mina rail corridor should be given a full evaluation.

On October 13, 2006, after a preliminary evaluation of the feasibility of the Mina rail corridor, DOE announced its intent to expand the scope of the Rail Alignment EIS to incorporate analysis of the potential environmental impacts associated with constructing and operating a railroad within the Mina rail corridor (71 *FR* 60484). DOE also announced that it would update, as appropriate, the information and analysis for other rail corridors analyzed in the Yucca Mountain FEIS. The scoping period for the expanded NEPA analysis began on October 13, 2006, and ended on December 12, 2006. The Department received approximately 790 comments during the public scoping period for the Supplemental Nevada Rail Corridor EIS and Rail Alignment EIS, and some comments after the close of the scoping period. The Department considered the content of all substantive comments in determining the scope of the expanded NEPA analysis.

S.2.3.2 TRIBAL INTERACTIONS

In 1987, DOE initiated the Native American Interaction Program to solicit input from and interact with tribes and organizations on the characterization of the Yucca Mountain Site and the possible construction and operation of a repository. These tribes and organizations—Southern Paiute; Western Shoshone; and Owens Valley Paiute and Shoshone people from Arizona, California, Nevada, and Utah—have cultural and historic ties to both the Yucca Mountain area and to the larger region that includes portions of the Mina rail corridor as well as the Carlin, Jean, and Valley Modified rail corridors. Ethnographic efforts eventually led to the involvement of 17 tribes and organizations in the Yucca Mountain Project American Indian and cultural resource studies. Those tribes formed the Consolidated Group of Tribes and Organizations, which consists of tribal representatives responsible for presenting issues concerning their respective tribal concerns and perspectives to DOE. DOE interactions with Tribes have produced several reports that record the regional history of American Indian people and the interpretation of American Indian cultural resources in the Yucca Mountain region. On June 2, 2004, DOE met with the Consolidated Group of Tribes and Organizations to introduce the proposed railroad project and learn of its members concerns and issues.

The American Indian Writers Subgroup, a subgroup of the Consolidated Group of Tribes and Organizations, prepared the *American Indian Perspectives on the Proposed Rail Alignment Environmental Impact Statement for the U.S. Department of Energy Yucca Mountain Project* providing insight into American Indian viewpoints and concerns regarding cultural resources along the Caliente rail alignment and long-term impacts of the DOE selection of a rail system to transport spent nuclear fuel and high-level radioactive waste to a geologic repository at Yucca Mountain. That document is a supplement to the American Indian Writers Subgroup document *American Indian Perspectives on the Yucca Mountain Site Characterization Project and the Repository Environmental Impact Statement*. The Department has held an ongoing series of meetings over the years with the Consolidated Group of Tribes and Organizations, and most recently on November 29, 2006, to present the proposed inclusion of the Mina rail corridor for analysis in this Supplemental Rail Corridor and Rail Alignment EIS and to provide an update on the ongoing analysis of the Caliente rail alignment. In addition DOE met with Walker River Paiute tribal representatives on several occasions in 2006 to discuss their interest in allowing DOE to evaluate a potential rail corridor, the Mina rail corridor, which would cross the Walker River Paiute Reservation. Tribal members toured the Yucca Mountain Site and attended scoping meetings.

S.2.4 Environmental Impacts

The first component of the Nevada Rail Corridor SEIS is the corridor-level analysis of the Mina rail corridor.

S.2.4.1 POTENTIAL IMPACTS OF THE MINA RAIL CORRIDOR

Where practical, DOE has quantified potential impacts and other characteristics of a Proposed Action to construct and operate a railroad in the Mina rail corridor. In other instances, it is not practical to quantify impacts and DOE provides a qualitative assessment of potential impacts. In the Nevada Rail Corridor SEIS, the Department has used the following descriptors to qualitatively characterize impacts where quantification of impacts was not practical:

- **Small** - For the issue, environmental effects would not be detectable or would be so minor that they would neither destabilize nor noticeably alter any important attribute of the resource.
- **Moderate** - For the issue, environmental effects would be sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

- **Large** - For the issue, environmental effects would be clearly noticeable and would be sufficient to destabilize important attributes of the resource.

Unless otherwise noted, potential impacts would be adverse.

S.2.4.1.1 Land Use and Ownership

Construction of a railroad in the Mina rail corridor would disturb approximately 37 to 41 square kilometers (9,000 to 10,000 acres) of land, depending on the combination of options. The corridor would cross up to 15 separate grazing allotments. The approximate disturbance area associated with the Mina rail corridor would constitute less than 1 percent of the land within those 15 grazing allotments. Within this regional perspective of nearby existing and reasonably foreseeable land uses and land ownership, the commitment of land for the proposed Mina rail corridor would constitute a minor proportion of overall land commitment.

A railroad in the Mina rail corridor would impact approximately 1.6 to 2.7 square kilometers (400 to 670 acres) of private land in the corridor, depending on the combination of options. This private land is used primarily for agricultural and mineral development purposes, and none contains private residences. If in locating the final alignment DOE could not avoid private lands, the Department would need to acquire access to those lands. If the rail line would divide private property, access to the property could be disrupted.

The Mina rail corridor would not cross or affect any Wilderness Areas, Wilderness Study Areas, or Areas of Critical Environmental Concern. A railroad in the Mina rail corridor would be consistent with the goals and policies of the resource management plans in the BLM-administered areas through which it would pass.

The Mina rail corridor would cross land on the Walker River Paiute Reservation. Railroad construction and operations activities on this land would require land agreements between DOE, the Bureau of Indian Affairs, and the Walker River Paiute Tribe. Prior to construction, DOE would be required to obtain both the permission to survey for a right-of-way and a right-of-way grant in accordance with 25 CFR Part 169, "Rights-of-Way Over Indian Lands." These regulations state that "Rights-of-way for railroads shall not exceed 15 meters (50 feet) in width on each side of the centerline of the road, except where there are heavy cuts and fills, when they shall not exceed 30 meters (100 feet) in width on each side of the road."

A portion of the Mina rail corridor, approximately 13 kilometers (8 miles) long, would cross through the Hawthorne Army Depot. A right-of-way grant to construct and operate a railroad through this area would require an agreement with between the Department of Defense and the U.S. Army Corps of Engineers for the use of the land and the existing rail line.

Approximately 27 kilometers (17 miles) of common corridor segment 6 would be within the boundaries of the Nevada Test Site, which is managed by DOE. Railroad construction in this area would require land-use authorization from the DOE Nevada Site Office and the BLM.

The BLM would require DOE to obtain a right-of-way grant to construct and operate a railroad on public land. The Department would adjust the project footprint (the area of disturbance) where practicable to avoid or minimize land-use conflicts and restrictions. Railroad construction and operation in the Mina rail corridor through existing road or utility rights-of-way would require an evaluation of impacts to the road or utility or use of the right-of-way with both the right-of-way holder and the BLM. DOE would protect existing utility rights-of-way from damage so that disruption to utility service or damage to lines would be at most small and temporary.

The implementation of several mining engineering practices in these areas could allow access to mining claims without affecting the claimant or the rail line, depending on the exact locations of the claims and access needs.

Rail line construction would result in loss of forage. Because the corridor would intersect grazing allotments, a rail line could create a barrier to livestock movement. Livestock could have difficulty accessing water if there was a deep cut or a high fill associated with the rail line. Ranch operations and livestock rotations could be disrupted. Livestock could be lost due to collisions with vehicles along roads used during the construction and operations phases and from collisions with trains during the operations phase.

Construction and operation of a railroad in the Mina rail corridor would impact access to land used by the public for recreation, requiring individuals to alter their access routes.

S.2.4.1.2 Air Quality

The Mina rail corridor would pass through rural parts of Nevada in areas that the U.S. Environmental Protection Agency considers to be in attainment or unclassifiable for criteria air pollutant National Ambient Air Quality Standards. Most rural areas of the United States are either in attainment or unclassifiable for all pollutants.

Impacts to air quality during railroad construction and operations in the Mina rail corridor would be small. During the relatively short construction phase, equipment emissions would result in a very small contribution of criteria air pollutants to the region. These pollutants would primarily come from the operation of construction equipment in rural areas or areas that are currently inhabited. Construction activities would also emit fugitive dust that would require DOE to implement dust suppression measures. Concentrations of criteria air pollutants and the generation of fugitive dust would decrease as the construction phase ended and the railroad became operational. During the operations phase, impacts to air quality would be smaller but would last longer.

S.2.4.1.3 Hydrology

Hydrologic hazards in the Mina rail corridor could include flash floods. Impacts to surface water associated with the alteration of drainage patterns or changes to erosion and sedimentation rates or locations would be small and localized. Any impacts on surface-water resources resulting from construction activities would generally be small and limited to the nominal width of the rail line construction right-of-way. DOE would use appropriate engineering standards and construction practices to avoid or minimize any potential impacts to surface water resources.

The groundwater analysis for the Nevada Rail Corridor SEIS based its calculations of water demand during the construction phase on earthwork needs and water that would be needed for soil compaction. Based on these considerations, total water demand for the Mina rail corridor would be approximately 7.32 million cubic meters (5,950 acre-feet). Groundwater use during the construction phase could result in a short-term decrease in the amount of available water in some hydrologic basins. To avoid adverse impacts to groundwater resources in the region, DOE would request the Nevada State Engineer to approve any potential plans to pump groundwater from new or existing wells or plans to otherwise obtain groundwater from other regional resources.

Groundwater demands during the operations phase would be small and limited to water needed to support maintenance activities and the smaller operations workforce. Operations water needs would be small and would have little effect on regional resources.

S.2.4.1.4 Biological Resources and Soils

The Mina rail corridor would primarily cross through remote areas that are characterized by a variety of vegetation communities, special status species (plants and animals including their habitats), game habitats, surface-water flows, and soil conditions along the route. The corridor would cross only one riparian area along the Walker River and one spring near Goldfield.

Some vegetation communities would be disturbed during construction activities in the Mina rail corridor. With the exception of the few riparian areas along the corridor, none of the vegetation communities are BLM-designated sensitive (unique or rare). The total land area disturbed within these vegetation communities in the corridor would be small compared to total land areas in Nevada that also support such vegetation communities.

The Mina rail corridor would cross through habitat that supports a low abundance of the desert tortoise (*Gopherus agasizii*), a federally listed threatened species under the Endangered Species Act. Disturbance of this habitat could disrupt normal tortoise movements or possibly result in mortality to some individual tortoises. DOE would work with the U.S. Fish and Wildlife Service to limit any impacts to the desert tortoise.

The Mina rail corridor would also cross riparian habitat for the Lahontan cutthroat trout (*Oncorhynchus clarkii henshawi*), a federally listed threatened species under the Endangered Species Act. Construction of a bridge over the Walker River, downstream of Walker Dam, would have to occur when the water flow was low and the species was rare or absent. Construction activities could degrade downstream water quality, but these impacts would be temporary and small. Any impacts to springs near the Mina rail corridor would be small.

The Mina rail corridor would cross habitat for some game species including big horn sheep, pronghorn sheep, mule deer, and mountain lions, and herd management areas for wild horses and burros. During the construction phase, these game animals would likely move away from the area due to noise and land disturbance. Noise from passing trains during the operations phase could disturb some animals. Any impacts would be small and would likely diminish over time because animals would become accustomed to the noise.

Land disturbance within the rail line construction right-of-way could increase the potential for soil erosion. DOE would use erosion control and dust suppression methods to reduce the potential for erosion, and would control the use of hazardous materials to limit the potential for soil contamination. Impacts to soil in the Mina rail corridor would be temporary and small.

S.2.4.1.5 Cultural Resources

Based on recent DOE searches of existing records, there are several cultural resources, which include archaeological and historic sites and structures, in the Mina rail corridor that are eligible or potentially eligible for listing on the *National Register of Historic Places*. Construction activities could degrade, cause the removal of, or alter the setting of cultural resources sites and cause the loss of cultural resources.

Before starting construction in the Mina rail corridor, DOE would perform additional field surveys and inventories to further locate and identify cultural resources. The Department would work closely with other federal agencies, tribal authorities, and state agencies to avoid and mitigate any potential adverse impacts to known cultural resources and those that might be discovered during construction activities.

DOE would not expect railroad operations and maintenance activities to result in any additional impacts to cultural resources in the Mina rail corridor.

S.2.4.1.6 Occupational and Public Health and Safety

The impact analysis for occupational health and safety focused on transportation impacts, worker industrial safety impacts, incident-free radiological impacts and nonradiological impacts, and radiological impacts in relation to accidents.

Nonradiological transportation impacts during the construction phase would be primarily from traffic accidents involving workers commuting to and from the construction sites, workers transporting construction materials to the construction sites, and from vehicle emissions produced by commuting workers and materials deliveries. DOE estimates that during the construction phase there could be 4 fatalities from traffic accidents and 0.54 latent cancer fatality from vehicle emissions. During railroad operations along the Mina rail corridor, there could be 3.6 vehicular-related fatalities.

DOE estimated nonradiological occupational health and safety impacts in relation to exposure of workers to physical hazards and nonradioactive hazardous chemicals over the region of influence for the Mina rail corridor. The Department based these estimates on the estimated number of hours worked and occupational incident rates for total recordable cases, lost workday cases, and fatalities. Industrial safety impacts resulting from railroad construction and operation are estimated to be about 0.92 fatality for the combined involved worker and noninvolved worker population.

The largest potential for radiological exposure during the railroad operations phase would be to workers involved in the transportation of spent nuclear fuel and high-level radioactive waste. That impact would be less 0.4 latent cancer fatality.

DOE estimated radiological impacts for members of the public along the Mina rail corridor. During 50 years of railroad operations, there would be less than one latent cancer fatality.

DOE estimated the radiological impacts from potential accident scenarios. For 50 years of railroad operations, the estimated number of worker and public latent cancer fatalities would be less than one.

S.2.4.1.7 Socioeconomics

The socioeconomic impacts analysis used a set of socioeconomic variables to provide a socioeconomic profile of conditions in the Mina rail corridor region of influence. Those variables considered changes to employment, population, economic measures, housing, and public services. The expected employment levels are a significant contributor to the analysis of socioeconomic impacts.

DOE estimated that during the railroad construction phase, workforce employment levels would range from about 340 to 2,100, depending on the length of the rail line, earthwork requirements, and phase of the project. Based on the identified levels of worker employment and the temporary and linear nature of the construction project, potential socioeconomics impacts to the local communities would be both short term and small.

DOE estimated that during the operations phase, workforce levels for operating and maintaining the railroad would be much less the levels estimated for the construction phase. There would be an estimated 42 workers involved in railroad operations. Given the relatively low number of employees necessary for railroad operations, the potential for socioeconomics impacts along the Mina rail corridor would be small.

These socioeconomic impacts for the construction and the operations phases are generally considered positive because of the jobs created, the increase disposable income, increases in gross regional product, and increases in services to local citizens as a result of increased tax revenue to local and state governments.

S.2.4.1.8 Noise and Vibration

Most of the Mina rail corridor would be in areas that are remote from human habitation. The distances from construction activities to the nearest receptors would be great; therefore, construction noise levels would be below the Federal Transit Administration noise guidelines.

DOE estimates that construction- and operations-train noise would be audible to receptors in Silver Peak and Goldfield. There would be no adverse noise impacts associated with these receptors because the noise levels would not exceed STB noise guidelines. Because transportation noise sources are audible throughout the United States, the audibility of train noise itself does not constitute an adverse noise impact.

Vibration levels during the railroad construction and operations phases would not exceed Federal Transit Administration damage or annoyance criteria.

S.2.4.1.9 Aesthetics

Railroad construction and operations in the Mina rail corridor would create small impacts to aesthetic resources, but would be consistent with BLM visual resource management objectives to retain the relative value of visual resources in the area.

S.2.4.1.10 Utilities, Energy, and Materials

Potential impacts to utilities, energy and materials would be small. Construction and operations needs would place limited demands on utilities such as public water and wastewater systems, telecommunications systems and providers of electric power. Regional service providers can be expected to adjust to any increasing needs. Needs for motor fuel during construction and operations activities would represent a very small fraction of Nevada’s motor fuel consumption and not affect regional availability. Raw materials, such as concrete, steel, and rock, consumed during the construction phase would be available from regional or national sources.

S.2.4.1.11 Waste Management

DOE would store and use hazardous materials such as oil, gasoline, diesel fuel, and solvents during railroad construction and operations, primarily for the operation and maintenance of equipment and cleaning of equipment and facilities. The use of hazardous materials would generate hazardous wastes. There is ample disposal capacity for hazardous wastes in the western United States.

DOE would dispose of nonrecyclable or nonreusable waste in permitted landfills. During the construction phase, it is likely that while some of the larger landfills would not see an appreciable change in the amount of waste received if they were utilized, some of the smaller landfills, if utilized, might see a substantial, although manageable, change in daily receipt of solid and industrial and special wastes. The estimated average daily disposal mass would be about 1.5 metric tons (1.7 tons).

During the railroad operations phase, generation of wastes would be substantially less than during the construction phase.

S.2.4.1.12 Environmental Justice

The largest concentration of low-income and minority populations in the Mina rail corridor is on the Walker River Paiute Reservation. However, most of the Mina rail corridor would cross BLM-administered public land or land owned by the Department of Defense, where there is sparse population. As a consequence, there are no concentrations of low-income or minority populations in Lyon, Mineral, Esmeralda, and Nye Counties that construction or operation of a railroad in the Mina rail corridor would be likely to affect.

Impacts from the rail line construction and operations in the Mina rail corridor would be small overall and would be unlikely to cause a disproportionately high and adverse effect on the low-income or minority populations along the corridor.

S.2.4.2 CUMULATIVE IMPACTS – NEVADA RAIL CORRIDOR SEIS

DOE evaluated public- and private-sector past, present, and reasonably foreseeable activities that could, when combined with the Nevada Rail Corridor SEIS Proposed Action, result in cumulative impacts. The DOE analysis of potential cumulative effects was primarily qualitative, but the Department quantified information to the extent feasible. The cumulative impacts regions of influence for analysis encompassed the Mina rail corridor, and areas with potential direct and indirect effects for each resource area. To assess potential cumulative impacts from other projects, DOE identified major projects within the regions of influence that could have interactions with the proposed railroad in space or time. Those major projects included a wide variety of projects including the proposed Yucca Mountain Repository, the Nevada Test and Training Range, the Nevada Test Site, and BLM land management (including rights-of-way).

> **Cumulative impacts**, as defined by the CEQ, "result from the incremental impact of [an] action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (Federal or non-Federal) or person undertakes such other actions" (40 CFR 1508.7). Cumulative impacts can result from individually minor but potentially significant actions that occur within a common context of time and space.

DOE determined that the cumulative impacts within most of the resource areas described in the Nevada Rail Corridor SEIS would be small in the Mina rail corridor region of influence unless noted otherwise.

In the Mina rail corridor region of influence, land use and management is changing because of increased construction and development, increased urbanization, and increased conversion of undeveloped land to other purposes or to multiple purposes. Federal agencies, primarily the BLM, will continue to be the major land manager throughout the regions of influence. The BLM has a major role in determining land use in the region though administration of federal lands, including development of resource management plans for the region. The incremental change to land use from constructing and operating the proposed railroad along the Mina rail corridor is projected to be small to moderate.

Overall, there is, and will continue to be, a broad contrast of how visual resource impacts are managed in the regions of influence, ranging from very little management for military mission-related activities to a formal visual resource management system on BLM-administered lands. DOE determined that operation of the proposed railroad would be visible in specific locations but would not dominate the viewsheds within the regions of influence. Changes to aesthetic resources in the regions of influence have already been affected by activities such as the Nevada Test and Testing Range, the Nevada Test Site, BLM management activities, and population growth. These changes will continue in future years, but the regions will generally maintain many of the remote and rural characteristics and conditions. The incremental change to aesthetic resources from constructing and operating the proposed railroad in the Mina rail corridor is projected to be small.

Cumulative impacts concerns regarding surface-water resources in the Mina rail corridor region of influence include changes to drainage patterns, infiltration rates, flood control, and spill/contamination potential. Impacts would generally be localized. Insufficient inflow from the Walker River into Walker Lake would continue to jeopardize Walker Lake's future as a viable fishery, with or without the proposed railroad in the Mina region of influence.

The Department anticipates that cumulative impacts to groundwater resources in the Mina rail corridor region of influence would range from small to large. Overall, the groundwater needs of the Proposed Action would represent a small portion of current cumulative water usage in the Mina rail corridor region of influence. However, in some proposed groundwater well locations for railroad use, cumulative demand would exceed perennial yield values. Water availability will continue to be a major regional cumulative impact issue in the coming years.

A railroad in the Mina rail corridor is projected to result in small to moderate incremental impacts to cumulative biological resources in their regions of influence. A railroad and other reasonably foreseeable and continuing projects in the region of influence would require coordinated mitigation and impact avoidance among project proponents to avoid and reduce cumulative biological impacts in the region of influence. BLM land management activities also play a major role in regional impact avoidance and mitigation.

The Proposed Action would be only one of the many reasonably foreseeable sources of socioeconomic change to portions of the regions of influence, and would be relatively less important to socioeconomic change than external economic development and population growth. The road systems in the regions of influence could experience higher traffic levels, possibly associated congestion, and increased road maintenance, but incremental impacts due to the proposed railroad would be small.

DOE anticipates that impacts to air quality in the Mina rail corridor region of influence would be small. DOE found that impacts from railroad construction in the Mina rail corridor would generate emissions of some criteria pollutants that could be higher than applicable air quality standards. While these effects would be localized in specific areas, any potential violation of air quality standards would be of concern in relation of both project-specific and cumulative impacts.

The proposed railroad would result in nonradiological and radiological health and safety impacts for workers and residents along the corridor. For members of the public situated along the Mina rail corridor, the radiological impacts during the operations phase would be a minimal contribution to the overall radiological impacts of the Yucca Mountain Repository, and incremental impacts of the proposed railroad would be small.

The Yucca Mountain FEIS evaluated the cumulative impacts of two additional inventories of spent nuclear fuel, high-level radioactive waste, and other radioactive wastes (Modules 1 and 2). These additional wastes would be above and beyond the amounts of wastes that have been analyzed for shipment, and their possible shipment could represent a cumulative impact on the resources analyzed. Although emplacement of this additional waste at Yucca Mountain would require legislative action by Congress, such shipment is a reasonably foreseeable action for purposes of NEPA analysis. Because the planned annual shipment rate of spent nuclear fuel and high-level radioactive waste to the Yucca Mountain Repository would be about the same as the Nevada Rail Corridor SEIS Proposed Action, the only cumulative impacts to arise would be due to the annual increase in the number of casks. Impacts from these additional casks would be similar to the generally small impacts summarized above.

S.2.4.3 SHARED USE

Construction and operation of a railroad in the Mina rail corridor could provide an option for shared use and operation of commercial rail service to serve the communities of Tonopah, Goldfield, and Beatty, and other Tribal, public, and commercial interests in the Mina rail corridor. The presence of a rail line could influence further development and land use in the corridor. Shared use would not require any changes in railroad design, and DOE anticipates that the small additional construction and operations activities would result in very little additional impacts over those described for the Proposed Action without shared use.

S.2.5 Comparison of the Proposed Action and the No-Action Alternative

CEQ NEPA implementing regulations state that agencies should provide a comparison of the environmental impacts of the Proposed Action and alternatives to the Proposed Action to sharply define the issues and provide a clear basis for choice. To that end, in the context within the Nevada Rail Corridor SEIS of a Proposed Action to evaluate the Mina rail corridor at a level of detail commensurate with that of the other rail corridors analyzed in the Yucca Mountain FEIS, Table S-1 provides an overview of potential impacts along the Mina rail corridor. Under the No-Action Alternative, there would be no impacts to existing conditions because DOE would not select a rail alignment within the Mina rail corridor for the construction and operation of a railroad.

Table S-1. Potentially affected resources - Mina rail corridor (page 1 of 3).

Resource	Impact/indicator
Land use	
Disturbed land[a]	9,000 to 10,000 acres (37 to 41 square kilometers), depending on rail corridor option
Land ownership/management authority	
Private land	400 to 670 acres (1.6 to 2.7 square kilometers) (1 to 2 percent of total ownership/authority)
Tribal trust lands and reservations	3,100 to 5,100 acres (12.5 to 20.5 square kilometers) (5 to 12 percent of total ownership/authority)
BLM-administered land	32,600 to 33,100 acres (132.1 to 133.9 square kilometers) (80 to 85 percent of total ownership/authority)
Department of Defense land (Hawthorne Army Depot)	1,200 acres (4.7 square kilometers) (3 percent of total ownership/authority)
DOE land (Nevada Test Site)	1,300 acres (5.3 square kilometers) (3 percent of total ownership/authority)
Air quality	
National Ambient Air Quality Standards attainment status	Areas in attainment or unclassifiable for air quality standards; small impacts from construction and operations
Hydrology	
Surface water	Small impacts associated with the alteration of drainage patterns or changes to erosion and sedimentation rates
Groundwater use	5,950 acre-feet (7.32 million cubic meters)
Biological resources and soils	Small impacts to habitat, wildlife, vegetation, and soils
Cultural resources (records search)	Five percent of area surveyed with 132 recorded sites; eligible affected sites would require mitigation during construction; indirect impacts would be small during operations phase.

Table S-1. Potentially affected resources - Mina rail corridor (page 2 of 3).

Resource	Impact/indicator
Occupational and Public Health and Safety	
Construction and Operations	
Industrial hazards	
Total recordable incidents	379
Lost workday cases	215
Fatalities	0.92 (combined involved and noninvolved workers)
Transportation (construction phase only)	
Traffic fatalities	4.0
Cancer fatalities	0.54
Incident-free radiological impacts (latent cancer fatalities)	
Operations phase only	
Public	0.00082
Workers	0.33
Radiological transportation accident fatalities	
Radiological accident risk (latent cancer fatalities)	0.0000074
Cancer fatalities from vehicle emissions	0.40
Transportation accident fatalities	
Worker commuting and material delivery	3.3
Radiological waste transportation	0.31
Socioeconomics	Construction employment: 6,500 worker-years over a minimum 5-year construction phase, primarily from Clark County and the Carson City/Washoe County area. Construction economic measures: Less than a 2-percent increase in gross regional product, real disposable personal income, and spending by state and local governments Construction public services: Small increase in local populations Operations employment: 42 workers Operations economic measures: less than a 2-percent increase in gross regional product, real disposable personal income, and spending by state and local governments Operations public services: Small to moderate increase to local populations in Lyon, Mineral, Nye, and Esmeralda Counties
Noise and Vibration	Construction noise levels would be below the Federal Transit Administration noise guidelines. Construction- and operations-train noise would be audible to receptors in Silver Peak and Goldfield. No adverse impacts from vibration.
Aesthetics	Small; construction and operation of a railroad primarily in BLM visual resource management Class III and IV would be consistent with BLM management objectives for those areas.

Table S-1. Potentially affected resources - Mina rail corridor (page 3 of 3).

Resource	Impact/indicator
Utilities, energy, and materials	
Diesel	33 million gallons (125 million liters)
Gasoline	660,000 gallons (2.5 million liters)
Steel	74,000 tons (67,000 metric tons)
Concrete	287,000 tons (260,000 metric tons)
Wastes	
Construction-related municipal waste; limited quantities of other waste types	1.7 tons (1.5 metric tons) per day
Environmental justice (disproportionately high and adverse impacts)	None identified

a. Land disturbance is based on an average construction right-of-way of 100 meters (325 feet).

S.2.6 New Information Regarding Other Corridors

S.2.6.1 CARLIN, JEAN, AND VALLEY MODIFIED RAIL CORRIDORS

After DOE completed the preliminary evaluation of the feasibility of the Mina rail corridor, the Department announced its intent to expand the scope of the Rail Alignment EIS to include the Mina corridor (71 *FR* 60484, October 13, 2006). DOE also announced that it would update the Yucca Mountain FEIS analysis of the Carlin, Jean, and Valley Modified rail corridors to identify significant new information or circumstances relevant to environmental concerns in those rail corridors. The purpose of the update is to include new information that could change the range or magnitude of potential environmental impacts described in the Yucca Mountain FEIS. That update is the second component of the Nevada Rail Corridor SEIS. Figure S-1 shows the Carlin, Jean, and Valley Modified rail corridors and their options.

The Carlin rail corridor would originate at the Union Pacific Railroad Mainline near Beowawe, Nevada, in north-central Nevada. The corridor would travel south through Crescent, Grass, and Big Smoky Valleys, passing west of Tonopah and east of Goldfield. It would then travel south following and periodically crossing the western boundary of the Nevada Test and Training Range, passing through Oasis Valley and across Beatty Wash. It would travel across Crater Flats and along Fortymile Wash to Yucca Mountain.

Depending on the combination of options, the Carlin rail corridor would be approximately 530 kilometers (330 miles) long from its link with the Union Pacific Railroad Mainline to Yucca Mountain.

The Jean rail corridor would originate at the existing Union Pacific Railroad Mainline near Jean, Nevada. It would travel northwest near Pahrump, Town of Amargosa Valley, Jean, Goodsprings, Sand Spring, and Lathrop Wells before it reached Yucca Mountain. Depending on the combination of options, the Jean rail corridor would range from 180 to 200 kilometers (110 to 130 miles) long from its origin to Yucca Mountain.

The Valley Modified rail corridor would originate near the existing Apex rail siding off the Union Pacific Railroad Mainline. It would travel northwest and pass north of the City of North Las Vegas, the City of Las Vegas, and near Indian Springs and parallel to U.S. Highway 95 before it entered the southwest corner of the Nevada Test Site and reached Yucca Mountain. Depending on actual starting point and combination of options, the corridor would range from 157 to 163 kilometers (98 to 101 miles) long from its origin to Yucca Mountain.

S.2.6.2 UPDATE OF ENVIRONMENTAL INFORMATION

DOE reviewed and updated the affected environment information reported in the Yucca Mountain FEIS, as appropriate, using the same data sources to the extent practicable. Updated information for the Carlin, Jean, and Valley Modified rail corridors is commensurate in content and detail with the presentation of corridor-level information in the Yucca Mountain FEIS. However, since DOE completed the Yucca Mountain FEIS, many data-management systems have advanced and now provide more data and specificity. The more advanced Caliente rail alignment design and plans provided a basis for updating estimates of potential environmental impacts for the Carlin, Jean, and Valley Modified corridors. To do this, DOE used primary impact indicators (parameters that describe alignment characteristics, such as length and earthwork quantities) from the Caliente rail alignment analyses, and calculated ratios to estimate the data at a corridor level.

Tables S-2, S-3, and S-4 summarize the results of the update to the primary impact indicators for the Carlin, Jean, and Valley Modified rail corridors, respectively, and compare them with the corridor information reported in the Yucca Mountain FEIS. The information reflects the total for railroad construction and operations unless otherwise noted. Sections S.2.6.2.1 through S.2.6.2.12 briefly describe the updated information.

S.2.6.2.1 Land Use and Ownership

Land use and ownership conflicts have increased since DOE issued the Yucca Mountain FEIS. The greatest changes to land uses associated with the Carlin and Jean rail corridors would be the significant increase in unpatented mining claims and the proposed construction of the Southern Nevada Supplemental Airport, respectively. Much has changed in relation to land use and ownership in the Valley Modified rail corridor, most notably potential land-use conflicts with Creech Air Force Base and Apex Industrial Park, and the release of the Quail Springs and Nellis A, B, and C Wilderness Study Areas to the public for sale or transfer (BLM land disposal). Impacts to private land would continue to be large for the Carlin and Jean rail corridors, as reported in the Yucca Mountain FEIS.

S.2.6.2.2 Air Quality

The Carlin rail corridor would be in areas that are in attainment or unclassifiable for criteria air pollutants. Construction activities along the Jean rail corridor could affect air quality in the Pahrump Valley near Pahrump, and nonattainment areas in the Las Vegas Valley for particulate matter with an aerodynamic diameter of 10 micrometers or less (PM_{10}) and carbon monoxide. The Pahrump area in Nye County is now subject to a Memorandum of Understanding with local regulatory agencies for air quality. Construction of a rail line in the Jean rail corridor would generate fugitive dust and could affect air quality. Construction activities in the Valley Modified rail corridor could affect air quality attainment and maintenance efforts for PM_{10} and carbon monoxide in the Las Vegas Valley. Railroad operations would be small contributors of criteria air pollutants in the Carlin, Jean, and Valley Modified rail corridors.

S.2.6.2.3 Hydrology

Impacts to surface-water resources from railroad construction and operations in the Carlin, Jean, and Valley Modified rail corridors would be the same as those reported in the Yucca Mountain FEIS. Impacts

Table S-2. Updated environmental information for the Carlin rail corridor (page 1 of 2).

Resource	Changes from Yucca Mountain FEIS to this analysis
Corridor length	No change
Land ownership	
BLM-administered land	Yucca Mountain FEIS: 44,000 to 49,000 acres (180 to 200 square kilometers) (approximately 86 percent) Updated analysis: 44,000 to 52,000 acres (180 to 210 square kilometers) (88 to 94 percent)
Private land	Yucca Mountain FEIS: 1,000 to 3,700 acres (7.3 to 15 square kilometers) (approximately 6.7 percent) Updated analysis: 1,600 to 2,300 acres (6.4 to 9.4 square kilometers) (3.27 to 4.02 percent)
Nevada Test and Training Range land	Yucca Mountain FEIS: 0 to 2,700 acres (0 to 10.9 square kilometers) (approximately 5.2 percent) Updated analysis: 0 to 11.4 square kilometers (0 to 2,800 acres) (0 to 4.9 percent)
Nevada Test Site land	No change
American Indian trust lands and reservations	No change
Air quality	
National Ambient Air Quality Standards attainment status	No change
Hydrology	
Surface water	No change
Groundwater use (construction phase)	Yucca Mountain FEIS: 660 acre-feet (810,000 cubic meters) Updated analysis: 5,800 acre-feet (7.13 million cubic meters)
Biological resources and soils	Six additional sensitive species recorded
Cultural resources (records search)	Yucca Mountain FEIS: 110 recorded sites Updated analysis: 120 recorded sites
Occupational and public health and safety	
Industrial hazards (construction and operations)	
Total recordable cases	Yucca Mountain FEIS: 210 Updated analysis: 391
Lost workday cases	Yucca Mountain FEIS: 105 Updated analysis: 224
Fatalities	Yucca Mountain FEIS: 0.41 Updated analysis: 1
Transportation hazards (construction only)	
Traffic fatalities	Yucca Mountain FEIS: 1.1 Updated analysis: 4
Cancer fatalities	Yucca Mountain FEIS: 0.14 Updated analysis: 0.6

Table S-2. Updated environmental information for the Carlin rail corridor (page 2 of 2).

Resource	Changes from Yucca Mountain FEIS to this analysis
Occupational and public health and safety (continued)	
Incident-free radiological impacts (latent cancer fatalities) (operations only)	
Public	Yucca Mountain FEIS: 0.0012 Updated analysis: 0.000088
Workers	Yucca Mountain FEIS: 0.31 Updated analysis: 0.33
Radiological transportation accident fatalities	
Radiological accident risk (latent cancer fatalities)	Yucca Mountain FEIS: 0.000000037 Updated analysis: 0.000001
Cancer fatalities from vehicle emissions	Yucca Mountain FEIS: 0.09 Updated analysis: 0.4
Nonradiological transportation accident fatalities	
Spent nuclear fuel and high-level radioactive waste transportation	Yucca Mountain FEIS: 0.54 Updated analysis: 0.31
Construction and operations workforce	Yucca Mountain FEIS: 0.7 Updated analysis: 3.3
Socioeconomics	
Estimated construction workforce	Yucca Mountain FEIS: 1,230 worker-years Updated analysis: 6,600 worker-years
Estimated operations workforce	Yucca Mountain FEIS: 47 workers per year Updated analysis: 42 workers per year
Noise and Vibration	No change
Aesthetics	No change
Utilities, energy, and materials (amount used)	
Diesel	Yucca Mountain FEIS: 10.6 million gallons (40 million liters) Updated analysis: 29 million gallons (110 million liters)
Gasoline	Yucca Mountain FEIS: 0.22 million gallons (0.82 million liters) Updated analysis: 0.63 million gallons (2.4 million liters)
Steel	Yucca Mountain FEIS: 82,000 tons (76,000 metric tons) Updated analysis: 95,000 tons (86,000 metric tons)
Concrete	Yucca Mountain FEIS: 456,000 tons (414,000 metric tons) Updated analysis: 364,000 tons (330,000 metric tons)
Waste Management	
Sanitary Solid Waste	Updated analysis: 1.7 tons (1.6 metric tons) per day
Environmental justice (disproportionately high and adverse impacts)	No change, none identified

associated with changes in drainage patterns or to erosion and sedimentation rates or locations would be small and localized.

Based on earthwork needs as opposed to terrain type, the estimated groundwater use for railroad construction in the Carlin, Jean, and Valley Modified rail corridors has increased substantially over that reported in the Yucca Mountain FEIS.

S.2.6.2.4 Biological Resources and Soils

There would be no differences in potential impacts to biological resources and soils from those reported in the Yucca Mountain FEIS for the Carlin, Jean, and Valley Modified rail corridors. DOE has identified additional records of sensitive species in all three corridors. Because all three corridors would cross some desert tortoise habitat, there would continue to be potential impacts to desert tortoise habitat and individuals of the species, as reported in the Yucca Mountain FEIS.

S.2.6.2.5 Cultural Resources

Since DOE completed the Yucca Mountain FEIS, there have been surveys that identified additional cultural resources in the Carlin, Jean, and Valley Modified rail corridors regions of influence. Grading and other construction activities could degrade, cause the removal of, or alter the setting of cultural resources sites and cause the loss of cultural resources.

S.2.6.2.6 Occupational and Public Health and Safety

The greatest potential impacts to health and safety would be from traffic accidents, mainly associated with commuting workers. In relation to industrial safety, the categories of worker impacts include total recordable incidents, lost workdays, and fatalities. Revised estimates of the number of workers needed to construct the railroad resulted in approximately a six-fold rise in the estimate of worker-years in comparison to the worker-years estimated in the Yucca Mountain FEIS (2,000 hours per worker-year). Since DOE completed the Yucca Mountain FEIS, there have been updates to the methods and data to estimate radiation doses for workers and members of the public. Because of the increase in the estimate of construction workers over that reported in the Yucca Mountain FEIS, there would be miminal increases in estimated traffic fatalities, and fatalities from exposure to vehicle emissions. DOE has estimated that radiological impacts to members of the public and workers from incident-free transportation and accident risks in the Carlin, Jean, and Valley Modified rail corridors would increase slightly over the estimate reported in the Yucca Mountain FEIS.

S.2.6.2.7 Socioeconomics

The Yucca Mountain FEIS discussion of socioeconomic impacts identified the number of employees that would be necessary to operate intermodal transfer stations. Based on the identified levels of employment, DOE concluded that the potential cumulative socioeconomic impacts to local communities would be small. Revised estimates of the number of workers needed to construct the rail line resulted in approximately a six-fold rise in the estimate of worker-years in comparison to the worker-years estimated in the Yucca Mountain FEIS (2,000 hours per worker-year).

In relation to employment levels for railroad construction in the Carlin, Jean, or Valley Modified rail corridor, the workforce requirements would vary based on the length of the corridor and earthwork requirements. Operations workforce levels for each corridor would change slightly from those reported in the Yucca Mountain FEIS. Given the short-term nature of construction and the relatively limited number of employees necessary for the railroad operations, the potential for socioeconomic impacts along a corridor would be both short-term and small. Clark County, which includes Las Vegas, dominates the region of influence with a 2006 estimated population of 1.89 million, which is approximately 7 percent more than the population DOE reported in the Yucca Mountain FEIS. Current population growth in Clark County would mask socioeconomic impacts due to the short-term growth in the workforce or the associated impact on population growth.

S.2.6.2.8 Noise and Vibration

Potential noise impacts would be small. The Carlin, Jean, and Valley Modified rail corridors mainly cross through unoccupied BLM-administered public lands. The number of trains per week on each line, approximately 17, would result in small impacts to potentially affected communities. DOE did not identify any significant new information or circumstances that would cause the affected environment or the estimated impacts from noise and vibration to change from that reported in the Yucca Mountain FEIS.

S.2.6.2.9 Aesthetics

Based on an evaluation of current BLM Resource Management Plans, there have been no changes to the visual setting classifications in the Carlin, Jean, and Valley Modified rail corridors since DOE completed the Yucca Mountain FEIS. Therefore, impacts to aesthetic resources would be the same as those reported in the Yucca Mountain FEIS. Most of the Carlin rail corridor would pass through BLM Visual Resource Management Class IV areas (the BLM designation that provides for management activities that require major modifications of the existing character of the landscape). Because the Jean rail corridor would cross Visual Resource Management Class II areas (the BLM designation that provides for the retention of the existing character of the landscape), impacts to the viewshed from railroad operations would cause a conflict with the visual resource classification. As reported in the Yucca Mountain FEIS, railroad operations in the Valley Modified rail corridor would have small impacts to visual resources in the area because the entire corridor would fall within the BLM-designated Class III areas (the BLM designation that provides for the partial retention of the existing character of the landscape).

S.2.6.2.10 Utilities, Energy, and Materials

Construction activities would use motor fuel, concrete, and steel. Quantities would be small in comparison to regional use and capacity, which would not be affected. Railroad operations would consume relatively small quantities of motor fuel and would not affect regional consumption. Estimates of steel and concrete consumption increased over those reported in the Yucca Mountain FEIS. The estimated impacts to utilities, energy, and materials from the railroad operations in the Carlin, Jean, or Valley Modified rail corridor would be small and similar to that reported in the Yucca Mountain FEIS. The estimated use of motor fuel by locomotives would has increased over that reported in the Yucca Mountain FEIS due to more weekly train trips, but overall motor fuel use impacts would remain small.

S.2.6.2.11 Waste Management

The Yucca Mountain FEIS evaluated waste management impacts that would be common to all rail corridors rather than for individual corridors. Information is now more readily available to differentiate between corridor–specific waste-management impacts. Therefore, DOE has included this information at a level of analysis similar to that of the Yucca Mountain FEIS. Construction activities would generate about 1.6 metric tons (1.7 tons) of municipal solid waste per day in the Carlin rail corridor, about one metric ton (1.1 tons) per day in the Jean rail corridor, and less than 1 metric ton (less than 1 ton) per day in the Valley Modified rail corridor. This volume could affect the capacity and closure dates of small rural landfills. Nevada has extensive waste disposal capacity and land for new capacity. DOE could transport waste to existing landfills with ample capacities, such as Apex. Volumes of other types of waste would be small, with no expected strain on disposal capacity.

Railroad operations would generate minimal amounts of waste. The Yucca Mountain FEIS estimated that the peak annual generation would be 910 metric tons (1,000 tons) of sanitary solid waste for each rail corridor; the updated estimates of post recycling waste for each corridor now average about half that amount.

S.2.6.2.12 Environmental Justice

The Yucca Mountain FEIS did not identify potential impacts to minority or low-income populations in the Carlin, Jean, and Valley Modified rail corridors. The environmental impacts updates for those rail corridors did not identify any new minority or low income populations or special pathways for impacts to such populations. Because no new impacts were identified, it is unlikely there would be any disproportionately high and adverse impacts to minority or low-income populations from railroad construction and operations along the Carlin, Jean, or Valley Modified rail corridors.

S.2.7 Issues to be Resolved

Within the context of the first purpose of the Rail Corridor SEIS, to analyze the Mina rail corridor at a level of detail commensurate with that of the rail corridors analyzed the Yucca Mountain FEIS, there are no issues that remain to be resolved. However, under the overarching Proposed Action to construct and operate a railroad in Nevada in the Mina rail corridor to transport spent nuclear fuel, high-level radioactive waste, and other materials to a repository at Yucca Mountain, it remains unresolved whether the BLM would choose to authorize DOE access to sufficient lands for railroad construction and operation under the right-of-way grant applied for by DOE. DOE would also need to apply to the Bureau of Indian Affairs to acquire a right-of-way in which to construct a rail line on the Walker River Paiute Reservation.

S.2.8 Areas of Controversy

The Yucca Mountain Project, including the transport of spent nuclear fuel and high-level radioactive waste along any chosen rail corridor through Nevada, has remained a controversial issue since its inception some 20 years ago, and has been strongly opposed in the State of Nevada by a variety of state, local, tribal, and citizen groups. A particular focus of controversy has been a state’s right to determine federal projects within its borders. Over the last decade the State of Nevada has filed multiple lawsuits against the federal government regarding the Yucca Mountain Project. In 2004, the State of Nevada petitioned the United States Court of Appeals for the District of Columbia Circuit to review the Yucca Mountain FEIS and the portion of the DOE Record of Decision governing the transportation of nuclear waste. The State of Nevada alleged that the FEIS was procedurally flawed, violated NEPA, and ignored STB railroad regulations. The State of Nevada also challenged the Record of Decision under the Administrative Procedure Act in determining a “mostly rail” plan to be the preferred means of shipping waste to the site, and argued that DOE exceeded its authority in selecting the Caliente corridor. On August 8, 2006, the Court denied Nevada’s petition.

In April 2007 the Tribal Council of the Walker River Paiute Tribe announced a resolution withdrawing their participation in the Rail Corridor SEIS and the Rail Alignment EIS, and renewing the Tribe’s past objection to the transportation of nuclear waste through its Reservation. Thus, in the Rail Alignment EIS, DOE has identified the Mina rail corridor as a nonpreferred alternative.

The Consolidated Group of Tribes and Organizations has consistently opposed the siting of a repository at Yucca Mountain and transportation of spent nuclear fuel and high-level radioactive waste to such a repository. Construction and operation of the proposed repository the proposed railroad are viewed to constitute an intrusion on the holy lands of the Southern Paiute, Western Shoshone, and Owens Valley

Paiute and Shoshone people; a disturbance to cultural, biological, botanical, geological, and hydrological resources; and intrusion on American Indian viewscapes, songscapes, storyscapes, and traditional cultural properties. DOE accepts these viewpoints as responsible opposing viewpoints. These issues could continue to be viewed as unresolved within the forum of American Indian cultures and beliefs.

S.2.9 Major Conclusions

DOE concludes that the Mina rail corridor warrants further study at the alignment level under NEPA, although as a nonpreferred alternative. In reaching this conclusion, DOE considered the environmental conditions and associated potential impacts of constructing and operating a railroad for each of 12 environmental resource areas, and found overall that impacts would be small. The Mina rail corridor coincides in part with an abandoned rail line and follows relatively flat terrain over much of its length, which would minimize the amount of cuts and fills and tend to reduce environmental impacts. However, cumulative impacts to groundwater resources for railroad construction and operations in the Mina rail corridor would be small to moderate.

On April 17, 2007, the Walker River Paiute Tribal Council passed a resolution withdrawing support for the Tribe's participation in the Supplemental Yucca Mountain Nevada Rail Corridor EIS and Rail Alignment EIS preparation process. The Tribal Council's resolution also renewed the Tribe's past objection to the transportation of nuclear waste through its Reservation. Accordingly, DOE has identified the Mina Implementing Alternative as nonpreferred in the Supplemental Yucca Mountain Nevada Rail Corridor EIS and Rail Alignment EIS.

DOE also concludes that, based on the analysis in the Nevada Rail Corridor SEIS, there are no significant new circumstances or information relevant to environmental concerns that would warrant further consideration of the Carlin, Jean, and Valley Modified rail corridors at the alignment level. In reaching this conclusion, the Department has updated the information for 12 environmental resource areas for those three rail corridors, which were evaluated in detail in the Yucca Mountain FEIS. Overall, the environmental conditions and associated potential environmental impacts for each rail corridor remain unchanged from, or are substantially similar to, those reported in the Yucca Mountain FEIS. Notably, however, potential land use and ownership conflicts in the Jean and Valley Modified rail corridors have increased, and although the amount of private land within the Carlin rail corridor appears to have decreased (based on a more refined analysis using land ownership databases), the complex land-ownership pattern (mix of private and public lands that would be crossed) remains unchanged. Such land-use and ownership conflicts and complexity increase the potential to adversely affect construction of a railroad, and increase the potential for delays that could affect the availability of a railroad in these corridors. Moreover, air quality management goals within the Jean rail corridor have changed since DOE completed the Yucca Mountain FEIS, and construction of a railroad could increase the potential for conflicts with these goals.

S.3 SUMMARY OF THE RAIL ALIGNMENT EIS

S.3.1 Purpose and Need for Agency Action

Based on its obligations under the NWPA and its decision to select the mostly rail scenario for the transportation of spent nuclear fuel and high-level radioactive waste, DOE needs to ship these materials by rail in Nevada to a repository at Yucca Mountain.

At present, there is no railroad to the Yucca Mountain Site. In the Yucca Mountain FEIS, DOE evaluated in detail five potential rail corridors within Nevada in which the Department could construct a railroad to link an existing rail line to Yucca Mountain: Caliente, Carlin, Caliente–Chalk Mountain, Jean, and Valley Modified rail corridors. Figure S-3 shows the five rail corridors analyzed in the Yucca Mountain FEIS.

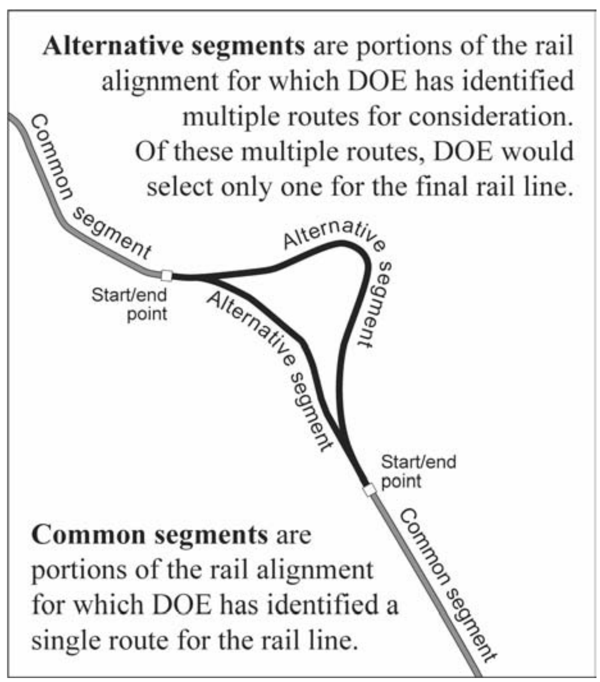
DOE prepared the Rail Alignment EIS to provide the background, data, information, and analyses to help decisionmakers and the public understand the potential environmental impacts that could result from constructing and operating a railroad for shipment of spent nuclear fuel, high-level radioactive waste, and other materials from an existing rail line in Nevada to a repository at Yucca Mountain. This railroad would consist of a rail line, railroad operations support facilities, and other related infrastructure. DOE will use the Rail Alignment EIS to decide whether to construct and operate the proposed railroad, and if so, to:

- Select a rail alignment (Caliente rail alignment or Mina rail alignment) in which to construct the railroad.
- Select the common segments and alternative segments within either a Caliente rail alignment or a Mina rail alignment. The Department would use the selected common segments and alternative segments to identify the public lands to be included in right-of-way applications.
- Decide where to construct proposed railroad operations support facilities.
- Decide whether to restrict use of the rail line to DOE trains, or whether to allow commercial shippers to operate over the rail line (Shared-Use Option).
- Determine what mitigation measures to implement.

S.3.2 Proposed Action and Alternatives

Under the Rail Alignment EIS Proposed Action, DOE would construct and operate a railroad in Nevada to transport spent nuclear fuel, high-level radioactive waste, and other materials to a repository at Yucca Mountain. DOE would also use the railroad to transport materials needed for construction, operation, and maintenance of the repository and rail line.

Under the Proposed Action Caliente Implementing Alternative (the **preferred alternative**), DOE would construct and operate a railroad along the Caliente rail alignment to run from a site in or near the City of Caliente, Nevada, to Yucca Mountain. The rail line would extend north from Caliente, Nevada, turn in a westerly direction and head to near the northwest corner of the Nevada Test and Training Range, and then continue south-southeast to Yucca Mountain. The rail line could range in length from approximately 528 to 541 kilometers (328 to 336 miles) depending on the combination of alternative segments (see Figure S-3).



Under the Proposed Action Mina Implementing Alternative (the **nonpreferred alternative**), DOE would construct and operate a railroad along the Mina rail alignment to run from a site near Wabuska, Nevada, to Yucca Mountain. The rail line would extend from near Wabuska, Nevada, in a southeasterly direction to Yucca Mountain. The total length of the Mina rail alignment could range from approximately

452 to 502 kilometers (281 to 312 miles), which includes portions of an existing rail line currently operated by the Department of Defense. Additionally, railroad operations along the Mina rail alignment would require DOE to operate trains on the Union Pacific Railroad Hazen Branchline, which extends from Hazen, Nevada, south to Wabuska (see Figure S-4).

Under the Shared-Use Option, the Department would allow commercial use of the rail line in under either implementing alternative.

The Rail Alignment EIS also considers the potential environmental impacts of a No-Action Alternative, under which DOE would not construct a railroad along the Caliente rail alignment or the Mina rail alignment.

Figure S-5 shows the two implementing alternatives and the rail line segments that would be the same under either implementing alternative.

For each rail alignment, DOE considered a series of common segments and a range of alternative segments (Figures S-3 and S-4, respectively). DOE applied various engineering, environmental, and design criteria to identify the common segments and alternative segments to be evaluated in the Rail Alignment EIS.

The Proposed Action includes acquiring a right-of-way grant from the BLM, which would authorize DOE access to sufficient lands for the rail alignment and railroad construction and operations support facilities. Under the Mina Implementing Alternative, DOE would need to obtain right-of-way access from the Walker River Paiute Tribe and the Bureau of Indian Affairs to access lands on the Walker River Paiute Reservation. Implementation of the Proposed Action would also require that DOE obtain access to some private land.

During construction of the proposed railroad, a right-of-way would be established that would occupy an approximately 300-meter (1,000-foot)-wide strip of land centered on the rail alignment within the rail corridor. During the railroad operations phase, the right-of-way would be reduced to an approximately 120-meter (400-foot)-wide strip.

Under the Proposed Action DOE would construct and operate the proposed railroad in accordance with applicable federal and State of Nevada laws and regulations, and in compliance with all stipulations and conditions in associated permits. To help ensure compliance with applicable requirements, DOE would implement an array of best management practices as part of the Proposed Action. Best management practices would include practices such as dust suppression and the use of silt fencing to control soil erosion during construction activities. DOE has identified potential mitigation measures to reduce environmental impacts where analyses indicate the potential for environmental impacts after DOE implemented engineering, site evaluation and planning practices, and best management practices.
Under the Proposed Action without shared use, the rail line would be restricted to DOE shipments. DOE would use the rail line to ship approximately 9,500 casks containing spent nuclear fuel and high-level radioactive waste from the Caliente or Wabuska area to the repository for up to 50 years of operations. DOE would also ship approximately 29,000 railcars of other materials, which would include repository construction materials, materials necessary for day-to-day operations of the railroad and the repository, and waste materials for disposal, such as scrap metal and solid waste. DOE anticipates that an average of approximately 17 one-way trains per week would travel along either rail line. (A one-way train means a single trip in either direction.)

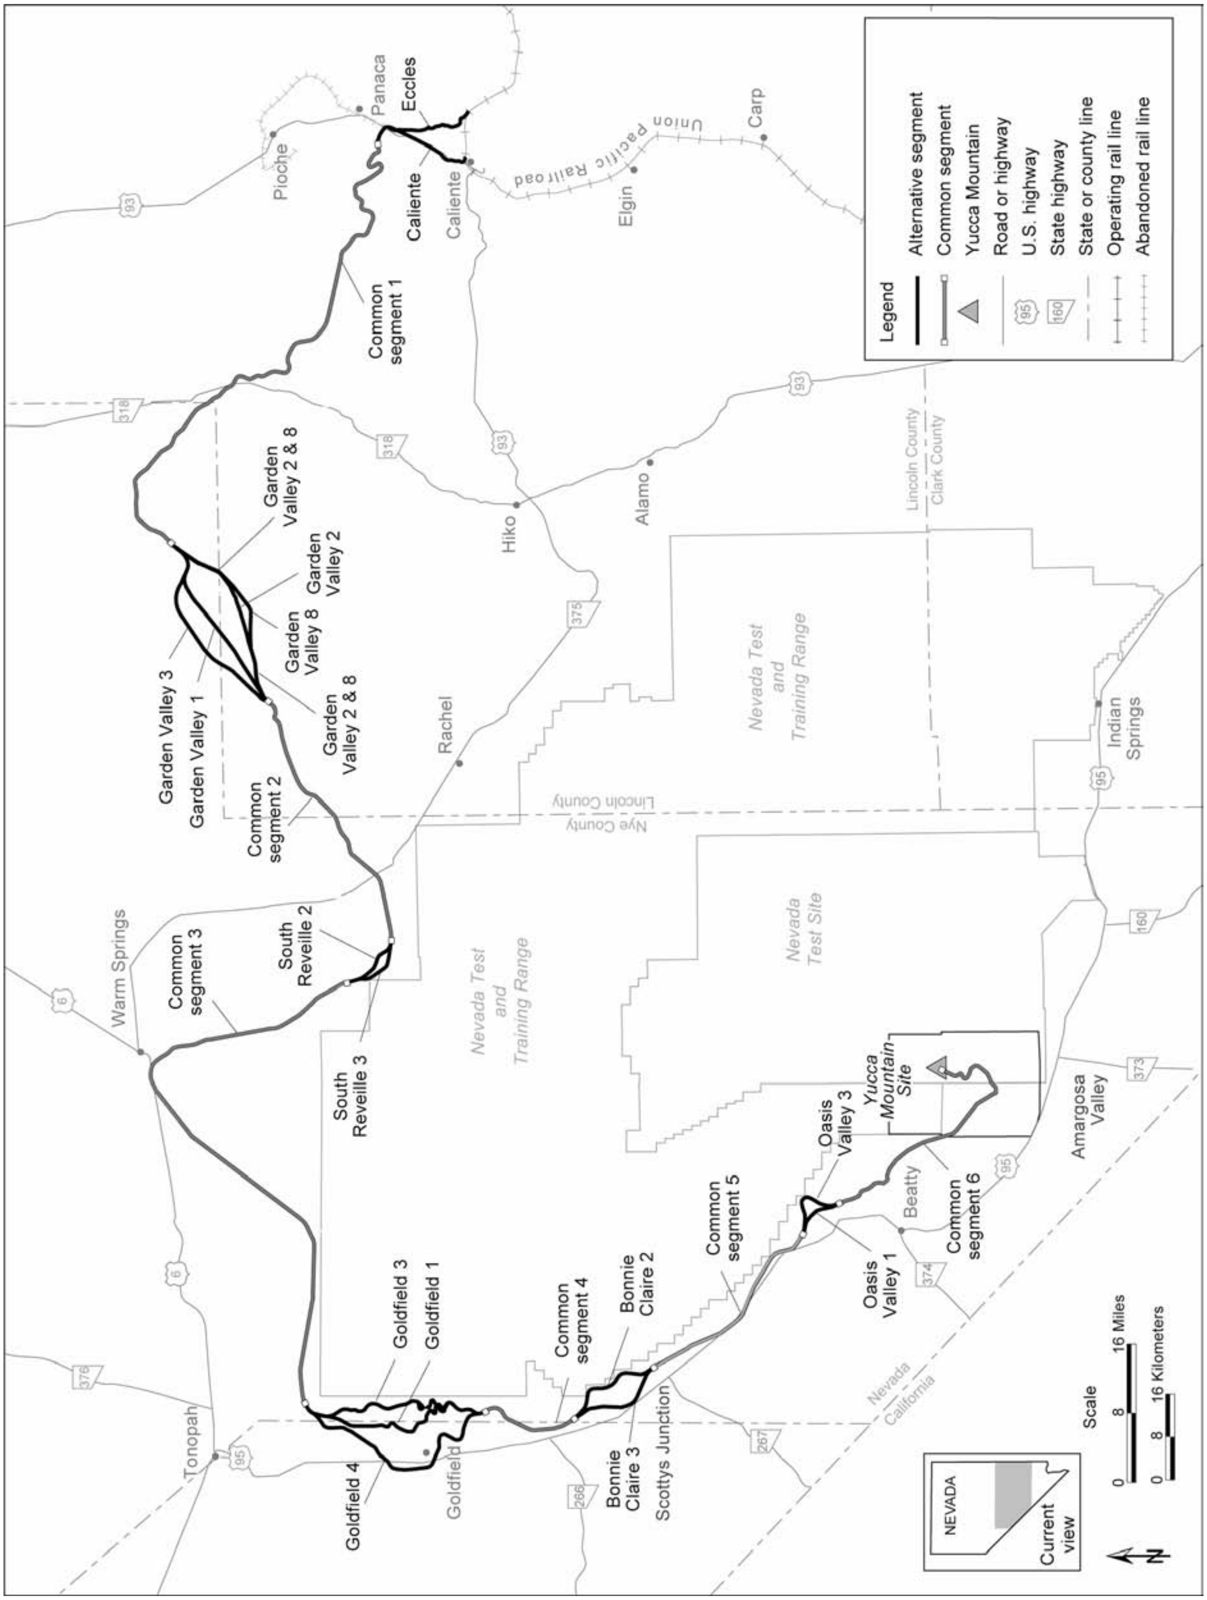


Figure S-3. Caliente rail alignment analyzed in the Rail Alignment EIS.

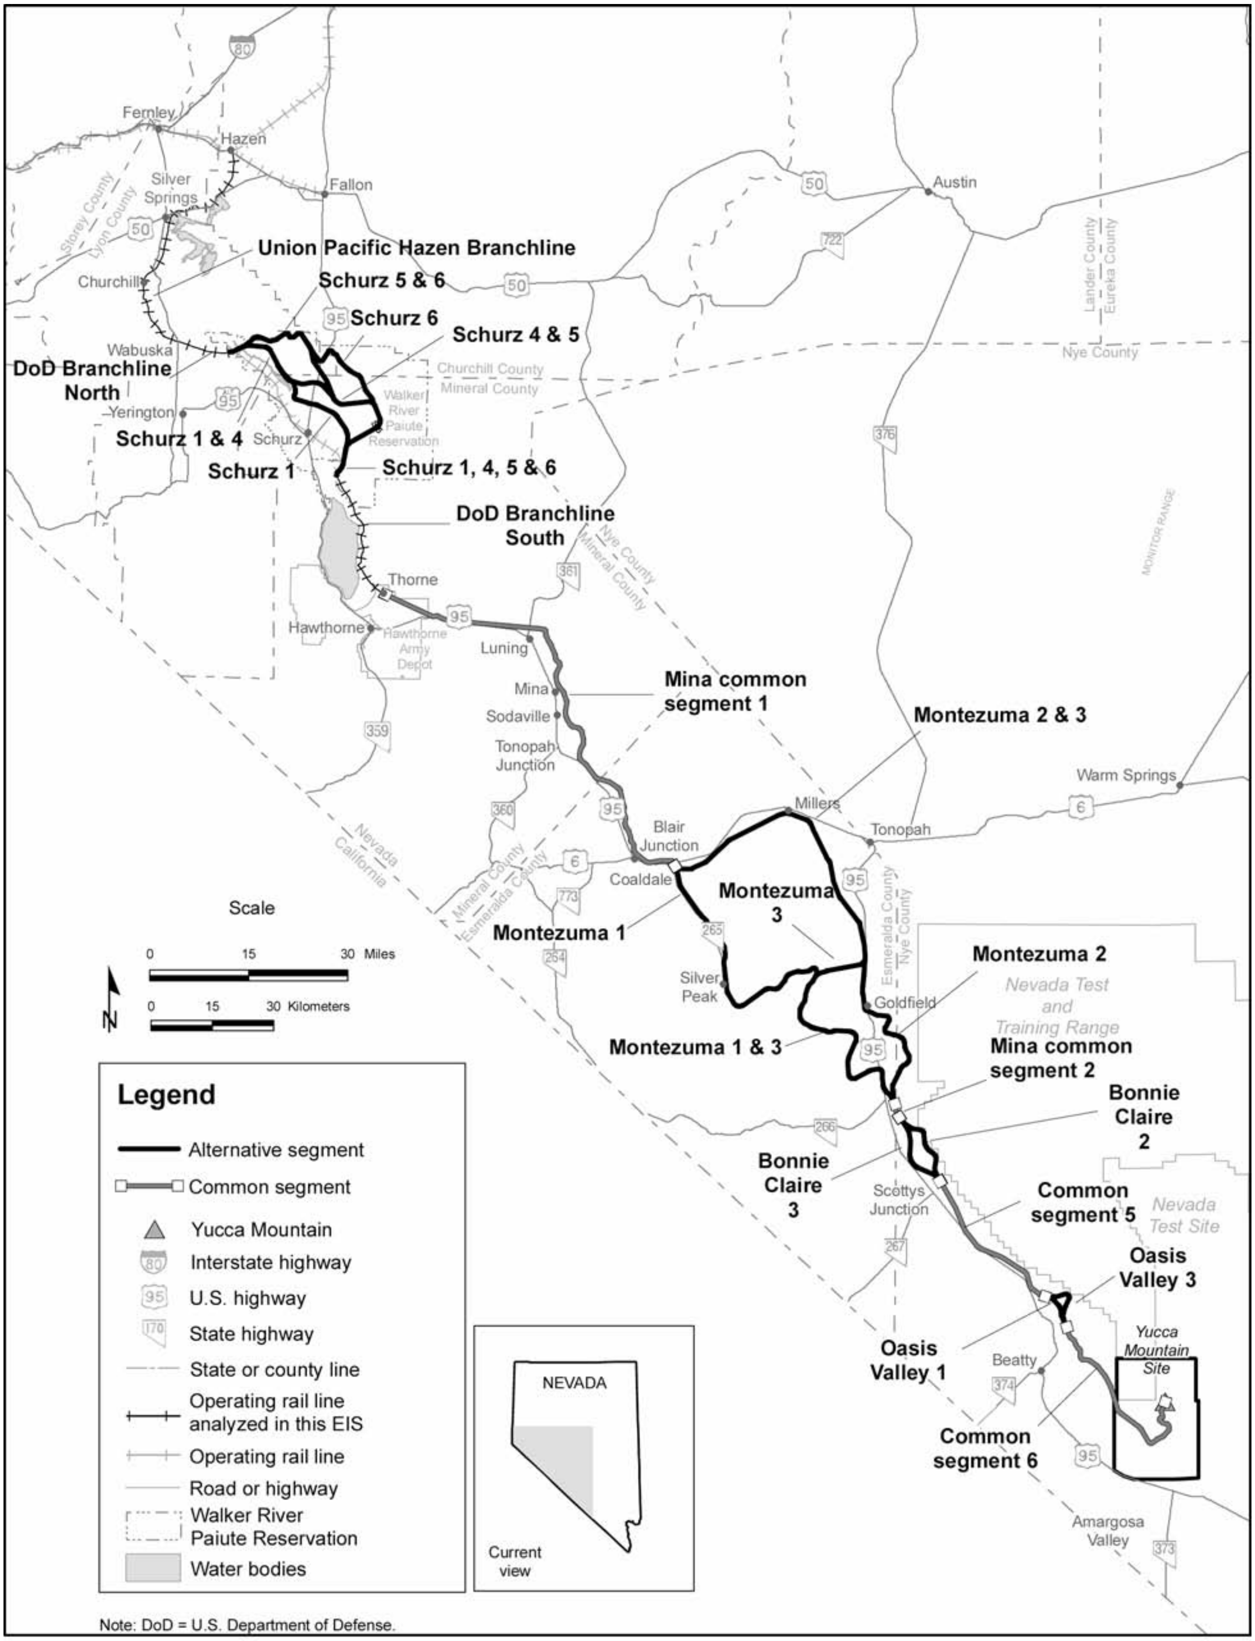

Figure S-4. Mina rail alignment analyzed in the Rail Alignment EIS.

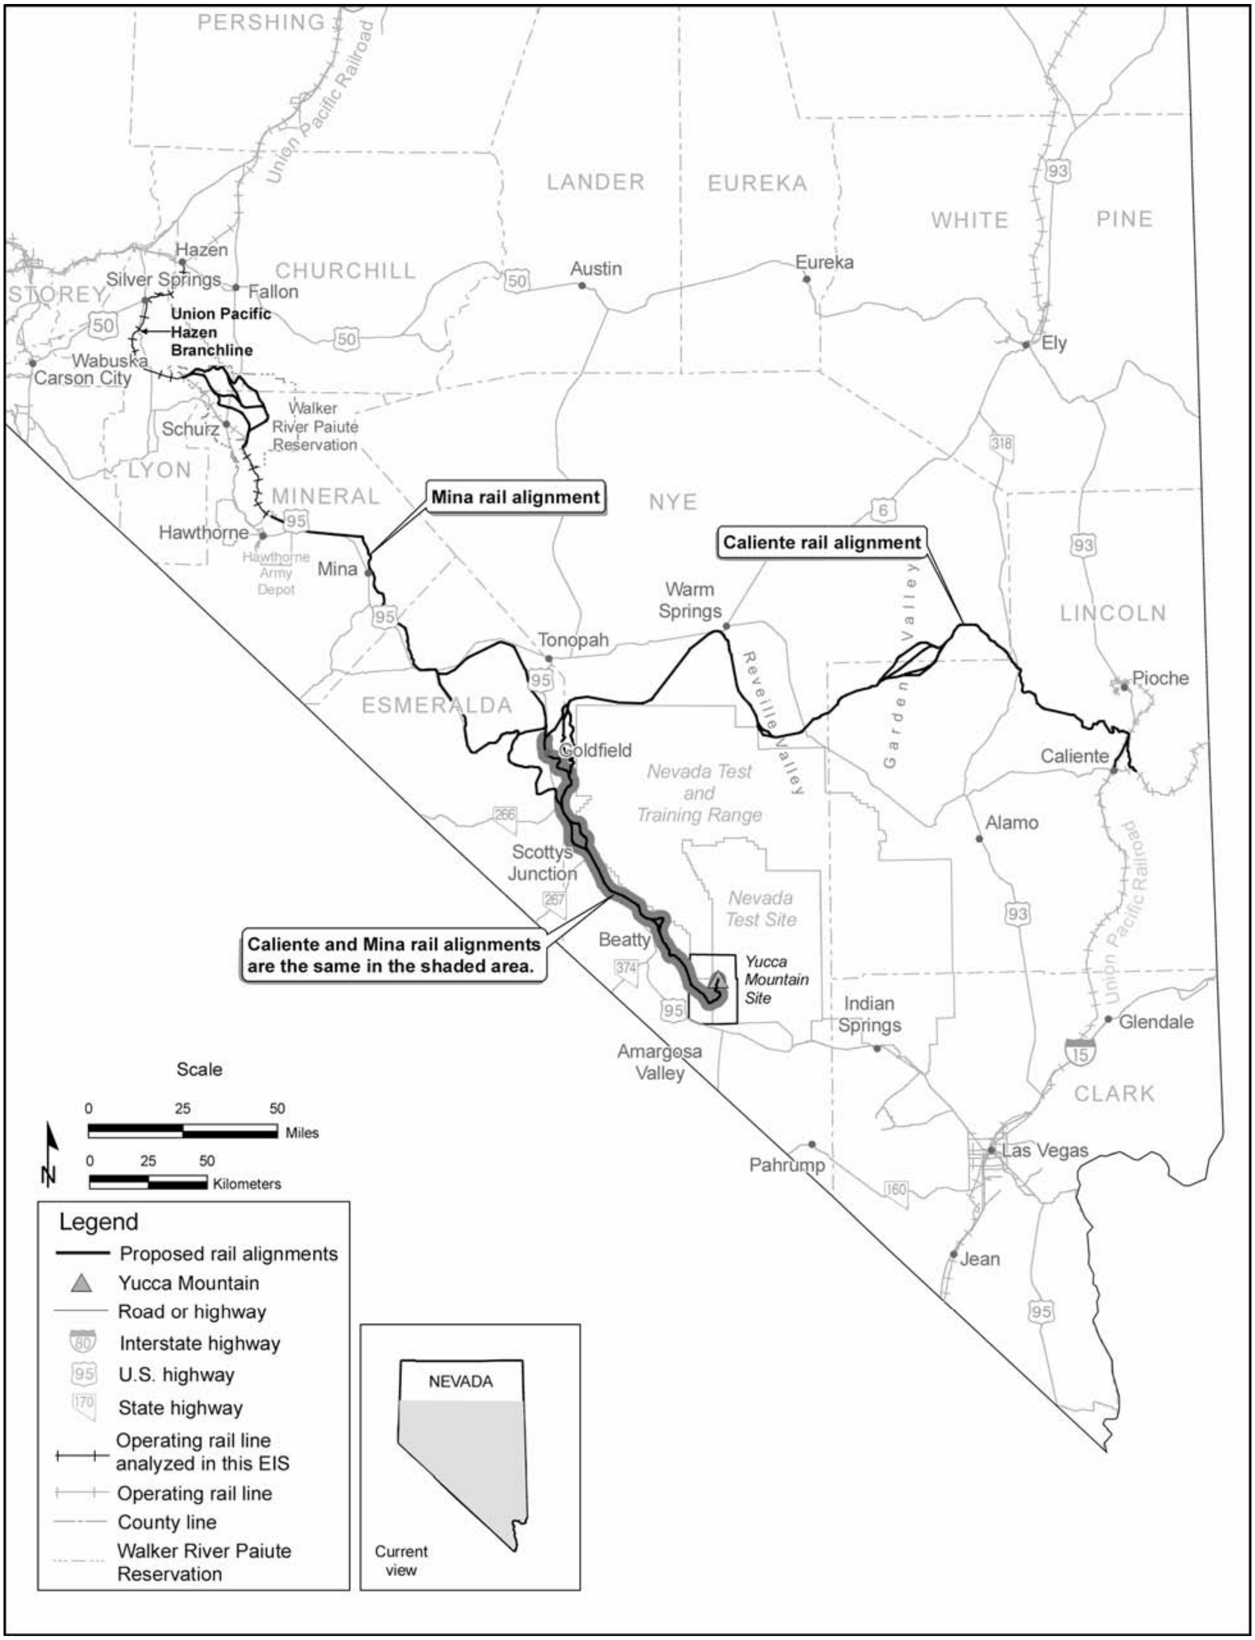

Figure S-5. The proposed Caliente and Mina rail alignments.

Both the Caliente and Mina Implementing Alternatives would require railroad operations support facilities. Under the Caliente Implementing Alternative, facilities would include:

- Interchange Yard
- Staging Yard
- Maintenance-of-Way Facilities
- Rail Equipment Maintenance Yard
- Cask Maintenance Facility
- Nevada Railroad Control Center and National Transportation Operations Center

Under the Mina Implementing Alternative, facilities would include:

- Staging Yard (which would encompass the Interchange Yard)
- Maintenance-of-Way Facility
- Rail Equipment Maintenance Yard
- Cask Maintenance Facility
- Nevada Railroad Control Center and National Transportation Operations Center.

Ballast is the coarse rock that is placed under the railroad tracks to support the railroad ties and improve drainage along the rail line.

Subballast is a layer of crushed gravel that is used to separate the ballast and roadbed for the purpose of load distribution and drainage.

The Department estimates the total cost to construct the railroad within the Caliente rail alignment would be approximately $2.2 billion (in year 2005 dollars with no escalation), whereas the total cost to construct the railroad within the Mina rail alignment would be approximately $1.7 billion (in year 2005 dollars with no escalation).

S.3.2.1 RAILROAD CONSTRUCTION

DOE anticipates that it would take 4 to 10 years to construct the proposed railroad along either rail alignment. Construction of the railroad would include construction of the rail line, the infrastructure necessary to support the construction and operation of the railroad (for example, construction camps, water wells, and ballast quarries), and operations support facilities. Construction activities would occur inside the 300-meter (1,000-foot)-wide construction right-of-way, except in some areas requiring deep cuts or high fills, which could extend beyond typical widths. The total construction footprint resulting from establishing this construction right-of-way under the Caliente Implementing Alternative would be approximately 170 square kilometers (41,000 acres) and under the Mina Implementing Alternative approximately 140 square kilometers (35,000 acres), but would vary depending on the final alternative segments selected. DOE would implement best management practices during this entire construction process.

Construction of the rail line would require obtaining water, ballast, subballast, steel for bridges, concrete ties, and rail. For purposes of analysis, DOE assumed that water would be obtained by pumping groundwater from new water-supply wells along the rail alignment. Under the Caliente Implementing Alternative, a maximum of 107 well sites would be required to supply the 6,100 acre-feet of water necessary for construction. Under the Mina Implementing Alternative, a maximum of 74 well sites would be required to supply the 5,950 acre-feet of water necessary for construction.

DOE would obtain ballast primarily by constructing new quarries along the rail alignment. New quarry sites would occupy a footprint of approximately 0.97 to 3.8 square kilometers (240 to 930 acres). Under the Caliente Implementing Alternative, the Department would construct up to four quarries from six potential locations along the rail alignment. Additionally, DOE is considering obtaining ballast from an existing quarry operation in Utah and shipping it to the proposed rail line. Under the Mina Implementing

Alternative, the Department would construct up to two quarries from five potential locations along the rail alignment.

Under either the Caliente or the Mina Implementing Alternative, DOE would obtain subballast from existing borrow sites along the rail alignment; waste rock generated at ballast quarry sites; from materials excavated during rail roadbed construction; or from the development of new subballast borrow sites established inside the construction right-of-way. Some of the borrow sites for the Mina Implementing Alternative would lie outside of the construction right-of-way. The Department would obtain steel, concrete ties, and rail from existing commercial sources.

DOE would construct the rail line in two major steps: (1) rail roadbed construction and (2) track construction. The rail roadbed would form the base upon which the subballast, ballast, concrete ties, and rail would be laid. Construction of the rail roadbed would require clearing, cuts and fills, and excavating earth. Track construction would involve the placement of subballast, ballast, concrete ties, and rail on top of the rail roadbed, building access roads, and establishing power and communication systems. Construction of the rail line would require DOE to establish construction camps along the rail alignment to provide housing for workers and a logistical base from which to conduct construction activities. Under the Caliente Implementing Alternative, the Department would establish up to 12 construction camps. Under the Mina Implementing Alternative, the Department would establish up to 10 construction camps. Each camp would occupy approximately 0.10 square kilometer (25 acres).

Under either the Mina or Caliente Implementing Alternative, DOE would construct bridges, ***culverts***, and at-grade and ***grade-separated*** road crossings. Under the Caliente Implementing Alternative, the Department would construct up to 240 bridges ranging in length from 7.3 to 300 meters (24 to 1,000 feet); up to 138 large culverts; and up to five grade-separated crossings of highways along the rail alignment. Under the Mina Implementing Alternative, the Department would construct up to 69 bridges ranging in length from 16 to 300 meters (50 to 1,000 feet); up to 60 large culverts; and up to four grade-separated crossings of highways along the rail alignment.

Crossings at other paved public roadways would be at-grade and DOE would install active warning devices, such as flashing lights and gates. For crossings at unpaved roads and private crossings, DOE would install passive warning devices, such as crossbucks and stop signs.

A **culvert** is a conduit for conveying surface water through an embankment. The typical culvert that would be utilized during construction is a box culvert, which is rectangular in cross section. Circular culverts, which are circular in cross section, would also be used when appropriate.

A **grade-separated crossing** occurs when a roadway and a rail line cross paths and one passes over or under the other via an overpass or underpass.

A **siding** is a track that runs parallel to the main line for a short distance and is used for passing and overtaking trains to prevent backups and keep traffic flowing.

Under either the Caliente or Mina Implementing Alternative, DOE would construct approximately 12 passing ***sidings*** approximately every 40 kilometers (25 miles) along the rail alignment. Under the Mina Implementing Alternative, DOE would also install sidings along the existing Department of Defense Branchline. Under either implementing alternative, DOE would construct temporary construction sidings at camps, quarries, and material laydown areas.

Table S-5 lists the attributes associated with rail line construction for each implementing alternative.

Table S-5. Project attributes associated with construction[a] of the proposed rail line.

Attribute	Caliente Implementing Alternative	Mina Implementing Alternative
Estimated number of bridges	Approximately 215 to 240, ranging in length from 3 to 7.3 meters (24 to 1,000 feet)	Approximately 58 to 69, ranging in length from 3 to16 meters (50 to 1,000 feet)
Estimated number of culverts	Approximately 96 to 138	Approximately 38 to 60
Communications towers	Approximately every 16 to 32 kilometers (10 to 20 miles) along the rail alignment, approximately 23 to 30 meters (75 to 100 feet) tall	
Estimated number of water wells needed to satisfy construction water demand	Minimum: 94 well sites containing 150 wells Maximum: 107 well sites containing 176 wells	Minimum: 58 well sites containing 77 wells Maximum: 74 well sites containing 110 wells
Sidings	12 sidings, ranging in length from 2,100 to 3,700 meters (7,000 to 12,000 feet)	12 sidings, ranging in length from 2,100 to 5,800 meters (7,000 to 19,000 feet)
Alignment access roads	The railroad alignment is planned to have an access road along most of its length. This road would be used primarily to support maintenance of the railroad infrastructure. In situations where rerouting existing roads to a common crossover point would be appropriate, DOE could use the access road to facilitate routing roads to a single crossing.	
Construction camps	Number: up to 12, with up to 6 operating at one time	Number: up to 10, with up to 6 operating at one time
	Function: To house the rail line construction workers and provide a logistical support area for construction. Location: One approximately every 50 kilometers (30 miles) along the rail alignment Employment: Up to 360 per camp (106 support staff and 254 contractors) Disturbed area: 0.10 square kilometer (25 acres) per camp	
Ballast quarries	Number: If necessary, up to four would be developed from six potential sites. Locations: One near Caliente; two in South Reveille Valley; one west of Goldfield; and two northeast of Goldfield	Number: If necessary, up to two would be developed from five potential sites. Locations: Two east of Hawthorne; one east of Silver Peak; and two west of Goldfield.
	Employees: Up to 30 at each quarry Disturbed Area: 0.32 to 0.49 square kilometer (80 to 120 acres) per site	
Construction train traffic	Ballast trains: Approximately 8 one-way trains[b] per day Concrete tie trains: Approximately 2 one-way trains per day Rail section trains: Approximately 4 one-way trains per day Other materials trains: Approximately 2 one-way trains per day Total: Approximately 16 one-way trains per day	
Total construction employment (required over the entire construction phase)	8,100 employees (the maximum number of employees in one year is 2,160)	7,600 employees (the maximum number of employees in one year is 2,160)

a. Construction would take place over a 4- to 10-year period.
b. A one-way train means a single trip in either direction.

S.3.2.2 RAILROAD OPERATIONS AND MAINTENANCE

Under the Proposed Action, the railroad would be expected to operate for up to 50 years for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials to the repository at Yucca Mountain. DOE would operate an average of 17 one-way trains per week to transport approximately 9,500 casks of spent nuclear fuel and high-level radioactive waste, and approximately 29,000 railcars of construction materials, diesel fuel, and supplies for the repository and facilities.

Under the Caliente Implementing Alternative, trains would arrive at the Interchange Yard on the Union Pacific Railroad Mainline near Caliente and proceed to the Staging Yard along either the Caliente or the Eccles alternative segment. Under the Mina Implementing Alternative, trains would arrive on the Union Pacific Railroad Mainline near Hazen and proceed to the Staging Yard at Hawthorne via the Union Pacific Railroad Hazen Branchline, the Department of Defense Branchline North, the selected Schurz alternative segment, and the Department of Defense Branchline South. Under the Caliente Implementing Alternative, two facilities (the Interchange Yard and the Staging Yard) would be required to fulfill the functional requirements of exchanging railcars between the Union Pacific Railroad Mainline and the proposed railroad. This is because there is not enough space where the Caliente rail alignment would intersect the Union Pacific Railroad Mainline to house all of the necessary functions of these facilities in one location. However, under the Mina Implementing Alternative, there is enough space to locate all the functions in a single facility (the Staging Yard) at Hawthorne. Once at a Staging Yard, Union Pacific Railroad locomotives would uncouple from cask cars and return to the mainline. The cask cars would go through all appropriate inspections in accordance with Federal Railroad Administration regulations (49 CFR Part 232 and 49 CFR Part 215). A DOE cask train would typically consist of two or three 4,000-horsepower diesel-electric locomotives followed by a buffer car; one to five cask cars followed by another buffer car; and one escort car carrying security personnel, as illustrated in Figure S-4. Naval spent nuclear fuel trains would typically include two or three locomotives, one to 12 cask cars, a buffer car in front of the first cask car and after the last cask car, and one to two escort cars.

Under either implementing alternative, following inspection and assembly of cask trains, trains would depart the Staging Yard and travel for less than 10 hours along the railroad to the Rail Equipment Maintenance Yard at the Yucca Mountain Site. Casks would then be transferred to control of the geologic repository operations area to be unloaded for repository storage. Empty casks would be transferred back to railroad control, and before they were returned to the Staging Yard for onward shipment, could be sent to a Cask Maintenance Facility for testing, inspection, maintenance, minor decontamination, and routine repair of the casks. The National Transportation Operations Center would oversee the shipment of casks from sites throughout the United States; train movements, rail operations, and emergency response operations along the proposed railroad would be coordinated from the Nevada Railroad Control Center. Both would be located either at the Rail Equipment Maintenance Yard or at the Staging Yard.

Under the Caliente Implementing Alternative, most rail line maintenance and inspection activities would be conducted in the Maintenance-of-Way Facilities, which consist of the Maintenance-of-Way Trackside Facility, Maintenance-of-Way Headquarters Facility, and two Satellite Maintenance-of-Way Facilities. Under the Mina Implementing Alternative, the Maintenance-of-Way Trackside Facility and the Maintenance-of-Way Headquarters Facility would be combined and housed in a single Maintenance-of-Way Facility. All maintenance and inspection activities would be performed out of this facility and two Satellite Maintenance-of-Way Facilities, one at the Staging Yard and one at the Rail Equipment Maintenance Yard. Maintenance activities along the Mina rail alignment would include maintaining the existing Department of Defense Branchline as needed.

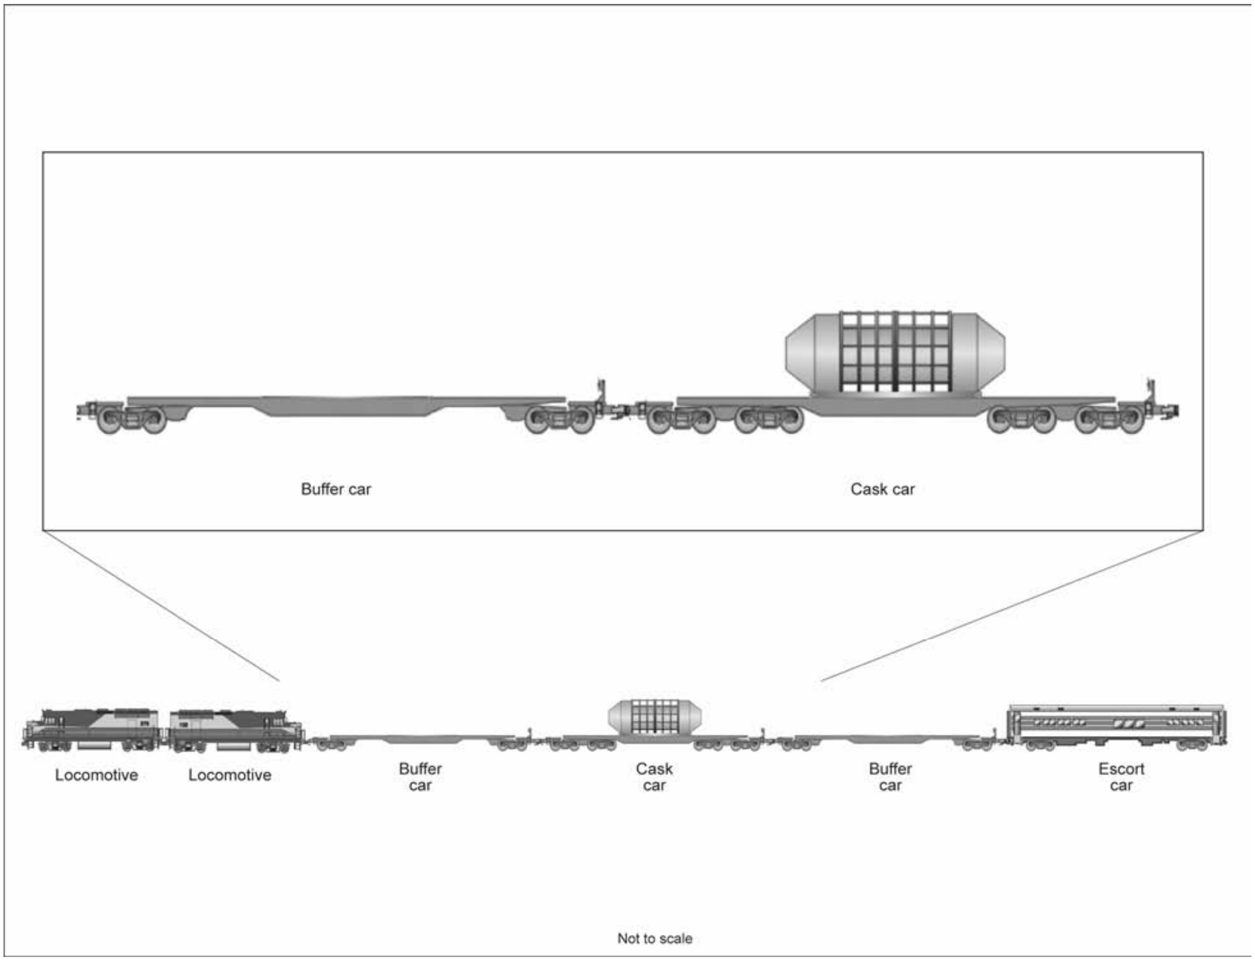

Figure S-4. Artist's conception of a repository train carrying one cask.

Table S-6 lists the rail facilities along the Caliente and Mina rail alignments and details their functions, their locations, and the number of personnel needed to operate each facility.

S.3.2.3 SHARED-USE OPTION

Under both implementing alternatives, DOE has analyzed a Shared-Use Option, under which (subject to STB approval) the Department would allow commercial shippers to use the rail line to ship general freight. The Shared-Use Option would require construction of commercial sidings to provide access for potential commercial shippers, and facilities for operation of commercial rail service. Funding for construction and commercial rail service could be provided by either the private sector or other government sources. The DOE design for the rail line (for example, grade and curvature) would accommodate shared use.

Commercial railcars would be hauled in trains that are separate from trains carrying spent nuclear fuel and high-level radioactive waste, but could be hauled with trains carrying other repository-related materials (for example, construction materials, water, and fuel). During the operations phase, trains carrying spent nuclear fuel and high-level radioactive waste would have priority over trains carrying commercial shipments.

Table S-6. Railroad operations support facilities – Caliente and Mina rail alignments (page 1 of 2).

Facility	Location	General function	Number of employees required for operations
Facilities along the Caliente rail alignment (excluding facilities common to the Caliente and Mina rail alignments)			
Facilities at the Interface with the Union Pacific Railroad Mainline			
Interchange Yard	Caliente or Eccles alternative segments Lincoln County	Handling point for the exchange of railcars containing construction and other materials between the Union Pacific Railroad Mainline and the proposed railroad	0 (employees would be based at the Staging Yard)
Staging Yard	Caliente alternative segment: Indian Cove or Upland option Eccles alternative segment: Eccles-North Lincoln County	Transfer point for casks and other materials delivered to the proposed railroad from around the country	50 (including employees for the potential Nevada Railroad Control Center and National Transportation Operations Center)
Maintenance-of-Way Facilities			
Maintenance-of-Way Headquarters Facility	South of Tonopah, near the intersection of U.S. Highway 95 and U.S. Highway 6 Esmeralda County	Coordination center for all maintenance activities along the proposed railroad	10
Maintenance-of-Way Trackside Facility	Common segment 3; 48 kilometers (30 miles) southeast of Tonopah Nye County	Base of operations for most maintenance activities along the rail alignment	40
Satellite Maintenance-of-Way Facility	Rail Equipment Maintenance Yard and Staging Yard Nye County and Lincoln County	Dispatch point for maintenance activities along the first third and final third of the rail line	0 (employees housed at the Maintenance-of-Way Trackside and Headquarters Facilities)
Staging Yard	Mina common segment 1 near Hawthorne Mineral County	Transfer point for casks and other materials delivered to the proposed railroad from around the country Handling point for the exchange of railcars containing construction and other materials between the Union Pacific Railroad and the proposed railroad	40

Table S-6. Rail line operations support facilities – Caliente and Mina rail alignments (page 2 of 2).

Facility	Location	General function	Number of employees required for operations
Facilities along the Mina rail alignment (excluding facilities common to the Caliente and Mina rail alignments)			
Maintenance-of-Way Facilities			
Maintenance-of-Way Facility	Montezuma alternative segment 1: Silver Peak option Montezuma alternative segments 2 and 3: Klondike option Esmeralda County	Coordination center and base of operations for all maintenance activities along the proposed railroad	40
Satellite Maintenance-of-Way Facility	Rail Equipment Maintenance Yard and Staging Yard Nye County and Lincoln County	Dispatch point for maintenance activities along the first third and final third of the rail line	0 (employees based at the Maintenance-of-Way Facility)
Facilities common to both the Caliente and Mina rail alignments			
Rail Equipment Maintenance Yard	Less than 1.6 kilometers (1 mile) south of the southern boundary of the geologic repository operations area Nye County	Receiving point for casks and other freight from the proposed railroad to the Yucca Mountain Repository; would also store, service, and maintain the rail cars and locomotives operating on the proposed railroad	40 (including employees for the potential Nevada Railroad Control Center and the National Transportation Operations Center)
Cask Maintenance Facility	Collocated with the Rail Equipment Maintenance Yard	Processing location for all transportation casks, including inspection, certification, maintenance and decontamination	30
Nevada Railroad Control Center and National Transportation Operations Center	Collocated with the Rail Equipment Maintenance Yard or the Staging Yard Nye County or Lincoln County	The Nevada Railroad Control Center would control operations along the proposed railroad; the National Transportation Operations Center would coordinate the national shipment of casks and other materials to the proposed railroad	15

Based on a study of potential commercial users, DOE estimated that approximately 8 one-way commercial trains could run per week along the Caliente rail alignment. For the Mina rail alignment, which would have the greater commercial potential, DOE estimated that approximately 18 one-way commercial trains could run on the rail line per week, 8 of which would travel only on the northern portion of the alignment.

S.3.2.4 RAILROAD ABANDONMENT

If DOE proposed to abandon the railroad after the operations phase, the Department could decide to remove ballast, track, ties, signaling, and other related materials. In addition, the Department could decide to decommission and dismantle facilities (for example, the Cask Maintenance Facility). The Department might not remove the rail roadbed, although the lands disturbed by the abandonment process would be reclaimed as required. If the Department decided to abandon the railroad, it would relinquish its regulatory right-of-way on BLM lands and the BLM would continue to manage the land. Abandonment of the railroad would be conducted in consultation with land-management entities, as appropriate, at the time of abandonment.

A decision about whether to abandon the railroad would be made near the completion of the shipping campaign, when more information would be available from the communities or the private business sector regarding the usefulness of maintaining portions of the rail line or individual facilities.

S.3.2.5 NO-ACTION ALTERNATIVE

CEQ regulations (40 CFR 1502.14) require that the alternatives analysis in an EIS include the alternative of no action. The No-Action Alternative provides a basis for comparison with a Proposed Action.

Under the Rail Alignment EIS No-Action Alternative, DOE would not select a rail alignment within the Caliente or the Mina rail corridor for the construction and operation of a railroad. DOE would relinquish public lands in the Caliente rail alignment that were withdrawn for study under Public Land Order 7653, and would also relinquish the public lands segregated from surface and mineral entry for 2 years in the Caliente and Mina rail alignments. The BLM would continue to manage public land for multiple uses. The location and extent of new mining claims and the associated development of mineral commodities, although not known with any certainty, would no longer be limited by the Public Land Orders.

Under the No-Action Alternative, there would be no impacts to land uses, natural, human health, social, economic, or cultural resources from construction and operation of a railroad in Nevada for shipments of spent nuclear fuel, high-level radioactive waste, and other materials from an existing rail line to a geologic repository at Yucca Mountain.

In the event that DOE were not to select a rail alignment in the Caliente corridor or in the Mina rail corridor, the future course that it would pursue to meet its obligations under the NWPA is uncertain.

S.3.3 Issues Raised by the Public

S.3.3.1 PUBLIC SCOPING

DOE provided two public scoping periods for the Rail Alignment EIS (the first between April 8 and June 1, 2004; the second between October 13 and December 12, 2006). DOE solicited written comments and held five public scoping meetings in Nevada in May 2004 (69 *FR* 18565).

In May 2006, the Walker River Paiute Tribal Council informed DOE that it would allow DOE to evaluate the environmental impacts of transporting nuclear waste across the Walker River Paiute Reservation in the Mina rail corridor. Following a preliminary evaluation, DOE solicited written comments on an expanded scope of the Rail Alignment EIS, and held one public scoping meeting in Washington, D.C., in October 2006, and eight in Nevada during November 2006 (71 *FR* 65785). In addition to publications in the *Federal Register*, DOE extensively advertised all meetings in a broad range of other media such as newspapers, letters, and press releases.

DOE received more than 4,100 comments from the first scoping period and nearly 800 from the second. Most of the comments DOE received during the second scoping period were similar to those from the first.

A number of commenters mentioned a variety of alternative segments that either should be considered or dismissed. DOE considered changes to alternative segments identified in the Notices of Intent, considered suggested new alternative segments, added some alternative segments, and adjusted or eliminated some alternative segments. Some commenters expressed concern about environmental resources to be considered that encompassed land-use issues, some specific land-use suggestions, air quality, socioeconomics, health and safety. DOE has conducted extensive analysis to encompass these issues. Other commenters expressed support for public or commercial use of the proposed rail line, and some commenters expressed the opposite viewpoint. DOE has therefore also analyzed a Shared-Use Option to allow a decision to be made on shared use. Various commenters noted best management practices and mitigation issues surrounding impacts associated with the construction and operation of the railroad (for example, to livestock, waterways and washes, and mining). In response DOE has developed a series of mitigation measures to avoid, minimize, rectify, reduce, and/or compensate for potential impacts, such as limiting fencing on public lands to those areas where grazing permittees might request it for livestock safety, positioning temporary pipelines so they would not obstruct natural drainage channels, and notifying all patented minerals lessees and claimants, and consulting with owners of active local mines and mining claims to ensure that impacts are minimized during construction. In addition, DOE and the BLM have solicited comments on potential mitigation measures from grazing permittees along the proposed rail line and considered these when developing mitigation measures.

Other commenters suggested that DOE identify and analyze the entire infrastructure necessary to construct and operate the proposed rail lines, including construction camps, ballast sources, borrow and fill areas, access roads, rail yards, maintenance facilities, and an operations center. DOE has done so. Commenters requested inclusion of detailed maps and plans, and to that end DOE has prepared a detailed map atlas as a reference to the Rail Alignment EIS. Comments specifically addressing the Mina rail alignment suggested that the scope of analysis should be from Hazen to Yucca Mountain. DOE has analyzed environmental impacts from Hazen to Yucca Mountain in the Rail Alignment EIS.

DOE considered the content all comments received during both public scoping periods in determining the scope of the Rail Alignment EIS.

S.3.3.2 TRIBAL UPDATE MEETINGS

DOE held a Tribal update meeting on June 2, 2004, to obtain comments from Tribal representatives from the Consolidated Group of Tribes and Organizations composed of 17 tribes and organizations with traditional ties to the Yucca Mountain area that have appointed representatives to represent their respective tribal concerns and perspectives. During the second scoping comment period for the Rail Alignment EIS, DOE held another meeting for the Consolidated Group of Tribes and Organizations on November 29, 2006, in Pahrump, Nevada. The Department considered all comments submitted during the meetings in the development of the scope of the EIS. Commenters called for continued consultation with tribes that would be culturally affected by the transportation of spent nuclear fuel and high-level radioactive waste. DOE is committed to continuing the consultation process throughout the development of the Rail Alignment EIS and plans to continue consultation with American Indians to ensure that tribal concerns and perspectives are considered.

S.3.3.3 BLM PUBLIC MEETINGS

On December 29, 2003, the BLM announced the receipt of an application from DOE requesting that approximately 1,249 square kilometers (308,600 acres) of public land in Nevada be withdrawn from surface and mineral entry for a period of 20 years to evaluate the land for the potential construction, operation, and maintenance of a rail line for the transportation of spent nuclear fuel and high-level radioactive waste (*Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada* (68 *FR* 74965, December 29, 2003). The *Federal Register* notice stated that the BLM had segregated the land from surface and mineral entry for up to 2 years while various studies and analyses are conducted to support a final decision on the withdrawal application. In a May 21, 2004, Notice of Public Meetings (69 *FR* 29323), the BLM invited the public to submit written comments on the proposed withdrawal and possible land-use plan amendments by June 30, 2004. The BLM held two public scoping meetings on the proposed withdrawal and possible land-use plan amendments. On January 10, 2007, the BLM issued a notice (72 *FR* 1235) of a DOE application for the withdrawal of 842 square kilometers (208,037 acres) of land (an additional 278 square kilometers [68,646 acres] of public lands for the Caliente rail corridor and 564 square kilometers [139,391 acres] of public lands for evaluation along the Mina rail corridor. Many of the public comments submitted to the BLM were similar to those at submitted DOE scoping meetings. DOE considered all the comments the BLM received in developing the scope for the Rail Alignment EIS; some of those comments led to the actions already described.

S.3.3.4 ADDITIONAL OUTREACH

In addition to the DOE and BLM scoping meetings, and comments from the Tribal Update Meetings, DOE used other information to define the scope of the Rail Alignment EIS. DOE worked with the Central Nevada Community Protection Working Group to gain the assistance of Nye, Lincoln, and Esmeralda Counties and the City of Caliente in obtaining information to support the EIS. Under a cooperative agreement with DOE, Lincoln County led an effort to interview landowners, business owners, county officials, elected officials, and other potentially interested parties. Comments received during these interviews closely mirrored the comments submitted to both DOE and the BLM. In addition, Nye County surveyed property owners along the Caliente rail corridor under a cooperative agreement with DOE. The surveys solicited comments on potential impacts of the proposed rail line and possible measures to mitigate those impacts. Also, the BLM interviewed grazing permittees along the Caliente rail corridor and asked for their comments on potential impacts associated with construction and operation of the proposed rail line and for their input on potential mitigation measures. DOE used the information obtained through these interviews and surveys to help define the scope of this Rail Alignment EIS.

S.3.4 Environmental Impacts

In the Rail Alignment EIS, potential impacts are identified as either direct or indirect, and either short term or long term. Where practicable, DOE has quantified potential impacts. In cases where it is not practical to quantify impacts, DOE provides a qualitative assessment of potential impacts. In the Rail Alignment EIS, DOE has used the following descriptors to qualitatively characterize impacts where quantification of impacts was not practical:

- ***Small***. Environmental effects would not be detectable or would be so minor that they would neither destabilize nor noticeably alter any important attribute of the resource.
- ***Moderate***. Environmental effects would be sufficient to alter noticeably, but not to destabilize, important attributes of the resource.
- ***Large***. Environmental effects would be clearly noticeable and would be sufficient to destabilize important attributes of the resource.

DOE would meet all applicable regulatory requirements during construction and operation of the rail line, and would implement an array of best management practices to help ensure compliance with requirements. In addition, DOE could implement measures to mitigate impacts remaining after final design and compliance with regulatory requirements and implementation of best management practices. Sections S.7.1 through S.7.15 summarize environmental impacts for each resource area DOE analyzed.

S.3.4.1 PHYSICAL SETTING

DOE examined the region of influence for physical setting to determine the potential for impacts on physiography, geology, and soils. The region of influence for physical setting includes the areas that would be directly and indirectly affected by construction and operation of the proposed railroad, and incorporates the nominal width of the rail line construction right-of-way (300 meters [1,000 feet] centered on the rail alignment). It also includes the footprints of construction camps, quarry sites, facility sites, access roads, and water wells that would be outside of the nominal width of the construction right-of-way.

DOE determined that land disturbance would be 55 to 61 square kilometers (14,000 to 15,000 acres) for the Caliente rail alignment and 40 to 48 square kilometers (9,900 to 12,000 acres) for the Mina rail alignment. Lands that are currently relatively undisturbed would be extensively graded, which would result in topsoil loss and increased potential for erosion. However, DOE would implement best management practices to minimize erosion and sedimentation during construction activities. DOE assessed that impacts from soil erosion would be small.

Perlite, a locally important mineral, occurs in the area of the Caliente rail alignment Caliente and Eccles alternative segments, and other minerals, such as limestone, metallic commercial minerals, and geothermal resources have been identified in some nearby mountains. Although no mineral resources would be removed, placement of the rail line could reduce the availability of perlite or limestone for mining. The Goldfield alternative segments would cross mining areas and could limit the boundaries for mining if mineral resources extend under the rail line.

Neither railroad construction nor operations would reduce the availability for mining of metallic minerals that have been identified in surrounding mountains. The Montezuma alternative segments would cross mining areas in the Goldfield Hills area, and limit the boundaries for mining if mineral resources extended under the rail line.

Along the Caliente rail alignment, construction in the Caliente or Eccles alternative segment and Caliente common segment 1 would result in a small loss of up to 1.4 kilometers (340 acres) of prime farmland soil. These prime farmland soils are found in isolated pockets and are unfarmed. In the Mina rail alignment, construction of Schurz alternative segment 1, 4, 5, or 6 would impact soils characterized as prime farmland directly adjacent to the banks of the Walker River. These areas are not farmed and DOE expects no change in their current agricultural land use. DOE expects that impacts to prime farmland soils would be small (up to 0.014 square kilometer [3.5 acres] would be lost). There would be a potential for leaks and spills that could contaminate soils during railroad operations; however, DOE would implement best management practices and consider mitigation measures to reduce any impacts.

The Shared-Use Option would require the construction of additional rail sidings within the rail line construction right-of-way in areas of relatively flat terrain. DOE determined that implementation of the Shared-Use Option would increase the surface disturbance area by less than 0.1 percent for either the Caliente or Mina rail alignment, and would add no impacts to physical setting beyond the permanent alterations already described.

S.3.4.2 LAND USE AND OWNERSHIP

The region of influence for land use and ownership is the nominal width of the rail line construction right-of-way and includes all private land, American Indian land, and public land fully or partially within that area. It also includes lands outside the nominal width of the rail line construction right-of-way, where there would be facilities, quarries, and wells to support construction and long-term operation of the railroad.

DOE would need to gain access to private land—up to 0.72 square kilometer (178 acres) for the Caliente rail alignment and up to 0.59 square kilometer (146 acres) for the Mina rail alignment. For the Caliente rail alignment, another possible 1.15 square kilometers (284 acres) of private land would be required to accommodate support facilities. Neither rail alignment would displace existing or planned land uses over a substantial area, nor would they substantially conflict with applicable land-use plans or goals. The areas with the highest density of private land either rail alignment would cross are the City of Caliente (Caliente rail alignment) and Goldfield (both rail alignments). For the Caliente alternative segment, some structures at the existing Union Pacific train yard and three structures along the former Pioche and Prince Branchline would need to be demolished or relocated. The Caliente alternative segment would also occupy portions of the access road and parking lot of the Caliente Hot Springs Motel. The motel could be adversely affected because of the rail line's proximity. Alternative segments near Goldfield would cross vacant private land, including patented mining claims and state and county land.

In response to concerns from the Timbisha Shoshone Tribe, DOE avoided Timbisha Shoshone Trust Lands during the development of the Caliente and Mina rail alignments. The closest rail line segment along either rail alignment would be common segment 5, which would be approximately 3 kilometers (2 miles) east of Timbisha Shoshone Trust Lands near Scottys Junction. DOE initially studied the Mina rail alignment with the permission of the Walker River Paiute Tribe and the Department designed the Schurz alternative segments with the aim of removing the existing Department of Defense Branchline through the town of Schurz in accordance with the Tribe's request. The Schurz alternative segments would utilize up to 0.5 percent of the land area of the Reservation (up to 5.3 square kilometers [1,300 acres]).

The Caliente rail alignment would utilize up to 162 square kilometers (40,000 acres) of BLM-administered land out of a total construction footprint of approximately 170 square kilometers (41,000 acres), and the Mina rail alignment would utilize up to 113 square kilometers (28,000 acres) of BLM-administered land out of a total construction footprint of approximately 125 square kilometers (31,000 acres).

The Mina rail alignment would cross 4.6 square kilometers (1,150 acres) of land within the Hawthorne Army Depot near its northern border, where it would not pose a conflict with the Depot's mission or land uses. Railroad construction would result in surface disturbance across a number of grazing allotments on BLM-administered land. However, because the land would be restored after the construction phase and the operations right-of-way would be smaller than the construction right-of-way, long-term impacts would be small. Individual rail line segments would result in less than a 2-percent loss of animal unit months (a measure of the amount of forage needed to sustain one animal for 1 month) across all affected allotments for either rail alignment. The rail line could require livestock on some allotments to adjust to new routes to access water and forage. Generally, livestock could learn new routes and acclimate to and cross the rail line. The rail line could pose additional risk to ranching operations because livestock could be struck by passing trains. DOE or the railroad's commercial operator would reimburse ranchers for such losses, as appropriate.

Most of the local mining activity along both the Caliente and Mina rail alignments would be outside the rail line construction right-of-way. DOE would need to negotiate the surface rights to cross the few affected unpatented mining claims the rail line would intersect. Along the Caliente rail alignment, the rail line would intersect unpatented mining claims along South Reveille alternative segments 2 and 3; Caliente common segment 3; Goldfield alternative segments 1, 3, and 4; Oasis Valley alternative segments 1 and 3; and common segment 6. The Mina rail alignment would intersect unpatented mining claims along Montezuma alternative segments 1, 2 and 3; Oasis Valley alternative segments 1 and 3; and common segment 6. The rail line could be affected by or affect underground mining tunnels or shafts. During the final engineering design, DOE would perform a survey to verify the locations of mining tunnels and shafts and implement measures to avoid adverse impacts.

Rail alignments have been developed to avoid Wilderness Areas and other scenic and recreational areas. Under either implementing alternative, DOE would construct crossings to prevent the rail line from obstructing access to private and public land. While there could be temporary road closures or detours during the construction phase, there would be no impact to land access during the operations phase. In addition, organized off-highway vehicle events permitted in the past by the BLM might need to alter their routes to avoid the rail line.

The rail alignments would cross a number of utility rights-of-way. DOE would negotiate crossing agreements with right-of-way holders and the BLM. DOE would protect existing utilities from damage so that disruption to utility service or damage to lines would be at most small and temporary. The project would require a BLM right-of-way outside existing BLM planning corridors for utilities; this right-of-way would be outside of right-of-way avoidance areas. Under the longest potential routes, approximately 25 percent of the Caliente rail alignment and 44 percent of the Mina rail alignment (new construction on BLM-managed land) would fall within existing planning corridors. In addition, to avoid the proliferation of new rights-of-way, the BLM could elect to grant future rights-of-way for new utilities adjacent to the proposed rail line.

S.3.4.3 AESTHETIC RESOURCES

DOE considered the region of influence for the aesthetic resources as the viewshed around all common segments, alternative segments, and facilities along the Caliente and Mina rail alignments. To ensure that seldom-seen views were included in this analysis, DOE used a conservative region of influence extending 40 kilometers (25 miles) on either side of the centerline of all common segments and alternative segments, and around facilities. Most of the lands that would be affected by the Proposed Action are BLM-administered public lands, including those on which the proposed railroad would be constructed. For this reason, DOE used BLM visual resource management classifications and contrast rating methodologies to evaluate aesthetic impacts to the surrounding viewshed. The BLM assigns visual resource management classes to lands under it jurisdiction, based on scenic quality and other factors, that range from Class I to Class IV, with Class I representing the highest visual values. Each class comes with specific visual resource management objectives that indicate the levels of project-related contrast that are acceptable. In this analysis, the primary basis for identifying potential adverse impacts to aesthetic resources was inconsistency with these BLM visual resource management objectives. The Department assessed the potential visual contrast between existing conditions and conditions expected during the project from key locations and compared these levels of contrast with the visual resource management objectives associated with the BLM classifications of the surrounding viewshed.

Along both the Caliente and the Mina rail alignments, DOE found that the contrast that would be caused by the rail line and support facilities would remain consistent with BLM visual resource management objectives during the operations phase, but could be inconsistent in certain locations during the construction phase. Along the Caliente rail alignment, a conveyor crossing of U.S. Highway 93 near the Caliente-Indian Cove location of the Staging Yard and along some portions of Garden Valley alternative segments 1, 2, 3, and 8, construction would temporarily not meet BLM visual resource management objectives for Class II areas.

Along the Mina rail alignment, DOE determined that construction of Schurz alternative segment 6 crossing of U.S. Highway 95 on the Walker River Paiute Reservation would temporarily not meet BLM objectives for Class III areas.

Overall, DOE anticipates that short-term visual impacts during the construction phase would range from small to large, and long-term impacts during the operations phase would range from small to moderate and would be consistent with applicable BLM visual resource management objectives.

Impacts to aesthetic resources during the construction phase under the Shared-Use Option would generally be the same as those under the Proposed Action without shared use. Construction of additional sidings would create small impacts to the visual setting because of the short duration of construction. Impacts to aesthetic resources during the construction phase under the Shared-Use Option for both the Caliente and Mina rail alignments would be generally the same as those under the Proposed Action without shared use. Construction of additional sidings would create small impacts to the visual setting because of the short duration of construction.

S.3.4.4 AIR QUALITY AND CLIMATE

The air quality and climate region of influence for the Caliente rail alignment encompasses Lincoln, Nye, and Esmeralda Counties. The air quality and climate region of influence for the Mina rail alignment encompasses Lyon, Mineral, Esmeralda, and Nye Counties, a small portion of Churchill County near Hazen, and the Walker River Paiute Reservation, the bulk of which lies within Mineral County with smaller portions within Lyon and Churchill Counties. The Caliente and Mina rail alignments would cross desert and semi-desert areas that generally have abundant hours of cloud-free days, low annual precipitation, and large daily ranges in temperature. All portions of the Caliente and Mina rail alignments would be within areas classified by the U.S. Environmental Protection Agency as in attainment for all National Ambient Air Quality Standards (NAAQS).

DOE examined emissions inventories to determine county-level increases in air pollutant emissions, and performed air quality simulations to determine potential changes in air pollutant concentrations at specific (population-center) receptors. An adverse impact to air quality would occur if it were shown that a proposed action would conflict with or obstruct implementation of a state or regional air quality management plan, or would exceed an NAAQS primary standard or contribute to existing or projected exceedances. DOE determined air pollutant concentrations that could result from railroad construction and operation along the Caliente and Mina rail alignments using the Environmental Protection Agency-recommended model for regulatory applications (AERMOD dispersion modeling system version 07026). To assess potential air quality impacts from railroad construction and operations along the Caliente rail alignment, DOE modeled emissions and resultant concentrations of criteria air pollutants where there are two population centers that would be near the rail line: Caliente in Lincoln County and Goldfield in Esmeralda County, and then compared the modeling results to the National Ambient Air Quality Standards. DOE likewise modeled air quality for the Mina rail alignment near the population centers that would be relatively close to the rail line: Schurz, Hawthorne, and Mina in Mineral County; and Silver Peak and Goldfield in Esmeralda County. DOE also performed modeling for the Caliente rail alignment for construction-related activities at a potential quarry site northwest of Caliente and a potential quarry site in South Reveille Valley; and for the Mina rail alignment at the potential Garfield Hills and Malpais Mesa quarry sites.

The analysis showed that criteria air pollutant concentrations along the Caliente or Mina rail alignments would not exceed the NAAQS during the construction or operation phases, with the following possible exceptions. During the construction phase for the Caliente rail alignment, the 24-hour NAAQS for PM_{10} (particulate matter with an aerodynamic diameter equal to or less than 10 micrometers) could be exceeded during quarry operations in South Reveille Valley. During the construction phase for the Mina rail alignment, the 24-hour NAAQS for both PM_{10} and $PM_{2.5}$ (particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers) could be exceeded near the construction right-of-way at Mina and Schurz during the relatively short (less than 6 months) construction period, at the Staging Yard at Hawthorne, and at the potential Garfield Hills quarry. However, DOE would be required to obtain a Surface Area Disturbance Permit Dust Control Plan issued by the State of Nevada Department of Environmental Protection prior to quarry and Staging Yard development. It is likely that requirements in the plan would reduce fugitive dust emissions, thus reducing the possibility of an NAAQS exceedance.

For the Caliente rail alignment, DOE determined that the highest increase in air pollutant emissions would occur during the construction phase. During the operations phase for the Caliente rail alignment, the highest increase would occur in the vicinity of the railroad operations support facilities. The highest increase in criteria air pollutant emissions would be for nitrogen oxides in Nye County, where construction emissions could be as much as 8,100 metric tons (8,900 tons) per year over the county's 2002 annual nitrogen oxides emissions. However, these emissions would be distributed over the entire length of the rail alignment in the county and no air quality standard would be exceeded.

For the Mina rail alignment, DOE determined that the highest increase in air pollutant emissions would occur during the construction phase. During the operations phase for the Mina rail alignment, the highest increase in air emissions from railroad operations would occur in the vicinity of the operations support facilities. The highest increase in criteria air pollutant emissions would be for nitrogen oxides in Esmeralda County, where construction emissions could be 3,570 metric tons (3,940 tons) per year higher than the 2002 county-wide nitrogen oxides emissions. However, these emissions would be distributed over the entire length of the rail alignment in the county and no air quality standard would be exceeded.

DOE determined that railroad construction and operations along either the Caliente or Mina rail alignment would not cause conflicts with state or regional air quality management plans.

Under the Shared-Use Options for both the Caliente and Mina rail alignments**,** total emissions would be increased marginally. DOE anticipates that impacts to air quality along the Caliente or Mina rail alignment under the Shared-Use Option would be similar to those under the Proposed Action without shared use.

S.3.4.5 SURFACE-WATER RESOURCES

The region of influence for surface-water resources would be limited in most cases to the nominal width of the construction right-of-way within the Caliente rail alignment or the Mina rail alignment. Railroad construction and operations along either rail alignment would potentially result in both direct and indirect impacts to surface-water resources. Many of these impacts are common impacts that would occur along the entire length of the rail alignments. Direct impacts would result from temporary or permanent grading, dredging, re-routing, or filling of surface-water resources. Indirect impacts would include potential increases in surface flow and non-point source pollution resulting from runoff from areas where surface grades and characteristics would be changed.

DOE anticipates that during the construction phase along the Caliente rail alignment, the Staging Yard and the Interchange Yard along either the Caliente or the Eccles alternative segment would require channelization of natural drainage surface waters to keep water out of railroad operations support facility sites. Changes in drainage patterns could result in changes in erosion and sedimentation rates or locations. However, in all instances where the rail alignment would come close to or cross a surface-water feature, impacts would be substantially minimized by the implementation of engineering design standards and best management practices.

The Caliente alternative segment is adjacent to wetlands and some wetland fill would be unavoidable. DOE proposes to construct the Caliente alternative segment over the abandoned Union Pacific Railroad roadbed, in part to minimize filling wetlands. Of the 0.28 square kilometer (68 acres) of wetlands delineated along the rail alignment, 0.05 square kilometer (12 acres) would be filled to construct the rail line. DOE could modify the final design of the rail line to avoid additional wetlands, such as those adjacent to the old rail roadbed along Meadow Valley Wash, by using a slightly narrower construction footprint; however, this would only slightly reduce the area of wetlands that would be filled.

Approximately 0.09 square kilometer (22 acres) of wetlands could be filled to construct a quarry siding at potential quarry CA-8B along the Caliente alternative segment. Approximately 0.19 square kilometer (47 acres) of wetlands would be filled for construction of the Staging Yard at Indian Cove near Caliente. The original wetland meadow area would be drained and built up above the level of the floodplain. Constructing an active drainage system and a channel around the site to keep the area dry and in a stable condition might be necessary. The proposed channel around the site would be approximately 1,680 meters (5,500 feet) long. These actions would require permits from the U.S. Army Corps of Engineers, and compliance with Section 404 of the Clean Water Act for stormwater runoff control measures.

The Eccles alternative segment Interchange Yard would require portions of Clover Creek to be filled to elevate the site out of the floodplain. For a length of approximately 1,400 meters (4,600 feet) along the bed of this ephemeral creek (for construction of the interchange tracks) the fill would extend approximately 7.6 to 15 meters (25 to 50 feet) into the creek bed. For a length of approximately 900 meters (2,900 feet) on the east end and 600 meters (2,000 feet) on the west end of the interchange tracks, (for construction of the interchange siding), the fill would extend approximately 8 meters (25 feet) into the creek. The total area that would be filled within the confines of Clover Creek would be approximately 0.033 square kilometer (8.2 acres).

Along the Mina rail alignment, there could be temporary impacts from disturbance of about 2,000 square meters (0.55 acre) of wetlands along Schurz alternative segments 1 and 4, and 3,000 square meters (0.73 acre) of wetlands along Schurz alternative segments 5 and 6 during construction of a bridge at the rail line crossing of the Walker River. Permanent fill or loss of wetlands would total about 20 square meters (0.005 acre) for Schurz alternative segments 1 and 4, or 28 square meters (0.007 acre) for emplacement of about 14 piers for Schurz alternative segments 5 and 6.

While some changes would be unavoidable, DOE would take steps to ensure that the alterations to natural drainage, sedimentation, and erosion processes would not increase future flood damage, increase the impact of floods on human health and safety, or cause identifiable harm to the function and values of floodplains. The Department would implement best management practices, including erosion control measures such as the use of silt fences and flow-control devices to reduce flow velocities and minimize erosion.

S.3.4.6 GROUNDWATER RESOURCES

The generally arid climate characterizing the southern Nevada region is consistent with a lack of shallow groundwater underlying much of the length of the Caliente and Mina rail alignments. The region of influence for groundwater resources includes portions of the aquifers that would be affected by groundwater withdrawals that DOE would make to obtain the water needed for railroad construction and operations. Groundwater resource features evaluated through impacts analysis include existing wells and nearby springs. Within the Caliente rail alignment region of influence, groundwater withdrawals for irrigation and agricultural purposes currently represent most of the groundwater usage. Within the Mina rail alignment region of influence, public supply-municipal, stock watering, and mining uses currently represent most of the groundwater usage.

To supply the approximately 7.5 billion cubic meters (6,100 acre feet) of water needed during the construction phase along the Caliente rail alignment, DOE estimates that it would need to install approximately 150 to 176 new wells. To supply the approximately 7.4 billion cubic meters (5,950 acre feet) of water needed during the construction phase along the Mina rail alignment, DOE estimates that it would need to install between approximately 77 and 110 new wells.

DOE analyses indicated that the effects of groundwater withdrawals from the proposed water-supply wells at the range of production rates that could be required to support a 4-year construction phase along either rail alignment would be localized in nature and extent, and hydrogeologic effects would be temporary. DOE determined that the short-term impacts caused by water withdrawals would be a series of localized drawdown cones of depression within the host aquifer surrounding each pumped well. DOE does not anticipate that proposed groundwater withdrawals would conflict with known regional or local aquifer management plans or the goals of governmental water authorities, and impacts from groundwater withdrawals on downgradient groundwater basins (or hydrographic areas) would tend to be very small.

DOE anticipates that the impact to groundwater resources from contaminants that might be released by construction equipment during the construction phase or during railroad operations would be small because of generally deep groundwater beneath most of the Caliente and Mina rail alignments.

Railroad operations along the Mina and Caliente rail alignments would result in small potential impacts to groundwater resources. The Department would discontinue operating most of the wells needed during the construction phase because there would not be a continued need for large-scale water production to support railroad operations. Additionally, groundwater withdrawal rates for those wells left in place to support operations would be expected to be very low.

Overall, water demands for railroad construction and operations along the Caliente or the Mina rail alignment would represent a small portion of current water-use amounts in their respective regions of influence, which would likely continue to be dominated by irrigation and agricultural withdrawals, with possibly increasing urban use from water transfers to the Las Vegas area. DOE determined that impacts to ground subsidence or groundwater quality that could result from railroad construction and operations along either rail alignment would be small.

Under the Shared-Use Option for either rail alignment, commercial-only facilities would require water for daily operation. The additional impacts to groundwater resources would be small, and overall would be similar to those described for the Proposed Action without shared use.

S.3.4.7 BIOLOGICAL RESOURCES

DOE considered two areas of assessment in analyzing the affected environment for biological resources: a region of influence consisting of the nominal width of the construction right-of-way and a larger study area consisting of a 16-kilometer (10-mile)-wide area extending 8 kilometers (5 miles) on either side of the centerline of the rail alignment to ensure the identification of sensitive habitat areas and transient or migratory wildlife. The Caliente and Mina rail alignments are situated within the "cold" Great Basin Desert that covers most of central and northern Nevada and the "hot" Mojave Desert that covers most of southern Nevada and much of southeastern California. Although the two deserts are distinguished climatically, they are also distinguished by their predominant vegetation and vegetation communities.

For both the Caliente rail alignment and the Mina rail alignment, DOE determined that there would be some indirect adverse impacts due to the potential for the introduction and spread of noxious and invasive weed species during construction activities; however, the Department would minimize or avoid impacts through implementation of best management practices and BLM-prescribed methods. DOE concluded that there would be a small mostly short-term indirect impact to game species during railroad construction and operations along either rail alignment, due to temporary displacement causing pressure on other areas for habitat and forage. There could be small direct impacts due to a small loss of forage from the removal of vegetation to construct the proposed railroad. In addition, railroad operations could result in possible wildlife collisions with trains and disturbance from noise caused by passing trains. However, these impacts would not impact the viability of any game species' population.

DOE determined that federally listed species potentially present along the Caliente and Mina rail alignments could include the Mojave Desert tortoise, southwestern willow flycatcher, yellow-billed cuckoo, Lahontan cutthroat trout, and Ute ladies'-tresses orchid. There would likely be small short-term indirect impacts to some BLM and State of Nevada special status animal species because they might avoid the area of the rail alignment or be displaced during construction activities. Any potential direct impact would be due to habitat fragmentation and disturbance and possible injury or loss of individuals of a species from collision with trains. There could be indirect impacts on small mammals as a result of possible changes to predator/prey interactions due to the construction of towers and other structures that would provide new perch habitat for raptors and other predatory birds. DOE determined that potential impacts from noise disturbance to migratory birds would be small and short term during construction and small from permanent habitat loss during the operations phase. Potential direct impacts to desert tortoise would be due to fragmentation of habitat and the possible crushing of occupied burrows during construction of common segment 6 and the Rail Equipment Maintenance Yard. Although these losses would be a minor decrease in the number if individual tortoises in the vicinity of the railroad, long-term survival of this species would not be affected. For both the Caliente rail alignment and Mina rail alignment, DOE determined that impacts to herd management areas and potential impacts to individual wild horses or burros would be small and would not significantly affect the management strategies utilized within the herd management areas.

DOE anticipates that for the Caliente rail alignment there would be short-term and long-term impacts to wetlands and riparian habitats from construction of the Caliente alternative segment and either of the potential Staging Yard locations (Indian Cove and Upland), and the Eccles alternative segment. Impacts from constructing the Caliente alternative segment would be mostly short term and small, because the rail line would be constructed over an abandoned rail roadbed and limited to existing bridge crossings that would require modifications. The Eccles alternative segment would result in a small short-term impact to riparian habitat and limited to bridge construction over Meadow Valley Wash. Construction of the Indian Cove Staging Yard could result in a moderate impact compared to the Upland option due to topographic constraints that could require possible draining and filling of the wetland. The proposed Eccles Interchange Yard could result in mostly small direct short-term impacts due to a small loss of riparian vegetation, and small short-term indirect impacts with the potential for change in stream flow and increase in sedimentation. DOE determined there would be a moderate impact to wildlife habitat along Garden Valley alternative segments 1 and 3. Localized and minor loss of roosting and foraging habitat for the southwestern willow flycatcher and western yellow-billed cuckoo could occur from construction of the Caliente alternative segment; however, because these species do not nest along the alignment, impacts would be small and limited to transient individuals.

DOE determined that for the Mina rail alignment there would be direct short-term impacts to riparian vegetation from construction of Schurz alternative segment 1, 4, 5, or 6 due to bridge construction over the Walker River. There would be no long-term impacts on riparian vegetation along the Walker River as a result of constructing any of the Schurz alternative segments. There would be short-term moderate impacts to wildlife habitat at the potential Malpais Mesa quarry site. Construction of the Walker River Bridge for Schurz alternative segment 1, 4, 5, or 6 could result in a moderate short-term indirect impact on Lahontan cutthroat trout; however, DOE could mitigate any anticipated impact.

Under the Shared-Use Option, there would be more train traffic; therefore, DOE anticipates wildlife interactions with train traffic (collisions, change in movement patterns, altered behavior, and nest abandonment) to be slightly increased. Nevertheless, DOE anticipates that this slight increase in train traffic would result in small impacts to the wildlife communities. The existing rail alignment design can accommodate shared use with little additional construction (a few sidings) and the Department does not anticipate any other additional impacts above those discussed.

S.3.4.8 NOISE AND VIBRATION

DOE analyzed potential impacts from noise based on current ambient noise levels, noise modeling for future activities (proposed railroad construction and operations), and identification of changes in noise levels at receptors within the regions of influence. The region of influence for noise and vibration for construction and operations of the railroad along either the Caliente or the Mina rail alignment includes the construction right-of-way and extends out to variable distances along each rail alignment (depending on several factors, including the number of trains per day, ambient noise level, train speed, and number of rail cars).

For operation of trains during the construction and operations phases, DOE analyzed noise impacts under established STB impact criteria (a noise level of 65 DNL or greater, with a 3 dBA or greater increase from the baseline). For noise impacts from construction activities, DOE used U.S. Department of Transportation, Federal Transit Administration, methods and construction noise guidelines. To evaluate potential vibration impacts from construction and operation activities, DOE used Federal Transit Administration building vibration damage and human annoyance criteria.

DOE determined that railroad construction and operations along the Caliente rail alignment would lead to an unavoidable increase in ambient noise from construction activities and passing trains. Noise from trains might be noticeable as new noise in residential areas near the rail line in Caliente and Goldfield. Because there is already a substantial amount of train activity in Caliente, additional train noise would be less noticeable than in other areas where there is currently no train activity and no train noise. For construction activities, noise levels in Caliente would be higher than Federal Transit Administration construction noise guidelines and would result in a temporary unavoidable impact. Train noise during the construction and operations phases would not cause adverse noise impacts because noise levels at receptors would be lower than STB adverse impact criteria.

DOE determined that railroad construction and operations along the Mina rail alignment could lead to an unavoidable increase in ambient noise from passing trains in areas of Nevada that are mostly uninhabited. Noise from trains might be noticeable as new noise in residential areas near the rail line in Silver Springs, Silver Peak, Mina, and Goldfield. Because there is already some train activity in Silver Springs, additional train noise would be less noticeable there than in other areas where there is currently no train activity and no train noise. Construction of any of the Schurz alternative segments would eliminate future noise and vibration associated with operation of the existing Department of Defense Branchline through Schurz. However, there would be construction noise associated with removal of this existing rail line, although this noise would be temporary and no adverse impact would be expected.

For construction activities, noise levels along the Mina rail alignment would be lower than Federal Transit Administration construction noise guidelines. For train noise during the construction phase, there would be temporary adverse impacts at receptors in Silver Springs. For train noise during the operations phase, estimated noise levels at 8 receptors in Silver Springs and 1 in Wabuska would be higher than impact criteria; therefore, there would be adverse impacts from noise associated with railroad operations at those locations. However, DOE would investigate mitigation methods for these nine locations. Mitigation methods, where reasonable and feasible, could include building sound insulation or the development of a Quiet Zone, which would allow the rail operator to reduce horn noise at specific crossings.

During the construction and operations phases along either the Caliente or Mina rail alignment, vibration levels would not exceed the Federal Transit Administration damage criteria for extremely fragile historic buildings. Therefore, DOE would expect no building damage due to vibration. In addition, train-generated vibration levels would be lower than Federal Transit Administration human annoyance criterion.

Under the Shared-Use Option for either rail alignment, increased rail traffic could result in noise impacts similar to the impacts described for the Caliente and Mina rail alignments without shared-use. Increased operations would not affect vibration impacts because vibration is evaluated on a maximum-level basis only.

S.3.4.9 SOCIOECONOMICS

DOE assessed impacts to socioeconomic conditions of in relation to population, housing, employment and income, and public services over the region of influence for the Caliente rail alignment within Lincoln, Esmeralda, Nye, and Clark Counties, and over the region of influence for the Mina rail alignment within Churchill, Lyon, Mineral, Nye, Esmeralda, and Clark Counties, the combined area of Washoe County and Carson City, and the Walker River Paiute Reservation.

The social and economic activities and changes associated with railroad construction along either rail alignment would include a brief elevation in project-related employment; increases in real disposable income; increases in state and local spending; increases in gross regional product; population increases; slower rate of growth in the level of employment as railroad project activities moved from construction to operations; and possible small stresses on transportation, including small traffic-delay impacts on road traffic at grade crossings. The percentage values of such changes would be low and DOE has assessed such impacts to be generally small.

Changes associated with railroad operations along either rail alignment would include increases in project-related employment (particularly associated with railroad facilities); slight population increases; possible small stresses on transportation, including small traffic-delay impacts on road traffic at grade crossings; some pressure on housing; and possible strains on public services (schools, health care, fire-protection) in southern Nye County where the Cask Maintenance Facility, Rail Equipment Maintenance Yard, and possibly the Nevada Railroad Control Center and the National Transportation Operations Center would be located. The percentage values of such changes would be low and DOE has assessed such impacts to be generally small to moderate.

Under the Shared-Use Option for either rail alignment, there would be little increase in impacts beyond those described for the Proposed Action without shared use. Based on the lengths of track involved under the Shared-Use Option, the incremental impacts to traffic from constructing the additional sidings would be a small fraction of the overall impacts for rail line construction under the Proposed Action without shared use. Thus, impacts to the transportation infrastructure under the Shared-Use Option would be small. Traffic-delay impacts at highway-rail grade crossings from construction trains would be consistent with the delay impacts under the Proposed Action without shared use. These impacts would be small.

S.3.4.10 OCCUPATIONAL AND PUBLIC HEALTH AND SAFETY

S.3.4.10.1 Nonradiological Occupational Health and Safety Impacts

DOE estimated nonradiological occupational health and safety impacts in relation to worker exposures to physical hazards and nonradioactive hazardous chemicals during the construction phase. DOE based these estimates on the number of hours worked and occupational incident rates for total recordable cases, lost workday cases, and fatalities.

Construction and operations workers might be exposed to physical hazards and to nonradiological hazardous chemicals related to operation and maintenance of construction equipment, rail line equipment, and facilities equipment, including maintenance of casks and maintenance-of-way activities, including welding, metal degreasing, painting, and related activities. Occupational health and safety impacts might also result from worker exposure to fuels, lubricants, and other materials used in railroad construction, operations, and maintenance.

The recorded incident rates of these exposure hazards during construction work at the Yucca Mountain Site have been small and are anticipated to be small for railroad construction and operations. Dust and soils hazards include potential occupational exposure to hazardous inhalable dust. However, occupational impacts associated with exposure to dust would be expected to be small. DOE would implement measures, such as processing and engineering controls, to reduce exposure to dust. Impacts to construction or operations workers from unexploded ordnance would be small due to implementation of inspection procedures and mitigation measures. Workers might also be exposed to biological hazards including infectious diseases (such as Hantavirus and West Nile Virus) and other biological hazards (such as venomous animals). The recorded incidence rates of these biological hazards are small, and DOE would expect small impacts to construction or operations workers from these biological hazards.

DOE used both qualitative and quantitative components to estimate transportation accident incidents and potential fatalities resulting from vehicular and train accidents.

DOE estimated the following:

- During the construction phase, along both the Caliente rail alignment and the Mina rail alignment, there would be six vehicular-related fatalities.
- During the operations phase along the Caliente rail alignment, there would be eight vehicular-related fatalities; along the Mina rail alignment, there would be seven vehicular-related fatalities.
- During railroad construction and operations along the Caliente rail alignment and the Mina rail alignment, modeling indicates that there would be 16 rail-related accidents and approximately one rail-related fatality.

For the Shared-Use Option, DOE estimated the following:

- During the operations phase along the Caliente rail alignment, there would be eight vehicular-related fatalities; along the Mina rail alignment, there would be seven vehicular-related fatalities.
- During the operations phase along the Caliente rail alignment, there would be 26 rail-related accidents and 4 rail-related fatalities; along the Mina rail alignment, there would be 36 rail-related accidents and 7 rail-related fatalities.
- Nonradiological fatality impacts to workers from industrial hazards from railroad and facility construction and operations along the Caliente rail alignment would be approximately three, and for the Mina rail alignment would be approximately two.

S.3.4.10.2 Radiological Occupational Health and Safety Impacts

Accidents - DOE estimated radiological impacts to workers and the public for incident-free transportation, the risk of transportation accidents, and the impacts of severe transportation accidents. The region of influence for radiological impacts to members of the public during incident-free transportation includes the area 0.8 kilometer (0.5 mile) on either side of the centerline of the rail alignments. The region of influence for occupational radiological impacts during incident-free operation includes the physical boundaries of railroad operations support facilities. For radiological accidents and sabotage, the populations within the region of influence are based on the population within 80 kilometers (50 miles) on either side of the centerlines of the rail alignments.

DOE estimated the following:

- For workers, the radiological impacts were estimated to be 0.34 latent cancer fatalities for the Caliente rail alignment and 0.35 latent cancer fatalities for the Mina rail alignment.
- For workers at the Cask Maintenance Facility, the radiological impacts were estimated to be 0.43 latent cancer fatalities. For workers at the Rail Equipment Maintenance Yard, the radiological impacts were estimated to be 0.0096 latent cancer fatalities.
- For members of the public, the radiological impacts were estimated to be 1.4×10^{-4} latent cancer fatalities for the Caliente rail corridor and 8.5×10^{-4} latent cancer fatalities for the Mina rail alignment.
- For members of the public, the radiological impacts from the Cask Maintenance Facility were estimated to be 7.0×10^{-6} latent cancer fatalities.
- The risk from transportation accidents was estimated to be 1.3×10^{-6} latent cancer fatalities for the Caliente rail alignment and 7.7×10^{-6} latent cancer fatalities for the Mina rail alignment.
- The impacts of the maximum reasonably foreseeable accident were estimated to be 0.0012 latent cancer fatalities in rural areas and 0.46 latent cancer fatalities in suburban areas along the Caliente rail alignment, and 0.0089 latent cancer fatalities in rural areas and 1.2 latent cancer fatalities in suburban areas along the Mina rail alignment. The frequency of this severe accident ranged from 6×10^{-7} to 7×10^{-7} per year.

Sabotage - In response to the terrorist attacks of September 11, 2001, and to intelligence information that has been obtained since then, the United States Government has initiated nationwide measures to reduce the threat of sabotage. These measures include security enhancements intended to prevent terrorists from gaining control of commercial aircraft and additional measures imposed on foreign passenger carriers and domestic and foreign cargo carriers, as well as charter aircraft.

The Federal Government has also greatly improved the sharing of intelligence information and the coordination of response actions among federal, state, and local agencies. DOE has been an active participant in these efforts. In addition to its domestic efforts, DOE is a member of the International Working Group on Sabotage for Transport and Storage Casks, which is investigating the impacts of sabotage events and exploring opportunities to enhance the physical protection of casks.

The Department, as required by the NWPA, would use Nuclear Regulatory Commission-certified shipping casks. Spent nuclear fuel is protected by the robust metal structure of the shipping cask, and by cladding that surrounds the fuel pellets in each fuel rod of an assembly. Further, the fuel is in a solid form, which would tend to reduce dispersion of radioactive particulates beyond the immediate vicinity of the cask, even if a sabotage event were to result in a breach of the multiple layers of protection.

In addition, the Nuclear Regulatory Commission has promulgated rules (10 CFR 73.37) and interim compensatory measures (67 *FR* 63167, October 10, 2002) specifically to protect the public from harm that could result from sabotage of spent nuclear fuel casks. The Department has committed to following these rules and measures (see 69 *FR* 18557, April 8, 2004).

For the reasons stated above, DOE believes that under general credible threat conditions the probability of a sabotage event that would result in a major radiological release would be low. Nevertheless, because of the uncertainty inherent in the assessment of the likelihood of a sabotage event, DOE has evaluated events in which a military jet or commercial airliner would crash into a spent nuclear fuel cask or a modern weapon (a high energy density device) would penetrate a spent nuclear fuel cask.

In the Yucca Mountain FEIS (Appendix J, Section J.3.3.1), DOE evaluated the ability of large aircraft parts to penetrate shipping casks and found that that neither the engines nor shafts would penetrate a cask and cause a release of radiological materials if an aircraft were to crash into a spent nuclear fuel cask. In the Yucca Mountain FEIS, DOE estimated the potential impacts of a sabotage event in which a high energy density device penetrates a rail cask. For the Rail Alignment EIS, DOE obtained more recent estimates of the fraction of spent nuclear fuel materials that would be released (release fractions) (DIRS 104918-Luna et al. 1999, all). Based on the more recent information DOE estimated that there would be 0.0028 latent cancer fatalities in rural areas and 1.1 latent cancer fatalities in suburban areas along the Caliente rail alignment, and 0.021 latent cancer fatalities in rural areas and 2.8 latent cancer fatalities in suburban areas along the Mina rail alignment.

In addition to analyzing the impacts of sabotage events, the Department would continue to modify its approach to ensuring safe and secure shipments of spent nuclear fuel and high-level radioactive waste between now and the time of shipments.

DOE also used both qualitative and quantitative components to estimate transportation accident incidents and potential fatalities resulting from vehicular and train accidents.

S.3.4.11 UTILITIES, ENERGY, AND MATERIALS

The Caliente rail alignment region of influence for public water systems and wastewater transported offsite for treatment and disposal is Lincoln, Nye, and Esmeralda Counties. The Mina rail alignment region of influence for public water systems and wastewater transported offsite for treatment and disposal is Lyon, Mineral, Esmeralda, and Nye Counties, and the Walker River Paiute Reservation, the bulk of which lies in Mineral County, with smaller portions in Churchill and Lyon Counties. The region of influence for telecommunications and electricity is limited to the companies that service the aforementioned counties. The region of influence for fossil fuels is limited to regional suppliers within the State of Nevada. The region of influence for construction materials is defined by the distribution networks and suppliers of that material to the general project area.

DOE determined that the demands placed on utilities, energy, and materials from constructing and operating the proposed rail line along either rail alignment would be met by existing supply capacities; therefore, potential impacts would be small. Utility interfaces would have the potential for short-term interruption of service, but would experience no permanent or long-term loss of service or prevention of future service-area expansions. Most water for construction along either rail alignment is planned to be supplied by new wells, although public water systems could be slightly affected by population increases attributable to construction employees. Wastewater treatment systems would not be directly affected directly by construction activities, because dedicated treatment systems would be provided at construction camps; however, there could be small impacts to wastewater treatment systems due to population increases attributable to construction employees. There would be very small impacts to telecommunications systems because during the construction phase, DOE would utilize a dedicated telecommunications system and rely little on existing telecommunications systems.

Peak electricity demand would be within capacity of regional providers. The demand for fossil fuels during construction would be approximately 6.5 percent and 6 percent of statewide use for the Caliente and Mina rail alignments, respectively, and could be met by existing regional supply systems and suppliers. During the operations phase, the demand for fossil fuels for either rail alignment would be less than 0.25 percent of statewide use. The primary materials that would be consumed during the construction phase would be steel; concrete, principally for rail ties, bridges, and drainage structures; and rock for ballast and subballast. DOE determined that construction material requirements for the Caliente rail alignment and for the Mina rail alignment would be a small fraction of current production rates within the respective regions of influence.

Under the Shared-Use Option for either rail alignment, the incremental demands on utilities, energy, and materials for construction of commercial sidings and support facilities would be sufficiently small that the anticipated impacts on these resources would be effectively the same as for the Proposed Action without shared use. Therefore, potential impacts to local, regional, or national suppliers of such resources under the Shared-Use Option along either rail alignment would be small.

Fossil-fuel requirements for transporting general freight under the Shared-Use Option would depend on the volume and distance of shared-use traffic. DOE estimated that the incremental annual diesel consumption for commercial shared-use traffic would be 5.5 million liters (1.5 million gallons), a rate that is less than 0.3 percent of current annual diesel fuel usage in Nevada. Most, if not all, of this fuel consumption would be offset by diesel fuel that would otherwise be used if the goods or materials were shipped by truck. Therefore, the impact to the capacities of national and regional fuel producers and distributors under the Shared-Use Option would be small.

S.3.4.12 HAZARDOUS MATERIALS AND WASTES

For both the Caliente and Mina rail alignments, the region of influence for the use of hazardous materials and the generation of hazardous and nonhazardous wastes includes the nominal width of the rail line construction right-of-way, and the locations of railroad construction and operations support facilities; for the disposal of hazardous wastes, it includes the entire continental United States (commercial hazardous waste disposal vendors could utilize facilities throughout the country); and for the disposal of low-level radioactive wastes, it includes DOE low-level waste disposal sites, sites in Agreement States, and U.S. Nuclear Regulatory Commission-licensed sites. The region of influence for the disposal of nonhazardous waste for the Caliente rail alignment includes the disposal facilities in Lincoln, Nye, Esmeralda, and Clark Counties; and for the Mina rail alignment includes the disposal facilities in Mineral, Nye, Esmeralda, and Clark Counties.

During railroad construction and operations, DOE would store and use hazardous materials such as oil, gasoline, diesel fuel, and solvents, primarily for the operation, maintenance, and cleaning of equipment and cleaning of equipment and facilities, which would result in the generation of associated hazardous wastes. During the railroad construction and operations phases, the Department would implement an Environmental Management System and a Pollution Prevention/Waste Minimization Program, which would include an evaluation of methods to eliminate, reduce, or minimize the amounts of hazardous materials used and hazardous wastes generated. Ample disposal capacity is available for the disposal of hazardous waste during the construction and operations phase. DOE would implement appropriate planning measures for the storage and handling of hazardous materials and comply with applicable regulations.

The Department would dispose of nonrecyclable or nonreusable waste in permitted landfills. During construction, it is likely that, if utilized, some of the larger landfills would not see an appreciable change in the amount of waste received if they were utilized; however, some of the smaller landfills, if utilized, might see a substantial, although manageable, change in daily receipt of solid, and industrial, and special wastes.

DOE estimates that railroad construction along the Caliente rail alignment would increase the overall rate of disposal of solid waste by less than 0.01 percent and industrial and special waste in the region of influence by about 0.261 percent. DOE anticipates that impacts to local landfills from the disposal of solid and industrial and special these wastes would be small (for the relatively large Apex Landfill) to moderate (for the smaller landfills such as Goldfield Class I).

DOE estimates that railroad construction along the Mina rail alignment could generate three times the amount of industrial and special waste as would railroad construction along the Caliente rail alignment.

This is because of wastes from dismantling the Department of Defense Branchline through the town of Schurz. However, to the extent practicable, these wastes would be recycled to minimize waste volumes. DOE estimates that railroad construction along the Mina rail alignment would increase the overall rate of disposal of solid waste by 0.077 percent and, industrial and special waste in the region of influence by about 0.41 percent and 9 percent. DOE anticipates that impacts to local landfills from the disposal of these solid, industrial, and special wastes would be small (for the relatively large Apex Landfill) to moderate (for the smaller landfills such as Goldfield Class I).

During railroad operations along either the Caliente or Mina rail alignment, the generation of wastes would be substantially less than during the construction phase. DOE anticipates that railroad operations along either alignment would produce similar amounts of wastes. Therefore, impacts to landfills during operations would be small, because ample disposal capacity would be available for either rail alignment.

Activities at the Cask Maintenance Facility would generate from 3,200 to 7,900 cubic meters (113,000 to 280,000 cubic feet) of Class A low-level radioactive waste throughout the railroad operations phase. DOE would control and dispose of site-generated low-level radioactive waste in a DOE low-level waste disposal site, a site in an Agreement State, or in a U.S. Nuclear Regulatory Commission-licensed site, all of which currently have ample capacity to accept these wastes. Therefore, impacts to low-level radioactive waste disposal facilities would be small. No low-level radioactive waste is anticipated to be generated during construction activities; therefore, no impacts to disposal facilities would occur.

Under the Shared-Use Option for either rail alignment, waste characteristics, generation rates, and disposal requirements would increase only slightly; therefore, any additional adverse impacts associated with the Shared-Use Option would be small.

S.3.4.13 CULTURAL RESOURCES

The region of influence for cultural resources (historic and prehistoric sites) includes the construction right-of-way (the area of potential direct and indirect impacts) and a 3.2-kilometer (2-mile)-wide area centered on the rail alignment (the area of potential indirect impacts).

Because of the length of the proposed rail line along the Caliente and Mina rail alignments, DOE is using a phased cultural resource identification and evaluation approach, described in 36 CFR 800.4(b)2, to identify specific cultural resources. Under this approach, DOE would defer final intensive field surveys (known as a Class III inventory) of the actual construction right-of-way, as provided in the Programmatic Agreement between DOE, the BLM, the STB, and the Nevada State Historic Preservation Office. The Programmatic Agreement states that an appropriate level of field investigation—including on-the-ground intensive surveys; evaluations of all recorded resources listed on the *National Register of Historic Places*; assessments of adverse effects; and applicable mitigation of identified impacts—be completed before any ground-disturbing construction activities that could impact a specific resource could begin.

Railroad construction and operations could lead to unavoidable changes in cultural landscapes, such as changes to ethnographic, rural historic, and historic viewscapes. Cultural landscapes along the Caliente rail alignment include historic-period Western Shoshone villages and surrounding use areas in the Oasis Valley, the Goldfield area, and Stone Cabin and Reveille Valleys; early ranching operations in the Stone Cabin and Reveille Valleys; the historic Mormon settlement of Meadow Valley Wash, and the Goldfield, Clifford, and Reveille Mining Districts. Cultural landscapes along the Mina rail alignment include historic-period Northern Paiute use of the Walker River and Walker Lake areas, historic-period Western Shoshone villages and surrounding use areas in the Oasis Valley and Goldfield areas, and historic mining in the Luning, Mina, and Goldfield districts.

DOE completed literature reviews and a Class II inventory (sample field surveys within the construction right-of-way) for 20 percent of each alternative segment and common segment along the Caliente and Mina rail alignments, and has thereby identified some potential areas of specific impacts. Additionally, DOE conducted an intensive Class III inventory along a 12-kilometer (7.4-mile) corridor within the Yucca Mountain Site boundary, which resulted in the identification of seven sites and five isolates (isolated artifacts).

Based on preliminary information and the sample surveys conducted to date, the magnitude of impacts along both the Caliente and Mina rail alignments would range from small to moderate due to the extensive effort DOE would undertake to avoid or mitigate impacts to cultural resources in accordance with the regulatory framework and with the terms of the Programmatic Agreement.

Impacts to cultural resources under the Shared-Use Option for either the Caliente or Mina rail alignment would be approximately the same as those under the Proposed Action without shared use. However, construction of any additional commercial-use sidings would have the potential to impact cultural resources.

S.3.4.14 PALEONTOLOGICAL RESOURCES

Paleontology is a science that uses fossil remains to study life in past geological periods. Paleontological resources are recognized as a fragile and nonrenewable record of the history of life on earth and a critical component of America's natural heritage, and once damaged, destroyed, or improperly collected, their scientific and educational value may be greatly reduced or lost forever. The region of influence for paleontological resources along both rail alignments is the rail line construction right-of-way, and the footprints of railroad construction and operations support facilities.

DOE used the BLM system to classify paleontological resource areas according to their potential for containing vertebrate fossils, or noteworthy occurrences of invertebrate or plant fossils. This classification system became the basis to analyze the magnitude of potential impacts from construction in the region of influence of the Caliente and Mina rail alignments.

DOE determined that there are no known paleontological resources along any of the Caliente or Mina rail alignments or at the proposed locations of railroad construction and operations support facilities. Therefore, the Department would not anticipate any impacts to paleontological resources during the construction or operations phase along either rail alignment. However, if DOE uncovered previously unknown paleontological resources during construction activities, the Department would consult with the BLM to develop appropriate conservation measures.

Under the Shared-Use Option for either rail alignment impacts to paleontological resources would be similar to the Proposed Action without shared-use.

S.3.4.15 ENVIRONMENTAL JUSTICE

The region of influence for environmental justice encompasses the regions of influence for all other resource areas because impacts in other resource areas could result in environmental justice impacts.

DOE performed the analysis of potential environmental justice impacts in accordance with Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low Income Populations*, and Council on Environmental Quality guidance. According to the Council on Environmental Quality, a minority population exists where either (a) the minority population of the affected area exceeds 50 percent; this calculation includes federally recognized American Indian lands, because American Indians are included in the definition of minority populations; or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. In addition to the 50-percent threshold, DOE used both the United States and the State of Nevada minority populations as bases for comparison.

The Council on Environmental Quality defines low-income by using the annual statistical poverty thresholds from the U.S. Census Bureau. A low-income community exists when the low-income population percentage in the area of interest is meaningfully greater than the low-income population in the general population. For purposes of the analysis of low-income communities, DOE used both the United States and the State of Nevada low-income populations as the bases for comparison. DOE assumed a 20-percent threshold above state low-income percentages in accordance with U.S. Nuclear Regulatory Commission guidance.

DOE determined whether there would be minority or low-income populations in the Caliente or Mina rail alignment regions of influence for environmental justice, and assessed whether any high and adverse impacts could fall disproportionately on minority or low-income populations. DOE also considered whether minority or low-income populations would be affected by an alternative in different ways than the general population, such as through unique exposure pathways or rates of exposure, special sensitivities, or different uses of natural resources.

For the Caliente rail alignment, the Department determined that railroad construction and operations would not result in disproportionately high and adverse impacts to minority or low-income populations. For the Mina rail alignment, DOE determined that the Schurz population center and the Walker River Census County Division are the only locations where the minority populations exceed the threshold of 50 percent, and the Walker River Census County Division to be the only location where the low-income population exceeds the threshold of 20 percent over the state average of 10.5 percent established by the Nuclear Regulatory Commission and the Council on Environmental Quality. Because there are no large and adverse impacts in these areas, it cannot be concluded that low-income and minority populations in these areas would be disproportionately affected. Constructing and operating the proposed railroad along the Mina rail alignment would not result in high and adverse impacts to minority or low-income populations.

Similarly, the Department determined that under the Shared-Use Option for either rail alignment, there would be not high and adverse impacts to minority or low-income populations.

S.3.5 American Indian Interests

Based on information provided by the Consolidated Group of Tribes and Organizations, American Indians are concerned that substantial and high adverse effects to a number of American Indian interests could be caused within and adjacent to the Caliente rail alignment region of influence, which also encompasses the southern segments of the Mina rail alignment. The Consolidated Group of Tribes and Organizations is a forum consisting of officially appointed tribal representatives, from 17 tribes and organizations, who are responsible for presenting their respective tribal concerns and perspectives to DOE. At the time of discussions with the Consolidated Group of Tribes and Organizations, the Mina rail alignment was not under consideration as an implementing alternative and the views of the Northern Paiute peoples who traditionally occupied lands north of Goldfield and Tonopah are not represented by this group. As part of any Proposed Action, the Department would continue to consult with American Indian tribes with regard to their interests and believes.

The proposed Mina rail alignment would pass through and directly affect the Walker River Paiute Reservation. In a letter dated April 29, 2007, the Walker River Paiute Tribal Council officially informed the Department of their withdrawal from the environmental impact statement process. The Tribal Council made the decision to withdraw based on information obtained during the Tribe's involvement with the Rail Alignment EIS process and input from Tribal members. The Tribe determined that the impacts and risks associated with nuclear shipments through the Reservation were too great and they reaffirmed a past objection to the transportation by any means of nuclear or radioactive waste through the Reservation.

American Indian views on construction and operation of a railroad along the Caliente rail alignment, as primarily expressed by the Consolidated Group of Tribes and Organizations, state that construction and operation of the proposed railroad would constitute an intrusion on the traditional lands of Southern Paiute, Western Shoshone, and Owens Valley Paiute and Shoshone people; would disturb cultural, biological, botanical, geological, and hydrological resources, including American Indian viewscapes, songscapes, storyscapes, and traditional cultural properties; would restrict the free access of American Indian people to their resources; and could cause substantial and high adverse effects to a number of American Indian interests within and adjacent to the region of influence. Within that forum of beliefs there would be an unavoidable impact to American Indian interests.

S.3.6 Cumulative Impacts

DOE evaluated public- and private-sector past, present, and reasonably foreseeable activities that could, when combined with the Proposed Action or Shared-Use Option, result in cumulative impacts. The DOE analysis of potential cumulative effects was primarily qualitative, but the Department quantified information to the extent feasible. The cumulative impacts regions of influence for analysis encompassed the Caliente and Mina rail alignments, and areas with potential direct and indirect effects for each resource area. To assess potential cumulative impacts from other projects, DOE identified major projects within the regions of influence that could have interactions with the proposed railroad in space or time. Those major projects included a wide variety of projects including the proposed Yucca Mountain Repository, the Nevada Test and Training Range, the Nevada Test Site, groundwater development, BLM land management (including rights-of-way), and power-plant construction.

DOE determined that the cumulative impacts within most of the resource areas described in the Rail Alignment EIS would be small in the Caliente and Mina rail alignment regions of influence unless noted otherwise.

In the Caliente and Mina rail alignment regions of influence, land use and management is changing because of increased construction and development, increased urbanization, and increased conversion of undeveloped land to other purposes or to multiple purposes. Federal agencies, primarily the BLM, will continue to be the major land manager throughout the regions of influence. The BLM has a major role in determining land use in the region though administration of federal lands, including development of resource management plans for the region. The incremental change to land use from constructing and operating the proposed railroad along the Caliente or the Mina rail alignment is projected to be small to moderate.

Overall, there is, and will continue to be, a broad contrast of how visual resource impacts are managed in the regions of influence, ranging from very little management for military mission-related activities to a formal visual resource management system on BLM-administered lands. DOE determined that operation of the proposed railroad would be visible in specific locations but would not dominate the viewsheds within the regions of influence. Changes to aesthetic resources in the regions of influence have already been affected by activities such as the Nevada Test and Testing Range, the Nevada Test Site, BLM management activities, and population growth. These changes will continue in future years, but the regions will generally maintain many of the remote and rural characteristics and conditions. The incremental change to aesthetic resources from constructing and operating the proposed railroad along the Caliente or the Mina rail alignment is projected to be small.

Cumulative impacts concerns regarding surface-water resources in the Caliente and Mina rail alignment regions of influence include changes to drainage patterns, infiltration rates, flood control, and spill/contamination potential. Regional impacts would generally be localized to each specific project. Insufficient inflow from the Walker River into Walker Lake would continue to jeopardize Walker Lake's future as a viable fishery, with or without the proposed railroad in the Mina rail alignment region of influence.

The Department anticipates that cumulative impacts to groundwater resources in the Caliente and Mina rail alignments regions of influence would range from small to large, depending on location along each alignment. Overall, the groundwater needs of the Proposed Action would represent a small portion of current cumulative water usage within the Caliente or Mina rail alignment regions of influence. However, in some proposed groundwater well locations for railroad use, cumulative demand would exceed perennial yield values. Water availability will continue to be a major regional cumulative impact issue in the coming years.

The Caliente or Mina rail alignment is projected to result in small to moderate incremental impacts to cumulative biological resources in their regions of influence. A railroad and other reasonably foreseeable and continuing projects in the region of influence would require coordinated mitigation and impact avoidance among project proponents to avoid and reduce cumulative impacts to biological resources. BLM land management activities also play a major role in regional impact avoidance and mitigation.

The Proposed Action would be only one of the many reasonably foreseeable sources of socioeconomic change to portions of the regions of influence, and would be relatively less important to socioeconomic change than external economic development and population growth. The road systems in the regions of influence could experience higher traffic levels, possibly associated congestion, and increased road maintenance, but incremental impacts due to the proposed railroad would be small.

DOE anticipates that impacts to air quality in the Caliente and Mina regions of influence would be small to moderate. DOE found that impacts from construction for either the Caliente or Mina rail alignment would generate emissions of some criteria pollutants that could be higher than applicable air quality standards. While these effects would be localized in specific areas, any potential violation of air quality standards would be of concern in relation to both project-specific and cumulative impacts.

The proposed railroad would result in nonradiological and radiological health and safety impacts for workers and residents along the alignments. For members of the public situated along the Caliente and Mina rail alignments, the radiological impacts during the operations phase would be a very small contribution to the overall radiological impacts of the Yucca Mountain Repository, and incremental impacts of the proposed railroad would be small.

The Yucca Mountain FEIS evaluated the cumulative impacts of two additional inventories of spent nuclear fuel, high-level radioactive waste, and other radioactive wastes (Modules 1 and 2). These additional wastes would be above and beyond the amounts of wastes that have been analyzed for shipment in the Rail Alignment EIS, and their possible shipment could represent a cumulative impact on the resources analyzed in the Rail Alignment EIS. Although emplacement of this additional waste at Yucca Mountain would require legislative action by Congress, such shipment is a reasonably foreseeable action for purposes of NEPA analysis. Because the planned annual shipment rate of spent nuclear fuel and high-level radioactive waste to the Yucca Mountain Repository would be about the same as the Proposed Action in the Rail Alignment EIS, the only cumulative impacts to arise would be due to the annual increase in the number of casks. Impacts from these additional casks would be similar to the generally small impacts summarized above.

It is possible that new economic activity associated with the Shared-Use Option might lead to induced effects, but the locations, scope, and types of these effects are not known at this time.

S.3.7 DOE Preferred Alternative

The Council on Environmental Quality NEPA implementing regulations require an agency to identify its preferred alternative to fulfill its statutory mission, if one or more exists, in a Draft EIS (40 CFR 1502.14[e]). For the Rail Alignment EIS, the DOE preferred alternative would be to construct and operate a railroad along the Caliente rail alignment and to implement the Shared-Used Option. The DOE preferred alignment along the Caliente rail alignment consists of the following: the Caliente alternative segment, common segment 1, Garden Valley alternative segment 1, common segment 2, South Reveille alternative segment 3, common segment 3, Goldfield alternative segment 3, Caliente common segment 4, Bonnie Claire alternative segment 3, common segment 5, Oasis Valley alternative segment 1, and common segment 6. Table S-7 lists the preferred alternative segments and identifies the bases for the Department's preferences. The table does not list common segments 1, 2, 3, 4, 5, and 6, because those are all included in the preferred alignment.

S.3.8 Issues to be Resolved

An issue that remains unresolved is the determination of land access. The BLM would need to authorize DOE access to sufficient lands for railroad construction and operation under a right-of-way grant applied for by DOE. Under the Mina Implementing Alternative, DOE would also need to apply to the Bureau of Indian Affairs to acquire a right-of-way in which to construct segments of the rail line on the Walker River Paiute Reservation. The DOE preferred alternative is to construct and operate a railroad along the Caliente rail alignment and within that alignment DOE has identified preferred alternative segments. However, it remains unresolved whether the BLM would choose to authorize DOE land access to those preferred alternative segments or to other alternative segments, or whether under the nonpreferred alternative the Bureau of Indian Affairs would grant DOE access to land on the Walker River Paiute Reservation.

Under each implementing alternative, DOE has analyzed a Shared-Use Option, under which the Department would allow commercial shippers to use the proposed rail line for shipments of general freight. A Shared-Use Option would be subject to STB approval, and it remains unresolved whether STB would grant such approval.

S.3.9 Areas of Controversy

The Yucca Mountain Project, including the transport of spent nuclear fuel and high-level radioactive waste, has remained a controversial issue since its inception some 20 years ago, and has been strongly opposed by the State of Nevada and a variety of state, local, tribal, and citizen groups. Over the last decade the State of Nevada has filed multiple lawsuits against the Federal Government regarding the Yucca Mountain Project. In 2004, the State of Nevada petitioned the United States Court of Appeals for the District of Columbia Circuit to review the Yucca Mountain FEIS and the portion of the DOE *Record of Decision* governing the transportation of nuclear waste. The State of Nevada alleged that the FEIS was procedurally flawed, violated NEPA, and ignored STB railroad regulations. The State of Nevada also challenged the Record of Decision under the Administrative Procedure Act in determining a "mostly rail" plan to be the preferred means of shipping waste to the site, and argued that DOE exceeded its authority in selecting the Caliente corridor. On August 8, 2006, the Court denied Nevada's petition.

Table S-7. Caliente rail alignment preferred alternative segments.[a]

DOE preferred alternative	Analysis factors
Caliente alternative segment	• The Eccles alternative segment would include an Interchange Yard that requires a large amount of fill in Clover Creek to enable construction of the Staging Yard. The Caliente alternative segment Interchange Yard location would avoid this impact to Clover Creek. • The Caliente alternative segment would have greater impacts to wetlands than the Eccles alternative segment. This would create greater regulatory complexity associated with obtaining a U.S. Army Corps of Engineers permit to fill jurisdictional waters. • The Caliente alternative segment would cross more private land than the Eccles alternative segment. • The Eccles alternative segment would be more complex to construct and would cost approximately twice as much as the Caliente alternative segment. • Based on scoping comments, more stakeholders prefer the Caliente alternative segment. • The Caliente alternative segment Indian Cove Staging Yard location would require filling 47 acres (0.19 square kilometer) of wetlands. The Upland Staging Yard location would avoid the impacts to wetlands associated with the Indian Cove location.[b]
Garden Valley alternative segment 1	• Engineering factors and regulatory complexity do not offer a means to discriminate among the Garden Valley alternative segments. • Garden Valley 1 would disturb less area than Garden Valley 2, 3, or 8.
South Reveille alternative segment 3	• No major environmental discriminator. • South Reveille 3 would avoid complex road and wash crossing that would be required for South Reveille 2.
Goldfield alternative segment 3	• Engineering uncertainty of crossing mining district associated with Goldfield 1. • Goldfield 4 would include two grade-separated crossings of U.S. Highway 95. • Goldfield 4 would have greater cultural resources impacts than Goldfield 1 or Goldfield 3. Goldfield 4 would enter the Goldfield Historic District. • Goldfield 3 would have fewer land-use conflicts than Goldfield 1 or Goldfield 4.
Bonnie Claire alternative segment 3	• No major environmental discriminator. • Bonnie Claire 2 would be close to the boundary of the Nevada Test and Training Range and would be more complex to construct than Bonnie Claire 3.
Oasis Valley alternative segment 1	• No major environmental discriminator. • Oasis Valley 1 would cross one parcel of private property. Oasis Valley 3 would not cross private property. • Oasis Valley 1 would require fewer earthworks for construction than Oasis Valley 3.

a. The DOE preferred rail alignment, Caliente, includes all six common segments.
b. DOE has not identified a preference for the Staging Yard location.

The Consolidated Group of Tribes and Organizations has consistently opposed the siting of the Yucca Mountain repository and transportation of spent nuclear fuel and high-level radioactive waste to such a repository. Construction and operation of the Yucca Mountain repository and proposed railroad are viewed to constitute an intrusion on the holy lands of the Southern Paiute, Western Shoshone, and Owens Valley Paiute and Shoshone people, as well as a disturbance to cultural, biological, botanical, geological, and hydrological resources, and to American Indian viewscapes, songscapes, storyscapes, and traditional cultural properties. DOE accepts these viewpoints as responsible opposing viewpoints. These issues may continue to be viewed as unresolved within the forum of American Indian cultures and beliefs.

Water needs for the Caliente or Mina rail alignments would represent a small portion of current cumulative water usage within the region of influence; however, water usage in some locations would continue to exceed perennial yield values. Water usage and water development projects will continue to be a major concern in the region of influence irrespective of the water demands associated with either rail alignment. Growth in water demand in Nevada has been very rapid: water usage against the backdrop of regional water transfer plans remains an overarching controversial issue.

Possible rail line alternative segments through Garden Valley have been considered controversial in that its use has been viewed as detrimental to the remote desert setting of *City*, a large complex of abstract sculptural and architectural forms made from earth, rock, and concrete extending over 2.5 kilometers (1.5 miles) in Garden Valley.

Some issues related to land use could be viewed as potentially controversial. Although the total amount of private land along either alignment would be small (about 1 percent for Caliente and 0.5 percent for Mina) compared to the total amount of land required for the alignment, there are individual landowners who could be directly affected. No residences would be directly affected. One local business along the Caliente rail alignment, the Caliente Hot Springs Hotel, could be adversely affected because of the rail line's proximity to the hotel.

S.3.10 Major Conclusions

DOE analysis shows that construction and operation of a railroad along the Caliente rail alignment or the Mina rail alignment for shipment of spent nuclear fuel, high-level radioactive waste, and other materials from an existing rail line in Nevada to a repository at Yucca Mountain would result in broadly similar but generally small impacts to natural, human-health, social, economic, and cultural resources. The environmental justice analyses indicate that there would be no disproportionately high and adverse human health or environmental impacts to minority or low-income populations from railroad construction and operations along either the Caliente rail alignment or the Mina rail alignment.

DOE recognizes that the Mina Implementing Alternative would, on balance, be environmentally preferable to the Caliente Implementing Alternative because, in general, the Mina Implementing Alternative would have fewer private-land conflicts, less surface disturbance, smaller impacts to wetlands, and smaller impacts to air quality than the Caliente Implementing Alternative. In addition, DOE has estimated that the total cost to construct the railroad along the Mina rail alignment would be approximately 20 percent less than to construct the railroad along the Caliente rail alignment ($1.7 billion compared to $2.2 billion [2005 dollars]). However, stemming from the Walker River Paiute Tribal Council decision to withdraw from participating in the Nevada Rail Corridor SEIS and the Rail Alignment EIS process, and to renew past objections to the transportation of nuclear waste through Walker River Paiute Reservation, the DOE preferred alternative is to construct and operate a railroad along the Caliente rail alignment.

Under the No-Action Alternative, there would be no impacts to natural, human-health, social, economic, or cultural resources. In the event that DOE were not to select a rail alignment, the future course that it would pursue to meet its obligations under the NWPA would become uncertain.

S.3.11 Comparison of Environmental Impacts

Council on Environmental Quality regulations that implement the procedural requirements of NEPA state that agencies should provide a comparison of the environmental impacts of the Proposed Action and its alternatives to sharply define the issues and provide a clear basis for choice. The comparison in this section is based on the information and analyses presented in subsequent chapters of this Rail Alignment EIS.

Tables S-8 through S-10 highlight the differences in potential impacts under the Proposed Action for the Caliente and Mina Implementing Alternatives and the No-Action Alternative. Table S-8 lists the range of potential impacts under the Proposed Action for the Caliente Implementing Alternative and the Mina Implementing Alternative considering the largest and smallest potential impacts of the different alternative segments. Table S-8 allows a comparison of the Proposed Action to the No-Action Alternative.

Potential impacts under the Shared-Use Option would be generally the same as impacts under the Proposed Action without shared use, unless noted otherwise in the tables. Potential commercial sidings and facilities that could be constructed under the Shared-Use Option would likely be constructed within the operations right-of-way to the extent practicable; therefore, the impacts of their construction are included within those impacts presented for the Proposed Action.

Tables S-9 and S-10 highlight potential impacts under the Proposed Action for the Caliente rail alignment and the Mina rail alignment, respectively. The tables include the alternative segments and common segments that could form each rail alignment. To make the tables more useful to the reader in discriminating between alternative segments, they focus on the major differences in impacts. Therefore, the tables do not include entries for all resource areas. Chapter 4 includes full summaries of potential impacts for each resource area.

These tables illustrate that the Mina Implementing Alternative would be environmentally preferable when compared to the Caliente Implementing Alternative. In general, the Mina Implementing Alternative would have fewer private-land conflicts, less surface disturbance, smaller wetlands impacts, and smaller air quality impacts than the Caliente Implementing Alternative. However, the Mina Implementing Alternative remains the nonpreferred alternative due to the objection of the Walker River Paiute Tribe to the transportation of spent nuclear fuel and high-level radioactive waste through its Reservation.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 1 of 17).

Resource Area	Proposed Action: Caliente Implementing Alternative	Proposed Action: Mina Implementing Alternative	No-Action Alternative
Physical setting	Total surface disturbance: 55 to 61 square kilometers (14,000 to 15,000 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 1.3 to 1.8 square kilometers (320 to 440 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.	Total surface disturbance: 40 to 48 square kilometers (9,900 to 12,000 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.011 to 0.014 square kilometer (2.7 to 3.5 acres). Less than 3 percent of the prime farmland soils of the Walker River Paiute Reservation.	No surface disturbance or prime farmland soils impacts because the rail line and associated facilities would not be constructed.
Land use and ownership	Land-use change on public lands for operations right-of-way. Private parcels the rail line would cross: 14 to 71. Area of private land affected: 0.33 to 0.72 square kilometer (82 to 178 acres). Private land needed for facilities: 1.15 square kilometers (284 acres) Active grazing allotments the rail line would cross: 24 to 27. Animal unit months lost: 1,019 to 1,050. (An animal unit month represents enough dry forage for one mature cow for one month.) Sections with unpatented mining claims that would be crossed: 32 to 37.	Land-use change on public lands and the Walker River Paiute Reservation for operations right-of-way. Private parcels the rail line would cross: 1 to 40. Area of private land affected: 0.21 to 0.59 square kilometer (52 to 146 acres). Active grazing allotments the rail line would cross: 5 to 8. Animal unit months lost: 159 to 246. Sections with unpatented mining claims that would be crossed: 23 to 30.	DOE would relinquish public lands along the Caliente rail alignment that were withdrawn for study under Public Land Order 7653. DOE would also relinquish the public lands segregated from surface and mineral entry for 2 years along the Caliente and Mina rail alignments.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 2 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Aesthetic resources	Small to moderate impact across Caliente rail alignment from operations. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads.	Same as the Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed. Public land would remain subject to BLM administration under applicable resource management plans. BLM would continue to manage public land for multiple use.
	Small impact from train operations. No contrast to strong contrast in the short term from passing trains.	Same as the Caliente Implementing Alternative.	
	Moderate impact from Staging Yard at Indian Cove. Moderate contrast from the operation of the facility in the Class III non-BLM lands, weak contrast from the track on BLM Class II lands at the north end; in each area, consistent with applicable BLM management objectives.	Small to moderate impact from Schurz alternative segments. Weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives. (Moderate to strong contrast in the short term from construction of the rail-over-road grade-separated crossing of U.S. Highway 95 for Schurz 6, which would not meet BLM Class III management objectives.)	
	Potential quarry CA-8B - Moderate impact. Moderate contrast in the short term from installation and use of the conveyor from the quarry across U.S. Highway 93. No long-term impact under the Proposed Action; conveyor would be removed at end of construction phase. Moderate impact under the Shared-Use Option from the use of a conveyor across U.S. Highway 93 for 6 to 8 years.	Small to moderate impact from Montezuma alternative segment 1. Weak contrast from new linear feature adjacent to State Route 265 and weak to moderate contrast in Clayton Valley; would meet BLM Class III and IV management objectives.	
		Potential Garfield Hills quarry - Moderate impact. Moderate contrast in the short term from quarrying, ballast production facilities, and conveyor close to viewers that would be compatible with BLM Class III management objectives. Small impact in long term; production facilities and conveyor would be removed and quarried areas restored after closure of quarry at end of construction phase.	

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 3 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Aesthetic resources (continued)		Potential Gabbs Range quarry - Small to moderate impact. Weak to moderate contrast in the short term from ballast production facilities close to viewers that would be compatible with BLM Class III management objectives. Small impact in long term; production facilities would be removed after closure of quarry at end of construction phase. Potential North Clayton quarry - Weak to moderate impact. Moderate contrast in the short term from production facilities close to viewers that would be compatible with BLM Class IV management objectives. Small impact in long term; production facilities would be removed and waste dumps restored after closure of quarry at end of construction phase.	
Air quality and climate – Lincoln County	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from the construction or operation of the railroad, the Caliente Interchange Yard, or potential quarry CA-8B. The closest approach to a NAAQS standard would be for 24-hour PM_{10} (38 percent of standard for rail line and potential quarry CA-8B) during the construction phase.	Not applicable. No portion of a rail line along the Mina rail corridor would be constructed in Lincoln County.	No impacts because the rail line and associated facilities would not be constructed.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 4 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Air quality and climate – Esmeralda County	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from railroad construction and operations. The closest approaches to a NAAQS standard would be for 24-hour PM_{10} (87 percent of standard) and 24-hour $PM_{2.5}$ (74 percent of standard), for rail line construction near Goldfield.	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from the railroad construction and operations or the potential Malpais Mesa quarry, with most values expected to be well below the NAAQS. The closest approach to a NAAQS standard would for 24-hour PM_{10} (63 percent of standard) and 24-hour $PM_{2.5}$ (54 percent of standard) for the rail line construction near Silver Peak.	No impacts because the rail line and associated facilities would not be constructed.
Air quality and climate – Nye County	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from the railroad construction operations, with the possible exception of 24-hour PM_{10}. Modeling at the potential quarry NN-9B site in the South Reveille Valley indicates a potential exceedance (160 percent of standard, temporary and localized) of the 24-hour PM_{10} NAAQS. However, operating restrictions in the required Surface Disturbance Permit would likely reduce PM_{10} emissions, making such an exceedance unlikely.	No exceedances of the NAAQS would be expected from the railroad construction and operations, with most values expected to be far below the NAAQS.	No impacts because the rail line and associated facilities would not be constructed.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 5 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Air quality and climate – Churchill County	Not applicable. No portion of the rail line along the Caliente rail alignment would be constructed in Churchill County.	No exceedances of the NAAQS would be expected from the railroad operations, with most values expected to be far below the NAAQS. There is no new rail line construction planned within Churchill County; the only construction activity would the operation of trains carrying construction material on the existing rail line.	No impacts because the rail line and associated facilities would not be constructed.
Air quality and climate – Lyon County	Not applicable. No portion of the rail line along the Caliente rail alignment would be constructed in Lyon County.	No exceedances of the NAAQS would be expected from the railroad construction and operations, with most values expected to be far below the NAAQS.	No impacts because the rail line and associated facilities would not be constructed.
Air quality and climate – Mineral County	Not applicable. No portion of the rail line along the Caliente rail alignment would be constructed in Mineral County.	Conservative modeling indicated potential exceedances of the NAAQS for PM_{10} and $PM_{2.5}$ in the following scenarios: • Rail line construction near Mina; 111 percent of the 24-hour PM_{10} NAAQS. • Rail line construction near Schurz, 186 percent of the 24-hour PM_{10} NAAQS. • Rail line construction near Schurz, 124 percent of the 24-hour $PM_{2.5}$ NAAQS. • Rail line construction near Schurz, 103 percent of the annual PM_{10} NAAQS. • Staging Yard construction near Hawthorne, 165 percent of the 24-hour PM_{10} NAAQS. • Staging Yard construction near Hawthorne, 118 percent of the 24-hour $PM_{2.5}$ NAAQS. • Staging Yard construction near Hawthorne, 102 percent of the annual PM_{10} NAAQS. • Operation of the potential Garfield Hills quarry near Hawthorne, 200 percent of the 24-hour PM_{10} NAAQS. However, operating restrictions in the required Surface Disturbance Permit would likely reduce PM_{10} and $PM_{2.5}$ emissions, making such exceedances unlikely. No exeedances for other criteria pollutants would be expected, with most values expected to be well below the NAAQS.	No impacts because the rail line and associated facilities would not be constructed.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 6 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Air quality and climate – Mineral County (continued)		Modeling of emissions from construction of the Staging Yard at Hawthorne found that the 24-hour PM_{10} and $PM_{2.5}$ NAAQS could be exceeded in the immediate vicinity of the Staging Yard under some conditions. Modeling of emissions from the operation of the potential quarry at Garfield Hills indicates that the 24-hour PM_{10} and $PM_{2.5}$ NAAQS could be potentially exceeded. However, the required Surface Disturbance Permit is anticipated to greatly reduce PM_{10} and $PM_{2.5}$ emissions, making an exceedance of the NAAQS unlikely.	
Surface-water resources	Caliente alternative segment: Approximately 0.05 square kilometer (12 acres) of wetlands would be filled. Long-term reduced and potentially eliminated access to Caliente Hot Springs. Eccles alternative segment: Negligible amount of wetlands would be filled. Caliente alternative segment: Indian Cove Staging Yard, approximately 0.19 square kilometer (47 acres) of wetlands would be filled; Upland Staging Yard, no wetlands would be filled. Potential quarry CA-8B: Approximately 0.09 square kilometer (22 acres) of wetlands would be filled to construct the quarry siding. Eccles alternative segment, Interchange Yard: Approximately 0.033 square kilometer (8.2 acres) of Clover Creek would be filled. Goldfield alternative segment 3: Long-term reduced and potentially eliminated access to Willow Springs.	Schurz alternative segments: Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 20 to 28 square meters (220 to 300 square feet) would be permanently filled to construct the bridge over the Walker River.	No impacts because the rail line and associated facilities would not be constructed. Erosion and sedimentation would continue under natural processes.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 7 of 17).

Resource Area	Proposed Action: Caliente Implementing Alternative	Proposed Action: Mina Implementing Alternative	No-Action Alternative
Groundwater resources	Physical impacts to existing groundwater resource features such as existing wells or springs resulting from railroad construction and operation would be small.	Physical impacts to existing groundwater resource features such as existing wells or springs resulting from railroad construction and operations would be small.	No impacts because the rail line and associated facilities would not be constructed.
	Groundwater withdrawals during construction from hydrographic areas in Panaca Valley, Sarcobatus Flat, and Oasis Valley could impact existing groundwater resources and users through localized and temporary drawdown of the water table. However, mitigation measures such as reducing the pumping rate or relocating proposed wells Pan V25/26, Pan V4, Pan V5, Pan V7/8, Pan V2, Pan V24, SaF1, OV3, OV4, and OV5/13 would minimize these impacts.	Groundwater withdrawals during construction from hydrographic areas in Clayton Valley, Sarcobatus Flat, Oasis Valley, and Columbus Salt Marsh could impact existing groundwater resources and users. However, mitigation measures such as reducing the pumping rate or relocating proposed wells CL-1a, SaF1, OV3, OV4, OV5/13, and CSM-2a would minimize these impacts.	
	The potential for groundwater withdrawals during the construction and operations phases to cause subsidence of the ground surface would be small.	Same as the Caliente Implementing Alternative.	
	The impact of proposed groundwater withdrawals on groundwater quality would be small, and the impact of withdrawals on downgradient hydrographic areas would be very small. The proposed withdrawals would not conflict with water quality standards protecting groundwater resources.	Same as the Caliente Implementing Alternative.	

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 8 of 17).

Resource Area	Proposed Action: Caliente Implementing Alternative	Proposed Action: Mina Implementing Alternative	No-Action Alternative
Biological resources	Short-term impact to 0.12 to 0.24 square kilometer (30 to 59 acres) wetland/riparian habitat. Long-term impact to 0.11 to 0.23 square kilometer (27 to 57 acres) wetland/riparian habitat. Short-term moderate impact on riparian and wetland vegetation along Oasis Valley alternative segment 3. Small to moderate impact on raptor nesting sites from the construction of potential quarry NN-9A. Short-term moderate impacts to desert bighorn sheep southwest of common segment 6.	Short-term impact to 0.01 to 0.05 square kilometer (2.5 to 12 acres) wetland/riparian habitat. Long-term impact to 0 to 0.01 square kilometer (0 to 2.5 acres) wetland/riparian habitat. Same as the Caliente Implementing Alternative. Small to moderate long-term impacts to Inter-Mountains Mixed Salt Desert Scrub and Inter-Mountain Basins Greasewood Flat along Schurz alternative segment 6. Moderate long-term impact to Inter-Mountains Mixed Salt Desert Scrub along Mina common segment 1. Short-term and long-term moderate impacts to western snowy plover along Mina common segment 1. Moderate impact to winterfat communities – Montezuma alternative segments and potential Gabbs Range quarry site. Long-term moderate impacts to Inter-Mountain Basins Mixed Salt Desert Scrub and Inter-Mountain Basins Big Sagebrush at potential North Clayton and Malpais Mesa quarry sites. Short-term moderate impacts to desert bighorn sheep southwest of common segment 6.	No impacts because the rail line and associated facilities would not be constructed.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 9 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Noise and vibration	Noise from construction activities in Caliente would exceed Federal Transit Administration guidelines. Daytime limits would be exceeded by 11 dBA from construction equipment noise and by 7 dBA from pile driving; 30-day DNL limit would be exceeded by 2 dBA from construction equipment noise and by 12 dBA from pile driving. Noise from construction equipment along the Eccles alternative segment would exceed limits by 5 dBA. No adverse noise or vibration impacts from construction trains or from operational train activity.	DOE estimates that 34 receptors would be included within the construction-train 65 DNL contours in Silver Springs, and 7 receptors would be included within the 65 DNL contours in Wabuska. These noise impacts would be considered temporary adverse impacts. Noise from operations would create adverse noise impacts at eight receptors in Silver Springs and one receptor in Wabuska. No vibration impacts from construction trains or from operational train activity.	No change to existing noise and vibration. No impacts because the rail line and associated facilities would not be constructed.
Socioeconomics – Throughout the region of influence	*Construction* Up to 1,083 animal unit months lost, valued at $57,000 (An animal unit month represents enough dry forage for one mature cow for one month.) *Operations* Continued lack of access to up to 1,083 animal unit months, valued at $57,000	*Construction* Up to 326 animal unit months lost, valued at $17,400 *Operations* Continued lack of access to up to 326 animal unit months, valued at $17,400	No impacts to existing socioeconomic conditions because the rail line and associated facilities would not be constructed.
Socioeconomics – Lincoln County	*Construction* Population: 1.7 percent increase Employment: 5.6 percent increase Real disposable income: 4.1 percent increase Gross regional product: 28 percent increase State and local government spending: 1.9 percent increase Traffic impacts to local highways: level of service on U.S. Highway 93 at Caliente would degrade from A to B	Not applicable	No impacts to existing socioeconomic conditions because the rail line and associated facilities would not be constructed.

	Caliente Implementing Alternative	Mina Implementing Alternative	
Occupational and public health and safety	Occupational radiological impacts: less than one latent cancer fatality Public radiological impacts: less than one latent cancer fatality Nonradiological industrial hazards during proposed railroad construction and operations: 2.22 worker fatalities Vehicular-related accidents during construction: 6 fatalities Vehicular-related accidents during operations: 8 fatalities Rail-related fatalities during construction and operations: 1.3 fatalities *Shared-Use Option* Vehicular-related accidents during construction: 6 fatalities Vehicular-related accidents during operations: 8 fatalities Rail-related fatalities during construction and operations: 4.6 fatalities	Occupational radiological impacts: less than one latent cancer fatality Public radiological impacts: less than one latent cancer fatality Nonradiological industrial hazards during proposed railroad construction and operations: 2 worker fatalities Vehicular-related accidents during construction: 6 fatalities Vehicular-related accidents during operations: 7 fatalities Rail-related accidents during construction and operations: 1.1 fatalities *Shared-Use Option* Vehicular-related accidents during construction: 6 fatalities Vehicular-related accidents during operations: 7 fatalities Rail-related fatalities during construction and operations: 7.4 fatalities	No impacts because the rail line and associated facilities would not be constructed or operated.
Utilities, energy and materials	Utility interfaces: Potential for short-term interruption of service during construction. No permanent or long-term loss of service or prevention of future service area expansions. Public water systems: Most water would be supplied by new wells; small effect on public water systems from population increase attributable to construction and operations employees.	Utility interfaces: Potential for short-term interruption of service during construction. No permanent or long-term loss of service or prevention of future service area expansions. Public water systems: Most water would be supplied by new wells; small effect on public water systems from population increase attributable to construction and operations employees.	No impacts because the rail line and associated facilities would not be constructed.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 16 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Utilities, energy, and materials (continued)	Wastewater treatment systems: Dedicated treatment systems would be provided at construction camps and operations facilities; small impact on public systems from population increase attributable to construction and operations employees. Fossil fuels: Demand would be approximately 6.5 percent of statewide use during construction and less than 0.25 percent of statewide use during operations. Demand could be met by existing regional supply systems and suppliers. Materials: Requirements generally would be very small in relation to supply capacity. *Shared-Use Option* Fossil fuels: Demand would be less than 0.3 percent of statewide use during operations. Demand could be met by existing regional supply systems and suppliers.	Wastewater treatment systems: Same as Caliente Implementing Alternative. Fossil fuels: Demand would be approximately 6 percent of statewide use during construction and less than 0.25 percent of statewide use during operations. Demand could be met by existing regional supply systems and suppliers. Materials: Same as Caliente Implementing Alternative. *Shared-Use Option* Fossil fuels: Same as Caliente Implementing Alternative.	
Hazardous materials and waste	Small (Apex Landfill) to moderate (smaller landfills) impacts during the construction phase and no impact to small impact during the operations phase from nonhazardous waste (solid and industrial and special waste) disposal. Small impacts from use of hazardous materials during the construction and operations phases. Small impacts from hazardous-waste disposal during the construction and operations phases. Small impacts during the operations phase from low-level radioactive waste disposal for wastes that would be generated at the Cask Maintenance Facility.	Same as Caliente Implementing Alternative. Same as Caliente Implementing Alternative. Same as Caliente Implementing Alternative. Same as Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed.

Table S-8. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 17 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Cultural resources	Numerous archaeological sites have been identified along segments of alignments subjected to sample inventory. Potential direct and indirect impacts to National Register-eligible sites and to other sites that might be identified during the complete survey. Construction could result in impacts to the early Mormon colonization cultural landscape, Pioche-Hiko silver mining community route, 1849 Emigrant Trail campsites, and American Indian trail systems. Indirect effects to a National Register-eligible rock-art site are likely from two quarry sites. More than 50 National Register-eligible sites have been identified along segments of alignments subjected to sample inventory.	Numerous archaeological sites have been identified along segments of alignments subjected to sample inventory. Potential direct and indirect impacts to National Register-eligible sites and to other sites that might be identified during the complete survey. More than 60 National Register-eligible sites have been identified along segments of alignments subjected to sample inventory.	No impacts because the rail line and associated facilities would not be constructed.
Paleontological resources	No direct impacts to known paleontological resources.	Same as Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed.
Environmental justice	Constructing and operating the proposed rail line along the Caliente rail alignment would not result in disproportionately high and adverse impacts to minority or low-income populations.	Same as Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed.

a. BLM = Bureau of Land Management; CO = carbon monoxide; dBA = A-weighted decibels; DNL = day-night average noise level; DOE = U.S. Department of Energy; NAAQS = National Ambient Air Quality Standards; NO_x = oxides of nitrogen; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO_2 = sulfur dioxide; VOCs = volatile organic compounds.

Table S-9. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments[a] (page 1 of 7).

Resource Area	Alternative segments and common segments	
	Interface with the Union Pacific Railroad – Caliente	Interface with the Union Pacific Railroad – Eccles
Physical setting	Total surface disturbance: 3.1 square kilometers (770 acres). Loss of prime farmland soils: 0.16 square kilometer (40 acres). Less than 0.1 percent of prime farmland soils in Lincoln County.	Total surface disturbance: 2.1 square kilometers (520 acres). Loss of prime farmland soils: 0.10 square kilometer (24 acres). Less than 0.1 percent of prime farmland soils in Lincoln County.
Land use and ownership	Private parcels crossed: 32. Area of private land affected: 0.31 square kilometer (77 acres). Active grazing allotments crossed: 2. Animal unit months lost: 6 (0.6 percent). Indian Cove Staging Yard area of private land affected: 0.73 square kilometer (180 acres) Upland Staging Yard, area of private land affected: 0.45 square kilometer (110 acres)	Private parcels crossed: 11. Area of private land affected: 0.32 square kilometer (80 acres). Active grazing allotments crossed: 4. Animal unit months lost: 18 (1.5 percent).
Aesthetic resources	Small to moderate impact. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads. Moderate impact from Staging Yard at Indian Cove. Moderate contrast from the operation of the facility in the Class III non-BLM lands, weak contrast from the track on BLM Class II lands at the north end; in each area, consistent with applicable BLM objectives. Potential quarry CA-8B - Moderate impact. Moderate contrast in the short term from installation and use of the conveyor from the quarry across U.S. Highway 93, consistent with surrounding non-BLM lands treated as Class III. No long-term impact under the Proposed Action; conveyor would be removed at end of construction phase.	Small to moderate impact. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads. Quarry CA-8B would not be developed for the Eccles alternative segment.
Surface-water resources	Caliente alternative segment: Approximately 0.05 square kilometer (12 acres) of wetlands would be filled. Long-term reduced and potentially eliminated access to Caliente Hot Springs. Indian Cove Staging Yard: Approximately 0.19 square kilometer (47 acres) of wetlands would be filled. Potential quarry CA-8B: Approximately 0.09 square kilometer (22 acres) of wetlands would be filled to construct the quarry siding.	Eccles alternative segment: Negligible amount of wetlands would be filled. Eccles Interchange Yard: Approximately 0.033 square kilometer (8.2 acres) of Clover Creek would be filled.

Table S-9. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments [a] (page 2 of 7).

Resource Area	Alternative segments and common segments	
	Interface with the Union Pacific Railroad – Caliente	Interface with the Union Pacific Railroad – Eccles
Groundwater resources	Groundwater withdrawals from the hydrographic area in Panaca Valley could impact existing groundwater users. However, mitigation measures such as reducing the pumping rate at or relocating proposed wells Pan V25/26, Pan V4, Pan V5, and Pan V3/6 would minimize these impacts.	Groundwater withdrawals from the hydrographic area in Panaca Valley could impact existing groundwater users. However, mitigation measures such as reducing the pumping rate at or relocating proposed wells Pan V3/6 and Pan V25/26 would minimize these impacts.
Biological resources	Caliente alternative segment and Interchange Yard: Short-term impact to 0.09 square kilometer (22 acres) wetland/riparian habitat. Long-term impact to 0.11 square kilometer (27 acres) wetland/riparian habitat. Upland Staging Yard: Short-term impact to 0.01 square kilometer (2.5 acres) wetland/riparian habitat. Long-term impact to less than 0.01 square kilometer (2 acres) wetland/riparian habitat. Indian Cove Staging Yard: Short-term impact to 0.09 square kilometer (22 acres) wetland/riparian habitat. Long-term impact to 0.04 square kilometer (9.9 acres) wetland/riparian habitat. Long-term moderate impact on riparian and wetland vegetation from the construction of a siding for potential quarry CA-8B.	Eccles alternative segment and Interchange Yard: Short-term impact to 0.10 square kilometer (24 acres) wetland/riparian habitat. Long-term impact to 0.10 square kilometer (24 acres) wetland/riparian habitat. Eccles-North Staging Yard: Short-term impact to 0.01 square kilometer (2.6 acres) wetland/riparian habitat. Long-term impact to 0.01 square kilometer (2.6 acres) wetland/riparian habitat.
Noise and vibration	Noise from construction activities would exceed Federal Transportation Administration guidelines. Daytime limits would be exceeded by 11 dBA from construction equipment noise and by 7 dBA from pile driving; 30-day DNL limit would be exceeded by 2 dBA from construction equipment noise and by 12 dBA from pile driving. There would be no adverse impacts from the operation of construction trains. There would be no receptors within the 65 DNL contour. There would be no adverse impacts from noise for the operation of trains along the rail alignment. No receptors would fall within the 3 dBA increase contour or the 65 DNL contour. There would be no adverse impacts from vibrations, which would fall below Federal Transportation Administration criteria.	Noise from construction activities would exceed Federal Transportation Administration guidelines. Construction equipment noise would cause daytime limits to be exceeded by 5 dBA. There would be no adverse impacts from the operation of construction trains. No receptors would fall within the 65 DNL contour. There would be no adverse impacts from noise for the operation of trains along the rail alignment. No receptors would be within the 65 DNL contour. There would be no adverse impacts from vibrations, which would fall below Federal Transportation Administration criteria.
Cultural resources	Potential direct and indirect impacts at three known National Register-eligible sites and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at two known potentially eligible sites and at other sites that might be identified during the complete survey.

Table S-9. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments[a] (page 3 of 7).

Resource Area	Alternative segments and common segments			
	Caliente common segment 1			
Physical setting	Total surface disturbance: 12 square kilometers (3,000 acres). Loss of prime farmland soils: 1.2 square kilometers (300 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.			
Land use and ownership	Private parcels crossed: 1. Area of private land affected: 0.0007 square kilometer (0.2 acre). Active grazing allotments crossed: 10. Animal unit months lost: 453 (0.7 percent).			
Cultural resources	Construction activities could result in impacts to the early Mormon colonization cultural landscape, the Pioche-Hiko silver mining community route, 1849 emigrant campsites, a National Register-eligible prehistoric site in the vicinity of Black Rock Springs, and to other sites that might be identified during the complete survey.			
	Garden Valley 1	Garden Valley 2	Garden Valley 3	Garden Valley 8
Physical setting	Total surface disturbance: 3.4 square kilometers (840 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.29 square kilometer (72 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.	Total surface disturbance: 3.6 square kilometers (890 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.4 square kilometer (99 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.	Total surface disturbance: 3.7 square kilometers (910 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0 square kilometer (0 acre).	Total surface disturbance: 3.7 square kilometers (910 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.36 square kilometer (89 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.
Land use and ownership	Active grazing allotments crossed: 5. Animal unit months lost: 120 (1.34 percent).	Active grazing allotments crossed: 4. Animal unit months lost: 131 (1.1 percent).	Active grazing allotments crossed: 5. Animal unit months lost: 126 (1.4 percent).	Active grazing allotments crossed: 4. Animal unit months lost: 131 (1.1 percent).

Table S-9. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments[a] (page 4 of 7).

Resource Area	Alternative segments and common segments			
	Garden Valley 1	Garden Valley 2	Garden Valley 3	Garden Valley 8
Aesthetic resources	Small impact. Track on some parts of the alternative segment would create a new linear feature that would not meet BLM Class II management objectives. Vegetated earthwork berms would reduce the contrast to levels consistent with Class II.	Small impact. Track on some parts of the alternative segment would create a new linear feature that would not meet BLM Class II management objectives. Vegetated earthwork berms would reduce the contrast to levels consistent with Class II.	Small impact. Track on some parts of the alternative segment would create a new linear feature that would not meet BLM Class II management objectives. Vegetated earthwork berms would reduce the contrast to levels consistent with Class II.	Small impact. Track on some parts of the alternative segment would create a new linear feature that would not meet BLM Class II management objectives. Vegetated earthwork berms would reduce the contrast to levels consistent with Class II.
Cultural Resources	Construction could result in direct and indirect impacts to American Indian trail systems and to other sites that might be identified during the complete survey.	Construction could result in direct and indirect impacts to American Indian trail systems, two National Register-eligible sites, and to other sites that might be identified during the complete survey.	Construction could result in direct and indirect impacts to American Indian trail systems and to other sites that might be identified during the complete survey.	Construction could result in direct and indirect impacts to American Indian trail systems and to other sites that might be identified during the complete survey.
	Caliente common segment 2			
Physical setting	Total surface disturbance: 4.1 square kilometers (1,000 acres). Would result in topsoil loss and increased potential for erosion.			
Land use and ownership	Active grazing allotments crossed: 3. Animal unit months lost: 128 (0.4 percent).			
Cultural resources	Potential indirect impacts include visual impacts to the Black Top archaeological locality; potential direct and indirect impacts to American Indian trail systems and a potential historic ranching cultural landscape, and to other sites that might be identified during the complete survey.			
	South Reveille 2		South Reveille 3	
Physical setting	Total surface disturbance: 4.8 square kilometers (1,200 acres). Would result in topsoil loss and increased potential for erosion.		Total surface disturbance: 5 square kilometers (1,240 acres). Would result in topsoil loss and increased potential for erosion.	
Land use and ownership	Active grazing allotments crossed: 1. Animal unit months lost: 54 (0.2 percent). Sections with unpatented mining claims the alignment would cross: 2 sections with 72 claims.		Active grazing allotments crossed: 1. Animal unit months lost: 58 (0.2 percent). Sections with unpatented mining claims the alignment would cross: 2 sections with 72 claims.

Resource Area	Alternative segments and common segments	
	South Reveille 2	South Reveille 3
Biological resources	Small to moderate impact on raptor nesting sites from the construction of potential quarry NN-9A.	Small to moderate impact on raptor nesting sites from the construction of potential quarry NN-9A.
Cultural resources	Rail line construction could represent a long-term indirect impact on a National Register-eligible rock-art site, and potential direct and indirect impacts at other sites that might be identified during the complete survey.	Rail line construction could represent a long-term indirect impact on a National Register-eligible rock-art site, and potential direct and indirect impacts at other sites that might be identified during the complete survey.

Resource Area	Caliente common segment 3
Physical setting	Total surface disturbance: 10 square kilometers (2,500 acres). Would result in topsoil loss and increased potential for erosion.
Land use and ownership	Active grazing allotments crossed: 3. Animal unit months lost: 250 (0.6 percent). Sections with unpatented mining claims the alignment would cross: 10 sections with 166 claims.
Cultural resources	Potential direct and indirect impacts at one known National Register-eligible archaeological site, and at other sites that might be identified during the complete survey.

Resource Area	Goldfield 1	Goldfield 3	Goldfield 4
Physical setting	Total surface disturbance: 9.8 square kilometers (2,400 acres). Would result in topsoil loss and increased potential for erosion.	Total surface disturbance: 10.2 square kilometers (2,500 acres). Would result in topsoil loss and increased potential for erosion.	Total surface disturbance: 6.5 square kilometers (1,600 acres). Would result in topsoil loss and increased potential for erosion.
Land use and ownership	Private parcels crossed: 6. Area of private land affected: 0.37 square kilometer (91 acres). Unpatented mining claims the alignment would cross: 14 sections with 474 claims.	Private parcels crossed: 2. Area of private land affected: 0.01 square kilometer (2 acres). Unpatented mining claims the alignment would cross: 14 sections with 359 claims.	Private parcels crossed: 37. Area of private land affected: 0.23 square kilometer (56 acres). Unpatented mining claims the alignment would cross: 19 sections with 538 claims.
Cultural resources	Potential direct and indirect impacts at possible Western Shoshone camps, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at one possible Western Shoshone camp, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at multiple National Register-eligible sites and in and around the town of Goldfield, at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.
Surface-water resources	No impact to Willow Springs.	Long-term reduced and potentially eliminated access to Willow Springs.	No impact to Willow Springs.

Table S-9. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments [a] (page 6 of 7).

Resource Area	Alternative segments and common segments	
	Caliente common segment 4	
Physical setting	Total surface disturbance: 1.1 square kilometers (270 acres). Would result in topsoil loss and increased potential for erosion.	
Cultural resources	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	
	Bonnie Claire 2	Bonnie Claire 3
Physical setting	Total surface disturbance: 1.9 square kilometers (470 acres). Would result in topsoil loss and increased potential for erosion.	Total surface disturbance: 1.9 square kilometers (470 acres). Would result in topsoil loss and increased potential for erosion.
Cultural resources	Potential direct and indirect impacts at one National Register-eligible archaeological site, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at one National Register-eligible archaeological site, and at other sites that might be identified during the complete survey.
	Common segment 5	
Physical setting	Total surface disturbance: 3.1 square kilometers (770 acres). Would result in topsoil loss and increased potential for erosion.	
Cultural resources	Potential direct and indirect impacts at two National Register-eligible archaeological sites, 20 additional resources that have been recorded within the region of influence, and at other sites that might be identified during the complete survey.	
	Oasis Valley 1	Oasis Valley 3
Physical setting	Total surface disturbance: 1 square kilometer (250 acres). Would result in topsoil loss and increased potential for erosion.	Total surface disturbance: 1.3 square kilometers (320 acres). Would result in topsoil loss and increased potential for erosion.
Land use and ownership	Private parcels crossed: 1. Area of private land affected: 0.04 square kilometer (9.9 acres). Active grazing allotments crossed: 1. Animal unit months lost: 8 (0.8 percent). Unpatented mining claims the alignment would cross: 2 sections with 14 claims.	Private parcels crossed: 0. Area of private land affected: 0. Active grazing allotments crossed: 1. Animal unit months lost: 13 (1.4 percent). Unpatented mining claims the alignment would cross: 2 sections with 14 claims.
Groundwater resources	Groundwater withdrawals from hydrographic area 228 (Oasis Valley) would impact existing groundwater users or groundwater resources. However, mitigation measures such as reducing the pumping rate at proposed wells OV3, OV4, and OV5 or drawing water from alternative wells nearby would minimize these impacts.	Groundwater withdrawals from hydrographic area 228 (Oasis Valley) would impact existing groundwater users or groundwater resources. However, mitigation measures such as reducing the pumping rate at proposed well OV13 or drawing water from alternative wells nearby would minimize these impacts.

Table S-9. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments[a] (page 7 of 7).

Resource Area	Alternative segments and common segments	
	Oasis Valley 1	Oasis Valley 3
Biological resources	No impact on riparian and wetland vegetation.	Short-term moderate impact on riparian and wetland vegetation.
Cultural resources	Potential direct and indirect impacts at a historic cattle ranch, campsite, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at a historic cattle ranch, campsite, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.
	Common segment 6	
Physical setting	Total surface disturbance: 5.5 square kilometers (1,400 acres). Would result in topsoil loss and increased potential for erosion.	
Cultural resources	Potential direct and indirect impacts at archaeological sites recorded in region of influence, including three National Register-eligible resources, and at other sites that might be identified during the complete survey.	
Land use and ownership	Sections with unpatented mining claims the alignment would cross: 4 sections with 34 claims.	
Biological resources	Short-term moderate impacts to desert bighorn sheep southwest of common segment 6.	

a. BLM = Bureau of Land Management; dBA = A-weighted decibels; DOE = U.S. Department of Energy.

Table S-10. Comparison of potential impacts under the Proposed Action – Mina rail alignment existing rail line, alternative segments, and common segments[a] (page 1 of 7).

Resource area	Existing rail line/alternative segments/common segments
	Union Pacific Railroad Hazen Branchline
Noise and vibration	DOE estimates that 34 receptors would be included within the construction train 65 DNL contours in Silver Springs, and 7 receptors would be included within the 65 DNL contours in Wabuska. These noise impacts would be considered temporary adverse impacts. Noise from operations would create adverse noise impacts at eight receptors in Silver Springs and one receptor in Wabuska. There would be no adverse impact from vibrations, which would fall below Federal Transportation Administration criteria.
	Department of Defense Branchline North
Physical setting	Total surface disturbance: 0.16 square kilometer (40 acres). Would result in topsoil loss and increased potential for erosion.

Table S-10. Comparison of potential impacts under the Proposed Action – Mina rail alignment existing rail line, alternative segments, and common segments[a] (page 2 of 7).

Resource area	Existing rail lines/alternative segments/common segments			
	Schurz alternative segment 1	Schurz alternative segment 4	Schurz alternative segment 5	Schurz alternative segment 6
Physical setting	Total surface disturbance: 4.6 square kilometers (1,100 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.011 square kilometer (2.7 acres). Less than 3 percent of the prime farmland soils of the Walker River Paiute Reservation.	Total surface disturbance: 6.1 square kilometers (1,500 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.012 square kilometer (3 acres). Less than 3 percent of the prime farmland soils of the Walker River Paiute Reservation.	Total surface disturbance: 6.9 square kilometers (1,700 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.014 square kilometer (3.5 acres). Less than 3 percent of the prime farmland soils of the Walker River Paiute Reservation.	Total surface disturbance: 6.5 square kilometers (1,600 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.014 square kilometer (3.5 acres). Less than 3 percent of the prime farmland soils of the Walker River Paiute Reservation.
Aesthetic resources	Small to moderate impact. Weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives.	Small to moderate impact. Weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives.	Small to moderate impact. Weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives.	Small to moderate impact. Weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives. Moderate to strong contrast in the short term from construction of the rail-over-road crossing of U.S. Highway 95 for Schurz 6, which would not meet BLM Class III management objectives.

Table S-10. Comparison of potential impacts under the Proposed Action – Mina rail alignment existing rail line, alternative segments, and common segments[a] (page 3 of 7).

Resource area	Existing rail line/alternative segments/common segments			
	Schurz alternative segment 1	Schurz alternative segment 4	Schurz alternative segment 5	Schurz alternative segment 6
Biological resources	No impacts to Inter-Mountains Mixed Salt Desert Scrub and Inter-Mountain Basins Greasewood Flat. Short-term impact to 0.03 square kilometer (6.4 acres) wetland/riparian habitat. Long-term impact to 0.01 square kilometer (3.1 acres) wetland/riparian habitat.	No impacts to Inter-Mountains Mixed Salt Desert Scrub and Inter-Mountain Basins Greasewood Flat. Short-term impact to 0.03 square kilometer (6.4 acres) wetland/riparian habitat. Long-term impact to 0.01 square kilometer (3.1 acres) wetland/riparian habitat.	No impacts to Inter-Mountains Mixed Salt Desert Scrub and Inter-Mountain Basins Greasewood Flat. Short-term impact to 0.02 square kilometer (4.9 acres) wetland/riparian habitat. No long-term impact to wetland/riparian habitat.	Small to moderate long-term impacts to Inter-Mountains Mixed Salt Desert Scrub and Inter-Mountain Basins Greasewood Flat. Short-term impact to 0.01 square kilometer (3.1 acres) wetland/riparian habitat. No long-term impact to wetland/riparian habitat.
Surface-water resources	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 20 square meters (220 square feet) would be permanently filled to construct the bridge over the Walker River.	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 20 square meters (220 square feet) would be permanently filled to construct the bridge over the Walker River.	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 28 square meters (300 square feet) would be permanently filled to construct the bridge over the Walker River.	Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 28 square meters (300 square feet) would be permanently filled to construct the bridge over the Walker River.
Cultural resources	Potential direct and indirect impacts at two potential National Register-eligible sites, at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at three potential National Register-eligible sites, at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey. Resource area	Existing rail line/alternative segments/common segments		
	Montezuma alternative segment 1	Montezuma alternative segment 2	Montezuma alternative segment 3
Aesthetic resources	Small to moderate impact. No to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, access roads. Weak contrast from new linear feature adjacent to State Route 265 and weak to moderate contrast in Clayton Valley; would meet BLM Class III and IV management objectives. Potential North Clayton quarry - Small to moderate impact. Moderate contrast in the short term from production facilities close to viewers that would be compatible with BLM Class IV management objectives. Small impact to no impact in long term; production facilities would be removed and waste dumps restored after closure of quarry at end of construction phase.	Small to moderate impact. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, access roads.	Small to moderate impact. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, access roads. Potential North Clayton quarry - Weak to moderate impact. Moderate contrast in the short term from production facilities close to viewers that would be compatible with BLM Class IV management objectives. Small impact to no impact in long term; production facilities would be removed and waste dumps restored after closure of quarry at end of construction phase.
Groundwater resources	Groundwater withdrawals from hydrographic area 143 (Clayton Valley) would impact existing users of groundwater in the vicinity of Silver Peak. However, mitigation measures such as reducing the pumping rate at proposed well CL-1a would minimize these impacts.	Groundwater withdrawals would not result in impacts on existing groundwater users or groundwater resources.	Groundwater withdrawals would not result in impacts on existing groundwater users or groundwater resources.

Table S-10. Comparison of potential impacts under the Proposed Action – Mina rail alignment existing rail line, alternative segments, and common segments[a] (page 6 of 7).

Resource area	Existing rail line/alternative segments/common segments		
	Montezuma alternative segment 1	Montezuma alternative segment 2	Montezuma alternative segment 3
Biological resources	Moderate impact to winterfat communities. Long-term moderate impacts to Inter-Mountain Basins Mixed Salt Desert Scrub and Inter-Mountain Basins Big Sagebrush at potential North Clayton and Malpais Mesa quarry sites.	Moderate impact to winterfat communities.	Moderate impact to winterfat communities. Long-term moderate impacts to Inter-Mountain Basins Mixed Salt Desert Scrub and Inter-Mountain Basins Big Sagebrush at potential Malpais Mesa quarry site.
Cultural resources	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.
	Mina common segment 2		
Physical setting	Total surface disturbance: 0.28 square kilometer (69 acres). Would result in topsoil loss and increased potential for erosion.		
Cultural resources	Potential direct and indirect impacts at archaeological sites identified along segments subjected to sample inventory, and at other sites that may be identified during the complete survey.		
	Bonnie Claire alternative segment 2	Bonnie Claire alternative segment 3	
Physical setting	Total surface disturbance: 1.9 square kilometers (470 acres). Would result in topsoil loss and increased potential for erosion.	Total surface disturbance: 1.9 square kilometers (470 acres). Would result in topsoil loss and increased potential for erosion.	
Cultural resources	Potential direct and indirect impacts at one National Register-eligible archaeological site, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at one National Register-eligible archaeological site, and at other sites that might be identified during the complete survey.	
	Common segment 5		
Physical setting	Total surface disturbance: 3.1 square kilometers (770 acres). Would result in topsoil loss and increased potential for erosion.		
Cultural resources	Potential direct and indirect impacts at two National Register-eligible archaeological sites, 20 additional resources that have been recorded within the region of influence, and at other sites that might be identified during the complete survey.		

Table S-10. Comparison of potential impacts under the Proposed Action – Mina rail alignment existing rail line, alternative segments, and common segments[a] (page 7 of 7).

Resource area	Existing rail line/alternative segments/common segments	
	Oasis Valley alternative segment 1	Oasis Valley alternative segment 3
Physical setting	Total surface disturbance: 1 square kilometer (250 acres). Would result in topsoil loss and increased potential for erosion.	Total surface disturbance: 1.3 square kilometers (320 acres). Would result in topsoil loss and increased potential for erosion.
Land use and ownership	Private parcels crossed: 1 Area of private land affected: 0.04 square kilometer (9.9 acres). Active grazing allotments crossed: 1 Animal unit months lost: 8 (0.8 percent). Unpatented mining claims the alignment would cross: 2 sections with 14 claims.	Private parcels crossed: 0 Area of private land affected: 0 Active grazing allotments crossed: 1 Animal unit months lost: 13 (1.4 percent). Unpatented mining claims the alignment would cross: 2 sections with 14 claims.
Groundwater resources	Groundwater withdrawals from hydrographic area 228 (Oasis Valley) would impact existing groundwater users or groundwater resources. However, mitigation measures such as reducing the pumping rate at proposed wells OV3, OV4, and OV5 or drawing water from nearby alternative wells would minimize these impacts.	Groundwater withdrawals from hydrographic area 228 (Oasis Valley) would impact existing groundwater users or groundwater resources. However, mitigation measures such as reducing the pumping rate at proposed well OV13 or drawing water from nearby alternative wells would minimize these impacts.
Biological resources	No impact on riparian and wetland vegetation.	Short-term moderate impact on riparian and wetland vegetation.
Cultural resources	Potential direct and indirect impacts at a historic cattle ranch, campsite, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at a historic cattle ranch, campsite, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.
	Common segment 6	
Physical setting	Total surface disturbance: 5.5 square kilometers (1,400 acres). Would result in topsoil loss and increased potential for erosion.	
Biological resources	Short-term moderate impacts to desert bighorn sheep southwest of common segment 6.	
Land use and ownership	Sections with unpatented mining claims the alignment would cross: 4 sections with 34 claims.	
Cultural resources	Potential direct and indirect impacts at archaeological sites recorded in region of influence, including three National Register-eligible resources, and at other sites that might be identified during the complete survey.

ABSTRACT: The Nevada Rail Corridor SEIS (DOE/EIS-0250F-S2D) analyzes the potential impacts of constructing and operating a railroad to connect the Yucca Mountain repository site to an existing rail line near Wabuska, Nevada (in the Mina rail corridor). The Nevada Rail Corridor SEIS analyzes the Mina rail corridor at a level of detail commensurate with that of the rail corridors analyzed in the Final *Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F). The Nevada Rail Corridor SEIS also updates relevant information regarding other rail corridors previously analyzed in the Yucca Mountain FEIS (Carlin, Jean, and Valley Modified) to identify any significant new circumstances or information relevant to environmental concerns.

The Rail Alignment EIS (DOE/EIS-0369D) analyzes the potential impacts of railroad construction and operation along common segments and alternative segments within the Caliente (selected in a previous Record of Decision, 69 *Federal Register* 18557) and Mina rail corridors for the purpose of determining an alignment for the construction and operation of a railroad for shipments of spent nuclear fuel, high-level radioactive waste, and other materials from an existing rail line in Nevada to a geologic repository at Yucca Mountain. The Rail Alignment EIS also analyzes the potential impacts of constructing and operating support facilities.

COOPERATING AGENCIES: The U.S. Bureau of Land Management, the Surface Transportation Board, and the U.S. Air Force are cooperating agencies in the preparation of the Nevada Rail Corridor SEIS and the Rail Alignment EIS.

PUBLIC COMMENTS: A 90-day comment period on this document begins with the publication of the Environmental Protection Agency Notice of Availability in the *Federal Register*. DOE will consider comments received after the 90-day period to the extent practicable. The Department will hold public hearings to receive comments on the document at the times and locations announced in local media and the DOE Notice of Availability. Written comments may also be submitted by U.S. mail to the U.S. Department of Energy at the above address in Las Vegas, via the Internet at *http://www.ymp.gov,* or by facsimile at 1-800-967-0739. This public comment period and the public hearings coincide with those of the *Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F-S1D).

READERS GUIDE

READERS GUIDE TO

Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada – Nevada Rail Transportation Corridor
DOE/EIS-0250F-S2D

and

Draft Environmental Impact Statement for a Rail Alignment for the Construction and Operation of a Railroad in Nevada to a Geologic Repository at Yucca Mountain, Nye County, Nevada
DOE/EIS-0369D

This NEPA document contains two separate analyses—

- The Nevada Rail Corridor SEIS supplements and updates the information on Nevada rail corridors reported in the Yucca Mountain EIS (DOE/EIS-0250F), which DOE completed in 2002.
- The Rail Alignment EIS provides detailed analyses of two rail corridors (Caliente and Mina) at the alignment level.

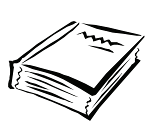
The Repository SEIS (DOE/EIS-0250F-S1D), published simultaneously with the Nevada Rail Corridor SEIS and the Rail Alignment EIS, is a separate, but related, analysis.

The Foreword, which immediately follows this Readers Guide, explains and graphically shows the relationship between the Nevada Rail Corridor SEIS, the Rail Alignment EIS, and the Repository SEIS. The Foreword also explains the relationship between those NEPA documents and the Repository SEIS, a separate, but related, environmental analysis.

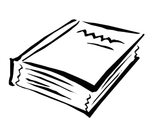
Readers might want to know…

How is the document structured?

This document has a summary and four volumes, as follows:

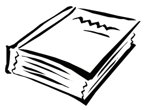


The Summary provides an overview of the information and analyses provided in Volumes I, II, III, and IV. From the Summary, readers will gain a general understanding of the proposed project, the environmental analyses, and potential environmental impacts. By its very nature, the Summary does not provide the engineering and scientific detail of the full document.

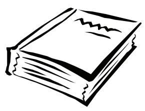


Volume I contains the Nevada Rail Corridor SEIS in its entirety, and Chapters 1 and 2 of the Rail Alignment EIS.

Volume II contains Chapter 3 of the Rail Alignment EIS, which describes the existing environmental setting and conditions for 15 environmental resource areas along the Caliente rail alignment and the Mina rail alignment.



Volume III contains Chapter 4 of the Rail Alignment EIS, which describes potential impacts to the existing environmental setting and conditions for 15 environmental resource areas along the Caliente rail alignment and the Mina rail alignment.



Volume IV contains Chapters 5, 6, 7, and 8 of the Rail Alignment EIS; a list of preparers, contributors, and reviewers; a glossary of terms, a reference list, Appendixes A through N, and an index.

In addition, DOE has developed a Map Atlas, which contains aerial photographs with digital overlays of the proposed railroad along the Caliente rail alignment and the Mina rail alignment. The Map Atlas is available on the Office of Radioactive Waste Management website at *www.ocrwm.doe.gov*.

The graphic on the next page shows the document structure and lists the contents of each volume.

Is this document difficult to understand?

This NEPA document is large and the subject of the proposed railroad project is complex. The analyses cover many environmental resource areas over long linear distances. DOE has endeavored to present this information in a logical format, and has included much of the information in tables and figures.

The Caliente and Mina rail alignments are treated fully and individually in the Rail Alignment EIS, Chapters 3 and 4. Although this approach results in repetition of some information, it allows readers interested in only one of the rail alignments easy access to information about that alignment.

The Department has provided tools and applied conventions to make the document as understandable and reader friendly as possible. For example:

- **Acronyms and Abbreviations** This document uses relatively few acronyms and abbreviations. Those used in text are spelled out at first use in each chapter; those used in tables and figures because of space limitations are defined in table and figure footnotes. The inside front cover of each volume of the document lists acronyms and abbreviations used in text. Each appendix has its own list of acronyms and abbreviations, as appropriate.

- **Definitions** Volume IV contains a glossary of terms. The glossary defines terms unique to this document and focuses on terms used in the environmental analyses and terms related to railroads. Glossary terms are shown in ***bold italics*** at first use in each chapter. Some glossary terms are also given in text boxes at appropriate places in the document.

- **Document Navigation** The Summary and each volume of this document contain detailed tables of contents, including lists of tables and figures. There is also a detailed index at the back of Volume IV.

Summary

High-level overview of the Nevada Rail Corridor SEIS and the Rail Alignment EIS.

Index

- **Units of Measure** DOE has used standard units of measure, both metric and English. The Metric Conversion Act of 1975 (Public Law 94-168) and Executive Order 12770, *Metric Usage in Federal Government Programs*, require federal agencies to "seek out ways to increase understanding of the metric system of measurement through educational information and guidance and in Government publications."

  DOE believes that providing measures in both metric and English units ensures understanding by a wider audience of readers who speak English, including those more familiar with the metric system of measurement.

  Generally, measurements given in text are provided in the metric unit followed by the English conversion in parentheses, and tables provide measures in metric units and include a footnote with the English conversion factor. The inside back cover of each volume of this document provides a conversion table (metric to English and English to metric).

- **Rounding** DOE has endeavored to provide numerical data at a level to permit a meaningful comparison of quantities. Some numbers in this document are rounded, others are not. Generally, DOE has not rounded numbers taken from source documents and used as inputs to analyses. Numbers resulting from analyses are rounded if the inclusion of more digits would not be meaningful for comparative purposes. Extremely large numbers or extremely small numbers might be given using what is known as scientific notation. The inside front cover of each volume of this document provides a brief explanation of scientific notation.

What is DIRS?

The acronym DIRS precedes technical references cited in this document. DIRS stands for Document Input Reference System, a Yucca Mountain Project database used to catalog and track the use of references in project documents. Documents in this system have been checked and verified suitable for use, including those requiring copyright permissions. Every reference cited in this EIS is traceable via its unique DIRS number. To the extent possible, each reference citation provides a pointer to the location of the cited information within the reference. If the citation is general and applies to the entire document, or if it is not possible to provide a specific pointer (for example, in large data sets), the citation is indicated as "all."

What does DTN mean?

Data sets referenced in this document are preceded by the abbreviation DTN, which stands for Data Tracking Number. The Yucca Mountain Project uses a controlled system for cataloging and tracking all data used in project technical documents. Data in this system have been checked and verified suitable for use. All project data cited in this EIS are traceable to the unique DTN.

If I have comments on this EIS, where do I send them?

The Cover Sheet preceding this Readers Guide provides information on the public comment period and how to submit comments.

FOREWORD

The U.S. Department of Energy (DOE or Department) has prepared two draft National Environmental Policy Act (NEPA) documents associated with the proposed disposal of spent nuclear fuel and high-level radioactive waste in a geologic repository at the Yucca Mountain Site in Nye County, Nevada:

- *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F-S1; the Repository SEIS).
- *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada – Nevada Rail Transportation Corridor* (Part 1) (DOE/EIS-0250F-S2D; the Nevada Rail Corridor SEIS), and *Draft Environmental Impact Statement for a Rail Alignment for the Construction and Operation of a Railroad in Nevada to a Geologic Repository at Yucca Mountain, Nye County, Nevada* (Part 2) (DOE/EIS-0369D; the Rail Alignment EIS).

The Repository SEIS evaluates the potential environmental impacts of constructing and operating the Yucca Mountain repository under the current repository design and operational plans, the purpose of which is to assist the U.S. Nuclear Regulatory Commission (NRC) in adopting, to the extent practicable, any EIS prepared pursuant to Section 114(f)(4) of the Nuclear Waste Policy Act, as amended (NWPA; 42 United States Code 10101 *et seq.*).

The Nevada Rail Corridor SEIS and the Rail Alignment EIS evaluate the potential environmental impacts of constructing and operating a railroad for shipments of spent nuclear fuel and high-level radioactive waste from an existing rail line in Nevada to the repository at Yucca Mountain, the purpose of which is to help the Department decide whether to construct and operate a railroad, and if so, within which corridor and along which alignment.

Background and Context

The NWPA directs the Secretary of Energy, if the Secretary decides to recommend approval of the Yucca Mountain site for development of a repository, to submit a final EIS with any recommendation to the President. To fulfill that requirement, the Department prepared the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F, February 2002) (Yucca Mountain FEIS).

On February 14, 2002, the Secretary transmitted to the President his recommendation (including the Yucca Mountain FEIS) for approval of the Yucca Mountain site for development of a geologic repository. The President considered the site qualified for application to the NRC for construction authorization and recommended the site to the U.S. Congress. Subsequently, Congress passed a joint resolution of the U.S. House of Representatives and the U.S. Senate designating the Yucca Mountain site for development as a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste. On July 23, 2002, the President signed the joint resolution into law (Public Law 107-200). The Department is now in the process of preparing an application for submittal to the NRC seeking authorization to construct the repository, as required by the NWPA (Section 114(b)).

Since completion of the Yucca Mountain FEIS in 2002, DOE has continued to develop the repository design and associated construction and operational plans. As now proposed, the newly designed surface and subsurface facilities would allow DOE to operate the repository following a primarily canistered approach in which most commercial spent nuclear fuel would be packaged at the reactor sites in transportation, aging, and disposal (TAD) canisters. Any commercial spent nuclear fuel arriving at the repository in packages other than TAD canisters would be repackaged by DOE at the repository into TAD canisters. DOE would construct the surface and subsurface facilities over a period of several years (referred to as phased construction) to accommodate an increase in spent nuclear fuel and high-level radioactive waste receipt rates as repository operational capability reaches its design capacity. To address the current repository design and operational plans, the Department announced its intent to prepare a Supplement to the Yucca Mountain FEIS (DOE/EIS-0250F-S1), consistent with NEPA and the NWPA. (*Supplement to the Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV*; 71 *Federal Register* [*FR*] 60490, October 13, 2006). The Repository SEIS supplements the Yucca Mountain FEIS by considering the potential environmental impacts of the construction, operation and closure of the repository under the current repository design and operational plans, and by updating the analysis and potential environmental impacts of transporting spent nuclear fuel and high-level radioactive waste to the repository, consistent with transportation-related decisions the Department made following completion of the Yucca Mountain FEIS.

On April 8, 2004, the Department issued a Record of Decision announcing its selection, both nationally and in the State of Nevada, of the mostly rail scenario analyzed in the Yucca Mountain FEIS as the primary means of transporting spent nuclear fuel and high-level radioactive waste to the repository (*Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV*; 69 *FR* 18557, April 8, 2004). Implementation of the mostly rail scenario ultimately would require the construction of a rail line to connect the repository site at Yucca Mountain to an existing rail line in the State of Nevada. To that end, in the same Record of Decision, the Department also selected the Caliente rail corridor from several corridors considered in the Yucca Mountain FEIS as the corridor in which to study possible alignments for a rail line. On the same day DOE selected the Caliente corridor, it issued a Notice of Intent to prepare an EIS under NEPA to study alternative alignments within the Caliente corridor (the Rail Alignment EIS; DOE/EIS-0369) (*Notice of Intent to Prepare an Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV*; 69 *FR* 18565, April 8, 2004).

During the subsequent public scoping process, DOE received comments suggesting that other rail corridors be considered, in particular, the Mina route. In the Yucca Mountain FEIS, DOE had considered but eliminated the Mina route from detailed study because a rail line within the Mina route could only connect to an existing rail line in Nevada by crossing the Walker River Paiute Reservation, and the Tribe had informed DOE that it would not allow nuclear waste to be transported across the Reservation.

Following review of the scoping comments, DOE held discussions with the Walker River Paiute Tribe and, in May 2006, the Tribal Council informed DOE that it would allow the Department to consider the potential impacts of constructing and operating a railroad to transport spent nuclear fuel and high-level radioactive waste across its reservation. On October 13, 2006, after a preliminary evaluation of the feasibility of the Mina rail corridor, DOE announced its intent to expand the scope of the Rail Alignment EIS to include the Mina corridor (*Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV*; 71 *FR* 60484). Although the expanded NEPA analyses, referred to as the Nevada Rail Corridor SEIS and the Rail Alignment EIS, evaluate the potential environmental impacts associated with the Mina rail corridor, DOE has identified the Mina alternative as nonpreferred because the Tribe has withdrawn its support for the EIS process.

Relationships Among the EISs

The Yucca Mountain FEIS, the Repository SEIS, and the Nevada Rail Corridor SEIS and the Rail Alignment EIS are related in several respects. The Nevada Rail Corridor SEIS supplements the rail corridor analysis of the Yucca Mountain FEIS by analyzing the potential environmental impacts associated with constructing and operating a railroad within the Mina corridor. The Nevada Rail Corridor SEIS analyzes the Mina corridor at a level of detail commensurate with that of the rail corridor analysis in the Yucca Mountain FEIS, and concludes that the Mina corridor warrants further study in the Rail Alignment EIS to identify an alignment for the construction and operation of a railroad.

The Nevada Rail Corridor SEIS also updates relevant information regarding three other rail corridors previously analyzed in the Yucca Mountain FEIS (Carlin, Jean, and Valley Modified). The update demonstrates that there are no significant new circumstances or information relevant to environmental concerns associated with these three rail corridors, and that they do not warrant further consideration in the Rail Alignment EIS. The Caliente-Chalk Mountain rail corridor, which also was included in the Yucca Mountain FEIS, would intersect the Nevada Test and Training Range, and was eliminated from further consideration because of U.S. Air Force concerns that a rail line within the Caliente-Chalk Mountain corridor would interfere with military readiness testing and training activities.

The Rail Alignment EIS tiers from the broader corridor analysis in both the Yucca Mountain FEIS and the Nevada Rail Corridor SEIS, consistent with the Council on Environmental Quality regulations (see 40 Code of Federal Regulations 1508.28). Under the Proposed Action considered in the Rail Alignment EIS, DOE analyzes specific potential impacts of constructing and operating a railroad along common segments and alternative segments within the Caliente and Mina corridors for the purpose of determining an alignment in which to construct and operate a railroad for shipments of spent nuclear fuel and high-level radioactive waste from an existing rail line in Nevada to a geologic repository at Yucca Mountain.

The Repository SEIS includes the potential environmental impacts of national transportation, and the potential impacts from the construction and operation of a rail line along specific alignments in either the Caliente or the Mina corridor, as described in the Rail Alignment EIS, to ensure that the Repository SEIS considers the full scope of potential environmental impacts associated with the proposed construction and operation of the repository. Conversely, the Rail Alignment EIS includes the potential impacts of constructing and operating the repository as a reasonably foreseeable future action in its cumulative impacts analysis. To ensure consistency, the Repository SEIS, the Nevada Rail Corridor SEIS, and the Rail Alignment EIS use the same inventory of spent nuclear fuel and high-level radioactive waste and the same number of rail shipments for analysis. Thus, the associated occupational and public health and safety impacts within the Nevada rail corridors under consideration are the same in both documents. Furthermore, to promote conformity, where appropriate, consistent analytical approaches were used in both documents to evaluate the various resource areas.

The figure that follows summarizes the relationship among the EISs.

Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (DOE/EIS-0250F)

Proposed Action:

- DOE would construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain.
- Repository operations would include transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain nationally and in Nevada by either mostly rail or mostly truck

Record of Decision

- Mostly rail nationally and in Nevada
- Caliente rail corridor to determine a rail alignment

Repository SEIS
(DOE/EIS-0250F-S1)

1. Supplements the Yucca Mountain FEIS in its entirety, as modified by:
   - Record of Decision (mostly rail, Caliente rail corridor) (69 *FR* 18557)
   - Outcome of the Nevada Rail Corridor SEIS (Mina rail corridor)
2. Otherwise the Proposed Action remains unchanged:
   - DOE would construct, operate and monitor, and eventually close a repository
   - During repository operations, shipments would occur by mostly rail
   - In Nevada, rail shipments would occur on a railroad to be constructed along an alignment within either the Caliente or the Mina rail corridor
   - Shipments also would arrive at repository by truck
3. To supplement Nevada transportation analysis, Repository SEIS incorporates by reference relevant information from the Rail Alignment EIS:
   - Affected environments for Caliente and Mina rail alignments
   - Environmental impacts from constructing and operating a railroad along Caliente or Mina rail alignment
   - Cumulative impacts associated with Caliente and Mina rail alignments

Nevada Rail Corridor SEIS (Part 1)
(DOE/EIS-0250F-S2)

1. Supplements the Nevada transportation analysis of the Yucca Mountain FEIS, as modified by:
   - Record of Decision (mostly rail) (69 *FR* 18557)
   - Proposed consideration of Mina rail corridor
2. Under the Proposed Action, DOE would construct and operate a railroad to connect the Yucca Mountain repository to an existing rail line near Wabuska, Nevada (the Mina rail corridor)
   - Mina corridor information and analyses at a level of detail commensurate with that of the other corridors in the Yucca Mountain FEIS
3. Considers other corridors in the Yucca Mountain FEIS for significant new circumstances or information relevant to environmental concerns
   - Review environmental information available since the Yucca Mountain FEIS
4. Conclusion:
   - Whether the Mina rail corridor warrants further detailed study to determine an alignment based on impact analysis
   - Whether there are significant changes or new information relevant to environmental concerns for the other corridors that would warrant further detailed study to determine an alignment

Rail Alignment EIS (Part 2)
(DOE/EIS-0369)

1. Tiers from the Yucca Mountain FEIS and the Nevada Rail Corridor SEIS
2. Proposed Action based on Record of Decision (69 *FR* 18557)
   - Under the Proposed Action, DOE would determine an alignment for the construction and operation of a railroad
     - ⇒ Caliente Implementing Alternative (preferred)
     - ⇒ Mina Implementing Alternative (nonpreferred)

Relationship between the Repository SEIS, the Nevada Rail Corridor SEIS, and the Rail Alignment EIS.

1. PURPOSE AND NEED FOR AGENCY ACTION

This chapter explains why DOE needs to construct and operate a railroad in Nevada, summarizes the process leading to the addition of a rail corridor for further study, and describes the interests and roles of cooperating agencies. It also describes the Rail Alignment EIS and Nevada Rail Corridor scoping processes; summarizes public scoping comments and how DOE acted on those comments; describes interactions with American Indian Tribes and tribal organizations; and the relationship of this Nevada Rail Corridor SEIS to other environmental documents.

Glossary terms are shown in ***bold italics***.

1.1 Purpose and Need

The United States has focused a national effort on siting and developing a ***geologic repository*** for ***disposal*** of ***spent nuclear fuel*** and ***high-level radioactive waste***, and on developing systems in preparation for transporting these materials from their locations throughout the country to a repository. On July 23, 2002, the President signed into law (Public Law 107-200) a joint resolution of the U.S. House of Representatives and the U.S. Senate designating the Yucca Mountain Site in Nye County, Nevada, for development as a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste.

Spent nuclear fuel is fuel that has been withdrawn from a reactor following irradiation.

- **Commercial spent nuclear fuel** comes from civilian nuclear power plants that generate electricity.
- **DOE spent nuclear fuel** comes from DOE production reactors, naval reactors, and university- and government-owned test and experimental reactors.

High-level radioactive waste is the highly radioactive material that results from the reprocessing of spent nuclear fuel and other highly radioactive material, which the U.S. Nuclear Regulatory Commission determines by rule requires permanent isolation.

After the Yucca Mountain Site was designated, the U.S. Department of Energy (DOE or the Department) initiated preparation of a license application to be submitted to the U.S. Nuclear Regulatory Commission seeking authorization to construct the repository. In addition, to be in a position to transport spent nuclear fuel and high-level radioactive waste to the repository should the Commission approve construction of the repository and receipt of these materials, DOE proceeded with certain decisions related to the transportation of these materials. On April 8, 2004, the Department announced that it would ship most spent nuclear fuel and high-level radioactive waste to the repository by rail (train) (*Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV*; 69 *Federal Register* [*FR*] 18557). Because rail access to Yucca Mountain is not currently available, DOE would have to build a rail line to connect to an existing rail line in Nevada.

1.2 Yucca Mountain Site-Selection and Recommendation Process

The Nuclear Waste Policy Act of 1982 (Public Law 97-425) acknowledged the Federal Government's responsibility to provide for the disposal of the Nation's spent nuclear fuel and high-level radioactive waste. This Act, as amended (42 United States Code [U.S.C.] 10101 *et seq.*), which the Nevada Rail

Corridor SEIS and the Rail Alignment EIS refer to as the NWPA, identifies the Yucca Mountain Site in Nye County, Nevada, as the site to be studied as a potential location for a geologic repository.

After completion of site characterization studies at Yucca Mountain, the Secretary of Energy, finding the site to be scientifically and technically suitable for development of a repository, submitted his recommendation, along with a comprehensive statement of the basis for the recommendation, to the President of the United States, George W. Bush, for approval of the Yucca Mountain Site for the development of a nuclear waste repository. As required by the NWPA, the Department prepared the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F, February 2002; DIRS 155970-DOE 2002, all) (Yucca Mountain FEIS), to accompany the Secretary's recommendation. The President considered the site qualified for application to the Nuclear Regulatory Commission for a construction authorization and recommended the site to the U.S. Congress. On July 23, 2002, the President signed into law (Public Law 107-200) a joint resolution of the U.S. House of Representatives and the U.S. Senate designating the Yucca Mountain Site for development as a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste.

1.3 Rail Corridors Considered in the Yucca Mountain FEIS and this Nevada Rail Corridor SEIS

In the Yucca Mountain FEIS, DOE analyzed a proposed action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain. As part of that action, DOE evaluated various modes of transporting spent nuclear fuel and high-level radioactive waste to the Yucca Mountain Site from 72 commercial and 5 DOE sites (now 4 DOE sites because the Department is moving spent nuclear fuel from the Fort St. Vrain site in Colorado to the Idaho National Laboratory in Idaho). Figure 1-1 shows these sites.

DOE evaluated two national transportation scenarios, the "mostly legal-weight truck scenario" and the "mostly rail scenario," and three Nevada transportation scenarios, referred to as the "Nevada mostly legal-weight truck scenario," the "Nevada mostly rail scenario," and the "Nevada mostly heavy-haul truck scenario."

Under the Nevada mostly rail scenario, DOE considered in detail five potential ***rail corridors*** (Caliente, Carlin, Caliente-Chalk Mountain, Jean, and Valley Modified) within the State of Nevada in which the Department could construct a ***railroad*** to link an existing rail line to a repository at Yucca Mountain. Figure 1-2 shows these five corridors.

> **Rail corridor:** A strip of land 400 meters (0.25 mile) wide through which DOE would identify an alignment (***rail alignment***) for the construction of a ***rail line*** in Nevada to a ***geologic repository*** at Yucca Mountain.
>
> **Rail route:** A path that a rail line would follow within a rail corridor.
>
> **Rail line:** An engineered feature incorporating the track, ties, ***ballast***, and ***subballast*** at a specific location.
>
> **Railroad:** A transportation system incorporating the rail line, operations support facilities, railcars, locomotives, and other related property and infrastructure.
>
> **Option:** A strip of land from one point along a corridor to another point on the same corridor that provides a different route.

On April 8, 2004 (69 *FR* 18557), the Department issued a ***Record of Decision*** announcing its selection, both nationally and in the State of Nevada, of the mostly rail scenario analyzed in the Yucca Mountain FEIS as the primary means of transporting spent nuclear fuel and high-level radioactive waste to the

Legend

- ▲ Yucca Mountain
- ★ Commercial Sites

  Note: The Yucca Mountain FEIS analysis considered three commercial site pairs—Salem and Hope Creek, Nine Mile Point and FitzPatrick, and Dresden and Morris—to be single sites because of their proximity to each other.

- ◉ DOE Sites

  Notes:

  The Yucca Mountain FEIS analysis included the high-level radioactive waste at West Valley. The State of New York owns the high-level radioactive waste and the site. Under the West Valley Demonstration Project Act, DOE is responsible for solidifying and transporting the high-level radioactive waste to a repository.

  The Yucca Mountain FEIS analysis included DOE spent nuclear fuel at a fifth DOE location, Fort St. Vrain in Colorado. DOE will move that waste to the Idaho National Laboratory for processing and it will be included in the laboratory inventory. Therefore, this map does not show Fort St. Vrain as a DOE source of spent nuclear fuel.

Notes: DOE = U.S. Department of Energy; FEIS = Final Environmental Impact Statement. Symbols do not reflect precise locations.

Figure 1-2. Five rail corridors evaluated in detail in the Yucca Mountain FEIS.

repository. Implementation of the mostly rail scenario ultimately would require the construction of a rail line to connect the repository site at Yucca Mountain to an existing rail line in the State of Nevada. To that end, in the same Record of Decision, the Department also selected the Caliente rail corridor from several corridors considered in the Yucca Mountain FEIS as the corridor in which to study possible alignments for a rail line. On the same day DOE selected the Caliente corridor, it issued a Notice of Intent to prepare an EIS under the National Environmental Policy Act (NEPA) to study alternative alignments (now referred to as alternative segments) within the Caliente corridor (the Rail Alignment EIS; DOE/EIS-0369) (*Notice of Intent to Prepare an Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV*; 69 *FR* 18565).

During subsequent public scoping, DOE received comments suggesting that DOE consider other rail corridors that DOE had not previously considered in detail, in particular, the Mina route. In the Yucca Mountain FEIS, DOE had considered but eliminated the Mina route from detailed study because a rail line within the Mina route could only connect to an existing rail line in Nevada by crossing the Walker River Paiute Reservation, and the Tribe had informed DOE that it would not allow nuclear waste to be transported across the Reservation (DIRS 182776-Collins 1991, all).

Following review of the scoping comments, DOE held discussions with the Walker River Paiute Tribe and, in May 2006, the Tribal Council informed DOE that it would allow the Department to consider the potential impacts of transporting spent nuclear fuel and high-level radioactive waste across its reservation (DIRS 182775-Williams 2006, all). DOE then prepared a preliminary feasibility study of the Mina rail corridor (DIRS 180222-BSC 2006, all).

On October 13, 2006, after a preliminary evaluation of the feasibility of the Mina rail corridor, DOE announced its intent to expand the scope of the Rail Alignment EIS to include the Mina corridor (*Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV*; 71 *FR* 60484). DOE also announced that it would update, as appropriate, the information and analysis for other rail corridors analyzed in the Yucca Mountain FEIS.

This expanded NEPA analysis includes the Nevada Rail Corridor SEIS (DOE/EIS-0250F-S2D), which updates the Nevada rail corridor analysis in the Yucca Mountain FEIS by analyzing the potential environmental impacts associated with constructing and operating a railroad within the Mina rail corridor (corridor-level analysis) and the Rail Alignment EIS (DOE/EIS-0369D), which analyzes the potential environmental impacts associated with constructing and operating a railroad along specific alignments within the Caliente rail corridor and the Mina rail corridor (alignment-level analysis). Figure 1-3 shows the location of the Mina rail corridor evaluated in this Nevada Rail Corridor SEIS, and the Caliente rail corridor evaluated in the Rail Alignment EIS.

This Nevada Rail Corridor SEIS supplements the Nevada transportation-related element of the Yucca Mountain FEIS, but only the element that remains a part of the Yucca Mountain FEIS Proposed Action–the Nevada mostly rail scenario. Under the Proposed Action considered in this Nevada Rail Corridor SEIS (described in more detail in Chapter 2), DOE would construct and operate a railroad to connect the Yucca Mountain Repository to an existing rail line near Wabuska, Nevada (the Mina rail corridor). Accordingly, this Nevada Rail Corridor SEIS analyzes the Mina rail corridor at a level of detail commensurate with that of the rail corridors analyzed in the Yucca Mountain FEIS (see Chapters 3 and 4 of this Nevada Rail Corridor SEIS).

The analysis of the Mina rail corridor is intended to support Departmental conclusions about whether the potential attributes, characteristics, and environmental impacts of constructing and operating a railroad within the Mina rail corridor are such that DOE should proceed with analyzing specific alignments within the Mina rail corridor in the Rail Alignment EIS. In Chapter 6 of this Nevada Rail Corridor SEIS, DOE concludes that the Mina rail corridor warrants further study to determine an alignment for the construction and operation of a railroad.

On April 17, 2007, the Tribal Council for the Walker River Paiute Tribe passed a resolution withdrawing support for the Tribe's participation in the preparation of the Nevada Rail Corridor SEIS and the Rail Alignment EIS. The Tribal Council based its decision on a review of information gathered to that time and input from Tribal members. The Tribal Council's resolution also renewed the Tribe's past objection to the transportation of nuclear waste through their Reservation (DIRS 181604-Williams 2007, all). Thus, although Mina is analyzed in detail in the Rail Alignment EIS, DOE has identified the Mina Implementing Alternative as nonpreferred.

This Nevada Rail Corridor SEIS also updates relevant information regarding other rail corridors previously analyzed in the Yucca Mountain FEIS (Carlin, Jean, and Valley Modified) to identify any significant new circumstances or information that would cause DOE to further consider these corridors. The Caliente-Chalk Mountain rail corridor, also previously analyzed in the Yucca Mountain FEIS, would conflict with the mission of the U.S. Air Force. Therefore, DOE has eliminated this corridor from further consideration and has not updated information concerning the Caliente-Chalk Mountain rail corridor in this Nevada Rail Corridor SEIS.

Chapter 5 of this Nevada Rail Corridor SEIS provides updated information and analyses for the Carlin, Jean, and Valley Modified rail corridors; Figure 1-3 shows the locations of these three rail corridors.

The updated information and analysis are intended to support Departmental conclusions about whether there are significant new circumstances or information relevant to environmental concerns for the Carlin, Jean, and Valley Modified corridors. Factors important to reaching a conclusion include the nature of the updated environmental information and associated changes to potential environmental impacts, including irreversible and irretrievable commitments of resources and cumulative impacts, since DOE completed the Yucca Mountain FEIS. Other factors include, as appropriate, changes to potential land-use conflicts and their potential to adversely affect construction of a rail line, and the potential delays that could affect the availability of a rail line in these corridors. In Chapter 6 of this Nevada Rail Corridor SEIS, DOE concludes that there are no significant new circumstances or information relevant to environmental concerns regarding these corridors. Therefore, the Rail Alignment EIS considers implementing alignment alternatives only in the Caliente and Mina corridors.

As Chapter 6 discusses, although the amount of private land within the Carlin rail corridor appears to have decreased since DOE completed the Yucca Mountain FEIS, the complex land-ownership pattern resulting from the mix of private and public lands the corridor would cross remains unchanged. Such land-use complexity increases the potential to adversely affect construction of a railroad, and increases the potential for delays that could affect the availability of a rail line in the Carlin rail corridor. In contrast, the Mina rail corridor would cross less private land, and the corresponding land-ownership pattern would be less complex. Therefore, although DOE announced its preference for the Carlin rail corridor in the *Federal Register* (69 *FR* 74951, December 29, 2003) the Department has concluded that the Carlin rail corridor does not warrant further consideration at the alignment level in the Rail Alignment EIS.

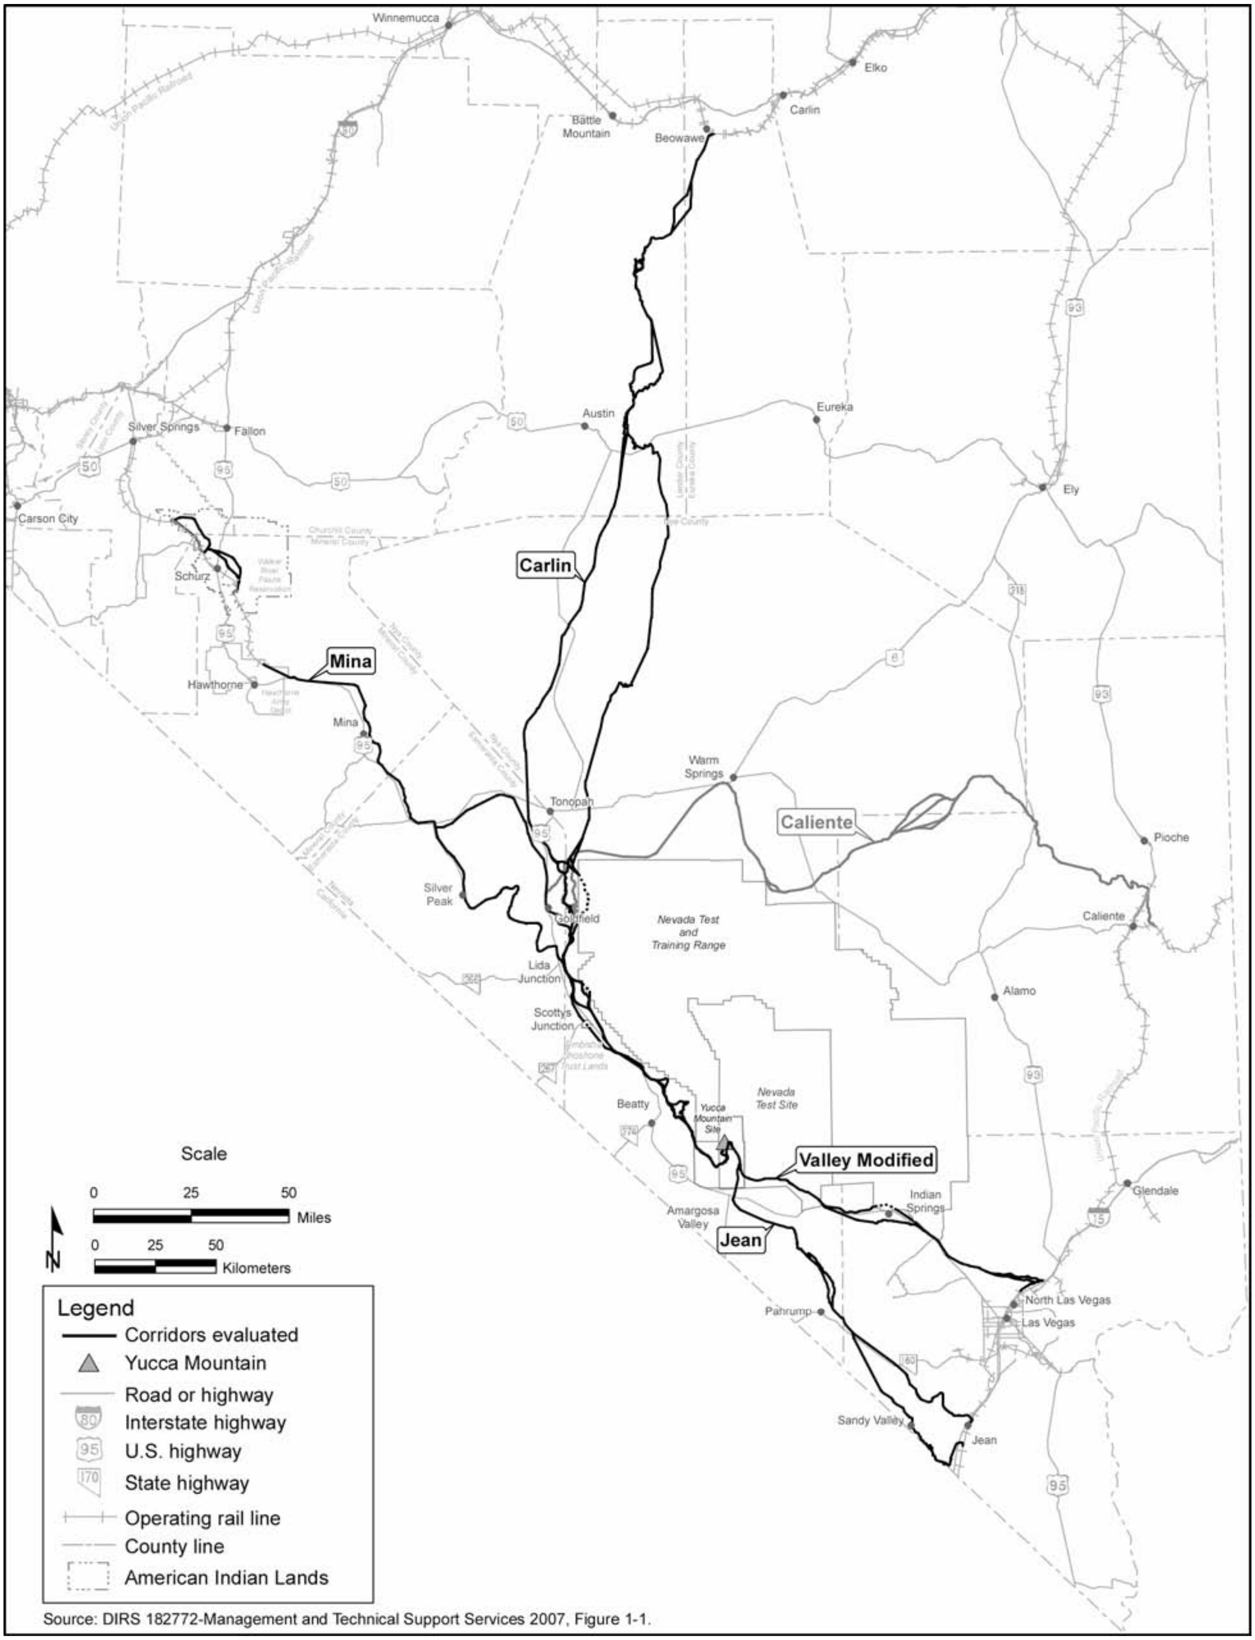

Figure 1-3. Four rail corridors and the Caliente corridor (pre-scoping, October 2006).

1.3.1 CALIENTE RAIL CORRIDOR

In its Record of Decision (69 *FR* 18557, April 8, 2004), DOE selected the Caliente rail corridor in which to evaluate possible ***rail alignments*** for construction and operation of a railroad within Nevada. The Department decided to evaluate alignments within the Caliente corridor based, in part, on the analyses of the Yucca Mountain FEIS. The Department, however, also considered other factors such as potential for construction delays, direct and indirect costs of each alignment, and comments received from the public.

DOE also considered potential land-use conflicts and their potential to adversely affect construction of a rail line. Compared to the other four corridors, the Caliente rail corridor appeared to have the fewest land-use or other conflicts that could lead to substantial delays in acquiring the necessary land and rights-of-way, or beginning construction. The Department concluded that the Valley Modified rail corridor could conflict with the Desert National Wildlife Range and local community plans for development in the greater Las Vegas metropolitan area. The Caliente-Chalk Mountain rail corridor would conflict with the U.S. Air Force mission on the Nevada Test and Training Range. The Jean rail corridor would require crossing relatively greater amounts of private land, and would pose greater potential land-use conflicts because of its proximity to the Las Vegas metropolitan area. The Carlin rail corridor also would require crossing relatively greater amounts of private land, and little infrastructure, such as roads and electric power, is available over long segments of the corridor, which would tend to make logistics and emergency response during construction more challenging.

The Department also considered concerns expressed by members of the public in Nevada. In these comments, the public stated that DOE should avoid rail corridors in the Las Vegas Valley.

DOE also considered the direct costs of constructing and operating a railroad, and the indirect costs resulting from potential delays in the availability of the railroad. The Jean and Valley Modified rail corridors would be the shortest among the five corridors and would have the lowest estimated construction costs. The Carlin and Caliente rail corridors would be the longest and, on the basis of construction costs alone, would be more expensive to develop. However, delays in rail line construction because of land-use or other conflicts and the resulting inability to accept spent nuclear fuel and high-level radioactive waste transported by rail to the repository in a timely manner would add to both the liability costs for delayed acceptance of commercial spent nuclear fuel and the costs of continued storage of high-level radioactive waste.

The Department considered irreversible and irretrievable commitments of resources in making its decision, recognizing that resources such as electric power, fossil fuels, construction materials, and water would be consumed during rail line construction within any of the five rail corridors considered in the Yucca Mountain FEIS. On balance, DOE concluded that these commitments would not significantly diminish the resources in question.

DOE concluded that the Caliente rail corridor would be preferable to the other corridors, and therefore decided to evaluate possible alignments for the rail line connecting the repository to an existing rail line in Nevada. This evaluation is included in the Rail Alignment EIS.

1.3.2 MINA RAIL CORRIDOR

DOE had previously considered, but eliminated the Mina rail corridor from detailed study because a rail line in that corridor could only connect to an existing rail line by crossing the Walker River Paiute Reservation, and the Tribe had informed DOE that it would not allow nuclear waste to be transported across its Reservation (DIRS 182776-Collins 1991, all).

Following review of the scoping comments, DOE held discussions with the Walker River Paiute Tribe and, in May 2006, the Tribal Council informed DOE that it would allow DOE to consider the potential impacts of constructing and operating a rail line to transport spent nuclear fuel and high-level radioactive waste across its Reservation (DIRS 182775-Williams 2006, all). On October 13, 2006, after a preliminary evaluation of the feasibility of the Mina rail corridor, DOE announced its intent to expand the scope of the Rail Alignment EIS to include the Mina rail corridor (71 *FR* 60484).

The analysis of the Mina rail corridor is intended to support DOE conclusions about whether the potential attributes, characteristics, and environmental impacts of constructing and operating a railroad in that corridor are such that DOE should proceed with analyzing specific alignments within the corridor in the Rail Alignment EIS.

However, in May 2007, the Walker River Paiute Tribal Council informed DOE that it was withdrawing its support for the Tribe's participation in the preparation of the Supplemental Rail Corridor EIS and Rail Alignment EIS. The Tribal Council based its decision on a review of information gathered to that time and input from Tribal members. The Tribal Council's resolution also renewed the Tribe's past objection to the transportation of nuclear waste through its Reservation (DIRS 181604-Williams 2007, all). Accordingly, in the Rail Alignment EIS DOE has identified the Mina Implementing Alternative as nonpreferred.

1.3.3 CARLIN, JEAN, AND VALLEY MODIFIED RAIL CORRIDORS

In the Amended Notice of Intent (71 *FR* 60484, October 13, 2006), DOE also announced that it would update, as appropriate, the information and analyses for other rail corridors analyzed in the Yucca Mountain FEIS (Carlin, Jean, and Valley Modified) to identify any significant new circumstances or information relevant to environmental concerns. DOE eliminated the Caliente-Chalk Mountain rail corridor, which would intersect the Nevada Test and Training Range, from detailed study because of U.S. Air Force concerns that a rail line within the Range would interfere with the military's mission; therefore, DOE did not include the Caliente-Chalk Mountain rail corridor in this Nevada Rail Corridor SEIS.

Chapter 5 of this Nevada Rail Corridor SEIS provides updated information and analyses for the Carlin, Jean, and Valley Modified rail corridors.

The updated information and analyses for the Carlin, Jean, and Valley Modified rail corridors are intended to support Departmental conclusions about the status of those corridors and whether, based on environmental considerations, any of those corridors should be further analyzed at the alignment level. In Chapter 6 of this Nevada Rail Corridor SEIS, DOE concludes that there are no significant new circumstances or information relevant to environmental concerns that would warrant further consideration of the Carlin, Jean, or Valley Modified rail corridors at the alignment level. DOE also concludes that the Mina rail corridor warrants further study to determine an alignment for the construction and operation of a railroad.

1.4 Cooperating Agencies

Pursuant to the NWPA, DOE is responsible for the disposal of spent nuclear fuel and high-level radioactive waste to protect public health, safety, and the environment, and for developing and implementing a plan for transporting spent nuclear fuel and high-level radioactive waste to a repository at Yucca Mountain. The Council on Environmental Quality regulations at 40 Code of Federal Regulations (CFR) 1501.6 emphasize agency cooperation early in the NEPA process and allow a lead agency (in this case, DOE) to request the assistance of other agencies that either have jurisdiction by law or have special expertise regarding issues considered in an EIS. The Bureau of Land Management (BLM), the Surface

Transportation Board (STB), and the U.S. Air Force are cooperating agencies in the development of this Nevada Rail Corridor SEIS and the Rail Alignment EIS, pursuant to Council on Environmental Quality Regulations, and have participated in its preparation. Cooperating agencies that could issue decisions concerning the Proposed Action and alternatives to the Proposed Action could adopt this Nevada Rail Corridor SEIS or the Rail Alignment EIS, in whole or in part, and use them as a basis for their decisions. These agencies have management and regulatory authority over lands and resources that would be crossed by or be close to the proposed railroad or they have special expertise related to the Proposed Action.

The Walker River Paiute Tribe, the Bureau of Indian Affairs, and the U.S. Army were cooperating agencies until the Walker River Paiute Tribe withdrew from participating in the EIS process. The Bureau of Indian Affairs and the U.S. Army withdrew as cooperating agencies after the Tribe withdrew.

1.4.1 BUREAU OF LAND MANAGEMENT

The BLM is an agency within the U.S. Department of the Interior and is responsible for administering more than 1 million square kilometers (250 million acres) of public lands, mostly in 12 western states, including Alaska. Congress enacted the Federal Land Policy and Management Act (43 U.S.C. 1701 *et seq*.) "to establish public land policy; to establish guidelines for its administration; to provide for the management, protection, development, and enhancement of the public lands; and for other purposes." It is the primary legislation guiding the BLM in its responsibility to manage the public lands and resources in a combination of ways that best serve the present and future needs of the American people.

To construct that portion of the proposed rail line that would cross public land, DOE would obtain a right-of-way from the BLM. BLM regulations at 43 CFR Part 2800 establish the procedures for processing right-of-way applications from federal agencies. The right-of-way application would include public land facilities that would be part of the proposed railroad. The BLM may adopt this Nevada Rail Corridor SEIS and the Rail Alignment EIS, as authorized by the Council on Environmental Quality regulations (40 CFR 1506.3) to satisfy its NEPA requirements for the right-of-way application. ***Right-of-way grants*** on public lands must be consistent with the applicable BLM ***resource management plan***(s). The BLM is a cooperating agency in the preparation of this Nevada Rail Corridor SEIS and the Rail Alignment EIS and could adopt and use the document to process a DOE right-of-way application for access to the public lands that would be required for construction and operation of the proposed railroad. The procedures for BLM adoption of another agency's EIS (*National Environmental Policy Act Handbook*, BLM Handbook H-1790-1; DIRS 182299-BLM 1988, all) specify that the BLM conduct an independent review of the EIS and issue its own Record of Decision. Cooperating agency status provides the BLM the opportunity to work closely with DOE during development of this Nevada Rail Corridor SEIS and the Rail Alignment EIS to encourage a product that meets the NEPA requirements for processing a right-of-way application.

> **Resource management plan:** A land-use plan for public lands as described by the Federal Land Management and Policy Act. Among other things, it establishes land areas for limited, restricted, or exclusive use; allowable resource uses; resource condition goals and objectives; general management practices to achieve the goals; the need for more specific management plans for certain areas; general implementation sequences; and monitoring intervals and standards (43 CFR Part 1610).

1.4.2 SURFACE TRANSPORTATION BOARD

The STB is a regulatory agency that Congress charged with the fundamental missions of resolving railroad rate and service disputes and reviewing proposed railroad construction, acquisitions, mergers, and abandonments. The STB is decisionally independent, although it is administratively affiliated with the U.S. Department of Transportation. The ICC [Interstate Commerce Commission] Termination Act of 1995 (Public Law No. 104-88) created the STB, which is the successor agency to the Interstate Commerce Commission.

The STB has jurisdiction over railroad rate and service issues, and rail structuring transactions such as new line construction, line sales, line abandonments, and railroad mergers. The STB also has jurisdiction over common-carrier rail lines that are part of the interstate rail network. A common-carrier rail line is one that holds itself out to the public for service and has an obligation to provide rail service to any and all shippers that request service along that line.

If the proposed railroad is to be operated as a common-carrier rail line, the Department would have to apply to the STB for a license to construct and operate (certificate of public convenience and necessity). As part of the licensing process, the STB must consider the environmental effects of rail line construction and operation. The STB Section of Environmental Analysis is responsible for preparing the appropriate NEPA documentation for rail line construction and operation cases that come before the STB. Because the STB is a cooperating agency in the preparation of this Nevada Rail Corridor SEIS and the Rail Alignment EIS, these NEPA documents are intended to satisfy the STB Section of Environmental Analysis NEPA obligations.

1.4.3 U.S. AIR FORCE

The mission of the U.S. Air Force, in conjunction with the other armed services, is to preserve the peace and security and provide for the defense of the United States, its Territories, Commonwealths, and possessions, and any U.S.-occupied areas. The U.S. Air Force agreed to become a cooperating agency as a consequence of its jurisdiction over airspace and land associated with the Nevada Test and Training Range that would have been affected by one or more of the potential rail line options (segments) analyzed in this Nevada Rail Corridor SEIS and the Rail Alignment EIS. DOE coordinates with and, at times, obtains approval from the responsible armed service when DOE actions might encroach on U.S. Department of Defense land and potentially affect military operations. Although DOE has decided not to pursue potential rail line options that would have entered the Nevada Test and Training Range, DOE is coordinating with the U.S. Air Force (for example, on the nature, extent, and location of U.S. Air Force overflights) to minimize impacts of the proposed rail line to the U.S. Air Force mission. In addition, the U.S. Air Force offers special expertise associated with portions of the rail corridors near the Nevada Test and Training Range.

1.5 Environmental Impact Statement Process

Council on Environmental Quality regulations (40 CFR Parts 1500 through 1508) that implement the procedural requirements of NEPA, and DOE NEPA regulations (10 CFR Part 1021) provide procedures to use when preparing an EIS. A major emphasis of the EIS process is to promote public awareness of the Proposed Action and its alternatives and to provide opportunities for public involvement. An agency prepares an EIS in a series of steps: (1) by publishing a Notice of Intent to prepare an EIS and implementing a process known as “public scoping,” as further discussed in Section 1.5.1, whereby comments are solicited from federal, state, and local agencies, American Indian tribes and organizations, other organizations, and the general public to assist in defining the proposed action, alternatives, and issues requiring analysis; (2) by preparing a Draft EIS for public review and comment; (3) by preparing a Final EIS that incorporates and responds to all substantive comments received on the Draft EIS; and (4) by preparing a Record of Decision to announce the agency’s decision on a project and explain the reasons for the decision.

1.5.1 DEPARTMENT OF ENERGY NOTICES OF INTENT AND SCOPING MEETINGS

On April 8, 2004, DOE published a Notice of Intent (69 *FR* 18565) announcing that it would prepare an EIS for the alignment, construction, and operation of a railroad (called the rail line in the Notice of Intent) for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials from a site near Caliente, Lincoln County, Nevada, to a geologic repository at Yucca Mountain, Nye County, Nevada. The Notice also announced the schedule for public scoping meetings, and invited and encouraged comments on the scope of the Rail Alignment EIS to ensure that all relevant environmental issues and reasonable alternatives would be addressed. To facilitate the scoping process, in the Notice of Intent DOE identified a preliminary list of issues and environmental resources that might be considered in the Rail Alignment EIS, and specifically invited comments on the following six questions to help define the scope of the EIS:

1. Should additional alternatives be considered that might minimize, avoid, or mitigate adverse environmental impacts (for example, looking beyond the corridor, avoiding Wilderness Study Areas, American Indian Trust Lands, or encroachment on the Nevada Test and Training Range)?
2. Should any of the preliminary alternatives be eliminated from detailed consideration?
3. Should additional environmental resources be considered?
4. Should DOE allow private entities to ship commercial commodities on its rail line?
5. What mitigation measures should be considered?
6. Are there national security issues that should be addressed?

The scoping comment period began with publication of the Notice of Intent in the *Federal Register* and was originally scheduled to close on May 24, 2004. In response to a request from the State of Nevada, DOE extended the comment period by 7 days, to June 1, 2004 (69 *FR* 22496, April 26, 2004), bringing the total length of the scoping comment period to 55 days. DOE held five public scoping meetings on the Rail Alignment EIS at the following locations on the following dates in Nevada:

- Amargosa Valley – Longstreet Hotel Casino, Nevada State Highway 373, May 3, 2004
- Goldfield – Goldfield Community Center, 301 Crook Street, May 4, 2004
- Caliente – Caliente Youth Center, U.S. Highway 93, May 5, 2004
- Reno – University of Nevada, Reno, Fifteenth and North Virginia, May 12, 2004
- Las Vegas – Cashman Center, 850 North Las Vegas Boulevard, May 17, 2004

In addition to the *Federal Register* notices announcing the meetings, DOE advertised the meetings in five local newspapers that have a total circulation of approximately 250,000; sent four separate press releases to media outlets, industry, and stakeholders; mailed several thousand letters to stakeholders, members of the public, and other interested parties; and distributed over 1,000 handbills in Esmeralda, Lincoln, and Nye Counties.

DOE conducted the public scoping meetings in an open-house format. Members of the public were invited to attend the meetings at their convenience, any time during meeting hours, and submit their comments in writing at the meeting, or in person to a court reporter who was available throughout the meeting. The open-house format provided for one-on-one discussions with DOE representatives responsible for the preparation of the Rail Alignment EIS. Approximately 440 people (number is approximate because some attendees did not sign in) attended the meetings and 86 submitted oral comments (that the court reporters transcribed) on the scope of the EIS.

DOE considered comments received during the scoping comment period on the scope of the Rail Alignment EIS, along with information BLM received, including results of interviews with grazing allotment permittees and other interested parties documented in *Proposed Yucca Mountain Corridor Affected Grazing Permittees* (DIRS 173845-Resource Concepts 2005, all). DOE sponsored an American Indian perspectives document in *American Indian Perspectives on the Proposed Rail Alignment Environmental Impact Statement for the U.S. Department of Energy's Yucca Mountain Project* (the American Indian Resource Document; DIRS 174205-Kane et al. 2005, all) (see section 1.5.3). DOE also considered information obtained through sources such as interviews with officials from Lincoln and Nye Counties.

On October 13, 2006, after a preliminary evaluation of the feasibility of the Mina rail corridor (DIRS 180222-BSC 2006, all), DOE announced its intent to expand the scope of the Rail Alignment EIS to include the Mina rail corridor as an alternative (*Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV;* 71 *FR* 60484). DOE specifically invited comments on the following four questions relative to the Mina rail corridor to help define the scope of the analysis:

1. Should additional alternative alignments (now called alternative segments) be considered that might minimize, avoid, or mitigate adverse environmental impacts (for example, looking beyond the Mina rail corridor, avoiding environmentally sensitive areas)?
2. Should any of the preliminary alternatives be eliminated from detailed consideration?
3. Should additional environmental resources be considered?
4. What mitigation measures should be considered?

In addition, DOE indicated interest in identifying any significant changes to, or significant new information relevant to, the rail corridors analyzed in the Yucca Mountain FEIS.

The second scoping comment period began with publication of the Amended Notice of Intent in the *Federal Register* and was originally scheduled to close on November 27, 2006. In response to requests from the public, DOE extended the comment period by 15 days, to December 12, 2006 (71 *FR* 65785, November 9, 2006), bringing the total length of the scoping comment period to 61 days. DOE held eight public scoping meetings during the second public scoping period at the following locations on the following dates in Nevada and Washington, D.C.:

- Washington, D.C. – L'Enfant Plaza Hotel, 480 L'Enfant Plaza, SW, October 30, 2006
- Amargosa Valley – Longstreet Hotel Casino, Nevada State Highway 373, November 1, 2006
- Las Vegas – Cashman Center, 850 North Las Vegas Boulevard, November 2, 2006
- Caliente – Caliente Youth Center, U.S. Highway 93, November 8, 2006
- Goldfield – Goldfield School Gymnasium, Hall and Euclid, November 13, 2006
- Hawthorne – Hawthorne Convention Center, 932 E. Street, November 14, 2006
- Fallon – Fallon Convention Center, 100 Campus Way, November 15, 2006
- Reno – University of Nevada, Reno, Lawlor Event Center, 1500 N. Virginia Street, November 27, 2006

In addition to the *Federal Register* notices announcing the meetings, DOE advertised the meetings in eight local newspapers, including the *Washington Post*. Total circulation of the newspapers is approximately 280,000 plus an additional 750,000 for the *Washington Post*. DOE sent four separate press releases to media outlets, industry, and stakeholders; mailed several thousand letters to stakeholders, members of the public, and other interested parties; and distributed over 1,300 handbills in Washoe, Churchill, Lyon, Mineral, Esmeralda, Lincoln, and Nye Counties.

DOE conducted the public scoping meetings in an open-house format. Members of the public were invited to attend the meetings at their convenience, any time during meeting hours, and submit their comments in writing at the meeting, or in person to a court reporter who was available throughout the meeting. The open-house format provided for one-on-one discussions with DOE representatives responsible for the preparation of this Nevada Rail Corridor SEIS and the Rail Alignment EIS. Approximately 330 people (number is approximate because some attendees did not sign in) attended the meetings, and 63 submitted oral comments (that the court reporters transcribed) on the scope of the expanded NEPA analysis.

1.5.2 PUBLIC SCOPING COMMENTS

DOE received more than 4,100 comments during the first public scoping period for the Rail Alignment EIS, and some after the close of the scoping period. DOE summarized all comments received in *Summary of Public Scoping Comments, Related to the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV* (DIRS 176463-Craig, Lechel, and Morton 2004, all) and considered the content of all substantive comments in determining the scope of the Rail Alignment EIS. During this scoping period, DOE also received comments suggesting that other rail corridors be considered in the Rail Alignment EIS, in particular the Mina corridor. Compelling arguments were presented in comments that the Mina rail corridor should be given a full evaluation.

The scoping period for this expanded NEPA document (this Nevada Rail Corridor SEIS and the Rail Alignment EIS) began on October 13, 2006, and ended on December 12, 2006. DOE received approximately 790 comments during this second public scoping period, and some comments after the close of the scoping period. DOE summarized all comments received (including those submitted after the close of the scoping period) in *Summary of Public Scoping Comments on the Expanded Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV* (DIRS 181379-DOE 2007, all) and considered the content of all comments in determining the scope of this expanded NEPA analysis.

Many of the comments received were applicable to this expanded EIS, including the Mina rail corridor, and the review of the Carlin, Jean, and Valley Modified rail corridors (Nevada Rail Corridor SEIS). Other comments related to the Repository SEIS (DOE/EIS-0250F-S1).

Table 1-1 summarizes the public scoping comments DOE received during both scoping periods held in 2004 and 2006, as they relate to corridor identification and evaluation.

1.5.3 TRIBAL INTERACTIONS MEETINGS

In 1987, DOE initiated the Native American Interaction Program to solicit input from and interact with tribes and organizations on the characterization of the Yucca Mountain Site and the possible construction and operation of a repository. These tribes and organizations—Southern Paiute; Western Shoshone; and Owens Valley Paiute and Shoshone people from Arizona, California, Nevada, and Utah—have cultural and historic ties to both the Yucca Mountain area and to the larger region that includes portions of the Mina rail corridor as well as the Carlin, Jean, and Valley Modified rail corridors.

Table 1-1. Public comments specific to this Nevada Rail Corridor SEIS resulting from the 2004 and 2006 scoping periods (page 1 of 3).

Comment Issue	Scoping comment summary	DOE comment summary response
Basis of corridor selection	Commenters sought clarification for, or questioned the basis of, the DOE decision to select the Caliente corridor. Commenters also questioned the basis for not selecting the other corridors such as Valley Modified or Caliente Chalk-Mountain.	On December 29, 2003, DOE announced it preference for the Caliente corridor (68 *FR* 74951). In that announcement, the Department also announced the Carlin corridor as its secondary preference. On April 8, 2004, the Department issued a *Federal Register* Notice that documented the detailed bases for the rail corridor decision. In large part the decision was based on the preference to avoid and minimize crossing of private lands.
Scope of Rail Alignment EIS	Two commenters suggested that before completing the comparative analysis of impacts of the Caliente, Mina, and No-Action Alternatives, DOE should update and distribute in draft form its comparative analysis of all previously considered rail routes (Carlin, Jean, and Valley Modified). This report should be the basis for development of the EIS and be a justification for inclusion or elimination of a particular route.	In its October 13, 2006, *Federal Register* Notice (71 *FR* 60484), DOE announced its intent to expand the scope of the Environmental Impact Statement for the Alignment Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV. Part of the intended expanded scope of the EIS was to proceed with the review of the environmental analyses presented in the Yucca Mountain FEIS for the Carlin, Jean, and Valley Modified corridors along with changes in the affected environment. As appropriate the environmental information and analyses were updated. This information is presented in Chapter 5 of this Nevada Rail Corridor SEIS.
Carlin corridor	A few commenters preferred the Carlin rail corridor to either the Mina or Caliente rail corridor because Carlin would be more protected and have less chance of sabotage. The EIS should address the concerns raised by Eureka County in its 2001 report on the Carlin rail corridor (see www.yuccamountain.org/impact_report/impact01.htm). Activities at Barrick Gold Mines' property in Crescent Valley have increased substantially since the Yucca Mountain FEIS was released. Other mining activities are occurring near Beowawe and it's possible that this part of Eureka County could one day rival the famous Carlin trend farther east near Elko.	The environmental information and analyses for the Carlin corridor have been reviewed and updated as appropriate. Based on these reviews and updates, the Department had found that for the most part, the environmental conditions and associated environmental impacts for each of the original corridors, including Carlin, remain unchanged from, or are substantially similar to, those reported in the Yucca Mountain FEIS. A DOE alignment-level evaluation of potential impacts from possible sabotage indicated that such impacts would not be a discriminator in the selection of a rail alignment; and therefore, would not be a discriminator in the selection of a rail corridor. Potential impacts from possible sabotage would be the same for any corridor. DOE acquired the cited Eureka County report and factored the information provided into its review of the Carlin corridor. Changes as appropriate can be found in Section 5.2 of this Nevada Rail Corridor SEIS. DOE noted that potential land use conflicts in the Carlin corridor have increased since publication of the Yucca Mountain FEIS.
Jean corridor	One commenter preferred the Jean Corridor because it would be the least expensive to construct.	DOE reviewed and updated the environmental information and impact analyses reported in the Yucca Mountain FEIS, as appropriate. DOE found that potential land-use conflicts and air quality concerns have increased since the Department completed the Yucca Mountain FEIS conflicts.

Table 1-1. Public comments specific to this Nevada Rail Corridor SEIS resulting from the 2004 and 2006 scoping periods (page 2 of 3).

Comment Issue	Scoping comment summary	DOE comment summary response
Valley Modified corridor	The EIS should consider substantial changes that have occurred elsewhere in Clark County relative to the Department's continued consideration of routes other than Mina and Caliente. Annexation of land by both the City of North Las Vegas and the City of Henderson, as well as privatization of BLM lands in the valley, have resulted in substantial real and planned changes since issuance of the Yucca Mountain FEIS. The development of the Ivanpah Airport in the southwestern part of Clark County should also be taken into consideration when evaluating both rail and truck routes.	DOE reviewed land-use changes for the Carlin, Jean, and Valley Modified rail corridors and updated that information. Section 5.4.1 of this Nevada Rail Corridor SEIS reports updated land-use information for the Valley Modified rail corridor; the Ivanpah Airport is addressed under several resource categories.
Changes in land use in Las Vegas and Clark county since 2002	The EIS should consider the many land-use changes that have occurred in the Las Vegas Metropolitan area since the Yucca Mountain FEIS was released. For example, as of June 2006, there were 105 projects planned or being built within 1 mile of the existing Union Pacific Railroad, I-15, State Route 160, and the beltway. Within this area are 132,951 housing units and 33,368,223 square feet of commercial property.	DOE reviewed land-use changes for the Carlin, Jean, and Valley Modified rail corridors and updated that information. Section 5.4.1 of this Nevada Rail Corridor SEIS reports updated land-use information for the Valley Modified rail corridor; the Ivanpah Airport is addressed under several resource categories.
Chalk Mountain corridor	Several commenters suggested that national security concerns by themselves should not have eliminated the Caliente Chalk-Mountain corridor.	In a letter to the U.S. Air Force (dated December 1, 2004), DOE eliminated from detailed study alignments within the Caliente rail corridor that would intersect the Nevada Test and Training Range because of concerns regarding military readiness testing and training activities. This letter was in response to a May 28, 2004, letter from the U.S. Air Force. DOE based its decision not to provide updates for the Caliente-Chalk Mountain rail corridor on the same rationale.

Table 1-1. Public comments specific to this Nevada Rail Corridor SEIS resulting from the 2004 and 2006 scoping periods (page 3 of 3).

Comment Issue	Scoping comment summary	DOE comment summary response
Suggested new routes and routes eliminated in 2002	Several commenters suggested new rail line routes to Yucca Mountain and alternatives to rail transport. One person suggested a new rail corridor originating from Baker, California, and extending through Death Valley Junction to Yucca Mountain. According to the commenter, this corridor would be shorter than the Mina rail corridor and easier to construct. Another commenter said that a rail route through the Tonopah Test Range would be reasonable considering that the Range will be closing in 2010. Another person suggested a rail route from Fallon southward through Gabbs Valley. Another person said that a route through the Nevada Test Site should be used, along with part of the Caliente corridor. One person questioned why the shortest distance to Yucca Mountain, via a 100-mile-long rail line through the Las Vegas Valley, was not being considered. One person suggested that all possible corridors to Yucca Mountain be considered in the EIS (such as one from Barstow, California, and Apex, Nevada), including those previously examined in the Yucca Mountain FEIS. One commenter requested that DOE study the Feather River rail line as an alternative to the Donner Pass rail line that passes through Reno. One commenter said that DOE should eliminate those routes that had already been eliminated in the Yucca Mountain FEIS, and focus only on the Mina and Caliente rail corridors. According to this commenter, there is no reason for DOE to reconsider in this EIS its decision that the Caliente corridor is preferred to the other four corridors previously evaluated; to do so would add unnecessary cost and complexity to preparation of the ongoing EIS and delay its issuance.	Most of the routes suggested in these scoping comments were eliminated from consideration for reasons similar to those for eliminating routes considered in the 1990 *Preliminary Rail Access Study* (DIRS 104792-1990, all). Over the years, DOE has evaluated numerous rail corridor modes for transporting spent nuclear fuel and high-level radioactive was to Yucca Mountain. Before DOE prepared the Yucca Mountain FEIS, the Department identified 10 potential rail line routes to Yucca Mountain (Valley, Arden, Crucero, Ludlow, Mina, Caliente, Carlin, Cherry Creek and Dike) in the 1990 *Preliminary Rail Access Study* (DIRS 104792-1990, all). Options within each route were developed wherever possible. The routes were chosen to maximize the use of federal lands, provide access to regional rail carriers, avoid obvious land-use conflicts, and meet current rail line engineering practices. After the development of these rail routes, Lincoln County and the City of Caliente identified three additional routes (identified as Lincoln County Routes A, B, and C). DOE evaluated the 10 rail line routes plus Lincoln County A, B, and C, for a total of 13 routes. In 1995 DOE reevaluated the routes in the *Nevada Potential Repository Preliminary Transportation Strategy, Study* 1 (DIRS 104795-CRWMS M&O 1995, all) and in the second part of the study in 1996 (DIRS 101214-CRWMS M&O 1996, all). One new route, Valley Modified, was added in the 1995 study based on updated information from the Bureau of Land Management. Three additional alignments – Caliente-Chalk Mountain, Elgin/Rox, and Hancock Summit-were evaluated in the *Nevada Potential Repository Preliminary Assessment of the Caliente-Chalk Mountain Rail Corridor* (DIRS 132219- CRWMS M&O 1997, all). The evaluation reviewed each potential rail corridor to identify land-use issues and access to regional carriers. The evaluations compared other factors for the routes, including favorable topography and avoidance of lands withdrawn from public use by federal action. DOE eliminated the Valley, Arden, Crucero, Ludlow, Mina, Cherry Creek, Dike, Elgin/Rox, Hancock Summit, and Lincoln County A, B, and C rail routes from further study. In 1995 (DIRS 104795-CRWMS M&O 1995, all) and 1996 (DIRS 101214-CRWMS M&O 1996, all) studies DOE determined that the Mina and Cherry Creek rail corridors should be assigned a status of "Eliminated from Detailed Evaluation – Monitor." For the most part, the environmental conditions and associated potential environmental impacts for each rail corridor remain unchanged from, or are substantially similar to, those considered in the Yucca Mountain FEIS. For these reasons, DOE concludes there are no significant new circumstances or information relevant to environmental concerns that would warrant further consideration of these three rail corridors at the alignment level. DOE did not update the information and analysis for the Caliente-Chalk Mountain rail corridor.

The Native American Interaction Program concentrates on the protection of cultural resources at Yucca Mountain and contributes to a government-to-government relationship with the tribes and organizations. Its purpose is to help DOE comply with various federal laws and regulations, including the American Indian Religious Freedom Act (42 U.S.C. 1996); the Archaeological Resources Protection Act (16 U.S.C. 470aa et seq.); the National Historic Preservation Act (16 U.S.C. 470 et seq.); the Native American Graves Protection and Repatriation Act (25 U.S.C. 3001); the American Indian and Alaska Native Tribal Government Policy; DOE Order 1230.2, American Indian and Tribal Government Policy; Executive Order 13007, Indian Sacred Sites, and Executive Order 13084, Consultation and Coordination with Indian Tribal Governments. These regulations and Executive Orders mandate the protection of archaeological sites and cultural items and require agencies to include American Indians and federally recognized tribes in discussions and interactions on major federal actions.

Initial ethnographic studies identified three tribal groups – the Southern Paiute, the Western Shoshone, and the Owens Valley Paiute and Shoshone – whose cultural heritage includes the Yucca Mountain region. Additional ethnographic efforts eventually led to the involvement of 17 tribes and organizations in the Yucca Mountain Project American Indian and cultural resource studies.

The 17 tribes and organizations have formed the Consolidated Group of Tribes and Organizations, which consists of tribal representatives who are responsible for presenting their respective tribal concerns and perspectives to DOE. A major priority of the Group has been the protection of cultural resources and environmental restoration at Yucca Mountain. Members of the Consolidated Group of Tribes and Organizations have participated in many ethnographic interviews and have provided DOE valuable insights into American Indian cultural and religious values and beliefs. These interactions have produced several reports that record the regional history of American Indian people and the interpretation of American Indian cultural resources in the Yucca Mountain region. On June 2, 2004, DOE met with the Consolidate Group of Tribes and Organizations to introduce the rail alignment project and learn of its members' concerns.

In October 2004, a group of designated tribal representatives participated with DOE representatives in a field reconnaissance trip along the proposed rail alignment, followed by a meeting with the consolidated group in late November 2004. Based on these efforts, these tribal representatives known as the American Indian Writers Subgroup, a subgroup of the Consolidated Group of Tribes and Organizations, prepared the American Indian Resource Document (DIRS 174205-Kane et al. 2005, all). This document provides insight into American Indian viewpoints and concerns regarding cultural resources along the Caliente rail alignment and long-term impacts of the DOE selection of a rail system to transport spent nuclear fuel and high-level radioactive waste to a geologic repository at Yucca Mountain, Nevada. This document is a supplement to the American Indian Writers Subgroup document produced in 1998 titled *American Indian Perspectives on the Yucca Mountain Site Characterization Project and the Repository Environmental Impact Statement* (DIRS 102043-AIWS 1998, all).

In July 2005, DOE held a tribal update meeting with the Consolidated Group of Tribes and Organizations. The rail alignment project and the document prepared by the American Indian Writers Subgroup were topics of discussion. In September 2005, DOE held a special meeting with the Group for discussions on the Environmental Assessment associated with a DOE request for the Public Land Order and associated regulatory actions. In April 2006, DOE again met with the American Indian Writers Subgroup for continued discussions and updates on the Caliente rail alignment. After each meeting the tribal representatives prepared a series of recommendations for DOE consideration. DOE received recommendations, categorized them, and assigned personnel to respond to the recommendations. On November 29, 2006, DOE met with the Group to present the proposed inclusion of the Mina rail corridor for analysis in this Nevada Rail Corridor SEIS and in the Rail Alignment EIS and to provide an update on the ongoing analysis of the Caliente rail alignment.

DOE met with Walker River Paiute tribal representatives on several occasions in 2006 and 2007 to discuss their interest in allowing DOE to evaluate a potential rail corridor, the Mina rail corridor, which would cross the Walker River Paiute Reservation. Tribal members toured the Yucca Mountain Site and attended scoping meetings.

1.6 Relationship to Other Environmental Documents

On October 13, 2006, the Department announced its intent to prepare a Supplement to the Yucca Mountain FEIS (DOE/EIS-0250F-S1), consistent with the NEPA and the NWPA, to evaluate the potential environmental impacts of the current repository design and operational plans (71 *FR* 60490). The primary purpose of the Repository SEIS is to assist the U.S. Nuclear Regulatory Commission in adopting, to the extent practicable, any EIS prepared pursuant to Section 114(f)(4) of the NWPA. As stated in the Foreword to this Nevada Rail Corridor SEIS and the Rail Alignment EIS, the Repository SEIS supplements the Yucca Mountain FEIS in its entirety, except for those transportation-related elements that were eliminated from the Department's Proposed Action (such as the mostly legal-weight truck scenario) by the 2004 Record of Decision. Therefore, under the Repository SEIS Proposed Action, DOE would construct, operate and monitor, and eventually close a repository at Yucca Mountain.

During repository operations, most shipments of spent nuclear fuel and high-level radioactive waste would arrive at the repository by rail, and in Nevada such shipments would be via a rail line constructed within either the Caliente or the Mina rail corridors. Accordingly, the Repository SEIS analyzes the potential environmental impacts from the construction, operation, and closure of the repository, and updates the analysis of the impacts of shipping most spent nuclear fuel and high-level radioactive waste by rail.

This Nevada Rail Corridor SEIS supplements the Yucca Mountain FEIS, to the extent that it analyzes the potential impacts of constructing and operating a rail line to connect the Yucca Mountain repository site to an existing rail line near Wabuska, Nevada (in the Mina rail corridor). This Nevada Rail Corridor SEIS analyzes the Mina rail corridor at a level of detail commensurate with that of the rail corridors analyzed in the Yucca Mountain FEIS. It also updates relevant information regarding the other rail corridors analyzed in the Yucca Mountain FEIS (Carlin, Jean, and Valley Modified) to identify any significant new circumstances or information relevant to environmental concerns.

The Rail Alignment EIS tiers from the broader corridor analysis in the Yucca Mountain FEIS and in this Nevada Rail Corridor SEIS. Under the Rail Alignment EIS Proposed Action, DOE analyzes the potential impacts of specific common segments and alternative segments within the Caliente and Mina rail corridors for the purpose of determining an alignment in which to construct and operate a railroad for shipments of spent nuclear fuel, high-level radioactive waste, and other materials from an existing rail line in Nevada to a geologic repository at Yucca Mountain.

The Repository SEIS, this Nevada Rail Corridor SEIS, and the Rail Alignment EIS are related to the extent that the potential transportation impacts associated with shipments to the repository are part of the total impacts associated with the Repository SEIS Proposed Action. Thus, the Repository SEIS incorporates by reference the rail alignment impact evaluations of the Rail Alignment EIS to ensure that the Repository SEIS considers the full scope of potential environmental impacts associated with its Proposed Action. Moreover, because the potential transportation impacts associated with shipments to the repository are part of the total impacts associated with the Repository SEIS Proposed Action, the Rail Alignment EIS considers potential impacts from constructing the repository as a reasonably foreseeable future action in its cumulative impacts analysis. To ensure consistency, the Repository SEIS, this Nevada Rail Corridor SEIS, and the Rail Alignment EIS use the same inventory of spent nuclear fuel and high-level radioactive waste and the same number of rail shipments for analysis. Thus, the associated occupational and public health and safety impacts within the Nevada rail corridors under consideration are the same in all three NEPA analyses. Furthermore, to promote conformity, in both EISs DOE used consistent analytical approaches to evaluate the various resource areas where appropriate.

A number of completed, in-preparation, or proposed DOE NEPA-related documents relate to this Nevada Rail Corridor SEIS. In addition, other federal agencies have prepared related documents. Consistent with Council on Environmental Quality regulations that implement the procedural requirements of NEPA (40 CFR Parts 1500 through 1508), DOE has used information from these documents in its analysis and has incorporated this material by reference as appropriate throughout this Nevada Rail Corridor SEIS. Table 1-2 lists these documents.

Table 1-2. NEPA documentation related to the proposed rail corridor (page 1 of 3).

Document	Relationship to this Nevada Rail Corridor SEIS
DOE documents	
Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada. Las Vegas, Nevada: U.S. Department of Energy, Nevada Field Office. 1996 (DOE/EIS-0243).	Examines the impacts from the continued operations of the Nevada Test Site.
Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-site Locations in the State of Nevada: U.S. Department of Energy, Nevada Field Office (DOE/EIS-0243-SA-01)	Documents the affected environment in 2002 and discusses any changes from the 1996 site-wide EIS (DOE/EIS-0243. Provides the status of new programs as of 2002.
Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada, U.S. Department of Energy (DOE/EIS-0250F).	Examines the impacts of construction, operation, monitoring, and eventual closure of a geologic repository at Yucca Mountain. Examines the potential impacts of transporting spent nuclear fuel and high-level radioactive waste nationally and in the State of Nevada.
Notice of Preferred Nevada Rail Corridor (68 *FR* 74951, December 29, 2003).	Announces the Caliente rail corridor, from the five rail corridors studied in the Yucca Mountain FEIS, as the DOE preferred rail corridor in which to construct a rail line.
Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (69 *FR* 18557, April 8, 2004).	Selects the mostly rail scenario analyzed in the Yucca Mountain FEIS as the mode of transportation on a national basis and within the State of Nevada. Selects the Caliente rail corridor for alignment, construction, and operation of a proposed railroad to Yucca Mountain.
Notice of Intent to Prepare an Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV (68 *FR* 18565, April 8, 2004).	Announces DOE intent to prepare an EIS for the alignment, construction, and operation of a railroad for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials from a site near Caliente, Lincoln County, Nevada to a geologic repository at Yucca Mountain, Nye County, Nevada.
Environmental Assessment for the Proposed Withdrawal of Public Lands within and Surrounding the Caliente Corridor, U.S. Department of Energy, (DOE/EA-1545).	Examines the environmental impacts of withdrawing public lands from surface and mineral entry for up to 20 years to allow evaluation of the land for the proposed rail corridor.
Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV (71 *FR* 60484, October 13, 2006).	Announced DOE intent to expand the scope of the Rail Alignment EIS to include the Mina rail alignment.

Table 1-2. NEPA documentation related to the proposed rail corridor (page 2 of 3).

Document	Relationship to this Yucca Mountain Nevada Rail Corridor SEIS
DOE documents (continued)	
Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (DOE/EIS-0250F-S1).	Updates the Yucca Mountain FEIS and examines the impacts of construction, operation, monitoring, and eventual closure of a geologic repository at Yucca Mountain. Examines the potential impacts of transporting spent nuclear fuel and high-level radioactive waste nationally.
Notice of Availability of the Draft Environmental Assessment for the Proposed Infrastructure Improvements for the Yucca Mountain Project, Nevada, U.S. Department of Energy (71 *FR* 38391, July 6, 2006).	DOE released a Draft Environmental Assessment (EA) in 2006 that evaluated several proposed improvements to infrastructure at the Yucca Mountain Repository Site and adjacent portions of the Nevada Test Site. Proposed infrastructure improvements that were analyzed in the Draft EA are being analyzed in the Yucca Mountain Repository Supplemental EIS. Hence, a Final Infrastructure EA will not be published.
Notice of Intent to Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement-Complex 2030 (71 *FR* 61731, October 19, 2006).	Announced DOE intent to prepare a supplement to the Stockpile Stewardship and Management Programmatic EIS to analyze the environmental impacts from continued transformation of the United States' nuclear weapons complex.
Notice of Intent to Prepare an Environmental Impact Statement for the Disposal of Greater-Than-Class-C Low-Level Radioactive Waste (72 *FR* 40135, July 23, 2007).	Announced DOE intent to prepare an EIS to evaluate disposal options for Greater-Than-Class-C low-level radioactive waste.
Notice of Intent to Prepare a Programmatic Environmental Impact Statement-Designation of Energy Corridors on Federal Land in 11 Western States, (70 *FR* 56647, September 28, 2005).	DOE is preparing an EIS as a co-lead agency with the BLM and other cooperating agencies to evaluate the impacts of designating corridors in the Western U.S. for use as electric transmission, communications, and natural gas transmission corridors. Potential corridors cross Nevada.
Other agency documents	
Proposed Tonopah Resource Management Plan and Final Environmental Impact Statement (DIRS 101523-BLM 1994, all).	Examines implementation of BLM management goals and actions in the Tonopah area.
Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement. (DIRS 176043-BLM 1998, all).	Examines implementation of BLM management goals and actions in the Las Vegas area.
Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada (68 *FR* 74965, December 29, 2003).	Announced the BLM receipt of a request from DOE to withdraw public land in the Caliente corridor from surface and mineral entry for a period of 20 years to evaluate the land for the potential construction, operation, and maintenance of a rail corridor for the transportation of spent nuclear fuel and high-level radioactive waste in Nevada. Segregates the land from surface and mineral entry for up to 2 years while various studies and analyses are made to support a final decision on the withdrawal application.
Draft - Resource Management Plan/Environmental Impact Statement for the Ely District (DIRS 174518-BLM 2005, all).	Examines implementation of BLM resource management plans, actions, and goals in the Ely area.
Final Environmental Impact Statement: Weber Dam Repair and Modification Project, (DIRS 182302-Bureau of Indian Affairs 2005, all).	Examines potential environmental impacts to the Walker River from repair and modification of the Weber Dam.

Table 1-2. NEPA documentation related to the proposed rail corridor (page 3 of 3).

Document	Relationship to this Yucca Mountain Nevada Rail Corridor SEIS
Public Land Order No. 7653; Withdrawal of Public Lands for the Department of Energy to Protect the Caliente Rail Corridor, Nevada (70 *FR* 76854, December 28, 2005).	Withdraws public lands within the Caliente rail corridor from surface and mineral entry, subject to valid existing rights, for 10 years to allow DOE to evaluate the lands for the potential construction, operation, and maintenance of a rail corridor.
Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada (72 *FR* 1235, January 10, 2007).	Announced BLM receipt of an application from DOE to withdraw public lands from surface and mineral entry through December 27, 2015, to evaluate the lands for the potential construction, operation, and maintenance of a rail line. This covers the Mina rail alignment and segments of the Caliente rail alignment not covered in Public Land Order No. 7653. Segregates the land from surface and mineral entry for up to 2 years while various studies and analyses are made to support a final decision on the withdrawal application.
Notice of Intent to "Prepare a Comprehensive Conservation Plan and Associated Environmental Impact Statement for the Desert National Wildlife Refuge Complex" (67 *FR* 54229, August 21, 2002).	The U.S. Fish and Wildlife Service manages the Desert National Wildlife Refuge in Southern Nevada. Part of the Valley Modified rail corridor would pass near the refuge.

2. PROPOSED ACTION AND ALTERNATIVES

This chapter describes the Proposed Action and the No-Action Alternative analyzed in this Nevada Rail Corridor SEIS. Section 2.2 describes the Proposed Action. Section 2.3 describes the No-Action Alternative. Section 2.4 summarizes the potential environmental impacts under the Proposed Action for the Mina rail corridor.

Glossary terms are shown in ***bold italics***.

2.1 Introduction

This Nevada Rail Corridor SEIS analyzes a ***Proposed Action*** and a ***No-Action Alternative***. It supplements the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Yucca Mountain FEIS; DOE/EIS-0250F; DIRS 155970-DOE 2002, all), to the extent that it analyzes the potential impacts of constructing and operating a railroad to connect the Yucca Mountain Site to an existing rail line near Wabuska, Nevada, within the Mina rail corridor. Under the Proposed Action, the U.S. Department of Energy (DOE or the Department) has analyzed in this Nevada Rail Corridor SEIS the Mina rail corridor at a level of detail commensurate with that of the rail corridors (Caliente, Caliente-Chalk Mountain, Carlin, Jean, and Valley Modified) analyzed in the Yucca Mountain FEIS. This Nevada Rail Corridor SEIS further provides updated information on the Carlin, Jean, and Valley Modified rail corridors (see Chapter 5 of this Nevada Rail Corridor SEIS). DOE eliminated the Caliente-Chalk Mountain rail corridor, which would cross part of the Nevada Test and Training Range, from further consideration because of U.S. Air Force concerns that a rail line would interfere with military mission activities (see Section 1.3 of this Nevada Rail Corridor SEIS).

Council on Environmental Quality and DOE regulations that implement the provisions of the National Environmental Policy Act (NEPA) require consideration of the alternative of no action. Under the No-Action Alternative in this Nevada Rail Corridor SEIS, DOE would not select a rail alignment within the Mina rail corridor for the construction and operation of a railroad. As such, the No-Action Alternative provides a basis for comparison to the Proposed Action.

This Nevada Rail Corridor SEIS also analyzes a Shared-Use Option for the Mina rail corridor under which DOE would allow commercial shippers to use the railroad for shipments of general freight.

2.2 Proposed Action

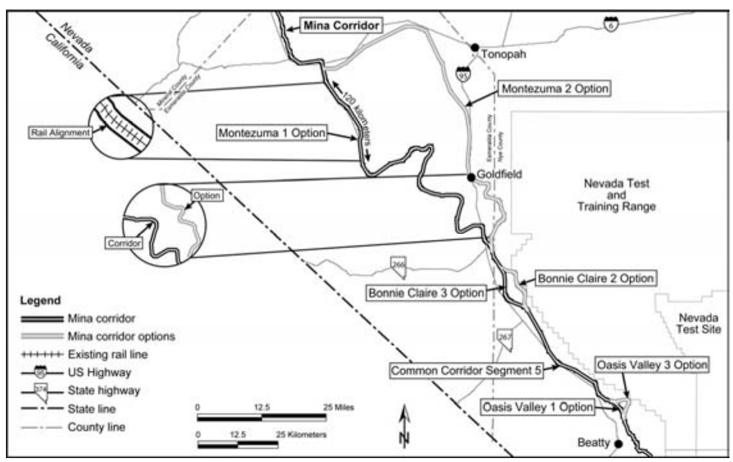
The Proposed Action in this Nevada Rail Corridor SEIS is to construct and operate a railroad within the Mina rail corridor to connect the Yucca Mountain repository to an existing rail line near Wabuska, Nevada. The purpose of this railroad would be to transport, in Nevada, spent nuclear fuel and high-level radioactive waste and other materials for repository constructions and operations to the Yucca Mountain Site.

The Proposed Action includes construction and operation of a railroad and the infrastructure necessary to support the construction and operation of a railroad within the Mina rail corridor. Construction would occur primarily within the rail corridor right-of-way and would require obtaining water, ballast, subballast, steel for bridges, concrete ties, and rail. DOE would first construct a rail roadbed and then track construction would occur. The rail roadbed would form the base upon which the ballast, concrete ties, and rail would be laid. Track construction would include the placement of concrete ties, rail, and ballast on top of the rail roadbed and establishing power and communication systems. DOE would also need to construct bridges, place ***culverts***, and create ***at-grade*** and ***grade-separated crossings*** along the rail line.

In this Nevada Rail Corridor SEIS, DOE analyzes construction of a rail line in the Mina rail corridor. During the construction and operations phases, certain support facilities and access features (for example, a staging yard and access roads) would be needed, and those are addressed insofar as information is available for this corridor-level analysis. However, DOE does not consider impacts from construction and operations support facilities a discriminator at the corridor level. A detailed analysis of construction and operations support facilities, including their locations, is provided in the Rail Alignment EIS.

On April 8, 2004 (69 *FR* 18557), the Department issued a ***Record of Decision*** announcing its selection, both nationally and in the State of Nevada, of the mostly rail scenario analyzed in the Yucca Mountain FEIS as the primary means of transporting spent nuclear fuel and high-level radioactive waste to the repository. In the same Record of Decision, the Department also selected the Caliente rail corridor from several corridors considered in the Yucca Mountain FEIS as the corridor in which to study possible alignments for a rail line. The Proposed Action in this Nevada Rail Corridor SEIS does not change the Department's decision to select the mostly rail scenario nor the selection of the Caliente rail corridor in which to study possible alignments for a rail line.

TERMS RELATED TO THE PROPOSED ACTION IN THIS NEVADA RAIL CORRIDOR SEIS



Rail corridor – A strip of land 400 meters (0.25 mile) wide through which DOE would identify an alignment for the construction of a railroad in Nevada to a geologic repository at Yucca Mountain.

Rail alignment – A strip of land less than 400 meters (0.25 mile) wide through which the location of a rail line would be identified. In the Rail Alignment EIS, the location of a rail line within a rail corridor.

Option – In the Yucca Mountain FEIS the terms for describing separate routes within a corridor were alternates, variations and options. For this Nevada Rail Corridor SEIS, only option is used and is applied more generally; option refers to a strip of land from one point along a corridor to another point on the same corridor that provides a different route.

Common corridor segment - Geographic region for which a single route has been identified.

2.2.1 MINA RAIL CORRIDOR

The Mina rail corridor is about 450 kilometers (280 miles) in length; however, construction of new rail line would range between about 386 kilometers (240 miles) and 409 kilometers (254 miles) because the corridor includes existing Department of Defense rail line between Wabuska and the Hawthorne Army Depot in Hawthorne, Nevada (DIRS 180222-BSC 2006, p. 5). Figure 2-1 shows the Mina rail corridor and its options.

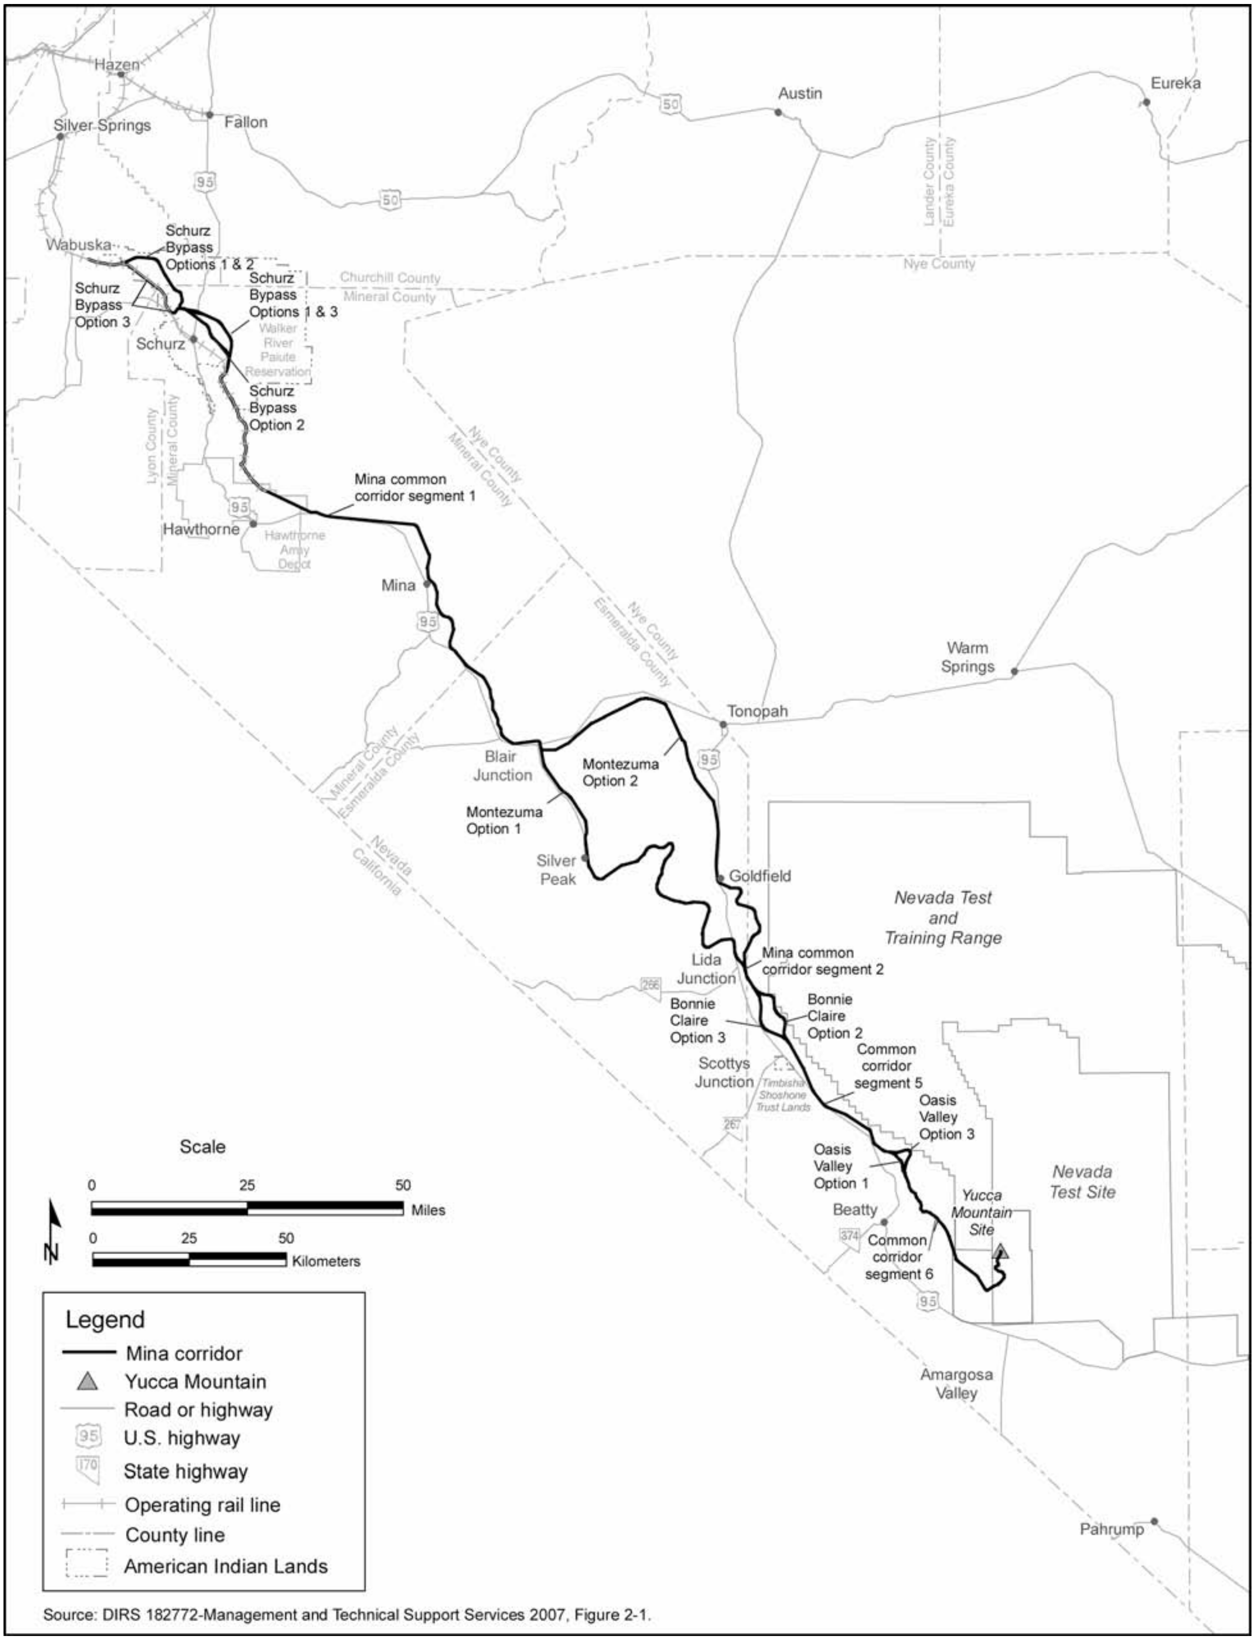


Figure 2-1. Mina rail corridor and options (pre-scoping, October 2006).

In the summer of 2006, DOE initiated a study to consider the feasibility of the Mina rail corridor and to identify specific common corridor segments and associated preliminary options (DIRS 180222-BSC 2006, all). In this feasibility study the Department identified rail line options on the Walker River Paiute Reservation to bypass Schurz, around the Montezuma Range, north of Scottys Junction (referred to as Bonnie Claire), and in Oasis Valley.

The Mina rail corridor originates at an existing rail line near Wabuska, Nevada, where it proceeds southeasterly through Hawthorne, to Blair Junction, and then on to Lida Junction. The construction of the new rail line from Hawthorne south would follow an abandoned rail line nearly to Yucca Mountain. At Lida Junction, the rail corridor trends southeasterly through Oasis Valley before turning north-northeast to Yucca Mountain. Sections 2.2.1.1 through 2.2.1.9 describe the Mina rail corridor common corridor segments and options.

2.2.1.1 Department of Defense Branchline

The Mina rail corridor would begin near Wabuska, Nevada, east of the Fort Churchill Siding on the Department of Defense rail line. The rail corridor proceeds southeast to a point about 29 kilometers (18 miles) northwest of the Town of Schurz. The Department of Defense Branchline is about 8 kilometers (5 miles) long (DIRS 180222-BSC 2006, p. 9). The rail corridor then crosses the Walker River Paiute Reservation, along one of three options that would bypass the town of Schurz.

2.2.1.2 Schurz Bypass Options

A May 2006 letter from the Tribal Council for the Walker River Paiute Tribe (DIRS 182775-Williams 2006, all) indicated that if DOE were to build a new rail line through the Reservation, the Tribe would prefer that the rail line avoid the town of Schurz. At present, an existing rail line travels through the middle of town. In response to the Tribe’s letter, DOE identified three options to bypass Schurz, as shown in Figure 2-2. All the Schurz bypass options would cross the Walker River and the Walker River Paiute Reservation.

Schurz bypass option 1 would begin at the existing Department of Defense Branchline about 29 kilometers (18 miles) northwest of Schurz and pass along the eastern side of Sunshine Flat. From there, it would pass east of Weber Reservoir and cross U.S. Highway 95 about 8 kilometers (5 miles) north of the intersection of U.S. Highway 95 and Alternate U.S. Highway 95. Schurz bypass 1 would be about 51 kilometers (32 miles) long and would reconnect with the Department of Defense Branchline about 13 kilometers (8 miles) south of Schurz (DIRS 180222-BSC 2006, pp. 9 and 27).

Schurz bypass option 2 would begin at the existing Department of Defense Branchline at the same point as Schurz bypass option 1. From there, it would pass east of Weber Reservoir and cross U.S. Highway 95 about 6.4 kilometers (4 miles) north of the intersection of Highway 95 and Alternate U.S. Highway 95. From there, it would trend to the southeast but stay to the east of Schurz and west of the location of Schurz bypass option 1 until it rejoined the existing Department of Defense Branchline about 13 kilometers (8 miles) south of Schurz. Schurz bypass option 2 would be about 50 kilometers (31 miles) long (DIRS 180222-BSC 2006, pp. 9 and 27).

Schurz bypass option 3 would begin at the Department of Defense Branchline about 9.7 kilometers (6 miles) northwest of Schurz. It would cross U.S. Highway 95 about 8 kilometers (5 miles) north of the intersection of U.S. Highway 95 and Alternate U.S. Highway 95, at which point it would continue southeast to a point where it would rejoin the existing Department of Defense Branchline about 13 kilometers (8 miles) south of Schurz. Schurz bypass option 3 would be about 50 kilometers (31 miles) long (DIRS 180222-BSC 2006, pp. 9 and 27).

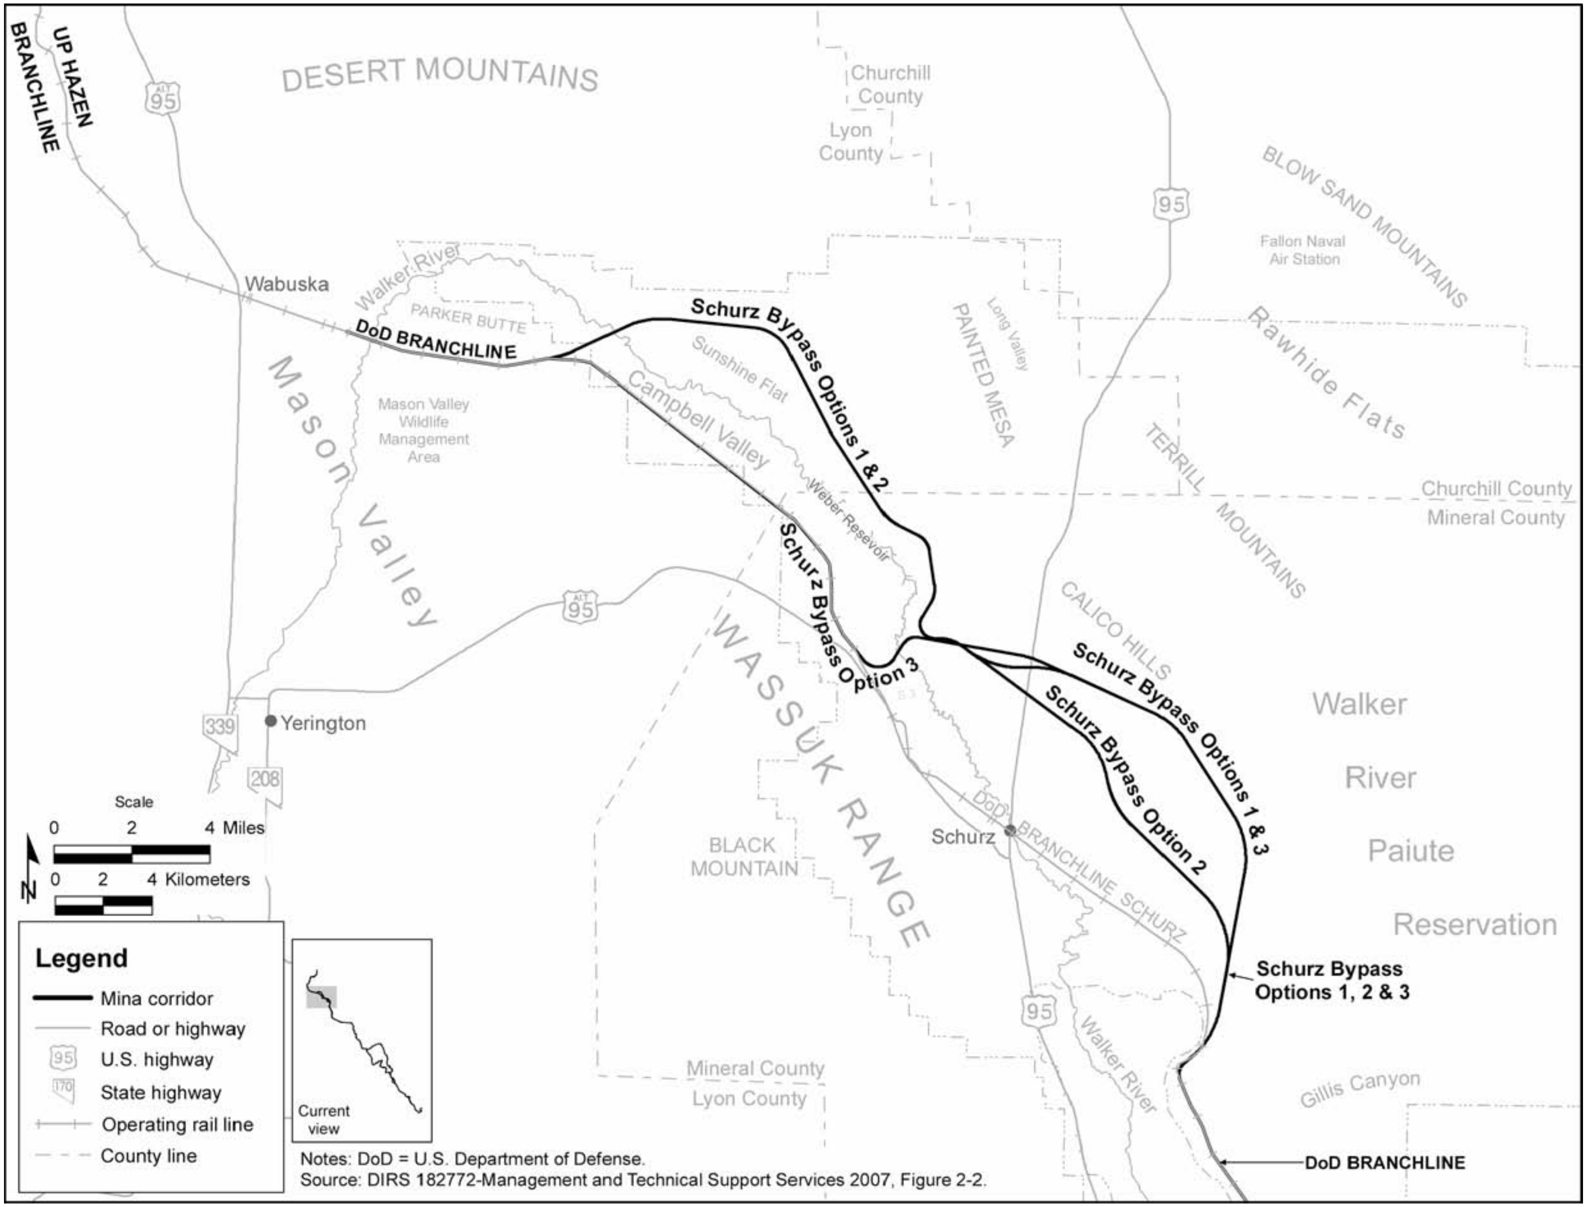

Figure 2-2. Schurz bypass options (pre-scoping, October 2006).

2.2.1.3 Common Corridor Segment 1

Common corridor segment 1 would begin north of Hawthorne and would trend southeast before turning east at U.S. Highway 95. It would trend east along U.S. Highway 95 through Soda Springs Valley for approximately 40 kilometers (25 miles). Continuing to parallel U.S. Highway 95, the rail line would cross State Route 361 and turn south for approximately 64 kilometers (40 miles). It would pass Luning and Mina along U.S. Highway 95. The rail line would then turn east before crossing U.S. Highway 95 in the area of Blair Junction and continuing for about 1.6 kilometers (1 mile) before joining the selected Montezuma options. Common corridor segment 1 would be approximately 160 kilometers (92 miles) long; which includes 21 miles of existing Department of Defense rail line (DIRS 180222-BSC 2006, pp. 9 and 27).

2.2.1.4 Montezuma Options

Montezuma option 1 would depart Common corridor segment 1 just southeast of Blair Junction. It would trend roughly southeast along State Route 265 passing to the east of Silver Peak in Clayton Valley. It would then turn to the northwest through Clayton Valley. It would then trend south between Clayton Ridge on the west and Montezuma Peak on the east before turning east, passing to the south of Montezuma Peak. The rail alignment would again turn roughly south, traveling to the west of the Goldfield Hills. It would then travel northwest, cross U.S. Highway 95, and turn south before joining Common corridor segment 2 near Lida Junction. Montezuma option 1 would be approximately 120 kilometers (73 miles) long (DIRS 180222-Nevada Rail Partners 2006, pp. 10 and 27).

Montezuma option 2 would depart Common corridor segment 1 just southeast of Blair Junction. It would trend northeast just south of U.S. Highway where it would follow an abandoned rail ***roadbed*** of the former Tonopah and Goldfield Railroad to north of Lone Mountain. Northeast of Lone Mountain, it would turn south into Montezuma Valley and run south before turning east and crossing U.S. Highway 95 south of Goldfield. It would then trend south before joining Common corridor segment 2 near Lida Junction. Montezuma option 2 would be approximately 120 kilometers (74 miles) long (DIRS 180222-Nevada Rail Partners 2006, pp. 10 and 27).

2.2.1.5 Common Corridor Segment 2

Common corridor segment 2 would begin at the end of the selected Montezuma option and run roughly southeast as a single route for about 3 kilometers (2 miles) before reaching the Bonnie Claire area. Common corridor segment 2 would be approximately 3 kilometers long (DIRS 180222-Nevada Rail Partners 2006, pp. 10 and 27).

2.2.1.6 Bonnie Claire Options

DOE is considering two options in the Bonnie Claire area, Bonnie Claire 2 and 3. The Department did not evaluate Bonnie Claire option 1 because it would cross Timbisha Shoshone Trust Lands (see Appendix C). Bonnie Claire option 2 would begin about 8 kilometers (5 miles) north of Stonewall Pass and trend east toward the Nevada Test and Training Range for about 5 kilometers (3 miles) before turning south for an additional 18 kilometers (11 miles). Bonnie Claire option 2 would generally follow the Nevada Test and Training Range boundary and end in Sarcobatus Flats north of Scottys Junction near the intersection of State Route 267 and U.S. Highway 95. Bonnie Claire option 2 would be approximately 19 kilometers (12 miles) long (DIRS 180222-BSC 2006, pp. 10 and 27).

Bonnie Claire option 3 would begin about 8 kilometers (5 miles) north of Stonewall Pass. It would trend generally south, parallel to U.S. Highway 95 to the east. Bonnie Claire option 3 would end in Sarcobatus Flats north of Scottys Junction near the intersection of State Route 267 and U.S. Highway 95. Bonnie

Claire option 3 would be approximately 19 kilometers (12 miles) long (DIRS 180222-BSC 2006, pp. 11 and 27).

2.2.1.7 Common Corridor Segment 5

Common corridor segment 5 would begin approximately 4 kilometers (2 miles) north of Scottys Junction and trend generally southeast through the Sarcobatus Flat area. Common corridor segment 5 would end approximately 6 kilometers (4 miles) north of Springdale, where it would connect to one of the selected Oasis Valley options. Common corridor segment 5 would be approximately 40 kilometers (25 miles) long (DIRS 180222-BSC 2006, p. 11).

2.2.1.8 Oasis Valley Options

DOE is considering two options in the Oasis Valley area, Oasis Valley 1 and 3. The Department did not evaluate Oasis Valley option 2 because the option's engineering factors and environmental and land-use features are similar to those for Oasis Valley option 1 (see Appendix C). Oasis Valley option 1 would begin about 3.2 kilometers (2 miles) north of Oasis Mountain, and run southeast. It would be approximately 9.7 kilometers (6 miles) long (DIRS 180222-BSC 2006, p 11).

Oasis Valley option 3 would begin about 3.2 kilometers (2 miles) north of Oasis Mountain, and run generally east and then south before it crossed Oasis Valley farther to the east than Oasis Valley option 1. Oasis Valley option 3 would be about 14 kilometers (9 miles) long (DIRS 180222-BSC 2006, p 11).

2.2.1.9 Common Corridor Segment 6

Common corridor segment 6 would begin about 3 kilometers (2 miles) east of U.S. Highway 95. Common corridor segment 6 would trend generally southeast for 40 kilometers (25 miles) from Oasis Valley to Beatty Wash. It would then turn north near the southern end of Busted Butte and then trend generally north, terminating at the Yucca Mountain Site. Common corridor segment 6 would be approximately 51 kilometers (32 miles) long (DIRS 180222-Nevada Rail Partners 2006, p. 11).

2.2.2 SHARED-USE OPTION

In the Yucca Mountain FEIS, the Department considered a Shared-Use Option as reasonably foreseeable and evaluated that option under cumulative impacts. For this Nevada Rail Corridor SEIS, the Department considers the Shared-Use option under the Proposed Action.

Construction and operation of a rail line in the Mina rail corridor could provide an option for shared use and operation of commercial rail service to serve communities along the corridor. The presence of a rail line could influence further development and land use in the corridor. The Shared-Use Option would not require any changes in design to that described for the Proposed Action in this Nevada rail corridor SEIS. However, shared use would require design and construction of additional commercial sidings and facilities to provide access and operational capabilities for commercial shippers. Trains carrying commercial shipments would be separate from trains carrying spent nuclear fuel and high-level radioactive waste.

2.2.3 OVERVIEW OF DESIGN EVOLUTION

In the Yucca Mountain FEIS and in this Nevada Rail Corridor SEIS and Rail Alignment EIS, DOE based its rail corridor design and associated construction and operations plans on standard railroad industry practices and in consideration of applicable regulations. Since issuing the Yucca Mountain FEIS, DOE has advanced its proposed design and associated plans to determine an alignment for the construction and operation of a railroad within the Caliente rail corridor (DIRS 180877-Nevada Rail Partners 2007, all). These current design and construction and operations plans, which meet standard industry practices and objectives, have advanced from those of the Yucca Mountain FEIS. The following engineering design details and associated operations plans for the Caliente rail alignment have been used in developing the Mina rail corridor for purposes of evaluating the potential environmental impacts from constructing and operating a railroad from Wabuska, Nevada, to Yucca Mountain.

- More detailed aerial mapping and contour analysis of the Caliente rail corridor and its options
- Corridor options to further avoid areas of environmental concern
- Use of material excavated from one area within the corridor to provide subballast for other areas; the use of any excess for widening the rail roadbed or development of a service road, thereby reducing the need for spoils areas
- Final grading requirements of slopes, installation of rock-fall protection devices, replacement of topsoil, revegetation and installation of other permanent erosion control systems, and an adjacent maintenance road within the corridor
- Changes to design criteria to now include a maximum horizontal curvature of 6 degrees with 2 percent compensated curves, use of 62-kilogram (136 lbs) rail and 30 centimeters (12 inches) of ballast, and a 9.4-meter (31-foot) top of cross section
- Use of a centralized train control signal system (monitoring equipment, signals, communications equipment) for train operations
- An increase in the total number of trains of up to 17 trains per week during the operations phase
- An operations period of up to 50 years
- More detailed design of certain facilities that would interface with the Union Pacific Railroad near Caliente, Nevada
- The average width land disturbed is 100 meters (325 feet) within the corridor based on conceptual rail alignment engineering and construction design (DIRS 180877-Nevada Rail Partners 2007, all)

DOE analyzed the construction and operations of a rail line within the Mina rail corridor. Where details regarding supporting facilities within the Mina rail corridor are known (staging yards, maintenance roads), they were analyzed in the appropriate resource area. Regardless of where in the document they are analyzed or considered, supporting facilities are not considered a discriminator at the corridor level. A detailed analysis of supporting facilities, including locations, is done at the alignment level in the Rail Alignment EIS.

2.2.4 RAIL LINE CONSTRUCTION IN THE MINA RAIL CORRIDOR

Unless otherwise indicated, all construction activities would occur inside the rail line ***construction right-of-way*** (nominally 150 meters [500 feet] on either side of the centerline of the rail alignment, for a ***nominal*** width of 300 meters [1,000 feet]). The total construction ***footprint*** would be approximately 140 square kilometers (35,000 acres), but would vary depending on the corridor options selected. However, based on land disturbance computations from the Air Quality Emission Factors and Socio-Economic Input Caliente Rail Corridor (DIRS 180921-Nevada Rail Partners 2007, all), DOE used an average width of the Caliente rail alignment of 100 meters (325 feet) to estimate land disturbance for the Mina rail corridor at 41 square kilometers (10,000 acres) (DIRS 180877-Nevada Rail Partners 2007, p. 2-10).

DOE would implement ***best management practices*** during the entire construction process, such as dust suppression and the use of silt fencing to control soil erosion during construction activities.

DOE anticipates that it would take a minimum of 4 years, and possibly up to 10 years, to construct the railroad in the Mina rail corridor. Construction would begin with the procurement of concrete ties and rail for track construction and steel for bridge construction. DOE would start constructing major bridges, culverts, and grade-separated crossings before other infrastructure because they would take longer to construct (DIRS 180922-Nevada Rail Partners 2007, Section 7.0).

Ballast is the coarse rock that is placed under the railroad tracks to support the railroad ties and improve drainage along the rail line.

Subballast is a layer of crushed gravel that is used to separate the ballast and roadbed for the purpose of load distribution and drainage.

Water, ***subballast, ballast***, steel for bridges, concrete ties, and rail would be required for rail line construction.

Approximately 90 percent of the water that would be used during construction would be used for earthwork compaction and control of excavation dust (DIRS 180922-Nevada Rail Partners 2007, pp. 9 and 10).

Approximately 4.5 metric tons of subballast per meter (1.5 tons of subballast per foot) of track construction would be required. The Department would obtain subballast from materials excavated during rail roadbed construction, or from existing ***borrow sites*** in the rail corridor (DIRS 180877-Nevada Rail Partners 2007, p. 2-3).

Approximately 5.1 metric tons of ballast per meter (1.7 tons of ballast per foot) of track construction would be needed along the rail line. Approximately one concrete tie for every 0.61 meter (2 feet) of track construction would be needed along the entire length of the rail line. DOE would obtain rail from commercial sources and weld it into 440-meter (1,440-foot) strings at a portable welding plant located within the construction right-of-way (DIRS 180922-Nevada Rail Partners 2007, pp. 3-1 to 3-10).

DOE would install grade crossings where the rail line would cross a roadway. In places where the rail line would cross a highway (for example, U.S. Highway 95), the routes would be grade-separated. Where the rail line would cross paved public roadways, the routes would cross at-grade and active warning devices, such as flashing lights and gates, would be installed. Where the rail line would cross unpaved roads, DOE would install passive warning devices such as crossbucks and stop signs (DIRS 180923-Nevada Rail Partners 2007, p. 6-9).

The rail roadbed would be constructed along the centerline of the rail line. Construction of the rail roadbed would require clearing, excavating earth and rock on previously undisturbed land and removing and stockpiling topsoil where needed. Construction would require both cuts and fills (DIRS 180922-Nevada Rail Partners 2007, Section 2.0).

During rail line construction, DOE would install an unpaved road parallel to the rail line inside the construction right-of-way. The Department could leave this access road in place to provide additional access to the rail line for maintenance. Because maintenance would be performed using on-rail vehicles or trains, no bridges would need to be constructed for access roads (DIRS 180922-Nevada Rail Partners 2007, Section 4.5).

DOE would construct ***sidings*** approximately every 40 kilometers (25 miles) so that trains running in opposite directions could pass one another. This spacing would result in approximately 10 to 12 sidings for the rail line. Sidings would be placed inside the ***operations right-of-way*** (nominally 61 meters [200 feet] on either side of the rail line centerline) (DIRS 180922-Nevada Rail Partners 2007, p. 2-3).

The Department would build a distribution line for electric power along the entire length of the corridor. Power to the distribution system would be fed from locations where existing high-voltage transmission lines intersected the corridor (DIRS 180922-Nevada Rail Partners 2007, p. 4-6).

DOE would install a communications system utilizing a fiber-optic communications cable, very-high-frequency (commonly called VHF) radio, satellite radios, and possibly satellite or cellular telephones. The Department would position communications towers at the beginning, end, and approximately every 16 to 32 kilometers (10 to 20 miles) along the rail line. These towers would be approximately 23 to 30 meters (75 to 100 feet) tall and would enable very-high-frequency radio communication between rail line personnel working in remote locations along the rail line. DOE would install 4.6-meter (15-foot)-tall ***wayside signals*** along the rail line to control train movements (DIRS 180922-Nevada Rail Partners 2007, pp. 2-2 and 2-3).

The final step in the construction of the railroad would be the commissioning of train operations. Each time a section of the track was completed and the signals and communications systems installed and tested, integrated testing would commence, utilizing train equipment to validate that all components were operating as designed. Successful testing would result in final jurisdictional inspection and commissioning, by the appropriate regulatory authority, of the rail line for normal operations (DIRS 180922-Nevada Rail Partners 2007, p. 7-4).

2.2.5 RAILROAD OPERATIONS AND MAINTENANCE

The rail line would be expected to operate for up to 50 years for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials to the repository at Yucca Mountain. DOE would operate and maintain the rail line in accordance with applicable regulations, guidelines, and standards of the Federal Railroad Administration, the Union Pacific Railroad, and the Association of American Railroads.

2.2.5.1 Railroad Operations

Railroad operations would begin immediately after construction was completed. The railroad would operate dedicated trains carrying spent nuclear fuel and high-level radioactive waste and trains carrying other materials, which could include construction materials, diesel fuel, and repository equipment. During the operations phase, DOE would use the rail line to transport approximately 9,500 railcars, each with a cask of spent nuclear fuel or high-level radioactive waste, and approximately 29,000 railcars of construction materials, diesel fuel, and supplies for the repository and facilities. The frequency of trains going to the repository would vary slightly, but would average 17 one-way trains or 8.5 round trips per week (derived from DIRS 175036-BSC 2005, Table 4.2).

Union Pacific Railroad trains carrying casks of spent nuclear fuel and high-level radioactive waste would arrive in Nevada via the Union Pacific Railroad Mainline, travel to Wabuska via the Union Pacific branchline, and then proceed to a staging yard.

The dedicated cask trains on the rail line would be assembled at the staging yard and would consist of two or three 4,000-horsepower diesel-electric locomotives followed by a ***buffer car***; one to five ***cask cars*** followed by another buffer car; and one ***escort car*** carrying security personnel. ***Naval spent nuclear fuel*** trains would typically include two or three locomotives, 1 to 12 cask cars, a buffer car in front of the first cask car and after the last cask car, and one to two escort cars. Trains would depart a staging yard and proceed along the rail line to the Yucca Mountain Site. Trains would require

A **buffer car** is a railcar that would be placed at the front of a cask train between the locomotive and the first cask car and at the back of the train between the last cask car and the escort car.

A **cask car** is a railcar that would be used to transport a cask of spent nuclear fuel or high-level radioactive waste.

An **escort car** is a passenger car that would carry security personnel.

fewer than 10 hours for the trip between a staging yard and the Yucca Mountain Repository (DIRS 180923-Nevada Rail Partners 2007, p. 5-1). After casks were unloaded at the site, the empty casks would be returned to service.

Freight trains carrying construction and other materials would arrive in Nevada via the Union Pacific Railroad Mainline, travel to Wabuska via the Union Pacific branchline, and then proceed to a nearby staging yard. From a staging yard, locomotives would transport the materials along the rail line to the repository.

A railroad control center, in coordination with a national transportation operations center, would control the operations along the rail line. DOE would use a satellite-based transportation tracking and communication system to track rail shipments of spent nuclear fuel and high-level radioactive waste to the repository (DIRS 180923-Nevada Rail Partners 2007, p. 6-6).

2.2.5.2 Railroad Maintenance

Maintenance of the rail line would be an ongoing process that would be concurrent with the operations phase of the railroad. The primary maintenance and inspection functions would include track inspection; signal testing and inspection; minor rail, tie, and turnout replacement; and routine ballasting and surfacing tasks. Maintenance activities would be scheduled to minimize the impact on planned train movements (DIRS 180923-Nevada Rail Partners 2007, Section 10.0).

Maintenance crews would access the work area using ***hi-rail trucks*** (vehicles capable of traveling on roads or on railroad tracks**)**, rail mounted machinery (tamper, track liner, etc), or maintenance trains. During rail line construction, DOE would construct unpaved roads parallel to the rail line inside the construction right-of-way. The Department could leave these access roads in place to provide additional access to the rail line for maintenance.

Following the final shipment of spent nuclear fuel, high-level radioactive waste, and other materials to the repository, DOE could abandon the rail line or could make it available to local communities or the private sector for other uses (DIRS 180923-Nevada Rail Partners 2007, Section 10.0).

2.3 No-Action Alternative

Council on Environmental Quality and DOE regulations that implement the procedural requirements of NEPA require consideration of the alternative of no action. Under the No-Action Alternative in this Nevada Rail Corridor SEIS, DOE would not construct and operate a railroad within the Mina rail corridor from Wabuska to Yucca Mountain. Therefore, the No-Action Alternative provides a basis for comparison to the Proposed Action.

2.4 Summary of Potential Environmental Impacts for the Mina Rail Corridor

Sections 2.4.1 through 2.4.12 summarize the potential environmental impacts associated with construction and operation of a railroad in the Mina rail corridor. Table 2-1 provides an overview of these potential impacts for the Mina rail corridor.

Table 2-1. Potentially affected resources – Mina rail corridor (page 1 of 2).

Resource	Impact/indicator
Land use	
Disturbed land[a]	9,000 to 10,000 acres (37 to 41 square kilometers), depending on rail corridor option
Land ownership/management authority	
Private land	400 to 670 acres (1.6 to 2.7 square kilometers) (1 to 2 percent of total ownership/authority)
Tribal trust lands and reservations	3,100 to 5,100 acres (12.5 to 20.5 square kilometers) (5 to 12 percent of total ownership/authority)
BLM-administered land	32,600 to 33,100 acres (132.1 to 133.9 square kilometers) (80 to 85 percent of total ownership/authority)
Department of Defense land (Hawthorne Army Depot)	1,200 acres (4.7 square kilometers) (3 percent of total ownership/ authority)
DOE land (Nevada Test Site)	1,300 acres (5.3 square kilometers) (3 percent of total ownership/ authority)
Air quality	
National Ambient Air Quality Standards attainment status	Areas in attainment or unclassifiable for air quality standards; small impacts from construction and operations
Hydrology	
Surface water	Small impacts associated with the alteration of drainage patterns or changes to erosion and sedimentation rates
Groundwater use	5,950 acre feet (7.32 million cubic meters)
Biological resources and soils	Small impacts to habitat, wildlife, vegetation, and soils
Cultural resources (records search)	Five percent of area surveyed with 132 recorded sites; eligible affected sites would require mitigation during construction; indirect impacts would be small during operations.
Occupational and public health and safety	
Construction and operations	
Industrial hazards	
Total recordable cases	379
Lost workday cases	215
Fatalities	0.92 (combined involved and noninvolved workers)
Transportation (construction phase only)	
Traffic fatalities	4.0
Cancer fatalities	0.54
Operations only	
Incident-free radiological impacts (latent cancer fatalities)	
Public	0.00082
Workers	0.33
Radiological transportation accident fatalities	
Radiological accident risk (latent cancer fatalities)	0.0000074
Cancer fatalities from vehicle emissions	0.40

Table 2-1. Potentially affected resources – Mina rail corridor (page 2 of 2).

Resource	Impact/indicator
Occupational and public health and safety (continued)	
Operations phase only	
Transportation accident fatalities	
Worker commuting and material delivery	3.3
Radiological waste transportation	0.31
Socioeconomics	Construction employment: 6,500 worker-years over a minimum 5-year construction phase, primarily from Clark County and the Carson City/Washoe County area Construction economic measures: Less than a 2-percent increase in gross regional product, real disposable personal income, and spending by state and local governments Construction public services: Small increase in local populations Operations employment: 42 workers Operations economic measures: less than a 2-percent increase in gross regional product, real disposable personal income, and spending by state and local governments Operations public services: Small to moderate increase to local populations in Lyon, Mineral, Nye, and Esmeralda Counties
Noise and vibration	Construction noise levels would be below the Federal Transit Administration noise guidelines. Construction- and operations-train noise would be audible to receptors in Silver Peak and Goldfield. No adverse impacts from vibration.
Aesthetics	Small; construction and operation of a railroad primarily in BLM visual resource management Class III and IV would be consistent with BLM management objectives for those areas
Utilities, energy, and materials	
Diesel fuel	33 million gallons (125 million liters)
Gasoline	660,000 gallons (2.5 million liters)
Steel	74,000 tons (67,000 metric tons)
Concrete	287,000 tons (260,000 metric tons)
Wastes	
Construction-related municipal waste; limited quantities of other waste types	1.7 tons (1.5 metric tons) per day
Environmental justice (disproportionately high and adverse impacts)	None identified

a. Land disturbance is based on an average construction right-of-way of 100 meters (325 feet) (DIRS 180877-BSC 2007, p. 2-10).

Where practical, DOE has ***quantified*** potential impacts and other characteristics of the Proposed Action. In other instances, it is not practical to quantify impacts and DOE provides a ***qualitative*** assessment of potential impacts. In this Nevada Rail Corridor SEIS, the Department has used the following descriptors to qualitatively characterize impacts only where quantification of impacts was not practical:

- **Small** - For the issue, environmental effects would not be detectable or would be so minor that they would neither destabilize nor noticeably alter any important attribute of the resource.
- **Moderate** - For the issue, environmental effects would be sufficient to alter noticeably, but not to destabilize, important attributes of the resource.
- **Large** - For the issue, environmental effects would be clearly noticeable and would be sufficient to destabilize important attributes of the resource.

Unless otherwise noted, potential impacts described in Table 2-1 would be adverse and are for both the construction and operations phases.

2.4.1 LAND USE AND OWNERSHIP

Construction of a railroad in the Mina rail corridor would disturb approximately 37 to 41 square kilometers (9,000 to 10,000 acres) of land, depending on the option selected (DIRS 180877-BSC 2007, p. 2-10). The Mina rail corridor would cross up to 15 separate grazing allotments. The approximate disturbance area associated with the Mina rail corridor would constitute less than 1 percent of the land within those 15 grazing allotments. Within this regional perspective of nearby existing and reasonably foreseeable land uses and land ownership, the commitment of land for the Mina rail corridor would constitute a minor proportion of overall land commitment. Impacts to private land could be approximately 1.6 to 2.7 square kilometers (400 to 670 acres), depending upon the option selected, which consists of primarily agricultural and mineral uses and contain no private residences.

The Mina rail corridor would not cross or affect any Wilderness Areas, Wilderness Study Areas, or areas of Critical Environmental Concern. The Mina rail corridor would be consistent with the goals and policies of the resource management plans in the BLM-administered areas through which it passes. A rail line in the Mina rail corridor could cross private lands. If, in locating the final alignment, DOE could not avoid private lands, the Department would need to acquire access to them to construct and operate the railroad. If private property was divided by the rail line, access to the property could be disrupted.

The rail corridor would cross land on the Walker River Paiute Reservation. Construction and operation of a rail line on this land will require land agreements between DOE, the U.S. Department of the Interior, Bureau of Indian Affairs, and the Walker River Paiute Tribe. Prior to construction, DOE would be required to obtain both the permission to survey for a right-of-way and a right-of-way grant in accordance with 25 CFR Part 169, “Rights-of-Way over Indian Lands.” These regulations state that “Rights-of-way for railroads shall not exceed 15 meters (50 feet) in width on each side of the centerline of the road, except where there are heavy cuts and fills, when they shall not exceed 30 meters (100 feet) in width on each side of the road.”

A portion of the Mina rail corridor, approximately 13 kilometers (8 miles) long, would cross through the Hawthorne Army Depot. A right-of-way grant to construct and operate a railroad through this area would require an agreement with the Department of Defense and the U.S. Army Corps of Engineers for the use of the land and the existing rail line.

Approximately 27 kilometers (17 miles) of common corridor segment 6 of the Mina rail corridor would be within the boundaries of the Nevada Test Site, which is managed by the DOE. Construction of a rail line within this area would require land use authorization from the DOE Nevada Site Office and the BLM.

BLM would require the DOE to obtain a ***right-of-way grant*** to construct and operate a railroad on public land. The Department would adjust the width of the construction right-of-way where practicable to avoid or minimize land-use conflicts and restrictions. Construction and operation of the railroad in the Mina rail corridor through existing rights-of-way would require an evaluation of the impact to the road or utility or use of the right-of-way with both the right-of-way holder and the BLM. DOE would protect existing utility rights-of-way from damage so that disruption to utility service or damage to lines would be at most small and temporary.

The implementation of several mining engineering practices in these areas could allow access to mining claims without affecting the claimant or the rail line, depending on the exact locations of the claims and access needs. Construction of the rail line would result in loss of forage. Because the corridor intersects grazing allotments, a rail line could create a barrier to livestock movement. Livestock could have difficulty accessing water if there was a deep cut or a high fill associated with the rail line. Ranch operations and livestock rotations could be disrupted. Livestock mortality could occur along roads used during rail line construction and operations and possibly by trains during the operations phase. Construction and operation of a rail line through the Mina corridor could impact access to land used by the public for recreation, requiring individuals to alter their access routes.

2.4.2 AIR QUALITY

The Mina rail corridor would pass through rural parts of Nevada that are in areas that are considered by the U.S. Environmental Protection Agency to be either ***in attainment*** or unclassifiable for ***criteria pollutant*** standards pursuant to ***National Ambient Air Quality Standards***. Most rural areas of the United States are either in attainment or unclassifiable for all pollutants.

The impacts to air quality during rail line construction and subsequent operation would be small. During the relatively short-term period for construction of a rail line in the Mina Corridor, equipment emissions would result in a minimal contribution of criteria pollutants to the region. The criteria pollutants emitted would primarily come from the operation of construction equipment in rural areas or areas that are currently uninhabited. Construction activities would also emit ***fugitive dust*** that would require DOE to implement dust suppression measures. Impacts to these air quality criteria pollutant concentrations and fugitive dust generation should decrease as the rail line and rail facility construction is completed and the railroad becomes operational. During operations these impacts would be smaller but would last longer during the period of operation.

Impacts associated with railroad operations and maintenance activities would be small.

2.4.3 HYDROLOGY

Hydrologic hazards in the Mina rail corridor could include flash floods. Impacts to surface water associated with the alteration of drainage patterns or changes to erosion and sedimentation rates or locations would be small and localized. Impacts on surface-water resources resulting from construction activities would generally be small and limited to within the nominal width of the construction right-of-way. Impacts to springs near the corridor would be small. DOE would use appropriate engineering standards and construction practices to help avoid minimize potential impacts on surface water resources.

Impacts associated with railroad operations and maintenance activities on surface water would be small.

The groundwater analysis for this Nevada Rail Corridor SEIS based its calculations of water demand for the construction of a rail line in the Mina rail corridor on earthwork needs and subsequent water for requirements for compaction. Based on these considerations, total water demand for the Mina rail corridor would be approximately 7.32 million cubic meters (5,950 acre-feet). Groundwater use during the construction phase could result in a short-term decrease in the amount of available water in some hydrologic basins.

DOE would request the Nevada State Engineer to approve any potential plans to pump groundwater from new or existing wells and otherwise obtain groundwater from other regional resources, so as to not adversely affect groundwater resources in the region. Groundwater demands during operation of the railroad would be small and be limited to water needed to support maintenance activities and a reduced workforce. These needs would be small and have little effect on regional resources.

2.4.4 BIOLOGICAL RESOURCES AND SOILS

The Mina rail corridor would primarily cross through remote areas that are characterized by a variety of vegetation communities, special status species (plants and animals including their habitats), game habitats, surface water flows, and soil conditions. The corridor only crosses one riparian area along the Walker River and one spring near Goldfield.

Some vegetation communities would be disturbed during construction activities within the 400-meter (0.25-mile)-wide corridor. With the exception of the few riparian areas in the corridor, none of the plant communities encountered are considered by BLM to be sensitive (unique or rare). The total land area disturbed within these vegetation communities in the corridor would be small when compared to the other land areas in Nevada that also support them.

The Mina rail corridor would cross through habitat that supports a low abundance of the desert tortoise (*Gopherus agasizii*), a federally listed threatened species under the Endangered Species Act. Disturbance of this habitat could disrupt normal movements or possibly result in some individual tortoise deaths. DOE would work with U.S. Fish and Wildlife Services to help limit impacts to the desert tortoise.

The rail corridor would also cross riparian habitat for the Lahontan cutthroat trout (*Oncorhynchus clarkii henshawi*), a federally listed threatened species under the Endangered Species Act. Construction of a bridge over the Walker River downstream of Walker Dam would have to occur when the water flow is low and the species would be rare or absent. Construction activities could temporarily degrade downstream water quality. As such, impacts would be temporary and small.

The rail corridor would cross habitat for some game species including bighorn sheep, pronghorn sheep, mule deer, and mountain lions, as well as herd management areas for wild horses and burro herds. During construction activities, the movement of these animals could temporarily be disrupted due to noise and land disturbance and they would likely move away from the area. Noise from passing trains during rail road operations could minimally disturb some animals. Impacts would be small and would likely diminish over time as animals acclimated to the presence of passing trains.

Soil erosion could increase from land disturbance during construction activities within the construction right-of way. Prime farmland occupies less than 1 percent of the soils in the corridor. DOE would use erosion control methods to help reduce the potential of direct impacts during construction. Use of hazardous materials would be controlled to limit the potential for soil contamination. Impacts to soil would be temporary and small.

Impacts associated with railroad operations and maintenance activities would be small.

2.4.5 CULTURAL RESOURCES

There could be impacts to cultural resources at different locations in the Mina rail corridor. There are several cultural resources, which include archaeological and historic sites and structures, in the corridor that are eligible or potentially eligible for inclusion on the *National Register of Historical Places*. Construction activities could degrade, cause the removal of, or alter the setting of cultural resources sites and cause the loss of cultural resources.

Before starting construction, DOE would perform additional field surveys and inventories to further locate and identify cultural resources along the corridor. The Department would work closely with other federal agencies, tribal authorities, and the state agencies to help avoid and mitigate potential adverse impacts to identified cultural resources in the corridor. DOE would use procedures and work with other agencies to help protect cultural resources encountered during the construction phase as a result of surface disturbances. Steps would be taken to avoid and protect them and to mitigate potential adverse impacts from both project related activities and the actions of others.

Railroad operations and maintenance activities are not expected to result in any additional impacts to cultural resources at archeological or historic sites.

2.4.6 OCCUPATIONAL AND PUBLIC HEALTH AND SAFETY

The impact analysis for occupational health and safety focused on transportation impacts, worker industrial safety impacts, incident-free radiological impacts and nonradiological impacts, and radiological impacts with respect to accidents.

Nonradiological transportation impacts during the construction phase of the project are expected to primarily result from traffic accidents involving workers commuting to and from the construction sites and transporting rail line construction materials to the construction sites and from vehicle emissions produced by commuting workers and material deliveries. Those impacts during the construction phase of the project are estimated to be 4 fatalities from traffic accidents and 0.54 latent cancer fatalities from vehicle emissions.

The largest potential for radiological exposure during the operations phase of the railroad would be to workers involved in the transportation of spent nuclear fuel and radioactive high level waste. That impact could be about 0.40 latent cancer fatalities.

Industrial safety impacts resulting from railroad construction and operation are estimated to be about 0.92 fatalities for the combined involved worker and noninvolved worker population.

DOE estimated nonradiological occupational health and safety impacts in terms of exposure of workers to physical hazards and nonradioactive hazardous chemicals over the region of influence for the Mina corridor. These estimates were based on the estimated number of hours worked and occupational incident rates for total recordable cases, lost workday cases, and fatalities. DOE estimated radiological impacts to workers and the public for incident-free transportation, transportation accidents and severe transportation accidents.

DOE estimated the following fatalities:

- Less than one latent cancer fatality to workers and the public from radiological impacts for up to 50 years of railroad operations in the Mina rail corridor.
- Nonradiological fatality impacts to workers from industrial hazards from railroad construction and operation in the Mina rail corridor could be 0.92.
- During railroad construction in the Mina rail corridor, there could be four vehicular-related fatalities.

- During railroad operations in the Mina rail corridor, there could be 3.6 vehicular-related fatalities.
- During railroad construction and operations in the Mina corridor, there could be 1.3 rail-related fatalities.

2.4.7 SOCIOECONOMICS

The socioeconomic impacts analysis used a set of socioeconomic variables to provide a socioeconomic profile of conditions in the Mina rail corridor region of influence. Those variables considered changes to employment, population, economic measures, housing, and public services. The expected employment levels are a significant contributor to the analysis of socioeconomic impacts.

During the construction phase of the project, DOE estimated that the workforce employment levels for construction would range from about 340 to 2,100, depending on the length of the rail line, earthwork requirements, and phase of the project. Based on the identified levels of worker employment and the temporary nature of a linear construction project, the socioeconomic impacts to the local communities would be both short term and small.

During the operations phase of the project, DOE estimated that the workforce levels for operating and maintaining the railway would be much less than that estimated for the construction phase. There would be an estimated 42 workers involved in railroad operations. Given the relatively low number of employees necessary for railroad operations, the potential for socioeconomic impacts in the corridor are estimated to be small.

These socioeconomic for both the construction and the operations phase are generally considered positive because of jobs created, increased disposable income, increases in gross regional product, and increases in services to local citizens as a result of increased tax revenue to local and state governments.

2.4.8 NOISE AND VIBRATION

2.4.8.1 Noise

For the most part, the Mina rail corridor would pass through areas that are remote from human habitation. Thus, the potential impacts for noise from the construction of a rail line would be temporary. The distances from construction activities to the nearest receptors would be great; therefore, construction noise levels would be below the Federal Transit Administration noise guidelines.

DOE estimates that construction noise and construction- and operation-train noise would be audible to receptors in Silver Peak and Goldfield. There would be no adverse noise impacts associated with these receptors because they would not experience a 3 dBA increase <u>and</u> 65 DNL or greater noise levels. The purpose of the 3 dBA increase component of STB noise guidelines is to identify potential impact areas and areas where train noise would be particularly audible. However, because transportation noise sources are audible throughout the United States, the audibility of train noise itself does not constitute an adverse noise impact.

2.4.8.2 Vibration

Based on the proposed construction equipment and Federal Transit Administration vibration data, DOE estimated potential ground-borne vibration levels due to construction activity. The vibration levels are below Federal Transit Administration building vibration damage criteria (0.20 inch per second for fragile buildings, and 0.12 inch per second for extremely fragile historic buildings). Therefore, DOE would expect no damage to buildings due to vibration during construction. In addition, because of relatively low vibration levels and the temporary nature of construction, human annoyance due to construction vibration would be low.

DOE evaluated the potential impacts from vibration for construction and operations trains by using train-induced vibration levels as a function of distance from a rail line, along with vibration levels likely to result in building damage or annoyance, in combination with information on the location of residences or other buildings in relation to the rail line. Because vibration is a function of train speed, construction-train vibration would be lower than operations-train vibration. Freight trains operating at 80 kilometers (50 miles) per hour would produce an annoyance-based vibration contour extending approximately 24 meters (80 feet) from the tracks (DIRS 177297-Hanson, Towers, and Meister 2006, p. 10-3). There are no buildings within approximately 24 meters of the Mina rail corridor, so construction and operations trains would produce no adverse vibration impacts

2.4.9 AESTHETICS

The Mina rail corridor would pass primarily through Class III (the BLM designation that provides for the partial retention of the existing character of the landscape) and IV (the BLM designation that provides for management activities that require major modifications of the existing character of the landscape) areas. Railroad construction and operations in these areas would be consistent with the BLM management objectives for these areas. Therefore, DOE expects potential impacts to aesthetic resources would be small.

2.4.10 UTILITIES, ENERGY, AND MATERIALS

Potential impacts to utilities, energy and materials would be small. Construction and operations needs would place limited demands on utilities such as public water and waste water systems, telecommunications systems and electric power. Regional service providers can be expected to adjust to increasing needs. Needs for motor fuel during construction and operations activities would represent a very small fraction of Nevada's motor fuel consumption and not affect regional availability. Raw materials consumed during the construction phase such as concrete, steel, and rock are expected to be available from regional or national sources.

2.4.11 WASTE MANAGEMENT

DOE would store and use hazardous materials such as oil, gasoline, diesel fuel, and solvents during railroad construction and operations, primarily for the operation and maintenance of equipment and cleaning of equipment and facilities, and associated hazardous wastes would be generated. Ample disposal capacity for hazardous wastes is available in the western United States.

DOE would dispose of nonrecyclable or nonreusable waste in permitted landfills. During construction, it is likely that while some of the larger landfills would not see an appreciable change in the amount of waste received if they were utilized, some of the smaller landfills, if utilized, might see a substantial, although manageable, change in daily receipt of solid and industrial and special wastes. The estimated average daily disposal mass would be about 1.5 metric tons (1.7 tons).

During the railroad operations phase, the generation of wastes would be substantially less than during the construction phase.

2.4.12 ENVIRONMENTAL JUSTICE

Because there would be small changes in long-term population attributable to activities in the corridor, impacts or stresses to the housing stock, infrastructure systems, or social services would be unlikely. A portion of the Mina rail corridor would cross lands in Esmeralda County where most of the land is managed by the BLM or owned by the Department of Defense, resulting in a sparse population. As a consequence, there are no concentrations of low-income or minority populations in Esmeralda County that the construction or operation of a railroad in the Mina rail corridor would be likely to affect.

Likewise, a rail line in the corridor would be unlikely to affect low-income or majority populations in Lyon County.

Nye County has a minority population of approximately 13 percent with approximately 11 percent of the total population considered low income.

Impacts from rail line construction and operations in the Mina rail corridor would be small overall and would be unlikely to cause a disproportionately high and adverse effect on the low-income or minority populations along the corridor. There are no special pathways for minority populations.

3. AFFECTED ENVIRONMENT AND EVALUATION OF IMPACTS – MINA RAIL CORRIDOR

This chapter describes the affected environment along the Mina rail corridor and potential impacts to environmental resources from constructing and operating a railroad in the corridor. Section 3.1 describes the bases and methodology DOE used to perform the evaluation; Section 3.2 describes the affected environment for each resource area and potential impacts to those resources.

Glossary terms are shown in ***bold italics***.

3.1 Bases and Methodology

3.1.1 BASES FOR EVALUATION

To evaluate potential environmental ***impacts*** and determine if the Mina ***rail corridor*** warrants further study, the bases for corridor evaluation are the *Mina Rail Route Feasibility Study* (DIRS 180222-BSC 2006, all); baseline and affected environment information from federal, state, and local sources; public scoping comments; and design and engineering knowledge the U.S. Department of Energy (DOE or the Department) has derived from its analyses of the Caliente rail corridor at the alignment level (DIRS 180877-Nevada Rail Partners 2007, all). This Nevada Rail Corridor SEIS presentation of the Mina rail corridor analysis is commensurate in content and detail with the presentation of corridor-level information in the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Yucca Mountain FEIS; DIRS 155970-DOE 2002, Chapter 6). This chapter describes the environmental attributes of the Mina rail corridor and potential impacts from implementing the Proposed Action.

3.1.2 METHODOLOGY

For the Mina rail corridor analysis, DOE performed a rail corridor design study to provide engineering, construction, and operations feasibility information (DIRS 180877-Nevada Rail Partners 2007, all). The study used many of the same methods used to advance the Caliente rail corridor design, as described in Section 2.2.3. DOE established baseline environmental conditions for each resource area through the collection of federal, State of Nevada, and local data commensurate with the information in the Yucca Mountain FEIS for the Mina rail corridor. Using the established baseline and ***affected environment***, while considering the evolution of engineering and design changes, DOE evaluated the magnitude and range of potential ***impacts*** for the Mina rail corridor.

For each resource area in this Nevada Rail Corridor SEIS, DOE evaluated impacts within a specified ***region of influence***. Table 3-1 lists information on the region of influence for each resource area; DOE used these same regions of influence for the cumulative impacts analysis (see Chapter 4).

Table 3-1. Regions of influence for each resource area analyzed in this Nevada Rail Corridor SEIS.

Resource area	Region of influence[a]
Land use and ownership	Land use and ownership entirely or partially within the 400-meter-wide rail corridor. Includes land use and ownership outside the corridor that could incur cumulative impacts.
Air quality	The U.S. Environmental Protection Agency (EPA)-designated air basins through which the corridor would pass.
Hydrology	The 400-meter width of the corridor and a 1-kilometer-wide area along each side of the corridor. *Surface Water:* Areas near where construction would take place that would be susceptible to erosion, areas affected by permanent changes in flow, and areas downstream of construction that could be affected by eroded soil or potential spills of construction contaminants. *Groundwater:* Aquifers that would underlie areas of construction and operation and aquifers DOE could use to obtain water for construction and operations support.
Biological resources	Resources within the 400-meter-wide corridor and a 5-kilometer-wide area along each side of the corridor. Includes habitat (including wetlands and riparian areas), sensitive species, and migratory ranges of big game animals and wild horses and burros that a rail line could affect.
Cultural resources	Coverage within the 400-meter-wide corridor. This area includes the area of potential disturbances that could have indirect impacts on cultural resources.
Occupational and public health and safety	*Traffic impacts:* The 400-meter width of the corridor and public highways used by workers and for shipments during construction and operations. *Worker industrial safety impacts:* The 400-meter-wide rail corridor. *Incident-free radiological and nonradiological impacts:* The 800-meter area on either side of the centerline of the rail corridor. *Radiological impacts with respect to accidents:* An area within an 80-kilometer radius from a potential occurrence location in the rail corridor.
Socioeconomics	Counties in Nevada the rail line would cross (Churchill, Lyon, Mineral, Esmeralda, and Nye) and the two areas where most workers would live, Clark County and the Carson City/Washoe County area.
Noise and vibration	Inhabited commercial and residential areas where noise and vibration from rail line construction and operations could be a concern.
Aesthetic resources	The viewshed around the rail corridor.
Utilities, energy, and materials	The regional supply infrastructure that would support rail line construction and operations.
Waste management	Counties in Nevada that a potential rail line would cross and that have existing municipal sanitary waste landfills; disposal facilities for other types of wastes.
Environmental justice	Locations of minority, low-income, and Native American populations along the rail corridor; this includes the regions of influence listed above.

a. To convert meters to feet, multiply by 3.2808; to convert kilometers to miles, multiply by 0.62137.

3.2 Affected Environment and Potential Impacts – Mina Rail Corridor

3.2.1 LAND USE AND OWNERSHIP

In the Yucca Mountain FEIS, DOE determined that an evaluation of impacts to land use and ownership should identify the current ownership of the land that its activities could disturb, and the present and anticipated future uses of the land. The Department defined the region of influence for land use and ownership impacts as land areas that would be disturbed or the ownership or use of which would change as a result of constructing and operating a railroad. In the Yucca Mountain FEIS, DOE evaluated land use and ownership in the 400-meter (0.25-mile)-wide corridor. The Department chose this width to provide enough space for final alignment to route the rail line around sensitive land features or engineering obstacles. The Yucca Mountain FEIS anticipated actual construction and operation in the corridor would mostly require less than about 61 meters (200 feet) of the 400-meter width. DOE has since determined, based on the Department's conceptual engineering for the Caliente rail alignment, that actual construction in the corridor would likely require less than 300 meters (1,000 feet) of the 400-meter width (DIRS 180877-Nevada Rail Partners 2007, p. 2-10). However, for consistency with the Yucca Mountain FEIS analysis, this Nevada Rail Corridor SEIS analysis uses the 400-meter corridor width.

Based on these criteria, DOE evaluated the potential impacts to land use and ownership from proposed railroad construction and operations. The BLM administers more than 45,000 square kilometers (11 million acres) in Lyon, Mineral, Esmeralda, and Nye Counties. Traditional land uses in most of the Mina rail corridor region of influence that would be directly and indirectly affected include grazing, mining, energy development, general recreation, utility rights-of-way, and wildlife management. Much of this land is not extensively disturbed, although it has been modified through activity such as grazing and mining.

Some BLM-administered lands have special designations that identify their uses or why they have been set aside. These include Wildlife Habitat Management Areas, Areas of Critical Environmental Concern, Wilderness Areas, and Wilderness Study Areas. Public lands in the Mina rail corridor region of influence provide a number of diverse recreation opportunities, and the BLM has designated certain lands as Special Recreation Management Areas.

Figures 3-1 and 3-2 show land ownership along the Mina rail corridor and its options. Most of the land that would be used for construction and operation of rail road in the Mina rail corridor would be BLM-administered land in Lyon, Mineral, Esmeralda, and Nye Counties. The proposed Mina rail corridor would cross three BLM administrative areas: Carson City, Battle Mountain, and Las Vegas. Each BLM Field Office manages lands within its administrative boundaries according to one or more Management Framework Plan or Resource Management Plan. The Las Vegas, Tonopah, and Carson City plans would apply to the Mina rail corridor. In addition to BLM authority, the range of potentially affected land ownership and management authority includes private land holdings (including land designated for commercial development), DOE lands, U.S. Department of Defense lands, and American Indian trust lands and reservations.

To evaluate land use and ownership in the Mina rail corridor, DOE obtained data from the latest editions of BLM Master Title Plats and online land record databases, such as BLM LR2000 (DIRS 182772-MTS 2007, p. 21). The Department also evaluated county and state land records and information from other federal agencies, universities, or commercial developments.

In response to a DOE application for a public land order, the BLM has segregated specific lands encompassing the Mina rail corridor from surface and mineral for 2 years (until January 10, 2009), as described in the *Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada* (72 *Federal Register* [*FR*] 1235, January 10, 2007).

3.2.1.1 Land Use and Ownership Affected Environment

Approximately 1 to 2 percent (1.6 to 2.7 square kilometers [400 to 670 acres) of the land in the Mina rail corridor is privately owned, with another 5 to 12 percent (12.5 to 20.1 square kilometers [3,100 to 5,000 acres], depending on option) on the Walker River Paiute Reservation (see Figures 3-1 and 3-2). Of the remaining land, approximately 3 percent (5.3 square kilometers [1,300 acres) is DOE-managed land on the Nevada Test Site. Approximately 3 percent (4.7 square kilometers [1,200 acres) has been withdrawn to the U.S. Department of Defense for the Hawthorne Army Depot, through which the Mina rail corridor would pass. Most of the land in the Mina rail corridor, approximately 80 to 85 percent (132.1 to 133.9 square kilometers [32,900 to 34,000 acres]), depending on option, is BLM-administered public land. Specifically, the BLM Carson City Field Office manages the land containing portions of the three Schurz bypass options and the first half of Mina common corridor segment 1 in accordance with the *Carson City Field Office Consolidated Resource Management Plan* (DIRS 179560-BLM 2001, all). The remainder of the land encompassing the Schurz Bypass options is on the Walker River Paiute Reservation. South of the Reservation, the corridor would cross through land managed by the BLM Battle Mountain Field Office/Tonopah Field Station, with land use and management objectives governed by the *Tonopah Resource Management Plan and Record of Decision* (DIRS 173224-BLM 1997, all). The BLM Las Vegas Field Office manages the remaining land the corridor would cross from approximately Beatty Wash to Yucca Mountain in accordance with the *Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement* (DIRS 176043-BLM 1998, all).

Construction of a railroad in the Mina rail corridor would begin near Wabuska, Nevada. From there, on the Walker River Paiute Reservation, the corridor proceeds southeast toward the town of Schurz. The three Schurz bypass options would be primarily on the Walker River Paiute Reservation. Schurz bypass options 1 and 2 would leave the existing Department of Defense Branchline approximately 29 kilometers (18 miles) northwest of Schurz, continue east of the Weber Reservoir, and cross U.S. Highway 95 east of Schurz. The first 1.8 kilometers (1.1 miles) of Schurz bypass options 1 and 2 would cross BLM-administered land; the remaining portions would cross the Walker River Paiute Reservation. Schurz bypass options 1 and 2 would not cross any private allotments on the Reservation (DIRS 180222-BSC 2006, p. 16). Both bypass options cross the Black Mountain Grazing allotment (DIRS 182772-MTS 2007, p. 21).

Schurz bypass option 3 would be almost entirely on the Walker River Paiute Reservation. This option would come within 91 meters (300 feet) of a private allotment along the Walker River and, as it bypassed the town of Schurz, would be about 800 meters (0.5 mile) east of private allotments that are used for agriculture and contain no private residences (DIRS 180222-BSC 2006, p. 16). Schurz bypass option 3 would also cross the Parker Butte Grazing Allotment (DIRS 182772-MTS 2007, p. 22).

South of Schurz bypass options 1, 2, and 3, the Mina rail corridor would include common corridor segment 1, which would be approximately 150 kilometers (92 miles) long, with 34 kilometers (21 miles) on an existing Department of Defense-managed rail line. The remaining 110 kilometers (71 miles) of common corridor segment 1 would cross predominantly BLM-administered public lands.

Figure 3-1. Mina rail corridor land use (north).

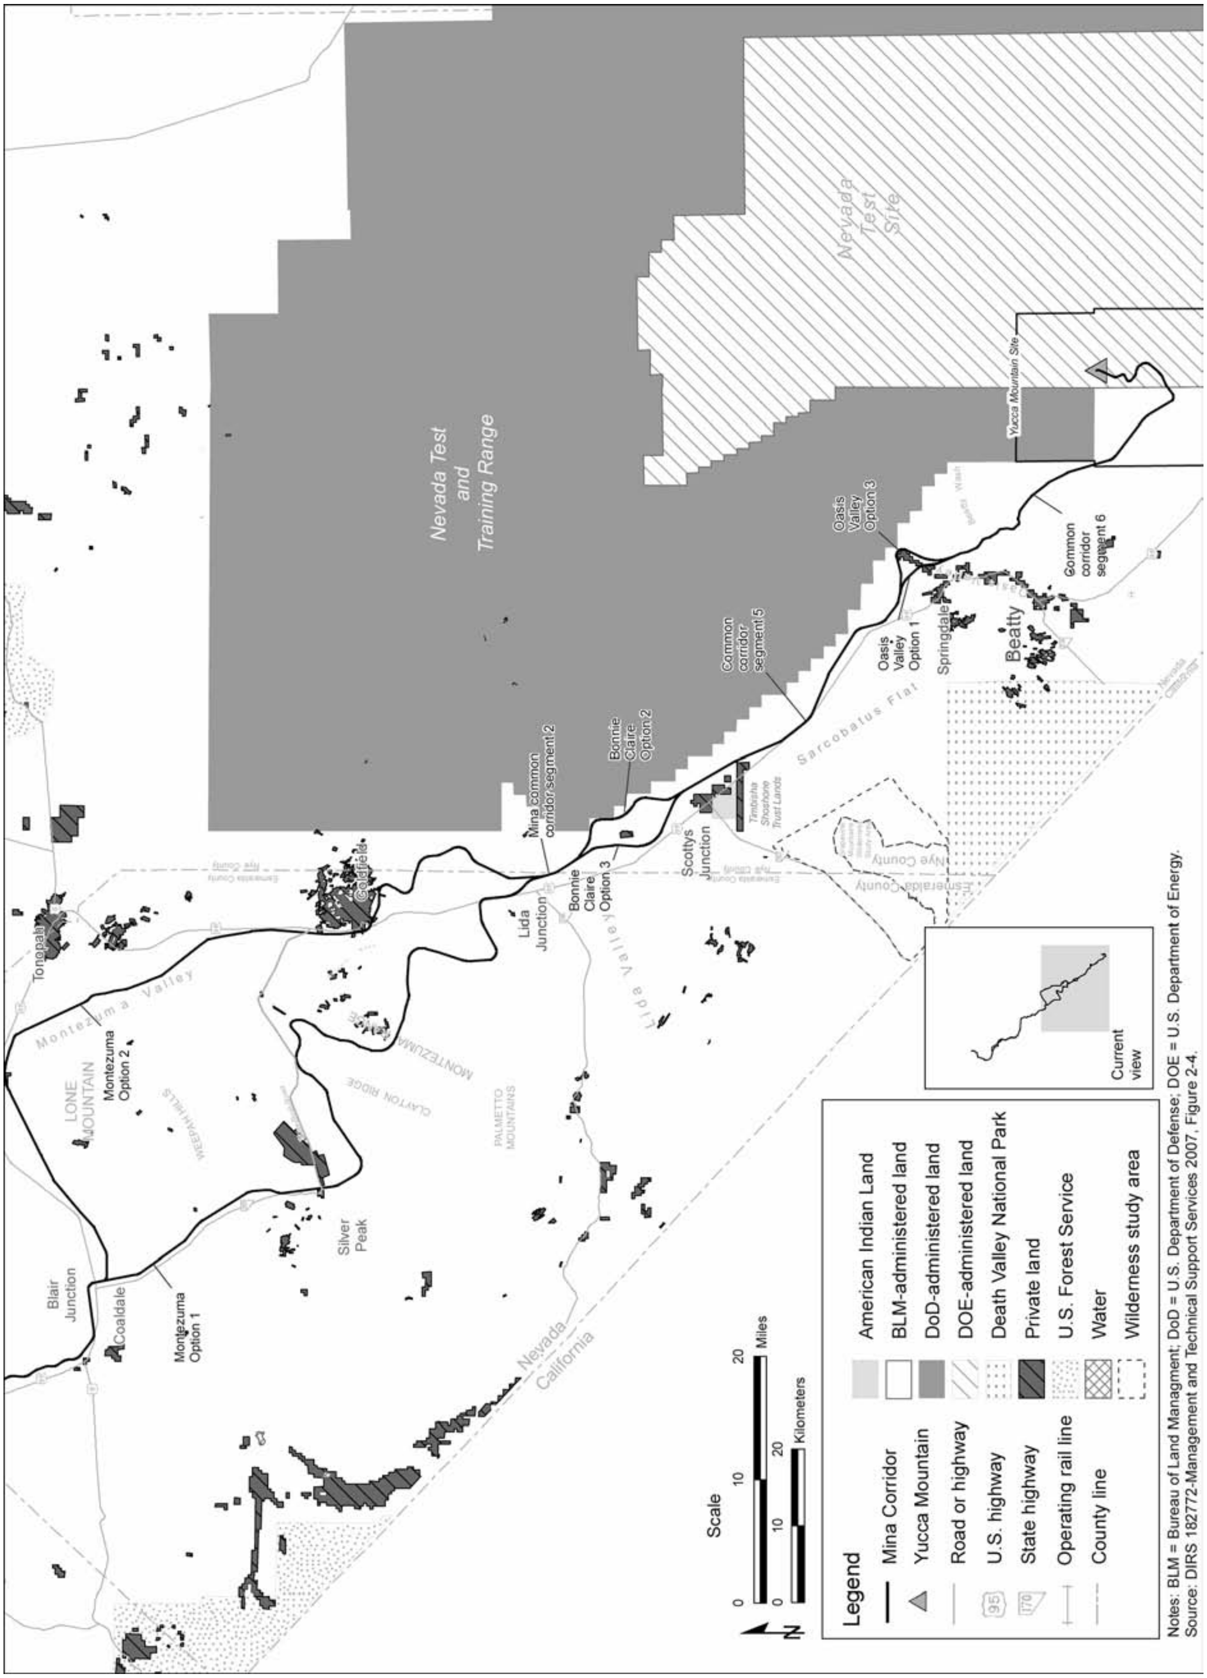

Figure 3-2. Mina rail corridor land use (south).

Due east of the Hawthorne Army Depot, common corridor segment 1 would cross approximately 3.2 kilometers (2 miles) of private property. As it traveled south, the center of the corridor would be within 150 meters (500 feet) of three other private land parcels and then pass just to the east of private property in Soda Springs Valley, southeast of Luning, and near Sodaville. It would pass through a mineral material site (an area in which the BLM has granted temporary rights to another party to obtain materials such as sand and gravel) at Redlich Pass. Common corridor segment 1 would cross a portion of a mineral material site at Coaldale and Blair Junction and then pass through another mineral material site. In addition, it would cross the Gillis Mountain, Garfield Flat, Pilot-Table Mountain, Bellville, Monte Cristo, and Silver Peak grazing allotments and an allotment the BLM Battle Mountain District/Tonopah Field Office has designated as the Columbia Salt Marsh. The corridor would also cross linear rights-of-way that include power transmission lines, telephones lines, State Route 361, U.S. Highway 95, water pipelines, and roads (DIRS 182772-MTS 2007, p. 22).

At this point, there are two options for the Mina rail corridor, Montezuma options 1 and 2, to bypass the Montezuma Range. From about 5.3 kilometers (3.3 miles) north to 5 kilometers (3 miles) south of Silver Peak, Montezuma option 1 would cross land the BLM has designated as suitable for disposal (sale). Montezuma option 1 would cross rights-of-way for power transmission lines, State Route 265, and access roads. Specifically, it would cross three mineral material sites at Goldfield Hills, touch one site at Lida Junction, and cross another at Scottys Junction. Montezuma option 1 would cross the Sheep Mountain, Silver Peak, Yellow Hills, Montezuma, and Magruder Mountain grazing allotments. It would also cross an allotment the BLM Battle Mountain District/Tonopah Field Office has designated as the Columbia Salt Marsh, and another listed as an unallocated allotment. The BLM administers most of the land along Montezuma option 1, except for one small piece of private property near Silver Peak (DIRS 182772-MTS 2007, p. 22).

Montezuma option 2 would tend to follow an abandoned rail line of the former Tonopah and Goldfield Railroad through Montezuma Valley, bypassing Tonopah on the west side and continuing through the town of Goldfield to the south until it connected to common corridor segment 2. As with Montezuma option 1, the BLM administers most of the land along Montezuma option 2; a small percentage of the land is privately owned. Montezuma option 2 would cross approximately 1.6 kilometers (1 mile) of a private allotment commonly called Millers. This property had been the location of a mill site for silver ore and a station on the former Tonopah and Goldfield Railroad; a portion of this property is of cultural significance (see Section 3.2.5). The BLM has designated lands to the east and west of this property as suitable for disposal. The corridor would cross more than 40 privately owned parcels of land near the town of Goldfield. Montezuma option 2 would cross rights-of-way for access roads, power transmission lines, and water pipelines. It would pass through two mineral material sites. Montezuma option 2 would also cross the Monte Cristo and Montezuma Grazing Allotments and an allotment the BLM Battle Mountain District/Tonopah Field Office has designated as the Columbia Salt Marsh (DIRS 182772-MTS 2007, p. 22).

Common corridor segment 2 would begin at the end of Montezuma option 1 or 2 at a point just east of Lida Junction. All of common corridor segment 2 would cross BLM-administered land and the Montezuma and Razorback Grazing Allotments (DIRS 182772-MTS 2007, p. 22).

The Mina rail corridor would continue south into Bonnie Claire options 2 and 3, common corridor segment 5, Oasis Valley options 1 and 3, and common corridor segment 6. Bonnie Claire options 2 and 3 would cross the Montezuma Grazing Allotment. Common corridor segment 5 would cross the Montezuma and Magruder Mountain Grazing Allotments. Oasis Valley options 1 and 3 would cross private property the Razorback Grazing Allotment. Common corridor segment 6 would cross the Montezuma and Razorback Grazing Allotments and a grazing allotment in Crater Flat west of Yucca Mountain the BLM has designated as unused (DIRS 182772-MTS 2007, p. 24).

DOE queried information for ***unpatented mining claims*** from the BLM LR2000 database (DIRS 182772-MTS 2007, p. 24) using the legal description for the Mina rail corridor (meridian, township, range, and section) and plotted locations of unpatented mining claims by sections (Figures 3-3 and 3-4). Of these, most of the unpatented mining claims are within the Goldfield area of the Mina rail corridor.

The Mina rail corridor and its options would not cross any Wilderness Areas or Wilderness Study Areas, Special Recreation Management Areas, or Areas of Critical Environmental Concern. It would cross areas used by the public for dispersed recreation, such as off-highway vehicle use and hunting.

3.2.1.2 Potential Impacts to Land Use and Ownership

The predominant land-use and ownership conflicts associated with the Mina rail corridor would involve private land holdings, the Walker River Paiute Reservation, the Hawthorne Army Depot, the Nevada Test Site, land the BLM has proposed as suitable for disposal, unpatented mining claims, rights-of-way, and grazing allotments.

Construction of a railroad in the Mina rail corridor would disturb approximately 37 to 41 square kilometers (9,000 to 10,000 acres) of land, depending on option. The Mina rail corridor would cross up to 15 separate grazing allotments. The approximate disturbance area associated with the proposed Mina rail corridor would constitute less than 1 percent of the land within those 15 grazing allotments. Within this regional perspective of nearby existing and reasonably foreseeable land uses and land ownership, the commitment of land for the proposed Mina rail corridor would constitute a minor proportion of overall land commitment. Impacts to private land could be approximately 1.6 to 2.7 square kilometers (400 to 670 acres), depending on option. This land consists of primarily agricultural and mineral uses and contains no private residences.

The Mina rail corridor would cross public lands managed by the BLM Carson City Field Office, the Battle Mountain/Tonopah offices, and the Las Vegas Field Office. Each has a resource management plan that establishes goals and objectives for the management of resources, which include public land uses and designations (DIRS 179560-BLM 2001, all; DIRS 173224-BLM 1997, all; DIRS 176043-BLM-1998, all). The Mina rail corridor would not cross or affect any Wilderness Areas, Wilderness Study Areas, or areas of Critical Environmental Concern. The Mina rail corridor would be consistent with the goals and policies of the resource management plans in the BLM-administered areas through which it passes.

As described in Section 3.2.1.1, a rail line in the Mina rail corridor would cross private lands. If in locating the final rail alignment DOE could not avoid private lands, the Department would need to acquire access to them to construct and operate the railroad. If private property was divided by the rail line, access to the property could be disrupted.

The rail corridor would cross land on the Walker River Paiute Reservation. Construction and operation of a railroad on this land would require an agreement between DOE, the Bureau of Indian Affairs, and the Walker River Paiute Tribe. Prior to construction, DOE would be required to obtain both the permission to survey for a right-of-way and a right-of-way grant in accordance with 25 CFR Part 169, "Rights-of-Way Over Indian Lands." These regulations state that "Rights-of-way for railroads shall not exceed 15 meters (50 feet) in width on each side of the centerline of the road, except where there are heavy cuts and fills, when they shall not exceed 30 meters (100 feet) in width on each side of the road."

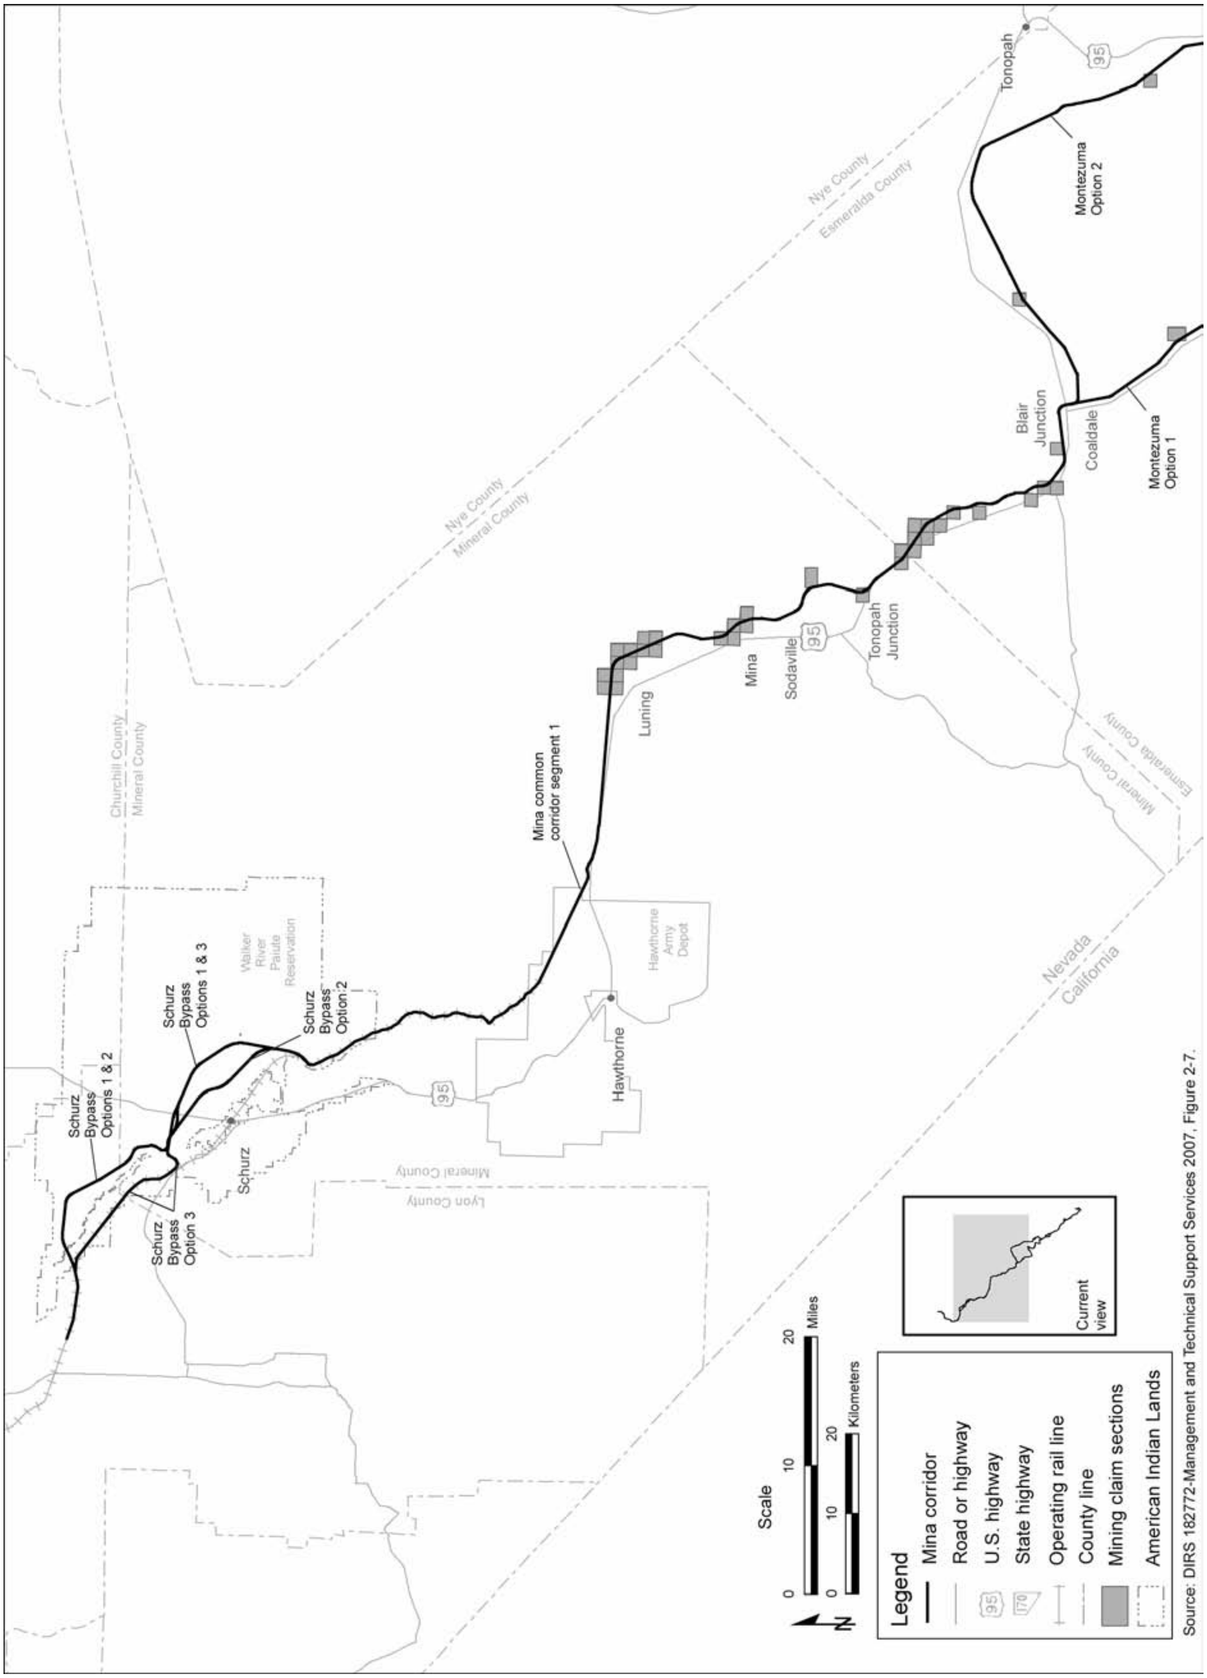

Figure 3-3. Sections containing unpatented mining claims within the Mina rail corridor (north).

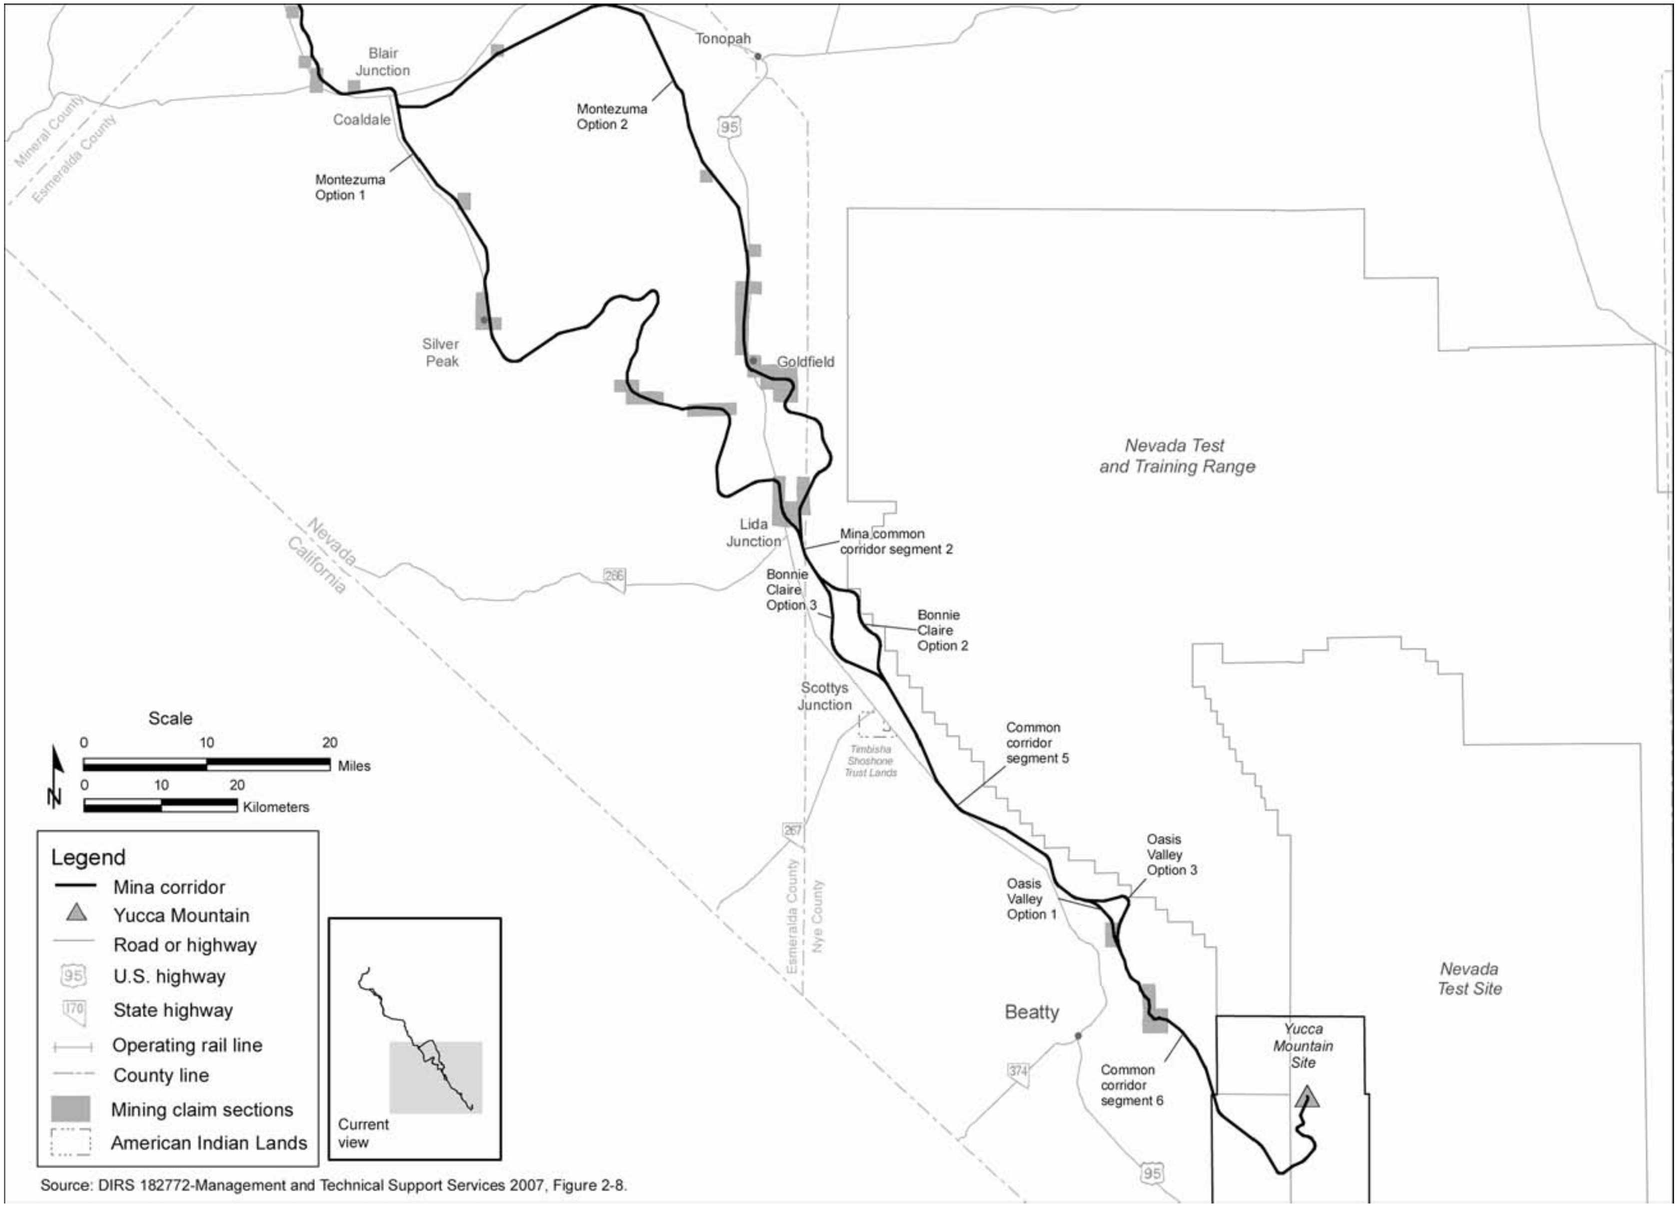

Figure 3-4. Sections containing unpatented mining claims within the Mina rail corridor (south).

The Mina rail corridor would not cross any privately held lands on the Reservation. Schurz option 3 would be within 91 meters (300 feet) of a private allotment. This and other privately held lands near Schurz option 3 are used for agriculture; there are no private residences on this land.

A portion of the Mina rail corridor, approximately 13 kilometers (8 miles) long, would cross through the Hawthorne Army Depot. To construct and operate a railroad through this area would require an agreement between DOE, the U.S. Department of Defense, and the U.S. Army Corps of Engineers for the use of the land and the existing rail line.

Approximately 27 kilometers (17 miles) of common corridor segment 6 would be within the boundaries of the Nevada Test Site, which DOE manages. Rail line construction with this area would require land use authorization from the DOE Nevada Site Office and the BLM.

BLM would require DOE to obtain a ***right-of-way grant*** to construct and operate a railroad on public land. DOE anticipates the right-of-way would have a nominal width of approximately 300 meters (1,000 feet) during construction, which is more than the 61-meter (200-feet)-wide corridor discussed in the Yucca Mountain FEIS, and within the 400-meter (0.25 mile)-wide corridor analyzed in this Nevada Rail Corridor SEIS. The Department would adjust the width of the construction right-of-way where practicable to avoid or minimize land-use conflicts and restrictions. Construction and operation of the railroad in the Mina rail corridor through existing rights-of-way would require an evaluation of the impact to the road or utility or use of the right-of-way with both the right-of-way holder and the BLM. DOE would protect existing utility rights-of-way from damage so that disruption to utility service or damage to lines would be, at most, small and temporary. The land needed to operate the railroad would be generally less than the land needed during construction. Therefore, DOE would reclaim the land no longer needed in accordance with standards set forth by the BLM as a condition of the right-of-way grant.

There could be impacts to mining activities such as mine operations or exploration if access roads were temporarily blocked or altered, making development of a claim less profitable. The Mina rail corridor ***region of influence*** contains a variety of mineral resources, with mining claims filed in accordance with BLM requirements, and several operating mines. Establishment of mining claims on federal land does not necessarily ever lead to actual development of mining operations on those sites. The implementation of several mining engineering practices in these areas could allow access to mining claims without affecting the claimant or the rail line, depending on the exact locations of the claims and access needs.

BLM has designated public land for disposal to allow for community expansion. While this designation provides the opportunity for disposal, it does not require it. Because disposal is a discretionary action, the BLM could choose not to dispose of these parcels if other priorities arose.

Grazing operations are a major BLM land-management program in the Mina rail corridor region of influence. Rail line construction would result in loss of forage. Because the corridor intersects grazing allotments, a rail line could create a barrier to livestock movement. Livestock could have difficulty accessing water if there was a deep cut or a high fill associated with the rail line. Ranching operations and livestock rotations could be disrupted. Livestock could be lost due to collisions with vehicles along roads used during the construction and operations phases, and possibly by collisions with trains during the operations phase.

A rail line in the Mina rail corridor could impact access to land the public uses for recreation, requiring individuals to alter their access routes. Recreational events, such as off-highway vehicle racing, on courses that cross the area of the Mina rail corridor would need to be rerouted. Alterations in access to land used by hunters, hikers, and others could affect recreational experiences.

During the operations phase, train and track inspection and maintenance activities would be confined to areas disturbed during the construction phase. Therefore, there would be no additional disturbances to land use and ownership.

3.2.2 AIR QUALITY

This section provides information on the existing air quality status in areas through which the Mina rail corridor would pass: Lyon, Mineral, Esmeralda, and Nye Counties, a small portion of Churchill County, and the Walker River Paiute Reservation. It also provides background information on the general climate in the area.

The air quality region of influence includes the Environmental Protection Agency-designated air basins through which the corridor would pass.

The Mina rail corridor air quality evaluation used the same qualitative methods described in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Appendix G). DOE evaluated the route for identified ***nonattainment*** or maintenance areas, and identified ***criteria pollutants*** potentially generated by construction or operations activities. Because the Department did not identify any nonattainment or maintenance areas, no detailed estimates of emission rates or comparisons to threshold levels for conformity were made.

3.2.2.1 Air Quality Affected Environment

The Mina rail corridor would pass through rural parts of Nevada that are either ***in attainment*** or unclassifiable under U.S. Environmental Protection Agency criteria pollutant standards. If there are not enough air quality data to determine the status of a remote or sparsely populated area, then the Environmental Protection Agency lists the area as unclassifiable. The agency considers unclassifiable areas as any area that cannot be classified on the basis of available information as meeting or not meeting the ***national ambient air quality standard*** for the pollutant. Unclassifiable areas are treated as attainment areas under the Clean Air Act and its implementing regulations. Most rural areas of the United States are either in attainment or unclassifiable for all pollutants. Table 3-2 lists federal standards for criteria pollutants.

Monthly climate summaries for Beatty and Goldfield (DIRS 182772-MTS 2007, p. 27) indicate that the southern portions of the Mina rail corridor have the highest annual precipitation, with annual averages of about 16 centimeters (6.5 inches). The northern portions of the corridor through Mina, Hawthorne, Schurz, and Wabuska have less precipitation, about 11 to 13 centimeters (4.5 to 5 inches) annually. Goldfield, at an elevation of about 1,700 meters (5,700 feet) has the highest average annual snowfall, 38 centimeters (15 inches). Average annual snowfall for most of the rest of the corridor is 10 to 13 centimeters (4 to 5 inches). The southernmost portions of the corridor have even less snowfall. Average annual temperatures vary mainly by elevation, highest at the lower elevations such as Beatty at 1,000 meters (3,300 feet) and lowest at higher elevations such as Tonopah and Goldfield at 1,600 and 1,700 meters (5,400 and 5,700 feet), respectively (DIRS 182772-MTS 2007, p. 27).

3.2.2.2 Potential Air Quality Impacts

Pollutants from construction equipment emissions would include ***carbon monoxide***, ***nitrogen dioxide***, ***sulfur dioxide***, and ***particulate matter*** with aerodynamic diameters equal to or less than 10 micrometers (***PM_{10}***) and equal to or less than 2.5 micrometers (***$PM_{2.5}$***).

Table 3-2. Federal standards for criteria pollutants.

Pollutant	Averaging time	National Ambient Air Quality Standards[a] Primary[b]	Secondary[c]
Ozone (O_3)[d]	1-hour	0.12 parts per million (ppm) (235 micrograms per cubic meter [μg/m^3])	Same as primary standard
	8-hour	0.08 ppm	
Carbon monoxide (CO)	8-hour	9.0 ppm (10 μg/m^3)	None
	1-hour	35 ppm (40 μg/m^3)	
Nitrogen dioxide (NO_2)	Annual average	0.053 ppm (100 μg/m^3)	Same as primary standard
	1-hour	-	
Sulfur dioxide (SO_2)	Annual average	80 μg/m^3 (0.03 ppm)	-
	24-hour	365 μg/m^3 (0.14 ppm)	-
	3-hour	-	1,300 μg/m^3 (0.5 ppm)
	1-hour	-	-
Suspended particulate matter (PM_{10})	24-hour	150 μg/m^3	Same as primary standard
	Annual arithmetic mean	50 μg/m^3	
Fine particulate matter ($PM_{2.5}$)[d]	24-hour	35 μg/m^3	Same as primary standard
	Annual arithmetic mean	15 μg/m^3	
Lead (Pb)	30-day average	-	-
	Calendar quarter	1.5 μg/m^3	Same as primary standard

a. National Ambient Air Quality Standards (other than O_3, particulate matter, and those based on annual averages or annual arithmetic mean) are not to be exceeded more than once a year. The O_3 standard is attained when the fourth highest 8-hour concentration in a year, averaged over 3 years, is equal to or less than the standard. For PM_{10}, the 24-hour standard is attained when 99 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. For $PM_{2.5}$, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. Contact the EPA for further clarification and current federal policies.

b. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health.

c. National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

d. The Environmental Protection Agency revised the level of the 24-hour $PM_{2.5}$ standard to 35 micrograms per cubic meter (μg/m^3) and retained the level of the annual $PM_{2.5}$ standard at 15.μg/m^3 (71 *FR* 61144, October 17, 2006).

Construction activities such as surface disturbance and use of haul trucks in the Mina rail corridor region of influence would emit PM_{10} and $PM_{2.5}$ in the form of ***fugitive dust***. Fugitive dust is a type of nonpoint source air pollution (small airborne particles that do not originate from a specific point). There could be short-term increases in concentrations of these air quality criteria pollutants as construction progressed along the corridor. The plumes associated with fugitive dust generation are often localized to the area being disturbed and are temporary. In ***arid*** areas such as the Mina corridor region of influence, generation and control of fugitive dust will always be a concern. DOE would implement mitigation measures to minimize emissions, reduce dust concentrations during construction activities, and meet current air quality standards for these pollutants. Thus, impacts would be small.

During railroad operations, potential impacts to air quality would result from diesel locomotives, which would emit carbon monoxide, nitrogen dioxide, sulfur dioxide, PM_{10}, and $PM_{2.5}$. Fugitive dust emissions would be greatly reduced during railroad operations as excavation would cease and equipment traffic would be limited to maintenance vehicles.

3.2.3 Hydrology

This section describes surface-water and groundwater resources, and impacts to those resources. The hydrology region of influence includes surface-water and groundwater resources within the 400-meter (0.25-mile)-wide corridor and within a 1-kilometer (0.6-mile) region of influence along each side of the corridor. The region of influence for surface water includes areas near construction activities, areas that would be affected by permanent changes in surface-water flow, and areas downstream of construction. The region of influence for groundwater includes hydrographic regions.

The Yucca Mountain FEIS analyzed surface water resources within the 400-meter (0.25-mile)-wide corridor and within 1 kilometer (0.6 mile) along each side of the corridor, and springs within 5 kilometers (3 miles) along each side of the corridor. The attributes used to assess surface water were the potential for introduction and movement of contaminants, potential for changes to runoff and infiltration rates, alterations in natural drainage, and potential for flooding or dredging and filling actions to aggravate or worsen any of these conditions.

The Yucca Mountain FEIS analysis also addressed the potential for a change in infiltration rates that could affect groundwater, the potential for introduction of contaminants, the availability of water for use for construction, the potential for changing flow patterns, and the potential that such use would affect other users.

DOE obtained information from (1) the National Hydrography Dataset Waterbody geospatial data that the U.S. Geological Survey developed in cooperation with Environmental Protection Agency; (2) the Geographic Names Information System Nevada geospatial database developed by the U.S. Geological Survey and the BLM; and (3) the National Wetlands Inventory database managed by the U.S. Fish and Wildlife Service (DIRS 182772-MTS 2007, p. 30).

3.2.3.1 Hydrology Affected Environment

3.2.3.1.1 Surface Water

The analysis of surface-water resources discusses proximity of the Mina rail corridor to ***playas***, seeps, springs, ***floodplains***, ***wetlands***, and ***perennial*** surface waters and is commensurate with the analyses in the Yucca Mountain FEIS. The National Wetlands Inventory identifies surface-water resources such as wetlands or lakes along the Mina rail corridor and its options. For clarification, most lakes identified for the Mina rail corridor are actually playas and are referred to as such in this section. In general, a playa forms in semiarid and ***arid*** environments when surface-water runoff temporarily fills a depression on the surface of the ground with water, creating a lake; playas are seasonal. Wetlands typically occur where surface water collects or groundwater discharges, which makes the area wet for extended periods.

The National Wetlands Inventory indicates that the only perennial surface water the Mina rail corridor and its options would cross is the Walker River. Schurz bypass options 1 or 2 would cross the Walker River just north of the Weber Reservoir, and Schurz bypass option 3 would cross it just south of the Weber Reservoir.

Table 3-3 summarizes surface-water resources within the region of influence and their proximity to the Mina rail corridor. This table also lists the location of a riparian area in relation to the corridor, further discussed in Section 3.2.4.

Table 3-3. Surface-water resources along the Mina rail corridor[a] (page 1 of 3).

Mina rail corridor option/common corridor segment	Distance from corridor	Feature[b]
Schurz bypass 1	Would be within/cross	Perennial stream/riparian area; corridor would cross the Walker River north of the Weber Reservoir.
Schurz bypass 1	Would be within/cross	Wetlands; corridor would cross and be adjacent to freshwater emergent wetland areas, where it would cross the Walker River.
Schurz bypasses 1 and 2	0.5 kilometer to 1 kilometer	Perennial lake/pond; corridor would be adjacent to Weber Reservoir.
Schurz bypass 3	Would be within/cross	Perennial stream; corridor would cross Walker River just north of the town of Schurz.
Schurz bypass 3	4 kilometers	Spring; Paiute Spring, and one unnamed spring, 3 kilometers west of U.S. Highway 95, 10 kilometers from the town of Schurz.
Schurz bypasses 1 and 3	Would be within/cross	Playas; corridor would cross five unnamed playas and be adjacent to several other unnamed playas in an unnamed valley, just south of the Calico Hills, approximately 8 kilometers east of Schurz.
Schurz bypasses 1 and 2	Would be within/cross	Playas; corridor would cross two unnamed playas, approximately 4.5 kilometers east of Schurz.
Schurz bypasses 1 and 3	1.2 to 1.3 kilometers	Springs; Double Springs and an unnamed spring, 10 kilometers east of the town of Schurz on the Walker River Paiute Reservation.
Schurz bypass 1	0.1 to 1 kilometer	Playas; playas, freshwater emergent wetland areas, and freshwater forested/shrub wetland areas adjacent to the corridor as all options come together joining with the existing Union Pacific Railroad Hazen Branchline. These areas are north of Walker Lake, adjacent to U.S. Highway 95, 7 kilometers from the town of Schurz.
Schurz bypass 1	2.6 to 4. 3 kilometers	Spring; three unnamed spring/seeps just north of Walker River, adjacent to U.S. Highway 95.

Table 3-3. Surface-water resources along the Mina rail corridor[a] (page 2 of 3).

Mina rail corridor option/common corridor segment	Distance from corridor	Feature[b]
Common corridor segment 1	Would be within/cross	Playas; corridor would cross two unnamed playas about 14 kilometers east of the town of Hawthorne.
Common corridor segment 1	Would be within/cross	Playas; corridor would cross large playas at the foot of the Garfield Hills along U.S. Highway 95, 20 kilometers outside of Hawthorne.
Common corridor segment 1	0.5 kilometer	Playa; corridor would be adjacent to a playa in Soda Springs Valley, along U.S. Highway 95, about 23 kilometers outside of Hawthorne.
Common corridor segment 1	1 kilometer	Playa; corridor would be adjacent to a large playa in Alkali Flat, just south of the town of Luning.
Common corridor segment 1	Crosses/encroaches	Playa; corridor would encroach and cross a large playa in the town of Mina.
Common corridor segment 1	3.5 kilometers	Spring; Southern Pacific Spring, 5 kilometers east of the town of Mina.
Common corridor segment 1	2.1 to 2.3 kilometers	Springs; Soda Springs, including two unnamed springs, just north of the town of Sodaville, along U.S. Highway 95.
Common corridor segment 1	2.6 kilometers	Springs; Martin Spring and an unnamed spring, 6 kilometers east from the town of Sodaville.
Common corridor segment 1	4.4 to 4.6 kilometers	Springs; three unnamed springs at the base of the Pilot Mountains, east of Sodaville.
Common corridor segment 1	3.2 to 4.9 kilometers	Springs; three unnamed springs within the Rhodes Salt Marsh, approximately 3 kilometers along U.S. Highway 95.
Common corridor segment 1	0.2 kilometer	Spring; corridor would encroach an unnamed spring 2 kilometers north of Coaldale.
Montezuma 2	Would be within/cross	Playa; corridor would cross two large playas and one small playa approximately 13 kilometers east of Blair Junction along U.S. Highway 95.
Montezuma 2	Would be within/cross	Small playas; corridor would cross and be adjacent to several small playas, approximately 18 to 20 kilometers from Blair Junction.
Montezuma 2	Would be within/cross	Playas; corridor would cross three small playas, totaling 0.0041 square kilometer, 10 kilometers southwest of Tonopah.

Table 3-3. Surface-water resources along the Mina rail corridor[a] (page 3 of 3).

Mina rail corridor option/common corridor segment	Distance from corridor	Feature[b]
Montezuma 2	1 kilometer	Playa; Millers Pond, a small playa, is adjacent to the corridor along U.S. Highway 95, approximately 5 kilometers from Millers.
Montezuma 2	1.9 to 2 kilometers	Springs; West Spring and three unnamed springs, 3 kilometers northwest of the town of Goldfield.
Montezuma 2	3.8 kilometers	Springs; Sulphur Spring and two unnamed springs, 4 kilometers west of Goldfield.
Montezuma 2	0.9 kilometer	Spring; Slaughterhouse Spring, 1.5 kilometers west of the town of Goldfield.
Montezuma 2	Would be within/cross	Spring; Rabbit Spring and one unnamed spring, within the outskirts of the town of Goldfield.
Montezuma 2	0.4 kilometer	Playa; large playa adjacent to corridor in Stonewall Flat, 3 kilometers northeast of Lida Junction.
Montezuma 1	0.5 kilometer	Spring; Hot Springs adjacent to the corridor in the town of Silver Peak.
Montezuma 1	0.9 kilometer	Spring; Silver Peak Spring adjacent to the corridor in the town of Silver Peak.
Montezuma 1	0.2 to 10 kilometers	Pond; evaporative pond east of the corridor just outside of Silver Peak, associated with local mining operations.
Montezuma 1	Would be within/cross	Pond; corridor would cross mine tailing pond in the town of Silver Peak.
Montezuma 1	4.6 to 4.7 kilometers	Spring; two springs (Twin Springs) 15 kilometers northeast of the town of Silver Peak.
Montezuma 1	3.1 to 3.6 kilometers	Spring; two unnamed springs near the top of Montezuma Peak, in the Montezuma Range.
Bonnie Claire 3	Would be within/cross	Playa; corridor would cross a large playa along U.S. Highway 95, 6 kilometers south of Lida Junction.
Oasis Valley 1	0.4 to 4.5 kilometers	Springs; More than 40 springs in the area of Oasis Valley between Springdale and Beatty along U.S. Highway 95.
Oasis Valley 3	0.2 kilometer	Pond; perennial pond, Colson Pond, is adjacent to the corridor in Oasis Valley, 7 kilometers from Springdale.
Oasis Valley 3	Would be within/cross	Spring; Warm Springs located adjacent to Colson Pond, within the corridor in Oasis Valley, 7 kilometers from Springdale.

b. To convert kilometers to miles, multiply by 0.62137, to convert square kilometers to acres, multiply by 247.10.

In addition to the surface-water resources identified in Table 3-3, the following floodplains occur within the region of influence of the Mina rail corridor:

<u>Montezuma option 1</u>

- Floodplain from Jackson Wash and Jackson Wash tributaries
- Alkali Lake Playa floodplain (not mapped by the Federal Emergency Management Agency)

<u>Montezuma option 2</u>

- Floodplain between Stonewall Mountains and Cuprite Hills and is associated with Stonewall Flat

<u>Bonnie Claire 3</u>

- Floodplains extending up tributaries of the Lida Valley Alkali Flat Playa and up the Stonewall Pass wash from the Bonnie Claire Flat area of Sarcobatus Flat

<u>Common corridor segment 5</u>

- Floodplain of the Amargosa River within Thirsty Canyon

<u>Oasis Valley option 1</u>

- Floodplain of the Amargosa River within Thirsty Canyon

<u>Oasis Valley option 3</u>

- Beatty Wash floodplain extending from the Amargosa River floodplain

<u>Common corridor segment 6</u>

- Busted Butte Wash draining east side of Yucca Mountain to Fortymile Wash (rail line would cross wash and tributaries)
- Drill Hole Wash draining east side of Yucca Mountain to Fortymile Wash (wash and tributary crossed)
- Midway Valley Wash draining east side of Yucca Mountain to Drill Hole Wash, then to Fortymile Wash

3.2.3.1.2 Groundwater

The State of Nevada is divided into hydrographic regions (groundwater basins) and subbasins (hydrographic areas).

The Mina rail corridor and its options would cross three hydrographic regions: Death Valley Basin (Region 14), Central (Region 10), and Walker River (Region 9). Figure 3-5 shows these hydrographic regions and their hydrographic areas. *Water Resources Assessment—Mina Rail Corridor* (DIRS 180887-Converse Consultants 2007, all) contains a quantitative overview of existing groundwater appropriations for each basin in the corridor and includes details on the status, type of use, and approximate quantity of water currently used in each basin.

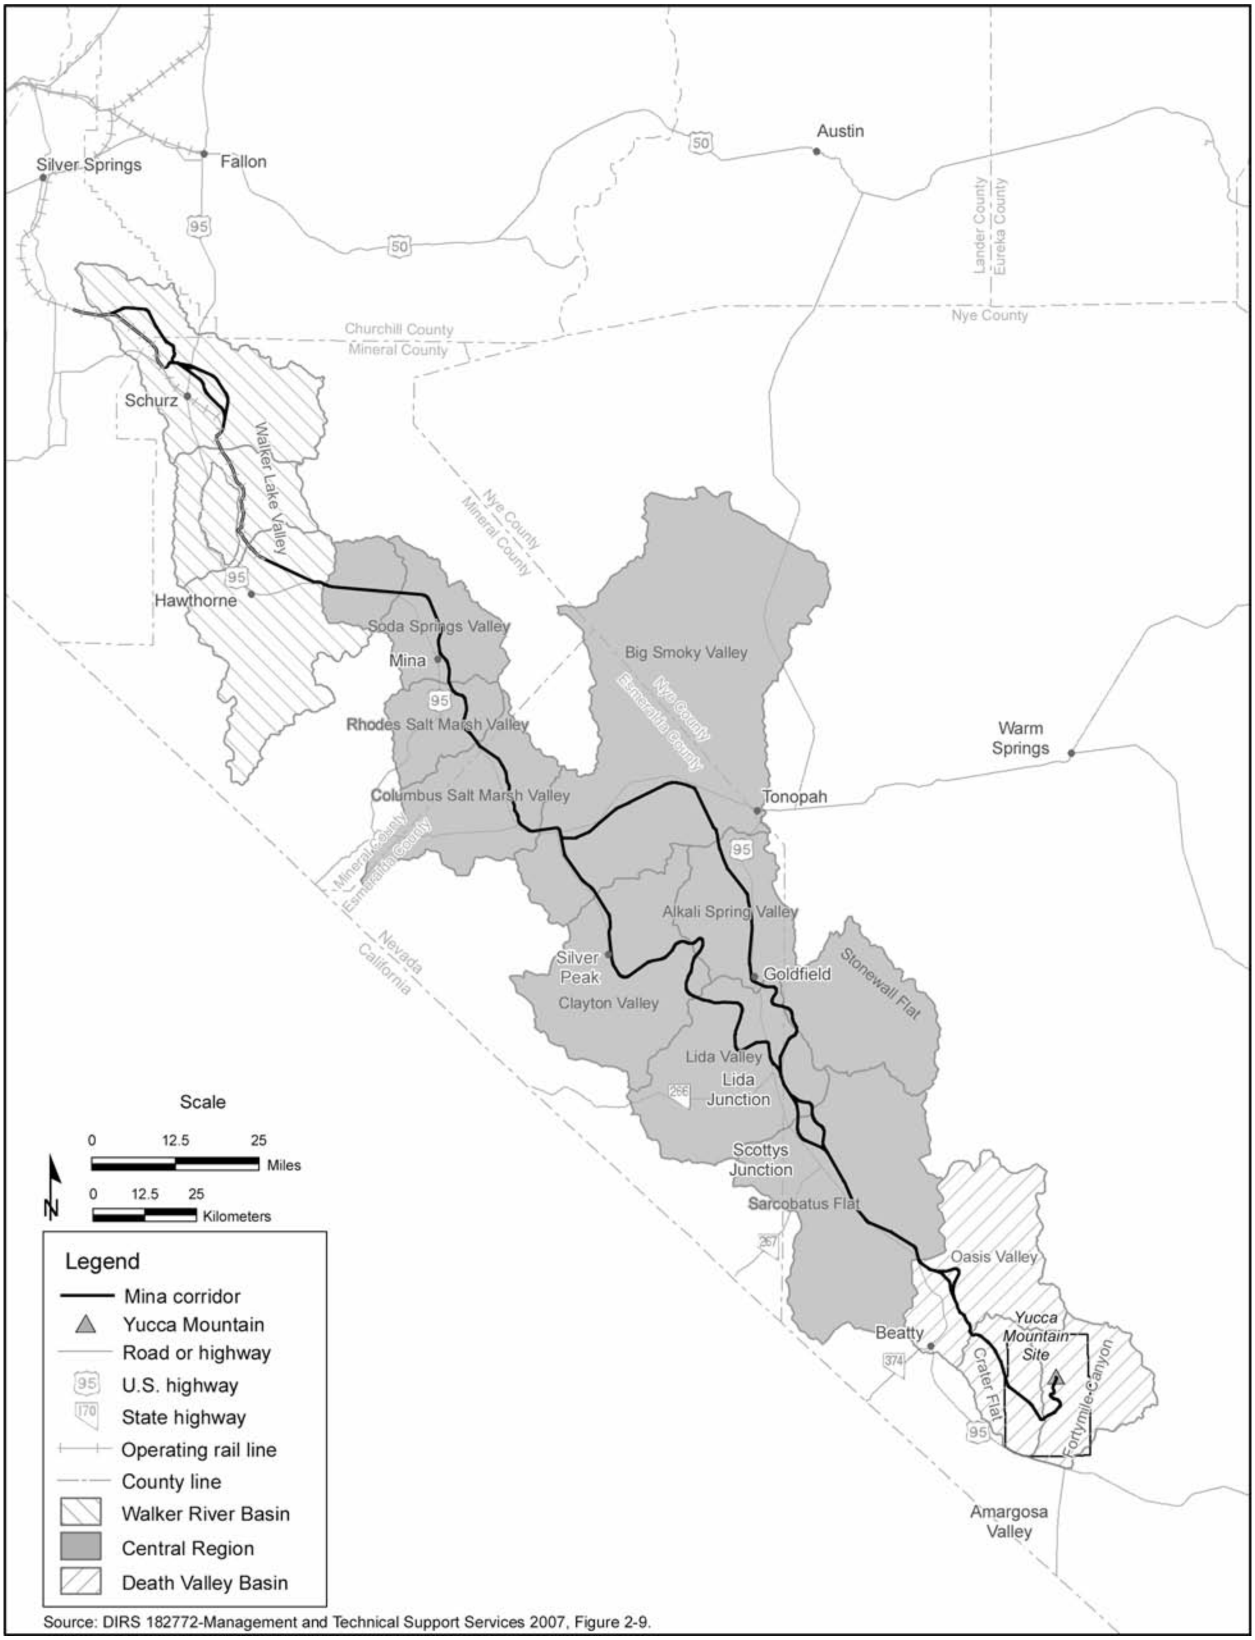

Figure 3-5. Hydrographic regions and areas associated with the Mina rail corridor.

3.2.3.2 Potential Impacts to Hydrology

3.2.3.2.1 Surface Water

Construction in previously undeveloped areas often results in changes to natural drainage. Construction could include regrading that would allow runoff from a number of minor drainage channels to collect in a single ***culvert*** or pass under a single bridge, which would result in water flowing from a single location on the downstream side rather than across a broader area. This would cause some localized changes in drainage patterns, but this probably would occur only in areas where natural drainage channels are small. Compaction of soil during construction could reduce water infiltration rates and change natural runoff and drainage patterns. However, some activities would disturb and loosen the ground for some time, which could cause higher infiltration rates. DOE would adhere to engineering design standards. Therefore, impacts associated with the alteration of drainage patterns or changes to erosion and sedimentation rates or locations would be small and localized.

Rail line construction could affect floodplains, either through direct alteration of the stream-channel cross section that would affect the flow pattern of the stream, or through indirect changes in the amount of impervious surfaces and additional water volume added to the floodplain.

Construction impacts associated with these floodplains would be similar to other identified drainage areas (the alteration of natural drainage patterns and possible changes in erosion and sedimentation rates or locations). Construction in washes or other flood-prone areas could reduce the area through which floodwaters would naturally flow, which could cause water levels to rise at the upstream side of crossings. Sedimentation would be likely to occur on the upstream side of crossings in areas where the flow of water was restricted enough to cause ponding. DOE would manage sedimentation of this type under a regular maintenance program (DIRS 155970-DOE 2002, p. 6-79). Therefore, impacts to floodplains from construction of the rail line that result in restrictions in flow and sedimentation would be small.

The Mina rail corridor is in a region where flash flooding is a primary concern. Although such flooding can be violent and hazardous, it is generally limited in its extent and duration, limiting the potential for impacts associated with the corridor; that is, any damage would be expected to be confined to a small portion of the corridor.

Construction of a bridge over the Walker River could have a temporary impact on the quality and flow of the river. Bridge construction would occur during periods of low flow, and DOE would implement erosion-control measures to ensure that these temporary impacts would be small. Bridge construction also could cause the temporary disturbance of freshwater emergent wetlands adjacent to the Walker River.

Installation of culverts or bridges at crossings of ephemeral streams along the corridor could alter drainage patterns and change erosion and sedimentation rates. These impacts would be confined to the area immediately around the crossing and would be small because DOE would comply with appropriate standards to design stream crossings to allow for the flow of flood waters and would implement erosion-control measures during construction of those crossings. For the same reasons, alteration of drainages would be unlikely to increase future flood damage, increase the impacts of floods on human health and safety, or cause harm to the natural and beneficial values of floodplains.

Some streams, adjacent wetlands, and ephemeral washes within the interstate Walker River and Death Valley hydrographic regions (see Figure 3-5) could be regulated under Section 404 of the Clean Water Act. The Department would meet the requirements of the Act prior to constructing crossings of any regulated streams, wetlands, or washes, including conducting an evaluation of alternative crossing locations and designs that would minimize impacts to wetlands and other waters. Impacts to regulated drainages would be the same as those described above.

The Mina corridor would cross three springs: Rabbit Springs and Warm Springs, and an unnamed spring. All three are in the Mina rail corridor. DOE would adjust the rail alignment in the corridor to avoid conducting surface-disturbing activities that may impact these springs.

Construction-related impacts could involve the possible release and spread of contaminants by precipitation or intermittent runoff events or, for options near surface water, possible release to the surface water, and the need for dredging or filling of ephemeral waters. Construction-related materials that could cause contamination would consist of petroleum products (fuels and lubricants) and coolants (antifreeze) necessary to support equipment operations.

Railroad operations in the Mina rail corridor would have little impact on surface waters beyond the alterations to drainage during rail line construction. Access roads and the rail roadbed would have runoff rates different from those of the natural terrain but, given the relatively small size of the potentially affected areas in a single drainage system, there would be little impact on overall runoff quantities.

Rail line maintenance would require periodic inspections of flood-prone areas (particularly after flood events) to verify the condition of the track and drainage structures. When necessary, sediment accumulating in these areas would be removed and disposed of appropriately. Similarly, eroded areas encroaching on the rail roadbed would be repaired.

3.2.3.2.2 Groundwater

Rail line construction would require water for soil compaction, dust control, and workforce use. The water DOE would use during the construction phase would come primarily from hydrographic basins. If the hydrographic basin is designated, this means that the permitted groundwater rights approach or exceed the estimated ***perennial yield***, water resources are being depleted or require additional administration, and the State Engineer has declared preferred uses of the water. Table 3-4 lists the designation status of the hydrographic basins and the percentage of the Mina rail corridor that would be in the respective basin. Approximately 39 percent of the total Mina rail corridor would be in designated basins.

DOE evaluated the water demand for rail line construction on the basis of earthwork needs and water needed for compaction. Earthwork needs would include excavation of common soil (alluvial material), ripable rock, and drill and blast (solid bedrock). Based on these considerations, total water demand for the Mina rail corridor would be approximately 7.32 million cubic meters (5,950 acre-feet) (DIRS 180877-BSC 2007, p. 2-7).

DOE estimates that the number of wells required to support construction of a rail line in the Mina rail corridor ranges from 86 to 108 wells at 60 to 77 sites, depending on corridor option. Of these, some locations might have two wells where production is anticipated to be low. Consistent with the groundwater resources analysis in the Yucca Mountain FEIS, DOE also assumed a 1-year period for construction activities in the vicinity of each well. The pumping of groundwater from multiple wells for rail line construction could cause a temporary decrease in groundwater resources resulting from the increased demand. Groundwater withdrawal could temporarily decrease the amount of water available for underflow to a downgradient basin or spring discharge. The Nevada State Engineer would need to approve water production from any well DOE proposed to install to support rail line construction. To grant approval, the State Engineer would have to determine that the short-term demand would not cause adverse impacts for other uses and users of the groundwater resource.

Table 3-4. Hydrographic basins the Mina rail corridor would cross.[a,b,c]

Hydrographic basin (and subbasin where applicable)	Length (kilometers)	Percent of total	Designated
Alkali Spring Valley	8	1.9	No
Big Smoky Valley/Tonopah Flat	24	5.8	Yes
Clayton Valley	53	12.8	No
Columbia Salt Marsh Valley	30	7.2	No
Crater Flat	29	7.0	No
Fortymile Canyon/Jackass Flats	14	3.4	No
Lida Valley	51	12.4	No
Oasis Valley	23	5.7	Yes
Rhodes Salt Marsh Valley	17	4.2	No
Sarcobatus Flat	48	11.7	Yes
Soda Springs Valley/Eastern Part	29	7.2	Yes
Soda Springs Valley/Western Part	18	4.5	Yes
Walker Lake Valley/Schurz Subarea	51	12.5	No
Walker Lake Valley/Whiskey Flat-Hawthorne Subarea	15	3.7	Yes

a. Source: DIRS 182772-MTS 2007, pp. 34 and 35.
b. To calculate water demand for each basin, multiply 5,600 acre-feet by the percentage of total.
c. Mina rail corridor basis of analysis consists of Schurz bypass option 1, common corridor segment 1, Montezuma option 1, common corridor segment 2, Bonnie Claire option 3, common corridor segment 5, Oasis Valley option 1, and common corridor segment 6.

Potential impacts to groundwater during the construction phase could include changes to infiltration rates, and new sources of contamination that could migrate to groundwater. Potential impacts would be spread over a large geographic area, so they would be small and temporary for a resource in a single area. Section 3.2.3.2.1 discussion of impacts to surface water describes potential contaminants that rail line construction could release. These contaminants would be the same for groundwater.

Construction activities would disturb and loosen the ground, which could produce greater infiltration rates. However, this situation would be short-lived because the access road and rail roadbed materials would become compacted and less porous. In either case, localized changes in infiltration would cause no noticeable change in the amount of recharge in the area.

If DOE obtained water from a source other than a newly installed well, such as importing water from another source, water would be obtained only from appropriated sources. That is, the water would be from allocations that the Nevada State Engineer had previously determined did not adversely affect groundwater resources.

Railroad operations would have little effect on groundwater resources. Water needs along the corridor would be greatly reduced and limited to water needed for maintenance and to support a greatly reduced work force. Possible changes to recharge, if any, would be the same as those at the completion of construction of the construction phase.

3.2.4 BIOLOGICAL RESOURCES AND SOILS

This section describes biological resources along the Mina rail corridor. Consistent with the Yucca Mountain FEIS, DOE considered the potential for impacts to vegetation communities; special status species (plants and animals), including their habitat; springs, wetlands, and riparian areas; big game habitat; and wild horse and burro ***herd management areas*** that could occur within the 400-meter (0.25-mile)-wide corridor. The analysis considered special status species and big game habitat within 5 kilometers (3 miles) of the corridor that could be affected by rail line construction. DOE also analyzed springs and riparian areas that could be affected by permanent changes in surface-water flows (see Table 3-3). Finally, DOE characterized soils, including soils that could support prime farmland, within the 400-meter-wide corridor (DIRS 182772-MTS 2007, p. 37).

DOE obtained location records for special status species from a statewide database managed by the Natural Heritage Program (DIRS 182772-MTS 2007, p. 37) that contains records of incidental observations of rare or protected plants, fish, and wildlife species. Other information sources included (1) the *Carson City Field Office Consolidated Resource Management Plan* (DIRS 179560-BLM 2001, all); (2) the *Tonopah Resource Management Plan and Record of Decision* (DIRS 173224-BLM 1997, all); (3) the *Biological Field Findings Report for Potential Rail Alignments along the Mina Route* (DIRS 182760-URS Corporation/Potomac-Hudson Engineering 2006, all); and (4) the *Mina Rail Route Feasibility Study* (DIRS 180222-BSC 2006, all). Additionally, DOE obtained location information from the National Hydrography Dataset Waterbody geospatial data that the U.S. Geological Survey developed in cooperation with the U.S. Environmental Protection Agency, the Geographic Names Information System Nevada geospatial database, and BLM Wild Horse and Burro Management Area Maps (DIRS 182772-MTS 2007, p. 37).

DOE obtained information from (1) the National Hydrography Dataset Waterbody geospatial data that the U.S. Geological Survey developed in cooperation with Environmental Protection Agency (2) the Geographic Names Information System Nevada geospatial database developed by the U.S. Geological Survey and the BLM and (3) the National Wetlands Inventory database managed by the U.S. Fish and Wildlife Service (DIRS 182772-MTS 2007, p. 37).

DOE used soil survey databases from the U.S. Department of Agriculture, Natural Resources Conservation Service (DIRS 176781-USDA 2006, all), to identify soil types and characteristics along the Mina rail corridor.

3.2.4.1 Biological Resources and Soils Affected Environment

3.2.4.1.1 Biological Resources

The following vegetation communities occur along the Mina rail corridor (DIRS 155970-DOE 2002, p. 3-70; DIRS 182760-URS Corporation/Potomac-Hudson Engineering 2006, all):

- Stabilized dunes, vegetated dunes, and sandy soils occur in isolated areas, primarily along the northern portions of the corridor, and riparian vegetation occurs along the Walker River.
- Mixed salt desert scrub occurs at low elevations in flat valley bottoms or salt flats along the northern portions of the corridor to about the Montezuma Valley.
- The semi-desert shrub steppe community is found along portions of Montezuma option 2 west of Tonopah.
- Mojave mid-elevation mixed salt desert scrub occurs at the southern ends of Montezuma options 1 and 2 and inter-mountain sagebrush steppe occurs as Montezuma 1 crossed the Montezuma Mountain Range.
- Creosote-bursage, blackbrush, hopsage, and Mojave mixed scrub occur along the southern portions of the corridor from about common corridor segment 2 to Yucca Mountain.

The corridor and its options would cross habitat for two species classified as threatened under the Endangered Species Act: the desert tortoise (*Gopherus agasizii*) and Lahontan cutthroat trout (*Oncorhynchus clarkii henshawi*). The desert tortoise also is classified as threatened by Nevada (Nevada Administrative Code 503.080). About 50 kilometers (30 miles) of the southern portion of the corridor from Beatty Wash to Yucca Mountain is habitat for desert tortoises. However, the abundance of desert tortoises along this portion of the corridor is low to very low (DIRS 103281-Karl 1981, pp. 76 to 92; DIRS 101914-Rautenstrauch and O'Farrell 1998, pp. 407 to 411). The corridor would cross potential habitat for the Lahontan cutthroat trout at the Walker River north or south of Weber Reservoir. The Lahontan cutthroat trout occurs in Walker Lake and in the Walker River upstream to the Weber Reservoir during spawning. The upstream spawning migration of trout is blocked by the Weber Reservoir dam, although the Bureau of Indian Affairs might build a fish ladder around that dam that will enable Lahontan cutthroat trout to migrate upstream of the dam. There are no areas classified as critical habitat for these threatened species within or near the corridor.

The Railroad Valley springfish (*Crenychthis nevadae*), which is federally and state (Nevada Administrative Code 503.065) classified as threatened, and the Sodaville milkvetch (*Atragalus lentiginousus Douglas var. sesquimetralis*), a species classified as critically endangered by Nevada (Nevada Administrative Code 527.010), occur in or near Soda Spring at Sodaville. This spring is about 2.1 kilometers (1.3 miles) from the Mina rail corridor (DIRS 180222-BSC 2006, p. 22). The federally and state-listed (Nevada Administrative Code 503.050) endangered Southwestern willow flycatcher (*Empidonax traillii extimus)* has been observed about 4.3 kilometers (2.7 miles) from the corridor north of Beatty along U.S. Highway 95 (DIRS 182772-MTS 2007, p. 38).

No plant species classified as sensitive by the BLM in Nevada have been found within the 400-meter (0.25-mile)-wide corridor. However, the following four BLM sensitive plant species have been observed within 5 kilometers (3 miles) of the corridor (DIRS 182772-MTS 2007, p. 38; DIRS 182760-URS Corporation/Potomac-Hudson Engineering 2006, all).

- Oryctes (*Oryctes nevadensis*) occurs about 5 kilometers (3 miles) from the southern portion of the Schurz bypass options, 2.6 kilometers (1.6 miles) from the start of common corridor segment 1, and about 0.64 kilometer (0.4 mile) from Mina common corridor segment 1 north of the town of Mina.
- Eastwood milkweed (*Asclepias eastwoodiana*) has been found about 4 kilometers (2.5 miles) east of Montezuma option 1 north the town of Silver Peak and west of Weepah Hills.
- Nevada dune beardtongue (*Penstemon arenarius*) has been found about 0.64 kilometer (0.4 mile) west of common corridor segment 6 in Sarcobatus Flats.
- Two populations of the black woollypod (*Astragalus funereus)* have been documented 0.1 and 0.48 kilometer (0.06 and 0.3 mile) outside the corridor just south of Beatty Wash.

The Oasis Valley pyrg or springsnail (*Pyrgulopsis micrococcus*), a BLM-designated sensitive species, has been observed in springs from about 1.8 to more than 5 kilometers (1.1 to 3 miles) west of Oasis Valley option 1 and common corridor segment 6 north of Beatty (DIRS 182772-MTS 2007, p. 38).

The state-protected Amargosa toad (*Bufo nelsoni*) (Nevada Administrative Code 503.075) occurs in numerous springs in Oasis Valley from 1.1 to more than 5 kilometers (0.7 to 3 miles) west of Oasis Valley option 1. The Oasis Valley speckled dace (*Rhinichthys osculus* ssp.), which also is state protected (Nevada Administrative Code 503.065), occurs more than 2.6 kilometers (1.6 miles) from Oasis Valley option 1 in the same areas.

Portions of common corridor segment 6 cross habitat for the chuckwalla (*Sauromalus ater*), a lizard classified as sensitive by the BLM in Nevada.

The Mina rail corridor would cross habitat for numerous birds classified as sensitive by the BLM in Nevada, including the western burrowing owl (*Athenes cunicularia*), peregrine falcon (*Falco peregrinus*), loggerhead shrike (*Lanius ludovicianus*), sage thrasher (*Oreoscotes montanus*), phainopepla (*Phainopepla nitens*), and Brewer's sparrow (*Spizella breweri*). Golden eagles (*Aquila chrysaetos*) are found throughout the corridor and bald eagles (*Haliaeetus leucocephalus*) winter along portions of the Walker River on the Walker River Paiute Reservation. These two species are protected under the Bald and Golden Eagle Protection Act. In addition, all migratory birds found along the corridor are protected under the Migratory Bird Treaty Act.

A documented occurrence of the fringed myotis (*Myotis thysanodes*), a BLM-designated sensitive species and state-protected bat (Nevada Administrative Code 503.030), took place on the west edge of Jackass Flats about 5 kilometers (3 miles) from the corridor (DIRS 182772-MTS 2007, p. 38). Other BLM-designated sensitive bats that may occur along the Mina rail corridor include the Townsend's big-eared bat (*Corynorhinus townsendii*); the spotted bat (*Euderma maculatum),* a Nevada threatened species; the California myotis (*Myotis californicus*); the western small-footed bat (*Myotis ciliolabrum*); the western pipistrelle (*Pipistrellus hesperus*); and the state-protected pallid bat (*Antrozous pallidus*) (DIRS 182772-MTS 2007, p. 39). The corridor may cross habitat for other mammals classified as sensitive by the BLM in Nevada, including the pygmy rabbit (*Brachylagus idahoensis*), and the dark kangaroo mouse (*Microdipidops megacephalus albiventer*).

From Hawthorne to Redlich Pass, common corridor segment 1 would pass near areas designated by the BLM as desert bighorn sheep (*Ovis Canadensis nelsoni*) yearlong habitat, and common corridor segment 2 would pass near yearlong bighorn sheep habitat north of Lone Mountain. Mina common corridor segment 6 would cross a bighorn sheep movement corridor in the Beatty Wash area. Portions of Mina common corridor segment 1 from Thorne to Blair Junction would be within 5 kilometers (3 miles) of BLM-designated yearlong habitat for pronghorn antelope (*Antilocapra americana*) and mule deer (*Odocoileus hemionus*). Montezuma option 2 would cross yearlong pronghorn antelope habitat in Montezuma Valley. Montezuma option 1 would cross yearlong mule deer habitat near the town of Silver Peak and in the Montezuma Range, and Oasis Valley option 3 would cross seasonal mule deer habitat. Mountain lions (*Felis concolor*), which are also classified as a game species in Nevada, are found throughout southern and central Nevada (DIRS 176043-BLM 1998, all, DIRS 173224-BLM 1997, all, DIRS 179560-BLM 2001, all).

The Mina rail corridor would cross four wild horse and burro management areas: Montezuma Peak, Goldfield, Stonewall, and Bullfrog. The corridor would pass within 5 kilometers (3 miles) of the Garfield Flat, Silver Peak, and Pilot Mountain (or Dunlap) Herd Management Areas (DIRS 182772-MTS 2007, p. 39).

The only riparian area the Mina rail corridor would cross would be along the Walker River (see Table 3-3). There are freshwater emergent wetlands and riparian habitat at both locations being considered for crossing that river. Section 3.2.3.1.1 describes playas and associated potential wetlands within and near the corridor.

Springs within the 400-meter (0.25-mile)-wide corridor are Rabbit Spring and one unnamed spring, which are on the upstream edge of Montezuma corridor option 2 near the town of Goldfield. Table 3-3 lists surface-water resources in the Mina rail corridor. Additional warm springs located adjacent to Colson Pond in the Oasis Valley would be within the 400-meter-wide corridor.

3.2.4.1.2 Soils

The Farmland Protection Policy Act requires Federal agencies to take into account the adverse effects of their programs on the preservation of farmlands, including the conversion of ***prime farmland***. DOE used the soil survey databases (DIRS 176781-USDA 2006, all) to locate soils along the corridor that are classified as supporting prime farmland. Less than 1 percent of the Mina rail corridor contains soils classified as prime farmland. Those soils are on the Walker River Paiute Reservation.

A number of soil types occur throughout the Mina rail corridor. The soil types in the vicinity of the corridor can be classified in more general terms as sandy soils or dune areas, which are characteristically alkaline, salty, and basic, containing calcium carbonate, and light-colored soils. These soils also include rocky outcrops; talus slopes; and granitic and gravelly areas (DIRS 182760-URS Corporation/Potomac-Hudson Engineering 2006, p. 31, Table 1). The Schurz bypass options would pass through areas of primarily sandy soils and between Hawthorne and Blair Junction, the corridor would contain mostly areas of alluvial soils. Montezuma option 1 would pass through areas of fine-grained soils at the playa in Clayton Valley, and Montezuma option 2 would pass through areas consisting of primarily sandy soils. The remainder of the corridor, south of Lida Junction, would pass through areas of alluvial and rocky soils (DIRS 180222-BSC 2006, p. 27, Table 3.2-1).

Other soil characteristics that are particularly relevant to the proposed rail corridor are ***erodes easily*** and ***blowing soil***. Soil with either of these characteristics can be quite susceptible to erosion. The erodes easily characteristic is a measure of the susceptibility of bare soil to be detached and moved by water. These soils, which tend to contain relatively high amounts of silts and ***loams***, tend to erode easily when disturbed. Approximately 19 percent of the Mina rail corridor has soils with this characteristic (DIRS 176781-USDA 2006, all). The blowing soil characteristic is based on the soil survey classification of susceptibility of a given soil to wind erosion. The blowing soil characteristic identifies areas where fine-textured, sandy materials predominate and where uncontrolled soil disturbance could result in increased wind erosion. Depending on options, between 23 and 26 percent of the Mina rail corridor would have soils with the blowing soil characteristic (DIRS 176781-USDA 2006, all).

3.2.4.2 Potential Impacts to Biological Resources and Soils

Rail line construction in the Mina rail corridor would involve clearing of vegetation, excavation, and filling for subgrade within the 400-meter (0.25-mile)-wide corridor. Maximum land disturbance within this area is approximately 37 to 41 square kilometers (9,000 to 10,000 acres).

With the exception of riparian areas, none of the vegetation communities in the Mina corridor (described in Section 3.2.4.1) are unique or rare in the region. A bridge over the riparian area along the Walker River would minimize disturbance to that vegetation community. The total land area disturbed within all community types would be small compared to the existing area of Nevada that supports those communities.

Clearing vegetation and disturbing the soil could create habitat for colonization by ***noxious weeds*** and ***invasive species*** in the Mina corridor. This could result in an increase in the abundance of such plants corridor, which in turn could lead to suppression of native species and increased fuel loads for wildfires. Reclamation of disturbed areas would enhance the recovery of native vegetation and reduce colonization by noxious weeds and invasive species.

There is desert tortoise habitat for about 50 kilometers (30 miles) along the southern end of the Mina rail corridor. Rail line construction would result in the permanent loss of desert tortoise habitat within the corridor. In addition, these construction activities could cause mortality of individual desert tortoises; however, desert tortoises are not abundant in this area and the likelihood of encountering tortoises would be low. Therefore, losses would be few. Relocating tortoises encountered along the route prior to construction would minimize losses of individuals. The presence of the rail line could interfere with the normal movements of individual tortoises. DOE would consult with the U.S. Fish and Wildlife Service (under Section 7 of the Endangered Species Act) regarding this species and would comply with all terms and conditions imposed by the U.S. Fish and Wildlife Service.

The Lahontan cutthroat trout, a federally listed species, occurs in the Walker River downstream of the Weber Dam during spawning and could occur upstream of that dam in the future if a fish ladder is constructed. Construction of a bridge across the Walker River could increase turbidity and sedimentation, which would temporarily degrade the quality of water. However, the bridge would be constructed during periods of low flow, when the species would be rare or absent from the river, so impacts would be small. The bridge would not affect the ability of trout to migrate up the river.

The only other federally listed species near the corridor are the southwestern willow flycatcher and the Railroad Valley springfish. There is no habitat for these species in the corridor and they would not be affected.

One population of the Sodaville milkvetch, a state-protected plant species, occurs near springs that are about 2.1 kilometers (1.3 miles) from the corridor and would not be affected. There are no known populations of BLM-designated sensitive plant species within the 400-meter (0.25-mile) corridor that could be directly or indirectly affected by land-clearing activities and rail line construction. There are populations of four BLM-designated sensitive plant species that have been documented within 5 kilometers (3 miles). DOE anticipates that corridor activities would not extend to these areas and that construction activities would not affect these populations.

Two state-protected species, the Amargosa toad and the Oasis Valley speckled dace, and one BLM-protected species, the Oasis Valley pyrg or spring snail, occur in springs outside the corridor, but within 5 kilometers (3 miles) in and near Oasis Valley. DOE anticipates that corridor activities would not extend to these areas and that construction activities would not affect these populations.

Rail line construction could impact BLM-designated sensitive birds and other migratory birds through loss of suitable nesting and foraging habitat, and birds avoiding areas where there were construction activities. Rail line construction could also impact BLM-designated sensitive bat and other mammal species through loss of suitable habitat, and avoidance of areas where there were construction activities. The area of permanent loss of habitat would be small compared to available habitat in the region.

The Mina rail corridor would cross habitat for bighorn sheep, pronghorn antelope, mule deer, and mountain lions. It also would cross wild horse and burro herd management areas. Construction activities would reduce some habitat in these areas and have the potential to disrupt movement patterns of wild horses, burros, and game species. These animals would probably avoid contact with humans at construction locations and would temporarily move to other areas during the construction phase.

Construction of the Schurz bypass options would cause impacts to wetlands and riparian habitat during construction of a bridge over the Walker River. The affected wetland and riparian areas would be small compared to the total area of these community types in the corridor. Construction of the bridge could also cause temporary increases in sedimentation, but would not alter the natural flow or stream channel of the Walker River. Prior to initiating construction activities, DOE would consult with the U.S. Army Corps of Engineers to determine if a Section 404 permit under the Clean Water Act would be required.

The Mina rail corridor would cross three springs (see Table 3-3): Rabbit Springs and Warm Springs, and an unnamed spring. All three are in the Mina corridor. DOE would adjust the rail alignment to avoid conducting surface-disturbing activities that could affect these springs.

Impacts to soils during the construction phase would be primarily due to land disturbance. Less than 1 percent of soils in the Mina rail corridor are classified as prime farmland. These are located along the

Schurz bypass options on the Walker River Paiute Reservation. Soils throughout the corridor probably would be subject to an increase in erosion potential during the construction phase. DOE would implement dust-suppression and other measures to reduce this potential. As construction proceeded, the rail roadbed would be covered with ballast rock, which would virtually halt erosion from that area. As construction ended, disturbed areas (other than the rail roadbed and access roads) would slowly recover. Other permanent erosion-control systems would be installed as appropriate. Introduction of contaminants into the soil would also be a potential concern. Proper control of hazardous materials during construction and prompt response to spills or releases would, however, reduce this concern. Impacts to soils would be limited to disturbed areas and would be temporary and small.

Railroad operations would not lead to additional habitat losses, although maintenance activities would prevent habitat recovery in the narrow band occupied by the rail line and access roads. There could be loss of habitat due to inadvertent fires along the right-of-way from rolling-equipment operations and maintenance activities. Although passing trains probably would cause mortality of individuals of some species, losses would be unlikely to affect regional populations because all species are widespread geographically.

Passing trains could disrupt wildlife, including game animals, horses, and burros, but such effects would be transitory. Noise from a train probably would disturb animals close to the track throughout the operations phase, but this disturbance would diminish with distance from the track and over time as animals acclimated to daily disturbances from passing trains. The frequency of trains using the corridor (an average of 17 one-way trains per week) indicates that disturbance of animals near the rail line would probably be minimal. Noise from the trains could cause animals to move away from the tracks and, possibly, cause changes in migratory patterns.

Impacts to soils during the operations phase would be small because train movement would not disturb soils, and maintenance of the railbed and rails would involve minimal disturbance beyond that which had occurred during the construction phase.

3.2.5 CULTURAL RESOURCES

Cultural resources include any historic and archaeological sites, buildings, structures, landscapes, or objects resulting from or modified by human activity and can include mining, ranching, and linear features such as roads and trails. Cultural resources designated as historic properties warrant consideration with regard to potential adverse impacts resulting from proposed federal actions.

The region of influence for cultural resources is the 400-meter (0.25-mile)-wide corridor. This area includes the area of potential disturbances that could have indirect impacts on cultural resources. DOE conducted an archeological site file search using records from the Desert Research Institute, the Nevada Cultural Resources Information System, and archeological information repositories at the Harry Reid Center at the University of Nevada-Las Vegas, and the Nevada State Museum in Carson City.

3.2.5.1 Cultural Resources Affected Environment

In 2007, DOE conducted a records search for the Mina rail corridor for a width of 400 meters (0.25 mile) and identified several cultural resources sites along the Schurz bypass options, some of which are eligible or potentially eligible for listing on the *National Register of Historic Places*. These include the historic Rawhide Western Railroad grade and Reese River Road stage route, and several prehistoric sites.

The Mina rail corridor would follow various lengths of some historic railroads between Hawthorne and Tonopah Junction, south toward the town of Silver Peak, and intersect or follow many segments of the former Las Vegas and Tonopah line along common corridor segment 2, south of the town of Goldfield. In these locations, DOE would refurbish the historic rail beds for use with the proposed rail line. Eligible or unevaluated resources associated with the railroads include the Sodaville to Tonopah freight road, railroad stations, abandoned grades, construction-related features, workers' encampments, and resources associated with Luning, Mina, Coaldale, and other towns established along the rail lines.

A portion of the Mina rail corridor would run just south of Miller's Townsite, a station on the Tonopah and Goldfield Railroad and a mill site for silver ore. The corridor would pass near known historic graves and the historic cemetery at Miller's Townsite. In addition, the corridor would run adjacent to Cuprite, an unrecorded railroad station along the abandoned rail line of the former Bullfrog Goldfield Railroad near Ralston. The station had a post office and served the mining camps of Lida, Hornsilver, Bonnie Claire, and Tule Canyon in the early twentieth century. Also, a number of prehistoric sites, some of which are eligible or potentially eligible for listing on the *National Register of Historic Places*, are located nearby.

A portion of the Mina rail corridor would run just west of the current boundary of the Goldfield Historic District, but early photographs of Goldfield reflect that the town extended west to the base of Malpais Mesa. To the north, a portion of the corridor would be just east of the Goldfield Cemetery, but there is historic confusion over some burial-plot locations, so the actual boundary location is in question. The corridor would also run through the extensive historic Goldfield dump, which is eligible for listing on the *National Register of Historic Places*. In addition, there is the potential for buried prehistoric sites at nearby springs, as evidenced by prehistoric rock art (DIRS 182772-MTS 2007, p. 42).

Other areas of the Mina rail corridor would be within 1.6 kilometers (1 mile) of several cultural resource sites, including a Western Shoshone village, petroglyphs near Beatty and Schurz, and Black Cone in Crater Flats, which ethnographers and American Indians have identified as places of religious significance or power (DIRS 102043-AIWS 1998, all).

The site-file search for the Mina rail corridor identified 132 previously recorded archaeological sites (see Table 3-5). The prehistoric and historic sites identified range in size from isolated artifacts and scatters of artifacts to town sites and transportation networks (such as stage roads and railroad grades). About 21 percent are considered to be eligible for listing on the *National Register of Historic Places*. There are 35 sites that have not been evaluated for eligibility. Based on the results of site-file searches for the Mina rail corridor, it appears that less than 5 percent of the corridor has been surveyed (DIRS 182772-MTS 2007, p. 43).

3.2.5.2 Potential Impacts to Cultural Resources

Prior to construction of a rail line, field surveys to identify cultural resources and potentially, measures to mitigate impacts to those resources, would be required. If cultural resources were encountered, a qualified archaeologist coordinating with the Nevada State Historic Preservation Officer and DOE would participate in directing activities to ensure that the resources were properly protected or the impact mitigated. DOE would implement procedures to avoid or reduce direct impacts to cultural resources in construction areas of surface-disturbing activities. Nevertheless, there could be direct impacts to cultural resources (such as disturbing the sites or crushing artifacts) during construction activities.

There could be indirect impacts to cultural resources during the construction phase as a result of increased access and increased numbers of workers near cultural resource sites. These factors would increase the probability for either intentional or inadvertent indirect impacts to cultural resources. However, overall impacts would be small.

No additional direct or indirect impacts to cultural resources would be expected during the operations phase.

Table 3-5. Number of previously recorded cultural resource sites within the 400-meter (0.25-mile) area of the Mina rail corridor.[a]

National Register of Historic Places status	Prehistoric	Historic	Prehistoric and historic	Unknown	***Totals***
Eligible	2	22	4	0	28
Not eligible	41	17	11	0	69
Unknown	15	15	2	3	35
Totals	58	54	17	3	132

a. Source: DIRS 182772-MTS 2007, p. 43.

3.2.6 OCCUPATIONAL AND PUBLIC HEALTH AND SAFETY

The analysis for occupational and public health and safety focuses on traffic, worker industrial safety, incident-free radiological and nonradiological impacts, and radiological impacts related to accidents. To estimate transportation impacts, DOE defines the region of influence for the Mina rail corridor as beginning at the Hazen siding in Churchill County, Nevada, and ending at Yucca Mountain. The impacts do not include those from transportation from the Nevada border to the Hazen siding. The region of influence for each includes:

- Traffic impacts: The 400-meter (0.25-mile)-wide rail corridor and public highways that would be used by workers and for shipments of materials and supplies during the construction and operations phases
- Worker industrial safety impacts: The 400-meter (0.25-mile)-wide rail corridor
- Incident-free radiological and nonradiological impacts: The 800-meter (0.5-mile)-wide area on either side of the centerline of the rail corridor
- Radiological impacts related to accidents: An area within an 80-kilometer (50-mile) radius from a potential occurrence location in the rail corridor

DOE obtained information from the Bureau of Labor Statistics for 2005. The Department also used the RADTRAN 5 computer program (DIRS 150898-Neuhauser and Kanipe 2000, all; DIRS 155430-Neuhauser, Kanipe, and Weiner 2000, all) and the RISKIND computer program (DIRS 101483-Yuan et al. 1995, all) where applicable.

3.2.6.1 Occupational and Public Health and Safety Affected Environment

During the construction and operations phases, common industrial hazards could cause health and safety impacts to workers. The categories of worker impacts include total recordable cases per 100 full-time-equivalent workers, lost-workday cases per 100 full-time-equivalent workers, and fatalities per 100 full-time-equivalent workers. Total recordable cases are occupational injuries or occupation-related illness that result in (1) a fatality, regardless of the time between the injury or the onset of the illness and death, (2) lost workday cases (nonfatal), and (3) incidents that result in the transfer of a worker to another job, termination of employment, medical treatment, loss of consciousness, or restriction of motion during work activities.

Table 3-6 lists Bureau of Labor Statistics incident-rate statistics for 2005 used to estimate total recordable cases, lost workday cases, and fatalities for involved and noninvolved workers during the construction and operations phases. For this analysis, involved workers are personnel who would be involved in construction or operations activities. Noninvolved workers are personnel who would be involved in

Table 3-6. Incident-rate statistics for estimation of industrial safety impacts from railroad construction and operations in the Mina rail corridor.[a]

Activity	Total recordable cases per 100 FTEs[b]		Lost workday cases per 100 FTEs		Fatalities per 100 FTEs	
	Involved	Noninvolved	Involved	Noninvolved	Involved	Noninvolved
Construction	5.6	2.4	3.1	1.3	0.011	0.0035
Operations	2.5	2.4	1.9	1.3	0.018	0.0035

a. Sources: DIRS 179129-BLS 2007, all; DIRS 179131-BLS 2006, all.
b. FTE = full-time equivalent; one full-time equivalent is 2,000 labor hours.

management, administration, and security. The Bureau of Labor Statistics compiled the health and safety statistics by employment sectors; the sectors used for this analysis include Heavy and Civil Engineering Construction; Management of Companies and Enterprises; Transportation and Warehousing: Rail Transportation; and Support Activities for Transportation. Sectors analyzed for fatality incident statistics included Construction, Professional and Business Services, and Transportation and Warehousing.

3.2.6.2 Potential Impacts to Occupational and Public Health and Safety

The occupational and public health and safety impact analysis focused on transportation impacts, worker industrial safety impacts, incident-free radiological and nonradiological impacts, and radiological and nonradiological impacts in relation to accidents.

3.2.6.2.1 Industrial Safety

The analysis based the estimates of industrial safety impacts from railroad construction on full-time-equivalent workers per year; with the assumption that there are 2,000 hours per worker-year this would be about 6,500 full-time-equivalent worker-years (DIRS 182772-MTS 2007, p. 44). The analysis based the estimates of industrial safety impacts from railroad operations in the Mina rail corridor on about 60 full-time-equivalent workers each year, about 2,000 worker-years. Table 3-7 lists estimated industrial safety impacts to workers during construction and the estimated industrial safety impacts of railroad operations based on Bureau of Labor Statistics in the Mina rail corridor for up to 50 years.

Table 3-7. Impacts to workers from industrial hazards during the construction and operations phases.[a]

Group and industrial hazard category	Construction	Operations[b]	Total
Involved worker			
Total recordable cases[c]	300	37	337
Lost workday cases	170	28	198
Fatalities	0.6	0.26	0.86
Noninvolved worker			
Total recordable cases	30	12	42
Lost workday cases	16	6.4	22.4
Fatalities	0.04	0.02	0.06
Totals[d]			
Total recordable cases	330	49	379
Lost workday cases	180	35	215
Fatalities	0.6	0.3	0.92

a. Estimates of worker-years multiplied by accident rate (DIRS 179129-BLS 2007, all; DIRS 179131-BLS 2006, all).
b. Totals for railroad operations occurring up to a 50-year operations period.
c. Total recordable cases include injuries and illness.
d. Totals might differ from sums of values due to rounding.

3.2.6.2.2 Transportation

This analysis includes estimated impacts from the transportation of construction material to the construction sites and impacts from commuting workers. There could be traffic fatalities and vehicle emission impacts during the movement of equipment and delivery of materials for construction, worker commutes to and from construction sites, and transport of water to construction sites. Table 3-8 lists the impacts of transportation during the construction phase. As shown, four of the fatalities could be from traffic accidents during the construction phase. An additional 0.54 fatality could be from cancer related to vehicle emissions during the construction phase.

Table 3-8. Transportation impacts during railroad construction in the Mina corridor.[a]

Transportation impact category	Traffic fatalities	Latent cancer fatalities	***Total***
Vehicle emission impacts (cancer fatality)			
Material delivery vehicles	–	0.04	
Worker commuting	–	0.5	
Subtotal		0.54	
Transportation accidents (fatalities)			
Material delivery vehicles	0.3	–	
Worker commuting	3.7	–	
Subtotal	4.0		
Totals[b]	4.0	0.54	4.6

a. Source: DIRS 182772-MTS 2007, p. 45.
b. Numbers are presented using two significant figures. Totals might differ from sums of values due to rounding.

The transportation of ***spent nuclear fuel*** and ***high-level radioactive*** waste in the Mina rail corridor could result in radiological and nonradiological impacts to workers and the public. Radiological impacts could result from ***radiation*** the rail ***cask*** contents would emit during incident-free transportation, from ***radionuclides*** released from the cask during transportation accidents, or from radiation the cask contents emitted because of a loss of shielding during a transportation accident. Nonradiological impacts (vehicle emission-related fatalities) could result from diesel locomotives and fugitive dust, and from nonradiological transportation accidents that involved workers and members of the public.

To estimate transportation impacts, DOE defined the region of influence beginning at the Hazen siding in Churchill County, Nevada, and ending at Yucca Mountain. For incident-free transportation, the potential human health impacts for transportation workers and populations along the corridor were estimated. Transportation workers would include train crews, security escorts, workers at the staging yard, and workers who could be exposed to radiation at sidings when a train carrying loaded casks passed. Members of the public would include people living within 0.8 kilometers (0.5 mile) of the Mina rail corridor and around the staging yard. The analysis used the RADTRAN 5 computer program (DIRS 150898-Neuhauser and Kanipe 2000; DIRS 155430-Neuhauser, Kanipe, and Weiner 2000) and the RISKIND computer program (DIRS 101483-Yuan et al. 1995) to estimate these impacts.

For transportation accidents, DOE estimated radiological impacts for accidents that involved releases of radioactive material from the shipping casks, accidents that involved a reduction in the shielding of the shipping casks, and accidents in which no release of radioactive material and no deformation of shielding occurred. For these accidents, the analysis used the RADTRAN 5 program to estimate radiological accident risks (probability of occurrence times consequences) for a complete spectrum of accidents. In addition, DOE estimated the number of traffic fatalities that would result from nonradiological transportation accidents.

Chapter 6 and Appendix J of the Yucca Mountain FEIS describe the methods and data DOE used to estimate the radiation doses for workers and members of the public. Since DOE completed the Yucca

Mountain FEIS, the repository design and operational plans have evolved. There have also been changes to some of the data DOE used to estimate radiation doses and radiological impacts. These changes include the use of updated latent cancer fatality conversion factors, radiation dosimetry, additional escorts, dedicated trains, 2000 Census data, shipment estimates, radionuclide inventories, exposure times and staffing estimates, and sabotage release fractions (DIRS 182772-MTS 2007, p. 46).

3.2.6.2.2.1 Workers along the Mina Rail Corridor. During the shipment of spent nuclear fuel and high-level radioactive waste from the Hazen siding to the repository, workers on the trains and those working along the rail line could be exposed to direct radiation from approximately 9,500 shipping casks. Table 3-9 lists the estimated radiation doses and impacts for involved workers. The estimated collective radiation dose for the operations phase would be 310 person-rem. The estimated number of latent cancer fatalities would be 0.18 (about 1 chance in 6 that there would be one cancer fatality in the exposed worker population) for a radiation-related latent cancer fatality in this group.

3.2.6.2.2.2 Workers at the Staging Yard. When shipping casks arrived at the staging yard, personnel would remove the railcars that carried the casks from the train, inspect them, and transfer them to another train for transport to Yucca Mountain. The escorts who had accompanied the shipping casks from their origin would be present during the inspection. For purposes of this analysis, DOE assumed these workers, inspectors, and escorts would be exposed to direct radiation from approximately 9,500 shipping casks. In addition, the analysis assumed that noninvolved workers would be exposed to direct radiation during these activities.

The estimated collective radiation dose for involved and noninvolved workers at the staging yard would be 250 person-rem. The estimated number of latent cancer fatalities for these workers would be 0.15. Staging yard and other facilities workers would participate in a radiation protection program and would not be exposed to radiation greater than the administrative control level for repository facilities of 0.5 rem per year. This requirement could limit the number of hours a worker would be able to work at the staging yard to fewer than 2,000 per year.

3.2.6.2.2.3 Maximally Exposed Workers. The maximally exposed worker could be an escort. This person could receive an estimated radiation dose of about 17 rem, based on a 0.5-rem-per-year radiation dose administrative control level (DIRS 174942-BSC 2005, Section 4.9.3.3). The estimated probability of a latent cancer fatality for a maximally exposed worker would be 0.01. Escorts and other railroad workers would participate in a radiation protection program and would not be exposed to radiation greater than the radiation dose administrative control level for repository facilities of 0.5 rem per year (DIRS 174942-BSC 2005, Section 4.9.3.3). In some cases, this requirement could limit escorts to work fewer than 2,000 hours per year on the railroad.

3.2.6.2.2.4 Members of the Public along the Mina Rail Corridor. During the shipment of spent nuclear fuel and high-level radioactive waste from the Hazen siding to Yucca Mountain, people along the rail line could be exposed to direct radiation from approximately 9,500 shipping casks.

Table 3-9 lists the radiation impacts for members of the public along the Mina rail corridor. The estimated collective radiation dose over the operations phase for members of the public would be 1.4 person-rem. The estimated number of latent cancer fatalities would be 0.00082 (about 1 chance in 1,200 that there would be one cancer fatality in the group of exposed members of the public).

The ***maximally exposed individual*** could be a person who lived beside the rail line operations right-of-way. The estimated radiation dose for this individual would be 0.0078 rem over the operations phase. The estimated probability of a latent cancer fatality for this individual would be 0.0000047.

Table 3-9. Operations impacts of transportation for the Mina rail corridor.[a]

Transportation impact category	Traffic fatalities	Radiation dose (rem or person-rem)	Probability of LCFs[b]	Number of LCFs	***Total***
Maximally exposed individual		0.0078	0.0000047	–	
Workers		550		0.33	
Along corridor	–	310	–	0.18	
At staging yard		250		0.15	
Maximally exposed worker	–	17	0.01	–	
Incident-free radiological impacts(LCFs)					
Public	–	1.4	–	0.00082	
Radiological accident (LCFs)		0.012	–	0.0000074	
Vehicle emission impacts (cancer fatalities)					
Waste transportation	–	–	–	0.0034	
Worker commuting	–	–	–	0.4	
Transportation accidents (fatalities)					
Waste transportation	0.31	–	–	–	
Worker commuting	3.3	–	–	–	
Totals	3.6	–	–	0.7	4.3

a. Source: DIRS 182772-MTS 2007, p. 46.
b. LCF = latent cancer fatality.

People along the Mina rail corridor could be exposed to diesel exhaust and fugitive dust from railroad operations and maintenance. Table 3-8 lists these nonradiological vehicle emission impacts. There could be 0.0034 fatality from waste transportation and 0.4 fatality from workers commuting.

3.2.6.2.3 Accidents

The potential risks of transportation could be associated with three types of accidents: (1) an accident that released radioactive material from the shipping cask, (2) an accident in which no release of radioactive material occurred but there was a deformation of shielding because of lead shield displacement, and (3) an accident in which no release of radioactive material and no deformation of shielding occurred. The impacts from these types of accidents are known as the radiological accident dose risk, and are quantified in terms of latent cancer fatalities. The impacts of traffic fatalities involving the casks were also estimated.

Table 3-9 lists impacts from these types of accidents. Over the operations phase, the estimated dose risk from a radiological accident would be 0.0000074 latent cancer fatality. Over this same time period, the estimated risk of a nonradiological transportation accident fatality would be 0.31.

In summary, Table 3-9 lists the estimated radiological and nonradiological impacts for workers and members of the public from the transportation of spent nuclear fuel and high-level radioactive waste in the Mina rail corridor. The estimated total number of fatalities for rail corridor operations would be 4.3. Approximately three of these fatalities would be from traffic accidents that involved commuting workers; other estimated impacts would be about 1 fatality. Estimated radiological exposures to workers would account for about 8 percent of the estimated fatalities, while radiological exposure of members of the public, and radiological accident risks, would account for less than 0.1 percent of the total fatalities. Estimated fatalities from vehicle emissions would account for about 9 percent of the total fatalities.

3.2.7 SOCIOECONOMICS

The Mina rail corridor would cross portions of Lyon, Mineral, Esmeralda, and Nye Counties and the Walker River Paiute Reservation. Most of the residential areas on the Reservation are within the boundaries of Mineral County, with a portion in Lyon County.

DOE evaluated potential impacts to five socioeconomic variables (employment, population, economic measures, housing, and public services) and developed a profile of the existing socioeconomic conditions in the region of influence. The breadth and depth of the evaluation mirrors that of the original corridor-level analysis provided in the Yucca Mountain FEIS. The analysis includes the present and anticipated impacts to those variables. The region of influence for the socioeconomics analysis is defined as those Nevada counties the Mina rail corridor would cross, and the two areas where most workers would be expected to reside (the Carson City/Washoe County area and Clark County). DOE also developed a general profile of the Walker River Paiute Reservation. The analysis estimated potential changes that could result from the railroad construction and operations.

To evaluate this resource area, DOE obtained data from the U.S. Census Bureau, the Nevada State Demographer, and other local and state sources. In addition, the Department utilized estimates and projections from the socio-demographic forecasting software program REMI, version 9, to develop baselines. The use of these sources is consistent with the Yucca Mountain FEIS in that the REMI projections include the same variables as those included in the Yucca Mountain FEIS.

3.2.7.1 Socioeconomics Affected Environment

3.2.7.1.1 Employment and Population

Table 3-10 lists population estimates and projections anticipated for the 50-year railroad operations phase through 2067, for the four counties the Mina rail corridor would cross. The table also lists population projections for Clark County and the Carson City/Washoe County area, because those jurisdictions, which represent the largest population centers in the southern and northern portions of the corridor, respectively, would potentially provide most of the rail line construction workers (DIRS 182772-MTS 2007, p. 48).

Table 3-10. Population baselines and projections for select Nevada counties and Nevada, 2005 to 2067.[a]

Jurisdiction/ year	2005	2010	2015	2020	2025	2030	2035	2067
Carson City/Washoe County	450,000	510,000	570,000	620,000	660,000	700,000	740,000	1,100,000
Lyon County	49,000	61,000	72,000	81,000	89,000	96,000	100,000	170,000
Mineral County	4,600	4,700	4,800	4,600	4,400	4,300	4,200	3,700
Esmeralda County	1,300	1,100	1,100	1,000	1,000	1,000	1,000	1,100
Nye County	41,000	52,000	61,000	68,000	73,000	78,000	84,000	131,000
Clark County	1,820,000	2,260,000	2,650,000	2,950,000	3,170,000	3,360,000	3,540,000	5,000,000
Nevada	2,540,000	3,060,000	3,540,000	3,900,000	4,190,000	4,430,000	4,680,000	6,650,000

a. Source: DIRS 178610-Bland 2007, all

Unless otherwise noted, all general demographic, social, economic, and housing information was estimated by the U.S. Census Bureau during the 2000 decennial national census and was reported in the Census American FactFinder.

Carson City has a land area of about 360 square kilometers (140 square miles). The person-per-square-mile density is approximately 370, which is considerably more than the average population density in Nevada of 18.2. Carson City had about 21,000 housing units in 2000 and a population of 52,500 that year. Carson City is the metropolitan center nearest the Mina rail corridor starting point. Per capita income in Carson City, $20,943, was near the state's average in the last decennial census. Carson City's unemployment rate of 4.6 was lower than Nevada's unemployment rate of 6.2 percent in 2000.

Washoe County has a land area of about 16,000 square kilometers (6,300 square miles) and a population density of approximately 54 per square mile, about three times the population density of the state. Washoe County had about 140,000 housing units in 2000 and a population of about 340,000. Washoe County has recently experienced strong growth; the 1990s saw an aggregate growth of nearly 33 percent and 2000-2005 saw an additional 16-percent growth in population. Per capita income in Washoe County was $24,277, about 10 percent higher than Nevada's per capita income that year. The Washoe County unemployment rate in 2000 was 5 percent; lower than the state's unemployment rate of 6.2 percent.

The Carson City/Washoe County area had a population of about 450,000 in 2005. The area's economy is dominated by the Services industry, in particular the Accommodations and Food Services sector. Services accounted for almost 42 percent of the area's employment in 2005. Table 3-11 displays information about the demographic, social, housing, and economic characteristics of the Carson City/Washoe County area in 2000.

Table 3-11. Demographic, social, housing, and economic characteristics for select Nevada counties, the Walker River Paiute Reservation, and Nevada.[a]

	Washoe County	Clark County	Esmeralda County	Lyon County	Mineral[b] County	Nye County	Walker River Paiute Reservation	Nevada

a. Source: DIRS 182772-MTS 2007, pp. 49 and 50.
b. Mineral County numbers include the Walker River Reservation.
c. Minority population is all individuals other than those who classify themselves as "white alone."
d. Values, except per capita income, have been rounded to two or three significant places.

Mineral County has a land area of about 9,800 square kilometers (3,800 square miles) and a population density of 1.4 per square mile. The county experienced population declines in the 1990s. Mineral County continues to experience modest declines in population; its estimated 2005 population was 4,600. It was about 5,100 in 2000. Hawthorne, in Mineral County, had a 2000 estimated population of 3,100 and a

2005 estimated population of 3,000. In the Mina rail corridor, the U.S. Census Bureau identifies only the Hawthorne community as being urban. All other communities are classified as rural. Luning had an estimated 2000 population of 86 people and an estimated 2005 population of 87. Mina had a 2000 estimated population of 310 residents and an estimated 2005 population of 280 (DIRS 182772-MTS 2007, p. 49). There are three major industries in Mineral County: Public Administration, Natural Resources/Mining/Utilities/and Construction and Services. Per capita income was estimated to be $16,952 in the last U.S. Census, about 77 percent of Nevada's per capita income. Unemployment in the county, 12.9 percent, was twice Nevada's unemployment in 2000. The county had about 2,900 housing units and a 23 percent vacancy rate in that year. Table 3-11 lists information about the demographic, social, housing, and economic characteristics of Mineral County in 2000.

Due to the nature of the census data, Mineral County's estimated and projected population figures include residents of the Walker River Paiute Reservation. The Reservation had an estimated population of 810 in 1990 and an estimated population of 850 in 2000 (DIRS 182772-MTS 2007, p. 50). There were about 350 housing units in 2000. Residents of the Reservation work primarily in retail trade, construction, and manufacturing. The 2000 unemployment rate was 22.6 percent, more than 3.5 times the Nevada unemployment rate in the same year. At the time of the last national census, per capita income on the Walker River Paiute Reservation, $10,092, was less than 50 percent of the Nevada per capita income in that year and about 60 percent of Mineral County per capita income. Table 3-11 lists information about the demographic, social, housing, and economic characteristics of the Walker River Paiute Reservation in 2000.

Lyon County has a land area of almost 5,200 square kilometers (2,000 square miles). The county has a population density of about 17.3 per square mile, reflecting the state's average population density per square mile. There were about 14,300 housing units in 2000 while the population was about 34,500. Lyon County grew almost as rapidly as Clark, Nye, and Washoe Counties. It had 49,000 residents in 2005, up from 21,000 in 1990 (DIRS 182772-MTS 2007, p. 50). Services provided about 30 percent of the county's jobs, Retail and Wholesale Trade about 20 percent, and Public Administration about 15 percent. Per capita income, $18,543, was about 14 percent lower than the state average in 2000. Unemployment was 6.9 percent, slightly higher than the state average. Table 3-11 lists information about the demographic, social, housing, and economic characteristics of Lyon County in 2000.

Esmeralda County experienced declines in population in the 1990s, but has reversed that trend in the 21st century, growing by approximately 20 percent from 2000 to 2005. An estimated 1,300 persons lived in Esmeralda County in 2005. In 2000, Goldfield, in Esmeralda County had an estimated population of 420; in 2005, the estimated population was 440. Silver Peak had a 2000 estimated population of 160 and a 2005 estimated population of 130 (DIRS 182772-MTS 2007, p. 50). The approximately 9,300-square-kilometer (3,600-square-mile) county has a population density of just 0.3 a square mile. The county had 833 housing units in 2000, but a 45 percent vacancy rate. The population in 2000 was about 970. Most jobs in Esmeralda County are in the Services industry or in the Public Administration industry, which includes the state and local government sector. Esmeralda County's per capital income was $18,971 in 2000. Unemployment, 3.3 percent, was about 50 percent of Nevada's unemployment rate in 2000. Table 3-11 lists information about the demographic, social, housing, and economic characteristics of Esmeralda County in 2000.

Nye County's land area is more than twice that of Clark County, about 47,000 square kilometers (18,000 square miles). The population per square mile is 1.8, about a tenth of the state's average. Nye County had about 16,000 housing units and a population about 32,000 in 2000. Nye County joined the rapid population escalation by growing approximately 81 percent in the 1990s and another 25 percent from 2000 to 2005. The county's estimated population in 2005 was 41,000. Nye County is dominated by one of the Nation's fastest growing unincorporated communities, Pahrump. Growing in popularity as a residential destination, Pahrump had an estimated population of 33,000 people in 2005 (an increase of 37 percent in 5 years), which represents more than 80 percent of the Nye County's total population that year. The Mina rail corridor would also pass near Beatty and Tonopah in Nye County. The estimated 2005 populations of Beatty and Tonopah were 1,000 and 2,600, respectively (DIRS 182772-MTS 2007, p. 51). Nye County's economy is driven by the Services industry which accounts for 44 percent of the jobs in the county. Other major industries include Retail and Wholesale trade and the Transportation/ Information/Finance/Accounting industry. The estimated per capita income in Nye County at the last national census, $17,962, was about 82 of the per capita income in Nevada. Unemployment was 7.1 percent, higher than the state's 6.2 percent. Table 3-11 lists information about the demographic, social, housing, and economic characteristics of the Nye County in 2000.

Clark County has a land area of almost 21,000 square kilometers (8,000 square miles) and a population density of about 173.9 per square mile. Clark County had about 560,000 housing units in 2000 and a population of about 1.38 million that year. Clark County's population grew even faster than that of Washoe County – a total of 81 percent in the 1990s and approximately 29 percent, to 1.8 million persons, by 2005. Clark County is the metropolitan center nearest the Mina rail corridor ending point. Per capita income in Clark County was $21,785, about the average of Nevada's that year. Unemployment in Clark County, 6.6 percent was slightly above the state's unemployment rate of 6.2 percent. The economy in Clark County is dominated by the Services industry, particularly the Accommodations and Food Services sector which accounts for almost 50 percent of employment in the county. The Transportation/ Information/ Finance/Accounting industry and the Trade industry, which is composed of retail and wholesale trade, are also major components of the economy. Table 3-11 lists information about the demographic, social, housing, and economic characteristics of the Clark County in 2000.

Table 3-11 lists characteristics of the four counties along the Mina rail corridor, the Walker River Paiute Reservation, Clark County, Washoe County, and the State of Nevada. The information in the table is the baseline for determining potential impacts to employment, population, existing housing stock, and demands on educational facilities and other public services. Table 3-12 lists information about the employment baselines in the counties that the Mina rail corridor would cross and information about Clark County and the Carson City/Washoe County area because most rail line construction workers are expected to come from those areas. Information about the State of Nevada is provided for comparison purposes.

Table 3-12. Employment baseline projections in Nevada counties in the Mina rail corridor, 2005 to 2067[a] (page 1 of 2).

Jurisdiction	2005	2010	2015	2020	2025	2035	2067
Carson City/Washoe County employment baseline	310,000	330,000	360,000	370,000	380,000	410,000	580,000
Lyon County employment baseline	14,000	17,000	18,000	19,000	20,000	23,000	37,000
Mineral County employment baseline	2,500	2,400	2,500	2,300	2,300	2,300	2,100
Esmeralda County employment baseline	470	470	450	440	440	430	460

3.2.7.1.2 Economic Measures

Baseline economic measures are provided for the four counties that the Mina rail corridor would cross, for Clark County and the combined Carson City/Washoe County area, and for the State of Nevada. Clark County dominates all economic measures in the state and is located near the southern end of the Mina corridor. The metropolitan Carson City/Washoe County area economy, near the northern end of the Mina corridor, is also much larger than the economies in the rural counties. Table 3-13 lists information on three economic measures: state/local government spending, real disposable income, and gross regional product.

Table 3-13. Economic measures: baselines and projections for select Nevada counties and Nevada, 2005 to 2067[a,b] (page 1 of 2).

	2005	2010	2015	2020	2025	2030	2035	2067
Carson City/Washoe County								
State/local government spending	1.90	2.17	2.56	2.89	3.18	3.47	3.77	5.85

b. All values are in 2006 dollars, in billions.

3.2.7.1.3 Public Services

3.2.7.1.3.1 Health Care. Lyon, Mineral, Nye, and Esmeralda Counties have some health care facilities, although all four counties are federally designated as health professional shortage areas for primary, dental, and mental health care (DIRS 180466-State of Nevada 2005, all; DIRS 180467-State of Nevada 2005, all; DIRS 173559-State of Nevada [n.d.], all; and DIRS 173560-State of Nevada [n.d.], all). Health care services are concentrated in Clark County, particularly in the Las Vegas area.

There is a public health clinic on the Walker River Paiute Reservation in Schurz. This clinic is staffed full time with a doctor and a nurse. This facility also has emergency medical services and emergency medical technicians (DIRS 180118-Gormsen and Merritt 2007, all).

3.2.7.1.3.2 Education. Lyon, Mineral, and Nye counties have elementary, middle, and high schools. In Nye County, the Community College of Southern Nevada has a campus in Pahrump that provides postsecondary school education. There are elementary and middle schools in Esmeralda County; high-school students from Esmeralda County attend school in Tonopah, Nye County (DIRS 155970-DOE 2002, p. 3-156).

3.2.7.1.3.3 Fire Protection. Lyon, Mineral, Nye, and Esmeralda counties have professional or volunteer fire departments. At present, the Nevada Test Site provides fire protection services to the Yucca Mountain Site.

3.2.7.1.3.4 Law Enforcement. Lyon, Mineral, Nye, and Esmeralda counties have sheriff's offices, with a ratio of 1.6, 3.9, 2.2, and 5 officers to 1,000 residents, respectively. The Walker River Paiute Reservation has a police department with four law enforcement officers, which yields a ratio of 3.4 officers per 1,000 residents (DIRS 182772-MTS 2007, p. 53).

3.2.7.1.3.5 Public Roadways. Because the Mina rail corridor is primarily in remote and rural areas, the rail line would cross paved highways and roads with low traffic, and low-usage unpaved roads, including county roads, private roads, and off-road vehicle trails. While many of the unpaved roads are important to the daily activities of landowners and ranchers in the area, these roads are not heavily traveled. The exception is the existing Union Pacific Railroad Branchline between Hazen and Wabuska, which crosses public roads with moderate traffic.

3.2.7.2 Potential Socioeconomics Impacts

3.2.7.2.1 Construction Phase

Sections 3.2.7.2.1.1 through 3.2.7.2.1.3 describe potential impacts to socioeconomics associated with construction and operation of a railroad in the Mina rail corridor.

3.2.7.2.1.1 Employment and Population. The incremental changes above the employment and population baselines in Mineral County would be the result of indirect jobs created to meet the consumption needs of workers.

Mineral County had an estimated population of about 4,630 and an employment baseline of 2,550 jobs in 2005. Mineral County could gain an estimated 45 residents as a result of the construction of a rail line in the Mina rail corridor, an increase of less than 1 percent over the population baseline. Mineral County could gain an estimated 90 jobs in 2010, 70 jobs in 2011 and 2012, and 45 jobs over the baseline from 2013 to 2067. The 1-year spike in 2010 would be an increase of about 3.8 percent above the 2010 employment baseline. The average change of 45 jobs is an increase of about 1.8 percent above the employment baseline in 2013.

Generally, potential impacts in Mineral County are expected to be small and transitory in nature.

The estimated number of workers needed to construct a railroad in the corridor would be approximately 6,500 worker-years over a minimum 5-year construction period. The average construction workforce would be 1,900 workers through each of the first 3 years of construction, with a peak of about 2,100 workers. The workforce would fall to 520 and 340 in years 4 and 5, respectively.

The construction labor pool in Clark County, the Carson City/Washoe County area and, to a lesser extent, Nye and Lyon Counties is large and would be able to provide most of the necessary construction workers. DOE estimates that about 50 percent of the workers would come from Clark County and about 50 percent would come from the Carson City/Washoe County area. Therefore, there would be limited in-migration during the construction phase in these or other counties. The baseline projected population growth and development in Clark and Nye Counties (the escalating in-migration of retirees and other individuals) would lead to greater socioeconomic impacts on services, including schools. This projected population growth (unrelated to railroad construction activities) would mask potential impacts from construction activities associated with the rail line.

Estimates for railroad construction workers and expected residential distribution patterns compared to applicable baselines lead to the conclusion that impacts to Esmeralda County would be small. Because of the very large base of available construction workers in the Carson City/Washoe County area and in Clark County and the large labor pool in Lyon and Nye Counties, DOE anticipates that very few workers would be likely to relocate to these communities; therefore, impacts to population and employment baselines would be small.

Population increases associated with a railroad construction workforce in the Mina rail corridor is estimated to be small in relation to the baseline population in Clark County and in Lyon, Nye, and Washoe Counties. Incremental population increases are expected to be minimal because worker in-migration is expected to be minimal. Mineral County’s incremental population increase of about 45 people would be less than 1 percent of the population baseline.

Because of the temporary nature of a linear construction project, workers would not be likely to relocate their families to communities along the corridor. Based on these assumptions, DOE estimates that impacts to population, and therefore to housing and schools, in the counties along the corridor would be small. It is likely that workers would spend a portion of their wages on food, gasoline, and other incidentals, but would spend most earnings in the counties where they live. Therefore, estimated impacts from construction activities on local populations would be small.

The analysis of Mineral County includes potential impacts to the population and employment baseline of the Walker River Paiute Reservation. Impacts to population and employment on the Reservation, if any, when considered individually rather than as part of the impacts to Mineral County, would be small because there would be no change to the employment base from in-migrating workers and no change to population because there would be no change to the employment baseline. The nature of the construction activities is sufficiently short in duration and transitory in nature that migration to Reservation land is considered unlikely.

Of the areas considered, the two most likely to experience changes in population from construction of a railroad in the Mina rail corridor are Clark County and the Carson City/Washoe County area, which are assumed to provide most of the construction workers. Estimates regarding the number of construction workers could affect employment, which in turn could result in changes to population baselines. Because the employment baselines in these areas are large, the expected employment increase of much less than 1 percent in Clark County and the Carson City/Washoe County area, respectively, are small in relation to those baselines. Similarly, the population changes in relation to the baselines are expected to be small and would likely be temporary.

Permanent residential patterns would not be likely to change, so impacts to county housing stocks and public education would be small. Workers and their families would continue to maintain a permanent residence in the counties where they live, with the workers commuting to construction camps for workweek assignments and returning to their permanent residences at the week's end. When considered individually, impacts to population and employment baselines in Esmeralda and Mineral Counties would be larger than that of the other counties considered in this analysis, but less than 1 percent. Esmeralda County would experience a peak population increase of about 20 in 2014, but those new residents would leave the county when after the end of the construction phase. The county could gain as many as 20 jobs at the beginning of the construction phase, but the railroad project would not contribute additional jobs after 2015. Impacts to schools and housing would be unlikely because the number of new residents in the counties as a result of rail line construction activities would be so small.

3.2.7.2.1.2 Economic Measures. The expected changes to economic measures attributable to the construction of a railroad in the Mina rail corridor would peak about 3 years after construction activities began. Changes to gross regional product, real disposable personal Income, and spending by state and local governments would be less than 2 percent above the baselines. Because Clark County and the Carson City/Washoe County area would supply most of the workers and be the permanent residences of most of the workers, Nye and Mineral Counties would be unlikely to experience noticeable changes in economic measures. Esmeralda County could experience a short-term spike in real disposable personal income and in gross regional product of 16.5 percent and 14.5 percent, respectively. Almost all of the incremental change would occur in the Accommodations and Food service industries. Spending by state and local governments could also have a short-term, but moderate increase of 4.2 percent, as local governments increased oversight personnel. The changes above the baselines would have no long-term effects on the economy.

Socioeconomic impacts attributable to the construction phase would be small in the four counties the rail line would cross. The impacts would also be small in Clark County and in the Carson City/Washoe County area, the population centers where most workers would live. The impacts would be positive; jobs would be created, real disposal personal income would increase, gross regional product would increase more quickly, and local and state governments would receive more revenue to provide public services.

3.2.7.2.1.3 Public Services. Construction impacts to public services at the county level would likely be small because the population projections with the project show very limited increases in overall counts. An additional demand on local health care capacity would be the primary impact on public services. The area that is likely to experience the greatest impact is southern Nye County.

3.2.7.2.2 Operations Phase

Sections 3.2.7.2.2.1 and 3.2.7.2.2.3 describe potential socioeconomic impacts during the railroad operations phase.

3.2.7.2.2.1 Employment and Population. Changes from baseline employment and population for some counties during railroad operations could induce socioeconomic impacts. There would be workers boarding the train as it enters the region and there would be escorts who would arrive with the cask trains. Regional workers would be needed for each train crew. There would be an estimated 42 workers for railroad operations. Because these operations workers would live in the railhead county, the most discernable impacts to population and employment from railroad operations would likely occur in Mineral County. Mineral County could gain about 45 residents as a result of railroad operations in the Mina rail corridor, an increase of less than 1 percent over the population baseline. Mineral County could gain about 45 jobs over the baseline railroad operations. This would be about a 1.8 percent increase over the employment baseline in 2015. Because the estimated operations workforce is small, increases in baseline population projections in the counties would not be likely to change. No impacts to housing would be likely from train crews. Changes to the employment and population baselines in Clark, Lyon, Nye, and Washoe Counties would be nearly imperceptible because of the large labor forces and population bases in these counties; current population growth in these counties would mask additional requirements for housing and public education. No impacts would be expected in Esmeralda County.

3.2.7.2.2.2 Economic Measures. Changes to economic measures would be expected to end in the final year of the construction phase. The impacts to baseline gross regional product, real disposable personal income, and spending by state and local governments would be less than 1 percent in Clark and Nye County and the Carson City/Washoe County area. In Mineral County, the impact of changes to economic baselines would be less than 2 percent. In Esmeralda County, the changes from the baseline would be very small when construction activities are completed and measures return to the projected baselines.

Socioeconomic impacts attributable to the operations phase would be small in the four counties the rail line would cross. The impacts would be small in Nye County and in Mineral County where most operations workers would live. The impacts would be positive; jobs would be created, real disposal personal income would increase, gross regional product would increase more quickly, and local and state governments would receive more revenue to provide public services.

3.2.7.2.2.3 Public Services. Railroad operations in the Mina rail corridor would result in small impacts to health care capacity in Lyon, Mineral, Nye, and Esmeralda Counties and on education infrastructure in southern Nye County (Pahrump). The exact extent of impacts to other public services would depend on the total number of workers and their residential locations, and operations activities in relation to existing system capacity. However, workers could create small to moderate impacts in the form of additional demand for fire-protection services in Lyon, Mineral, Nye, and Esmeralda Counties.

3.2.8 NOISE AND VIBRATION

Day-night average noise level (DNL): The energy average of A-weighted decibels (dBA) sound level over 24 hours; includes an adjustment factor for noise between 10 p.m. and 7 a.m. to account for the greater sensitivity of most people to noise during the night. The effect of nighttime adjustment is that one nighttime event, such as a train passing by between 10 p.m. and 7 a.m., is equivalent to 10 similar events during the day.

A-weighted decibels (dBA): A measure of noise level used to compare noise from various sources. A-weighting approximates the frequency response of the human ear.

The Yucca Mountain FEIS analysis for noise considered typical day-night sound levels and the distance of the rail line from communities, and estimated the impacts to communities from railroad construction and operations. The Yucca Mountain FEIS analysis for vibration considered the typical background level of ground vibration, the number of trains, and the distance of the rail line from historic structures or sites of cultural significance, and estimated the impacts from railroad operations.

The Yucca Mountain FEIS noise analysis used daytime and nighttime noise standards adopted by the State of Washington (Washington Administrative Code 173-58-040 to 173-60-040) for residential and commercial areas as benchmarks and for establishing the region of influence for potential impacts. To evaluate the impacts of noise from construction and operations activities for receptors in the region of influence near transportation facilities and corridors, DOE used benchmarks of:

- 60 ***A-weighted decibels*** (dBA) for residential use (nighttime reduction to 50 dBA)
- 65 dBA for light commercial
- 70 dBA for industrial zones

The analysis in the Yucca Mountain FEIS assumed that a limitation of 10 dBA above the benchmark is allowable if the duration is less than 5 minutes in an hour.

DOE has updated the criteria to determine the level of potential impacts from noise and vibration along the Mina rail corridor. For noise impacts from construction activities, DOE used U.S. Department of Transportation, Federal Transit Administration, methods (DIRS 177297-Hanson, Towers, and Meister 2006, all) and construction noise guidelines listed in Table 3-14.

Table 3-14. Federal Transit Administration construction noise guidelines.[a,b]

Land use	8-hour L_{eq} (dBA)		30-day average DNL (dBA)
	Day	Night	
Residential	80	70	75[c]
Commercial	85	85	80[d]
Industrial	90	90	85[d]

a. Source: DIRS 177297-Hanson, Towers, and Meister 2006, p. 12-8.
b. dBA=A-weighted decibels; DNL = day-night average noise level; L_{eq} = equivalent sound level.
c. In urban areas with very high ambient noise levels (DNL greater than 65 dBA), DNL from construction projects should not exceed existing ambient +10 dBA.
d. Twenty-four hour L_{eq}, not DNL.

For operation of trains during the construction and operations phases, DOE analyzed noise impacts under established Surface Transportation Board (STB) criteria. The STB has environmental review regulations for noise analysis (49 CFR 1105.7e (6)), with the following criteria:

- An increase in noise exposure as measured by DNL of 3 dBA or more
- An increase to a noise level of 65 DNL or greater

If the estimated noise-level increase at a location would exceed either criterion, the STB then estimates the number of affected receptors (such as schools, libraries, residences, retirement communities, and nursing homes). The two components (3 dBA increase, 65 DNL) of the STB criteria are implemented separately to determine an upper bound of the area of potential noise impact. However, current noise research indicates that both criteria must be met to cause an adverse noise impact (DIRS 173225-STB 2003, p. 4-82). That is, sound levels would have to be greater than or equal to 65 DNL and increase by 3 dBA or more for an adverse noise impact to occur.

Consistent with the analysis conducted in the Yucca Mountain FEIS, DOE based the estimates of potential operations impacts from noise on the passage of a two-locomotive, 10-railcar train traveling at 80 kilometers (50 miles) per hour. Current estimates of train size are similar, with two to three locomotives and four to nine cask, buffer, and escort cars, with six railcars being typical (DIRS 175036-BSC 2005). DOE considered the proximity of the Mina rail corridor to centers of population and frequency of shipments. Table 3-15 lists communities within 5 kilometers (3 miles) of the Mina rail corridor.

Table 3-15. Communities within 5 kilometers of the Mina rail corridor.

Community name	Approximate distance (kilometers)[a]
Goldfield	0.1
Silver Peak	0.3
Hawthorne	0.7
Mina	1.5
Schurz	1.8
Luning	2.7
Sodaville	2.7

a. To convert kilometers to miles, multiply by 0.62137.

There are three potential ground-borne vibration (vibration propagating through the ground) impacts of general concern: annoyance to humans, damage to buildings, and interference with vibration-sensitive activities. The approach for analyzing potential vibration impacts is based on estimates of project-generated vibration and measurements of current ambient vibration conditions. To evaluate potential vibration impacts from construction and operation activities, DOE used Federal Transit Administration building vibration damage and human annoyance criteria. Under these criteria, if vibration levels exceeded 80 VdB (human annoyance criterion for infrequent events) or if the vibration levels (measured as peak particle velocity) exceeded 0.20 inches per second for fragile buildings or 0.12 inches per second for extremely fragile historic buildings, then there could be a vibration impact (DIRS 177297-Hanson, Towers, and Meister 2006, all).

The region of influence for noise and vibration for construction and operation of a railroad along the Mina rail corridor includes the construction right-of-way out to variable distances, depending on several analytical factors (***ambient noise*** level, train speed, number of trains per day, and number of railcars).

3.2.8.1 Noise and Vibration Affected Environment

Most of the Mina rail corridor would pass through unpopulated BLM-administered public lands, primarily in a quiet ***desert*** environment where natural phenomena such as wind, rain, and wildlife account for most of the ambient sound. The sound level at a specific location depends on nearby and distant sources of sound. Sound levels in populated areas tend to be higher than in unpopulated areas because of human activity and higher levels of transportation noise. Manmade noise in some areas of the region of influence is caused by vehicles traveling along public highways and high-altitude commercial jets. Baseline sound conditions vary somewhat in the Mina rail corridor and are site-specific. Most of the region of influence for the Mina rail corridor is typical of other desert environments in which the DNL values range from 14 dBA on calm days up to 38 dBA on windy days (DIRS 102224-Brattstrom and Bondello 1983, p. 170). In 2005, DOE conducted noise measurements in Goldfield. Ambient noise levels ranged from 30 to 44 dBA with a day-night sound level of 47 dBA (DIRS 182772-MTS 2007, p.

57). In March 2007, DOE conducted noise measurements near Silver Peak, Mina, and Schurz (DIRS 182772-MTS 2007, p. 57). The noise associated with railroad operations is part of the existing environment in the Schurz area where the presence of the railroad is very evident. The sounds associated with the existing branchline include wayside noise (noise generated by the cars and locomotives), and horn sounding. The Federal Railroad Administration requires train engineers to sound horns when approaching most grade crossings. Horn sounding is generally not required at private crossings. Wayside noise and horn sounding are common in Schurz and along other portions of the existing Department of Defense branchline. The day-night sound levels ranged from 34 to 48 dBA, consistent with expectations for rural towns. The other rural communities along the Mina rail corridor would likely have similar background noise levels (DIRS 182772-MTS 2007, p. 57).

Ambient vibration levels were so low that they were essentially immeasurable for Schurz, Mina, and Silver Peak. The measured ambient vibration level in Goldfield was 25 VdB.

3.2.8.2 Potential Noise and Vibration Impacts

The conclusion of this analysis using the updated impact criteria from the Federal Transit Administration and STB are broadly consistent with the conclusion that would be obtained using the methodology presented in the Yucca Mountain FEIS.

3.2.8.2.1 Noise

3.2.8.2.1.1 Construction. For the most part, the Mina rail corridor would pass through areas that are remote from human habitation. Thus, the potential for noise impacts during the construction phase would be limited. Nevertheless, some people could be affected, including persons living near the corridor, using nearby recreational areas, or living in nearby rural communities. The distances from construction activities to the nearest receptors would be great; therefore, construction noise levels would be below the Federal Transit Administration noise guidelines listed in Table 3-14.

3.2.8.2.1.2 Construction Train Noise. As the rail roadbed, track, and bridges were completed, construction trains would be employed to move railroad ties, ballast, and other rail-construction equipment to other construction areas. Up to 16 one-way trains per day could pass by certain receptor locations construction phase. As with operations trains, locomotive horn sounding at grade crossings would be the dominant noise source.

DOE estimates that construction-train noise would be audible to receptors in Silver Peak and Goldfield. There would be no adverse noise impacts associated with these receptors because they would not experience a 3 dBA increase and 65 DNL or greater noise levels. The purpose of the 3 dBA increase component of STB noise guidelines is to identify potential impact areas and areas where train noise would be particularly audible. However, because transportation noise sources are audible throughout the United States, the audibility of train noise itself does not constitute an adverse noise impact.

3.2.8.2.1.3 Operations. DOE based the estimates of potential operations impacts from noise on the passage of a two- to three-locomotive, four- to eight-railcar train (one to five cask cars, two buffer cars, and one escort car). Because train speed has a direct correlation to noise generated, DOE used the top train speed to conservatively estimate potential noise levels. At present, there is no train activity in Mina, Silver Peak, or Goldfield.

DOE estimates that operations train noise would be audible to receptors in Silver Peak and Goldfield. There would be no adverse noise impacts associated with these receptors because they would not experience a 3 dBA increase and 65 DNL or greater noise levels. The purpose of the 3 dBA increase component of STB noise guidelines is to identify potential impact areas and areas where train noise would be particularly audible. However, because transportation noise sources are audible throughout the United States, the audibility of train noise itself does not constitute an adverse noise impact.

3.2.8.2.2 Vibration Impact

3.2.8.2.2.1 Construction. Based on the proposed construction equipment and Federal Transit Administration vibration data, DOE estimated potential ground-borne vibration levels due to construction activity. The vibration levels would be below Federal Transit Administration building vibration damage criteria (0.20 inch per second for fragile buildings, and 0.12 inch per second for extremely fragile historic buildings). Therefore, DOE would expect no damage to buildings due to vibration during construction. In addition, because of relatively low vibration levels and the temporary nature of construction, human annoyance due to construction vibration would be low.

3.2.8.2.2.2 Construction and Operations Train Vibration. DOE evaluated the potential impacts from vibration for construction and operations trains by using train-induced vibration levels as a function of distance from a rail line, along with vibration levels likely to result in building damage or annoyance, in combination with information on the location of residences or other buildings in relation to the rail line.

Construction trains would travel at lower speeds than operations trains. Because vibration is a function of train speed, construction-train vibration would be lower than operations-train vibration. Freight trains operating at 80 kilometers (50 miles) per hour would produce an annoyance-based vibration contour extending approximately 24 meters (80 feet) from the tracks (DIRS 177297-Hanson, Towers, and Meister 2006, p. 10-3). There are no buildings within approximately 24 meters of the Mina rail corridor, so operations trains would produce no adverse vibration impacts; neither would there be adverse vibration impacts from construction trains.

Unlike noise, vibration impacts are evaluated on the basis of maximum level. A freight train traveling at 80 kilometers (50 miles) per hour will generate a vibration velocity level of 95 decibels with respect to 1 micro-inch per second (VdB), measured 3 meters (10 feet) from the tracks (DIRS 177297-Hanson, Towers, and Meister 2006, p. 10-3). This level of vibration is substantially lower than levels that can cause cosmetic building damage (0.20 inch per second), nominally a vibration velocity of 106 VdB, or 100 VdB, assuming a crest factor of 2 (DIRS 176857-Martin 1980, all). This level of vibration is even lower than that which can cause structural damage (126 VdB) (DIRS 175495-Nicholls, Johnson, and Duvall 1971, all). There are no buildings within 3 meters of the Mina rail corridor; therefore, there would be no adverse vibration impacts to buildings.

3.2.9 AESTHETICS

The region of influence for aesthetics is the ***viewshed*** surrounding the 400-meter (0.25-mile)-wide corridor and all support facilities.

Most of the land in the Mina rail corridor is BLM-administered land, with additional areas under the jurisdiction of the Walker River Paiute Tribe, the U.S. Army, or private land owners. Because the Mina rail corridor would primarily cross BLM-administered land, DOE used the BLM methodologies for classifying visual resource quality and determining impacts to visual resources (DIRS 173053-BLM 1986, all; DIRS 173052-BLM 1984, all).

The BLM classifies lands under its jurisdiction using the visual resource management classification system. Classifications are based on a particular area's ***scenic quality***, visual sensitivity (***sensitivity levels***), and distance from travel or observation points (DIRS 101505-BLM 1986, all). The BLM uses a combination of the ratings of these three factors to assign a visual resource inventory class to a piece of land, ranging from Class I to Class IV, with Class I representing the highest visual values. Each visual resource class is subsequently associated with a management objective, defining the way the land may be developed or used. Each BLM district assigns visual resource management classes to its lands during the resource management planning process.

BLM management objectives associated with the four Visual Resource Management classes are:

- Class I: To preserve the existing character of the landscape. The level of change to the characteristic landscape should be very low and must not attract attention.
- Class II: To retain the existing character of the landscape. The level of change to the characteristic landscape should be low.
- Class III: To partially retain the existing character of the landscape. The level of change to the characteristic landscape should be moderate.
- Class IV: To provide for management activities that require major modification of the existing character of the landscape. The level of change to the characteristic landscape can be high.

The BLM uses visual resource contrast ratings to assess the visual impacts of proposed projects and activities on the existing landscape (DIRS 173053-BLM 1986, all). The BLM looks at basic elements of design to determine levels of contrast created between a proposed project and the existing viewshed. Contrast ratings are determined from locations called "key observation points," which are usually along commonly traveled routes such as highways or frequently used county roads or in communities. Depending on the visual resource management objective for a particular location, varying levels of contrast are acceptable. BLM Handbook H-8431-1, *Visual Resource Contrast Rating* (DIRS 173053-BLM 1986, all) describes this process.

BLM Visual Resource Management classifications for lands along the Mina rail corridor were primarily taken from the *Carson City Field Office Consolidated Resource Management Plan* (DIRS 179560-BLM 2001, all), the *Tonopah Resource Management Plan and Record of Decision* (DIRS 173224-BLM 1997, all), and the *Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement* (DIRS 176043-BLM 1998, all). Visual Resource Management classifications for lands not administered by the BLM were assigned using BLM methodologies (DIRS 173053-BLM 1986, all; DIRS 173052-BLM 1984, all) and considering scenic quality ratings reported in the Yucca Mountain FEIS where applicable (DIRS 155970-DOE 2002, pp. 3-158 and 3-159).

3.2.9.1 Aesthetics Affected Environment

Applicable BLM resource management plans (DIRS 173224- BLM 1997, all; DIRS 103079-BLM 1998, all; DIRS 179560-BLM 2001, all) show that most of the Mina rail corridor would be in Visual Resource Management Class III or IV lands, with the exception of a small section of existing rail line east of Walker Lake that crosses a Class II area. Other than east of Walker Lake, the Mina rail corridor in Churchill and Mineral Counties and on the Walker River Paiute Reservation would cross exclusively through areas considered Class III by default classification of the Carson City BLM office (DIRS 179571-Knight 2007, all). Montezuma option 1 would cross a Class III area centered on State Route 265 from Blair Junction to Silver Peak, and would be within about 2 kilometers (1.2 miles) of Class II areas in the Montezuma Range and Clayton Ridge areas. Approximately 10 kilometers (6 miles) of common corridor segment 6 would also be in Class III lands before it crossed the Yucca Mountain Site boundary.

3.2.9.2 Potential Aesthetics Impacts

The greatest impact on visual resources during the construction phase would be the presence of workers, camps, vehicles, large earth-moving equipment, laydown yards, borrow areas, and dust generation. These activities, however, would have a short duration. The Mina rail corridor and its options have all been affected to some extent by human activity. Only a limited portion of the overall construction time would be spent in one place; the exception to this would be places where major structures such as bridges would be built.

During the operations phase, visual impacts would be due to the existence of the rail line. The passage of 17 trains per week would have a small impact.

Construction and operation of a railroad through the primarily Class III and IV areas along the Mina rail corridor would generally be consistent with the BLM visual resource management objectives for these areas. Therefore, DOE expects the potential impacts to aesthetic resources would be small.

3.2.10 Utilities, Energy, and Materials

3.2.10.1 Utilities, Energy, and Materials Affected Environment

The Mina rail corridor would be in remote Nevada countryside, but is within the southern Nevada supply chain for the commodities required during the construction and operations phases.

3.2.10.2 Potential Utilities, Energy, and Materials Impacts

This section describes potential impacts to utilities, energy, and materials as a result of constructing and operating a railroad in the Mina rail corridor. Consumption of motor fuel, steel, and concrete during the construction and operations phases could impact the availability of these materials in the region of influence.

Electric power for construction would be initially supplied by portable generators. New power lines would be installed to provide power for construction services and would be extended, via underground distribution, along the rail roadbed to meet all other construction and operational needs.

The major providers of electricity in the region of influence, including the Nevada Power Company, Sierra Pacific Power Company, Valley Electric Association, Inc., and Lincoln County Power District No. 1 would have adequate generating capacity or power-purchase capabilities to supply the project during peak demand without disrupting service to the providers' respective coverage areas. Demand is expected to remain relatively stable in the serviced areas, increasing at about 1 to 2 percent annually, and is not expected to impact the capacity of service providers. In cooperation with the affected utilities, DOE would perform electrical capacity analyses to ensure adequate capacity exists, including the evaluation of the conditions of existing electric facilities and determination of appropriate interface equipment to meet the needs of both parties, prior to any connection into a transmission or distribution line; therefore, impacts to electricity services would be small.

Construction equipment would consume motor fuel (diesel and gasoline), which would represent the largest energy resource usage during the construction phase. The total motor fuel use in Nevada in 2005 was about 5.8 billion liters (1.5 billion gallons) (DIRS 182772-MTS 2007, p. 61). Table 3-16 includes the estimated amounts of diesel fuel and gasoline expected to be consumed during the construction phase.

Table 3-16. Construction materials and fuel estimates for the Mina rail corridor.[a]

Length (kilometers)[b,c]	Diesel fuel use (million liters)[d]	Gasoline use (million liters)	Steel (thousand metric tons)[e]	Concrete (thousand metric tons)
410	125	2.5	67	260

a. Sources: DIRS 180877-Nevada Rail Partners 2007, Table 2-1; DIRS 182772-MTS 2007, p. 61.
b. Corridor length listed for comparative evaluation.
c. To convert kilometers to miles, multiply by 0.623.
d. To convert liters to gallons, multiply by 0.264.
e. To convert metric tons to tons, multiply by 1.102.

Approximately 27 percent of the total construction phase fuel consumption would occur in the peak construction year. This would represent only about 0.6 percent of the motor fuel consumed annually in Nevada. Unlike overall state use, construction activities would use primarily diesel fuel, and during the peak year would consume about 2.2 percent of all special fuel (mainly diesel) used annually in Nevada. Nevada motor fuel use will continue to increase in the future, so the actual project percent use would be lower than these values (DIRS 182772-MTS 2007, p. 61).

Steel for rails, concrete (principally for rail ties, bridges, and drainage structures), and rock for ballast would be the primary materials that the construction of a rail line would consume. Table 3-16 lists estimates of steel and concrete consumption. Nationally, steel rail production often exceeds the need and there would be sufficient production flexibility and capacity to meet rail line construction demands. Thus, the impact on steel availability would be small. Because DOE would purchase precast concrete components from national suppliers in staggered preordered phases, and because construction would involve a small amount of cast-in-place concrete via the use of onsite batch plants, the impact on availability of concrete would be small.

During the operations phase, the amount of motor fuel used by locomotives would be small compared to regional availability. The amount of materials needed for rail line maintenance activities would be negligible and would not impact the supply.

3.2.11 WASTE MANAGEMENT

The region of influence for waste management includes counties the Mina rail corridor would cross and that have existing municipal sanitary waste landfills and disposal facilities for other types of wastes.

3.2.11.1 Waste Management Affected Environment

The Mina rail corridor would run through the Walker River Paiute Reservation, and Lyon, Mineral, Esmeralda, and Nye Counties. Of these, Lyon County and the Walker River Paiute Reservation have no landfill. The Goldfield landfill, in Esmeralda County, which serves a population of fewer than 1,500 received about 3.6 metric tons (4 tons) of solid waste per day in 2003. Nye County disposed of about 250 metric tons (280 tons) of waste during 2003 at three different landfills, but the county plans to close two of these landfills by 2011, which would represent 96 percent of the county's current waste disposal capacity. The Hawthorne Landfill in Mineral County disposed of about 25 metric tons (28 tons) per day in 2003; it has an estimated closure date of 2041. In comparison, the Apex Landfill in Clark County, which serves the Las Vegas Valley and has an estimated closure data of 2047, received 8,000 metric tons (8,800 tons) daily during 2003 (DIRS 182772-MTS 2007, pp. 61 to 62).

3.2.11.2 Potential Waste Management Impacts

Construction activities would generate hazardous and nonhazardous solid wastes, and recyclable material. DOE would dispose of nonhazardous wastes in permitted landfills. Hazardous waste such as corrosives and solvents would be shipped to a permitted hazardous waste treatment and disposal facility. All waste would be handled in accordance with applicable environmental, occupational safety, and public health and safety requirements.

Railroad construction and operations would generate solid municipal waste, estimated to be approximately 750 metric tons (830 tons) during the peak year of construction (DIRS 180922-Nevada Rail Partners 2007, Table 6-3). Approximately 25 percent of the generated waste would be recyclable, which would result in 550 metric tons (620 tons) of waste for disposal at municipal landfills (DIRS 180922-Nevada Rail Partners 2007, Table 6-3). The estimated total mass of waste during the construction phase would be about 2,000 metric tons (2,200 tons). This mass of waste would occupy about 5,000 cubic meters (6,600 cubic yards) of landfill volume at a waste density of 420 kilograms per cubic meter (700 pounds per cubic yard), which is typical of smaller landfills. The estimated average daily disposal mass would be about 1.5 metric tons (1.7 tons) (derived from DIRS 180922-Nevada Rail Partners 2007, Table 6-3).

For the landfills in rural counties, this would represent an increase in waste disposal volume. As an example, disposal of solid waste during the construction phase could represent a nearly 50-percent increase in daily waste volume for the Goldfield landfill and could hasten its closure (now estimated to be in 2023 (DIRS 182772-MTS 2007, p. 62). Waste generated during the construction phase could be trucked to larger landfills, where impacts on waste disposal capacity would be small.

Railroad operations would periodically generate waste during maintenance activities. Some locomotive and railcar maintenance could generate used oil and solvents that DOE would recycle or dispose of as hazardous waste.

3.2.12 ENVIRONMENTAL JUSTICE

3.2.12.1 Environmental Justice Affected Environment

The largest concentration of ***low-income*** or ***minority*** populations in the Mina rail corridor occurs in Mineral County and on the Walker River Paiute Reservation. The corridor would cross American Indian tribal lands, with the three Schurz bypass options almost entirely on the Walker River Paiute Reservation (DIRS 180222-BSC 2006, p. 16).

There are approximately 1.4 square kilometers (350 acres) of the Reservation lands in the corridor (DIRS 180222-BSC 2006, p. 15). The population of the Reservation, estimated to be 853 persons in 2000, is low-income and consists mainly of American Indians, a minority population.

The poverty rate in Mineral County is 15 percent, which exceeds the rate of poverty (11 percent) in the State of Nevada, while the poverty rate of Walker River Paiute Reservation residents is 32 percent. Nevada’s per capita income is approximately the same as the national average of about $22,000 but the per capita income on the Reservation is less than half that of residents in the state. Table 3-17 lists Walker River Paiute Reservation, Mineral County, and State of Nevada economic characteristics.

The Mineral County unemployment rate is approximately twice the rate of the state; with Nevada unemployment statistics mirroring the Nation’s unemployment rate. The unemployment rate on the Walker River Paiute Reservation however, is more than three times that of the state. Table 3-18 lists labor and employment characteristics on the Walker River Paiute Reservation, in Mineral County, and in Nevada.

Table 3-17. Economic characteristics of the Walker River Paiute Reservation, Mineral County, and the State of Nevada, 2000.[a]

Characteristic	Walker River Paiute Reservation	Mineral County	Nevada
Total population	853	5,100	2,000,000
Median household income (dollars)	$24,000	$33,000	$45,000
Per capita income (dollars)	$10,000	$17,000	$22,000
Individuals below poverty level	270	760	210,000
Percent individuals below poverty level	32	15	11

a. Source: DIRS 182772-MTS 2007, p. 63.

3.2.12.2 Potential Environmental Justice Impacts

3.2.12.2.1 Socioeconomics

Because there would be small changes in long-term population attributable to activities in the Mina rail corridor, impacts or stresses to the housing stock, infrastructure systems, or social services would be unlikely. A portion of the Mina rail corridor would cross lands in Esmeralda County where most of the land is administered by the BLM or owned by the U.S. Department of Defense, resulting in a sparse population. As a consequence, there are no concentrations of low-income or minority populations in Esmeralda County that construction or operation of a railroad in the Mina rail corridor would be likely to affect. DOE further concluded that there were no special pathways (unique practices and activities creating opportunities for increased impacts) that could not be mitigated. Likewise, a railroad in the corridor would be unlikely to affect low-income or minority populations in Lyon County.

Table 3-18. Labor and employment characteristics of the Walker River Paiute Reservation, Mineral County, and the State of Nevada, 2000.[a]

Characteristic	Walker River Paiute Reservation	Mineral County	Nevada
Total population	853	5,070	2,000,000
Population 16 years and older	570	4,000	1,540,000
In labor force, civilian	340	2,400	990,000
Employed	260	2,100	930,000
Unemployed	77	310	62,000
Percent unemployed	23	13	6.2
Labor participation rate	60	60	65
Individuals employed in construction industry	28	130	86,000

a. Source: DIRS 182772-MTS 2007, p. 64.

Nye County has a minority population of approximately 13 percent, with approximately 11 percent of the total population considered low income.

Socioeconomic impacts from railroad construction and operation in the Mina rail corridor would be small overall and would be unlikely to adversely or disproportionately affect the low-income or minority populations along the corridor. Impacts to socioeconomic variables would be neither high nor adverse.

4. CUMULATIVE IMPACTS – MINA RAIL CORRIDOR

This chapter describes potential cumulative impacts in connection with constructing and operating a railroad in the Mina rail corridor. This analysis considers past, present, and reasonably foreseeable future and continuing actions. This chapter also addresses unavoidable adverse impacts, the relationship between short-term uses and long-term productivity, and potentially irreversible or irretrievable commitments of resources for the Mina rail corridor.

Glossary terms are shown in ***bold italics***.

4.1 Introduction

The U.S. Department of Energy (DOE or the Department) combined potential ***impacts*** reported in Chapter 3 of this Nevada Rail Corridor SEIS with the potential impacts of other relevant past, present, and ***reasonably foreseeable future actions*** in the ***region of influence*** for the Mina rail corridor. These combined impacts are called ***cumulative impacts***. Council on Environmental Quality (CEQ) regulations (40 Code of Federal Regulations [CFR] 1500 to 1508) that implement the procedural requirements of the National Environmental Policy Act (42 United States Code [U.S.C.] 4321 *et seq.*) (NEPA) require a cumulative impacts analysis as part of the environmental impact statement (EIS) process.

Cumulative Impact: The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7).

DOE structured the cumulative impact assessments in the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DIRS 155970-DOE 2002, Section 8.4.2) (Yucca Mountain FEIS) by identifying actions that could have effects that coincided in time and space with the effects from the proposed repository and associated transportation activities. The analysis of cumulative transportation impacts reported in the Yucca Mountain FEIS evaluated the environmental impacts of constructing and operating a branch rail line in Nevada combined with the impacts of other federal, non-federal, and private actions.

4.1.1 REGIONS OF INFLUENCE

The regions of influence for this cumulative impacts analysis encompass the potentially affected areas specific to the Mina rail corridor. For the cumulative impacts analysis, the resource-specific regions of influence would generally be the same as those for the resource areas described in Chapter 3 and used for impact analyses in this Nevada Rail Corridor SEIS. Table 3-1 lists the regions of influence for each environmental resource for the Mina rail corridor.

4.1.2 APPROACH AND ANALYTICAL PERSPECTIVE

DOE used the following approach, analytical perspective, and considerations to perform this cumulative impacts analysis:

- Where the analysis indicated a potential for cumulative impacts, information is quantified to the extent practicable (for example, land disturbance and water demand); however, the cumulative impacts analysis is primarily ***qualitative***.

- The analysis considers federal, state and local government, and private activities.
- Projects included in the analysis have potential interaction in time (the foreseeable future) or space with the effects from implementation of the Proposed Action.
- Effects from past and existing projects and activities are primarily considered in the Chapter 3 discussions for each resource area (such as mining and grazing).
- DOE considers reasonably foreseeable actions as those future actions for which there is a reasonable expectation that the action could occur, such as a Proposed Action under analysis, a project that has already started, or a future action that has obligated funding.

DOE has assessed potential cumulative impacts under the Proposed Action qualitatively and quantitatively to the extent available information allows. Not all quantitative information is additive because of different methodologies or conflicting regions of influence.

DOE identified activities relevant to the cumulative impacts analysis from reviews of information available from government agencies, such as environmental impact statements, land-use and natural resource management plans, and from private organizations. DOE reviewed this information for relevance to this cumulative impacts analysis based on potential geographical and temporal relationships with construction and operation of the proposed rail line in the Mina rail corridor. Not all actions identified in this analysis would have cumulative impacts on all resource areas.

This section describes some future actions in general terms because the projects are in an early stage of planning or development, or they are broad concepts of activity (for example, Bureau of Land Management [BLM] resource management planning). This analysis focuses more on geographic interaction of projects than timing of interactions because the actual timeframes for many of the reasonably foreseeable future actions are uncertain.

The approach taken for this cumulative impact analysis is consistent with the intent of CEQ regulations at 40 CFR 1502.22, *Incomplete or Unavailable Information*. This regulation directs agencies how to proceed when evaluating reasonably foreseeable significant adverse effects on the human environment in an environmental impact statement and there is incomplete or unavailable information. While information describing the characteristics and potential effects of other projects and activities within the regions of influence is primarily qualitative and, in some cases is incomplete or unavailable, there is enough information to complete cumulative impacts analysis for the Mina rail corridor regions of influence.

4.1.3 RELATIONSHIP OF THIS ANALYSIS TO THE YUCCA MOUNTAIN FEIS CUMULATIVE IMPACTS ANALYSIS

The Yucca Mountain FEIS provided an analysis of potential cumulative impacts associated with construction and operation of a repository at Yucca Mountain. The portions of that analysis relevant and still valid to the Mina rail corridor (DIRS 155970-DOE 2002, Section 8.4.2) is incorporated in this Nevada Rail Corridor SEIS cumulative impacts analysis, as appropriate.

To evaluate potential environmental impacts, including cumulative impacts, of the revised repository design and operational plans, DOE has prepared *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F-S1) (Repository SEIS), which includes an analysis of cumulative impacts as they relate to the Yucca Mountain Repository. Section 4.2.1.2.1 includes a description of the repository, as currently proposed, and additional context about the repository as a reasonably foreseeable action. This Nevada Rail Corridor SEIS incorporates updated cumulative impacts analyses from the Repository SEIS, as appropriate.

4.1.4 RESPONSIBILITY FOR MITIGATION OF CUMULATIVE IMPACTS

DOE is responsible for impacts associated with activities for which it is the project proponent. DOE would plan and design a railroad within the Mina rail corridor to avoid sensitive and regionally important resources like Wilderness Areas and Wilderness Study Areas and to avoid or minimize impacts to sensitive environmental areas (such as wetlands) and private property. In addition, DOE would construct and operate the railroad in compliance with all applicable requirements. Actions undertaken by other proponents are subject to a variety of environmental requirements to avoid, minimize, or otherwise reduce adverse impacts on the environment.

To help comply with requirements and to eliminate or reduce potential environmental impacts, DOE would implement a variety of engineering site planning actions, and ***best management practices,*** all of which are parts of the Proposed Action. The DOE best management practices include the practices, techniques, methods, processes, and activities commonly accepted and used throughout the construction and railroad industries that facilitate compliance with applicable requirements and that provide an effective and practicable means of preventing or minimizing the environmental impacts of an action. Such practices would avoid, minimize, or otherwise reduce the direct and indirect environmental impacts of the DOE Proposed Action, thereby avoiding or minimizing the DOE contribution to direct, indirect, and cumulative environmental impacts in the Mina rail corridor cumulative impacts regions of influence.

To the extent the DOE Proposed Action would contribute cumulatively to impacts on regional resources, or to other activities such as BLM land management activities, DOE would take additional ***mitigation*** and monitoring actions to reduce identified impacts associated with its Proposed Action, as practicable. DOE continues to coordinate with public- and private-sector project proponents to foster adequate consideration of cumulative environmental issues.

4.1.5 ORGANIZATION OF THE ANALYSIS

Section 4.2 summarizes potential cumulative impacts associated with implementing the Proposed Action in the Mina rail corridor.

4.2 Mina Rail Corridor

Section 4.2.1 summarizes the projects and activities considered in this Nevada Rail Corridor SEIS cumulative impacts analysis. Section 4.2.2 describes the potential cumulative impacts identified in this Nevada Rail Corridor SEIS. Figure 4-1 shows the locations of these major projects and activities, including:

1. Naval Air Station Fallon
2. Federal and nonfederal actions on the Walker River Paiute Reservation
3. Hawthorne Army Depot
4. Walker River Basin Restoration
5. Monte Cristo’s Castle (proposed state park)
6. Timbisha Shoshone Trust Lands (federal land transfer)
7. Yucca Mountain Geologic Repository
8. Nevada Test Site
9. Nevada Test and Training Range

This section also considers other relevant projects and actions not shown on the map, such as:

- BLM planning and management actions – There are a variety of BLM past, present, and reasonably foreseeable actions within the three BLM management areas (Carson City, Battle Mountain, and Las Vegas) relevant to the Mina rail corridor.
- Various rights-of-way – Many future utility or other rights-of-way corridors are not shown on Figure 4-1 because specific routes are not known. For example, DOE and the BLM are preparing a programmatic EIS for potential designation of energy corridors on federal land in western states (DOE and BLM Energy Corridor Programmatic EIS; 70 *FR* 56647, September 28, 2005).
- Energy and mineral development activities.
- Other regional economic development plans and activities within Lyon, Mineral, Esmeralda, and Nye Counties.

The Mina rail corridor ranges in length from about 410 to 450 kilometers (255 to 280 miles), depending on the option considered. As a linear project, land disturbance and other direct impacts are most likely to occur within the relatively narrow construction and operations rights-of-way. However, for some resources, there could be other direct and indirect impacts outside the rights-of-way.

To evaluate the potential for cumulative impacts, DOE identified and reviewed public and private actions in the Mina rail corridor region of influence to determine if the impacts associated with these actions could coincide in time or space with potential impacts from construction and operation of the proposed railroad in the Mina rail corridor. Only those projects and activities DOE believes would have the potential for cumulative impacts are identified herein. In some cases, similar actions have been grouped together and listed by category of action.

4.2.1 PROJECTS AND ACTIVITIES INCLUDED IN THE CUMULATIVE IMPACTS ANALYSIS

4.2.1.1 Past and Present Actions

The descriptions of existing (baseline) environmental conditions and impacts (see Chapter 3) associated with the various environmental resource regions of influence for the Mina rail corridor considered in this Nevada Rail Corridor SEIS include the relationships between proposed railroad construction, operation, and abandonment, and past and present actions such as:

- Operations at major federal facilities such as the proposed Yucca Mountain Repository, the Nevada Test and Training Range, the Nevada Test Site, the Hawthorne Army Depot, and Naval Air Station Fallon
- BLM resource management planning and land management uses
- Traditional land uses such as regional ranching, mining, and recreation
- Military operations
- Walker River Basin restoration activities
- Residential, commercial, and industrial development activities associated with growth in the Mina rail corridor cumulative impacts region of influence, including the Pahrump area and the Reno-Carson City area adjacent to the northern portion of the Mina rail corridor region of influence.

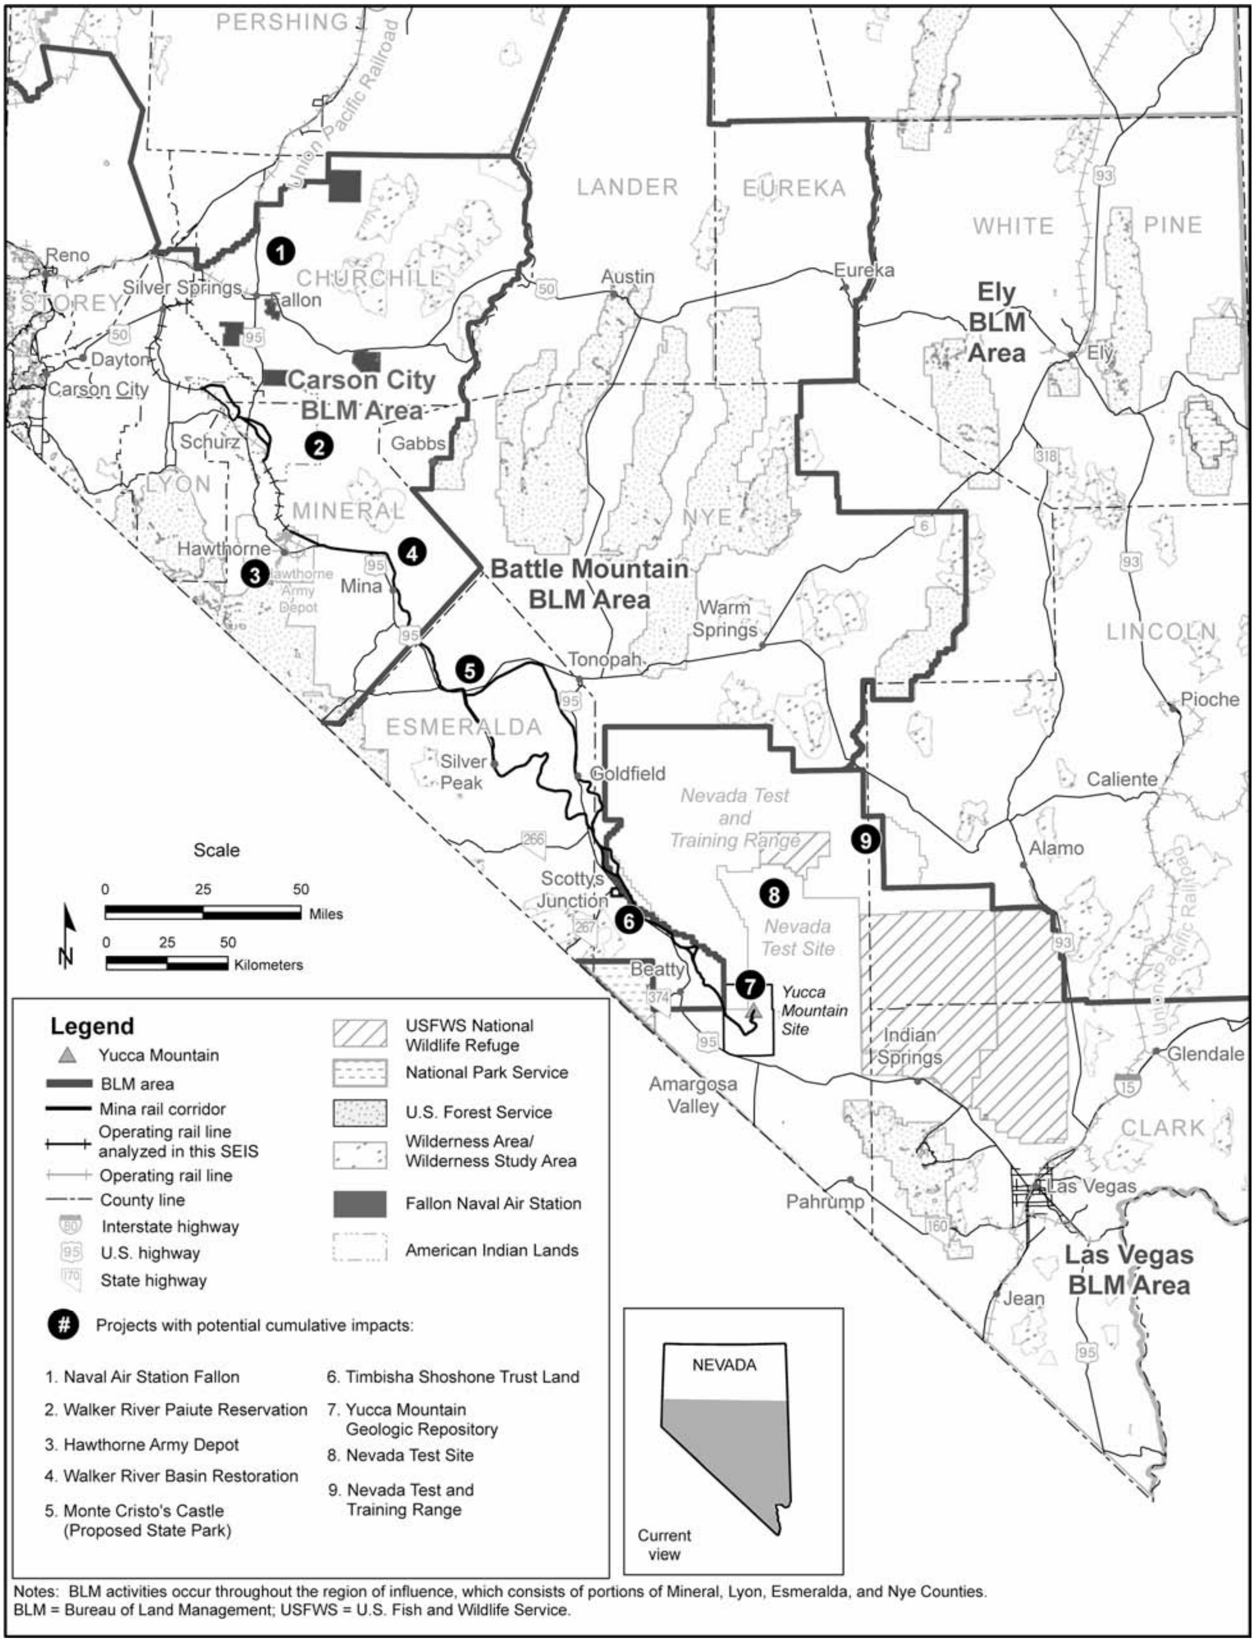

Figure 4-1. Major reasonably foreseeable future actions and continuing activities in the Mina rail corridor cumulative impacts region of influence.

DOE also considered reasonably foreseeable future actions and the continuation of existing actions in the Mina rail corridor cumulative impacts region of influence. Figure 4-1 shows the locations of individual projects and activities.

4.2.1.2 Reasonably Foreseeable Future and Continuing Federal Actions

Sections 4.2.1.2.1 through 4.2.1.2.8 describe reasonably foreseeable future and continuing federal agency actions that could result in cumulative impacts when combined with the incremental impacts of the Proposed Action.

4.2.1.2.1 Yucca Mountain Repository

The Proposed Action in this Nevada Rail Corridor SEIS is directly related to the proposed geologic repository at Yucca Mountain, which is a reasonably foreseeable project (see Figure 4-1, Project #7). In the Yucca Mountain FEIS (DIRS 155970-DOE 2002, all) and the *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Repository SEIS; DOE/EIS-0250F-S1) DOE proposes to construct, operate and monitor, and eventually close a geologic repository for the ***disposal*** of 70,000 metric tons (77,000 tons) of heavy metal of ***spent nuclear fuel*** and ***high-level radioactive waste*** in a ***repository*** at Yucca Mountain in Nye County, Nevada. The Department proposed to dispose of this material using the natural geologic features of Yucca Mountain, along with engineered barriers, as a total system to help ensure long-term ***isolation*** of the materials from the ***accessible environment***. As analyzed in the Repository SEIS, the repository design and associated construction and operational plans require the following:

- DOE spent nuclear fuel and high-level radioactive waste would be placed in disposable ***canisters*** at the DOE sites, and as much as 90 percent of the ***commercial spent nuclear*** fuel would be placed in transportation, aging, and disposal (TAD) canisters at the commercial sites prior to shipment. The remaining commercial spent nuclear fuel (about 10 percent) would be transported to the repository in dual-purpose canisters (canisters suitable for storage and transportation), or would be uncanistered.
- Most spent nuclear fuel and high-level radioactive waste would be transported from 72 commercial and 4 DOE sites to the repository in Nuclear Regulatory Commission-certified transportation casks placed on trains dedicated only to these shipments.
- At the repository, DOE would conduct waste handling activities to manage thermal output of the commercial spent nuclear fuel and to package the spent nuclear fuel into TAD canisters. The disposable canisters and TAD canisters would be placed into ***waste packages*** for disposal in the repository. A waste package is a container that consists of the barrier materials and internal components in which DOE would place the canisters that contained spent nuclear fuel and high-level radioactive waste.
- DOE would place approximately 11,000 waste packages, containing no more than a total of 70,000 metric tons (77,000 tons) of heavy metal, of spent nuclear fuel and high-level radioactive waste in the repository at Yucca Mountain.
- When authorized by the Nuclear Regulatory Commission, the repository would be closed permanently.
- The project would require surface and subsurface facilities and associated infrastructure, such as the onsite road and water distribution networks and emergency response facilities, a four-lane access road that would extend from U.S. Highway 95 to the existing access road at Gate 510.

- DOE assumes that the following facilities would be constructed outside the Yucca Mountain Site boundary: a training facility to support the Project Prototype Testing and the Operator Training and Qualification programs; temporary accommodations for construction workers; a Sample Management Facility to consolidate, upgrade, and improve storage and warehousing for scientific samples and materials; and a marshalling yard and warehouse for construction materials.

The Nuclear Regulatory Commission, through its licensing process, would regulate repository construction, operation and monitoring, and closure. Repository operations would only begin after the Commission granted DOE a license to receive and possess spent nuclear fuel and high-level radioactive waste. DOE is currently preparing an application to the Commission for authorization to construct the repository.

The Yucca Mountain FEIS and this Repository SEIS evaluate the cumulative impacts of two additional inventories (referred to as Modules 1 and 2), which include spent nuclear fuel and high-level radioactive waste in addition to that of the Proposed Action inventory, and other radioactive wastes generally considered unsuitable for near-surface disposal. Inventory Module 1 or 2 could have cumulative impacts on the operation of proposed railroad. Regarding potential cumulative impacts from Inventory Module 1 or 2, there would be no cumulative construction impacts because the need for a new railroad would not change; that is, any rail corridor DOE selected for construction of the proposed railroad to serve the Yucca Mountain FEIS Proposed Action would also serve Module 1 or 2. In addition, because the planned annual shipment rate of spent nuclear fuel and high-level radioactive waste to the Yucca Mountain Repository would be about the same for Module 1 or 2 and the Yucca Mountain FEIS Proposed Action, the only cumulative operations impacts would result because of the assumed increase in the number of casks required for Module 1 or 2. Because the Modules 1 and 2 inventories would exceed the NWPA disposal limit of 70,000 metric tons (77,000 tons) of heavy metal considered in the Yucca Mountain FEIS and Repository SEIS Proposed Actions, the emplacement of any such waste at Yucca Mountain would require legislative action by Congress unless a second licensed repository was in operation. The 70,000 metric tons of heavy metal limit is comprised of 63,000 metric tons (69,000 tons) of heavy metal from commercial utilities and 7,000 metric tons (7,000 tons) of heavy metal from DOE.

DOE is preparing the *Programmatic Environmental Impact Statement for the Global Nuclear Energy Partnership* (DOE/EIS-0396). Global Nuclear Energy Partnership (GNEP) would encourage expansion of domestic and international nuclear energy production while reducing nuclear proliferation risks, and reduce the volume, thermal output, and ***radiotoxicity*** of spent nuclear fuel before disposal in a geologic repository. DOE anticipates that its Programmatic EIS will evaluate a range of alternatives, including a proposal to recycle spent nuclear fuel and separate many of the high-heat ***fission products*** and the uranium and ***transuranic*** components. The full implementation of GNEP would involve the construction and operation of advanced reactors, which would be designed to generate energy while destroying the transuranic elements. DOE also anticipates evaluating project-specific proposals to construct and operate an advanced fuel-cycle research facility at one or more locations in the United States.

The United States use a “once through” fuel cycle in which a nuclear power reactor uses nuclear fuel only once, and then the utility places the spent nuclear fuel in storage while awaiting disposal. GNEP would establish a fuel cycle in which the uranium and transuranic materials would be separated from the spent nuclear fuel and reused in thermal or advanced nuclear reactors.

DOE anticipates that by about 2020 the commercial utilities will have produced about 86,000 metric tons (95,000 tons) of heavy metal of spent nuclear fuel, which exceeds the DOE disposal limit of 63,000 metric tons (69,000 tons) of heavy metal of commercial spent nuclear fuel at the Yucca Mountain Repository. If DOE were to decide, in a GNEP ***Record of Decision***, to proceed with its proposal to recycle spent nuclear fuel, the Department anticipates that the necessary facilities would not commence operations until 2020 or later. Although the spent nuclear fuel-recycling concept has not yet been implemented and the capacity of a separations facility has not been determined, one or more separations facilities could be designed with a total capacity sufficient to recycle the spent nuclear fuel discharged by commercial utilities. GNEP facilities initially could be designed to have the capacity to recycle the amount of spent nuclear fuel being generated by commercial utilities. Consequently, the Department believes there would be no change in the spent nuclear fuel and high-level radioactive waste inventory, and therefore the number of casks of spent nuclear fuel and high-level radioactive waste shipped to the Yucca Mountain repository analyzed under the Proposed Action in this Nevada Rail Corridor SEIS would remain unchanged (that is, the shipment of approximately 9,500 casks containing spent nuclear fuel and high-level radioactive waste that would be produced).

Overall, development of a GNEP fuel cycle has the potential to decrease the amount (number of assemblies) of spent nuclear fuel that would require geologic disposal, but would increase the number of casks of high-level radioactive waste requiring disposal in a geologic repository in the long term. Consequently, A GNEP fuel cycle could affect the nature of the inventory that represents the balance of Inventory Module 1 (that is, commercial spent nuclear fuel in amounts greater than 63,000 metric tons [69,000 tons] of heavy metal). Nevertheless, given the uncertainties inherent at this time in estimating the amount of spent nuclear fuel and high-level radioactive waste that would result from full or partial implementation of GNEP, this Nevada Rail Corridor SEIS analyzes rail transportation of approximately 9,500 casks of spent nuclear fuel and high-level radioactive waste.

The Department is currently preparing the *Disposal of Greater-Than-Class-C Low-Level Radioactive Waste Environmental Impact Statement* (DOE/EIS-0375). This EIS addresses the disposal of wastes with concentrations greater than Class C (GTCC), as defined in Nuclear Regulatory Commission regulations at 10 CFR Part 61, and DOE Low-Level Radioactive Waste and transuranic waste having characteristics similar to Greater-Than-Class-C waste and which otherwise do not have a path to disposal. DOE proposes to evaluate alternatives for GTCC low-level waste disposal in a geologic repository; in intermediate depth boreholes; and in enhanced near surface facilities. Candidate locations for these disposal facilities would be the Idaho National Laboratory in Idaho; the Los Alamos National Laboratory and the Waste Isolation Pilot Plant in New Mexico; the Nevada Test Site and the proposed Yucca Mountain Repository in Nevada; the Savannah River Site in South Carolina; the Oak Ridge Reservation in Tennessee; and the Hanford Site in Washington. DOE will also evaluate disposal at generic commercial facilities in arid and humid locations. The Repository SEIS evaluates the potential cumulative impacts of disposal of these wastes at Yucca Mountain as a reasonably foreseeable action, which are included in Inventory Module 2.

4.2.1.2.2 Nevada Test Site (Continuation of Activities)

The Nevada Test Site, adjacent to the Nevada Test and Training Range, engages in a number of defense-related material and management activities, waste management, environmental restoration, and non-defense research and development (see Figure 4-1, Project #8). The Nevada Test Site was established in 1951 as the Nation’s proving ground for developing and testing nuclear weapons. The site is on land administratively held by the BLM, but the Nevada Test Site land was withdrawn for use by the Atomic Energy Commission and its successors (including DOE). At present, the DOE National Nuclear Security Administration manages the site. It consists of about 3,200 square kilometers (800,000 acres) of land.

The *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996, all) described existing and projected future actions at the Nevada Test Site. That EIS was followed by a *Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 162638-DOE 2002, all). DOE activities at the Nevada Test Site include stockpile stewardship and management (helping ensure the U.S.

nuclear weapon stockpile is safe, secure, and reliable), materials disposition (removal of nuclear materials in a safe and timely manner), and nuclear emergency response. Activities at the Nevada Test Site since the 1996 EIS and 2002 supplement analysis have continued to support these missions in accordance with federal law, DOE policies and missions, and NEPA requirements. There are a number of other programmatic DOE waste management initiatives that can affect current and potential future operations at the Nevada Test Site, many of which require NEPA analyses. The Nevada Test Site also produces annual environmental reports that describe program activities and related environmental issues and activities.

DOE is currently preparing the *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement–Complex 2030* (Complex Transformation Supplemental PEIS [formerly known as the Complex 2030 SEIS]; DOE/EIS-0236-S4). That SEIS will analyze the environmental impacts of the continued transformation of the United States nuclear weapons complex by implementing the National Nuclear Security Administration's vision of the complex as it would exist in 2030, and alternatives to that action. Part of the proposed action in that SEIS is to identify one or more sites for conducting National Nuclear Security Administration flight test operations. Existing Department of Defense and DOE test ranges (for example, the White Sands Missile Range in New Mexico and the Nevada Test Site in Nevada) would be considered as alternatives to the continued operation of the Tonopah Test Range in Nevada.

Another part of the proposed action in the Complex Transformation Supplemental PEIS is to accelerate dismantlement activities. The DOE sites that will be considered as potential locations for the consolidated plutonium centers and consolidation of Category I (high strategic significance) and II (moderate strategic significance) special nuclear materials include Los Alamos National Laboratory, the Nevada Test Site, the Pantex Plant, the Y-12 National Security Complex, and the Savannah River Site.

DOE manages several types of radioactive and hazardous waste (***low-level radioactive waste***, ***mixed low-level waste*** [referred to as mixed waste], transuranic waste, high-level radioactive waste, and ***hazardous waste***) generated by past and present nuclear defense research activities at many DOE sites across the United States, including the Nevada Test Site. The Department manages each of those waste types separately because they have different components, levels of radioactivity, and regulatory requirements. DOE needs facilities like the Nevada Test Site to manage its radioactive and hazardous wastes to maintain safe, efficient, and cost-effective control of these wastes; comply with applicable federal and state laws; and protect public health and safety and the environment. In *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DIRS 101816-DOE 1997, all) DOE evaluated the environmental impacts of managing the five waste types. The Nevada Test Site will continue to be a major facility involved in DOE waste management programs, including serving as a disposal site for certain waste types generated off the site, and for on-site wastes primarily from environmental restoration and remediation activities.

The Nevada Test Site is a candidate disposal location for Greater-Than-Class-C Low-Level Radioactive Waste which is currently being examined in the *Disposal of Greater-Than-Class-C Low-Level Radioactive* Waste *Environmental Impact Statement* (DOE/EIS-0375). That DOE EIS will address the disposal of wastes with concentrations greater than Class C, as defined in Nuclear Regulatory Commission regulations at 10 CFR Part 61, and DOE low-level radioactive waste and transuranic waste having characteristics similar to Greater-Than-Class-C low-level waste and that might not have an identified path to disposal. DOE proposes to evaluate alternatives for Greater-Than-Class-C low level waste disposal in a geologic repository; in intermediate-depth boreholes; and in enhanced near-surface facilities.

4.2.1.2.3 BLM Resource Planning and Management

The presence of BLM-administered public land is a very important factor affecting how and where activities occur within the region of influence. Many private and federal projects in the region of influence, including the proposed ***railroad***, would involve use of BLM-administered land. Therefore, these projects would require BLM-issued ***right-of-way grants*** before they could proceed. Right-of-way grants have two general forms: linear (applicable to such projects as transmission lines, railroads, and pipelines), and non-linear (applicable to projects at one specific location). Rights-of-way on BLM-administered land are extensive in the region. These rights-of-way vary greatly in size and scope of activity, ranging from small communication sites to large linear rights-of-way for highways or transmission lines.

The BLM administers most of the public lands along the proposed Mina rail corridor. The BLM manages these lands through a multiple-use concept (which means managing public lands and their various resource values so that they are utilized in the combination that will best meet the present and future needs of the American people) in accordance with the Federal Lands Policy and Management Act of 1976 (43 U.S.C. 1732 *et seq*.) and other federal legislation. The proposed Mina rail corridor would cross three BLM management areas (Carson City, Battle Mountain, and Las Vegas). The Carson City Field Office manages its federal lands through a Consolidated ***Resource Management Plan*** developed in 2001. The Carson City Field Office was previously divided into eight planning units, all of which were consolidated into the 2001 Carson City Resource Management Plan. The Battle Mountain and Las Vegas management areas are operating under resource management plans adopted in 1998 and 1997, respectively (DIRS 176043-BLM 1998, all; DIRS 173224-BLM 1997, all).

Grazing operations are a major BLM land-management program in the Mina rail corridor region of influence and result in both direct and indirect cumulative impacts to vegetation, habitats, and wildlife.

The Mining and Mineral Policy Act of 1970 (30 U.S.C 1601 *et seq.*) declares that it is the continuing policy of the federal government to foster and encourage private enterprise in the development of a stable domestic minerals industry and orderly economic development of domestic mineral resources, including sand and gravel, geothermal, coal, and oil and gas. Sections 102(a)(7), (8), and (12) of the Federal Land Policy and Management Act of 1976, directs public lands be managed in a manner that recognizes the Nation's need for domestic sources of minerals and other resources. The Geothermal Steam Act of 1970 (30 U.S.C 1001 *et seq*.), which was amended and supplemented by the Energy Policy Act of 1992 as amended (42 U.S.C 13201 *et seq.*) provides the framework for geothermal leasing by the BLM. The BLM Carson City Field Office may issue leases for geothermal resources located in multiple areas within the Mina rail corridor cumulative impacts region of influence.

4.2.1.2.4 Walker River Paiute Reservation (Federal Actions)

The Walker River Paiute Reservation consists of more than 130 square kilometers (323,000 acres) of land between Yerington, Nevada, and Walker Lake (See Figure 4-1, Project #2). Although the Reservation is recognized as a sovereign entity under the non-federal actions discussion below, federal agencies could also be taking actions on the Reservation. The Bureau of Indian Affairs operates the Weber Dam and Weber Reservoir, which impounds water from the Walker River just north of the community of Schurz for use on the Reservation. Constructed in the 1930's, the dam needs several repairs and modifications to address a number of deficiencies identified as a result of inspections and a safety analysis conducted in the 1980s under the Bureau of Indian Affairs Dam Safety Maintenance and Repair Program, created as part of the Indian Dams Safety Act. Additionally, the U.S. Fish and Wildlife Service is involved in recovery efforts for the threatened Lahontan cutthroat trout (*Oncorhynchus clarki henshawi*). Lahontan cutthroat trout are stocked in Walker Lake and occur in the Walker River upstream to Weber Reservoir. Weber Dam currently blocks movement further upstream, and prevents spawning by cutthroat trout;

however, in the near future a fish ladder might be developed at that dam to allow fish movement. Reestablishment of a self-sustaining population of Lahontan cutthroat trout in the Walker River system is a prerequisite for recovery of this species.

4.2.1.2.5 Nevada Test and Training Range (Continuation of Activities)

The U.S. Air Force operates the Nevada Test and Training Range in south-central Nevada (see Figure 4-1, Project #9), a national test and training facility for military equipment and personnel consisting of approximately 12 million square kilometers (3 million acres). Military training maneuvers and jet aircraft are visible in the Mina rail corridor cumulative impacts study area. In 2005, the U.S. Air Force designated the Indian Springs Air Force Auxiliary Airfield to Creech Air Force Base and expanded its mission and infrastructure to play a major role in the war on terrorism. The base is home to two key military operations: the MQ-1 unmanned aerial vehicle and the Unmanned Aerial Vehicle Battle laboratory.

The 1,600-square-kilometer (390,000-acre) BLM-administered National Wild Horse Management Area is within the boundary of the Nevada Test and Training Range. More than 3,200 square kilometers (800,000 acres) of the Nevada Test and Training Range comprise the Desert National Wildlife Range. The U.S. Air Force and the U.S. Fish and Wildlife Service jointly manage this area.

In *Renewal of the Nellis Air Force Range Land Withdrawal: Legislative Environmental Impact Statement* (DIRS 103472-USAF 1999, all) the U.S. Air Force addressed the potential environmental consequences of extending the land withdrawal to continue using the Nevada Test and Training Range lands for military use. Activities at the Nevada Test and Training Range change, as necessary, to meet military test and training needs.

In 2004, the BLM prepared a resource management plan for about 8,900 square kilometers (2.2 million acres) of withdrawn public lands within the Nevada Test and Training Range (DIRS 178102-BLM 2004, all). The plan guides the management of the affected Nevada Test and Training Range natural resources 20 years into the future (2024). The decisions, directions, allocations, and guidelines within the plan are based on the primary use of the withdrawn area for military training and testing purposes.

4.2.1.2.6 Hawthorne Army Depot

The Hawthorne Army Depot occupies more than 590 square kilometers (147,000 acres) in Mineral County, Nevada (see Figure 4-1, Project #3). Hawthorne Army Depot was commissioned in 1930 as a Naval ammunition depot, and was transferred to the Army in October 1977, and renamed Hawthorne Army Ammunition Plant. It was converted to a government-owned, contactor-operated installation in December 1980. In 1994 the name changed back to the Hawthorne Army Depot. Control of Hawthorne Army Depot is maintained by the U.S. Army, which is responsible for the plans, installation, operation, and equipment of the Depot. The mission of Hawthorne Army Depot is to support the Army, Air Force, and Navy. It also has the capabilities to receive, maintain, store, and issue ammunition and explosive ordnance items. The Hawthorne Army Depot also has the responsibility to renovate, recover, or dispose of unserviceable ammunition and explosives. These latter operations are referred to as demilitarization activities.

The primary ordnance areas at Hawthorne Army Depot extend over 400 square kilometers (100,000 acres) that cross U.S. Highway 95. This area is surrounded on its northeast, east, south, and west by fencing and on its north and northwest by a boundary line that includes a portion of Walker Lake. The southern one-third of Walker Lake is within the ordnance area. The Mount Grant watershed is in the northwest part of the installation. This watershed consists of about 180 square kilometers (45,000 acres), and is a resource that Hawthorne Army Depot maintains to supply its primary potable water needs.

Hawthorne Army Depot has 2,572 buildings and structures, which are comprised of offices, production buildings, ammunition storage magazines, and warehouses. The Depot is bordered by BLM-administered public grazing lands, and the installation completely surrounds the town of Hawthorne. Hawthorne Army Depot is planning to construct a rail siding, known as the Wabuska Spur, which would increase the Depot's outloading capacity.

4.2.1.2.7 Naval Air Station Fallon

Naval Air Station Fallon is in the Lahontan Valley of west-central Nevada, approximately 113 kilometers (70 miles) east of Reno and 10 kilometers (6 miles) southeast of the City of Fallon (See Figure 4-1, Project #1). NAS Fallon administers approximately 32 square kilometers (7,900 acres) of withdrawn and acquired land associated with the air station and 95 square kilometers (234,000 acres) of land associated with the Fallon Range Training Complex. The Fallon Range Training Complex airspace overlies portions of Washoe, Lyon, Churchill, Pershing, Mineral, Nye, Lander, and Eureka counties, most of which is BLM-administered public land.

In January of 2005, the Navy and the BLM issued the *Final Environmental Impact Statement: Proposed Fallon Range Training Complex Requirements Naval Air Station Fallon, Nevada*. The Naval Strike and Air Warfare Center at Naval Air Station Fallon proposes to implement changes at the Fallon Range Training Complex to meet Chief of Naval Operations-mandated training requirements resulting from the real world threat environment. The proposed changes would allow the Navy to update and consolidate Navy training on public and Navy-administered lands and to update existing airspace overlying these lands. The changes evaluated in that EIS include developing new fixed and mobile electronic warfare sites, developing new tracking instrumentation subsystem sites, developing additional targets at two of its training ranges, laying fiber-optic cable to two training ranges, utilizing Navy-administered lands in Dixie Valley for close-air-support training, performing Hellfire missile and high altitude weapons delivery training at two of its training ranges, and changes to special use airspace. That EIS provided a comprehensive evaluation of the environmental impacts, including cumulative impacts, associated with the Navy's proposed changes.

4.2.1.2.8 Timbisha Shoshone Trust Land (Federal Action)

The Secretary of the Interior issued a draft report to Congress (DIRS 103470-Timbisha Shoshone Tribe [n.d.], all) describing a plan to establish trust lands for people of the Timbisha Shoshone Tribe in portions of the Mojave Desert in eastern California and southwestern Nevada (See Figure 4-1, Project #6). On November 1, 2000, the President signed Bill S. 2102 (Public Law 106-423) to provide a permanent land base for the Timbisha Shoshone Tribe within its ancestral homeland in five separate parcels. Lands in the designated area for tribal purposes were then identified, including land parcels containing water rights. The parcel near Scottys Junction (about 11 square kilometers [2,800 acres]) is approximately 3.2 kilometers (2 miles) from the proposed Mina rail corridor. The Timbisha Shoshone Tribe is actively evaluating economic development opportunities on this Scottys Junction parcel. The locations and nature of these future development opportunities are not known and are not considered to be reasonably foreseeable for purposes of this cumulative impacts analysis.

4.2.1.3 Reasonably Foreseeable Future Non-Federal Actions

Non-federal and private actions in the Mina rail corridor cumulative impacts region of influence primarily involve mineral resource development projects, Walker River Paiute tribal activities, and some residential and general economic development initiatives and efforts. As previously noted, many of these privately sponsored projects would interact with the BLM land-management policies and procedures through the need to acquire right-of-way grants to initiate proposed activities on BLM-administered land.

4.2.1.3.1 Walker River Paiute Reservation

The Walker River Paiute Reservation consists of more than 130 square kilometers (323,000 acres) of land between Yerington, Nevada, and Walker Lake (see Figure 4-1, Project #2). The 2000 census reported a population of 853 on the Reservation. The rural community of Schurz is the only community within the boundaries of the Reservation. Land use on the Reservation consists primarily of open range used for cattle grazing or other agricultural activities. The Department of Defense Branchline from Wabuska extends south through the Reservation to its termination point at the Hawthorne Army Depot.

4.2.1.3.2 Power Plants, Transmission Lines, Pipelines, and Other Infrastructure

There are transmission lines, pipelines, and telecommunications infrastructure within the Mina rail corridor cumulative impacts region of influence. The region of influence has the potential for wind, solar, and geothermal energy development, although the magnitude and specific locations of these energy development projects are not known. As indicated in Section 4.2.1.2.3, the BLM may issue geothermal leases within the Mina rail corridor region of influence. The approval of any leases and subsequent development of geothermal resources would be subject to environmental review and would be guided by BLM resource management plans.

The BLM has designated certain corridors in the area that should be used for most utility purposes; however, use of other BLM-administered land requiring new right-of-way grants has traditionally been considered on a case-by-case basis. As previously noted, the DOE and BLM Energy Corridor Programmatic EIS is an attempt to identify appropriate right-of-way corridors throughout the western United States, including Nevada. This effort could influence the location of rights-of-way in the Mina rail corridor cumulative impacts region of influence in future years.

4.2.1.3.3 Mining

The region of influence contains a variety of mineral resources, with ***mining claims*** filed in accordance with BLM requirements, and several operating mines. Establishment of mining claims on federal land do not necessarily ever lead to actual development of mining operations on those sites. Major cumulative impact issues involving mining projects include potential land-use conflicts and wastes from mining operations. Mineral resource locations of note within the region of influence include:

- Nevada Western Silica Corporation holds mining claims for a large, high-grade silica deposit near Lida Junction, south of Goldfield in Esmeralda County. There are at least 24 million cubic meters (32 million cubic yards) of silica on site. The Mina rail corridor passes within 2.4 kilometers (1.5 miles) of the claims.
- Chemetall Foote Corporation runs an operation in Silver Peak, Nevada, that mines lithium carbonate. The company pumps lithium rich groundwater to the ground surface and then collects the lithium powder as the water evaporates. Chemetall Foote pumps the groundwater onto dry lake beds in the Clayton Valley to facilitate the evaporation process. Once removed from the water, the raw lithium material is processed in an on-site plant into market-ready, lithium-containing products.
- Metallic Ventures Gold holds mining claims near Goldfield in a historic high-grade gold-producing district. The project is currently in the pre-feasibility stage of development.

Mining activities are expected to continue within the Mina rail corridor cumulative impacts region of influence. Mining activities are heavily regulated and must comply with all applicable environmental laws, rules, and regulations. The BLM has an extensive regulatory framework for mineral resource development on federal lands that strives to balance mining activities and mineral extraction with other resource management goals.

4.2.1.3.4 Walker River Basin Restoration

The decline in water quality throughout the Walker River Basin, particularly in Walker Lake, and concerns related to the Lahontan Cutthroat Trout, have resulted in organized restoration efforts throughout the basin (See Figure 4-1, Project #4). The water level in Walker Lake has dropped substantially since the late 1800s, and levels of total suspended solids have increased. The increased levels of total dissolved solids, along with other physical, biological, and chemical conditions in the watershed and lake, have stressed fisheries and other aquatic life in the lake and changed the resident fish population. The Walker Lake Working Group is a nonprofit organization building public support for developing a long-term solution to protect the lake without jeopardizing the upstream community. The Group has developed a restoration strategy focused on three objectives: 1) reestablishment of spawning runs of the Lahontan cutthroat trout; 2) providing sufficient water so that total dissolved solids levels are low enough to support the Walker Lake ecosystem; and 3) acquiring and transferring water rights for environmental and recreational purposes.

4.2.1.3.5 Monte Cristo's Castle (Proposed State Park) (This has a federal component involving the BLM.)

In 2005, the State of Nevada proposed a new state park near Blair Junction (See Figure 4-1, Project #5). If approved, the park would be known as Monte Cristo's Castle and would highlight the unique geology of the area. As proposed, the park would include approximately 23 square kilometers (5,800 acres) of land just north of the intersection of U.S. Highway 95 and State Route 265 at Blair Junction. As currently envisioned, the proposed park would include hiking areas and interpretive trails with displays about the unique geologic formations in the area. In June 2007, the Nevada State Legislature provided for establishment of the State Park, which would be on land currently administered by the BLM. To transfer the land to the State of Nevada for establishment of the State Park, the BLM would perform an environmental assessment and other work required as part of the Recreation and Public Purpose Lease process.

4.2.1.3.6 Other Regional Economic Development

Cumulative impacts issues associated with regional economic development actions include socioeconomic effects and overall growth in the region of influence. There are several ongoing or planned regional economic development initiatives in the northern portion of the Mina rail corridor cumulative impacts region of influence south and east of the Carson City/Reno area. For example, a county-owned airport near the community of Silver Springs, Nevada, plans to expand its operations, pave its runway, and promote the development of nearby industrial parks totaling approximately 3.8 square kilometers (950 acres). Western Nevada Rail Park is approximately 1 kilometer (35 miles) east of Reno along Alternate U.S. Highway 50. When complete, the rail park would include roughly 1 square kilometer (240 acres) of industrial park serviced by the Union Pacific Railroad mainline. A master-planned community is being developed near the community of Dayton, Nevada. The development contains approximately 12 square kilometers (2,900 acres) consisting of approximately 2,300 single family homes, 0.02 square kilometer (4 acres) of multi-family units, 0.11 square kilometer (27 acres) of commercial land, 1 square kilometer of industrial land, and 0.08 square kilometer (20 acres) for a resort/casino and an improved 1,600-meter (5,400-foot) airstrip. Support infrastructure, including new elementary, middle, and high schools, fire station, municipal water and wastewater utilities, community center, and a health and fitness center, are already in place to support the development. As the Reno and Carson City metropolitan areas continue to grow and expand, additional privately sponsored developments can be expected within the northern portion of the Mina rail corridor cumulative impacts region of influence.

Additionally, major transportation corridors such as U.S. Highway 95 through the region of influence into both the Reno and Las Vegas areas will continue to grow and expand, and present additional regional economic development opportunities. A perceived need for support to the Nevada Test Site has led the Nye County Economic Development Board to designate the Nevada Science and Technology Corridor. The Science and Technology Corridor extends from Indian Springs in Clark County in the south to Tonopah in the north, passing through the Pahrump Valley, Mercury (entrance to the Nevada Test Site), Amargosa Valley, Beatty and Goldfield, with industrial park and technology initiatives associated with the Tonopah Aeronautics and Technology Park, the Nevada Science and Technology Park in Amargosa Valley, and the Pahrump Center for Technology Training and Development. The locations and nature of specific future development opportunities are not known and are not considered to be reasonably foreseeable for the purposes of this cumulative impacts analysis.

Nye County has completed a Yucca Mountain Project Gateway Area Concept Plan with proposed activities for the area around the entrance to the proposed repository site (DIRS 182345-Nye County 2007, all). This plan presents Nye County’s conceptual, multi-phased land-use guidance for communities adjacent to and near the site entrance area. Nye County proposed this plan with the objective that land development would occur in an orderly and consistent manner and to increase opportunities for industrial and commercial development beneficial to the repository program. Nye County views this plan as a starting point for development of the infrastructure, institutional capacity, and facilities to support the proposed repository. The county developed the plan to use and manage existing initiatives while expanding and improving the area.

4.2.2 POTENTIAL CUMULATIVE IMPACTS

Located primarily in portions of Esmeralda, Nye, Lyon, and Mineral Counties, the Mina rail corridor cumulative impacts region of influence covers millions of acres of land. Most of this land is undeveloped federally managed public land, although much of it has been affected by such human activities as ranching and mining.

Potential cumulative impacts are often discussed herein within the context of the existing regulatory framework (primarily federal and state laws and regulations) and the BLM resource management planning goals and objectives. For example, the existing regulatory frameworks for water and air consider a regional and cumulative impacts perspective, because regulatory decisions consider the potential effects from other projects and a proposed action. As the primary regional land manager, BLM planning and management actions consider the cumulative effects for many resources through stated planning goals and objectives, which are often based on quantitative criteria.

The following analysis of potential cumulative impacts associated with the Mina rail corridor is organized by resource area, with Sections 4.2.2.1 through 4.2.2.12 summarizing potential cumulative impacts in the same order of resource discussions in Chapter 3.

4.2.2.1 Land Use and Ownership

4.2.2.1.1 Land-Use Changes

Many of the past, present, and reasonably foreseeable future actions in the Mina rail corridor region of influence result in land use changes. Land-use change can also alter land ownership and land-management responsibilities, and preclude future activities from these areas. Most of the land in the Mina rail corridor region of influence is BLM-administered land in Lyon, Mineral, Esmeralda, and Nye Counties. The BLM manages more than 45,000 square kilometers (11 million acres) in those four counties. One of the primary land uses in and around the proposed Mina rail corridor on those

BLM-administered lands is grazing. Regional grazing activities are often affected by BLM land-management plans and activities.

Other existing and reasonably foreseeable major land uses in the Mina rail corridor region of influence include:

- Reno and Carson City Expansion – A minimum of approximately 25 square kilometers (6,300 acres) of industrial, commercial, and residential developments associated with growth and expansion of the Reno and Carson City Metropolitan areas into the northern portion of the Mina rail corridor cumulative impacts region of influence.
- Hazen industrial parks – Two industrial parks at Hazen are being developed. The Great Basin Industrial Park, a 9.3-square-kilometer (2,300-acre) industrial and residential project is being developed alongside the existing Union Pacific Railroad mainline. Churchill County has already approved this project. The Rail Park across the Union Pacific Railroad mainline from the Great Basin Industrial Park spans approximately 1.9 square kilometers (480 acres) and is currently in the planning stage.
- Naval Air Station Fallon and the Fallon Range Training Complex – Naval Air Station Fallon administers approximately 30 square kilometers (8,000 acres) of withdrawn and acquired land associated with the air station and 950 square kilometers (234,000) acres of land associated with the Fallon Range Training Complex.
- Walker River Paiute Reservation – Approximately 1,300 square kilometers (323,000 acres) of land managed by the Walker River Paiute Tribal Council.
- Hawthorne Army Depot – Approximately 600 square kilometers (147,000 acres) of land managed by the Army for purposes of receiving, issuing, storing, renovating, inspecting, demilitarizing, and disposing of conventional ammunition. An offer from a private firm of 40 square kilometers (10,000 acres) to expand the Depot's military training and other missions is in the preliminary planning stages.
- Nevada Test and Training Range – About 12,000 square kilometers (3 million acres) of land the U.S. Air Force has withdrawn for special-purpose use, with about 530 square kilometers (130,000 acres) of that land disturbed by Air Force tactical target complexes and associated infrastructure.
- Nevada Test Site – About 3,200 square kilometers (800,000 acres) of land DOE has withdrawn for special-purpose use.
- Yucca Mountain Repository – About 6.3 square kilometers (1,600 acres) of land disturbance, most of which would be on the Nevada Test Site (already withdrawn for Nevada Test Site activities).
- Right-of-way corridors that might be established when the DOE and BLM Energy Corridor Programmatic EIS is completed.

The proposed Mina rail corridor would disturb up to 41 square kilometers (10,000 acres) of land, most of which would be within the nominal width of the rail line construction right-of-way. Therefore, the proposed Mina rail corridor would directly affect about 0.25 percent of the BLM-administered land in the four counties. The Mina rail corridor would cross up to 15 separate grazing allotments, which constitute about 11,700 square kilometers (2.9 million acres) of BLM-administered land. The approximate disturbance area associated with the proposed Mina rail corridor would constitute less than 1 percent of the land within those 15 grazing allotments. Within this regional perspective of nearby existing and reasonably foreseeable land uses and land ownership, the commitment of land for the proposed Mina rail corridor and associated facilities would constitute a small proportion of overall cumulative land commitment. Use of private land for the proposed rail line would be small, and the rail line would not displace existing or planned land uses on private lands over a substantial area, nor would they substantially conflict with applicable land-use plans or goals.

Considering both the proposed railroad and existing and reasonably foreseeable land uses and land ownership in the Mina rail corridor region of influence, cumulative impacts from land-use changes would be small.

4.2.2.1.2 Existing or Potential Land-Use Conflicts

The Federal Government administers most of the land in the Mina rail corridor region of influence, with the BLM, DOE, and the Department of Defense (Air Force and Army) acting as the major federal land managers. The Mina rail corridor region of influence also includes Walker River Paiute Reservation lands. Private land holdings are small, and generally associated with Chemetall Foote Corporation's lithium mine near Silver Peak and other towns in the Mina rail corridor region of influence. Traditional land uses in most of the Mina rail corridor region of influence that would be directly and indirectly affected include grazing, mining, and wildlife management. Much of this land is not extensively disturbed, although it has been modified through activity such as grazing and mining.

Over time, human activity in the area, while relatively minor on a regional basis, has begun to change the natural and traditional conditions, and land-use conflicts occasionally result from this human activity. The Nevada Test Site and Nevada Test and Training Range lands have been withdrawn for special purpose and use. Both of these areas are inaccessible to the general public and land use is that of "dominant use," in which the specific DOE and U.S. Air Force missions, respectively, for these lands have ultimate priority over all other potential land uses. Hawthorne Army Depot and Naval Air Station Fallon lands were also withdrawn for special use, are inaccessible to the general public, and land use is that of dominant use in which the specific Army and Navy missions, respectively, for these lands have ultimate priority over all other potential land uses. Walker River Paiute Reservation lands are managed by a sovereign tribal government and used by Reservation inhabitants accordingly. Around these primary regional land uses are other uses, including mineral development, recreation, urban development, and rights-of-way for various infrastructure. All of these activities and land uses result from a much more intensive land usage involving human activity.

Construction and operation of a railroad in the proposed Mina rail corridor could have direct and indirect conflicts with grazing uses, access to grazing infrastructure, access to mineral resources, recreational resources, other linear rights-of-way (for example, utility corridors), and wildlife movement patterns in some locations.

Even with the existing and reasonably foreseeable land-use changes, the region as a whole would continue its traditional ways, with grazing and wildlife habitat as major land uses. Cumulative impacts related to land-use conflicts would be small.

4.2.2.1.3 Energy and Mineral Development

Existing and potential future energy and mineral development occurs in various locations throughout the Mina rail corridor cumulative impacts region of influence. In addition to the traditional energy and mineral development (primarily hard-rock mining and industrial mineral development), more recently this development includes geothermal and wind resources. The BLM administers energy and mineral development, evaluates and approves various proposed mineral-development operations, and evaluates and approves geothermal energy development projects on federal lands proposed by private companies. The existing energy development environment includes a mix of old and new, involving both non-renewable and renewable energy resource development.

Because of the scope and extent of typical mining operations, mineral resources that become actual operating mines could result in environmental and land-use issues. Within the Mina rail corridor region of influence, most mining-and energy-development activities would occur on federal lands, and the BLM will have a major role in mitigating and monitoring potential effects through its mining and reclamation requirements, NEPA, and other elements of the regulatory framework. Mineral exploration will continue to occur in many parts of the Mina rail corridor region of influence, and some level of conflict from mining exploration and development with other land uses could be unavoidable.

Any potential conflict of the proposed railroad with energy and mineral development would be small in scope and occur in localized areas, and the effects of any such conflicts would be mitigated through the existing regulatory framework and BLM policies and plans. All existing and foreseeable projects would be subject to regulatory requirements and BLM policies and plans related to energy and mineral development. Therefore, cumulative impacts resulting in land-use conflicts related to energy and mineral development in the Mina rail corridor would be small.

4.2.2.1.4 BLM Land Sales and Other Disposals

While specific initiatives for land disposals in the Mina rail corridor region of influence have not yet been developed, the BLM has plans to designate for potential future disposal (sale) approximately 750 square kilometers (185,000 acres) of public lands in the area, including lands that are difficult and uneconomic to manage (for example, scattered parcels south of Hawthorne and in Smith and Mason Valleys, checkerboard lands near Fernley, Silver Springs, and the Carson sink); land that would support community expansion (such as land west of Yerington, land surrounding the towns of Luning, Mina, Sodaville, Fallon, Gabbs, Reno, Verdi, and lands east of Montgomery Pass, near Honey Lake Valley and Dixie Valley); lands with possible agricultural potential (for example, Smith Valley, Mason Valley, Honey Lake Valley, and Edwards Creek); and lands along the East Walker River identified for exchange to benefit BLM programs.

Approximately 91 square kilometers (22,600 acres) have been identified for potential disposal in the vicinity of the Goldfield, about 23 square kilometers (5,800 acres) have been identified for potential disposal near Scottys Junction, and 160 square kilometers (39,000 acres) have been identified for potential disposal near Beatty. Land disposal areas have also been identified near Coaldale Junction, Blair Junction, Silver Peak, and Millers.

While the proposed railroad would operate within the regional context of the BLM land-disposal efforts and any related implications and effects, the railroad would have no affect on, nor would it be affected by, the BLM land-disposal efforts.

4.2.2.1.5 Recreational Land Use

Public lands in the Mina rail corridor region of influence provide a number of diverse recreation opportunities, and the BLM has designated certain lands as recreation management areas. Demand for recreation is increasing as more people move to and recreate in the Mina rail corridor cumulative impacts region of influence. Dispersed recreation, the principal opportunities available within the Mina rail corridor region of influence, requires a variety of sites but needs no special facilities. These opportunities include caving, photography, automobile touring, backpacking, bird watching, fishing, hunting, primitive camping, hiking, rock climbing, and competitive and non-competitive off-highway vehicle events. An example of increasing interest in recreation areas is the proposal for the Monte Cristo's Castle as a state park near Blair Junction; this park would highlight the unique geology of the area and include hiking areas and interpretive trails with displays about the geologic formations in the area.

The BLM has a major role in recreation opportunities in the Mina rail corridor region of influence. BLM field offices regularly evaluate new opportunities for recreational resources that would provide both passively and actively managed recreation opportunities. There are many such areas that the BLM has designated for recreational use, such as a campground and other day-use facilities at Walker Lake, which attract about 35,000 visitors per year. Other forms of dispersed recreation in the region of influence include hunting, camping, and off-highway vehicle use. Increased demand for off-highway vehicle use from the increasing regional population, including the Las Vegas and Reno-Carson City areas, is expected to continue. Many areas of BLM-administered land in Clark County previously used for off-highway vehicle recreation have been closed, causing a shift in use into other BLM areas. As growth and development occur in the Mina rail corridor cumulative impacts region of influence, recreational resources will continue to be in demand, but the potential for conflict with recreational resources also will increase. Recreational resource locations, quality, and availability will evolve as the Mina rail corridor region of influence changes.

For a variety of reasons, the Pahrump area is growing very rapidly. Both developed and undeveloped recreational opportunities in the area are abundant, with very easy access to public lands for activities such as hiking, camping, sightseeing, and rockhounding. The town of Pahrump is planning for development of 6 square kilometers (1,500 acres), to be called the Last Chance Park, on lands currently administered by the BLM and already used for various types of recreation. The plans include construction of access roads, restrooms, parking areas, and turn-outs, and the placing of signs, bike racks, benches, a pole-and-cable fence, trash cans, and picnic tables. Much of the park would be dedicated to horseback riding, hiking, and biking paths, with the remainder allotted to all-terrain vehicle motorized use. Potential environmental impacts and issues will be identified and assessed through the NEPA process.

DOE has sited the proposed Mina rail corridor to avoid Wilderness Areas and other major recreational resources to the maximum extent practicable. Given the limited effects on regional population, vast regional recreational opportunities, and limited direct interaction of the proposed railroad with recreational resources, cumulative impacts to access to and use of recreational resources in the Mina rail corridor region of influence would be small.

4.2.2.1.6 BLM Rights-of-Way

As urbanization and other development occur in the Mina rail corridor region of influence, the need for utility and other rights-of-way will increase. The BLM has developed certain preferred corridors over federal lands that it uses to the maximum extent possible for linear rights-of-way, such as for utilities. This keeps many right-of-way purposes together in one location instead of spreading them out over more dispersed areas.

The land-use changes authorized by a BLM right-of-way grant would also have the potential to impact other resource areas as those land-use changes occur. Before approval of right-of-way applications, the BLM evaluates the impacts of the projects through appropriate NEPA evaluation. Use of land for right-of-way purposes is consistent with BLM regulations and planning processes, and any land-use changes or disturbances associated with those rights-of-way are mitigated to the extent practicable and according to BLM policies. As required for the issuance of rights-of-way, the project proponent prepares and submits to the BLM a Plan of Development for each proposed right-of-way. The Plan of Development describes the methods and procedures to be used to construct the proposed action on the right-of-way, including site-specific stipulations, terms, and conditions to satisfy all BLM requirements. Certain rights-of-way are long-term and result in unavoidable impacts through land disturbance and the exclusion of other present or future land uses.

Utility and other right-of-way crossings are common to linear projects such as roads, railroads, and pipelines. Land areas for the Mina rail corridor would cross or overlap existing or proposed utility rights-of-way in approximately 22 to 29 locations. This situation would be typical of other linear rights-of-way. The crossings would be accomplished with small impact using standard engineering procedures and appropriate design details.

Cumulative impacts to BLM rights-of-way and right-of-way holders would be small.

4.2.2.1.7 Other BLM Land-Management Actions

The Federal Land Policy Management Act of 1976 (Public Law 94-579) mandates that the BLM manage its public lands from a multiple-use perspective. The Federal Land Policy Management Act specifically mentions balancing renewable and nonrenewable resources, including but not limited to, recreation, range, timber, minerals, watershed, wildlife, fish, natural, scenic, scientific, and historic values. Therefore, the BLM mission to manage the lands to meet multiple-use objectives is challenging, because many of the resources and associated values often overlap.

Within the context of the Mina rail corridor cumulative impacts region of influence, the BLM planning process and management goals and objectives within BLM plans are key determinants of the compatibility of the proposed Mina rail corridor with other projects in region of influence. As noted in Section 4.2.1 there are many continuing and reasonably foreseeable activities that involve the BLM. Because the BLM is and will remain the major land manager in and around the Mina rail corridor region of influence, BLM land-management goals, objectives, and subsequent land-management actions will largely determine if and how new projects and activities occur.

BLM resource management objectives and goals can serve to encourage or restrict activities in certain locations. Areas needing special management attention (such as ***Areas of Critical Environmental Concern***) are also identified in the planning process to protect and prevent irreparable damage to important historical, cultural, or scenic values, fish and wildlife resources, or other natural systems or processes, or to protect life and ensure safety from natural hazards. Multiple-use management goals and objectives become more challenging as cumulative development and land-use changes encroach on open land in the Mina rail corridor region of influence.

The proposed Mina rail corridor would cross three BLM management areas including Las Vegas, Battle Mountain, and Carson City. Each BLM Field Office manages lands within its administrative boundaries according to one or more Management Framework Plan or Resource Management Plan. The Las Vegas, Tonopah, and Carson City plans would apply to the Mina rail corridor. These programs and resource management plans require a number of public and private partnerships and a collaborative approach to land management and planning.

Grazing operations are a major BLM land-management program in the Mina rail corridor region of influence. Grazing results in both direct and indirect cumulative impacts to vegetation, habitats, and wildlife in the Mina rail corridor region of influence. The environmental impacts associated with grazing operations are a function of the location, timing, intensity, duration, and frequency of grazing. Grazing animals directly affect plant communities through trampling and nutrient redistribution. The most noticeable impacts occur around waters, salt blocks, fencelines, and other areas where animals concentrate. With proper grazing management, these concentration areas are limited in extent and mitigated regularly through management procedures such as moving salt blocks and hauling water to the grazing animals. While grazing can stimulate growth of some plants and provide other benefits, it can also reduce plant abundance, density, and vigor, especially in sandy soils.

Ultimately, the BLM land-management efforts and content of the resource management plans will play a major role in the magnitude, location, and extent of direct, indirect, and cumulative impacts in the Mina rail corridor region of influence, and in the relative balance among multiple uses and resource values chosen for the public lands. DOE recognizes the importance of these land-management actions and encourages readers to review specific resource management plans for more detailed information. As discussed in Chapter 2 of this Nevada Rail Corridor SEIS, the proposed railroad would be subject to BLM decisions and approval, and the BLM would consider effects of the railroad on BLM resource management planning, land-management activities, and BLM-administered natural resources. The proposed railroad's contribution to cumulative impacts to BLM land-management planning and actions in the Mina corridor alignment region of influence would be small.

4.2.2.1.8 Urbanization and Economic Development Initiatives

In response to increased economic development goals, the urbanized areas in the Mina rail corridor region of influence have generally planned for and solicited ways to grow and develop. Concepts such as industrial-park development, airport expansion, increased retail opportunities, and housing are prominent goals of the public and private sectors in the Mina rail corridor region of influence. Several regional economic development initiatives are under way or planned in the northern portion of the Mina rail corridor cumulative impacts region of influence. This trend is likely to continue, with land-use and ownership changes and potential land-use conflicts becoming an increasing issue and challenge for the future. However, it is likely that the rural nature of the overall Mina rail corridor cumulative impacts region of influence will remain largely in tact. With or without the proposed railroad, urbanization and economic development activities, while increasing, would not generally change the overall undeveloped character of the Mina rail corridor region of influence.

With or without the proposed railroad, urbanization and economic development activities, while increasing, would not generally change the overall undeveloped character of the Mina rail corridor region of influence.

4.2.2.2 Air Quality and Climate

Emissions of concern in the Mina rail corridor region of influence include ***fugitive dust*** and emissions resulting from the operation of machinery and equipment. Construction activities such as surface disturbance and use of haul trucks in the Mina rail corridor region of influence would cause the generation of fugitive dust. Fugitive dust is a type of non-point source pollution – small airborne particles that do not originate from a specific point. These ***particulate matter*** emissions are regulated according to their size (less than or equal to 2.5 micrometers [$PM_{2.5}$] and less than or equal to 10 micrometers [PM_{10}]). Control of fugitive dust is generally provided by water suppression, or in some cases, application of a chemical compound designed to minimize dust emissions. Most of the projects and activities identified in this analysis would generate some level of fugitive dust. The plumes associated with the generation of fugitive dust are often localized to the area being disturbed and are temporary. In ***arid*** areas such as the Mina rail corridor cumulative impacts region of influence, generation and control of fugitive dust will always be a concern. Emissions resulting from the operation of machinery and equipment include ***sulfur dioxide***, ***oxides of nitrogen***, ***volatile organic compounds***, and ***carbon monoxide***.

There is a comprehensive air quality permitting system in Nevada to evaluate and approve only those projects that are allowable within quantitative ***air quality*** thresholds. The Nevada Division of Environmental Control, Bureau of Air Pollution Control, has established and implemented air pollution control requirements in Nevada Revised Statutes 445B.100 through 445B.825, inclusive, and Nevada Revised Statutes 486A.010 through 486A.180, inclusive. The Bureau of Air Pollution Control has jurisdiction over air quality programs in all counties in the state except Washoe and Clark. The Bureau of

Air Pollution Control also has jurisdiction over all fossil fuel-fired units in the state that generate steam for electrical production. The DOE Proposed Action in the Mina rail corridor would be subject to the permitting requirements noted above, and would occur in air basins that are classified as ***in attainment*** with air quality standards or are unclassifiable. The State of Nevada will not grant permits for activities that cannot show compliance with the applicable federal and state regulations.

Cumulative impacts to air quality would be small.

4.2.2.3 Hydrology

4.2.2.3.1 Surface-Water Resources

4.2.2.3.1.1 Changes in Drainage, Infiltration Rates, and Flood Control. Construction of major projects in previously undeveloped areas often results in changes to natural drainage. Construction could include regrading that would allow runoff from a number of minor drainage channels to collect in a single *culvert* or pass under a single bridge, which would result in water flowing from a single location on the downstream side rather than across a broader area. This could cause some localized changes in drainage patterns, but this probably would occur only in areas where natural drainage channels are small. Compaction of soil during construction could reduce water infiltration rates and change natural runoff and drainage patterns. However, some activities would disturb and loosen the ground for some time, which could cause higher infiltration rates.

Construction in ***washes*** or other flood-prone areas could reduce the area through which floodwaters naturally flow. This could result in water building up, or ponding, on the upstream side of crossings during flood events, and then slowly draining through the culverts or bridges. These alterations to natural drainage, sedimentation, and erosion would be unlikely to increase future flood damage, increase the impact of floods on human health and safety, or cause significant harm to the natural and beneficial values of ***floodplains***.

Insufficient inflow from the Walker River into Walker Lake would continue to jeopardize the future of Walker Lake as a viable fishery, with or without the proposed railroad. If developed, the proposed railroad would not result in further inflow reductions into Walker Lake. Mitigation measures that could be implemented by the U.S. Fish and Wildlife Service or other entities could improve the chances for a viable fishery in the lake in future years.

As a linear project up to 450 kilometers (280 miles) long, the proposed Mina rail corridor would pose new surface drainage challenges because of the existing characteristics of terrain, topography, soils, and physical features. Construction activities that could temporarily block surface drainage channels include moving large amounts of soil and rock to develop the rail roadbed (subgrade) and constructing temporary access roads to reach construction initiation points and major structures, such as bridges, and to allow movement of equipment to construction initiation points. However, project planning and best management practices would help avoid or reduce the scope of these changes, and impacts would be very localized.

Project planning and best management practices would help avoid or reduce potential impacts from the proposed railroad or other ongoing or reasonably foreseeable future actions. Potential cumulative impacts due to changes in drainage, infiltration rates, and flood control would be very small and localized.

4.2.2.3.1.2 Spill and Contamination Potential. Major construction activities and other projects in the region of influence would use materials including petroleum products (fuels and lubricants) and coolants (antifreeze) necessary to operate construction equipment, and could include solvents used in cleaning or degreasing actions. A release or spill of contaminants to a stream or river would have the greatest potential for adverse environmental impacts; a release of contaminants to dry impermeable soil would have the least potential for adverse impacts. Other projects would face similar situations. Spill-control and -management plans (and standard operating procedures for the construction industry) would reduce the likelihood of spills. Construction and operation of a railroad in the proposed Mina rail corridor would be typical of major activities that use materials that could cause contamination through spills. While the risk of a spill and associated water contamination cannot be totally eliminated, risks can be managed so that the risk would be small.

While the risk of a spill and associated water contamination cannot be totally eliminated, risks can be managed through regulatory controls so that the resulting cumulative impacts would be small.

4.2.2.3.2 Groundwater Resources

Existing and proposed future development within the Mina corridor region of influence presents the challenge of matching water supply with water demand. Because water availability is a potential resource constraint in the region of influence over time, water demand can be both competitive among potential users and controversial among users and the general public. To allocate water uses, the State of Nevada uses a water permit application process coordinated by the State Engineer. Once granted, water rights in Nevada have the standing of both real and personal property. It is possible to buy or sell water rights and change the water's point of diversion, manner of use, and place of use by filing the appropriate application with the State Engineer. Overall, because the water permitting and allocation process considers the broad range of factors noted above, the process serves as a way to manage potential cumulative impacts of water demand and use within each basin.

Representative existing and reasonably foreseeable water users in the Mina rail corridor region of influence include:

- Public-supply/municipal, agricultural (stock watering), and mining uses collectively comprise approximately 87 percent of groundwater use within the Mina rail corridor region of influence.
- The Nevada Test Site uses approximately 830,000 cubic meters (673 acre-feet) of water per year.
- Yucca Mountain Repository demands would range from about 218,000 to 527,000 cubic meters (176 to 427 acre-feet) of water per year between calendar years 2010 and 2013, which represents the period of the highest water demand for the Mina rail corridor project. The Repository would use approximately 76,700 to 397,000 cubic meters (62 to 322 acre-feet) of water per year in calendar year 2014 through completion of operation.

It is estimated that a railroad in the proposed Mina rail corridor would use up to about 7.32 million cubic meters (5,950 acre-feet) of water during the construction phase, with about 80 percent of that water use occurring in the first 2 years of construction. About 23,000 cubic meters (17 acre-feet) of water would be needed annually during the operations phase. DOE would obtain water for railroad construction and operations from proposed new wells installed in various water basins along the rail corridor. Committed groundwater resources in the Mina rail corridor region of influence already exceed annual perennial yield values (a measure of available groundwater supply replenished each year through recharge) within some of the groundwater basins (hydrographic areas) that would be affected by the proposed railroad. While designated groundwater basins are not considered closed to additional appropriations, the State Engineer could impose additional restrictions and preferred uses of the water in these designated basins.

Overall, the needs of the proposed railroad would represent a small portion of current cumulative water usage within the Mina rail corridor region of influence, which in some locations would continue to exceed perennial yield values.

4.2.2.4 Biological Resources and Soils

4.2.2.4.1 Habitat Loss and Fragmentation

Past, present, and reasonably foreseeable future actions in the Mina rail corridor cumulative impacts region of influence would result in substantial cumulative land disturbance. Existing activities such as the Nevada Test and Training Range, the Nevada Test Site, Naval Air Station Fallon and the Hawthorne Army Depot have already resulted in land disturbance and substantial changes to existing biological resources, and projects such as the various proposed industrial parks and master-planned communities in the northern portion of the Mina rail corridor cumulative impacts region of influence would continue this trend. Such land disturbances result in altered natural biological and ecological conditions, and directly serve to reduce the amount of natural land available as habitat and open space.

The primary adverse construction-related impacts on vegetation communities from ground disturbance would be the physical destruction or removal of vegetation, and the permanent or temporary removal or compaction of topsoil or other growing medium for the plants. These effects would occur with any major activity resulting in ground disturbance, including the proposed railroad. As more activity occurs, the cumulative loss of vegetative communities and associated habitats would increase. Management of these effects would typically be considered in project planning and mitigation, including projects on BLM-administered land. Much of the emphasis in land management in the Mina rail corridor region of influence concerns the maintenance or reconstruction of healthy habitats.

Habitat destruction would lead to direct impacts such as wildlife injury and mortality, alteration of behavior and movement patterns, and the indirect impacts of reduced vegetative health, reduced biological diversity, and locally degraded ecological function. When there is extensive habitat fragmentation, the individuals or populations of particular species might have difficulty surviving. Habitat destruction arises from a number of sources, including projects that involve land disturbance, and land-management actions, including wild horse and burro management. Though any project that causes disturbance of vegetation contributes to habitat fragmentation, linear projects that impose any degree of impediment to movements, like the proposed railroad, amplify the potential effects.

Measures to avoid, minimize or otherwise reduce impacts are typically implemented by project proponents and encouraged by government agencies and generally include actions to reduce or avoid habitat fragmentation and loss. Such actions would include minimizing land disturbance, using existing roads, interim reclamation, combined roads/utility rights-of-way for pipelines and cables, noise reduction, centralization of facilities, and employee training and education.

An Integrated Natural Resources Management Plan was prepared for the Hawthorne Army Depot in 2004 (DIRS 182761-Bishop 2007, all). The plan is being used to ensure that natural resource conservation and Army mission activities are integrated and are consistent with federal stewardship requirements on mission lands. The plan describes an ecosystem management approach that provides guidance to avoid the impacts of habitat loss and fragmentation, conserve biodiversity, and improve and enhance natural resource integrity while supporting sustainable economies and communities.

In areas proposed for railroad operational purposes, the impacts to vegetation would typically be moderate in scope, and cumulatively add to habitat loss and fragmentation. However, in areas slated for short-term use during construction, revegetation and reclamation efforts would result in replacement of topsoil, reseeding of native species, monitoring for success, and eventual return of a native vegetation community somewhat comparable to pre-disturbance conditions.

Cumulative impacts due to habitat loss and fragmentation would be small to moderate through the construction and operations phases throughout the Mina rail corridor region of influence.

4.2.2.4.2 Invasive Species and Noxious Weeds

Invasive species and noxious weeds naturally move into new areas over time, but this occurrence has been accelerated in many areas through human activity, either intentionally or by accident. In many cases these plants have been moved into North America from another continent. They have been accidentally introduced through contaminated grain or hay, or sometimes intentionally introduced for erosion control or as ornamentals. In addition, livestock and vehicles can cause invasive species and noxious weeds to spread, birds could carry seed, or the species can be brought in with contaminated fill dirt. Regardless of how they were introduced, invasive species and noxious weeds possess characteristics that allow them to compete aggressively with native vegetation. Invasive species and noxious weeds impact native plants, animals, and natural ecosystems by:

- Reducing biodiversity
- Altering hydrologic conditions
- Altering soil characteristics
- Altering fire intensity and frequency
- Interfering with natural succession
- Competing for pollinators
- Displacing rare plant species
- Replacing complex communities with single-species monocultures

From a cumulative impacts perspective, any time land is disturbed and native vegetation is lost there is an opportunity for noxious weeds to replace the native vegetation. While the BLM and other land owners/ managers in the area have implemented programs to minimize this potential, invasion of noxious weeds cannot always be prevented. Therefore, coordinated multi-agency management actions and efforts are needed to mitigate the effects from cumulative land disturbance. Management of noxious and invasive weeds is essential for restoration of native plant community health and resiliency. If noxious and invasive weeds were not managed, they would continue to gradually replace more desirable native species throughout the Mina rail corridor region of influence.

Linear disturbances such as pipelines, roads, utility corridors, or rail lines that cross relatively undisturbed land have the potential to exacerbate the spread of invasive species and noxious weeds into areas not previously affected. As the invasive or noxious weeds become established along the linear features they spread to adjacent areas, affecting the plant and animal communities beyond the actual disturbance, and are able to out-compete native species by responding more rapidly to the infrequent availability of water.

These impacts could occur as a result of constructing and operating the proposed railroad in Mina rail corridor, but strict adherence to best management practices should reduce the potential for impacts. Cumulative impacts due to the introduction and spread of invasive species and noxious weeds would be small.

4.2.2.4.3 Special-Status Species

Habitat for several special status species would be disturbed and individuals of several species could be lost as a result of constructing and operating the proposed railroad in the Mina rail corridor. Through the NEPA and permitting processes, each proposed project and land-management planning effort in the Mina rail corridor region of influence will face challenges for the protection of various special status species. There are a number of special status species that could be affected by cumulative impacts in the Mina rail corridor region of influence. Recent attention has focused on several specific species, including the desert tortoise (*Gopherus agassizii*) and Lahontan cutthroat trout, as discussed below.

The Mojave population of the desert tortoise is listed as threatened under the Endangered Species Act of 1973 (16 U.S.C. 1531 to 1544). It is found within the proposed Mina rail corridor region of influence in the southwestern-most 48 kilometers (30 miles), from the Beatty Wash area to Yucca Mountain (DIRS 101830-Bury et al. 1994, pp. 55 to 72). The desert tortoise is found in southern California, parts of southern Utah, and in the southern portions of Nevada, with the tortoises potentially affected by the proposed Mina rail corridor at the extreme northern extent of their range. While relative abundance of the tortoise is low in much of the Mina rail corridor region of influence, every action that could disturb soil or vegetation within the tortoise's range has potential cumulative impacts of loss or fragmentation of the species' habitat or the direct mortality of individual desert tortoises, which in turn would affect the health and extent of the collective population of the species. In the area near the Yucca Mountain Site, construction activities would have similar impacts on the desert tortoise.

The threatened Lahontan cutthroat trout is stocked in Walker Lake and occurs upstream to Weber Reservoir. Weber Dam currently blocks movement further upstream, and prevents spawning by cutthroat trout; however, in the near future a fish ladder might be developed at that dam to allow fish movement. Reestablishment of a self-sustaining population of Lahontan cutthroat trout in the Walker River system is a prerequisite for recovery of this species. With mitigation, the Mina rail corridor activities would have minimal effects on the trout, but the existing problem with Weber Dam blocking movement of the trout further upstream would remain.

BLM resource management plans sometimes place restrictions on other activities (for example, grazing, wild horse and burro abundance, off-road vehicle use, mineral activities) so that desert tortoise or other special status species habitat can be protected. However, off-road vehicle use, shooting, and collecting of individuals continue to impact tortoise populations. Habitat protection efforts for the desert tortoise are coordinated among a number of federal, state, and local governmental agencies, with the cumulative impact perspective a major factor in determining allowable impacts to the tortoise. Restoration plans and habitat conservation plans also affect the required mitigation measures, best management practices, and standard operating procedures for the protection of the desert tortoise or other special status species.

Private landowners, corporations, state or local governments, or other non-federal landowners who wish to conduct activities on their land that might incidentally harm (or "take") wildlife listed as endangered or threatened must first obtain an incidental take permit from the U.S. Fish and Wildlife Service. To obtain a permit, the applicant must develop a Habitat Conservation Plan, designed to offset any harmful effects the proposed activity might have on the species. There is a single species (desert tortoise) Habitat Conservation Plan being developed in the Pahrump area of Nye County. Habitat Conservation Plans would support development of private lands while accounting for the potentially affected species.

No major effects on special status species are projected to result from construction and operation of the proposed railroad in the Mina rail corridor. DOE would conduct any required consultation with the U.S. Fish and Wildlife Service in accordance with the Endangered Species Act. There is a substantial regulatory framework, to which all projects are subject, that serves to evaluate and protect special status species. Therefore, cumulative impacts to special status species would be small.

4.2.2.4.4 Known or Potentially Contaminated Soils

The major sources of existing soil contamination problems in the Mina rail corridor region of influence are mining, the Nevada Test Site, and the Hawthorne Army Depot. There have been mining activities in the region for many years, and mining wastes from older operations (before the regulatory framework required waste management and clean-up) still remain.

The problems associated with the Nevada Test Site have been described in recent NEPA documentation (DIRS 101811-DOE 1996, all; DIRS 162638-DOE 2002, all). Historic contamination of soils resources on the Nevada Test Site is primarily from radioactive-waste management sites and past nuclear testing activities. Environmental restoration and remediation is occurring at contaminated Nevada Test Site locations in accordance with the facility's Environmental Restoration Program, but much of the contamination is long-term and the land and soil are not restorable to useful condition. For most of the contaminated soils within the Nevada Test Site boundary, DOE is planning only a characterization and long-term monitoring program. Contaminated areas on the Nevada Test Site are generally defined and access is restricted for reasons of safety and security.

The Hawthorne Army Depot has an Installation Restoration Program that outlines proposed future investigations and remedial actions at each Solid Waste Management Unit and other areas of concern at the installation. There are soil and groundwater contamination issues, with the primary contaminants of concern being compounds associated with explosives and heavy metals. Environmental restoration and remediation is ongoing at a number of sites. Other sites have achieved the status of no further remedial action planned. Contaminated areas on the Hawthorne Army Depot are generally defined and access is restricted for reasons of safety and security.

Contaminated soils or spills can impact other resources such as water resources, biological resources, and land use. Spills of hazardous materials are possible with regional activities, but the current regulatory framework to manage and control hazardous materials and wastes ensures that actions are in place to minimize impacts. While potential impacts associated with hazardous materials and wastes from current and future mining operations in the region are controlled through the existing regulatory framework, mining wastes from old mining extraction and processing activities, especially in the Goldfield area, remain a concern related to soil contamination.

The proposed railroad could result in very localized contamination of soils through occasional spills (such as fuel, oil, and solvents). However, such incidents would be minor in scope and quickly mitigated in accordance with plans and regulations. All existing and foreseeable projects would be subject to the same regulations. Cumulative impacts related to contamination of soils would likely be small.

4.2.2.5 Cultural Resources

Cultural resources include historic and archaeological sites, buildings, structures, landscapes, and objects. Most reasonably foreseeable projects in the Mina rail corridor region of influence will involve at least some ground disturbance. With that ground disturbance, cultural resources could be destroyed, damaged, or discovered for recovery or mitigation. As part of the evaluation of proposed projects on federal land, the existing regulatory framework requires that cultural resources be identified and protected. With information on the location of a proposed project and the estimated extent of ground disturbance, cultural resource specialists can be called on to perform appropriate surveys and inventories of cultural resources in the potentially disturbed area.

Because cultural resources are typically on or below the ground, they can be damaged by other activities, such as off-highway vehicle use. As the major land manager in the Mina rail corridor region of influence, the BLM has an extensive cultural resource management program and manages federal land with protection of cultural resources as a key management objective. Once ground is disturbed and facilities are constructed on the land, the opportunity for identification of cultural resources is usually lost. Therefore, the BLM and other land managers in the area (for example, DOE on the Nevada Test Site and the Air Force on the Nevada Test and Training Range) employ cultural resource specialists and involve tribal representatives, as appropriate. Mission activities on the Nevada Test Site, on the Nevada Test and Training Range, and at the Yucca Mountain Repository also could cause unintended adverse impacts to cultural resources. DOE, the BLM, and other federal agencies in the Mina rail corridor region of influence are committed to public education and employee training regarding the protection of cultural resources.

Based on the extent of cultural resource site finds within BLM-administered land and on the Nevada Test Site, and data collected to date on the proposed Mina corridor, other cultural resources in the Mina rail corridor region of influence are likely to be discovered as projects proceed. Also, it is likely that only a portion of currently undiscovered sites would ultimately be found eligible for the *National Register of Historic Places*.

Impacts to cultural resources in the Mina rail corridor region of influence would be small because the Department would conduct intensive field surveys and implement mitigation measures, including avoidance. Other project proponents would be subject to the same regulatory framework and BLM policies and procedures. Cumulative impacts to cultural resources in the Mina rail corridor region of influence would be small.

4.2.2.6 Occupational and Public Health and Safety

4.2.2.6.1 Nonradiological Health and Safety

Throughout the Mina rail corridor region of influence, continuing and reasonably foreseeable activities have the potential to result in occupational injuries or fatalities including, but not necessarily limited to sources such as tripping, being cut on equipment or material, dropping heavy objects, catching clothing in moving machine parts, and other types of accidents. Other occupational risks include biological hazards, dust and soils hazards, air quality hazards, transportation accidents, and noise hazards. Biological hazards include potential human health effects from rodent-borne diseases, soil-borne diseases, insect-borne diseases, and venomous animals. Dust and soils hazards include potential human health effects from exposure to inhalable soils and dusts containing hazardous constituents, and potential occupational encounters with unexploded ordnance.

While occupational injuries or fatalities are unavoidable with human activity, public and private facilities within the Mina rail corridor cumulative activity area are highly regulated. There is a substantial regulatory framework for occupational health and safety, with the Occupational Safety and Health Administration programs and regulations forming the basis for protection of workers. Through DOE Order 440.1A, *Worker Protection Management for DOE Federal and Contractor Employees*, the Department has prescribed the Occupational Safety and Health Act Standards that contractors are to meet in their work at government-owned, contractor-operated facilities. The Department of Labor, Bureau of Labor Statistics, measures occupational incident rates, including total recordable cases, lost workday cases, and fatalities, associated with the work environment.

There are no data on injury/illness incident rates for the Mina rail corridor cumulative impacts region of influence. Injury/illness incidence rates in Nevada generally run higher than those in the United States as a whole. The economic segments with the highest injury/illness incidence rates in Nevada are construction and goods-producing industries.

Additional traffic is especially a concern with the construction phases of reasonably foreseeable projects. The construction phase of a project not only brings construction workers to the work sites, but also means an increase in slow-moving and bulky traffic involving the transportation of construction equipment. Use of trucks for hauling hazardous or other dangerous materials is also an increasing concern as traffic increases on the road network. To minimize traffic impacts at the entrance to the Yucca Mountain Site, a new interchange at the Site entrance with U.S. Highway 95 has been proposed for both traffic flow and safety reasons. Increased traffic would not necessarily mean an increase in the rate of traffic accidents, but the number of accidents would increase if the rate of traffic accidents stayed the same and traffic increased. Therefore, transportation safety concerns would increase and there could be an increased workload for traffic-accident responders in the Mina rail corridor region of influence with the cumulative growth in traffic.

From a transportation safety standpoint, rail cars loaded with live munitions currently travel between Wabuska, Nevada, and the Hawthorne Army Depot. Under the Proposed Action, health and safety risks associated with accidents involving these rail cars would be reduced as the trains would be routed away from the populated community of Schurz on the Walker River Paiute Reservation.

Nonradiological transportation impacts specifically associated with the proposed railroad would include vehicular fatalities and nonradiological rail accidents and fatalities associated with railroad operations. Vehicular fatalities would be the result of commute trips from workers responsible for railroad operations. The number of incidents would be proportional to the number of trains and casks moved by rail.

Other regional activities would also cumulatively add to the totals beyond the railroad-related impacts, but cumulative nonradiological health and safety in the Mina rail corridor region of influence would be small within the context of the overall region of influence.

4.2.2.6.2 Radiological Health and Safety

Existing and reasonably foreseeable future activity (such as the Nevada Test Site and Yucca Mountain Repository activity managed by DOE) in the Mina rail corridor region of influence involves the storage, handling, transportation, use, and disposal of radioactive materials and wastes. Staff at the Nevada Test Site and the Yucca Mountain Repository would be separate, and it is not anticipated that there would be any cumulative exposures to workers from both operations. The modes of transportation of radioactive wastes for the Nevada Test Site (shipment by truck) and the Yucca Mountain Repository (shipment by rail) would differ. Radiological impacts associated with railroad operations would be higher under Yucca Mountain Inventory Module 1 or 2 operations compared to the level of transportation under this Nevada Rail Corridor SEIS Proposed Action.

There is an extensive regulatory framework associated with transportation safety, and the proposed railroad would operate in compliance with these laws and regulations. The regulatory framework and implementation of appropriate standard operating procedures would reduce the potential for accidents. Coordination of plans for proposed railroad construction and operation with local emergency response providers would be important to limit the potential for accidents, and for an effective response to an accident should one occur.

Operation of the proposed railroad in the Mina rail corridor under the Proposed Action would result in a small contribution to cumulative radiological health and safety impacts. Cumulative radiological impacts in the Mina rail corridor region of influence would be small.

4.2.2.7 Socioeconomics

The economic roots of the Mina rail corridor cumulative impacts region of influence have traditionally been based on mineral development, military operations and support, and livestock grazing. These activities will continue to be the primary economic drivers in the Mina rail corridor cumulative impacts region of influence. Additionally, the expansion of the Reno and Carson City metropolitan areas in the northern reaches of the Mina rail corridor cumulative impacts region of influence will continue to occur, providing additional economic inputs. While the proposed railroad would be a major development in the Mina rail corridor region of influence, its long-term economic development potential would be limited and would primarily be related to construction activities.

Population growth in the Mina rail corridor cumulative impacts region of influence has generally been stagnant in much of the area. However, many in the region desire growth and development. It is uncertain if there is sufficient economic development growth potential in these areas to support the desired growth. It is possible that some areas would grow at the expense of other areas, or that recently developed plans for growth turn out to be unrealistic. Provision of housing to meet market demand is a private-sector activity, with the private-housing sector assumed to build to the needed level to meet housing demand at the appropriate locations. One of the factors that will affect how and where growth occurs is the availability of infrastructure to support the growth. Beyond the traditional infrastructure needs like roads, sewer, water, and public buildings, modern infrastructure such as the availability of fiber-optic lines might also affect growth patterns. For example, the availability of fiber-optic lines or other high-technology infrastructure is likely to be a substantial growth discriminator for both businesses and individuals. The locations of and extent to which factors such as fiber-optic lines would ultimately affect growth cannot be projected at this time.

The potential future land disposals identified in Section 4.2.2.1.4, if implemented by the BLM, could have the potential to provide land for private-sector projects such as housing, industrial or commercial facilities, or other developments.

The State of Nevada has developed population projections for the Mina rail corridor cumulative impacts region of influence (DIRS 178807-Hardcastle 2006, all) as follows:

- Esmeralda County is projected to experience a small decrease in population from 2005 to 2026.
- Nye County is projected to add more than 32,000 people from 2005 to 2026.
- Lyon County is projected to add more than 41,000 people from 2005 to 2026.
- Mineral County is projected to experience a small decrease in population from 2005 to 2026.

Population projections are always subject to change with new information, and the Nevada State Demographer incorporates foreseeable economic development into the population projections.

Nye County's projected growth continues a recent trend, with growth in Pahrump very evident over the past several years. Growth in Pahrump is being driven by low-cost land, proximity to the Las Vegas metropolitan area, and relocation of retirees to the area. Growth in Nye County is also directly linked to existing and future Yucca Mountain Site operations. Growth in Lyon County is due largely to its proximity to Carson City and Reno.

As discussed in Section 3.2.7, Socioeconomics, DOE used an economic model to estimate the potential socioeconomic impacts of the proposed railroad (DIRS 182251-REMI 2007, all). The model includes consideration of construction and operations employment and wages, project-related spending, and other parameters that could affect the socioeconomic environment. The model included a future baseline of socioeconomic parameters that would represent a cumulative impacts baseline without a railroad in the proposed Mina rail corridor.

Consistent with the methodology established in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, p. 4-43), most of the construction workers for the proposed Mina rail corridor are assumed to be residents of Clark County. This assumption is made because the construction sectors in Nye, Esmeralda, Lyon and Mineral Counties are not large enough to provide enough workers for construction activities. Under this scenario, Clark County is projected to attain the largest levels of construction-related employment, income, and spending effects from the proposed project, followed by Mineral, Nye, Esmeralda, and Lyon Counties. Mineral County would experience the largest employment percentage increase during the construction phase, with an estimated increase of about 6 percent above baseline conditions. The socioeconomic analysis also considers a second scenario, which assumes that half of the construction workers for the Mina rail corridor reside in the combined Washoe County-Carson City area, and the other half reside in Clark County. This second scenario is considered because Washoe County and Carson City may be more likely than Clark County to supply construction workers for the northern portions of the Mina rail corridor. Under this second scenario, the beneficial economic effects on Clark County would be reduced, while the Washoe County-Carson City area would gain some of these beneficial aspects of the proposed railroad. In any case, the overall effects of the proposed Mina rail corridor project on the Clark County or Washoe County economies would still be relatively small.

Employee locations for the operations phase would follow the same general pattern and relative magnitude of the construction phase, but there would be fewer operations jobs than construction jobs. Gains in employment during the operations phase would be felt most strongly in Esmeralda County, where the peak percentage change in average annual employment is projected to be 6.3 percent above baseline conditions during full operations. Mineral County is the only other county in the region of influence projected to experience more than a 1-percent change in average annual employment at any point during the operations phase (2.6 percent).

Population changes that would result from construction and operation of the proposed railroad in the Mina rail corridor are also projected to generally follow this pattern. During the construction phase, the upper bound of increase to population would be about 3 percent or less of the future cumulative population baseline in all four counties. The operations-phase population change would have the largest percentage increase compared to the cumulative baseline in Esmeralda County (about 7 percent average annual increase over the baseline). There are no projected impacts to population on the Walker River Paiute Reservation.

Strains on housing infrastructure during the construction phase would not be anticipated because most construction workers could be housed in construction camps at strategic locations along the Mina rail corridor, rather than in nearby communities. Contractors might elect to use commercially available facilities to house construction personnel at locations such as Hawthorne, Tonopah, Goldfield, Beatty, and Pahrump.

Some infrastructure impacts would be expected where construction activities or operating facilities were near communities. For example, construction workers, including those from the proposed railroad, could strain the existing health care service capacity in the Mina rail corridor region of influence, particularly in Hawthorne, Goldfield, and Tonopah. Operations-related population gains could also result in identifiable effects on health and education-related services.

The road network in the Mina rail corridor region of influence consists generally of two-lane highways and unpaved roads. U.S. Highway 95 is the major north-south highway in the region of influence. In rural, less populated parts of the Mina rail corridor cumulative impacts region of influence, roads are adequate to handle existing and projected future traffic flow. However, the array of new and proposed activities throughout the Mina rail corridor region of influence would have the potential to strain parts of the existing roadway infrastructure. There could be some traffic delays at existing rail-highway grade crossings, and grade separation might be necessary at some crossings in Churchill, Lyon, and Mineral Counties. However, cumulative traffic levels in the region would likely continue to increase as overall regional growth and development occurs.

Any road improvement and maintenance responsibilities in the region of influence are handled by the Nevada Department of Transportation through a Statewide Transportation Plan and a Statewide Transportation Improvement Program. The Statewide Transportation Improvement Program includes a 3-year list of federally funded and regionally important non-federally funded transportation projects and programs consistent with the goals and strategies of the Statewide Transportation Plan. Routine highway improvements and maintenance projects for the period 2006 through 2015 have been identified for Nye, Esmeralda, Lyon, and Mineral Counties as part of the Nevada Department of Transportation planning processes. The level of cumulative traffic changes would generally not be sufficient for major upgrades of regional roads.

Overall, the proposed railroad project would have a small impact on economic development and growth, housing and community infrastructure, and traffic in the Mina rail corridor region of influence. While there is some limited potential for induced growth impacts, the specific locations and scope of these actions is unknown at this time, and any such actions are projected to be small. Cumulative impacts to socioeconomics in the Mina rail corridor region of influence would be small.

4.2.2.8 Noise and Vibration

4.2.2.8.1 Railroad Noise

In the Mina rail corridor cumulative impact region of influence, there is an existing branchline extending from Hazen, Nevada, to the Hawthorne Army Depot. The noise associated with railroad operations is part of the existing environment, specifically in the Schurz area where the railroad's presence is very evident. The sounds associated with the existing branchline include wayside noise (noise generated by the cars and locomotives), and horn sounding. The individual operating rules of each railroad require train engineers to sound horns when approaching most grade crossings. Horn sounding is generally not required at private crossings. Wayside noise and horn sounding are common in Schurz and along other portions of the existing branchline.

Hawthorne Army Depot is planning to construct a rail siding, known as the Wabuska Spur, which would increase the Depot's rail capacity. Increased rail capacity could cause increases in overall rail traffic on the existing branchline and could result in more wayside noise and horn sounding near Hawthorne.

Transportation of spent nuclear fuel and high-level radioactive waste casks would result in as many as eight one-way trips per week along the Mina rail corridor. Train activity associated with supply and maintenance of the Yucca Mountain Repository is also proposed along the completed rail line (as many as seven one-way trips per week), as is Mina rail corridor maintenance activity (about two one-way trips per week), for a total of about 17 one-way trips per week. During the construction phase, completed portions of the rail line could also be used to deliver ballast to construction areas.

Potential noise impacts from the proposed railroad in the Mina rail corridor would be expected to be small. However, the railroad would introduce or expand noise sources into areas of the Mina rail corridor region of influence that previously had very limited railroad noise. This could result in incremental annoyance effects for some persons.

While adverse noise effects could increase for some in the Mina rail corridor region of influence, selection of the Mina rail corridor would substantially reduce noise impacts in Schurz, because the existing rail line through Schurz would be eliminated and replaced by one of Schurz alternative corridor segments. This would provide a substantial reduction in annoyance effects for people in Schurz.

4.2.2.8.2 Urban Noise

Urban noise includes automobiles, construction activities, barking dogs, and other human activities generally within an identifiable community. At present, urban noise in the Mina rail corridor region of influence is limited because there are only a few cities and communities. However, with economic development and growth goals throughout the Mina rail corridor region of influence, the number and scope of urbanized areas is expected to increase. Urban noise is generally localized and is differentiated from aircraft and railroad noise sources, which move with the source from one location to another, while urban noise is within identifiable geographic borders associated with the locations of populations.

The proposed railroad would have a very small effect on urbanization in the area, and its effect on urban noise in the Mina rail corridor region of influence would be small. Cumulative impacts related to urban noise would be small.

4.2.2.8.3 Aircraft Noise

Aircraft-related noise from engines and sonic booms is common throughout the Mina rail corridor cumulative impacts region of influence, and can cause “startle” and annoyance effects. The noise associated with military aircraft is consistent with the “dominant use” of the area for military and defense-related activities on the Nevada Test and Training Range and at Naval Air Station Fallon. Noise effects associated with Nevada Test and Training Range or Naval Air Station Fallon missions would be considered necessary and unavoidable. Commercial air traffic also contributes to noise impacts in the region of influence.

The proposed railroad would not contribute to cumulative aircraft noise.

4.2.2.8.4 Vibration

Vibration can be perceived on land surfaces and within buildings with certain types of activities. Construction activity is one of the more common sources of vibration, but railroad construction vibration would be very localized and typically minor in scope and duration. In the Mina rail corridor cumulative impacts region of influence, other possible sources of vibration include occasional testing activities at the Nevada Test and Training Range and sonic booms from aircraft-related military activities in the airspace above the region of influence. These events would also tend to be short-term and localized.

Cumulative impacts from vibration would be small.

4.2.2.9 Aesthetic Resources

Cumulative impacts to aesthetic resources from the proposed railroad in the Mina rail corridor and other regional activities would primarily result from modifications to natural ***viewsheds***. The natural setting of the Mina rail corridor region of influence includes vast and expansive viewsheds typical of much of the western United States. The open spaces and wide vistas offer interesting cloud, weather, and landscape interactions. Human activity disturbs the natural viewsheds with views of land disturbances such as buildings, roads, removal of vegetation, power lines, equipment, and vehicles. Activity that disturbs substantial areas of land can result in impacts to visual resources from fugitive dust and ground scars that create a contrast with the surrounding environment and draw the viewer’s attention. Additionally, most man-made structures are designed and built for their functionality and safety, not for their visual appeal or compatibility with the visual character of the landscape. For example, projects with construction-related equipment, facilities, and activities can include the presence of workers, camps, vehicles, and machinery, laydown yards, and dust. The likely addition of explosive bunkers at the Hawthorne Army Depot and projected wind-energy development are examples of other long-term changes in the visual setting that are reasonably foreseeable. Each type of project has its unique visual features but generally, new projects would not be consolidated into any specific location within the region of influence.

While the area has a history of railroad use, the presence of a railroad and associated train traffic in the Mina rail corridor would be an identifiable change to the regional viewsheds from some observation points and provide a noticeable contrast with natural visual attributes. The passage of a train would attract the attention of an observer, both because of the noise associated with the train and the contrast with the landscape, especially if the train were to fall in the foreground or middle ground ***distance zones*** of the viewshed. Visual impacts of passing trains would be temporary, but visual impacts of the track would be long term.

Visual resources within the Mina rail corridor region of influence have been considered through application of the BLM Visual Resource Management System. The BLM uses this system to identify and classify the BLM-administered lands within established visual resource objectives, and evaluates proposed activities within the Visual Resource Management System framework to consider consistency with the visual resource objectives. Ground disturbances in the regional environment will last for long periods without restoration and reclamation efforts. The magnitude and extent of potential impacts to visual resources vary based on the number of viewers affected, distance and atmospheric conditions of viewing, degree of visual contrast compared to existing visual attributes, viewer sensitivity to the visual changes, and compatibility with existing land uses. The BLM generally requires ground disturbances to be restored and reclaimed as part of project approval.

There would be no known interactions of the proposed railroad with other reasonably foreseeable activities that would affect a Class I or Class II area in the Mina rail corridor region of influence.

4.2.2.10 Utilities, Energy, and Materials

4.2.2.10.1 Utilities

From a cumulative impacts perspective within the Mina rail corridor region of influence, utility crossings are and will continue to be commonplace with little impact other than minor ground disturbance. Utility and other right-of-way crossings are common to linear projects such as roads, railroads, and pipelines. The rail line would cross or encroach upon existing or proposed utility rights-of-way in a variety of locations. This situation would be typical for other rights-of-way in the region. The crossings would be accomplished with small impact using standard engineering procedures and appropriate design details.

Many regional activities, including the proposed railroad, would increase demands on public water systems, wastewater systems, telecommunications systems, electric power systems, and other utilities. However, regional service providers are projected to be able to adjust to increasing demand, and overall cumulative impacts to utilities would be small.

4.2.2.10.2 Energy and Materials Usage

Large projects such as pipelines, transmission lines, and power plants that could occur in the Mina rail corridor cumulative impacts region of influence require materials and energy to construct and operate. Energy and materials resources necessary for construction or operation of these projects are often obtained within regional or, in some cases, national markets.

Energy and materials (for example, steel and concrete) that would be needed for construction and operation of the proposed railroad in the Mina rail corridor are not constrained in regional markets, and proposed railroad needs would represent a small percentage of the cumulative annual materials use within the Mina rail corridor cumulative impacts region of influence. While the regional markets for various construction-related materials and energy sources will continue to grow as the region develops, there is no evidence of potential limits to growth from constrained material or energy supplies. Cumulative impacts from energy and materials usage in the Mina rail corridor region of influence would be small.

4.2.2.11 Waste Management

4.2.2.11.1 DOE Waste-Management Activities

DOE has had waste-management programs at the Nevada Test Site for several decades. While the Nevada Test Site missions have changed over time (with an emerging focus on national security, energy, and environmental issues), waste management and disposal at the Nevada Test Site has been one of the primary long-term land uses. There are two active waste management and disposal sites on the Nevada Test Site:

- Area 5 occupies 2.9 square kilometers (720 acres) and is in Frenchman Flat north of Mercury, Nevada.
- Area 3 occupies 0.52 square kilometer (130 acres) north of Mercury in Yucca Flat.

Environmental restoration efforts are underway at various locations throughout the Nevada Test Site. The Nevada Test Site waste-management program currently includes management and disposal operations for hazardous waste, mixed waste, and low-level radioactive waste. Transportation of the waste is accomplished by truck from both on-site and off-site sources. There are no plans for Nevada Test Site activities to include use of the proposed railroad for shipment of wastes.

The proposed railroad would not contribute to cumulative impacts associated with DOE waste-management activities on the Nevada Test Site.

At present, Yucca Mountain Repository-development efforts are focused on preparing an application to the U.S. Nuclear Regulatory Commission for authorization to construct the repository for spent nuclear fuel and high-level radioactive waste. The Yucca Mountain FEIS (DIRS 155970-DOE 2002, all) and the Repository SEIS (DOE/EIS-0250F-S1) describe operations at the Yucca Mountain Site in detail.

4.2.2.11.2 Sanitary and Construction Wastes

As the populated areas in the Mina rail corridor cumulative impacts region of influence expand and grow, the volume of ***sanitary waste*** generated will also expand. Project proponents are legally required to dispose of nonhazardous and nonradiological construction and other solid waste in appropriately permitted solid waste landfills. Nevada has 24 operating municipal landfills with a combined capacity to accept more than 11,000 metric tons (12,000 tons) of waste per day. However, the number of operating landfills has decreased substantially over the past 15 years, and while there is sufficient capacity to accept waste for the State of Nevada as a whole, there are some areas, such as Pahrump, that have limited capacity for future years.

Railroad construction- and operations-related waste would add only a fraction of a percent to the total waste stream in the state. If there were a constraint to landfill capacity at some future time, additional land would be needed to expand or open a new landfill. Because of the relative scarcity of private land in the Mina rail corridor region of influence, land used for this purpose might need to come from BLM-administered federal land. As an alternative to local government landfill provision, private companies can also be expected to seek business opportunities to provide solid- and hazardous-waste management, transportation, and disposal.

DOE would store and use hazardous materials (such as oil, gasoline and solvents) during the railroad construction phase, and would control and manage these materials in accordance with the extensive federal and state regulatory framework. Other major projects would have similar waste streams, and project plans and requirements would call for disposal of such wastes in permitted facilities and materials management according to accepted industry practices.

The proposed railroad's contribution to impacts from the generation and management of sanitary and construction wastes would be small. Cumulative impacts to waste disposal facilities in the Mina rail corridor region of influence would be small.

4.2.2.12 Environmental Justice

4.2.2.12.1 Potential Effects to Low-Income and/or Minority Populations

Environmental justice impacts result when high and adverse human health or environmental impacts fall disproportionately on low-income and minority populations. If high and adverse impacts are found to have disproportionate impacts on environmental justice populations as compared to the general population of the area, the impacts would be mitigated to the extent practical by the federal agencies involved in the proposed action.

Based on individual and group values, beliefs, and goals, there is a difference in perspective as to the potential effects of activities in the Mina rail corridor region of influence on low-income and/or minority populations among the different stakeholders and other interested parties. *American Indian Perspectives on the Proposed Rail Alignment Environmental Impact Statement for the U.S. Department of Energy's Yucca Mountain Project* (DIRS 174205-Kane et al. 2005), prepared by the American Indian Writers Subgroup of the Consolidated Group of Tribes and Organizations, discusses cultural resources, American Indian values and their relationship to environmental justice, and broader American Indian values. DOE considers the American Indian Writers Subgroup conclusions to be responsible opposing viewpoints for purposes of its environmental justice responsibilities. DOE has concluded that there are no identifiable environmental or human health impacts associated with the proposed railroad in the Mina rail corridor that would disproportionately affect low-income or minority populations. Additionally, there are no identified effects to subsistence hunting and gathering traditions in the Mina rail corridor region of influence. Therefore, the DOE incremental contribution to cumulative environmental justice impacts to low-income and/or minority populations under the Proposed Action in the Mina rail corridor region of influence would be small.

The largest concentration of low-income or minority populations along the Mina rail corridor occurs in Mineral County and on the Walker River Paiute Reservation. The corridor would cross American Indian tribal lands, with the three Schurz bypass options almost entirely on the Walker River Paiute Reservation (DIRS 180222-BSC 2006, pp. 15 and 16). There are approximately 1.4 square kilometers (350 acres) of Reservation lands in the corridor (DIRS 180222-BSC 2006, p. 15). The population of the Reservation, estimated to be 853 persons in 2000, is low-income and consists mainly of American Indians, a minority population. The poverty rate in Mineral County is 15 percent, which exceeds the rate of poverty (11 percent) in the State of Nevada, while the poverty rate of Walker River Paiute Reservation residents is 32 percent, nearly three times the rate of poverty in the state. The only moderate or large impacts that were identified relate to noise impacts from construction. These impacts would not occur on the Walker River Paiute Reservation; therefore, there would be no large and adverse effects that would disproportionately affect a low income or minority community and there are no special pathways that would result in disproportionately large and adverse effects to low-income or minority communities.

Cumulative impacts to low-income or minority populations along the Mina rail corridor would be small, if any.

4.2.2.12.2 Economic Opportunity

Existing and reasonably foreseeable projects and activities in the Mina rail corridor region of influence would present economic opportunities for some people in the area. Economic opportunities include employment, wages, revenue from business operation, and other economic stimuli associated with growth and development. DOE and other project proponents in the Mina rail corridor region of influence have a legally mandated equal opportunity approach to these economic opportunities. Potential for economic gain would be distributed equally to persons or businesses in the area that seek employment or business opportunity. While not all people would gain economically from the cumulative group of projects and activities, the opportunity for gain does not favor one population group or another based on minority or income status.

Because there would be small changes in long-term population attributable to activities in the Mina rail corridor, impacts or stresses to the housing stock, infrastructure systems, or social services would be unlikely. Socioeconomic impacts from railroad construction and operation in the Mina rail corridor would be small overall and would be unlikely to adversely or disproportionately affect the low-income or minority populations in the corridor.

4.3 Unavoidable Adverse Impacts/Irretrievable Commitments of Resources

This section addresses unavoidable adverse impacts that could remain after the application of ***mitigation*** measures, the relationship between short-term uses of the human environment and the maintenance and enhancement of long-term productivity, and potentially irreversible or irretrievable commitments of resources for the Mina rail corridor.

4.3.1 UNAVOIDABLE ADVERSE IMPACTS

This section summarizes potential impacts associated with construction and operation of a railroad in the Mina rail corridor that could be unavoidable and adverse and that could remain after DOE implemented mitigation measures.

4.3.1.1 Land Use and Ownership

Railroad construction and operation in the Mina rail corridor could result in altered access to some private land holdings, land associated with the Walker River Paiute Reservation, the Hawthorne Army Depot, ***unpatented mining claims***, rights-of-way, and grazing allotments (through loss of forage and grazing footprint).

4.3.1.2 Air Quality

Railroad construction in the Mina rail corridor would result in temporary increases in ***criteria air pollutants***, mainly fugitive dust. Railroad operations would result in small increases in criteria air pollutants.

4.3.1.3 Hydrology

Railroad construction in the Mina rail corridor could alter natural surface-water drainage patterns. Impacts associated with the alteration of drainage patterns or changes to erosion and sedimentation rates or locations would be small and localized. In addition, construction could require the withdrawal and use of groundwater. In many areas the rail line could cross, other uses or commitments of groundwater resources would approach or exceed the perennial yields of the underlying groundwater basins. This would potentially be a small and adverse, although not permanent, impact.

4.3.1.4 Biological Resources and Soils

Railroad construction in the Mina rail corridor could cause habitat loss and the loss of small numbers of individual plants and animals. Disturbed soils could result in increased erosion during the construction phase, even with the implementation of best management practices.

4.3.1.5 Cultural Resources

Although DOE would implement best management practices and mitigation measures related to cultural resources, grading and other construction activities could degrade, cause the removal of, or alter the setting of archaeological sites or other cultural resources and cause the loss of archaeological information in the Mina rail corridor.

4.3.1.6 Socioeconomics

Population growth associated with railroad construction and operations in the Mina rail corridor could result in additional infrastructure and public services needs. This probably would occur in the communities with the largest labor pools and where the workers resided permanently – the Reno and Las Vegas areas.

4.3.1.7 Noise and Vibration

During the construction phase, noise levels at locations such as Goldfield would be noticeable, and could approach or potentially exceed Federal Transit Administration or Federal Housing Authority construction noise guidelines during events such as rock blasting. This unavoidable impact would be temporary. Railroad operations along the Mina rail corridor could lead to an unavoidable, but small increase in ambient noise from passing trains in residential areas near Silver Peak, Mina, and Goldfield. No unavoidable adverse impacts associated with vibration are expected for either the construction or operations phases.

4.3.2 RELATIONSHIP BETWEEN SHORT-TERM USES AND LONG-TERM PRODUCTIVITY

Railroad construction could lead to a long-term loss of productivity in disturbed areas along the Mina rail corridor. In the context of transportation, long-term refers to the period of environmental recovery after the end of the construction phase or the active use of a transportation route for purposes supporting the Yucca Mountain Repository.

The land-cover types along the Mina rail corridor are widely distributed in the region. A loss of vegetation and grazing forage from a disturbed area in the corridor would have little effect on the regional productivity of plants and animals.

Productivity loss for soils would be limited to areas affected by land clearing and construction. These areas would not be available for revegetation and habitat for some time. Disturbed areas would recover, however, and eventually would return to pre-disturbance conditions, although the process of recovery would be slow in the arid environment.

4.3.3 IRREVERSIBLE OR IRRETRIEVABLE COMMITMENT OF RESOURCES

Railroad construction would result in some irretrievable or irreversible commitments of resources. Many resources could be retrievable at a later date through such actions as removing roadbeds, revegetating land, and recycling materials. Land uses could change in the rail corridor until railroad operations were complete, thereby limiting or eliminating other land uses for that period. However, at the end of the operations phase land along the corridor could revert to public or private ownership.

The loss of cultural resources would result in an irretrievable commitment of resources. Mitigation approaches involving the recovery of archaeological resources before construction activities degraded the sites would reduce the finite number of such resources in the Yucca Mountain region. However, the context of the sites would be destroyed.

DOE would use about 125 million liters (33 million gallons) of diesel fuel and 2.5 million liters (0.66 million gallons) of gasoline in Nevada during the construction phase (DIRS 180877-Nevada Rail Partners 2007, p. 2-7). This would be about 0.6 percent of the annual motor fuel consumption in the state. Construction use of diesel fuel would be about 2.2 percent of annual consumption. Operational use of motor fuel by locomotives would be a very small fraction of Nevada motor fuel use.

5. NEW INFORMATION REGARDING OTHER RAIL CORRIDORS

This chapter summarizes environmental information from the Yucca Mountain FEIS regarding the Carlin, Jean, and Valley Modified rail corridors, provides updated information on these corridors as appropriate, and considers the effect of any changes on the potential environmental impacts of the Carlin, Jean, and Valley Modified rail corridors. This chapter also describes present and reasonably foreseeable actions that would affect direct, indirect, and cumulative impacts in the regions of influence for these rail corridors.

Glossary terms are shown in ***bold italics***.

5.1 Introduction

In the Amended Notice of Intent dated October 13, 2006, the U.S. Department of Energy (DOE or the Department) announced that it would update as appropriate the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Yucca Mountain FEIS; DIRS 155970-DOE 2002, all) information and analyses for the Carlin, Jean, and Valley Modified ***rail corridors*** to determine if there are significant new circumstances or information relevant to environmental concerns (71 *FR* 60484). The Department has eliminated the Caliente-Chalk Mountain rail corridor, which would intersect the Nevada Test and Training Range, from further review because of U.S. Air Force concerns that a rail line on the Range would interfere with the Air Force mission and objectives (DIRS 182772-MTS 2007, p. 9). For clarity, any options in the Carlin, Jean, and Valley Modified rail corridors that would cross onto the Nevada Test and Training Range are depicted in figures with dashed lines. Additionally, DOE has informed the Timbisha Shoshone Tribe that any corridor options that would cross Timbisha Shoshone Trust Lands have been eliminated from consideration (DIRS 174558-Sweeney 2004, all).

5.1.1 GENERAL METHODOLOGY

DOE reviewed and updated the ***affected environment*** information in the Yucca Mountain FEIS, as appropriate, using the same data sources to the extent possible. However, since DOE completed the Yucca Mountain FEIS, many data management systems, such as geographic information systems, and data sources, such as the BLM LR2000, have advanced and currently provide more data and specificity than was previously available.

Since DOE completed the Yucca Mountain FEIS, the design and plans for the construction of a rail line within the Caliente rail corridor have advanced (see Section 2.2.3). The advanced Caliente rail design and plans provide a basis for updating information about and estimating environmental impacts for the other corridors analyzed in the Yucca Mountain FEIS. The approach DOE used to estimate changes in environmental impacts for the Carlin, Jean, and Valley Modified rail corridors is based on primary impact indicators. A primary impact indicator is the most important contributor or parameter used to determine the impacts of a particular environmental resource area. To update the information on the Carlin, Jean, and Valley Modified rail corridors, parameters that describe corridor characteristics (such as length of corridor and earthwork quantities) derived from Caliente rail alignment analyses provided ratios to estimate the data at a corridor level.

In addition, DOE updated the baseline environmental conditions for each resource area through the collection of federal, state, and local data commensurate with the information in the Yucca Mountain FEIS for the Carlin, Jean, and Valley Modified rail corridors. Using updated affected environments as the new baselines, while considering the evolution of engineering and design changes, DOE evaluated how the magnitude and range of potential impacts might have changed from those reported in the Yucca Mountain FEIS. DOE also considered present and reasonably foreseeable actions that would affect direct, indirect, and cumulative impacts within the regions of influence for these rail corridors.

Sections 5.1.1.1 through 5.1.1.12 describe the general approach DOE used to update the environmental conditions for each resource area for the Carlin, Jean, and Valley Modified rail corridors.

5.1.1.1 Land Use and Ownership

In the Yucca Mountain FEIS, DOE determined that an evaluation of impacts to land use and ownership should identify the current ownership of the land that its activities could disturb, and the present and anticipated future uses of the land. The Yucca Mountain FEIS defined the ***region of influence*** for impacts to land-use and ownership as land areas that would be disturbed or whose ownership or use would change as a result of constructing and operating a railroad. In the Yucca Mountain FEIS, DOE evaluated land use and ownership within the 400-meter (0.25-mile)-wide corridor. The update in this Nevada Rail Corridor SEIS used the same region of influence. Based on these criteria, DOE evaluated the potential impacts to land use and ownership from the construction and operation of the railroad. The Bureau of Land Management (BLM) manages most of the public lands through which the Carlin, Jean, and Valley Modified rail corridors would pass. Traditional land uses in most of the areas that would be directly and indirectly affected include grazing, mining, energy development, general recreation, utility rights-of-way, and wildlife management. Much of this land is not extensively disturbed, although it has been modified through activity such as grazing and mining.

Some BLM-administered lands have special designations that identify their uses or why they have be set aside. These include Wildlife Habitat Management Areas, Areas of Critical Environmental Concern, Wilderness Areas, and Wilderness Study Areas. Public lands in the Mina rail corridor region of influence provide a number of diverse recreation opportunities, and the BLM has designated certain lands as Special Recreation Management Areas.

Most of the land encompassing the Carlin, Jean, and Valley Modified rail corridors is BLM-administered public land. Each BLM Field Office manages lands within its administrative boundaries according to one or more Management Framework Plan or Resource Management Plan. In addition to BLM-administered land, the range of potentially affected land ownership includes private land holdings (including land designated for commercial development), other federal lands (DOE lands, U.S. Department of Defense lands), and American Indian trust lands and reservations.

To evaluate land use and ownership in the Carlin, Jean, and Valley Modified rail corridors, DOE obtained data from the latest editions of BLM Master Title Plats and online land record databases, such as BLM LR2000 (DIRS 182772-MTS 2007, p. 66). The Department also evaluated county and state land records and information from other federal agencies, universities, or commercial developments.

5.1.1.2 Air Quality

The update to air quality information includes changes in attainment status for the counties through which the Carlin, Jean, and Valley Modified rail corridors would pass. As in the Yucca Mountain FEIS, DOE defined the regions of influence for air quality as the air basins through which the corridors would pass. To update this air quality information, DOE obtained data from the Nevada Bureau of Air Quality to determine attainment status for counties that could be affected, and used the same qualitative methods as the Yucca Mountain FEIS. Areas in violation of one or more of the ***criteria pollutant*** standards are classified as ***nonattainment areas***. If there are not enough air quality data to determine the status of a remote or sparsely populated area, then the U.S. Environmental Protection Agency lists the area as unclassifiable. Unclassifiable areas are considered to be in attainment.

The region of influence includes the air basins in the vicinity of sources of criteria pollutant emissions that could be affected during railroad construction and operations. In particular, the air basins of the Las Vegas Valley (for ***particulate matter*** with aerodynamic diameters equal to or less than 10 micrometers [$\boldsymbol{PM_{10}}$] and ***carbon monoxide***) and the Pahrump Valley (for PM_{10}) where criteria pollutant concentrations are already an issue. If nonattainment or maintenance areas are not identified, detailed estimates of emission rates or comparisons to threshold levels for conformity were not made.

5.1.1.3 Hydrology

The Yucca Mountain FEIS analyzed surface-water resources within the 400-meter (0.25-mile)-wide corridor and within 1 kilometer (0.6 mile) of each side of the corridor. For this Nevada Rail Corridor SEIS, the region of influence for surface water, including springs, is the same as the Yucca Mountain FEIS. Information for this update was obtained from (1) the National Hydrography Dataset Waterbody geospatial data that the U.S. Geological Survey developed in cooperation with U.S. Environmental Protection Agency; (2) the Geographic Names Information System Nevada geospatial database developed by the U.S. Geological Survey and the BLM; and (3) the National Wetlands Inventory database managed by the U.S. Fish and Wildlife Service (DIRS 182772-MMTS 2007, p. 66).

In the Yucca Mountain FEIS, the Department used terrain types to estimate total water demand. Since DOE completed the Yucca Mountain FEIS, the Department has canvassed similar projects throughout Nevada and determined that the excavation type, not the terrain, would more accurately estimate total water demand associated with the rail line construction. DOE applied ratios based on earthwork to the corridors to estimate water demand in relation to the values for the Caliente rail alignment. DOE updated the water demand based on earthwork needs and reevaluated the water required for compaction. Earthwork needs would include excavation of common (alluvial) ripable rock, and drilling and blasting of solid bedrock.

5.1.1.4 Biological Resources and Soils

The update of information for biological resources and soils assessed changes in baseline biological resources and soils conditions for the Carlin, Jean, and Valley Modified rail corridors within the same region of influence as the Yucca Mountain FEIS. These changes in baseline conditions include vegetation cover, soil types, new or delisted special status species, critical habitat, and wildlife management areas. Consistent with the Yucca Mountain FEIS, this update considered the potential for impacts to vegetation communities; special status species (plants and animals), including their habitat; springs, wetlands, and riparian areas; big game habitat; and wild horse and burro herd management areas that in the 400-meter (0.25-mile)-wide corridor. This update also considered special status species and big game habitat within 5 kilometers (3 miles) of each side of the corridor that could be affected by rail line construction, and springs and riparian areas within this area that could be affected by permanent changes in surface-water flows.

DOE obtained location records for special status species from a statewide database managed by the Natural Heritage Program (DIRS 182772-MTS 2007, p. 67) that contains records of observations of rare or protected plants, fish, and wildlife species. Other information sources included (1) the *Carson City Field Office Consolidated Resource Management Plan* (DIRS 179560-BLM 2001, all); (2) the *Tonopah*

Resource Management Plan and Record of Decision (DIRS 173224-BLM 1997, all); (3) the *Biological Field Findings Report for Potential Rail Alignments along the Mina Route* (DIRS 182760-URS Corporation/Potomac-Hudson Engineering 2006, all); and (4) the *Mina Rail Route Feasibility Study* (DIRS 180222-BSC 2006, all. Additional DOE obtained information from the National Hydrography Dataset Waterbody geospatial data that the U.S. Geological Survey developed in cooperation with the U.S. Environmental Protection Agency, the Geographic Names Information System Nevada geospatial database and the BLM Wild Horse and Burro Management Area Maps (DIRS 182772-MTS 2007, p. 67).

5.1.1.5 Cultural Resources

The update to cultural resources information assesses changes in the baseline cultural resources conditions since DOE completed the Yucca Mountain FEIS. These changes include a review of surveys completed since DOE completed the Yucca Mountain FEIS and the number of sites and their potential for listing on the *National Register of Historic Places*. The region of influence was a corridor width of 400 meters (0.25 miles), which was the same as the Yucca Mountain FEIS. This update used records from the Desert Research Institute, the Nevada Cultural Resources Information System, and archaeological information repositories at the Harry Reid Center at the University of Nevada-Las Vegas, and the Nevada State Museum in Carson City.

As part of this update, the Department completed cultural resources records searches for the Carlin, Jean and Valley Modified rail corridors. The records searches identified the presence of cultural resources, including historic and archaeological sites.

5.1.1.6 Occupational and Public Health and Safety

The update for occupational and public health and safety focuses on traffic, worker industrial safety, incident-free radiological and nonradiological impacts, and radiological impacts related to accidents. Since DOE completed the Yucca Mountain FEIS, there have been updates to the methods and data to estimate the radiation doses for workers and members of the public (DIRS 182757-MTS 2007, all). The impacts for the Carlin, Jean, and Valley Modified rail corridors reflect new information, as described in Section 3.2.6 of this Nevada Rail Corridor SEIS.

Based on the conceptual design and plans for the construction of a rail line in the Caliente rail corridor, DOE has determined that the estimated workforce has increased the Department completed the Yucca Mountain FEIS. To update occupational and public health and safety impacts, DOE used employment levels scaled from the Caliente rail corridor analysis.

The region of influence for each includes:

- Traffic impacts: The 400-meter (0.25-mile) width of the corridor and public highways used by workers and for shipments during construction and operations.
- Worker industrial safety impacts: The 400-meter-wide rail corridor.
- Incident-free radiological and nonradiological impacts: The 800-meter (0.5-mile) area on either side of the centerline of the rail corridor.
- Radiological impacts with respect to accidents: An area within an 80-kilometer (50-mile) radius from a potential occurrence location in the rail corridor.

DOE obtained information from the Bureau of Labor Statistics for 2005, and used the RADTRAN 5 computer program (DIRS 150898-Neuhauser and Kanipe 2000, all; DIRS 155430-Neuhauser, Kanipe, and Weiner 2000, all) and the RISKIND computer program (DIRS 101483-Yuan et al. 1995, all) where applicable.

5.1.1.7 Socioeconomics

The update to information on socioeconomics includes changes to the employment and population baselines for the three corridors. The region of influence for this update is the Nevada counties through which the corridors would pass, and the two areas where most workers would be expected to reside (the Carson City/Washoe County area and Clark County).

DOE obtained data from the U.S. Census Bureau, the Nevada State Demographer, and other local and state sources. In addition, the Department utilized estimates and projections from the socio-demographic forecasting software program REMI, version 9, to develop baselines.

5.1.1.8 Noise and Vibration

To assess and update the baseline conditions for noise and vibration, DOE reviewed the input parameters used for the noise and vibration analysis in the Yucca Mountain FEIS. This included the population within the region of influence for noise and vibration, relevant noise standards, and the frequency and number of trains. DOE has updated the criteria to determine the level of potential impacts from noise and vibration. For noise impacts from construction activities, DOE used U.S. Department of Transportation, Federal Transit Administration, methods (DIRS 177297-Hanson, Towers, and Meister 2006, all) and construction noise guidelines. For operation of trains during the construction and operations phases, DOE analyzed noise impacts under established Surface Transportation Board (STB) criteria (49 CFR 1105.7e(6)). To evaluate potential vibration impacts from construction and operations activities, DOE used Federal Transit Administration building vibration damage and human-annoyance criteria (DIRS 177297-Hanson, Towers, and Meister 2006, all). This update assessed the distance of the rail line from communities along the rail line and estimated the noise impacts from railroad construction and operation to these communities. For the update to impacts from vibration, DOE considered typical background levels of ground vibration, the number of trains, and the distance of the rail line from historic structures or sites of cultural significance. The updated criteria for noise and vibration do not affect the level of impacts presented in the Yucca Mountain FEIS.

5.1.1.9 Aesthetics

Consistent with the Yucca Mountain FEIS, the region of influence for aesthetics in this Nevada Rail Corridor SEIS is based on a 400-meter (0.25 mile)-wide corridor and its ***viewshed***. This update considered changes to the visual sensitivity ratings of viewsheds in Nevada and the BLM Visual Resource Management System objectives as described BLM Handbook H-8431-1, Visual Resource Contrast Rating (DIRS 173053-BLM 1986, all). DOE reviewed BLM plans, including the Elko Resource Management Plan, the Las Vegas Resource Management Plan, and the Tonopah/Battle Mountain Resource Management Plan. The analysis of potential impacts on aesthetic resources considered BLM ratings for both federal and non-federal land areas. Non-federal lands were granted the rating of surrounding BLM lands or else assigned the BLM rating of Class III. The regions of influence included the landscapes along the rail corridor with aesthetic quality that construction and operations of a railroad could affect.

5.1.1.10 Utilities, Energy, and Materials

The Yucca Mountain FEIS evaluated utilities, energy, and materials impacts common to all corridors and noted that these impacts would include the use of motor fuel, steel, and concrete. Since DOE completed the Yucca Mountain FEIS, information on the baseline supply of utilities, energy, and construction materials has been updated. For example, annual motor fuel use in Nevada was updated from the Federal Highway Administration database. DOE applied the engineering methods used during recent work on the Caliente rail alignment to estimate the amount of earthwork for the Carlin, Jean, and Valley Modified rail corridors. The Department used the estimated amount of earthwork to determine fuel use because fuel use is proportional to the quantity of earthwork needed. In addition, applying the engineering methods used for the Caliente alignment, DOE developed material requirement estimates based on the length of rail line for steel (main track rail) and concrete (main track ties).

5.1.1.11 Waste Management

Waste management impacts are based on the estimated generation of solid municipal waste from rail line construction in each of the three corridors. The Yucca Mountain FEIS evaluated common waste management impacts for all corridors rather than for individual corridors. Information to allow differentiation between corridor waste management impacts is now much more readily available. Consistent with the Yucca Mountain FEIS, this update estimated the peak annual generation of sanitary solid waste. However, based on advanced databases, this update was then able to estimate the impact that the waste generated would have on the individual landfills serving the respective corridor, rather than on landfills on a state-wide basis as the Yucca Mountain FEIS did. DOE obtained information on landfills from the Nevada Division of Environmental Protection database (DIRS 174041-NDEP 2007, all).

5.1.1.12 Environmental Justice

Consistent with the Yucca Mountain FEIS, DOE evaluated the potential impacts to two specific populations, those defined as low income and those defined as minority. For the Yucca Mountain FEIS, the region of influence for the environmental justice analysis was defined as the Nevada counties the corridors would cross. DOE identified low income and minority populations by examining 1990 and 2000 U.S. Census Bureau block group data in the region of influence.

Census data for the year 2000 concerning minority communities in Nevada was available at the block group level for the Yucca Mountain FEIS analysis; however, 2000 Census data on low-income communities were not. Therefore, the information on low-income communities was from the 1990 Census. As a consistent criterion for identifying minority and low-income blocks and block groups, DOE employed a 10-percent threshold, meaning that the environmental analysis focused on blocks and block groups in Nevada having a 10-percent or greater minority population or low-income population than the state averages. DOE adopted the 10-percent threshold for the Yucca Mountain FEIS from a 1995 Nuclear Regulatory Commission document, *Interim NRC Procedure for Environmental Justice Reviews* (DIRS 103426-NRC 1995, all). This threshold is consistent with the recent revision of Nuclear Regulatory Commission guidance on environmental justice (DIRS 157276-NRC 1999, all).

For determining minority populations for the update in this Nevada Rail Corridor SEIS, DOE followed the Council on Environmental Quality guidance (DIRS 103162-CEQ 1997, all) and the approach used in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Section 3.1.13). DOE considered that a minority population exists where either: (a) the minority population of the affected area exceeds 50 percent; or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. (DOE used both the United States and the State of Nevada minority populations.)

The Department used the Council on Environmental Quality definition of low-income and the annual statistical poverty thresholds from the U.S. Census Bureau. A low-income community exists when the low-income population percentage in the area of interest is meaningfully greater than the low-income population in the general population. For purposes of the analysis of low-income communities, DOE applied the U.S. Nuclear Regulatory Commission guidance of a 20-percent threshold above the state average of 11 percent (that is, 31 percent) for low-income populations (69 *FR* 52040, August 24, 2004).

For this update, DOE used 2000 Census Bureau information block group data to determine both low-income and minority populations for this update.

5.2 Carlin Rail Corridor

Table 5-1 summarizes the results of the update to the primary impact indicators for the Carlin rail corridor and compares them with the corridor information reported in the Yucca Mountain FEIS. The information reflects the total for rail road construction and operations, unless otherwise noted.

The Carlin rail corridor would originate at the Union Pacific Railroad Mainline near Beowawe in north-central Nevada. The corridor would travel south through Crescent, Grass, and Big Smoky Valleys, passing west of Tonopah and east of Goldfield. It would then travel south following and periodically crossing the western boundary of the Nevada Test and Training Range, passing through Oasis Valley and across Beatty Wash. It would travel across Crater Flats and along Fortymile Wash to Yucca Mountain. Depending on the option, the Carlin rail corridor would be approximately 530 kilometers (330 miles) long from its link with the Union Pacific Railroad Mainline to Yucca Mountain.

Options to the Carlin rail corridor range from 510 kilometers to 540 kilometers (320 to 340 miles). The two main corridor options are the Big Smoky Valley option and the Monitor Valley option. The Yucca Mountain FEIS contains detailed descriptions of the Carlin rail corridor and its options, which are shown in Figure 5-1.

5.2.1 LAND USE AND OWNERSHIP

In the Yucca Mountain FEIS, DOE determined that an evaluation of impacts to land use and ownership should identify the current ownership of the land that its activities could disturb, and the present and anticipated future uses of the land. In the Yucca Mountain FEIS, DOE evaluated land use and ownership in the 400-meter (0.25-mile)-wide corridor. The region of influence for land-use and ownership impacts was defined as land areas that would be disturbed or whose ownership or use would change as a result of the construction and operation of a rail line within this corridor. The purpose of the 400-meter width was to provide sufficient space for final alignment to route the rail line around sensitive land features or engineering obstacles. The region of influence for this Nevada Rail Corridor SEIS is the same as the Yucca Mountain FEIS.

Traditional land uses in most of the Carlin rail corridor region of influence that would be directly and indirectly affected include grazing, mining, energy development, general recreation, utility rights-of-way, and wildlife management. Much of this land is not extensively disturbed, although it has been modified through activity such as grazing and mining.

Some BLM-administered lands have special designations which denote their use or what they have been set aside for. These include Wildlife Habitat and Management Areas, Areas of Critical Environmental Concern, Wilderness Areas, and Wilderness Study Areas. Public lands in the Carlin rail corridor region of influence provide a number of diverse recreation opportunities, and the BLM has designated certain lands as Special Recreation Management Areas.

Table 5-1. Updated environmental information for the Carlin rail corridor (page 1 of 2).

Resource	Changes from Yucca Mountain FEIS to this analysis
Corridor length	No change
Land ownership	
BLM-administered land	Yucca Mountain FEIS: 44,000 to 49,000 acres (180 to 200 square kilometers) (approximately 86 percent) Updated analysis: 44,000 to 52,000 acres (180 to 210 square kilometers) (88 to 94 percent)
Private land	Yucca Mountain FEIS: 1,00 to 3,700 acres (7.3 to 15 square kilometers) (approximately 6.7 percent) Updated analysis: 1,600 to 2,300 acres (6.4 to 9.4 square kilometers) (3.27 to 4.02 percent)
Nevada Test and Training Range land	Yucca Mountain FEIS: 0 to 2,700 acres (0 to 10.9 square kilometers) (approximately 5.2 percent) Updated analysis: 0 to 11.4 square kilometers (0 to 2,800 acres) (0 to 4.9 percent)
Nevada Test Site land	No change
American Indian trust lands and reservations	No change
Air quality	
National Ambient Air Quality Standards attainment status	No change
Hydrology	
Surface water	No change
Groundwater use (construction phase)	Yucca Mountain FEIS: 660 acre-feet (810,000 cubic meters) Updated analysis: 5,800 acre-feet (7.13 million cubic meters
Biological resources and soils	Six additional sensitive species recorded
Cultural resources (records search)	Yucca Mountain FEIS: 110 recorded sites Updated analysis: 120 recorded sites
Occupational and public health and safety	
Industrial hazards (construction and operations)	
Total recordable cases	Yucca Mountain FEIS: 210 Updated analysis: 391
Lost workday cases	Yucca Mountain FEIS: 105 Updated analysis: 224
Fatalities	Yucca Mountain FEIS: 0.41 Updated analysis: 1
Transportation hazards (construction only)	
Traffic fatalities	Yucca Mountain FEIS: 1.1 Updated analysis: 4
Cancer fatalities	Yucca Mountain FEIS: 0.14 Updated analysis: 0.6

Table 5-1. Updated environmental information for the Carlin rail corridor (page 2 of 2).

Resource	Changes from Yucca Mountain FEIS to this analysis
Occupational and public health and safety (continued)	
Incident-free radiological impacts (latent cancer fatalities) (operations only)	
Public	Yucca Mountain FEIS: 0.0012 Updated analysis: 0.00008
Workers	Yucca Mountain FEIS: 0.31 Updated analysis: 0.33
Radiological transportation accident fatalities	
Radiological accident risk (latent cancer fatalities)	Yucca Mountain FEIS: 0.000000037 Updated analysis: 0.000001
Cancer fatalities from vehicle emissions	Yucca Mountain FEIS: 0.09 Updated analysis: 0.4
Nonradiological transportation accident fatalities	
Spent nuclear fuel and high-level radioactive waste transportation	Yucca Mountain FEIS: 0.54 Updated analysis: 0.31
Construction and operations workforce	Yucca Mountain FEIS: 0.7 Updated analysis: 3.3
Socioeconomics	
Estimated construction workforce	Yucca Mountain FEIS: 1,230 worker-years Updated analysis: 6,600 worker-years
Estimated operations workforce	Yucca Mountain FEIS: 47 workers per year Updated analysis: 42 workers per year
Noise and vibration	No change
Aesthetics	No change
Utilities, energy, and materials (amount used)	
Diesel	Yucca Mountain FEIS: 10.6 million gallons (40 million liters) Updated analysis: 29 million gallons (110 million liters)
Gasoline	Yucca Mountain FEIS: 0.22 million gallons (0.82 million liters) Updated analysis: 0.63 million gallons (2.4 million liters)
Steel	Yucca Mountain FEIS: 82,000 tons (76,000 metric tons) Updated analysis: 95,000 tons (86,000 metric tons)
Concrete	Yucca Mountain FEIS: 456,000 tons (414,000 metric tons) Updated analysis: 364,000 tons (330,000 metric tons)
Waste management	
Sanitary solid waste	Updated analysis: 1.7 tons (1.6 metric tons) per day
Environmental justice (disproportionately high and adverse impacts)	No change, none identified

To obtain current land use and ownership data, DOE consulted the latest edition of the BLM Master Title Plats and online land record databases, such as BLM LR2000. The Department also evaluated county and state land records, along with information managed by other federal agencies, universities, or commercial developments.

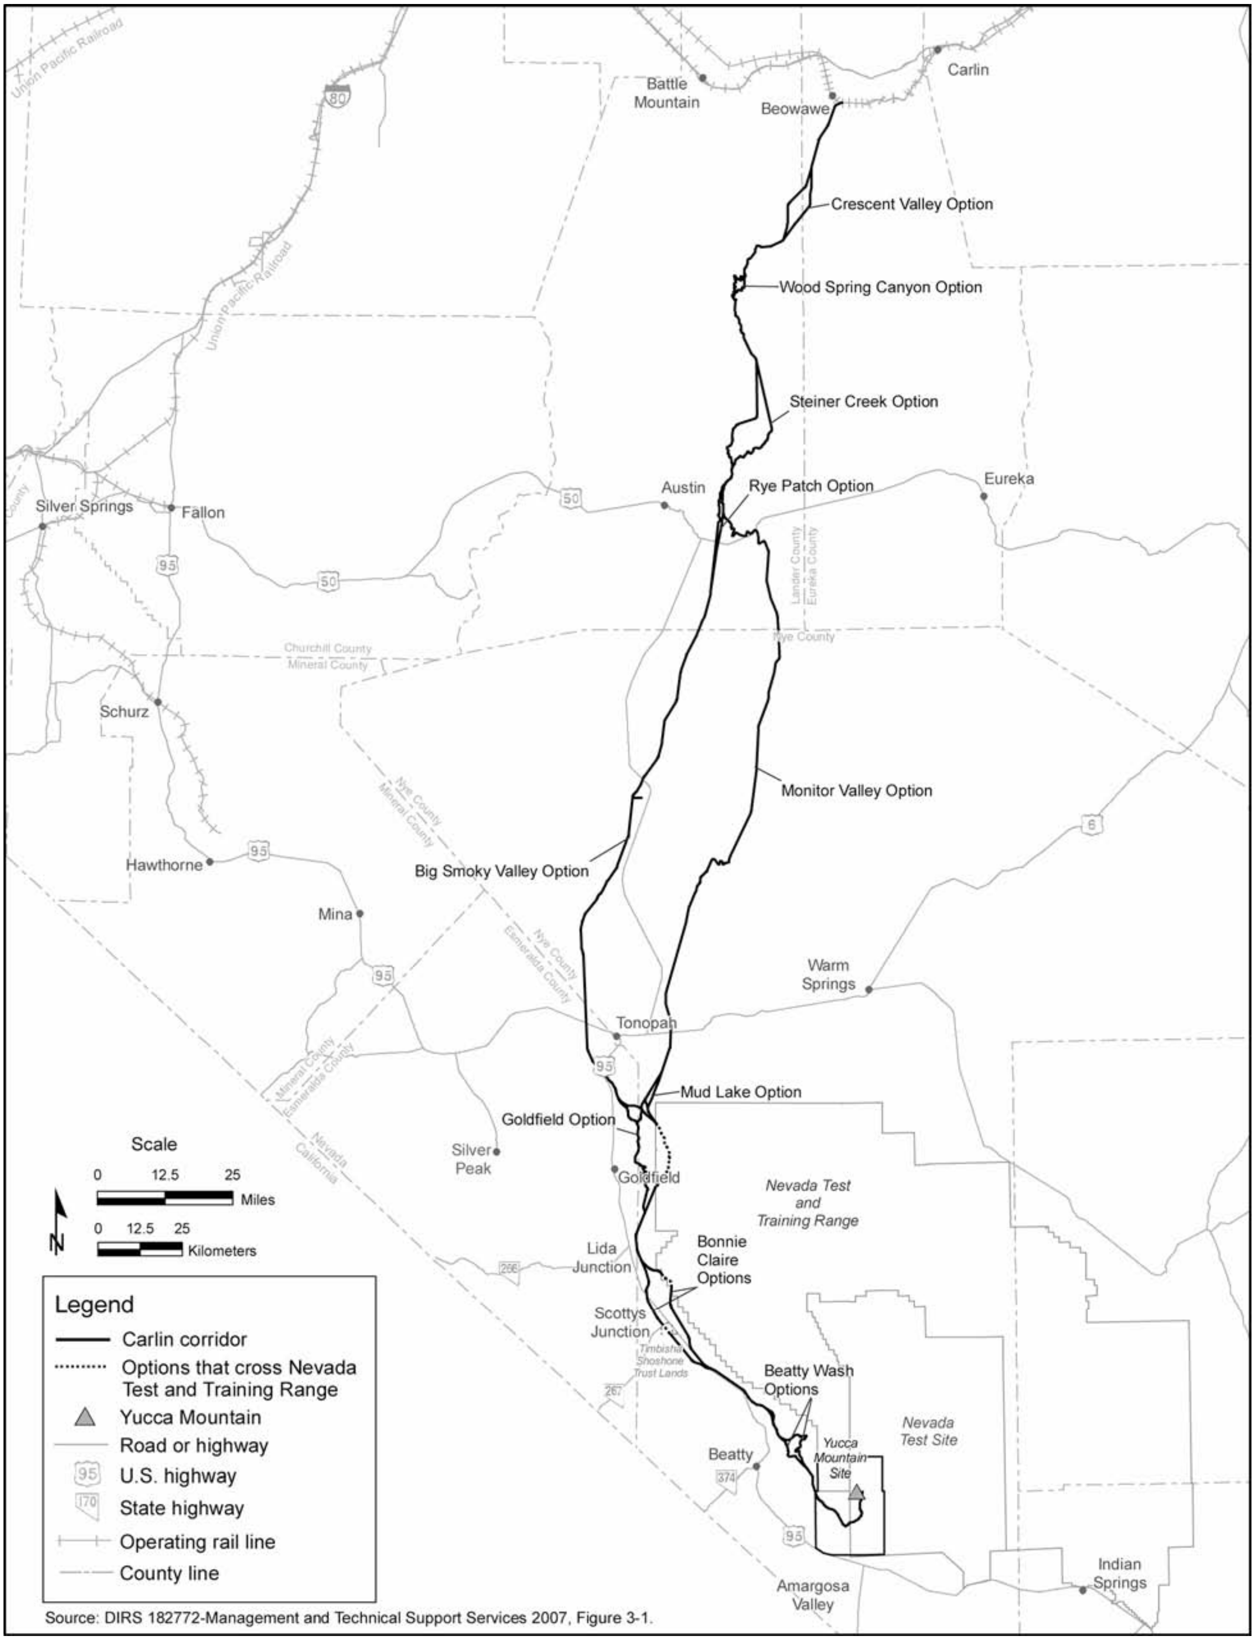

Figure 5-1. Carlin rail corridor and options (2002).

Potential impacts from construction and operation of a railroad in the Carlin rail corridor would be consistent with those that DOE reported in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Section 6.3.2.1.1). The following paragraphs discuss information gathered in relation to land use in the Carlin rail corridor since DOE completed the Yucca Mountain FEIS.

The Yucca Mountain FEIS reported that the BLM administered approximately 86 percent of the land in the corridor (180 to 200 square kilometers [44,000 to 49,000 acres]), the Department of Defense managed 5.2 percent (0 to 10.9 square kilometers), DOE managed 2.2 percent (4.6 square kilometers [1,100 acres]), and less than 1 percent (0 to 1.6 square kilometers) was held in trust by the Timbisha Shoshone Tribe. The Department of Defense lands were on the Nevada Test and Training Range.

Current land holdings for the Carlin rail corridor are as follows: BLM-administered land, approximately 88 to 94 percent (180 to 210 square kilometers [44,000 to 52,000 acres]); Department of Defense land, about 0 to 4.9 percent (0 to 11.4 square kilometers [2,800 acres]); DOE land, approximately 2 percent (unchanged); and Timbisha Shoshone trust lands less than 1 percent (unchanged) (DIRS 182772-MTS 2007, p. 73). The change in estimates of amount of BLM-administered land and private property within this corridor are, in part, the result of using databases whose land ownership data have been refined and enhanced since completion of the Yucca Mountain FEIS.

The Yucca Mountain FEIS reported that about 6.7 percent (7.3 to 15 square kilometers [1,800 to 3,700 acres]) of the land within the Carlin rail corridor was private property. Currently, DOE estimates that private property occupies about 3.3 to 4 percent (6.4 to 9.4 square kilometers [1,600 to 2,300 acres]) of the land in the corridor (DIRS 182772-MTS 2007, p. 73). Similar to changes in BLM administered land, the change in the amount of private land reflects, in part, the use of more recent databases whose land ownership data have been enhanced since the Yucca Mountain FEIS. The highest density of private land occurs within the first 30 kilometers (19 miles) of the corridor (near Beowawe), although other concentrations of private property occur near Crescent Valley. In the Crescent Valley area, for instance, much of the private property lies in single sections (2.6 square kilometers [1 square mile]) of land that are separated by BLM-administered sections (as shown in Figure 5-3 for the area south of Crescent Valley). As a general criterion, DOE minimized crossing private property when it identified the Carlin rail corridor; however, as a result the corridor tends to cross private parcels of land owned by many individuals, which creates a correspondingly complex ownership pattern.

The Bonnie Claire option in the Carlin rail corridor would cross and divide an 11-square-kilometer (2,800-acre) portion of the Timbisha Shoshone trust lands near Scottys Junction, Nevada.

Since DOE completed the Yucca Mountain FEIS, the BLM has found that a 0.43-square-kilometer (100-acre) parcel of public land near Hadley, Nevada, is suitable for direct (noncompetitive) sale to Round Mountain Gold Corporation for expansion of the existing Hadley Airport (*Notice of Realty Action: Direct (Non-Competitive) Sale of Public Lands, Nye County, NV*; 72 *FR* 4290, January 30, 2007); Figure 5-2 shows the location of the airport in relation to the Carlin rail corridor. This land, which is approximately 2.6 kilometers (1.6 miles) from the center of the Carlin rail corridor, was purchased by the Round Mountain Gold Corporation on May 11, 2007.

The Carlin rail corridor would pass near historic and currently established mining districts. At the time DOE completed the Yucca Mountain FEIS, the number of unpatented claims staked in Nevada had been steadily dropping since the BLM instituted a requirement in 1991 for an annual fee for each claim. Since the DOE completed the Yucca Mountain FEIS, the prices of gold and other metallic resources have been steadily rising, which has caused a resurgence in the number of mining claims. Unpatented mining claims have been, and continue to be, staked along the corridor, with sections containing the greatest number of claims located near the Crescent Valley and Goldfield areas (see Figure 5-3). According to a mineral assessment prepared for Lander County, exploration and development activity is increasing in and around the Crescent Valley area for gold, silver, barite and geothermal resources (DIRS 182772-MTS 2007, p. 73).

The Cortez Gold Mines are near the northern end of the Carlin rail corridor, in the vicinity of Crescent Valley, and have been expanding their mining operations since DOE completed the Yucca Mountain FEIS. The Cortez Gold Mines, also called the Cortez Joint Venture, is the oldest continuously operating gold mining operation in Nevada; Figure 5-3 shows the location of the mine in relation to the Carlin rail corridor. The Cortez Gold Mines are among the largest annual producers of gold in the state of Nevada, and considered one of Nevada's major mines (DIRS 182772-MTS 2007, p. 74). Since DOE completed the Yucca Mountain FEIS, the Cortez Gold Mine has proposed an expansion of its Pipeline/South Pipeline Project, which is an open-pit gold mining and processing operation (*Notice of Intent To Prepare an Environmental Impact Statement To Analyze the Proposed Amendment to the Pipeline/South Pipeline Plan of Operations (NVN–067575) for the Cortez Hills Expansion Project*; 70 *FR* 72308, December 2, 2005). The BLM has granted authorization to Cortez Gold Mine to disturb approximately 37 square kilometers (9,000 acres) associated with the Pipeline/South Pipeline Project, which was under BLM consideration when DOE completed the Yucca Mountain FEIS. The proposed expansion would include an additional 25 square kilometers (6,100 acres). The proposed expansion is less than 1.6 kilometers (1 mile) from the outer boundary of the Carlin rail corridor. The EIS for the proposed expansion project is in preparation, so it is unknown what impacts it could have; in addition, the project could undergo modifications and boundary adjustments.

DOE reviewed information in the Mineral Resources Data System and the Abandoned Mine database (DIRS 182772-MTS 2007, p. 74) to determine if additional mines, active or abandoned, have been located and documented since DOE completed the Yucca Mountain FEIS. Updates to these data systems revealed that the Carlin rail corridor would cross Mammoth, Diamondfield Property, Aloha, Tognoni Spring, Goldfield Bullion, Future Group, and Wright Prospect mines. The Monitor Valley option would cross Nevada State Pit, and there is an abandoned mine on the Steiner Creek option. Of these, Nevada State Pit, Tognoni Spring, and Diamondfield Property are "past producers," meaning that mining activities occurred in the past but no mining operations are currently underway.

The classification for Wright Prospect and Future Group is "occurrence," meaning that discovery of an outcrop has occurred and there could be some land disturbance, but there is currently no mining operation underway. Aloha, Goldfield Bullion, and Mammoth are "prospect sites," meaning there has been discovery of a mineral resource but no mining (DIRS 182772-MTS 2007, p. 74).

During the Goldfield mining history, several patents were issued for mining claims along the Carlin rail corridor, as reported in the Yucca Mountain FEIS. With a patented mining claim, the claimholder owns the land and the minerals. Effective October 1, 1994, Congress imposed a moratorium on spending appropriated funds for the acceptance or processing of mineral patent applications that had not yet received First Half Final Certificates (the required first step for patent issuance) or were not in Washington, D.C., for Secretary of Interior review of First Half Final Certificates on or before September 30, 1994. Until the moratorium is lifted, the BLM will not accept applications for mining claim patents. Therefore, the numbers and locations of patented mining claims remain unchanged from those reported in the Yucca Mountain FEIS.

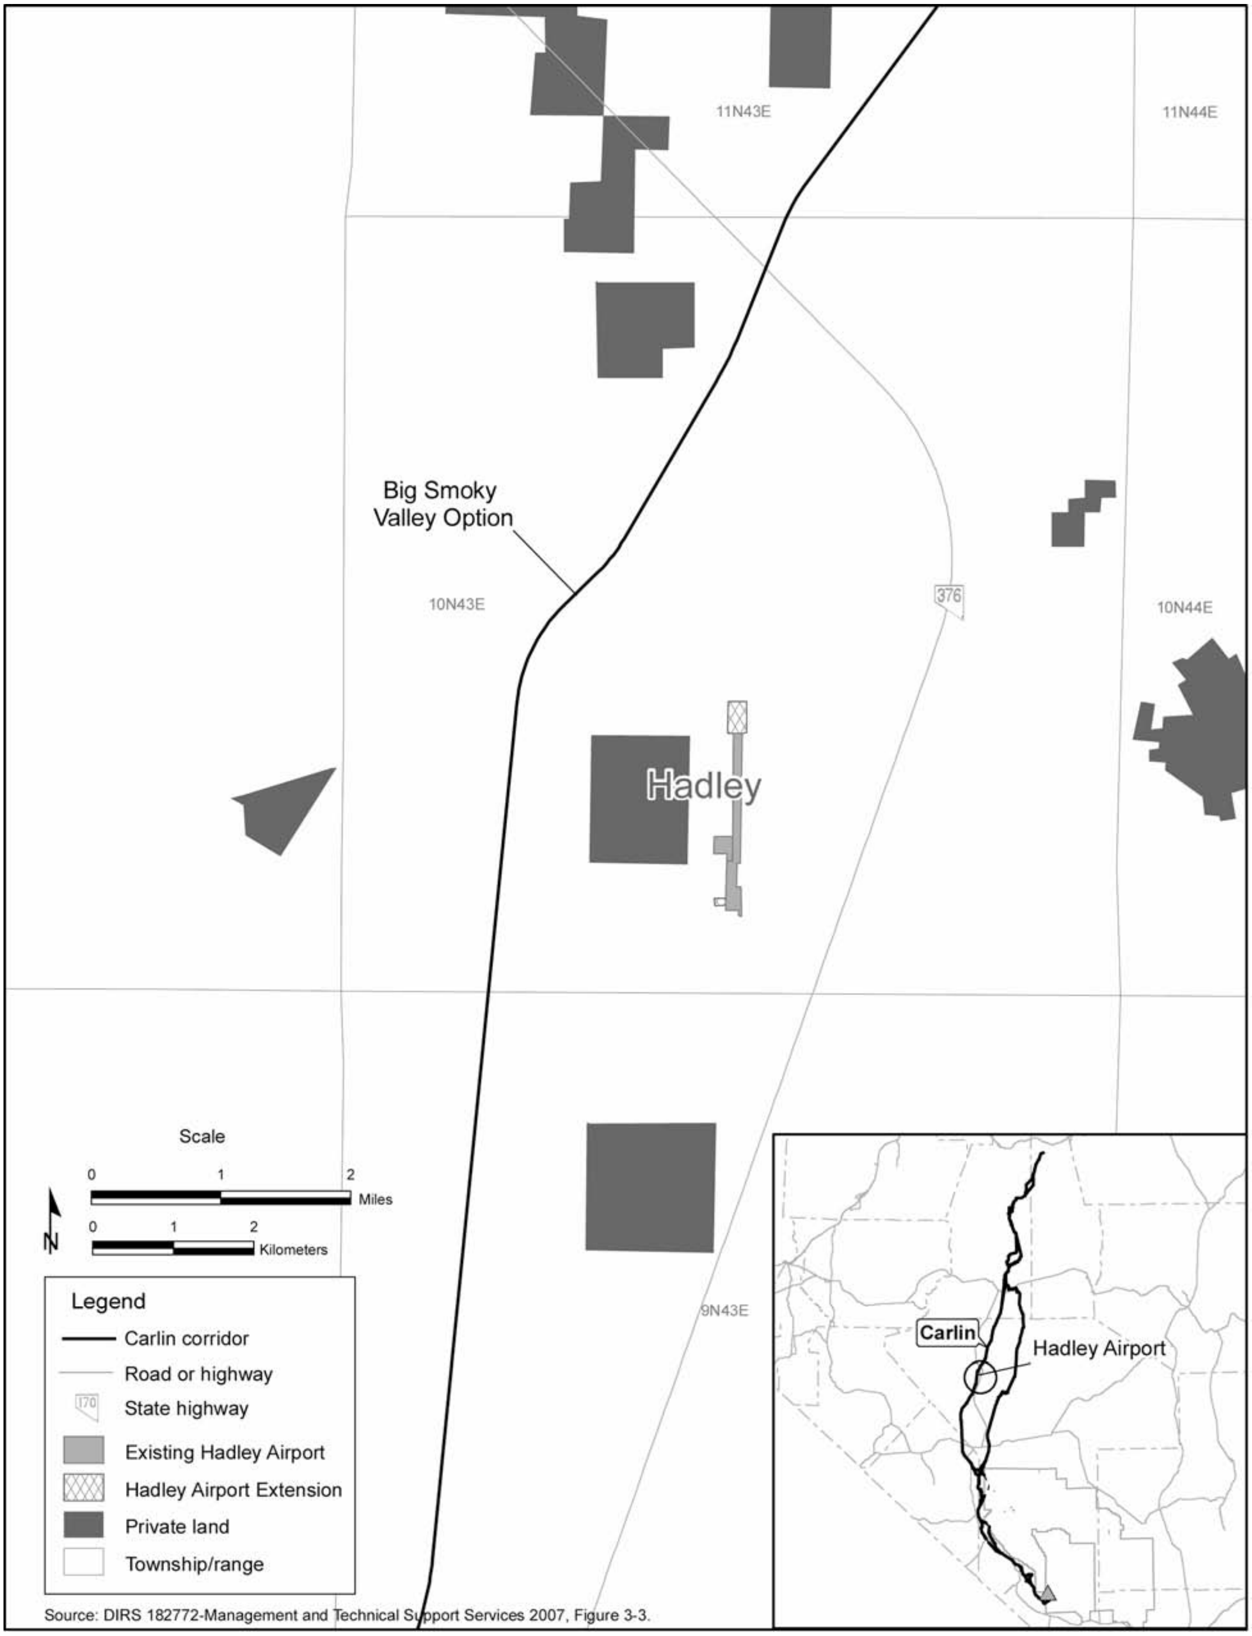

Figure 5-2. Hadley Airport location.

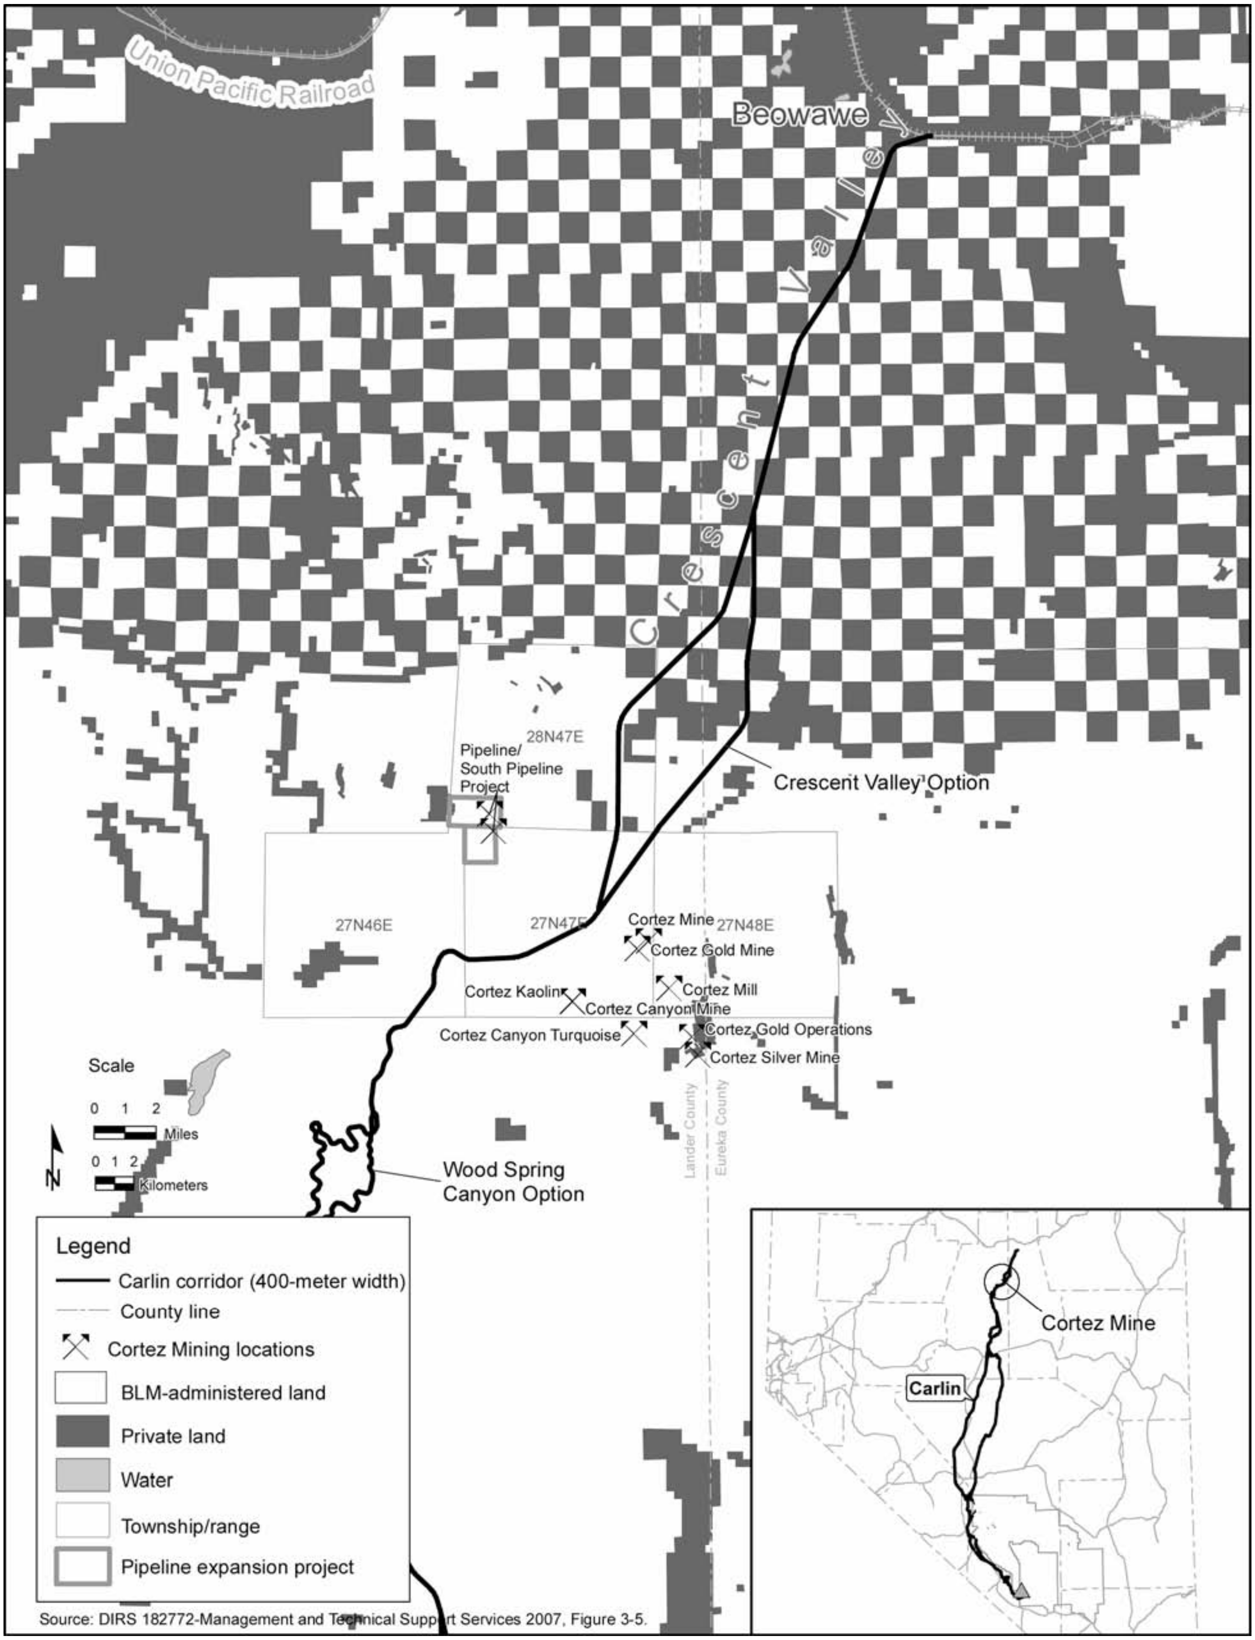

Figure 5-3. Cortez Mine location.

During an evaluation of Wilderness Areas and Wilderness Study Areas potentially affected by the Carlin rail corridor, the Yucca Mountain FEIS determined that only the Steiner Creek option would encroach on the Simpson Park Wilderness Study Area. The status of this Wilderness Study Area has not changed; therefore, this constitutes a land-use conflict. The Yucca Mountain FEIS reported that the Carlin rail corridor and its options would cross 12 BLM grazing allotments. The BLM has since updated their grazing allotment information, which indicates Carlin and its options would now cross the Geyser, South Buckhorn, Carico Lake, Grass Valley, Simpson Park, Potts, Monitor, Hunts Canyon, Kingston, Wildcat Canyon, Smoky, Francisco, San Antone, Montezuma and Razorback grazing allotments, along with an allotment the BLM has designated as being unused. According to this data source, the Carlin rail corridor also crosses the Ralston and Silver King grazing allotments; however, the BLM Battle Mountain District Office reports this same area as just the Ralston grazing allotment.

As reported in the Yucca Mountain FEIS, the corridor would cross six wild horse and burro herd management areas, the Bates Mountain pronghorn antelope release area, three riparian habitats, and the Simpson Park habitat management area (see Section 5.2.4). According to the Yucca Mountain FEIS, the Carlin rail corridor would cross a Desert Land Entry Withdrawal. Since DOE completed the Yucca Mountain FEIS, the BLM has authorized or received proposals for additional Desert Land Entry Withdrawals within or adjacent to the Carlin rail corridor (DIRS 182772-MTS 2007, p. 74). For example, the Monitor Valley Option crosses or is adjacent to six Desert Land Entries. Of these, three have been issued patents, one has been authorized by BLM and is awaiting patent, and two others have applications in process with the BLM. The BLM grants Desert Land Entry Withdrawals to individuals to reclaim, irrigate, and cultivate arid and semiarid public lands of the western United States. The Yucca Mountain FEIS reported that the Carlin rail corridor would cross linear land features such as rights-of-way for utilities and roads. A review of BLM land records, including Master Title Plats, indicated the authorization of additional rights-of-way since DOE completed the Yucca Mountain FEIS (DIRS 182772-MTS 2007, p. 75).

5.2.2 AIR QUALITY

The Yucca Mountain FEIS evaluated air quality impacts common to all of the proposed corridors and noted that these impacts would include temporary increases in ***criteria air pollutant*** concentrations from construction of a rail line. The Yucca Mountain FEIS did not identify any air quality impacts unique to the Carlin rail corridor. The update did not find any indication that the air quality status of the counties and areas along the Carlin rail corridor has changed since DOE completed the Yucca Mountain FEIS (DIRS 182772-MTS 2007, p. 82).

Areas in violation of one or more of the criteria pollutant standards are classified as nonattainment areas. If there is not enough air quality data to determine the status of a remote or sparsely populated area, then the Environmental Protection Agency lists the area as unclassifiable and the area is considered to be in attainment. The Carlin rail corridor would pass through rural parts of Nye, Esmeralda, Lander, and Eureka Counties in Nevada that are either in attainment or unclassifiable for criteria air pollutants under the Environmental Protection Agency (DIRS 182772-MTS 2007, p. 82). Since no nonattainment or maintenance areas were identified, no detailed estimates of emission rates or comparisons to threshold levels for conformity were made.

Fuel use by construction equipment would emit ***carbon monoxide, nitrogen dioxide, sulfur dioxide***, and particulate matter with diameters of 10 micrometers or less (***PM_{10}***) and 2.5 micrometers or less (***$PM_{2.5}$***) Construction activities would also emit PM_{10} in the form of ***fugitive dust*** from excavation, truck traffic, and operation of concrete batch plants (DIRS 180877-Nevada Rail Partners 2007, p. 2-6). The emissions would be temporary and would cover a sizeable area as construction progressed along the length of the corridor.

Air quality impacts common to all corridors during railroad operations would result from diesel locomotives, which would emit carbon monoxide, nitrogen dioxide, sulfur dioxide, PM_{10} and $PM_{2.5}$. The number of locomotive engines in use and the associated operational characteristics would not differ appreciably from those in the Yucca Mountain FEIS. Therefore, there should be no measurable differences in potential impacts from those in the Yucca Mountain FEIS.

5.2.3 HYDROLOGY

This section describes surface-water and groundwater resources and impacts to those resources. The Yucca Mountain FEIS analyzed surface water and groundwater resources within the 400-meter (0.25-mile)-wide corridor and within 1 kilometer (0.6 mile) of each side of the corridor. For this Nevada Rail Corridor SEIS, the region of influence for hydrology, was the same as for the Yucca Mountain FEIS.

5.2.3.1 Surface Water

The Yucca Mountain FEIS identified potential surface-water resources, which include springs, streams, ***riparian areas***, and reservoirs within the region of influence along the corridor (DIRS 155970-DOE 2002, Table 6-37). As noted in the Yucca Mountain FEIS, the spread of construction-related materials by precipitation or intermittent runoff events, releases to surface waters, and the alteration of natural drainage patterns or runoff rates that could affect downgradient resources would be unlikely. Based on the information collected for this update, impacts to surface-water resources from construction of a rail line in the Carlin rail corridor would be the same as those reported in the Yucca Mountain FEIS.

The Carlin rail corridor, including all of its options, would cross 11 different mapped ***100-year flood*** zones or flood zone groups (DIRS 182772-MTS 2007, p. 82). These remain unchanged since DOE completed the Yucca Mountain FEIS. Although unlikely, the spread of construction-related materials by precipitation or intermittent runoff events could occur during the construction of a rail line. Impacts associated with changes in drainage patterns or to erosion and sedimentation rates or locations would be small and localized.

5.2.3.2 Groundwater

In the Yucca Mountain FEIS, the Department used terrain types to estimate total water demand. Since DOE completed the Yucca Mountain FEIS, DOE has canvassed similar projects throughout Nevada and determined that the amount and type of earthwork, not the terrain, would more accurately estimate total water demand associated with the construction of a rail line. Therefore, DOE updated the water demand based on earthwork needs. This resulted in an estimated water demand for the Carlin rail corridor of approximately 7.1 million cubic meters (5,800 acre feet) (DIRS 180877-Nevada Rail Partners 2007, p. 2-7) compared to the estimate based on terrain types reported in the Yucca Mountain FEIS of 810,000 cubic meters (660 acre-feet). To accommodate this increase in estimated water demand, DOE would need to draw more water than originally estimated in the Yucca Mountain FEIS from the underlying hydrographic basins and pump from additional wells. Groundwater withdrawal could temporarily affect discharge from nearby wells or springs. DOE would conduct detailed analyses if new wells required for construction of the rail line were to be located near other water sources.

Construction of a rail line would require water for soil compaction, dust control, and workforce use. Water use during construction would come primarily from groundwater resources, specifically hydrographic basins. If the hydrographic basin is designated, permitted groundwater rights approach or exceed the estimated perennial yield, water resources are being depleted or require additional administration, and the Nevada State Engineer has declared preferred uses of water. Table 5-2 updates the designation status of the hydrographic basins and the percentage of the Carlin rail corridor that would

Table 5-2. Hydrographic basins associated with the Carlin rail corridor.[a,b]

Hydrographic basin (and subbasin where applicable)	Length (kilometers)[c]	Percentage of total[d]	Designated
Alkali Spring Valley	21	4	No
Big Smoky Valley/Northern Part	110	21	Yes
Big Smoky Valley/Tonopah Flat	76	14	Yes
Carico Lake Valley	4.4	0.82	No
Crater Flat	29	5.5	No
Crescent Valley	80	15	Yes
Fortymile Canyon/Jackass Flats	13	2.4	No
Grass Valley	55	10	No
Lida Valley	24	4.4	No
Oasis Valley	23	4.4	Yes
Ralston Valley	27	5.1	Yes
Sarcobatus Flat	48	9	Yes
Stonewall Flat	21	3.9	No

a. Source: DIRS 182772-MTS 2007, p. 83.
b. To calculate water demand for each basin, multiply the total water demand for a given corridor by the percentage of total.
c. To convert kilometers to miles, multiply by 0.62137.
d. Based on primary option in Yucca Mountain FEIS.

be in the respective basin. The total percentage of the Carlin rail corridor that would be in designated basins is about 68 percent. The Yucca Mountain FEIS estimated that about 70 percent of the Carlin rail corridor would be in designated basins.

Railroad operations in the Carlin rail corridor would have little impact on groundwater resources. Possible changes in recharge, if any, would be the same as those at the completion of construction.

5.2.4 BIOLOGICAL RESOURCES AND SOILS

Potential impacts to biological resources and soils from the construction and operation of a railroad in the Carlin rail corridor would be consistent with those reported in the Yucca Mountain FEIS. Maximum land disturbance for the construction of a rail line in the Carlin rail corridor would not differ from the estimates in the Yucca Mountain FEIS; therefore, the potential impacts would not change.

Consistent with the Yucca Mountain FEIS, this update considered the potential for impacts to vegetation communities; special status species (plants and animals), including their habitat; springs, wetlands, and riparian areas; big game habitat; and wild horse and burro herd management areas that may occur within the 400-meter (0.25-mile)-wide corridor. The analysis considered special status species and big game habitat within 5 kilometers (3 miles) of the corridor that may be affected by construction of the rail line. DOE also analyzed springs and riparian areas that could be affected by permanent changes in surface-water flows.

5.2.4.1 Biological Resources

The Carlin rail corridor would start in the Great Basin. The predominant land-cover types in this area are salt desert scrub and sagebrush. There are areas of pinon-juniper forests near the corridor. The corridor would pass through the Mojave Desert, which has predominant land-cover types of creosote-bursage, Mojave mixed scrub, and salt desert scrub.

Table 5-3 lists the special status species, big game habitat, and herd management areas identified in the Yucca Mountain FEIS and identifies additional information resulting from this update. The updated version of the Nevada Natural Heritage Program database examined for Nevada Rail Corridor SEIS included observations of six additional sensitive species not included in the Yucca Mountain FEIS. They are:

- Lahontan cutthroat trout (*Oncorhynchus clarkii henshawi*)
- Southwestern willow flycatcher (*Empidonax traillii extimus*)
- Crescent Dunes serican scarab (*Serica ammomenisco*)
- Eastwood milkweed (*Asclepias eastwoodiana*)
- Ripley's springparsley/Sanicle biscuitroot (*Cymopterus ripleyi var. saniculoides*)
- Toquima milkvetch (*Astragalus toquimanus*)

There are no other known changes to game habitat, sensitive species, or springs and riparian areas within the corridor or within 5 kilometers (3 miles) of the corridor than reported in the Yucca Mountain FEIS.

5.2.4.2 Soils

The Yucca Mountain FEIS classified soils in the rail corridor with four attributes: shrink swell, erodes easily, unstable fill, and blowing soil. As noted in the Yucca Mountain FEIS, the shrink swell and erodes easily attributes are common in the Carlin rail corridor. The Yucca Mountain FEIS also reported that there were no soils classified as prime farmlands within the Carlin rail corridor. For the update, no new information was identified on the attributes of the soils surveyed in the corridor (DIRS 182772-MTS 2007, p. 86).

The Yucca Mountain FEIS reported construction activities would temporarily disturb soils in and adjacent to about 19 square kilometers (4,700 acres) of land. Disturbance of erodible soils could lead to increased silt loads in water courses or increased soil transport by wind. Erosion control during construction, and revegetation or other means of soil stabilization after construction, would minimize these concerns.

Table 5-3. Special status species, big game habitat, and herd management areas associated with the Carlin rail corridor[a] (page 1 of 3).

a. Sources: Data collected from DIRS 182772-MTS 2007, pp. 105 to 106; DIRS 182760-URS Corporation/Potomac-Hudson Engineering 2006, all).

b. Habitat for the Lahontan cutthroat trout, a threatened species under the Endangered Species Act, crosses the Big Smoky Valley and Monitor Valley options of the Carlin rail corridor north and northeast of Round Mountain in Nye County.

c. Portions of the Carlin rail corridor pass through winter habitat, brood rearing habitat, and nesting habitat of the sage grouse (Centrocercus urophasianus). Conservation of the greater sage grouse has become an important concern due to a decline in population and habitat. Since DOE completed the Yucca Mountain FEIS, the State of Nevada has developed a Greater Sage-Grouse Conservation Plan. This plan involves a number of state and federal agencies, including the Nevada Department of Wildlife, the California Department of Fish and Game, the Nevada and California BLM State Offices, and the U.S. Fish and Wildlife Service, among others. The Plan's highest priorities focus on maintaining sage-grouse habitats that are currently intact and highly productive. In addition, it emphasizes the enhancement of degraded seasonal habitats that have the greatest potential for recovery (DIRS 182772-Management and Technical Support Services 2007, all).

According to the Yucca Mountain FEIS, the impacts to soils would be transitory and small. The soils within the Carlin rail corridor and the potential impacts to these soils remain unchanged since DOE completed the Yucca Mountain FEIS.

5.2.5 CULTURAL RESOURCES

The effects of rail line construction in the Carlin rail corridor on cultural resources would be essentially the same as those DOE reported in the Yucca Mountain FEIS. Impacts to cultural resources from railroad operations in the Carlin rail corridor would be unlikely.

Cultural resources include any prehistoric or historic archaeological sites, buildings, structures, landscapes, or objects resulting from or modified by human activity and can include mining, ranching, and linear features such as roads and trails. Cultural resources designated as historic properties warrant consideration with regard to potential adverse impacts resulting from proposed federal actions.

For this update, DOE conducted an archaeological site file search using records from the Desert Research Institute, the Nevada Cultural Resources Information System, and archaeological information repositories at the Harry Reid Center at the University of Nevada-Las Vegas, and the Nevada State Museum in Carson City.

The records search revealed the presence of 120 known archaeological sites within the 400 meters (0.25 mile) width of the Carlin rail corridor. The difference between the 110 sites reported in the Yucca Mountain FEIS and the 120 identified in the new survey reflects the addition of sites recorded in the past decade, particularly in the vicinity of Yucca Mountain, where cultural resources inventories have been ongoing. Of the 120 known sites, 11 are eligible or potentially eligible for inclusion on the *National Register of Historic Places* (DIRS 182772-MTS 2007, p. 87).

The types of sites found in the new survey records are the same as those reported in the Yucca Mountain FEIS. The total amount of archaeological inventories conducted is approximately 3 percent of the total area for the Carlin rail corridor. Prior to construction of a rail line, field surveys and potentially mitigation of cultural resources would be required.

5.2.6 OCCUPATIONAL AND PUBLIC HEALTH AND SAFETY

5.2.6.1 Industrial Safety

The categories of worker impacts include total recordable incidents, lost workdays, and fatalities. Recordable incidents or cases are occupational injuries or occupation-related illnesses that result in (1) a fatality, regardless of the time between the injury or the onset of the illness and death, (2) lost workday cases (nonfatal), and (3) incidents that result in the transfer of a worker to another job, termination of employment, medical treatment, loss of consciousness, or restriction of motion during work activities.

Revised estimates of the number of workers needed to construct the rail line resulted in 6,600 worker-years in comparison to the 1,230 worker-years estimated in the Yucca Mountain FEIS (2,000 hours per worker-year). Estimates of industrial safety impacts incorporate Bureau of Labor Statistics data for 2005 (DIRS 179131-BLS 2006, all; DIRS 179129-BLS 2007, all). The Yucca Mountain FEIS used 1998 data from the same source. Industrial safety impacts from operations in the Carlin rail corridor would be lower than those reported in the Yucca Mountain FEIS because of differences in the labor statistics used. Operation of the railroad would require about 60 workers each year an increase from 47 workers estimated in the Yucca Mountain FEIS. Table 5-4 lists estimated industrial safety impacts reported in the Yucca Mountain FEIS as well as the updated information.

5.2.6.2 Transportation

Since DOE completed the Yucca Mountain FEIS, there have been updates to the methods and data used to estimate the radiation doses for workers and members of the public. Section 2.2.3 of this Nevada Rail Corridor SEIS describes updates to the methods and data used to estimate impacts for the rail corridors. The impacts for the Carlin rail corridor reflect new information resulting from these changes.

Updates for transportation estimated impacts during construction from the transportation of construction materials to the construction sites and impacts from commuting workers. Operation of the railroad could result in incident-free radiological impacts, risks from radiological accidents, impacts from vehicle emissions from waste transportation and commuting workers, and traffic fatalities associated with waste transport and commuting workers.

The Yucca Mountain FEIS evaluated traffic fatality and vehicle emission impacts from the movement of equipment and delivery of materials for construction, worker commutes to and from construction sites, and transport of water to construction sites. Table 5-5 lists the impacts of transportation during the construction period. Due to the increased number of construction workers from the estimate in the Yucca Mountain FEIS, estimated traffic fatalities could increase from 1.1 to 4, and fatalities from exposure to

Table 5-4. Impacts to workers from industrial hazards during railroad construction and operations in the Carlin rail corridor.[a]

Group and industrial hazard category	Construction: Yucca Mountain FEIS[b]	Construction: Update[c]	Operations: Yucca Mountain FEIS[d]	Operations: Update[e]	Total: Yucca Mountain FEIS	Total: Update
Involved worker

a. Source: DIRS 182772-MTS 2007, p. 88.
b. Totals might differ from sums of values due to rounding.

vehicle emissions could increase from 0.14 to 0.6. Total transportation impacts from construction could be about 5 fatalities.

The transportation of spent nuclear fuel and high-level radioactive waste in the Carlin rail corridor could result in radiological and nonradiological impacts to workers and the public. Radiological impacts could result from radiation that the rail casks emitted during incident-free transportation, from radionuclides released from the rail cask during transportation accidents, or from radiation that the rail cask emitted because of a loss of shielding during a transportation accident. Nonradiological impacts (vehicle emission-related fatalities) would result from diesel locomotives and fugitive dust. Nonradiological impacts could also result from traffic accidents that involved workers and members of the public.

Table 5-6 lists the impacts of using the Carlin rail corridor to ship spent nuclear fuel and high-level radioactive waste calculated using updated methods and data. The impacts presented reflect those from the mainline to the repository. This is in contrast to the Yucca Mountain FEIS, where the Nevada impacts started where the mainline intersects the Nevada border.

Table 5-6. Operations impacts of transportation for the Carlin rail corridor.[a]

Transportation impact category	Traffic fatalities		Number of cancers		Total	
	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update
Incident-free radiological impacts (LCFs)[b]						
Public (LCFs)	–	–	0.0012	0.000088		
Workers (LCFs)	–	–	0.31	0.33		
Radiological accident risks (LCFs)			0.000000037	0.000001		
Vehicle emission impacts (cancer fatalities)						
Waste transportation	–	–	0.0008	0.00038		
Worker commuting	–	–	0.09	0.4		
Transportation accidents (fatalities)						
Waste transportation	0.054	0.31	–	–

Totals[c]	0.7	3.6	0.4	0.7	1.1	4.3

a. Source: DIRS 182772-MTS 2007, p. 90.
b. LCF = latent cancer fatality.
c. Totals might differ from sums of values due to rounding.

For members of the public, estimated radiological impacts from incident-free (routine) transportation decreased from those in the Yucca Mountain FEIS, from 0.0012 to 0.000088 latent cancer fatality. This would be due primarily to the change in analysis for the Nevada rail line to model dedicated trains for shipments to the repository (DIRS 182772-MTS 2007, p. 89), which would be partially offset by the increase in the latent cancer fatality conversion factor.

For workers, estimated radiological impacts from incident-free transportation would increase from 0.31 to 0.33 latent cancer fatality. The increase would be due primarily to the increase in the latent cancer fatality conversion factor, the use of additional escorts in all areas, and the estimation of impacts for uninvolved workers at the staging yard, which would be partially offset by the decrease in the exposure time at the staging yard.

Estimated radiological accident risks would increase from 0.000000037 to 0.000001 latent cancer fatality. This would be due primarily to the use of the combined Track Class 3 transportation accident rate (DIRS 182772-MTS 2007, p. 89) based on train kilometers and railcar kilometers and the increase in the latent cancer fatality conversion factor. Although this is an increase, radiological accident risk would still be a negligible contributor to the overall transportation risk.

Estimated impacts from waste transportation vehicle emissions would decrease from 0.0008 to 0.00038 fatality. This would be due primarily to decreases in populations along the Carlin rail corridor. Vehicle emission impacts from commuting workers could increase from those reported in the Yucca Mountain FEIS because of the longer operations phase.

Estimated impacts from nonradiological transportation accidents would increase from 0.054 to 0.31 fatality. This is the most notable change to accident risk and would be due primarily to the use of the updated rail fatality rate (DIRS 178016-DOT 2005, all) and from accounting for the presence of locomotives and buffer cars in the estimation of the number of nonradiological transportation accident fatalities. Due to the increase in the number of workers, traffic fatalities associated with commuting workers could also increase.

Overall, the estimated total number of transportation-related fatalities from operation of a railroad in the Carlin rail corridor has increased from 1.0 fatality reported in the Yucca Mountain FEIS to 4.3 fatalities in the current assessment. This change is due primarily to the increase in the number of fatalities from traffic accidents.

5.2.7 SOCIOECONOMICS

In the Yucca Mountain FEIS, DOE used construction costs, workforce estimates, and state and regional economic data to identify potential direct and indirect changes in state and regional economic activity. The Department noted that construction activities would cause short-term, temporary increases in employment and population.

Revised estimates of the number of workers needed to construct the rail line in the Carlin rail corridor resulted in 6,600 worker-years in comparison to the 1,230 worker-years estimated in the Yucca Mountain FEIS. Operation of the railroad would require about 42 workers each year in comparison to the 47 workers estimated in the Yucca Mountain FEIS.

The Yucca Mountain FEIS estimated population baselines for Clark, Nye, and Lincoln Counties and the Rest of Nevada on projections by state and local agencies including the Nevada State Demographer, Nye County, and Clark County, which was prepared by the University of Nevada Las Vegas. The rest of Nevada included Eureka, Lander, and Esmeralda Counties. The original baseline estimate was that the 2006 population in the region of influence would be approximately 1.73 million. The updated baseline, which incorporates the Nevada State Demographer's more current data, indicates that the estimated 2006 population in the region was approximately 1.94 million (DIRS 182772-MTS 2007, p. 90).

Clark County, which includes Las Vegas, dominates the region of influence with a 2006 estimated population of 1.89 million, which is approximately 7 percent more than the population that DOE reported in the Yucca Mountain FEIS. Population growth in the unincorporated town of Pahrump dominates Nye County's growing popularity as a residential destination. Since DOE completed the Yucca Mountain FEIS, Pahrump, the largest population center in Nye County, has experienced double-digit growth. The estimated population of Pahrump increased from 23,000 in July 1999 to 33,000 by July 2005, an increase of about 45 percent. In the same period, the State Demographer estimates that Nye County as a whole grew from a population of about 31,000 to about 41,000. The Carlin rail corridor would pass near the towns of Beatty and Tonopah. The State Demographer estimated the 2005 population of Beatty to be slightly over 1,000 and the 2005 population of Tonopah to be about 2,600 (DIRS 182772-MTS 2007, p. 91). The average annual impact from the construction and operation of a railroad to the baselines population in Clark, Nye, and Lincoln Counties and the rest of Nevada would be small.

Because the construction workforce is expected to come largely from Clark County and the Carson City/Washoe County area, any changes to the regional employment and population baselines would be small. Changes in employment and population in Nye and Lincoln Counties, including the communities within those counties, is unlikely because workers would lives near the rail line and would be unlikely to return to Nye or Lincoln Counties as permanent residents once construction ends. Current population growth in these counties would mask socioeconomic impacts due to the short-term growth in the workforce or the associated impact on population growth.

5.2.8 NOISE AND VIBRATION

The Yucca Mountain FEIS analysis for noise considered typical day-night sound levels, the distance of the rail line from communities along the rail line, and estimated the impacts from the construction and operation of a railroad to these communities. The Yucca Mountain FEIS analysis for vibration considered typical background level of ground vibration, the number of trains, and the distance of the rail line to historic structures or sites of cultural significance, and estimated the impacts from the operation of a railroad. There are no significant new circumstances or information that would cause the affected environment or the estimated impacts from noise or vibration to change from what was reported in the Yucca Mountain FEIS.

5.2.9 AESTHETICS

Based on a corridor-level analysis and an evaluation of current BLM resource management plans, there have been no changes to Visual Resource Management classifications for the Carlin rail corridor since DOE completed the Yucca Mountain FEIS. Under the current BLM plans, the Carlin rail corridor would pass through Visual Resource Management Class IV lands. Therefore, impacts would be the same as those discussed in the Yucca Mountain FEIS.

5.2.10 UTILITIES, ENERGY, AND MATERIALS

The Yucca Mountain FEIS evaluated utilities, energy, and materials impacts common to all corridors and noted that these impacts would include the use of motor fuel, steel, and concrete. The estimated impacts from these resources associated with the construction and operation of a railroad in Nevada would be small, similar to those in the Yucca Mountain FEIS.

The Carlin rail corridor would pass through rural parts of Nye, Esmeralda, Lander, and Eureka Counties in Nevada that have little access to support services. Electric power for construction would be initially supplied by portable generators. New power lines would be installed to provide power for construction services and would be extended, via underground distribution along the rail roadbed to meet all other construction and operational needs. Construction equipment would consume motor fuel (diesel and gasoline). The total motor fuel use in Nevada in 2005 was about 5.8 billion liters (1.5 billion gallons) (DIRS 182772-MTS 2007, p. 91). Highway motor fuel use in the state in 2005 increased 6.2 percent over that in 2004, the largest percentage increase for any state and attributable to Nevada's growing population. Table 5-7 lists the estimated amounts of diesel fuel and gasoline for construction for the Carlin rail corridor, which are higher than the estimates in the Yucca Mountain FEIS. The annual average use of motor fuel would be about 0.52 percent of that consumed annually in Nevada. Unlike overall state use, construction activities would use primarily diesel fuel, which would be about 2.1 percent of all special fuel (mainly diesel) used annually in Nevada.

Steel for rails, concrete (principally for rail ties, bridges, and drainage structures), and rock for ballast would be the primary materials that the construction of a rail line would consume. Table 5-7 lists estimates of steel and concrete consumption, which have changed from those in the Yucca Mountain FEIS.

Table 5-7. Construction fuel and materials impacts for the Carlin rail corridor.[a]

	Diesel fuel use (million liters)[d]		Gasoline use (million liters)		Steel (thousand metric tons)[e]		Concrete (thousand metric tons)	
Length (kilometers)[b,c]	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update
530	40	110	0.82	2.4	74	86	414	330

a. Source of Update: DIRS 180877-Nevada Rail Partners 2007, p. 2-7, Table 2-1; DIRS 182772-MTS 2007, p. 92.
b. Corridor length used for comparative evaluation.
c. To convert kilometers to miles, multiply by 0.623.
d. To convert liters to gallons, multiply by 0.264.
e. To convert metric tons to tons, multiply by 1.102.

The estimated impacts to utilities, energy, and materials from the operation of a railroad in Nevada would be small, similar to those in the Yucca Mountain FEIS. The use of motor fuel by locomotives would increase over that in the Yucca Mountain FEIS due to more weekly train trips.

5.2.11 WASTE MANAGEMENT

The Yucca Mountain FEIS evaluated common waste management impacts for all corridors rather than for individual corridors. Information to allow differentiation between corridor waste management impacts is now much more readily available. Therefore, DOE has included this information at a level of analysis that was similar to the Yucca Mountain FEIS.

Waste generation and management impacts common to all corridors would result from construction and operation a railroad in the Carlin rail corridor. There would be relatively minor quantities of industrial, hazardous, and sanitary waste.

The Yucca Mountain FEIS estimated the peak annual generation of sanitary solid waste would be 910 metric tons (1,000 tons). DOE now estimates that solid municipal waste from construction facilities would be 750 metric tons (830 tons) during the peak year of construction. An assumed 25 percent of the waste would be recyclable, which would result in 570 metric tons (620 tons) for disposal at municipal landfills. The estimated total mass of waste that would be generated during rail line construction is about 2,000 metric tons (2,200 tons). This mass of sanitary solid waste would occupy about 5,100 cubic meters (6,600 cubic yards) of landfill volume at a waste density of 410 kilograms per cubic meter (700 pounds per cubic yard) (DIRS 182772-MTS 2007, p. 92). The estimated average daily disposal mass would be about 1.6 metric tons (1.7 tons) per day.

For the landfills in rural counties, this would represent a potential increase in volume of waste requiring processing. The Goldfield landfill, which serves a population of fewer than 1,500 people in Esmeralda County, received about 3.6 metric tons (4 tons) of solid waste per day in 2003 (DIRS 182772-MTS 2007, p. 92). Disposal of solid waste generated during the construction phase would represent nearly a 50-percent increase in daily waste volume for the Goldfield landfill and could hasten its estimated closure date of 2023. Nye County disposed of about 250 metric tons (280 tons) of waste during 2003 at three different landfills (DIRS 182772-MTS 2007, p. 92), but the county plans to close two of these landfills by 2011, which would represent 96 percent of the county's current waste disposal capacity. The Austin and Battle Mountain landfills in Lander County disposed of about 2.7 and 12 metric tons (3 and 13 tons) per day, respectively, in 2003; their estimated closure dates are 2041 and 2069. For comparison, the Apex Landfill in Clark County, which serves the Las Vegas Valley, receives 8,000 metric tons (8,800 tons) each day (DIRS 174041-State of Nevada 2004, pp. 6 and 7). Waste generated during construction could be trucked to larger landfills with small impact on waste disposal capacity.

Railroad operations would periodically generate waste during maintenance activities. Locomotive and railcar maintenance could generate used oil and solvents that DOE would recycle or dispose of as regulated waste.

5.2.12 ENVIRONMENTAL JUSTICE

The Yucca Mountain FEIS environmental justice analysis considered the potential for disproportionately high and adverse impacts on two segments of the overall population—minority communities and low-income communities. In the Yucca Mountain FEIS, DOE employed a criterion for identifying minority and low-income communities by applying a 10-percent threshold, meaning that the environmental analyses for environmental justice purposes focused on Census blocks and Census block groups having minority or low-income populations at least 10 percent higher than state averages.

For Nevada Rail Corridor SEIS, DOE adopted new criteria based upon revised NRC guidance. The new criteria are Census blocks having a 50 percent or higher minority population (10 percent higher than the State average), and Census block groups having a 30.5 percent low-income population (20 percent higher than the State average).

Updates for the 2000 U.S. Census Bureau block group data used in the Yucca Mountain FEIS to examine the location and concentration of low income populations were not available at the time DOE completed the Yucca Mountain FEIS. Instead, the Yucca Mountain FEIS used 1990 U.S. Census Bureau block group data to identify low income populations. For Nevada Rail Corridor SEIS, DOE used the more current 2000 U.S. Census Bureau block group data to identify both low income and minority populations. The next set of comprehensive Census Bureau data will not be released until the 2010 Census, thus, the 2000 data is still considered the most current data set. The region of influence identified in the Yucca Mountain FEIS for the Carlin rail corridor has remained the same. Furthermore, county level U.S. Census Bureau data estimates for 2006 suggest that while the population in southern Nevada is growing rapidly, the location of concentrations of minority and low income populations have remained relatively constant and static since 2000 (DIRS 182772-MTS 2007, p. 93).

DOE concluded in the Yucca Mountain FEIS that there would not be any high and adverse impacts from transportation of spent nuclear fuel and high-level radioactive waste in Nevada on any populations, and that disproportionately high and adverse effects would be unlikely for any specific segment of the population, including minorities and low-income communities. DOE further concluded that there were no special pathways (unique practices and activities creating opportunities for increased impacts) that could not be mitigated. Therefore, the Yucca Mountain FEIS concluded that there were no environmental justice impacts associated with any proposed rail corridor.

Since the DOE completed the Yucca Mountain FEIS, DOE has not identified any new large and adverse impacts to any population. DOE has also not identified any new minority or low income populations in the Carlin rail corridor region of influence, and has not identified any special pathways that could increase impacts to these populations. Therefore, DOE maintains that there would be no environmental justice impacts associated with the Carlin rail corridor.

5.3 Jean Rail Corridor

Table 5-8 summarizes the results of the update to the primary impact indicators for the Jean rail corridor and compares them with the corridor information published in the Yucca Mountain FEIS. The information reflects the total for the construction and operation of the rail corridor unless otherwise noted.

Table 5-8. Updated environmental information for the Jean rail corridor (page 1 of 2).

Resource	Changes from the Yucca Mountain FEIS to this analysis
Corridor length	No change
Land ownership	
BLM-administered land	Yucca Mountain FEIS: 15,000 to 17,000 acres (60 to 69 square kilometers (about 83 percent)
	Updated analysis: 15,000 to 18,000 acres (61 to 73 square kilometers) (85.5 to 87.2)
Private land	No change
Nevada Test Site land	No change
Air quality	
National Ambient Air Quality Standards attainment Status	The Pahrump area in Nye County is now subject to a Memorandum of Understanding with regulatory agencies to better control fugitive emissions of PM_{10} and thereby avoid being designated a nonattainment area.
Hydrology	
Surface water	No change
Groundwater use (construction)	Yucca Mountain FEIS: 405 acre-feet (500,000 cubic meters)
	Updated analysis: 3,380 acre-feet (4.17 million cubic meters)
Biological resources and soils	Two additional sensitive species recorded
Cultural resources (records search)	Yucca Mountain FEIS: 6 recorded sites
	Updated analysis: 45 recorded sites
Occupational and public health and safety	
Industrial hazards (construction and operations)	
Total recordable cases	Yucca Mountain FEIS: 148
	Updated analysis: 246
Lost workday cases	Yucca Mountain FEIS: 76
	Updated analysis: 143
Fatalities	Yucca Mountain FEIS: 0.3
	Updated analysis: 0.9
Transportation hazards (construction only)	
Traffic fatalities	Yucca Mountain FEIS: 0.7
	Updated analysis: 2.5
Cancer fatalities	Yucca Mountain FEIS: 0.09
	Updated analysis: 0.3
Incident-free radiological impacts (latent cancer fatalities) (operations only)	
Public	Yucca Mountain FEIS: 0.00085
	Updated analysis: 0.00019
Workers	Yucca Mountain FEIS: 0.22
	Updated analysis: 0.21
Radiological transportation accident fatalities	
Radiological accident risk (latent cancer fatalities)	Yucca Mountain FEIS: 0.000000015
	Updated analysis: 0.0000018
Cancer fatalities from vehicle emissions	Yucca Mountain FEIS: 0.07
	Updated analysis: 0.3

Table 5-8. Updated environmental information for the Jean rail corridor (page 2 of 2).

Resource	Changes from the Yucca Mountain FEIS to this analysis
Nonradiological transportation accident fatalities	
Spent nuclear fuel and high-level radioactive waste transportation	Yucca Mountain FEIS: 0.019 Updated analysis: 0.11
Construction and operations workforce	Yucca Mountain FEIS: 0.5 Updated analysis: 2
Socioeconomics	
Estimated construction workforce	Yucca Mountain FEIS: 855 worker-years Updated analysis: 4,100 worker-years
Estimated operations workforce	Yucca Mountain FEIS: 36 workers per year Updated analysis: 32 workers per year
Noise and vibration	No changes
Aesthetics	No changes
Utilities, energy, and materials (amount used)	
Diesel	Yucca Mountain FEIS: 6.9 million gallons (26 million liters) Updated analysis: 22.7 million gallons (86 million liters)
Gasoline	Yucca Mountain FEIS: 1.3 million gallons (0.5 million liters) Updated analysis: 4.2 million gallons (1.6 million liters)
Steel	Yucca Mountain FEIS: 28,000 tons (26,000 metric tons) Updated analysis: 33,000 tons (30,000 metric tons)
Concrete	Yucca Mountain FEIS: 165,000 tons (150,000 metric tons) Updated analysis: 132,000 tons (120,000 metric tons)
Waste management	
Sanitary Solid Waste	Updated analysis: 1 ton (0.91 metric ton) per day
Environmental justice (disproportionately high and adverse impacts)	No changes, none identified

The Jean rail corridor would originate at the existing Union Pacific Railroad Mainline near Jean, Nevada. It would travel northwest near Pahrump, Town of Amargosa Valley, Jean, Goodsprings, Sand Spring, and Lathrop Wells before it reached Yucca Mountain. The State Line option would pass near Primm, Nevada.

Jean rail corridor options would range from 180 to 200 kilometers (110 to 130 miles) long. Figure 5-4 shows the corridor and its options. The Yucca Mountain FEIS contains detailed corridor and option descriptions.

5.3.1 LAND USE AND OWNERSHIP

The following paragraphs discuss information gathered in relation to land use in the Jean rail corridor since DOE completed the Yucca Mountain FEIS. The change in the estimates of the amount of BLM-administered land and private property within this corridor are in part the result of using more accurate databases of land ownership for this Nevada Rail Corridor SEIS. Land use and ownership conflicts with commercial growth have increased since those reported in the Yucca Mountain FEIS.

The Yucca Mountain FEIS reported that the BLM administered approximately 83 percent of the land in the corridor (60 to 69 square kilometers [15,000 to 17,000 acres]), DOE managed 12 percent (8.5 square kilometers [2,100 acres), and approximately 5 percent was private land (0.1 to 3.5 square kilometers [25 to 865 acres]).

Current land holdings for the Jean rail corridor are as follows: BLM-administered land, approximately 85 to 87 percent (61 to 73 square kilometers [15,000 to 18,000 acres); DOE land, approximately 10 to 13 percent (8.8 square kilometers [2,200 acres]); and private land, about 0.19 to 4.2 percent (0.1 to 3.5 square kilometers [25 to 870 acres]). The Jean rail corridor has two options, Wilson Pass and Stateline Pass, off the Union Pacific Railroad mainline. The Wilson Pass option would cross private property at the Bluejay, Snowstorm, and Pilgrim mines and run south of the Toiyabe National Forest in the Spring Mountains (Figure 5-4). The western option of the Jean rail corridor in Pahrump Valley also would intersect private property. The eastern option in that area would avoid those private parcels.

The Yucca Mountain FEIS reported that the Wilson Pass option would cross the Old Spanish Trail/Mormon Road special recreation management area, and four areas that the BLM has designated as available for sale or transfer. The option would be within approximately 1.6 kilometer (1 mile) of the Toiyabe National Forest. There have been no changes to the status of these areas since DOE completed the Yucca Mountain FEIS. The Yucca Mountain FEIS also reported that the Jean rail corridor would cross two wild horse and burro herd management areas and a BLM Class II Visual Resource Area (see Sections 5.3.4 and 5.3.9, of this Nevada Rail Corridor SEIS, respectively).

The Stateline Pass option would begin in Ivanpah Valley and cross through the proposed Ivanpah Valley Airport in the area between Interstate Highway 15 and the Union Pacific Railroad rail line. Clark County was considering the construction of the airport when DOE completed the Yucca Mountain FEIS. On October 27, 2000, President Clinton signed the Ivanpah Valley Airport Public Land Transfer Act, which permitted the Secretary of the Interior to convey public lands for sale to the Clark County Department of Aviation (Public Law 106-362, 114 Stat. 1404). Since DOE completed the Yucca Mountain FEIS, the Clark County Department of Aviation has purchased the property and is preparing an EIS (*Notice of Intent To Prepare an Environmental Impact Statement for the Southern Nevada Supplemental Airport, Clark County, NV, and To Conduct Public Scoping Meetings*, 71 *FR* 52367, September 5, 2006). If constructed, the Ivanpah Valley Airport, which is now called the Southern Nevada Supplemental Airport, would be a major public air carrier serving the greater Las Vegas metropolitan area, second to McCarran International Airport; Figure 5-5 shows the location of the proposed airport in relation to the Jean rail corridor.

The Stateline Pass option would cross the California-Nevada boundary and would cross into the Stateline Wilderness Area established by the California Desert Conservation Act. This wilderness area designation remains unchanged since DOE completed the Yucca Mountain FEIS.

DOE evaluated information in the Mineral Resources Data System and the Abandoned Mine database (DIRS 182772-MTS 2007, p. 96) to determine if there are any newly located mines, active or abandoned, since DOE completed the Yucca Mountain FEIS. In addition to the mines reported in the Yucca Mountain FEIS, the primary alignment for Jean would cross an abandoned mine and Purple Sage Claims. The Wilson Pass option would cross the Red Cloud Mine. Of these, Purple Sage Claims is an occurrence mine site, which means there has been discovery of an outcrop and there might be some land disturbance, but there is no mining operation underway at present. Red Cloud Mine is a past producer, which means mining occurred in the past but no mining operation is underway at present (DIRS 182772-MTS 2007, p. 96).

According to the Yucca Mountain FEIS, the Jean rail corridor would cross as many as eight BLM grazing allotments, depending on the option. The BLM has since updated their grazing allotment information. Updated information indicates that the Jean rail corridor and its options would cross up to 10 allotments: Mount Sterling, Wheeler Wash, Younts Spring, Stump Spring, Black Butte, Table Mountain, Spring

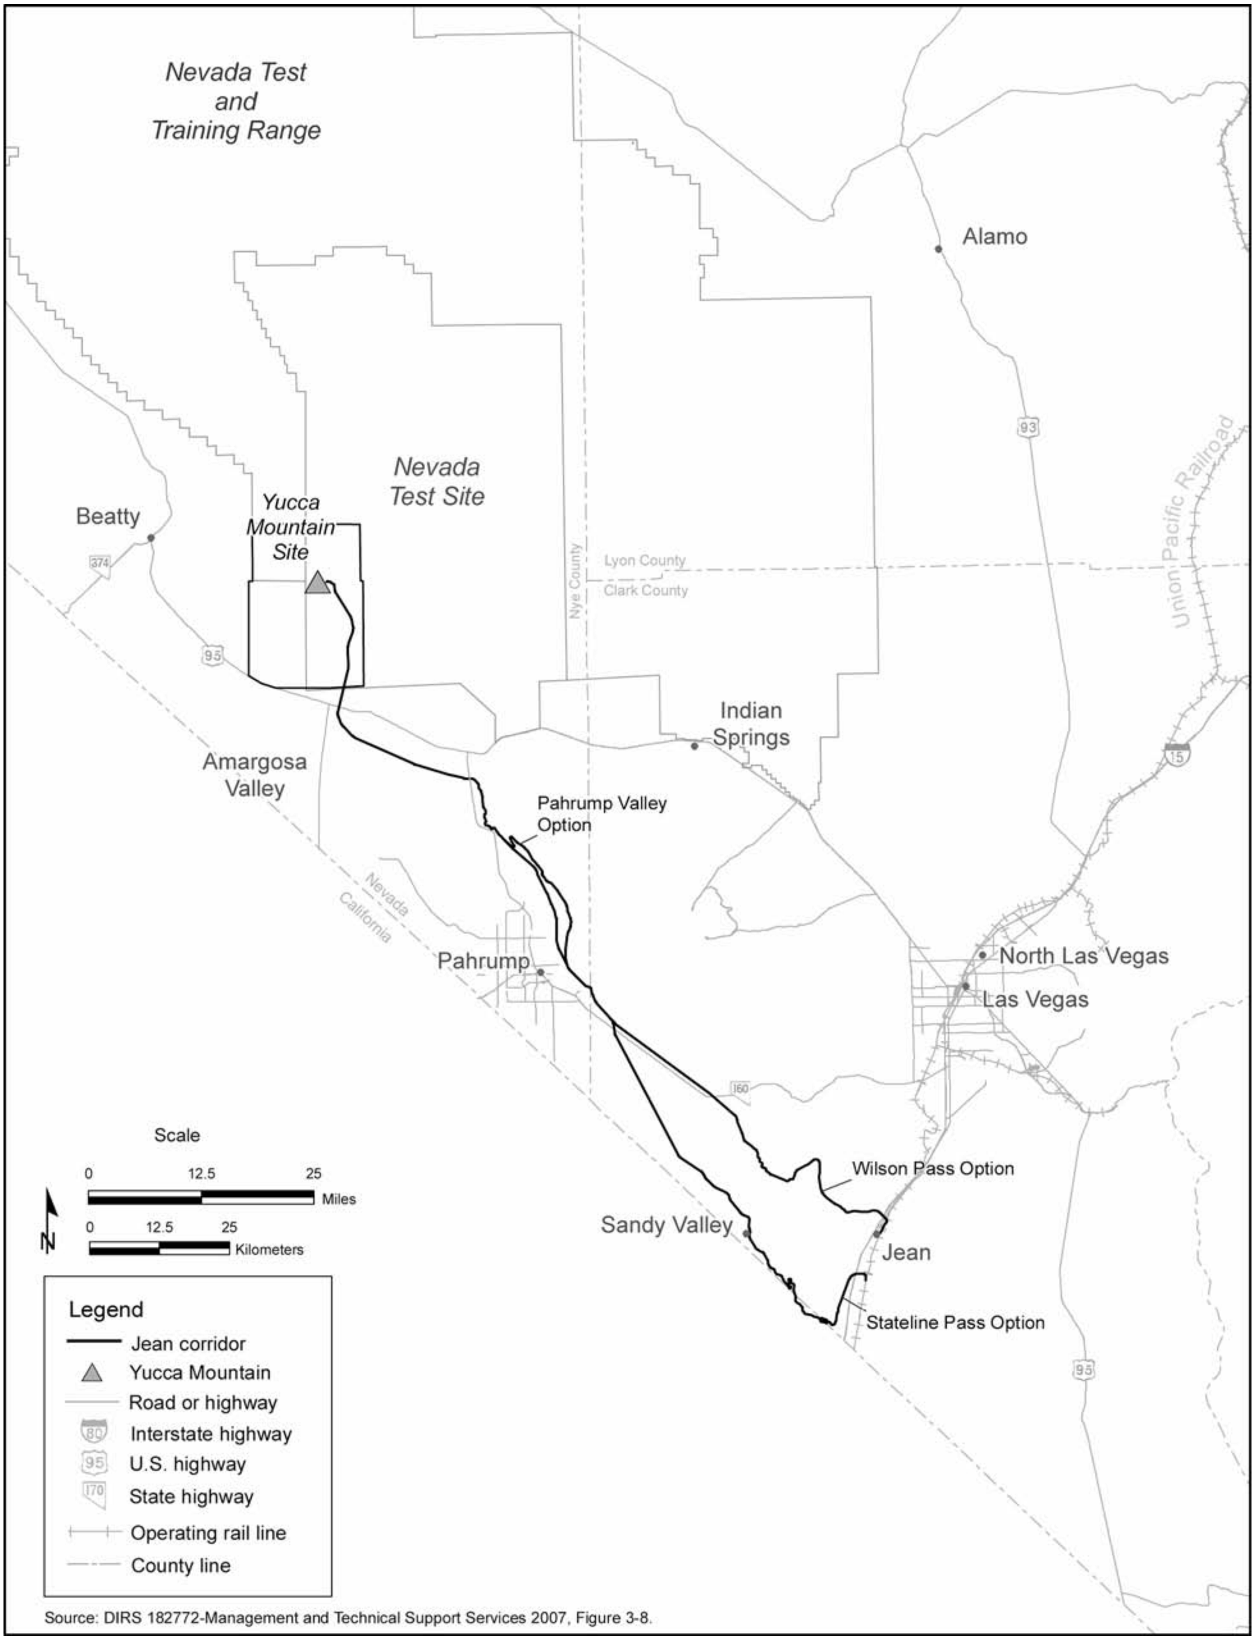

Figure 5-4. Jean rail corridor and options (2002).

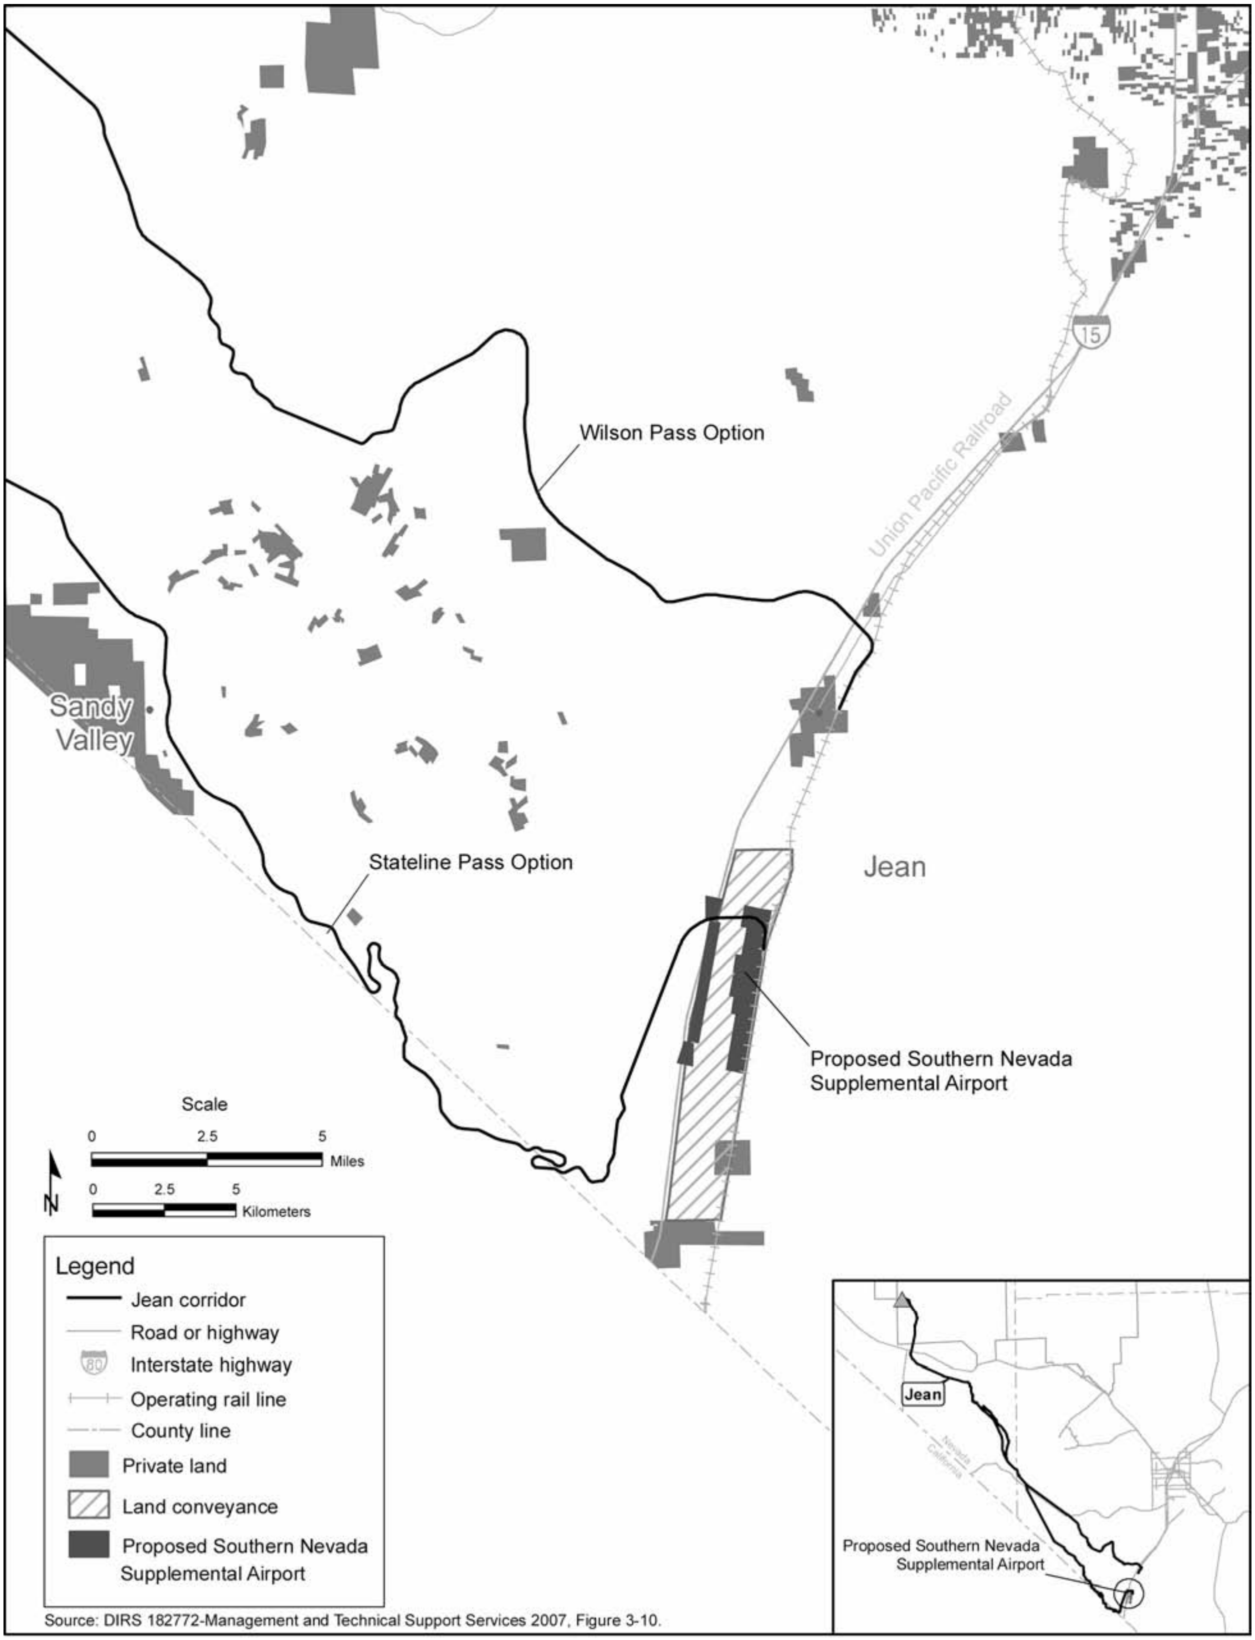

Figure 5-5. Location of proposed Southern Nevada Supplemental Airport.

Mountain, Roach Lake, two allotments BLM has designated as unused, and one designated as private (DIRS 182772-MTS 2007, p. 96).

The Yucca Mountain FEIS reported the Jean rail corridor would cross linear land features such as rights-of-way for utilities and roads. A review of BLM land records, including Master Title Plats, indicated the authorization of additional rights-of-way since DOE completed the Yucca Mountain FEIS (DIRS 182772-MTS 2007, p. 96).

5.3.2 AIR QUALITY

The Yucca Mountain FEIS evaluated air quality impacts common to all proposed rail corridors and noted that the impacts would include temporary increases in criteria pollutant concentrations from construction of the rail line. Construction equipment would emit carbon monoxide, nitrogen dioxide, sulfur dioxide, PM_{10}, and $PM_{2.5}$. Construction activities would emit PM_{10} and $PM_{2.5}$ in the form of fugitive dust from land clearing and filling, equipment traffic, activity of a quarry, and operation of concrete batch plants. The emissions would be temporary and would cover a large area as construction progressed along the length of the corridor.

Areas in violation of one or more of the criteria pollutant standards are classified as nonattainment areas. If there is not enough air quality data to determine the status of a remote or sparsely populated area, then the Environmental Protection Agency lists the area as unclassifiable and are considered to be in attainment. The Jean rail corridor would pass through rural parts of Clark and Nye Counties in Nevada and one option would pass through a portion of rural San Bernardino County in California. A portion of the corridor would be in the Pahrump Valley in Nye County. At the time DOE completed the Yucca Mountain FEIS, these rural areas were all either unclassifiable or in attainment for criteria pollutants.

Since that time, however, the town of Pahrump and the nearby surrounding area have experienced double-digit growth and resultant development (DIRS 182772-MTS 2007, p. 102). The development has led to areas of cleared land, which has increased fugitive dust emissions. The Nevada Bureau of Air Quality Planning began monitoring the ambient air quality in Pahrump in January 2001. During 2001, 2002, and 2003 the 24-hour ambient air standard for PM_{10} was exceeded 27 times. Under the Clean Air Act, this means that Pahrump is no longer attaining the 24-hour standard of 150 micrograms per cubic meter (DIRS 182772-MTS 2007, p. 102). However, the U.S. Environmental Protection Agency has revoked, effective December 17, 2006 (71 *FR* 61144), the annual standard for PM_{10} from the National Ambient Air Quality Standards, citing a lack of evidence that links health problems to long-term exposure to coarse particle pollution.

In September 2003, the Environmental Protection Agency Region IX Administrator, the Nevada Division of Environmental Protection Administrator, the Nye County Board of Commissioners, and the Pahrump Town Board signed the Memorandum of Understanding and implement a Clean Air Action Plan for the Pahrump Valley and defines the limits of the plan as Nevada Hydrographic Area 162. It sets measurable and enforceable milestones for the development and implementation of a Clean Air Action Plan, which will serve as the area's official air quality improvement plan, with quantified emission reduction measures. If a Plan milestone is not achieved, the area will receive a traditional nonattainment area designation and be subject to federal requirements to meet air quality standards.

Under the conditions of the Memorandum of Understanding, Nye County will have until 2009 to bring the area into attainment. Control strategies were to have been in place by 2006 and are to remain in place to ensure that the Pahrump Valley continues to attain the air quality standards in the future.

During preparation of the Yucca Mountain FEIS, DOE conducted an air quality conformity review for the Jean rail corridor and determined that a conformity determination was not necessary because the entire corridor area was either in attainment or unclassifiable for criteria pollutants (DIRS 182772-MTS 2007, p. 102). Since the original air quality conformity review, the State of Nevada has monitored the town of Pahrump for ambient concentrations of PM_{10} and has signed the Memorandum of Understanding to improve air quality in the vicinity of Pahrump.

Because of the effective change in PM_{10} attainment status for the Pahrump Valley portion of the Jean rail corridor, this update used the air quality conformity review conducted for the Jean rail corridor in support of the Yucca Mountain FEIS to estimate potential PM_{10} emissions for comparison to the air quality General Conformity threshold level. A portion of the Jean rail corridor would cross the Las Vegas Valley, which was and remains a nonattainment area for PM_{10} and carbon monoxide (DIRS 182772-MTS 2007, p. 103).

The PM_{10} emissions for Jean rail route construction activities could exceed the General Conformity threshold level of 63 metric tons (70 tons) per year. Reviews of updated and more detailed information and methods (DIRS 180921-Nevada Rail Partners 2007, all; DIRS 180877-Nevada Rail Partners 2007, all) considered rail line construction and additional contributions from access roads, unpaved roads, storage piles, a batch plant, coarse stockpiles, and a quarry. The reviews indicated potential construction fugitive dust and PM_{10} emissions would increase above those originally estimated for the Yucca Mountain FEIS. Before any construction activities in the Jean rail corridor and Pahrump Valley, DOE would need to perform more detailed air quality calculations to evaluate the impacts of construction activities.

The State of Nevada has prepared a 2001 base-year emissions inventory for the Pahrump Valley area of 110,000 metric tons (120,000 tons) per year (DIRS 182772-MTS 2007, p. 103). The estimated emissions for rail line construction in the Jean rail corridor would be about 0.78 percent of this base-year inventory. A comparison for future years is not possible until finalization of the Clean Air Action Plan or State Implementation Plan.

Potential air quality impacts during rail line operation would result from diesel locomotives, which would emit carbon monoxide, nitrogen dioxide, sulfur dioxide, $PM_{10,}$ and $PM_{2.5}$. Because the earthwork is complete, the extent of these impacts would be smaller during operations than during construction activities but would last longer. The number of locomotive engines in use and the associated operational characteristics would not differ appreciably from those in the Yucca Mountain FEIS. Therefore, there should be no measurable differences in potential impacts from those in the Yucca Mountain FEIS.

5.3.3 HYDROLOGY

This section describes surface-water and groundwater resources and impacts to those resources. The Yucca Mountain FEIS analyzed surface-water resources within the 400-meter (0.25-mile)-wide corridor and within 1 kilometer (0.6 mile) of each side of the corridor. For this Nevada Rail Corridor SEIS, the region of influence for hydrology was the same as for the Yucca Mountain FEIS.

5.3.3.1 Surface Water

There are no lakes, streams, or other perennial surface-water features along the Jean rail corridor or its options. The corridor and its options would cross seven mapped 100-year flood zones or flood zone groups (DIRS 155970-DOE 2002, Table 6-61). These remain unchanged since DOE completed the Yucca Mountain FEIS.

Impacts to surface-water resources from construction and operation of a railroad in the Jean rail corridor would be the same as those in the Yucca Mountain FEIS for all three options. Although unlikely, the spread of construction-related materials by precipitation or intermittent runoff events could occur during rail line construction. Impacts associated with changes in drainage patterns or to erosion and sedimentation rates or locations would be small and localized.

5.3.3.2 Groundwater

In the Yucca Mountain FEIS, the Department used terrain types to estimate total water demand. Since DOE completed the Yucca Mountain FEIS, DOE has canvassed similar projects throughout Nevada and determined that the amount and type of earthwork, not the terrain, would more accurately estimate total water demand associated with the construction of a rail line. Therefore, DOE updated the water demand based on earthwork needs. This resulted in an estimated water demand for the Jean rail corridor of approximately 4.17 million cubic meters (3,400 acre-feet) (DIRS 180877-Nevada Rail Partners 2007, p. 2-7) compared to the estimate based on terrain types reported in the Yucca Mountain FEIS of 500,000 cubic meters (410 acre-feet). To accommodate this increase in estimated water demand, DOE would need to draw more water than originally estimated in the Yucca Mountain FEIS from the underlying hydrographic basins and pump from additional wells. Groundwater withdrawal could temporarily affect discharge from nearby wells or springs. DOE would conduct detailed analyses if new wells required for construction of the rail line were to be located near other water sources.

Construction of a rail line would require water for soil compaction, dust control, and workforce use. Water use during construction would come primarily from groundwater resources, specifically from hydrographic basins. If the hydrographic basin is designated, permitted groundwater rights approach or exceed the estimated perennial yield, water resources are being depleted or require additional administration, and the Nevada State Engineer has declared preferred uses of the water. Table 5-9 updates the designation status of the hydrographic basins and the percentage of the Jean rail corridor that is in the respective basins. The total percentage of the Jean rail corridor in designated basins is about 87 percent. The Yucca Mountain FEIS estimated that about 90 percent of the length of the Jean rail corridor would be in designated basins.

Table 5-9. Hydrographic basins associated with the Jean rail corridor.[a,b]

Hydrographic basin (and subbasin where applicable)	Length (kilometers)[c]	Percentage of total[d]	Designated
Amargosa Desert	42	23	Yes
Fortymile Canyon/Jackass Flats	21	12	No
Ivanpah Valley/Southern Part	31	17	Yes
Mesquite Valley	20	11	Yes
Pahrump Valley	64	35	Yes
Rock Valley	3.3	1.8	No

a. Source: DIRS 182772-MTS 2007, p. 104.
b. To calculate water demand for each basin, multiply the total water demand for a given corridor by the percentage of total.
c. km = kilometer; to convert kilometers to miles, multiply by 0.62137.
d. Based on primary option in Yucca Mountain FEIS.

Operations along the completed rail line would have little impact on groundwater resources. Possible changes in recharge, if any, would be the same as those at the completion of construction.

5.3.4 BIOLOGICAL RESOURCES AND SOILS

Potential impacts to biological resources and soils from the construction and operation of a railroad in the Jean rail corridor would be consistent with those reported in the Yucca Mountain FEIS. Maximum land disturbance for the construction of a rail line in the Jean rail corridor would not differ from the estimates in the Yucca Mountain FEIS and therefore the potential impacts would not change.

Consistent with the Yucca Mountain FEIS, this update considered the potential for impacts to vegetation communities; special status species (plants and animals), including their habitat; springs, wetlands, and riparian areas; big game habitat; and wild horse and burro herd management areas that may occur within the 400-meter (0.25-mile)-wide corridor. The analysis considered special status species and big game habitat within 5 kilometers (3 miles) of the corridor that may be affected by construction of the rail line. DOE also analyzed springs and riparian areas that could be affected by permanent changes in surface-water flows.

5.3.4.1 Biological Resources

The area encompassing the Jean rail corridor is in the Mojave Desert; the predominant land-cover types are creosote-bursage, Mojave mixed scrub, and blackbrush.

Table 5-10 presents the special status species, big game habitat, and herd management areas identified in the Yucca Mountain FEIS and identifies additional information resulting from this update. The updated version of the NNHP database examined for Nevada Rail Corridor SEIS included observations of two additional sensitive species not included in the Yucca Mountain FEIS. They are the Half-ring milkvetch/ Mojave milkvetch (*Astragalus mohavensis* var. *hemygurus*) and the Spring Mountains pyrg (*Pyrgulopsis deaconi*).

DOE evaluated surface-water resources, which include springs, streams, riparian areas, and reservoirs for all options. No springs, perennial streams, or riparian areas occur within the Jean rail corridor. These remain unchanged since DOE completed the Yucca Mountain FEIS. Eleven springs or groups of springs are outside the corridor, but are within 5 kilometers (3 miles) of the corridor.

There are no other known changes to the existence of game habitat, sensitive species, or springs in or within 5 kilometers (3 miles) of the Jean rail corridor in comparison to information in the Yucca Mountain FEIS. The Ash Meadows National Wildlife Refuge is 9 kilometers (about 6 miles) outside the Jean rail corridor.

5.3.4.2 Soils

The Yucca Mountain FEIS classified soils in the rail corridor locations with four attributes: shrink swell, erodes easily, unstable fill, and blowing soil. As noted in the Yucca Mountain FEIS, the shrink swell and blowing soils attributes are common in the Jean rail corridor, although a portion of the corridor would pass through areas that consist of soils with erodes easily and unstable fill attributes. The Yucca Mountain FEIS also reported that there were no soils classified as prime farmlands within the Jean rail corridor. No significant new information was identified on the attributes of the soils surveyed in the Jean rail corridor.

The Yucca Mountain FEIS reported the construction of the Jean rail corridor would temporarily disturb soils in and adjacent to 9.3 square kilometers (2,300 acres) of land. Disturbance of erodible soils could lead to increased silt loads in water courses or increased soil transport by wind. Erosion control during construction, and revegetation or other means of soil stabilization after construction, would minimize

Table 5-10. Special status species, big game habitat, and herd management areas associated with the Jean rail corridor[a] (page 1 of 2).

these concerns. Impacts to soils in the corridor, including its options, would be small, but could occur throughout construction. The soils within the Jean rail corridor and the potential impacts to these soils remain unchanged DOE completed the Yucca Mountain FEIS.

5.3.5 CULTURAL RESOURCES

The effects of rail line construction in the Jean rail corridor on cultural resources would be essentially the same as those DOE reported in the Yucca Mountain FEIS. Impacts to cultural resources from operation of a rail line in the Jean rail corridor would be unlikely.

Cultural resources include any prehistoric or historic archaeological sites, buildings, structures, landscapes, or objects resulting from or modified by human activity and include mining, ranching, and linear features such as roads and trails. Cultural resources designated as historic properties warrant consideration with regard to potential adverse impacts resulting from proposed federal actions.

For this update, DOE conducted an archaeological site file search using records from the Desert Research Institute, the Nevada Cultural Resources Information System, and archaeological information repositories at the Harry Reid Center at the University of Nevada-Las Vegas, and the Nevada State Museum in Carson City.

The records search revealed the presence of 45 known archaeological sites within the 400 meters (0.25 mile) width of the Jean rail corridor. The difference between the six sites reported in the Yucca Mountain FEIS and the 45 identified in the new survey reflects the addition of sites recorded in the past decade, particularly in the vicinity of Yucca Mountain, where cultural resources inventories have been ongoing. Of the 45 known sites, 11 are eligible or potentially eligible for inclusion on the *National Register of Historic Places* (DIRS 182772-MTS 2007, p. 107).

The types of sites found in the new survey records are the same as those reported in the Yucca Mountain FEIS. The total amount of archaeological inventories conducted is approximately less than 1 percent of the total area for the Jean rail corridor. Prior to construction of a rail line, field surveys and potentially mitigation of cultural resources would be required.

5.3.6 OCCUPATIONAL AND PUBLIC HEALTH AND SAFETY

5.3.6.1 Industrial Safety

The categories of worker impacts include total recordable incidents, lost workdays, and fatalities. Recordable incidents or cases are occupational injuries or occupation-related illnesses that result in (1) a fatality, regardless of the time between the injury or the onset of the illness and death, (2) lost workday cases (nonfatal), and (3) incidents that result in the transfer of a worker to another job, termination of employment, medical treatment, loss of consciousness, or restriction of motion during work activities.

Revised estimates of the number of workers needed to construct the rail line resulted in 4,100 worker-years in comparison to the 855 worker-years estimated in the Yucca Mountain FEIS (2,000 hours per worker-year). Estimates of industrial safety impacts incorporate updated Bureau of Labor Statistics data for 2005 (DIRS 179131-BLS 2006, all; DIRS 179129-BLS 2007, all). The Yucca Mountain FEIS used 1998 data from the same source. Industrial safety impacts from operations in the Jean rail corridor would be lower than those in the Yucca Mountain FEIS because of differences in the labor statistics used. Operation of the railroad would require about 32 workers each year. Table 5-11 lists estimated industrial safety impacts reported in the Yucca Mountain FEIS as well as the updated information.

Table 5-11. Impacts to workers from industrial hazards during railroad construction and operations for the Jean rail corridor.[a]

Group and industrial hazard category	Construction		Operations		Total	
	Yucca Mountain FEIS[b]	Update[c]	Yucca Mountain FEIS[d]	Update[e]	Yucca Mountain FEIS	Update
Involved worker						
Total recordable cases[f]	67	180	73	37	140	217
Lost workday cases	33	100	40	28	73	128
Fatalities	0.09	0.36	0.20	0.26	0.29	0.62
Noninvolved worker						
Total recordable cases	4.0	19	4.1	8.9	8.1	27.9
Lost workday cases	1.5	10	1.5	4.8	3.0	14.8
Fatalities	0.004	0.03	0.004	0.01	.008	.04
Totals[e]						
Total recordable cases	71	200	77	46	148	246
Lost workday cases	35	110	41	33	76	143
Fatalities	0.10	0.6	0.20	0.3	0.3	0.9

a. Estimates of worker-years multiplied by accident rate (DIRS 179131-BLS 2006, all; DIRS 179129-BLS 2007, all).
b. Estimated workforce to construct the railroad would be 855 worker-years.
c. Estimated workforce to construct the railroad would be 4,100 worker-years.
d. Totals for 24 years for operations.
e. Totals for 33 years of operations within a 50-year period.
f. Total recordable cases include injuries, illnesses, and fatalities.

5.3.6.2 Transportation

Since DOE completed the Yucca Mountain FEIS, there have been updates to the methods and data to estimate the radiation doses for workers and members of the public. Section 3.2.6 of this Nevada Rail Corridor SEIS describes updates to the methods and data used to estimate impacts for the rail corridors. The impacts for the Jean rail corridor reflects new information resulting from these changes.

Updates for transportation estimated impacts during construction from the transportation of construction materials to the construction sites and impacts from commuting workers. Operation of the railroad could result in incident-free radiological impacts, risks from radiological accidents, impacts from vehicle emissions from waste transportation and commuting workers, and traffic fatalities associated with waste transport and commuting workers.

The Yucca Mountain FEIS evaluated traffic fatality and vehicle emission impacts from the movement of equipment and delivery of materials for construction, worker commutes to and from construction sites, and transport of water to construction sites. Table 5-12 lists the impacts of transportation during the construction period. Due to the increased number of construction workers from the estimate in the Yucca Mountain FEIS, estimated traffic fatalities could increase from 0.7 to 2.5, and fatalities from exposure to vehicle emissions could increase from 0.09 to 0.3. Total transportation impacts from construction could be about 2.8 fatalities.

Table 5-12. Transportation impacts during railroad construction for the Jean rail corridor.[a]

	Traffic fatalities		Number of cancers		Total	
Transportation impact category	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update
Vehicle emission impacts (cancer fatalities)						
Material delivery vehicles	–	–	0.02	0.02	0.02	0.02
Worker commuting	–	–	0.07	0.3	0.07	0.3
Transportation accidents (fatalities)						
Material delivery vehicles	0.2	0.2	–	–	0.2	0.2
Worker commuting	0.5	2.3	–	–	0.5	2.3
Totals[b]	0.7	2.5	0.09	0.3	0.79	2.8

a. Source: DIRS 182772-MTS 2007, p. 109.
b. Totals might differ from sums of values due to rounding.

The transportation of spent nuclear fuel and high-level radioactive waste in the Jean rail corridor would result in radiological and nonradiological impacts to workers and the public. Radiological impacts would result from radiation that the rail casks emitted during incident-free transportation, from radionuclides released from the rail cask during transportation accidents, or from radiation that the rail cask emitted because of a loss of shielding during a transportation accident. Nonradiological impacts (vehicle emission-related fatalities) could result from diesel locomotives and fugitive dust. Nonradiological impacts could also result from traffic accidents that involved workers and members of the public.

Table 5-13 lists the impacts of using the Jean rail corridor to ship spent nuclear fuel and high-level radioactive waste calculated using updated methods and data. The impacts presented reflect those from the mainline to the repository. This is in contrast to the Yucca Mountain FEIS, where the Nevada impacts started where the mainline intersects the Nevada border.

For members of the public, estimated radiological impacts from incident-free (routine) transportation decreased from those in the Yucca Mountain FEIS, from 0.00085 to 0.00019 latent cancer fatality. This would be due primarily to the change in analysis for the Nevada rail line to model dedicated trains for shipments to the repository (DIRS 182772-MTS 2007, p. 110), which would be partially offset by the increase in the latent cancer fatality conversion factor.

For workers, estimated radiological impacts from incident-free transportation would decrease from 0.22 to 0.21 latent cancer fatality. The decrease would be due primarily to the decrease in the exposure time at the staging yard, which would partially offset by the increase in the latent cancer fatality conversion factor, the use of escorts in all areas, and the estimation of impacts for non involved workers at the staging yard.

Estimated radiological accident risks increased from 0.000000015 to 0.0000018 latent cancer fatality. This would be due primarily to the use of the combined Track Class 3 transportation accident rate (DIRS 182772-MTS 2007, p. 110) based on train kilometers and railcar kilometers and the increase in the latent cancer fatality conversion factor, and the increase in the population along the Jean rail corridor. Although this is an increase, radiological accident risk would still be a negligible contributor to the overall transportation risk.

Table 5-13. Operations impacts of transportation for the Jean rail corridor.[a]

Transportation impact category	Traffic fatalities		Number of cancers	
	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update
Incident-free radiological impacts (LCFs)[b]				
Public (LCFs)	–	–	0.00085	0.00019
Workers (LCFs)	–	–	0.22	0.21
Radiological accident risks (LCFs)	-	-	0.000000015	0.0000018
Vehicle emission impacts (cancer fatalities)				
Waste transportation	–	–	0.00032	0.00083
Worker commuting	–	–	0.07	0.3
Transportation accidents (fatalities)				
Waste transportation	0.019	0.11	–	–
Worker commuting	0.5	2.0	–	–
Totals[c]	0.52	2.1	0.3	0.5

a. Source: DIRS 182772-MTS 2007, pp. 109 to 110.
b. LCF = latent cancer fatality.
c. Totals might differ from sums of values due to rounding.

Estimated impacts from waste transportation vehicle emissions would increase from 0.00032 to 0.00083 fatality. This would be due primarily to the increase in populations along the Jean rail corridor. Vehicle emission impacts from commuting workers could increase from those reported in the Yucca Mountain FEIS because of the longer operations phase.

Estimated impacts from nonradiological transportation accidents would increase from 0.019 to 0.11 fatality. This is the most notable change to accident risk and would be due primarily to the use of the updated rail fatality rate (DIRS 178016-DOT 2005, all) and from accounting for the presence of locomotives and buffer cars in the estimation of the number of nonradiological transportation accident fatalities. Traffic fatalities associated with commuting workers could also increase due to the increase in the numbers or workers.

Overall, the estimated total number of transportation-related fatalities from operation of a rail line in the Jean rail corridor has increased from 0.82 fatality reported in the Yucca Mountain FEIS to 2.6 fatalities in the current assessment. This change is due primarily to the increase in the number of fatalities from traffic accidents.

5.3.7 SOCIOECONOMICS

In the Yucca Mountain FEIS, DOE used construction costs, workforce estimates, and state and regional economic data to identify potential direct and indirect changes in state and regional economic activity. The Department noted that construction activities would cause short-term, temporary increases in employment and population.

Revised estimates of the number of workers needed to construct the rail line in the Jean rail corridor resulted in 4,100 worker-years in comparison to the 855 worker-years estimated in the Yucca Mountain FEIS. Operation of the railroad would require about 32 workers each year in comparison to the 36 workers estimated in the Yucca Mountain FEIS.

Clark County, which includes Las Vegas, dominates the region of influence with a 2006 estimated population of 1.89 million, which is approximately 7 percent more than the population that DOE reported in the Yucca Mountain FEIS. Population growth in the unincorporated town of Pahrump dominates Nye County's growing popularity as a residential destination. Since DOE completed the Yucca Mountain FEIS, Pahrump, the largest population center in Nye County, has experienced double-digit growth. The estimated population of Pahrump increased from 23,000 in July 1999 to 33,000 by July 2005, an increase of about 45 percent (DIRS 182772-MTS 2007, p. 111). In the same period, the State Demographer estimates that Nye County as a whole grew from about 31,000 to about 41,000. The average annual impact from the construction and operation of a railroad to the baselines population in Clark and Nye Counties would be small.

Because the construction workforce is expected to come largely from Clark County and the Carson City area, any changes to the regional employment and population baselines would be small. Changes in employment and population in Nye County, including the communities within that county, is unlikely because workers would live near the rail line and would be unlikely to return to Nye County as permanent residents once construction ends. Current population growth in these counties would mask socioeconomic impacts due to the short-term growth in the workforce or the associated impact on population growth.

5.3.8 NOISE AND VIBRATION

The Yucca Mountain FEIS analysis for noise considered typical day-night sound levels, the distance of the rail line from communities along the rail line, and estimated the impacts from the construction and operation of a railroad to these communities. The Yucca Mountain FEIS analysis for vibration considered typical background level of ground vibration, the number of trains, and the distance of the rail line from to historic structures or sites of cultural significance, and estimated the impacts from the operation of a railroad. There are no significant new circumstances or information that would cause the affected environment or the estimated impacts from noise or vibration to change from what was reported in the Yucca Mountain FEIS.

5.3.9 AESTHETICS

Based on a corridor-level analysis and an evaluation of current BLM resource management plans, there have been no changes to Visual Resource Management classifications for the Jean rail corridor since

DOE completed the Yucca Mountain FEIS. As discussed in the Yucca Mountain FEIS, the Wilson Pass Option of the Jean rail corridor would pass through Visual Resource Management Class II areas. The BLM established objective for Class II areas, in order to retain the existing character of the landscape, is that the level of change to the characteristic landscape should be low. Therefore, impacts from the construction and operation of the railroad would continue to be a conflict with the visual resource classification.

5.3.10 UTILITIES, ENERGY, AND MATERIALS

The Yucca Mountain FEIS evaluated utilities, energy, and materials impacts common to all corridors and noted that these impacts would include use of motor fuel, steel, and concrete. The estimated impacts from these resources associated with the construction and operation of a railroad in Nevada would be small, similar to those in the Yucca Mountain FEIS.

The Jean rail corridor would pass through rural parts of Clark and Nye Counties in Nevada, and one of the options would cross a portion of rural San Bernardino County in California, that have little access to support services for much of the corridor. Electric power for construction would be initially supplied by portable generators. New power lines would be installed to provide power for construction services and would be extended, via underground distribution along the rail roadbed to meet all other construction and operational needs. Construction equipment would consume motor fuel (diesel and gasoline). The total motor fuel use in Nevada in 2005 was about 5.8 billion liters (1.5 billion gallons) (DIRS 182772-MTS 2007, p. 111). Highway motor fuel use in the State in 2005 increased 6.2 percent over that in 2004, the largest percentage increase for any state and attributable to Nevada's growing population. Table 5-14 lists the estimated amounts of diesel fuel and gasoline for rail line construction in the Jean rail corridor, which are higher than the estimates in the Yucca Mountain FEIS. Based on a construction period of 43 months, the annual average use of motor fuel would be about 0.42 percent of that consumed annually in Nevada. Unlike overall state use, construction activities would use primarily diesel fuel, which would be about 1.6 percent of all special fuel (mainly diesel) used annually in Nevada.

Steel for rails, concrete (principally for rail ties, bridges, and drainage structures), and rock for ballast would be the primary materials that the construction of a rail line would consume. Table 5-14 lists estimates of steel and concrete consumption, which have increased over those reported in the Yucca Mountain FEIS.

The estimated impacts to utilities, energy, and materials from the operation of a railroad in Nevada would be small and similar to those in the Yucca Mountain FEIS. The use of motor fuel by locomotives would increase over that in the Yucca Mountain FEIS due to more weekly train trips, but the overall use would still be small.

5.3.11 WASTE MANAGEMENT

The Yucca Mountain FEIS evaluated common waste management impacts for all corridors rather than for individual corridors. Information to allow differentiation between corridor waste management impacts is now much more readily available. Therefore, this information has been included at a level of analysis that was similar to the Yucca Mountain FEIS.

Table 5-14. Construction energy and materials impacts for the Jean rail corridor.[a]

Length (kilometers)[b,c]	Diesel fuel use (million liters)[d]		Gasoline use (million liters)		Steel (thousand metric tons)[e]		Concrete (thousand metric tons)	
	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update
180	26	86	0.5	1.6	26	30	150	120

a. Update source: DIRS 180877-Nevada Rail Partners 2007, p. 2-7, Table 2-1; DIRS 182772-MTS 2007, p. 112.
b. Corridor length used for comparative evaluation.
c. To convert kilometers to miles, multiply by 0.623.
d. To convert liters to gallons, multiply by 0.264.
e. To convert metric tons to tons, multiply by 1.102.

Waste generation and management impacts common to all corridors would result from construction and operation a railroad in the Jean rail corridor. There would be relatively minor quantities of construction debris and sanitary waste.

The Yucca Mountain FEIS estimated the peak annual generation of sanitary solid waste would be 910 metric tons (1,000 tons). DOE now estimates that solid municipal waste from construction facilities would be 500 metric tons (550 tons) during the peak year of construction. An assumed 25 percent of the waste would be recyclable, which would result in about 380 metric tons (410 tons) of waste to be disposed of at municipal landfills. The estimated total mass of waste that would be generated during construction of the rail line is about 1,200 metric tons (1,300 tons). This mass of sanitary solid waste would occupy about 2,900 cubic meters (3,800 cubic yards) of landfill volume at a waste density of 410 kilograms per cubic meter (700 pounds per cubic yard) (DIRS 182772-MTS 2007, p. 112). Heavier equipment used at large facilities such as the Apex Landfill in Clark County would result in greater waste compaction and less waste volume. The estimated average daily disposal mass would be about 1 metric ton (1.1 tons) per day.

A rail line in the Jean rail corridor would represent an increase in waste volume requiring processing for rural counties. Nye County disposed of about 250 metric tons (280 tons) of waste during 2003 at three different landfills (DIRS 182772-MTS 2007, p. 112), but the county plans to close two of these landfills by 2011, which represent 96 percent of the county's current waste disposal capacity. The Apex Landfill in Clark County serves the Las Vegas Valley and receives 8,000 metric tons (8,800 tons) each day (DIRS 174041-State of Nevada 2004, pp. 6 and 7). The estimated closure for this landfill is in 2047. Waste generated during construction could be trucked to the larger landfill with negligible impact on waste disposal capacity.

Operations would generate waste during periodic maintenance activities. Locomotive and railcar maintenance could generate used oil and solvents that DOE would recycle or dispose of as regulated waste.

5.3.12 ENVIRONMENTAL JUSTICE

The Yucca Mountain FEIS environmental justice analysis considered the potential for disproportionately high and adverse impacts on two segments of the overall population – minority communities and low-income communities. In the Yucca Mountain FEIS, DOE employed a criterion for identifying minority and low-income communities by applying a 10-percent threshold, meaning that the environmental analyses for environmental justice purposes focused on Census blocks and Census block groups having minority or low-income populations at least 10-percent higher than state averages.

For this Nevada Rail Corridor SEIS, DOE adopted new criteria based upon revised U.S. Nuclear Regulatory Commission guidance. The new criteria are Census blocks having a 50 percent or higher minority population (for example, 10 percent higher than the state average), and Census block groups having a 30.5 percent low-income population (for example 20 percent higher than the state average).

Updates for the 2000 U.S. Census Bureau block group data used in the Yucca Mountain FEIS to examine the location and concentration of low income populations were not available at the time DOE completed the Yucca Mountain FEIS. Instead, the Yucca Mountain FEIS used 1990 U.S. Census Bureau block group data to identify low income populations. For Nevada Rail Corridor SEIS, DOE used the more current 2000 U.S. Census Bureau block group data to identify both low income and minority populations. The next set of comprehensive Census Bureau data will not be released until the 2010 Census, thus, the 2000 data is still considered the most current data set. The region of influence identified in the Yucca Mountain FEIS for the Jean rail corridor has remained the same. Furthermore, county level U.S. Census Bureau data estimates for 2006 suggest that while the population in southern Nevada is growing rapidly, the location of concentrations of minority and low-income populations have remained relatively constant and static since 2000 (DIRS 182772-MTS 2007, p. 113).

DOE concluded in the Yucca Mountain FEIS that there would not be any high and adverse impacts from transportation of spent nuclear fuel and high-level radioactive waste in Nevada on any populations, and that disproportionately high and adverse effects would be unlikely for any specific segment of the population, including minorities and low-income communities. DOE further concluded that there were no special pathways (unique practices and activities creating opportunities for increased impacts) that could not be mitigated. Therefore, the Yucca Mountain FEIS concluded that there were no environmental justice impacts associated with any proposed rail corridor.

Since DOE completed the Yucca Mountain FEIS, DOE has not identified any new large and adverse impacts to any population. DOE has also not identified any new minority or low income populations in the Jean rail corridor region of influence, and has not identified any special pathways that could increase impacts to these populations. Therefore, DOE maintains that there would be no environmental justice impacts associated with the Jean rail corridor.

5.4 Valley Modified Rail Corridor

Table 5-15 summarizes the results of the update to the primary impact indicators for the Valley Modified rail corridor and compares them with the corridor information published in the Yucca Mountain FEIS. The information reflects the total for the construction and operation of the rail corridor unless otherwise noted.

The Valley Modified rail corridor would originate near the existing Apex rail siding off the Union Pacific Railroad Mainline. It would travel northwest and pass north of the City of North Las Vegas, and Las Vegas and near the Town of Indian Springs and parallel to U.S. Highway 95 before it entered the southwest corner of the Nevada Test Site and reached Yucca Mountain (see Figure 5-6).

Valley Modified rail corridor options would range from 157 to 163 kilometers (98 to 101 miles) long. Figure 5-6 shows the corridor and its options. The corridor has two possible starting locations and two possible options until they merge north of the City of Las Vegas in the Apex area. The Valley Modified rail corridor has three options – Valley Connection, Sheep Mountain, and Indian Hills. The Yucca Mountain FEIS contains detailed descriptions of the corridor and its options.

5.4.1 LAND USE AND OWNERSHIP

Much has changed in relation to the land-use and ownership in the Valley Modified rail corridor since DOE issued the Yucca Mountain FEIS. The change in the estimates of the amount of BLM-administered land and private property within this corridor are in part the result of using more accurate databases of land ownership for Nevada Rail Corridor SEIS. Notable changes include potential land use conflicts with Creech Air Force Base and Apex Industrial Park. In addition, Congress has since released the Quail Springs and Nellis A, B, and C Wilderness Study Areas from Wilderness Study Area status, which expanded the land disposal boundary for the Las Vegas area.

The Yucca Mountain FEIS reported that the BLM administered approximately 53 percent (30 to 37 square kilometers [7,400 to 9,000 acres]) of the land in the corridor, the Department of Defense managed 11 percent (3.6 to 7.5 square kilometers [900 to 1,900 acres]), DOE managed 32 percent (20.6 square kilometers [5,100 acres]), the Fish and Wildlife Service controlled 3 percent (1.7 to 4.1 square kilometers [420 to 1,000 acres]), and less than 1 percent was private land (DIRS 182772-MTS 2007, p. 115).

Current land holdings for the Valley Modified rail corridor are as follows, the BLM administers about 51 to 54 percent (31 to 36 square kilometers [7,700 to 8,900 acres]), the Department of Defense manages 7.5 to 13 percent (4.3 to 9.4 square kilometers [1,100 to 2,300 acres]), DOE manages 32 percent (unchanged), the U.S. Fish and Wildlife Service controls about 3 percent (unchanged), and less than 1 percent is private land (unchanged) (DIRS 182772-MTS 2007, p. 115).

In 2005, the U.S. Air Force designated the Indian Springs Air Force Auxiliary Airfield to Creech Air Force Base and expanded its mission and infrastructure (GlobalSecurity.org 2005). The base is home to two key military operations: the MQ-1 Predator unmanned aerial vehicle and the Unmanned Aerial Vehicle Battle laboratory. The Yucca Mountain FEIS reported the Valley Modified rail corridor would pass through this area, which at the time was predominantly vacant land under Air Force management. At present, the corridor would cross infrastructure the Air Force constructed to support the mission of Creech Air Force Base. The Indian Hills option would bypass this land-use conflict.

The Apex Industrial Park is an 85-square-kilometer (21,000-acre) area privately held by the VesCor real estate development company. It is approximately 21 kilometers (13 miles) northeast of downtown Las Vegas and about 6 kilometers (4 miles) from the Las Vegas metropolitan area. It is one of the few large contiguous industrial properties in Southern Nevada. Since DOE issued the Yucca Mountain FEIS, this industrial park has gone beyond a proposed activity to one in which 24 square kilometers (6,000 acres) is available for immediate sale and development, with nearly half already sold (DIRS 182772-MTS 2007, p. 116). The Valley Modified rail corridor would cross approximately 0.5 square kilometers (110 acres) of the Apex Industrial Park.

The BLM is currently preparing an EIS and initiating public scoping for UNEV, LLC, proposal to construct and operate a liquid petroleum products pipeline from Woods Cross, Utah, to the Apex Industrial Park in Nevada. This proposed activity is approximately 13 kilometers (8 miles) north of the Valley Modified rail corridor.

Table 5-15. Updated environmental information for the Valley Modified rail corridor (page 1 of 2).

Resource	Changes from the Yucca Mountain FEIS to this analysis
Corridor length	No change
Land ownership	
BLM-administered land	Yucca Mountain FEIS: 7,400 to 9,100 acres (29.9 to 36.7 square kilometers (approximately 53 percent) Updated analysis: 7,700 to 8,900 acres (31 to 36 square kilometers) (51 to 53.7 percent)
Private land	Yucca Mountain FEIS: 49 acres (0.18 square kilometer) (about 3 percent) Updated analysis: 49 to 99 acres (0.2 to 0.4 square kilometer) (about 0.3 to 0.6 percent)
Nevada Test and Training Range land	Yucca Mountain FEIS: 900 to 1,900 acres (3.6 to 7.5 square kilometers) (about 11 percent) Updated analysis: 900 to 1,900 acres (4.3 to 9.4 square kilometers) (about 7.5 to 13.3 percent)
Nevada Test Site land	No change
U.S. Fish and Wildlife Service	No change
Air quality	
National Ambient Air Quality Standards attainment status	No change (potential for construction air quality impacts from PM_{10} and carbon monoxide)
Hydrology	
Surface water	No change
Groundwater use (construction)	Yucca Mountain FEIS: 395 acre-feet (395,000 cubic meters) Updated analysis: 320 acre-feet (3.44 million cubic meters)
Biological resources and soils	Six additional sensitive species recorded
Cultural resources (records search)	Yucca Mountain FEIS: 19 recorded sites Updated analysis: 45 recorded sites
Occupational and public health and safety	
Industrial hazards (construction and operations)	
Total recordable cases	Yucca Mountain FEIS: 111 Updated analysis: 176
Lost workday cases	Yucca Mountain FEIS: 57 Updated analysis: 103
Fatalities	Yucca Mountain FEIS: 0.25 Updated analysis: 0.5
Transportation hazards (construction only)	
Traffic fatalities	Yucca Mountain FEIS: 0.4 Updated analysis: 1.5
Cancer fatalities	Yucca Mountain FEIS: 0.05 Updated analysis: 0.2

Table 5-15. Updated environmental information for the Valley Modified rail corridor (page 2 of 2).

Resource	Changes from the Yucca Mountain FEIS to this analysis
Occupational and Public Health and Safety (continued)	
Incident-free radiological impacts (latent cancer fatalities) (operations only)	
Public	Yucca Mountain FEIS: 0.00065 Updated analysis: 0.00014
Workers	Yucca Mountain FEIS: 0.22 Updated analysis: 0.21
Radiological transportation accident fatalities	
Radiological accident risk (latent cancer fatalities)	Yucca Mountain FEIS: 0.0000000029 Updated analysis: 0.0000013
Cancer fatalities from vehicle emissions	Yucca Mountain FEIS: 0.07 Updated analysis: 0.2
Nonradiological transportation accident fatalities	
Spent nuclear fuel and high-level radioactive waste transportation	Yucca Mountain FEIS: 0.016 Updated analysis: 0.095
Construction and operations workforce	Yucca Mountain FEIS: 0.5 Updated analysis: 1.3
Socioeconomics	
Estimated construction workforce	Yucca Mountain FEIS: 405 worker-years Updated analysis: 2,500 worker-years
Estimated operations workforce	Yucca Mountain FEIS: 36 workers per year Updated analysis: 32 workers per year
Noise and vibration	No changes
Aesthetics	No changes
Utilities, energy, and materials (amount used)	
Diesel	Yucca Mountain FEIS: 3.4 million gallons (13 million liters) Updated analysis: 13 million gallons (49 million liters)
Gasoline	Yucca Mountain FEIS: 0.07 million gallons (0.27 million liters) Updated analysis: 0.26 million gallons (1 million liters
Steel	Yucca Mountain FEIS: 24,000 tons (22,000 metric tons) Updated analysis: 29,000 tons (26,000 metric tons)
Concrete	Yucca Mountain FES: 143,000 tons (130,000 metric tons) Updated analysis: 110,000 tons (100,000 metric tons)
Waste management	
Sanitary solid waste	Updated analysis: 0.7 tons (0.6 metric tons)per day
Environmental justice (disproportionately high and adverse impacts)	No changes, none identified

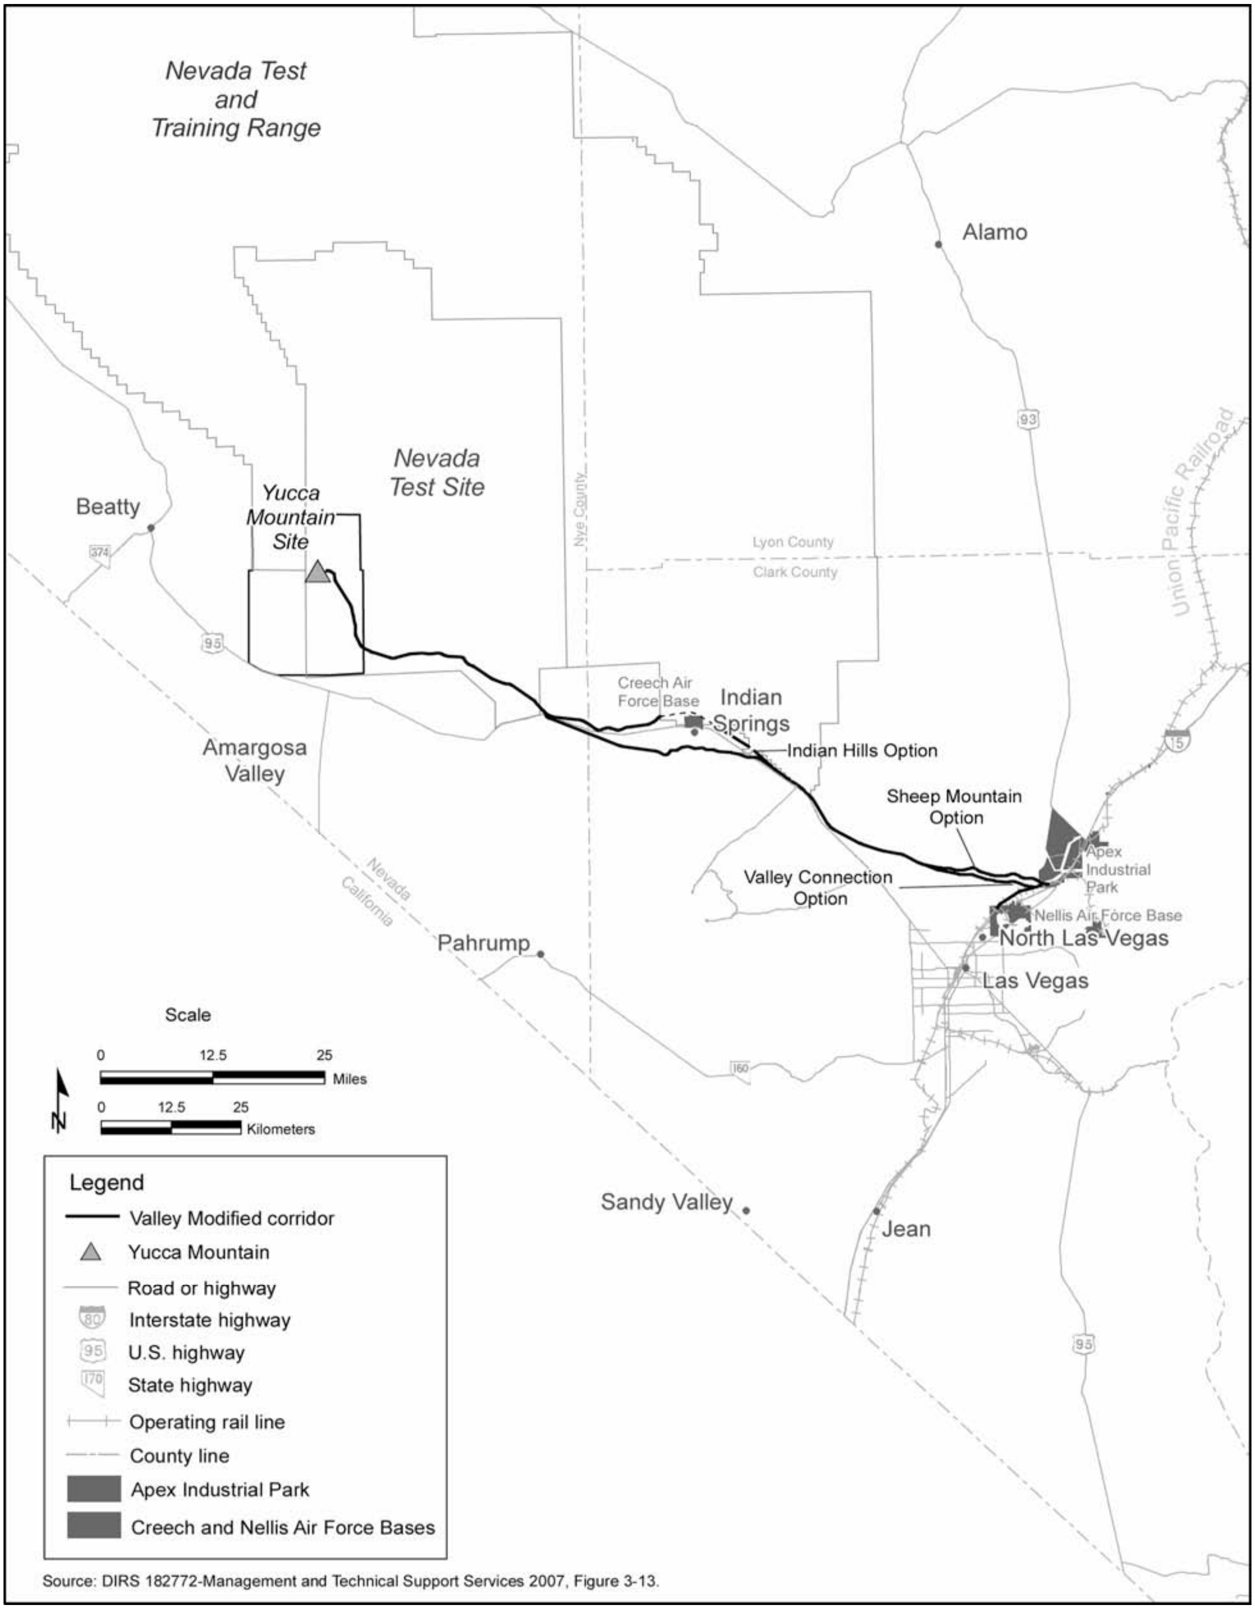

Figure 5-6. Valley Modified rail corridor and options.

The Yucca Mountain FEIS reported the corridor would cross the Quail Springs and Nellis A, B, and C Wilderness Study Areas, and one area designated as available for sale or transfer. In particular, the Indian Hills option would cross U.S. Fish and Wildlife Service lands, would pass almost entirely within a BLM utility corridor, and would cross a BLM Withdrawal Area for a power project. The Sheep Mountain option would pass through Quail Springs and Nellis A, B, and C Wilderness Study Areas, and the Nellis Small Arms Range. Of these land uses, the only changes have been to Quail Springs and Nellis A, B, and C. The Clark County Conservation of Public Land and Natural Resources Act (Public Law 107-282, 116 Stat. 1994) released these areas from the designation of Wilderness Study Areas in 2002 thus expanding the land disposal boundary for the Las Vegas area. The land formerly containing the Quail Springs Wilderness Study Area was sold to Clark County in 2002. The land formerly containing Nellis A, B, and C's have not yet been sold. These areas are under consideration for conservation areas to protect rare plant species, and will undergo NEPA analysis before the BLM offers these for sale or transfer.

The Yucca Mountain FEIS reported the Sheep Mountain option would pass through the Desert National Wildlife Refuge. Upon further evaluation, the Sheep Mountain and Valley Connection Options, and a portion of the common corridor segment just north of these options would pass through the Desert National Wildlife Refuge. The Desert National Wildlife Refuge established in 1936 includes a 610-square-kilometer (1.5-million-acre) area to protect the desert bighorn sheep and its habitat. In 1979, approximately 580 square kilometers (1.4 million acres) of this land were found to be suitable for further consideration as wilderness and were proposed for designation as a unit of the National Wilderness Preservation System. This means the area remains in proposed wilderness status and is managed as wilderness in accordance with National Wildlife Refuge System policy; public use is limited to wildlife observation, primitive camping, and picniking. This current land status would present a land conflict. According to the U.S. Fish and Wildlife Service, the Comprehensive Conservation Plan Environmental Impact Statement process, currently underway, is evaluating the wilderness status of this area (DIRS 182772-MTS 2007, p. 116).

The Yucca Mountain FEIS reported the corridor would cross three BLM grazing allotments (Wheeler Slope, Indian Springs, and Las Vegas Valley). The BLM has since updated their grazing allotment information. The Valley Modified rail corridor now crosses the Mount Sterling, Indian Springs, Wheeler Wash (formerly Wheeler Slope), Lucky Stripe, and the Las Vegas Valley grazing allotments, depending on the option.

DOE evaluated information in the Mineral Resources Data System and the Abandoned Mine database to determine if the addition of active or abandoned mines has occurred since DOE issued the Yucca Mountain FEIS. There are no known active or abandoned mines in the Valley Modified rail corridor or its options and, therefore, no change since the Yucca Mountain FEIS.

The Yucca Mountain FEIS reported that the Valley Modified rail corridor would cross linear land features such as rights-of-way for utilities, and roads. A review of BLM records, including Master Title Plats, indicated the authorization of additional rights-of-way since DOE completed the Yucca Mountain FEIS (DIRS 182772-MTS 2007, pp. 116 to 117).

5.4.2 AIR QUALITY

The Yucca Mountain FEIS evaluated air quality impacts common to all proposed corridors and noted these would include temporary increases in criteria pollutant concentrations from construction of the rail line. Construction equipment would emit carbon monoxide, nitrogen dioxide, sulfur dioxide, and PM_{10} and $PM_{2.5}$. Construction activities would emit PM_{10} in the form of fugitive dust from land clearing and filling, equipment traffic, activity of a quarry, and operation of concrete batch plants. The emissions would be temporary and would cover a sizeable area as construction progressed along the corridor.

The Valley Modified rail corridor would pass north of the metropolitan Las Vegas area and on through rural parts of Clark and Nye Counties. A portion of the corridor would be in the Las Vegas Valley in Clark County. When DOE prepared the Yucca Mountain FEIS, the Las Vegas Valley was in nonattainment for the criteria pollutants, carbon monoxide and PM_{10}. Areas in violation of one or more of the criteria pollutant standards are classified as nonattainment areas. The Las Vegas Valley remains officially in nonattainment for these two criteria pollutants (DIRS 182772-MTS 2007, p. 119), although progress has been made since 2000; the Valley is attaining the carbon monoxide National Ambient Air Quality Standard (70 *FR* 31353), and the U.S. Environmental Protection Agency approved implementation plans for PM_{10} in 2004 (69 *FR* 32277).

During preparation of the Yucca Mountain FEIS, DOE conducted an air quality conformity review for areas of the Valley Modified rail corridor in the Las Vegas Valley (DIRS 182772-MTS 2007, p. 119). This review determined that construction activities in the Las Vegas Valley would be likely to exceed the General Conformity threshold level for PM_{10}. Reviews of updated and more detailed information and methods (DIRS 180921-Nevada Rail Partners 2006, all; DIRS 180877-Nevada Rail Partners 2007, all) considered rail line construction and additional contributions from construction of access roads, unpaved roads, storage piles, batch plant, coarse stockpiles, and a quarry. The reviews indicated potential construction fugitive dust and PM_{10} emissions would increase above those originally estimated for the Yucca Mountain FEIS. Before any construction activities in the Valley Modified rail corridor, DOE would need to perform more detailed air quality calculations to evaluate the impacts of construction activities.

Potential air quality impacts during railroad operations would result from diesel locomotives, which would emit carbon monoxide, nitrogen dioxide, sulfur dioxide, PM_{10}, and $PM_{2.5}$. Because the earthwork is complete, the extent of these impacts would be smaller during operations than during construction activities but would last longer. The number of locomotives in use and the associated operational characteristics would not differ appreciably from those described in the Yucca Mountain FEIS. Therefore, measurable differences in potential impacts from those described in the Yucca Mountain FEIS are unlikely and remain small.

5.4.3 HYDROLOGY

This section describes surface-water and groundwater resources and impacts to those resources. The Yucca Mountain FEIS analyzed surface-water resources within the 400-meter (0.25-mile)-wide corridor and within 1 kilometer (0.6 mile) along each side of the corridor. For the Nevada Rail Corridor SEIS, the region of influence for hydrology is the same as for the Yucca Mountain FEIS.

5.4.3.1 Surface Water

The corridor and its options would cross only two mapped, 100-year flood zones or flood zone groups (DIRS 155970-DOE 2002, Table 6-74). These remain unchanged since DOE published the Yucca Mountain FEIS. Impacts to surface-water resources from the rail line construction in the Valley Modified rail corridor would be the same as those reported in the Yucca Mountain FEIS for all three options. Although unlikely, the spread of construction-related materials by precipitation or intermittent runoff events could occur during the construction of the rail line. Impacts associated with altering drainage patterns or changing erosion and sedimentation rates or locations would be small and localized.

5.4.3.2 Groundwater

In the Yucca Mountain FEIS, the Department used terrain types to estimate total water demand. Since DOE completed the Yucca Mountain FEIS, the Department has canvassed similar projects throughout Nevada and determined that the amount and type of earthwork, not the terrain, would more accurately estimate total water demand associated with the construction of a rail line. Therefore, DOE updated the water demand based on earthwork needs. This resulted in an estimated water demand for the Valley Modified rail corridor of approximately 3.44 million cubic meters (2,800 acre-feet) (DIRS 180877-Nevada Rail Partners 2007, p. 2-7) compared to the estimate based on terrain types reported in the Yucca Mountain FEIS of 395,000 cubic meters (320 acre-feet). To accommodate this increase in estimated water demand, DOE would need to draw more water than originally estimated in the Yucca Mountain FEIS from the underlying hydrographic basins and pump from additional wells. Groundwater withdrawal could temporarily affect discharge from nearby wells or springs. DOE would conduct detailed analyses if new wells required for construction of the rail line were to be located near other water sources.

Water use during construction would come primarily from groundwater resources, specifically, hydrographic basins. If the hydrographic basin is designated, permitted groundwater rights approach or exceed the estimated perennial yield, water resources are being depleted or require additional administration, and the Nevada State Engineer has declared preferred uses of the water. Table 5-16 updates the designation status of the hydrographic basins and the percentage of the Valley Modified rail corridor that is in the respective basin. The total percentage of the Valley Modified rail corridor in designated basins is about 54 percent. The Yucca Mountain FEIS estimated that about 70 percent of the length of the Valley Modified rail corridor would be in designated basins.

Table 5-16. Hydrographic basins associated with the Valley Modified rail corridor.[a,b]

Hydrographic basin (and subbasin where applicable)	Length (kilometers)[c]	Percentage of total[d]	Designated
Fortymile Canyon/Jackass Flats	17	11	No
Indian Springs Valley	29	18	Yes
Las Vegas Valley	56	36	Yes
Mercury Valley	19	12	No
Rock Valley	18	12	No
Three Lakes Valley	19	12	No

a. Source: DIRS 182772-MTS 2007, p. 120.
b. To calculate water demand for each basin, multiply the total water demand for a given corridor by the percentage of total.
c. km = kilometer; to convert kilometers to miles, multiply by 0.62137.
d. Based on primary option in Yucca Mountain FEIS.

Operations along the completed rail line would have little impact on groundwater resources. Possible changes in recharge, if any, would be the same as those at the completion of construction.

5.4.4 BIOLOGICAL RESOURCES AND SOILS

Potential impacts to biological resources and soils from the construction and operation of a railroad in the Valley Modified rail corridor would be consistent with those reported in the Yucca Mountain FEIS. Maximum land disturbance for the construction of a rail line in the Valley Modified rail corridor would not differ from the estimates in the Yucca Mountain FEIS and therefore the potential impacts would not change.

Consistent with the Yucca Mountain FEIS, this update considered the potential for impacts to vegetation communities; special status species (plants and animals), including their habitat; springs, wetlands, and riparian areas; big game habitat; and wild horse and burro herd management areas that may occur within the 400-meter (0.25-mile)-wide corridor. The analysis considered special status species and big game habitat within 5 kilometers (3 miles) of the corridor that may be affected by construction of the rail line. DOE also analyzed springs and riparian areas that could be affected by permanent changes in surface-water flows.

5.4.4.1 Biological Resources

The Valley Modified rail corridor is in the Mojave Desert; the predominant land-cover types are creosote-bursage and Mojave mixed scrub.

Table 5-17 presents the special status species, big game habitat, and herd management areas identified in the Yucca Mountain FEIS and identifies additional information resulting from this update. The updated version of the NNHP database examined for Nevada Rail Corridor SEIS included observations of six additional sensitive species not included in the Yucca Mountain FEIS. They include the:

- Southwestern willow flycatcher (*Empidonax traillii extimus*)
- Clarke phacelia *(Phacelia filiae)*
- Clokey buckwheat (*Eriogonum heermannii var. clokeyi*)
- Fringed myotis (*Myotis thysanodes*)
- Las Vegas buckwheat (*Eriogonum corymbosum var. nilesii*)
- Planoconvex cordmoss (*Entosthodon planoconvexus*)

Table 5-17. Special status species, big game habitat, and herd management areas associated with the Valley Modified rail corridor[a] (page 1 of 2).

Resource	Type	Yucca Mountain FEIS		Nevada Rail Corridor SEIS

a. Source: Data collected from DIRS 182772 MTS 2007, pp. 121 and 122; DIRS 182760-URS Corporation/Potomac-Hudson Engineering 2006, all.

b. Pahrump pool fish have been introduced into ponds in Floyd Lamb State Park and into the outflow of Corn Creek Springs, both of which are outside the region of influence for surface waters.

DOE evaluated surface-water resources, which include springs, streams, riparian areas, and reservoirs for all options. No springs, perennial streams, or riparian areas occur in the Valley Modified rail corridor. These remain unchanged since DOE completed the Yucca Mountain FEIS.

There are no other known changes to the information in the Yucca Mountain FEIS on existence of game habitat, sensitive species, or springs within 5 kilometers (3 miles) of the corridor.

5.4.4.2 Soils

The Yucca Mountain FEIS classified soils in the Valley Modified rail corridor with four attributes: shrink swell, erodes easily, unstable fill, and blowing soil. As noted in the Yucca Mountain FEIS, the shrink swell and blowing soils attributes are common in the Valley Modified rail corridor. The Yucca Mountain FEIS also reported that there were no soils classified as prime farmlands within the Valley Modified rail corridor. No significant new information was readily available about the attributes of the soils surveyed in the corridor.

According to the Yucca Mountain FEIS, soils in and adjacent to the Valley Modified rail corridor would be disturbed on approximately 5 square kilometers (1,200 acres) of land during construction of the rail line. Impacts to soils in the corridor would be small, but could occur throughout construction. Shrink-swell soils occur along much of the corridor, as does the potential for blowing soils. Disturbance during construction would increase the amount of soil that could be transported by wind because the existing vegetation would be disturbed, at least temporarily. Vegetation or other means of soil stabilization after construction could minimize this. The soils within the Valley Modified rail corridor and the potential impacts to these soils remain unchanged since DOE completed the Yucca Mountain FEIS.

5.4.5 CULTURAL RESOURCES

The effects of rail line construction in Valley Modified rail corridor on cultural resources would be essentially the same as those DOE reported in the Yucca Mountain FEIS. Impacts to cultural resources from operation of a railroad in the Valley Modified rail corridor would be unlikely.

Cultural resources include any prehistoric or historic archaeological sites, buildings, structures, landscapes, or object resulting from or modified by human activity and include mining, ranching, and linear features such as roads and trails. Cultural resources designated as historic properties warrant consideration with regard to potential adverse impacts resulting from proposed federal actions.

For this update, DOE conducted an archaeological site-file search using records from the Desert Research Institute, the Nevada Cultural Resources Information System, and archaeological information repositories at the Harry Reid Center at the University of Nevada-Las Vegas, and the Nevada State Museum in Carson City.

The records search revealed the presence of 45 known archaeological sites within the 400 meters (0.25 mile) width of the Valley Modified rail corridor. The difference between the 19 sites reported in the Yucca Mountain FEIS and the 45 identified in the new survey reflects the addition of sites recorded in the past decade, particularly in the vicinity of Yucca Mountain, where cultural resources inventories and improvements in cultural resources records have been ongoing. Of the 45 known sites, 12 are eligible or potentially eligible for inclusion on the *National Register of Historic Places* (DIRS 182772-MTS 2007, p. 123).

The types of sites found in the new survey records are the same as those reported in the Yucca Mountain FEIS. The total amount of archaeological inventories conducted is approximately less than 1 percent of the total area for the Valley Modified rail corridor. Prior to construction of a rail line, field surveys and potentially mitigation of cultural resources would be required.

5.4.6 OCCUPATIONAL AND PUBLIC HEALTH AND SAFETY

5.4.6.1 Industrial Safety

The categories of worker impacts include total recordable incidents, lost workdays, and fatalities. Recordable incidents or cases are occupational injuries or occupation-related illnesses that result in (1) a fatality, regardless of the time between the injury or the onset of the illness and death, (2) lost workday cases (nonfatal), and (3) incidents that result in the transfer of a worker to another job, termination of employment, medical treatment, loss of consciousness, or restriction of motion during work activities.

Revised estimates of the number of workers needed to construct the rail line resulted in 2,500 worker-years in comparison to the 405 worker-years estimated in the Yucca Mountain FEIS (2,000 hours per worker-year). Estimates of industrial safety impacts incorporate updated Bureau of Labor Statistics data for 2005 (DIRS 179131-BLS 2006, all; DIRS 179129-BLS 2007, all). The Yucca Mountain FEIS used 1998 data from the same source. Industrial safety impacts from operations in the Valley Modified rail corridor would be lower than those in the Yucca Mountain FEIS because of differences in the labor statistics used. Operation of the railroad would require about 45 workers each year. Table 5-18 lists estimated industrial safety impacts reported in the Yucca Mountain FEIS as well as the updated information.

5.4.6.2 Transportation

Since DOE completed the Yucca Mountain FEIS, there have been updates to the methods and data to estimate the radiation doses for workers and members of the public. Section 3.2.6 of this Nevada Rail Corridor SEIS describes updates to the methods and data used to estimate impacts for the rail corridors. The impacts for the Valley Modified rail corridor reflects new information resulting from these changes.

Updates for transportation estimated impacts during construction from the transportation of construction materials to the construction sites and impacts from commuting workers. Operation of the railroad could result in incident-free radiological impacts, risks from radiological accidents, impacts from vehicle emissions from waste transportation and commuting workers, and traffic fatalities associated with waste transport and commuting workers.

The Yucca Mountain FEIS evaluated traffic fatality and vehicle emission impacts from the movement of equipment and delivery of materials for construction, worker commutes to and from construction sites, and transport of water to construction sites. Table 5-19 lists the impacts of transportation during the construction phase. Due to the increased number of construction workers from the estimate in the Yucca

Mountain FEIS, estimated traffic fatalities could increase from 0.4 to 1.5, and fatalities from exposure to vehicle emissions could increase from 0.05 to 0.2. Total transportation impacts from construction could be about 1.7 fatalities.

Transportation of spent nuclear fuel and high-level radioactive waste in the Valley Modified rail corridor could result in radiological and nonradiological impacts to workers and the public. Radiological impacts could result from radiation that the rail casks emitted during incident-free transportation, from radionuclides released from the rail cask during transportation accidents, or from radiation the rail cask emitted because of a loss of shielding during a transportation accident. Nonradiological impacts (vehicle emission-related fatalities) could result from diesel locomotives and fugitive dust. Nonradiological impacts could also result from traffic accidents that involved workers and members of the public.

Table 5-18 Impacts to workers from industrial hazards during railroad construction and operations for the Valley Modified rail corridor.[a]

Group and industrial hazard category	Construction		Operations		Total	
	Yucca Mountain FEIS [b]	Update[c]	Yucca Mountain FEIS [d]	Update[e]	Yucca Mountain FEIS	Update

Worker commuting	–	–	0.03	0.2		
Transportation accidents (fatalities)						
Material delivery vehicles	0.1	0.1	–	–		
Worker commuting	0.2	1.4	–	–		
Totals[b]	0.4	1.5	0.05	0.2	0.45	1.7

a. Source: DIRS 182772-MTS 2007, p. 125.
b. Totals might differ from sums of values due to rounding.

Table 5-20 lists the impacts of using the Valley Modified rail corridor to ship spent nuclear fuel and high-level radioactive waste calculated using updated methods and data. The impacts presented reflect those from the mainline to the repository. This is in contrast to the Yucca Mountain FEIS, where the Nevada impacts started where the mainline intersects the Nevada border.

For members of the public, estimated radiological impacts from incident-free (routine) transportation decreased from those in the Yucca Mountain FEIS, from 0.00065 to 0.00014 latent cancer fatality. This

Table 5-20. Operations impacts of transportation for the Valley Modified rail corridor.[a]

Transportation impact category	Traffic fatalities		Number of cancers	
	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update
Incident-free radiological impacts (LCFs)[b]				
Public (LCFs)	Not applicable	–	0.00065	0.00014
Workers (LCFs)	–	–	0.27	0.21
Radiological accident risks (LCFs)	-	-	0.0000000029	0.0000013
Vehicle emission impacts (cancer fatalities)				
Waste transportation	–	–	0.000047	0.0006
Worker commuting	–	–	0.07	0.2
Transportation accidents (fatalities)				
Waste transportation	0.016	0.1	–	–
Worker commuting	0.5	1.3	–	–
Totals[c]	0.5	1.4	0.3	0.4

a. Source: DIRS 182772-MTS 2007, p. 126.
b. LCF = latent cancer fatality.
c. Totals might differ from sums of totals due to rounding.

would be due primarily to the change in analysis for the Nevada rail line to model dedicated trains for shipments to the repository (DIRS 182772-MTS 2007, p. 125), which would be partially offset by the increase in the latent cancer fatality conversion factor.

For workers, estimated radiological impacts from incident-free transportation would decrease from 0.27 to 0.21 latent cancer fatality. The decrease would be due primarily to the decrease in the exposure time at the staging yard, which would partially offset by the increase in the latent cancer fatality conversion factor, the use of escorts in all areas, and the estimation of impacts for non involved workers at the staging yard.

Estimated radiological accident risks increased from 0.0000000029 to 0.0000013 latent cancer fatality. This would be due primarily to the use of the combined Track Class 3 transportation accident rate (DIRS 182772-MTS 2007, p. 125) based on train kilometers and railcar kilometers and the increase in the latent cancer fatality conversion factor, and the increase in the population along the Valley Modified rail corridor. Although this is an increase, radiological accident risk would still be a negligible contributor to the overall transportation risk.

Estimated impacts from waste transportation vehicle emissions would increase from 0.000047 to 0.0006 fatality. This would be due primarily to the increase in populations along the Valley Modified rail corridor. Vehicle emission impacts from commuting workers could increase from those reported in the Yucca Mountain FEIS because of the longer operations phase.

Estimated impacts from nonradiological transportation accidents would increase from 0.016 to 0.095 fatality. This is the most notable change to accident risk and would be due primarily to the use of the updated rail fatality rate (DIRS 178016-DOT 2005, all) and from accounting for the presence of locomotives and buffer cars in the estimation of the number of nonradiological transportation accident fatalities. Traffic fatalities associated with commuting workers could also increase.

Overall, the estimated total number of transportation-related fatalities from operation of a railroad in the Valley Modified rail corridor has increased from 0.8 fatality reported in the Yucca Mountain FEIS to 1.8 fatalities in the current assessment. This change is due primarily to the increase in the number of fatalities from traffic accidents.

5.4.7 SOCIOECONOMICS

In the Yucca Mountain FEIS, DOE used construction costs, workforce estimates, and state and regional economic data to identify potential direct and indirect changes in state and regional economic activity. The Department noted that construction activities would cause short-term, temporary increases in employment and population.

Revised estimates of the number of workers needed to construct the rail line in the Valley Modified rail corridor resulted in 2,500 worker-years in comparison to the 405 worker-years estimated in the Yucca Mountain FEIS.

Operation of the railroad would require about 32 workers each year in comparison to the 36 workers estimated in the Yucca Mountain FEIS. Increased workforce estimates would not notably affect the regional economy. Given the relatively low number of employees necessary for the operation of the railroad, the potential for socioeconomic impacts in the corridor would be short-term and small.

Clark County, which includes Las Vegas, dominates the region of influence with a 2006 estimated population of 1.89 million, which is approximately 7 percent more than the population that DOE reported in the Yucca Mountain FEIS. Population growth in the unincorporated town of Pahrump dominates Nye County's growing popularity as a residential destination. Since DOE completed the Yucca Mountain FEIS, Pahrump, the largest population center in Nye County, has experienced double-digit growth. The estimated population of Pahrump increased from 23,000 in July 1999 to 33,000 by July 2005, an increase of about 45 percent (DIRS 182772-MTS 2007, p. 127). In the same period, the State Demographer estimates that Nye County, as a whole, grew from about 31,000 to about 41,000. The average annual impact from the construction and operation of a railroad to the baselines population in Clark and Nye Counties would be small.

Because the construction workforce is expected to come largely from Clark County, any changes to the regional employment and population baselines would be nearly imperceptible. Meaningful changes in employment and population due to the construction and operation of the railroad is unlikely. Current population growth in these Clark and Nye counties would mask socioeconomic impacts due to the short-term growth in the workforce or the associated impact on population growth.

5.4.8 NOISE AND VIBRATION

The Yucca Mountain FEIS analysis for noise considered typical day-night sound levels, the distance of the rail line from communities along the rail line, and estimated the impacts from the construction and operation of a railroad to these communities. The Yucca Mountain FEIS analysis for vibration considered typical background level of ground vibration, the number of trains, and the distance of the rail line from to historic structures or sites of cultural significance, and estimated the impacts from the operation of a railroad. There are no significant new circumstances or information that would cause the affected environment or the estimated impacts from noise and vibration to change from what was reported in the Yucca Mountain FEIS.

5.4.9 AESTHETICS

Based on a corridor-level analysis and an evaluation of current BLM resource management plans, there have been no changes to Visual Resource Management classifications for the Valley Modified rail corridor since DOE completed the Yucca Mountain FEIS and, therefore, impacts would be the same as those discussed in the Yucca Mountain FEIS. As stated in the Yucca Mountain FEIS, operation of a railroad in the Valley Modified rail corridor would cause small impacts to visual resources in the area because the entire corridor would fall within the BLM Class III designation.

5.4.10 UTILITIES, ENERGY, AND MATERIALS

The Yucca Mountain FEIS evaluated utilities, energy, and materials impacts common to all corridors and noted that these impacts would include the use of motor fuel, steel, and concrete. The estimated impacts from these resources associated with the construction and operation of a railroad in Nevada would be small, similar to those in the Yucca Mountain FEIS.

The Valley Modified rail corridor would pass north of the Las Vegas metropolitan area. Electric power for construction would be initially supplied by portable generators. New power lines would be installed to provide power for construction services and would be extended, via underground distribution along the rail roadbed to meet all other construction and operational needs. Construction equipment would also consume motor fuel (diesel and gasoline). The total motor fuel use in Nevada in 2005 was about 5.8 billion liters (1.5 billion gallons) in 2005 (DIRS 182772-MTS 2007, p. 127). Highway motor fuel use in the state in 2005 increased 6.2 percent over that in 2004, the largest percentage increase for any state and attributable to Nevada's growing population. Table 5-21 lists the estimated amounts of diesel fuel and gasoline for construction for the Valley Modified rail corridor, which are higher than the estimates in the Yucca Mountain FEIS. Based on a construction period of 40 months, the annual average use of motor fuel would be about 0.27 percent of that consumed annually in Nevada. Unlike overall state use, construction activities would use primarily diesel fuel, which would be about 1 percent of all special fuel (mainly diesel) used annually in Nevada.

Table 5-21. Construction energy and materials impacts for the Valley Modified rail corridor.[a]

Length (kilometers)[b,c]	Diesel fuel use (million liters)[d]		Gasoline use (million liters)		Steel (thousand metric tons)[e]		Concrete (thousand metric tons)	
	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update	Yucca Mountain FEIS	Update
160	13	49	0.27	1.0	22	26	130	100

a. Sources: DIRS 180877-Nevada Rail Partners 2007, p. 2-7, Table 2-1; DIRS 182772-MTS 2007, p. 128.
b. Rail corridor length used for comparative evaluation.
c. To convert kilometers to miles, multiply by 0.623.
d. To convert liters to gallons, multiply by 0.264.
e. To convert metric tons to tons, multiply by 1.102.

Steel for rails, concrete (principally for rail ties, bridges, and drainage structures), and rock for ballast would be the primary materials that the construction of a rail line would consume. Table 5-21 lists estimates of steel consumption, which have increased over those in the Yucca Mountain FEIS, and concrete consumption, which have decreased from those in the Yucca Mountain FEIS.

The estimated impacts to utilities, energy, and materials from the operation of a railroad in Nevada would be small, similar to those in the Yucca Mountain FEIS. The estimated use of motor fuel by locomotives would increase over that in the Yucca Mountain FEIS due to more weekly train trips, but the overall use would still be small.

5.4.11 WASTE MANAGEMENT

The Yucca Mountain FEIS evaluated common waste management impacts for all corridors rather than for individual corridors. Information to allow differentiation between corridor waste management impacts is now much more readily available. Therefore, this readily available information has been included at a level of analysis that was similar to the Yucca Mountain FEIS.

Waste generation and management impacts common to all corridors would result from construction and operation a railroad in the Valley Modified rail corridor. There would be relatively low amounts of construction debris and sanitary waste generated.

The Yucca Mountain FEIS estimated that the peak annual generation would be 910 metric tons (1,000 tons) of sanitary solid waste. DOE now estimates solid municipal waste from construction facilities would be 380 metric tons (410 tons) during the peak year of construction. An assumed 25 percent of the waste generated would be recyclable, which would result in about 280 metric tons (310 tons) of waste for disposal at municipal landfills. The estimated total mass of waste generated during construction of the rail line would be about 760 metric tons (840 tons). This mass of sanitary solid waste would occupy about 1,800 cubic meters (2,400 cubic yards) of landfill volume at a waste density of 410 kilograms per cubic meter (700 pounds per cubic yard) (DIRS 182772-MTS 2007, p. 128). Heavier equipment used at large facilities such as the Apex Landfill in Clark County would result in greater waste compaction and less waste volume. The estimated average daily disposal mass would be about 0.6 metric ton (0.7 ton) per day.

Nye County disposed of about 250 metric tons (280 tons) of waste during 2003 at three different landfills (DIRS 182772-MTS 2007, p. 128), but the county plans to close two of these landfills by 2011, which would represent 96 percent of the county's current waste disposal capacity. The Apex Landfill in Clark County serves the Las Vegas Valley and receives 8,000 metric tons (8,800 tons) each day (DIRS 174041-State of Nevada 2004, pp. 6 and 7). The estimated closure is in 2047. Waste generated during construction could be trucked to larger landfills with small impact on waste disposal capacity.

Operations would generate waste during periodic maintenance activities. Locomotive and railcar maintenance could generate used oil and solvents that DOE would recycle or dispose of as hazardous chemicals.

5.4.12 ENVIRONMENTAL JUSTICE

The Yucca Mountain FEIS environmental justice analysis considered the potential for disproportionately high and adverse impacts on two segments of the overall population – minority communities and low-income communities. In the Yucca Mountain FEIS, DOE employed a criterion for identifying minority and low-income communities by applying a 10-percent threshold, meaning that the environmental analyses for environmental justice purposes focused on Census blocks and Census block groups having minority or low-income populations at least 10 percent higher than state averages.

For Nevada Rail Corridor SEIS, DOE adopted new criteria based upon revised NRC guidance. The new criteria are Census blocks having a 50 percent or higher minority population (for example, 10 percent higher than the State average), and Census block groups having a 30.5 percent low-income population (for example, 20 percent higher than the State average).

Updates for the 2000 U.S. Census Bureau block group data used in the Yucca Mountain FEIS to examine the location and concentration of low income populations were not available at the time DOE completed the Yucca Mountain FEIS. Instead, the Yucca Mountain FEIS used 1990 U.S. Census Bureau block group data to identify low income populations. For Nevada Rail Corridor SEIS, DOE used the more current 2000 U.S. Census Bureau block group data to identify both low income and minority populations. The next set of comprehensive Census Bureau data will not be released until the 2010 Census, thus, the 2000 data is still considered the most current data set. The region of influence identified in the Yucca Mountain FEIS for the Valley Modified rail corridor has remained the same. Furthermore, county level U.S. Census Bureau data estimates for 2006 suggest that while the population in southern Nevada is growing rapidly, the location of concentrations of minority and low income populations have remained relatively constant and static since 2000 (DIRS 182772-MTS 2007, p. 129).

DOE concluded in the Yucca Mountain FEIS that there would not be any high and adverse impacts from transportation of spent nuclear fuel and high-level radioactive waste in Nevada on any populations, and that disproportionately high and adverse effects would be unlikely for any specific segment of the population, including minorities and low-income communities. DOE further concluded that there were no special pathways (unique practices and activities creating opportunities for increased impacts) that could not be mitigated. Therefore, the Yucca Mountain FEIS concluded that there were no environmental justice impacts associated with any proposed rail corridor.

Since DOE completed the Yucca Mountain FEIS, the Department has not identified any new large and adverse impacts to any population. DOE has also not identified any new minority or low income populations in the Valley Modified rail corridor region of influence, and has not identified any special pathways that could increase impacts to these populations. Therefore, DOE maintains that there would be no environmental justice impacts associated with the Valley Modified rail corridor.

6. CONCLUSION

DOE concludes that the Mina rail corridor warrants further study at the alignment level under the National Environmental Policy Act, although as a nonpreferred alternative. In addition, DOE concludes that, based on the analyses described herein, there are no significant new circumstances or information relevant to environmental concerns that would warrant further consideration of the Carlin, Jean, or Valley Modified rail corridor at the alignment level.

Glossary terms shown in ***bold italics***.

The U.S. Department of Energy (DOE or the Department) concludes that the Mina ***rail corridor*** warrants further study to determine an alignment for the construction and operation of a ***railroad***. In reaching this conclusion, DOE considered the environmental conditions and associated potential environmental impacts of constructing and operating a railroad for each of 12 environmental resource areas and found overall that impacts would be small. The Mina rail corridor coincides in part with an abandoned rail line and follows relatively flat terrain over much of its length, which would minimize construction earthworks (***cuts*** and ***fills***); this would tend to reduce environmental impacts. Cumulative impacts to groundwater resources for construction and operation of a railroad in the Mina rail corridor ***region of influence***, however, would be small to moderate.

On April 17, 2007, the Walker River Paiute Tribal Council passed a resolution withdrawing the Tribe from participating in the Supplemental Yucca Mountain Nevada Rail Corridor EIS and Rail Alignment EIS preparation process. The Tribal Council's resolution also renewed the Tribe's past objection to the transportation of nuclear waste through their Reservation. Accordingly, DOE has identified the Mina Implementing Alternative as nonpreferred in this Supplemental Yucca Mountain Nevada Rail Corridor EIS and Rail Alignment EIS.

In addition, the Department has updated the environmental information in 12 resource areas for three of the other rail corridors (Carlin, Jean, and Valley Modified) evaluated in detail in the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Yucca Mountain FEIS). For the most part, the environmental conditions and associated potential environmental impacts for each rail corridor remain unchanged from, or are substantially similar to, those reported in the Yucca Mountain FEIS. Notably, however, land use and ownership conflicts in the Jean and Valley Modified corridors have increased, and, although the amount of private land within the Carlin rail corridor appears to have decreased (based on a more refined analysis using land ownership databases) since DOE completed the Yucca Mountain FEIS, the complex land-ownership pattern resulting from the mix of private and public lands the corridor would cross remains unchanged. Such land use and ownership conflicts and complexity increase the potential to adversely affect construction of a railroad, and to increase the potential for delays that could affect the availability of a railroad in these corridors. Moreover, air quality management goals in the Jean corridor have changed since DOE completed the Yucca Mountain FEIS, and construction of a railroad could increase the potential for conflicts with these goals. For these reasons, the Department concludes there are no significant new circumstances or information relevant to environmental concerns that would warrant further consideration of these three rail corridors at the alignment level.

1. PURPOSE AND NEED FOR AGENCY ACTION

This chapter explains why DOE needs to construct and operate a railroad in Nevada, summarizes the process leading to the selection of the Caliente and Mina rail corridors for further study, and describes the interests and roles of cooperating agencies. It also describes the Supplemental Rail Corridor EIS and Rail Alignment EIS scoping process, and summarizes public scoping comments and how DOE acted on those comments.

Glossary terms are shown in ***bold italics***.

1.1 Background

The United States has focused a national effort on siting and developing a ***geologic repository*** for the ***disposal*** of ***spent nuclear fuel*** and ***high-level radioactive waste*** and on developing systems for transporting these materials from their present locations throughout the country to that repository.

Spent nuclear fuel is fuel that has been withdrawn from a nuclear reactor following irradiation.

- **Commercial spent nuclear fuel** comes from civilian nuclear power plants that generate electricity.
- **DOE spent nuclear fuel** comes from DOE production reactors (such as defense nuclear material production reactors), naval reactors, and university- and government-owned test and experimental reactors.

High-level radioactive waste is the highly radioactive material that results from the reprocessing of spent nuclear fuel and other highly radioactive material, which the U.S. Nuclear Regulatory Commission determines by rule requires permanent isolation.

The Nuclear Waste Policy Act of 1982 (Public Law 97-425) acknowledged the Federal Government's responsibility to provide for the disposal of the Nation's spent nuclear fuel and high-level radioactive waste, and initiated a process to select sites for technical study as potential geologic repository locations. In 1987, Congress amended the Nuclear Waste Policy Act. This Act, as amended (42 United States Code [U.S.C.] 10101 *et seq.*), which this ***environmental impact statement*** (EIS) refers to as the NWPA, identifies the ***Yucca Mountain Site*** in Nye County, Nevada, as the site to be studied as a potential location for a geologic repository.

After completion of ***site characterization*** studies at Yucca Mountain, the Secretary of Energy found the site to be scientifically and technically suitable for development of a repository. On February 14, 2002, the Secretary submitted his recommendation, along with a comprehensive statement of the basis for the recommendation, to the President of the United States, George W. Bush, for approval of the Yucca Mountain Site for the development of a ***nuclear waste repository***. As required by the NWPA, the U.S. Department of Energy (DOE or the Department) had prepared an EIS, *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DIRS 155970-DOE 2002, all) (Yucca Mountain FEIS), to accompany the Secretary's recommendation to the President.

On February 15, 2002, the President, in accordance with the NWPA, approved the Secretary of Energy's recommendation of the Yucca Mountain Site for development as a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste. On July 23, 2002, the President signed into law a joint resolution of the U.S. House of Representatives and the U.S. Senate designating the Yucca Mountain

Site for development as a geologic repository (Yucca Mountain Development Act of 2002, Public Law 107-200).

As part of its obligations under the NWPA, DOE is responsible for developing a system to transport spent nuclear fuel and high-level radioactive waste to the repository. In the Yucca Mountain FEIS, DOE analyzed a ***proposed action*** to construct, operate, monitor, and eventually close a geologic repository at Yucca Mountain in southern Nevada for the disposal of spent nuclear fuel and high-level radioactive waste. As part of that action, DOE evaluated various modes of transporting spent nuclear fuel and high-level radioactive waste from 72 commercial sites and five DOE sites nationwide to the Yucca Mountain Site. (Note: DOE now plans to move all spent nuclear fuel from Fort St. Vrain to Idaho National Laboratory before the repository at Yucca Mountain is scheduled to open. Therefore, the number of DOE sites is four.) Figure 1-1 shows the locations of the commercial and DOE sites that would ship spent nuclear fuel and high-level radioactive waste to Yucca Mountain.

The Yucca Mountain FEIS examined various national transportation scenarios and Nevada transportation scenarios to evaluate and compare the range of potential transportation ***impacts*** to human health. DOE evaluated two national transportation scenarios, referred to as the "mostly legal-weight truck scenario" and the "mostly rail scenario," and three Nevada transportation scenarios, referred to as the "Nevada mostly legal-weight truck scenario," the "Nevada mostly rail scenario," and the "Nevada mostly heavy-haul truck scenario." In the Yucca Mountain FEIS, DOE identified the mostly rail scenario as its preferred mode of transportation, both nationally and in Nevada (DIRS 155970-DOE 2002, p. 1-3), due in part to lower potential impacts to the health and safety of workers and the public.

1.2 Purpose and Need

Based on its obligations under the NWPA and its decision to select the mostly rail scenario for the transportation of spent nuclear fuel and high-level radioactive waste, DOE needs to ship these materials by rail in Nevada to a repository at Yucca Mountain.

At present, there is no ***railroad*** to the Yucca Mountain Site. In the Yucca Mountain FEIS, DOE evaluated in detail five potential ***rail corridors*** within Nevada in which the Department could construct a railroad to link an existing ***rail line*** to Yucca Mountain: Caliente, Carlin, Caliente-Chalk Mountain, Jean, and Valley Modified rail corridors (DIRS 155970-DOE 2002, Chapter 6). Figure 1-2 shows the five rail corridors analyzed in the Yucca Mountain FEIS.

The Yucca Mountain FEIS did not specify a rail corridor preference, but on December 29, 2003, in the subsequent *Notice of Preferred Nevada Rail Corridor* (68 *Federal Register* [*FR*] 74951) (see Appendix A), DOE announced its preference for the Caliente rail corridor. Figure 1-3 shows the Caliente ***rail alignment***, including ***alternative segments*** considered, as analyzed in this Rail Alignment EIS. The Caliente rail alignment is an engineered refinement of the Caliente rail corridor analyzed in the Yucca Mountain FEIS.

Rail corridor: A strip of land 400 meters (0.25 mile) wide through which DOE would identify an alignment (***rail alignment***) for the construction of a ***rail line*** in Nevada to a ***geologic repository*** at Yucca Mountain.

Rail alignment: An engineered refinement of a rail corridor in which DOE would identify the location of a rail line. A rail alignment is comprised of ***common segments*** and ***alternative segments***.

Railroad: A transportation system incorporating the rail line, operations support facilities, railcars, locomotives, and other related property and infrastructure.

Rail line: An engineered feature incorporating the track, ties, ***ballast***, and ***subballast*** at a specific location.

Legend

- ▲ Yucca Mountain
- ★ Commercial Sites

  Note: The Yucca Mountain FEIS analysis considered three commercial site pairs—Salem and Hope Creek, Nine Mile Point and FitzPatrick, and Dresden and Morris—to be single sites because of their proximity to each other.

- ◉ DOE Sites

  Notes:

  The Yucca Mountain FEIS analysis included the high-level radioactive waste at West Valley. The State of New York owns the high-level radioactive waste and the site. Under the West Valley Demonstration Project Act, DOE is responsible for solidifying and transporting the high-level radioactive waste to a repository.

  The Yucca Mountain FEIS analysis included DOE spent nuclear fuel at a fifth DOE location, Fort St. Vrain in Colorado. DOE will move that waste to the Idaho National Laboratory for processing and it will be included in the laboratory inventory. Therefore, this map does not show Fort St. Vrain as a DOE source of spent nuclear fuel.

Notes: DOE = U.S. Department of Energy; FEIS = Final Environmental Impact Statement. Symbols do not reflect precise locations.

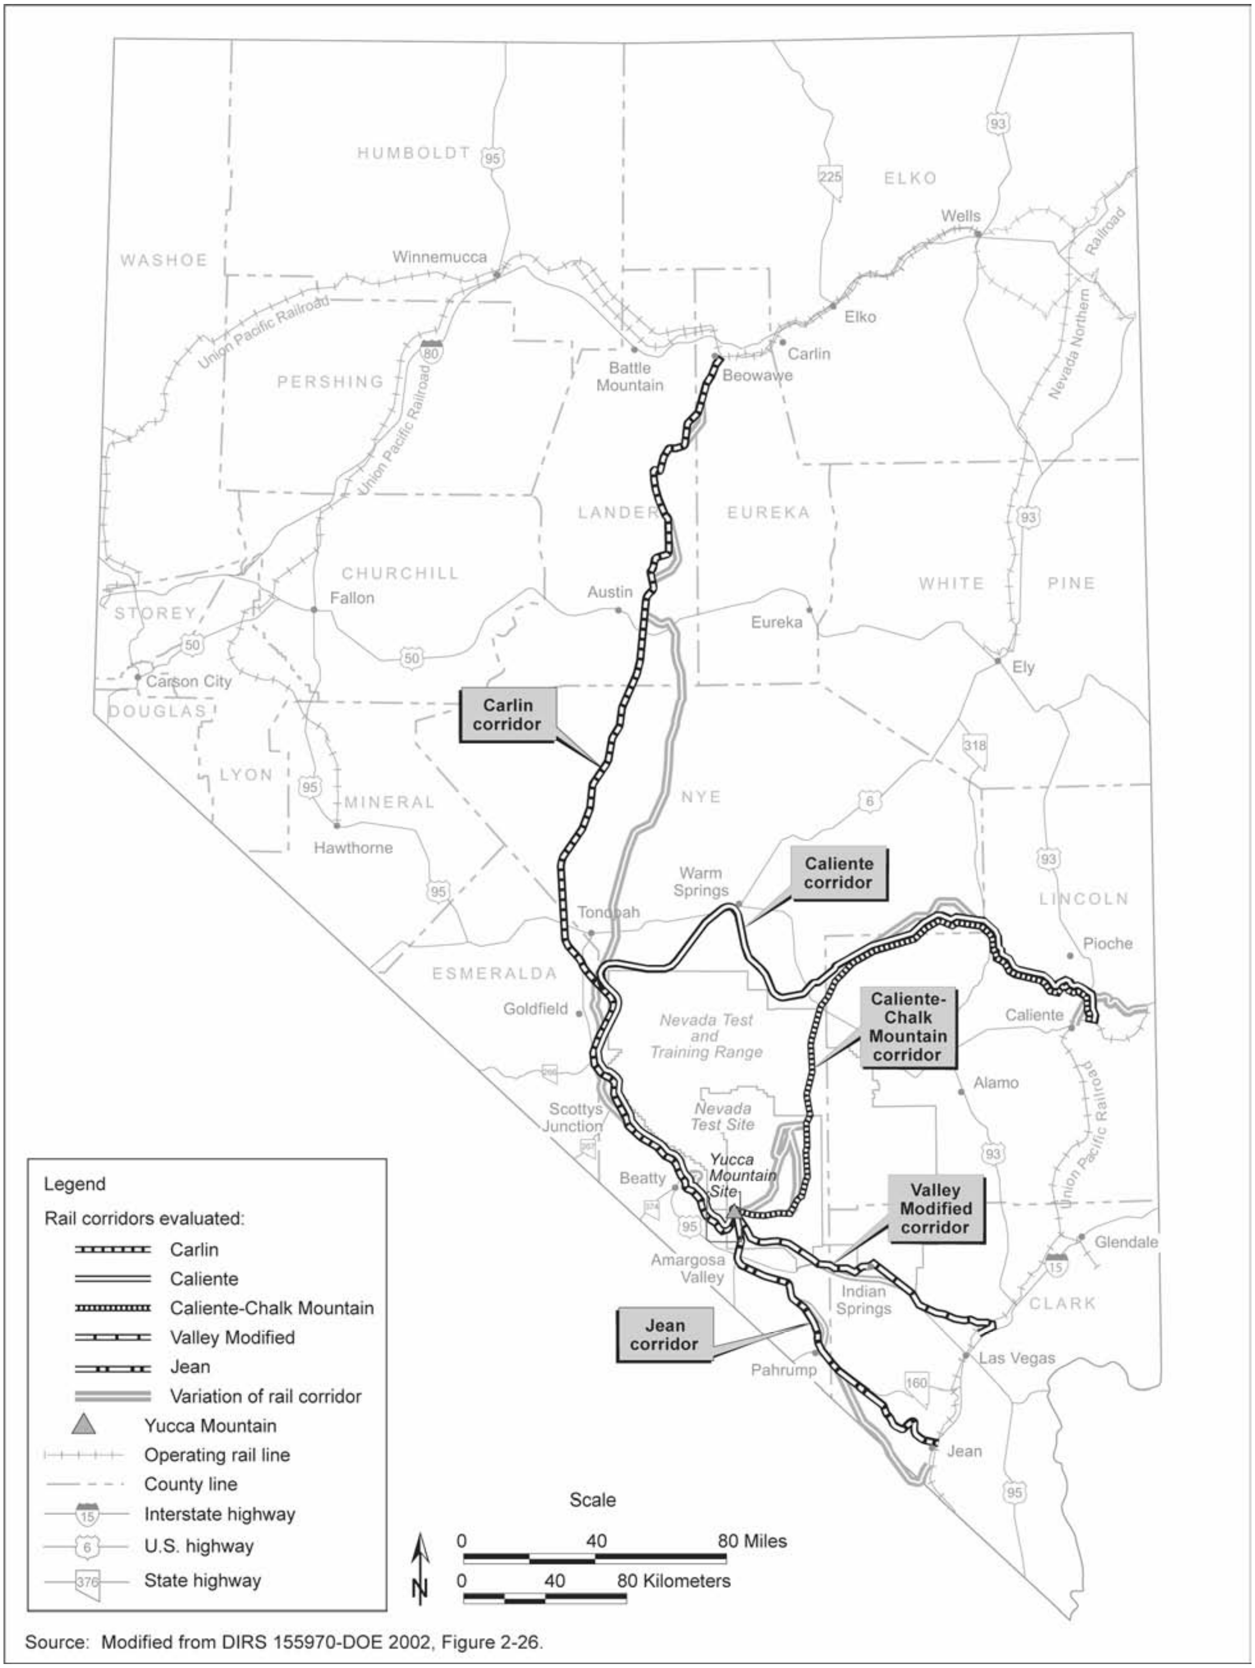
Figure 1-1. Locations of commercial and DOE sites that would ship spent nuclear fuel and high-level radioactive waste to Yucca Mountain.



Source: Modified from DIRS 155970-DOE 2002, Figure 2-26.

Figure 1-2. Five rail corridors evaluated in the Yucca Mountain FEIS.

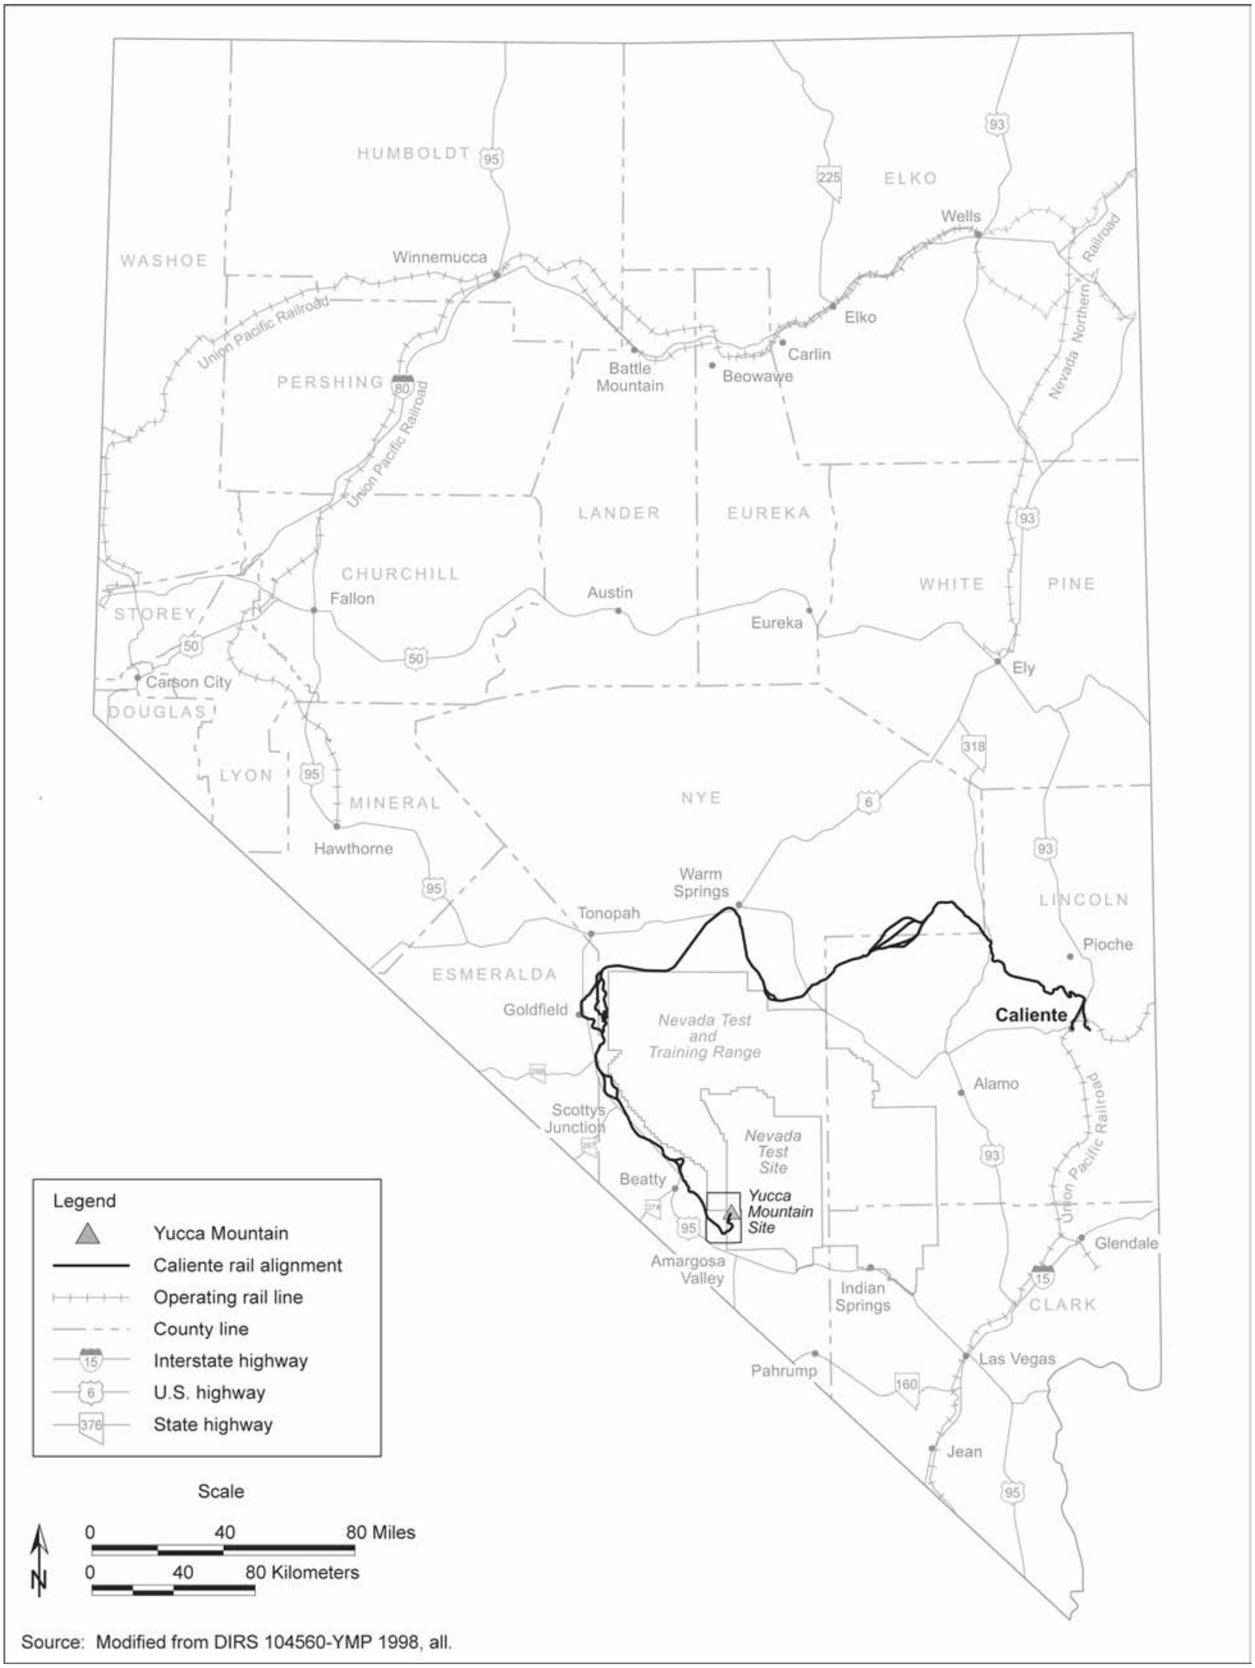


Figure 1-3. Caliente rail alignment analyzed in this Rail Alignment EIS.

In 2004, DOE announced the selection of the mostly rail scenario analyzed in the Yucca Mountain FEIS for transporting spent nuclear fuel and high-level radioactive waste nationally and within Nevada (*Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV*, 69 *FR* 18557, April 8, 2004). Implementation of the mostly rail scenario ultimately would require the construction of a rail line to connect the repository site at Yucca Mountain to an existing rail line in the State of Nevada. DOE also announced in that ***Record of Decision*** that it had selected the Caliente rail corridor for further evaluation for the construction and operation of a railroad in Nevada. (The Record of Decision referred to construction and operation of a rail line. However, this Rail Alignment EIS refers to construction and operation of a railroad, which better describes the ***infrastructure*** required under the Proposed Action.)

During the subsequent public scoping process, DOE received comments suggesting that other rail corridors be considered, in particular, the Mina route. In the Yucca Mountain FEIS, DOE had considered but eliminated the Mina route from detailed study because a rail line within the Mina route could only connect to an existing rail line in Nevada by crossing the Walker River Paiute Reservation, and the Tribe had informed DOE that it would not allow nuclear waste to be transported across the Reservation.

Following the review of the scoping comments, DOE held discussions with the Walker River Paiute Tribe and, in May 2006, the Tribal Council informed DOE that it would allow the Department to consider the potential impacts of constructing and operating a railroad to transport spent nuclear fuel and high-level radioactive waste across its reservation. On October 13, 2006, after a preliminary evaluation of the feasibility of the Mina rail corridor, DOE announced its intent to expand the scope of the Rail Alignment EIS to include the Mina corridor (*Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV;* 71 *FR* 60484). Although the expanded NEPA analysis, the Nevada Rail Corridor SEIS and the Rail Alignment EIS, analyze the potential environmental impacts associated with the Mina rail corridor, it identifies the Mina alternative as nonpreferred because the Tribe has withdrawn its support for the EIS process. Figure 1-4 shows the existing rail lines, alternative segments, and ***common segments*** along the Mina rail alignment, as analyzed in this Rail Alignment EIS.

1.3 Selection of the Caliente Rail Corridor for Further NEPA Evaluation

In the Yucca Mountain FEIS, DOE identified the mostly rail scenario as its preferred mode for transporting spent nuclear fuel and high-level radioactive waste to a repository at Yucca Mountain, both nationally and in Nevada (DIRS 155970-DOE 2002, p. 1-3). DOE stated that the Yucca Mountain FEIS could be used to support the choice among Nevada rail corridors (DIRS 155970-DOE 2002, p. 1-3), but additional field surveys, state and local government and American Indian tribal consultations, environmental and engineering analyses, and further National Environmental Policy Act (NEPA; 42 U.S.C. 4321 *et seq.*) review would be required to support a decision about the selection of a specific rail alignment within a rail corridor.

DOE also stated that if the Yucca Mountain Site was approved, it would issue at some future date a Record of Decision to select a mode of transportation and that if mostly rail was selected, DOE would announce a preference for one of the rail corridors and then publish a Record of Decision announcing the selection of a rail corridor (DIRS 155970-DOE 2002, p. 1-3). On December 29, 2003, DOE announced its preference for the Caliente rail corridor (68 *FR* 74951). On April 8, 2004, DOE announced the selection of the mostly rail scenario analyzed in the Yucca Mountain FEIS for transporting spent nuclear fuel and high-level radioactive waste nationally and within Nevada (69 *FR* 18557). The DOE decision to select the mostly rail scenario was based on analyses in the Yucca Mountain FEIS (specifically those

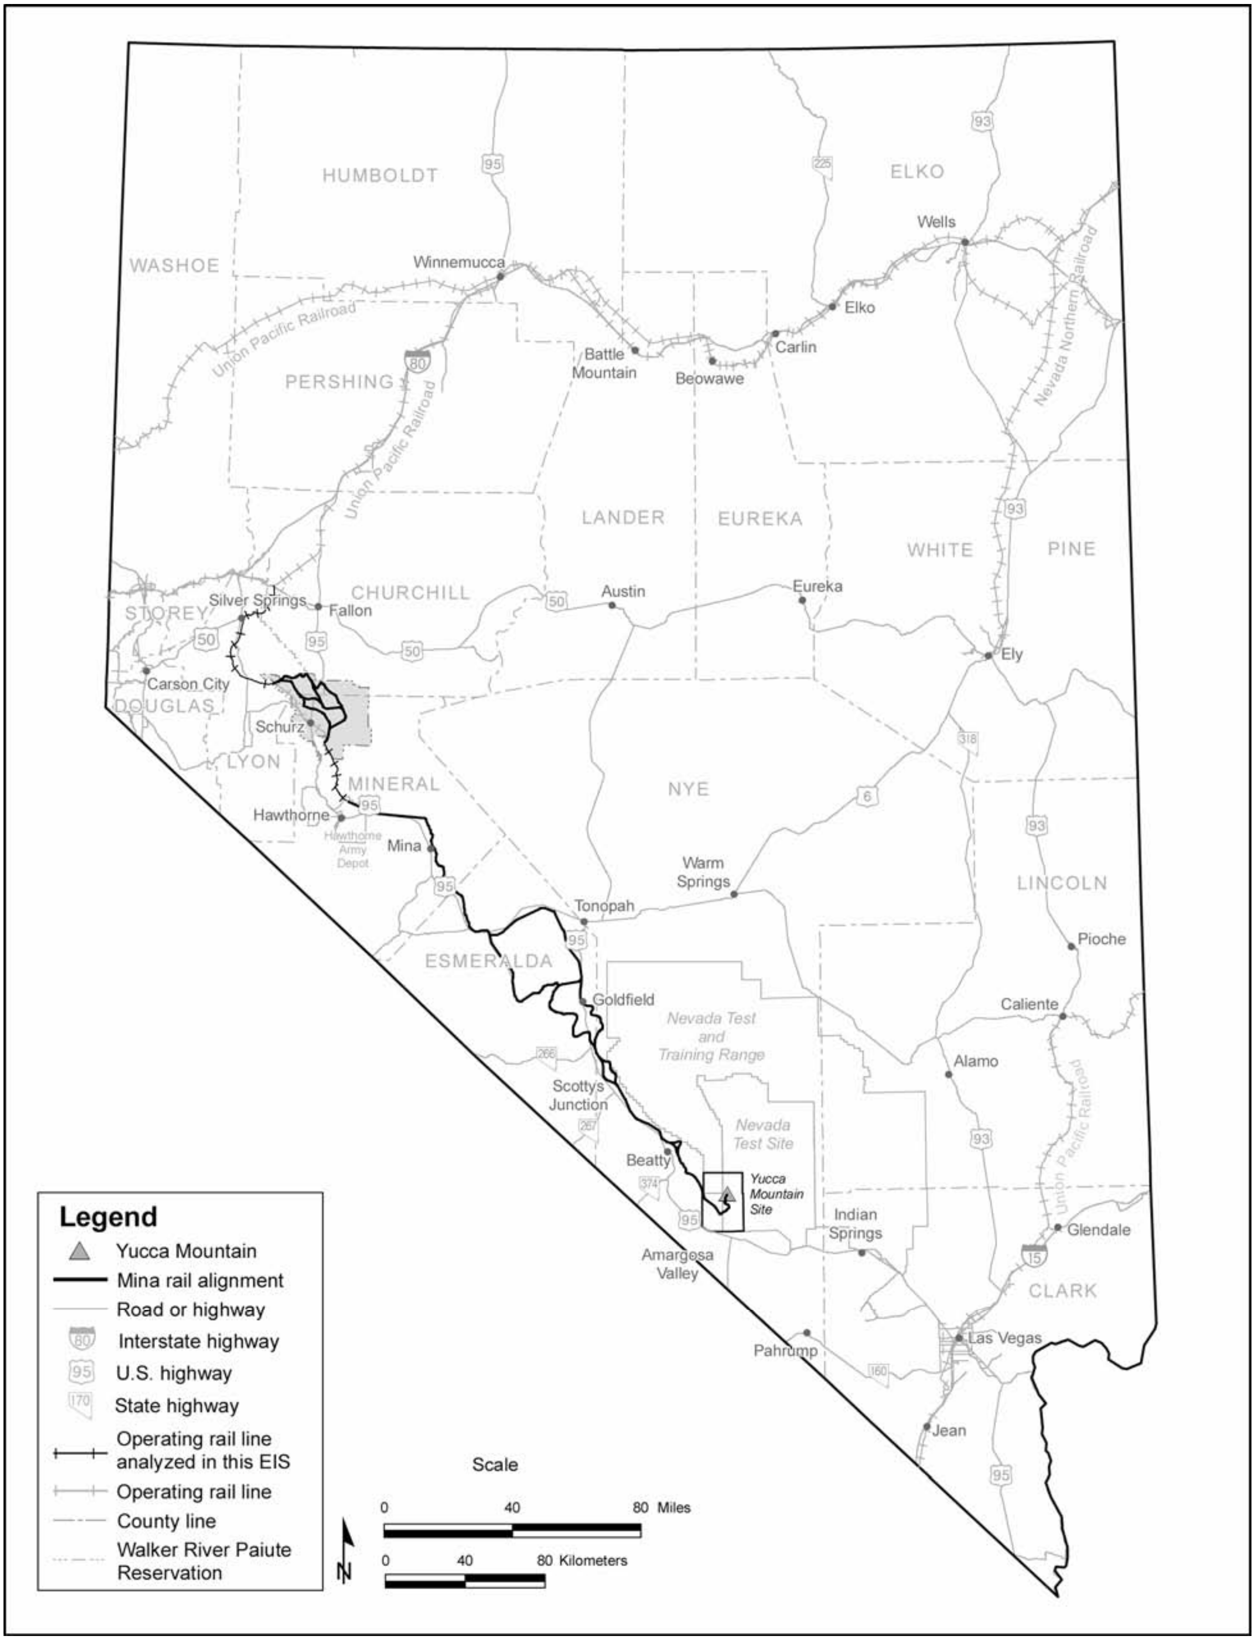

Figure 1-4. Mina rail alignment analyzed in this Rail Alignment EIS.

analyses related to impacts on the health and safety of workers and the public), preferences expressed by the State of Nevada, consideration of irreversible and irretrievable commitments of resources, and ***cumulative impacts*** from transporting other radioactive materials. DOE also announced that it had selected the Caliente rail corridor for further evaluation for the construction and operation of a railroad within Nevada. This decision was based primarily on the analyses in the Yucca Mountain FEIS, including land-use conflicts and their potential to adversely affect railroad construction. DOE considered the direct and indirect costs associated with railroad construction and operation within each rail corridor, potential for construction delay, and comments received from the public. DOE received comments from the public stating opposition to all the rail corridors and, in particular, stating that DOE should avoid rail corridors in the Las Vegas Valley. The DOE preference for the Caliente rail corridor considered many factors, including its more remote location, the diminished likelihood of land-use conflicts, concerns raised by Nevadans, and national security issues the U.S. Air Force raised regarding the Caliente–Chalk Mountain rail corridor.

Overall, it appeared that the Caliente rail corridor would have the fewest land-use or other conflicts that could lead to substantial delays in acquiring the necessary land and rights-of-way or that could lead to substantial delays in beginning construction. DOE also considered the direct costs of constructing and operating the proposed railroad, and the indirect costs resulting from potential delays in the availability of the railroad. The Jean and Valley Modified rail corridors are the shortest and would have the lowest estimated construction costs. The Carlin and Caliente rail corridors are the longest and, on the basis of construction cost alone, would be more expensive to develop. However, railroad construction delays because of land-use or other conflicts, and the resulting inability to accept large amounts of spent nuclear fuel and high-level radioactive waste transported via a railroad to the repository in a timely manner, could add both to the liability costs for delayed acceptance of ***commercial spent nuclear fuel*** and to the costs of continued ***storage*** of DOE wastes. Therefore, DOE concluded that the Caliente rail corridor would be preferable to the other rail corridors and selected the Caliente rail corridor as the one within which to evaluate possible alignments for the rail line connecting the repository to an existing rail line in Nevada (69 *FR* 18557, April 8, 2004).

1.4 Selection of the Mina Rail Corridor for Further NEPA Evaluation

DOE originally identified the Mina rail corridor in a series of three transportation studies prior to preparation of the Yucca Mountain FEIS, as follows:

- *Preliminary Rail Access Study* (DIRS 104792-YMP 1990, all)
- *Nevada Potential Repository Preliminary Transportation Strategy Study 1* (DIRS 104795-CRWMS M&O 1995, all)
- *Nevada Potential Repository Preliminary Transportation Strategy Study 2* (DIRS 101214-CRWMS M&O 1996, all)

The Department did not study the Mina rail corridor in detail in the Yucca Mountain FEIS because a railroad in the that corridor could only connect to an existing rail line in Nevada by crossing the Walker River Paiute Reservation, and the Walker River Paiute Tribe had informed DOE in 1991 that it would not allow nuclear waste to be transported across its Reservation.

During the first scoping period for this Rail Alignment EIS, DOE received comments from the public suggesting that the Department consider the Mina rail route. DOE held discussions with the Walker River Paiute Tribe regarding the availability of the Mina route for evaluation. In May 2006, the Tribal

Council informed DOE that it would allow the Department to evaluate the environmental impacts of transporting nuclear waste across the Reservation.

DOE prepared a preliminary feasibility study of the Mina ***rail route*** to identify a specific rail corridor and associated preliminary common segments and alternative segments (DIRS 180222-BSC 2006, all). The preliminary feasibility study considered the original Mina rail route, which was referred to as Option 6 in the *Preliminary Rail Access Study,* and refined the route using updated design criteria, literature reviews, limited field studies, and initial design analyses. The feasibility study concluded that construction, operation, and maintenance of a railroad in the Mina rail corridor appeared to be feasible.

On October 13, 2006, DOE announced its intent to expand the scope of this Rail Alignment EIS to incorporate analysis of the potential environmental impacts associated with constructing and operating a railroad within the Caliente rail corridor or the Mina rail corridor. DOE also announced that it would supplement the rail corridor analysis of the Yucca Mountain FEIS. DOE announced that it would update, as appropriate (that is, identify any significant new circumstances or information relevant to environmental concerns), the information and analysis for other rail corridors analyzed in the Yucca Mountain FEIS. *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada – Nevada Rail Transportation Corridor* (DOE/EIS-0250F-S2D; the Nevada Rail Corridor SEIS) provides the analysis and information regarding the Mina rail corridor and the other rail corridors analyzed in the Yucca Mountain FEIS. In the Nevada Rail Corridor SEIS, DOE concludes that the Mina rail corridor warrants further study to determine an alignment for the construction and operation of a railroad. That alignment-level study is included in this Rail Alignment EIS.

1.5 Cooperating and Consulting Agencies

Pursuant to the NWPA, DOE is responsible for the disposal of spent nuclear fuel and high-level radioactive waste to protect public health, safety, and the environment, and for developing and implementing a plan for transporting spent nuclear fuel and high-level radioactive waste to a repository at Yucca Mountain. The Council on Environmental Quality regulations at 40 Code of Federal Regulations (CFR) 1501.6 emphasize agency cooperation early in the NEPA process and allow a lead agency (in this case, DOE) to request the assistance of other agencies that either have jurisdiction by law or have special expertise regarding issues considered in an EIS. The Bureau of Land Management (BLM or the Bureau); the Surface Transportation Board (STB); and the U.S. Air Force are cooperating agencies in the development of this Rail Alignment EIS (see Section 1.5.1), pursuant to Council on Environmental Quality regulations, and have participated in the preparation of the EIS. Cooperating agencies that could issue decisions concerning the Proposed Action and alternatives to the Proposed Action could adopt the Nevada Rail Corridor SEIS and the Rail Alignment EIS in whole or in part and use them as a basis for their decisions. These agencies have management and regulatory authority over lands and resources that would be crossed by or be close to the proposed railroad or they have special expertise related to the Proposed Action.

The Walker River Paiute Tribe, the Bureau of Indian Affairs, and the U.S. Army are consulting agencies in the development of the Nevada Rail Corridor SEIS and the Rail Alignment EIS (see Section 1.5.2).

1.5.1 COOPERATING AGENCIES

1.5.1.1 Bureau of Land Management

The BLM is an agency within the U.S. Department of the Interior and is responsible for administering more than 1 million square kilometers (250 million acres) of ***public lands***, mostly in 12 western states, including Alaska. Congress enacted the Federal Land Policy and Management Act (43 U.S.C. 1701 *et seq.*) "to establish public land policy; to establish guidelines for its administration; to provide for the management, protection, development, and enhancement of the public lands; and for other purposes." It is the primary legislation guiding the BLM in its responsibility to manage the public lands and resources in a combination of ways that best serve the present and future needs of the American people.

To construct that portion of the proposed railroad that would cross public land, DOE must obtain a ***right-of-way grant*** from the BLM. BLM regulations at 43 CFR Part 2800 establish the procedures for processing right-of-way applications from federal agencies. The right-of-way application would include public land required for access roads, ***construction camps***, water wells, and other facilities that would be part of the proposed railroad. The BLM may adopt this Rail Alignment EIS as authorized by 40 CFR 1506.3 to satisfy the NEPA requirements for the right-of-way application. The BLM will determine whether to grant a right-of-way for the construction and operation of the DOE-proposed railroad.

Resource management plan: A land-use plan for public lands as described by the Federal Land Management and Policy Act. Among other things, it establishes land areas for limited, restricted, or exclusive use; allowable resource uses; resource condition goals and objectives; general management practices to achieve the goals; the need for more specific management plans for certain areas; general implementation sequences; and monitoring intervals and standards (43 CFR Part 1610).

Right-of-way grants on public lands must be consistent with the applicable BLM ***resource management plan***(s). Four resource management plans cover the areas of the Caliente rail alignment and the Mina rail alignment. These resource management plans are included in the following four documents:

- *Draft – Resource Management Plan/Environmental Impact Statement for the Ely District* (DIRS 174518-BLM 2005, all)
- *Tonopah Resource Management Plan and Record of Decision* (DIRS 173224-BLM 1997, all)
- *Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement* (DIRS 176043-BLM 1998, all)
- *Carson City Field Office Consolidated Resource Management Plan* (DIRS 179560-BLM 2001, all)

Free-use permit: An authorization to extract mineral materials from public lands at no charge. The BLM issues free-use permits to a federal or state agency when the materials are for use in a public project (43 CFR Part 3620).

The BLM will determine whether the proposed railroad is consistent with these resource management plans and, if not, whether to amend them.

DOE could need one or more quarries to provide rail line construction materials. The potential quarry sites analyzed in this Rail Alignment EIS are all on BLM-administered land, with the exception of one potential site, which would be partially on private land. Before excavating materials at any of the potential quarry sites, DOE would obtain ***free-use permits*** from the BLM. Additional rights-of-way might also be required to facilitate transporting the materials to the construction site. Free-use permits are issued to federal and state agencies under the Materials Act of 1947 (30 U.S.C. 601 *et seq.*) for use of common varieties of sand, stone, and gravel. BLM regulations at 43 CFR Part 3604 establish procedures for the designation of free-use permits.

The BLM agreed to be a cooperating agency in the preparation of this Rail Alignment EIS to increase the potential for the Bureau to adopt and use the EIS to process a DOE right-of-way application for access to the public lands that would be required for construction and operation of the proposed railroad. The procedures for BLM adoption of another agency's EIS (DIRS 182299-BLM 1988, all) specify that the

BLM conduct an independent review of the EIS and issue its own Record of Decision. Cooperating agency status provides the Bureau the opportunity to work closely with the lead agency during development of the NEPA document to encourage a product that meets the NEPA requirements for processing a right-of-way application. Cooperating agency status does not imply endorsement of the lead agency's preferred alternative.

In December 2003, DOE notified the BLM that it would be submitting an application for a ***Public Land Order*** to administratively withdraw 1,249 square kilometers (308,600 acres) of public land encompassing the Caliente rail corridor, from surface and mineral entry for up to 20 years, to evaluate the land for the potential construction, operation, and maintenance of the proposed railroad for the transportation of spent nuclear fuel and high-level radioactive waste to a geologic repository at Yucca Mountain. Upon receipt of the DOE notification, the BLM issued a notice announcing the segregation of the land from surface and mineral entry for up to 2 years to allow a ***case file*** containing various studies and analyses to be prepared to support a final decision on the ***withdrawal*** application (*Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada*, 68 *FR* 74965, December 29, 2003). Although in its 2003 withdrawal application DOE sought a 20-year land withdrawal, DOE determined that a 10-year land withdrawal would be adequate for conducting necessary activities. DOE prepared *Environmental Assessment for the Proposed Withdrawal of Public Lands Within and Surrounding the Caliente Rail Corridor* (DIRS 176452-DOE 2005, all) to support the Public Land Order request. The BLM was a cooperating agency in the preparation of that environmental assessment.

Public Land Order: An order affecting, modifying, or canceling a withdrawal or reservation that has been issued by the Secretary of the Interior pursuant to powers of the President delegated to the Secretary by Executive Order 9146 of April 24, 1942, or 9337 of April 24, 1943.

The BLM processed the DOE Public Land Order request in accordance with its regulations at 43 CFR Part 2310, which define the procedures and analyses necessary to meet public involvement requirements and to develop and process the case file for submission to the Secretary of the Interior. The Secretary of the Interior issued Public Land Order No. 7653, withdrawing the requested public lands within the Caliente rail corridor from surface and mineral entry for 10 years to allow DOE to evaluate the lands for the potential construction, operation, and maintenance of the proposed railroad (*Public Land Order No. 7653; Withdrawal of Public Lands for the Department of Energy to Protect the Caliente Rail Corridor; Nevada,* 70 *FR* 76854, December 28, 2005). The Public Land Order does not affect existing ***mining claims*** or other activities such as grazing rights, water rights, and recreational uses. Some of the Caliente alternative segments evaluated in this Rail Alignment EIS are outside the land subject to Public Land Order No. 7653.

In December 2006, DOE filed another application with the BLM to withdraw an additional 842 square kilometers (208,037 acres) of public lands from surface and mineral entry through December 27, 2015 (the same date as the expiration of Public Land Order No. 7653), to evaluate the lands for the potential construction, operation, and maintenance of the proposed railroad. This application included 278 square kilometers (68,646 acres) of public lands that encompass the Caliente rail alignment that fall outside of Public Land Order No. 7653 and 564 square kilometers (139,391 acres) of public lands encompassing the Mina rail alignment. The BLM issued a notice of proposed withdrawal and announced the segregation of the lands for up to 2 years to allow a case file to be prepared to support the final decision on the withdrawal application (*Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada*, 72 *FR* 1235, January 10, 2007).

1.5.1.2 Surface Transportation Board

The STB is an economic regulatory agency that Congress charged with the fundamental missions of resolving railroad rate and service disputes and reviewing proposed railroad constructions, acquisitions, mergers, and abandonments. The STB is decisionally independent, although it is administratively affiliated with the U.S. Department of Transportation. The ICC (Interstate Commerce Commission) Termination Act of 1995 (Public Law No. 104-88) created the STB, which is the successor agency to the Interstate Commerce Commission.

The STB has jurisdiction over railroad rate and service issues, and rail structuring transactions such as new line construction, line sales, line abandonments, and railroad mergers. The STB has exclusive jurisdiction over rail transportation that is part of the interstate rail network. All railroads (except private carriers) have a common-carrier obligation to provide reasonable service upon reasonable request.

If the proposed railroad were to be operated as a common-carrier rail line, the Department would have to apply to the STB for a license to construct and operate the railroad (certificate of public convenience and necessity). DOE would need a license to construct and operate the proposed railroad as a common-carrier rail line. As part of the licensing process, the STB must consider the environmental effects of railroad construction and operation. The STB Section of Environmental Analysis is responsible for preparing the appropriate NEPA documentation for railroad construction and operation cases under the jurisdiction of the STB. If any NEPA documentation were required in addition to this Rail Alignment EIS to support the STB decision to issue a license, DOE would provide additional information as necessary.

1.5.1.3 U.S. Air Force

The mission of the U.S. Air Force, in conjunction with the other armed services, is to preserve the peace and security and provide for the defense of the United States, its Territories, Commonwealths, and possessions, and any U.S.-occupied areas. The Caliente rail corridor skirts the northern and western boundaries of the Nevada Test and Training Range. The Air Force agreed to become a cooperating agency as a consequence of its jurisdiction over airspace and land on the Nevada Test and Training Range that would be affected by one or more of the alternative segments. DOE coordinates and at times obtains approval from the responsible armed service when DOE actions might encroach on U.S. Department of Defense land and potentially affect military operations. Although DOE has decided not to pursue alternative segments that would have entered the Nevada Test and Training Range, DOE is coordinating with the Air Force (for example, on the nature, extent, and location of Air Force overflights) to minimize any impacts of the proposed railroad to Air Force operations. In addition, the U.S. Air Force offers special expertise associated with the project area around the Nevada Test and Training Range.

1.5.2 CONSULTING AGENCIES

1.5.2.1 Walker River Paiute Tribe

The Walker River Paiute Tribe is a Northern Paiute tribe and is a federally recognized tribal entity eligible to receive services from the Bureau of Indian Affairs. If DOE constructed and operated the proposed railroad along the Mina rail alignment, the Department would construct a segment of the rail line on the Walker River Paiute Reservation to bypass Schurz and operate over segments of the existing Department of Defense Branchline that runs through the Reservation. DOE would need to apply to the Bureau of Indian Affairs for a right-of-way in which to construct the railroad (see Section 1.5.2.2). The Walker River Paiute Tribe had initially agreed to become a cooperating agency in the preparation of the Nevada Rail Corridor SEIS and the Rail Alignment EIS to allow the Tribe to make an informed decision on granting a right-of-way and because of the Tribe's special expertise associated with the environmental resources on the Reservation. However, on April 17, 2007, the Walker River Paiute Tribal Council announced a resolution that withdrew the Tribe from participating in the EIS process. The Walker River Paiute Tribe also decided to withdraw as a cooperating agency.

1.5.2.2 Bureau of Indian Affairs

The Bureau of Indian Affairs, an agency of the U.S. Department of the Interior, is responsible for the administration and management of 225,410 square kilometers (55.7 million acres) of land held in trust by the United States for American Indians, Indian tribes, and Alaska Natives. There are 561 federally recognized tribal governments in the United States. The Bureau of Indian Affairs is also responsible for developing forestlands, leasing assets on these lands, directing agricultural programs, protecting water and land rights, and developing and maintaining infrastructure and economic development.

To build the proposed railroad along the Mina rail alignment, the Department would construct a segment of rail line on the Walker River Paiute Reservation to bypass Schurz and would operate over segments of the existing Department of Defense Branchline that runs through the Reservation. DOE would need to apply to the Bureau of Indian Affairs for a right-of-way in which to construct the rail line. Bureau of Indian Affairs regulations in 25 CFR Part 169 establish procedures for the issuance of rights-of-way over Indian lands. The Bureau of Indian Affairs was a cooperating agency in the preparation of the Nevada Rail Corridor SEIS and the Rail Alignment EIS to fulfill its NEPA responsibilities associated with any decision to grant a right-of-way for railroad construction and operation and because of its expertise in American Indian issues. However, the Bureau of Indian Affairs decided not to remain a cooperating agency due to the nonpreferred status of the Mina Implementing Alternative resulting from the Walker River Paiute Tribe's withdrawal from the EIS process.

1.5.2.3 U.S. Army

The mission of the U.S. Army is to serve the American people, to defend the Nation, to protect vital national interests, and to fulfill national military responsibilities. The Mina rail alignment includes segments of an Army-owned rail line (referred to in this document as the Department of Defense Branchlines) that runs from the Fort Churchill ***siding*** near Wabuska, Nevada, to the Hawthorne Army Depot near Hawthorne, Nevada. In addition, DOE is considering constructing a segment of rail line and a staging yard facility on the Hawthorne Army Depot. The U.S. Army, through the Hawthorne Army Depot and the U.S. Army Corps of Engineers, was a cooperating agency in the preparation of the Nevada Rail Corridor SEIS and the Rail Alignment EIS to ensure that the Army fulfilled its NEPA responsibilities associated with any decision to allow DOE to construct a segment of rail line and a staging yard facility on Army-controlled property. In addition, the U.S. Army offered special expertise associated with the project area around Hawthorne Army Depot. The U.S. Army decided not to remain a cooperating agency due to the nonpreferred status of the Mina Implementing Alternative resulting from the Walker River Paiute Tribe's withdrawal from the EIS process.

1.6 Environmental Impact Statement Process

Council on Environmental Quality regulations that implement the procedural requirements of NEPA (40 CFR Parts 1500 through 1508) and DOE NEPA regulations (10 CFR Part 1021) provide procedures to use when preparing an EIS. A major emphasis of the EIS process is to promote public awareness of the proposed action and its alternatives and to provide opportunities for public involvement. An agency prepares an EIS in a series of steps: (1) by publishing a Notice of Intent to prepare an EIS and implementing a process known as "scoping," whereby comments are solicited from federal, state, and local agencies, American Indian tribes and organizations, other organizations, and the general public to assist in defining the proposed action, alternatives, and issues requiring analysis; (2) by preparing a Draft EIS for public review and comment; (3) by preparing a Final EIS that incorporates and responds to all comments received on the Draft EIS; and (4) by preparing a Record of Decision to announce the agency's decision on a project and explaining the reasons for the decision.

In the Yucca Mountain FEIS, DOE noted that determining the specific rail alignment in which to construct the proposed railroad would require further NEPA analysis. This Rail Alignment EIS addresses the selection of a rail alignment within which to construct, operate, and possibly abandon the proposed railroad for ***shipment*** of spent nuclear fuel, high-level radioactive waste, and ***other materials*** from an existing rail line in Nevada to a repository at Yucca Mountain, Nye County, Nevada.

DOE will use this Rail Alignment EIS to decide whether to construct and operate the proposed railroad, and if so, to:

- Select a rail alignment in which to construct the railroad.
- Select the common segments and combination of alternative segments within the selected alignment. The Department would use the selected combination of segments to identify the public lands to be included in a right-of-way application to the BLM.
- Decide where to construct certain proposed railroad operations support facilities.
- Decide whether to restrict use of the rail line to DOE trains, or whether to allow common carriers to operate over the rail line.
- Determine what ***mitigation*** measures to implement.

1.6.1 DEPARTMENT OF ENERGY NOTICES OF INTENT AND SCOPING MEETINGS

On April 18, 2004, DOE published a Notice of Intent (69 *FR* 18565) announcing that it would prepare an EIS for the alignment, construction, and operation of a railroad (called rail line in the Notice of Intent) for shipment of spent nuclear fuel, high-level radioactive waste, and other materials from a site near Caliente, Lincoln County, Nevada, to a geologic repository at Yucca Mountain, Nye County, Nevada. The Notice also announced the schedule for public scoping meetings, and invited and encouraged comments on the scope of this Rail Alignment EIS to ensure that all relevant environmental issues and reasonable alternatives would be addressed. To facilitate the scoping process, in the Notice of Intent DOE identified a preliminary list of issues and environmental resources that might be considered in this Rail Alignment EIS, and specifically invited comments on the following six questions to help define the scope of the EIS.

1. Should additional alternatives be considered that might minimize, avoid, or mitigate adverse environmental impacts (for example, looking beyond the 400-meter [0.25-mile]-wide corridor, avoiding ***Wilderness Study Areas***, American Indian Trust Lands, or encroachment on the Nevada Test and Training Range)?
2. Should any of the preliminary alternatives be eliminated from detailed consideration?
3. Should additional environmental resources be considered?
4. Should DOE allow private entities to ship commercial commodities on the rail line?
5. What mitigation measures should be considered?
6. Are there national security issues that should be addressed?

The scoping comment period began with publication of the Notice of Intent in the *Federal Register* and was originally scheduled to close on May 24, 2004. In response to a request from the State of Nevada, DOE extended the comment period by 7 days, to June 1, 2004 (69 *FR* 22496, April 26, 2004), bringing the total length of the scoping comment period to 55 days. DOE held five public scoping meetings on this Rail Alignment EIS at the following locations on the following dates in Nevada:

- Amargosa Valley – Longstreet Hotel Casino, Nevada State Highway 373, May 3, 2004
- Goldfield – Goldfield Community Center, 301 Crook Street, May 4, 2004
- Caliente – Caliente Youth Center, U.S. Highway 93, May 5, 2004
- Reno – University of Nevada, Reno, Fifteenth and North Virginia, May 12, 2004
- Las Vegas – Cashman Center, 850 North Las Vegas Boulevard, May 17, 2004

In addition to the *Federal Register* notices announcing the meetings, DOE advertised the meetings in five local newspapers that have a total circulation of approximately 250,000; sent four separate press releases to media outlets, industry, and stakeholders; mailed several thousand letters to stakeholders, members of the public, and other interested parties; and distributed over 1,000 handbills in Lincoln, Nye, and Esmeralda Counties.

DOE conducted the public scoping meetings in an open-house format. Members of the public were invited to attend the meetings at their convenience, any time during meeting hours, and submit their comments in writing at the meeting, or in person to a court reporter who was available throughout the meeting. The open-house format provided for one-on-one discussions with DOE representatives responsible for the preparation of this Rail Alignment EIS. Approximately 440 people attended the meetings (this count is approximate because not all attendees signed in), and 86 submitted oral comments (that the court reporters later transcribed) on the scope of the EIS.

DOE considered all comments received on the scope of this Rail Alignment EIS, along with information the BLM received, including results of interviews with ***grazing allotment*** permittees and other interested parties documented in *Proposed Yucca Mountain Corridor Affected Grazing Permittees* (DIRS 173845-Resource Concepts 2005, all). DOE considered American Indian perspectives documented in *American Indian Perspectives on the Proposed Rail Alignment Environmental Impact Statement for the U.S. Department of Energy's Yucca Mountain Project* (DIRS 174205-Kane et al. 2005, all). DOE also considered information obtained through sources such as the interviews Lincoln and Nye Counties conducted under a cooperative agreement with the Department.

On October 13, 2006, DOE published an Amended Notice of Intent (71 *FR* 60484) announcing the expanded scope of this Rail Alignment EIS to include detailed analysis of alternative segments (called alternative alignments in the Amended Notice of Intent) within the Mina rail corridor, should the Mina corridor warrant further consideration based on the Nevada Rail Corridor SEIS analysis. The Notice also announced the schedule for public scoping meetings, and invited and encouraged comments on the scope of this Rail Alignment EIS to ensure that all relevant environmental issues and reasonable alternatives would be addressed. To facilitate the scoping process, in the Amended Notice of Intent DOE provided a brief summary of public comments received during the previous scoping period and identified a preliminary list of issues and environmental resources that might be considered in this Rail Alignment EIS. DOE also specifically invited comments on the following four questions related to the Mina rail corridor to help define the scope of the analysis:

1. Should additional alternative alignments (now called alternative segments) be considered that might minimize, avoid, or mitigate adverse environmental impacts (for example, looking beyond the 400-meter [0.25-mile]-wide Mina corridor, avoiding environmentally sensitive areas)?
2. Should any of the preliminary alternative segments be eliminated from detailed consideration?
3. Should additional environmental resources be considered?
4. What mitigation measures should be considered?

The second scoping comment period began with publication of the Amended Notice of Intent in the *Federal Register* and was originally scheduled to close on November 27, 2006. In response to requests from the public, DOE extended the comment period by 15 days, to December 12, 2006 (71 *FR* 65785, November 9, 2006), bringing the total length of the scoping comment period to 61 days. DOE held eight public scoping meetings during the second public scoping period at the following locations on the following dates in Nevada and Washington, D.C.:

- Washington, D.C. – L'Enfant Plaza Hotel, 480 L'Enfant Plaza, SW, October 30, 2006
- Amargosa Valley – Longstreet Hotel Casino, Nevada State Highway 373, November 1, 2006
- Las Vegas – Cashman Center, 850 North Las Vegas Boulevard, November 2, 2006
- Caliente – Caliente Youth Center, U.S. Highway 93, November 8, 2006
- Goldfield – Goldfield School Gymnasium, Hall and Euclid, November 13, 2006
- Hawthorne – Hawthorne Convention Center, 932 E. Street, November 14, 2006
- Fallon – Fallon Convention Center, 100 Campus Way, November 15, 2006
- Reno – University of Nevada, Reno, Lawlor Event Center, 1500 N. Virginia Street, November 27, 2006

In addition to the *Federal Register* notices announcing the meetings, DOE advertised the meetings in eight local newspapers, including the Washington Post. Total circulation of the newspapers is approximately 280,000 plus an additional 750,000 for the Washington Post. DOE sent four separate press releases to media outlets, industry, and stakeholders; mailed several thousand letters to stakeholders, members of the public, and other interested parties; and distributed over 1,300 handbills in Washoe, Churchill, Lyon, Mineral, Esmeralda, Lincoln, and Nye Counties.

DOE conducted the public scoping meetings in an open-house format. Members of the public were invited to attend the meetings at their convenience, any time during meeting hours, and submit their comments in writing at the meeting, or in person to a court reporter who was available throughout the meeting. The open-house format provided for one-on-one discussions with DOE representatives responsible for the preparation of this Rail Alignment EIS. Approximately 330 people attended the meetings (this count is approximate because not all attendees signed in), and 63 submitted oral comments (that the court reporters transcribed) on the scope of the EIS.

In addition to the second public scoping period for this Rail Alignment EIS, DOE held concurrent public scoping periods for its Repository SEIS (DOE/EIS-0250F-S1D) and the Nevada Rail Corridor SEIS (DOE/EIS-0250F-S2D). To ensure proper consideration of all public comments, DOE assigned each comment to one or more SEIS or EIS. The Department reviewed all comments for applicability to this the Nevada Rail Corridor SEIS, the Rail Alignment EIS, and the Repository SEIS and assigned them accordingly. DOE has considered all comments, including those received after the close of the scoping period, on the scope of these documents.

1.6.2 SCOPING COMMENTS

Section 1.6.2.1 summarizes the scoping comments received during the first scoping period and refers to the Caliente rail alignment. Section 1.6.2.2 summarizes scoping comments received during the second scoping period, in which most comments referred to the Mina rail alignment.

1.6.2.1 Caliente Rail Alignment

DOE received more than 4,100 comments during the first public scoping period for this Rail Alignment EIS, and some after the close of the scoping period. DOE summarized all comments received (including those submitted after the close of the scoping period) in *Summary of Public Scoping Comments Related to the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV* (DIRS 176463-Craig, Lechel, and Morton 2004*,* all), and considered the content of all comments in determining the scope of the EIS. Table 1-1 summarizes the comments that address the six questions listed in the Notice of Intent and any other comments that led to changes in the scope of the EIS. Table 1-1 also notes DOE responses to those comments and directs the reader to sections of the EIS that address certain issues.

1.6.2.2 Mina Rail Alignment

DOE received nearly 800 comments during the second public scoping period for this Rail Alignment EIS, and some comments after the close of the scoping period. DOE summarized all comments received (including those submitted after the close of the scoping period) in *Summary of Public Scoping Comments on the Expanded Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV* (DIRS 181379-Oakes 2007*,* all), and considered the content of all comments in determining the scope of the EIS. Table 1-2 summarizes the comments that address the four questions listed in the Amended Notice of Intent and any other comments that led to changes in the scope of the EIS. Many of the comments received were similar in nature to comments received during the first scoping period. Table 1-2 focuses on comments that changed the scope of the EIS beyond those listed in Table 1-1. Table 1-2 also notes DOE responses to those comments and directs the reader to sections of the EIS that address certain issues.

1.6.3 TRIBAL UPDATE MEETINGS

The Consolidated Group of Tribes and Organizations is composed of 17 tribes and organizations with appointed representatives who are responsible for representing their respective tribal concerns and perspectives. In 1987, DOE began a long-term relationship with the Consolidated Group of Tribes and Organizations to inventory and evaluate the American Indian cultural resources in the Yucca Mountain area. The primary focus of the group has been the protection of cultural resources and environmental restoration.

The American Indian Writers Subgroup is composed of representatives from the Western Shoshone, Owens Valley Paiute and Shoshone, and Southern Paiute groups. The Consolidated Group of Tribes and Organizations appointed these representatives to write the American Indian perspective of a proposed railroad in the Caliente corridor. DOE has provided members of the American Indian Writers Subgroup with opportunities to travel along the Caliente rail corridor, funding, technical assistance, and other resources necessary to develop a resource document that expresses American Indian perspectives on the proposed railroad.

DOE held a tribal update meeting in Las Vegas, Nevada, on June 2 and June 3, 2004, to obtain comments from tribal representatives from the Consolidated Group of Tribes and Organizations. During the second scoping comment period for this Rail Alignment EIS, DOE held another meeting for the Consolidated Group of Tribes and Organizations on November 29, 2006, in Pahrump, Nevada. DOE considered all comments submitted during the meetings in the development of the scope of the EIS. Commenters called for continued consultation with tribes that would be culturally affected by the transportation of spent nuclear fuel and high-level radioactive waste, not only in Nevada but across the country. DOE is committed to continuing the consultation process throughout the development of this Rail Alignment EIS

Table 1-1. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Caliente rail alignment[a] (page 1 of 5).

Notice of Intent question	Scoping comment summary	DOE response summary
Should additional alternatives be considered that might minimize, avoid, or mitigate adverse environmental impacts?	DOE received many comments regarding proposed alternative segments or rail corridors that should either be included for consideration or dismissed. Suggestions for new alternative segments gave justifications such as minimizing risks to population centers, avoiding American Indian Trust Lands, bypassing private lands, avoiding impacts to mining and ranching operations, maintaining access to the local transportation network, avoiding sensitive biological and cultural resource areas, and avoiding impacts to the Nevada Test and Training Range.	DOE considered changes to the alternative segments identified in the Notice of Intent and the new alternative segments suggested during scoping. Some of these proposed alternative segments are studied in detail in this Rail Alignment EIS, and others were eliminated from detailed study. Chapter 2 of this Rail Alignment EIS provides information about the proposed alternative segments considered in detail. Chapter 2 and Appendix C discuss other alternative segments suggested during scoping but dismissed from further consideration, and describe the evolution of the rail alignments considered in this Rail Alignment EIS and the reasons for dismissing certain alternative segments.
	Commenters suggested a rail alignment along, but outside, the western boundary of the Nevada Test and Training Range.	As described in Chapter 2 of this Rail Alignment EIS, DOE investigated alternative segments along, but outside, the western boundary of the Nevada Test and Training Range. DOE analyzed several alternative segments close to the boundary of the Nevada Test and Training Range in detail. All common segments and alternative segments analyzed in detail in this Rail Alignment EIS are outside the Nevada Test and Training Range.
	DOE received comments regarding potential environmental impacts associated with constructing and operating the proposed railroad. A number of commenters expressed concern about the proximity of the rail line to Wilderness Study Areas and suggested that DOE avoid those areas. The President signed the Lincoln County Conservation, Recreation, and Development Act into law on December 1, 2004 (Public Law 108-424). It designates Wilderness Areas in Lincoln County, including the Weepah Springs Wilderness Area.	DOE adjusted or eliminated alternative segments to avoid Wilderness Study Areas and Wilderness Areas. For example, one of the proposed alternative segments that would have passed through the White River area (White River 2) would have crossed into the Weepah Springs Wilderness Area for a short distance. DOE adjusted this alternative segment to avoid the Wilderness Area. In addition, the common segment of the rail alignment that would pass through Reveille Valley would cross into the Reveille Valley Wilderness Study Area for a short distance. DOE identified two new alternative segments (South Reveille 2 and 3) to avoid the Wilderness Study Area.
	Commenters urged DOE to adopt an alternative segment that would bypass Garden Valley. Commenters suggested an alternative segment that would follow existing highways from Caliente to Tonopah (U.S. Highway 93 to Route 375 to Route 6). Other commenters suggested an alternative segment that would pass through Coal Valley and Murphy Gap in the Golden Gate Range.	DOE considered several alternative segments that would bypass Garden Valley. While the alternative segments that would avoid Garden Valley were determined not to be reasonable and were eliminated from detailed study due to feasibility and cost issues, DOE added and studied in detail, Garden Valley 3 and Garden Valley 8 to the proposed alternative segments to provide more alternatives within Garden Valley and to reduce environmental impacts.

Table 1-1. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Caliente rail alignment[a] (page 2 of 5).

Notice of Intent question	Scoping comment summary	DOE response summary
Should additional alternatives be considered that might minimize, avoid, or mitigate adverse environmental impacts? (continued)	Commenters suggested interfacing with the Union Pacific Railroad Mainline at Elgin.	DOE considered the Elgin alternative segment to connect to the Union Pacific Railroad Mainline. However, the Elgin alternative segment would cross several areas of private land and would require steep grades coming out of Rainbow Canyon. DOE determined that this alternative segment was not reasonable and eliminated it from detailed study.
	Commenters suggested relocating the Goldfield alternative segments farther west to avoid the historic mining district, private property, and access roads.	DOE added Goldfield alternative segment 4, which would run to the west of Goldfield and avoid the mining district.
Should any of the preliminary alternatives be eliminated from detailed consideration?	Commenters suggested that a Bonnie Claire alternative segment (Bonnie Claire 1) should either be eliminated from consideration or moved, because it would cross Timbisha Shoshone Trust Lands. The Air Force indicated that Bonnie Claire 2 was unacceptable because it would enter the Nevada Test and Training Range.	DOE eliminated Bonnie Claire 1 from detailed study, adjusted Bonnie Claire 2 to avoid the Nevada Test and Training Range, and added a new alternative segment (Bonnie Claire 3, which would avoid the Timbisha Shoshone Trust Lands and the Nevada Test and Training Range) for detailed study.
Should additional environmental resources be considered?	Commenters expressed concern about potential impacts to private land, ranching, mining, and other land-use issues. Commenters expressed interest in how construction and operation of the proposed railroad might affect access to public and private lands. Commenters requested that DOE provide maps showing the proposed railroad in relation to grazing allotments and private property. DOE and the BLM also solicited and received comments from grazing permittees that described the potential impacts to ranching operations that could occur if DOE constructed the proposed railroad (see DIRS 173845-Resource Concepts 2005, all). Comments from grazing permittees also included suggested measures DOE could consider to mitigate potential impacts.	DOE initially selected the Caliente rail corridor in which to determine an alignment for a rail line, in part to minimize private land-use conflicts. This Rail Alignment EIS analyzes potential land-use impacts, including impacts to ranching (see Section 4.2.2, Land Use and Ownership). DOE has prepared a detailed Map Atlas (DIRS 182844-ICF 2007, Part B) that shows the proposed locations of the rail line and the infrastructure associated with construction and operation of the proposed railroad. The Map Atlas also shows private property and grazing allotment boundaries.

Table 1-1. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Caliente rail alignment[a] (page 3 of 5).

Notice of Intent question	Scoping comment summary	DOE response summary
Should additional environmental resources be considered? (continued)	Commenters stated that the impacts of the rail line to the *City* sculpture in Garden Valley must be thoroughly assessed in terms of disturbance of viewsheds, loss of visual resources, and noise. One commenter stated that the prevailing silence and the undisturbed environment are essential to the character of the sculpture.	DOE conducted ***ambient noise*** monitoring in Garden Valley and in other locations along the Caliente rail corridor to provide a ***baseline*** from which to analyze potential noise impacts (see Sections 3.2.8 and 4.2.8, Noise and Vibration). DOE also prepared photo simulations of the four Garden Valley alternative segments and used BLM methodology for analyzing impacts to visual resources (see Sections 3.2.3 and 4.2.3, Aesthetic Resources).
	Commenters asked how silica and ***erionite*** would be disposed of, and how DOE would prevent worker and public exposure to these materials.	DOE has analyzed the potential risks of exposure to silica and erionite and has identified best management practices to reduce public and worker exposure (see Section 4.2.10, Occupational and Public Health and Safety).
	Commenters highlighted the generation of dust and impacts to air resources that could occur during construction and noted potential impacts on fragile ***desert*** soils.	DOE has analyzed the potential for impacts to air resources and desert soils and identified the best management practices and mitigation measures to control dust generation and soil erosion (see Section 4.2.1, Physical Setting, and Section 4.2.4, Air Quality and Climate).
	Commenters requested that DOE analyze the socioeconomic impacts of construction and operations jobs on rural communities.	This Rail Alignment EIS includes analysis of socioeconomic impacts from railroad construction and operations on rural communities (see Section 4.2.9, Socioeconomics).
	Commenters stated that the Rail Alignment EIS must fully analyze the possible environmental impacts of potential ***accidents*** and train derailments, and the potential for an attack on a train carrying spent nuclear fuel or high-level radioactive waste, making the assumption that the ***cask*** sustains significant damage and is breached. One commenter noted that the dismissal of this concern on the grounds that such an event is not likely enough to be significant would not be acceptable. Commenters stated that the Rail Alignment EIS must identify the methodology DOE would employ to regularly inspect the rail line to ensure its integrity and safety.	DOE has analyzed the risks of accidents and releases that could occur during the railroad operations phase (see Section 4.2.10, Occupational and Public Health and Safety). This Rail Alignment EIS also analyzes releases that could occur from acts of terrorism. In the Yucca Mountain FEIS, DOE analyzed the environmental implications of transporting spent nuclear fuel and high-level radioactive waste throughout the United States by rail. DOE has incorporated security measures into its planning for transportation of these materials, both nationally and in Nevada.

Table 1-1. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Caliente rail alignment[a] (page 4 of 5).

Notice of Intent question	Scoping comment summary	DOE response summary
Should additional environmental resources be considered? (continued)	Commenters expressed concern about the potential impact to local economies and communities from development of the proposed railroad. These concerns included the potential economic loss resulting from restricted access to the land adjacent to the rail line, and the negative public perception of the area of the railroad. One commenter expressed concern about the possible displacement of community members through the government's use of eminent domain.	DOE has analyzed the potential socioeconomic impacts of the proposed railroad, and the potential land-use conflicts that could occur (see Section 4.2.9, Socioeconomics, and Section 4.2.2, Land Use and Ownership).
	Several commenters stated that the Rail Alignment EIS must thoroughly address the safety measures and adequacy of emergency response in case of a rail accident or accidental release of radioactive material. Specifically, commenters mentioned addressing the need to provide support facilities close to established communities and the need to define the acceptable statistical probabilities of health and environmental risks.	DOE has evaluated the risk of accidents and releases of radioactive material (see Section 4.2.10, Occupational and Public Health and Safety). Appendix L, Supplemental Transportation Information, discusses emergency response.
Should DOE allow private entities to ship commercial commodities on its rail line?	Commenters expressed support for public or commercial use of the rail line. Commenters noted the potential for economic development (that is, maximize value and minimize risk); shipping of various commodities such as building materials, oil, and minerals from mining; and use by passengers or tourists pursuing various recreational interests.	As described in Chapter 2, DOE prepared a shared-use report to assess the demand for shared use and to identify a potential level of rail traffic that could be generated under shared use. The Department has analyzed the ***Shared-Use Option*** in this Rail Alignment EIS to make an informed decision on shared use.
	Other commenters stated that the rail line should be used only for DOE shipments and should not be made available for shared use.	DOE has analyzed the Shared-Use Option in this Rail Alignment EIS to provide decisionmakers with enough information to make an informed decision on shared use.

Table 1-1. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Caliente rail alignment[a] (page 5 of 5).

Notice of Intent question	Scoping comment summary	DOE response summary
What mitigation measures should be considered?	Various commenters noted best management practices and mitigation issues surrounding impacts to livestock, fencing, revegetation of disturbed areas, waterways and washes, mining and mineral development, and truck transportation. More than 200 commenters indicated that the Rail Alignment EIS should address how ranchers and miners would be compensated for loss of grazing and mineral development rights, either financially or through granting of new grazing rights in other areas.	DOE developed a series of mitigation measures to avoid, minimize, rectify, reduce, or compensate for potential impacts associated with construction and operation of the proposed railroad. DOE and the BLM solicited comments on potential mitigation measures from grazing permittees along the rail alignment, and considered these comments when developing mitigation measures. Chapter 7 describes potential mitigation measures. In addition, DOE would implement best management practices during construction and operation of the railroad. Best management practices are considered part of the Proposed Action and are also described in Chapter 7.
Are there national security issues that should be addressed?	The Air Force indicated that for national security, safety, and training reasons, it would be unacceptable for alternative segments to enter the Nevada Test and Training Range.	DOE concluded that such alternative segments would not be reasonable and eliminated from detailed study all proposed alternative segments that would have entered the Nevada Test and Training Range.
Other comments that affected the scope of this Rail Alignment EIS	Commenters suggested that DOE identify and analyze the entire infrastructure necessary to construct and operate the proposed railroad, including construction camps, ***ballast*** sources, borrow and fill areas, access roads, rail yards, maintenance facilities, and an operations center.	DOE has identified the entire infrastructure necessary for construction and operation of the proposed railroad (see Chapter 2), and this Rail Alignment EIS analyzes the potential impacts associated with that infrastructure.

a. Source: DIRS 176463-Craig, Lechel, and Morton 2004, all.

Table 1-2. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Mina rail alignment[a] (page 1 of 3).

Amended Notice of Intent question	Scoping comment summary	DOE response summary
Should additional alternative alignments (segments), be considered that might minimize, avoid, or mitigate adverse environmental impacts?	DOE received many comments regarding proposed alternative segments. For example, commenters suggested that DOE avoid Silver Peak in favor of a route that avoids the steep grades, length, and construction costs associated with Montezuma alternative segment 1. Other commenters suggested linking the Silver Peak and Goldfield alternative segments (Montezuma alternative segments 1 and 2). Other commenters suggested that DOE avoid all communities in the Mina rail corridor.	As described in Chapter 2, DOE added Montezuma alternative segment 3, which provides an alternative that avoids the communities of Silver Peak and Goldfield. Montezuma alternative segment 3 incorporates parts of Montezuma alternative segments 1 and 2 and links them at the northern end of the Montezuma Range. DOE has avoided the communities of Luning, Mina, and Sodaville by keeping Mina common segment 1 on the eastern side of Soda Spring Valley.
	DOE received a suggestion that Mina common segment 1 in the Redlich area be moved east due to mining exploration.	DOE moved Mina common segment 1 east to avoid mining operations.
	Commenters suggested that DOE evaluate alternative segments in the Crater Flat area to facilitate possible rail spurs to areas identified by Nye County for potential industrial development.	DOE evaluated the location of common segment 6 in the Crater Flat area and determined that rail line construction sidings could be left in place to facilitate shared use in this area. Shared-use opportunities are described in Chapter 2 and shared-use impacts are described in Chapter 4.
Should any of the preliminary alternatives be eliminated from detailed consideration?	Commenters suggested that DOE move Oasis Valley alternative segments 1 and 3 at least 5 miles east of their current location. These commenters expressed concerns about potential noise and vibration to a ranch located approximately 8 miles north of Beatty.	As described in Chapter 2, DOE considered the suggestion of moving Oasis Valley alternative segments 1 and 3 to the east, but decided that this was not feasible due to land-use conflicts with the Nevada Test and Training Range.

Table 1-2. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Mina rail alignment[a] (page 2 of 3).

Amended Notice of Intent question	Scoping comment summary	DOE response summary
Should additional environmental resources be considered?	Commenters requested that DOE consider the impacts on grade crossings in Lyon County on the existing Union Pacific Railroad Hazen Branchline. Commenters questioned whether the grade crossings at Hazen (Alternate U.S. Highway 50), Silver Springs (U.S. Highway 50), Fort Churchill State Historic Park (Alternate U.S. Highway 95), and at Wabuska (Alternate U.S. Highway 95) would need to be grade separated due to the increase in rail traffic proposed by DOE.	DOE performed a ***quantitative*** analysis of the impacts to all of the public road grade crossings along the existing Union Pacific Railroad and Department of Defense Branchlines. The analysis included consideration of whether any existing grade crossings need to be grade separated. This analysis is described in Section 4.3.9, Socioeconomics.
	Commenters suggested that the Rail Alignment EIS address a planned industrial and rail park in the Hazen area. Other commenters suggested inclusion of a planned airport in the Hazen area.	The Western Nevada Rail Park and the expansion of the airport near Silver Springs are considered in the cumulative impacts analysis (see Chapter 5).
	Commenters suggested that the scope of the Rail Alignment EIS include sufficiently large regions of influence for each resource studied so that real impacts can be assessed from railroad construction and operation. For example, commenters suggested that the scope for the Mina rail alignment should be from Hazen to Yucca Mountain.	The scope of the Rail Alignment EIS for the Mina rail alignment considers railroad operations impacts and rail traffic during construction from Hazen to Yucca Mountain. For rail line and facility construction, the scope includes Wabuska to Yucca Mountain (Wabuska being the most northerly location where DOE is proposing any rail line construction, in this case, a siding). The scope does include construction impacts from Hazen to Wabuska, but only in relation to the increase in rail traffic from trains carrying construction materials during the construction phase. Chapters 2, 3, and 4 describe this approach in more detail.
	DOE received comments highlighting plans to establish a new state park at Monte Cristo's Castle near Blair Junction. The comments suggested that the Mina rail alignment could interfere with and prevent access to the park from U.S. Highways 95 and 96.	DOE considered potential impacts associated with the Mina rail alignment on the development of the new park at Monte Cristo's Castle (see Section 4.3.2, Land Use, and Chapter 5, Cumulative Impacts).
	Commenters requested that the Rail Alignment EIS describe the fiscal consequences of ***stigma***-induced impacts to counties and cities along all waste-shipment routes in Nevada and along the Caliente and Mina rail alignments. Commenters suggested that the Rail Alignment EIS analyze stigma effects from both routine shipments and accidents. Commenters also suggested that DOE conduct a perceived risk assessment to evaluate cultural concerns along the rail alignments.	DOE considered stigma-induced impacts and perceived risk but found that analysis of impacts is highly uncertain. Section 4.1.3 describes the Department's consideration of stigma and perceived risk.

Table 1-2. Summary of Rail Alignment EIS scoping comments and DOE responses related to the Mina rail alignment[a] (page 3 of 3).

Amended Notice of Intent question	Scoping comment summary	DOE response summary
What mitigation measures should be considered?	Commenters suggested that the Rail Alignment EIS discuss all proposed efforts to monitor and mitigate impacts from construction and operation of the railroad.	Chapter 7 describes potential mitigation measures. In addition, DOE would implement best management practices during construction and operation of the railroad. Best management practices are considered part of the Proposed Action and are also described in Chapter 7.
Other comments that affected the scope of this Rail Alignment EIS	Commenters urged DOE to begin working with affected jurisdictions and individual property owners to ensure that they are involved in the decisionmaking process.	In addition to the scoping meetings, DOE has held several informational meetings with affected units of local government and has involved the counties in discussions about shared-use opportunities. Appendix B provides a description of interagency and intergovernmental interactions.
	Commenters suggested that DOE include a list of the environmental features and engineering and design factors used to determine the range of reasonable alternatives.	Appendix C describes the environmental and engineering factors DOE used in developing the range of reasonable alternatives.
	Commenters suggested that the Rail Alignment EIS include detailed maps and plan views of all common segments and alternative segments for the Caliente and Mina rail alignments. Commenters suggested that the maps show the relationship of the proposed railroad to the existing transportation network, including all highway and road crossings, rights-of-way according to ownership, and land use.	DOE prepared a detailed Map Atlas (DIRS 182843 and DIRS 182844-ICF 2007, all) that shows the proposed locations of the Caliente and Mina rail alignments and the infrastructure associated with construction and operation of the railroad. The Map Atlas shows the existing transportation network, proposed road crossings, ***cut*** and ***fill*** areas, rights-of-way, private property, and grazing allotment boundaries.

a. Source: DIRS 181379-Oakes 2007, all.

and plans to continue consultation with American Indians to ensure that tribal concerns and perspectives are considered. In response to comments received from the Consolidated Group of Tribes and Organizations, and as a result of DOE cultural resource surveys, the Department avoided certain American Indian sites in the areas of North Pahroc summit, Reveille Valley, and Beatty. Appendix B contains information on additional American Indian consultation and input to this Rail Alignment EIS.

DOE supported the American Indian Writers Subgroup, which submitted input to this Rail Alignment EIS. The subgroup developed *American Indian Perspectives on the Proposed Rail Alignment Environmental Impact Statement for the U.S. Department of Energy's Yucca Mountain Project* (DIRS 174205-Kane et al. 2005, all). The Subgroup prepared the document for the Caliente rail alignment. No such document was prepared for the Mina rail alignment.

1.6.4 BLM NOTICE OF INTENT AND PUBLIC MEETINGS

On December 29, 2003, the BLM announced the receipt of an application from DOE requesting that approximately 1,249 square kilometers (308,600 acres) of public land in Nevada be withdrawn from surface and mineral entry for 20 years to evaluate the land for the potential construction, operation, and maintenance of a railroad for the transportation of spent nuclear fuel and high-level radioactive waste (68 *FR* 74965). The *Federal Register* notice stated that the BLM had segregated the land from surface and mineral entry for up to 2 years while various studies and analyses are conducted to support a final decision on the withdrawal application. In a May 21, 2004, Notice of Public Meetings (69 *FR* 29323), the BLM invited the public to submit written comments on the proposed withdrawal and possible land-use plan amendments by June 30, 2004. The BLM held two public scoping meetings on the proposed withdrawal and possible land-use plan amendments. Many of the comments the BLM received were similar to those DOE received (as described in Table 1-1). For example, many of the alternatives suggested in the BLM scoping meetings were the same as those DOE received. Commenters also raised concerns about impacts to mining, grazing, visual resources, water resources, and recreation. DOE considered all comments the BLM received in developing the scope for this Rail Alignment EIS and some of these comments led to the actions described in Table 1-1.

1.6.5 ADDITIONAL INFORMATION

In addition to the DOE and BLM scoping meetings, and comments from the Tribal update meetings, DOE used other information to define the scope of this Rail Alignment EIS. The Department worked with the Central Nevada Community Protection Working Group to gain the assistance of Nye, Lincoln, and Esmeralda Counties and the City of Caliente in obtaining information to support the EIS. Under a cooperative agreement with DOE, Lincoln County led an effort to interview landowners, business owners, county officials, elected officials, and other potentially interested parties. Comments received during these interviews closely mirrored the comments previously submitted to both DOE and the BLM. In addition, Nye County surveyed property owners along the Caliente rail corridor under a cooperative agreement with DOE. The surveys solicited comments on potential impacts of the proposed railroad and possible measures to mitigate those impacts. In addition, the BLM interviewed grazing permittees along the Caliente rail corridor and asked for their comments on potential impacts associated with construction and operation of the proposed railroad and for their input on potential mitigation measures. DOE used the information obtained through these interviews and surveys to help define the scope of this Rail Alignment EIS.

1.7 Relationship to Other NEPA-Related Documents

A number of completed, in-preparation, or proposed DOE NEPA documents relate to this Rail Alignment EIS. The Foreword to this Rail Alignment EIS describes the relationships between the Yucca Mountain FEIS, the Repository SEIS (DOE/EIS-0250F-S1D), the Rail Corridor SEIS (DOE/EIS-0250F-S2D), and the Rail Alignment EIS (DOE/EIS-0369D).

In addition, other federal agencies have prepared related EISs. Consistent with Council on Environmental Quality regulations that implement the provisional requirements of NEPA (40 CFR Parts 1500 through 1508), DOE has used information from these documents in its analysis and has incorporated this material by reference as appropriate throughout this Rail Alignment EIS. Table 1-3 lists these documents.

Table 1-3. NEPA documentation related to the proposed railroad[a] (page 1 of 3).

Document	Relationship to this Rail Alignment EIS
Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada, DOE/EIS-0250F (DIRS 155970-DOE 2002, all)	Examines the impacts of constructing, operating, monitoring, and eventually closing a geologic repository at Yucca Mountain. Examines the potential impacts of transporting spent nuclear fuel and high-level radioactive waste nationally and in the State of Nevada.
Notice of Preferred Nevada Rail Corridor (68 *FR* 74951, December 29, 2003)	Announces the Caliente rail corridor, from the five rail corridors studied in the Yucca Mountain FEIS, as the DOE preferred rail corridor in which to construct a railroad.
Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada (68 *FR* 74965, December 29, 2003)	Announced BLM receipt of a request from DOE to withdraw public land in the Caliente rail corridor from surface and mineral entry for a period of 20 years to evaluate the land for the potential construction, operation, and maintenance of a railroad for the transportation of spent nuclear fuel and high-level radioactive waste in Nevada. Segregates the land from surface and mineral entry for up to 2 years while various studies and analyses are made to support a final decision on the withdrawal application.
Record of Decision on Mode of Transportation and Nevada Rail Corridor for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, NV (69 *FR* 18557, April 8, 2004)	Selected the mostly rail scenario analyzed in the Yucca Mountain FEIS as the mode of transportation nationally and within the State of Nevada. Selects the Caliente rail corridor for alignment, construction, and operation of a proposed railroad to Yucca Mountain.
Notice of Intent to Prepare an Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV (69 *FR* 18565, April 8, 2004)	Announced the DOE intent to prepare an EIS for the alignment, construction, and operation of a railroad for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials from a site near Caliente, Lincoln County, Nevada, to a geologic repository at Yucca Mountain, Nye County, Nevada.

Table 1-3. NEPA documentation related to the proposed railroad[a] (page 2 of 3).

Document	Relationship to this Rail Alignment EIS
Environmental Assessment for the Proposed Withdrawal of Public Lands Within and Surrounding the Caliente Corridor, DOE/EA-1545 (DIRS 176452-DOE 2005, all)	Examines the environmental impacts of withdrawing public lands from surface and mineral entry for up to 20 years to allow evaluation of the land for the proposed railroad.
Notice of Intent to Prepare an Environmental Impact Statement for the Disposal of Greater-Than-Class-C Low-Level Radioactive Waste (72 *FR* 40135, July 23, 2007)	Announced the DOE intent to prepare an EIS to evaluate disposal options for Greater-Than-Class-C ***low-level radioactive waste***.
Notice of Intent to Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030 (71 *FR* 61731, October 19, 2006)	Announced the DOE intent to supplement the Stockpile Stewardship and Management Programmatic EIS to analyze the environmental impacts from continued transformation of the United States' nuclear weapons complex.
Notice of Intent to Prepare a Programmatic Environmental Impact Statement for the Global Nuclear Energy Partnership (72 *FR* 331, January 4, 2007)	Announced the DOE intent to prepare a programmatic EIS to analyze the potential environmental impacts of recycling spent nuclear fuel.
Public Land Order No. 7653; Withdrawal of Public Lands for the Department of Energy to Protect the Caliente Rail Corridor, Nevada (70 *FR* 76854, December 28, 2005)	Withdraws public lands within the Caliente rail corridor from surface and mineral entry, subject to valid existing rights, for 10 years to allow DOE to evaluate the lands for the potential construction, operation, and maintenance of a rail line.
Amended Notice of Intent to Expand the Scope of the Environmental Impact Statement for the Alignment, Construction, and Operation of a Rail Line to a Geologic Repository at Yucca Mountain, Nye County, NV (71 *FR* 60484, October 13, 2006)	Announced the DOE intent to expand the scope of the Rail Alignment EIS to include the Mina rail alignment.
Notice of Proposed Withdrawal and Opportunity for Public Meeting; Nevada (72 *FR* 1235, January 10, 2007)	Announced BLM receipt of an application from DOE to withdraw public lands from surface and mineral entry through December 27, 2015, to evaluate the lands for the potential construction, operation, and maintenance of a rail line. This covers the Mina rail alignment and segments of the Caliente rail alignment not covered in Public Land Order No. 7653. Segregates the land from surface and mineral entry for up to 2 years while various studies and analyses are made to support a final decision on the withdrawal application.
Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada, DOE/EIS-0250F-S1	Updates the Yucca Mountain FEIS and examines the impacts of construction, operation, monitoring, and eventual closure of a geologic repository at Yucca Mountain. Examines the potential impacts of transporting spent nuclear fuel and high-level radioactive waste nationally.

Table 1-3. NEPA documentation related to the proposed railroad[a] (page 3 of 3).

Document	Relationship to this Rail Alignment EIS
Proposed Las Vegas Resource Management Plan and Final Environmental Impact Statement (DIRS 103079-BLM 1998, all)	Examines implementation of BLM management goals and actions in the Las Vegas area.
Proposed Tonopah Resource Management Plan and Final Environmental Impact Statement (DIRS 101523-BLM 1994, all)	Examines implementation of BLM management goals and actions in the Tonopah area.
Draft - Resource Management Plan/Environmental Impact Statement for the Ely District (DIRS 174518-BLM 2005, all)	Examines implementation of BLM resource management plans, actions, and goals in the Ely area.
Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada. DOE/EIS-0243. Las Vegas, Nevada: U.S. Department of Energy, Nevada Field Office. (DIRS 101811-DOE 1996, all)	Examines the impacts from the continued operations of the Nevada Test Site.
Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-site Locations in the State of Nevada: DOE/EIS-0243-SA-01. Las Vegas, Nevada: U.S. Department of Energy, National Nuclear Security Administration, Nevada Field Office. (DIRS 162638-DOE 2002, all)	Documents the ***affected environment*** in 2002 and discusses any changes from the 1996 Site-wide EIS (DOE/EIS-0243). Provides the status of new programs as of 2002.
Notice of Intent to Prepare a "Programmatic Environmental Impact Statement (PEIS) – Designation of Energy Corridors on Federal Land in 11 Western States" (70 *FR* 56647, September 28, 2005)	DOE is preparing an EIS in conjunction with the BLM and other agencies to evaluate the impacts of designating corridors in the western United States for use primarily as electric transmission, communications and natural gas transmission corridors. Potential corridors would cross Nevada.
Notice of Availability of the Draft Environmental Assessment for the Proposed Infrastructure Improvements for the Yucca Mountain Project, Nevada (71 *FR* 38391, July 6, 2006)	DOE released a Draft Environmental Assessment in 2006 that evaluated several proposed improvements to infrastructure at the Yucca Mountain Repository Site and adjacent portions of the Nevada Test Site. Proposed infrastructure improvements that were analyzed in the Draft EA are being analyzed in the Yucca Mountain Repository Supplemental EIS. Hence, a Final Infrastructure EA will not be published.
Final Environmental Impact Statement: Weber Dam Repair and Modification Project (DIRS 182302-Miller Ecological Consultants 2005, all)	Examines potential environmental impacts to the Walker River from repair and modification of the Weber Dam.

a. BLM = Bureau of Land Management; DOE = U.S. Department of Energy; EA = environmental assessment; EIS = environmental impact statement; FEIS = final environmental impact statement; *FR* = *Federal Register*.

2. PROPOSED ACTION AND ALTERNATIVES

2.1 Introduction

This chapter describes the ***Proposed Action*** and ***No-Action Alternative*** analyzed in this Rail Alignment ***environmental impact statement*** (EIS). As shown in Figure 2-1, the Proposed Action includes two implementing ***alternatives***, each with a ***Shared-Use Option***. Glossary terms are shown in ***bold italics***.

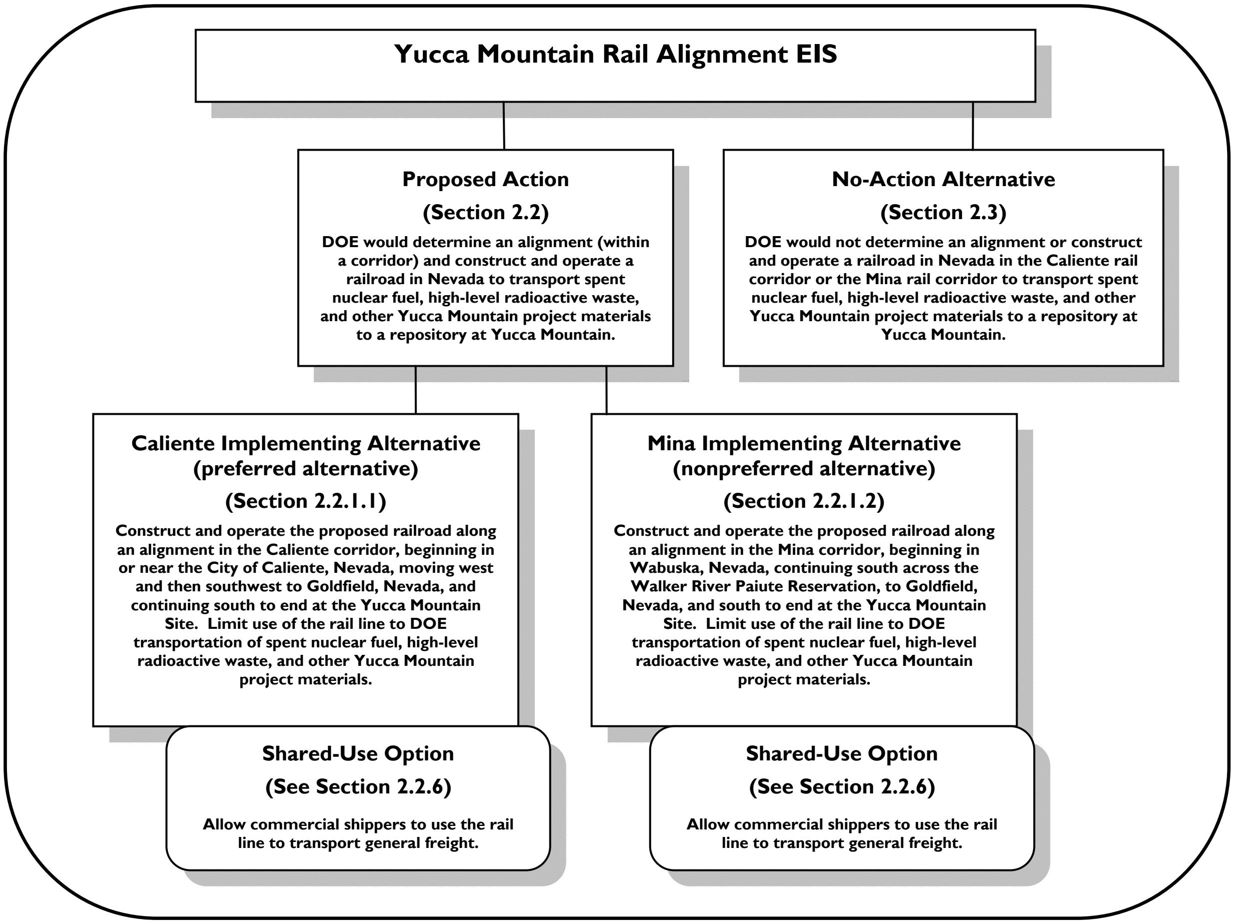

Figure 2-1. Alternatives analyzed in this Rail Alignment EIS.

Under the Proposed Action **Caliente Implementing Alternative**, the U.S. Department of Energy (DOE or the Department) would determine a ***rail alignment*** within the Caliente ***rail corridor*** and would construct, operate, and potentially abandon a ***railroad*** for the ***shipment*** of ***spent nuclear fuel***, ***high-level radioactive waste***, and ***other materials*** within Nevada. The proposed railroad would run from a site in or near the City of Caliente, Lincoln County, Nevada, to a ***geologic repository*** at Yucca Mountain, Nye County, Nevada. The Caliente Implementing Alternative is the DOE **preferred alternative** (see Section 2-4). Section 2.2.1.1 describes the Caliente Implementing Alternative.

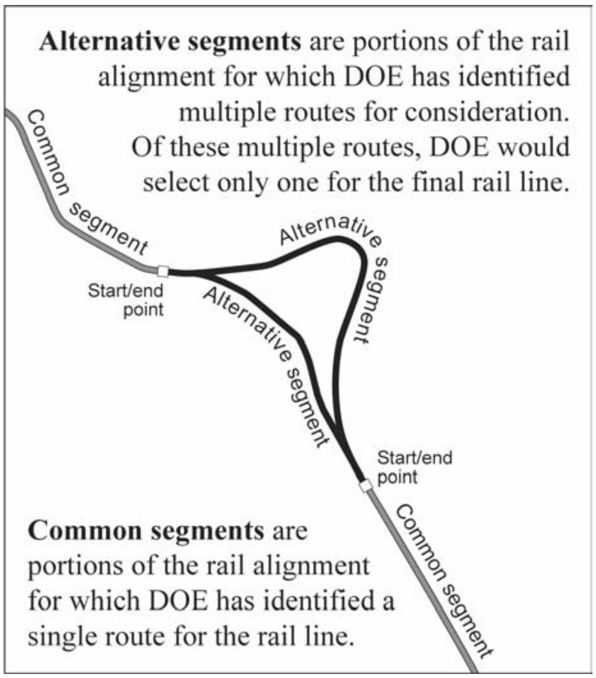
Under the Proposed Action **Mina Implementing Alternative**, DOE would determine a rail alignment within the Mina rail corridor and would construct, operate, and potentially abandon a railroad for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials within Nevada. The proposed railroad would run from Wabuska, Lyon County, Nevada, to a geologic ***repository*** at Yucca

Mountain, Nye County, Nevada. The Mina Implementing Alternative is the DOE **nonpreferred alternative** (see Section 2.4). Section 2.2.1.2 describes the Mina Implementing Alternative.

In each of the rail corridors, DOE considered a range of ***alternative segments*** and a series of ***common segments*** and eliminated the unreasonable alternative segments from detailed analysis based on environmental criteria and engineering factors. Appendix C, Evolution of Common Segments and Alternative Segments, describes the elimination process.

Under either Proposed Action implementing alternative, the **Shared-Use Option** would allow commercial and other shippers to use the ***rail line***. Under the Shared-Use Option, other organizations could construct commercial ***sidings*** (see Section 2.2.2.8) and additional facilities that would allow commercial commodities (such as nonmetallic minerals or stone) to be transported on the rail line. Section 2.2.6 describes the Shared-Use Option.

Council on Environmental Quality regulations (40 Code of Federal Regulations [CFR] 1502.14) that implement the procedural requirements of the National Environmental Policy Act (NEPA; 42 United States Code [U.S.C.] 4321 *et seq.*) require that the alternatives analysis in an EIS include the alternative of no action. Under the **No-Action Alternative**, DOE would not determine a rail alignment or construct the proposed railroad within the Caliente rail corridor or the Mina rail corridor. The No-Action Alternative provides a basis for comparison with the Proposed Action. Section 2.3 describes the No-Action Alternative in greater detail.



Council on Environmental Quality regulations require an agency to identify its preferred alternative, if one or more exists, in the draft EIS (40 CFR 1502.14[e]). For this Rail Alignment EIS, the DOE preferred alternative would be to construct, operate, and possibly abandon a railroad along the Caliente rail alignment for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials within Nevada to the ***Yucca Mountain Site***, and to implement the Share-Use Option. Section 2.4 describes the DOE preferred and nonpreferred alternatives in greater detail.

Section 2.5 summarizes potential environmental ***impacts*** under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative.

2.2 Proposed Action

Under the Proposed Action, DOE would determine an alignment (within a corridor) and construct and operate a railroad (called rail line in the Notice of Intent [69 *Federal Register* {*FR*} 18565, April 8, 2004] and the Amended Notice of Intent [71 *FR* 60484, October 13, 2006]) in Nevada to transport spent nuclear fuel, high-level radioactive waste, and other materials to a repository at Yucca Mountain. There are two implementing alternatives under the Proposed Action – the Caliente Implementing Alternative, under which the Department would construct the proposed railroad in the Caliente rail corridor, and the Mina Implementing Alternative, under which the Department would construct the proposed railroad in the Mina rail corridor (Figure 2-2). DOE would also use the railroad to transport materials needed for construction, operation, and maintenance of the proposed railroad and the proposed repository at Yucca Mountain.

A rail line in the Caliente rail corridor would extend north from Caliente, Nevada, turn in a westerly direction and head to near the northwest corner of the Nevada Test and Training Range, and then continue south-southeast to Yucca Mountain. The rail line could range in length from approximately 528 to 541 kilometers (328 to 336 miles) (DIRS 180916-Nevada Rail Partners 2007, Table E-2), depending on the specific alternative segments DOE selected.

A rail line in the Mina rail corridor would extend from near Wabuska, Nevada, in a southeasterly direction to Yucca Mountain. The total length of the rail line could range from approximately 452 to 502 kilometers (281 to 312 miles), including the existing Department of Defense Branchlines. The portions of the Mina rail alignment that would require construction of a new rail line could range in length from approximately 410 to 459 kilometers (255 to 285 miles), depending on the combination of alternative segments (DIRS 180872-Nevada Rail Partners 2007, Table 4-2).

The southern portion of each rail alignment would be the same for approximately 190 kilometers (120 miles) from south of Goldfield to Yucca Mountain.

As discussed in Section 1.5.1, the Proposed Action includes acquiring a ***right-of-way grant*** from the U.S. Department of the Interior, Bureau of Land Management (BLM), which would authorize DOE access to sufficient lands for the rail alignment, rail facilities, and associated construction ***infrastructure*** (for example, ***construction camps***, access roads, and quarries for ***ballast***). DOE would also need to obtain access to some private land. In addition, under the Mina Implementing Alternative, DOE would need to obtain right-of-way access from the Walker River Paiute Tribe/Bureau of Indian Affairs to access lands on the Walker River Paiute Reservation. Sections 3.2.2 and 3.3.2 describe land use and ownership along the Caliente rail alignment and the Mina rail alignment, respectively.

During construction of the proposed railroad, a ***construction right-of-way*** would be established that would nominally occupy a 300-meter (1,000-foot)-wide strip of land centered on the rail alignment (that is, 150 meters [500 feet] on either side of the rail

Right-of-way grant: Authorization from the BLM to use a specific portion of public land for construction and operation of the proposed railroad. The land covered by the right-of-way grant would include the area of construction, known as the construction right-of-way, and the area of operations, known as the operations right-of-way.

Construction right-of-way: Property over which DOE would obtain access for construction of the railroad, nominally 150 meters (500 feet) on either side of the centerline of the rail alignment (for a total width of nominally 300 meters [1,000 feet]). The width could vary at specific locations to accommodate, for example, certain deep cuts and fills, and construction of drainage controls. The construction right-of-way would also include the locations of construction support facilities (such as quarries) and operations support facilities (such as the Staging Yard).

Operations right-of-way: Property over which access would be obtained for operation of the proposed railroad. In most cases, the width of the operations right-of-way would be less than that of the construction right-of-way (nominally 61 meters [200 feet] on either side of the rail line centerline, for a total width of 122 meters [400 feet]). The width could vary at specific locations to accommodate, for example, access and maintenance roads and drainage structures. The operations right-of-way would also include the locations of operations support facilities (such as the Staging Yard).

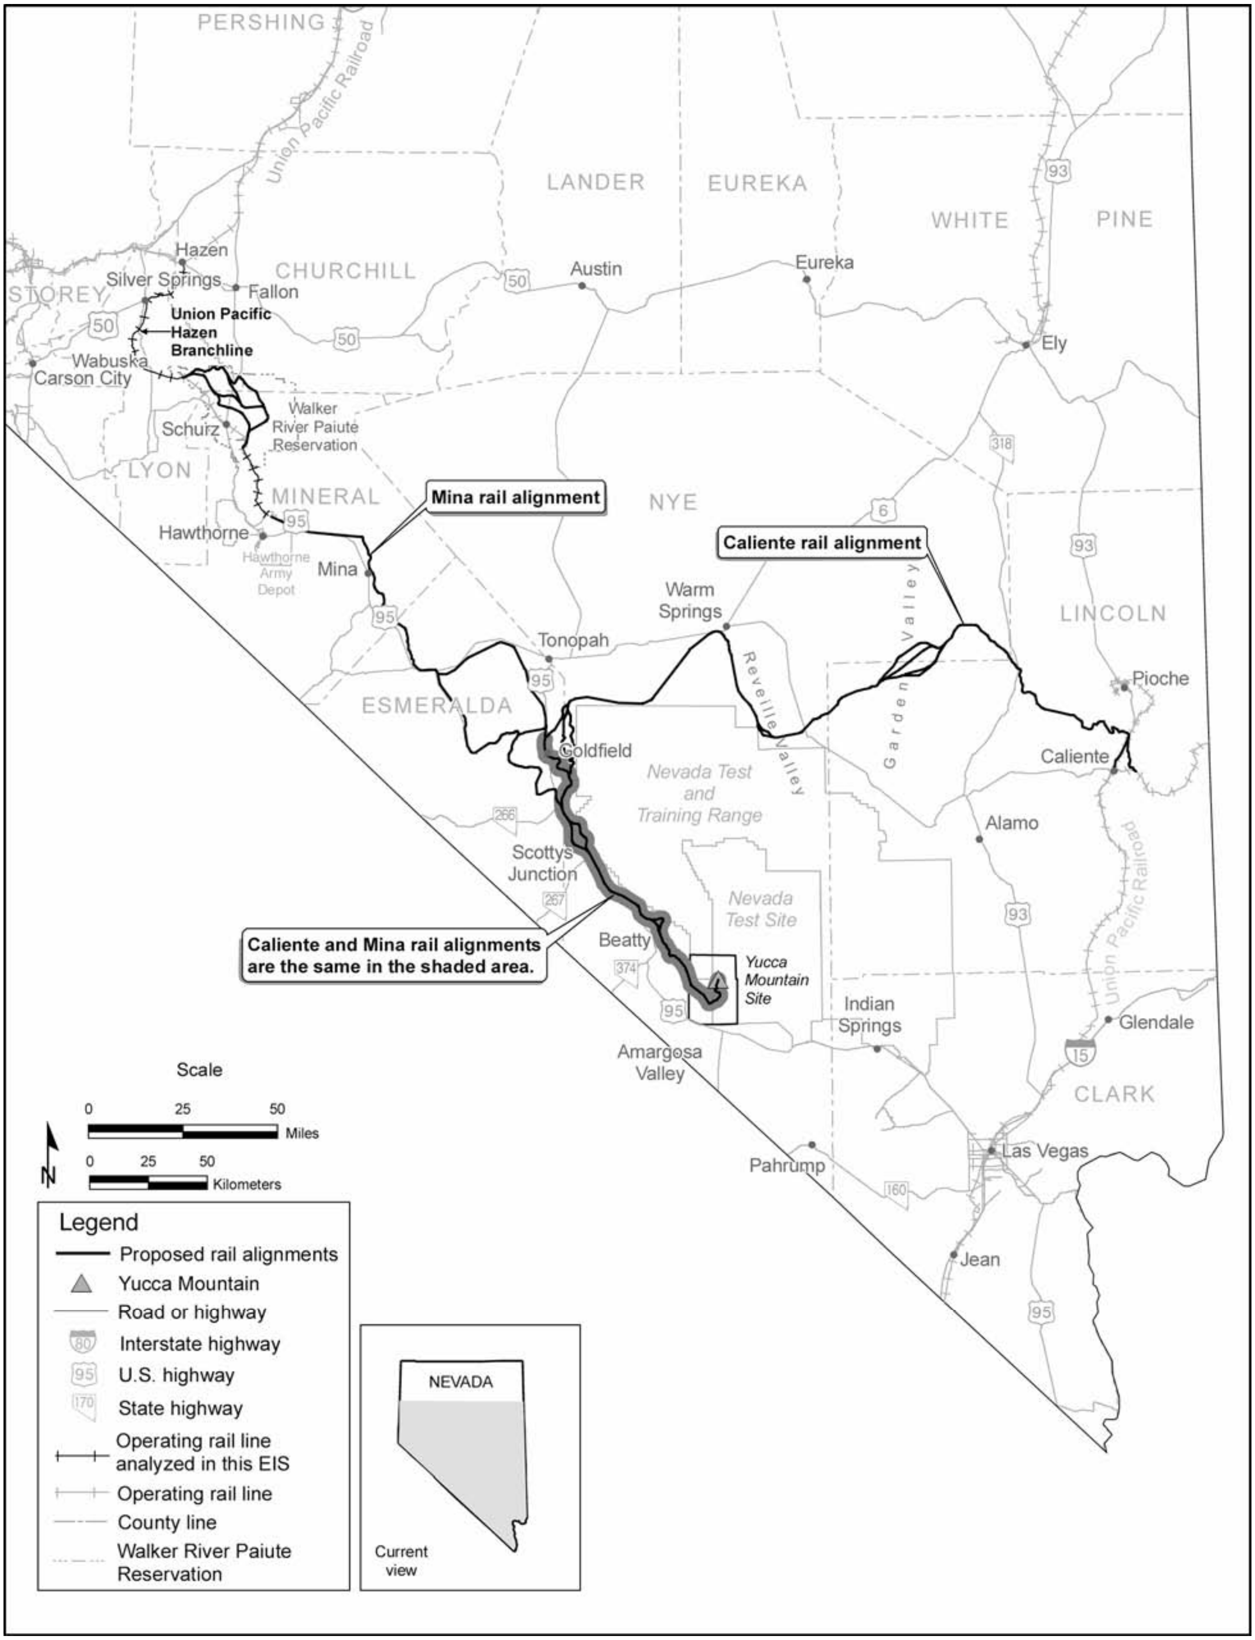


Figure 2.2. The proposed Caliente and Mina rail alignments.

alignment centerline). The width of the construction right-of-way would vary as necessary and would be minimized to reduce impacts to, for example, sensitive environmental features (Figure 2-3) (DIRS 180918-Nevada Rail Partners 2007, p. ii).

During the railroad operations phase, the right-of-way would be reduced to a smaller width (nominally 61 meters [200 feet] on either side of the centerline of the rail line). DOE would minimize this ***operations right-of-way*** to the extent practicable and would determine the operations right-of-way in consultation with the BLM. Lands formerly inside the construction right-of-way but not included in the operations right-of-way would be reclaimed (restored to natural conditions), as appropriate.

Under the Caliente Implementing Alternative, the Department estimates the total cost to construct the railroad would be approximately $2.2 billion (in year 2005 dollars) (DIRS 176176-BSC 2007, p. ES-1). Under the Mina Implementing Alternative, the Department estimates that the total cost of construction would be approximately $1.7 billion (in year 2005 dollars) (DIRS 182778-BSC 2007, p. ES-1).

Both ***implementing alternatives*** would require operations support facilities (see Section 2.2.4). Under the Caliente Implementing Alternative, facilities would include:

- ***Interchange Yard***
- ***Staging Yard***
- Maintenance-of-Way Headquarters Facility
- Maintenance-of-Way Trackside Facility
- ***Rail Equipment Maintenance Yard***
- ***Cask Maintenance Facility***
- ***Nevada Railroad Control Center*** and National Transportation Operations Center

Under the Mina Implementing Alternative, facilities would include:

- Staging Yard
- Maintenance-of-Way Facility
- Rail Equipment Maintenance Yard
- ***Cask Maintenance Facility***
- Nevada Railroad Control Center and National Transportation Operations Center

Although the specific facilities identified under each implementing alternative are different, in total they would provide the same functions under either implementing alternative. For example, due to the need to support road-based maintenance activities, which would not be easy to access from along the Caliente rail alignment, the Caliente Implementing Alternative would require the Maintenance-of-Way Trackside Facility and the Maintenance-of-Way Headquarters Facility. However, under the Mina Implementing Alternative, a single Maintenance-of-Way Facility would house all of the functions for both of these facilities.

Under the Caliente Implementing Alternative, two facilities (the Interchange Yard and the Staging Yard) would be required to fulfill the functional requirements of exchanging railcars between the Union Pacific Railroad Mainline and the proposed railroad. This is because there is not enough space where the Caliente rail alignment would intersect the Union Pacific Railroad Mainline to house all of the necessary functions of these facilities in one location. However, under the Mina Implementing Alternative, there is enough space to locate all the functions in a single facility (the Staging Yard) at Hawthorne.

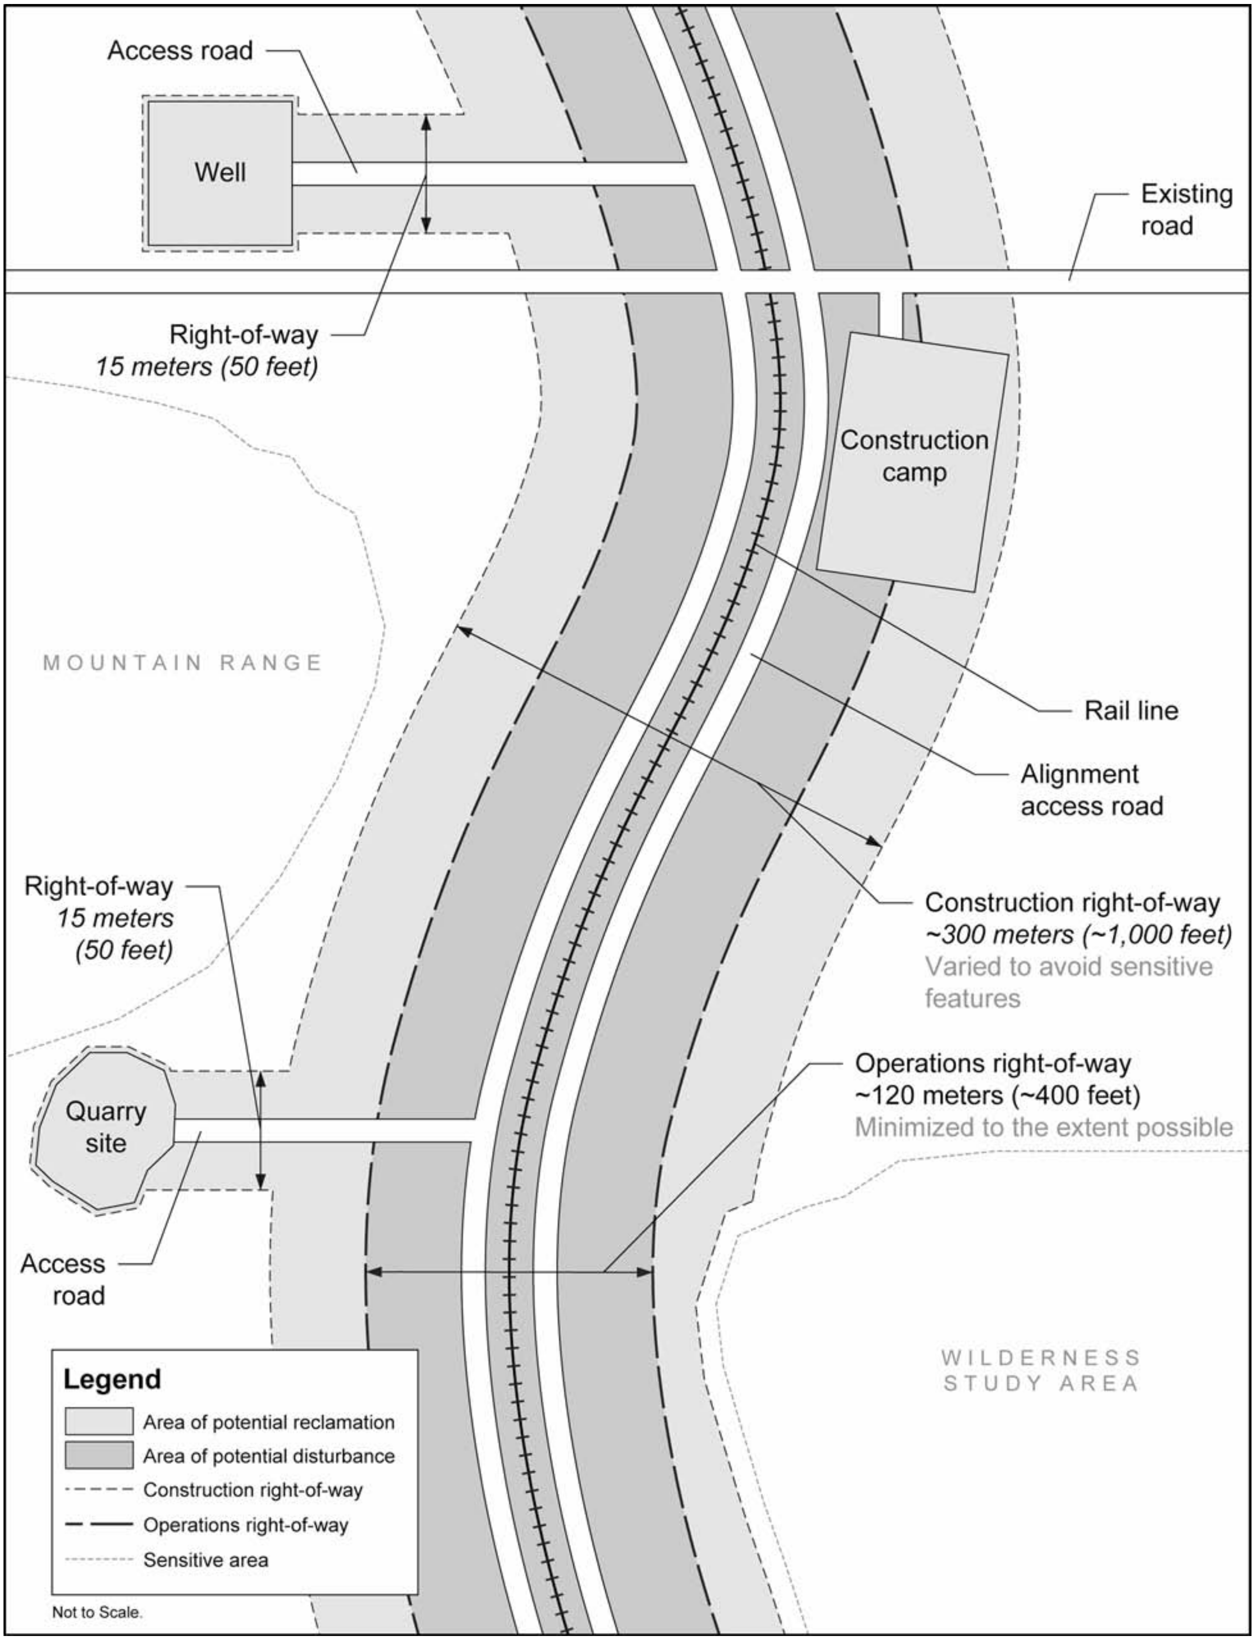

Figure 2-3. The construction and operations rights-of-way.

DOE would construct and operate the proposed railroad in accordance with applicable federal and State of Nevada laws and regulations, and in compliance with all stipulations and conditions in associated permits. Chapter 6, Statutory, Regulatory, and other Applicable Requirements, describes such requirements. To help ensure compliance with applicable requirements, DOE would implement an array of ***best management practices*** as part of the Proposed Action. Best management practices would include practices such as dust suppression and the use of silt fencing to control soil erosion during construction activities. Chapter 7, Best Management Practices and Impacts Mitigation, describes representative best management practices DOE would implement during construction and operation of the proposed railroad.

> **Best management practices:** Practices, techniques, methods, processes, and activities commonly accepted and used throughout the construction and railroad industries that DOE would implement as part of the Proposed Action to facilitate compliance with applicable requirements and that provide an effective and practicable means of preventing or minimizing the environmental impacts of an action.

> **Mitigation** (40 CFR 1508.20) includes:
>
> - Avoiding the impact altogether by not taking a certain action or parts of an action.
> - Minimizing impacts by limiting the degree or magnitude of the action and its implementation.
> - Rectifying the impact by repairing, rehabilitating, or restoring the affected environment.
> - Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action.
> - Compensating for the impact by replacing or providing substitute resources or environments.

Chapter 4, Environmental Impacts, describes the potential environmental impacts of constructing and operating a railroad under the Proposed Action. Where impact analyses results indicate the potential for environmental impacts despite DOE engineering and site evaluation and planning practices and implementation of best management practices, DOE has developed potential ***mitigation*** measures as a step toward reducing the environmental impacts of the project. Chapter 7 identifies the measures DOE would consider to mitigate impacts remaining after engineering and site evaluation and planning, and the implementation of best management practices.

Under the Proposed Action without shared use, use of the railroad would be restricted to DOE shipments; DOE would not allow commercial use of the rail line. DOE would use the railroad to ship approximately 9,500 ***casks*** containing spent nuclear fuel and high-level radioactive waste from the Caliente or Wabuska areas to the repository over an operations phase of up to 50 years (DIRS 180923-Nevada Rail Partners 2007, p. 4-1). Each cask would be shipped on an individual ***cask car***. DOE would also ship approximately 29,000 railcars of other materials, which would include repository construction materials, materials necessary for day-to-day operations of the railroad and the repository, and waste materials for disposal, such as scrap metal and ***solid waste*** (DIRS 180923-Nevada Rail Partners 2007, p. 4-2). Together, these activities equal approximately 17 one-way trips per week during railroad operations along either the Caliente or Mina rail alignment. Table 2-1 summarizes the expected frequencies of the types of trains that would operate on the railroad.

During planning and design of the proposed railroad, DOE employed various engineering and site evaluation measures to avoid, minimize, or otherwise reduce environmental impacts. As the environmental analyses have progressed, DOE has refined the design of the railroad to avoid certain sensitive environmental features and reduce potential impacts to sensitive areas by, for example, limiting the project's ***footprint*** in such areas. As part of the Proposed Action, the Department would continue to incorporate refinements through final engineering and design. The following are examples of the types of design and engineering factors DOE has and will continue to consider, as practicable:

Table 2-1. Summary of potential train frequencies.[a,b]

Train type	Approximate peak frequency (one-way, per week)
Cask trains	8
Repository construction materials and supplies trains	7
Maintenance-of-way trains	2
Total	17[c]

a. Source: DIRS 175036-BSC 2005, Table 4.2.
b. Average frequencies; actual frequencies would vary from year to year over the operating life of the railroad.
c. The equivalent of 8.5 round-trip trains going from the Staging Yard to the repository and back in 1 week.

- Follow the contours of the land to the greatest extent practicable to reduce earthwork, ground disturbance, and visual intrusion.
- Design the rail line and facilities to be consistent with appropriate Nevada building codes.
- Where necessary, limit the area of disturbance (the footprint) to minimize potential impacts to ***wetlands***, highways, and private lands to the extent practicable.
- Reduce the potential for erosion, landslides, mudslides, and rockfalls by establishing proper rail ***roadbed*** grades; building mid-slope benches; varying ***cut*** slope dimensions (depending on the strength and stability of the bedrock); implementing additional stabilization measures (such as rock-bolting or slope terracing); and using stormwater erosion control measures.
- Where practicable, use abandoned rail roadbeds to limit construction impacts.
- Avoid springs, ***riparian*** areas, and wetland ***habitats*** or narrow the project footprint in such areas to the extent practicable.
- Avoid, minimize, or otherwise reduce impacts to special status species to the greatest extent practicable by making adjustments to site locations during final design.
- Design communications systems to be used during construction so as to not interfere with other services operating in the same geographic areas.
- Incorporate hydraulic modeling into the final design process to ensure that ***ephemeral stream*** crossings are properly engineered so that they would not contribute to erosion and sediment pollution, and to minimize impacts to downstream surface-water resources.
- Ensure roadway improvements are in accordance with Nevada Department of Transportation, county, and BLM requirements.
- During final design of the railroad, consider the specific locations of manmade surface-water features in relation to the rail alignment and include consultations with the owners to develop, as appropriate, measures to minimize or otherwise mitigate potential impacts to such manmade systems.
- Minimize filling of wetlands by incorporating avoidance into final engineering and design of the railroad to the extent practicable.
- Incorporate hydraulic modeling into the engineering design process to ensure that all stream crossings would be designed to limit the adverse impacts of flooding to nearby populations and resources.
- Design the railroad to avoid springs and other surface-water resources whenever practicable. In the few cases where there would be springs inside the construction right-of-way, incorporate avoidance into final engineering and design of the railroad to the extent practicable.

This chapter describes the Proposed Action in detail. Tables 2-2 through 2-7 summarize and briefly describe the project attributes associated with the Proposed Action along each of the rail alignments, including operations support facilities.

2.2.1 RAIL ALIGNMENTS

This section describes the Caliente rail alignment alternative segments and common segments (Section 2.2.1.1) and the Mina rail alignment existing rail lines, alternative segments, and common segments (Section 2.2.1.2).

Common segments are portions of the rail alignments for which DOE has identified a single route for the rail line. Along the Caliente rail alignment, there are six common segments, starting with Caliente common segment 1 south of Panaca, and moving west sequentially to common segment 6 near Yucca Mountain. In total, the common segments constitute approximately 380 kilometers (236 miles) of the total length of the Caliente rail alignment (DIRS 180916-Nevada Rail Partners 2007, p. 4-6).

There are four common segments along the Mina rail alignment – Mina common segment 1, which would start west of Hawthorne and continue to Blair Junction; Mina common segment 2, which would start south of Lida Junction; common segment 5; and common segment 6. (Common segments 5 and 6 are the same as common segments 5 and 6 along the Caliente rail alignment.) In total, the common segments constitute approximately 211 kilometers (131 miles) of the Mina rail alignment (DIRS 180872-Nevada Rail Partners 2007, p. 4-2).

Alternative segments are portions of the rail alignments for which DOE is considering two or more reasonable alternative ***routes*** for the rail line. The alternative segments were originally numbered sequentially as they were proposed or developed (for example, Garden Valley 1, Garden Valley 2, and so on); however, DOE eliminated some of those alternative segments from detailed analysis because they were unreasonable. As a result, the remaining alternative segments analyzed in this Rail Alignment EIS are not necessarily numbered sequentially. For example, DOE eliminated the South Reveille 1 and South Reveille 4 alternative segments from consideration; thus, only South Reveille 2 and South Reveille 3 remain. Appendix C describes alternative segments eliminated from detailed study for both the Caliente and Mina rail alignments.

In some cases, two or more alternative segments follow the same route for a few kilometers before splitting and following unique paths. When this occurs, the route on the map is designated with the names of both alternative segments. For example, along the Caliente rail alignment, Garden Valley alternative segments 1 and 2 follow the same route for a few kilometers.

DOE applied various environmental, engineering, and design criteria to generate the common segments and alternative segments to be evaluated in this Rail Alignment EIS. Appendix C provides a detailed discussion of the alternative-segment selection and elimination process; Table C-1 lists the engineering criteria the Department utilized in the identification and analysis of alternative segments and common segments along the Caliente and Mina rail alignments.

DOE based the conceptual design of the rail line on the application of specific criteria used by the commercial rail industry. These criteria govern the horizontal and vertical geometry, structural integrity, and other factors critical to safe and sustained operation of a railroad. In addition, other factors such as environmental constraints and community concerns have been important to the rail alignment-development process. These factors include for example, the consideration of Wilderness Areas and ***Wilderness Study Areas***, avoiding disturbance of private lands where practicable, and avoidance of culturally or biologically sensitive areas.

Table 2-2. General project attributes associated with the Proposed Action.

Attribute	Caliente Implementing Alternative	Mina Implementing Alternative
Length	Total length (all new construction): 328 to 336 miles (528 to 541 kilometers)	Total length: 281 to 312 miles (452 to 502 kilometers) New construction: 255 to 285 miles (410 to 459 kilometers)
Construction phase	4 to 10 years (depending on funding availability for construction activities)	
Operations phase	Up to 50 years	
Construction right-of-way	Nominally 500 feet (150 meters) on either side of the centerline of the rail alignment	
Operations right-of-way	Nominally 200 feet (61 meters) on either side of the centerline of the rail line	

Table 2-3. Project attributes associated with construction of the proposed railroad (page 1 of 2).

Attribute	Caliente Implementing Alternative	Mina Implementing Alternative
Estimated number of bridges	Approximately 215 to 240, ranging in length from 24 to 1,000 feet (7.3 to 300 meters)	Approximately 58 to 69, ranging in length from 50 to 1,000 feet (16 to 300 meters)
Estimated number of culverts	Approximately 96 to 138	Approximately 38 to 60
Estimated number of water wells needed to satisfy construction water demand	Minimum: 94 well sites containing 150 wells Maximum: 107 well sites containing 176 wells	Minimum: 58 well sites containing 77 wells Maximum: 74 well sites containing 110 wells
Sidings	12 sidings, ranging in length from 7,000 to 12,000 feet (2,100 to 3,700 meters)	12 sidings, ranging in length from 7,000 to 19,000 feet (2,100 to 5,800 meters)
Alignment access roads	The railroad alignment is planned to have an access road along most of its length. This road would be used primarily to support maintenance of the railroad infrastructure. In situations where rerouting existing roads to a common crossover point would be appropriate, DOE could use the access road to facilitate routing roads to a single crossing.	
Construction camps	Number: Up to 12; with up to 6 operating at one time	Number: Up to 10; with up to 6 operating at one time
	Function: To house construction workers and provide a logistical support area for construction Location: One approximately every 30 miles (50 kilometers) along the rail alignment Employment: Up to 360 per camp (106 support staff and 254 construction staff) Disturbed area: 25 acres (0.10 square kilometer) per camp	
Total construction employment (required over the entire construction phase)	8,100 employees (total man years)	7,600 employees (total man years)
Peak employment (in any given year during construction)	2,160 employees	2,160 employees

Table 2-3. Project attributes associated with construction of the proposed railroad (page 2 of 2).

Attribute	Caliente Implementing Alternative	Mina Implementing Alternative
Ballast quarries	Number: If necessary, up to four would be developed from six potential sites. Locations: One near Caliente; two in South Reveille Valley; one west of Goldfield; and two northeast of Goldfield.	Number: If necessary, up to two would be developed from five potential sites. Locations: Two east of Hawthorne; one east of Silver Peak; and two west of Goldfield.

Attribute	Caliente and Mina Implementing Alternatives	
Ballast quarries	Employment:	Up to 30 at each quarry
	Disturbed area:	240 to 930 acres (0.97 to 3.8 square kilometers)
Construction train traffic (one-way traffic; that is, one train per day is the equivalent of one trip between the beginning of the line and Yucca Mountain)	Ballast trains:	Approximately 8 per day
	Concrete tie trains:	Approximately 2 per day
	Rail section trains:	Approximately 4 per day
	Other material trains:	Approximately 2 per day
	Total:	Approximately 16 per day
Communications towers	Approximately every 10 to 20 miles (16 to 32 kilometers) along the rail alignment, approximately 55 to 100 feet (23 to 30 meters) tall	

Table 2-4. Project attributes associated with the operation and maintenance of the proposed railroad.

Attribute	Caliente and Mina Implementing Alternatives	
Train traffic (one-way traffic)	Cask trains:	Approximately 8 per week
	Maintenance-of-way trains:	Approximately 2 per week
	Repository supply/construction trains:	Approximately 7 per week
	Total:	Approximately 17 per week
Operational characteristics	Travel time:	Less than 10 hours from the Staging Yard to the Rail Equipment Maintenance Yard
	Train operating speed limits:	25 to 50 miles (40 to 80 kilometers) per hour
	Number of casks to be shipped:	Approximately 9,500 total casks containing spent nuclear fuel or high-level radioactive waste
Cask train components	Locomotives:	2 to 3
	Cask cars:	1 to 12 (3 typical)
	Buffer cars:	2
	Escort cars:	1 to 2

Table 2-5. Project attributes associated with railroad operations support facilities along the Caliente rail alignment (excluding segments in common with the Mina rail alignment).

Facility	Description	
Interchange Yard	Function:	Handling point for the exchange of railcars containing construction and other materials between the Union Pacific Railroad Mainline and the proposed railroad
	Location:	Beginning of the Eccles or Caliente alternative segment
	Employment:	0 (employees would be based at the Staging Yard)
	Disturbed area:	Caliente: 15 acres (0.061 square kilometer)
		Eccles: 30 acres (0.12 square kilometer)
Staging Yard	Function:	Transfer point for casks and other materials shipped to the proposed railroad
	Location:	Caliente alternative segment, Indian Cove; Caliente alternative segment, Upland; or Eccles alternative segment, Eccles-North
	Employment:	50
	Disturbed area:	50 acres (0.20 square kilometer)
Maintenance-of-Way Trackside Facility	Function:	Operational base for maintenance and inspection activities
	Location:	Caliente common segment 3: Approximately 30 miles (50 kilometers) southeast of Tonopah; or anywhere along Caliente common segment 3 between the analyzed location and the start of the Goldfield alternative segments
	Employment:	40
	Disturbed area:	15 acres (0.061 square kilometer)
Maintenance-of-Way Headquarters Facility	Function:	Coordination center for all maintenance and inspection activities on the proposed railroad
	Location:	Approximately 8 kilometers south of Tonopah; or anywhere along U.S. Highway 95 between the analyzed location south of Tonopah and the intersection of Goldfield alternative segment 4 and U.S. Highway 95
	Employment:	10
	Disturbed area:	3 acres (0.013 square kilometer)

Table 2-6. Project attributes associated with railroad operations support facilities along the Mina rail alignment (excluding segments in common with the Caliente rail alignment) (page 1 of 2).

Facility	Description	
Staging Yard	Function:	Transfer point for casks and other materials shipped to the proposed railroad
		Handling point for the exchange of railcars containing construction and other materials between the Union Pacific Railroad and the proposed railroad
	Maintenance-of-way trains:	Approximately 2 per week
	Location:	Mina common segment 1, Hawthorne
	Employment:	40
	Disturbed area:	50 acres (0.20 square kilometer)

Table 2-6. Project attributes associated with railroad operations support facilities along the Mina rail alignment (excluding segments in common with the Caliente rail alignment) (page 2 of 2).

Facility	Description	
Maintenance-of-Way Facility	Function:	Coordination center and operational base for all maintenance and inspection activities for the proposed railroad
	Location:	Montezuma alternative segment 1, Silver Peak; or Montezuma alternative segments 2 and 3, Klondike
	Employment:	40
	Disturbed area:	15 acres (0.061 square kilometer)

Table 2-7. Project attributes associated with the common railroad operations support facilities along the Caliente and Mina rail alignments.

Facility	Caliente and Mina Implementing Alternatives	
Rail Equipment Maintenance Yard	Function:	The termination point for the proposed railroad and the staging area for the delivery of loaded cask cars and other materials to the repository receiving and inspection area
	Location:	Less than 1 mile (1.6 kilometers) south of the southern boundary of the geologic repository operations area
	Employment:	40 (including employees for the Nevada Railroad Control Center and National Transportation Operations Center)
	Disturbed area:	100 acres (0.41 square kilometer)
Cask Maintenance Facility	Function:	Processing location for empty transportation casks used to transport canistered fuel, including testing, inspection, maintenance, and decontamination
	Location:	For purposes of analysis, collocated with the Rail Equipment Maintenance Yard
	Employment:	30
	Disturbed area:	20 acres (0.081 square kilometer)
Satellite Maintenance-of-Way Facilities	Function:	Dispatch point for maintenance activities along the first third and final third of the rail line
	Location:	Two locations: one at the Rail Equipment Maintenance Yard and one at the Staging Yard
	Employment:	Employees housed at the Rail Equipment Maintenance Yard and the Staging Yard
	Disturbed area:	0 (along the Caliente rail alignment, employees housed at the Maintenance-of-Way Facilities; along the Mina rail alignment, employees housed at the Maintenance-of-Way Facility)
Nevada Railroad Control Center and National Transportation Operations Center	Function:	Nevada Railroad Control Center would control operations along the rail line in Nevada; National Transportation Operations Center would coordinate the national shipment of casks and other materials to the proposed railroad
	Location:	Integrated with either the Rail Equipment Maintenance Yard or the Staging Yard
	Employment:	15 (included in the employment number for the Rail Equipment Maintenance Yard)
	Disturbed area:	0 (integrated with the Rail Equipment Maintenance Yard or the Staging Yard)

Design requirements for the proposed railroad would meet or exceed American Railway Engineering and Maintenance-of-Way Association recommendations (DIRS 162040-AREMA 2001, all) consistent with common industry practice for a ***Class 1 commercial railroad***. Appendix C provides a more detailed explanation of the engineering and design considerations DOE used to develop the rail alignment common segments and alternative segments.

Class 1 commercial railroad: The Surface Transportation Board defines a Class 1 commercial railroad as one with an annual operating revenue exceeding $277.7 million.

Section 2.4 identifies the DOE preferred alternative segments.

2.2.1.1 Caliente Rail Alignment

This section describes the alternative segments and common segments along the Caliente rail alignment, beginning in or near the City of Caliente and moving north, west, and then south along the rail alignment toward Yucca Mountain. Figure 2-4 shows the Caliente rail alignment divided into seven map areas, starting with Caliente map area 1 at the beginning of the rail alignment (the east side) and ending with Caliente map area 7 at the end of the rail alignment (the southwest side). Figures in Sections 2.2.1.1.1 through 2.2.1.1.12 show the alternative segments and common segments. The Map Atlas (DIRS 182843-ICF 2007, Part A) contains more than 500 detailed maps depicting all of the Caliente rail alignment alternative segments and common segments, railroad ***construction and operations support facilities***, and engineered features, such as cut and ***fill*** areas.

2.2.1.1.1 Alternative Segments at the Interface with Union Pacific Mainline

DOE is considering either the Caliente or the Eccles alternative segment to connect the proposed railroad to the existing Union Pacific Railroad Mainline in or near the City of Caliente, as shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 1 through 24) and on Figure 2-5.

The Caliente alternative segment would begin in Caliente, enter Meadow Valley at Indian Cove, and extend generally north through Meadow Valley and along U.S. Highway 93. This alternative segment would then cross U.S. Highway 93 about 5 kilometers (3 miles) southwest of Panaca and connect to Caliente common segment 1 about 1 kilometer (0.6 mile) northwest of U.S. Highway 93 and 18 kilometers (11 miles) south of Pioche. The Caliente alternative segment would be approximately 18 kilometers long (DIRS 180916-Nevada Rail Partners 2007, p. E-4).

The Eccles alternative segment would begin along Clover Creek about 8 kilometers (5 miles) east of Caliente and trend generally north to enter Meadow Valley from the southeast (see Figure 2-5). This alternative segment would then cross U.S. Highway 93 about 5 kilometers (3 miles) southwest of Panaca and connect to Caliente common segment 1 about 1 kilometer (0.6 mile) northwest of U.S. Highway 93 and 18 kilometers (11 miles) south of Pioche. The Eccles alternative segment would be about 19 kilometers (12 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-4).

2.2.1.1.2 Caliente Common Segment 1 (Dry Lake Valley Area)

Caliente common segment 1 is shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 25 through 107) and on Figures 2-5 and 2-6. It would begin at the end of the Caliente or Eccles alternative segment. Common segment 1 would trend generally west from Meadow Valley through the Chief Range (Bennett Pass) and across Dry Lake Valley and the North Pahroc Range. On the west side of the North Pahroc Range, common segment 1 would cross Nevada Route 318 near Timber Mountain about 5 kilometers (3 miles) southeast of the Lincoln and Nye County line. It would continue to the northwest

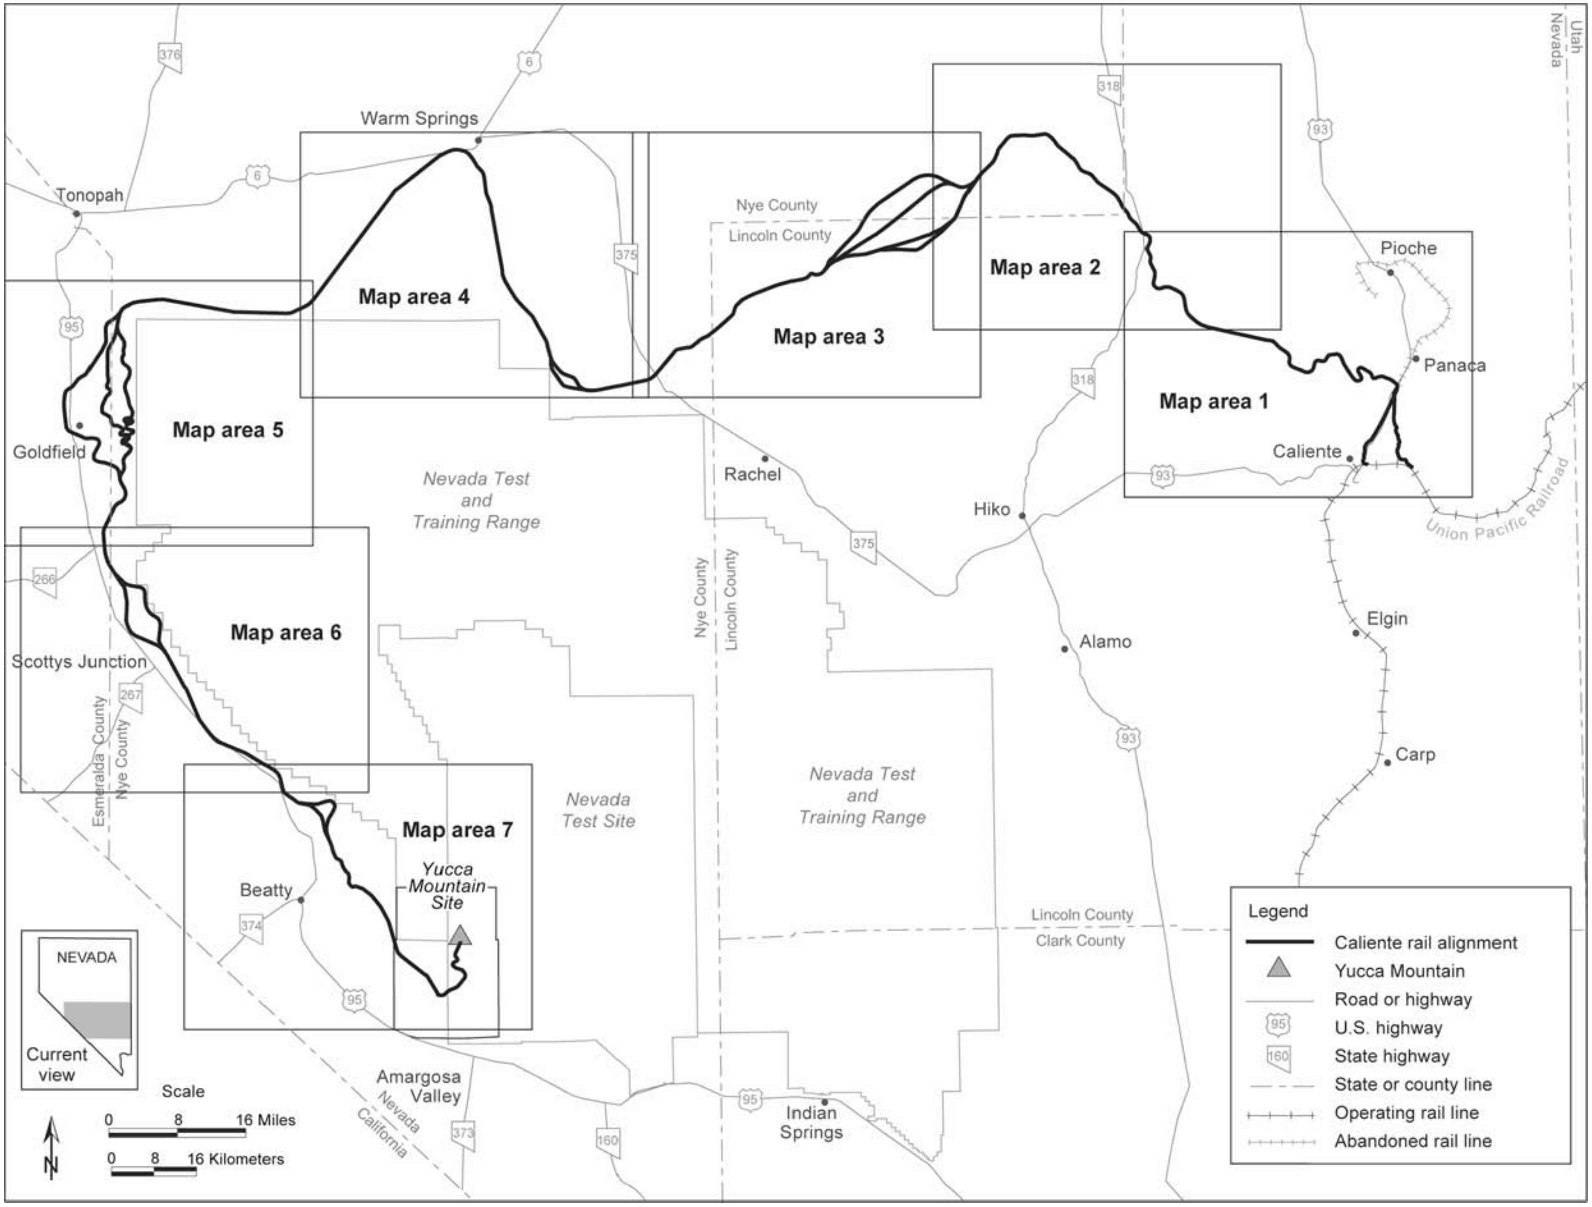

Figure 2-4. Map key for areas along the Caliente rail alignment.

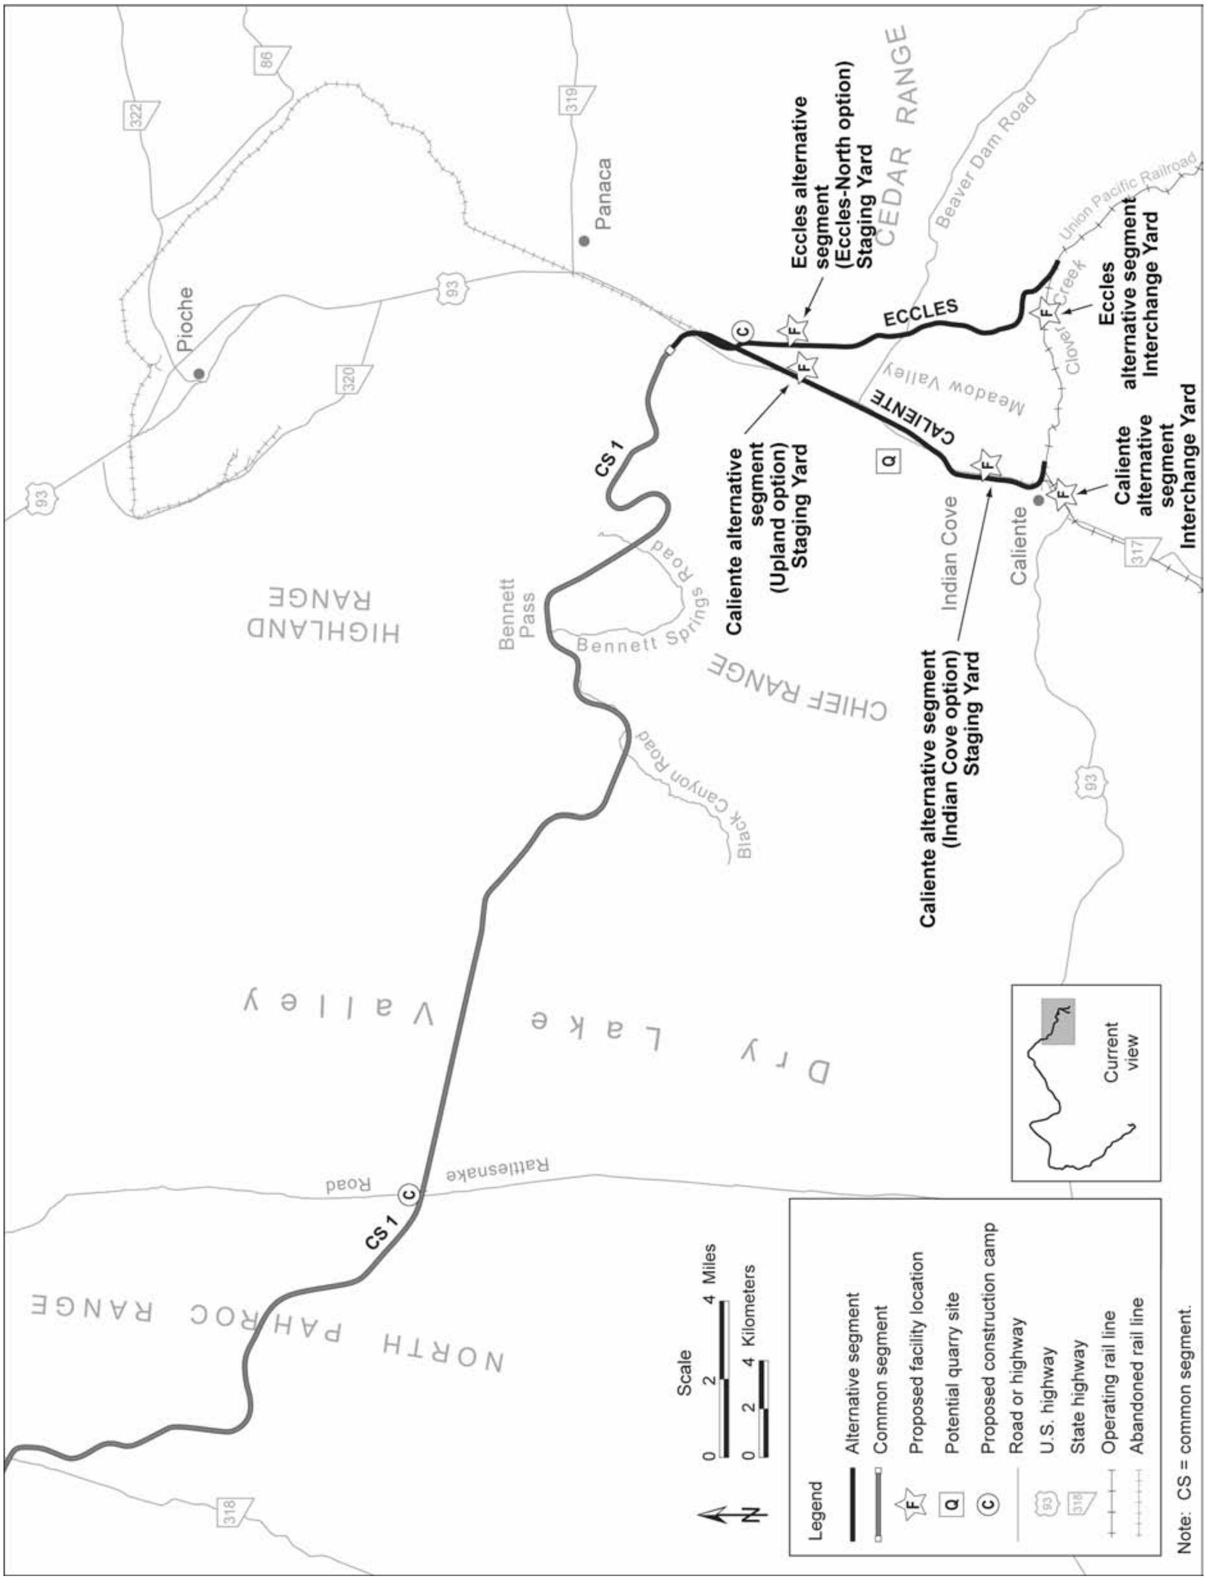

Figure 2-5. Common segments, alternative segments, and related sites within Caliente map area 1.

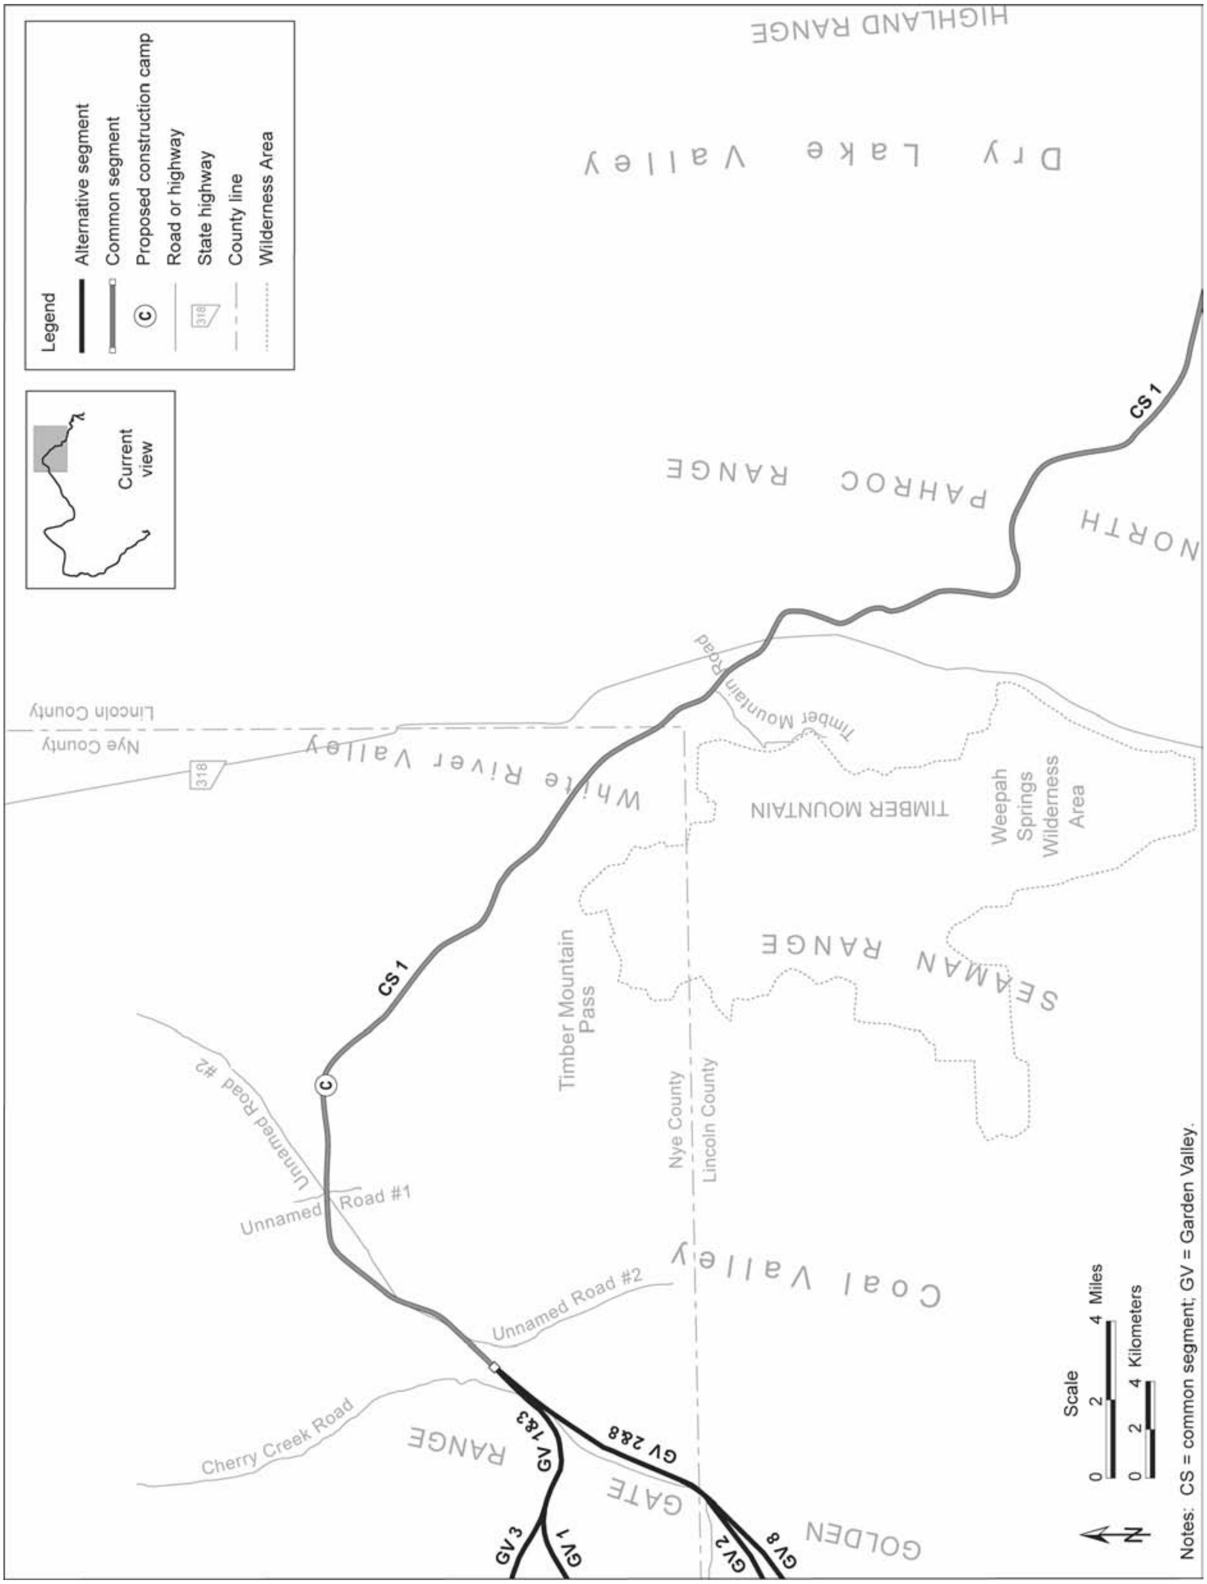

Figure 2-6. Common segments, alternative segments, and related sites within Caliente map area 2.

and then west, passing the northern end of the Seaman Range before turning southwest through Coal Valley. It would then connect to one of the Garden Valley alternative segments about 8 kilometers (5 miles) north of the Lincoln and Nye County line and 28 kilometers (17 miles) west of Nevada Route 318 (see Figure 2-7). Caliente common segment 1 would be approximately 110 kilometers (71 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-5).

2.2.1.1.3 Garden Valley Alternative Segments

DOE is considering four alternative segments in the Garden Valley area, referred to as Garden Valley 1, 2, 3, and 8, and shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 110 through 179) and on Figure 2-7.

Garden Valley alternative segment 1 would begin at the end of Caliente common segment 1 and run due west through the Golden Gate Range for about 7 kilometers (4 miles), trend in a southwesterly direction through Garden Valley, cross the Lincoln and Nye County line, and connect to Caliente common segment 2 about 5 kilometers (3 miles) north of the Worthington Mountains Wilderness Area. Garden Valley alternative segment 1 would be approximately 35 kilometers (22 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-6).

Garden Valley alternative segment 2 would begin at the end of Caliente common segment 1 and run to the south of the locations of Garden Valley alternative segments 1 and 3 (see below), crossing the Lincoln and Nye County line. Garden Valley 2 would continue southwestwardly through the Golden Gate Range at Water Gap, turn westward through Garden Valley, and continue southwesterly to connect to Caliente common segment 2 about 5 kilometers (3 miles) north of the Worthington Mountains Wilderness Area. Garden Valley alternative segment 2 would be about 35 kilometers (22 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-6).

Garden Valley alternative segment 3 would begin at the end of Caliente common segment 1 and run due west through the Golden Gate Range and then in a northwesterly direction until turning southwest to run along the southeast base of the Quinn Canyon Range. Continuing in a southwesterly direction, it would run through Garden Valley, cross the Lincoln and Nye County line, and connect to Caliente common segment 2 about 5 kilometers (3 miles) north of the Worthington Mountains Wilderness Area. Garden Valley alternative segment 3 would be approximately 37 kilometers (23 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-6).

Garden Valley alternative segment 8 would begin at the end of Caliente common segment 1 and run to the south of the locations of Garden Valley alternative segments 1 and 3, crossing the Lincoln and Nye County line and paralleling Cherry Creek Road. It would continue southwestwardly through the Golden Gate Range at Water Gap, would turn westward through Garden Valley, parallel Garden Valley Road, and run in a southwesterly direction before turning sharply westward. Garden Valley alternative segment 8 would proceed westward and connect to Caliente common segment 2 about 5 kilometers (3 miles) north of the Worthington Mountains Wilderness Area. Garden Valley alternative segment 8 would be about 37 kilometers (23 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-6).

2.2.1.1.4 Caliente Common Segment 2 (Quinn Canyon Range Area)

Caliente common segment 2 is shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 180 through 219) and on Figures 2-7 and 2-8. It would begin at the west end of Garden Valley and would trend southwest through Sand Springs Valley. It would cross State Route 375 near the south end of Railroad Valley before connecting to one of the South Reveille alternative segments near the southern end of the Reveille Range. Caliente common segment 2 would be approximately 50 kilometers (31 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-7).

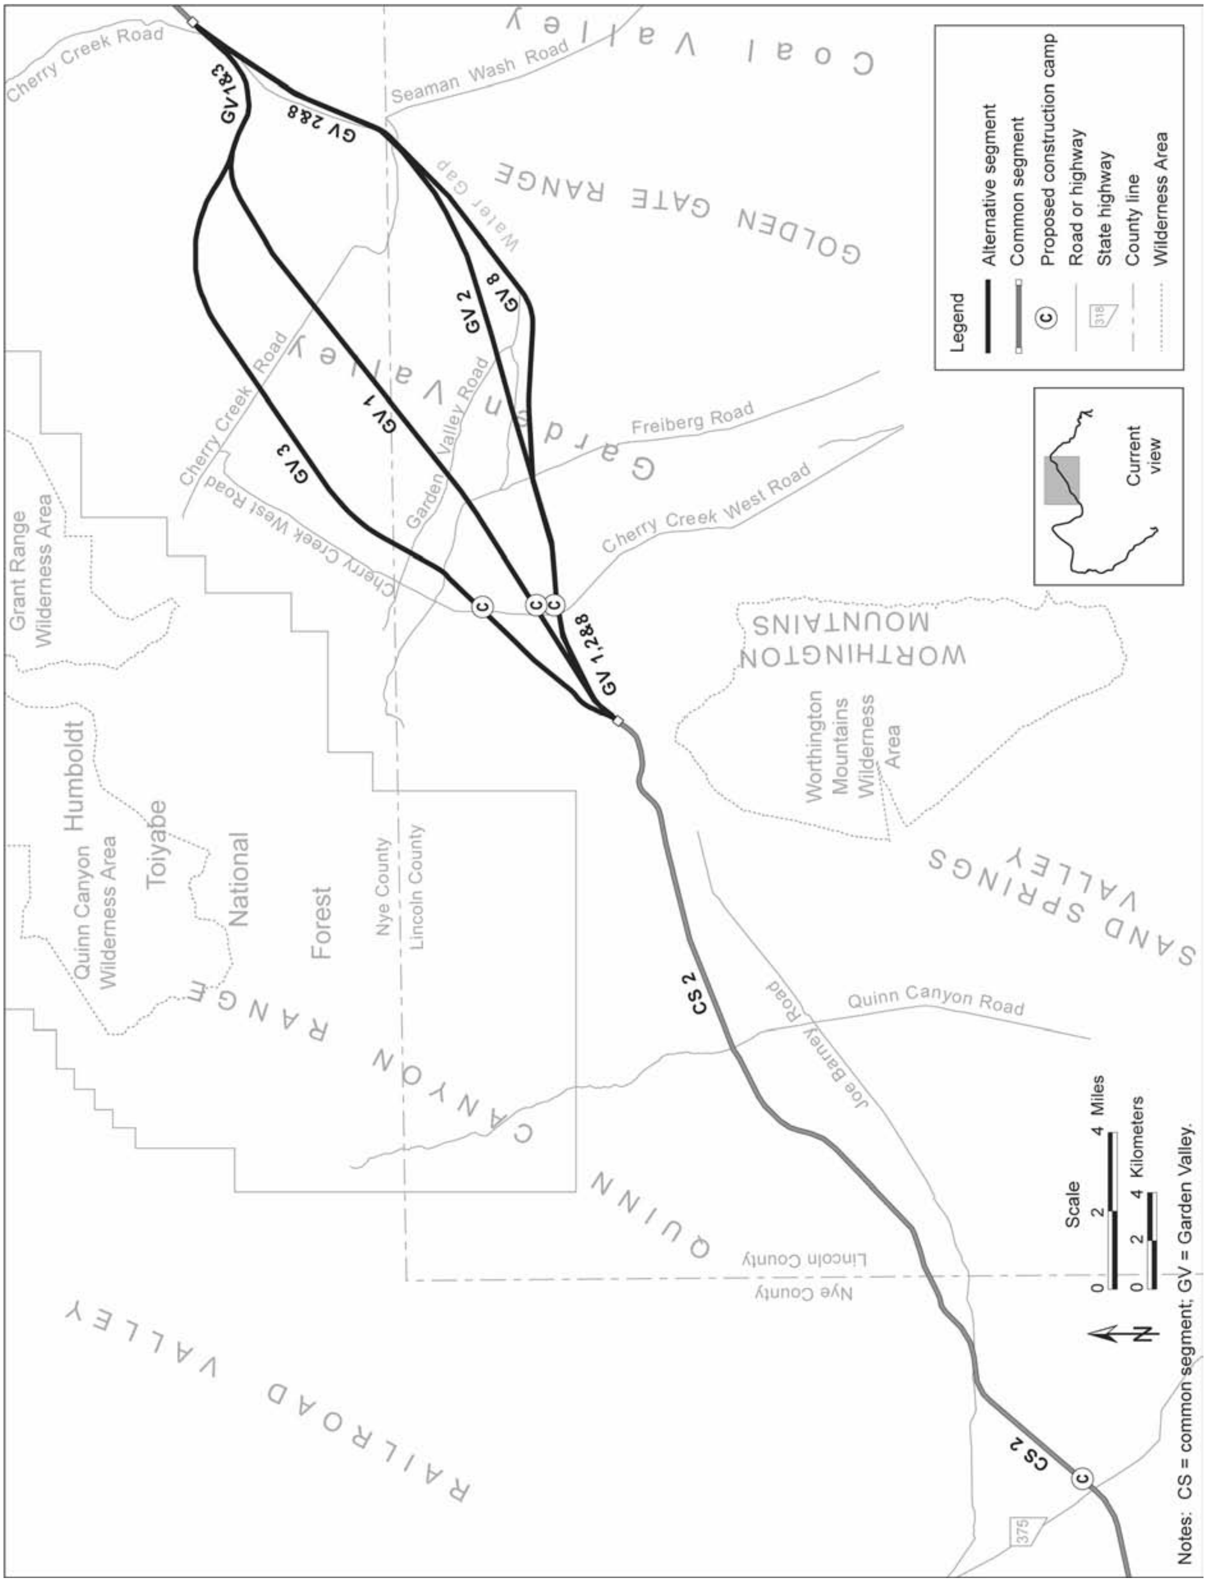

Figure 2-7. Common segments, alternative segments, and related sites within Caliente map area 3.

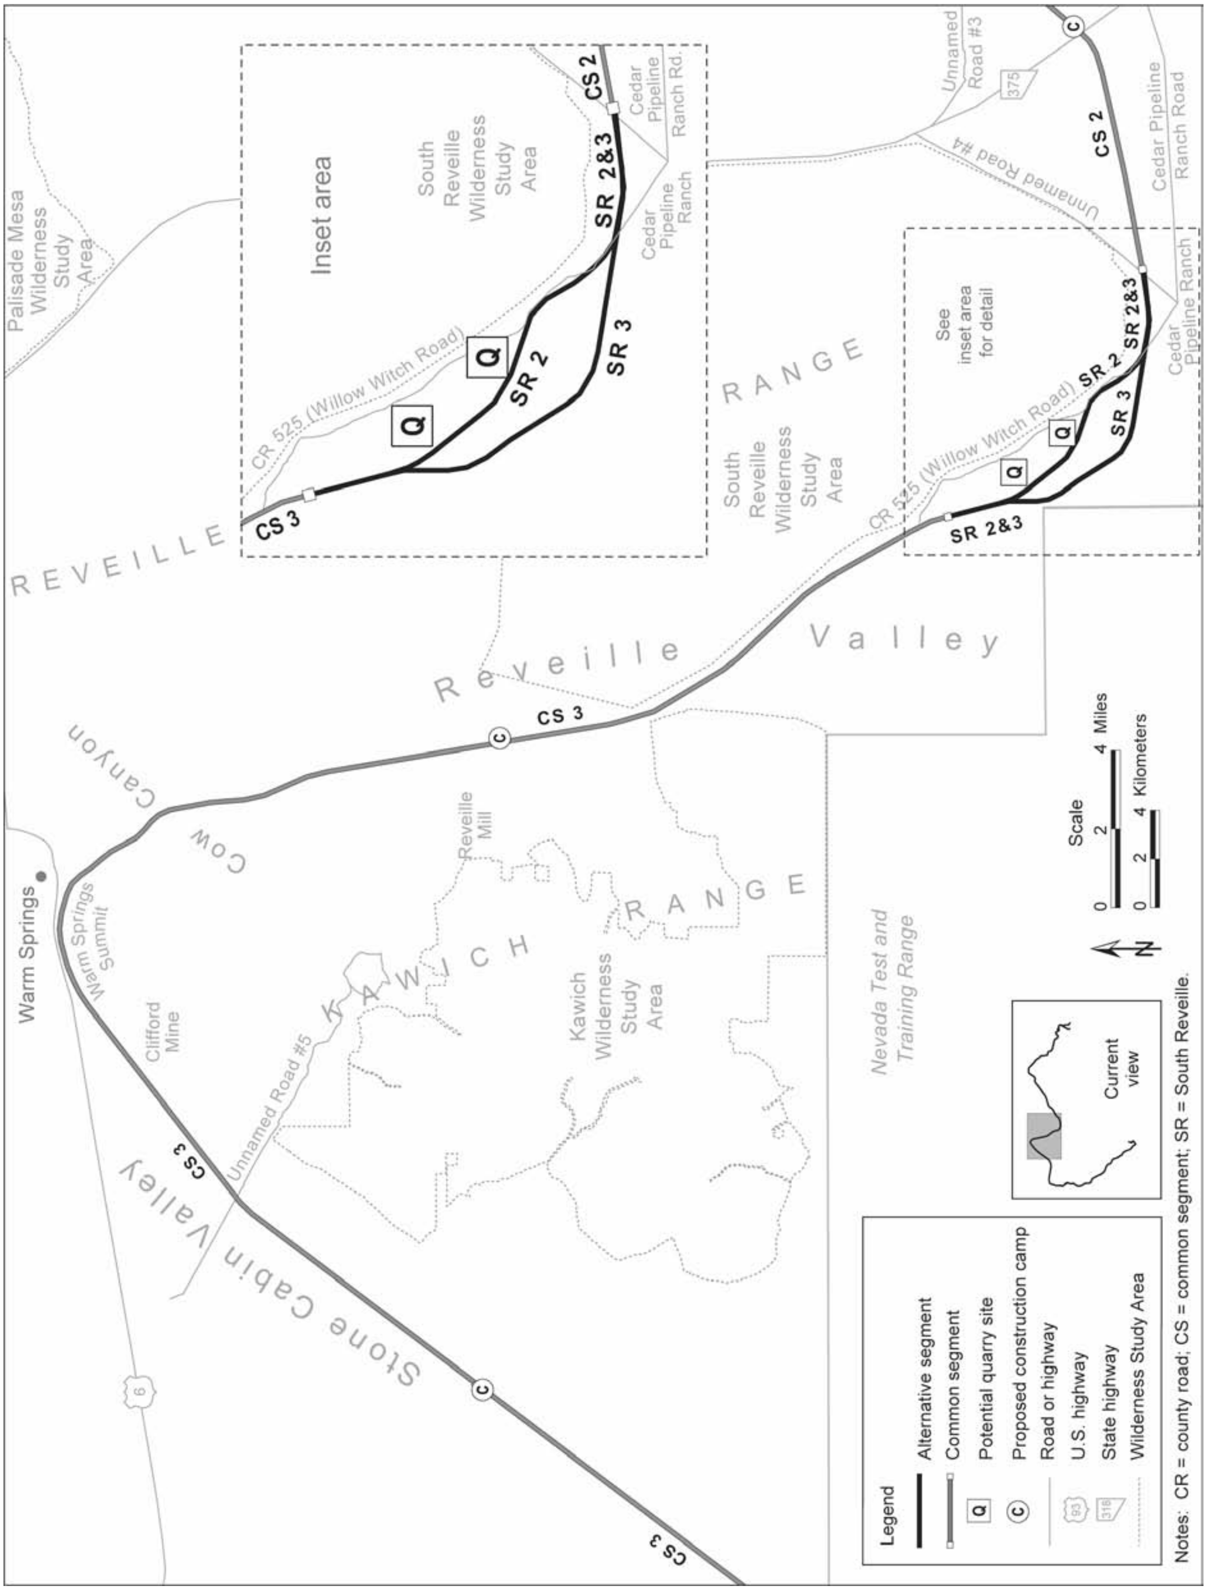

Figure 2-8. Common segments, alternative segments, and related sites within Caliente map area 4.

2.2.1.1.5 South Reveille Alternative Segments

DOE is considering two alternative segments southwest of the South Reveille Wilderness Study Area. These are referred to as South Reveille alternative segments 2 and 3 and are shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 220 through 238) and on Figure 2-8.

Either of these alternative segments would begin 5 kilometers (3 miles) south of the South Reveille Wilderness Study Area at the end of Caliente common segment 2. South Reveille alternative segment 2 would trend to the northwest along the border of the South Reveille Wilderness Study Area. South Reveille alternative segment 3 would trend northwest a few kilometers to the west and roughly parallel to South Reveille alternative segment 2. South Reveille alternative segment 2 or 3 would connect to Caliente common segment 3 in Reveille Valley about 14 kilometers (9 miles) west of State Route 375. South Reveille alternative segment 2 would be approximately 18.8 kilometers (11.7 miles) long and South Reveille alternative segment 3 would be approximately 19.8 kilometers (12.3 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-8).

2.2.1.1.6 Caliente Common Segment 3 (Stone Cabin Valley Area)

Caliente common segment 3 is shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 239 through 319) and on Figures 2-8 and 2-9. It would begin at the end of South Reveille alternative segment 2 or 3 in Reveille Valley, run north across Cow Canyon before turning to the southwest at Warm Springs Summit in the Kawich Range, and run to the southwest around the Kawich Range and turn to the west approximately 3 kilometers (2 miles) north of the Nevada Test and Training Range. It would continue west through Ralston Valley before connecting to one of the Goldfield alternative segments, just east of the Esmeralda and Nye County line. Caliente comment segment 3 would be approximately 110 kilometers (70 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-9).

2.2.1.1.7 Goldfield Alternative Segments

DOE is considering three alternative segments in the Goldfield area. These are referred to as Goldfield alternative segments 1, 3, and 4 and are shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 320 through 392) and on Figure 2-9.

Goldfield alternative segment 1 would extend south into the Goldfield Hills area, passing east of Black Butte. It would turn east near Espina Hill and head south to the east of Blackcap Mountain. It would wind around a series of hills and valleys to maintain an acceptable ***grade*** to meet the rail line design criteria. Goldfield 1 would run for approximately 11 kilometers (7 miles) along an abandoned rail line before joining Caliente common segment 4. In total, Goldfield alternative segment 1 would be approximately 47 kilometers (29 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-10).

Goldfield alternative segment 3 would extend south into the Goldfield Hills area and farther to the east than the other Goldfield alternative segments. Similar to Goldfield alternative segment 1, Goldfield alternative segment 3 would wind around a series of hills and valleys to maintain an acceptable grade to meet the rail line design criteria. Also like Goldfield alternative segment 1, Goldfield alternative segment 3 would run for approximately 11 kilometers (7 miles) along an abandoned rail line before joining Caliente common segment 4. In total, Goldfield alternative segment 3 would be approximately 50 kilometers (31 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-10).

The western Goldfield alternative segment, Goldfield 4, would depart Caliente common segment 3 to the north of Black Butte and trend southwest. It would then cross U.S. Highway 95 and turn south toward Goldfield. After passing through the southwestern edge of Goldfield and crossing U.S. Highway 95

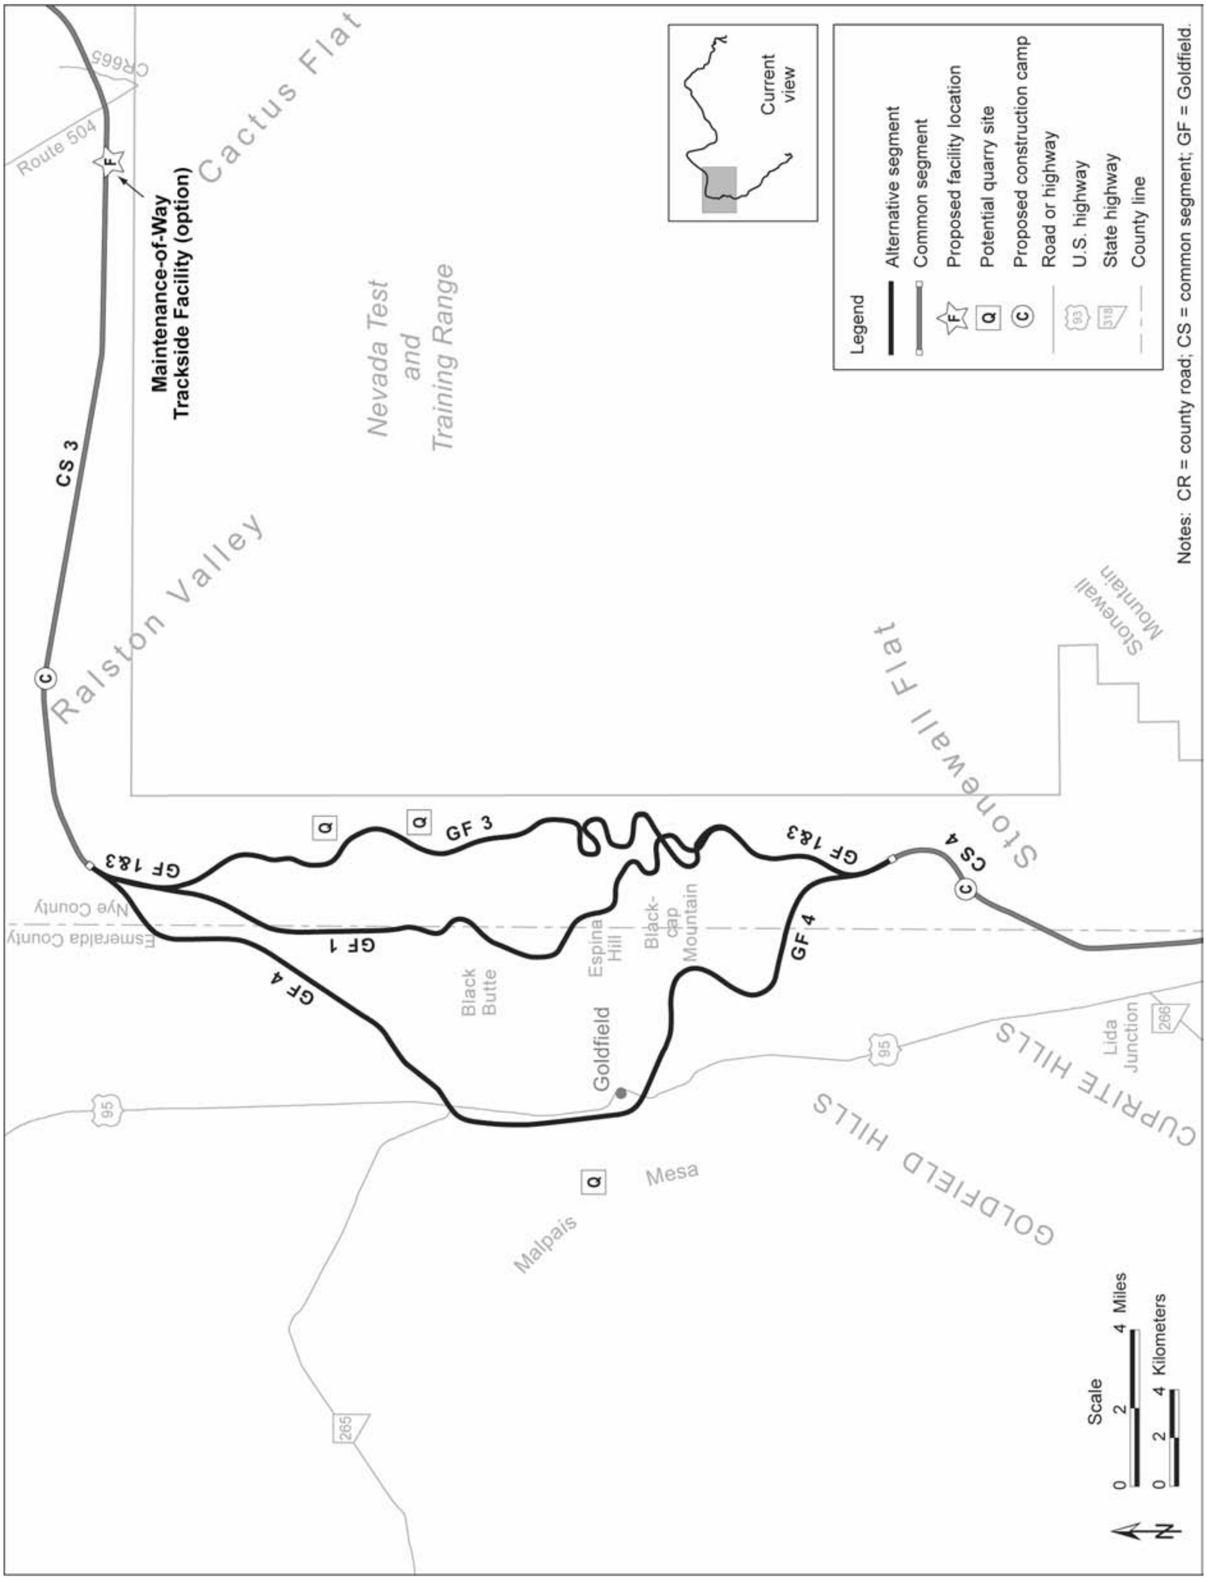

Figure 2-9. Common segments, alternative segments, and related sites within Caliente map area 5.

again, Goldfield alternative segment 4 would turn south to connect with Caliente common segment 4. Goldfield alternative segment 4 would be approximately 53 kilometers (33 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-8).

2.2.1.1.8 Caliente Common Segment 4 (Stonewall Flat Area)

Caliente common segment 4 is shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 393 through 399) and on Figures 2-9 and 2-10. It would run south through Stonewall Flat along the Esmeralda and Nye County line. It would end about 6 kilometers (3.5 miles) southeast of the intersection of State Route 266 and U.S. Highway 95, and 8 kilometers (5 miles) north of Stonewall Pass, where it would connect to one of the Bonnie Claire alternative segments. Caliente common segment 4 would be approximately 11 kilometers (7 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-10).

2.2.1.1.9 Bonnie Claire Alternative Segments

DOE is considering two alternative segments in the area north of Scottys Junction, Bonnie Claire alternative segments 2 and 3, which are shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 399 through 424) and on Figure 2-10.

Bonnie Claire alternative segment 3 would begin at the end of Caliente common segment 4 about 8 kilometers (5 miles) north of Stonewall Pass. Bonnie Claire alternative segment 3 would trend generally south, paralleling U.S. Highway 95 to the east. After approximately 10 kilometers (6 miles), it would turn southeast and continue for an additional 10 kilometers through Sarcobatus Flat, where it would join common segment 5 approximately 4 kilometers (2 miles) north of Scottys Junction near the intersection of State Route 267 and U.S. Highway 95. Bonnie Claire alternative segment 3 would be approximately 19 kilometers (12 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-11).

Bonnie Claire alternative segment 2 would begin at the end of Caliente common segment 4 about 8 kilometers (5 miles) north of Stonewall Pass and would trend east toward the Nevada Test and Training Range for about 5 kilometers (3 miles) before turning south for an additional 17 kilometers (11 miles). Bonnie Claire alternative segment 2 would generally follow the Nevada Test and Training Range boundary and would join common segment 5 in Sarcobatus Flat to the north of Scottys Junction near the intersection of State Route 267 and U.S. Highway 95. Bonnie Claire alternative segment 2 would be approximately 21 kilometers (13 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-11).

2.2.1.1.10 Common Segment 5 (Sarcobatus Flat Area)

Common segment 5 is shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 425 through 452) and on Figures 2-10 and 2-11. This common segment would begin 4 kilometers (2 miles) north of Scottys Junction and trend generally southeast through the Sarcobatus Flat area, approximately 100 meters (330 feet) east of U.S. Highway 95 at its closest point. Common segment 5 would end approximately 6 kilometers (4 miles) north of Springdale, where it would connect to one of the Oasis Valley alternative segments. Common segment 5 would be about 40 kilometers (25 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-12).

2.2.1.1.11 Oasis Valley Alternative Segments

DOE is considering two alternative segments in the Oasis Valley area, Oasis Valley alternative segments 1 and 3, which are shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 453 through 466) and on Figure 2-11.

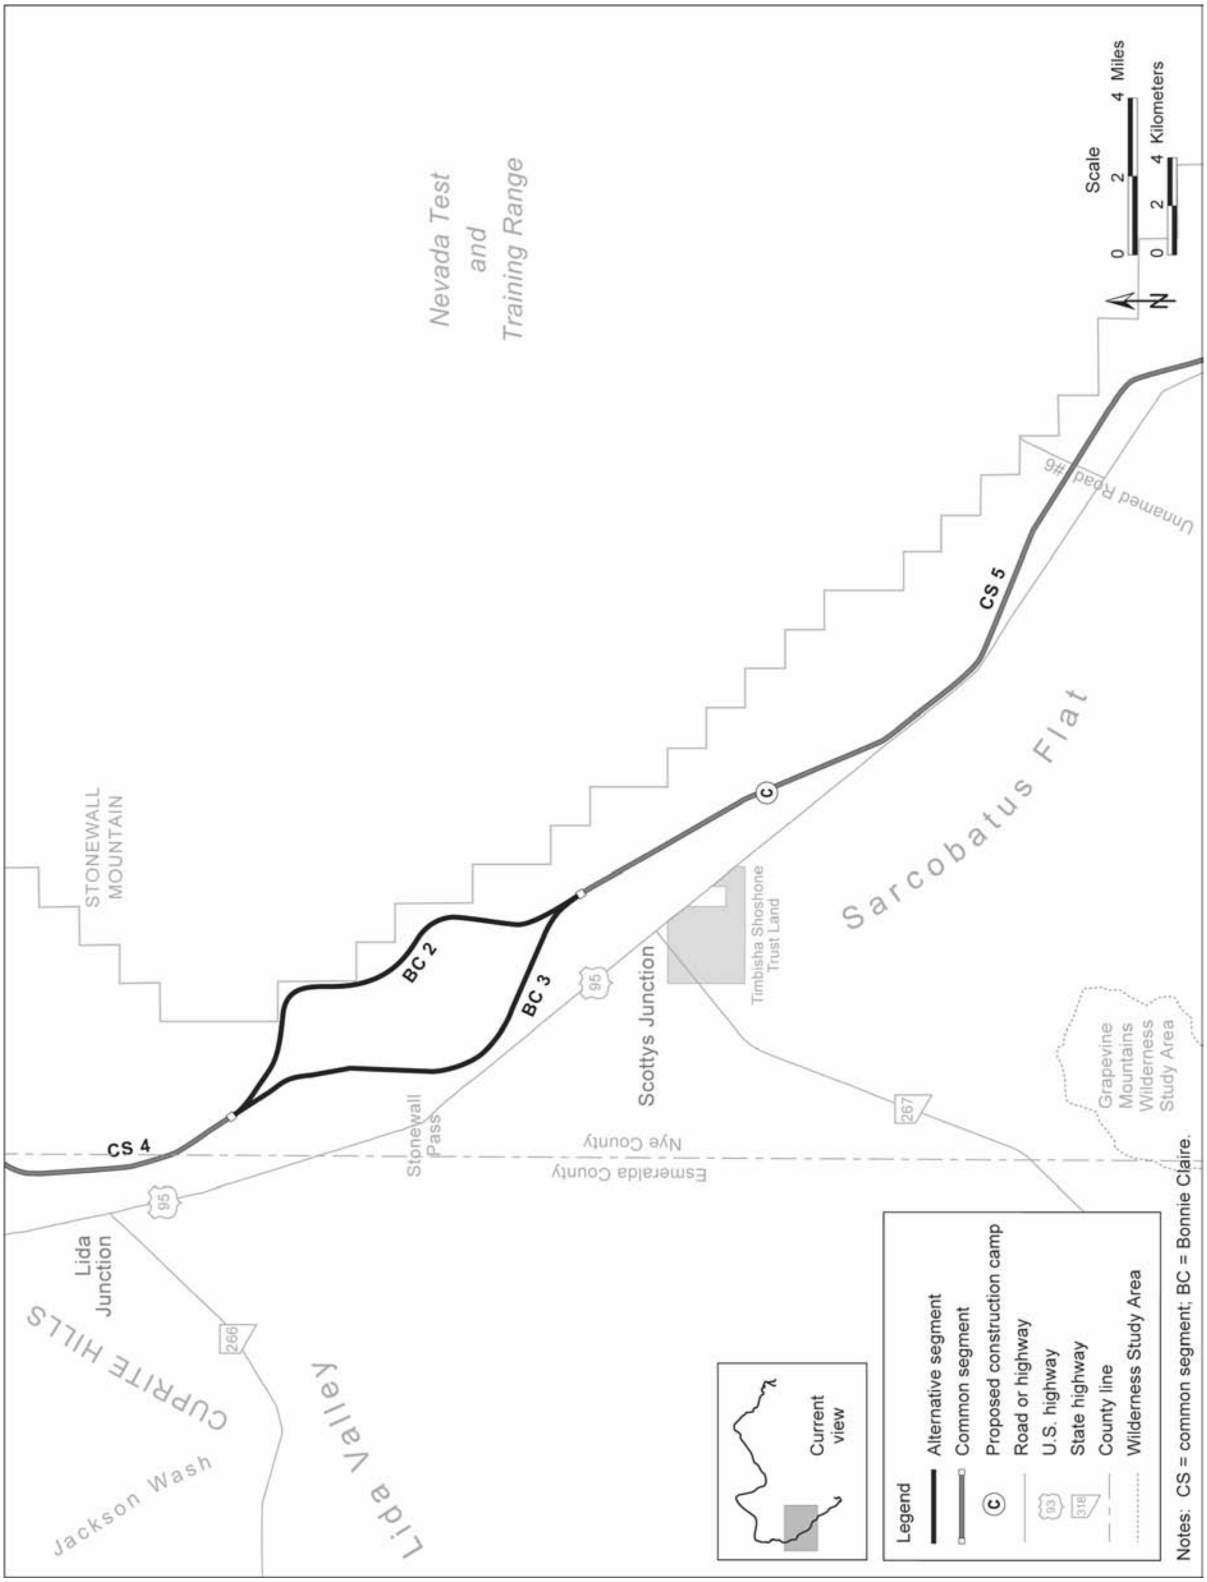

Figure 2-10. Common segments, alternative segments, and related sites within Caliente map area 6.

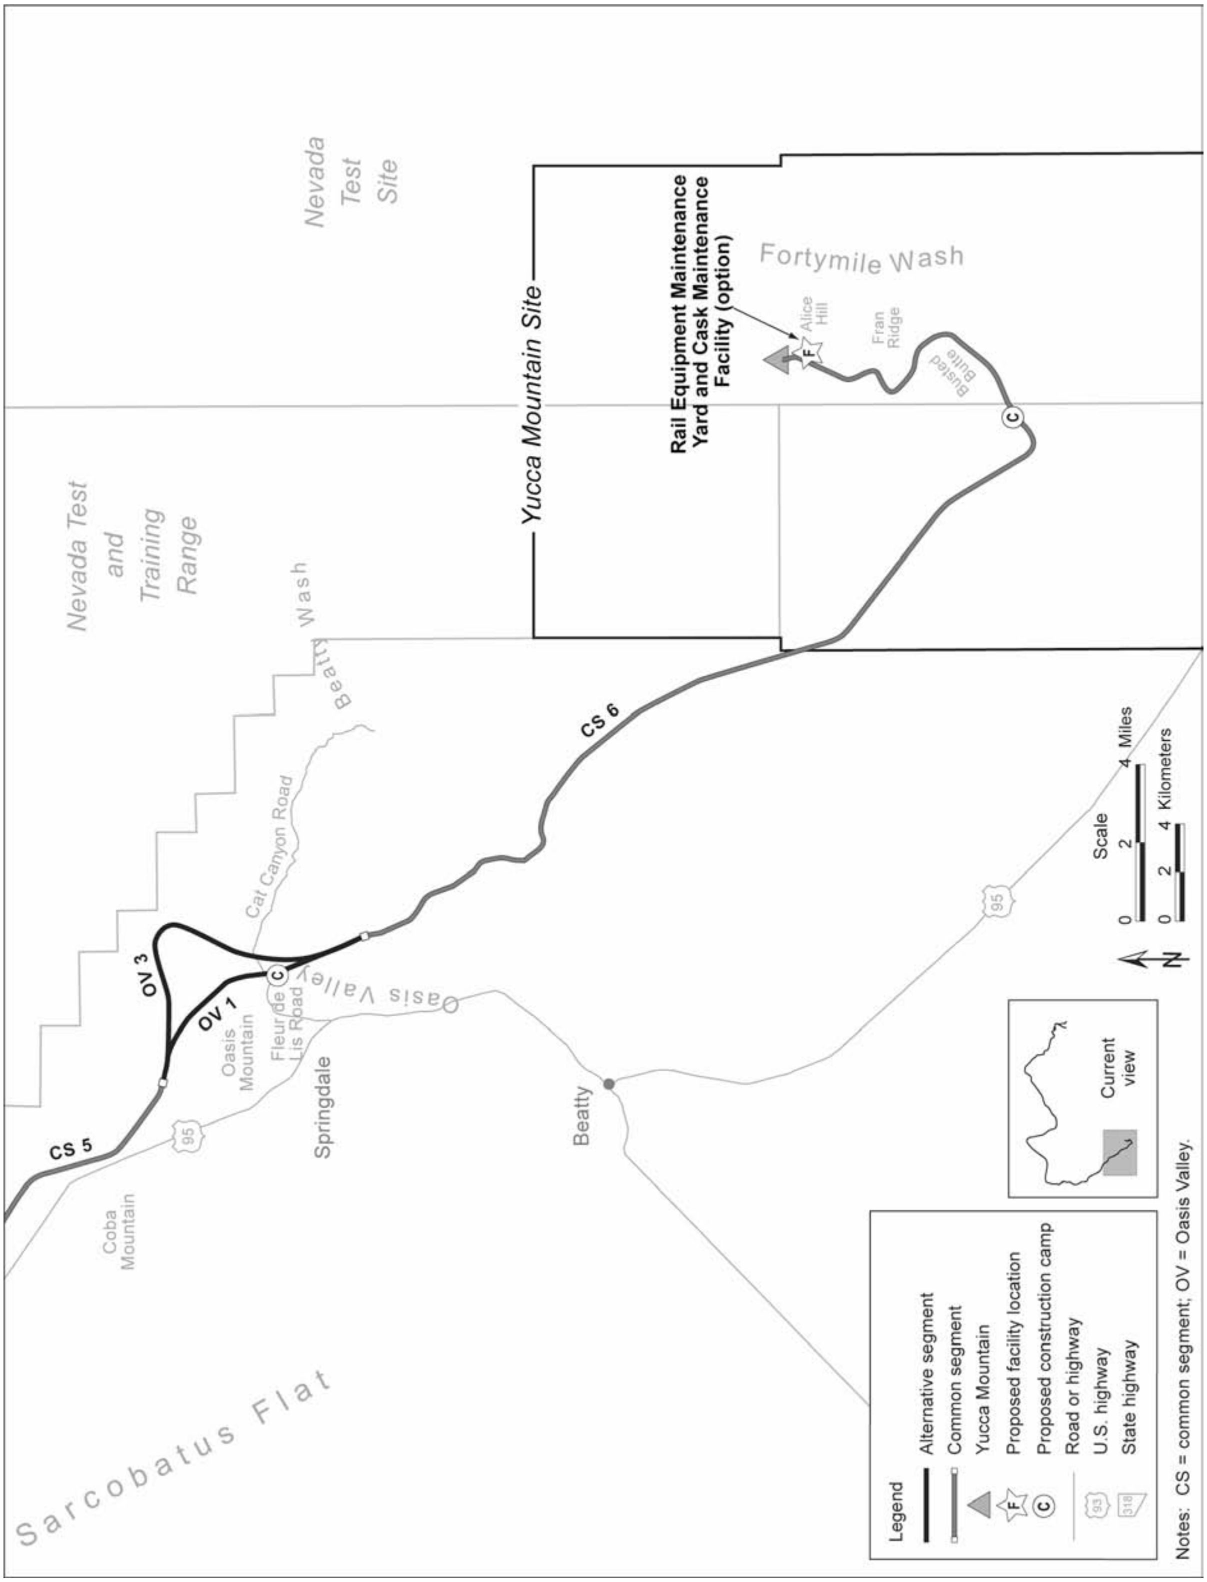

Figure 2-11. Common segments, alternative segments, and related sites within Caliente map area 7.

Oasis Valley alternative segment 1 would begin at the end of common segment 5 approximately 6 kilometers (4 miles) north of Springdale, and would run southeast to connect to common segment 6. Oasis Valley alternative segment 1 would be approximately 10 kilometers (6 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-13).

Oasis Valley alternative segment 3 would begin at the end of common segment 5 approximately 6 kilometers (4 miles) north of Springdale, and would run generally east and then south before crossing Oasis Valley farther to the east than Oasis Valley 1 and connecting to common segment 6. Oasis Valley alternative segment 3 would be 14 kilometers (9 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-13).

2.2.1.1.12 Common Segment 6 (Yucca Mountain Approach)

Common segment 6, shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 466 through 500) and on Figure 2-11, would begin about 3 kilometers (2 miles) east of U.S. Highway 95. This common segment would trend generally southeast for 40 kilometers (25 miles) from Oasis Valley to Beatty Wash. It would then turn north at the southern end of Busted Butte, running west of Fran Ridge and then trending generally north for an additional 11 kilometers (7 miles) until terminating at the Rail Equipment Maintenance Yard inside the ***Yucca Mountain Site boundary***. Common segment 6 would be approximately 51 kilometers (32 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-14).

2.2.1.2 Mina Rail Alignment

This section describes the existing Union Pacific Railroad Hazen Branchline between Hazen and Wabuska and the existing rail lines, alternative segments, and common segments along the Mina rail alignment, which would extend from near Wabuska to the Rail Equipment Maintenance Yard inside the Yucca Mountain Site boundary.

DOE would need to ship spent nuclear fuel, high-level radioactive waste, and other materials over the existing Union Pacific Railroad Hazen Branchline before transferring the cargo to the proposed railroad. This shipping activity would increase train traffic from approximately eight one-way trains to 17 one-way trains per week. Because this activity would cause rail traffic on the branchline to increase by more than 100 percent, Surface Transportation Board (STB) regulations require that DOE analyze the operations impacts of the increased traffic along the line. Therefore, although DOE does not consider the Union Pacific Railroad Hazen Branchline part of the Mina rail alignment, it is included in this Rail Alignment EIS for the purposes of analyzing these operations impacts.

Operation of the proposed railroad along the Mina rail alignment would also require operating on portions of existing Department of Defense Branchlines. These existing rail lines are described below for purposes of proposed railroad operations only; there would be no new track construction along these existing rail lines. However, DOE would install sidings (described in Section 2.2.6.2) and a fiber-optic communications cable (described in Section 2.2.2.9) along these existing branchlines. Additionally, as part of routine operations and maintenance, DOE would expect to perform maintenance activities along Department of Defense Branchlines North and South. Section 2.2.3.2 describes these maintenance activities.

Figure 2-12 shows the Union Pacific Railroad Hazen Branchline and the Mina rail alignment divided into eight map areas, starting with Mina map area 1 near Hazen (to the north) and ending with Mina map area 8 at the end of the rail alignment (to the south). Figures in Section 2.2.1.2.1 through 2.2.1.2.11 show existing rail lines, alternative segments, and common segments within each of these map areas. The Map Atlas (DIRS 182844-ICF 2007, Part B) contains more than 500 detailed maps depicting all of the Mina

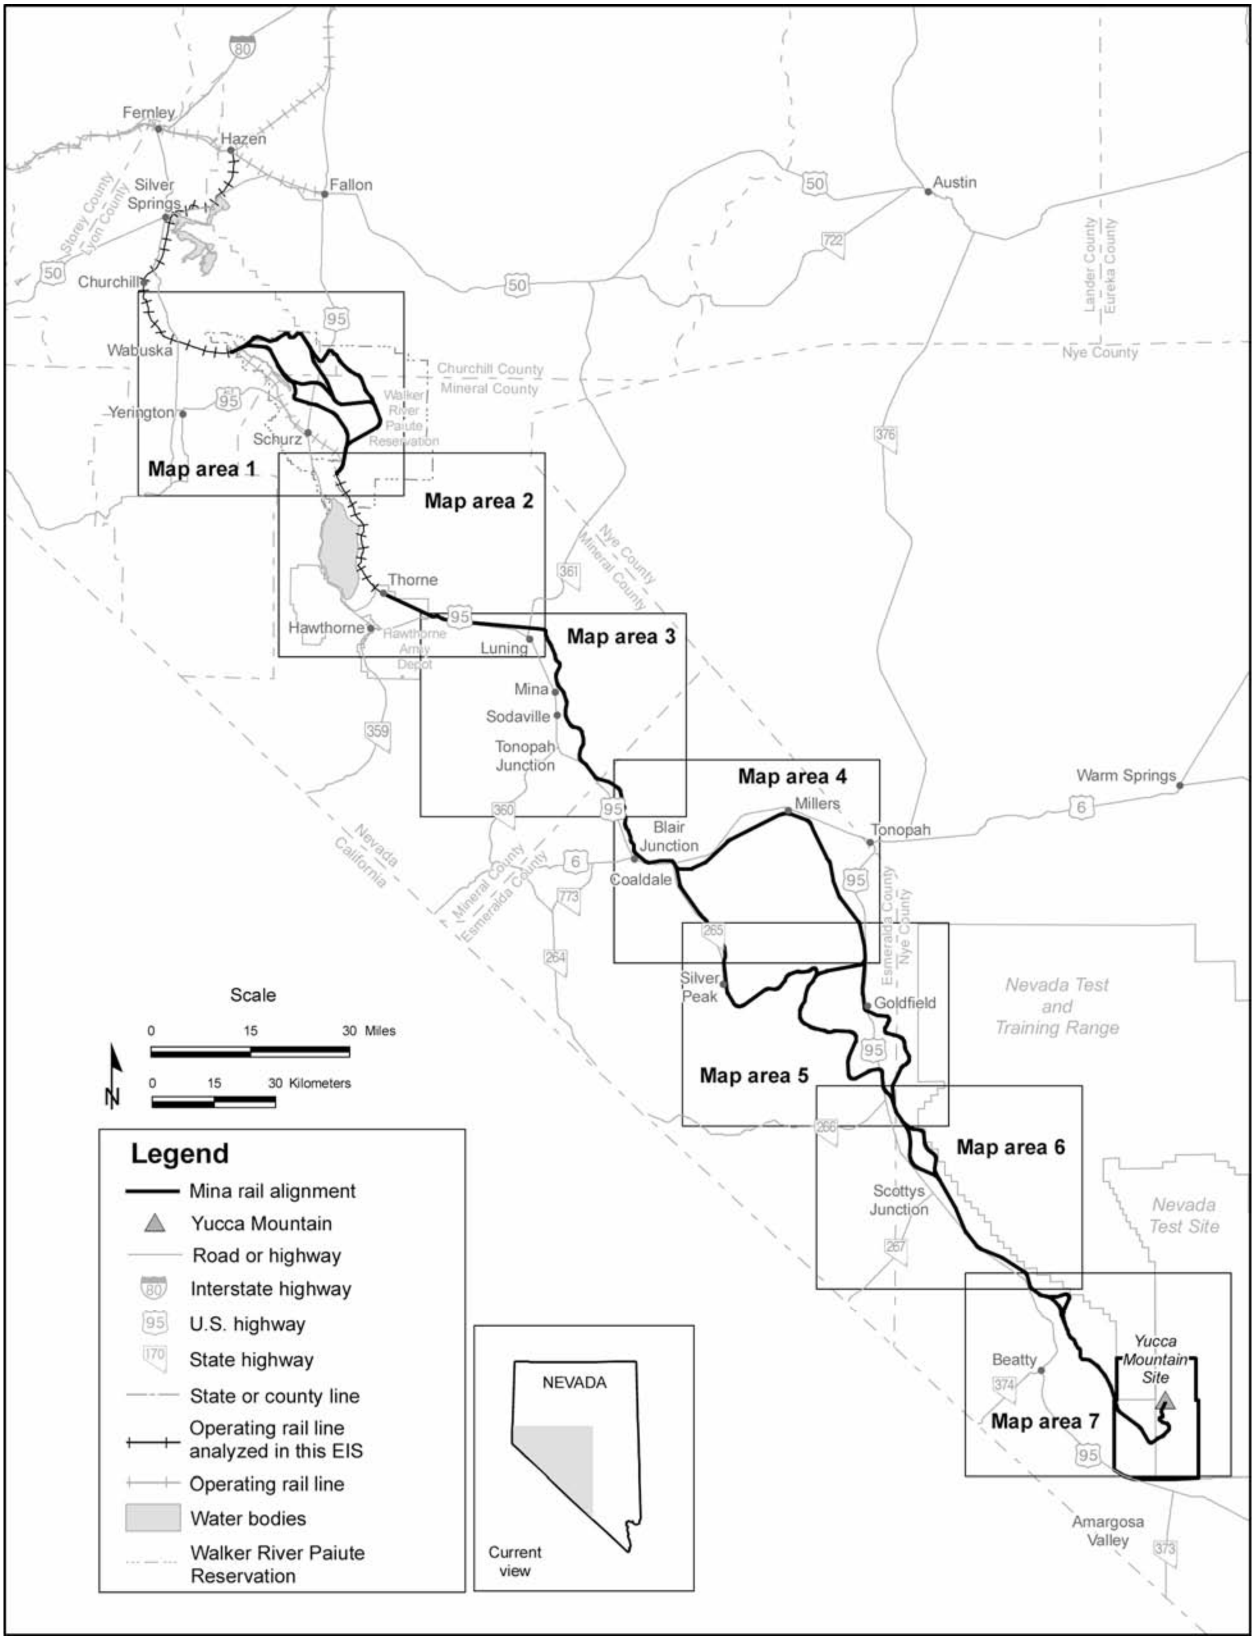

Figure 2-12. Map key for areas along the Mina rail alignment.

alternative segments and common segments, railroad operations support facilities, and engineered features, such as cut and fill areas.

2.2.1.2.1 Union Pacific Railroad Hazen Branchline

The Union Pacific Railroad Hazen Branchline, shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 1 to 46) and on Figure 2-13, is an existing rail line that begins near Hazen, Nevada. From Hazen, it runs south and then southwest for approximately 11 kilometers (7 miles) before meeting and paralleling U.S. Highway 50 west for about 13 kilometers (8 miles) north of the Lahontan Reservoir. The rail line then crosses U.S. Highway 50 and turns southwest about 1.5 kilometers (1 mile) east of Silver Springs. It continues south for the next 16 kilometers (10 miles), flanking Alternate U.S. Highway 95 to the east. The rail line then crosses Alternate U.S. Highway 95 and trends southwest for about 3 kilometers (2 miles) before turning south for the next 14 kilometers (9 miles). The rail line then turns east for 4 kilometers (2.5 miles) and crosses Alternate U.S. Highway 95 at Wabuska. The Union Pacific Railroad Hazen Branchline connects with Department of Defense Branchline North approximately 3 kilometers after crossing Alternate U.S. Highway 95. In total, the Union Pacific Railroad Hazen Branchline is approximately 69 kilometers (43 miles) long, as shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 1 to 46).

There is existing rail traffic along the Union Pacific Railroad Hazen Branchline that would continue during and after construction of the proposed railroad. For purposes of analysis in this EIS, DOE estimated that approximately four one-way Union Pacific Railroad trains en route to Wabuska and four one-way Department of Defense trains en route to the Hawthorne Army Depot would run on this portion of the rail line per week.

2.2.1.2.2 Department of Defense Branchline North

Department of Defense Branchline North is shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 47 through 55) and on Figure 2-13. It is an existing rail line that begins east of Wabuska. It trends east through a valley just south of Parker Butte and north of the Mason Valley Wildlife Management Area. In total, Department of Defense Branchline North is about 8.1 kilometers (5 miles) long, as shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 47 to 55).

There is existing rail traffic along Department of Defense Branchline North that would continue after construction of the proposed railroad. For purposes of analysis in this EIS, DOE estimated that approximately four one-way Department of Defense trains would run on this portion of the rail line per week.

2.2.1.2.3 Schurz Alternative Segments

At present, the Department of Defense Branchline runs south directly through Schurz on the Walker River Paiute Reservation. This Rail Alignment EIS refers to this portion of existing rail line as Department of Defense Branchline through Schurz. Under the Mina Implementing Alternative, DOE would remove this portion of the Department of Defense Branchline, and by way of the Schurz alternative segments, the rail alignment would bypass Schurz. Rail line removal activities would include removing all portions of the track and ties, but leaving the rail roadbed in place. DOE is considering four alternative segments to bypass Schurz to the east and connect the proposed railroad to existing Department of Defense Branchline North east of Wabuska. These four alternative segments are referred to as Schurz 1, 4, 5, and 6 and are shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 54 to 154) and on Figure 2-13.

Schurz alternative segment 1 would begin at the end of the existing Department of Defense Branchline North, would cross the Walker River, and would trend east and then southeast, roughly parallel to the

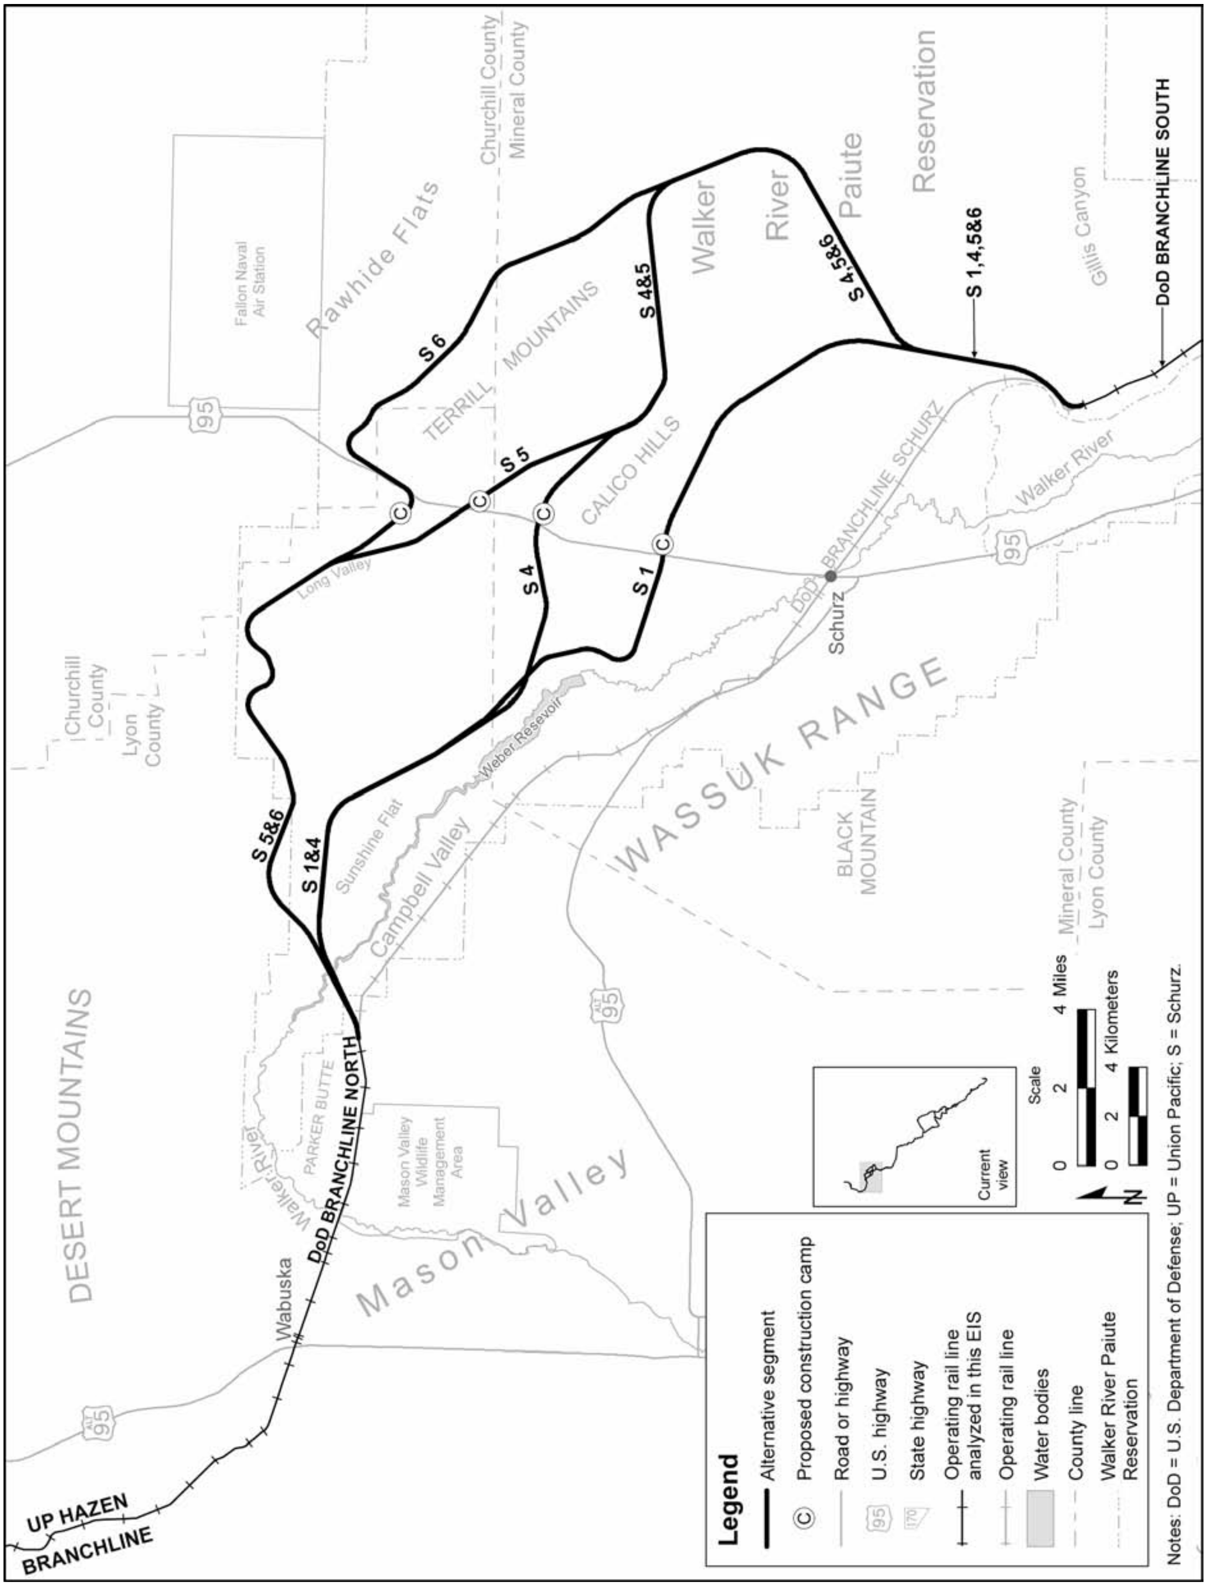

Figure 2-13. Mina rail alignment map area 1.

Walker River, for approximately 10 kilometers (6 miles). From the Walker River, Schurz alternative segment 1 would continue in a southeasterly and then easterly direction for approximately 6 kilometers (4 miles). It would trend to the south through Sunshine Flat for approximately 19 kilometers (12 miles). After crossing U.S. Highway 95 with a ***grade-separated crossing***, the rail line would pass south of the Calico Hills. Schurz alternative segment 1 would continue south for another 6 kilometers before joining the existing Department of Defense Branchline South. Schurz alternative segment 1 would be about 52 kilometers (32 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E).

Schurz alternative segment 4 would begin at the end of the existing Department of Defense Branchline North, would cross the Walker River, and would trend east and then southeast, roughly parallel to the Walker River, for approximately 10 kilometers (6 miles). From the Walker River, the rail line would trend generally southeast and east for about approximately 12 kilometers (7.5 miles) and would cross U.S. Highway 95 with a grade-separated crossing. Between the Terrill Mountains and Calico Hills, it would run due east for about 11 kilometers (7 miles). It would then trend southwest for approximately 16 kilometers (10 miles) and would continue in a roughly southern direction for about 6 kilometers (4 miles) before joining the existing Department of Defense Branchline South. Schurz alternative segment 4 would be about 64 kilometers (40 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E).

Schurz alternative segment 5 would begin at the end of the existing Department of Defense Branchline North, would cross the Walker River, and would run east for approximately 14 kilometers (9 miles). This alternative segment would then turn southeast and travel through Long Valley and across U.S. Highway 95 with a grade-separated crossing. South of the Terrill Mountains, it would turn due east and run for about 11 kilometers (7 miles). It would then trend south and southwest for approximately 16 kilometers (10 miles). It would continue in a roughly southern direction for about 6 kilometers (4 miles) before joining the existing Department of Defense Branchline South. Schurz alternative segment 5 would be approximately 71 kilometers (44 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E).

Schurz alternative segment 6 would begin at the end of existing Department of Defense Branchline North, would cross the Walker River, and would run east for approximately 14 kilometers (9 miles). This alternative segment would then turn southeast and travel through Long Valley before turning sharply northeast and crossing U.S. Highway 95 and into Churchill County. After following U.S. Highway 95 for about 4 kilometers (2.5 miles), the rail line would then turn southeast and run along the eastern edge of the Terrill Mountains for approximately 16 kilometers (10 miles) and into Mineral County. It would then trend southwest for approximately 16 kilometers. The rail line would continue south for about 6 kilometers (4 miles) before joining the existing Department of Defense Branchline South. Schurz alternative segment 6 would be approximately 72 kilometers (45 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E).

Following construction of one of the Schurz alternative segments, rail traffic on the existing Department of Defense Branchline through Schurz would be diverted to the proposed railroad. For purposes of analysis in this Rail Alignment EIS, DOE estimated that approximately two Department of Defense trains en route to the Hawthorne Army Depot would run on this portion of the rail line per week.

2.2.1.2.4 Department of Defense Branchline South

Department of Defense Branchline South is shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 156 through 175) and on Figure 2-14. It is existing track that starts where the Schurz alternative segments would end, about 13 kilometers (8 miles) south of Schurz. The rail line trends generally south for 10 kilometers (6 miles) before leaving the Walker River Paiute Reservation, and continues generally south for another 24 kilometers (15 miles) on the east side of Walker Lake. Department of Defense Branchline South ends near Hawthorne, where it would join Mina common segment 1. Department of

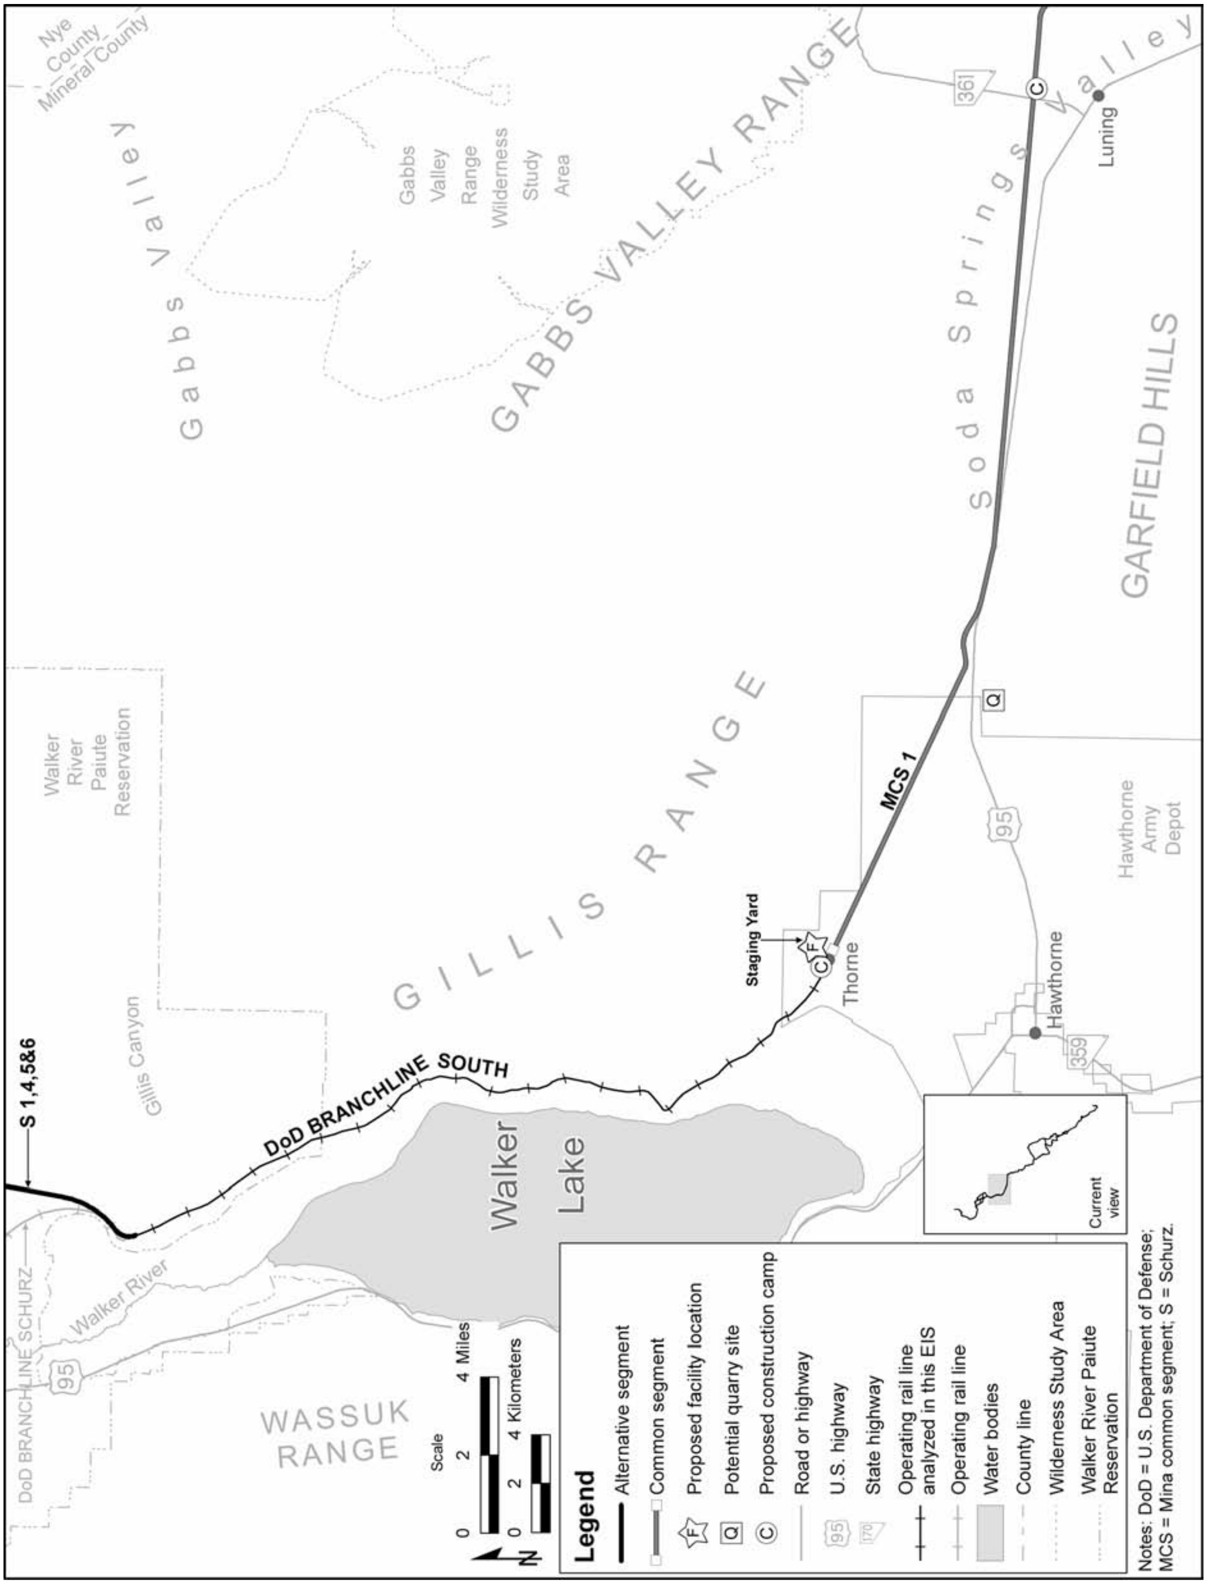

Figure 2-14. Mina rail alignment map area 2.

Defense Branchline South is approximately 35 kilometers (22 miles) long, as shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 156 to 175).

There is existing rail traffic along Department of Defense Branchline South that would continue during and after construction of the proposed railroad. For purposes of analysis in this EIS, DOE estimated that approximately four one-way Department of Defense trains en route to the Hawthorne Army Depot would run on this portion of the rail line per week.

2.2.1.2.5 Mina Common Segment 1 (Soda Spring Valley Area)

Mina common segment 1 is shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 174 through 255) and on Figures 2-15 and 2-16. It would begin north of Hawthorne and would trend southeast before turning east at U.S. Highway 95. It would trend east along U.S. Highway 95 through Soda Springs Valley for approximately 40 kilometers (25 miles). Continuing to parallel U.S. Highway 95, the rail line would cross State Route 361 and turn south for approximately 64 kilometers (40 miles). It would pass Luning and Mina, which are along U.S. Highway 95 and would be approximately 1.5 to 3 kilometers (1 to 2 miles) to the east of the rail alignment. The rail line would then turn east before crossing U.S. Highway 95 with a grade-separated crossing in the area of Blair Junction and continuing for about 1.5 kilometers (1 mile) before joining one of the Montezuma alternative segments. Mina common segment 1 would be approximately 116 kilometers (72 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E).

2.2.1.2.6 Montezuma Alternative Segments

DOE is considering three alternative segments in the Montezuma area, referred to as Montezuma alternative segments 1, 2, and 3 and shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 255 through 416) and on Figures 2-16 and 2-17.

Montezuma alternative segment 1 would begin at the end of Mina common segment 1 just southeast of Blair Junction. It would trend roughly southeast along State Route 265 through part of the Big Smoky Valley and west of the Weepah Hills for approximately 37 kilometers (23 miles), passing to the east of Silver Peak in Clayton Valley. It would then turn to the northwest through Clayton Valley and run through a pass between Clayton Ridge and Paymaster Ridge close to Silver Peak Road. It would then trend south for the next 11 kilometers (7 miles) between Clayton Ridge on the west and Montezuma Peak on the east before turning east for about the next 13 kilometers (8 miles), passing to the south of Montezuma Peak. The rail alignment would again turn roughly south for approximately 11 kilometers, traveling to the west of the Goldfield Hills. It would then travel northwest, cross U.S. Highway 95, and turn south before joining Mina common segment 2 near Lida Junction. Montezuma alternative segment 1 would be approximately 117 kilometers (73 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E).

Montezuma alternative segment 2 would begin at the end of Mina common segment 1 just southeast of Blair Junction. It would trend northeast for about 35 kilometers (22 miles) just south of U.S. Highway 95. Northeast of Lone Mountain, it would turn south into Montezuma Valley and run south for 59 kilometers (31 miles) before turning east and crossing U.S. Highway 95 south of Goldfield. It would then trend south for about 37 kilometers (23 miles) before joining Mina common segment 2 near Lida Junction. Montezuma alternative segment 2 would be approximately 119 kilometers (74 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E). Montezuma alternative segment 3 would begin at the end of Mina common segment 1 just southeast of Blair Junction. It would trend northeast for about 35 kilometers (22 miles) just south of U.S. Highway 95. Northeast of Lone Mountain, it would turn south into Montezuma Valley and trend south for 37 kilometers (23 miles). North of Goldfield, it would turn west and trend along the northern portion of the Montezuma Range for 12 kilometers (7.5 miles).

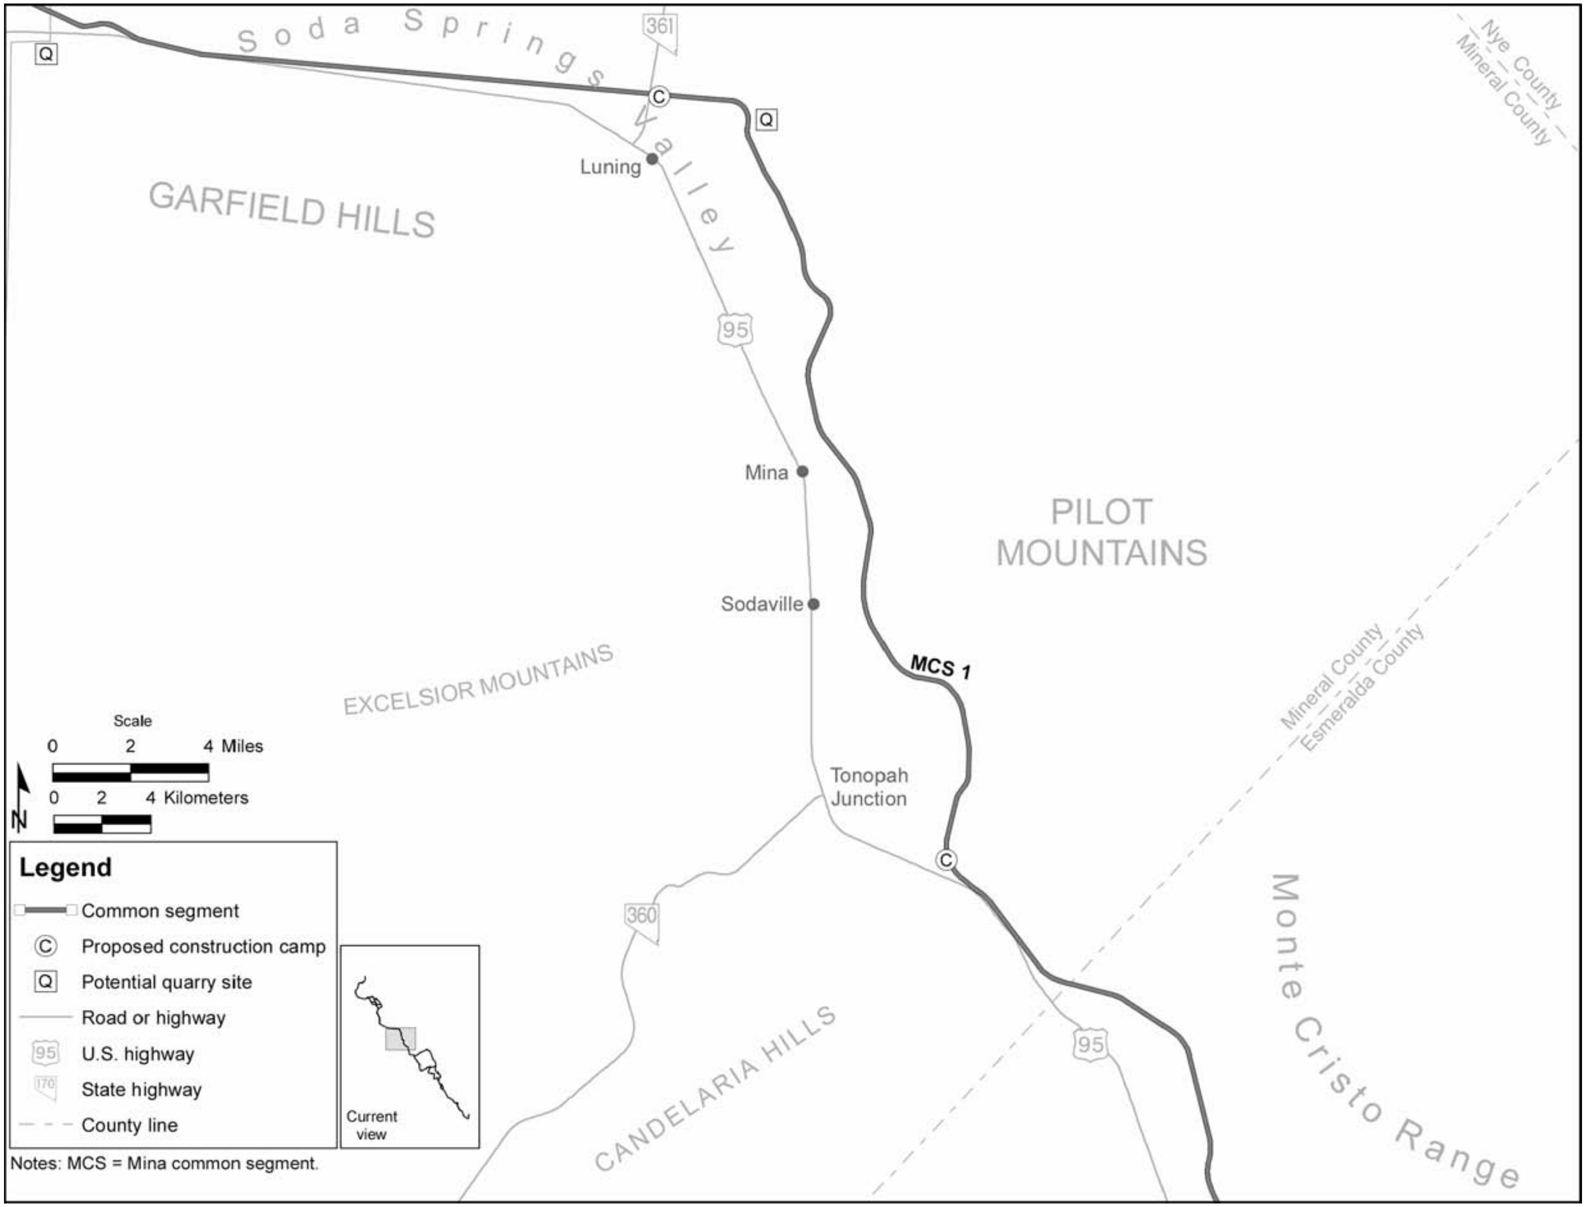

Figure 2-15. Mina rail alignment map area 3.

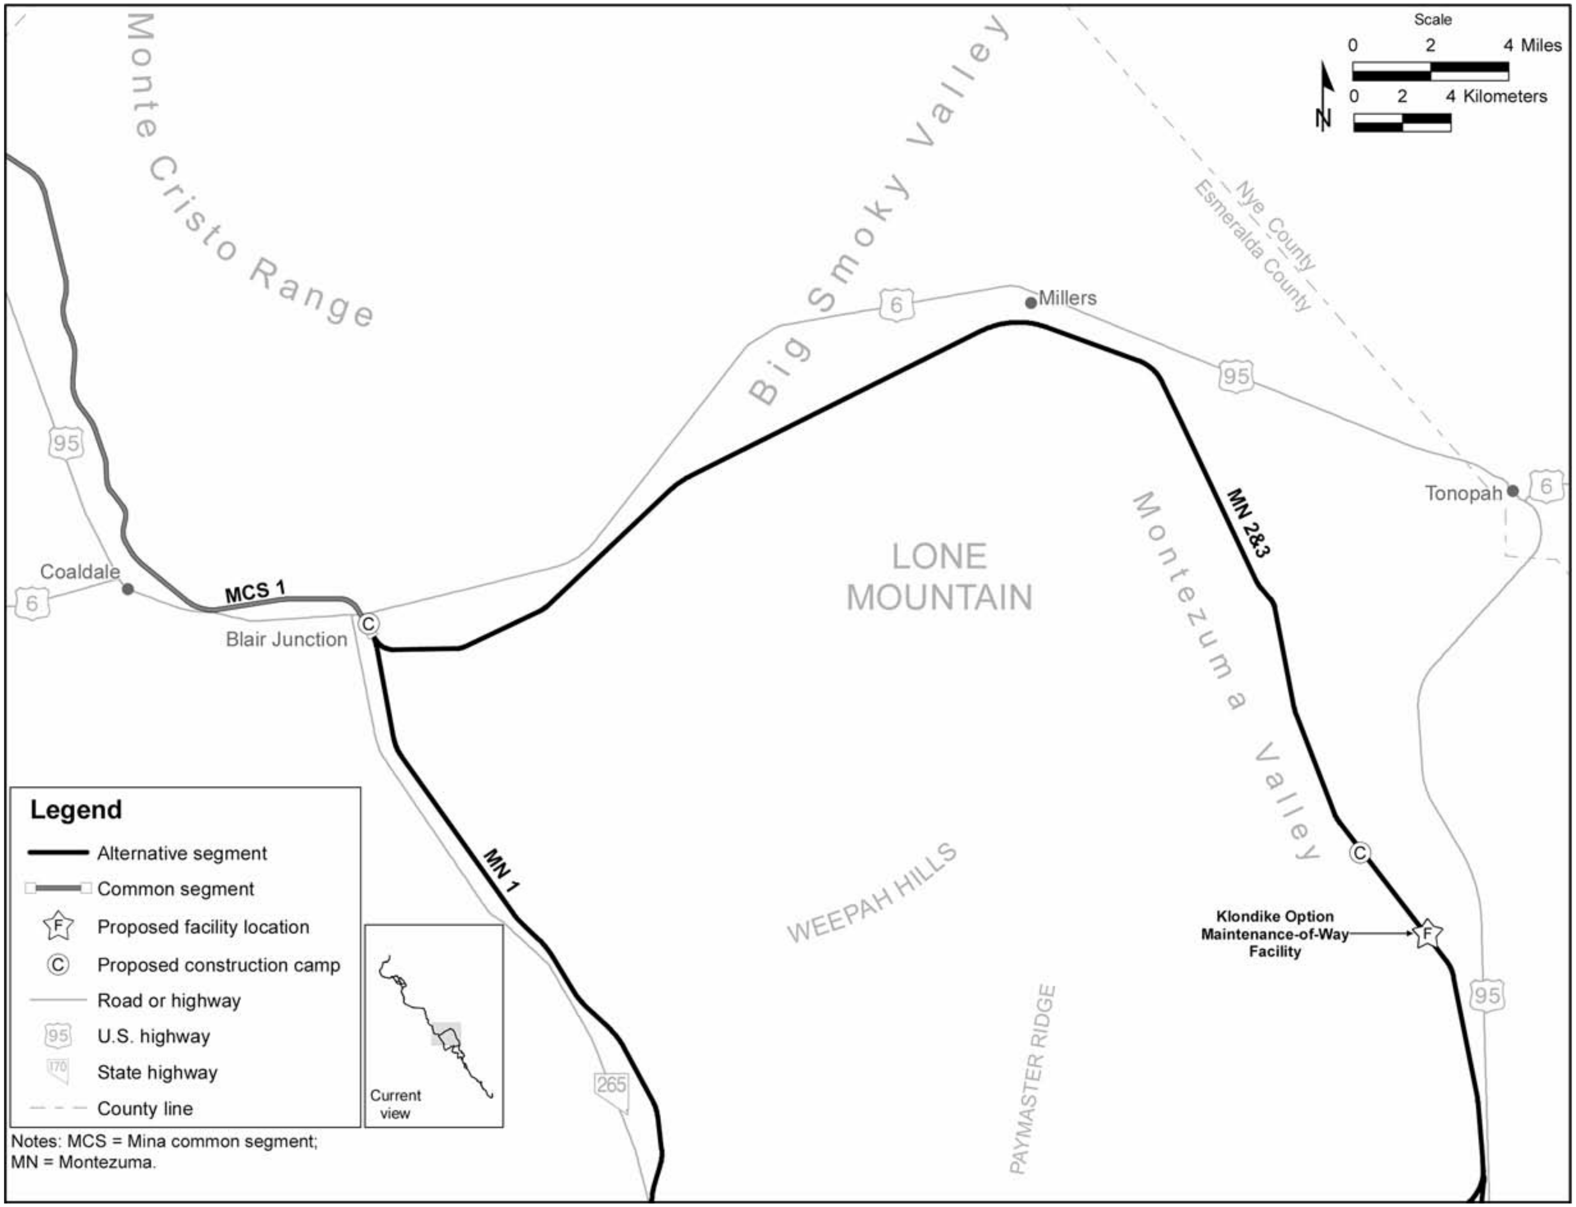

Figure 2-16. Mina rail alignment map area 4.

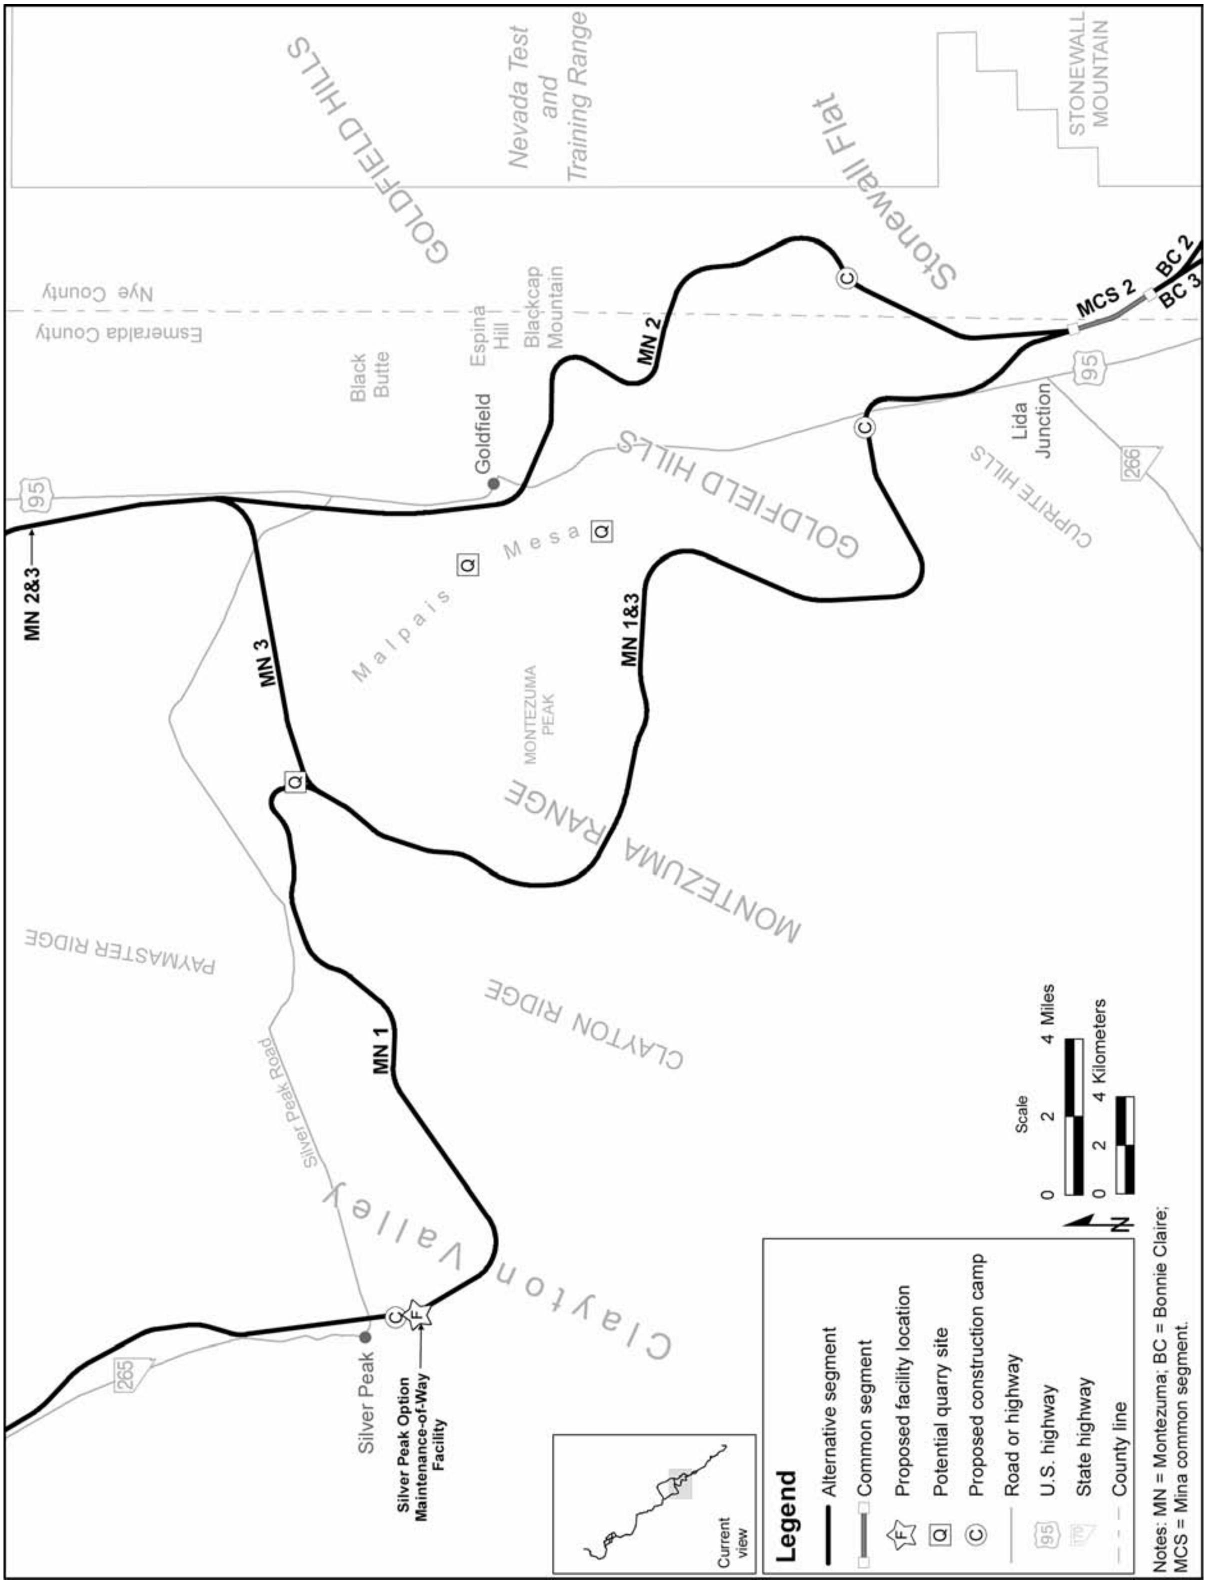

Figure 2-17. Mina rail alignment map area 5.

It would then trend south for the next 11 kilometers (7 miles) between Clayton Ridge on the west and Montezuma Peak on the east before turning east for about the next 13 kilometers (8 miles), passing to the south of Montezuma Peak. The rail alignment would again turn roughly south for approximately 11 kilometers, traveling to the west of the Goldfield Hills. It would then travel northwest, cross U.S. Highway 95, and turn south before joining Mina common segment 2 near Lida Junction. Montezuma alternative segment 3 would be approximately 140 kilometers (88 miles) long (DIRS 180872-Nevada Rail Partners 2007, Appendix E).

2.2.1.2.7 Mina Common Segment 2 (Lida Junction Area)

Mina common segment 2 is shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 417 through 418) and on Figures 2-17 and 2-18. It would begin at the end of one of the Montezuma alternative segments and run roughly southeast for about 3.4 kilometers (2.1 miles) before joining one of the Bonnie Claire alternative segments (DIRS 180916-Nevada Rail Partners 2007, p. E-12).

2.2.1.2.8 Bonnie Claire Alternative Segments

DOE is considering two alternative segments in the area north of Scottys Junction, Bonnie Claire alternative segments 2 and 3, which are shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 419 through 441) and on Figure 2-18.

Bonnie Claire alternative segment 3 would begin at the end of Mina common segment 2 about 8 kilometers (5 miles) north of Stonewall Pass, and would trend generally south, paralleling U.S. Highway 95 to the east. After approximately 10 kilometers (6 miles), it would turn southeast and continue for an additional 10 kilometers through Sarcobatus Flat, where it would join common segment 5 approximately 4 kilometers (2.5 miles) north of Scottys Junction near the intersection of State Route 267 and U.S. Highway 95. Bonnie Claire alternative segment 3 would be approximately 19 kilometers (12 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-12).

Bonnie Claire alternative segment 2 would begin at the end of Mina common segment 2 about 8 kilometers (5 miles) north of Stonewall Pass and would trend east toward the Nevada Test and Training Range for about 5 kilometers (3 miles) before turning south for an additional 17 kilometers (11 miles). Bonnie Claire 2 would generally follow the Nevada Test and Training Range boundary and would join common segment 5 in Sarcobatus Flat to the north of Scottys Junction near the intersection of State Route 267 and U.S. Highway 95. Bonnie Claire alternative segment 2 would be approximately 21 kilometers (13 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-12).

2.2.1.2.9 Common Segment 5 (Sarcobatus Flat Area)

Common segment 5 is shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 441 through 467) and on Figures 2-18 and 2-19. This common segment would begin 4 kilometers (2.5 miles) north of Scottys Junction and trend generally southeast through the Sarcobatus Flat area, approximately 100 meters (330 feet) east of U.S. Highway 95 at its closest point. Common segment 5 would end approximately 6 kilometers (4 miles) north of Springdale, where it would connect to one of the Oasis Valley alternative segments. Common segment 5 would be approximately 40 kilometers (25 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-13).

2.2.1.2.10 Oasis Valley Alternative Segments

DOE is considering two alternatives in the Oasis Valley area, Oasis Valley 1 and Oasis Valley 3, which are shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 467 through 479) and on Figure 2-19.

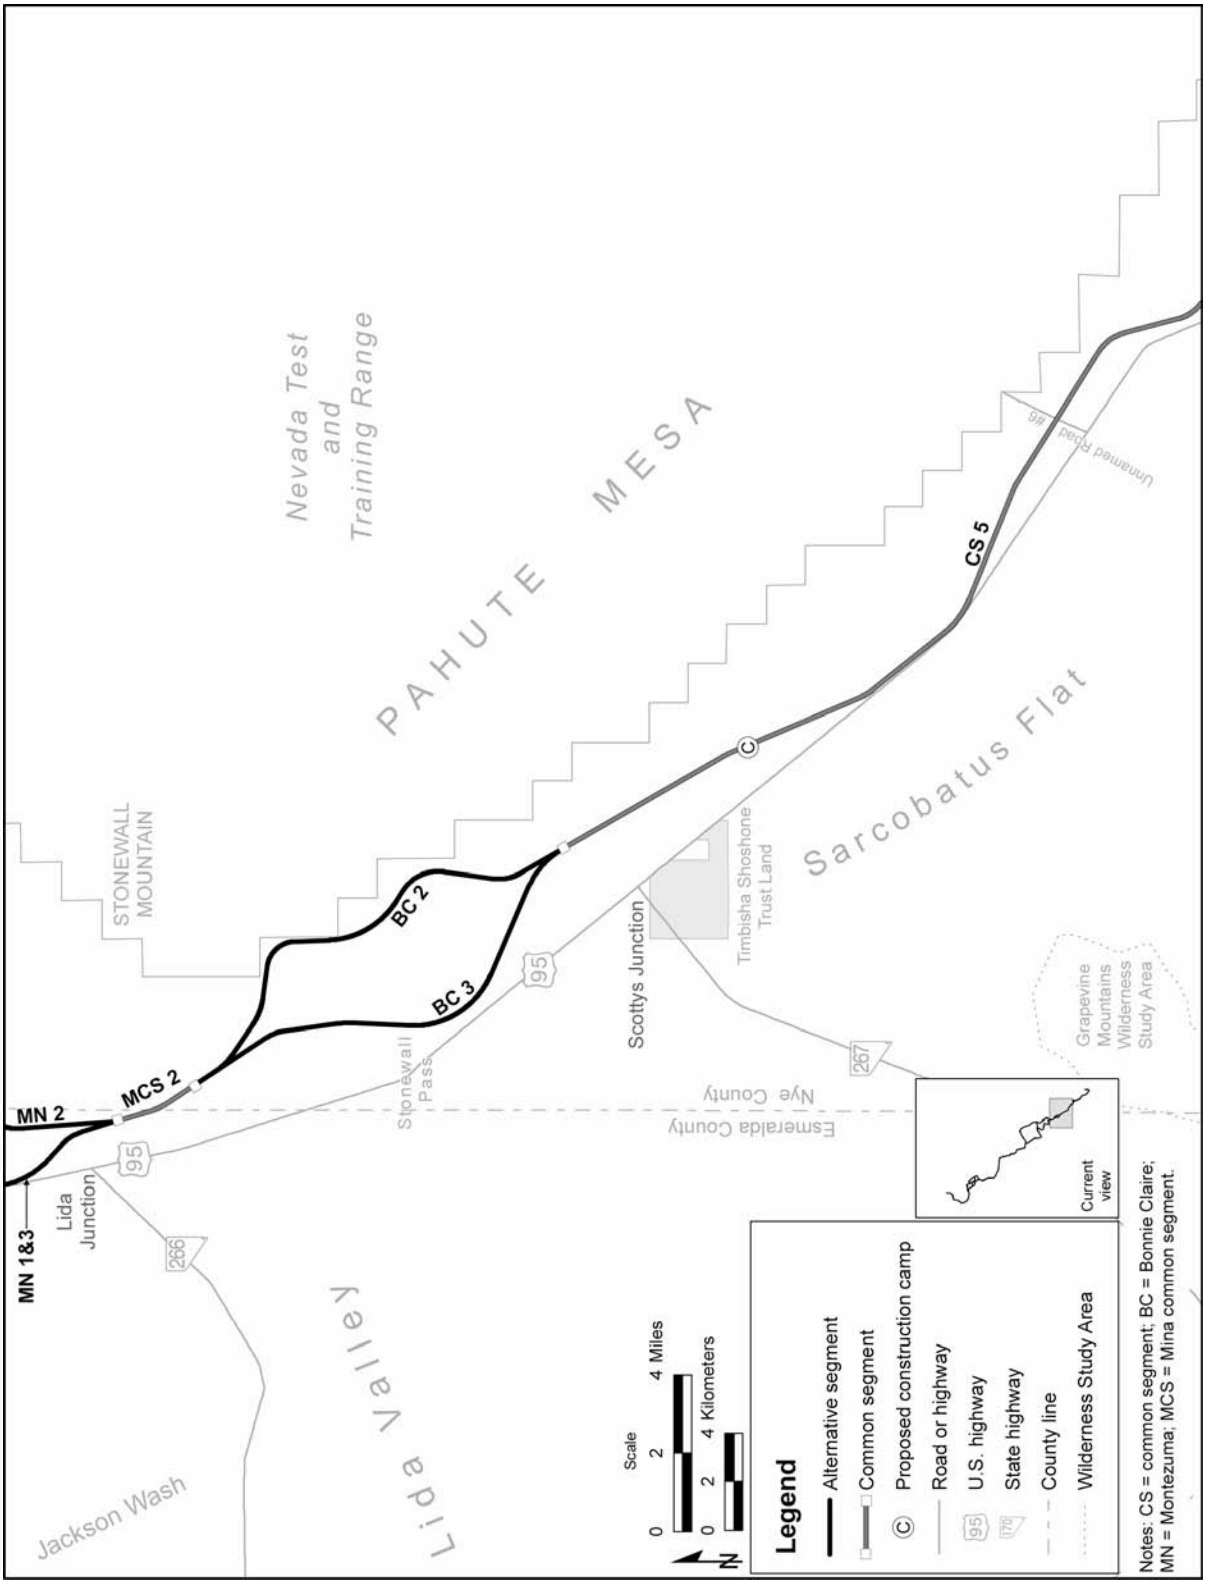

Figure 2-18. Mina rail alignment map area 6.

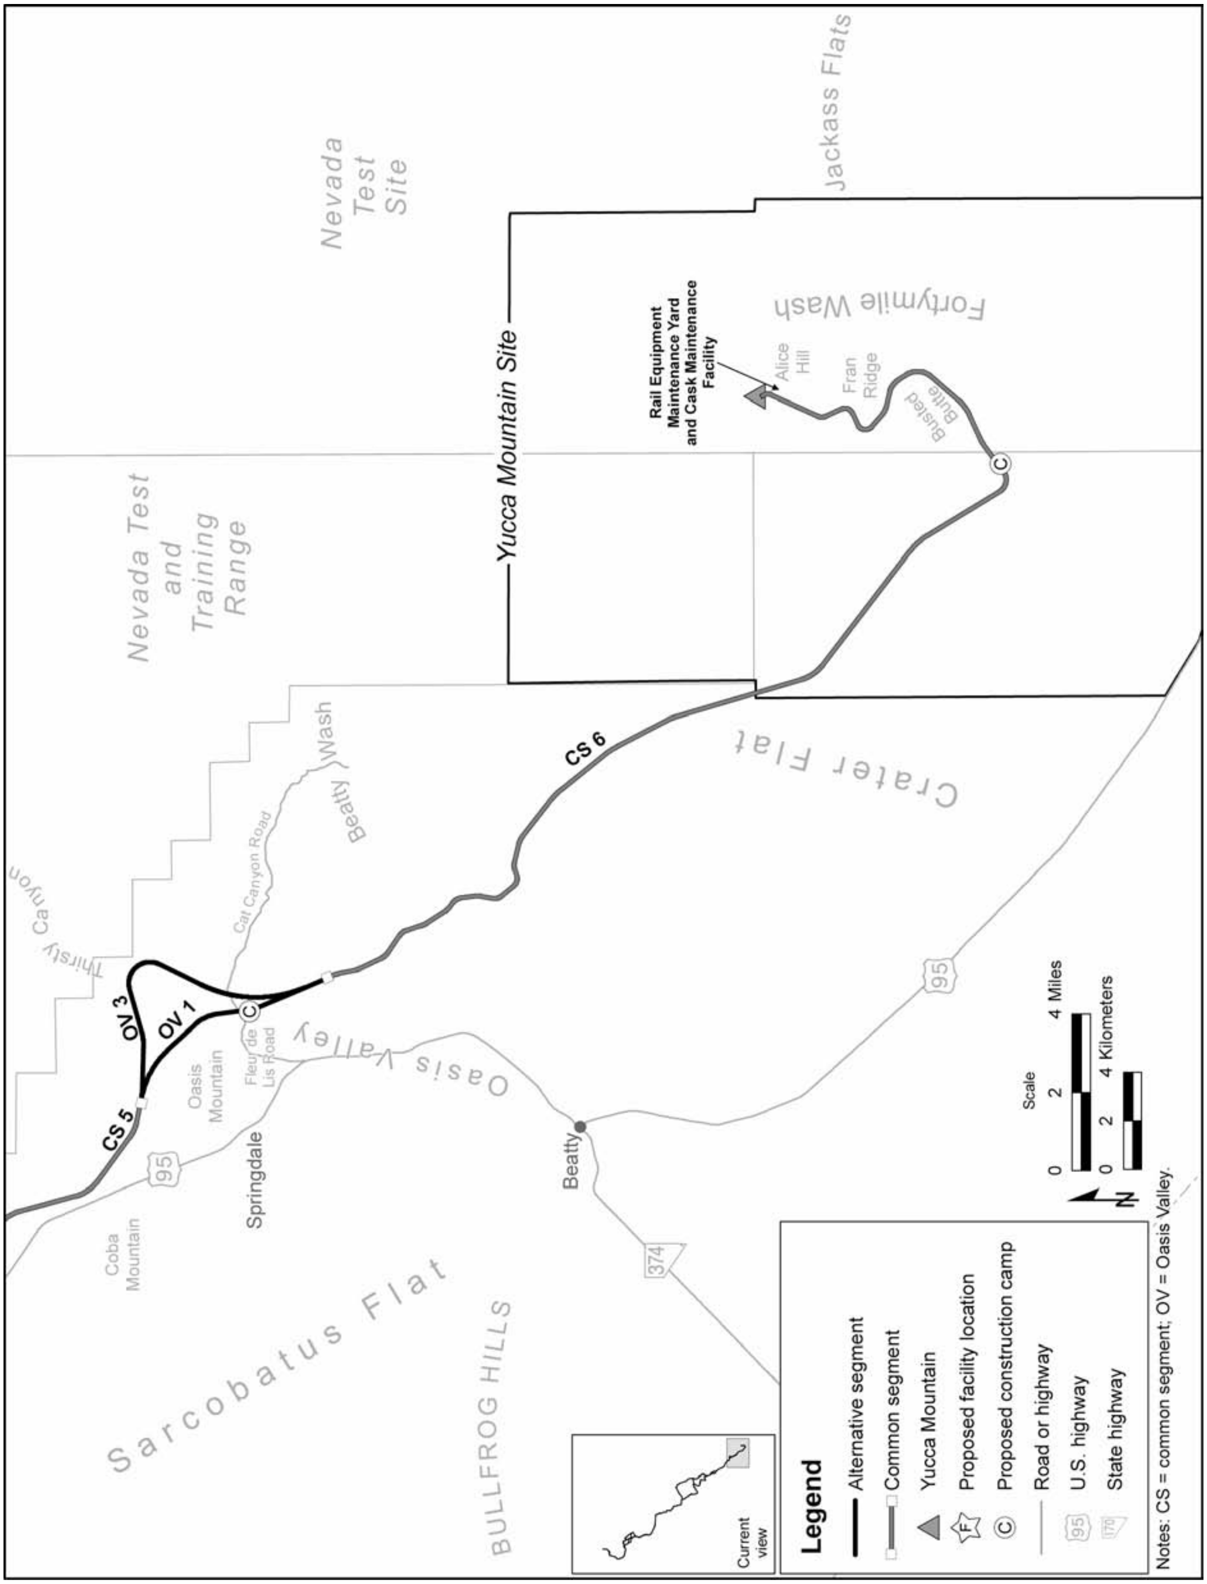

Figure 2-19. Mina rail alignment map area 7.

Oasis Valley alternative segment 1 would begin at the end of common segment 5 approximately 6 kilometers (4 miles) north of Springdale, would run southeast and connect to common segment 6. Oasis Valley 1 would be approximately 10 kilometers (6 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-14).

Oasis Valley alternative segment 3 would begin at the end of common segment 5 approximately 6 kilometers (4 miles) north of Springdale, and would run generally east and then south before crossing Oasis Valley farther to the east than Oasis Valley 1 and connecting to common segment 6. Oasis Valley 3 would be approximately 14 kilometers (9 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-14).

2.2.1.2.11 Common Segment 6 (Yucca Mountain Approach)

Common segment 6, shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 479 through 511) and on Figure 2-19, would begin about 3 kilometers (2 miles) east of U.S. Highway 95. This common segment would trend generally southeast for 40 kilometers (25 miles) from Oasis Valley to Beatty Wash. It would then turn north at the southern end of Busted Butte, running west of Fran Ridge and then trending generally north for an additional 11 kilometers (7 miles) until terminating at the Rail Equipment Maintenance Yard inside the Yucca Mountain Site boundary. Common segment 6 would be approximately 51 kilometers (32 miles) long (DIRS 180916-Nevada Rail Partners 2007, p. E-15).

2.2.2 RAILROAD CONSTRUCTION

DOE anticipates that it would take a minimum of 4 years to construct the proposed railroad under either implementing alternative. As illustrated in Figure 2-20, the construction phase would begin with the construction of water wells, construction camps, and quarries; and with the procurement of concrete ties and rail for track construction and steel for bridge construction. Approximately 1 month after beginning construction and while these previous activities were in progress, construction of the rail roadbed, ***culverts***, bridges, and grade-separated crossings would begin simultaneously at multiple points along the rail alignment. Near the start of year 2, quarries would begin to produce ballast and stockpiling of rails would begin. Shortly thereafter, track construction would begin and would move sequentially along the rail alignment toward Yucca Mountain. Construction would begin on signals and communications structures shortly after the end of year 1 (DIRS 180922-Nevada Rail Partners 2007, Section 7.0).

As shown in Figure 2-20, under the Caliente Implementing Alternative, construction of railroad operations support facilities would begin with construction of the Interchange Yard and the Staging Yard. Next, near the start of year 2, construction of the Cask Maintenance Facility would begin. At the end of year 2, DOE would begin constructing the Maintenance-of-Way Trackside Facility and the Rail Equipment Maintenance Yard. Finally, near the end of year 3, the Department would begin constructing the Maintenance-of-Way Headquarters Facility.

Under the Mina Implementing Alternative, construction of railroad operations support facilities would begin with construction of the Staging Yard. Next, near the start of year 2, DOE would begin constructing the Cask Maintenance Facility. Finally, at the end of year 2, the Department would begin constructing the Maintenance-of-Way Facility and the Rail Equipment Maintenance Yard.

Although DOE anticipates that construction would take a minimum of approximately 4 years, this Rail Alignment EIS accounts for the possibility that it could take longer (up to 10 years) because annual funding levels might not be sufficient to complete construction in 4 years. The construction sequence under a 10-year schedule would be largely the same as for the 4-year schedule, except that under the 10-year schedule construction of the rail roadbed would occur sequentially, starting at the beginning of the rail alignment and moving toward Yucca Mountain.

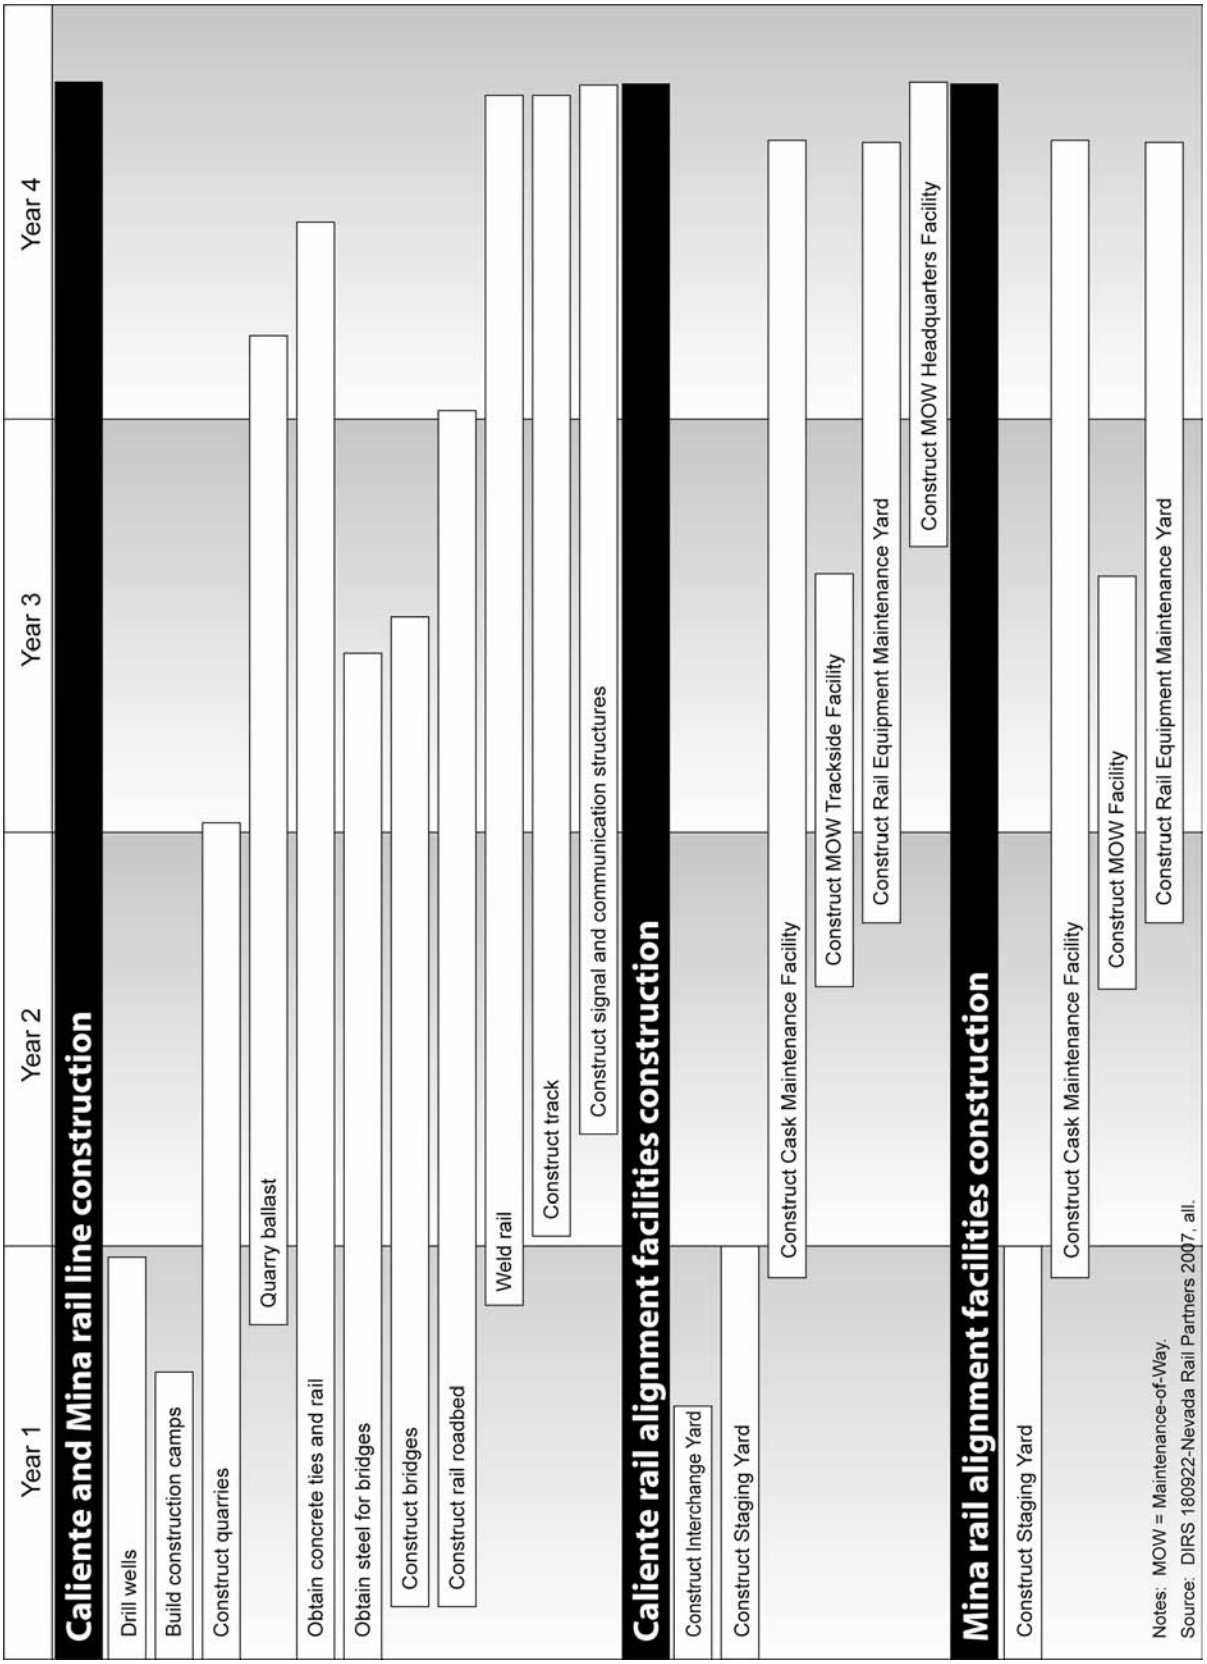

Figure 2-20. Four-year schedule for railroad construction.

Unless otherwise indicated, all construction activities would occur inside the construction right-of-way (nominally 150 meters [500 feet] on either side of the rail alignment centerline, resulting in a ***nominal*** total width of 300 meters [1,000 feet]). In some areas requiring deep cuts or high fills, the construction right-of-way could extend beyond this nominal width. Under the Caliente Implementing Alternative, the total construction footprint resulting from establishing this construction right-of-way would be approximately 164 square kilometers (40,600 acres), but would vary depending on alternative segments. Under the Mina Implementing Alternative, the total construction footprint would be approximately 125 square kilometers (30,900 acres), but would vary depending on alternative segments.

DOE would implement best management practices during this entire construction process (see Chapter 7).

2.2.2.1 Geotechnical Exploration Program

Before constructing the proposed railroad, DOE would conduct a geotechnical exploration program to gather data on subsurface conditions along the rail alignment. These data would support the final design of bridge foundations, embankments, deep cuts, major culverts, potential quarry sites, fills, and excavations. This work would involve collecting geotechnical information by drilling ***boreholes*** at locations along the rail alignment. Under the Caliente Implementing Alternative, there would be approximately 3,200 boreholes; under the Mina Implementing Alternative, there would be approximately 2,100 boreholes. DOE would also obtain any other required permits and approvals, as necessary.

Drilling would be done with portable rigs, assumed for purposes of assessment to be diesel-powered rigs on wheels or skids. The land area disturbed for each drill hole would be approximately 6 by 15 meters (20 by 50 feet). On average, borings would reach a depth of about 15 meters (50 feet) or less; however, some borings might be 30 to 60 meters (100 to 200 feet) deep.

There are various areas along the Caliente and Mina rail alignments that would cross, intersect, or parallel areas with abandoned mines. In these areas, DOE would drill boreholes to sample the subsurface conditions to help indicate the presence of an underground void. If either a borehole or obvious surface subsidence indicated the possible presence of such a void, the Department would conduct further investigations, including additional boreholes, ground-penetrating radar, and/or ***seismic*** analysis, to determine the extent of the feature. In all cases, the Department would develop appropriate engineered solutions to address the situation.

If DOE encountered such features during the construction phase, similar processes, as outlined above, would be employed to determine the appropriate engineering solution. Only if the discovered feature was so extensive that constructing the rail line would be infeasible would the Department consider realignment around the feature.

2.2.2.2 Construction Camps

Construction of the proposed railroad would take place in areas with low population densities and an insufficient workforce. To maintain an adequate workforce during the construction phase, DOE would establish construction camps along the rail alignment to provide housing for construction workers and a logistical base from which to conduct construction activities. These camps would be located approximately every 50 kilometers (30 miles) along the rail alignment. Under the Caliente Implementing Alternative, the Department would establish up to 12 construction camps (Figure 2-21). Under the Mina Implementing Alternative, the Department would establish up to 10 construction camps (Figure 2-22). Along either rail alignment, up to six of these camps could be operational at any one time.

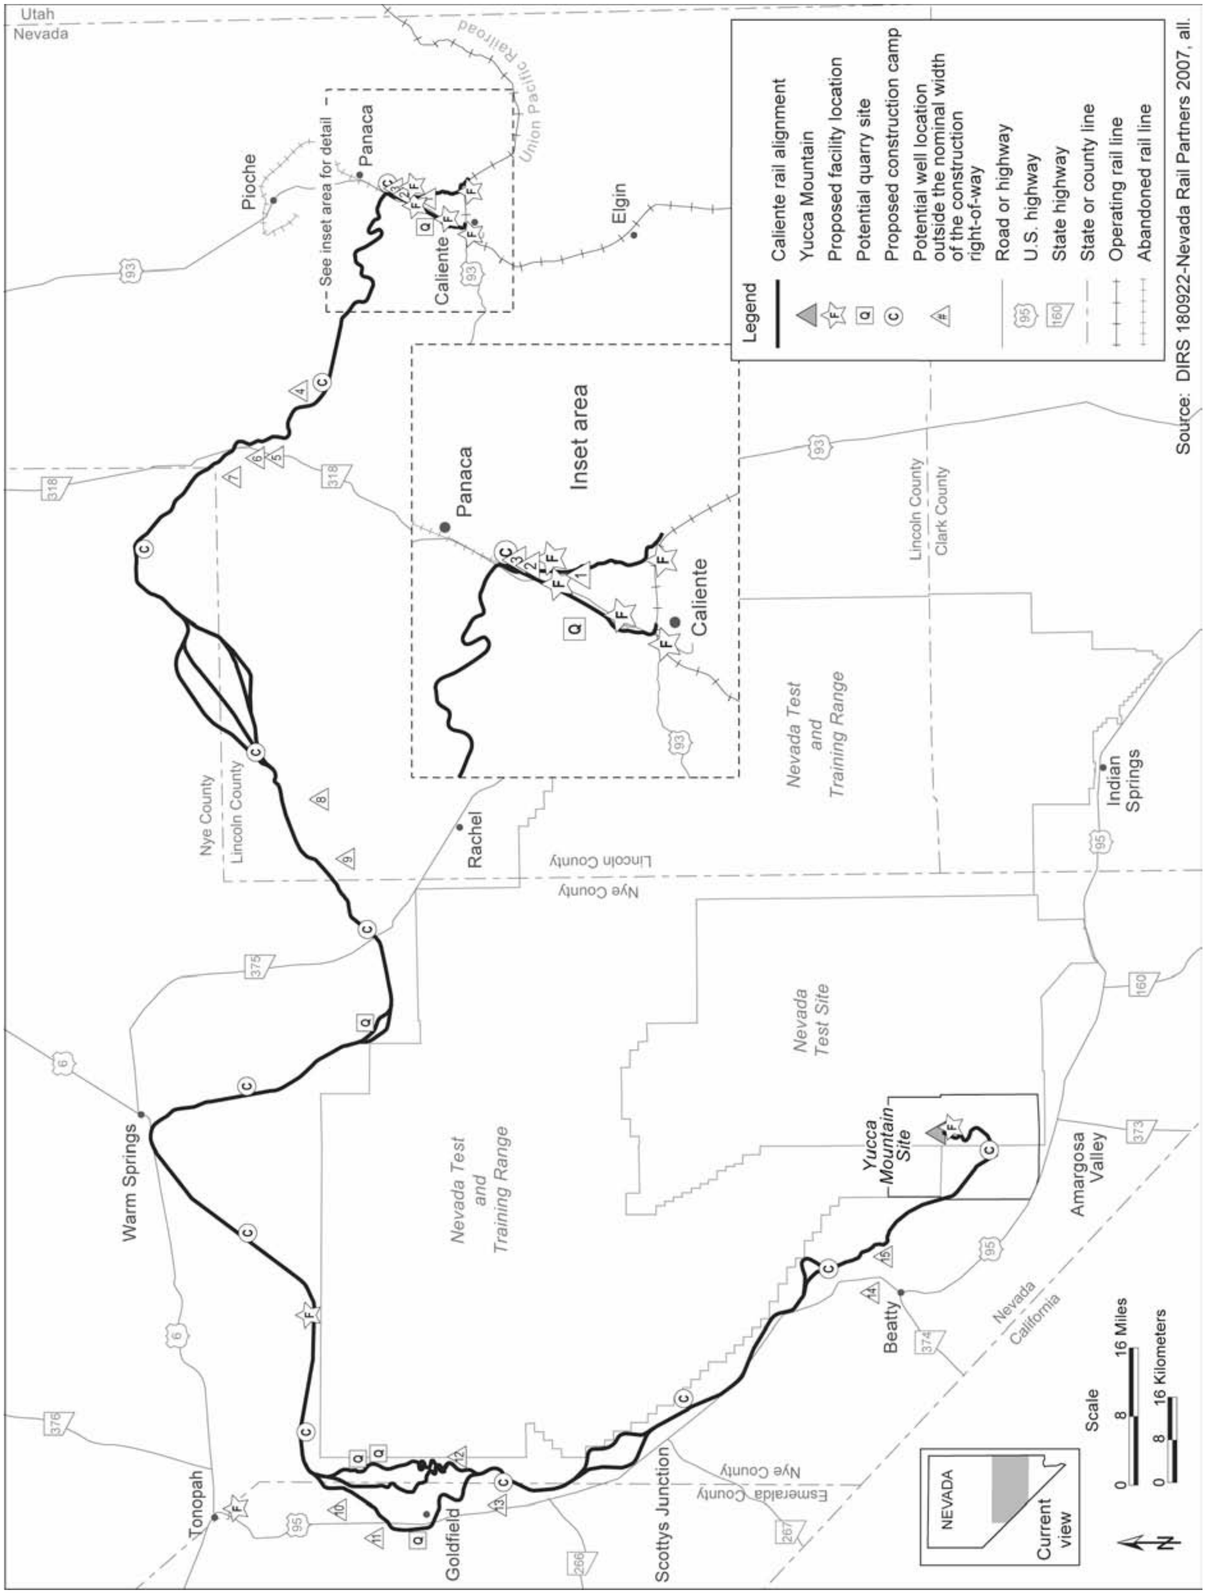

Figure 2-21. Potential quarry, water-well, and construction-camp locations along the Caliente rail alignment.

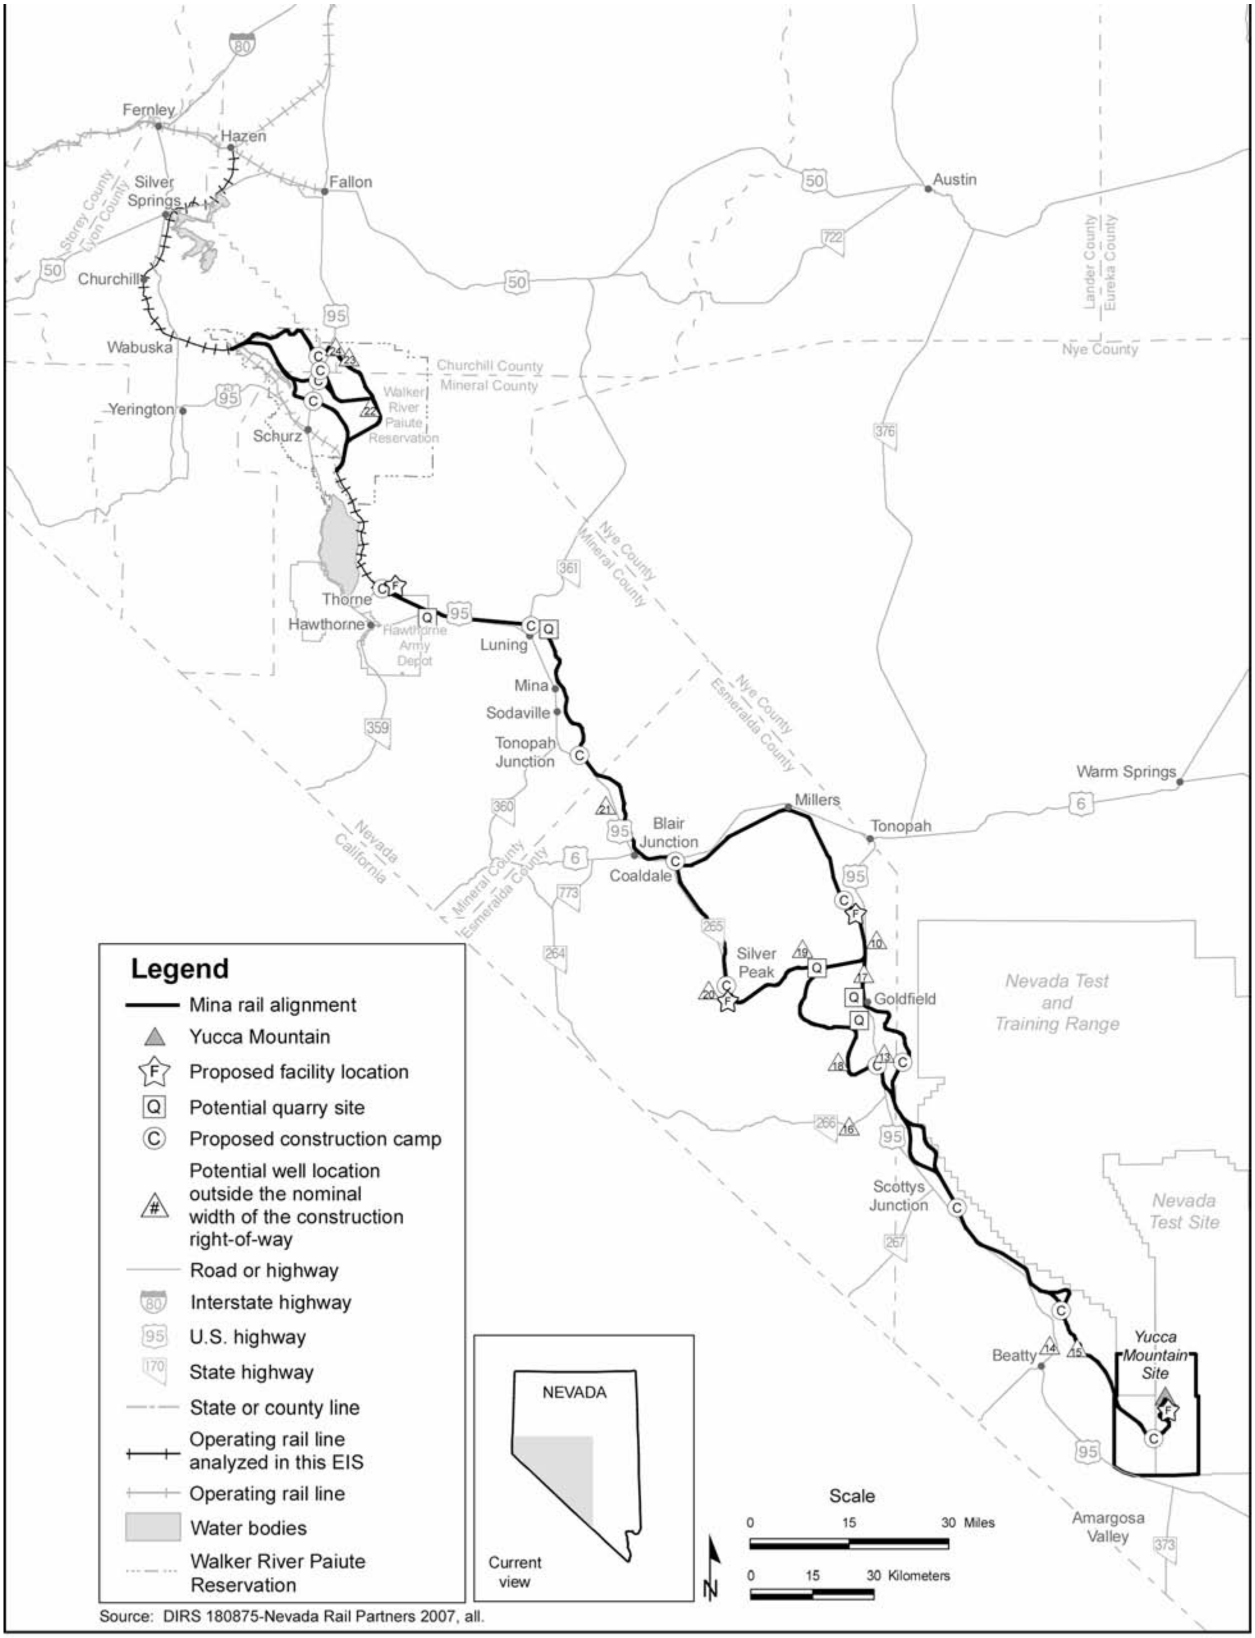

Figure 2-22. Potential quarry, water-well, and construction-camp locations along the Mina rail alignment.

With the exception of construction camp 12, all camps would be operational on an as-needed basis during the rail line construction phase. If needed, DOE might utilize construction camp 12 for repository construction activities beyond the rail line construction phase. However, the design of the camp would not be altered for this purpose.

Each construction camp would be fenced and would occupy approximately 0.10 square kilometer (25 acres). Each site would consist of office space; housing for approximately 360 workers; a utility zone dedicated to power supply; temporary trash storage, ***wastewater treatment*** and potable water treatment areas; a worker support area consisting of first aid facilities and a service station with above-ground storage tanks for construction vehicles and equipment fueling and maintenance; dining facilities; and a material laydown and maintenance area. Figure 2-23 shows the typical site layout for a construction camp. Each camp would be secured and guarded (DIRS 180922-Nevada Rail Partners 2007, Section 4.1). Water demand for the construction camps is anticipated to be approximately 110,000 liters (29,000 gallons) per day per camp and would be met from new wells drilled near each construction camp (DIRS 180922-Nevada Rail Partners 2007, p. 4-6). Water would be stored onsite in tanks for camp use. Each camp would generate approximately 95,000 liters (25,000 gallons) of wastewater per day, which would be processed in a temporary wastewater treatment facility. DOE anticipates that it would use the wastewater effluent (that is, ***gray water***) produced at the wastewater treatment facility along the rail alignment for soil compaction and dust suppression. Power needs would be met at each camp through a substation connecting to the power line that would be laid along the rail line (see Section 2.2.2.7), with backup generators available at each camp for emergencies. Each camp would use approximately 54,000 kilowatt-hours of energy per day (DIRS 180922-Nevada Rail Partners 2007, p. 4-6).

For ease of access, DOE would establish construction camps close to public roads. In most cases, the Department would develop additional access roads to connect the construction camps to these public roads. With the exception of a new roadway that would be constructed to access proposed construction camp 12 (for either the Caliente or the Mina rail alignment), all of these access roads would be developed by improving existing unpaved public roads that would intersect the rail line. Tables 2-8 and 2-9 list the roads the Department would improve to access each construction camp along the Caliente rail alignment and the Mina rail alignment, respectively. Improvements would consist of grading the existing unpaved roads and constructing a gravel surface on the roads when necessary (DIRS 180922-Nevada Rail Partners 2007, pp. 4-2 to 4-9).

The locations and characteristics of access roads are discussed here and in subsequent sections. The locations of all access roads (to water wells, quarry sites, and construction camps) in this Rail Alignment EIS are considered representative and subject to change during the design and construction process.

For purposes of analysis, DOE estimates that railroad construction workers would work a 3-week work cycle, with 2 straight weeks working from the construction camps and 1 week off (DIRS 180922-Nevada Rail Partners 2007, p. 4-5). Construction would occur continuously throughout the year, with multiple crews rotating in and out of the construction camps to ensure continuity.

All railroad construction workers would complete cultural and biological resources sensitivity and protection training to minimize the potential for intentional or unintentional harm to cultural and biological sites. The training would include descriptions of different biological and cultural resources types and their importance, procedures to follow if resources are encountered in the field, and employment-related and legal penalties for not following the requirements. For example, workers could encounter desert tortoises, an ***endangered species***, in the field during construction activities. Personnel would be trained to recognize them and then notify the appropriate authorities of any desert tortoise sightings. DOE would develop procedures that would outline the necessary steps that need to be taken in the event of an encounter with a desert tortoise.

e. For Oasis Valley alternative segment 3, the required access road would be slightly longer than the distance listed here.

Following the completion of construction, DOE would consult with the BLM regarding abandonment and reclamation of the construction camps. The abandonment process would include dismantling each camp, dismantling the electrical substation, removing the temporary wastewater treatment facility, and reclaiming the land by returning it to as natural a state as practicable.

2.2.2.3 Rail Alignment Access Roads

During the construction phase, DOE would install unpaved access roads parallel to and on both sides of the rail line within the construction right-of-way. These access roads would be utilized primarily to provide construction workers access to rail line construction sites. The roads would be approximately 7.3 meters (24 feet) wide, be graded, and have a gravel surface.

Under the Caliente Implementing Alternative, the rail alignment access roads would parallel the entire length of the rail line except over bridges. Under the Mina Implementing Alternative, the rail alignment access roads would parallel only the newly constructed portions of the rail line. The existing branchlines that are part of the Mina rail alignment would be accessed by existing roads.

The rail alignment access roads could improve land access along most of the rail alignment. While most of the rail alignment would follow or be within a few kilometers of existing unpaved roads and trails that are currently open for public use, the new access roads could be of better quality in some areas than nearby existing roads, increasing the likelihood of use. Recreational use of public land along the access roads (as with other similar roads on public land) would be monitored by the BLM to ensure compliance with its land management goals, as stated in applicable BLM ***resource management plans***.

After the construction phase, the rail alignment access roads would remain in place to provide additional access to the rail line for maintenance and emergency response, and to act as firebreaks. It is important to note that DOE would not maintain the access roads as public roads and the Department would post signs indicating potential users would proceed on the access roads at their own risk.

2.2.2.4 Acquisition of Materials

Water, ballast, ***subballast***, steel for bridges, concrete ties, and rail would be required for construction of the proposed railroad. This section briefly describes acquisition and use of these materials.

2.2.2.4.1 Water

For purposes of analysis, DOE assumed that it would obtain all required water from ***groundwater*** pumped from new water-supply wells the Department would construct along the rail alignment inside, and in selected locations, outside the nominal 300-meter (1,000-foot)-wide construction right-of-way (see Sections 4.2.6 and 4.3.6, Groundwater Resources). DOE is aware that there could be other approaches for obtaining some of the water required for construction, including purchasing or leasing water from established municipalities or other existing permitted water-rights holders. This approach, if used for satisfying part of the total water demand, would result in the need for fewer new water-supply wells than are assumed and described in this Rail Alignment EIS. DOE anticipates obtaining all water from groundwater basins along either rail alignment regardless of the method used. New water-supply wells is the only method for obtaining water that would require new construction; therefore, this EIS analyzes the impacts of obtaining all required water from new water-supply wells to illustrate the maximum impacts of the suite of potential water obtainment activities. Table 2-10 lists construction-water requirements for the Caliente and Mina rail alignments.

The amount of water needed for earthwork compaction would be directly related to the amount of fill required. Most of the water needed during the construction phase would be for earthwork compaction. Although the Caliente and Mina rail alignments are different lengths (the Caliente rail alignment would be about 120 kilometers [75 miles] longer than the Mina rail alignment), the amount of fill for the two alignments would be similar (see Tables 2-24 and 2-25). Therefore, the amount of water needed for earthwork compaction would be similar for the two alignments.

For new well construction, DOE would submit an application to the State of Nevada to appropriate groundwater for use during the railroad construction phase. Table 2-11 lists the number of potential water wells and well sites the Department has identified along the Caliente and Mina rail alignments and the number of wells estimated to be required to satisfy construction-water demand.

Figure 2-21 shows the locations of wells outside the nominal width of the Caliente rail alignment construction right-of-way; Figure 2-22 shows the locations of wells outside the nominal width of the Mina rail alignment construction right-of-way; and Table 2-12 lists the number of well sites at each mapped location on both figures.

A 3-meter (10-foot)-wide unimproved dirt access road and a 10- to 15-centimeter (4- to 6-inch)-diameter water pipeline would be required from the well locations along the rail alignment (both inside and outside the construction right-of-way) to lined and fenced earthen reservoirs located immediately along the rail alignment and would be approximately 930 square meters (10,000 square feet) in area by 3 meters (10 feet) deep. These earthen reservoirs would be constructed to temporarily store the water needed to

Table 2-10. Construction-water requirements.[a]

Water-usage category	Caliente rail alignment (cubic meters)[b,c,d]	Mina rail alignment (cubic meters)[b,c,d]
Earthwork compaction	6,780,00	6,590,000
Construction personnel	460,000	460,000
Dust control along access roads	250,000	250,000
Quarry operations	37,000	37,000
Totals	7,530,000	7,340,000

meet daily water demand during construction. DOE would determine the exact number of earthen reservoirs based on the number of wells constructed and the location of those wells in relation to one another. After the completion of rail line construction, DOE would fill the reservoirs with soil and reclaim them (DIRS 180922-Nevada Rail Partners 2007, Section 4.4.4).

Some wells would continue to operate after the completion of construction to serve as the water source for facility operations (discussed in Section 2.2.4). Well closure would be conducted in compliance with State of Nevada regulations. The well sites and access roads would be reclaimed accordingly (DIRS 180922-Nevada Rail Partners 2007, Section 4.4).

For some wells constructed outside the construction right-of-way, DOE would need access roads from the well location to the rail line. Most of these access roads could be existing roads, which DOE could improve. Improvements might consist of grading or resurfacing the existing unpaved roads. In addition, a few well locations would require new roads (DIRS 180922-Nevada Rail Partners 2007, pp. 4-2 to 4-9). For the Caliente rail alignment, Figure 2-22 shows the locations of wells that would require access roads, and Table 2-13 lists the estimated lengths of the access roads to these wells. For the Mina rail alignment, Figure 2-23 shows the locations of wells that would require access roads and Table 2-14 lists the estimated lengths of the access roads to these wells.

As shown in Table 2-10, approximately 90 percent of the water that would be used during construction would be used for earthwork compaction and control of excavation dust (DIRS 180922-Nevada Rail Partners 2007, p. 4-2). DOE would use standard construction dust-control measures, including routine watering of unpaved surfaces; wet suppression for material storage, handling, and transfer operations; and application of appropriate and approved chemical dust suppressants. The efficiency of these controls varies depending on site characteristics, but typically ranges from a 50- to 80-percent reduction in ***fugitive dust*** emissions (DIRS 103676-Cowher, Muleski, and Kinsey 1988, all).

2.2.2.4.2 Ballast

Approximately 4.9 metric tons of ballast per meter (1.7 tons of ballast per foot) of track construction would be needed along the rail line. Table 2-15 lists the total ballast requirements for rail line construction along the Caliente and Mina rail corridors.

Under the Caliente Implementing Alternative, the Department would obtain ballast from two potential sources: existing commercial quarries or new quarries developed along the proposed rail alignment. Ultimately, the option utilized would depend on the alternative segments selected. If DOE selected the Caliente alternative segment, the Department anticipates it would obtain ballast needed for the entire rail line from new quarries developed along the rail alignment. However, if DOE selected the Eccles alternative segment, there would not be a suitable quarry location available along this portion of the rail alignment and the Department would obtain ballast from an existing commercial quarry. The Milford Quarry in Utah, approximately 200 kilometers (120 miles) east of Caliente on the Union Pacific Railroad in Milford, Utah, is the nearest active quarry that processes large quantities of ballast. Ballast would be transported by rail from this quarry to the proposed rail line. If the Department selected the Eccles alternative segment, one or two additional quarries would still need to be developed along the rail alignment (DIRS 180922-Nevada Rail Partners 2007, pp. 3-1 to 3-6).

Table 2-15. Ballast requirements for rail line construction.

Rail alignment	Ballast required (metric tons)[a,b]
Caliente[c]	3.12 million to 3.19 million
Mina[d]	2.49 million to 2.73 million

a. To convert metric tons to tons, multiply by 1.1023.
b. Numbers rounded to three significant figures.
c. Source: Derived from DIRS 180922-Nevada Rail Partners 2007, p. 3-1.
d. Source: Derived from DIRS 180875-Nevada Rail Partners 2007, p. 3-1.

Ballast is the coarse rock that is placed under the railroad tracks to support the railroad ties and improve drainage along the rail line.

Subballast is a layer of crushed gravel that is used to separate the ballast and roadbed for the purpose of load distribution and drainage.

Table 2-16 lists potential quarry sites along the Caliente and Mina rail alignments. DOE has identified six potential quarry sites at four general locations along the Caliente rail alignment that have adequate quantities and quality of suitable material to produce ballast for rail line construction. If DOE decided to obtain all of the required ballast from new quarries, the Department would develop up to four of the six identified potential quarries (DIRS 180922-Nevada Rail Partners 2007, pp. 3-1 to 3-6). Figures 2-24 to 2-27 show the site layouts for each of the potential quarry sites along the Caliente rail alignment. Each quarry site layout outlines the maximum quarry impact area, which is the best estimate of the extent of the area that would be needed to house all of the facilities at each quarry site.

Under the Mina Implementing Alternative, the Department would obtain ballast from new quarries developed along the rail alignment. DOE has identified five potential quarry sites, two of which would be developed on an as-needed basis. Figures 2-28 through 2-32 show the site layouts for each of the potential quarry sites along the Mina rail alignment. Each quarry site layout outlines the quarry impact area, which is the best estimate of the extent of the area that would be needed to house all of the facilities at each quarry site.

Figure 2-33 shows the layout of a typical quarry site. Each quarry would occupy a maximum footprint of approximately 0.97 to 3.8 square kilometers (240 to 930 acres) and would consist of a 24-meter (80-foot)-deep by 0.04-square-kilometer (10-acre) pit, a 12-meter (40-foot)-tall by 0.057-square-kilometer (14-acre) tailings disposal area, and a 0.04-square-kilometer (10-acre) railroad siding to accommodate up to 80 railroad ballast cars. Thirty employees would be needed to operate each quarry during peak years (DIRS 180922-Nevada Rail Partners 2007, Section 3.1.3).

Table 2-16. Potential quarry sites.

Caliente rail alignment[a]		Mina rail alignment[b]	
Up to four sites developed from the following six potential locations:	Maximum quarry impact area (square kilometers)	Two sites developed from the following five potential locations:	Maximum quarry impact area (square kilometers)
Quarry site CA-8B (Caliente alternative segment)	1.6	Garfield Hills quarry site (Mina common segment 1)	1.4
Quarry site NN-9A (South Reveille alternative segment 2 or 3)	2.0	Gabbs Range quarry site (Mina common segment 1)	0.97

Not to scale

Source: DIRS 180922-Nevada Rail Partners 2007, p. 3-3.

Figure 2-33. Typical quarry site.

Each quarry site would require both power and water for operations. Power would be provided by connecting to the local power supply grid and constructing substations on site. Each quarry would be anticipated to use approximately 28,000 kilowatt-hours of electricity per day of operations. In case of emergency, backup power would be available through on-site backup generators. Water needs would be met through wells constructed near the quarry sites. Water needs would vary depending on the specific process selected at each site to wash the excavated rock during the crushing and screening processes, but are estimated to be approximately 140,000 liters (38,000 gallons) of water per day of operations at each quarry site (DIRS 180922-Nevada Rail Partners 2007, Section 3.1.3).

For any new quarry developed along either rail alignment, DOE would need to obtain a ***free-use permit*** from the BLM, which would allow DOE to mine ballast on BLM-administered lands (DIRS 180922-Nevada Rail Partners 2007, pp. 3-1 to 3-6).

DOE would haul the quarried ballast by truck or mechanical conveyor from the quarry pit to the railroad siding and then transport it to the track under construction. Rail transportation would be possible because each quarry would be operational only after construction of the rail line had reached the quarry rail sidings (DIRS 180922-Nevada Rail Partners 2007, pp. 3-1 to 3-6). DOE would need to construct new or improve existing access roads to each quarry site from the rail line. Improvements would consist of grading the existing unpaved roads and constructing a gravel surface on the roads when necessary. Tables 2-17 and 2-18 list the estimated length of road improvements and new quarry access roads along the Caliente and Mina rail alignments, respectively.

2.2.2.4.3 Subballast

Approximately 4.6 metric tons of subballast per meter (1.5 tons of subballast per foot) of track construction would be required. Table 2-19 lists the total subballast requirements for rail line construction along the Caliente and Mina rail alignments.

> A **borrow site** is an area where material (usually soil, gravel, or sand) is excavated for use in engineered embankments

Under the Caliente Implementing Alternative, the Department would obtain subballast primarily from materials excavated during rail roadbed construction and from ***borrow sites*** established inside the rail line construction right-of-way. Additionally, subballast could be produced by crushing rock in quarries or crushing rock from major excavations. Subballast would be trucked along the proposed rail alignment and placed as the final step in the construction of the rail roadbed. DOE would establish borrow sites inside the construction right-of-way, as necessary, during grading and leveling activities and would use suitable excavated material as fill whenever practicable. Any excess material from these activities would be distributed evenly along embankments as non-structural fill (DIRS 180922-Nevada Rail Partners 2007, pp. 3-1 to 3-6).

Under the Mina Implementing Alternative, the Department would obtain subballast from one (or more) of four sources: by utilizing waste rock generated at ballast quarry sites; from materials excavated during rail roadbed construction; from existing borrow sites along the rail alignment; or from the development of new subballast borrow sites along the rail alignment. New subballast borrow sites would be required for construction along the Mina rail alignment because rail roadbed construction would not generate enough material to meet subballast requirements. New subballast borrow sites would be located approximately every 16 to 32 kilometers (10 to 20 miles) along the rail alignment, which would result in the development of approximately 15 to 30 new sites. Figure 2-34 illustrates a typical subballast borrow site.

Table 2-19. Subballast requirements for rail line construction.

Rail alignment	Subballast required (metric tons)[a,b]
Caliente[c]	2.72 million to 2.81 million
Mina[d]	2.18 million to 2.39 million

a. To convert metric tons to tons, multiply by 1.1023.
b. Numbers rounded to three significant figures.
c. Source: DIRS 180921-Nevada Rail Partners 2007, p. A-5.
d. Source: DIRS 180875-Nevada Rail Partners 2007, p. A-6.

2.2.2.4.4 Concrete Ties and Rail

Approximately one concrete tie for every 0.6 meter (2 feet) of track construction would be needed along the entire length of the rail line (DIRS 180922-Nevada Rail Partners 2007, p. 3-1). Concrete ties would be shipped to the Staging Yard by rail and then distributed from there when needed for use.

DOE would obtain rail from commercial sources and weld it into 440-meter (1,440-foot) strings at a portable welding plant located within the construction right-of-way. Under the Caliente Implementing Alternative, this plant would initially be established near Caliente. Under the Mina Implementing Alternative, this plant would initially be established near Hawthorne. In either case, the welding plant would later be relocated at 80- to 160-kilometer (50- to 100-mile) increments along the rail alignment as construction progressed. Once ready for use, the strings would be transported by rail to the construction sites (DIRS 180922-Nevada Rail Partners 2007, p. 3-2).

2.2.2.4.5 Bridge Steel and Concrete

For either the Caliente or the Mina rail alignment, existing commercial manufacturers would supply the steel required for bridges. The bridge steel would be transported to the construction site by rail or by truck.

DOE would obtain concrete for site placement activities at bridge construction sites from portable concrete batch plants established near construction sites. Precast concrete bridge elements would be manufactured at existing commercial sources off the project site and trucked to bridge construction sites.

2.2.2.5 Bridge, Culvert, and Grade Crossing Construction

DOE would start constructing bridges, large culverts, and grade-separated crossings before other infrastructure because these features would take longer to construct. DOE would analyze the construction and use of bridges and culverts case-by-case and could utilize culverts whenever feasible.

Tables 2-20 and 2-21 list the approximate number of bridges and large culverts (those with a diameter greater than 0.91 meter [3 feet]) proposed for each alternative segment and common segment along the Caliente rail alignment and Mina rail alignment, respectively. Numerous smaller culverts would also be utilized along the rail alignment, but would not be identified until a later design stage. Fewer bridges and culverts would be required for the Mina rail alignment because it would only pass through two mountain ranges (versus seven for the Caliente rail alignment) and would pass through more flat areas.

Construction of bridges and culverts across areas of intermittent water flow would minimize physical changes to drainage channels. Most of the bridges would be short-span, precast concrete bridges. These

c. Large culverts are all culverts greater than 0.91 meter (3 feet) in diameter.

would be shipped to the construction sites in pieces and assembled on site. Figure 2-35 shows a schematic of a typical precast concrete bridge. In a few places, DOE would construct ***plate girder bridges*** instead of precast concrete bridges. In addition to the bridges listed in Tables 2-20 and 2-21, on common segment 6 of both the Caliente and the Mina rail alignments, DOE would construct one longer, specially designed bridge across Beatty Wash. This bridge would span 313 meters (1,027 feet) at an elevation of 52 meters (170 feet) and would take approximately 2 years to construct (DIRS 180922-Nevada Rail Partners 2007, p. 7-1). Figure 2-36 shows a schematic of the planned bridge.

Culverts are features that would be built into the rail roadbed to allow water to flow under the rail line. Intense, short-duration rainfalls in the area of the Caliente and Mina rail alignments can cause high peak flows that include relatively large volumes of sediment. These sediment-laden flows create a need for drainage structures where the flows would cross the proposed rail line. Culverts and bridges can be incorporated into track construction to manage rainfall and sediment flow. When flow rates would be higher than 28,000 liters (1,000 cubic feet) per second, bridges might be the most desirable alternative to accommodate sediment and rain flow. Where very wide and shallow depths of flow would occur during a ***100-year flood*** event, or the flow would be divided into multiple natural channels that would cross the rail line, multiple culverts could be constructed, along with some small bridges where the main flow would occur (DIRS 180918-Nevada Rail Partners 2007, p. ii).

To maintain access to existing private and public roads across the proposed rail line, DOE would install grade crossings where the rail line would cross a roadway (see Tables 2-22 and 2-23). In places where the rail line would cross a highway (for example, U.S. Highways 93 and 95, and State Routes 318 and 375), the routes would be grade-separated. Where the rail line would cross paved public roadways,

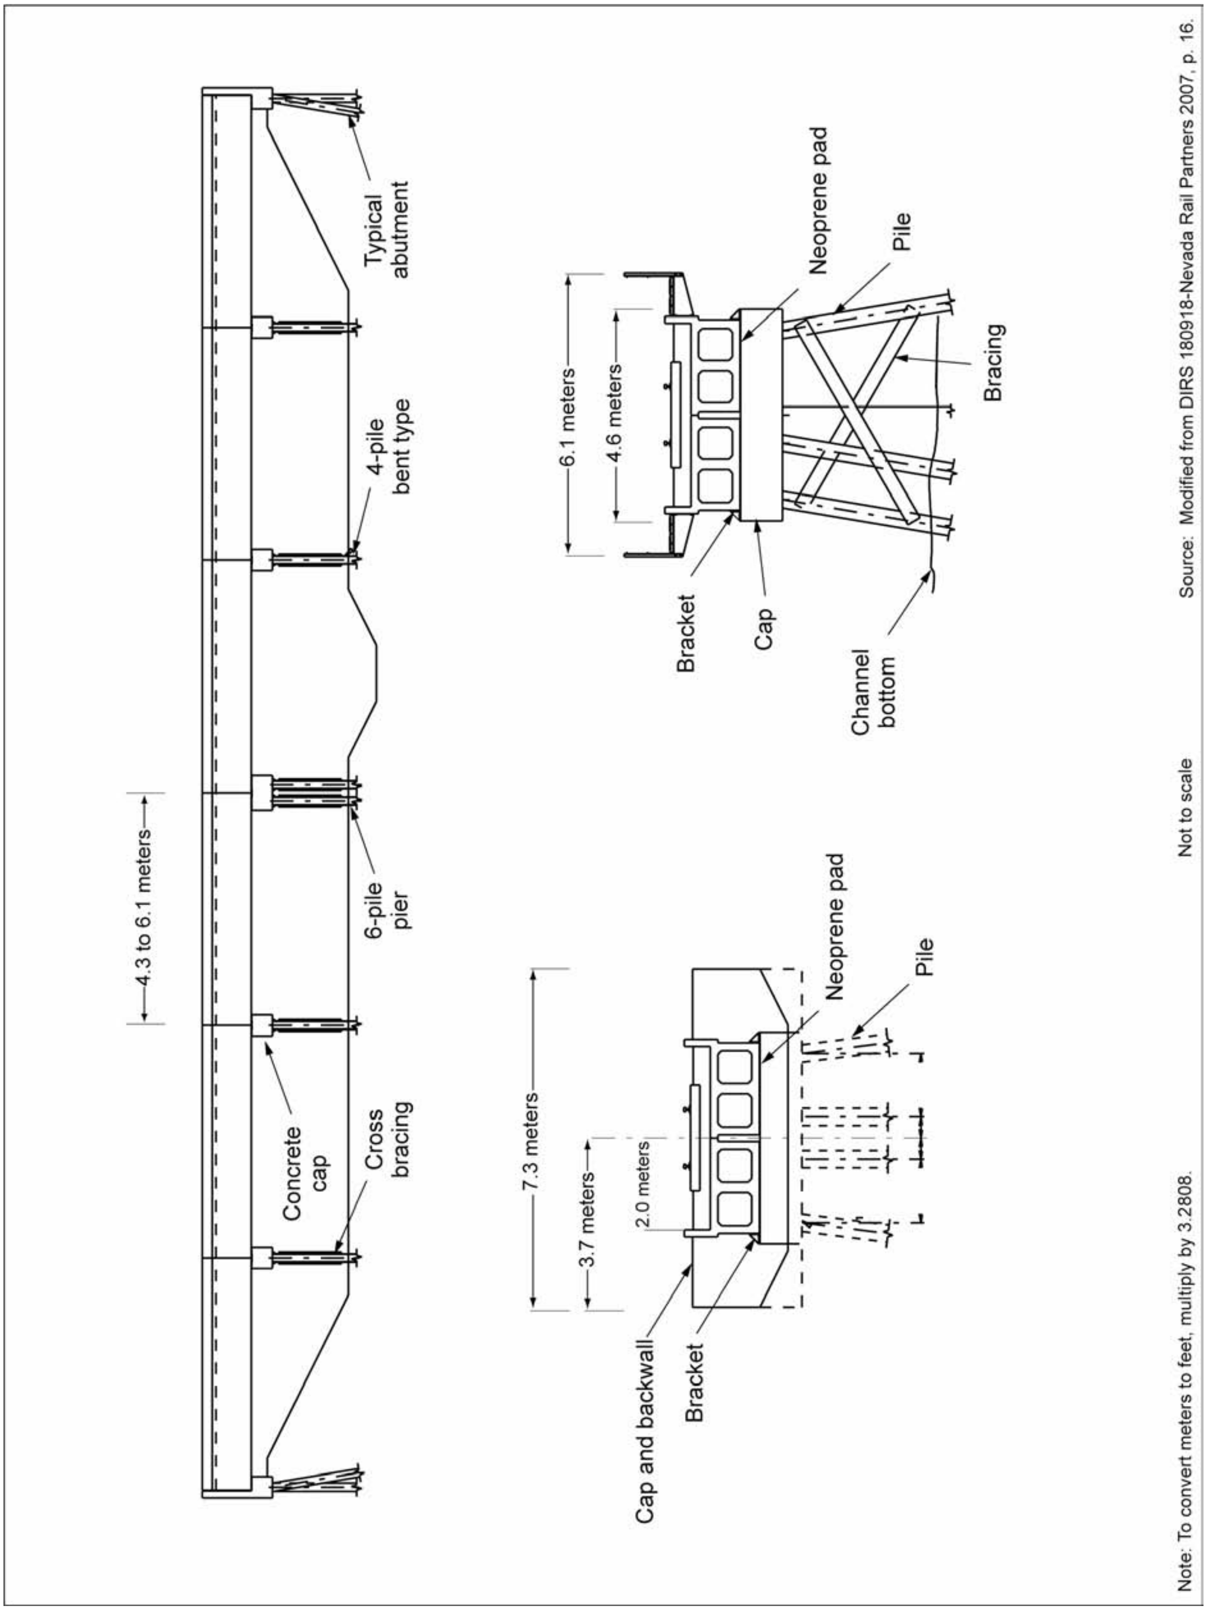

Figure 2-35. Cross-section of a typical bridge.

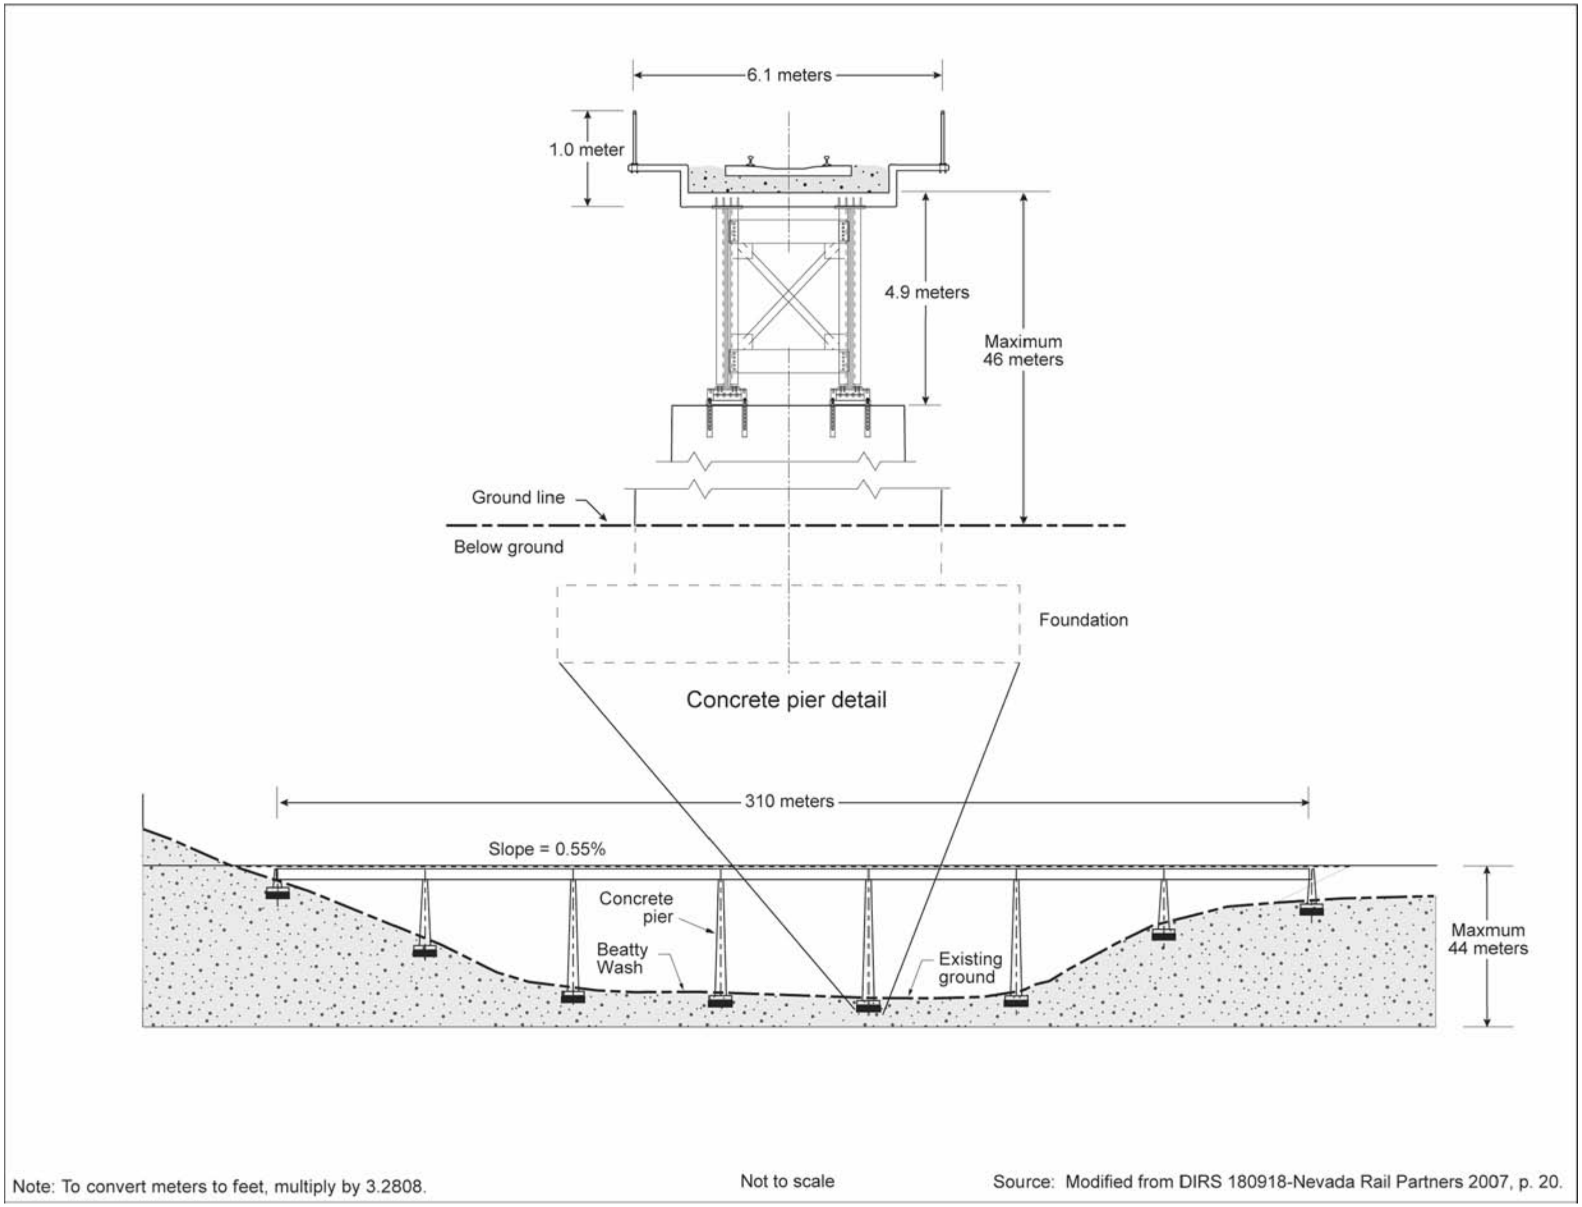

Figure 2-36. Cross-section of a planned bridge across Beatty Wash.

the routes would cross ***at-grade*** and active warning devices, such as flashing lights and gates, would be installed. Where the rail line would cross unpaved roads and private crossings, DOE would install passive warning devices such as crossbucks and stop signs (DIRS 180923-Nevada Rail Partners 2007, p. 6-9). At locations where several road crossings would occur in close proximity (generally over a distance of 0.8 kilometer [0.5 mile] or less) some minor rerouting and consolidation of crossings could occur but would not prevent crossing of the rail line. The regulatory authority to make decisions regarding roads, road closures, and rail line crossings rests with the BLM and county and local governments. DOE would work in close consultation with these groups to assure access is maintained. Tables 2-22 and 2-23 list proposed grade-separated crossings along the Caliente and Mina rail alignments, respectively.

Table 2-22. Grade-separated crossings along the Caliente rail alignment.[a]

2.2.2.6 Rail Roadbed Construction

Before any track could be placed, DOE would have to construct a suitable rail roadbed. The rail roadbed would form the base upon which the ballast, concrete ties, and rail would be laid. Figure 2-37 shows a cross-section of the design of the track and rail roadbed. Under the Caliente Implementing Alternative with a 4-year construction schedule, construction of the rail roadbed would begin simultaneously at multiple points along the rail alignment; however, under a 10-year construction schedule, rail roadbed construction would start near Caliente and progress toward Yucca Mountain. Under the Mina

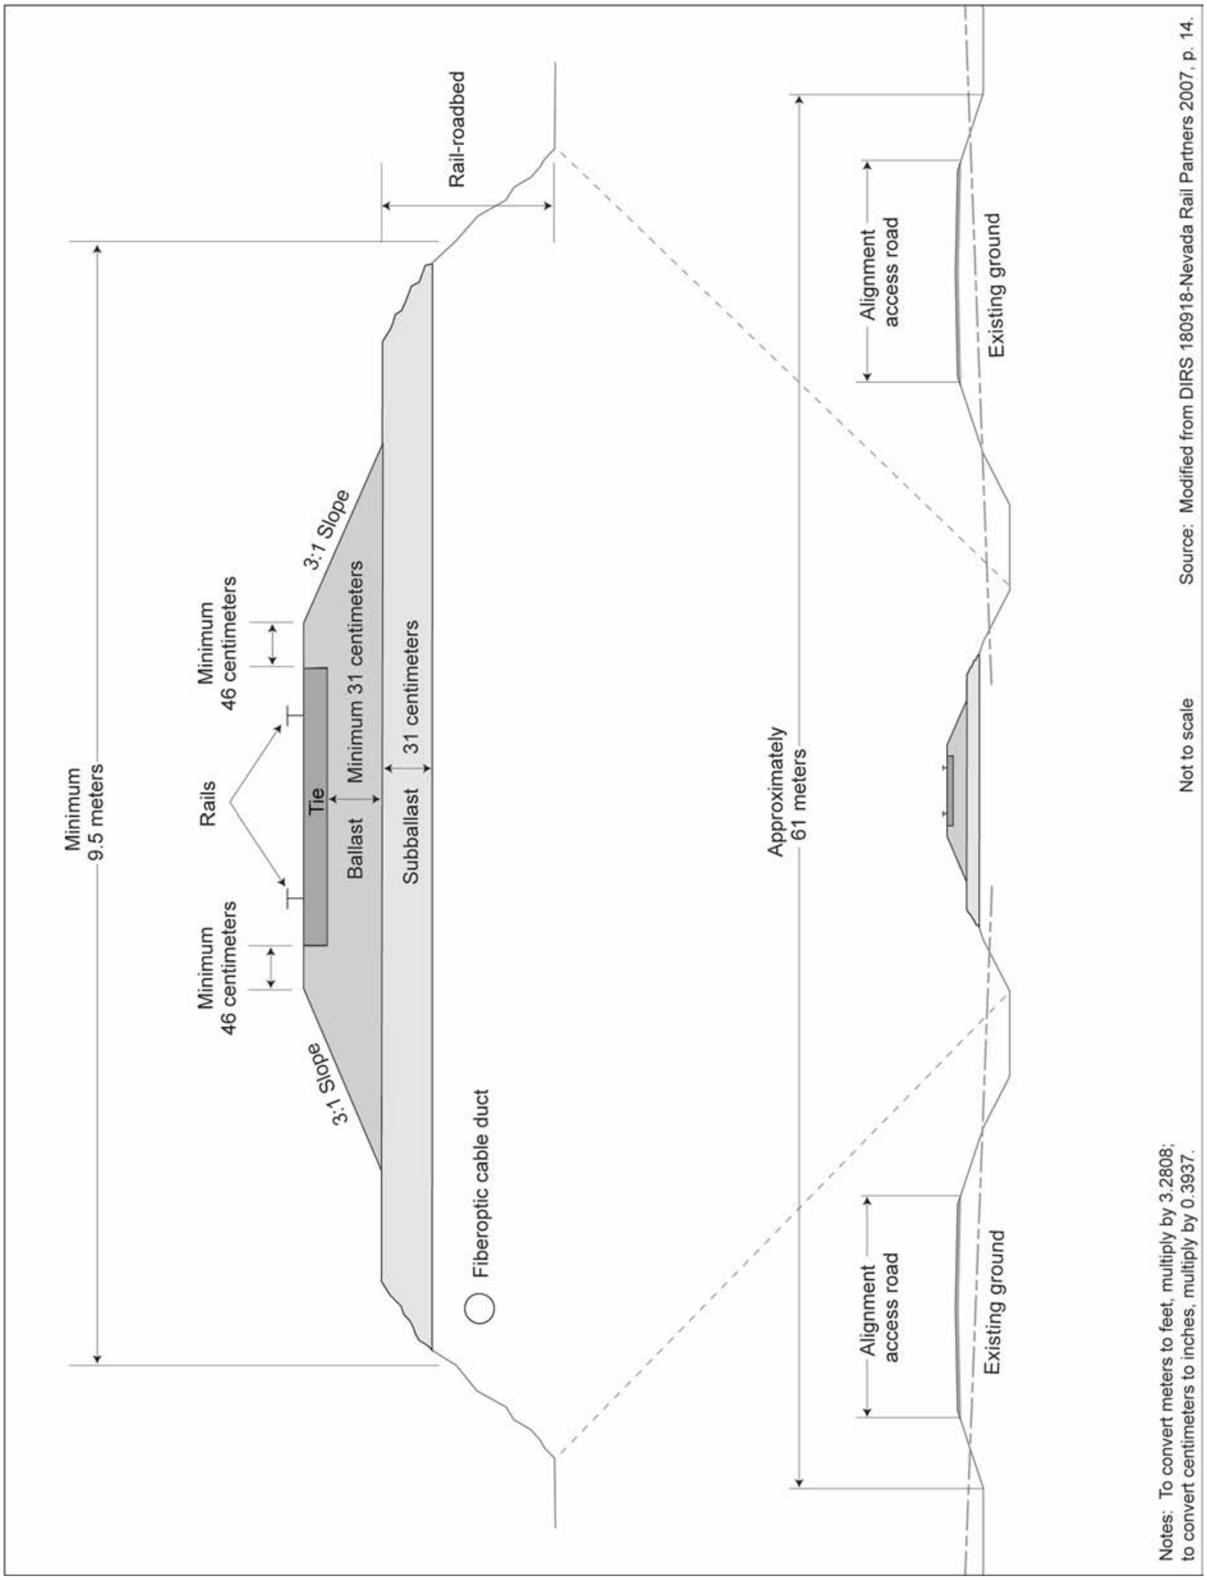

Figure 2-37. Cross-section of a typical rail and roadbed design.

Implementing Alternative, construction would follow the same progression as the Caliente rail alignment under either the 4- or 10-year schedule; however, under a 10-year construction schedule, rail roadbed construction would start near Wabuska and progress toward Yucca Mountain. Along either alignment, the rail roadbed would be constructed along the centerline of the proposed rail line (DIRS 180922-Nevada Rail Partners 2007, p. 7-1).

Construction of the rail roadbed would require clearing, excavating earth and rock on previously undisturbed lands, and removing and stockpiling topsoil where needed. Construction would require both cuts and fills. Figure 2-38 illustrates a typical cut area and a typical fill area. Tables 2-24 and 2-25 list the proposed level of disturbance, volume of cuts, and volume of fills for each segment of the Caliente rail alignment and the Mina rail alignment, respectively. The volume of cuts generated would vary depending on the rock type or material where the cut occurred.

Typical heavy-duty construction equipment (including front-end loaders, bulldozers, graders, water wagons, compactors, excavators, drill rigs, cranes, scrapers, generators, compressors, dump trucks, and other diesel-powered and gas-powered support equipment) would be used for drilling, blasting, clearing, excavation, screening, and crushing work (DIRS 180922-Nevada Rail Partners 2007, p. 7-1). To establish a stable rail roadbed for the track, construction crews would excavate some areas and fill others, as determined by terrain features. Suitable material excavated from one area would be used in an area that would require fill material, unless the distance was excessive. In such a case, DOE would establish a borrow site adjacent to the area requiring fill material and would dispose of the unused excavated material along the embankments of the rail line. In most cases, borrow and disposal sites would be inside the construction right-of-way.

Under the Mina Implementing Alternative, portions of the rail line would be built on existing rail roadbeds. A short portion of Schurz alternative segments 4, 5, and 6, Mina common segment 1, and Montezuma alternative segments 2 and 3 all contain existing rail roadbeds that would be suitable for construction of the proposed railroad.

d. To convert square kilometers to acres, multiply by 247.10.

2.2.2.7 Power Distribution Line

Under either the Caliente or the Mina Implementing Alternative, the Department would build a distribution line for electric power along the entire length of the rail alignment. The purpose of this distribution line would be to provide electric power to equipment needed for normal operation of the

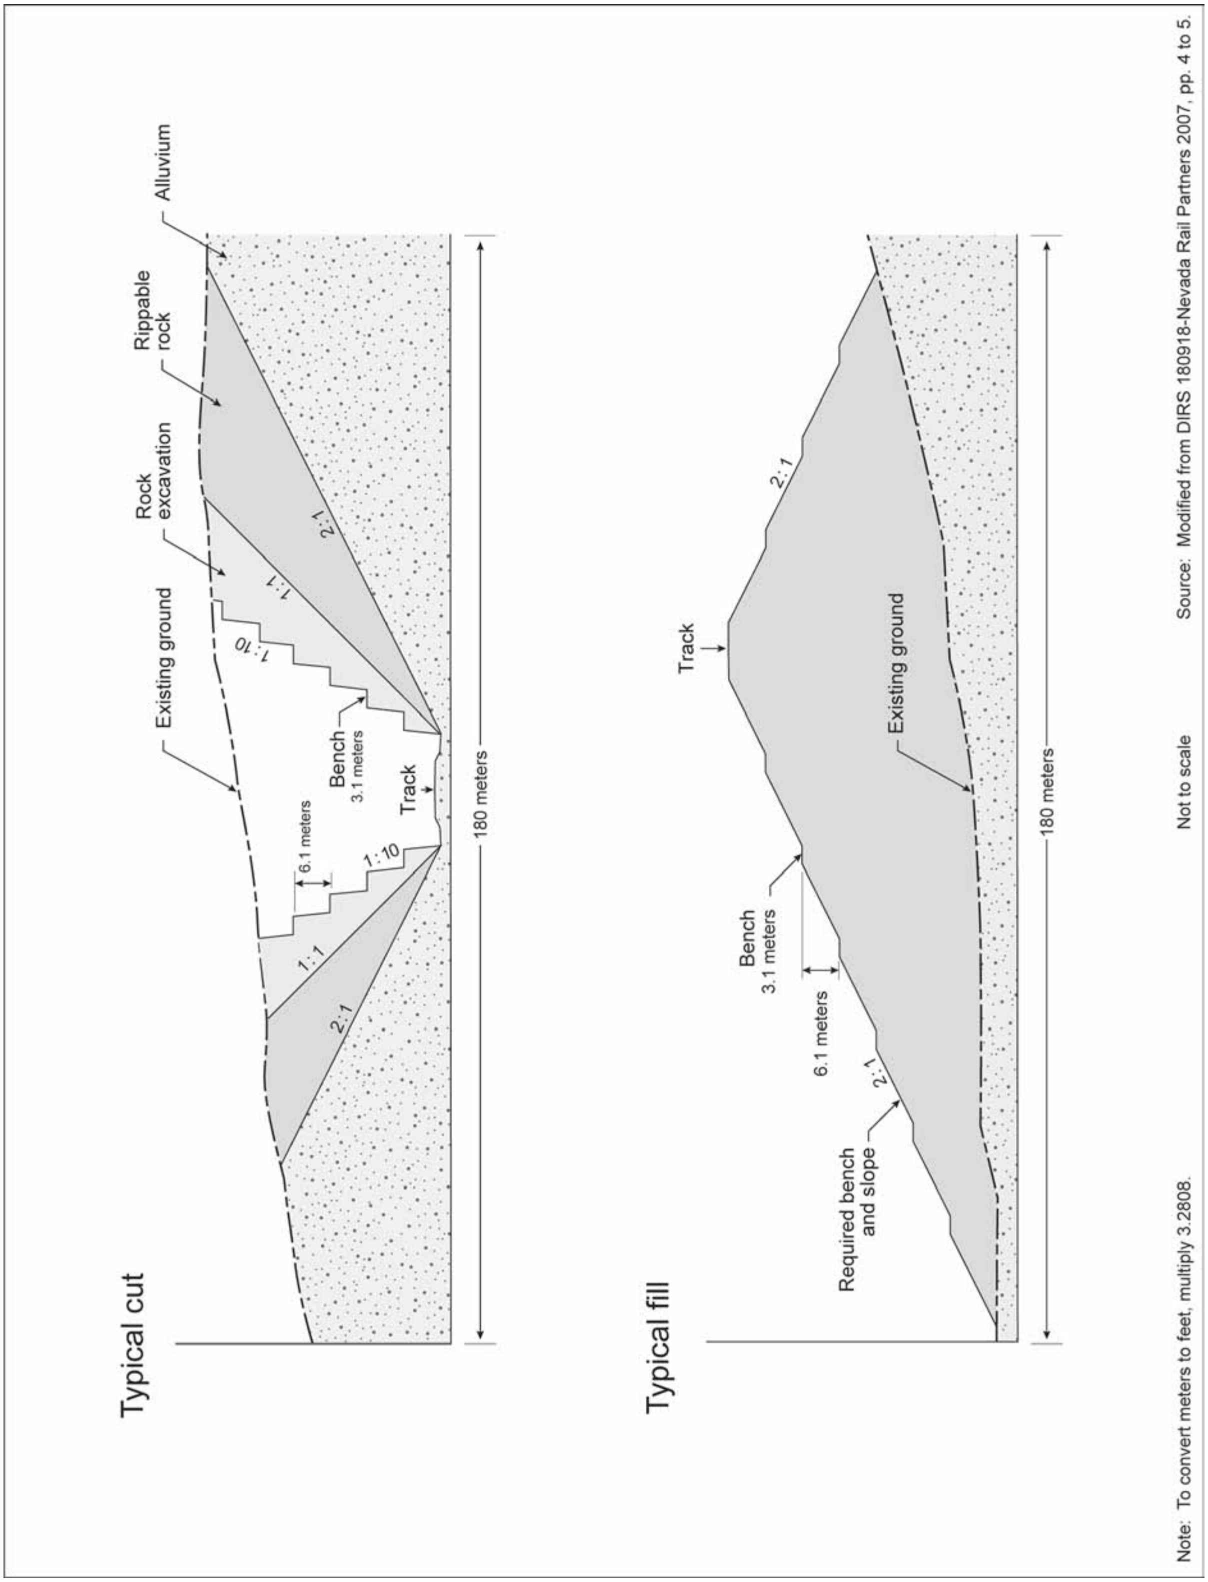

Figure 2-38. Cross-sections of a representative cut and representative fill area along the rail alignment.

railroad, such as signals and switches, and to be able to provide the capacity to meet expected power loads for facilities and operation of the railroad.

An underground high-voltage 25-kilovolt distribution line would be placed inside a trench that would be laid within the rail roadbed as it was prepared for the rail line. DOE would use the same trench to accommodate a fiber-optic line that would be the backbone for a signals and communication system for the railroad (as discussed in Section 2.2.2.9). This trench could be encased in concrete when further protection was needed. Bridge crossings would be accomplished by attaching a conduit for the distribution line to the bridge. Power to the distribution system would be fed from five locations where existing high-voltage transmission lines intersected the rail alignment. At these intersections, DOE would construct electric substations to feed the 25-kilovolt distribution line from the 115-kilovolt and/or 138-kilovolt transmission lines inside the construction right-of-way. These substations would occupy a fenced area of 15-by-15 meters (50-by-50 feet). Along the Mina rail alignment, the underground distribution line would be buried along existing Department of Defense Branchlines North and South.

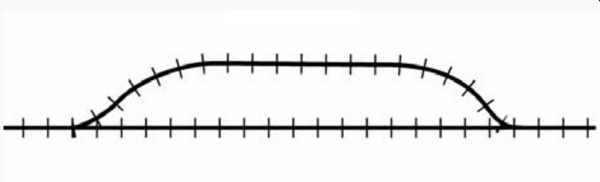
This underground distribution line could be considered as existing in sections, each end being fed at 25-kilovolts from a substation from each transmission-line intersection. If more transmission-line intersections were later identified beyond the five initially planned, shorter sections (under 80 kilometers [50 miles]) and lower line losses would allow a lower operating voltage of 13.5 kilovolts to become feasible. A 13.5-kilovolt distribution line would be more desirable from engineering and cost perspectives. Where DOE needed power to operate railroad systems, the Department would place step-down transformers trackside within 3-by-3 meter (10-by-10 foot) fenced areas.

2.2.2.8 Track Construction

Under the Caliente Implementing Alternative, track construction would begin at the start of the proposed railroad near Caliente and move west and then south along the rail alignment until it reached the Rail Equipment Maintenance Yard. Under the Mina Implementing Alternative, track construction would begin near Wabuska and move south until it reached the Rail Equipment Maintenance Yard.

Track construction would consist of placing concrete ties, rail, and ballast on top of the rail roadbed. First, concrete ties would be placed on the subballast; then DOE would use special rail equipment to unload and secure 440-meter (1,440-foot) rail strings onto the concrete ties with rail fasteners; and finally, DOE would unload ballast from rail ballast cars and dump the ballast evenly on the skeleton track in successive passes. The Department would use special equipment to raise and line the track with 7 to 10 centimeters (3 to 4 inches) of ballast on successive passes until the total depth of the ballast was a minimum of 30 centimeters (12 inches) under the ties (DIRS 180922-Nevada Rail Partners 2007, pp. 7-1 and 7-2). Figure 2-38 shows a typical cross section of the rail and underlying rail roadbed.

A **siding** is a track that runs parallel to the main line for a short distance and is used for passing and overtaking trains to prevent backups and keep traffic flowing.



Along both the Caliente and Mina rail alignments, DOE would construct sidings approximately every 40 kilometers (25 miles) so that trains running in opposite directions could pass one another. This spacing would result in approximately 12 sidings along the rail line. Sidings would be placed inside the operations right-of-way (nominally 61 meters [200 feet] on either side of the rail line centerline). Under the Caliente Implementing Alternative, sidings would range in length from approximately 2,100 to 3,700 meters (7,000 to 12,000 feet) (DIRS 180922-Nevada Rail Partners 2007, p. 2-3). Under the Mina Implementing Alternative, sidings would range in length from 2,100 to 5,800 meters (7,000 to 19,000 feet). In both cases, sidings would be designed to accommodate a maximum train length of 1,700 meters (5,500 feet). Along the Mina rail alignment, DOE would also install sidings along existing Department of Defense Branchlines North and South.

In some locations in Garden Valley where the presence of the newly constructed rail line would be incompatible with BLM management objectives for visual resources, DOE could construct low, rolling, earthwork berms with soils and vegetation that match the surroundings to mask the linear track from viewers.

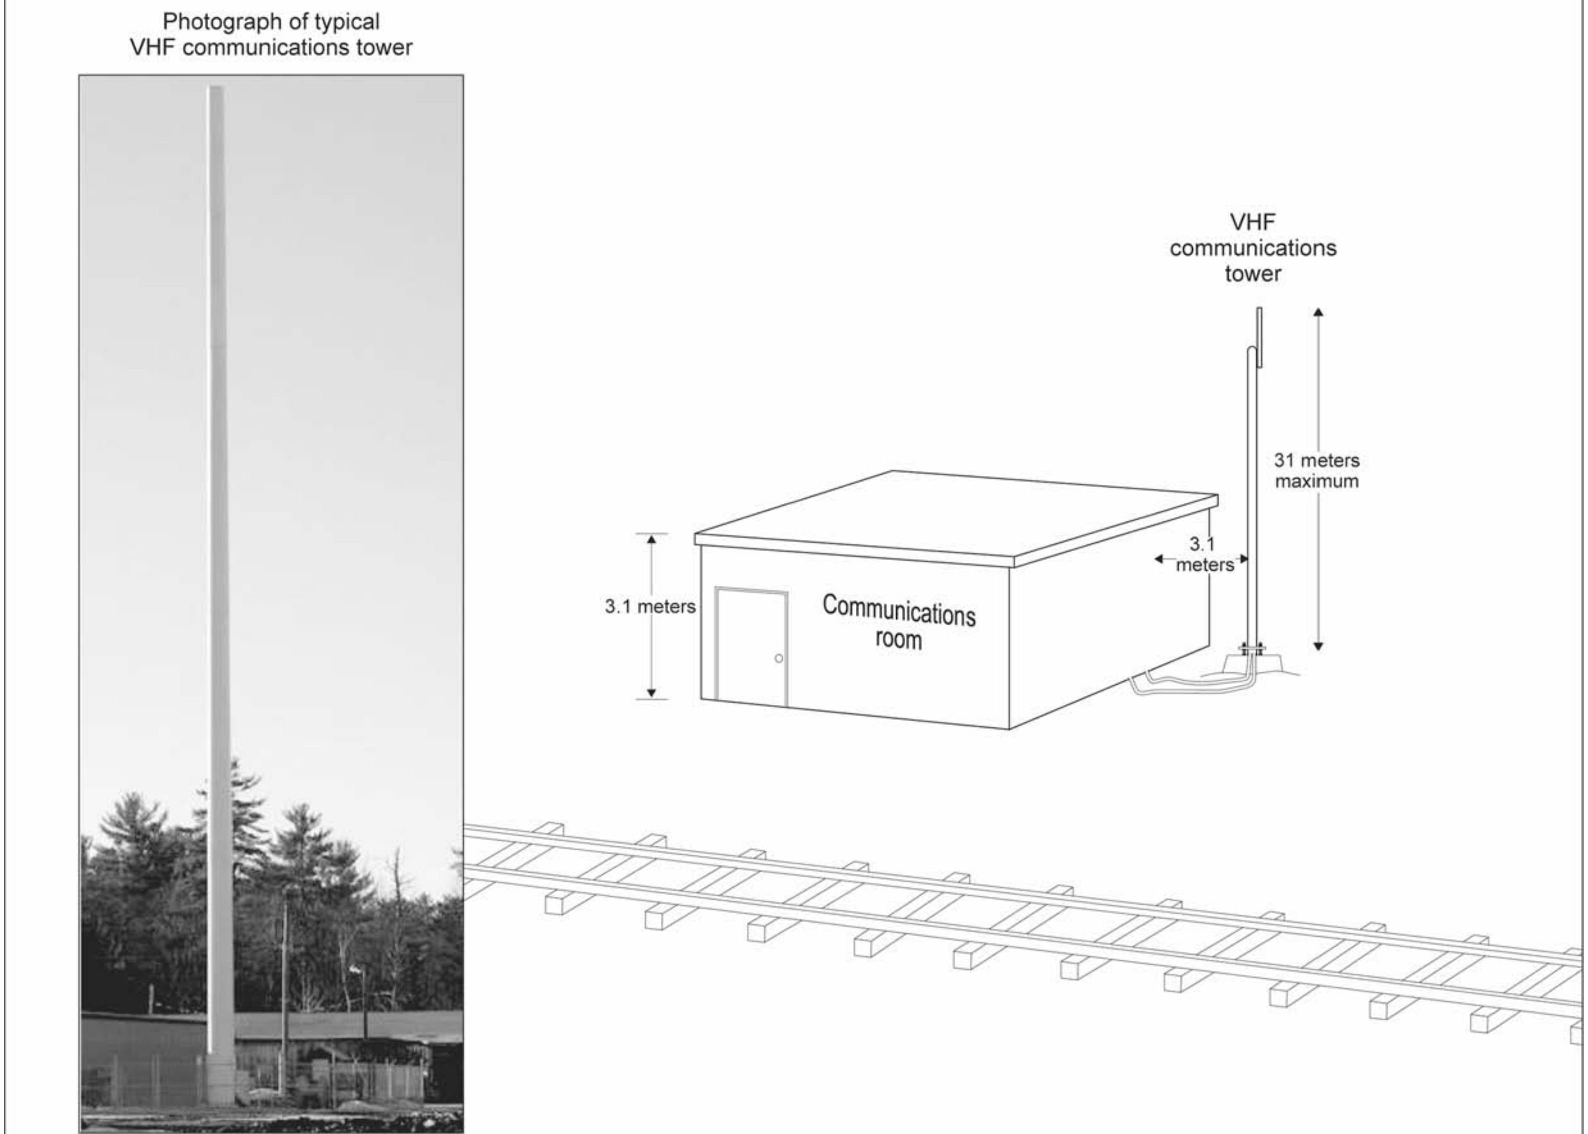
2.2.2.9 Signals and Communication Construction

Along both the Caliente and Mina rail alignments, DOE would install a communications system utilizing a fiber-optic communications cable, very-high-frequency (VHF) radio, satellite radios, and possibly satellite or cellular telephones. These systems would facilitate communications between the train operator, the Nevada Railroad Control Center (see Section 2.2.3.1.3), maintenance personnel, and ***signal blocks***. The backbone of the communications system would be the fiber-optic communications cable. This cable, which would be buried along the entire length of the rail line, would provide a common high-speed communication medium for communications applications and the control systems. To ensure continuous communications along the entire length of the Mina rail alignment, DOE would also bury this cable along existing Department of Defense Branchlines North and South.

DOE would position communications towers at the beginning, end, and approximately every 16 to 32 kilometers (10 to 20 miles) along the rail line. These towers would be approximately 23 to 30 meters (75 to 100 feet) tall, would be fenced, and would enable VHF radio communication between railroad personnel working in remote locations along the rail line. Figure 2-39 shows an example of a typical remote communications facility (DIRS 180923-Nevada Rail Partners 2007, Section 6.0).

In the case of a complete failure of the VHF radio communications system, communications would continue through a dispatch radio system utilizing satellite radios. DOE would install these backup systems in maintenance equipment, in its locomotives, and at the Nevada Railroad Control Center. In addition, DOE is considering outfitting all relevant personnel with satellite telephones, which would allow communication to continue if both the VHF and satellite radio systems failed.

DOE would use a railroad control signaling system to maintain safe train separation during operation of the proposed railroad. The proposed centralized traffic control system is a typical railroad system that uses electronic track circuits to control signal blocks and authorize train movements. DOE would install 4.6-meter (15-foot)-tall ***wayside signals*** along the rail line to control train movements. At ***at-grade crossings*** with paved public roadways, DOE would install active warning devices in the form of flashing lights, gates, and barriers. At at-grade crossings with unpaved roadways and private crossings, DOE would install passive warning devices (signs only). In addition, the signaling system would have the capability to warn the train operators about broken rails, rockslides, and certain equipment defects (DIRS 180923-Nevada Rail Partners 2007, Section 6.0).



Notes: VHF = very high frequency; to convert meters to feet, multiply by 3.2808.   Not to scale   Source: Modified from DIRS 180923-Nevada Rail Partners 2007, pp. 6-5 and 6-6.

Figure 2-39. An example of a typical remote communications facility.

2.2.2.10 Restoration of Areas Disturbed During Construction

Under the Caliente Implementing Alternative, DOE would construct the railroad in accordance with BLM rights-of-way; under the Mina Implementing Alternative, DOE would construct the railroad in accordance with BLM and/or Bureau of Indian Affairs rights-of-way. During and following construction, DOE would implement a program to:

- Identify the methods of restoration required on lands disturbed during the construction phase
- Restore and revegetate disturbed lands not required for railroad operations
- Monitor restoration programs and remediate revegetated areas as required

This program would meet DOE and BLM requirements for the restoration of disturbed sites. As part of the program, DOE would conduct reclamation inventories and develop site-specific restoration plans prior to construction. Cacti and yucca (Joshua Trees) would be salvaged, as required by State of Nevada law, prior to ground-clearing activities, maintained at nurseries, and replanted after construction was complete. DOE would stockpile topsoil on site and manage it to prevent erosion and maintain soil viability, as appropriate. Chapter 7 describes restoration programs in more detail.

2.2.2.11 Commissioning of Train Operations

The final step in railroad construction would be the commissioning of train operations. Each time a section of the track was completed and the signals and communications systems installed and tested, integrated testing would commence utilizing train equipment to validate that all components were operating as designed. Successful testing would result in final jurisdictional inspection and commissioning of the railroad for normal operations by the appropriate regulatory body.

2.2.3 RAILROAD OPERATIONS AND MAINTENANCE

Under the Proposed Action, the railroad would be expected to operate for up to 50 years for the shipment of spent nuclear fuel, high-level radioactive waste, and other materials to Yucca Mountain. DOE would operate and maintain the railroad in accordance with applicable regulations, guidelines, and standards of the Federal Railroad Administration, the Union Pacific Railroad, and the Association of American Railroads.

Operation of the proposed railroad would begin immediately after construction was completed. At that time, the railroad would be available to deliver materials to support construction of the repository. Maintenance of the proposed railroad would be an ongoing process that would be concurrent with the operations phase of both the railroad and the repository. Following the final shipment of spent nuclear fuel, high-level radioactive waste, and other materials to the repository, DOE could abandon the railroad (including its facilities) (see Section 2.2.5) or could make them available to local communities or the private sector for other uses.

Unless otherwise noted, all descriptions of railroad operations and maintenance activities apply to both the Caliente and Mina rail alignments.

2.2.3.1 Railroad Operations

The proposed railroad would operate dedicated trains carrying spent nuclear fuel and high-level radioactive waste and trains carrying other materials, which could include construction materials, diesel fuel, and repository equipment. During the operations phase, DOE would use the railroad to transport approximately 9,500 casks of spent nuclear fuel and high-level radioactive waste, and approximately

29,000 railcars of construction materials, diesel fuel, and supplies for the repository and facilities. The frequency of trains going to the repository would vary slightly, but would average 17 one-way trains per week (see Table 2-4) (calculated from DIRS 175036-BSC 2005, Table 4.2).

Under the Mina Implementing Alternative, the region-of-influence for analyses of potential impacts on ***air quality***, noise and vibration, socioeconomics, and occupational and public health and safety would include railroad operations along the Mina rail alignment and the existing Union Pacific Railroad Hazen Branchline (that is, the entire length of the rail line from Hazen to Yucca Mountain). At present, the Union Pacific Railroad and the Department of Defense operate a few trains per week along the existing branchlines. This rail traffic would continue after DOE constructed the proposed railroad. From Hazen to Wabuska, there are approximately four one-way Union Pacific Railroad trains per week that operate on the Hazen Branchline. From Hazen to Hawthorne, there are approximately four one-way Department of Defense trains per week that operate on the Hazen Branchline and the Department of Defense Branchlines (DIRS 180154-Sullivan 2007, all).

2.2.3.1.1 Operation of Spent Nuclear Fuel and High-Level Radioactive Waste Trains

Under the Proposed Action, Union Pacific Railroad trains carrying casks of spent nuclear fuel and high-level radioactive waste would arrive in Nevada via the Union Pacific Railroad Mainline and would proceed directly to the Staging Yard (see Section 2.2.4.1.1.2). Under the Caliente Implementing Alternative, trains would arrive at the proposed railroad on the Union Pacific Railroad Mainline near Caliente and proceed to the Staging Yard along either the Caliente or the Eccles alternative segment. Under the Mina Implementing Alternative, trains would arrive on the Union Pacific Railroad Mainline near Hazen and proceed to the Staging Yard via the Union Pacific Railroad Hazen Branchline, the Department of Defense Branchline North, one of the Schurz alternative segments, and the Department of Defense Branchline South.

Once at the Staging Yard, Union Pacific Railroad locomotives would uncouple from ***cask cars*** and return to the mainline. The cask cars would be inspected in accordance with Federal Railroad Administration regulations (49 CFR Part 232 and 49 CFR Part 215). Qualified inspectors would conduct all inspections, which would include an inspection of the suspension system, car body, draft system, air brakes and wheels. DOE would maintain records of these inspections. Following completion of the inspections, cask cars would be coupled to dedicated railroad cask trains (DIRS 180923-Nevada Rail Partners 2007, Section 7.2).

The dedicated cask trains on the proposed railroad would consist of two or three 4,000-horsepower diesel-electric locomotives followed by a ***buffer car***; one to five cask cars followed by another buffer car; and one ***escort car*** carrying security personnel. A typical ***DOE spent nuclear fuel***/high-level radioactive waste train carrying three loaded cask cars would weigh approximately 1,300 metric tons (1,400 tons) (see Table 2-26) (DIRS 180923-Nevada

> A **buffer car** is a railcar that would be placed at the front of a cask train between the locomotive and the first cask car and at the back of the train between the last cask car and the escort car.
>
> A **cask car** is a railcar that would be used to transport casks of spent nuclear fuel or high-level radioactive waste.
>
> An **escort car** is a passenger car that would carry security personnel.

Table 2-26. Train components, weights, and lengths.[a]

Component	Weight (metric tons)[b]	Length (meters)[c]	Number
Locomotive (DOE and Navy)	140 to 180	23	2 to 3
DOE cask and cask car	240	18 to 27	1 to 5
Naval cask and cask car	355	18 to 27	1 to 12
Buffer car (DOE and Navy)	72	18[d]	2
Escort car (DOE and Navy)	72 to 119	24[e]	DOE trains: 1 Navy trains: 1 to 2

a. Source: DIRS 180923-Nevada Rail Partners 2007, Section 5.2.2.
b. To convert metric tons to tons, multiply by 1.1023.
c. To convert meters to feet, multiply by 3.2808.
d. Buffer cars could be up to 23 meters long, but as analyzed in this Rail Alignment EIS, are assumed to be 18 meters long.
e. Escort cars could range in length from 18 to 26 meters long, but as analyzed in this Rail Alignment EIS, are assumed to be 24 meters long.

Rail Partners 2007, Section 4.3). Figure 2-40 shows an artist's conception of a repository train. Naval spent nuclear fuel trains would typically include two or three locomotives, one to 12 cask cars, a buffer car in front of the first cask car and after the last cask car, and one to two escort cars.

Following the inspection process and the assembly of dedicated cask trains, trains would depart the Staging Yard and proceed along the proposed railroad to the Rail Equipment Maintenance Yard (see Section 2.2.4.3.1). In accordance with U.S. Department of Transportation regulations (49 CFR 174.14), railcars with spent nuclear fuel or high-level radioactive waste casks would have to be moved within 48 hours of arriving at the Staging Yard (DIRS 180923-Nevada Rail Partners 2007, Section 5.1).

Trains would require fewer than 10 hours for the trip between the Staging Yard and the Rail Equipment Maintenance Yard (DIRS 180923-Nevada Rail Partners 2007, Section 5.1). The federal hours-of-service regulations (49 CFR Part 228) limit train and engine crews to 12 hours on duty. If the trip were to exceed 12 hours, a crew-change point and local crew-welfare arrangements would be required. Although 49 CFR Part 228 would not apply to the Proposed Action, DOE would adopt the regulation's policies regarding a crew's maximum hours on duty.

The Rail Equipment Maintenance Yard would serve as the termination point of the proposed railroad and the staging area for delivery of loaded cask cars to be accepted at the Yucca Mountain Repository. Once at the Rail Equipment Maintenance Yard, casks would be transferred to the geologic repository operations area for removal of the spent nuclear fuel or high-level radioactive waste. A railroad crew would bring cask cars from the Rail Equipment Maintenance Yard to the boundary of the geologic repository operations area.

After casks were unloaded at the repository, the empty casks would be transferred back to railroad control. Before casks were returned to the Staging Yard for shipment where needed to sites across the United States, the empty casks might be sent to the Cask Maintenance Facility (see Section 2.2.4.3.2). Cask Maintenance Facility personnel would perform testing, inspections, maintenance, minor decontamination, and routine repair of the casks.

Sections 3.2.10 and 4.2.10 (Caliente rail alignment) and 3.3.10 and 4.3.10 (Mina rail alignment), Occupational and Public Health and Safety, discuss the ***affected environment*** and potential occupational health and safety impacts for operation of the Cask Maintenance Facility. DOE would ensure worker radiological health and safety by maintaining compliance with the requirements outlined in 10 CFR 835 and/or 10 CFR 20. Chapter 6 discusses regulations that would apply to the Cask Maintenance Facility.

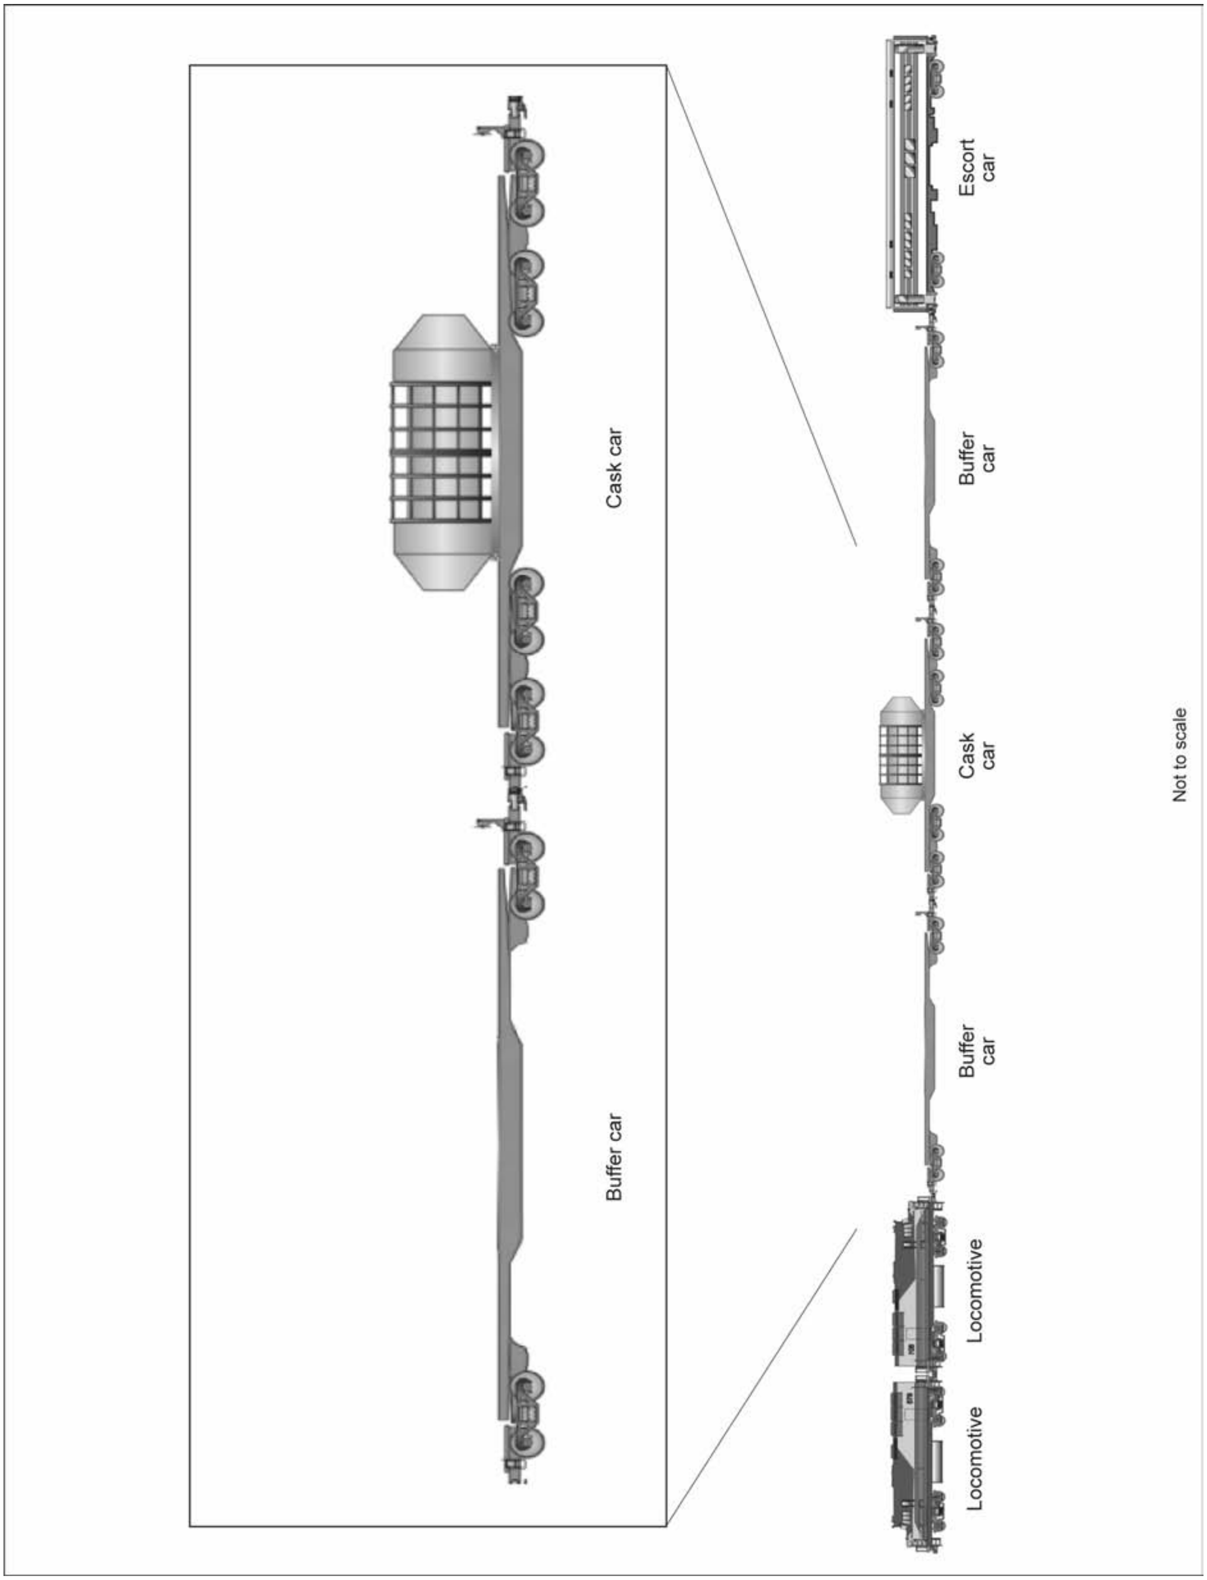


Figure 2-40. Artist's conception of a repository train carrying one cask.

2.2.3.1.2 Operations of Trains Carrying Other Materials

Under the Caliente Implementing Alternative, freight trains carrying construction and other materials (such as fuel oil and empty ***waste packages***) would arrive in Nevada via the Union Pacific Railroad Mainline and proceed directly to the Interchange Yard (see Section 2.2.4.1.1.1). Once at the Interchange Yard, Union Pacific Railroad locomotives would uncouple from their freight cars on the interchange tracks and continue on their route. Locomotives would move from the Staging Yard to the Interchange Yard, be coupled with the freight cars, and train crews would bring them to the Staging Yard for further administrative processing and inspection. From the Staging Yard, locomotives would transport the materials along the rail line to the Rail Equipment Maintenance Yard. Rail cars for return to the Union Pacific Railroad would be handled in the reverse order (DIRS 180923-Nevada Rail Partners 2007, Section 5.0).

Waste packages would consist of two thick metal cylinders, one nested within the other. The inner cylinder would be made of stainless steel to provide structural strength. The outer cylinder would be made of a nickel alloy that is highly resistant to corrosion.

Under the Mina Implementing Alternative, freight trains carrying construction and other materials would arrive in Nevada via the Union Pacific Railroad Mainline and proceed to the Staging Yard at Hawthorne via the Union Pacific Railroad Hazen Branchline, Department of Defense Branchline North, one of the Schurz alternative segments, and Department of Defense Branchline South. DOE does not plan a separate Interchange Yard along the Mina rail alignment because there is enough space to house the interchange tracks and the Staging Yard in the same location. Once at the Staging Yard, casks would go through administrative processing and inspection. From the Staging Yard, locomotives would transport the materials along the rail line to the Rail Equipment Maintenance Yard.

The same level of security necessary for railcars carrying spent nuclear fuel or high-level radioactive waste would not be necessary for railcars carrying construction or other materials. Therefore, no escort cars would be required for trains transporting construction or other materials.

2.2.3.1.3 Coordination of Shipments

The Nevada Railroad Control Center, in coordination with the DOE National Transportation Operations Center, would control the operation of the proposed railroad. Both of these facilities would be either at the Rail Equipment Maintenance Yard (see Section 2.2.4.3.1) or at the Staging Yard (see Section 2.2.4.1.1.2 [Caliente rail alignment] and Section 2.2.4.2.1 [Mina rail alignment]). The National Transportation Operations Center would oversee the shipment of casks from sites throughout the United States to the proposed railroad. All train movements, rail operations, and emergency response operations along the proposed railroad would be coordinated from the Nevada Railroad Control Center, which would have a link to both the National Transportation Operations Center and the geologic repository operations area. Section 2.2.4.3.3 describes the Nevada Railroad Control Center and the Nation Transportation Operations Center in more detail (DIRS 180923-Nevada Rail Partners 2007, Section 6.1).

DOE would use a satellite-based transportation tracking and communication system to track rail shipments of spent nuclear fuel and high-level radioactive waste to the repository. This system would provide government personnel (for example, DOE, Nuclear Regulatory Commission, and state and tribal governments) with information about shipments to the repository and would enable routine communications between government escorts accompanying shipments and the National Transportation Operations Center (DIRS 180923-Nevada Rail Partners 2007, Section 6.1). Communications between government escorts accompanying shipments, the National Transportation Operations Center, and rail carriers handling the shipments would occur in a variety of ways, as required in support of normal operations and in response to off-normal or emergency situations.

2.2.3.1.4 Coordination with State and Local Governments

Under Nuclear Regulatory Commission interim guidance, NUREG 0561, *Requirements for Physical Protection of Irradiated Reactor Fuel in Transit* (10 CFR 73.37), DOE would make available to state governors specific information about shipments, such as departure times and locations during travel.

Section 180(c) of the Nuclear Waste Policy Act (NWPA, as amended [42 U.S.C. 10101]) requires DOE to provide technical assistance and funding to states and American Indian tribes for training public safety officials and tribes in jurisdictions through which it plans to transport spent nuclear fuel and high-level radioactive waste. The training, including drills and exercises, would include procedures for the safe routine transportation of these materials, and ***accident*** and emergency response procedures. DOE would provide carriers with shipping papers containing emergency information, including contacts and telephone numbers, which would be readily available during transport for inspection by appropriate officials, and would provide clearly identifiable markings, labels, and placards of hazardous contents.

DOE is developing the policy and procedures for implementing this assistance and would institute these plans before it began shipments to the repository. In the event of an incident involving a shipment of spent nuclear fuel or high-level radioactive waste, the dispatcher in the Nevada Railroad Control Center would notify local authorities and the National Transportation Operations Center.

Chapter 6 provides a more detailed description of applicable laws and regulations.

2.2.3.2 Maintenance

2.2.3.2.1 Railroad Maintenance

Under the Caliente Implementing Alternative, most of the maintenance and inspections required to operate a safe and reliable railroad would be performed out of the Maintenance-of-Way Facilities, which consist of the Maintenance-of-Way Trackside Facility (see Section 2.2.4.1.2.1), Maintenance-of-Way Headquarters Facility (see Section 2.2.4.1.2.2), and two Satellite Maintenance-of-Way Facilities (see Section 2.2.4.1.2.3). Staff at the Headquarters Facility would plan and schedule all maintenance and inspection activities originating from the trackside and satellite facilities in coordination with the Nevada Railroad Control Center. Maintenance activities would be scheduled to minimize the impact on planned train movements (DIRS 180923-Nevada Rail Partners 2007, Section 10.0).

The Maintenance-of-Way Trackside Facility would serve as the base of operations for most maintenance activities on the proposed railroad. The two Satellite Maintenance-of-Way Facilities, which would be located at the Staging Yard and the Rail Equipment Maintenance Yard, would be the dispatch points for routine maintenance along the first third (in the case of the Staging Yard location) and the final third (in the case of the Rail Equipment Maintenance Yard location) portions of the rail line. The primary maintenance and inspection functions of these facilities would include track inspection; signal testing and inspection; minor rail, tie, and turnout replacement; and routine ballasting and surfacing tasks. Additional maintenance to be performed on an as-needed basis would include:

- Ultrasonic rail testing (performed annually) to detect internal flaws such as cracks in the rail
- Rail grinding to maintain the structural integrity of the rail, reduce noise, and prevent wear and tear to the trains
- Weed and brush control (annually or as needed)

- Vehicle and equipment maintenance (as needed)
- Track surfacing (as needed) to maintain a level and aligned track

> **Hi-rail trucks** are vehicles capable of traveling on roads or on railroad tracks.

Maintenance crews would access the work area using ***hi-rail trucks***, rail mounted machinery (such as a tamper or track liner), or maintenance trains, all of which would originate from the Maintenance-of-Way Headquarters Facility, the Maintenance-of-Way Trackside Facility, or one of the two Satellite Maintenance-of-Way Facilities. During rail line construction, DOE would install unpaved roads parallel to the rail line inside the construction right-of-way. The Department would leave these rail alignment access roads in place to provide additional access to the rail line for maintenance and emergency response, and to act as firebreaks. Because all maintenance would be performed using on-rail vehicles or trains, no bridges would need to be constructed for access roads (DIRS 180923-Nevada Rail Partners 2007, Section 10.0).

In the case of a maintenance train dispatched for activities that would extend for more than 1 day, the maintenance train would be moved to the nearest siding to allow line traffic to pass. Slow-order running (that is, reduced speed limit) could be necessary for the trains running through the area undergoing track maintenance. Maintenance trains might consist of a locomotive and crew cars with provisions, and human habitability systems, such as toilets. Power for lighting, cooling, and refrigeration would be provided from the locomotive; external lighting and equipment would be powered using diesel generators (DIRS 180923-Nevada Rail Partners 2007, Section 10.0).

DOE would implement an asset protection program based on American Railway Engineering and Maintenance-of-Way Association guidelines and industry practices. Examples include:

- Detectors to determine if any wheel bearings are overheating, which could cause the train to derail.
- Impact detectors to indicate that a wheel is warped or has flat spots. Wheels having these defects can shatter or damage miles of rail due to excessive impacts.
- Dragging-detection equipment to indicate if objects are dragging under the train, which could damage the track structure.

In addition to maintenance activities, the staff at the Maintenance-of-Way Headquarters Facility would be responsible for responding to any minor rail accident or derailment. They would coordinate response activities to recover locomotives, railcars, casks, or other equipment that might have derailed. In the event of an accident requiring additional capability, an outside contractor would be retained to assist with any repair or recovery activities (DIRS 180923-Nevada Rail Partners 2007, Section 10.0).

Under the Mina Implementing Alternative, the functionalities described above for the Maintenance-of-Way Trackside Facility and the Maintenance-of-Way Headquarters Facility would be combined and housed in a single Maintenance-of-Way Facility. All maintenance activities would be performed out of this facility and two Satellite Maintenance-of-Way Facilities, one at the Staging Yard and one at the Rail Equipment Maintenance Yard. Maintenance activities along the Mina rail alignment would include maintaining the existing Department of Defense Branchlines as needed (DIRS 180876-Nevada Rail Partners 2007, Section 10.0).

2.2.3.2.2 Maintenance of the Fleet of Locomotives and Railcars

Locomotive maintenance would be an ongoing activity that would occur at the locomotive light repair shop at the Rail Equipment Maintenance Yard. This facility would be responsible for servicing, cleaning, fueling, washing, inspecting, provisioning, and maintaining locomotives and buffer cars. Heavy repair of locomotives would be performed, on a scheduled basis and for any major breakdowns, at an offsite commercial locomotive repair facility. Escort cars would be maintained at the escort car service shop, which would be at the Rail Equipment Maintenance Yard. This facility would be responsible for cleaning the cars, restocking supplies, and servicing toilets. Cask cars and buffer cars would be maintained at the Rail Equipment Maintenance Yard.

2.2.4 RAILROAD OPERATIONS SUPPORT FACILITIES

The Proposed Action includes the construction and operation of several facilities that would be required for operation of the proposed railroad. Under the Caliente Implementing Alternative, these would include, as described in Table 2-27 and shown in Figure 2-41:

- Facilities at the Interface with the Union Pacific Railroad Mainline (Staging and Interchange Yards)
- Maintenance-of-Way Facilities (Headquarters Facility, Trackside Facility, and Satellite Facilities)
- Rail Equipment Maintenance Yard
- Cask Maintenance Facility
- Nevada Railroad Control Center and National Transportation Operations Center

Under the Mina Implementing Alternative, facilities would include, as described in Table 2-27 and shown in Figure 2-42:

- Staging Yard
- Maintenance-of-Way Facility
- Satellite Maintenance-of-Way Facilities
- Rail Equipment Maintenance Yard
- Cask Maintenance Facility
- Nevada Railroad Control Center and National Transportation Operations Center

For both the Caliente and Mina rail alignments, the Rail Equipment Maintenance Yard would be in the same location and would have the same functions.

Sections 2.2.4.1 and 2.2.4.2 describe the functions, sizes, and possible locations of these facilities along the Caliente and Mina rail alignments. DOE would construct these facilities at the same time it is constructing the rail line, and would coordinate facilities construction with rail line construction. DOE would use typical heavy construction equipment and employ best management practices during construction of these railroad facilities.

2.2.4.1 Caliente Rail Alignment Facilities

2.2.4.1.1 Facilities at the Interface with the Union Pacific Railroad Mainline

2.2.4.1.1.1 Interchange Yard. The purpose of the Interchange Yard would be to allow the exchange of railcars containing construction and other materials between the Union Pacific Railroad and the proposed railroad. It would consist of three tracks constructed along the existing Union Pacific Railroad Mainline (DIRS 180919-Nevada Rail Partners 2007, p. 4-1). Under the Caliente Implementing Alternative, the Department would locate the Interchange Yard either at the beginning of the Eccles alternative segment (see Figure 2-43 and Map Atlas [DIRS 182843-ICF 2007, Part A, Plate 2]) or the beginning of the Caliente alternative segment (see Figure 2-44 and Map Atlas [DIRS 182843-ICF 2007, Part A, Plates 12 and 13]).

Table 2-27. Railroad operations support facilities – Caliente and Mina rail alignments (page 1 of 2).

Facility	Location	General function	Number of employees required for operations
Facilities along the Caliente rail alignment (see Section 2.2.4.1)			
Facilities at the Interface with the Union Pacific Railroad Mainline (see Section 2.2.4.1.1)			
Interchange Yard	Caliente or Eccles alternative segment Lincoln County	Handling point for the exchange of railcars containing construction and other materials between the Union Pacific Railroad Mainline and the proposed railroad	0 (employees would be based at the Staging Yard)
Staging Yard	Caliente alternative segment: Indian Cove or Upland option Eccles alternative segment: Eccles-North Lincoln County	Transfer point for cask trains and other materials delivered to the proposed railroad from around the country	50 (including employees for the Nevada Railroad Control Center and National Transportation Operations Center if at the Staging Yard)
Maintenance-of-Way Facilities (see Section 2.2.4.1.2)			
Maintenance-of-Way Headquarters Facility	Approximately 8 kilometers[a] south of Tonopah; or, anywhere along U.S. Highway 95 between the analyzed location south of Tonopah and the intersection of Goldfield alternative segment 4 and U.S. Highway 95 Esmeralda County	Coordination center for all maintenance activities along the proposed railroad	10
Maintenance-of-Way Trackside Facility	Approximately 50 kilometers southeast of Tonopah along Caliente common segment 3, or anywhere along Caliente common segment 3 between the analyzed location and the start of the Goldfield alternative segments Nye County	Base of operations for most maintenance activities along the rail alignment	40
Satellite Maintenance-of-Way Facility	Staging Yard and Rail Equipment Maintenance Yard Lincoln County and Nye County	Dispatch point for maintenance activities along the first third and final third of the rail line	0 (employees housed at the Maintenance-of-Way Trackside and Headquarters Facilities)
Facilities along the Mina rail alignment (see Section 2.2.4.2)			
Staging Yard	Mina common segment 1 near Hawthorne Mineral County	Transfer point for casks and other materials delivered to the proposed railroad from around the country Handling point for the exchange of railcars containing construction and other materials between the Union Pacific Railroad and the proposed railroad	40

Table 2-27. Railroad operations support facilities – Caliente and Mina rail alignments (page 2 of 2).

Facility	Location	General function	Number of employees required for operations
Facilities along the Mina rail alignment (see Section 2.2.4.2)			
Maintenance-of-Way Facility	Montezuma alternative segment 1, Silver Peak option Montezuma alternative segments 2 and 3, Klondike option Esmeralda County	Coordination center and base of operations for all maintenance activities along the proposed railroad	40
Satellite Maintenance-of-Way Facility	Staging Yard and Rail Equipment Maintenance Yard Mineral County and Nye County	Dispatch point for maintenance activities along the first third and final third of the rail line	0 (employees based a the Maintenance-of-Way Facility)
Facilities common to both the Caliente and Mina rail alignments (see Section 2.2.4.3)			
Rail Equipment Maintenance Yard	Less than 1.6 kilometers south of the southern boundary of the geologic repository operations area Nye County	Termination point for the proposed railroad and the staging area for the delivery of loaded cask cars and other materials to the repository receiving and inspection area	40 (including employees for the Nevada Railroad Control Center and National Transportation Operations Center if located at the Rail Equipment Maintenance Yard)
Cask Maintenance Facility	Collocated with the Rail Equipment Maintenance Yard Nye County	Processing location for all transportation casks, including inspection, certification, maintenance and decontamination	30
Nevada Railroad Control Center and National Transportation Operations Center (see Section 2.2.3)	Collocated with the Rail Equipment Maintenance Yard or the Staging Yard Nye County, Lincoln County, or Mineral County	Nevada Railroad Control Center would control operations along the proposed railroad; the National Transportation Operations Center would coordinate the national shipment of casks and other materials to the proposed railroad	15

a. To convert kilometers to miles, multiply by 0.62137.

The Interchange Yard at Caliente would be in the City of Caliente across from the former Union Pacific Railroad Caliente station. The site is flat, open, and not occupied by any structures. Site preparation for the Interchange Yard at Caliente would be minimal.

The Interchange Yard at Eccles would be approximately 8 kilometers (5 miles) east of the City of Caliente. It would be constructed immediately adjacent to the Union Pacific Railroad Mainline within the confines of Clover Creek (DIRS 180919-Nevada Rail Partners 2007, p. 4-2). Clover Creek drains an area of about 970 square kilometers (240,000 acres) east of the site. Drainage through the site is from east to west, toward Meadow Valley and Caliente. Construction of the Interchange Yard at Eccles would require portions of Clover Creek to be filled to elevate the site out of the ***floodplain***. For construction of the interchange tracks, the fill would extend approximately 15 to 23 meters (50 to 75 feet) into the creek for a length of approximately 1,400 meters (4,600 feet) along the creek. For construction of the interchange siding, the fill would extend approximately 7.6 meters (25 feet) into the ***ephemeral creek*** bed for a length of approximately 900 meters (3,000 feet) on the east end and 600 meters (2,000 feet) on the west end of the interchange tracks. DOE would perform this work in compliance with Section 404 of the Clean Water Act permitting requirements and all applicable federal and state regulations.

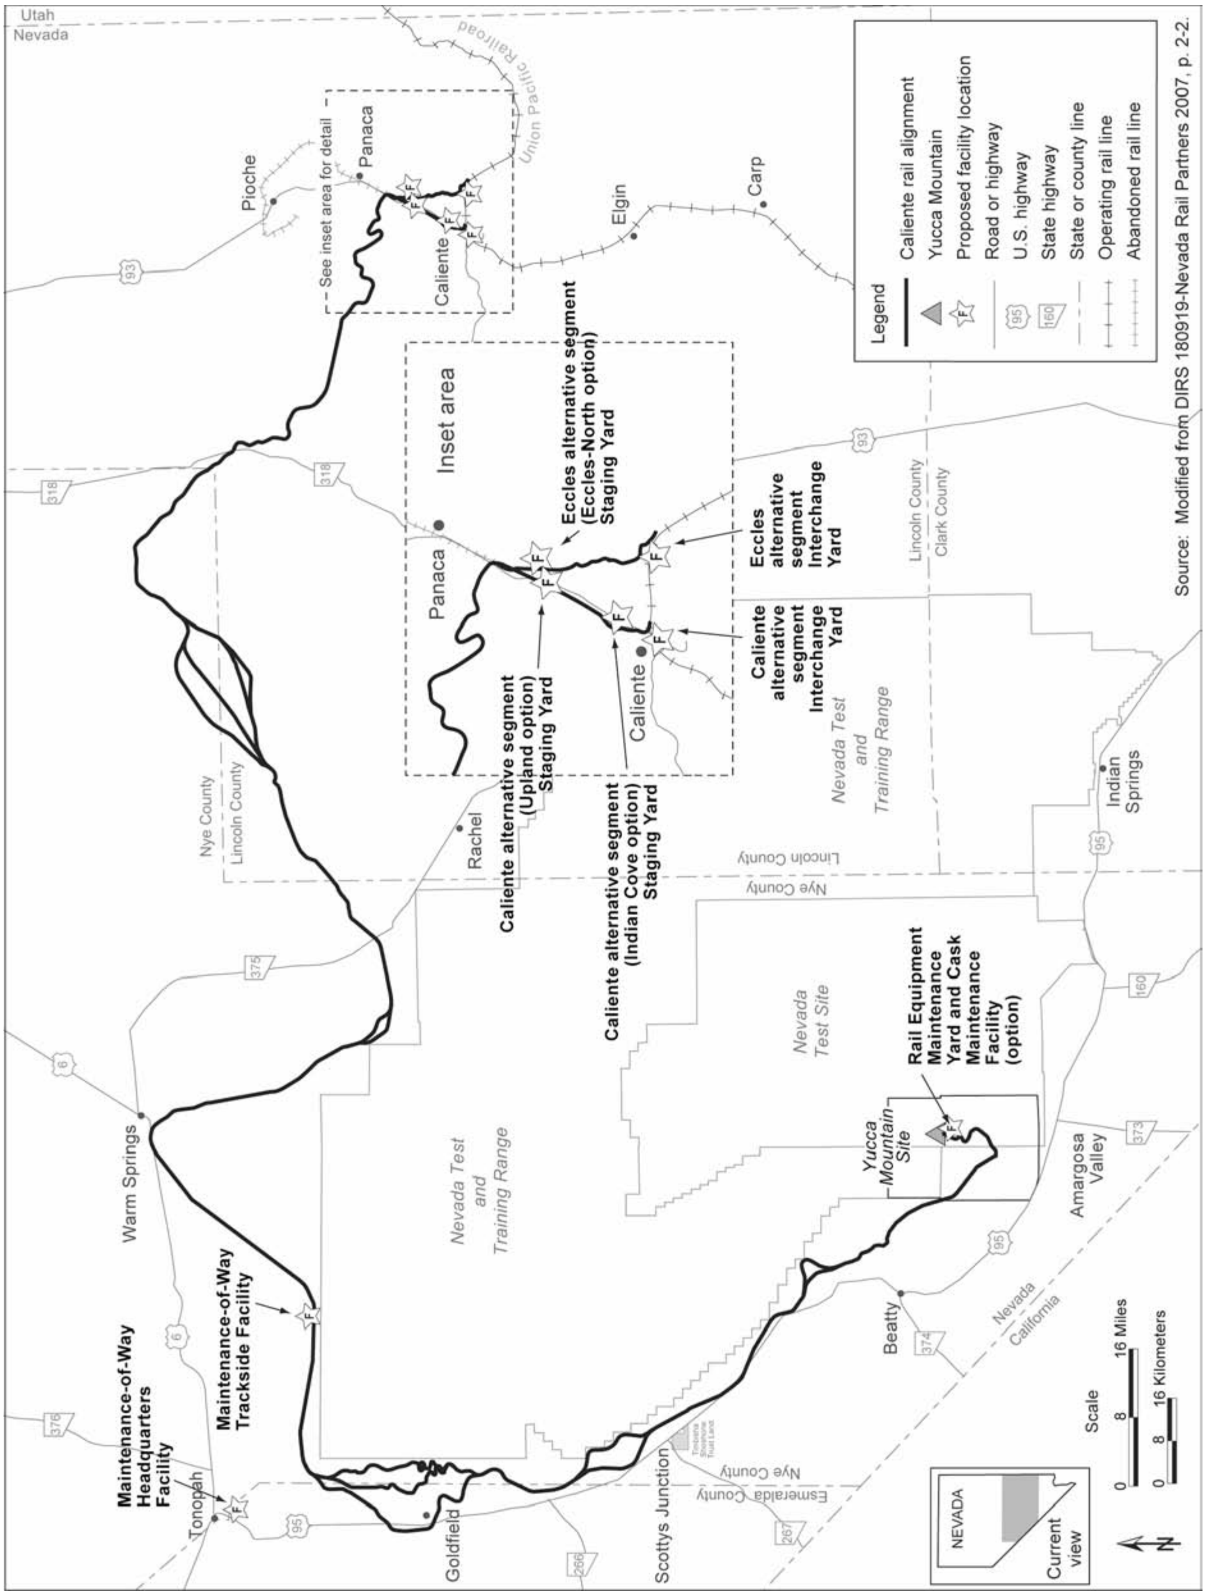

Figure 2-41. Proposed facilities along the Caliente rail alignment.

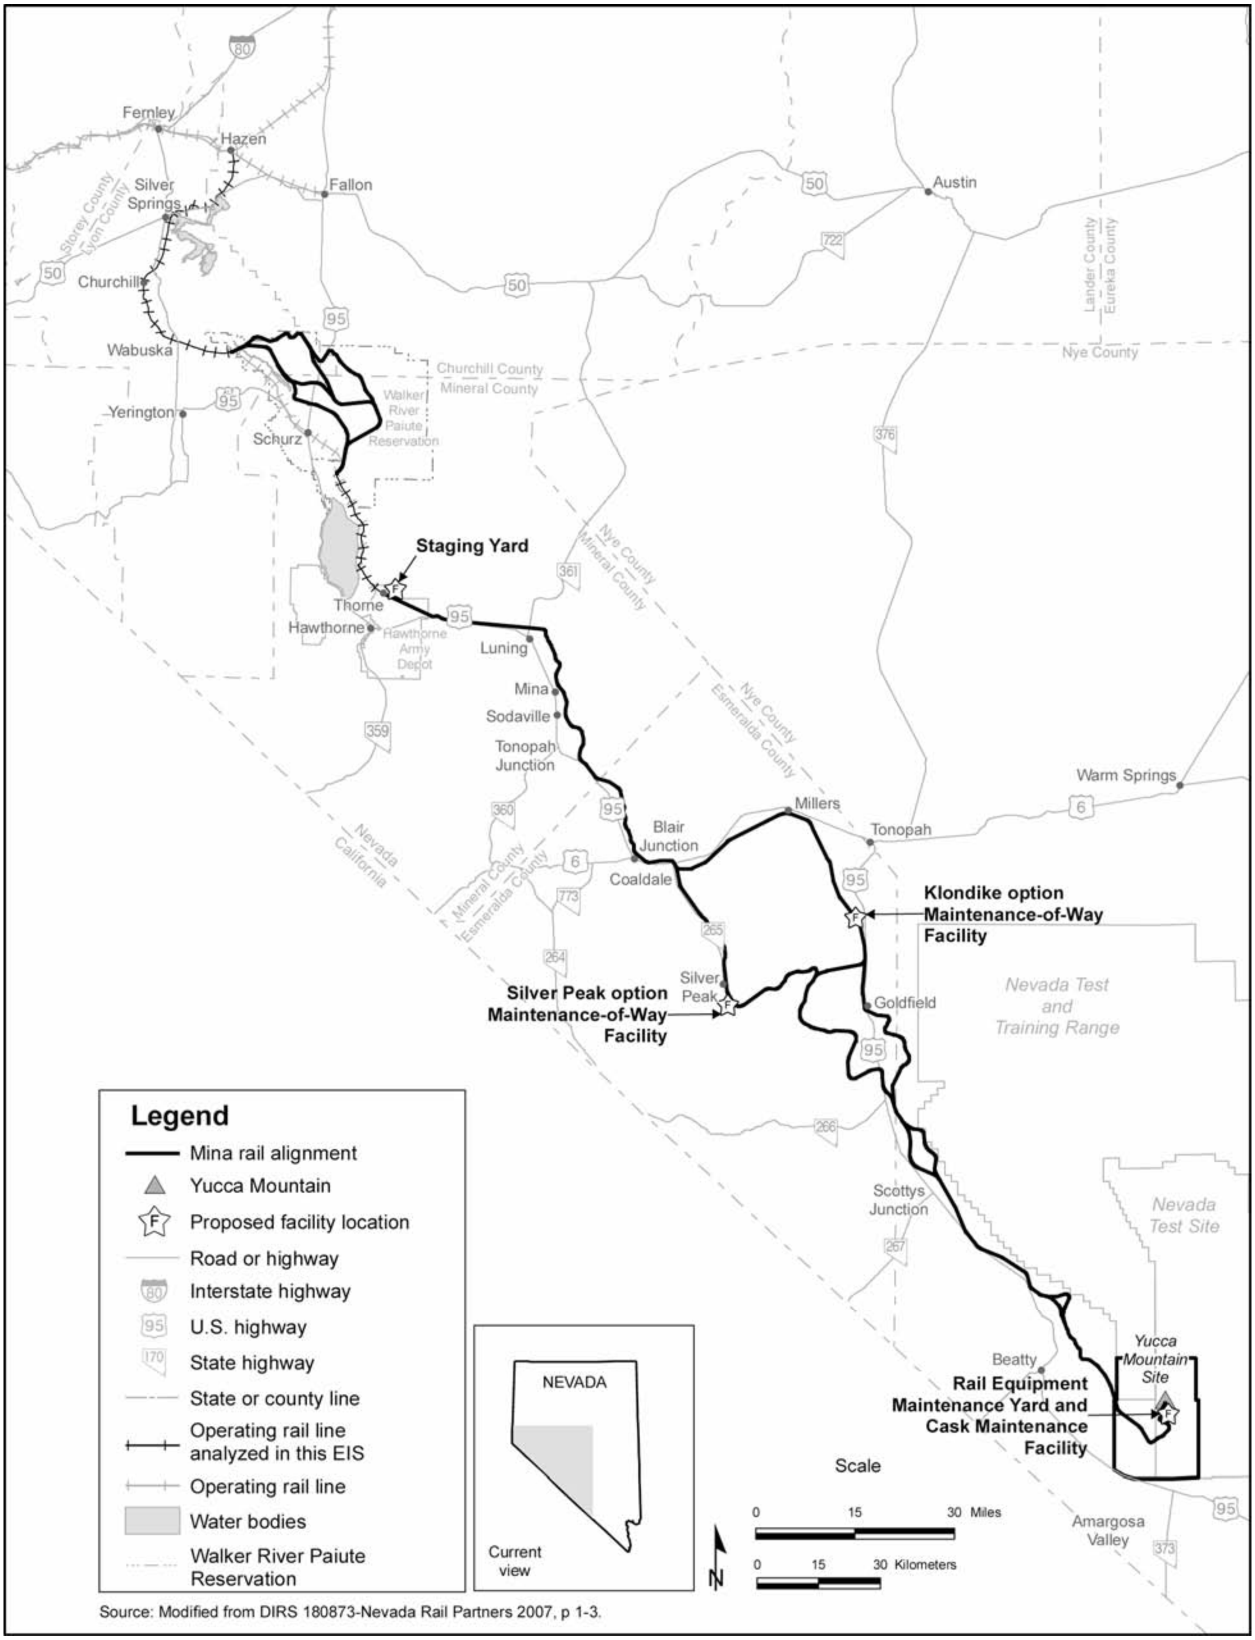

Figure 2-42. Proposed facilities along the Mina rail alignment.

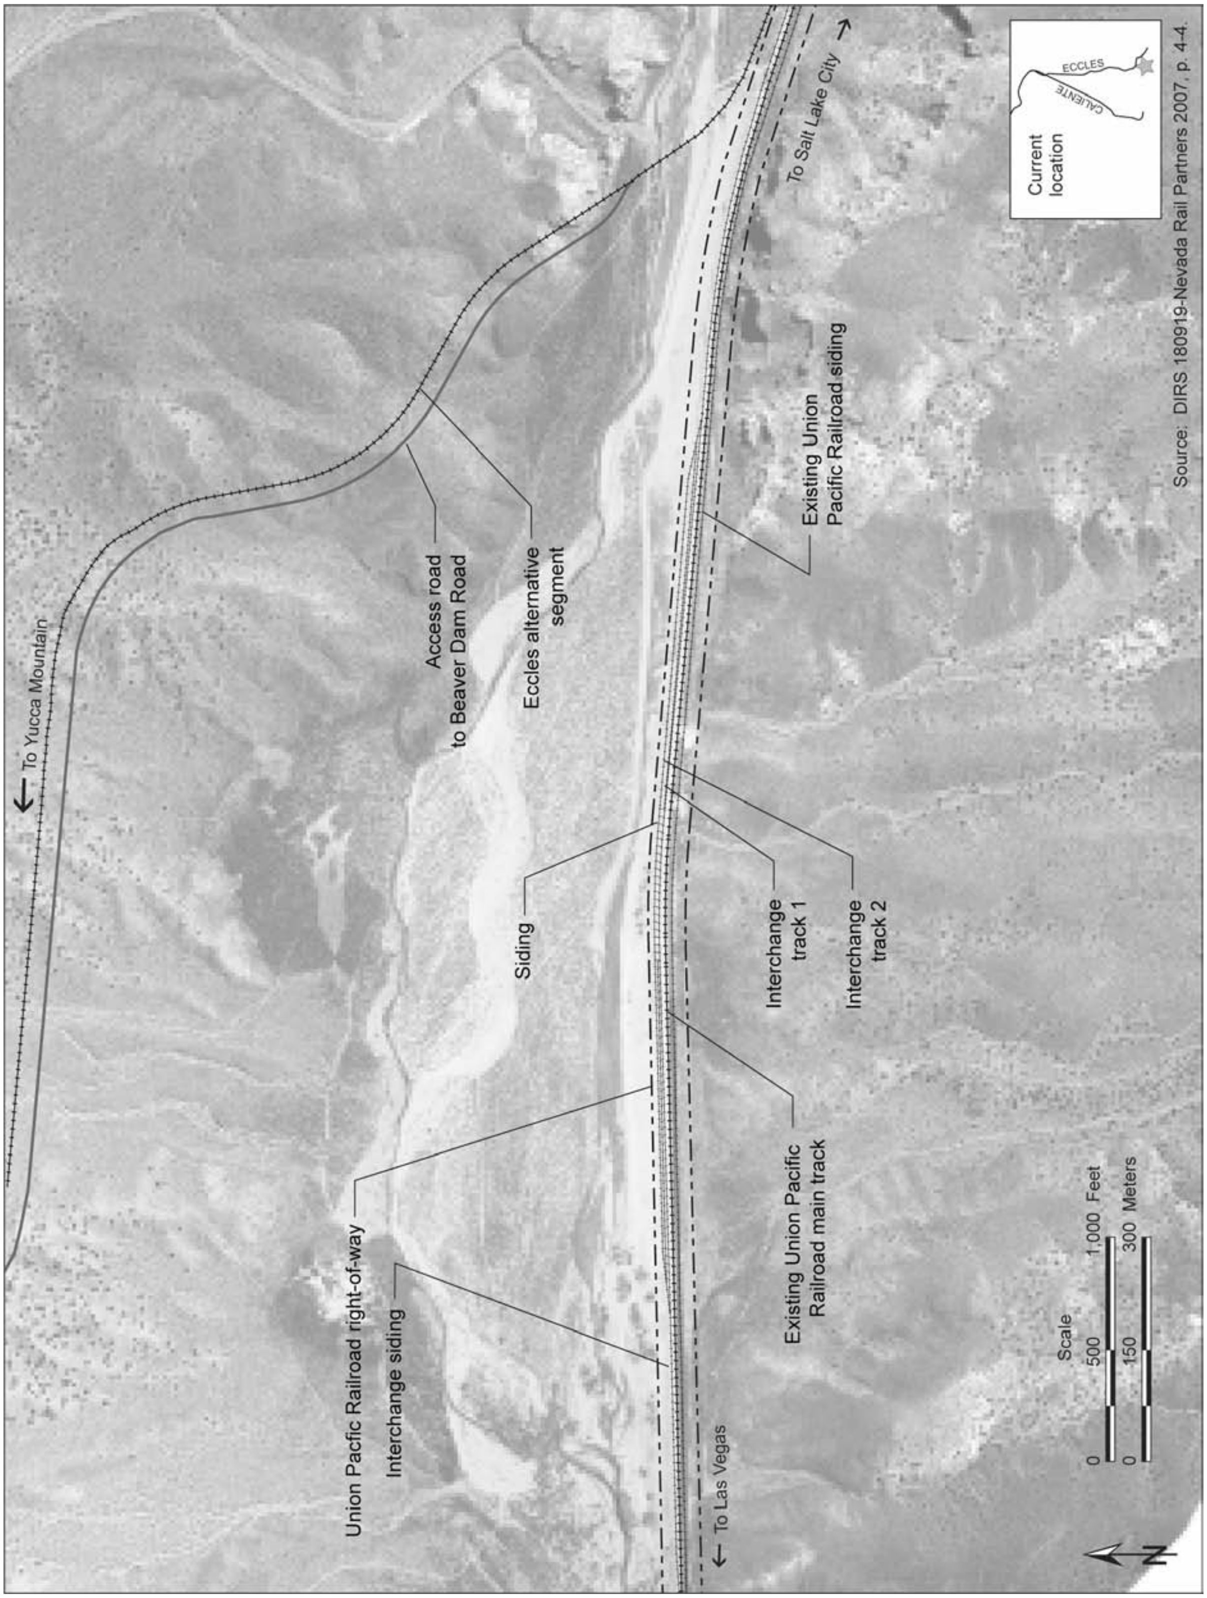

Figure 2-43. Interchange Yard – Eccles.

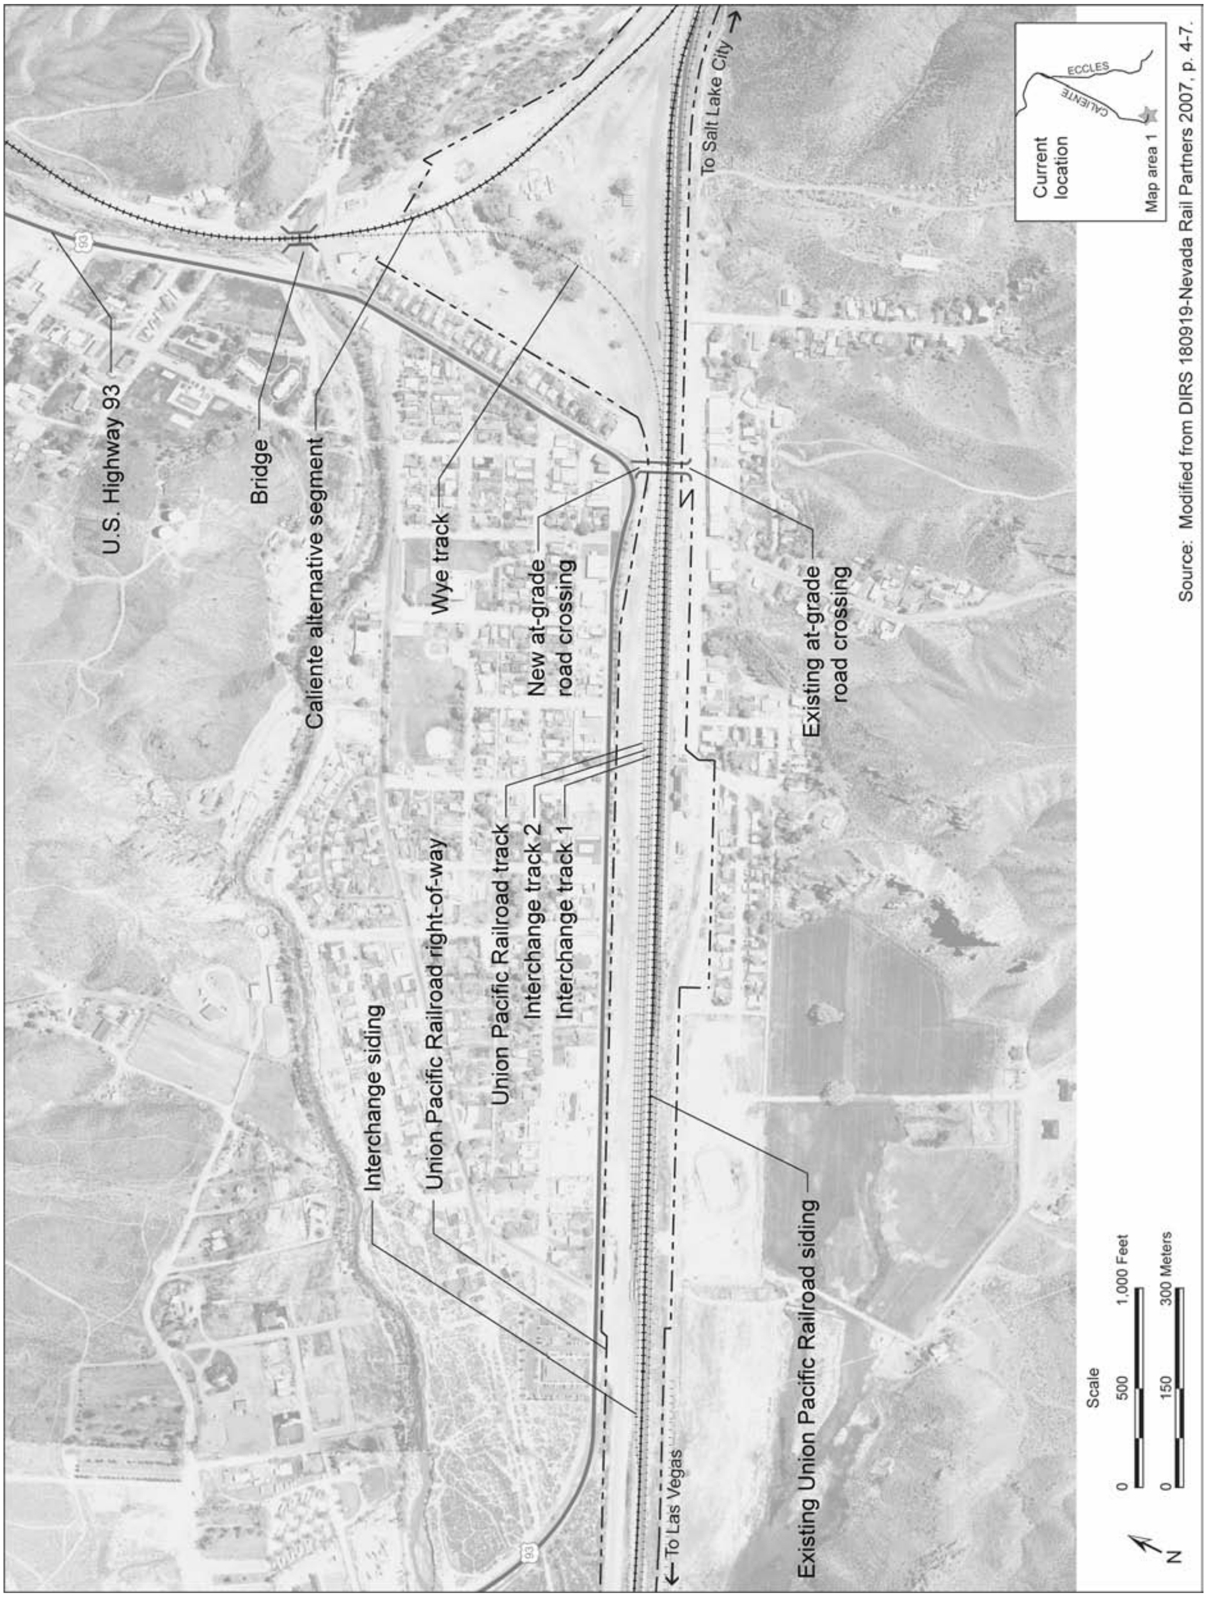

Source: Modified from DIRS 180919-Nevada Rail Partners 2007, p. 4-7.

Figure 2-44. Interchange Yard – Caliente.

> A **wye track** is a triangular arrangement of tracks coming off of the mainline that allows a train or locomotive to safely turn around.

The conceptual design for the Interchange Yard includes a ***wye track,*** which would allow trains to change directions. The design for the Interchange Yard in Caliente includes such a wye track; however, at the site for the Eccles Interchange Yard, grades would prohibit construction of a wye track. If DOE selected the Eccles alternative segment, the wye track would have to be at the Eccles-North location for the Staging Yard (see Section 2.2.4.1.1.2).

2.2.4.1.1.2 Staging Yard. The Staging Yard would be used to hold cask cars and hold and sort cars containing construction and other materials for movement to the Rail Equipment Maintenance Yard. The Staging Yard would include a ***locomotive sanding area*** and fueling area, a maintenance warehouse, a Satellite Maintenance-of-Way Facility (see Section 2.2.4.1.2.3), and a yard office, which could serve as the location of the Nevada Railroad Control Center and National Transportation Operations Center (see Section 2.2.3). The Staging Yard would be one of the first facilities constructed and would serve as the staging area for materials to be used during the construction phase. When construction was complete, DOE would use this yard to support the shipment of supplies to Yucca Mountain (DIRS 180919-Nevada Rail Partners 2007, p. 5-2).

DOE is considering three locations for the Staging Yard: two along the Caliente alternative segment (Indian Cove [Figure 2-45 and the Map Atlas [DIRS 182843-ICF 2007, Part A, Plates 3 and 4] and Upland [Figure 2-46 and the Map Atlas [DIRS 182843-ICF 2007, Part A, Plate 9]) and one along the Eccles alternative segment (Eccles-North [Figure 2-47 and the Map Atlas [DIRS 182843-ICF 2007, Part A, Plates 20 and 21]). DOE is considering these locations because of their proximity to the Union Pacific Railroad Mainline, proximity to a major road, and engineering feasibility. The Staging Yard would occupy approximately 0.20 square kilometer (50 acres).

The Staging Yard would have a normal power demand of 386 kilowatts (or 290 kilowatts without the Nevada Railroad Control Center and National Transportation Operations Center). DOE would build a substation connected to existing transmission lines to supply this power at the selected location for the Staging Yard, and would use diesel-powered backup generators. Approximately 21,000 liters (5,500 gallons) of water per day would be needed during the operations phase at the Staging Yard. These needs would be met by connecting to wells drilled during the construction phase. Approximately 21,000 liters (5,500 gallons) of wastewater per day would be generated at the Staging Yard. Wastewater disposal would be by local septic systems and leach fields (DIRS 180919-Nevada Rail Partners 2007, p. 5-4).

Operation of the Interchange Yard and the Staging Yard would require a workforce of approximately 50.

2.2.4.1.2 Maintenance-of-Way Facilities

Maintenance and inspection of track, bridges, culverts, grade crossings, signal equipment, communications equipment, and other wayside facilities and equipment would be performed from the Maintenance-of-Way Trackside Facility, the Maintenance-of-Way Headquarters Facility, and two Satellite Maintenance-of-Way Facilities (DIRS 180919-Nevada Rail Partners 2007, p. 7-1).

2.2.4.1.2.1 Maintenance-of-Way Trackside Facility. The Trackside Facility would occupy approximately 0.61 square kilometer (15 acres) and would consist of an administrative building; a warehouse for storage of spare parts and small tools; and an outside storage area for heavy materials (for example, spare concrete ties, rail, and ballast) and large on-track track maintenance machines. Figure 2-48 is a schematic of the Maintenance-of-Way Trackside Facility (DIRS 180919-Nevada Rail Partners 2007, p. 7-2); the proposed location of this facility is shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 303 to 305).

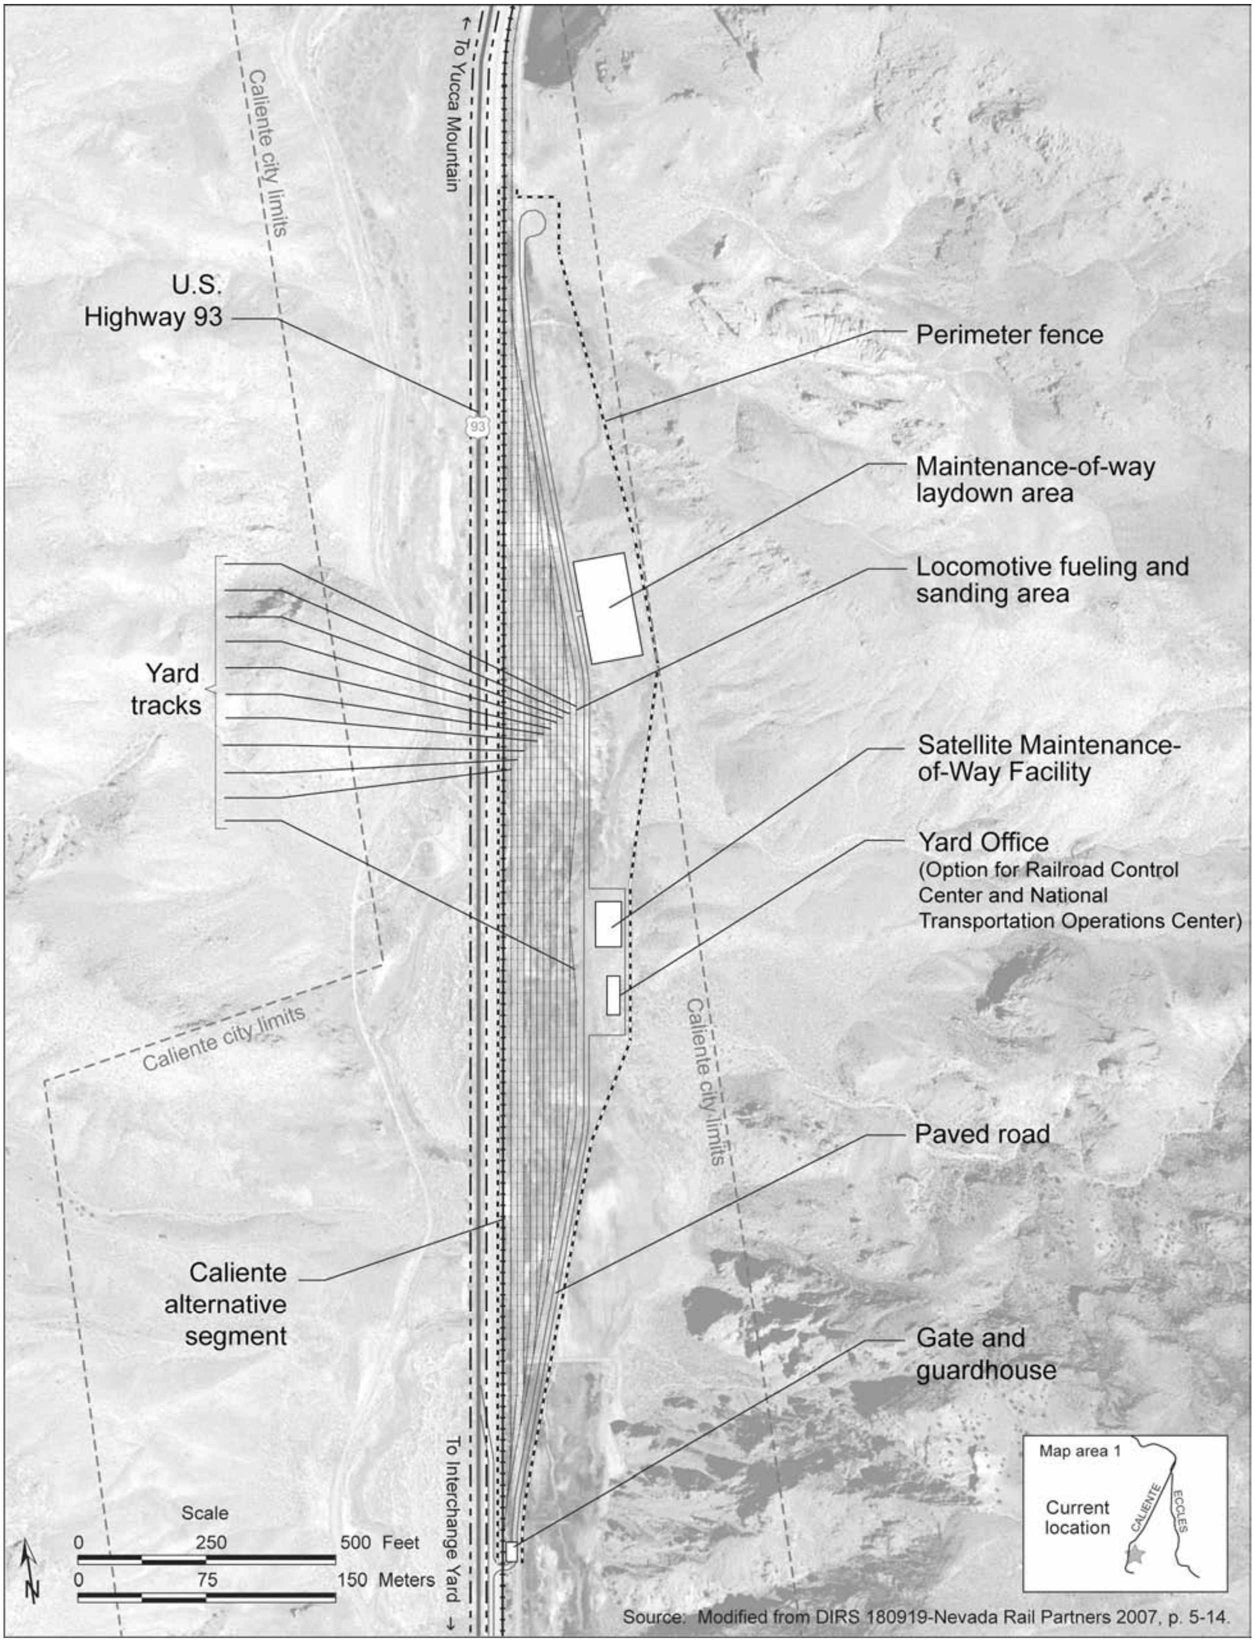

Figure 2-45. Staging Yard – Caliente-Indian Cove option.

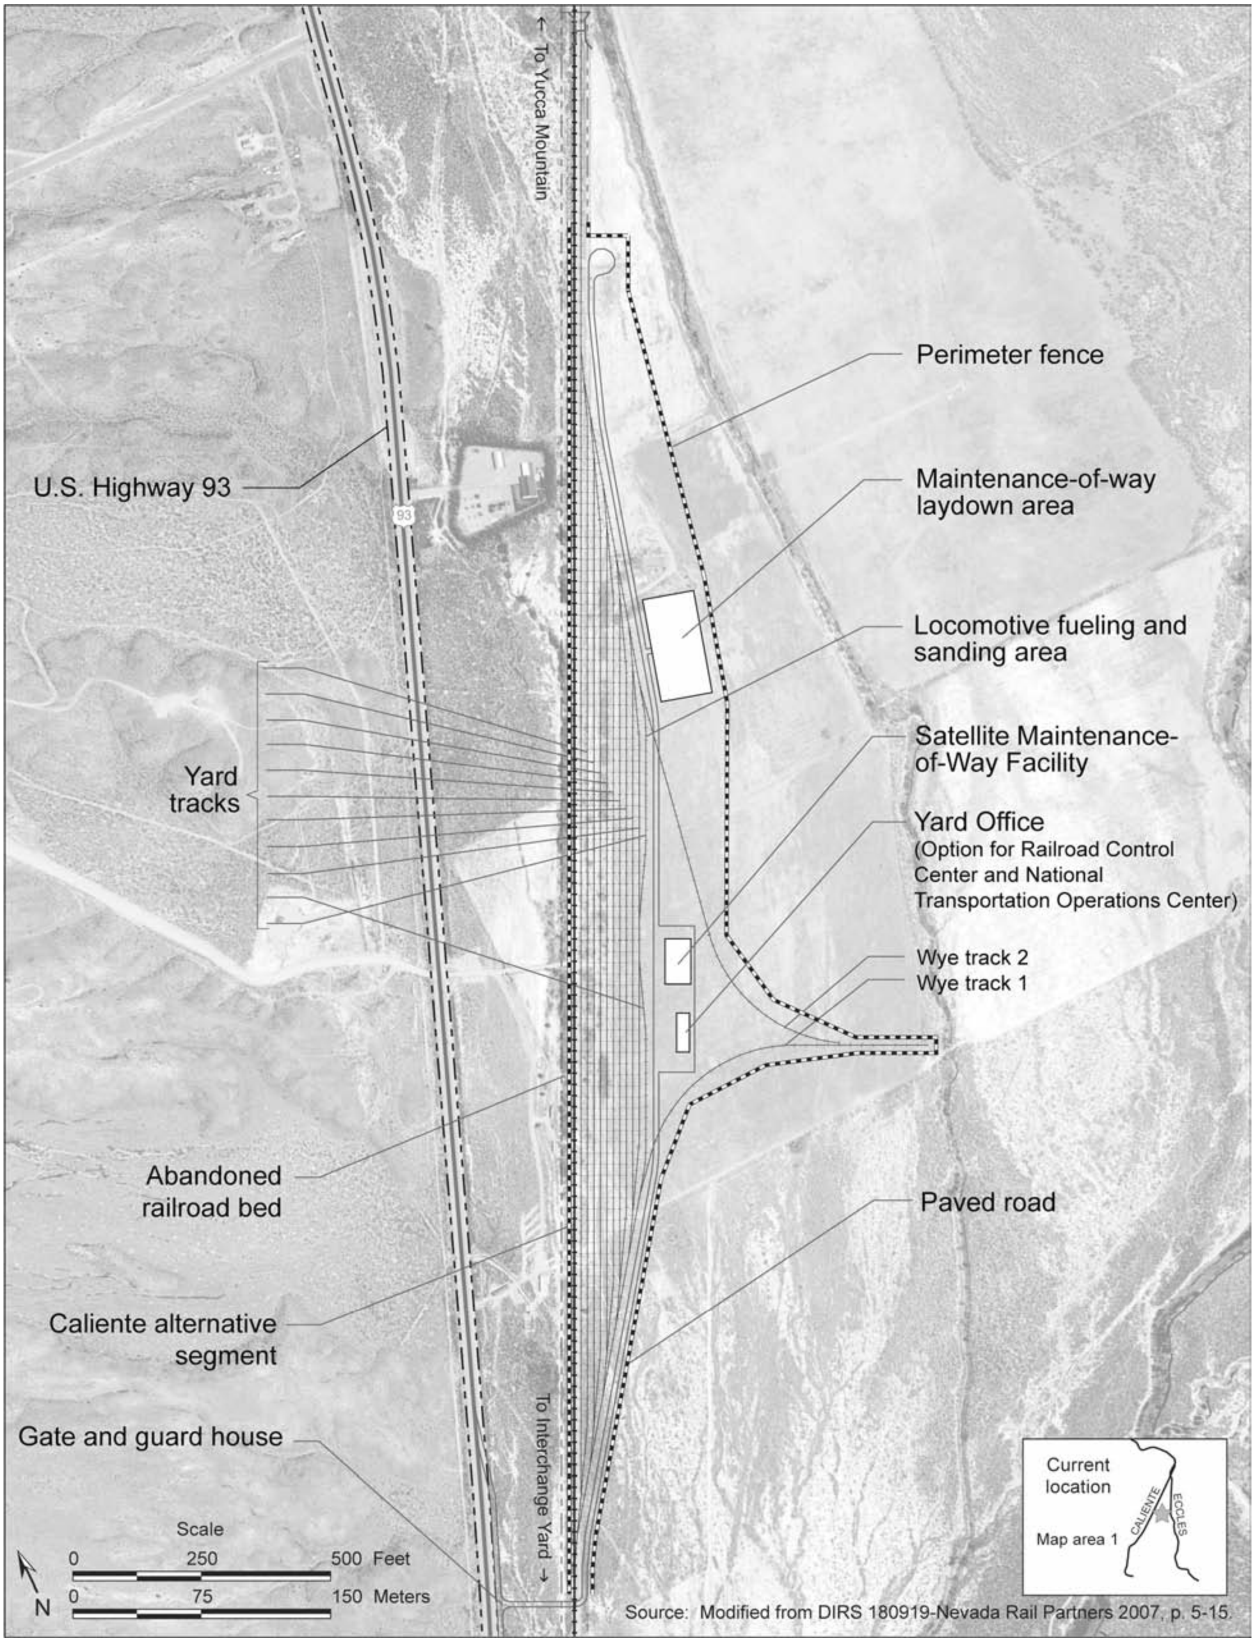

Figure 2-46. Staging Yard – Caliente-Upland option.

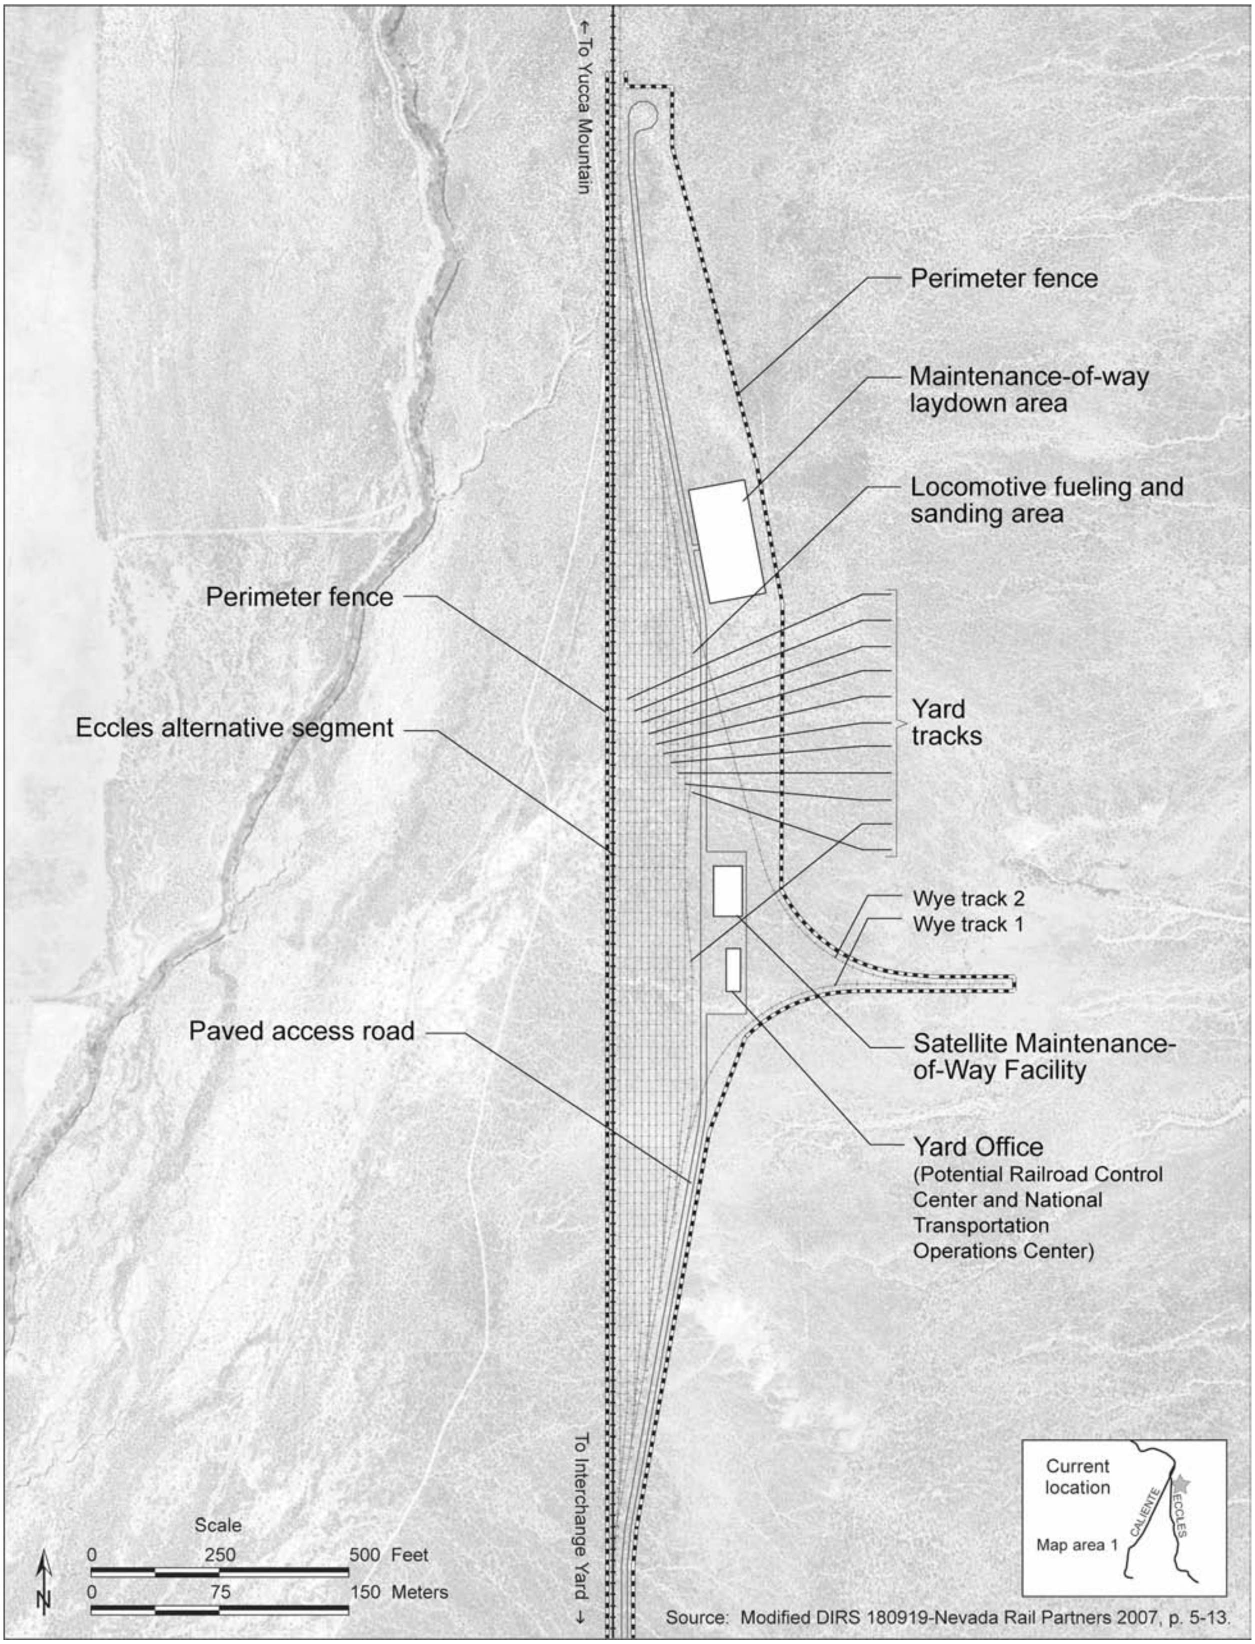

Figure 2-47. Staging Yard – Eccles-North option.

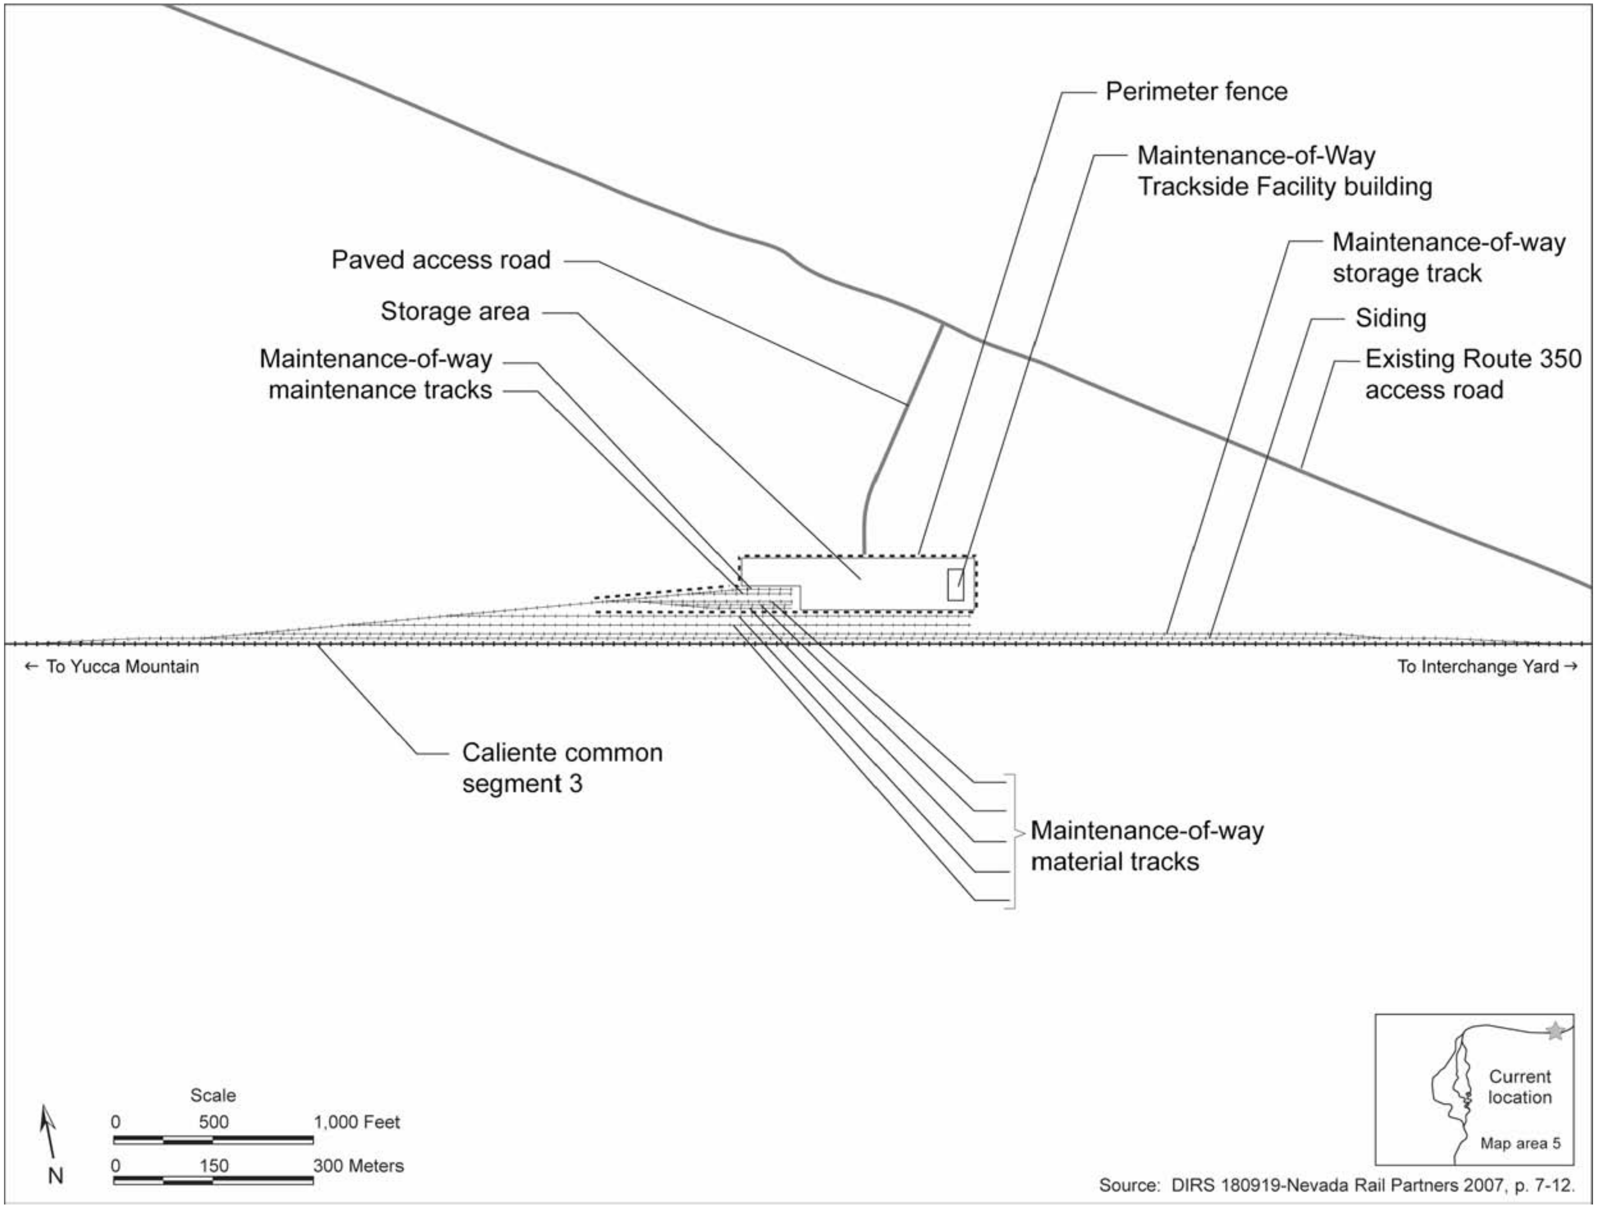

Figure 2-48. Maintenance-of-Way Trackside Facility schematic.

For purposes of analysis in this Rail Alignment EIS, the Trackside Facility is assumed to be along Caliente common segment 3 approximately 48 kilometers (30 miles) southeast of Tonopah; however, it could also be anywhere along Caliente common segment 3 between this analyzed location and the start of the Goldfield alternative segments.

Water needs at the Maintenance-of-Way Trackside Facility would be met by using wells drilled during the construction phase. Approximately 9,500 liters (2,500 gallons) per day of water would be required during the operations phase. The Maintenance-of-Way Trackside Facility would have a normal power demand of 78 kilowatts, which would be met by tying into nearby commercial electric-power distribution lines. In addition, electric power from the proposed railroad distribution line could be available for use, as would diesel-power standby generators. Approximately 11,000 liters (3,000 gallons) of wastewater per day would be generated at the Trackside Facility, which would be disposed of using new, local septic systems and leach fields.

Approximately 40 persons would be employed at the Maintenance-of-Way Trackside Facility.

2.2.4.1.2.2 Maintenance-of-Way Headquarters Facility. The Maintenance-of-Way Headquarters Facility would occupy less than 0.013 square kilometer (3.2 acres) of land. This building would house the maintenance organization supervisory and administrative staff, have parking for hi-rail trucks needed for maintenance activities, and also have space for storage of spare parts, tools, and small track-maintenance machines. Figure 2-49 is a schematic of the Maintenance-of-Way Headquarters Facility (DIRS 180919-Nevada Rail Partners 2007, p. 7-2).

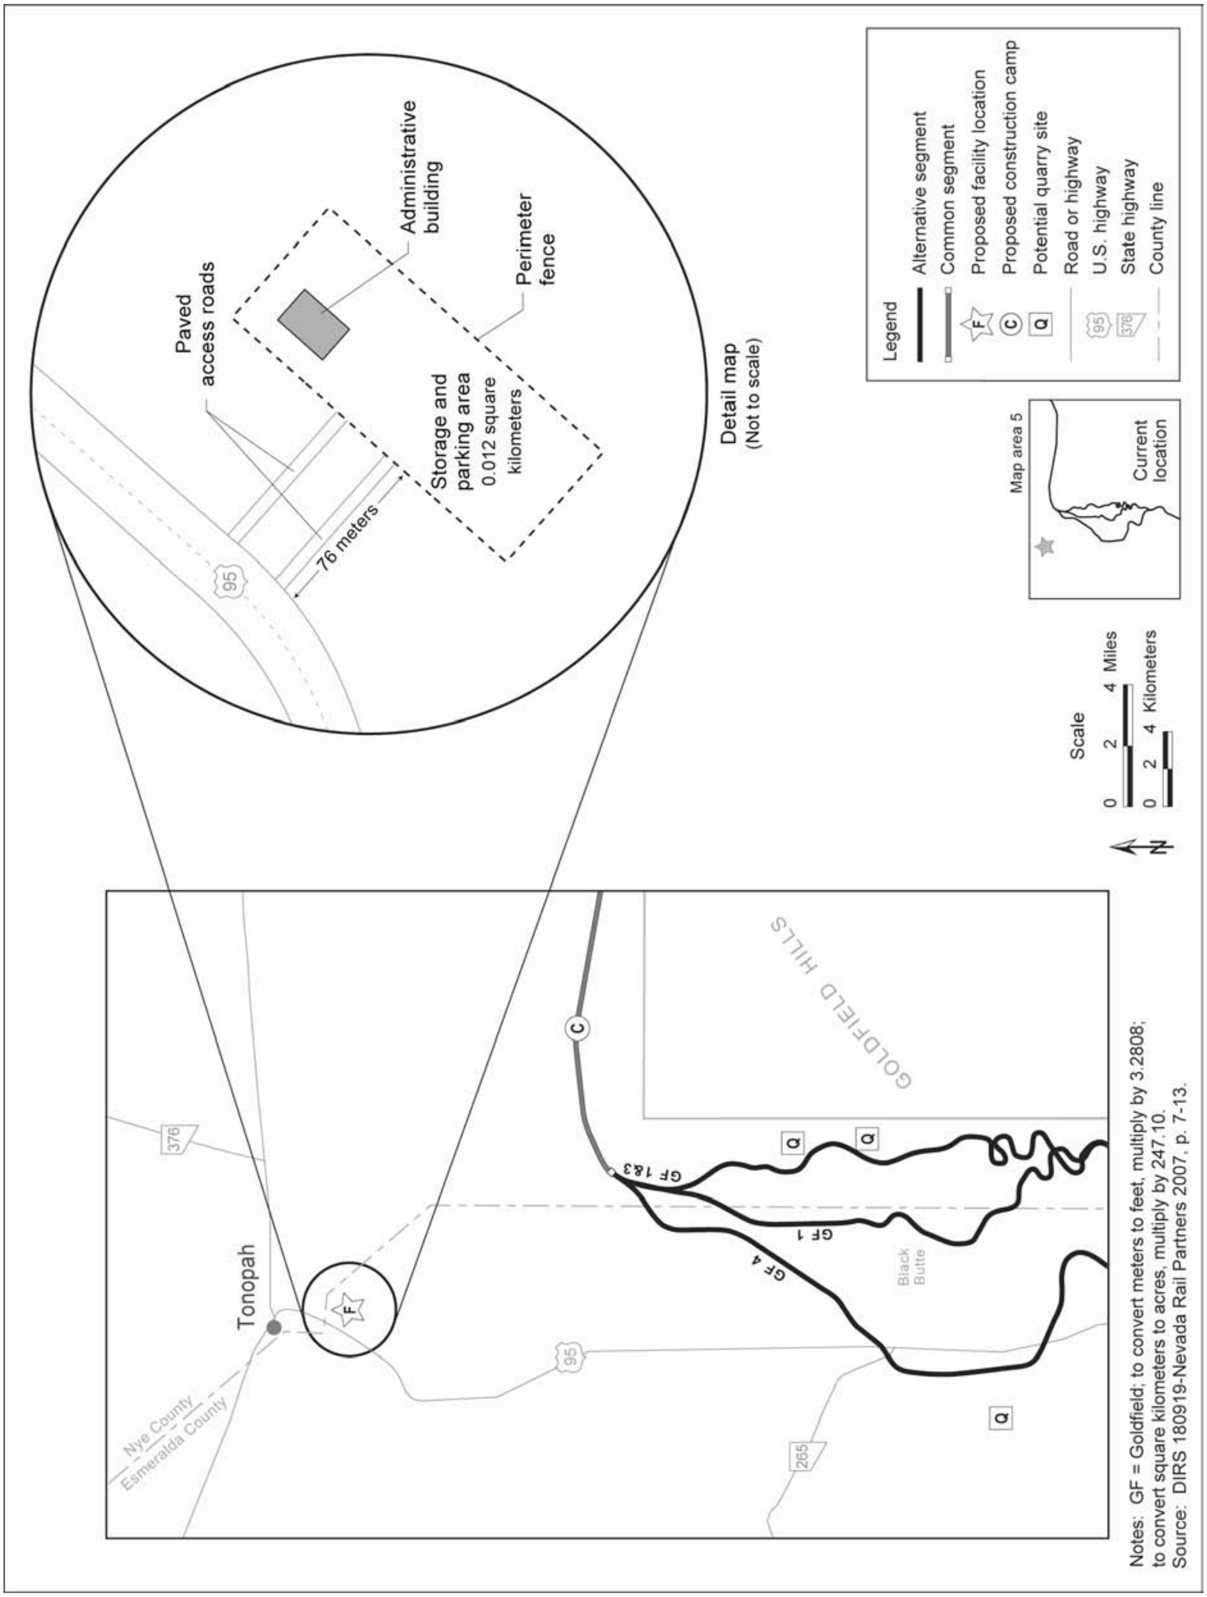
For purposes of analysis in this Rail Alignment EIS, the Headquarters Facility is assumed to be 8 kilometers (5 miles) south of Tonopah near the intersection of U.S. Highway 95 and U.S. Highway 6; however, it could also be anywhere along U.S. Highway 95 between this analyzed location and the intersection of U.S. Highway 95 and Goldfield alternative segment 4.

Water needs at the Maintenance-of-Way Headquarters Facility would be met by using water wells drilled during construction or supplied by a local municipality. Approximately 11,000 liters (3,000 gallons) of water per day would be required. The Maintenance-of-Way Headquarters Facility would have a normal power demand of 406 kilowatts, which would be met by tying into nearby commercial electric-power distribution lines. Approximately 11,000 liters (3,000 gallons) of wastewater per day would be generated at the Maintenance-of-Way Headquarters Facility, which would be disposed of using local septic systems and leach fields.

Approximately 10 persons would be employed at the Maintenance-of-Way Headquarters Facility.

2.2.4.1.2.3 Satellite Maintenance-of-Way Facilities. The Satellite Maintenance-of-Way Facilities would be at the Staging Yard and the Rail Equipment Maintenance Yard (see Sections 2.2.4.1.1 and 2.2.4.3.1). The Satellite Facility at the Staging Yard would handle the maintenance needs of the eastern third of the rail line. The Satellite Facility at the Rail Equipment Maintenance Yard would handle the maintenance needs of the Rail Equipment Maintenance Yard and the western third of the rail line approaching the Rail Equipment Maintenance Yard (DIRS 180919-Nevada Rail Partners 2007, p. 7-1).

Sections 2.2.4.1.1.2 and 2.2.4.3.1 describe power, water, and wastewater-handling needs for the Satellite Maintenance-of-Way Facilities because these facilities would be housed at the Staging Yard and the Rail Equipment Maintenance Yard. Employees for the Satellite Maintenance-of-Way Facilities would be based at the Maintenance-of-Way Headquarters Facility and Trackside Facility.



Notes: GF = Goldfield; to convert meters to feet, multiply by 3.2808; to convert square kilometers to acres, multiply by 247.10.
Source: DIRS 180919-Nevada Rail Partners 2007, p. 7-13.

Figure 2-49. Maintenance-of-Way Headquarters Facility schematic.

2.2.4.2 Mina Rail Alignment Facilities

2.2.4.2.1 Staging Yard

Along the Mina rail alignment, the Staging Yard would include the functions described for the Interchange Yard and the Staging Yard along the Caliente rail alignment (see Sections 2.2.4.1.1.1 and 2.2.4.1.1.2).

For the Mina rail alignment, the Staging Yard would be near Hawthorne along Mina common segment 1. The Staging Yard would be used to hold cask cars and hold and sort cars containing construction and other materials for movement to the Rail Equipment Maintenance Yard. The Staging Yard would include a locomotive fueling and sanding area, a maintenance warehouse, a Satellite Maintenance-of-Way Facility (see Section 2.2.4.2.2.2), the Interchange Yard, and a yard office, which could serve as the location of the Nevada Railroad Control Center and the National Transportation Operations Center (see Section 2.2.3). The Staging Yard would be one of the first facilities constructed and would serve as the staging area for materials to be used during the construction phase. When construction was complete, DOE would use this yard to support the shipment of supplies to Yucca Mountain (DIRS 180919-Nevada Rail Partners 2007, p. 5-2). Figure 2-50 is a schematic of the proposed Staging Yard at Hawthorne; the proposed location of this facility is shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 173 and 174).

The purpose of the Interchange Yard would be to allow the exchange of railcars containing construction and other materials between the Union Pacific Railroad Mainline and the proposed railroad. The conceptual design for the Interchange Yard includes a wye track, which would allow trains to change directions.

The Staging Yard would have a normal power demand of 386 kilowatts with the Nevada Railroad Train Control Center and National Transportation Operations Center (or 290 kilowatts without). DOE would build a substation connected to existing transmission lines to service this power need, and would use diesel-powered backup generators.

Approximately 21,000 liters (5,500 gallons) of water per day would be needed during the operations phase at the Staging Yard. These needs would be met by connecting to wells drilled during the construction phase or from the Hawthorne Army Depot potable and non-potable water systems. Approximately 21,000 liters (5,500 gallons) of wastewater per day would be generated at the Staging Yard. Wastewater disposal would be by local septic systems and leach fields (DIRS 180919-Nevada Rail Partners 2007, p. 5-4). Operation of the Staging Yard, including the Interchange Yard, would require a workforce of approximately 40 onsite.

2.2.4.2.2 Maintenance-of-Way Facilities

2.2.4.2.2.1 Maintenance-of-Way Facility. Maintenance of track, bridges, culverts, grade crossings, signal equipment, communications equipment, and other wayside facilities and equipment would be performed from the Maintenance-of-Way Facility and two Satellite Maintenance-of-Way Facilities (DIRS 180919-Nevada Rail Partners 2007, p. 7-1).

The Maintenance-of-Way Facility would occupy approximately 0.024 square kilometer (6 acres) and would be located either along Montezuma alternative segment 1 near Silver Peak (Figure 2-51) or along Montezuma alternative segments 2 and 3 near Klondike (Figure 2-52). The proposed locations of this facility are shown in the Map Atlas (DIRS 182844-ICF 2007, Part B, Plates 275 and 338). It would consist of an administrative building; a warehouse for storage of spare parts and small tools; a parking

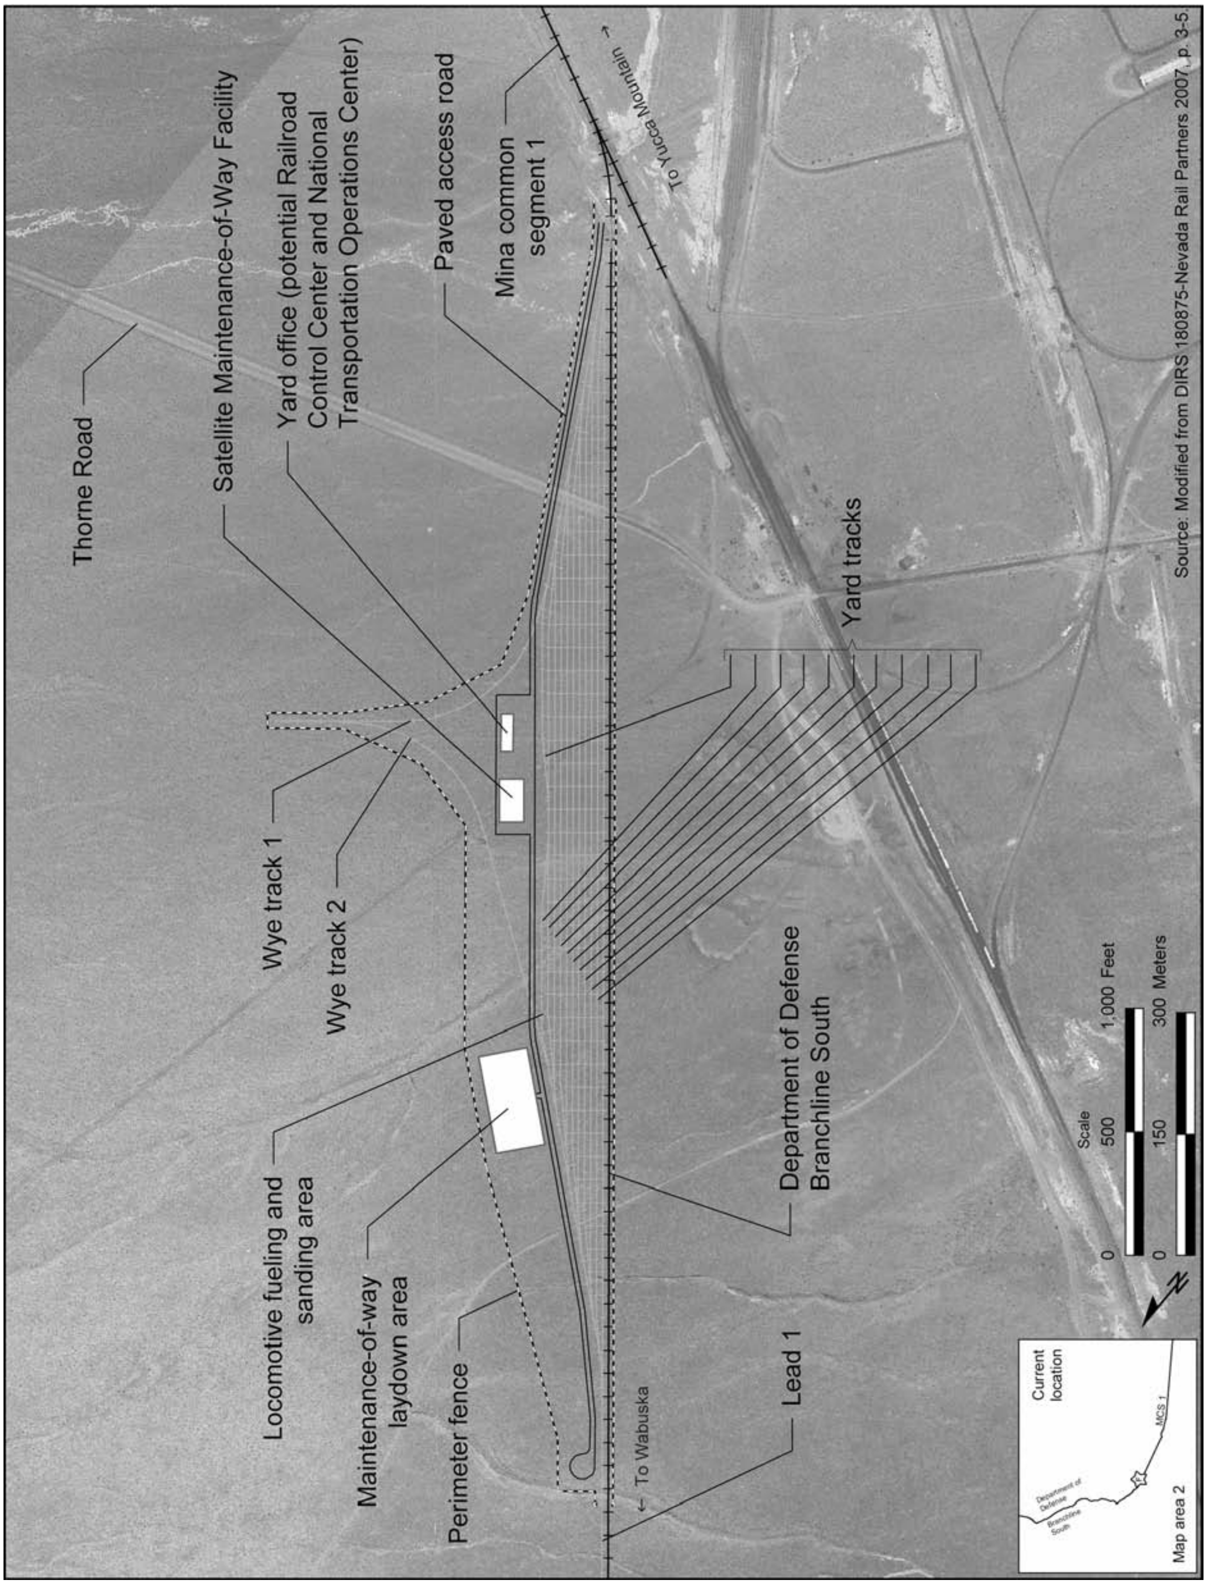


Figure 2-50. Staging Yard – Hawthorne.

area for hi-rail trucks needed for maintenance activities; and an outside storage area for heavy materials (for example, spare concrete ties, rail, and ballast) and large on-track track maintenance machines. The administrative building would house the maintenance organization supervisory and administrative staff.

Water needs at the Maintenance-of-Way Facility would be met by using wells drilled during the construction phase. Approximately 11,000 liters (3,000 gallons) per day of water would be required during the operations phase. Normal power demand would be approximately 484 kilowatts, which would be met by tying into nearby commercial electric power distribution lines. In addition, electric power from the proposed railroad distribution line could be available for use, as would diesel-power standby generators. Approximately 11,000 liters (3,000 gallons) of wastewater per day would be generated at the Maintenance-of-Way Facility, which would be handled using local treatment systems.

Approximately 40 persons would be employed at the Maintenance-of-Way Facility.

2.2.4.2.2.2 Satellite Maintenance-of-Way Facilities. The Satellite Maintenance-of-way Facilities would be at the Staging Yard and the Rail Equipment Maintenance Yard (see Sections 2.2.4.2.1 and 2.2.4.3.1). The Satellite Facility at the Staging Yard would handle the maintenance needs of the eastern third of the rail line. The Satellite Facility at the Rail Equipment Maintenance Yard would handle the maintenance needs of the Rail Equipment Maintenance Yard and the western third of the rail line approaching the Rail Equipment Maintenance Yard (DIRS 180919-Nevada Rail Partners 2007, p. 7-1).

Sections 2.2.4.2.1 and 2.2.4.3.1 describe power, water, and wastewater-handling needs for the Satellite Maintenance-of-Way Facilities because these facilities would be housed at the Staging Yard and the Rail Equipment Maintenance Yard. Employees for the Satellite Maintenance-of-Way Facilities would be based at the Maintenance-of-Way Facility.

2.2.4.3 Facilities Common to both the Caliente and Mina Rail Alignments

2.2.4.3.1 Rail Equipment Maintenance Yard and Interface with the Geologic Repository Operations Area

The Rail Equipment Maintenance Yard would be the termination point for the proposed railroad and would serve as the staging area for the delivery of loaded cask cars and other materials to the repository receiving and inspection area. The facility would be on a 0.41-square-kilometer (100-acre) site, less than 1.6 kilometers (1 mile) south of the southern boundary of the geologic repository operations area. This area would include a Satellite Maintenance-of-Way Facility (see Sections 2.2.4.1.2.3 and 2.2.4.2.2.2), a locomotive light repair facility, a car repair shop, and an escort-car service facility, and could serve as the location of the Cask Maintenance Facility (see Section 2.2.4.3.2) and the Nevada Railroad Control Center and the National Transportation Operations Center. Figure 2-53 is a schematic of the Rail Equipment Maintenance Yard incorporating the Cask Maintenance Facility (DIRS 180919-Nevada Rail Partners 2007, p. 6-1); the proposed location of the Rail Equipment Maintenance Yard is shown in the Map Atlas (DIRS 182843-ICF 2007, Part A, Plates 499 and 500, and DIRS 182844-ICF 2007, Part B, Plates 510 and 511).

The Rail Equipment Maintenance Yard would include a shop for washing, inspecting, and repairing locomotives and railcars; communications equipment; and housing for train crews and escort personnel (located in the same building as the Nevada Railroad Control Center and National Transportation Operations Center). This facility would also house a 190,000-liter (50,000-gallon) above-ground diesel fuel storage tank (for locomotive fueling); an 830,000-liter (220,000-gallon) fire-water storage tank; an access road; parking areas; areas for railcar storage; train makeup and locomotive sanding areas; and

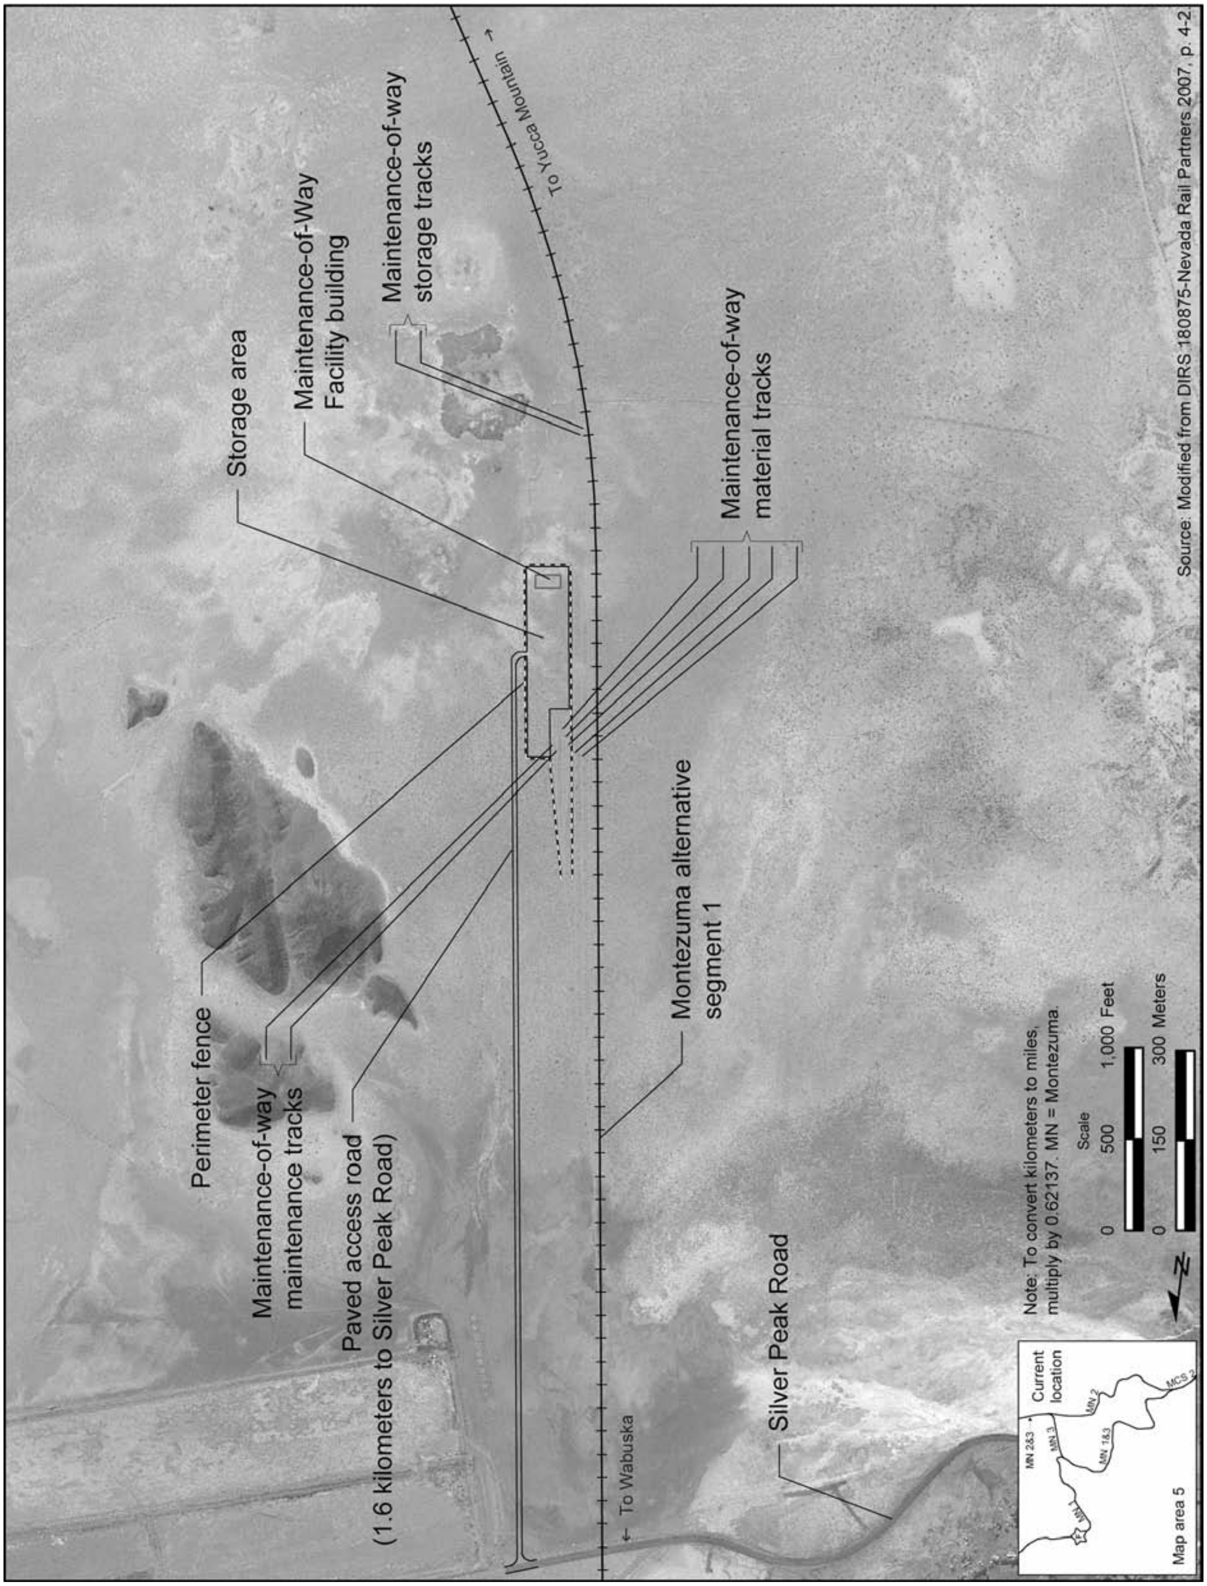

Figure 2-51. Maintenance-of-Way Facility – Silver Peak option.

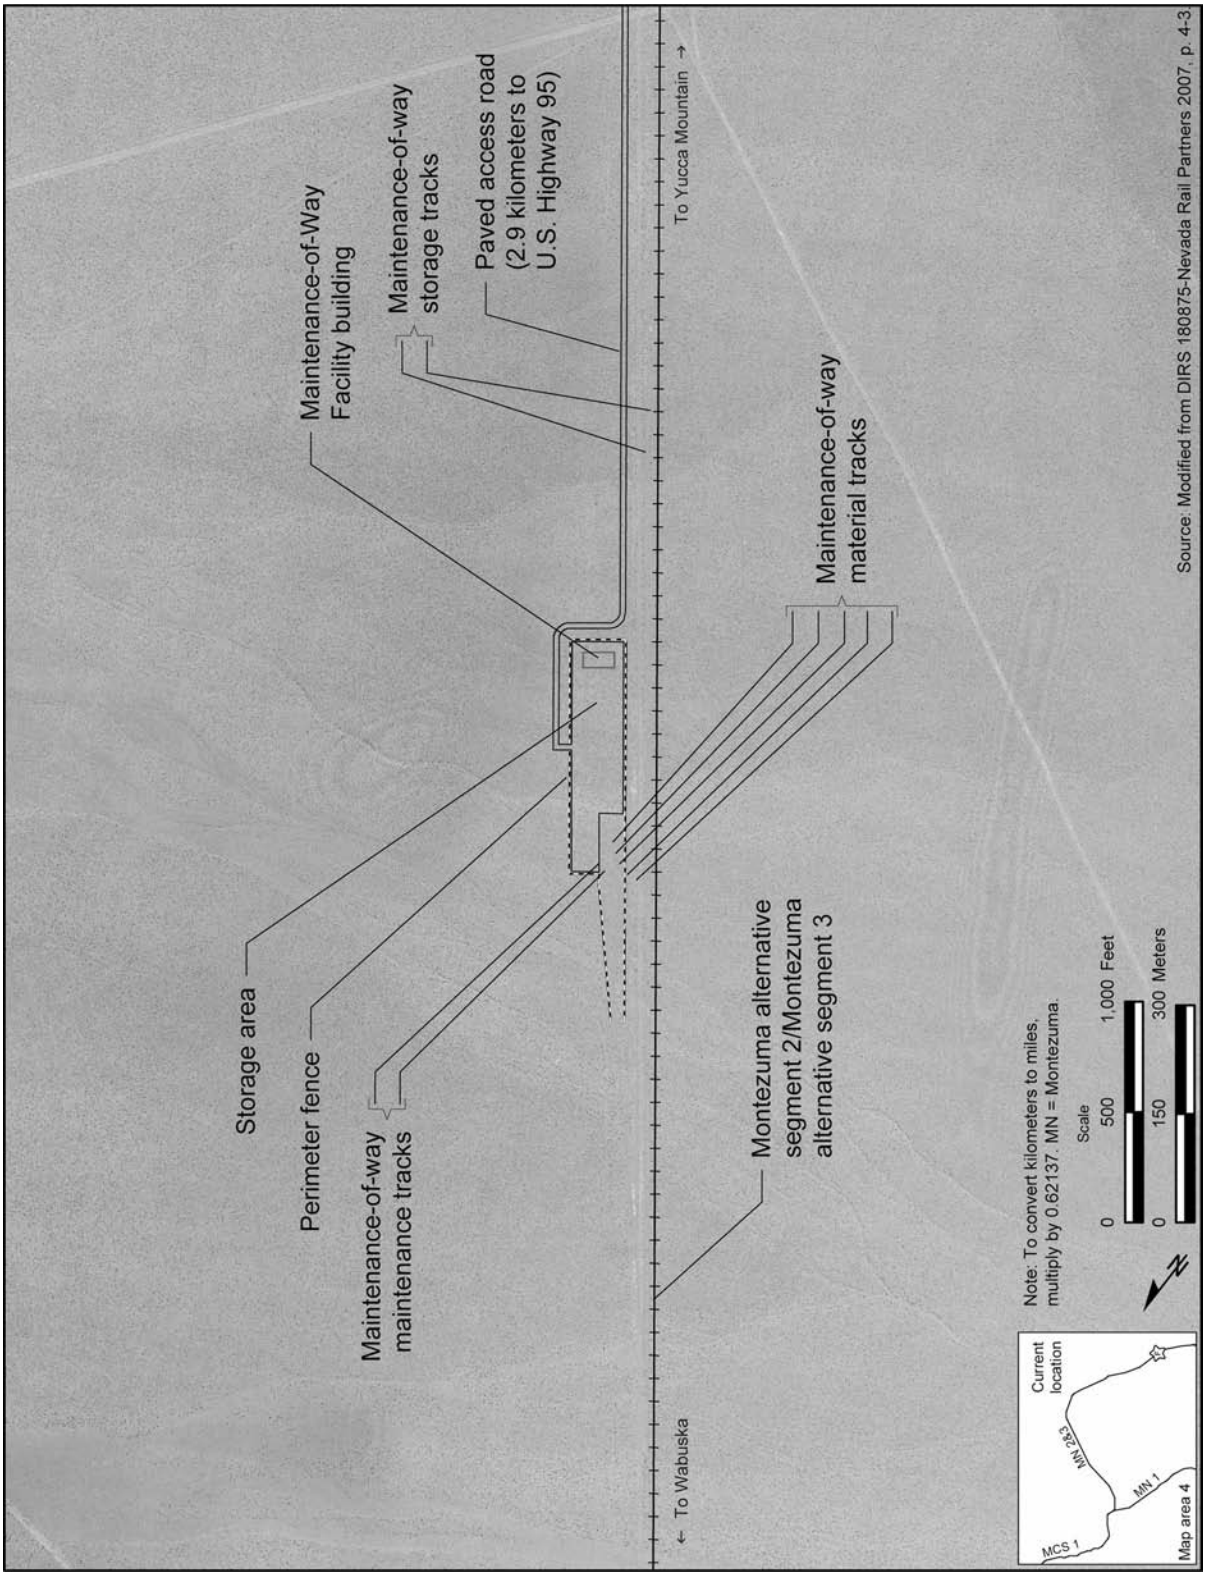

Figure 2-52. Maintenance-of-Way Facility – Klondike option.

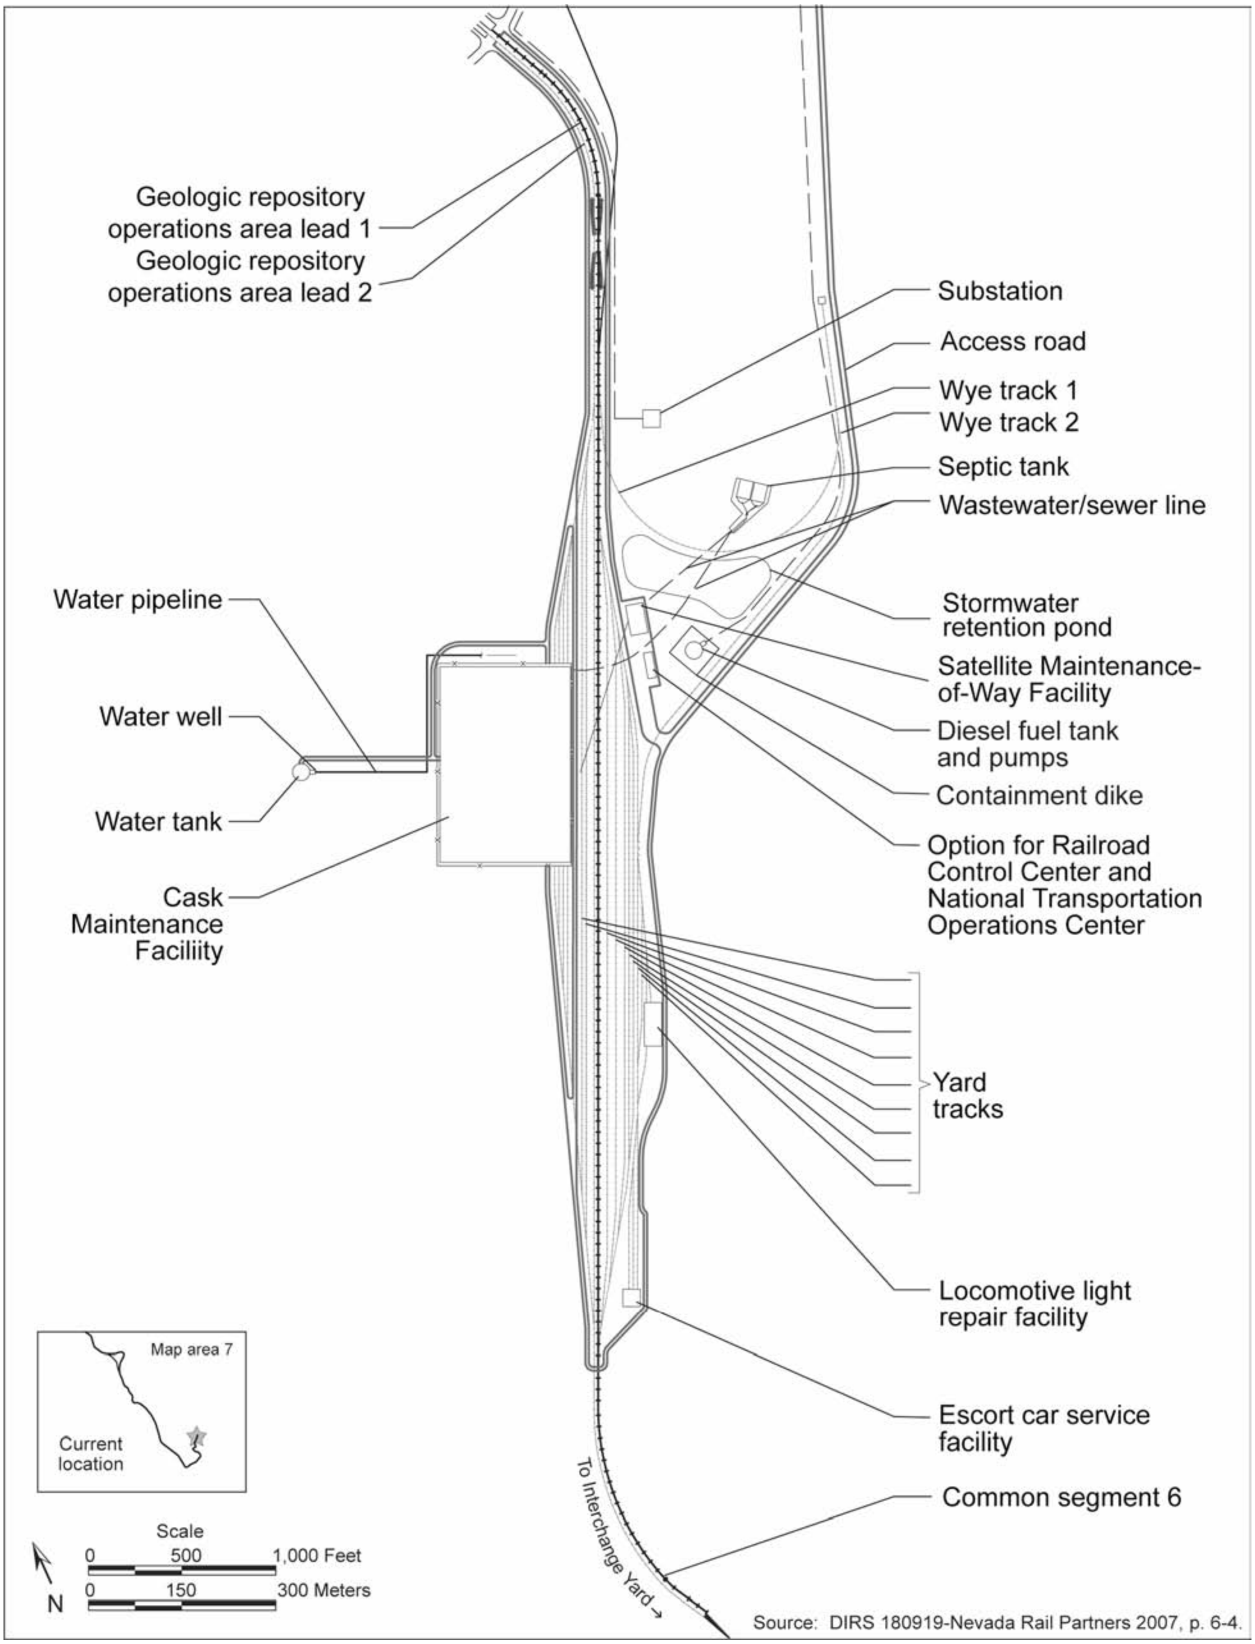

Figure 2-53. Potential Rail Equipment Maintenance Yard.

escort car maintenance and replenishing areas (DIRS 180919-Nevada Rail Partners 2007, pp. 6-3 and 6-4).

The interface with the geologic repository operations area would consist of a double track spur leading into the repository area for delivery of casks and supplies to the repository (DIRS 180919-Nevada Rail Partners 2007, p. 6-3).

Water needs at the Rail Equipment Maintenance Yard would be met by tapping into the geologic repository operations area water supply and constructing pipelines to the Rail Equipment Maintenance Yard. Approximately 23,000 liters (6,000 gallons) of water per day would be required during the operations phase (DIRS 180919-Nevada Rail Partners 2007, p. 6-6). Power requirements would be approximately 6 megawatts and would be met by tying into a new substation built for the facility or by tapping into an existing nearby power source (DIRS 181033-Hamilton-Ray 2007, all). Approximately 23,000 liters (6,000 gallons) of wastewater per day would be generated at the Rail Equipment Maintenance Yard, which would be handled using local treatment systems (DIRS 180919-Nevada Rail Partners 2007, p. 6-6).

The Rail Equipment Maintenance Yard would require an estimated 40 people to operate, including employees for the Nevada Railroad Control Center and National Transportation Operations Center.

2.2.4.3.2 Cask Maintenance Facility

The primary purpose of the Cask Maintenance Facility would be to process empty transportation casks used for shipping canistered fuel to ensure that all casks are road-ready. Transportation casks used for shipping bare spent nuclear fuel would be sent to an outsourced licensed facility elsewhere in the United States.

The basic functions of the Cask Maintenance Facility would be those necessary to ensure cask compliance with a Nuclear Regulatory Commission-issued Certificate of Compliance. The facility would consist of a 2,800-square-meter (30,000-square-foot) building with four tracks leading in and out. DOE anticipates that a staff of 30 would be required to operate the facility, which could be:

- Collocated with the Rail Equipment Maintenance Yard
- Along any portion of the Caliente rail alignment between Caliente and the Yucca Mountain Site boundary or any portion of the Mina rail alignment between Hawthorne and the Yucca Mountain Site boundary
- Outsourced to a licensed facility with the necessary services elsewhere in the United States

By being collocated with the Rail Equipment Maintenance Yard, the Cask Maintenance Facility would interface with repository operations. This location would allow the facility to service the casks prior to their return to the nuclear utility sites and would allow Cask Maintenance Facility personnel to take advantage of infrastructure and support services already available at the repository site. The power, water, and sewage needs of the Cask Maintenance Facility would be met by tapping into infrastructure developed at Yucca Mountain to support construction and operation of the repository. Power requirements would be approximately 2 megawatts and would be supplied from the newly constructed substation connected to the proposed 138-kilovolt transmission line system into the nearby geologic repository operations area (DIRS 181033-Hamilton-Ray 2007, all). Wastewater would be handled by the geologic repository operations area septic and wastewater treatment system.

This Rail Alignment EIS analyzes the impacts of collocating the Cask Maintenance Facility with the Rail Equipment Maintenance Yard inside the Yucca Mountain Site boundary. If DOE subsequently proposed to locate the Cask Maintenance Facility outside the Yucca Mountain Site boundary, the Department would perform additional NEPA analyses to determine the environmental impacts of placing the facility at a different location, as appropriate.

2.2.4.3.3 Nevada Railroad Control Center and National Transportation Operations Center

The National Transportation Operations Center would oversee the shipment of casks from sites throughout the United States to the proposed railroad. Once casks arrived at the railroad in Nevada, the Nevada Railroad Control Center would oversee their shipment to the repository at Yucca Mountain. The Nevada Railroad Control Center would oversee all train movements, rail operations, and emergency response operations along the proposed railroad (DIRS 180923-Nevada Rail Partners 2007, Section 6.1).

The Nevada Railroad Control Center and National Transportation Operations Center would be at either the Rail Equipment Maintenance Yard or the Staging Yard. Together, these facilities would require approximately 320 square meters (3,400 square feet) of office space and would require approximately 15 employees to operate. Personnel at the Nevada Railroad Control Center would primarily be responsible for directing all rail operations along the proposed railroad, including coordinating shipments to the proposed railroad with the National Transportation Operations Center; coordinating maintenance-of-way trains along the rail line; coordinating with security personnel; and maintaining communications with emergency response personnel during an accident (DIRS 180923-Nevada Rail Partners 2007, Section 6.1).

Sections 2.2.4.1.1.2, 2.2.4.2.1, and 2.2.4.3.1 describe power, water, and wastewater-handling needs for the Nevada Railroad Control Center and National Transportation Operations Center because these facilities would be housed at either the Rail Equipment Maintenance Yard or the Staging Yard.

2.2.5 RAILROAD ABANDONMENT

If built and operated, the proposed railroad could be abandoned after shipments to the repository were complete. DOE could decide to remove ballast, track, ties, signaling, and other related infrastructure. In addition, DOE could decide to decommission and dismantle facilities such as the Cask Maintenance Facility. DOE might not remove the rail roadbed, although the Department would reclaim the lands disturbed by the abandonment process. If DOE decided to abandon the railroad, it would relinquish its regulatory right-of-way and the BLM would continue to manage the land. Any abandonment of the railroad would be conducted in consultation with the BLM and other land-management entities, as appropriate, at the time of abandonment.

Analysis of railroad abandonment would be performed near the completion of the shipping campaign, when an accurate assessment could be made regarding the usefulness of maintaining portions of the rail line or individual facilities.

2.2.6 SHARED-USE OPTIONS

2.2.6.1 Overview

Under each Implementing Alternative, DOE has analyzed a Shared-Use Option, under which the Department would allow commercial shippers to use the rail line for general freight shipments. General freight would include stone and other nonmetallic minerals, petrochemicals, nonradioactive waste materials, or other commodities that private companies would ship or receive. Implementation of the

Shared-Use Option would require an STB license to construct and operate the railroad as a common-carrier rail line.

The Shared-Use Option would entail construction of commercial sidings to provide access for potential commercial shippers, and facilities for operation of commercial rail service. Funding for such construction and commercial rail service could be provided by either the private sector or other government sources. The Shared-Use Option would not require any changes to the design (for example, grade or curvature) of the proposed rail line from that described for the Proposed Action without shared use.

Commercial railcars would be hauled in trains that are separate from trains carrying spent nuclear fuel and high-level radioactive waste, but could be hauled with trains carrying other repository-related materials (for example, construction materials, water, and fuel). During the operations phase, trains carrying spent nuclear fuel and high-level radioactive waste would have priority over trains carrying commercial shipments.

Under a DOE-funded cooperative agreement, Nye County commissioned a study of the potential economic benefits to Nye, Esmeralda, and Lincoln Counties of the rail line along the Caliente rail alignment (DIRS 174090-Smith 2005, all). This report presented low-, mid-, and high-range estimates of commercial freight shipments on the rail line, based on interviews with potential shippers.

While preparing this Rail Alignment EIS, DOE conducted independent telephone interviews with each of the potential shippers identified in the Nye County study. Further consultation with representatives from Nye, Esmeralda, Mineral, and Churchill Counties, and with other ***stakeholders***, identified additional potential shippers along the Mina rail alignment. DOE interviewed these potential shippers in person and via telephone. Through these efforts, DOE estimated different levels of commercial freight demand for the Caliente and Mina rail alignments (DIRS 180694-Ang-Olson and Gallivan 2007, all).

DOE projected the total commercial freight demand on a rail line along the Caliente rail alignment would be approximately 223 carloads weekly (Table 2-28), which is similar to the mid-range demand scenario in the Nye County study (DIRS 174090-Smith 2005, all).

Table 2-28. Potential commercial freight shipments under the Shared-Use Option – Caliente rail alignment.[a]

Commodity	Weight (metric tons)[b]		Carloads	
	Per week	Per year	Per week	Per year
Stone	3,250	169,000	36	1,860
Other nonmetallic minerals	9,620	500,000	106	5,500
Petrochemicals	5,240	273,000	58	3,000
Nonradioactive waste materials	1,220	64,000	13	700
Other commodities	900	44,000	10	480
Totals	20,190	1,050,000	223	11,540

a. Source: DIRS 180694-Ang-Olson and Gallivan 2007, all.
b. To convert metric tons to tons, multiply by 1.1023.

DOE projected that total freight demand on a rail line along the Mina rail alignment would be approximately 514 carloads per week. Of this total, approximately 210 carloads would travel on dedicated unit trains that would not pass south of the Walker River Paiute Reservation (Table 2-29).

Most potential shippers expressed a willingness to truck their product to or from a siding, although the maximum acceptable trucking distance varied considerably among the shippers. Some shippers would need to construct storage or loading/unloading facilities at the sidings. Potential shippers did not express any interest in either a long spur or a short spur/siding location that would not be served by existing paved or gravel roads.

Table 2-29. Potential commercial freight shipments under the Shared-Use Option – Mina rail alignment.[a]

Commodity	Weight (metric tons)[b]		Carloads	
	Per week	Per year	Per week	Per year
Stone	16,890	878,000	186	9,660
Other nonmetallic minerals	4,830	251,000	50	2,760
Petrochemicals	240	13,000	3	140
Nonradioactive waste materials[c]	20,360[c]	1,059,000[c]	224[c]	11,650[c]
Other commodities	5,080	264,000	51	2,900
Totals	47,400	2,465,000	514	27,110

a. Source: DIRS 180694-Ang-Olson and Gallivan 2007, all.
b. To convert metric tons to tons, multiply by 1.1023.
c. Nineteen thousand one-hundred fifty metric tons (211 carloads) weekly would travel on dedicated unit trains that would not pass south of the Walker River Paiute Reservation.

2.2.6.2 Facilities and Sidings

2.2.6.2.1 Commercial-Use Sidings

Under the Shared-Use Option, DOE would construct the proposed rail line as described in Section 2.2.2, and others would construct commercial-use sidings. At these commercial-use sidings, which would be constructed within the operations right-of-way, commercial freight railcars would be set out and picked up. Commercial-use sidings would be constructed adjacent to passing sidings. As described in Section 2.2.2.8, DOE would construct passing sidings approximately every 40 kilometers (25 miles) so that trains running in opposite directions would be able to pass one another. Along the Caliente rail alignment, these passing sidings would be approximately 1,800 to 3,700 meters (6,000 to 12,000 feet) long to accommodate a maximum train length of 1,700 meters (5,500 feet). Along the Mina rail alignment, these passing sidings would be 2,100 to 5,800 meters (7,000 to 19,000 feet) long. For purposes of analysis, DOE assumed it would construct passing sidings in locations where commercial access would be needed. A commercial access siding (also known as a ***team track***) could then be constructed as a third track parallel to the mainline and the passing siding. Commercial-access sidings would generally be less than 300 meters (980 feet) long and would be double-ended (switches at both ends). Figure 2-54 is a schematic of a typical commercial access siding. To the extent practicable and appropriate, DOE also would accommodate the construction of additional access sidings, or short-spur lines, by private shippers. Commercial-access sidings could be constructed for use by any shipper or for use by a single shipper (called an ***industry track***). Possible locations for access sidings along the Caliente rail alignment include Caliente, the Panaca/Bennett Pass area, the Warm Springs Summit area, the Tonopah area, Goldfield, and the Beatty/Oasis Valley area. Possible locations for new access sidings along the Mina rail alignment include Luning, Mina, the Goldfield area, Silver Peak, and the Beatty/Oasis Valley area.

DOE assumes that the commercial-access sidings would be constructed at the same time as the proposed railroad, although construction could occur at a later date. The construction approach would be the same

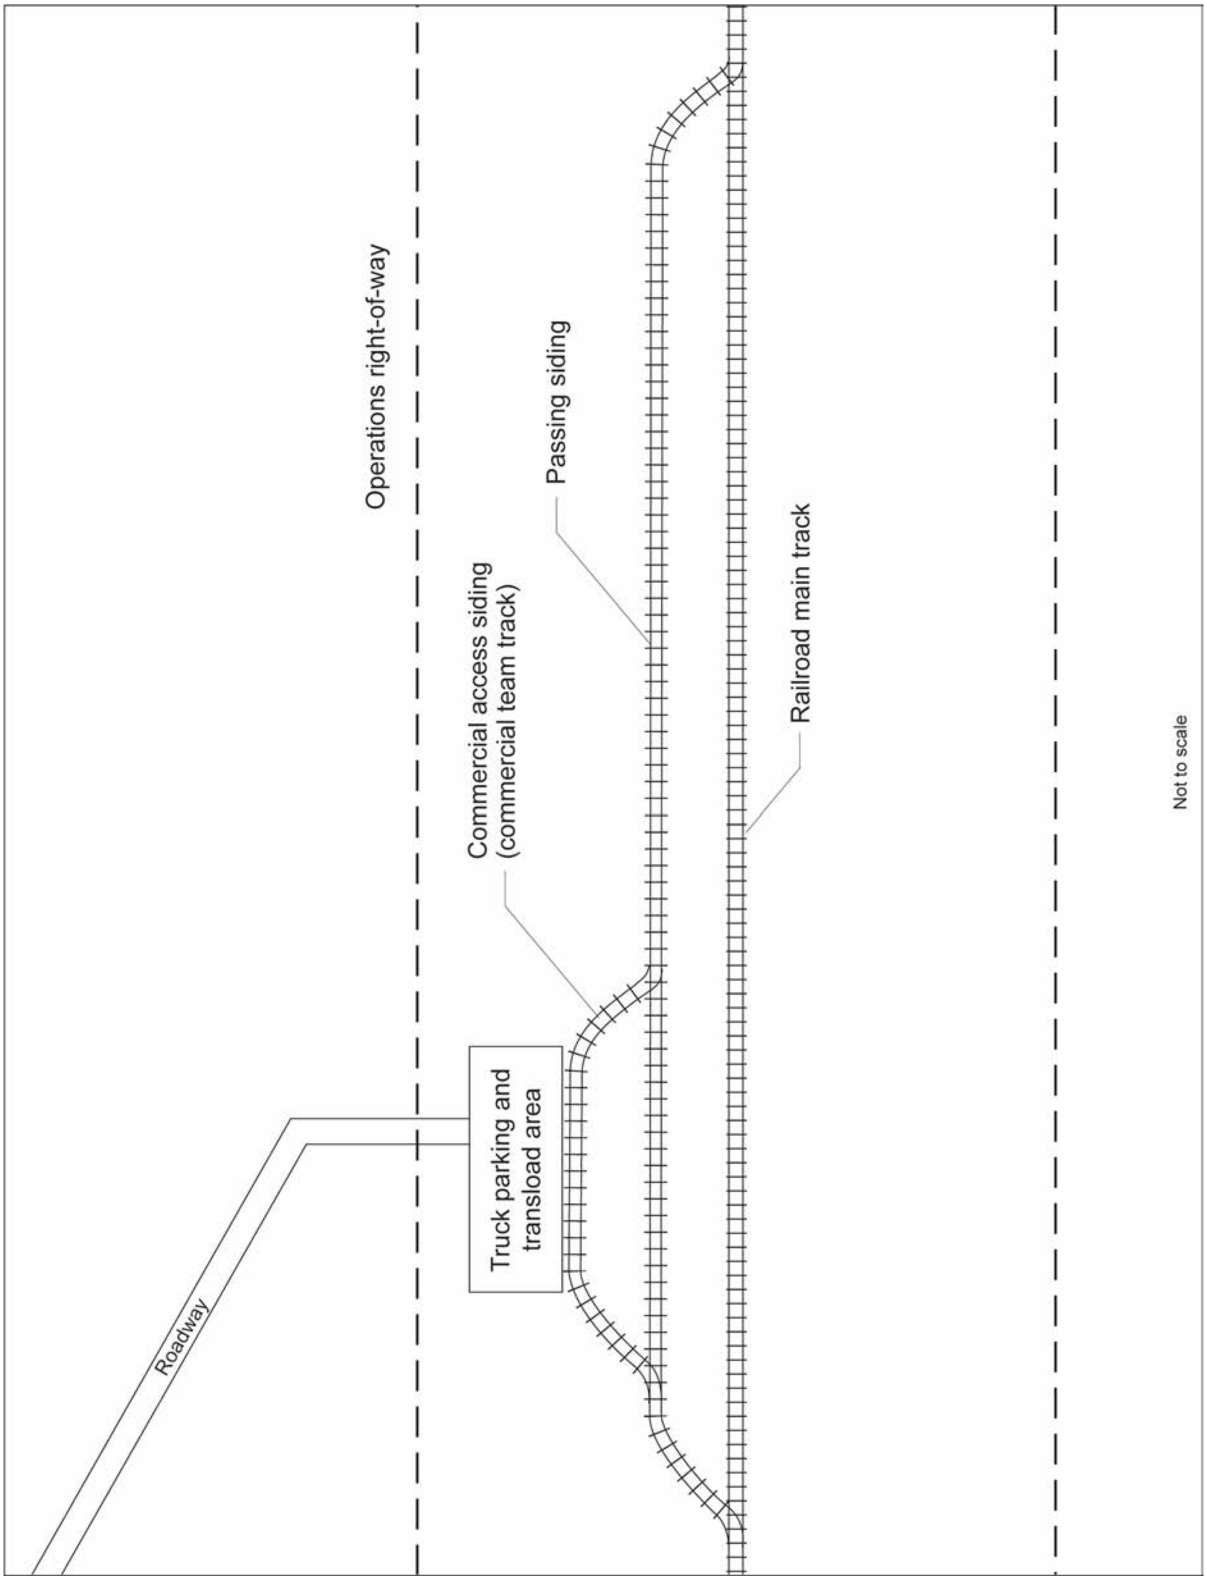

Figure 2-54. Commercial access siding schematic (conceptual).

as described in Section 2.2.2, with phased construction and implementation of appropriate best management practices. Because commercial sidings would be built at the locations of passing sidings, the incremental effort to construct commercial sidings would be minimized. Although some additional materials and labor would be needed, the increase beyond that described in Section 2.2.2 would be small and additional construction camps would not be required. Temporary access roads built for the construction of the proposed railroad would also be used for construction of commercial sidings; therefore, no new roads would be needed to support construction of commercial sidings.

The commercial sidings proposed to be constructed under the Shared-Use Option would represent an increase of less than 0.5 percent over the entire length of track laid under the Proposed Action without the Shared-Use Option for either the Caliente or Mina rail alignment. The land area disturbed under the Shared-Use Option as compared to the Proposed Action without the Shared-Use Option would be less than 0.1 percent.

Commercial sidings and the additional facilities for shared use described in Section 2.2.6.2.2 would be constructed within the operations right-of-way, as practicable. Any facilities constructed outside the operations right-of-way would need the appropriate approval from the BLM.

2.2.6.2.2 Additional Facilities for Shared Use

The supporting infrastructure at team tracks and industry tracks would vary with the types and amounts of commodities being shipped. Most, or all, commercial-access sidings would have facilities for transferring freight between railcars and trucks. They might require a paved or unpaved parking area where trucks could access the freight cars, along with a loading dock (for transferring machinery or pallets) and possibly other specialized loading equipment (such as tanks for storing petroleum products or conveyers for moving some nonmetallic minerals).

An existing paved or unpaved road would provide truck access to the loading facilities. Commercial sidings and truck-loading facilities would be on relatively flat terrain near existing roads whenever feasible. Some improvements to existing roads might be required.

The Shared-Use Option could require construction and operation of one or more facilities to allow commercial rail service, which would be funded by the private sector or other government sources. Commercial trains would not have access to the restricted areas at the Cask Maintenance Facility or the restricted area designated for the geologic repository operations area, including the Rail Equipment Maintenance Yard. A commercial-service end-of-line facility could be constructed at or near the last commercial stop, probably in the Beatty/Oasis Valley area, which would provide an area for locomotive and railcar parking. Commercial railcars would be serviced at one or more separate maintenance facilities, possibly in the Caliente area (Caliente rail alignment), the Tonopah/Goldfield area (Caliente or Mina rail alignment), the Hawthorne area (Mina rail alignment), or at the commercial service end-of-line facility. These facilities would consist of about 100 meters (330 feet) of track (in addition to the access sidings) for parking and maintenance of locomotives and other railcars.

2.2.6.3 Operation and Maintenance under the Shared-Use Option

The commercial rail service and facilities would be operated and maintained in accordance with the appropriate Federal Railroad Administration standards and requirements, and applicable regulations of the State of Nevada. All such work would also be conducted in accordance with other appropriate industry codes, standards, engineering principles, and practices, with particular attention to those that incorporate system safety, human factors, reliability, availability, maintainability, habitability standards, and environmental protection. Shared-use rail service would begin after the completion of proposed railroad construction. Maintenance of the commercial rail facilities would be an ongoing process that would be concurrent and coordinated with maintenance of the proposed railroad, as described in Section 2.2.3.2.

2.2.6.3.1 Operations

During the proposed railroad operations phase, approximately eight one-way commercial trains would run per week along the Caliente rail alignment. Along the Mina rail alignment, approximately 18 one-way commercial trains would run per week, eight of which would travel only on the northern portions of the rail alignment. Ten trains per week would pass south of Hawthorne. For comparison, an average total of 17 one-way trains would run between the Staging Yard and the Rail Equipment Maintenance Yard each week, carrying casks and other materials, as described in Section 2.2.3. The commercial trains (not including the locomotive) could consist of up to 60 cars and would be approximately 1,100 meters (3,600 feet) long. Depending on the weight of the train, three or four locomotives could be required. Commercial trains would haul a range of products to and from businesses, including stone and other nonmetallic minerals, oil and petroleum products, and nonradioactive waste materials. Commercial railcars would also be hauled in trains carrying materials related to the construction (for example, reinforcing steel and cement) and operation (for example, waste packages, fuel oil) of the repository.

The operating characteristics of these commercial trains cannot be accurately defined; therefore, DOE cannot describe the travel times and operational movements of these trains. The Nevada Railroad Control Center described in Section 2.2.3 would control and coordinate commercial rail service movements and would therefore maintain overall safety of operations along the railroad. During operation of commercial service, there would be an increase in truck traffic to and from the commercial sidings, but an overall decrease in truck traffic due to the shift to rail for transporting commercial freight. Under the Proposed Action without shared use, private companies near the rail line would continue to ship and receive freight using truck-only transport. Under the Shared-Use Option, some of those shipments would be diverted to rail, generally using trucks to access the commercial rail sidings.

2.2.6.3.2 Maintenance

Industry-track owners would likely perform maintenance of the industry track sidings, and commercial operators would likely perform maintenance of team track sidings. Because the commercial rail service would primarily use the same track as the cask trains, there would be only minimal need for maintenance beyond the anticipated levels of the Proposed Action without shared use. Maintenance techniques for commercial facilities would be similar to those described in Section 2.2.3.2.

2.2.6.4 Abandonment

Under the Shared-Use Option, the current assumption is that DOE would not abandon the proposed railroad upon completion of the DOE shipping campaign. Local communities or the private sector could maintain the rail line, and possibly some facilities not within the Yucca Mountain Site boundary, for other uses. DOE would decommission and dismantle facilities that would not be useful to local communities or the private sector.

2.3 No-Action Alternative

Council on Environmental Quality regulations (40 CFR 1502.14) require that the alternatives analysis in an EIS include the alternative of no action. Under the No-Action Alternative in this Rail Alignment EIS, DOE would not select a rail alignment within the Caliente or Mina rail corridor for the construction and operation of a railroad. As such, the No-Action Alternative provides a basis for comparison with the Proposed Action.

In the event that DOE were not to select a rail alignment in the Caliente or Mina rail corridor, the future course that it would pursue to meet its obligation under the NWPA is highly uncertain.

Under the No-Action Alternative, DOE would relinquish the ***public lands*** withdrawn from surface and mineral entry for purposes of evaluating the lands for the potential construction, operation, and maintenance of a railroad (70 *FR* 76854, December 28, 2005). These lands would then become available for surface and mineral entry.

2.4 DOE Preferred Alternative

The Council on Environmental Quality NEPA implementing regulations require an agency to identify its preferred alternative, if one or more exists, in the Draft EIS (40 CFR 1502.14[e]). For this Rail Alignment EIS, the DOE preferred alternative is to construct and operate a railroad along the Caliente rail alignment and to implement the Shared-Use Option. DOE identified preferred alternative segments within the Caliente rail alignment based on analysis of environmental impacts, engineering and cost factors, and regulatory compliance issues, including permit requirements and challenges, stakeholder preference, land-use conflicts, and uncertainties (See Table 2-30). All six of the common segments along the Caliente rail alignment are part of the DOE preferred alternative (Figure 2-55).

Table 2-30. Caliente rail alignment preferred alternative segments[a] (page 1 of 2).

DOE preferred alternative	Analysis factors
Caliente alternative segment	• The Eccles alternative segment would include an Interchange Yard that requires a large amount of fill in Clover Creek to enable construction of the Staging Yard. The Caliente alternative segment Interchange Yard location would avoid this impact to Clover Creek. • The Caliente alternative segment would have greater impacts to wetlands than the Eccles alternative segment. This would create greater regulatory complexity associated with obtaining a U.S. Army Corps of Engineers permit to fill jurisdictional waters. • The Caliente alternative segment would cross more private land than the Eccles alternative segment. • The Eccles alternative segment would be more complex to construct and would cost approximately twice as much as the Caliente alternative segment. • Based on scoping comments, more stakeholders prefer the Caliente alternative segment. • The Caliente alternative segment Indian Cove Staging Yard location would require filling 47 acres (0.19 square kilometer) of wetlands. The Upland Staging Yard location would avoid the impacts to wetlands associated with the Indian Cove location.[b]
Garden Valley alternative segment 1	• Engineering factors and regulatory complexity do not offer a means to discriminate among the Garden Valley alternative segments. • Garden Valley 1 would disturb less area than Garden Valley 2, 3, or 8.
South Reveille alternative segment 3	• No major environmental discriminator. • South Reveille 3 would avoid complex road and wash crossing that would be required for South Reveille 2.

Table 2-30. Caliente rail alignment preferred alternative segments[a] (page 2 of 2).

Preferred alternative segment	Analysis factors
Goldfield alternative segment 3	• Engineering uncertainty of crossing ***mining district*** associated with Goldfield 1. • Goldfield 4 would include two grade-separated crossings of U.S. Highway 95. • Goldfield 4 would have greater cultural resources impacts than Goldfield 1 or Goldfield 3. Goldfield 4 would enter the Goldfield Historic District. • Goldfield 3 would have fewer land-use conflicts than Goldfield 1 or Goldfield 4.
Bonnie Claire alternative segment 3	• No major environmental discriminator. • Bonnie Claire 2 would be close to the boundary of the Nevada Test and Training Range and would be more complex to construct than Bonnie Claire 3.
Oasis Valley alternative segment 1	• No major environmental discriminator. • Oasis Valley 1 would cross one parcel of private property. Oasis Valley 3 would not cross private property. • Oasis Valley 1 would require fewer earthworks for construction than Oasis Valley 3.

a. The DOE preferred rail alignment, Caliente, includes all six common segments.
b. DOE has not identified a preference for the Staging Yard location.

2.5 Comparison of Environmental Impacts

Council on Environmental Quality regulations that implement the procedural requirements of NEPA state that agencies should provide a comparison of the environmental impacts of the Proposed Action and its alternatives to sharply define the issues and provide a clear basis for choice. The comparison in this chapter is based on the information and analyses presented in subsequent chapters of this Rail Alignment EIS.

Tables 2-31 through 2-33 highlight the differences in potential impacts under the Proposed Action Caliente and Mina Implementing Alternatives and the No-Action Alternative. Table 2-31 lists the range of potential impacts under the Proposed Action for the Caliente Implementing Alternative and the Mina Implementing Alternative considering the largest and smallest potential impacts of the different alternative segments. Table 2-31 allows a comparison of the Proposed Action to the No-Action Alternative.

Potential impacts under the Shared-Use Option would be generally the same as impacts under the Proposed Action without shared use, unless noted otherwise in the tables. Potential commercial sidings and facilities that could be constructed under the Shared-Use Option would likely be constructed within the operations right-of-way to the extent practicable; therefore, the impacts of their construction are included within those impacts presented for the Proposed Action.

Tables 2-32 and 2-33 highlight potential impacts under the Proposed Action for the Caliente rail alignment and the Mina rail alignment, respectively. The tables include the alternative segments and common segments that could form each rail alignment. To make the tables more useful to the reader in discriminating between alternative segments, they focus on the major differences in impacts. Therefore, the tables do not include entries for all resource areas. Chapter 4 includes full summaries of potential impacts for each resource area.

These tables illustrate that the Mina Implementing Alternative would be environmentally preferable when compared to the Caliente Implementing Alternative. In general, the Mina Implementing Alternative would have fewer private-land conflicts, less surface disturbance, smaller wetlands impacts, and smaller air quality impacts than the Caliente Implementing Alternative. However, the Mina Implementing Alternative remains the nonpreferred alternative due to the objection of the Walker River Paiute Tribe to the transportation of spent nuclear fuel and high-level radioactive waste through its Reservation.

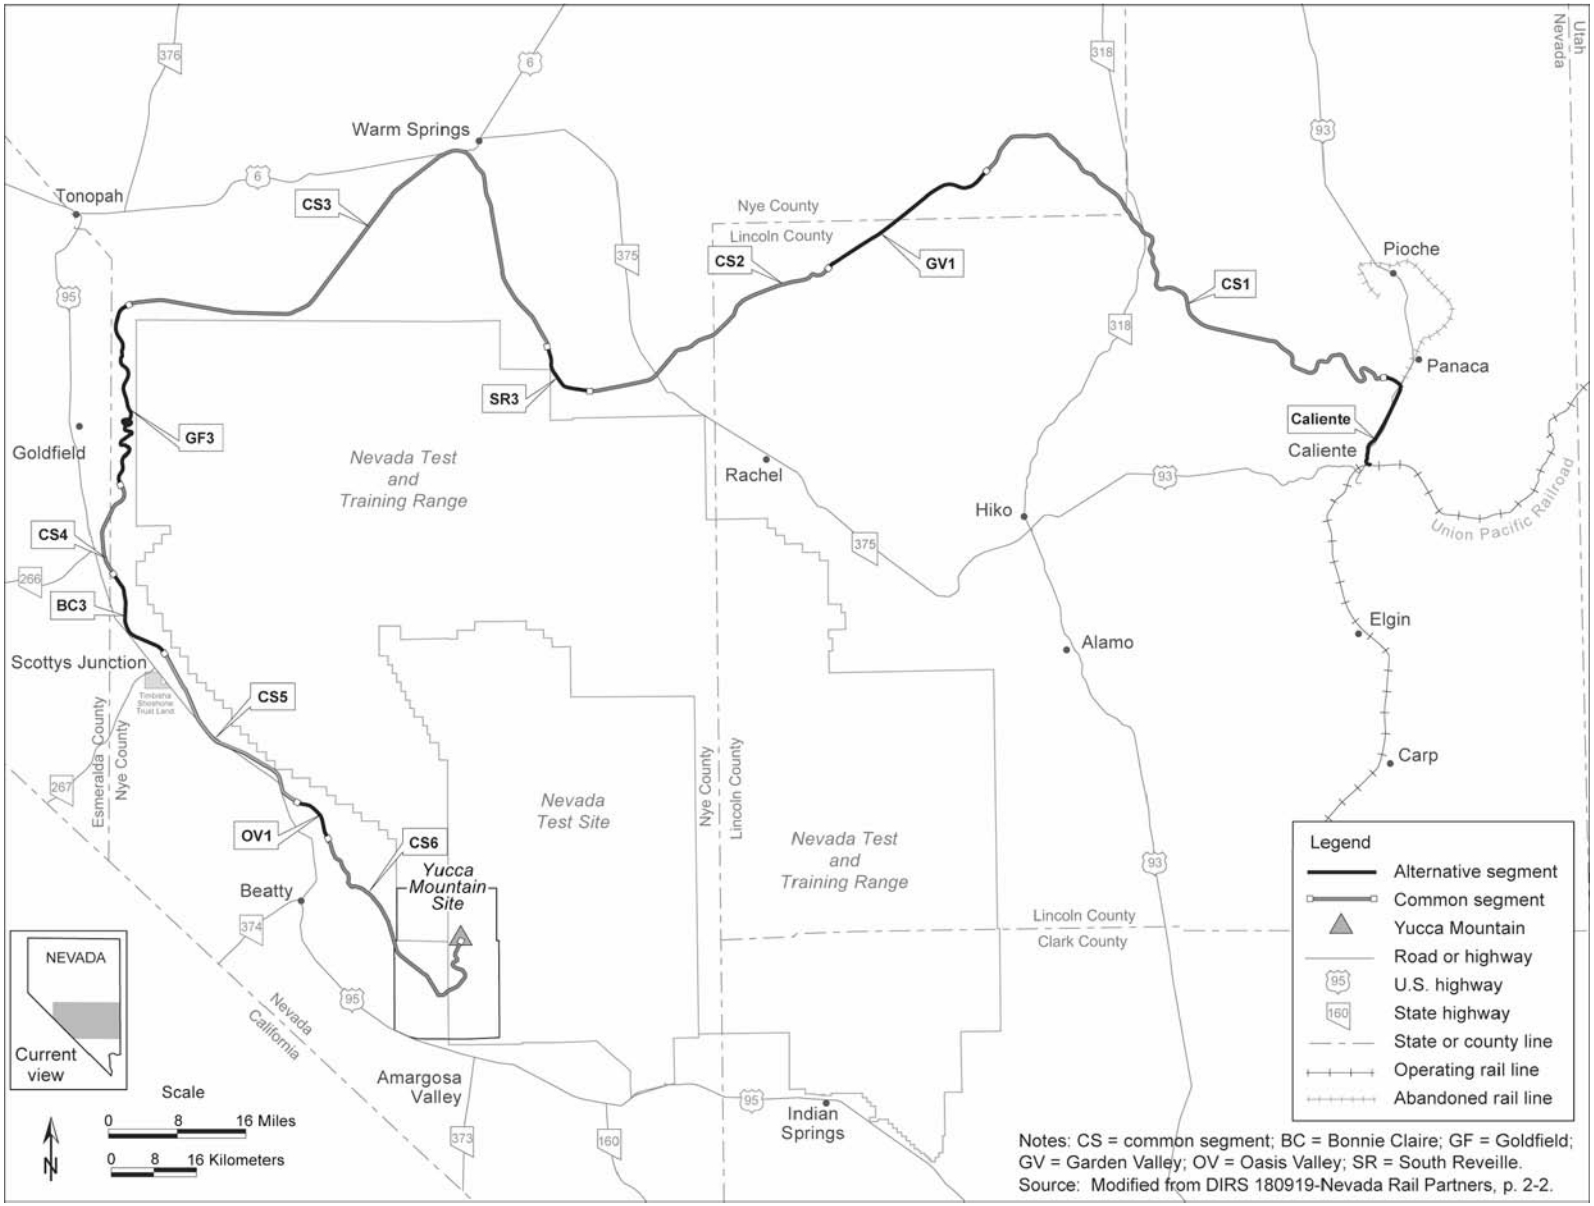

Figure 2-55. Preferred Caliente rail alignment, combination of common segments and alternative segments.

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 1 of 17).

Resource Area	Proposed Action: Caliente Implementing Alternative	Proposed Action: Mina Implementing Alternative	No-Action Alternative
Physical setting	Total surface disturbance: 55 to 61 square kilometers (14,000 to 15,000 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 1.3 to 1.8 square kilometers (320 to 440 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.	Total surface disturbance: 40 to 48 square kilometers (9,900 to 12,000 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.011 to 0.014 square kilometer (2.7 to 3.5 acres). Less than 3 percent of the prime farmland soils of the Walker River Paiute Reservation.	No surface disturbance or prime farmland soils impacts because the rail line and associated facilities would not be constructed.
Land use and ownership	Land-use change on public lands for operations right-of-way. Private parcels the rail line would cross: 14 to 71. Area of private land affected: 0.33 to 0.72 square kilometer (82 to 178 acres). Private land needed for facilities: 1.15 square kilometers (284 acres) Active grazing allotments the rail line would cross: 24 to 27. Animal unit months lost: 1,019 to 1,050. (An animal unit month represents enough dry forage for one mature cow for one month.) Sections with unpatented mining claims that would be crossed: 32 to 37.	Land-use change on public lands and the Walker River Paiute Reservation for operations right-of-way. Private parcels the rail line would cross: 1 to 40. Area of private land affected: 0.21 to 0.59 square kilometer (52 to 146 acres). Active grazing allotments the rail line would cross: 5 to 8. Animal unit months lost: 159 to 246. Sections with unpatented mining claims that would be crossed: 23 to 30.	DOE would relinquish public lands along the Caliente rail alignment that were withdrawn for study under Public Land Order 7653. DOE would also relinquish the public lands segregated from surface and mineral entry for 2 years along the Caliente and Mina rail alignments.

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 2 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Aesthetic resources	Small to moderate impact across Caliente rail alignment from operations. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads.	Same as the Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed. Public land would remain subject to BLM administration under applicable resource management plans. BLM would continue to manage public land for multiple use.
	Small impact from train operations. No contrast to strong contrast in the short term from passing trains.	Same as the Caliente Implementing Alternative.	
	Moderate impact from Staging Yard at Indian Cove. Moderate contrast from the operation of the facility in the Class III non-BLM lands, weak contrast from the track on BLM Class II lands at the north end; in each area, consistent with applicable BLM management objectives.	Small to moderate impact from Schurz alternative segments. Weak to moderate contrast as rail line and crossing structures would, in places, attract the attention of viewers, but would meet BLM Class III management objectives. (Moderate to strong contrast in the short term from construction of the rail-over-road grade-separated crossing of U.S. Highway 95 for Schurz 6, which would not meet BLM Class III management objectives.)	
	Potential quarry CA-8B - Moderate impact. Moderate contrast in the short term from installation and use of the conveyor from the quarry across U.S. Highway 93. No long-term impact under the Proposed Action; conveyor would be removed at end of construction phase. Moderate impact under the Shared-Use Option from the use of a conveyor across U.S. Highway 93 for 6 to 8 years.	Small to moderate impact from Montezuma alternative segment 1. Weak contrast from new linear feature adjacent to State Route 265 and weak to moderate contrast in Clayton Valley; would meet BLM Class III and IV management objectives.	
		Potential Garfield Hills quarry - Moderate impact. Moderate contrast in the short term from quarrying, ballast production facilities, and conveyor close to viewers that would be compatible with BLM Class III management objectives. Small impact in long term; production facilities and conveyor would be removed and quarried areas restored after closure of quarry at end of construction phase.	

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 3 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Aesthetic resources (continued)		Potential Gabbs Range quarry - Small to moderate impact. Weak to moderate contrast in the short term from ballast production facilities close to viewers that would be compatible with BLM Class III management objectives. Small impact in long term; production facilities would be removed after closure of quarry at end of construction phase. Potential North Clayton quarry - Weak to moderate impact. Moderate contrast in the short term from production facilities close to viewers that would be compatible with BLM Class IV management objectives. Small impact in long term; production facilities would be removed and waste dumps restored after closure of quarry at end of construction phase.	
Air quality and climate – Lincoln County	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from the construction or operation of the railroad, the Caliente Interchange Yard, or potential quarry CA-8B. The closest approach to a NAAQS standard would be for 24-hour PM_{10} (38 percent of standard for rail line and potential quarry CA-8B) during the construction phase.	Not applicable. No portion of a rail line along the Mina rail corridor would be constructed in Lincoln County.	No impacts because the rail line and associated facilities would not be constructed.

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 4 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Air quality and climate – Esmeralda County	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from railroad construction and operations. The closest approaches to a NAAQS standard would be for 24-hour PM_{10} (87 percent of standard) and 24-hour $PM_{2.5}$ (74 percent of standard), for rail line construction near Goldfield.	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from the railroad construction and operations or the potential Malpais Mesa quarry, with most values expected to be well below the NAAQS. The closest approach to a NAAQS standard would for 24-hour PM_{10} (63 percent of standard) and 24-hour $PM_{2.5}$ (54 percent of standard) for the rail line construction near Silver Peak.	No impacts because the rail line and associated facilities would not be constructed.
Air quality and climate – Nye County	Using conservative modeling assumptions, no exceedances of the NAAQS would be expected from the railroad construction operations, with the possible exception of 24-hour PM_{10}. Modeling at the potential quarry NN-9B site in the South Reveille Valley indicates a potential exceedance (160 percent of standard, temporary and localized) of the 24-hour PM_{10} NAAQS. However, operating restrictions in the required Surface Disturbance Permit would likely reduce PM_{10} emissions, making such an exceedance unlikely.	No exceedances of the NAAQS would be expected from the railroad construction and operations, with most values expected to be far below the NAAQS.	No impacts because the rail line and associated facilities would not be constructed.

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 5 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Air quality and climate – Churchill County	Not applicable. No portion of the rail line along the Caliente rail alignment would be constructed in Churchill County.	No exceedances of the NAAQS would be expected from the railroad operations, with most values expected to be far below the NAAQS. There is no new rail line construction planned within Churchill County; the only construction activity would the operation of trains carrying construction material on the existing rail line.	No impacts because the rail line and associated facilities would not be constructed.
Air quality and climate – Lyon County	Not applicable. No portion of the rail line along the Caliente rail alignment would be constructed in Lyon County.	No exceedances of the NAAQS would be expected from the railroad construction and operations, with most values expected to be far below the NAAQS.	No impacts because the rail line and associated facilities would not be constructed.
Air quality and climate – Mineral County	Not applicable. No portion of the rail line along the Caliente rail alignment would be constructed in Mineral County.	Conservative modeling indicated potential exceedances of the NAAQS for PM_{10} and $PM_{2.5}$ in the following scenarios: • Rail line construction near Mina; 111 percent of the 24-hour PM_{10} NAAQS. • Rail line construction near Schurz, 186 percent of the 24-hour PM_{10} NAAQS. • Rail line construction near Schurz, 124 percent of the 24-hour $PM_{2.5}$ NAAQS. • Rail line construction near Schurz, 103 percent of the annual PM_{10} NAAQS. • Staging Yard construction near Hawthorne, 165 percent of the 24-hour PM_{10} NAAQS. • Staging Yard construction near Hawthorne, 118 percent of the 24-hour $PM_{2.5}$ NAAQS. • Staging Yard construction near Hawthorne, 102 percent of the annual PM_{10} NAAQS. • Operation of the potential Garfield Hills quarry near Hawthorne, 200 percent of the 24-hour PM_{10} NAAQS. However, operating restrictions in the required Surface Disturbance Permit would likely reduce PM_{10} and $PM_{2.5}$ emissions, making such exceedances unlikely. No exeedances for other criteria pollutants would be expected, with most values expected to be well below the NAAQS.	No impacts because the rail line and associated facilities would not be constructed.

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 6 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Air quality and climate – Mineral County (continued)		Modeling of emissions from construction of the Staging Yard at Hawthorne found that the 24-hour PM_{10} and $PM_{2.5}$ NAAQS could be exceeded in the immediate vicinity of the Staging Yard under some conditions. Modeling of emissions from the operation of the potential quarry at Garfield Hills indicates that the 24-hour PM_{10} and $PM_{2.5}$ NAAQS could be potentially exceeded. However, the required Surface Disturbance Permit is anticipated to greatly reduce PM_{10} and $PM_{2.5}$ emissions, making an exceedance of the NAAQS unlikely.	
Surface-water resources	Caliente alternative segment: Approximately 0.05 square kilometer (12 acres) of wetlands would be filled. Long-term reduced and potentially eliminated access to Caliente Hot Springs. Eccles alternative segment: Negligible amount of wetlands would be filled. Caliente alternative segment: Indian Cove Staging Yard, approximately 0.19 square kilometer (47 acres) of wetlands would be filled; Upland Staging Yard, no wetlands would be filled. Potential quarry CA-8B: Approximately 0.09 square kilometer (22 acres) of wetlands would be filled to construct the quarry siding. Eccles alternative segment, Interchange Yard: Approximately 0.033 square kilometer (8.2 acres) of Clover Creek would be filled. Goldfield alternative segment 3: Long-term reduced and potentially eliminated access to Willow Springs.	Schurz alternative segments: Of the 0.065 square kilometer (16 acres) of wetlands crossed in this area, only 20 to 28 square meters (220 to 300 square feet) would be permanently filled to construct the bridge over the Walker River.	No impacts because the rail line and associated facilities would not be constructed. Erosion and sedimentation would continue under natural processes.

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 7 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Groundwater resources	Physical impacts to existing groundwater resource features such as existing wells or springs resulting from railroad construction and operation would be small.	Physical impacts to existing groundwater resource features such as existing wells or springs resulting from railroad construction and operations would be small.	No impacts because the rail line and associated facilities would not be constructed.
	Groundwater withdrawals during construction from hydrographic areas in Panaca Valley, Sarcobatus Flat, and Oasis Valley could impact existing groundwater resources and users through localized and temporary drawdown of the water table. However, mitigation measures such as reducing the pumping rate or relocating proposed wells Pan V25/26, Pan V4, Pan V5, Pan V7/8, Pan V2, Pan V24, SaF1, OV3, OV4, and OV5/13 would minimize these impacts.	Groundwater withdrawals during construction from hydrographic areas in Clayton Valley, Sarcobatus Flat, Oasis Valley, and Columbus Salt Marsh could impact existing groundwater resources and users. However, mitigation measures such as reducing the pumping rate or relocating proposed wells CL-1a, SaF1, OV3, OV4, OV5/13, and CSM-2a would minimize these impacts.	
	The potential for groundwater withdrawals during the construction and operations phases to cause subsidence of the ground surface would be small.	Same as the Caliente Implementing Alternative.	
	The impact of proposed groundwater withdrawals on groundwater quality would be small, and the impact of withdrawals on downgradient hydrographic areas would be very small. The proposed withdrawals would not conflict with water quality standards protecting groundwater resources.	Same as the Caliente Implementing Alternative.	

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 8 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Biological resources	Short-term impact to 0.12 to 0.24 square kilometer (30 to 59 acres) wetland/riparian habitat. Long-term impact to 0.11 to 0.23 square kilometer (27 to 57 acres) wetland/riparian habitat. Short-term moderate impact on riparian and wetland vegetation along Oasis Valley alternative segment 3. Small to moderate impact on raptor nesting sites from the construction of potential quarry NN-9A. Short-term moderate impacts to desert bighorn sheep southwest of common segment 6.	Short-term impact to 0.01 to 0.05 square kilometer (2.5 to 12 acres) wetland/riparian habitat. Long-term impact to 0 to 0.01 square kilometer (0 to 2.5 acres) wetland/riparian habitat. Same as the Caliente Implementing Alternative. Small to moderate long-term impacts to Inter-Mountains Mixed Salt Desert Scrub and Inter-Mountain Basins Greasewood Flat along Schurz alternative segment 6. Moderate long-term impact to Inter-Mountains Mixed Salt Desert Scrub along Mina common segment 1. Short-term and long-term moderate impacts to western snowy plover along Mina common segment 1. Moderate impact to winterfat communities – Montezuma alternative segments and potential Gabbs Range quarry site. Long-term moderate impacts to Inter-Mountain Basins Mixed Salt Desert Scrub and Inter-Mountain Basins Big Sagebrush at potential North Clayton and Malpais Mesa quarry sites. Short-term moderate impacts to desert bighorn sheep southwest of common segment 6.	No impacts because the rail line and associated facilities would not be constructed.

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 9 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Noise and vibration	Noise from construction activities in Caliente would exceed Federal Transit Administration guidelines. Daytime limits would be exceeded by 11 dBA from construction equipment noise and by 7 dBA from pile driving; 30-day DNL limit would be exceeded by 2 dBA from construction equipment noise and by 12 dBA from pile driving. Noise from construction equipment along the Eccles alternative segment would exceed limits by 5 dBA. No adverse noise or vibration impacts from construction trains or from operational train activity.	DOE estimates that 34 receptors would be included within the construction-train 65 DNL contours in Silver Springs, and 7 receptors would be included within the 65 DNL contours in Wabuska. These noise impacts would be considered temporary adverse impacts. Noise from operations would create adverse noise impacts at eight receptors in Silver Springs and one receptor in Wabuska. No vibration impacts from construction trains or from operational train activity.	No change to existing noise and vibration. No impacts because the rail line and associated facilities would not be constructed.
Socioeconomics – Throughout the region of influence	*Construction* Up to 1,083 animal unit months lost, valued at $57,000 (An animal unit month represents enough dry forage for one mature cow for one month.) *Operations* Continued lack of access to up to 1,083 animal unit months, valued at $57,000	*Construction* Up to 326 animal unit months lost, valued at $17,400 *Operations* Continued lack of access to up to 326 animal unit months, valued at $17,400	No impacts to existing socioeconomic conditions because the rail line and associated facilities would not be constructed.
Socioeconomics – Lincoln County	*Construction* Population: 1.7 percent increase Employment: 5.6 percent increase Real disposable income: 4.1 percent increase Gross regional product: 28 percent increase State and local government spending: 1.9 percent increase Traffic impacts to local highways: level of service on U.S. Highway 93 at Caliente would degrade from A to B	Not applicable	No impacts to existing socioeconomic conditions because the rail line and associated facilities would not be constructed.

Resource Area	Proposed Action: Caliente Implementing Alternative	Proposed Action: Mina Implementing Alternative	No-Action Alternative
Utilities, energy, and materials (continued)	Wastewater treatment systems: Dedicated treatment systems would be provided at construction camps and operations facilities; small impact on public systems from population increase attributable to construction and operations employees.	Wastewater treatment systems: Same as Caliente Implementing Alternative.	
	Fossil fuels: Demand would be approximately 6.5 percent of statewide use during construction and less than 0.25 percent of statewide use during operations. Demand could be met by existing regional supply systems and suppliers.	Fossil fuels: Demand would be approximately 6 percent of statewide use during construction and less than 0.25 percent of statewide use during operations. Demand could be met by existing regional supply systems and suppliers.	
	Materials: Requirements generally would be very small in relation to supply capacity.	Materials: Same as Caliente Implementing Alternative.	
	Shared-Use Option Fossil fuels: Demand would be less than 0.3 percent of statewide use during operations. Demand could be met by existing regional supply systems and suppliers.	*Shared-Use Option* Fossil fuels: Same as Caliente Implementing Alternative.	
Hazardous materials and waste	Small (Apex Landfill) to moderate (smaller landfills) impacts during the construction phase and no impact to small impact during the operations phase from nonhazardous waste (solid and industrial and special waste) disposal.	Same as Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed.
	Small impacts from use of hazardous materials during the construction and operations phases.	Same as Caliente Implementing Alternative.	
	Small impacts from hazardous-waste disposal during the construction and operations phases.	Same as Caliente Implementing Alternative.	
	Small impacts during the operations phase from low-level radioactive waste disposal for wastes that would be generated at the Cask Maintenance Facility.	Same as Caliente Implementing Alternative.	

Table 2-31. Comparison of potential impacts under the Proposed Action (Caliente Implementing Alternative and Mina Implementing Alternative) and the No-Action Alternative[a] (page 17 of 17).

Resource Area	Proposed Action		No-Action Alternative
	Caliente Implementing Alternative	Mina Implementing Alternative	
Cultural resources	Numerous archaeological sites have been identified along segments of alignments subjected to sample inventory. Potential direct and indirect impacts to National Register-eligible sites and to other sites that might be identified during the complete survey. Construction could result in impacts to the early Mormon colonization cultural landscape, Pioche-Hiko silver mining community route, 1849 Emigrant Trail campsites, and American Indian trail systems. Indirect effects to a National Register-eligible rock-art site are likely from two quarry sites. More than 50 National Register-eligible sites have been identified along segments of alignments subjected to sample inventory.	Numerous archaeological sites have been identified along segments of alignments subjected to sample inventory. Potential direct and indirect impacts to National Register-eligible sites and to other sites that might be identified during the complete survey. More than 60 National Register-eligible sites have been identified along segments of alignments subjected to sample inventory.	No impacts because the rail line and associated facilities would not be constructed.
Paleontological resources	No direct impacts to known paleontological resources.	Same as Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed.
Environmental justice	Constructing and operating the proposed rail line along the Caliente rail alignment would not result in disproportionately high and adverse impacts to minority or low-income populations.	Same as Caliente Implementing Alternative.	No impacts because the rail line and associated facilities would not be constructed.

a. BLM = Bureau of Land Management; CO = carbon monoxide; dBA = A-weighted decibels; DNL = day-night average noise level; DOE = U.S. Department of Energy; NAAQS = National Ambient Air Quality Standards; NO_x = oxides of nitrogen; PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers; SO_2 = sulfur dioxide; VOCs = volatile organic compounds.

Table 2-32. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments[a] (page 1 of 7).

Resource Area	Alternative segments and common segments	
	Interface with the Union Pacific Railroad – Caliente	Interface with the Union Pacific Railroad – Eccles
Physical setting	Total surface disturbance: 3.1 square kilometers (770 acres). Loss of prime farmland soils: 0.16 square kilometer (40 acres). Less than 0.1 percent of prime farmland soils in Lincoln County.	Total surface disturbance: 2.1 square kilometers (520 acres). Loss of prime farmland soils: 0.10 square kilometer (24 acres). Less than 0.1 percent of prime farmland soils in Lincoln County.
Land use and ownership	Private parcels crossed: 32. Area of private land affected: 0.31 square kilometer (77 acres). Active grazing allotments crossed: 2. Animal unit months lost: 6 (0.6 percent). Indian Cove Staging Yard area of private land affected: 0.73 square kilometer (180 acres) Upland Staging Yard, area of private land affected: 0.45 square kilometer (110 acres)	Private parcels crossed: 11. Area of private land affected: 0.32 square kilometer (80 acres). Active grazing allotments crossed: 4. Animal unit months lost: 18 (1.5 percent).
Aesthetic resources	Small to moderate impact. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads. Moderate impact from Staging Yard at Indian Cove. Moderate contrast from the operation of the facility in the Class III non-BLM lands, weak contrast from the track on BLM Class II lands at the north end; in each area, consistent with applicable BLM objectives. Potential quarry CA-8B - Moderate impact. Moderate contrast in the short term from installation and use of the conveyor from the quarry across U.S. Highway 93, consistent with surrounding non-BLM lands treated as Class III. No long-term impact under the Proposed Action; conveyor would be removed at end of construction phase.	Small to moderate impact. No contrast to moderate contrast in the long term from the installation of linear track, signals, communications towers, power poles connecting to the grid, and access roads. Quarry CA-8B would not be developed for the Eccles alternative segment.
Surface-water resources	Caliente alternative segment: Approximately 0.05 square kilometer (12 acres) of wetlands would be filled. Long-term reduced and potentially eliminated access to Caliente Hot Springs. Indian Cove Staging Yard: Approximately 0.19 square kilometer (47 acres) of wetlands would be filled. Potential quarry CA-8B: Approximately 0.09 square kilometer (22 acres) of wetlands would be filled to construct the quarry siding.	Eccles alternative segment: Negligible amount of wetlands would be filled. Eccles Interchange Yard: Approximately 0.033 square kilometer (8.2 acres) of Clover Creek would be filled.

Table 2-32. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments[a] (page 2 of 7).

Resource Area	Alternative segments and common segments	
	Interface with the Union Pacific Railroad – Caliente	Interface with the Union Pacific Railroad – Eccles
Groundwater resources	Groundwater withdrawals from the hydrographic area in Panaca Valley could impact existing groundwater users. However, mitigation measures such as reducing the pumping rate at or relocating proposed wells Pan V25/26, Pan V4, Pan V5, and Pan V3/6 would minimize these impacts.	Groundwater withdrawals from the hydrographic area in Panaca Valley could impact existing groundwater users. However, mitigation measures such as reducing the pumping rate at or relocating proposed wells Pan V3/6 and Pan V25/26 would minimize these impacts.
Biological resources	Caliente alternative segment and Interchange Yard: Short-term impact to 0.09 square kilometer (22 acres) wetland/riparian habitat. Long-term impact to 0.11 square kilometer (27 acres) wetland/riparian habitat. Upland Staging Yard: Short-term impact to 0.01 square kilometer (2.5 acres) wetland/riparian habitat. Long-term impact to less than 0.01 square kilometer (2 acres) wetland/riparian habitat. Indian Cove Staging Yard: Short-term impact to 0.09 square kilometer (22 acres) wetland/riparian habitat. Long-term impact to 0.04 square kilometer (9.9 acres) wetland/riparian habitat. Long-term moderate impact on riparian and wetland vegetation from the construction of a siding for potential quarry CA-8B.	Eccles alternative segment and Interchange Yard: Short-term impact to 0.10 square kilometer (24 acres) wetland/riparian habitat. Long-term impact to 0.10 square kilometer (24 acres) wetland/riparian habitat. Eccles-North Staging Yard: Short-term impact to 0.01 square kilometer (2.6 acres) wetland/riparian habitat. Long-term impact to 0.01 square kilometer (2.6 acres) wetland/riparian habitat.
Noise and vibration	Noise from construction activities would exceed Federal Transportation Administration guidelines. Daytime limits would be exceeded by 11 dBA from construction equipment noise and by 7 dBA from pile driving; 30-day DNL limit would be exceeded by 2 dBA from construction equipment noise and by 12 dBA from pile driving. There would be no adverse impacts from the operation of construction trains. There would be no receptors within the 65 DNL contour. There would be no adverse impacts from noise for the operation of trains along the rail alignment. No receptors would fall within the 3 dBA increase contour or the 65 DNL contour. There would be no adverse impacts from vibrations, which would fall below Federal Transportation Administration criteria.	Noise from construction activities would exceed Federal Transportation Administration guidelines. Construction equipment noise would cause daytime limits to be exceeded by 5 dBA. There would be no adverse impacts from the operation of construction trains. No receptors would fall within the 65 DNL contour. There would be no adverse impacts from noise for the operation of trains along the rail alignment. No receptors would be within the 65 DNL contour. There would be no adverse impacts from vibrations, which would fall below Federal Transportation Administration criteria.
Cultural resources	Potential direct and indirect impacts at three known National Register-eligible sites and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at two known potentially eligible sites and at other sites that might be identified during the complete survey.

Table 2-32. Comparison of potential impacts under the Proposed Action – Caliente rail alignment alternative segments and common segments [a] (page 3 of 7).

Resource Area	Alternative segments and common segments			
	Caliente common segment 1			
Physical setting	Total surface disturbance: 12 square kilometers (3,000 acres). Loss of prime farmland soils: 1.2 square kilometers (300 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.			
Land use and ownership	Private parcels crossed: 1. Area of private land affected: 0.0007 square kilometer (0.2 acre). Active grazing allotments crossed: 10. Animal unit months lost: 453 (0.7 percent).			
Cultural resources	Construction activities could result in impacts to the early Mormon colonization cultural landscape, the Pioche-Hiko silver mining community route, 1849 emigrant campsites, a National Register-eligible prehistoric site in the vicinity of Black Rock Springs, and to other sites that might be identified during the complete survey.			
	Garden Valley 1	Garden Valley 2	Garden Valley 3	Garden Valley 8
Physical setting	Total surface disturbance: 3.4 square kilometers (840 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.29 square kilometer (72 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.	Total surface disturbance: 3.6 square kilometers (890 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.4 square kilometer (99 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.	Total surface disturbance: 3.7 square kilometers (910 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0 square kilometer (0 acre).	Total surface disturbance: 3.7 square kilometers (910 acres). Would result in topsoil loss and increased potential for erosion. Loss of prime farmland soils: 0.36 square kilometer (89 acres). Less than 0.1 percent of prime farmland soils in Lincoln and Nye Counties.
Land use and ownership	Active grazing allotments crossed: 5. Animal unit months lost: 120 (1.34 percent).	Active grazing allotments crossed: 4. Animal unit months lost: 131 (1.1 percent).	Active grazing allotments crossed: 5. Animal unit months lost: 126 (1.4 percent).	Active grazing allotments crossed: 4. Animal unit months lost: 131 (1.1 percent).

Unpatented mining claims the alignment would cross: 2 sections with 14 claims.
Groundwater resources	Groundwater withdrawals from hydrographic area 228 (Oasis Valley) would impact existing groundwater users or groundwater resources. However, mitigation measures such as reducing the pumping rate at proposed wells OV3, OV4, and OV5 or drawing water from nearby alternative wells would minimize these impacts.	Groundwater withdrawals from hydrographic area 228 (Oasis Valley) would impact existing groundwater users or groundwater resources. However, mitigation measures such as reducing the pumping rate at proposed well OV13 or drawing water from nearby alternative wells would minimize these impacts.
Biological resources	No impact on riparian and wetland vegetation.	Short-term moderate impact on riparian and wetland vegetation.
Cultural resources	Potential direct and indirect impacts at a historic cattle ranch, campsite, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.	Potential direct and indirect impacts at a historic cattle ranch, campsite, archaeological sites identified along segments subjected to sample inventory, and at other sites that might be identified during the complete survey.
	Common segment 6	
Physical setting	Total surface disturbance: 5.5 square kilometers (1,400 acres). Would result in topsoil loss and increased potential for erosion.	
Biological resources	Short-term moderate impacts to desert bighorn sheep southwest of common segment 6.	
Land use and ownership	Sections with unpatented mining claims the alignment would cross: 4 sections with 34 claims.	
Cultural resources	Potential direct and indirect impacts at archaeological sites recorded in region of influence, including three National Register-eligible resources, and at other sites that might be identified during the complete survey.

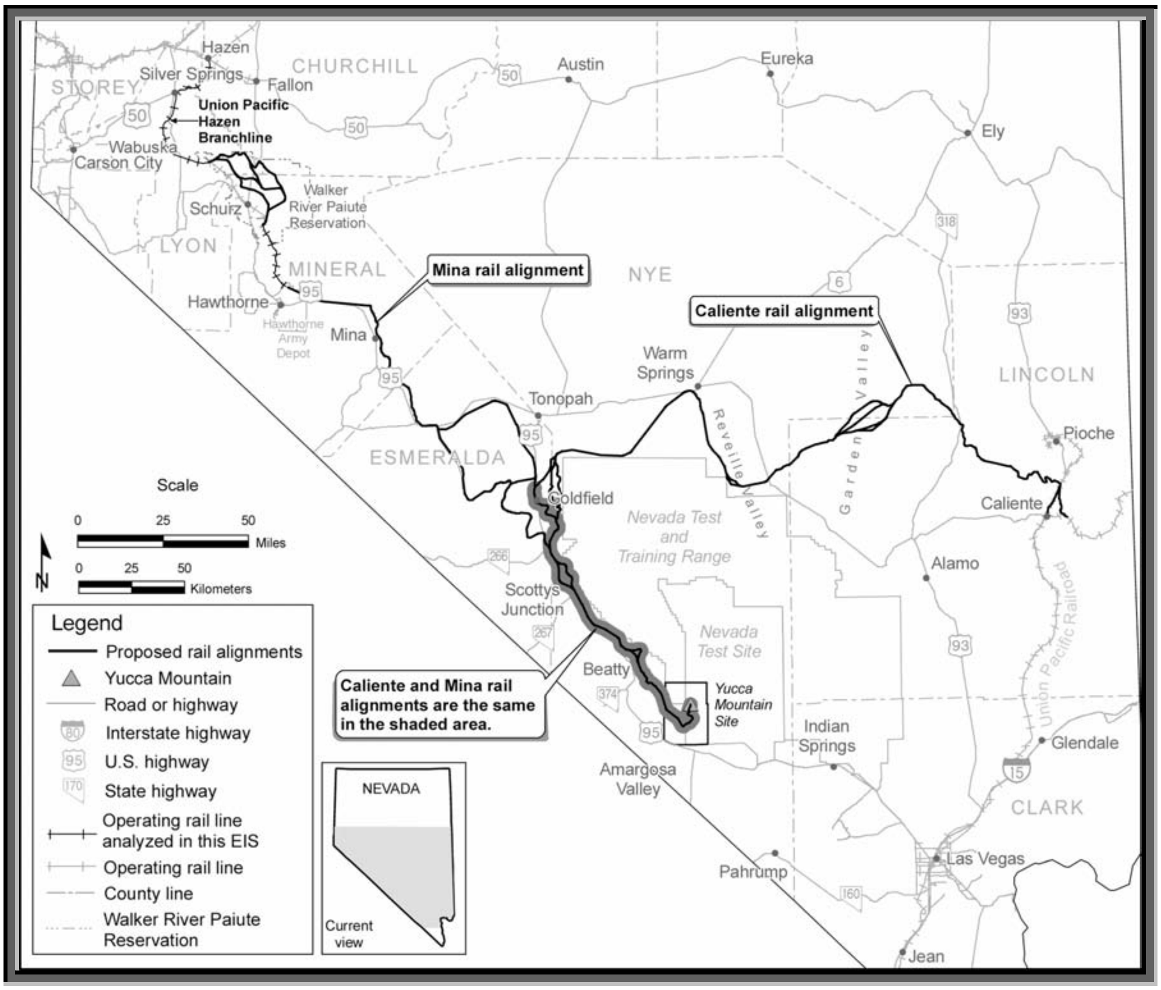
October 2007

3. AFFECTED ENVIRONMENT

This chapter describes the environmental setting and existing conditions in the areas encompassing Caliente rail alignment and Mina rail alignment alternative segments and common segments; it provides a baseline for use in evaluating the potential project-related environmental impacts of constructing and operating the proposed railroad. Section 3.2 describes the affected environment along the Caliente rail alignment; Section 3.3 describes the affected environment along the Mina rail alignment; and Section 3.4 describes American Indian interests in the affected environment.

Glossary terms shown in ***bold italics***.



3.1 Introduction

The U.S. Department of Energy (DOE or the Department) has compiled extensive information about the environmental resources that could be affected if the Department constructed and operated the proposed ***railroad*** along a ***rail alignment*** within either the Caliente ***rail corridor*** or the Mina rail corridor. DOE used this information to establish the baseline against which it assessed potential ***impacts*** under the ***Proposed Action*** and ***Shared-Use Option*** (see Chapter 4, Environmental Impacts).

DOE obtained baseline environmental information from many sources, including DOE-sponsored reports and studies, other federal agencies (for example, the Bureau of Land Management), the State of Nevada, and local governments.

Descriptions of the ***affected environments*** along the Caliente rail alignment and the Mina rail alignment focus on environmental resources within and adjacent to the ***alternative segments*** and ***common segments***, and the proposed locations of railroad ***construction and operations support facilities*** outside the ***nominal*** width of the rail line ***construction right-of-way***.

This chapter describes the environmental setting and existing conditions for the following resource areas:

- Physical setting (physiography, geology, and soils)
- Land use (grazing, mineral and energy resources, recreation and land access, utility and transportation corridors) and ownership (private and ***public lands***)
- Aesthetic (visual) resources
- ***Air quality*** and climate
- Surface-water resources (streams and ***washes***, ***waters of the United States***, ***wetlands***, ***floodplains***)
- Groundwater resources (***hydrographic areas***, wells, springs)
- Biological resources (vegetation, wildlife, special status species, Nevada game species, wild horses and burros)
- Noise and vibration
- Socioeconomics (employment and income, population and housing, public services, and transportation)
- Occupational and public health and safety (nonradiological and radiological)
- Utilities, energy, and materials (public suppliers of water, ***wastewater treatment***, and electricity; fossil fuels; construction materials)
- Hazardous materials and waste (use of materials and generation of wastes)
- Cultural resources (archaeological, historical, cultural)
- Paleontological resources (***fossils***)
- ***Environmental justice***

Proposed Action: To determine a rail alignment within a rail corridor in which to construct and operate a railroad to transport spent nuclear fuel, high-level radioactive waste, and other materials from an existing railroad in Nevada to a repository at Yucca Mountain, Nye County, Nevada. The Proposed Action includes the construction of railroad construction and operations support facilities.

This Rail Alignment EIS analyzes two alternatives that would implement the Proposed Action: the Caliente rail alignment and the Mina rail alignment.

This Rail Alignment EIS also analyzes a Shared-Use Option for each implementing alternative, under which DOE would allow commercial shippers to use the rail line for transportation of general freight.

Rail corridor: A strip of land 400 meters (0.25 mile) wide through which DOE would identify an alignment for the construction of a ***rail line*** in Nevada to a geologic repository at Yucca Mountain

Rail alignment: An engineered refinement of a rail corridor in which DOE would identify the location of a rail line. A rail alignment is comprised of common segments and alternative segments.

Construction right-of-way: Nominally, 150 meters (500 feet) on either side of the centerline of the rail alignment (a nominal width of 300 meters [1,000 feet]). In some locations along the rail alignment, the nominal width of the construction right-of-way would be greater (for example, to accommodate certain deep cuts and fills and construction of drainage structures) or less (for example, to avoid sensitive environmental resources). The rail line construction right-of-way is generally linear, but also includes specific locations of construction and operations support facilities (such as quarries, some water wells, and access roads) outside the linear construction right-of-way.

3.2 Caliente Rail Alignment

> The **region of influence** is the physical area that bounds the environmental, sociologic, economic, or cultural features of interest for analysis purposes.

This section describes the affected environment along the Caliente rail alignment. The scope of the affected environment reflects the ***region of influence*** for each resource area. DOE expects that most potential impacts would occur within a certain distance from the centerline of the rail alignment and within the ***footprints*** of construction and operations support facilities. However, resource area regions of influence vary, depending on the nature and type of the resource. Each environmental resource section fully describes the region of influence for the resource. Table 3-1 summarizes the regions of influence for the Caliente rail alignment analyzed in this Rail Alignment Environmental Impact Statement (EIS).

Table 3-1. Regions of influence for environmental resource areas – Caliente rail alignment (page 1 of 4).

Resource area	Region(s) of influence
Physical setting	All areas that would be directly or indirectly affected by construction and operation of the proposed railroad. These areas include the nominal width of the rail line construction right-of-way, and the footprints of construction and operations support facilities outside the nominal width of the construction right-of-way. See Section 3.2.1.1.
Land use and ownership	The nominal width of the construction right-of-way, including all private land (including patented mining claims), American Indian lands, and public land fully or partially within this area. Also includes the locations of construction and operations support facilities outside the nominal width of the construction right-of-way. See Section 3.2.2.1.
Aesthetic resources	The ***viewshed*** around all alternative segments, common segments, and proposed locations of construction and operations support facilities. DOE used a conservative region of influence extending 40 kilometers (25 miles) on either side of the centerline of the rail alignment. See Section 3.2.3.1.
Air quality and climate	The air basins bounded by Lincoln, Nye, and Esmeralda Counties. See Section 3.2.4.1.
Surface-water resources	The nominal width of the construction right-of-way for most of the analysis. In cases where surface-water flow patterns (including floodwaters) could be modified or surface-water drainage patterns could carry eroded soil, sedimentation, or spills downstream, the region of influence extends to 1.6 kilometers (1.0 mile) on either side of the centerline of the rail alignment. See Section 3.2.5.1.
Groundwater resources	***Aquifers*** that would underlie areas of proposed railroad construction and operations, portions of groundwater aquifers DOE would use to obtain water for construction and operations support and that would be affected by these groundwater withdrawals, and nearby springs that might be affected by such groundwater withdrawals. The horizontal extent of the region of influence varies depending on the particular aspects of the specific project activity. See Section 3.2.6.1.

Table 3-1. Regions of influence for environmental resource areas – Caliente rail alignment (page 2 of 4).

Resource area	Region(s) of influence
Biological resources	DOE used two areas of assessment to describe the affected environment for biological resources: a region of influence and a study area. *Region of influence*: Generally, the nominal width of the construction right-of-way. For facilities that would be outside the nominal width of the construction right-of-way (such as quarries), the footprint of the proposed facility. *Study area*: A 16-kilometer (10-mile)-wide area, extending 8 kilometers (5 miles) on either side of the centerline of the rail alignment, for use in database and literature searches to ensure the identification of sensitive ***habitat*** areas near the Caliente rail alignment and transient or migratory wildlife, particularly special status species, that could pass through the region of influence. See Section 3.2.7.1.
Noise and vibration	The nominal width of the construction right-of-way out to variable distances, depending on several analytical factors (***ambient*** sound level, train speed, number of trains per day, and number of railcars). For construction and operations support facilities, the region of influence varies depending on the magnitude of noise those facilities would generate and ***ambient noise*** levels, which would affect how far away the noise might be heard. Therefore, the region of influence varies along the rail alignment. Also includes the locations of receptors that might be affected by noise, vibration, or both. See Section 3.2.8.1.
Socioeconomics	*Employment and income, population and housing, and public services:* Lincoln, Nye, Esmeralda, and Clark Counties in Nevada. *Transportation resources:* Public roadways near the Caliente rail alignment and the alignment itself.. See Section 3.2.9.1.
Occupational and public health and safety	*Nonradiological region of influence* The region of influence for public nonradiological impacts includes: • The nominal width of the construction right-of-way • Public roads in Lincoln, Nye, and Esmeralda Counties that the workforce would use during railroad construction and operations • Railroad construction and operations support facilities including access roads, water wells, and quarries where workers would perform construction, operations, or maintenance activities *Radiological region of influence* The region of influence for radiological impacts for incident-free transportation includes the area 0.8 kilometer (0.5 mile) on either side of the centerline of the rail alignment. The region of influence for occupational radiological impacts for incident-free operation also includes the physical boundaries of railroad operations support facilities, where workers would perform operations involving ***casks*** and ***cask cars***. Railroad operations support facilities within the radiological region of influence include only the ***Interchange Yard***, the ***Staging Yard***, the ***Rail Equipment Maintenance Facility***, and the ***Cask Maintenance Facility*** because DOE anticipates that ***radioactive*** materials would be managed only at those facilities. See Section 3.2.10.1.

Table 3-1. Regions of influence for environmental resource areas – Caliente rail alignment (page 3 of 4).

Resource area	Region(s) of influence
Occupational and public health and safety (continued)	For purposes of this Rail Alignment EIS, the affected environment for public radiological impacts includes: • Residents within the region of influence of the Caliente rail alignment, including persons who live within 0.8 kilometer (0.5 mile) of either side of the centerline of the rail alignment. For the public radiological impact analysis, DOE evaluated four specific alignments: the alignment that would have the highest exposed population; the shortest alignment; the longest alignment, and the alignment that would have the lowest population. • Individuals at locations such as residences or businesses near the rail alignment. • Individuals within the region of influence for radiological impacts for potential public exposure related to accidents and sabotage. This includes the area 80 kilometers (50 miles) on either side of the centerline of the rail line. See Section 3.2.10.1.
Utilities, energy, and materials	*Regions of influence for utilities and energy* • Public water systems: Systems in Lincoln, Nye, and Esmeralda Counties and communities within those counties. • Wastewater treatment: For wastewater transported offsite for treatment and disposal, the existing permitted treatment facilities in Lincoln, Nye, and Esmeralda Counties and communities within those counties. (Note: For wastewater treated using other methods [for example, on-site portable wastewater-treatment facilities], DOE would recycle treated wastewater, and there is no associated region of influence.) • Telecommunications: For telephone and fiber-optic telecommunications, the southern Nevada region serviced by Nevada Bell Telephone Company (AT&T Nevada), Citizens Telecommunications Company of Nevada, and Lincoln County Telephone System, Inc. • Electricity: Areas serviced by the southern Nevada electrical grid operated by Caliente Public Utilities, Lincoln County Power District No. 1, Nevada Power Company, Sierra Pacific Power Company, and Valley Electric Association, Inc. • Fossil fuels: Regional suppliers within the State of Nevada that could most economically supply the project. *Regions of influence for materials* • The region of influence for cast-in-place concrete and ***subballast*** is limited to the State of Nevada. Subballast, sand, and gravel would be generated from ***overburden*** at quarries and ***borrow sites*** near the rail alignment. There is a high likelihood DOE would also find subballast, sand, and gravel along ***cuts*** for the proposed rail line on ***alluvial fans***. DOE would use some of the natural sand and gravel excavated from cuts and crushed rock from the quarries to make concrete aggregate. See Section 3.2.11.1.

Table 3-1. Regions of influence for environmental resource areas – Caliente rail alignment (page 4 of 4).

Resource area	Region(s) of influence
Utilities, energy, and materials (continued)	*Regions of influence for materials* (continued) • DOE would obtain ballast rock from potential quarry sites close to the construction right-of-way during the construction phase and from commercial quarry sites in southern Utah and in California during the operations phase. Therefore, the region of influence for obtaining ballast rock would encompass the State of Nevada during the construction phase, and Utah and California during the operations phase. • Other materials, including steel, steel rail, general building materials, concrete ties, and other precast concrete could be procured and shipped from various national suppliers. Therefore, the region of influence for these materials is national. See Section 3.2.11.1.
Hazardous materials and waste	*Use of hazardous materials and the generation of hazardous and nonhazardous wastes*: The nominal width of the construction right-of-way, and the locations of construction and operations support facilities outside that area. *Disposal of low-level radioactive waste:* DOE low-level waste disposal sites, sites in ***Agreement States***, and U.S. Nuclear Regulatory Commission-licensed sites. *Disposal of hazardous wastes*: The entire continental United States. *Disposal of nonhazardous waste*: Disposal facilities in Lincoln, Nye, Esmeralda, and Clark Counties in Nevada. See Section 3.2.12.1.
Cultural resources	Two levels of coverage, based on distance from the rail alignment: • Level I. The first level of coverage is within the nominal width of the rail line construction right-of-way, the area where ground disturbance could directly or indirectly impact cultural resources. • Level II. The second level of coverage is a 3.2-kilometer (2-mile)-wide area centered on the rail alignment. This area includes potential disturbances that could indirectly impact cultural resources. See Section 3.2.13.1.
Paleontological resources	The nominal width of the rail line construction right-of-way, and the footprints of railroad construction and operations support facilities. Section 3.2.14.1
Environmental justice	An area encompassing the regions of influence for all other resource areas. Includes populations that could be affected by the project that have cultural or religious ties to the area. See Section 3.2.15.1.

3.2.1 PHYSICAL SETTING

This section describes physiography, geology, and soils along the Caliente rail alignment. Characterization of the physical setting also identifies relationships to other resource areas described in this Rail Alignment EIS, such as aesthetics, land use, biological (vegetation) resources, and surface-water resources.

Section 3.2.1.1 describes the region of influence for physical setting along the Caliente rail alignment; Section 3.2.1.2 describes the general physical setting and characteristics in the region of influence; and Section 3.2.1.3 describes the physical setting in more detail for the Caliente rail alignment alternative segments and common segments.

3.2.1.1 Region of Influence

The region of influence for physical setting along the Caliente rail alignment includes all areas that would be directly or indirectly affected by construction and operation of the proposed railroad. These areas include the nominal width of the ***rail line*** construction right-of-way, and the footprints of facilities outside the nominal width of the construction right-of-way.

3.2.1.2 General Setting and Characteristics

3.2.1.2.1 Physiography

The Caliente rail alignment would cross the Basin and Range Physiographic Province, which is characterized in this area by north-trending, linear mountain ranges separated by broad sediment-filled valleys. Most of the Caliente rail alignment would cross the southern Great Basin, a subdivision of the Basin and Range Province. The mountain ranges are mostly tilted, ***fault***-bounded crustal blocks as much as 80 kilometers (50 miles) long and 24 kilometers (15 miles) wide. Mountain ranges typically rise from 300 to 1,500 meters (980 to 4,900 feet) above the adjacent valley floors and occupy 40 to 50 percent of the total land area. As shown in Figure 3-1, from northeast to southwest, a rail line along the Caliente rail alignment would use gaps, passes, and valleys to cross or travel near the following mountain ranges: Cedar Range, Highland Range, Chief Range, North Pahroc Range, Seaman Range, Golden Gate Range, Quinn Canyon Range, Reveille Range, Kawich Range, Hot Creek Range, and Goldfield Hills.

From east to west, the rail line would cross lowlands in Meadow Valley Wash, Dry Lake Valley, White River Valley, Coal Valley, Garden Valley, Sand Spring Valley, Railroad Valley, Reveille Valley, Stone Cabin Valley, Cactus Flat, Ralston Valley, Mud Lake, Stonewall Flat, Lida Valley, Sarcobatus Flat, Oasis Valley, Crater Flat, and Jackass Flats (Figure 3-1). All lowlands, with the exception of Meadow Valley Wash, Oasis Valley, Crater Flat, and Jackass Flats, have interior drainage to ***playas*** or dry washes and are therefore closed basins. Section 3.2.5 describes surface-water resources in the Caliente rail alignment region of influence. Sediment in the valleys are composed of coarse to fine alluvial debris (boulders, cobbles, sand, silt and clay) eroded from the adjacent mountains. Large alluvial fans, a common landform in the region, begin from the base of the mountains, and sometimes extend far into the valleys.

Alluvial fan: A low, outspread, relatively flat-to-gently sloping mass of loose rock material, shaped like an open fan or a segment of a cone, deposited by a stream where it issues from a narrow mountain valley on a plain or break valley.

Playas: A nearly level area at the bottom of a desert basin that does not drain to a river and is temporarily covered with water from heavy rains or snowmelts. Normally a dry lakebed that may contain water in response to seasonally high runoff.

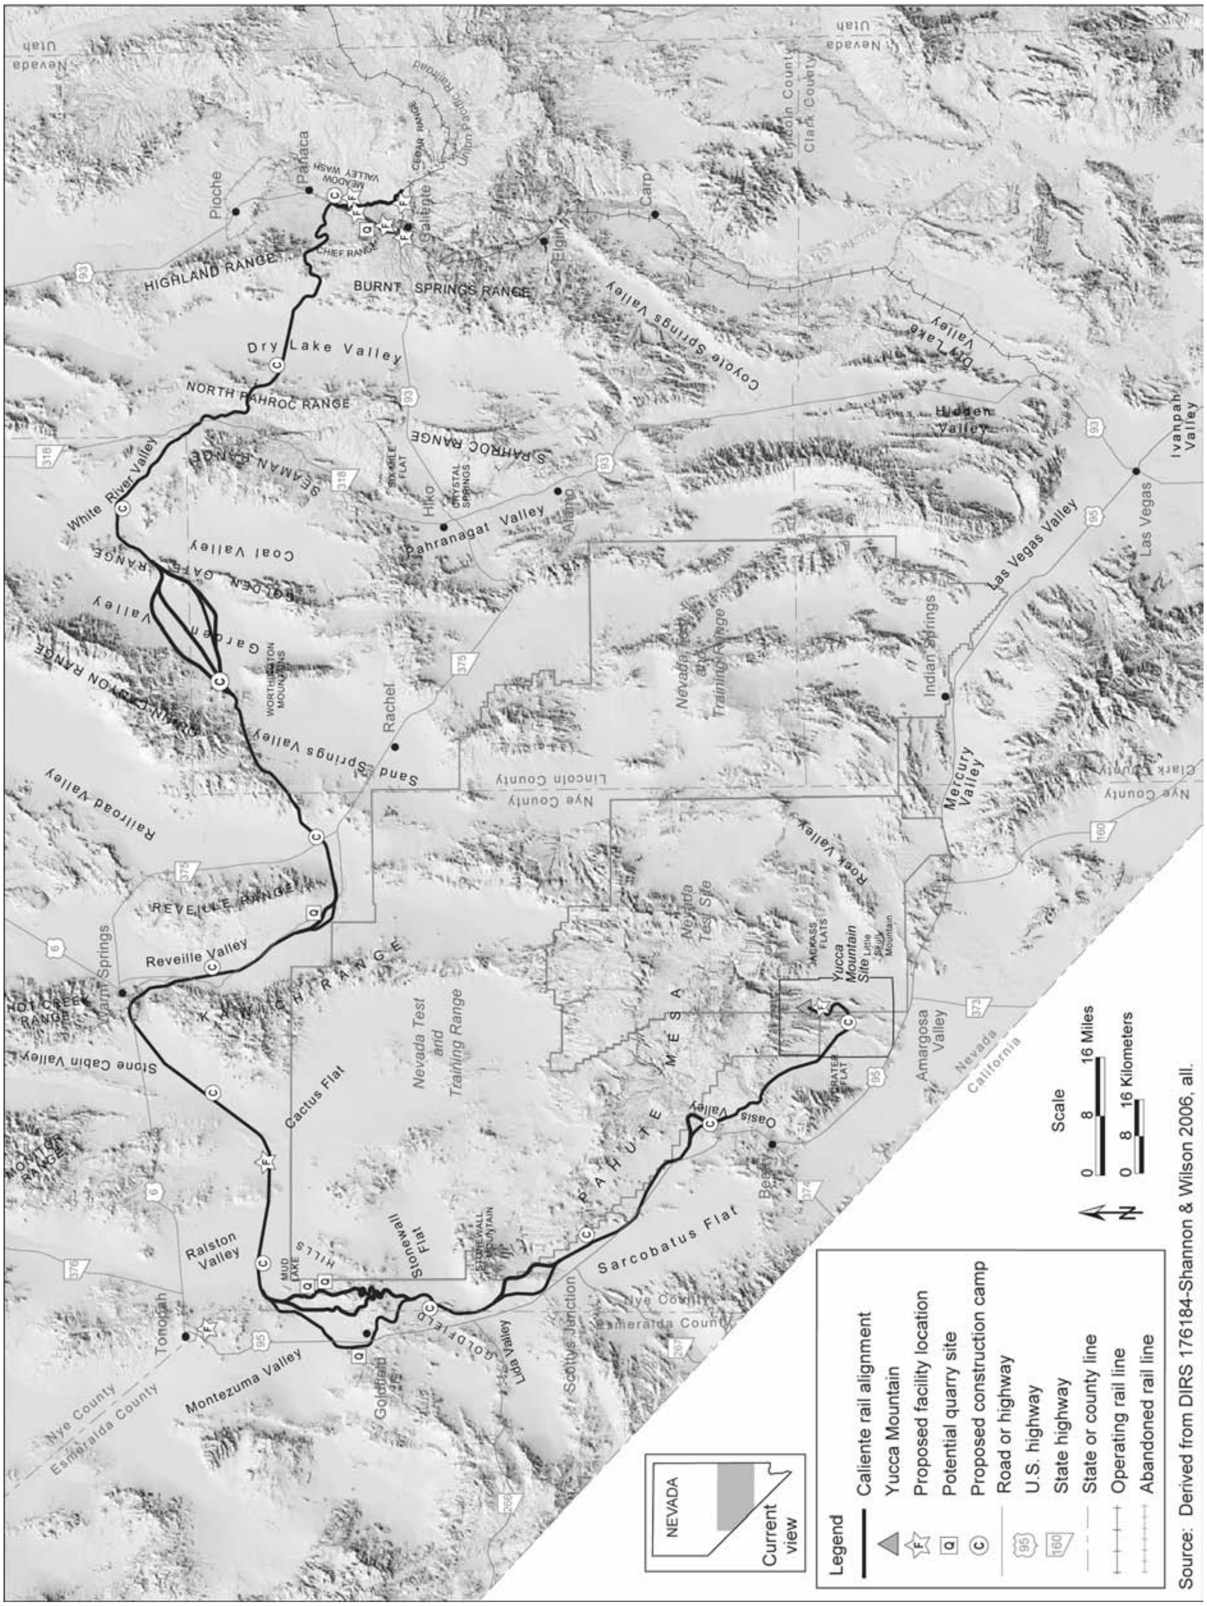


Figure 3-1. Physiographic setting along the Caliente rail alignment.

Playas occur in the lowest parts of some valleys. After heavy rains or snowmelt, the lowlands can fill with water. Evaporation of this water over days or weeks leaves a variety of salts near the surface that limit the growth of vegetation. These valleys are sometimes referred to as closed basins, because no surface water flows out of them.

Elevations along the Caliente rail alignment range from about 980 meters (3,200 feet) above mean sea level at the base of Busted Butte on the west side of Jackass Flats to about 1,900 meters (6,200 feet) above mean sea level at Warm Springs Summit in the Kawich Range (DIRS 176184-Shannon & Wilson 2006, Figure 3, Plates 70 and 71).

3.2.1.2.2 Geology

This section summarizes regional geology along the Caliente rail alignment. The geotechnical report to support the preliminary design effort (DIRS 176184-Shannon & Wilson 2006, all) provides a more detailed discussion of regional geology.

The Caliente rail alignment would cross a region of complex stratigraphic and structural elements that includes major north-south trending basins and ranges and broad volcanic uplands. Table 3-2 provides a generalized stratigraphic description and lists rock sequences according to the geologic age during which they were deposited, and their locations from east to west along the Caliente rail alignment. Table 3-2 also defines the geologic periods discussed in the geology sections of this Rail Alignment EIS.

In general, the age and ***lithology*** of rocks exposed to the east and west of the South Reveille Range are quite different. To the east, Tertiary ***volcanic rocks*** and Paleozoic ***sedimentary rocks***, largely of marine origin, are the principal rocks exposed; to the west, Tertiary volcanic rocks are the principal rocks exposed. The Tertiary volcanic rocks in the western area overlie Paleozoic sedimentary rocks, but these sedimentary rocks are compositionally different from the Paleozoic rocks in the eastern area. The Tertiary volcanic rocks, in turn, are covered in many areas by a variety of late Tertiary and Quaternary alluvial deposits.

Soils in the valleys were primarily formed from late Tertiary and Quaternary and some Paleozoic debris eroded from neighboring mountains, wind-blown sand and silt, fine-grained lake deposits, evaporite deposits, marsh and playa sediments, and spring-carbonate deposits. In some areas, alluvial fans are thin and overlie bedrock surfaces. Elsewhere, basin-fill sediments are more than 1,200 meters (4,000 feet) thick (DIRS 176184-Shannon & Wilson 2006, p. 12).

Volcanic rocks are rocks that have been ejected at or near the earth's surface. ***Tuffs***, lava flows, volcanic ***breccias***, basalt, andesite, and rhyolite are types of volcanic rocks that are found in the Great Basin. They are differentiated by chemistry and texture.

Sedimentary rocks are rocks formed by the accumulation of sediment in water or land. Sandstone, chert, limestone, dolomite, shale, siltstone, and mudstone are types of sedimentary rocks that are found in the Great Basin. They are differentiated by chemistry, deposition, and grain size.

Metamorphic rocks are rocks in which the original mineralogy, texture, or composition has changed due to the effects of pressure, temperature, or the gain or loss of chemical components.

The oldest ***outcrops*** in the region are Precambrian Era ***metamorphic rocks***, which are exposed in hills west of Goldfield alternative segment 4 and west of Caliente common segment 6. Other than these two exposures, Precambrian rocks are covered by younger rocks.

Table 3-2. General stratigraphy – Caliente rail alignment.[a]

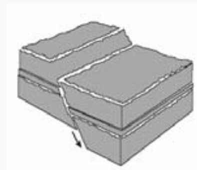
Geologic period[b]	Eastern portion of the Caliente rail alignment[c]	Central portion of the Caliente rail alignment[d]	Western portion of the Caliente rail alignment[e]	Southern portion of the Caliente rail alignment (southwest Nevada volcanic field)[f]
Cenozoic Era[g] (less than 65 Ma)-Quaternary Period (less than 1.6 Ma)	Stream channel, floodplain, and valley floor alluvium; wind-blown, playa, and landslide deposits; fan alluvium; terrace, marsh, spring, and lake beach deposits.	Stream channel and floodplain alluvium; wind-blown, playa, and landslide deposits; fan alluvium; basin-fill deposits.	Stream channel and floodplain alluvium; wind-blown, playa, and landslide deposits; fan alluvium; basin-fill deposits.	Stream channel and floodplain alluvium; wind-blown, playa, and landslide deposits; fan alluvium; basin-fill deposits. Basalt flows.
Cenozoic Era[g] (less than 65 Ma)-Tertiary Period (65 to 1.6 Ma)	Late Tertiary rocks include conglomerate and sandstone. Mid-Tertiary rocks include tuffs and rhyolitic to basaltic lava flows. Early Tertiary rocks include lake-derived limestone and conglomerate, marine limestone, shale, mudstone, sandstone, and siltstone.	Late Tertiary rocks include basalt flows and andesite flows. Mid-Tertiary rocks include tuffs, dacite lava flows, and andesite lava flows. Early Tertiary rocks include sandstone, conglomerate, and calcareous siltstone and mudstone.	Late Tertiary rocks include conglomerate and sandstone. Mid-Tertiary rocks include tuffs, basalt, and andesite. Early Tertiary rocks are not exposed in the region.	Silicic ash-flow tuffs; minor basalts. Predominantly volcanic rocks of the southwestern Nevada volcanic field.
Mesozoic Era (240 to 65 Ma)	No rocks of this age are exposed along this portion of the alignment.	No rocks of this age are exposed along this portion of the alignment.	Quartz monzonite and granodiorite.	Granitic rocks of late Mesozoic (Cretaceous) age occur. No other rocks of this age are exposed along this portion of the alignment.
Paleozoic Era (570 to 240 Ma)	Alternating marine and terrestrial sediments comprised mostly of shale, quartzite, limestone, and dolomite.	Alternating marine and terrestrial sediments comprised mostly of shale, quartzite, limestone, and dolomite.	Rocks of Late and Middle Paleozoic age are not exposed along this portion of the alignment. Rocks of early Paleozoic (Ordovician and Cambrian) are largely limestone and dolomite.	Alternating marine and terrestrial sediments comprised mostly of shale, quartzite, limestone, and dolomite.
Precambrian Era (greater than 570 Ma)	Rocks of this age are not exposed along this portion of the alignment.	Rocks of this age are not exposed along this portion of the alignment.	Conglomerate, quartzite, sandstone, shale, dolomite, limestone, chert, and diabase overlie old ***igneous*** and metamorphic rocks that form the crystalline "basement."	Conglomerate, quartzite, sandstone, shale, dolomite, limestone, chert, and diabase overlie old igneous and metamorphic rocks that form the crystalline "basement."

a. Source: DIRS 176184-Shannon & Wilson 2006, Tables 2 and 3.
b. Ma = approximate years ago in millions.
c. Includes Meadow Valley Wash; Dry Lake and White River Valleys; and Chief, North Pahroc, and Seaman Ranges.
d. Includes Railroad, Reveille, Stone, and Cabin Valleys; Cactus Flat; Golden Gate, Quinn Canyon, and Kawich Ranges.
e. Includes Goldfield Hills, Stonewall Flat, Lida Valley, and Stonewall Mountain.
f. Includes Sarcobatus Flat, Pahute Mesa, Oasis Valley, Crater Flat, Yucca Mountain, Jackass Flats, Rock Valley, and Yucca Flat.
g. The Cenozoic Era consists of both the Quarternary and the Tertiary periods.

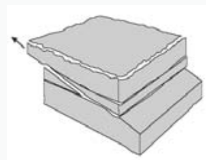
During the late Paleozoic Era, the area was periodically covered by shallow seas to the east that generally deepened westward. Thick layers of limestone, shale, and sandstone, now exposed widely in the mountains along Caliente common segment 1, are the remains of these Paleozoic seas. By early Mesozoic time, the seas had retreated westward across the region for the last time (DIRS 176184-Shannon & Wilson 2006, pp. 9 to 11).

Faulting is movement of the earth's crust that produces relative displacement of adjacent rock masses along a fracture. Generally, the fracture is referred to as a fault.

Splay faults are minor faults that branch off of a primary fault, or interconnect to form a fault zone.



A **normal fault** is a fault where the block above an inclined fault has moved down relative to the other block.



A **thrust fault** is a fault that occurs when squeezing forces push the block above an inclined fault up in relation to the other block.

Source: DIRS 155970-DOE 2002, Figure 3-9.

Major east-west compression occurred periodically in the Great Basin between about 350 million and 65 million years ago (DIRS 169734-BSC 2004, p. 2-16). This compression moved large sheets of old rock great distances upward and eastward over young rocks along ***thrust faults*** to produce mountains. Most of the thrust fault traces have eroded away; however, a remnant of the Pahranagat Fault has been identified south of the Garden Valley alternative segments (DIRS 176184-Shannon & Wilson 2006, Plate 4). Range-bounding ***normal faults***, which have developed in response to ***crustal extension*** over the past 20 million years, are conspicuous features in this part of Nevada and are especially visible in parts of Nye County. These faults have surface traces that form distinctive segments 5 to 30 kilometers (3.1 to 19 miles) long (DIRS 174214-Kleinhampl and Ziony 1985, p. 144). Although generally coincident with the range fronts, in places these normal faults, and shorter ***splay faults*** radiating outward from these normal faults, extend into adjacent valleys where they are buried by recent alluvial deposits. Both the exposed and buried parts of active faults could be capable of rupturing the surface.

Crustal extension in the region, which began about 20 million years ago, is still occurring (DIRS 176184-Shannon & Wilson 2006, p. 12). Present-day mountains and valleys were well developed by about 11.5 million years ago. Evidence of recent, continuing crustal extension is based on Holocene-age (about the last 10,000 years) faults, recurring ***earthquakes***, and geothermal features (some of which are used for commercial purposes such as spas and pools). The Holocene-age faults are visible in many valleys in Nye County that the Caliente rail alignment would cross (Figure 3-2).

Evidence of crustal extension is seen in the Walker-Lane Structural Belt, a 96-kilometer (60-mile)-wide deformation zone that parallels the Nevada-California border from Las Vegas to northern California. The belt includes generally northwest-trending faults that were active within the last 20 million years (DIRS 176184-Shannon & Wilson 2006, p. 14). Ruptures along these faults or along buried faults are possible and could cause earthquakes. Section 3.2.1.2.2.1 provides more information on ***seismic*** activity along the Caliente alignment.

The southwestern Nevada volcanic field is a volcanic plateau that developed between 16 and 7 million years ago, with the greatest eruptions occurring between 14 and 11 million years ago (DIRS 176184-Shannon & Wilson 2006, p. 11). The volcanic field encompasses common segment 5, the Oasis Valley alternative segments, and common segment 6 (Sarcobatus Flat, Pahute Mesa, Oasis Valley, Crater Flat, Yucca Mountain, Jackass Flats, and Rock Valley).

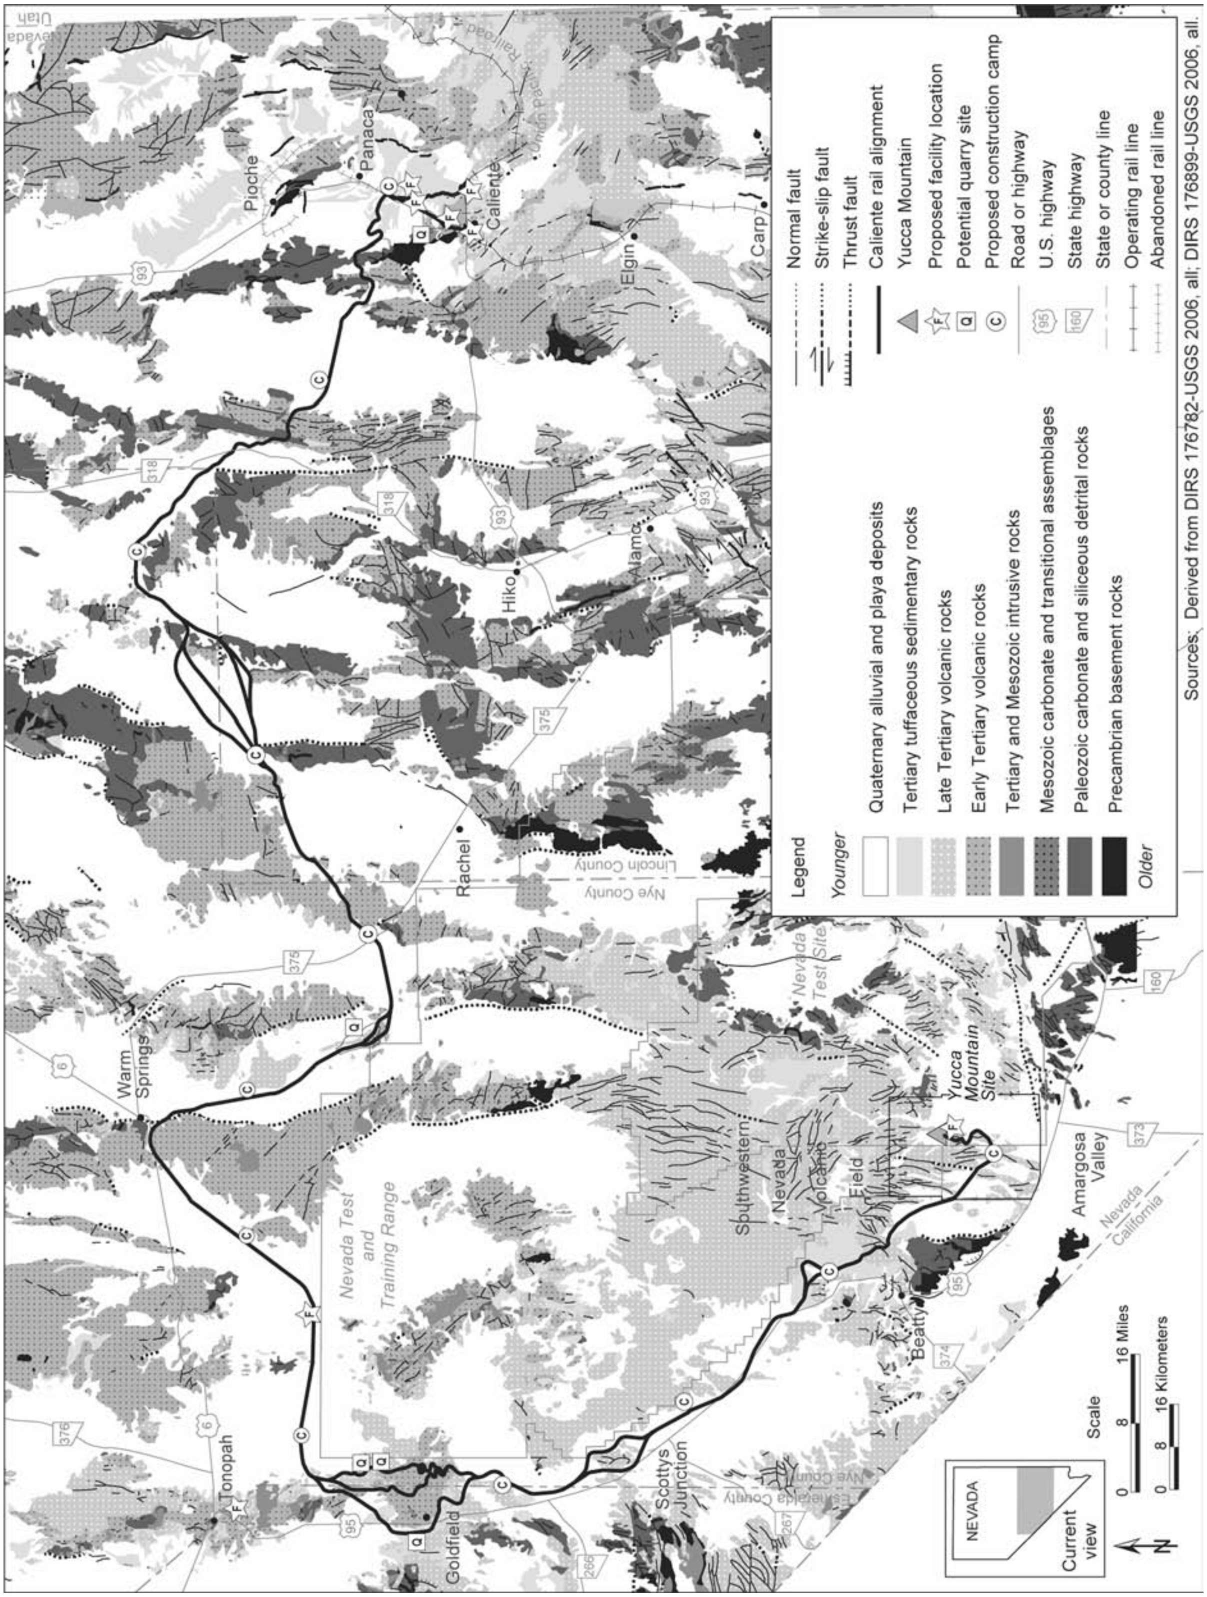


Figure 3-2. Geologic setting along the Caliente rail alignment.

The volcanic field has a complex history of volcanism and deformation (DIRS 169734-BSC 20040, pp. 2-4 through 2-15). Eruption of 17 ash-flow ***tuff*** sequences and lava flows occurred from at least seven large, overlapping ***caldera*** complexes to form the southwestern Nevada volcanic field. The youngest caldera-forming events associated with this feature occurred between 7.5 and 7.6 million years ago with eruptions east of Caliente common segment 4 (DIRS 176184-Shannon & Wilson 2006, p. 11). The mid-Tertiary eruptions deposited ash and created volcanic-ash flows with minor lava flows and reworked materials. Only Tertiary and younger rocks are exposed in the southwestern Nevada volcanic field area.

3.2.1.2.2.1 Faulting and Seismic Activity. Historically, there have been numerous earthquakes in the Great Basin region as a result of ongoing crustal extension (see Figure 3-3). Consistent with geologic evidence, the historical record of Holocene-age ***seismicity*** (occurring within the last 10,000 years) suggests that seismic activity was concentrated in the western part of the Great Basin, and to a lesser extent, in the eastern part (DIRS 176184-Shannon & Wilson 2006, p. 15 and Plate 4). Modern earthquakes in the southern Great Basin predominantly occur at depths of 2 to 12 kilometers (1.2 to 7 miles) below Earth’s surface (DIRS 169734-BSC 20040, p. 4-35).

The southern Great Basin contains many Quaternary fault traces; however, there are few instances of surface rupture within the last 10,000 years (DIRS 176184-Shannon & Wilson 2006, p. 15). These faults are characterized by discontinuous scarps (vertical displacement along a fault), from surface displacement. Studies of Holocene faults in the Great Basin have calculated slip rates of 0.001 to 0.01 millimeter (0.000039 to 0.00039 inch) per year, with a surface-rupturing recurrence interval of about 100 years (DIRS 176905-Workman et al. 2002, p. 18). Studies of fractures other than ***block-bounding faults*** around Yucca Mountain determined that fault displacements of about 0.10 centimeter (0.039) would have an exceedance ***probability*** of once every 100,000 years (DIRS 169734-BSC 2004, p. 4-64).

Figure 3-3 shows the number and locations of earthquakes of magnitude 3.0 and greater on the Richter scale based on available historical and recorded data from 1852 to 2004. Most of the earthquakes around the Caliente rail alignment fall within a magnitude range of 3.0 to 3.9, the range that most people begin to feel ground shaking (DIRS 180969-USGS 2006, all). As magnitude increases, the potential for damage from ground shaking also increases.

Five seismic events with a magnitude 5.0 or greater occurred within 30 kilometers (19 miles) of the Caliente rail alignment, several occurring on the Nevada Test Site north of Yucca Mountain. Most seismic events on the Nevada Test Site are associated with historical underground testing, not natural ***faulting***. Seismic activity from manmade tests has not activated local faults (DIRS 169734-BSC 2004, pp. 4-33 and 4-35). A magnitude 6.0 earthquake was also recorded within the Chief Range southeast of the City of Caliente. A 1992 earthquake near Little Skull Mountain is the largest recorded earthquake in the vicinity of Yucca Mountain. The 5.6 magnitude event was apparently triggered by a 7.3 magnitude earthquake at Landers, California, which occurred 300 kilometers (190 miles) southwest of Yucca Mountain, and 20 hours earlier (DIRS 169734-BSC 2004, pp. 4-38 and 4-39). Since 1978, DOE has monitored seismic activity in the area around Yucca Mountain to pinpoint seismic events (DIRS 155970-DOE 2002, p. 3-32). In the area around the Caliente rail alignment, earthquakes with a magnitude of 6.1 to 6.4 are predicted to have a return period of 2,500 years (DIRS 174296-Shannon & Wilson 2005, p. 14).

Through the National Earthquake Hazard Reduction Program, national and regional shaking-hazard maps are used to determine the probability of seismic-related damage based on regional earthquake occurrence rates and how far the shaking travels horizontally (DIRS 174194-USGS 2005, all). These maps are used to meet modern seismic design provisions for the construction of buildings, bridges, highways, and utilities. Shaking-hazard maps, also known as peak acceleration maps, show the levels of horizontal shaking that have a certain probability of being exceeded in a 50-year period (see Figure 3-4). When an

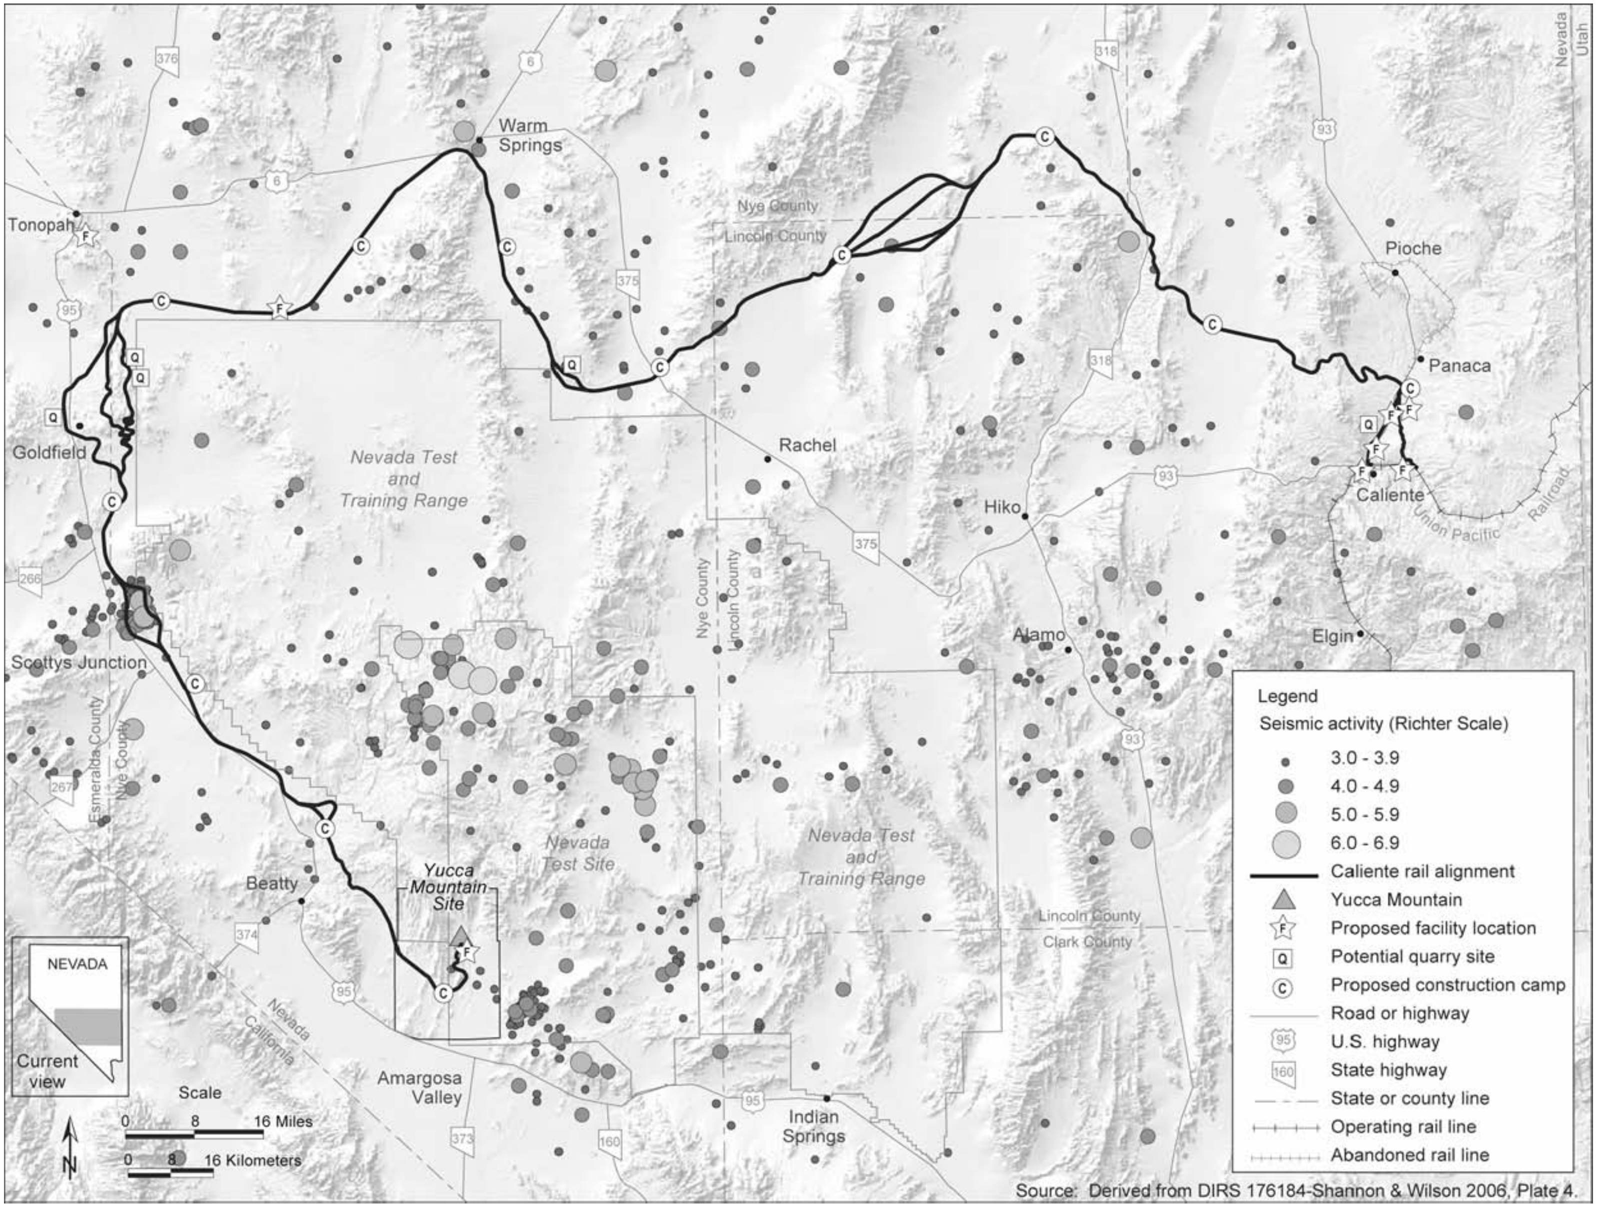

Figure 3-3. Seismic activity in Nevada along the Caliente rail alignment from 1852 to 2004.

earthquake occurs, the forces caused by the shaking can be measured as a percentage of the constant known as *g*, which is the acceleration of a falling object due to gravity. The resulting map uses contour lines to show the amount of shaking a location would experience during any area earthquake, regardless of its distance to the epicenter.

The predicted peak horizontal accelerations tend to decrease from west to east across the Caliente rail alignment. Most of the Caliente rail alignment would have a 2-percent probability of exceeding a peak horizontal acceleration of 30-percent *g* within a 50-year period (see Figure 3-4) and a 10-percent probability of exceeding a peak horizontal acceleration of 10 percent *g* within a 50-year period (DIRS 174296-Shannon & Wilson 2005, Figure 3). The southern section of Goldfield alternative segment 4, Caliente common segment 4, the Bonnie Claire alternative segments, and the northern section of common segment 5 would have a 2-percent probability of exceeding a peak ground acceleration range 40-percent *g* in 50 years. In other words, the alignment would experience shaking of 40-percent or less from a seismic event with a return period of about 2,500 (DIRS 174296-Shannon & Wilson 2005, p. 14). A peak horizontal acceleration of 10 percent *g* could cause minor structural damage to normal buildings, while 40-percent *g* could cause damage to most structures.

3.2.1.2.2.2 Mineral and Energy Resources. For more than 100 years, parts of the southern Great Basin have produced substantial amounts of base and precious metals, particularly gold and silver (DIRS 173841-Shannon & Wilson 2005, p. 16). Parts of the Caliente rail alignment, especially in the vicinity of the Goldfield and Clifford Mining Districts, have been intensely mined and have extensive surface and underground mine workings. Energy resources reported along and near the rail alignment include low-temperature geothermal water and indications of small areas with petroleum resources. Section 3.2.2, Land Use and Ownership, describes ***mining districts*** and associated land claims along the Caliente rail alignment in more detail.

3.2.1.2.2.3 Potential Sources of Construction Materials. As described in Chapter 2, there would be local sources for some rail line construction materials. The estimated quantity of ***ballast*** required for construction of a rail line along the Caliente rail alignment would range from 3.12 to 3.19 million metric tons (3.44 to 3.52 million tons) (DIRS 176172-Nevada Rail Partners 2006, p. 3-1). DOE has identified six potential ballast quarry sites along the Caliente rail alignment with topographic and geologic characteristics suitable to accommodate excavation and preparation facilities. Figures 2-25 through 2-28 show the potential quarry locations along the Caliente rail alignment (South Reveille alternative segment 2, South Reveille alternative segment 3, Goldfield alternative segment 3, and Goldfield alternative segment 4). The topography and geology of potential quarry sites are described in more detail in the discussion of the alternative segment with which they are associated (Sections 3.2.1.3.1.2, 3.2.1.3.5.2, and 3.2.1.3.7.2). There is also a high likelihood the Department would find suitable sands and gravels on the alluvial fans within the rail line construction right-of-way for use as ***subballast***. A final determination of subballast suitability would be made if DOE decided to implement the Proposed Action along the Caliente rail alignment. Section 3.2.11, Utilities, Energy, and Materials, describes the regional supply chains for other construction materials.

3.2.1.2.3 Soils

DOE used soil survey databases from the U.S. Department of Agriculture, Natural Resources Conservation Service (DIRS 176781-MO0603GSCSSGEO.000), to identify soil types and characteristics along the Caliente rail alignment. Approximately 95 percent of the project area has been surveyed. However, soil surveys around the Nevada Test and Training Range have not been completed. For areas with no available soils data, the Department does not consider the unavailable data critical to the design and construction of a railroad along the Caliente rail alignment, because soils are expected to be similar to

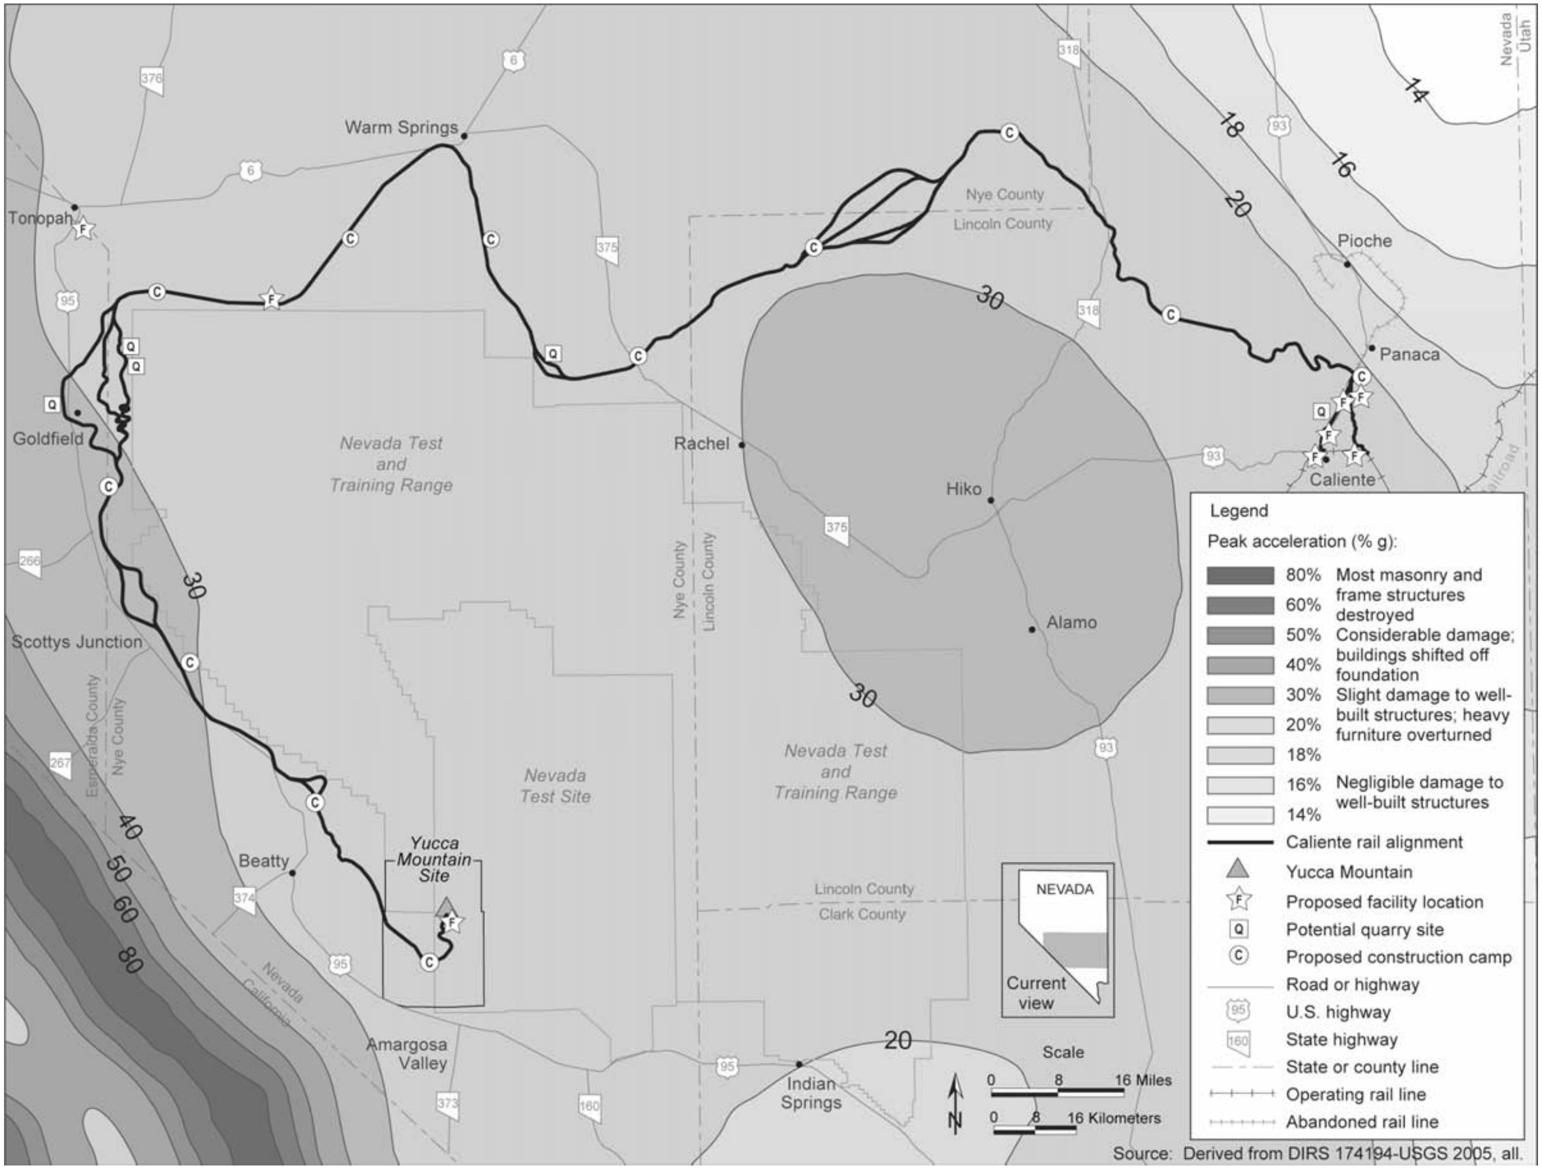

Figure 3-4. Seismic hazards along the Caliente rail alignment: peak acceleration (percent *g*) with 2-percent probability of exceedance in 50 years.

those already surveyed. In addition, as part of the final design, DOE would place geotechnical borings along the entire rail alignment to obtain site-specific soils data.

This Rail Alignment EIS identifies the specific soil characteristics relevant to railroad construction and operations. From a potential impact perspective, soil designated as supporting ***prime farmland*** is considered one of the relevant characteristics. The Natural Resources Conservation Service (DIRS 181427-NRCS 2007, Part 622.04(a)) defines prime farmland as:

> Land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops and that is available for these uses. It has the combination of soil properties, growing season, and moisture supply needed to produce sustained high yields of crops in an economic manner if it is treated and managed according to acceptable farming methods. In general, prime farmland has an adequate and dependable water supply from precipitation or irrigation, a favorable temperature and growing season, an acceptable level of acidity or ***alkalinity***, an acceptable content of salt or sodium, and few or no rocks. Its soils are ***permeable*** to water and air. Prime farmland is not excessively eroded or saturated with water for long periods of time, and it either does not flood frequently during the growing season or is protected from flooding.

The prime farmland soil label is applied to the soil types and associations that the National Resources Conservation Service identifies as satisfying this definition. Three percent, or about 1.8 square kilometer (440 acres), of the rail line construction right-of-way would contain soils classified as prime farmland (see Figure 3-5). Lincoln County has about 1,600 square kilometers (400,000 acres) and Nye County has 610 square kilometers (150,000 acres) of prime farmland soils (DIRS 176781-MO0603GSCSSGEO.000). Esmeralda County does not have any soils classified as prime farmland. The amount of prime farmland soils within the Caliente rail alignment construction right-of-way would be less than 0.1 percent of the total prime farmland soils in Lincoln and Nye Counties. DOE has also contacted the Nevada Natural Resources Conservation Service office to collaborate on the identification of prime, unique statewide, or locally important farmland along the alignment. This correspondence is described further in Section 4.2.1.2.1.3, and in the individual segment discussions in Section 4.2.1.2.2.

Table 3-3 lists the prime farmland and quantity of soils with other characteristics along the Caliente rail alignment. The table lists the percentage of the area within the nominal width of the construction right-of-way that contains soils with a particular characteristic. In some locations along the rail alignment, DOE would occupy and disturb less of the construction right-of-way to avoid sensitive environmental resources and private property. Because different combinations of alternative segments and common segments would be different lengths and have different disturbed areas, DOE judged the impacts from soil erosion based on the acreage of specific soil types that would be affected by construction-related disturbance. Section 4.2.1.2.1.3 provides a more detailed discussion of how railroad construction and operations could affect topsoil.

Other soil characteristics that are particularly relevant to railroad construction and operations are classified on Table 3-3 as ***erodes easily*** and ***blowing soil***. Soil with either of these characteristics can be quite susceptible to erosion. As seen in Table 3-3, these soil types are found in similar amounts within each group of alternative segments.

The erodes easily characteristic is a measure of the susceptibility of bare soil to be detached and moved by water. These soils, which tend to contain relatively high amounts of silts and ***loams***, tend to erode easily when disturbed. About 15 percent of the entire Caliente rail alignment has soils with this characteristic (DIRS 176781-MO0603GSCSSGEO.000).

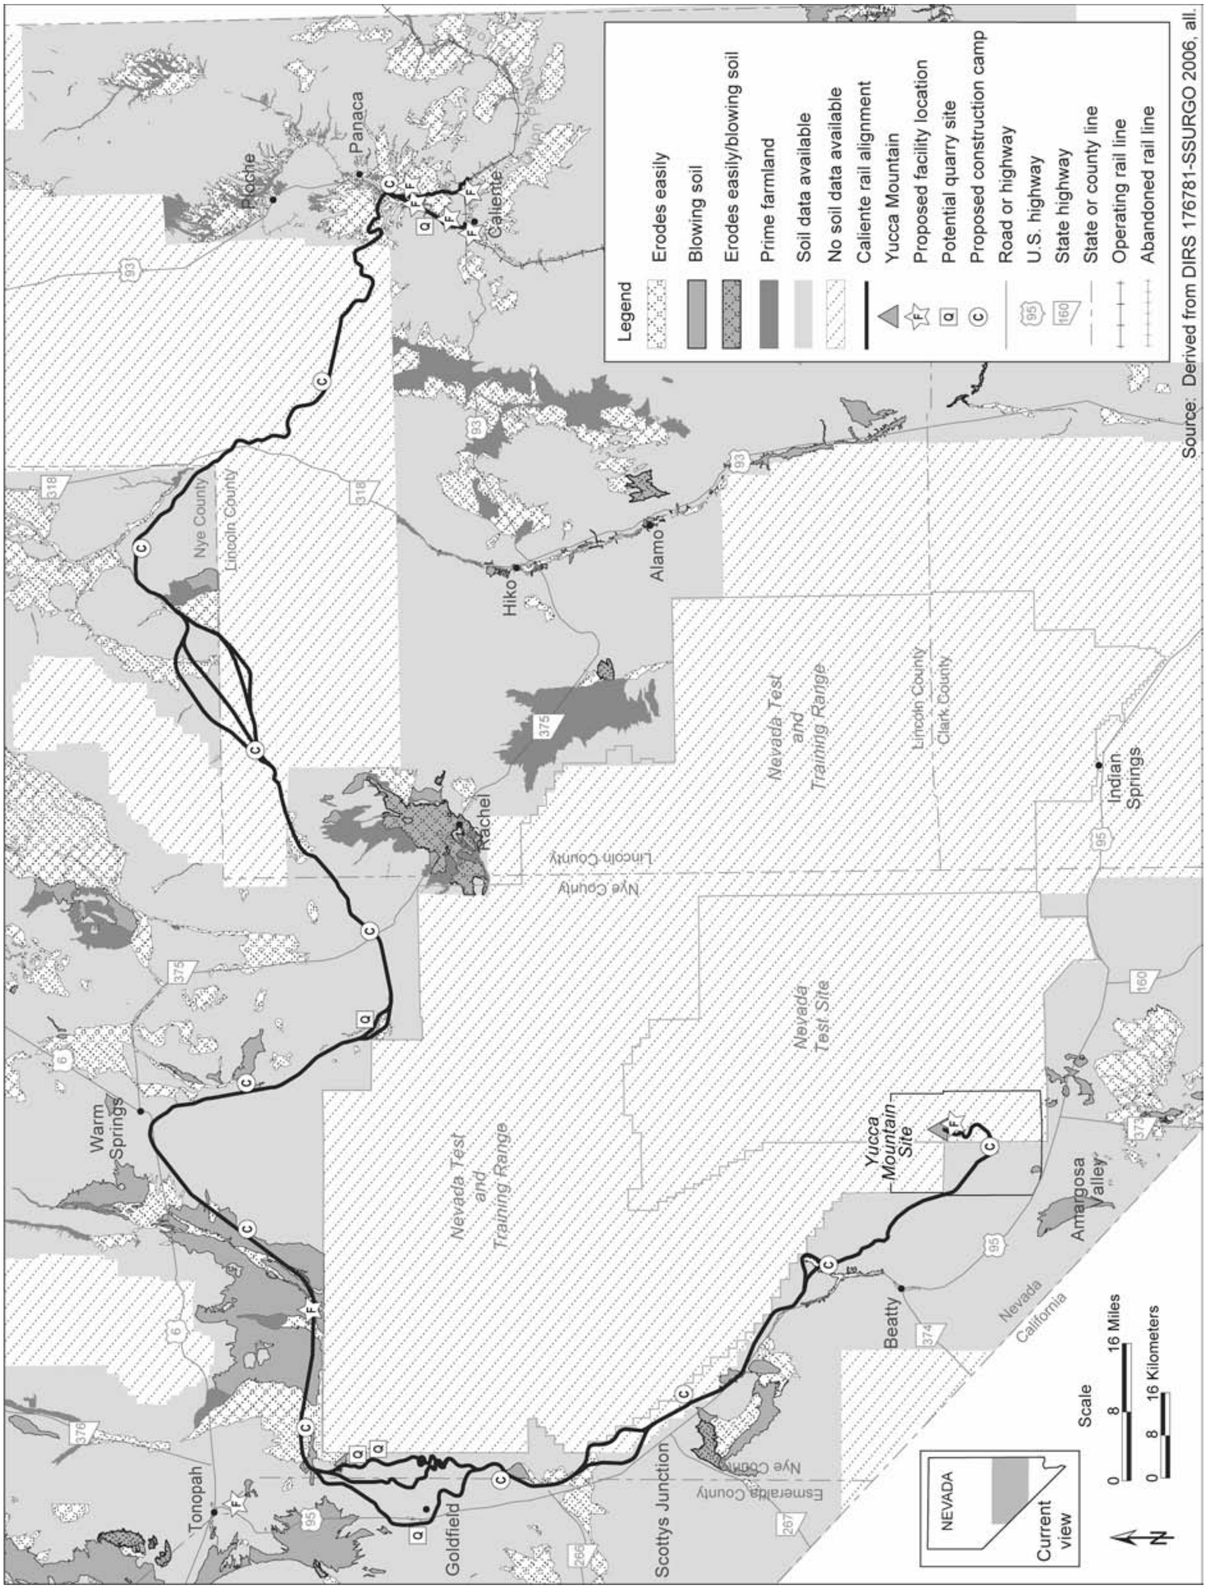

Figure 3-5. Soils with prime farmland, erodes easily, and blowing soil characteristics along the Caliente rail alignment.

Table 3-3. Percent of soil characteristics within the Caliente rail alignment construction right-of-way.[a]

Rail line segment	Percent prime farmland	Percent blowing soil	Percent erodes easily	Percent soil survey coverage[b]
Caliente alternative segment	5.2	c	74	100
Eccles alternative segment	4.8	c	71	100
Caliente common segment 1	10	c	18	100
Garden Valley alternative segment 1	8.4	5.7	13	100
Garden Valley alternative segment 2	11	6.1	22	100
Garden Valley alternative segment 3	c	2.1	12	100
Garden Valley alternative segment 8	9.8	6	14	100

a. Source: DIRS 176781-MO0603GSCSSGEO.000.
b. There are data gaps around the Nevada Test and Training Range because those soil surveys have not been completed.
c. Characteristic not present. Soil percentages do not add up to 100 percent.

The blowing soil characteristic is based on the soil survey classification of susceptibility of a given soil to wind erosion. This classification method uses eight groupings. Soils assigned to Group 1 are the most susceptible to wind erosion and those assigned to Group 8 are the least susceptible. Soils listed in Table 3-3 with the blowing soil characteristic are those assigned to erodibility Group 1 or 2 (DIRS 181427-NRCS 2007, Exhibit 618-16). The blowing soil characteristic identifies areas where fine-textured, sandy materials predominate and where uncontrolled soil disturbance could result in increased wind erosion. Depending on combination of alternative segments and common segments, between 7.6 and 8.2 percent of the entire Caliente rail alignment would have soils with the blowing soil characteristic (DIRS 176781-MO0603GSCSSGEO.000). Figure 3-5 identifies the locations of prime farmland, erodes easily, and blowing soils.

3.2.1.3 Setting and Characteristics along Alternative Segments and Common Segments

3.2.1.3.1 Alternative Segments at the Interface with Union Pacific Railroad Mainline

3.2.1.3.1.1 Physiography. The physiography of the area where the Caliente rail alignment would interface with the Union Pacific Railroad Mainline is dominated by Meadow Valley Wash, the Cedar Range to the east, and the Chief Range to the west (see Figures 2-5 and Figure 3-6). There are terraces and alluvial fans on both sides of Meadow Valley Wash (DIRS 156091-Borup and Bagley 1976, pp. 5 and 6). The Caliente and Eccles alternative segments would start at different locations near Clover Creek, which is dry most of the year, and extend north, crossing Meadow Valley Wash. Elevations range from about 1,340 meters (4,400 feet) above mean sea level in the areas of Clover Creek and Meadow Valley Wash to just over 1,520 meters (5,000 feet) above mean sea level in the more rugged area north of Clover Creek.

3.2.1.3.1.2 Geology. The area where the Caliente rail alignment would interface with the Union Pacific Railroad Mainline is largely composed of recent sedimentary deposits and some volcanic rocks. The Caliente and Eccles alternative segments would not cross known Quaternary fault traces. Nonmetallic minerals (perlite, a glassy volcanic rock with high water content that can be used for insulation and acoustic tiles, and quartzite, a hard rock made up almost entirely of the mineral quartz) found within these rocks have been commercially mined in the vicinity of the Caliente alternative segment. Section 3.2.2, Land Use and Ownership, provides additional information about the mining districts around the Caliente rail alignment.

Neither the Caliente nor the Eccles alternative segment would cross Quaternary faults. There was a magnitude 6.0 earthquake in the Chief Range area southeast of the City of Caliente. Otherwise, there have been few earthquakes in the area within the past 150 years.

The site of potential quarry CA-8B is in hilly terrain north of the City of Caliente, west of the Caliente alternative segment. ***Basalt*** would be excavated from the Cobalt Canyon formation (DIRS 176172-Nevada Rail Partners 2006, Figure 3-C).

Geothermal resources close to the proposed Caliente rail alignment in the Caliente area are being used commercially in a hotel spa and for space heating (DIRS 173841-Shannon & Wilson 2005, pp. 115 and 116). Hot springs in the Caliente area are indicative of high heat flow within the Earth, and are related to the crustal extension of the southern Great Basin. There are no other energy resources along the Caliente or Eccles alternative segments.

3.2.1.3.1.3 Soils. Soils in the area of the Interface with the Union Pacific Railroad Mainline occur mainly on floodplains, low terraces, and alluvial fans (DIRS 156091-Borup and Bagley 1976, all). Most of these soils are on nearly level to moderate slopes, are very thick, and are well drained to moderately well drained. Other soils are very thin to moderately thick, are well drained, and gently slope to steep soils and rock outcrops.

About 5.2 and 4.8 percent of the soils in the Caliente and Eccles alternative segments, respectively, are classified as prime farmland (see Table 3-3). Along the Caliente alternative segment, soil associations classified as prime farmland are within the Caliente city limits, and are primarily on private residential land. Along the Eccles alternative segment, the southern prime farmland soils are on alluvial fan deposits in the Little Mountain ***Grazing Allotment***. The northern prime farmland soils are on alluvial fans in the Peck Grazing Allotment. Section 3.2.2, Land Use and Ownership, provides additional information about grazing allotments. About 74 and 71 percent of the soil along the Caliente and Eccles alternative segments, respectively, are classified as erodes easily. There are no soils anywhere along the Caliente or Eccles alternative segments with the blowing soil characteristic.

3.2.1.3.2 *Caliente Common Segment 1 (Dry Lake Valley Area)*

3.2.1.3.2.1 Physiography. From east to west, Caliente common segment 1 would cross between, through, or around the Chief, Highland, and Black Canyon Ranges, Dry Lake Valley, the North Pahroc Range, White River Valley, the Seaman Range, Coal Valley, and the Golden Gate Range (see Figures 3-6

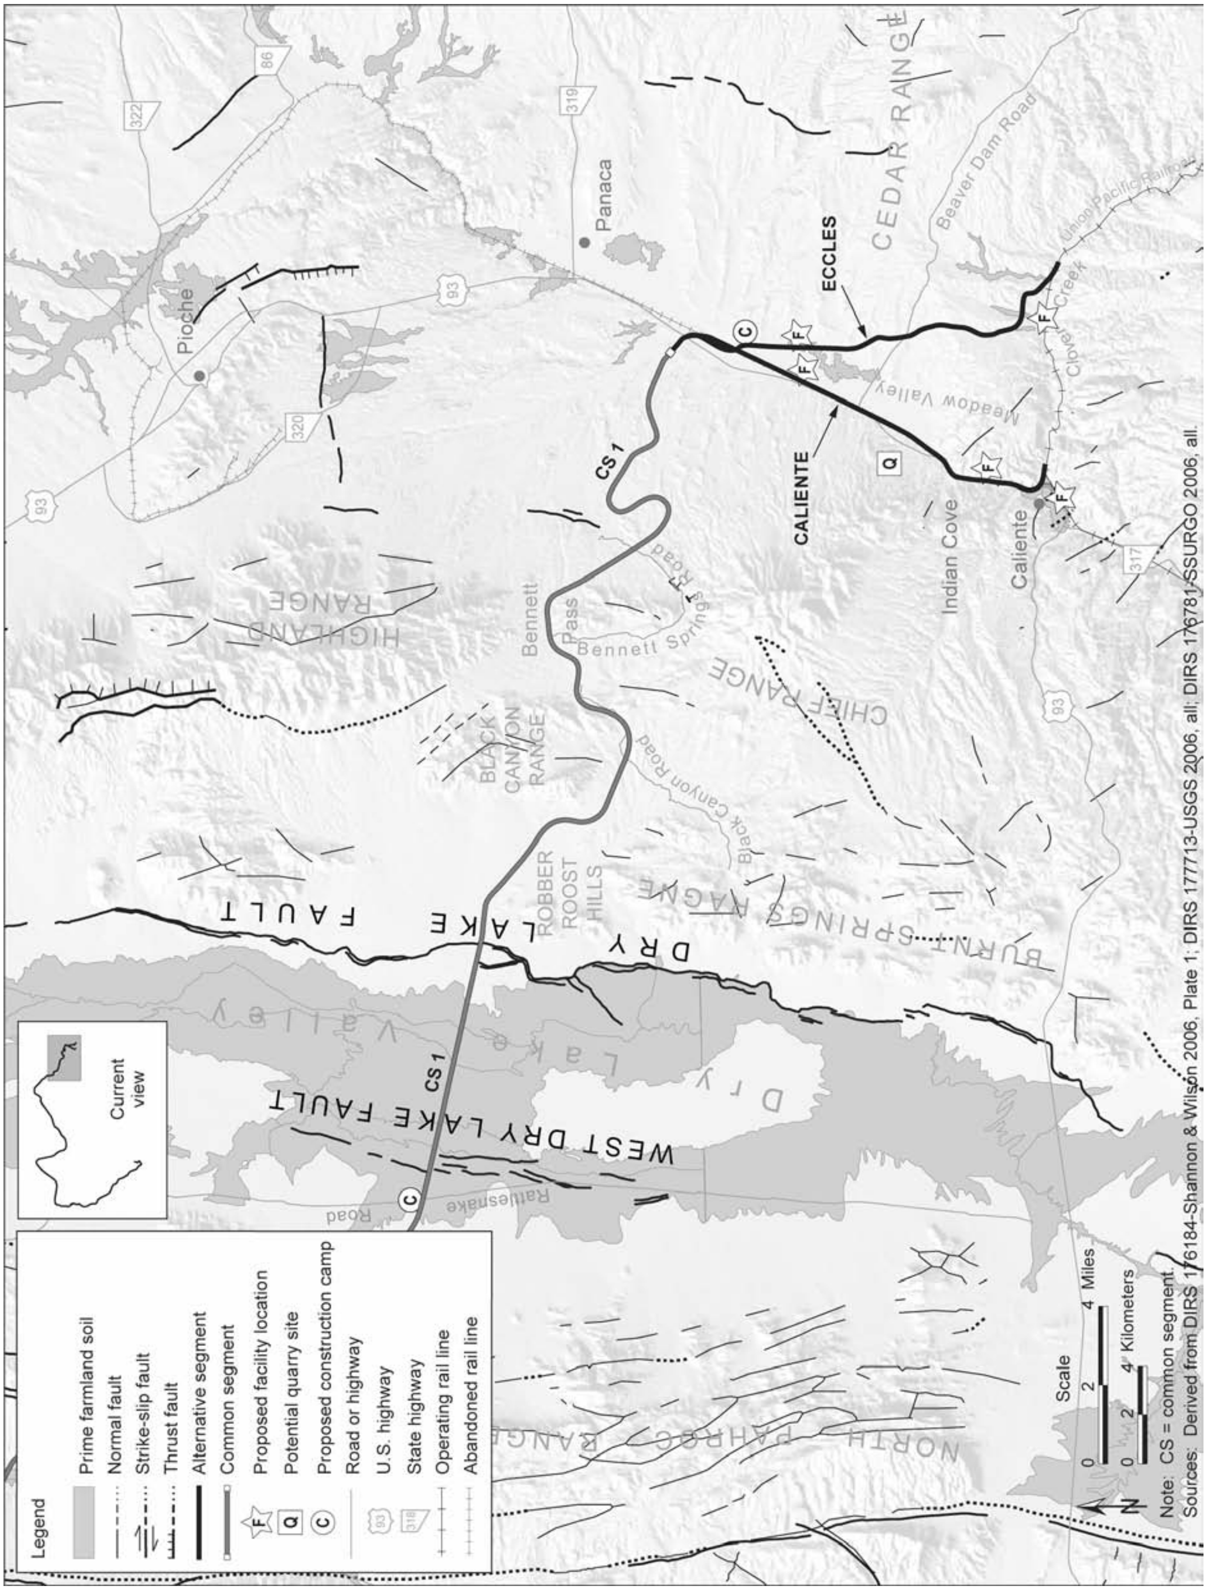

Figure 3-6. Physiographic features of the common segment and alternative segments within map area 1.

and 3-7). Bennett Pass, at an elevation of about 1,730 meters (5,700 feet) above mean sea level, separates the Highland and Black Canyon Ranges to the north from the Chief Range to the south. This segment of the Caliente rail alignment would travel through Bennett Pass, then south of the Black Canyon Range and curve around Robber Roost Hills and the Burnt Springs Range. The segment would then cross Dry Lake Valley, a wide, nearly flat depression with elevations generally ranging from 1,400 to 1,420 meters (4,600 to 4,660 feet) above mean sea level.

Turning northwest, Caliente common segment 1 would enter the northern section of the North Pahroc Range. In this area, elevations generally range from 1,600 to 1,700 meters (5,200 to 5,600 feet) above mean sea level. The segment would then head north along the east side of the White River Valley for about 10 kilometers (6.2 miles) and would cross the dry White River and proceed northwest of State Route 318, north of the Seaman Range, in the vicinity of Timber Mountain. The northern portion of the Seaman Range trends northwesterly and merges at the north end of Coal Valley with the Golden Gate Range, which trends north-northeasterly. North of this point, the Golden Gate Range merges with the broad expanse of White River Valley (see Figure 3-7). The Caliente rail alignment would go around the rugged Seaman Range. In this area, Caliente common segment 1 would encounter elevations ranging from 1,500 to 1,650 meters (5,000 to 5,400 feet) above mean sea level.

3.2.1.3.2.2 Geology. Bedrock at the surface along Caliente common segment 1 is quite variable. The segment would cross old sedimentary rocks in the eastern mountain passes and more recent volcanic rocks around the North Pahroc and Golden Gate Ranges (DIRS 176184-Shannon & Wilson 2006, Table 5). The valleys are covered with modern-day ***alluvium***, and most contain playas.

Most earthquakes in the area have been of magnitude 3.0 or less, with the exception of the Timber Mountain area, where there was an earthquake of magnitude 5.0 (see Figure 3-3). Caliente common segment 1 would cross three prominent faults in the area, the Dry Lake and the West Dry Lake faults (Figure 3-6) and faults of the North Pahroc Range (Figure 3-7). These discontinuous faults are identified by offset bedrock or alluvial deposits, and were last active more than 11,000 years ago.

The Quaternary deposits in Dry Lake Valley contain naturally occurring surface fissures that range in size from about 27 meters (90 feet) to several kilometers long and up to 4.6 meters (15 feet) wide (DIRS 176184-Shannon & Wilson 2006, pp. 43 and 44). The cracks in Dry Lake Valley appear to be related to tectonic movements caused by faulting along the east and west margins of the valley (DIRS 176184-Shannon & Wilson 2006, Plate 4).

Limestone deposits are known mineral resources in the vicinity of Caliente common segment 1 (DIRS 173841-Shannon & Wilson 2005, p. 108 and Plate 1). Warm springs are the only known energy resources near the common segment. Section 3.2.2, Land Use and Ownership, describes mining districts and mineral and energy resources along the segment.

3.2.1.3.2.3 Soils. Soils along Caliente common segment 1 are predominantly very thick, well-drained, silty loams, with some thin, well-drained, gravelly sandy loams (DIRS 176781-MO0603GSCSSGEO.000). In this area, there are also badlands, semi-***arid*** areas with steeply gullied topography caused by rapid erosion, where runoff occurs rapidly and erosion is severe. There is a wide range of soil types along Caliente common segment 1 (DIRS 176781-MO0603GSCSSGEO.000). Soil depths vary from thin to very thick. Most of the well-drained soils in the White River area occur on ***fan piedmonts***, ***fan remnants***, and ***fan skirts***.

> **Fan piedmonts, fan remnants,** and **fan skirts** refer to locations within a large ***alluvial fan***. Fan piedmonts refer to the area along the base of a mountain slope. Fan remnants refer to parts of an older alluvial fan that remain after erosion has removed most of the fan. Fan skirts refer to the area along the base of the alluvial fan in a valley.

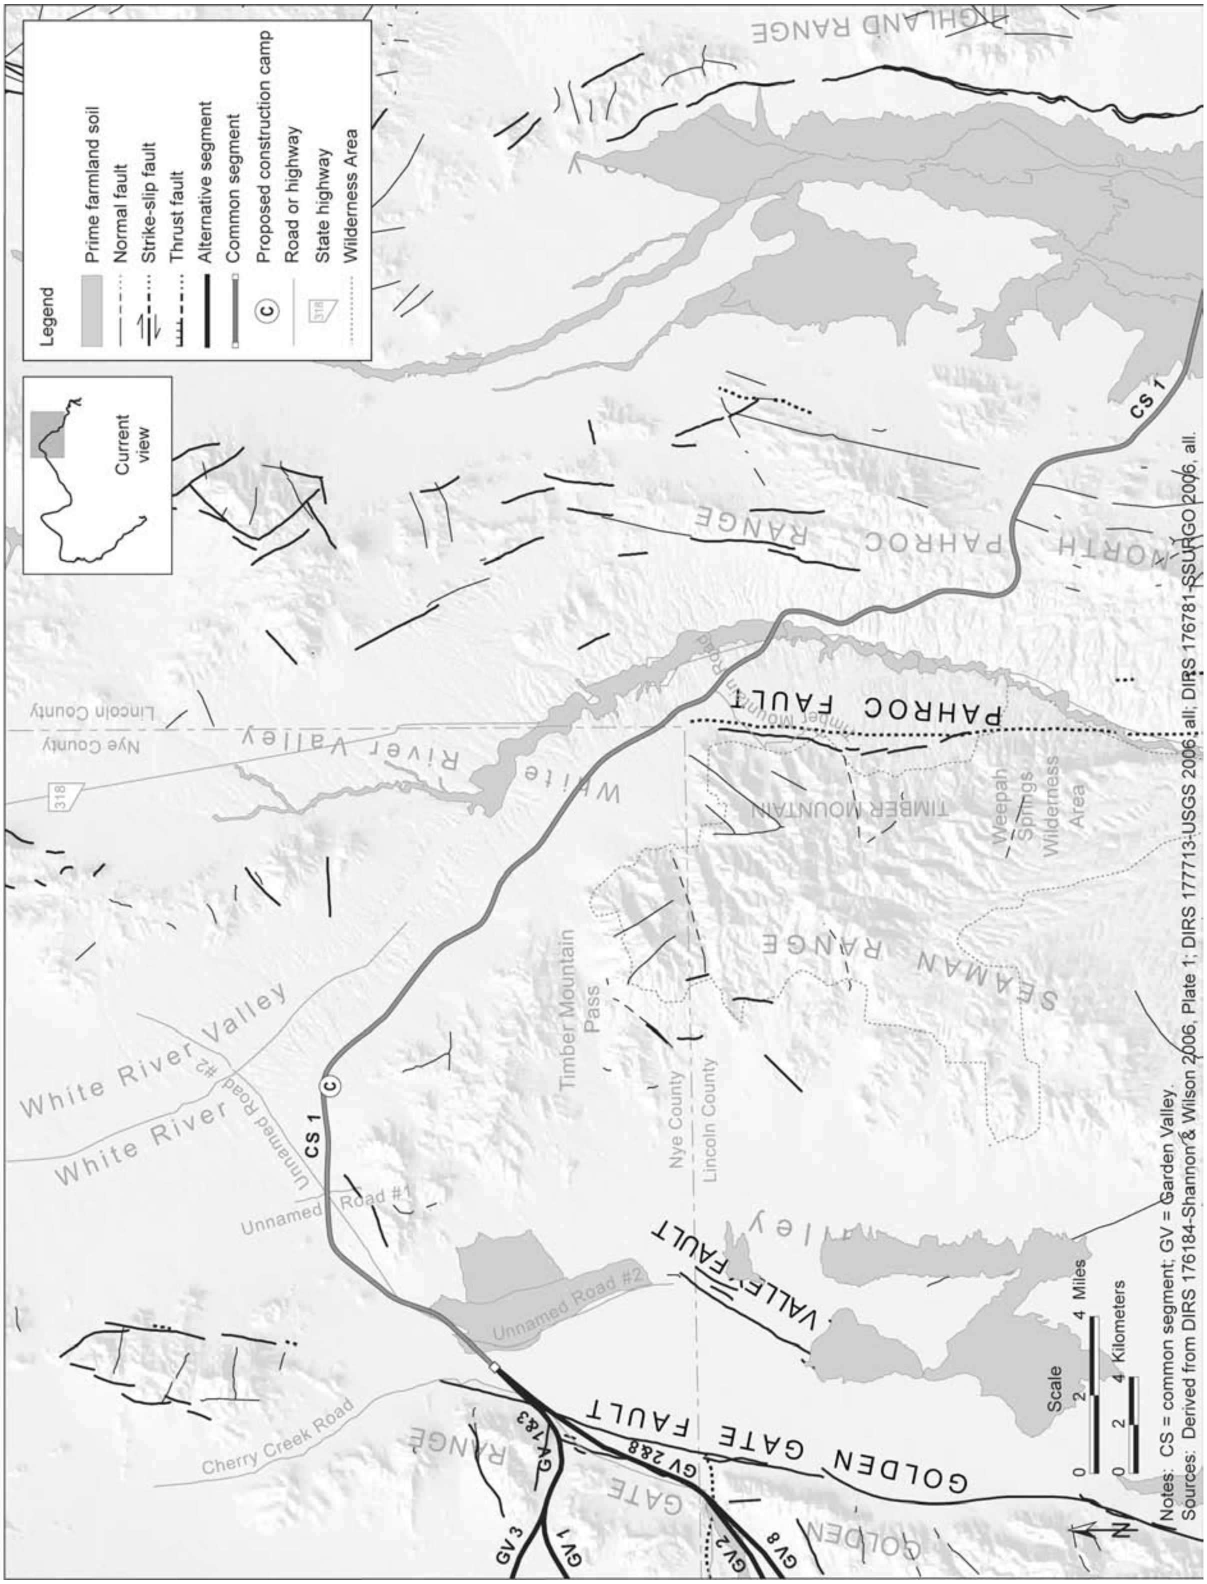

Figure 3-7. Physiographic features of the common segment and alternative segments within map area 2.

Soils classified as prime farmland make up 2.6 percent of the soils along Caliente common segment 1. Soils with the erodes easily characteristic comprise 18 percent of the soils. None of the available soils data include soils with the blowing soil characteristic.

3.2.1.3.3 *Garden Valley Alternative Segments*

3.2.1.3.3.1 Physiography. All of the Garden Valley alternative segments would cross the Golden Gate Range and pass through Garden Valley, which is a broad, nearly flat depression. From north to south along the Golden Gate Range, there are two unnamed gaps and two named gaps (Water Gap and Murphy Gap). Garden Valley alternative segments 1 and 3 would cross the Golden Gate Range through the northernmost unnamed gap. This gap, a relatively gentle pass, has an elevation of about 1,600 meters (5,200 feet) above mean sea level. Garden Valley alternative segments 2 and 8 would cross Golden Gate Range farther to the south at Water Gap, which has an elevation of 1,580 meters (5,200 feet) (Figure 3-8).

3.2.1.3.3.2 Geology. The Garden Valley alternative segments would cross a variety of sedimentary and volcanic rocks in gaps of the Golden Gate Range. The floor of Garden Valley is covered with thick alluvial sediments. The Garden Valley alternative segments would cross the northernmost exposure of the Golden Gate Fault. This fault is a complex zone that consists of discontinuous traces extending along the eastern border of the Golden Gate Range. It is uncertain when this fault was last active; however there is record of movement occurring about 15,000 years ago (DIRS 177713-MO0607LFAFUS96.000, Fault Number 1393).

Other than gravel and alluvial materials present on the floor of Garden Valley, the Garden Valley alternative segments would not cross any known commercial mineral deposits.

3.2.1.3.3.3 Soils. The Nye and Lincoln County soil surveys indicate that soils in the area of Garden Valley are mostly very thick and well-drained, and occur on fan piedmonts (DIRS 176781-MO0603GSCSSGEO.000).

Some soils classified as prime farmland are found along the alternative segments. Less than 1 percent of soils along Garden Valley alternative segment 2 are prime farmland, less than 1 percent along Garden Valley alternative segments 1 and 3, and no prime farmland soils along Garden Valley alternative segment 8. Soils with the erodes easily characteristic range from 13 percent for Garden Valley alternative segment 1, 22 percent for Garden Valley alternative segment 2, 12 percent for Garden Valley alternative segment 3, to 14 percent for Garden Valley alternative segment 8 (Table 3-3). The alternative segments also contain blowing soils, 5.7 percent along Garden Valley alternative segment 1, 6.1 percent along Garden Valley alternative segment 2, 2.1 percent along Garden Valley alternative segment 3, and 6 percent along Garden Valley alternative segment 8.

3.2.1.3.4 *Caliente Common Segment 2 (Quinn Canyon Range Area)*

3.2.1.3.4.1 Physiography. The area of Caliente common segment 2 is dominated by the Worthington Mountains to the south and east and the rugged Quinn Canyon and Reveille Ranges to the north (see Figures 3-8 and 3-9). This common segment would pass from Garden Valley to Sand Springs Valley and through foothills of the Quinn Canyon Range to Railroad Valley. Elevations in this area generally range from 1,620 to 1,800 meters (5,300 to 5,900 feet) above mean sea level.

3.2.1.3.4.2 Geology. Caliente common segment 2 would primarily cross recent alluvial deposits through the valleys, and sedimentary bedrock along the southern tip of the Quinn Canyon Range. There are few recorded earthquakes within the vicinity of the rail alignment in this area. The alignment would

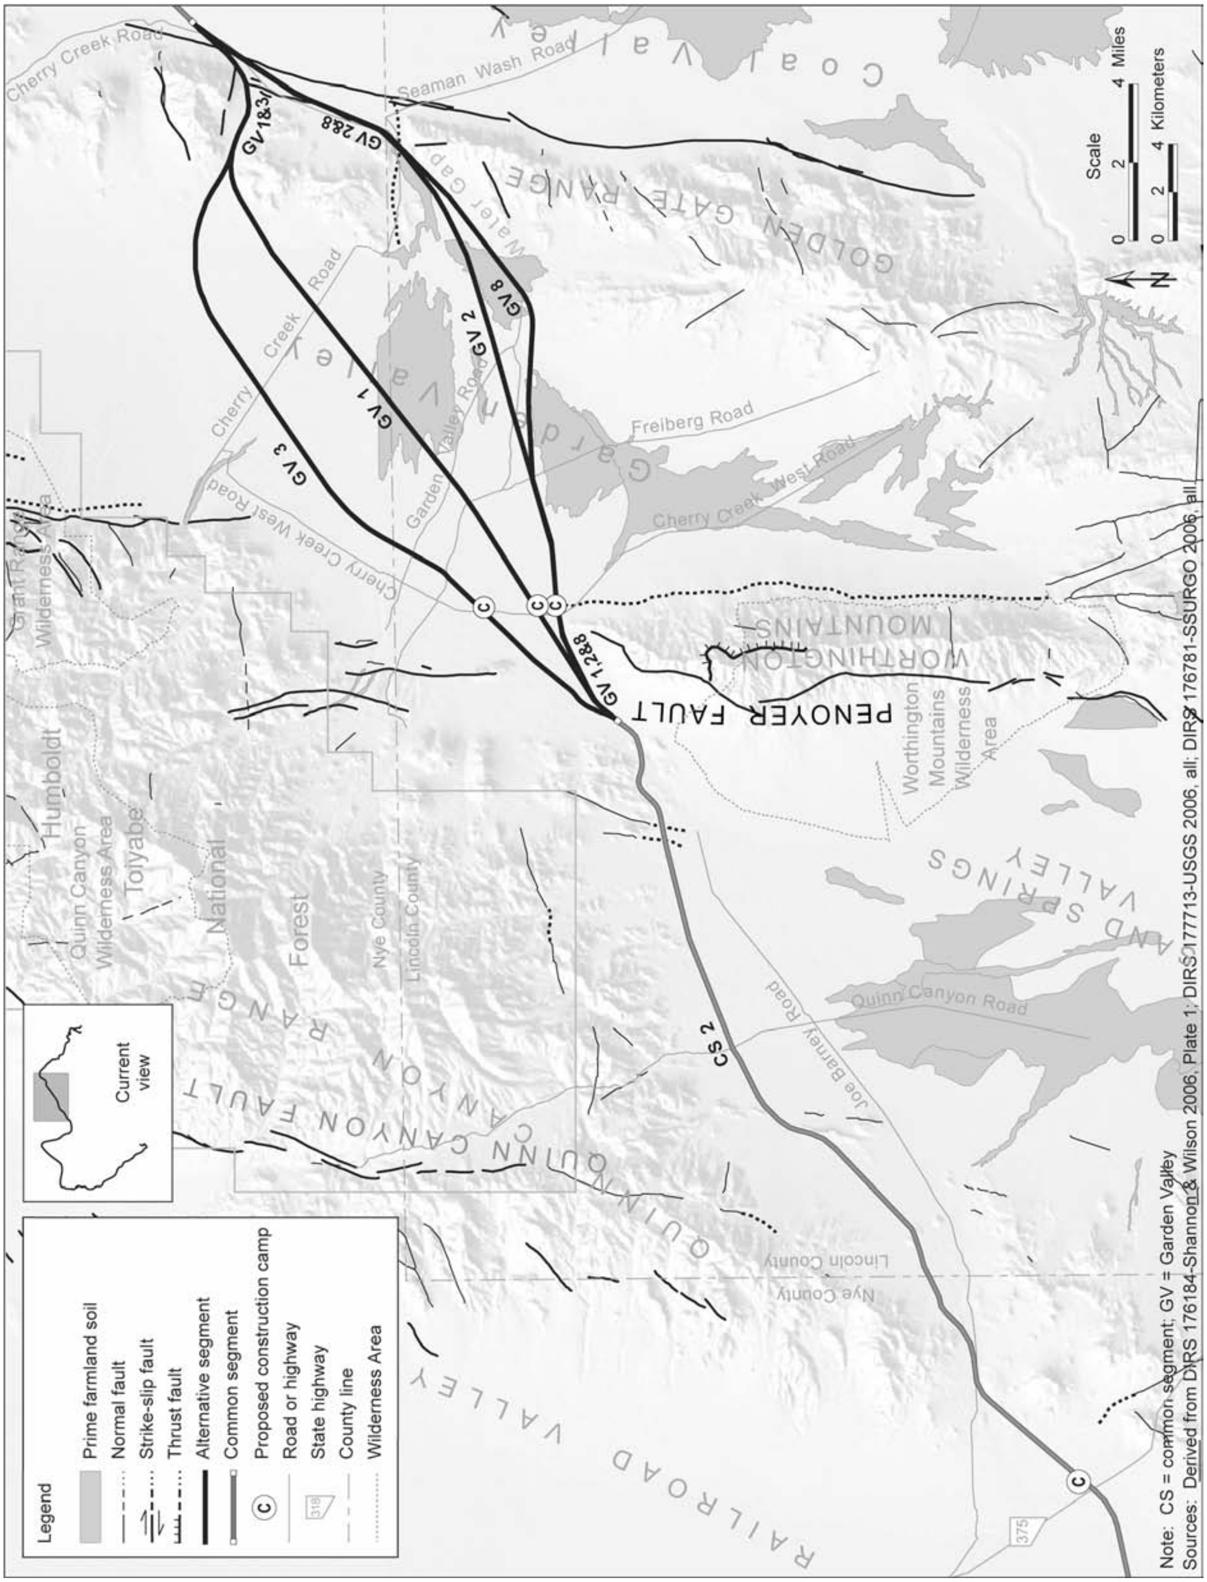

Figure 3-8. Physiographic features of the common segment and alternative segments within map area 3.

not cross recent fault traces or approach any energy resources. Other than gravel used for construction purposes, there is no commercial production in the area.

3.2.1.3.4.3 Soils. Caliente common segment 2 contains soils composed largely of fine sand underlain by ***hardpan*** (a layer of hard subsoil that prevents the ***infiltration*** of water or roots). The soils are thick to moderately thick and fine-textured (DIRS 176781-MO0603GSCSSGEO.000). The soils are formed on alluvium derived from volcanic rocks.

About 16 percent of the soils have the erodes easily characteristic. The data indicate that there are no prime farmland soils or soils with the blowing soil characteristic in this area.

3.2.1.3.5 *South Reveille Alternative Segments*

3.2.1.3.5.1 Physiography. South Reveille alternative segments 2 and 3 would enter Reveille Valley south of the Reveille Range (see Figure 3-9). The valley floor is relatively uniform, with elevations ranging from about 1,700 to 1,830 meters (5,700 to 6,000 feet) above mean sea level.

3.2.1.3.5.2 Geology. The South Reveille alternative segments would cross recent alluvium and volcanic flows. The alternative segments would not cross any Quaternary fault scarps, and there have been few earthquakes recorded in the area within the last 150 years. Recently, there has been some prospecting for gold and silver in the area around the alternative segments. However, there is a low potential for mineral resources in the area. Section 3.2.2, Land Use and Ownership, describes land uses, including mineral exploration. There are no known energy resources around the alternative segments.

Potential quarry NN-9A would be in the southern portion of Reveille Valley. The site would be about 32 to 48 kilometers (20 to 30 miles) from State Route 375, the nearest paved road. The quarry pit would mine a basalt ridge and the plant facilities would be in the valley below (DIRS 176172-Nevada Rail Partners 2006, pp. B-2 and B-3).

Potential quarry NN-9B also would be in the southern portion of Reveille Valley, about 2 kilometers (1.2 miles) southeast of the site of potential quarry NN-9A. The quarry pit would mine a separate basalt ridge, with the plant facilities in the valley below, next to the South Reveille alternative segment 2 rail ***siding*** (DIRS 176172-Nevada Rail Partners 2006, pp. C-1 and C-2).

3.2.1.3.5.3 Soils. South Reveille Valley is dominated by very thick, well-drained, fan piedmont soils. These soils are derived from volcanic breccia and tuff. Nineteen percent of the soils along South Reveille alternative segment 2 have soils with the erodes easily characteristic; 15 percent of the soils along South Reveille alternative segment 3 have that characteristic. Additionally, 6.3 percent of South Reveille alternative segment 2 soils have the blowing soils characteristic; South Reveille alternative segment 3 contains none. There are no prime farmland soils along either of the South Reveille alternative segments.

3.2.1.3.6 Caliente Common Segment 3 (Reveille Valley to Mud Lake)

3.2.1.3.6.1 Physiography. The physiography of Caliente common segment 3 is characterized, from east to west, by the Reveille Valley, Stone Cabin Valley, Cactus Flat, Ralston Valley, and Mud Lake (see Figures 3-9 and 3-10). The Reveille Range would border the common segment on the east. The Hot Creek Range (the extension of the Kawich Range north of Warm Springs Summit) would border this common segment to the north. Caliente common segment 3 would cross Cow Canyon near Warm Springs Summit. Warm Springs, a cluster of hot springs, discharges just east of Warm Springs Summit in the Kawich Range. The Maintenance-of-Way Trackside Facility would be next to the rail alignment in the northern section of Cactus Flat. The Maintenance-of-Way Headquarters Facility would be 8.0 kilometers (5.0 miles) south of Tonopah, adjacent to U.S. Highway 95.

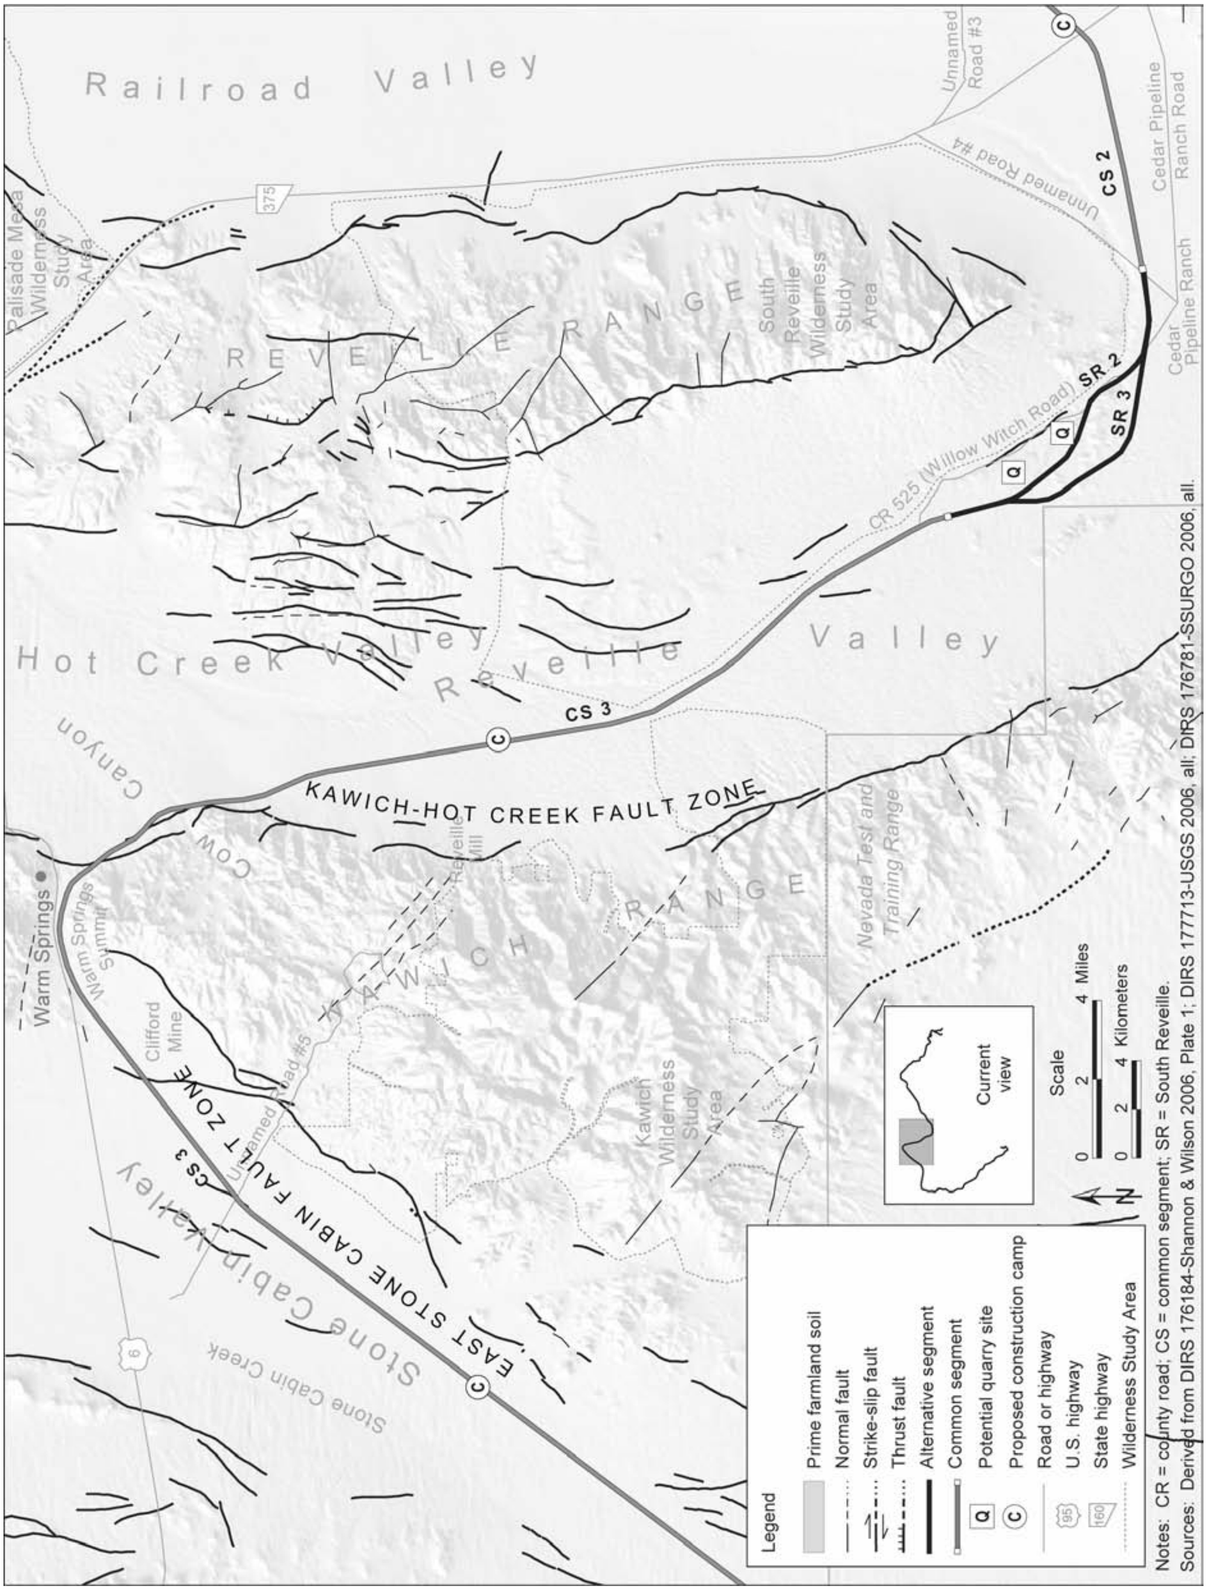

Figure 3-9. Physiographic features of the common segments and alternative segments within map area 4.

Rail alignment elevations would range from 1,650 to 1,900 meters (5,400 to 6,200 feet) above mean sea level at Warm Springs Summit and 1,600 to 1,700 meters (5,200 to 5,600 feet) above mean sea level around Mud Lake.

3.2.1.3.6.2 Geology. Caliente common segment 3 would cross the length of Reveille Valley. Reveille Valley, a ***graben*** (a basin formed between normal faults), developed from displacements along the West Reveille fault and the western Hot Creek Reveille fault. At Warm Springs Summit, the common segment would cross young volcanic rocks that make up most of the Kawich Range. Stone Cabin Valley, Cactus Flat, and Ralston Valley consist of Quaternary alluvial materials, with some playa deposits in the lowest elevations of northern Cactus Flat and southern Ralston Valley. Runoff in southern Ralston Valley flows to Mud Lake, another playa. Some Quaternary alluvial deposits in Reveille Valley have been displaced by these faults, indicating movement within the past 1.6 million years.

Caliente common segment 3 would parallel the Kawich-Hot Creek fault zone along the eastern side of the Hot Creek and Kawich Ranges. Displacement along this fault has occurred throughout the Quaternary, most recently about 130,000 years ago (DIRS 177713-MO0607LFAFUS96.000, Fault Number 1355). The common segment would both parallel and cross the East Stone Cabin fault zone, which forms the northwestern border of the Kawich Range with Stone Cabin Valley (see Figure 3-9). The most recent movement along this fault was also about 130,000 years ago (DIRS 177713-MO0607LFAFUS96.000, Fault Number 1354).

There are several commercial minerals found in the area around Caliente common segment 3 (DIRS 173841-Shannon & Wilson 2005, Plate 1). The Warm Springs summit area has documented sources of gold, silver, base metals, barite, and turquoise. As described in Section 3.2.2, Land Use and Ownership, there are also several mining districts in the area. There are also hot springs in the Warm Springs Summit area. Other than gravel and alluvial materials present on the floor of Stone Cabin Valley, Cactus Flat, and Ralston Valley, Caliente common segment 3 would not cross any known commercial mineral deposits.

3.2.1.3.6.3 Soils. Soils along Caliente common segment 3 occur on alluvial fan remnants, skirts, piedmonts, and in the eastern portion, on alluvial flats (DIRS 176781-MO0603GSCSSGEO.000). They are derived from various sources, including wind-blown sand, mixed alluvium, and fine-grained playa deposits.

Soils with the erodes easily characteristic comprise about 17 percent of the soils, and soils with the blowing soil characteristic comprise about 32 percent of the soils (see Table 3-3). As part of the pre-construction process, stability tests would ensure that fine-grained playa soils would be suitable for construction. The proposed rail alignment would not cross any soils considered to be prime farmland.

3.2.1.3.7 Goldfield Alternative Segments

3.2.1.3.7.1 Physiography. The physiography of the Goldfield area is dominated by the Goldfield Hills (see Figure 3-10) and the extensive surface and underground mine workings associated with the mining district. The Goldfield area also includes part of the Mud Lake basin to the north and the Montezuma Valley and Malpais Mesa to the west. There are several prominent hills, ridges, and plateaus in the area, which the Goldfield alternative segments would either cross or go around. The central Goldfield alternative segment, Goldfield 1, would wind through the central part of Goldfield Hills, coming within about 1.9 kilometers (1.2 miles) of Black Butte, Espina Hill, and Blackcap Mountain. Goldfield alternative segments 3 and 4 would weave through the western section of the Goldfield Hills, using passes and valleys to maintain an appropriate ***grade*** (see Figure 3-10). The alternative segments would reach elevations ranging from 1,800 to 1,900 meters (6,000 feet to 6,200 feet) above mean sea level.

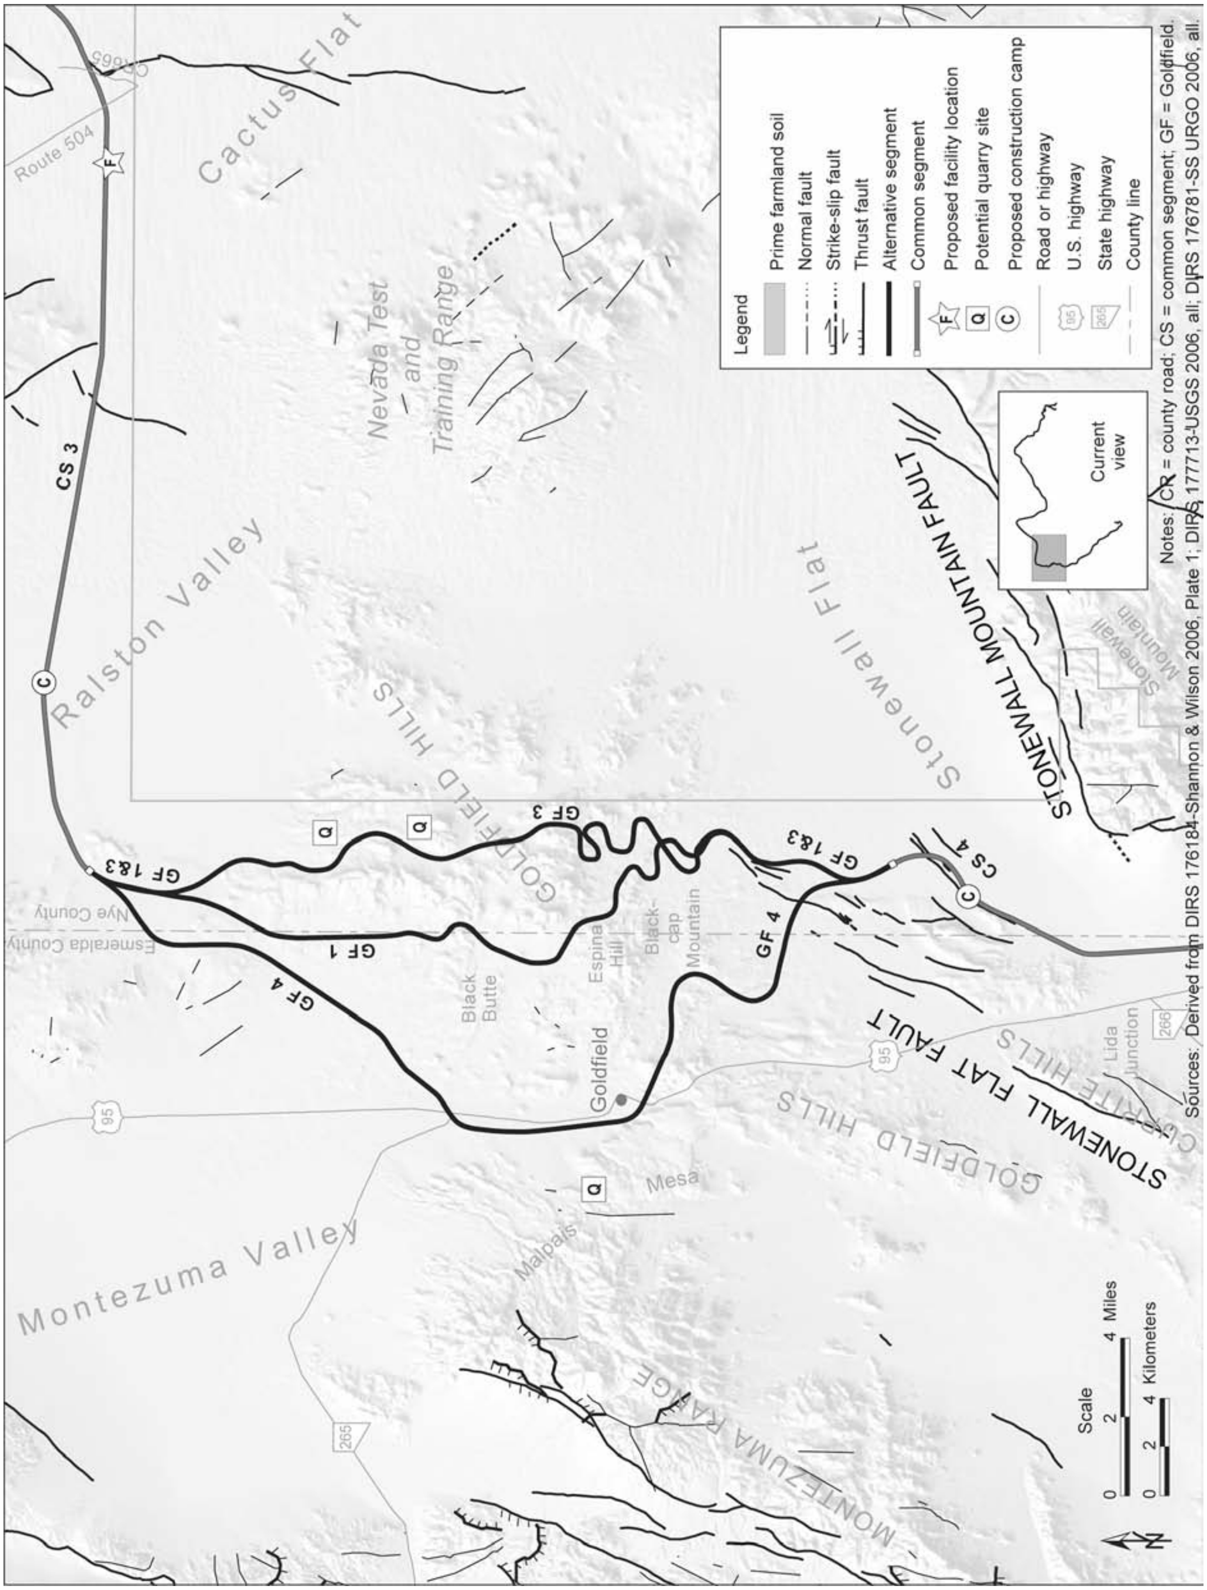

Figure 3-10. Physiographic features of the common segments and alternative segments within map area 5.

3.2.1.3.7.2 Geology. In the Goldfield area, the principal outcrops consist of young volcanic rocks. A combination of heat, water, and fractures in the bedrock contributed to the alteration and mineralization of the area volcanic rocks. This has resulted in an area with metallic mineral deposits (DIRS 173841-Shannon & Wilson 2005, pp. 68 to 70). The Goldfield Mining District has been extensively mined for gold, silver, and copper ore since the early 1900s. Nonmetallic minerals such as zeolite are also found in the area. Section 3.2.2, Land Use and Ownership, describes the local mining districts. There are no geothermal or other energy resources near the Goldfield alternative segments.

Potential quarry NS-3A would be on the basalt hills and surrounding valley northeast of Goldfield along Goldfield alternative segment 3. The quarry pit would encompass two hills on either side of a wash, with the plant facilities located in the valley below. Potential quarry NS-3B would be next to the site of NS-3A along Goldfield alternative segment 3 in a valley flanked by hills. The quarry pit would be adjacent to the rail alignment, and the plant facility would be to the east in the valley. Potential quarry ES-7 would be on Malpais Mesa, west of Goldfield along Goldfield alternative segment 4 (DIRS 176172-Nevada Rail Partners 2006, Figures 3-C and 3-D).

All of the Goldfield alternative segments would cross the northeastern edge of the Stonewall Flat fault zone. These faults offset bedrock in the Cuprite Hills, and are generally not well understood. The last fault movement was calculated to have occurred within the last 130,000 years (DIRS 177713-MO0607LFAFUS96.000, Fault Number 1089).

3.2.1.3.7.3 Soils. Soils along the Goldfield alternative segments include those derived from loose volcanic rock alluvium (DIRS 176781-MO0603GSCSSGEO.000). This area has well drained to excessively drained soils on mountains, hills, and fan piedmonts.

Soils with the blowing soil characteristic range from about 7.5 percent along Goldfield alternative segment 4 to 9.1 percent along Goldfield alternative segment 3; there are no soils with the erodes easily characteristic along any of the Goldfield alternative segments (see Table 3-3). None of the Goldfield alternative segments would cross prime farmland soils.

3.2.1.3.8 *Caliente Common Segment 4 (Stonewall Flat Area)*

3.2.1.3.8.1 Physiography. The physiography of Caliente common segment 4 is characterized by Stonewall Flat and Lida Valley, both depressions with numerous alkali flats (see Figures 3-10 and 3-11), and elevations between 1,400 and 1,500 meters (4,700 and 4,900 feet) above mean sea level. Stonewall Mountain is also a prominent feature that borders the common segment on the east.

3.2.1.3.8.2 Geology. In Stonewall Flat, a graben formed in part by the northeast-trending Stonewall Mountain Fault, Caliente common segment 4 would mostly cross fan and stream-channel alluvium, in addition to a small outcrop of volcanic rocks of Stonewall Mountain (DIRS 176184-Shannon & Wilson 2006, Table 5). There has been some seismic activity around the Cuprite Hills and at Stonewall Mountain within the past 150 years (see Figure 3-3).

There are metallic minerals, including copper, silver, and gold, along this common segment. The deposits occur in sedimentary and volcanic rocks that have been altered by hot fluids. Quartz veins are also mined for silica. Drilling in the Cuprite Hills suggests the existence of a large geothermal system in the area, with multiple warm heat-flow wells drilled in the Cuprite Hills (DIRS 173841-Shannon & Wilson 2005, Plate 1). Except for alluvium, there are no construction materials along the common segment.

3.2.1.3.8.3 Soils. Soils along Caliente common segment 4 are derived from alluvium and occur on fan piedmonts, fan skirts, and drainage ways (DIRS 176781-MO0603GSCSSGEO.000). Soils with the blowing soil characteristic comprise 1.4 percent of the soils along this common segment. Soils with the erodes easily characteristic comprise about 41 percent of the soils. Caliente common segment 4 would not cross any prime farmland soils.

3.2.1.3.9 *Bonnie Claire Alternative Segments*

3.2.1.3.9.1 Physiography. The physiography of the Bonnie Claire area is characterized by the southern boundary of Lida Valley and the northern portion of Sarcobatus Flat, which are depressions with numerous alkali flats. Pahute Mesa would be to the east of the alternative segments; Stonewall Mountain would be to the northeast (see Figure 3-11). Bonnie Claire alternative segment 2 would pass to the east of an unnamed 1,500-meter (4,900-foot)-high bedrock knoll that separates Sarcobatus Flat and Lida Valley; Bonnie Claire alternative segment 3 would pass this knoll to the west (DIRS 176184-Shannon & Wilson 2006, Figure 3). Elevations in this area range from about 1,250 to 1,400 meters (4,100 to 4,600 feet) above mean sea level.

3.2.1.3.9.2 Geology. The Bonnie Claire alternative segments would cross the eastern portion of the southwestern Nevada volcanic field. Bonnie Claire 3 would cross a mixture of young volcanic rocks and ash-flow sedimentary rocks, while Bonnie Claire 2 would primarily cross alluvium on the western edge of Sarcobatus Flat (DIRS 176184-Shannon & Wilson 2006, Table 5).

The two alternative segments would bypass a sequence of interconnected unnamed faults. These faults are not well studied, although recent seismic activity has been recorded in the area. In 1999, there was a magnitude 5.3 earthquake in the area between the Bonnie Claire alternative segments. As seen in Figure 3-3, many aftershocks were recorded in the area, most between magnitudes 2.0 and 3.5. Since then, earthquakes immediately around the Bonnie Claire alternative segments have been below magnitude 3.0 (DIRS 176184-Shannon & Wilson 2006, Plate 4).

Metallic minerals such as gold and copper have been found within the volcanic rocks around the Bonnie Claire alternative segments. The Wagner Mining District is in this area, and is discussed in more detail in Section 3.2.2, Land Use and Ownership.

There are no energy or geothermal resources in the area surrounding the Bonnie Claire alternative segments, and other than gravel and alluvial materials present on the floor of Lida Valley, the Bonnie Claire alternative segments would not cross any known mineral deposits.

3.2.1.3.9.3 Soils. Soils along Bonnie Claire alternative segments 2 and 3 are derived from alluvium and ***colluvium***, and are found on hills, alluvial fan piedmonts, and fan skirts. Soils are mainly identified for Bonnie Claire alternative segment 3, because soil data are not available for the area around the Nevada Test and Training Range.

Soils with the erodes easily characteristic comprise 27 and 25 percent of the soils for Bonnie Claire alternative segments 2 and 3, respectively. Available data do not indicate any soils with the blowing soil or prime farmland characteristic.

3.2.1.3.10 Common Segment 5 (Sarcobatus Flat Area)

3.2.1.3.10.1 Physiography. The physiography of common segment 5 consists of most of Sarcobatus Flat. Pahute Mesa would be to the northeast (see Figure 3-11). Coba Mountain is a prominent feature in the area, and extends from common segment 5 to the southwest (see Figure 3-12). Rail alignment elevations in the Sarcobatus Flat area would range from 1,200 to 1,250 meters (3,900 feet to 4,100 feet) above mean sea level.

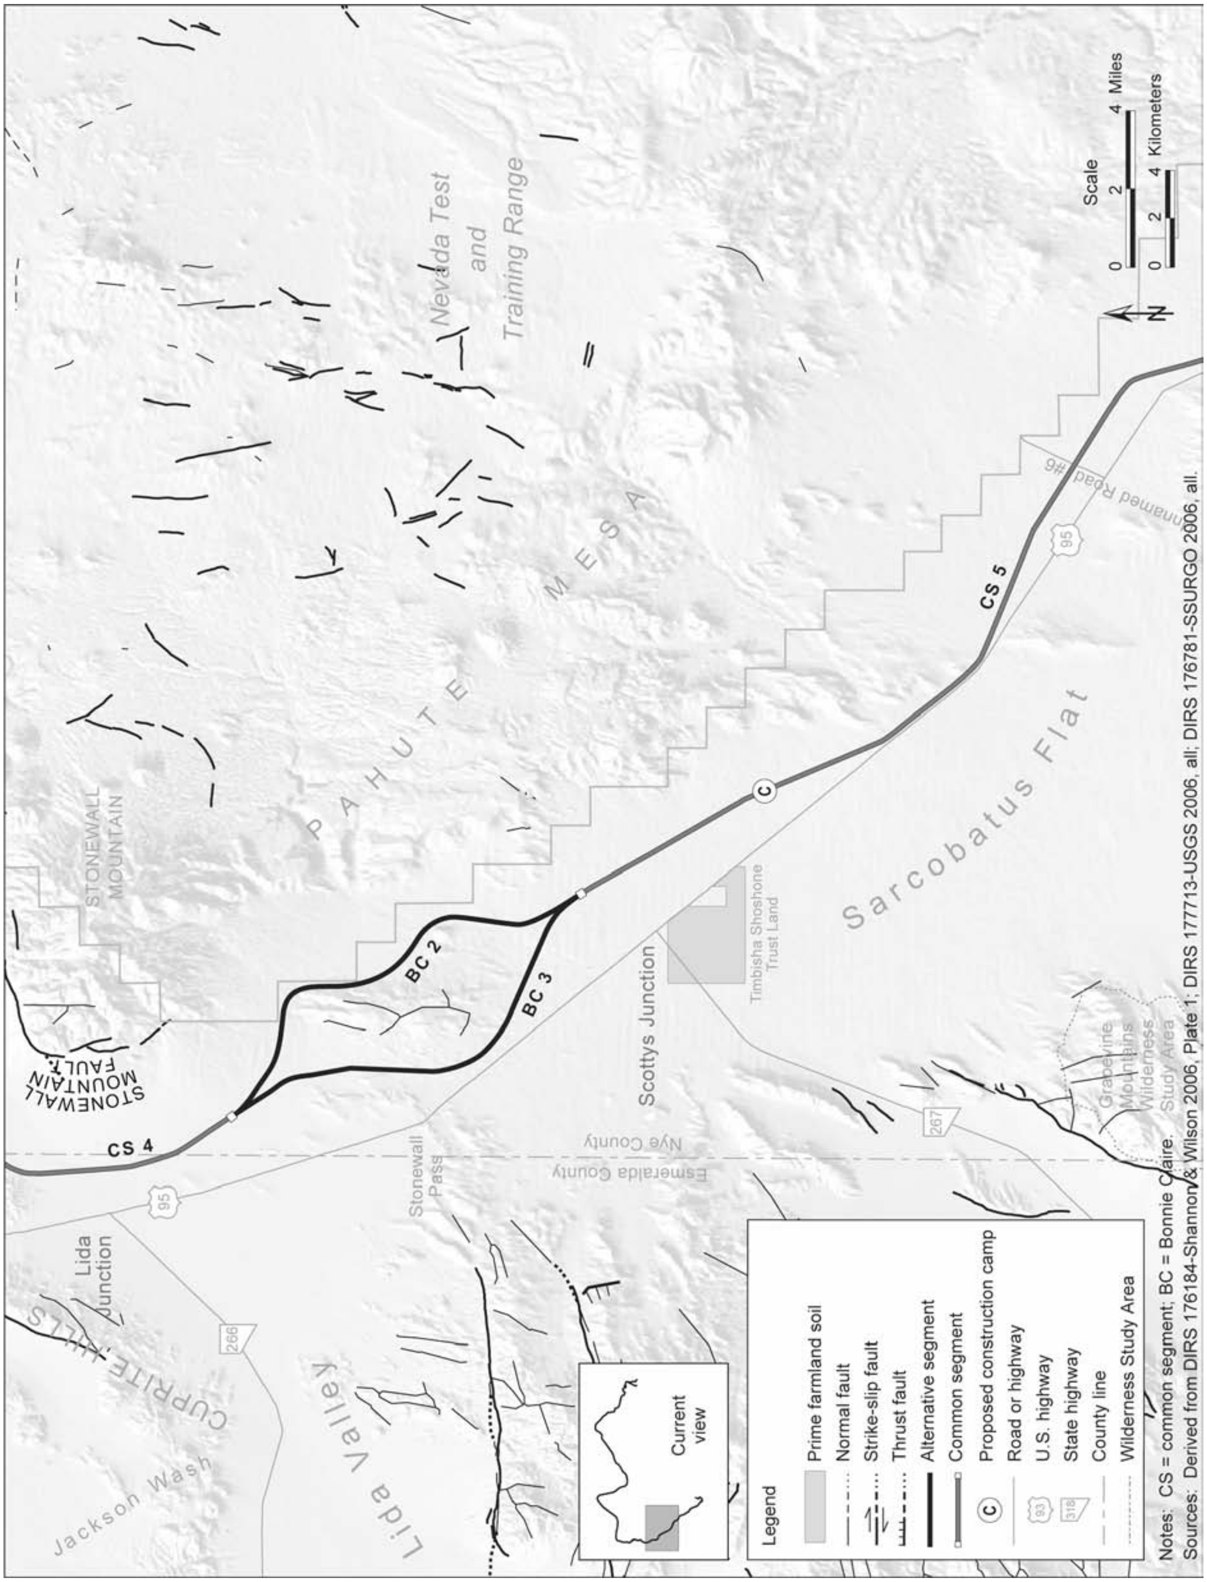

Figure 3-11. Physiographic features of the common segments and alternative segments within map area 6.

3.2.1.3.10.2 Geology. Common segment 5 would cross Quaternary alluvium and mid-Tertiary ash-flow tuffs, minor lava flows, and reworked materials associated with the southwestern Nevada volcanic field. The common segment would not cross Quaternary faults (see Figures 3-11 and 3-12). Commercial minerals found within the area include gold and silver (DIRS 173841-Shannon & Wilson 2005, pp. 51 and 52). Additionally, an actively mined, relatively large gravel pit at the alluvial fan boundary between Pahute Mesa and Sarcobatus Flat would be within 0.8 kilometer (0.5 mile) of the rail alignment in this area.

Geothermal occurrences in Sarcobatus Valley include one warm spring and one hot well, which would be about 0.20 kilometer (0.12 mile) from the rail alignment.

3.2.1.3.10.3 Soils. Area soils are derived from alluvial deposits and are well drained. They occur on alluvial flats and fan piedmonts. Soils with the blowing soil characteristic comprise about 2.6 percent of the soils. There are no soils along common segment 5 with the erodes easily or prime farmland characteristics.

3.2.1.3.11 *Oasis Valley Alternative Segments*

3.2.1.3.11.1 Physiography. Oasis Valley alternative segments 1 and 3 would be in Oasis Valley, which is incised by the Amargosa River, an ***ephemeral stream***, and tributary washes (see Figure 3-12). Elevations range from about 1,200 to 1,300 meters (3,900 to 4,200 feet) above mean sea level. At the northwest end, the alternative segments would cross alluvial fans extending from Pahute Mesa on the north and Oasis Mountain (in Bullfrog Hills) on the south.

3.2.1.3.11.2 Geology. The two Oasis Valley alternative segments would cross sedimentary rocks overlain in part by recent sediment from alluvial fans and Amargosa River floodplain deposits. Small outcrops of young volcanic rocks from the southwestern Nevada volcanic field area are also exposed. The rail alignment would not cross Quaternary faults, commercial mineral operations, geothermal resources or materials suitable for construction purposes.

3.2.1.3.11.3 Soils. Soils along Oasis Valley alternative segments 1 and 3 are derived from alluvium and are well drained to somewhat excessively drained. Soils occur on fan skirts and fan piedmonts. Oasis Valley 1 contains approximately 13 percent soils with the blowing soil characteristic, while Oasis Valley 3 contains approximately 5.3 percent of blowing soils. There are no prime farmland or erodes easily soils along either of the Oasis Valley alternative segments.

3.2.1.3.12 Common Segment 6 (Yucca Mountain Approach)

3.2.1.3.12.1 Physiography. The physiography of common segment 6 is characterized by Beatty Wash, Crater Flat, and several ridges and valleys that make up Yucca Mountain, Busted Butte, and Jackass Flats (see Figure 3-12). The common segment would go around the east side of Busted Butte, with Fortymile Wash and most of Jackass Flats to the east. North of Busted Butte, it would cross a series of washes and valleys flanked by multiple ridges, where it would terminate near Yucca Mountain. Rail alignment elevations would range from about 1,300 meters (4,300 feet) at Tram Ridge to 1,000 meters (3,300 feet) above mean sea level at the base of Busted Butte (DIRS 176184-Shannon & Wilson 2006, Figure 3, Sheets 70 and 71).

3.2.1.3.12.2 Geology. This area is in the southern edge of the southwestern Nevada volcanic field. Common segment 6 would cross a variety of alluvial deposits and sedimentary rocks, and young volcanic rocks. Faults in the area increase in number closer to the Yucca Mountain uplands. The fault traces generally trend to the north, including the Bare Mountain Fault and the eastern and western Yucca

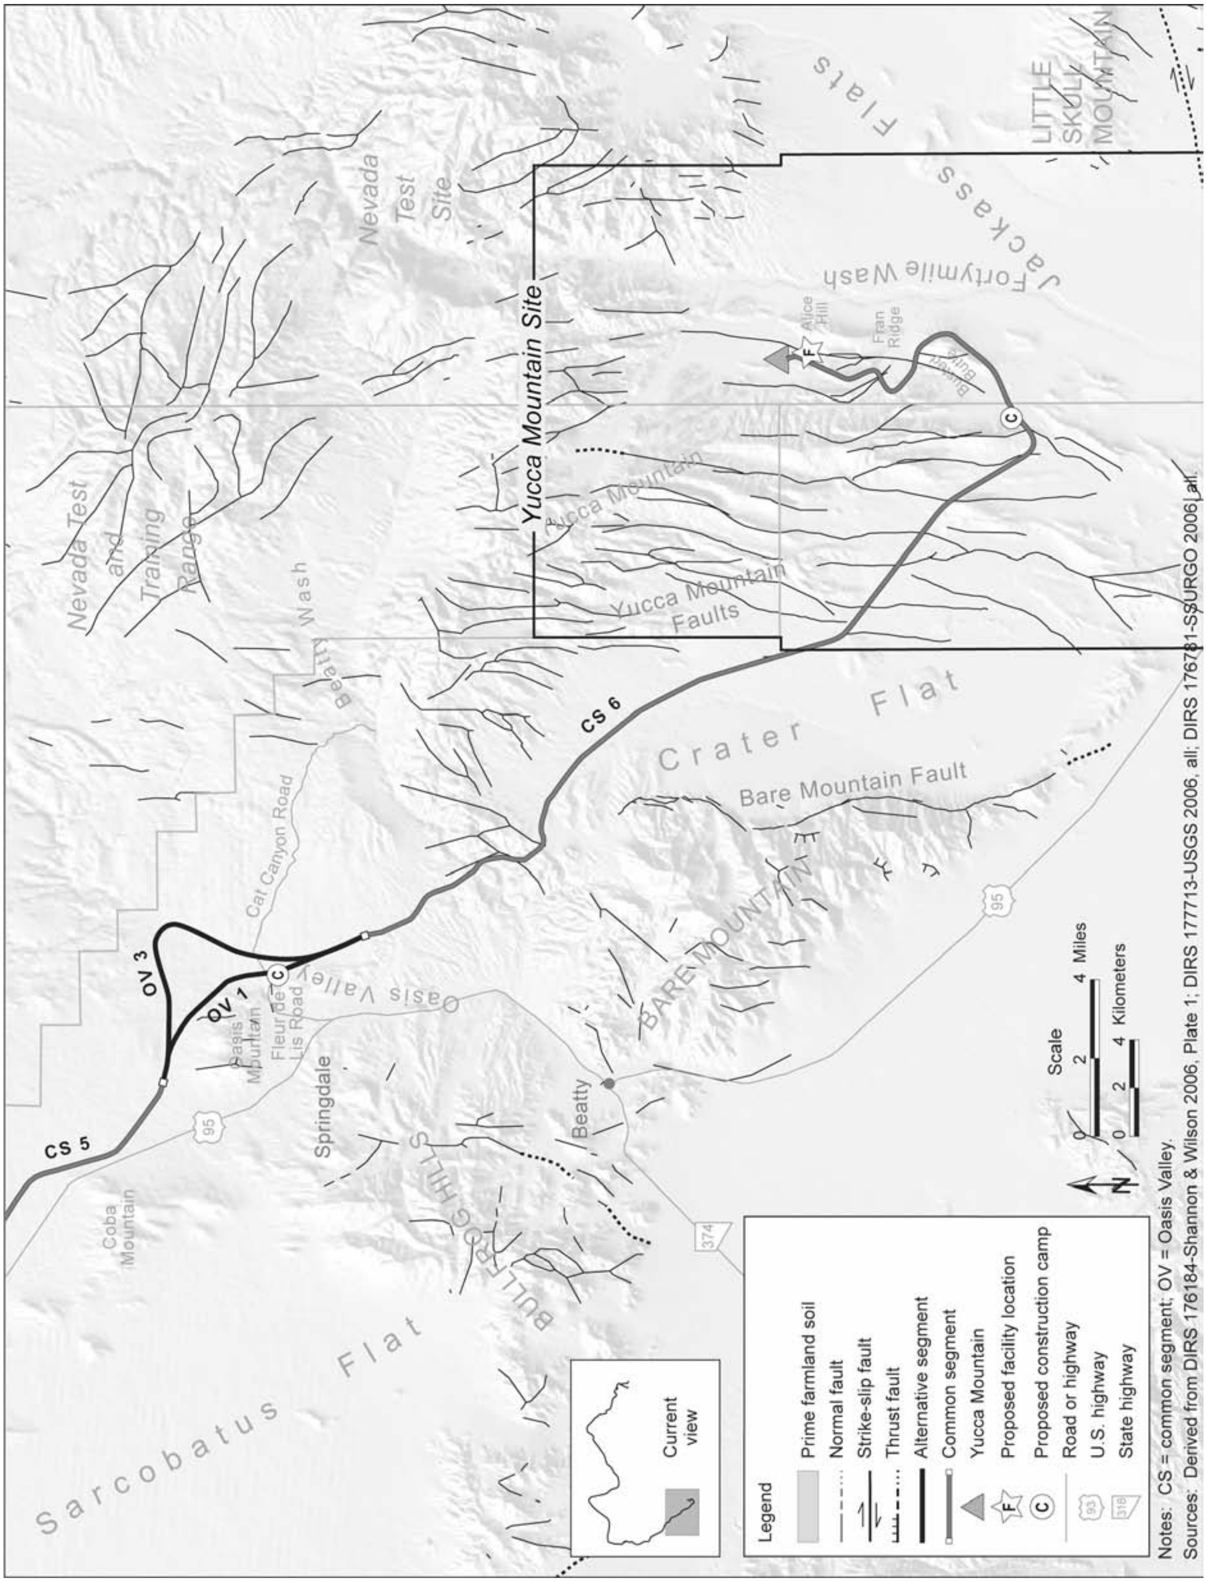

Figure 3-12. Physiographic features of the common segments and alternatives segments within map area 7.

Mountain fault groups. Displacements along faults are characterized in terms of the amount of movement per seismic event. For the set of block-bounding faults of primary significance to the ***Yucca Mountain Site***, these surface values range from 0 to 1.7 meters (0 to 5.6 feet) per event (DIRS 155970-DOE 2002, Table 3-8).

DOE has monitored seismic activity at the Nevada Test Site since 1978. The largest recorded earthquake within 50 kilometers (30 miles) of Yucca Mountain was the Little Skull Mountain earthquake in 1992 (DIRS 169734-BSC 2004, p. 4-34 and Figure 4-19), which had a magnitude of 5.6 (DIRS 169734-BSC 2004, p. 4-38). DOE buildings on the Nevada Test Site were damaged and there was also damage in Beatty, Town of Amargosa Valley, and Mercury, Nevada. DOE would continue to monitor the seismic activity around Yucca Mountain with an array of monitoring stations spread throughout the area.

The bedrock around common segment 6 contains metallic minerals, such as gold and silver, and nonmetallic deposits, including fluorspar and silica (DIRS 173841-Shannon & Wilson 2005, pp. 38 to 45). There are also several hot springs around the Beatty Wash area, some of which are used by a hotel (DIRS 173841-Shannon & Wilson 2005, Plate 1).

3.2.1.3.12.3 Soils. Soils along common segment 6 occur on fan piedmonts, skirts, and fan remnants. The soils derived from Tertiary volcanic rocks and Quaternary alluvium are well drained to somewhat excessively drained. Soils on alluvial flats are derived from lake deposits and are well drained. None of the soils along common segment 6 contain prime farmland, blowing soil, or soils with the erodes easily characteristic.

3.2.2 LAND USE AND OWNERSHIP

This section describes the affected environment for land use and ownership along and adjacent to the Caliente rail alignment. At the recommendation of the U.S. Bureau of Land Management (BLM; a cooperating agency in the preparation of this Rail Alignment EIS), DOE organized this section by types of land uses rather than by rail line segments to enable the reader to quickly review issues of concern to them. The section provides an overview of land uses on private, American Indian, and public lands. The BLM and DOE manage public land the Caliente rail alignment would cross. The uses of public land discussed in detail in this section include grazing (within BLM-designated ***grazing allotments***), mineral and energy extraction, and recreation. This section also discusses land access and existing utility rights-of-way.

Section 3.2.2.1 describes the region of influence for land use and ownership; Section 3.2.2.2 describes private land, including relevant land-use plans; Section 3.2.2.3 describes American Indian land; Section 3.2.2.4 describes public lands, BLM ***resource management plans***, and project-related land ***withdrawals***; and Section 3.2.2.5 describes the general environmental setting and land-use characteristics along the Caliente rail alignment.

Other sections of this Rail Alignment EIS describe additional subjects related to land use. Section 3.2.1, Physical Setting, describes farmland and prime farmland in more detail; Section 3.2.7, Biological Resources, describes ***herd management areas***; and Section 3.2.11, Utilities, Energy, and Materials addresses utilities. Section 3.4 describes American Indian interests in and views on the Proposed Action.

3.2.2.1 Region of Influence

The region of influence for land use and ownership is the nominal width of the rail line construction right-of-way, and includes all private land (including patented ***mining claims***), American Indian lands, and public land that would be fully or partially within the construction right-of-way. The land use and ownership region of influence also includes the locations of construction and operations support facilities outside the nominal width of the rail line construction right-of-way.

Although the ***operations right-of-way*** would be smaller than the construction right-of-way, DOE evaluated the construction right-of-way as the basis for identifying potential land-use impacts because:

- It provides a more conservative estimate of the amount of land that would be utilized than the operations right-of-way, providing an upper bound for analysis.
- The construction phase encompasses the most intensive land use in terms of noise, human activity, and disruptions to land access.
- The construction right-of-way footprint would be the basis for the initial right-of-way applications submitted to the BLM for the project.

3.2.2.2 Private Land

Private lands in Lincoln, Nye, and Esmeralda Counties are either clustered in towns and along highways, or they are widely scattered. Private land makes up a very small portion of these counties. Figure 3-13 provides an overview of privately owned lands near the Caliente rail alignment.

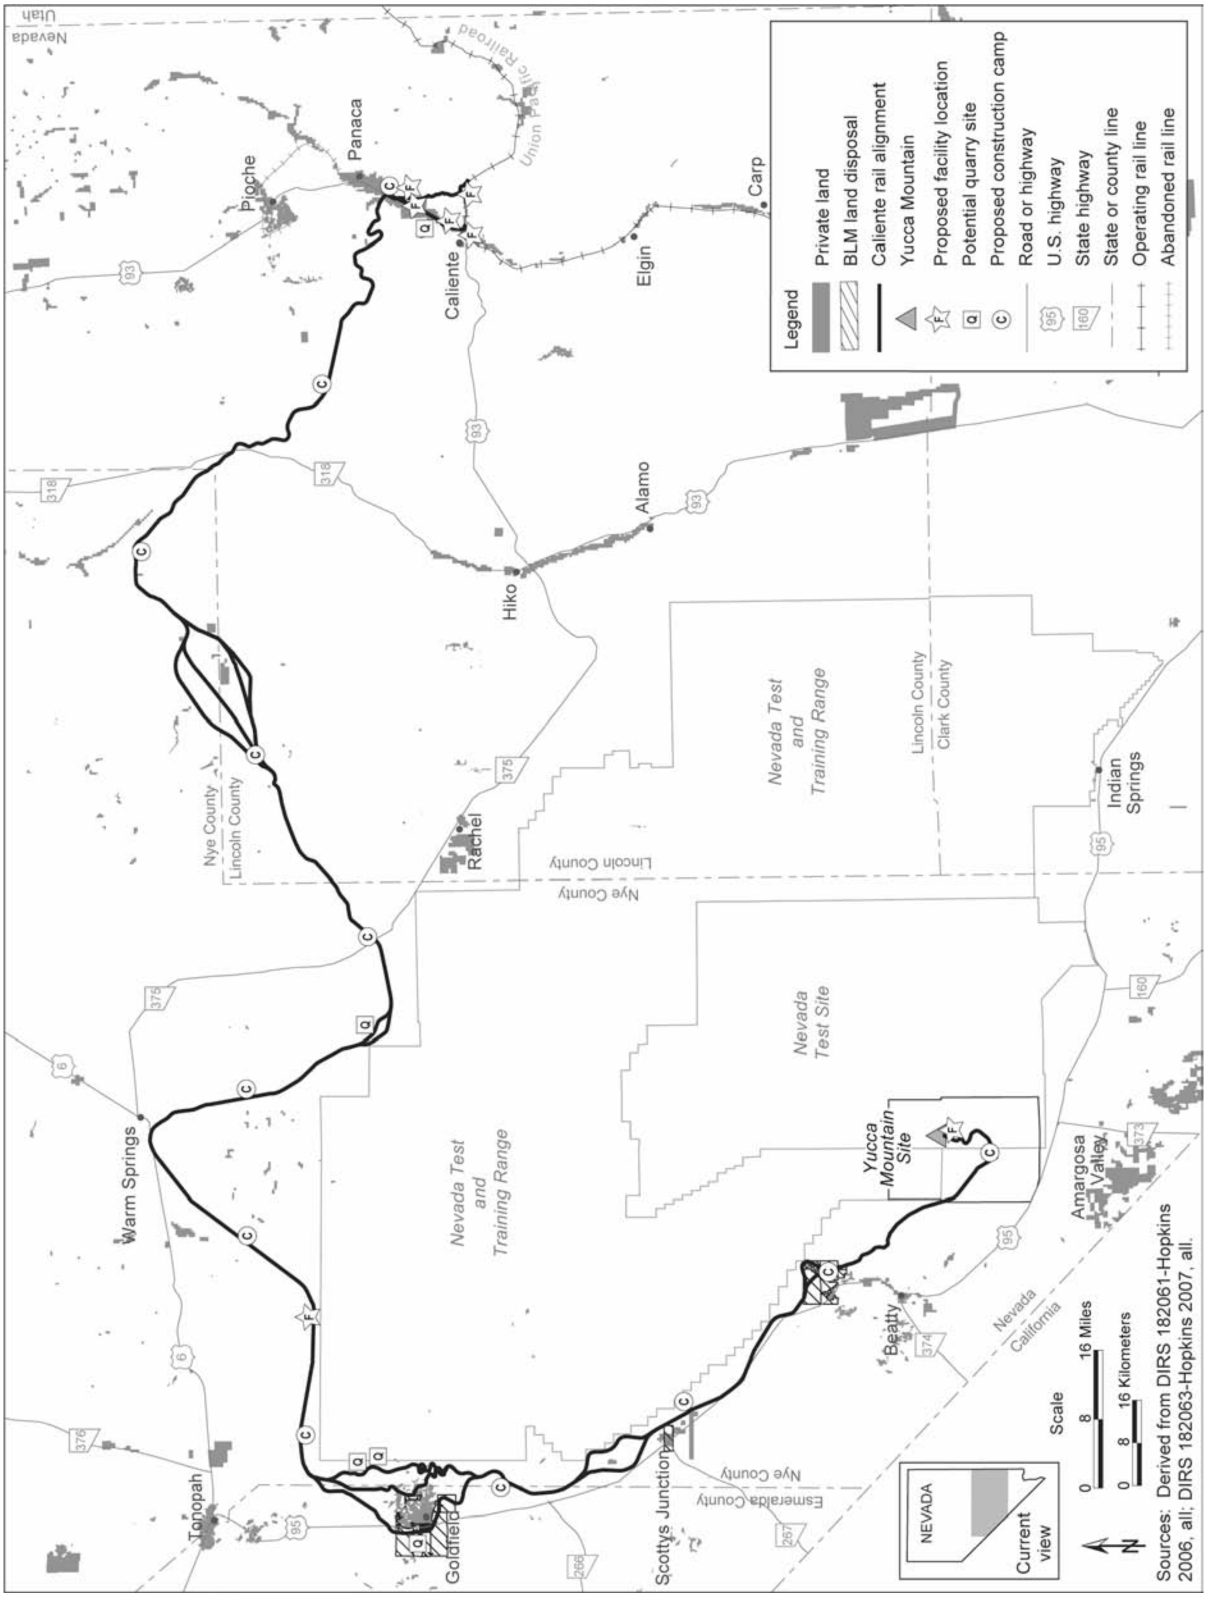

Figure 3-13. Private land along the Caliente rail alignment.

3.2.2.2.1 County Land-Use Plans

The Caliente rail alignment would cross parts of Lincoln, Nye, and Esmeralda Counties. County plans that affect land use along the rail alignment include the *Lincoln County Master Plan* (DIRS 174520-State of Nevada 2001, all), *Nye County Comprehensive Plan* (DIRS 147994-McRae 1994, all), and *Esmeralda County Master Plan* (DIRS 176770-Duval et al. 1976, all).

3.2.2.2.1.1 Lincoln County. The *Lincoln County Master Plan* guides the county's growth, management of natural resources, provisions for public services and facilities, and the protection of public health, safety, and welfare. Lincoln County is the third largest county in Nevada, covering approximately 28,000 square kilometers (11,000 square miles), and the Federal Government manages more than 97 percent of that land (DIRS 174520-State of Nevada 2001, p. 3-5). The BLM manages most public land in the county; the U.S. Forest Service manages the portions of the Humboldt-Toiyabe National Forest that fall within the county. Lincoln County is primarily rural and most residents live in Pioche (also the county seat), Panaca, Alamo, the City of Caliente, and the communities of Rachel, Hiko, Ash Springs, Richardville, Caselton, and Ursine. The rest of Lincoln County is sparsely settled.

3.2.2.2.1.2 Nye County. Nye County has an area of approximately 47,000 square kilometers (18,000 square miles) and is the largest county in Nevada. The Federal Government manages almost 93 percent of the county's land. Federally owned or managed lands in Nye County include the Nevada Test and Training Range, the Nevada Test Site, BLM-administered public land, a portion of Death Valley National Park, and portions of the Humboldt-Toiyabe National Forest. Private lands in Nye County are used for residential, commercial, and industrial purposes largely, but not exclusively, within the boundaries of unincorporated towns, and agricultural and mining uses both inside and outside these towns. The *Nye County Comprehensive Plan* guides growth and development, but is not equivalent to a zoning ordinance, nor does it regulate the use of land. However, the Nye County Board of Commissioners may choose to enact a zoning ordinance or other growth-management mechanisms to accomplish certain objectives of the plan. The plan also serves as a framework for local land-use plans and other growth-management mechanisms (DIRS 147994-McRae 1994, all).

3.2.2.2.1.3 Esmeralda County. The BLM manages more than 92 percent of the approximately 9,300 square kilometers (3,600 square miles) in Esmeralda County. Two percent of the land in Esmeralda County is National Forest land, and a small portion of the county falls within Death Valley National Park. Less than 5 percent of the land in the county is privately owned. The two most heavily populated areas in Esmeralda County at the issuance of the *Esmeralda County Master Plan* were Goldfield and Silver Peak (DIRS 176770-Duval et al. 1976, p. 25). Goldfield is the county seat for Esmeralda County; there are no incorporated cities in the county. Under the *Esmeralda County Master Plan*, land use has been divided into three basic categories: multiple use, agriculture, and urban expansion. The multiple-use category is suggested for those areas where federal or state ownership is expected to remain. Grazing, mining and prospecting, and recreation activities are recommended under the multiple-use concept. The plan also recommends that residential and commercial development be concentrated in the existing communities of Goldfield and Silver Peak, where public facilities can be most economically concentrated (DIRS 176770-Duval et al. 1976, p. 73).

3.2.2.2.2 Local Land-Use Planning

The initial design phase for the Caliente rail alignment emphasized avoiding towns and populated areas wherever feasible. Caliente and Goldfield are the most densely populated places along the Caliente rail alignment. Zoning and land use within Caliente is governed by the *City of Caliente Master Plan* (Caliente Master Plan) (DIRS 157312-Sweetwater and Anderson 1992, all). Goldfield does not have a master plan or zoning plan.

3.2.2.2.2.1 City of Caliente. The Caliente alternative segment would pass through the City of Caliente, which is in Lincoln County along U.S. Highway 93 and encompasses approximately 5.5 square kilometers (1.9 square miles) (DIRS 176855-U.S. Census Bureau 2003, p. 5). City services include restaurants, gas stations, motels, a small casino, and a variety of stores. Land uses within the City of Caliente include residential, governmental (administrative), commercial, industrial, agricultural, and recreational.

Commercial and industrial uses comprise approximately 11 percent of the land use and residential areas encompass approximately 9 percent of the land in the city (DIRS 157312-Sweetwater and Anderson 1992, p. 27). There are agricultural operations on approximately 0.3 square kilometer (80 acres) of land (approximately 8 percent) within Caliente, primarily within floodplains (DIRS 157312-Sweetwater and Anderson 1992, p. 24). Roads and utilities make up approximately 17 percent of land use in Caliente. Though vacant land occupies approximately 44 percent of the city land base, steep slopes and floodplains have limited the city's development potential.

Union Pacific Railroad Mainline tracks (Caliente Line) cross Caliente in approximately a northeast to south direction. Caliente has long been a central maintenance and switching center for railroad operations. The Caliente Line, at full capacity, operates 25 to 30 trains a day (DIRS 176807-Union Pacific 2005, all).

The Caliente Master Plan outlines strategies for both steady and rapid growth. Overall the plan fosters the following key development concepts (DIRS 157312-Sweetwater and Anderson 1992, p. 49):

- Caliente's role will continue to be residential, with tourism, the service industry, the [existing] railroad, and associated activities as primary economic activities.
- Residential expansion should occur primarily on open land to the north of U.S. Highway 93 (toward the cemetery) and should be predominantly single-family.
- The existing commercial core should be rehabilitated and continue as the commercial hub of Caliente.
- Small-scale, clean industrial uses should be promoted. A large site for major economic centers should be located north of the city out of the mouth of Antelope Canyon.
- Caliente should develop and improve recreational and tourist attractions.

One goal outlined in the master plan that could be specifically relevant to the Caliente rail alignment because it addresses rail operations is (DIRS 157312-Sweetwater and Anderson 1992, p. 54):

> If Caliente is to be a distribution point for goods brought into the county, trains should be switched onto the Pioche Spur Line and materials unloaded at a location north of the City. This will reduce disruption to the community due to noise, traffic, dust, or trains blocking the vehicle crossing.

The *Lincoln County Master Plan* states that the NTS Development Corporation is cooperating with the City of Caliente in the development of the Meadow Valley Industrial Park, to be located along U.S. Highway 93 and the Union Pacific Railroad in Caliente (DIRS 174520-State of Nevada 2001, pp. 24 and 25).

The City of Caliente has an undated zoning map developed by Design Concepts West showing zones for residential areas, administrative and professional areas, commercial areas, industrial areas, and parks and recreational areas. Most of the land adjacent to the Union Pacific Railroad tracks is zoned general commercial or industrial. There are exceptions adjacent to the former Pioche and Prince Branchline north of the Caliente Hot Springs, where the Lincoln County Hospital, senior citizens apartments, and a trailer court are immediately west of U.S. Highway 93. There is no zoning designation for the land that encompasses the former Pioche and Prince Branch (DIRS 180121-DC West [n.d.], all).

3.2.2.2.2.2 Goldfield. Goldfield alternative segment 4 would pass through Goldfield. Goldfield, an unincorporated town, is the county seat for Esmeralda County. The Goldfield census county division encompasses an area of more than 3,900 square kilometers (1,500 square miles) (DIRS 176855-U.S. Census Bureau 2003, p. 5). During its most prominent mining period at the beginning of the 20th Century, a number of passenger and freight railroad lines served Goldfield. The Goldfield Historic District, listed on the *National Register of Historic Places* in 1982 and entered onto the *Nevada State Register of Historic Places* on December 7, 2005, is in Goldfield and roughly bounded by Fifth Street, Miner Avenue, Spring Street, Elliot Street, and Crystal Avenue (DIRS 176854-National Register of Historic Places 1982, all). Although there is no zoning plan for Goldfield, the historic nature of its buildings and features are generally protected by the designation of its historic district. The Goldfield Historic District would be about 0.7 kilometer (0.4 mile) northwest of the Goldfield alternative segment 4 construction right-of-way.

3.2.2.2.3 Private Parcels

Most of the privately owned lands closest to the Caliente rail alignment are in or near Caliente and Goldfield. Figure 3-13 shows privately owned lands in or near the Caliente rail alignment. Note that patented mining claims are also private land, and are reflected in this private land information.

Table 3-4 lists the number of privately owned parcels of land that would be within the construction right-of-way of each Caliente alternative segment and common segment. Figures 3-14 through 3-25 show privately owned land along the Caliente rail alignment. Figures 3-15 through 3-18 show detailed land parcel maps for the Caliente and Eccles alternative segments.

Table 3-4. Private land that would be within or intersect the Caliente rail alignment construction right-of-way.

Rail line segment[a]	Number of parcels	Total area across parcels (square kilometers)[b]
Eccles alternative segment	11	0.32
Caliente alternative segment	32	0.31
Potential quarry CA-8B (siding only)[c]	2	0.18
Staging Yard at Caliente-Indian Cove	6	0.73
Staging Yard at Caliente-Upland	17	0.45
Caliente common segment 1	1	0.002
Goldfield alternative segment 1[c]	6	0.38
Goldfield alternative segment 3[c]	2	0.001
Goldfield alternative segment 4[d]	37	0.23
Oasis Valley alternative segment 1	1	0.02

a. No other segments would intersect private land.
b. To convert square kilometers to acres, multiply by 247.10.
c. All parcels are patented mining claims.
d. Four of the parcels are patented mining claims.

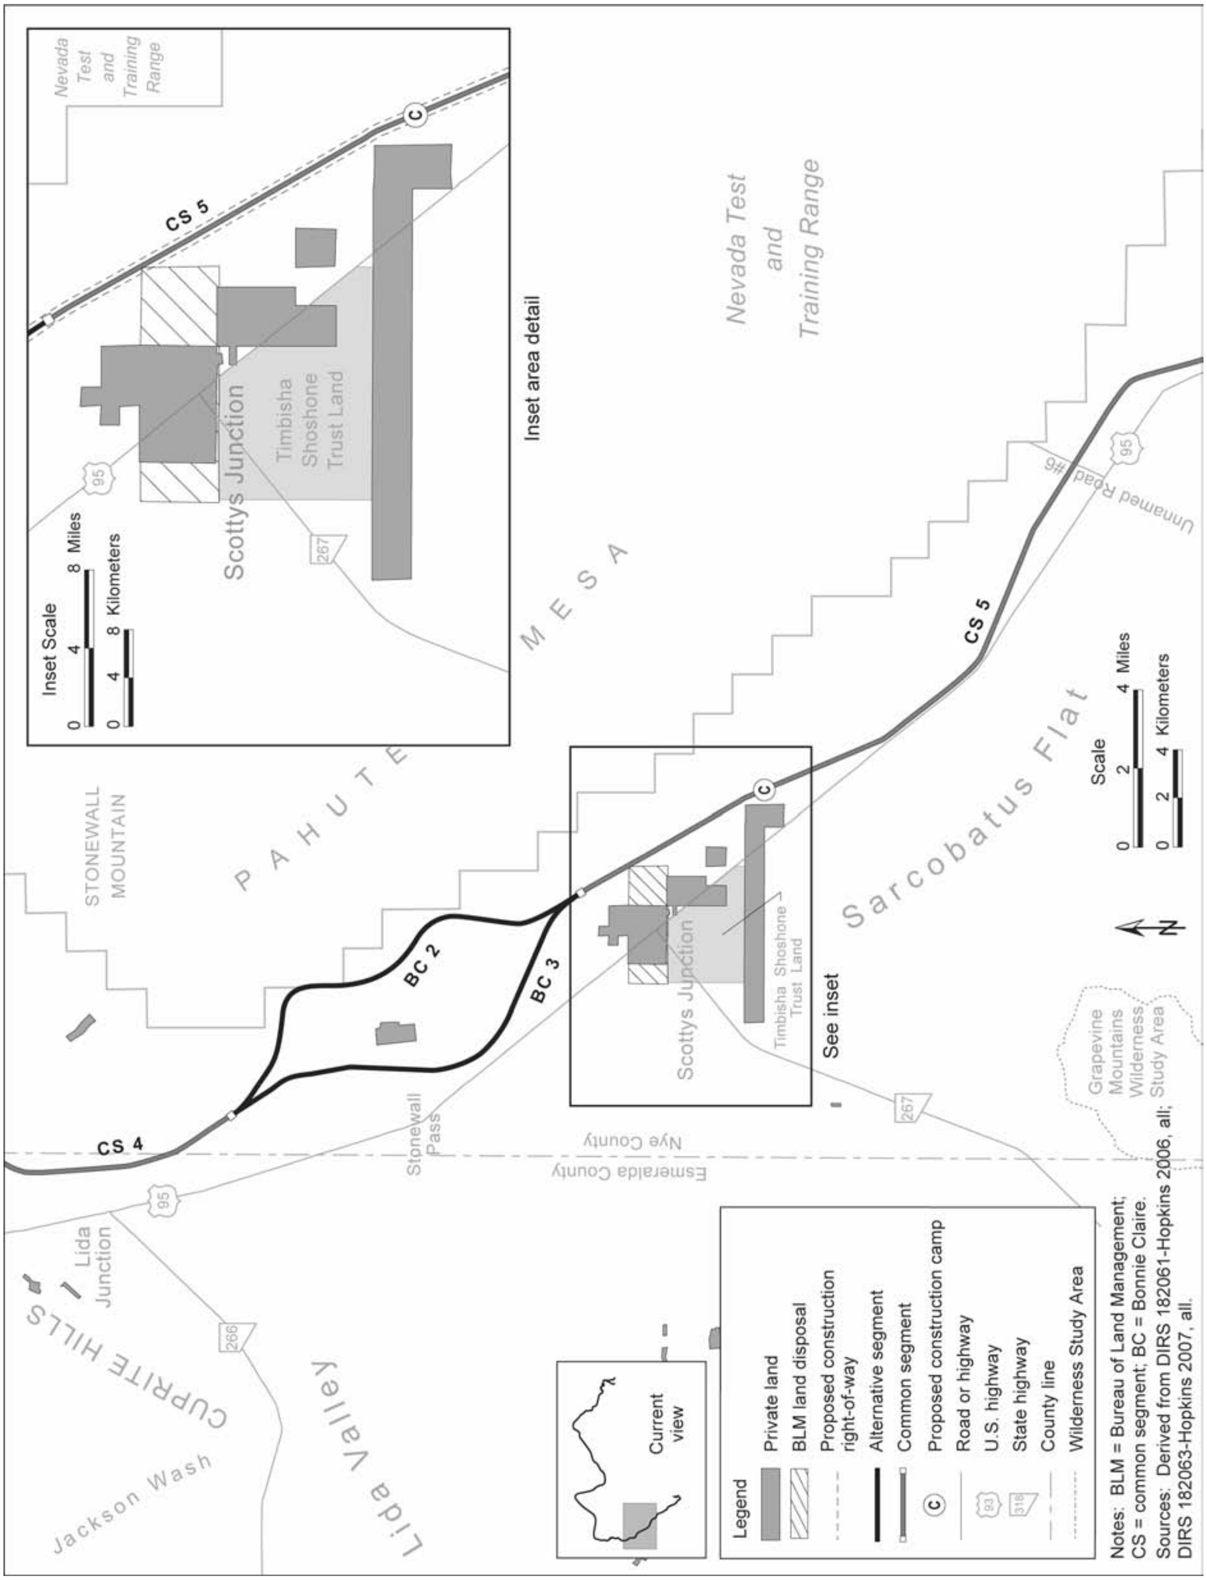

Figure 3-24. Private land within map area 6.

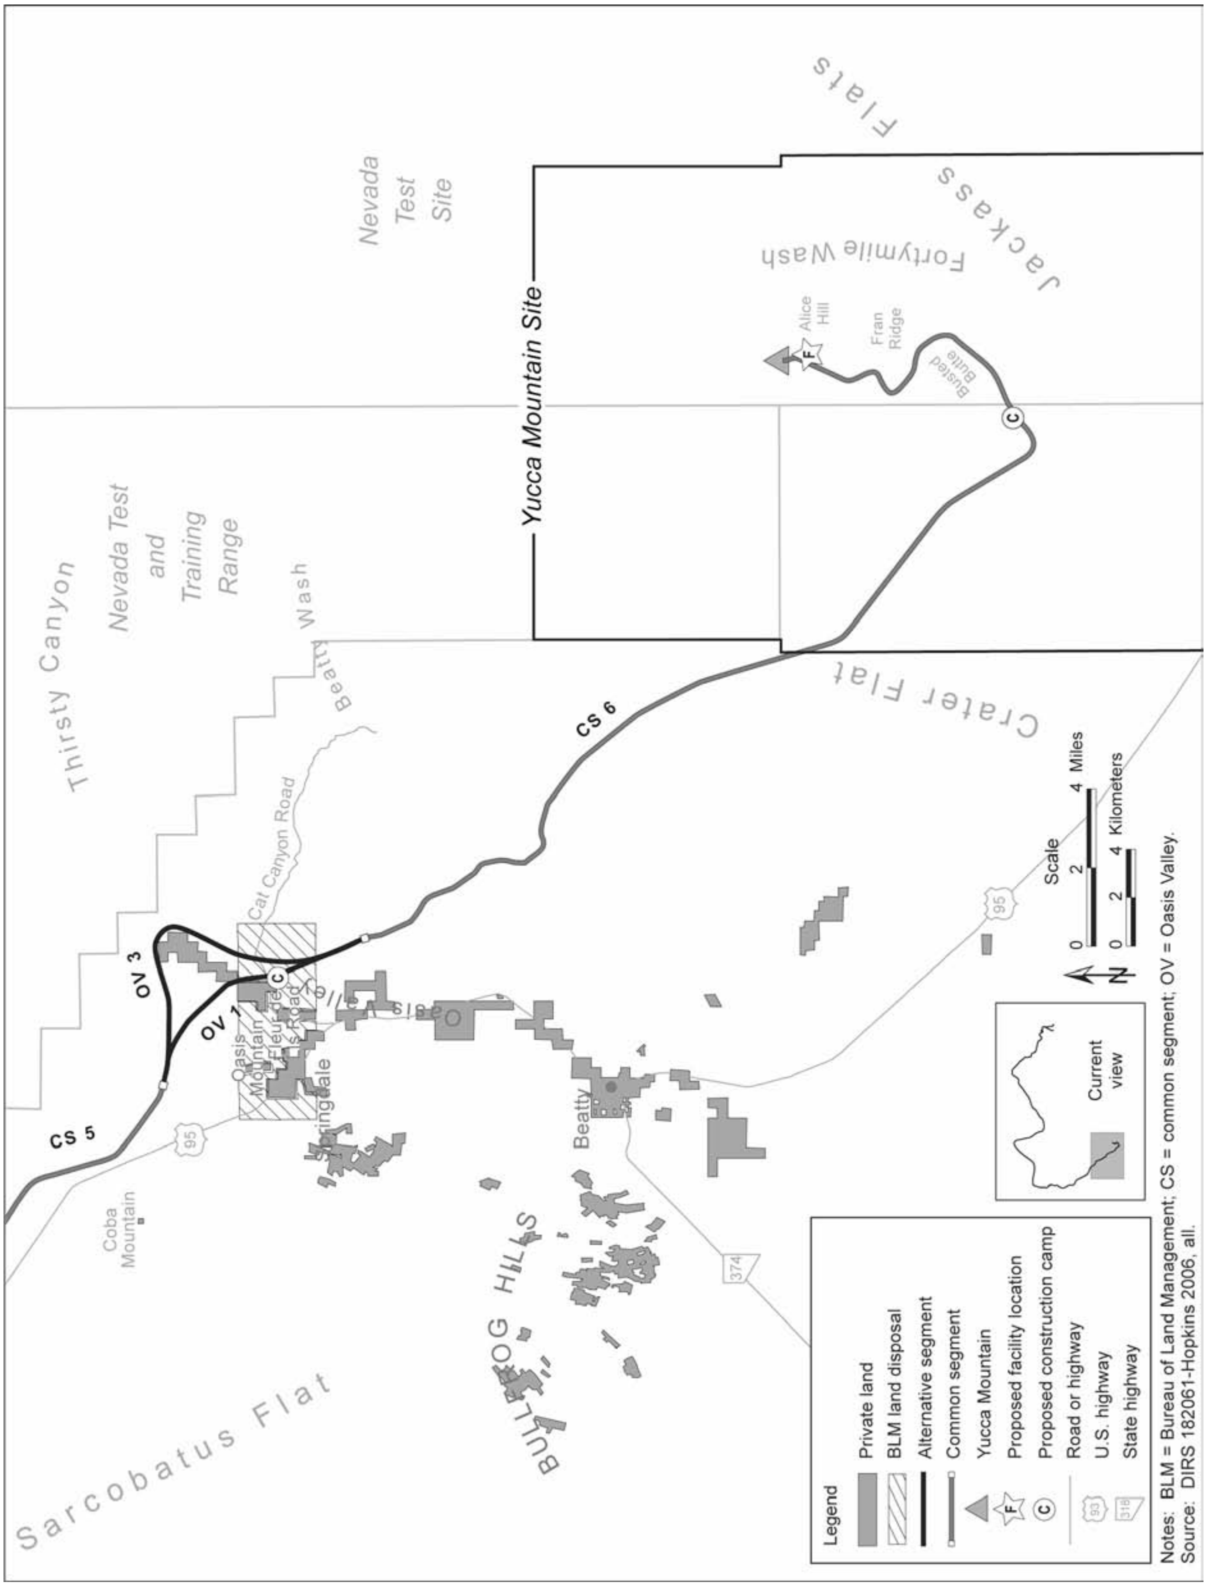

Figure 3-25. Private land within map area 7.

3.2.2.2.4 Pioche and Prince Branchline

There is an abandoned rail line from the former Union Pacific Railroad, Pioche and Prince Branchline in Caliente, which runs north generally parallel to U.S. Highway 93 (see Figure 3-14). The Union Pacific Railroad acquired the primary segments of right-of-way comprising the Pioche and Prince Branchline between 1901 and 1907. The Railroad retired the line on February 11, 1984, and received a certification of abandonment from the Interstate Commerce Commission to discontinue part of its operation in Nevada on the spur (DIRS 176910-IDT 2006, p. 7).

To be conservative in the assessment of potential land-use impacts, DOE assumed that all of the land underlying this abandoned rail line is privately owned. However, it is important to note that DOE is considering using this abandoned rail line for the proposed rail line to minimize potential impacts to environmental resources, such as wetlands.

3.2.2.3 American Indian Land

The closest American Indian land to the Caliente rail alignment would be the Timbisha Shoshone Trust Land. The Timbisha Homeland Act transferred 31.4 square kilometers (7,754 acres) of land into trust for the Timbisha Shoshone Tribe. The land is not contiguous; it is made up of five separate parcels in California and Nevada. The parcel near Scottys Junction covers approximately 11.39 square kilometers (2,800 acres).

During the first public scoping period for this Rail Alignment EIS, the Timbisha Shoshone Tribe requested that DOE alter the Caliente rail alignment to avoid their land (DIRS 174558-Sweeney 2004, all). DOE adjusted the proposed ***rail route*** based on this request, and the segment nearest the Timbisha Shoshone Trust Land near Scottys Junction, common segment 5, would be more than 3 kilometers (2 miles) east, as shown in Figure 3-24.

3.2.2.4 Public Land

Several agencies manage public lands near or encompassing the Caliente rail alignment, including the BLM, DOE, the U.S. Department of Defense, and the U.S. Forest Service.

The BLM and DOE manage approximately 159 square kilometers (39,000 acres) and 4.1 square kilometers (1,100 acres), respectively, of land that would be within the rail line construction right-of-way. The U.S. Department of Defense and the U.S. Forest Service manage lands near the Caliente rail alignment, but those lands would be outside the rail line construction right-of-way.

3.2.2.4.1 BLM-Administered Land

Approximately 97 percent of the lands along the Caliente rail alignment are BLM-administered public lands. Therefore, the proposed railroad project would in large part be subject to BLM land-use plans. The BLM manages public lands under the multiple-use concept, which balances the present and future needs of the American people. The BLM implements this concept through resource management plans, which are long-range, comprehensive land-use plans intended to provide for multiple uses and identify planning objectives and policies for designated areas. Resource management plan objectives are implemented through activity plans, such as allotment management plans and wildlife habitat management plans.

BLM resource management plans that apply to the Caliente rail alignment are included in the following:

- *Draft - Resource Management Plan/Environmental Impact Statement for the Ely District* (Draft Ely District Resource Management Plan; DIRS 174518-BLM 2005, all)
- *Tonopah Resource Management Plan and* ***Record of Decision*** (Tonopah Resource Management Plan; DIRS 173224-BLM 1997, all)
- *Record of Decision for the Approved Las Vegas Resource Management Plan and Final Environmental Impact Statement* (Las Vegas Resource Management Plan; DIRS 176043-BLM 1998, all)

The BLM issued the Draft Ely District Resource Management Plan in June 2005. The Caliente and Eccles alternative segments, all of Caliente common segment 1, all of the Garden Valley alternative segments, and the beginning of Caliente common segment 2 would be within the area covered by the Draft Ely District Resource Management Plan. Most of the rail alignment would then pass through lands covered by the Tonopah Resource Management Plan. A portion of common segment 6 would pass through lands covered by the Las Vegas Resource Management Plan; the section of common segment 6 that would be on the Nevada Test Site also falls within the BLM Las Vegas area but is managed by DOE. Table 3-5 lists the distances each Caliente rail alignment segment would pass through lands administered by the various BLM districts.

Areas of Critical Environmental Concern are places within the public lands where special management attention is required to protect and prevent irreparable damage to important historic, cultural, or scenic values, fish and wildlife resources, and other natural systems or processes, or to protect life and safety from natural hazards (DIRS 181386-BLM 2001, p. 2).

To construct and operate the proposed railroad along the Caliente rail alignment, DOE would apply for a BLM ***right-of-way grant***. Section 503 of the Federal Land Policy and Management Act (DIRS 181386-BLM 2001; 43 United States Code [U.S.C.] 1761) authorized the BLM to grant, issue, or renew rights-of-way over, upon, under, or through public lands. BLM policy is to encourage prospective applicants to locate their proposals within existing corridors. Resource management plans describe these corridors and right-of-way avoidance areas – areas for which the BLM would avoid granting new rights-of-way unless there are no other options. ***Areas of Critical Environmental Concern*** are generally considered right-of-way avoidance areas.

Resource management plans also designate areas of potential land disposal (sale) within their management areas. Therefore, DOE must assess whether a railroad along the Caliente rail alignment would conflict with or adversely affect BLM land-disposal plans. Section 203(a) of the Federal Land Policy and Management Act allows for public land to be sold (disposed of) if it meets one of the following criteria:

- The land is difficult or uneconomic to manage as a part of the public lands.
- The land is not suitable for management by another federal department or agency.
- The land was acquired for a specific purpose and it is no longer required for that, or any other, federal purpose.
- Disposal of the land will serve important public objectives that can be achieved prudently or feasibly only if the land is removed from public ownership and these objectives outweigh other public objectives or values that will be served by maintaining the land in federal ownership.

Table 3-5. Caliente rail alignment crossing distances within each BLM resource management plan area.

Rail line segment	Ely District/Draft Resource Management Plan area (kilometers)[a,b]	Battle Mountain District/Tonopah Resource Management Plan area (kilometers)	Las Vegas District/Resource Management Plan area (kilometers)
Caliente alternative segment	18	0	0
Eccles alternative segment	19	0	0
Caliente common segment 1	110	0	0
Garden Valley alternative segment 1	35	0	0
Garden Valley alternative segment 2	35	0	0
Garden Valley alternative segment 3	37	0	0
Garden Valley alternative segment 8	37	0	0
Caliente common segment 2	31	19	0
South Reveille alternative segment 2	0	19	0
South Reveille alternative segment 3	0	19	0
Caliente common segment 3	0	110	0
Goldfield alternative segment 1	0	47	0
Goldfield alternative segment 3	0	50	0
Goldfield alternative segment 4	0	53	0
Caliente common segment 4	0	11	0
Bonnie Claire alternative segment 2	0	21	0
Bonnie Claire alternative segment 3	0	19	0
Common segment 5	0	40	0
Oasis Valley alternative segment 1	0	10	0
Oasis Valley alternative segment 3	0	14	0
Common segment 6	0	38	13
Total rail alignment distance by BLM district (shortest to longest alignment)	198 to 201	316 to 327	13

a. To convert kilometers to miles, multiply by 0.62137.
b. Individual segment lengths are rounded to two significant figures.

Sections 3.2.2.4.1.1 through 3.2.2.4.1.3 describe the planning areas and objectives of the applicable Resource Management Plans in relation to lands and realty, corridors, and access and recreation.

3.2.2.4.1.1 Draft Ely District Resource Management Plan. The Ely District Planning Area consists of public lands in White Pine County, Lincoln County, and a portion of Nye County in east-central Nevada. This district was previously subdivided into three resource areas (Egan, Schell, and Caliente) but would be managed as a single administrative unit under this Resource Management Plan. The Ely Field Office manages approximately 46 square kilometers (11 million acres) of public lands out of the approximately 56 square kilometers (14 million acres) within the boundaries of the district (DIRS 174518-BLM 2005, Executive Summary p. 7). Of this planning area, the BLM manages 5,400 square kilometers (1.34 million acres) in Nye County, 18,000 square kilometers (4.44 million acres) in White Pine County, and 23,000 square kilometers (5.62 million acres) in Lincoln County (DIRS 174518-BLM 2005, pp. 2.5-112). Draft management objectives (under the Draft Resource Management Plan preferred alternative) related to land tenure adjustments, corridors, and access are listed below (DIRS 174518-BLM 2005, Section 2.5.12).

- Land and realty
  - Retain public land or interest in land that would contribute to the restoration and health of land within the district.
  - Existing or newly designated Areas of Critical Environmental Concern totaling approximately 1,400 square kilometers (350,000 acres) would be withdrawn from ***surface entry***. (There are no Areas of Critical Environmental Concern within the Caliente rail alignment region of influence; the closest Area of Critical Environmental Concern would be 60 kilometers [37 miles] away.)
  - Dispose of land in designated areas (approximately 390 square kilometers [96,000 acres]). (Some of this land could be in the vicinity of the Caliente and Eccles alternative segments.)
- Corridors
  - Designated corridors would be 0.8 kilometer (0.5 mile) wide.
  - Proactively designate new corridors and communication sites.
  - Land Use Authorizations (rights-of-way, permits, leases, and easements) would be issued on a case-by-case basis. Areas of Critical Environmental Concern would be avoidance or exclusion areas.
- Access and recreation
  - Off-highway vehicle use would be restricted to designated roads and trails; recreation management on approximately 3,000 square kilometers (730,000 acres) would emphasize off-highway vehicle use of designated roads and trails.
  - Emphasis would be to promote recreation across a wide spectrum of opportunities, both developed and undeveloped.

3.2.2.4.1.2 Tonopah Resource Management Plan. Located in south-central Nevada in Nye and Esmeralda Counties, the Tonopah Planning Area encompasses approximately 25,000 square kilometers (6.1 million acres) of public land and approximately 670 square kilometers (165,000 acres) of private land. Significant resources and program emphases include locatable minerals, livestock grazing, wild horses and burros, realty, cultural resources, and wildlife (DIRS 173224-BLM 1997, p. 1). Relevant land-use management objectives related to land and realty, corridors, and access are summarized below.

- Land and realty
  - Discretionary disposal of approximately 274 square kilometers (68,000 acres) of public land (DIRS 173224-BLM 1997, p. 2). Approximately 931 square kilometers (230,000 acres) have been identified for potential disposal in the vicinity of Goldfield, about 23 square kilometers (5,800 acres) have been identified for potential disposal near Scottys Junction, and approximately 160 square kilometers (39,000 acres) have been identified for potential disposal near Beatty (acreage based on BLM GIS data, DIRS 181617-Hopkins 2007).
- Corridors
  - Approximately 1,100 kilometers (670 miles) designated for transportation and utility corridors in the planning area (DIRS 173224-BLM 1997, p. 2).
  - Rights-of-way allowed (if compatible with values) on approximately 600 square kilometers (150,000 acres) (DIRS 173224-BLM 1997, p. 2). (There are no right-of-way exclusion areas within the Caliente rail alignment region of influence.)

  - Designated right-of-way corridors within the planning area will be 5 kilometers (3 miles) wide except where there are topographic constraints. Grants for rights-of-way are still required for facilities placed within designated corridors. Designation of a corridor does not mean that future rights-of-way are restricted to corridors, nor does it mean that the BLM has committed to approving all right-of-way applications within corridors (DIRS 173224-BLM 1997, p. A-38).
- Access and recreation
  - Vehicles unrestricted on 77 percent of the planning area.
  - Vehicles limited to existing roads and trails in primitive and semi-primitive non-motorized and semi-primitive motorized areas.
  - Designates seven Special Recreation Management Areas (DIRS 173224-BLM 1997, p. 2).

3.2.2.4.1.3 Las Vegas Resource Management Plan. The Las Vegas Resource Management Plan provides a comprehensive framework for managing approximately 13,000 square kilometers (3.3 million acres) of public lands in Clark County and the southern portion of Nye County administered by the BLM Las Vegas Field Office. Approximately 2,830 square kilometers (700,000 acres) of this planning area is in Nye County. Significant resources and program emphases in the plan include threatened and ***endangered species***; land disposal actions; wilderness management; wildlife habitat; special status species; ***riparian*** areas; forestry and vegetative products; livestock grazing; wild horses and burros; land acquisition priorities; rights-of-way; cultural resources; hazardous materials management; recreation; utility corridors; and minerals (DIRS 176043-BLM 1998, p. 2). Relevant land-use management objectives related to land and realty, corridors, and access are summarized below (DIRS 176043-BLM 1998, Appendix A, p. 16).

- Land and realty
  - Dispose of approximately 710 square kilometers (175,000 acres) of public lands through sale, exchange or recreation and public-purpose patent to provide for the orderly expansion and development of southern Nevada.
  - All public lands within the planning area, unless otherwise classified, segregated or withdrawn, and with the exception of Areas of Critical Environmental Concern and ***Wilderness Study Areas***, are available for land-use leases and permits at the discretion of the BLM.
  - Terminate or modify any unused, outdated, or unnecessary classifications/segregations and withdrawals on public lands to reduce the area of segregation in the plan area.
  - Acquire private lands to enhance the recovery of special status species, protect valuable resources, and facilitate the management of adjacent BLM lands.
- Corridors

  All Areas of Critical Environmental Concern and all lands within 0.4 kilometer (0.25 mile) of significant caves, exclusive of any designated corridors, are designated as right-of-way avoidance areas. (There are no Areas of Critical Environmental Concern within the Caliente rail alignment region of influence; the closest area is 140 kilometers [84 miles] south of common segment 6.)
- Access and recreation
  - Ensure that a wide range of recreation opportunities are available for recreation users in concert with protecting the natural resources on public lands that attract users.
  - Provide opportunities for off-road vehicle use while protecting wildlife habitat, cultural resources, hydrological and soil resources, non-motorized recreation opportunities, natural and aesthetic values, and other uses of the public land.

The Las Vegas Proposed Resource Management Plan/Final Environmental Impact Statement briefly mentions the Yucca Mountain Project in sections titled "Income and Employment" and "Social Setting, Attitudes, and Values." In the Income and Employment section the document notes that there could be population growth in Amargosa Valley as a result of construction and operation of the Yucca Mountain Project. In the Social Setting, Attitudes, and Values section the document notes that people residing in Las Vegas (urbanites) expressed a higher concern than people residing in rural locations about wildlife and ***ecosystem*** values when recording their risk assessment for the proposed Yucca Mountain Project in a 1995 social research survey conducted by the University of Nevada Las Vegas (DIRS 176043-BLM 1998, pp. 3-81 and 3-82).

3.2.2.4.2 Project-Related Public Land Withdrawals

The BLM announced Public Land Order 7653 on December 28, 2005 (70 *Federal Register* [*FR*] 76854). The Order withdrew approximately 1,249 square kilometers (308,600 acres) of public lands within the Caliente rail corridor from surface and mineral entry for 10 years to allow DOE to evaluate the lands for the potential construction, operation, and maintenance of the proposed railroad to Yucca Mountain. The withdrawal applies only to BLM-administered public lands. The withdrawal area extends approximately 0.8 kilometer (0.5 mile) from either side of the centerline of the proposed rail alignment. The actions covered by this withdrawal meet the BLM definition of ***casual use*** as set forth in 43 Code of Federal Regulations (CFR) 2801.5. On January 10, 2007, the BLM announced that DOE had filed an application requesting a second land withdrawal (72 *FR* 1235). The Department filed the application to cover post-scoping changes in the Caliente rail alignment and to address the addition of the Mina rail alignment. The application requested the withdrawal of an additional 842 square kilometers (208,037 acres) of public lands from surface and mineral entry through December 27, 2015, so DOE could evaluate the lands for the potential construction, operation, and maintenance of a railroad to Yucca Mountain. Chapter 6 of this Rail Alignment EIS includes detailed information about the land withdrawal process.

The BLM granted DOE a right-of-way reservation (N-47748) for Yucca Mountain ***site characterization*** activities (DIRS 102218-BLM 1988, all). This reservation comprises 210 square kilometers (52,000 acres). The land in this reservation is open to public use, with the exception of about 20 square kilometers (5,000 acres) near the site of the proposed ***repository*** that were withdrawn in 1990 from the mining and mineral leasing laws to protect the physical integrity of the repository block. The lands in

Withdrawal: Withholding an area of federal land from settlement, sale, location, or surface entry under some or all of the general land laws, for the purpose of limiting activities under those laws to maintain other public values in the area or reserving the area for a particular public purpose or program

Casual use: Activities ordinarily resulting in no or negligible disturbance of the public lands, resources, or improvements. Examples of casual use include surveying, marking routes, and collecting data to use to prepare grant applications.

Right-of-way: The public lands the BLM authorizes a holder to use or occupy under a grant.

Grant: Any authorization or instrument (for example, easement, lease, license, or permit) the BLM issues under Title V of the Federal Land Policy and Management Act (43 U.S.C. 1761 *et seq.*).

Mineral entry closure: The land is not available for the location of mining claims because the land has been withdrawn from public use, including the operation of the General Mining Law (DIRS 181386-BLM 2001, 43 CFR 3830.5).

Surface entry closure: Land closed to surface entry cannot be used for appropriation of any non-federal interest or claim (other than mining claims), land sales, any public land disposal action, or other action that would cause the title for the land to be transferred away from the Federal Government (DIRS 176452-DOE 2005; 43 CFR 3809.5).

this reservation are not withdrawn from the mining and mineral leasing laws and contain a number of ***unpatented mining claims*** (DIRS 155970-DOE 2002, p. 3-9). This existing right-of-way reservation would be the basis for the planned land withdrawal for the Yucca Mountain Site, as described in the *Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DIRS 155970-DOE 2002, DOE/EIS-0250F-S1), where the land would transfer from BLM administrative responsibility to DOE control.

3.2.2.4.3 Department of Defense-Managed Land, Nevada Test and Training Range

The U.S. Department of Defense administers the Nevada Test and Training Range, which the U.S. Air Force uses for training. The Caliente rail alignment would not cross onto the Nevada Test and Training Range land. Detailed information about land use and resources on the Nevada Test and Training Range is available in the *Proposed Nevada Test and Training Range Resource and Management Plan and Final Environmental Impact Statement* (DIRS 178103-BLM 2003, all).

The airspace above the Nevada Test and Training Range and some adjacent locations consist of the Desert and Reveille Military Operations Areas and five "restricted areas": R-4806E, R-4806W, R-4807A, R-4807B, and R-4809 (DIRS 103472-USAF 1999, p. 3.1-2).

Airspace to the east of the Nevada Test and Training Range is designated as the Desert Military Operations Area and airspace to the north is designated as the Reveille Military Operations Area. These Areas are used for air-to-air intercept training, which consists of high speed operations, abrupt maneuvers, and supersonic flight. These areas are not considered restricted airspace and civil aircraft, under certain restrictions, are permitted to fly through a military operations area when it is in use while exercising certain precautions. Civil aircraft are allowed in these locations because the types of military flight maneuvers conducted in these areas are considered nonhazardous and therefore, compatible, with other airspace uses (DIRS 103472-USAF 1999, pp. 3.1-4 and 3.1-6). Portions of the Caliente rail alignment that would be on land under the Desert Military Operations Area include the Caliente and Eccles alternative segments; Caliente common segment 1; Garden Valley alternative segments 1, 2, 3, and 8; Caliente common segment 2, South Reveille alternative segments 2 and 3; and a portion of Caliente common segment 3. More than half the length of common segment 3 would be on land under the Reveille Military Operations Area.

Restricted airspace consists of areas where nonparticipating aircraft are subject to restriction during scheduled periods when hazardous activities are being performed. Restricted areas designated as joint use by the Federal Aviation Administration allow air traffic control to route non-participating aircraft through this airspace when it is not in use or when appropriate separation can be provided. Those areas not designated as joint use cannot be accessed by either nonparticipating civil or military aircraft at any time (DIRS 103472-USAF 1999, p. 3.1-3).

Restricted area R-4807A is designated joint use and land beneath it is comprised of an electronic battlefield with numerous tactical targets and manned electronic combat threat simulators. Portions of the Caliente rail alignment that would be on land below R-4807A include portions of common segment 5; the Oasis Valley alternative segments 1 and 2; and a portion of common segment 6 (DIRS 103472-USAF 1999, pp. 3.1-3, 3.1-4, and 3.1-6).

Restricted area R-4808S is controlled by DOE for Nevada Test Site activities and is designated joint use. The Federal Aviation Administration Los Angeles Air Route Traffic Control Center also uses R-4808S for civil aircraft overflights (DIRS 103472-USAF 1999, pp. 3.1-3, 3.1-4, and 3.1-6). A portion of common segment 6 would be on land below R-4808S as it approached the Yucca Mountain Site.

3.2.2.4.4 DOE-Managed Land, Nevada Test Site

Portions of common segment 6 and some railroad operations support facilities would be on Nevada Test Site land (see Figure 3-25), which DOE administers. Detailed information about current and future uses of the Nevada Test Site is available in *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996, all). As discussed previously, land that makes up the proposed Yucca Mountain Site would be withdrawn and transferred to DOE control. Currently, a Memorandum of Agreement between the DOE National Nuclear Security Administration and the Office of Civilian Radioactive Waste Management allows the use of about 230 square kilometers (58,000 acres) on the Nevada Test Site for Yucca Mountain Project activities.

3.2.2.4.5 U.S. Forest Service Land

The Caliente rail alignment would pass within 3.2 kilometers (2 miles) of a portion of the Humboldt-Toiyabe National Forest, which the Ely Ranger District of the U.S. Forest Service manages and which would be outside the rail line construction right-of-way.

3.2.2.5 General Environmental Setting and Land-Use

Major public land uses along the Caliente rail alignment include grazing, mineral and energy extraction, and recreation. The rail alignment would cross numerous public roads and trails that provide access to public and private land and would cross BLM-authorized rights-of-way for utilities.

3.2.2.5.1 BLM Grazing Allotments

The Taylor Grazing Act of 1934 (43 U.S.C. 315-3160), as amended, authorizes the Federal Government to issue permits for grazing livestock in grazing districts to settlers, residents, and other livestock owners for an annual payment of reasonable fees. An applicant who owns a base property or controls a water source may apply to the BLM for a lease or permit to use public lands for the grazing of livestock. The BLM grazing administration regulations (43 U.S.C. 4100.0-5) define a base property as land that has the capability to produce crops or forage that can be used to support authorized livestock for a specified period of the year, or water that is suitable for consumption by livestock and is available and accessible to livestock when the public lands are used for livestock grazing. The grazing allotments are leased or permitted for 10 years and may be renewed under specific circumstances.

Livestock permitted on grazing allotments include cattle, sheep, goats, horses, and burros. Cattle and sheep are the typical livestock grazed within the Caliente rail alignment region of influence. The grazing lease or permit specifies the types and numbers of livestock based on the property acreage, the period of use, and the amount of use in ***animal unit months***. The intent of assigning animal unit months is to allow grazing on public lands without exceeding the capacity of the allotment to sustain livestock (43 CFR Part 4100).

> **Animal unit month:** A standardized unit of measurement of the amount of forage necessary for the complete sustenance of one animal for 1 month; also, a unit of measurement of grazing privileges that represents the privilege of grazing one animal for 1 month (43 CFR Part 4100).

Depending on the combination of common segments and alternative segments, the Caliente rail alignment would cross up to 24 active grazing allotments, and 3 inactive allotments (Ralston, Montezuma, and one labeled Unused) (see Figures 3-26 through 3-33). Tables 3-6 and 3-7 list information about grazing allotments within the Caliente rail alignment region of influence.

Montezuma[e]	2,180		Goldfield alternative segment 4 would cross six pipelines.
Razorback[e]	300	959	None
Unused[f]	2,130		None

a. To convert square kilometers to acres, multiply by 247.10. Land area values rounded to two significant digits except values over 1,000, which are rounded to the nearest 10.
b. Source: GIS for water resources.
c. Source: DIRS 174518-BLM 2005.
d. Agreement decision stating permittee will take non-use (voluntary or for conservation and protection of range lands). Therefore, total active use occurring on the allotment would be less than shown.
e. Source: DIRS 173224-BLM 1997 (area of allotment may include private land).
f. Source: DIRS 173845-Resource Concepts 2005.

Access to a water source is an essential requirement for livestock grazing in the high desert of Nevada. In accordance with the Nevada State Water Law, the State Engineer in the Nevada Division of Water Resources may issue permits for water rights to applicants who can demonstrate a beneficial use for the water. Once permitted, water rights are treated as property rights and can be bought and sold

(DIRS 178301-State of Nevada [n.d.], all). Because water rights greatly influence the uses and value of land in this generally arid region, any impacts to water rights can directly affect land use. (See Section 3.2.6 for a description of ***groundwater*** resources.)

It is essential to provide adequate water for livestock within reasonable distances of grazing areas. Stockwater is water that is physically diverted from the natural water course or storage of water for use by livestock or wildlife. There are several methods for developing stockwater, including spring developments; wells, ponds, or dugouts; and pipelines with a trough or tank for storage. Table 3-7 lists stockwater features within each Caliente rail alignment segment.

3.2.2.5.2 Mineral and Energy Resources

3.2.2.5.2.1 Mineral Resources. Commercial prospecting for minerals of value began in southern Nevada in the mid-1800s and continues to the present. Minerals currently mined include metallic and nonmetallic minerals. Gold and silver are the most valuable metallic minerals mined in Nevada. Nonmetallic minerals include borate, limestone, clay, building stones, silica, aggregates, gypsum, and salt used in industrial processes and building materials (DIRS 150524-Tingley 1998, all).

There is potential mining activity on private land (patented mining claims) and public land (unpatented mining claims). Figure 3-34 shows mining districts and areas near the Caliente rail alignment. Figures 3-34 through 3-41 show the locations of sections with unpatented mining claims in relation to the construction right-of-way.

The Caliente rail alignment would cross some ***mining areas*** and mining districts, as discussed below. Section 4.2.2.2.3 discusses potential impacts to individual mining claims.

Caliente common segment 1 would cross the northernmost portion of the Seaman Range Mining District. The vast majority of historic mining activity in the district occurred more than 5 kilometers (3 miles) south and southwest of Caliente common segment 1 (DIRS 173841-Shannon & Wilson 2005, p. 104). In the past, this district has been mined for mercury, uranium, gold, zinc, copper, and jasperoid.

The South Reveille alternative segments and Caliente common segment 3 would pass within 2 miles of the Reveille Valley Mining Area. Exploration work in this area since 1988 has focused on finding near-surface, bulk-mineable, precious metal mineralization. Redhawk Resources is conducting this exploration under a 90-year lease agreement with private owners under the Alien Gold Project (DIRS 173841-Shannon & Wilson 2005, pp. 95 and 96).

A portion of Caliente common segment 3 would cross the Clifford Mining District, which is near Warm Springs. The Clifford Mining District is generally south of U.S. Highway 6 in Stone Cabin Valley, trending southwest from Warm Springs. The geology of this district is favorable for gold and silver (DIRS 173841-Shannon & Wilson 2005, pp. 83 to 86). Ore-grade mineralization and exploration programs in the area have led to gold production.

Goldfield alternative segments 1, 3, and 4 would cross the Goldfield Mining District. Goldfield is the largest center of mining within the region of influence. The Goldfield Mining District consists of the Goldfield Main, McMahon Ridge, and Gemfield areas, and is in the Goldfield Hills to the northeast and southwest of Goldfield, Nevada. An additional area (referred to as the Tom Keane area) has been the subject of 2003 exploration efforts. The Goldfield Project, owned by Metallic Ventures Gold, Inc., consists of 385 patented and 849 unpatented claims (wholly owned or controlled) covering more than 83 square kilometers (20,600 acres) in Esmeralda and Nye Counties (DIRS 173841-Shannon & Wilson 2005, pp. 60, 62, and 72).

Sources: Derived from DIRS 182061-Hopkins 2006, all; DIRS 182063-Hopkins 2007, all.

Figure 3-41. Mineral and energy resources within map area 7.

Goldfield alternative segment 1 would cross the Diamondfield Mining District, which is approximately 8 kilometers (5 miles) northeast of Goldfield and is approximately 1.6 kilometers (1 mile) long. There is limited published information on this district, which is known to include ore bodies containing gold and silver. The total recorded value of production of the district is approximately $50,000, but actual production could be as much as $1 million to $2 million (DIRS 173841-Shannon & Wilson 2005, p. 70).

A portion of Caliente common segment 4 would cross the westernmost portion of the Stonewall Mining District, although most of the past mining activity in this district is approximately 5 kilometers (3 miles) east of the common segment. This district was reportedly prospected for gold and silver as early as 1905 (DIRS 173841-Shannon & Wilson 2005, p. 56). Veins of gold and silver currently under exploration in this district are prominent at areas mined in the past and continue easterly away from the rail alignment.

The Bonnie Claire alternative segments would be west of the Scottys Junction Mining Area and the Wagner Mining District would lie between these segments. Neither segment's construction right-of-way would cross these mining locations. The Wagner Mining District has a number of patented mining claims although none would fall within the construction right-of-way for either Bonnie Claire alternative segment. The main rock types within the Wagner Mining District are shale, quartzite, and intercalated limestone. There was evidence of active exploration efforts in this district by several companies in 2005 (DIRS 173841-Shannon & Wilson 2005, p. 55).

The closest mining districts to common segment 5 would be Clarkdale Mining District to its east and Bullfrog Mining District to its south where it would meet the Oasis Valley alternative segments. The Oasis Valley alternative segments are between the Bullfrog Mining District and the Thirsty Canyon-Sleeping Butte Mining Area. The Clarkdale Mining District contains discontinuous, narrow zones containing some gold and silver mineralization (DIRS 173841-Shannon & Wilson 2005, p. 52). The Bullfrog Mining District contains small, localized areas of gold, silver and lesser copper mineralization (DIRS 173841-Shannon & Wilson 2005, p. 46). The Thirsty Canyon-Sleeping Butte Mining Area has been historically quarried for decorative rock and building stone (DIRS 173841-Shannon & Wilson 2005, p. 49).

Common segment 6 would cross the northeastern portion of the Bare Mountain Mining District, although the vast majority of past mining activity occurred more than 3 kilometers (2 miles) south of this common segment. The district contains gold-bearing veins, and some veins contain silver. The district also contains a variety of minerals and semi-precious stones, including opal, chalcopyrite, malachite, azurite, galena, pyrite, limonite, hematite, fluorite, fluorspar, and gypsum (DIRS 173841-Shannon & Wilson 2005, pp. 38, 41, and 42).

The only patented mining claims that would fall within or intersect the Caliente rail alignment construction right-of-way would be along the Goldfield alternative segments (see Table 3-4). Table 3-8 lists the number of sections containing unpatented mining claims the rail line construction right-of-way could cross. The existence of abandoned or active mining tunnels and shafts near the rail alignment would also be a concern for safety reasons. There are several tunnels, shafts, and underground mines within the construction right-of-way along the Goldfield alternative segments. There is one tunnel along Goldfield alternative segment 1, four underground mines/shafts along Goldfield alternative segment 3, and one tunnel along Goldfield alternative segment 4. DOE obtained the data on locations of tunnels and caves, mining shafts, and underground mines from the Nevada Bureau of Mines and Geology (DIRS 181617-Hopkins 2007). However, none of the tunnels, shafts, and underground mines in this dataset that fall within the construction right-of-way is identified as having been field verified by the Nevada Bureau of Mines and Geology. Furthermore, this dataset might not include very old tunnels, shafts, and underground mines that were not recorded.

3.2.2.5.2.2 Energy Resources. The Basin and Range Province is considered a favorable area for geothermal resources because it has higher-than-average heat flow and is an area of crustal expansion, where faults can provide permeable reservoirs and conduits for deep circulation of water, and the crust is so thin it has a higher-than-average heat flux. Several hundred wells have been drilled in Nevada to discover high-temperature geothermal steam resources (DIRS 173841-Shannon & Wilson 2005, p. 32).

Table 3-8. Number of unpatented mining claims that may intersect with the Caliente rail alignment construction right-of-way.[a]

Rail line segment	Numbers of sections with unpatented mining claims	Unpatented mining claims across all sections [b]
South Reveille 2	2	72
South Reveille 3	2	72
Caliente common segment 3	10	166
Goldfield 1	14	474
Goldfield 3	14	359
Goldfield 4	19	538
Caliente common segment 4	5	169
Oasis Valley 1	2	14
Oasis Valley 3	2	14
Common segment 6	4	34

a. Source: DIRS 181617-Hopkins 2007.
b. Data are provided by Township, Range, and Section and might not fall within the rail line construction right-of-way. DOE would need to verify the actual numbers and locations of unpatented mining claims before applying for a right-of-way grant.

Geothermal resources are present as hot springs and thermal waters near Caliente Hot Springs, Bennett Spring, Pedro Spring, Sarcobatus Flat, Scottys Junction, Panaca (Owl Warm Springs), Cedar Spring, Stonewall Flat, and Beatty Warm Springs (DIRS 173841-Shannon & Wilson 2005, pp. 23 and 24). There are geothermal occurrences (springs and wells) in Sarcobatus Valley along U.S. Highway 95 south of Scottys Junction (DIRS 173841-Shannon & Wilson 2005, p. 50). However, there would be no geothermal resources within the construction right-of-way of any of the Caliente rail alignment alternative segments or common segments.

Fourteen sections of land constitute a single oil and gas lease (one permittee) 19 kilometers (12 miles) north of Beatty along the southwest flank of Pahute Mesa in southern Nye County (DIRS 179587-Wilson 2007, all). For reference, a section is a unit of land equal to 2.6 square kilometers (1 square mile), as defined under the public land survey system. Oasis Valley alternative segment 3 would cross 7 of the 14 sections and Oasis Valley alternative segment 1 would cross 2 sections of this oil and gas lease block.

3.2.2.5.3 Recreation

This section describes the recreational areas within or near the Caliente rail alignment region of influence. Figures 3-42 through 3-49 show recreational areas near the Caliente rail alignment.

3.2.2.5.3.1 Lincoln County. There are two state parks in the vicinity of the Caliente rail alignment in Lincoln County. The Kershaw-Ryan State Park is approximately 2.4 kilometers (1.5 miles) south of the City of Caliente, along State Route 317 (Rainbow Canyon Road). This park is approximately 3.2 kilometers (2 miles) southwest of the Caliente alternative segment and not within the region of influence. The Cathedral Gorge State Park is 2.6 kilometers (1.6 miles) west of U.S. Highway 93, approximately 5.3 kilometers (3.3 miles) northeast of Caliente common segment 1, and not within the region of influence.

Recreation on BLM-administered lands in Lincoln County has traditionally been dispersed. Primary recreation activities in Lincoln County include hunting, camping, exploration and site-seeing, off-highway vehicle competition events, and rock-art viewing.

A **Back Country Byway** is a vehicle route that traverses scenic corridors utilizing secondary or back country road systems (DIRS 181598-BLM [n.d.]).

Under the preferred alternative of the Draft Ely District Resource Management Plan (DIRS 174518-BLM 2005, p. 2.4-36), the BLM would designate two ***Back Country Byways*** (Silver State Trail Byway and Rainbow Canyon Byway) near the Caliente rail alignment. The Silver State Off-Highway Vehicle Trail is approximately 420 kilometers (260 miles) long and consists of a series of existing backcountry roads that are open for use by off-highway vehicle enthusiasts. Caliente rail alignment common segment 1 would cross the most trails, including the Silver State Off-Highway Vehicle Trail in two places (see Figure 3-43). The northern portion of the proposed Rainbow Canyon Back Country Byway would include portions of U.S. Highway 93 in Caliente. The Caliente and Eccles alternative segments would cross the Byway. The Rainbow Canyon Back Country Byway is made up of paved and unpaved ***class 3 or 4 roads***.

The Draft Ely District Resource Management Plan preferred alternative would also designate Chief Mountain as an off-highway vehicle use emphasis area (see Figure 3-43). The Chief Mountain area is frequently used for off-highway vehicles. The south access point is at Oak Springs Summit on the north side of U.S. Highway 93 approximately 8 kilometers (5 miles) west of Caliente. Portions of common segment 1 would cross this proposed off-highway vehicle use emphasis area.

A number of BLM-permitted off-highway vehicle races and special recreation events take place annually in areas around the Caliente rail alignment common segments and alternative segments in Lincoln County (DIRS 178416-Nevada Rail Partners 2007, all). The largest number of BLM-approved race routes are in and around Caliente and Panaca, and the Eccles and Caliente alternative segments would each cross previously used routes approximately 10 times. Caliente common segment 1 would cross previously used routes approximately 20 times, primarily east of Dry Lake Valley and in the Pahroc Range. Recent off-highway vehicle events in the area have included the Las Vegas to Reno Race and the Silver State 300. Most approved race routes are on existing roads and trails.

There are two Wilderness Areas along the Caliente rail alignment in Lincoln County – the Weepah Springs Wilderness Area and the Worthington Mountains Wilderness Area. Caliente common segment 1 would be 1.6 kilometers (1 mile) from the Weepah Springs Wilderness Area at its closest point (see Figure 3-44). Caliente common segment 2 would be 0.9 kilometer (0.6 mile) from the Worthington Mountains Wilderness Area at its closest point (see Figure 3-45).

The Weepah Springs and Worthington Mountains Wilderness Areas are predominantly natural areas, with only some evidence of localized human activity. Recreational uses of both areas include day hiking; backpacking; caving; photography; horseback riding; rockhounding; big game and upland bird hunting; wildflower viewing; bird watching, sightseeing; and ***heritage tourism*** (DIRS 176796-Winslow 2006, p. 3).

Particularly scenic locales in these Wilderness Areas include natural arches, caves, vistas from the ridgeline of the Worthington Mountains and the summit of Timber Mountain in the Weepah Springs Wilderness Area. Caliente rail alignment common segment 2 would be 3.2 kilometers (2 miles) from the Humboldt-Toiyabe National Forest at its closest point. The Ely Ranger District of the U.S. Forest Service manages this part of the Forest, which is bordered by Railroad Valley on the west and Garden Valley on the east. Hunting, photography, wildlife viewing, camping, and hiking are the dominant recreation uses of the area. Most of the recreational use is along Little Cherry Creek and Hooper Canyon. Approximately 33 kilometers (21 miles) of poor- or very-poor-condition trails are either not used or are only lightly used (DIRS 176796-Winslow 2006, all). Access to this part of the Humboldt-Toiyabe National Forest is by unimproved roads from State Highway 318 or State Highway 375, which the Caliente rail alignment would not cross.

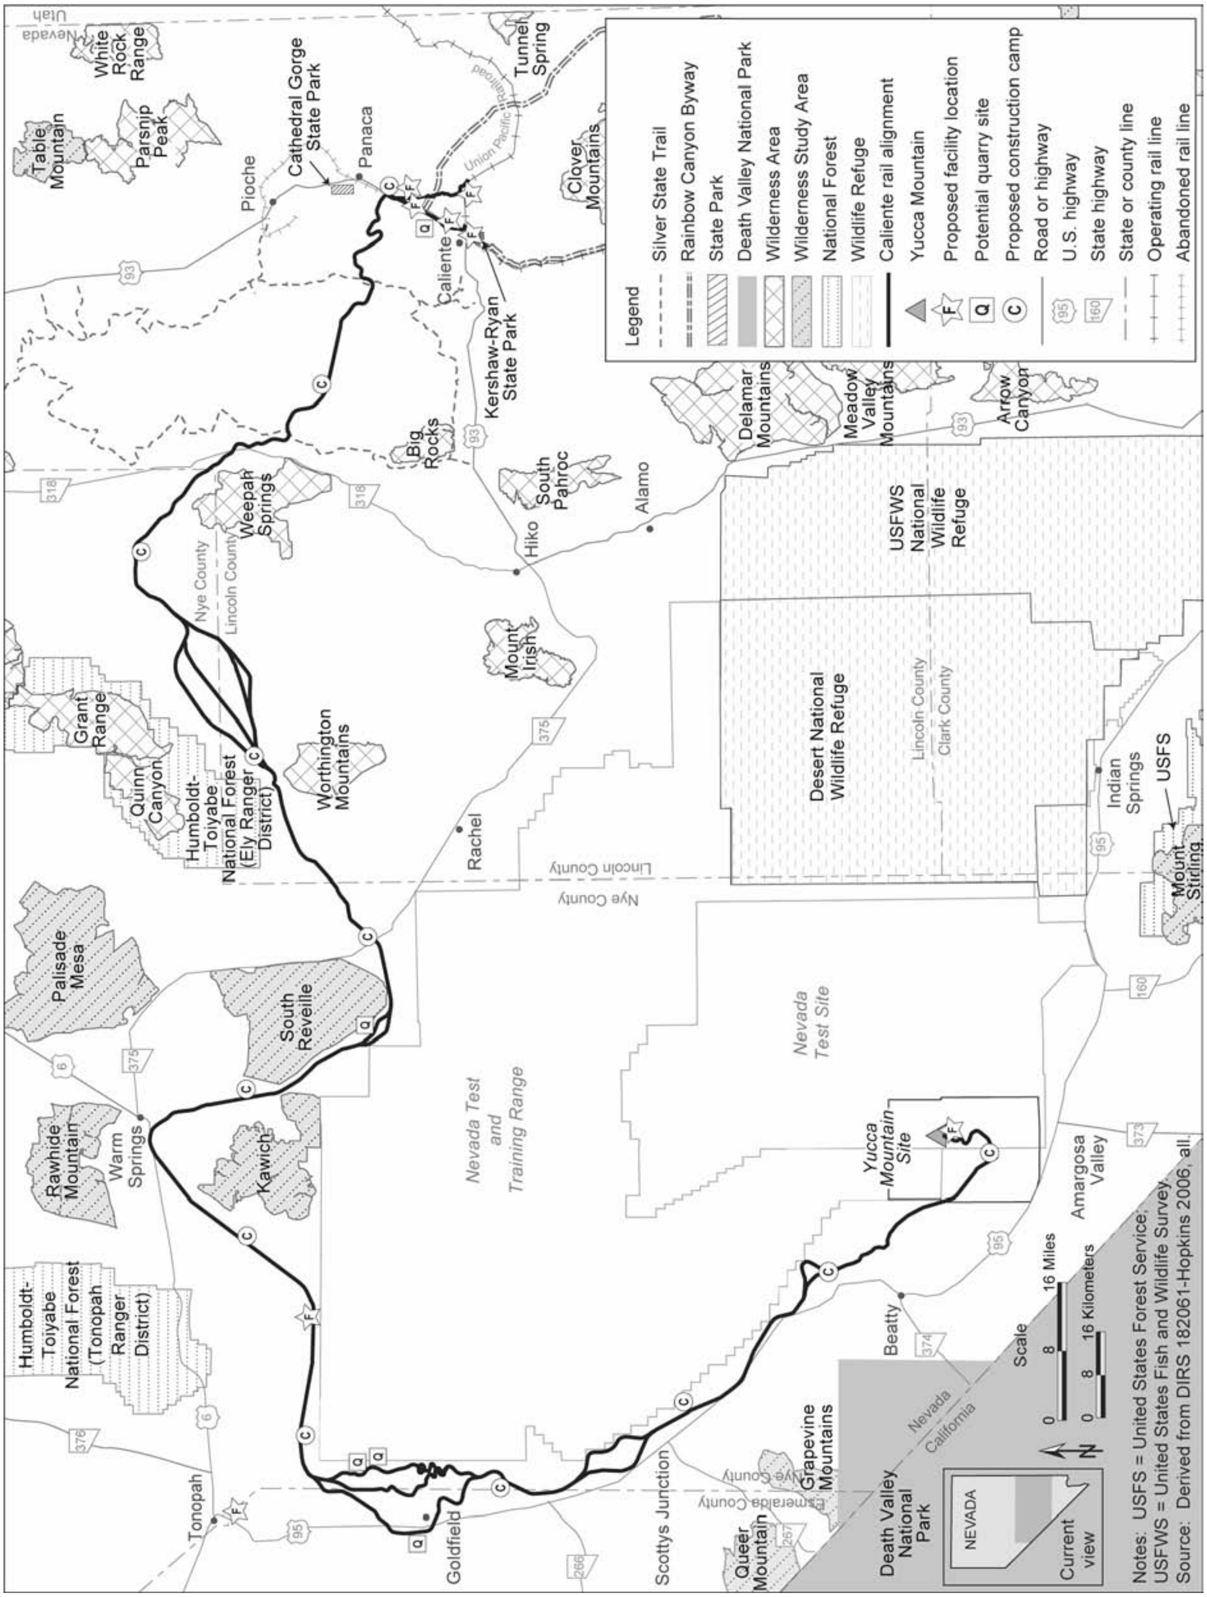

Figure 3-42. Recreation areas and roads along the Caliente rail alignment.

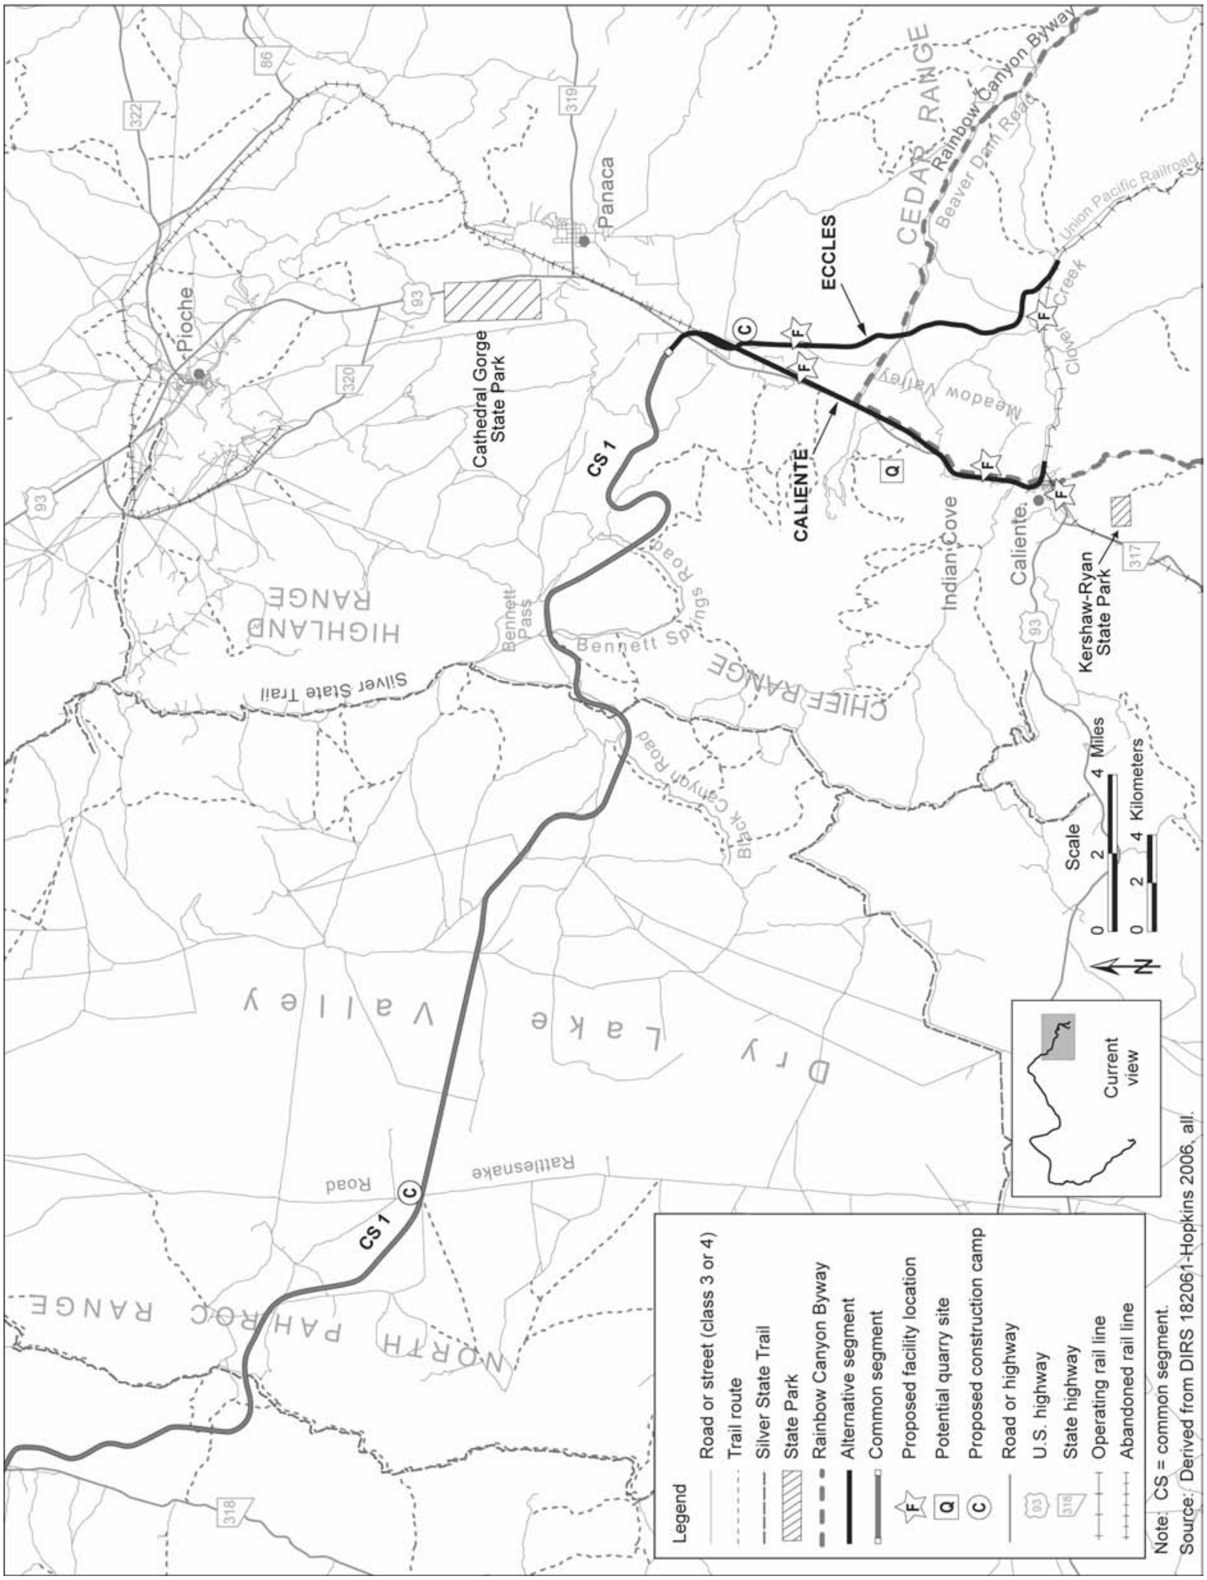

Figure 3-43. Recreation areas and roads within map area 1.

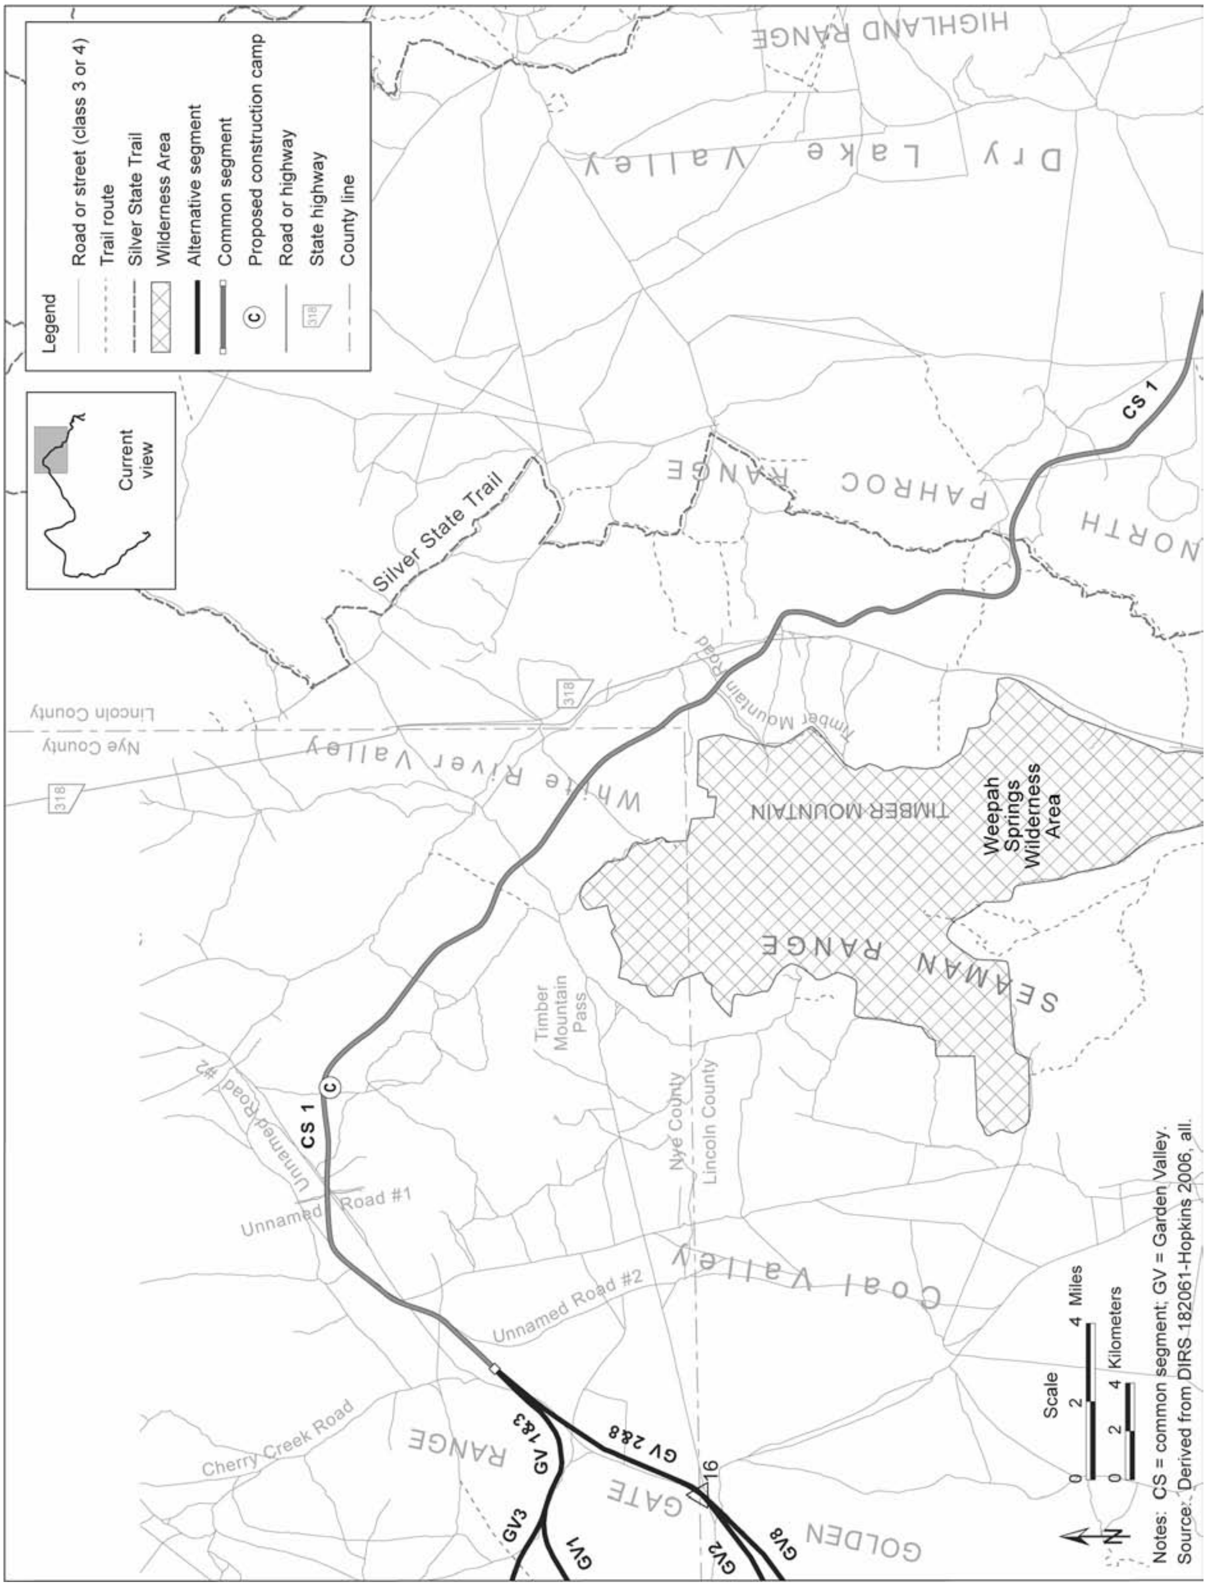

Figure 3-44. Recreation areas and roads within map area 2.

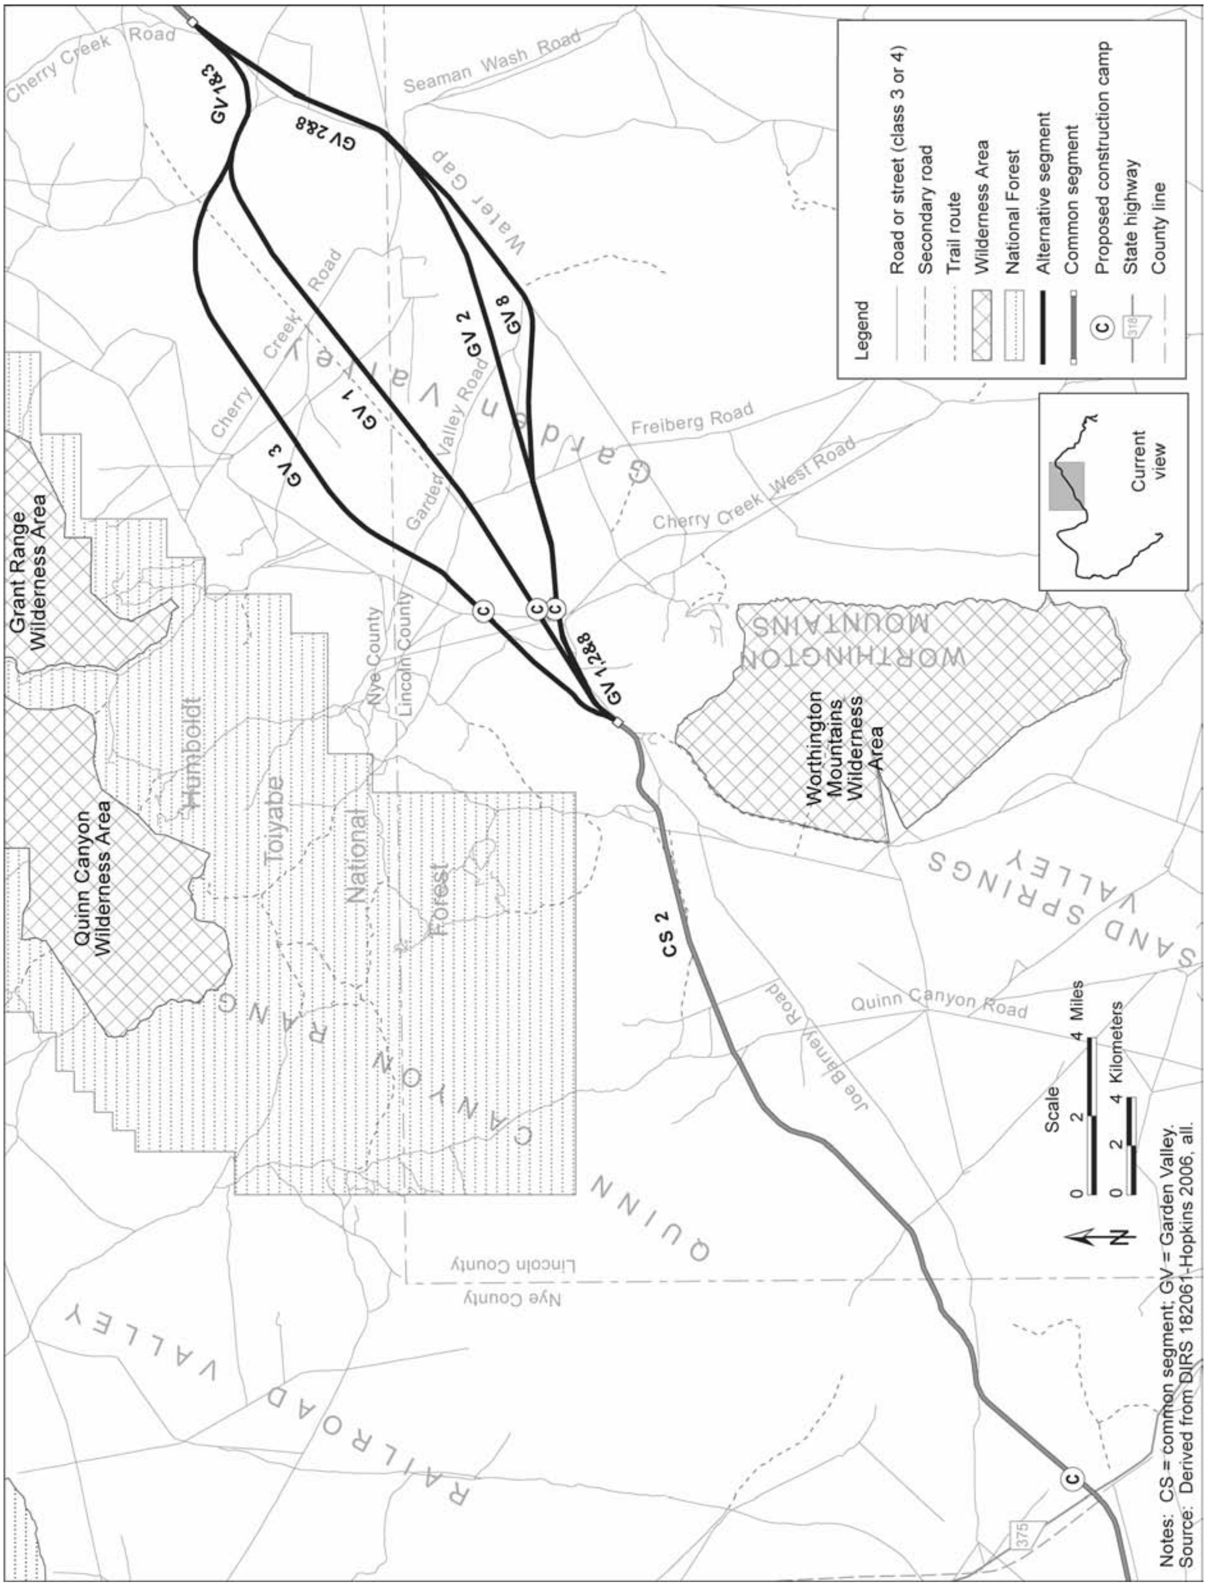

Figure 3-45. Recreation areas and roads within map area 3.

Figure 3-46. Recreation areas and roads within map area 4.

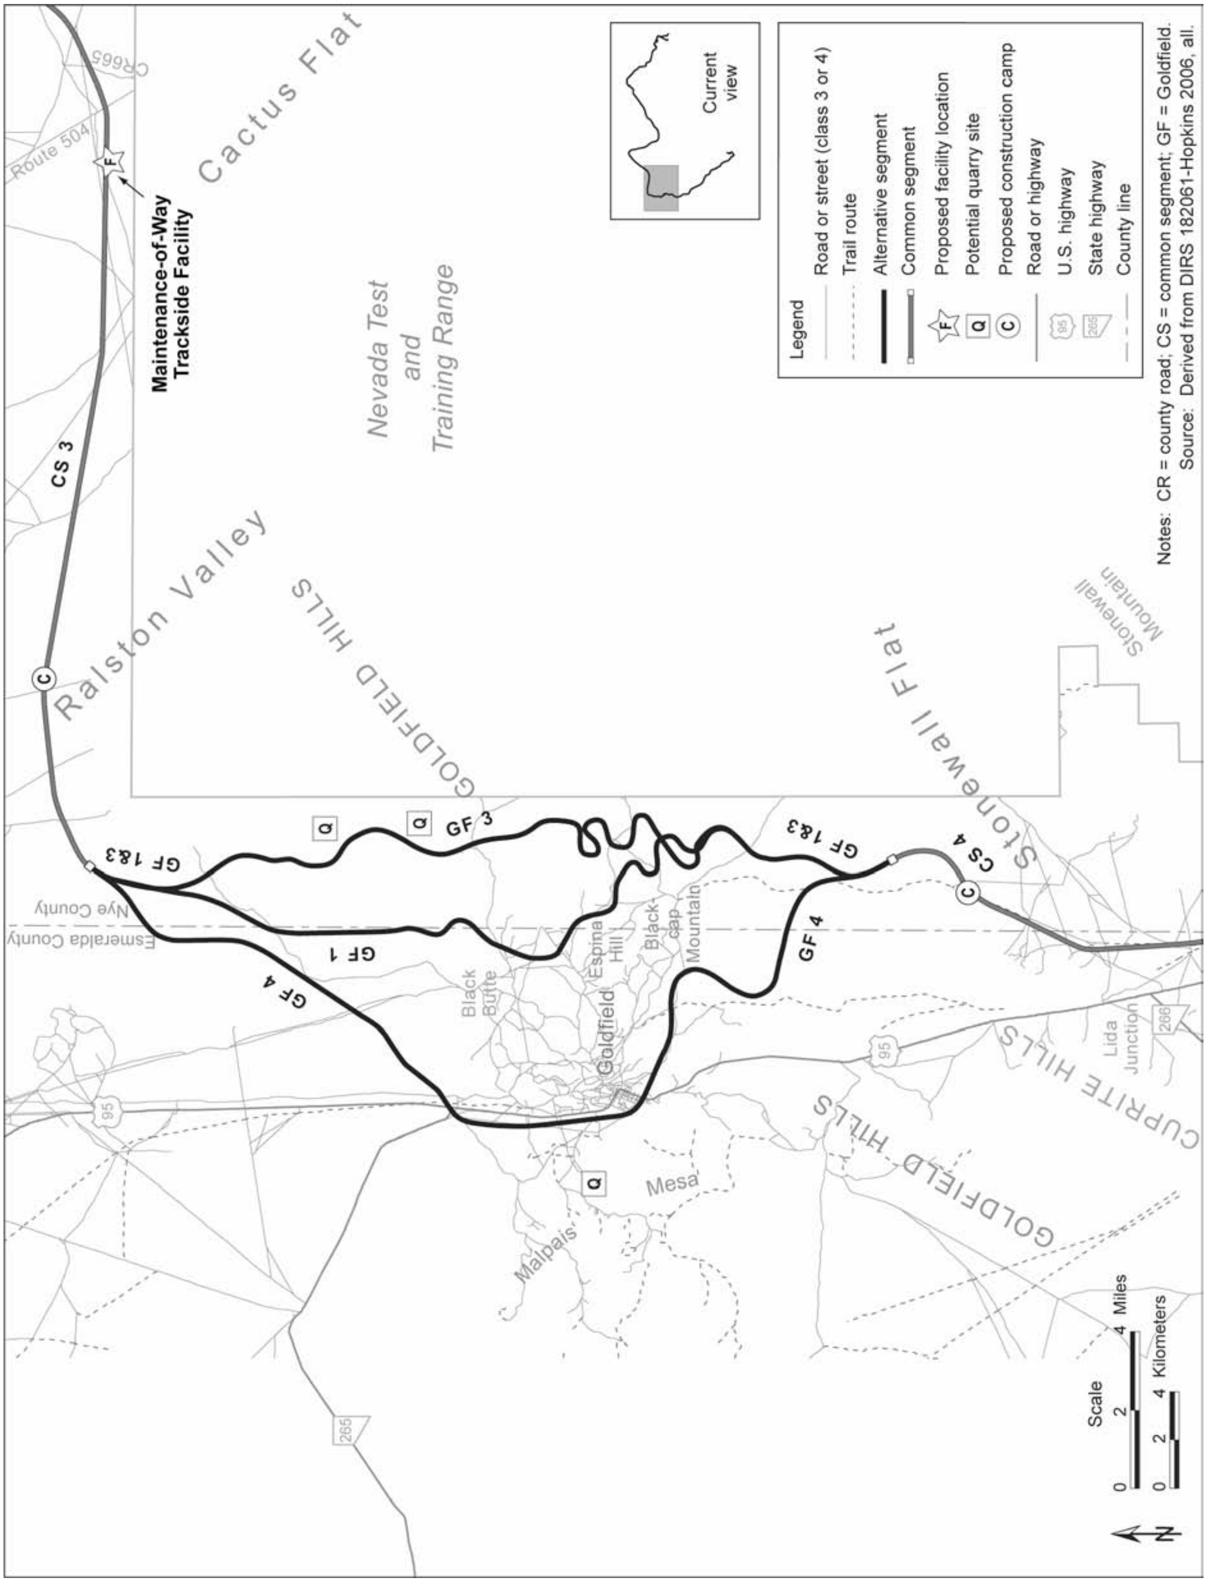

Figure 3-47. Recreation areas and roads within map area 5.

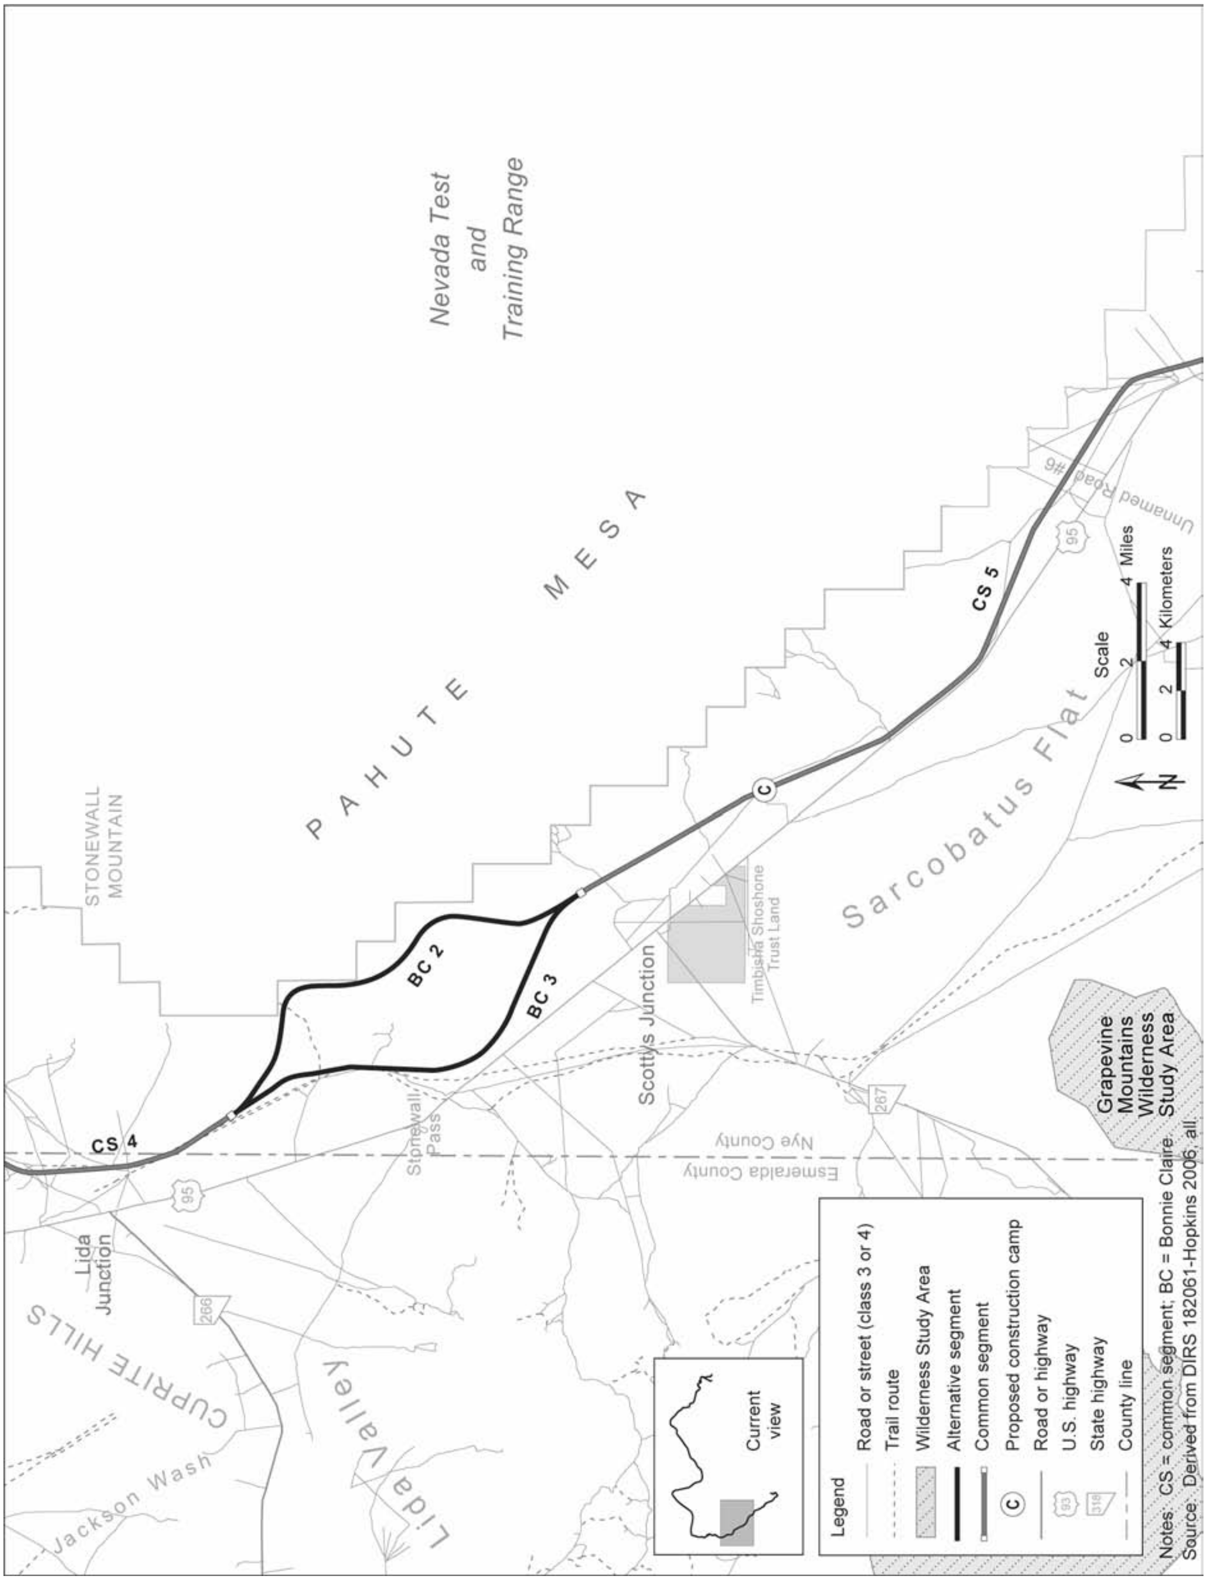

Figure 3-48. Recreation areas and roads within map area 6.

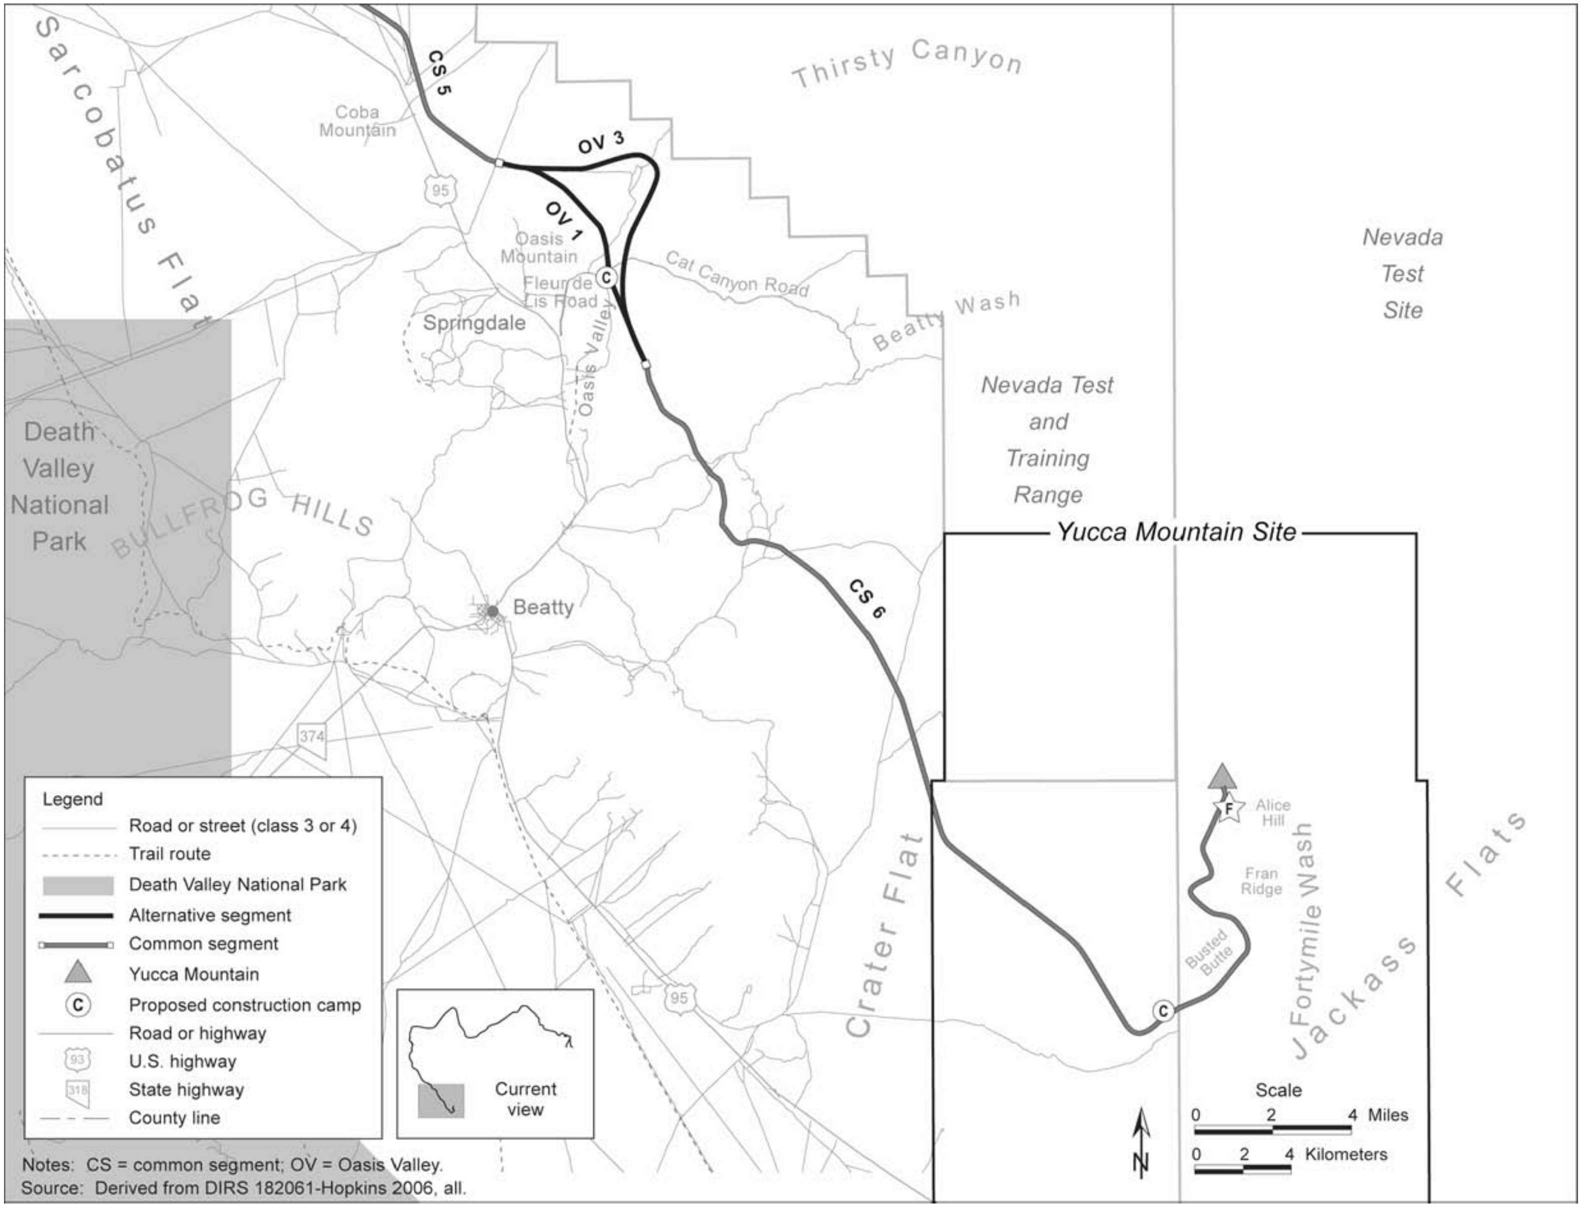

Figure 3-49. Recreation areas and roads within map area 7.

3.2.2.5.3.2 Nye County. Recreation on BLM-administered lands in Nye County is generally dispersed, and there would be no developed recreation sites within 1.6 kilometers (1 mile) of the Caliente rail alignment (see Figure 3-46). Dispersed recreation opportunities in Nye County include hunting, camping, exploration and sightseeing, and off-highway vehicle recreation and competition events.

There are two Wilderness Study Areas along the Caliente rail alignment in Nye County – the Kawich Wilderness Study Area and the South Reveille Wilderness Study Area. Caliente common segment 2 would be within 0.3 kilometer (0.2 mile) of the Kawich Wilderness Study Area at its closest point. The South Reveille Wilderness Study Area would be 30 meters (100 feet) from the centerline of Caliente common segment 2. The Kawich Wilderness Study Area consists of rugged, mountainous country with a high central plateau and several mountain peaks. The South Reveille Wilderness Study Area is a thick, multi-ridged swath of steep-sided mountain rising to crests and flat-topped summits between 2,400 and 2,700 meters (8,000 and 9,000 feet). Sheer cliffs form the mountain sides in many places and large canyons with steep walls run out to the edge of the valleys (DIRS 176796-Winslow 2006, p. 5).

Very few BLM-permitted off-highway vehicle races and special recreation events occur within the region of influence for the Caliente rail alignment common segments and alternative segments in Nye County (DIRS 178416-Nevada Rail Partners 2007, all). Both common segments 3 and 6 would cross race routes several times. All approved race routes the rail line would cross are on existing roads and trails.

3.2.2.5.3.3 Esmeralda County. Recreation in Esmeralda County is generally dispersed and includes competitive off-highway vehicle events, sometimes near the proposed rail alignment. The county is home to numerous largely abandoned towns and historical sites, many of which are in old mining districts, and areas for hunting and fishing (DIRS 176770-Duval et al. 1976, p. 28). No Areas of Critical Environmental Concern (see Section 3.2.2.4.1) fall within the rail alignment region of influence in Esmeralda County. The closest Wilderness Area or Wilderness Study Area to the rail alignment would be Queer Mountain Wilderness Study Area, which would be approximately 20 kilometers (12 miles) away from common segment 5, far outside the construction right-of-way.

A number of BLM-permitted off-highway vehicle races and special recreation events take place annually in areas around the Caliente rail alignment common segments and alternative segments in Esmeralda County (DIRS 178416-Nevada Rail Partners 2007, all). Recent permitted recreation events in the area have included the Las Vegas to Reno Race and the Nevada 1000 Race off-highway vehicle events. The largest number of BLM-approved race routes occur in and around Tonopah and Goldfield, and Goldfield alternative segment 4 would cross multiple routes. Most approved race routes are on existing roads and trails.

3.2.2.5.4 Land Access

The Caliente rail alignment would cross a number of class 3 or 4 roads and unpaved trail routes (see Table 3-9). The intersections of the Caliente rail alignment with these roads and trails could impact access to public lands (for recreational and land management activities) and to private property.

> A **class 3 road** is a light-duty, paved or improved road.
>
> A **class 4 road** is an unimproved, unsurfaced road (includes track roads in back country).
>
> **Trail routes** are trails and roads passable only with a 4-wheel drive vehicle (also called Jeep trails).
>
> Source: DIRS 181386-BLM 2001.

3.2.2.5.5 Utilities

3.2.2.5.5.1 Utility Rights-of-Way. Figures 3-50 through 3-57 show the major utilities and utility corridor networks in the region of influence. The figures do not identify smaller, local electric distribution lines, typically in the 14- to 25-kilovolt range, with linear right-of-way reservations along major roads, or local water, sewer, power, or telephone lines serving individual residences or businesses, or their corresponding rights-of-way.

Table 3-9. Trails and class 3 or 4 roads the Caliente rail alignment alternative segments and common segments would cross.

Segment	Lincoln County roads	Lincoln County trails	Nye County roads	Nye County trails	Esmeralda County roads	Esmeralda County trails
Eccles alternative segment[a]	8	0	0	0	0	0
Caliente alternative segment[a]	7	0	0	0	0	0
Caliente common segment 1[b]	19	7	12	1	0	0
Garden Valley alternative segment 1	6	0	2	1	0	0
Garden Valley alternative segment 2	9	0	3	0	0	0
Garden Valley alternative segment 3	6	0	4	1	0	0
Garden Valley alternative segment 8	10	1	3	0	0	0
Caliente common segment 2	7	1	5	0	0	0
South Reveille alternative segment 2	0	0	1	0	0	0
South Reveille alternative segment 3	0	0	1	0	0	0
Caliente common segment 3	0	0	30	0	0	0
Goldfield alternative segment 1	0	0	6	0	9	0
Goldfield alternative segment 3	0	0	5	0	0	0
Goldfield alternative segment 4	0	0	0	1	41	2
Caliente common segment 4	0	0	2	1	11	0
Bonnie Claire alternative segment 2	0	0	0	1	0	0
Bonnie Claire alternative segment 3	0	0	2	2	0	0
Common segment 5	0	0	14	0	0	0
Oasis Valley alternative segment 1	0	0	3	0	0	0
Oasis Valley alternative segment 3	0	0	3	0	0	0
Common segment 6	0	0	7	0	0	0

a. Both the Caliente and Eccles alternative segments would cross the Rainbow Canyon Back Country Byway.
b. Caliente common segment 1 would cross the Silver State Trail in two places.

3.2.2.5.5.2 Utility Corridors. As stated in Section 3.2.2.4.1, BLM resource management plans designate utility and transportation corridors to consolidate the location of new and existing rights-of-way whenever feasible. Table 3-10 lists the extent to which DOE would construct each Caliente rail alignment segment within BLM-designated corridors.

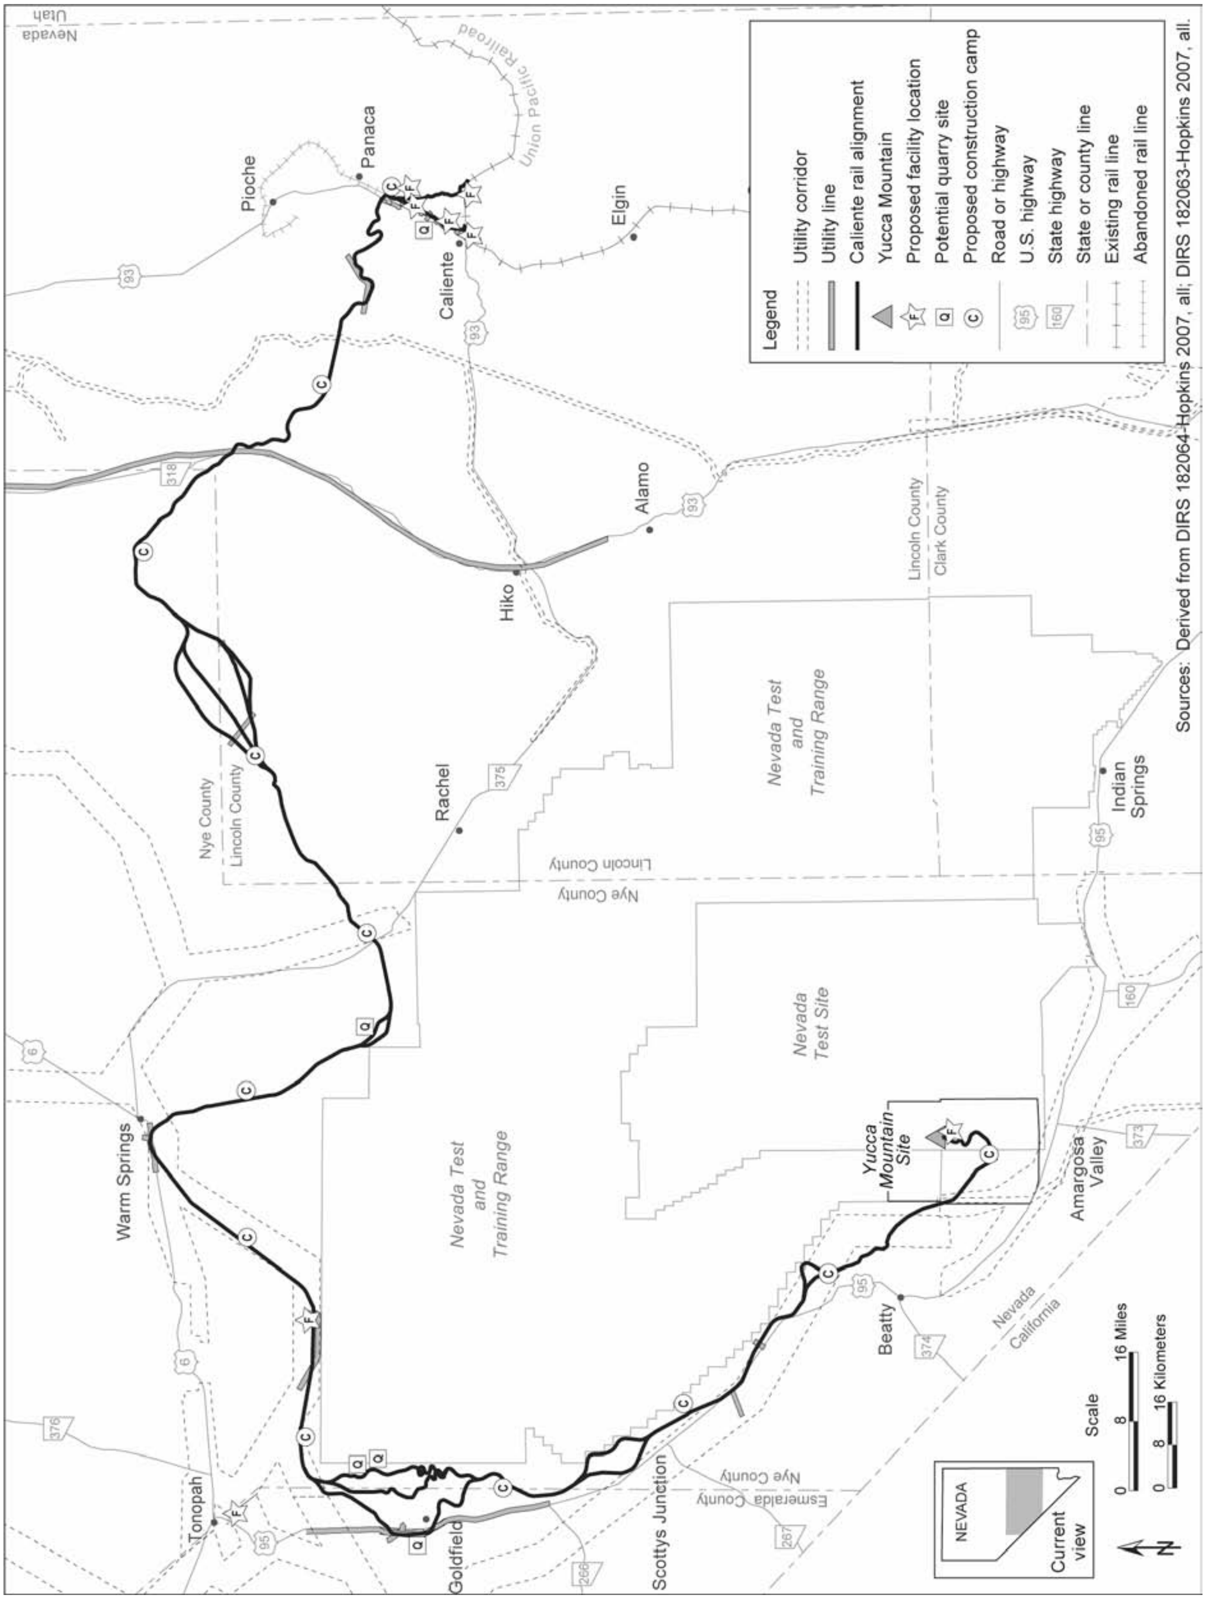

Figure 3-50. Utility corridors along the Caliente rail alignment.

Table 3-11 identifies locations of where the rail line construction right-of-way and the possible locations for the ***Staging Yard*** could cross utility corridors. Figures 3-51 through 3-57 do not show all of the individual crossings because some of the locations are very close together. Utility lines listed in Table 3-11 are depicted on the figures by the location number designated in the table. For clarification, see Volume III-A of this Rail Alignment EIS, Map Atlas. Table 3-12 identifies utilities corridors at potential quarry sites.

The locations of potential utility crossings shown on figures and listed in tables are approximate and would be reviewed and verified after completion of the final rail design.

3.2.3 AESTHETIC RESOURCES

This section describes the aesthetic (visual) setting in the region of influence along the Caliente rail alignment. Section 3.2.3.1 describes the region of influence for aesthetic resources; Section 3.2.3.2 describes the methods DOE used to classify visual values; and Section 3.2.3.3 describes the environmental setting and characteristics for aesthetic resources along the Caliente rail alignment.

3.2.3.1 Region of Influence

The region of influence for aesthetic resources is the viewshed around all Caliente rail alignment alternative segments, common segments, and proposed locations of rail line construction and operations support facilities.

BLM guidance subdivides landscapes into three ***distance zones*** based on relative visibility from travel routes or observation points. "Foreground-middleground" zone includes areas less than 5 to 8 kilometers (3 to 5 miles) away. "Background" zone includes areas visible beyond the foreground-middleground zone but usually less than 24 kilometers (15 miles) away. Areas not seen as foreground-middleground or background are in the "seldom-seen" zone (DIRS 101505-BLM 1986, Section IV). To ensure that seldom-seen views were included in this analysis, DOE used a conservative region of influence extending 40 kilometers (25 miles) on either side of the centerline of the Caliente rail alignment.

3.2.3.2 Methodology for Classifying Visual Values

Most of the lands along the Caliente rail alignment are BLM-administered public lands. Therefore, DOE used BLM methodologies for evaluating visual values. The BLM considers visual resources when addressing aesthetic issues during BLM planning. These resources include natural or manmade physical features that give a landscape its character and value as an environmental factor. The BLM uses a visual resource management system to classify the aesthetic value of its lands and to set management objectives (DIRS 173052-BLM 1984, all).

Scenic quality is a measure of the visual appeal of a tract of land. Areas are rated based on key factors including landform, vegetation, water, color, adjacent scenery, scarcity, and cultural modifications (DIRS 101505-BLM 1986, Section II).

Sensitivity levels are a measure of public concern for scenic quality. Areas are ranked high, medium, or low based on types of users, amount of use, public interest, adjacent land uses, and whether they are special areas (DIRS 101505-BLM 1986, Section III).

The BLM classification of visual resource value, the visual resource inventory, involves assessing visual resources and assigning them to one of four visual resource management classes based on three factors: ***scenic quality***, visual sensitivity (***sensitivity levels***), and distance from travel or observation points (DIRS 101505-BLM 1986, all). The BLM uses a combination of the ratings of these three factors to assign a visual resource inventory class to a piece of land, ranging from Class I to Class IV, with Class I representing the highest visual values. Each visual resource class is subsequently associated with a management objective, defining the way the land may be developed or used. Each BLM district assigns visual resource management classes to its lands during the resource management planning process. Table 3-13 lists the BLM management objectives for visual resource classes.

The BLM uses visual resource contrast ratings to assess the visual impacts of proposed projects and activities on the existing landscape (DIRS 173053-BLM 1986, all).

Table 3-13. BLM visual resource management classes and objectives.[a]

Visual resource class	Objective	Acceptable changes to land
Class I	Preserve the existing character of the landscape.	Provides for natural ecological changes but does not preclude limited management activity. Changes to the land must be small and must not attract attention.
Class II	Retain the existing character of the landscape.	Management activities may be seen but should not attract the attention of the casual observer. Changes must repeat the basic elements of form, line, color, and texture of the predominant natural features of the characteristic landscape.
Class III	Partially retain the existing character of the landscape.	Management activities may attract attention but may not dominate the view of the casual observer. Changes should repeat the basic elements in the predominant natural features of the characteristic landscape.
Class IV	Provides for management activities that require major modifications of the existing character of the landscape.	Management activities may dominate the view and be the major focus of viewer attention. An attempt should be made to minimize the impact of activities through location, minimal disturbance, and repeating the basic elements.

a. Source: DIRS 101505-BLM 1986, Section V.B.

The Bureau looks at basic elements of design to determine levels of contrast created between a proposed project and the existing viewshed. Depending on the visual resource management objective for a particular location, varying levels of contrast are acceptable.

Contrast ratings are determined from locations called key observation points, which are usually along commonly traveled routes such as highways or frequently used county roads or in communities. To identify key observation points along the Caliente rail alignment, DOE considered the following factors: angle of observation, number of viewers, how long the project would be in view, relative project size, season of use, and light conditions. BLM guidance (DIRS 173053-BLM 1986, Section IIC) recommends that key observation points for linear projects, such as the proposed railroad, include the following:

- Most-critical viewpoints (for example, views from communities at road crossings)
- Typical views encountered in representative landscapes, if not covered by critical viewpoints
- Any special project or landscape features such as river crossings and substations

3.2.3.3 Visual Setting and Characteristics

3.2.3.3.1 General Visual Setting and Characteristics

The Class IV lands in the Caliente rail alignment region of influence consist of landscapes that are generally flat in form and horizontal in line, with gray and brown colors from soil and rock, and texture ranging from flat to slightly rough, depending on whether the broad flat valleys and alluvial fans include any topographic features such as hills, buttes, or eroded stream channels. Vegetation is usually small, low, and rounded in form (for example, grasses, shrubs, and small trees), horizontal in line, brown or gray-green in color, and light-to-medium in texture with irregular spacing. Structures are rare, but could include transmission towers, ranch buildings, or similar structures. Class III lands generally include more varied forms, lines, colors, and textures, including vertical lines in topography and vegetation, brighter greens in vegetation, visible blues from water, and dense texture from forested lands or rough texture in eroded rock. Class I and II lands are mostly in mountains that include forested areas and open rock exposures, with mixed forms including slopes and ridges; rounded lines; a wide range of rock and soil colors, and vegetation that changes color with the seasons; and variable texture that is often dense in forested areas.

Special areas are lands where measures must be taken to protect visual values. Special areas often include designated natural areas, Wilderness Study Areas, scenic rivers, and scenic roads. Special areas are not necessarily unique or picturesque, but the management objective for a special area is to preserve its natural characteristics (DIRS 101505-BLM 1986, Section III.5).

Sections 3.2.3.3.2.1 through 3.2.3.3.2.12 describe visual resources along and near the Caliente rail alignment alternative segments and common segments. The discussions highlight resources of high visual value, identify current visual resource management classifications, ***special areas***, and key observation points.

DOE excerpted visual resource management classifications for lands along the Caliente rail alignment primarily from BLM resource management plans from districts the alignment would cross (DIRS 173224-BLM 1997, all; DIRS 103079-BLM 1998, all; DIRS 174518-BLM 2005, all). The BLM Las Vegas and Ely Districts provided Geographic Information System data from their resource management plans as a source for mapping the visual resource management classes in their districts (DIRS 103079-BLM 1998, Map 2-9; DIRS 174518-BLM 2005, Map 2.4-5). Geographic Information System data used in this analysis from the BLM Ely District corresponds to the preferred alternative in the *Draft - Resource Management Plan/Environmental Impact Statement for the Ely District* (Draft Ely Resource Management Plan; DIRS 174518-BLM 2005, all). DOE used information from this draft resource management plan because BLM Ely District personnel indicated that it would be better to use the most recent visual inventory data (DIRS 174635-Quick 2005, all), even though visual resource management classes will not be confirmed until the Draft Ely Resource Management Plan is finalized.

The Department based visual resource classification boundaries for the BLM Battle Mountain District on the *Tonopah Resource Management Plan and Record of Decision* (DIRS 173224-BLM 1997, pp. 6, 7, and 27, and Map 8), and developed visual resource management classifications for non-BLM lands using BLM methodology (DIRS 173053-BLM 1986, all; DIRS 173052-BLM 1984, all), considering scenic quality ratings reported in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, pp. 3-158 and 3-159) where available. DOE confirmed visual resource management classifications in telephone communications and meetings with BLM personnel responsible for visual resource management for the Las Vegas and Battle Mountain Districts (DIRS 174631-Quick 2005, all; DIRS 174632-Quick 2005, all; DIRS 176988-Quick 2006, all).

Figure 3-58 is a map of visual resource management classifications for lands surrounding the Caliente rail alignment based on the sources identified above. As the figure shows, most of the lands surrounding the alternative segments and common segments are Class IV lands, which are common to the area. However, there are a few locations where the alternative segments and common segments would cross Class II or III lands or be very close to Class I, II, or III lands.

DOE selected 37 key observation points along the Caliente rail alignment to evaluate the visual impacts of constructing and operating the proposed railroad. Figure 3-58 also shows the locations of key observation points. Appendix D, Aesthetics, contains photos taken at each key observation point. Table 3-14 lists visual resource management classes in the viewshed of each key observation point.

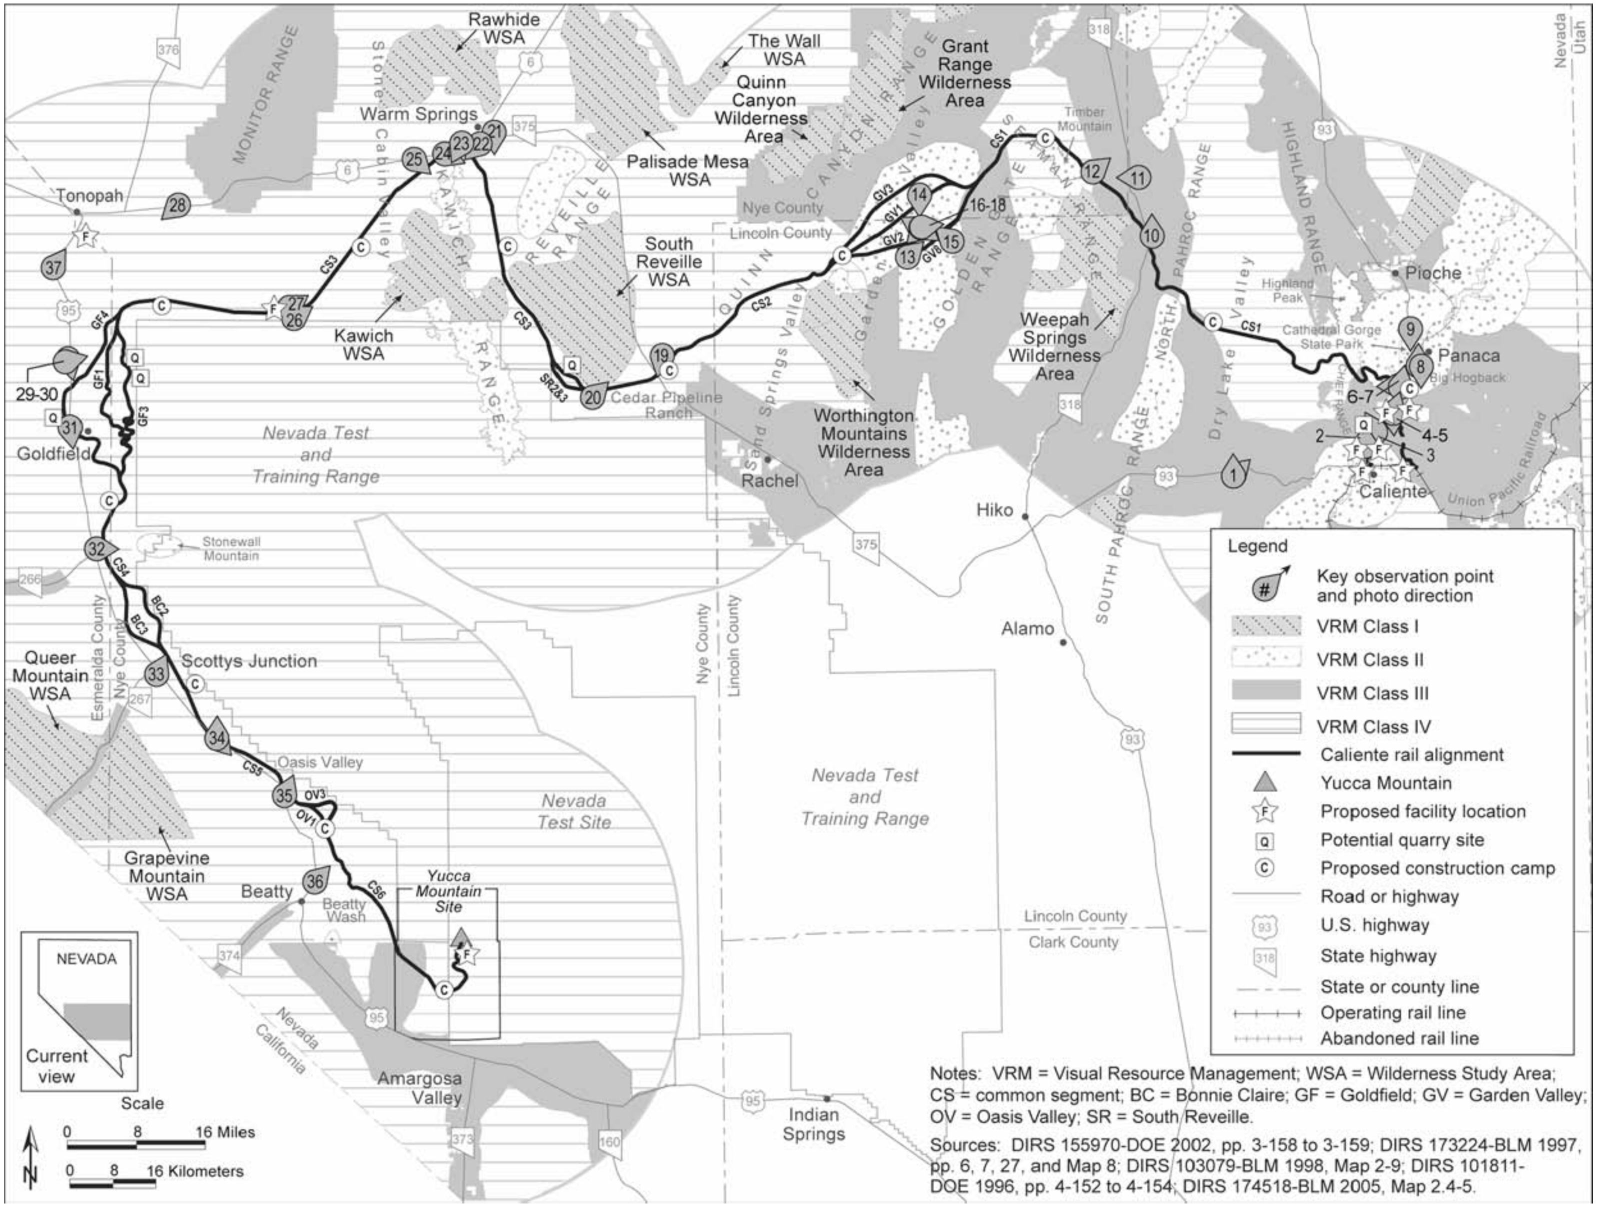

Figure 3-58. Visual resource management classifications and key observation points along the Caliente rail alignment.

Table 3-14. Key observation points and visual resource management classes in the Caliente rail alignment viewshed[a] (page 1 of 2).

Key observation point	Location	Visual resource management classes[b]
1	U.S. Highway 93 at Dry Lake Valley	Surrounding lands (III and IV), Highland and Chief Ranges (II and III)

11	Off county road west of State Route 318 north of where rail line would cross	Surrounding lands (III), Timber Mountain (II), Weepah Springs Wilderness (I)
12	Where rail line would cross Timber Mountain Pass Road	Surrounding lands (III), Timber Mountain (II), Weepah Springs Wilderness (I)
13 and 15	County roads on south side of Garden Valley	Garden Valley (II), Golden Gate Range (III), Quinn Canyon Range (III), Quinn Canyon Wilderness (I), Grant Range Wilderness (I), Worthington Mountains (II), Worthington Mountains Wilderness (I)
14	County road in middle of Garden Valley	Garden Valley (II), Golden Gate Range (III), Quinn Canyon Range (III), Quinn Canyon Wilderness (I), Grant Range Wilderness (I), Worthington Mountains (II), Worthington Mountains Wilderness (I)
16 to 18	Top of *City* structure elements	Garden Valley (II), Golden Gate Range (III), Quinn Canyon Range (III), Quinn Canyon Wilderness (I), Grant Range Wilderness (I), Worthington Mountains (II), Worthington Mountains Wilderness (I)
19	State Route 375 near where rail line would cross	Surrounding lands (IV)
20	Cedar Pipeline Ranch	Surrounding lands (IV), Kawich Range (II), Reveille Range (II), Quinn Canyon Range (III), South Reveille Wilderness Study Area (I)
21	State Route 375 near U.S. Highway 6	Surrounding lands (IV), Kawich Range (II), Kawich Wilderness Study Area (I)
22	U.S. Highway 6 near State Route 375	Surrounding lands (IV), Kawich Range(II), Kawich Wilderness Study Area (I)
23	U.S. Highway 6 on east side of Warm Springs Summit	Surrounding lands (IV), Kawich Range (II)

Table 3-14. Key observation points and visual resource management classes in the Caliente rail alignment viewshed[a] (page 2 of 2).

Key observation point	Location	Visual resource management classes[b]
24	Warm Springs Summit	Surrounding lands (IV), Kawich Range (II)
25	U.S. Highway 6 at a mine access road	Surrounding lands (IV), Kawich Range (II), Kawich Wilderness Study Area (I)
26	Nevada Test and Training Range Road near where rail line would cross	Surrounding lands (IV), Kawich Wilderness Study Area (I)
27	Nevada Test and Training Range Road	Surrounding lands (IV), Kawich Wilderness Study Area (I)
28	U.S. Highway 6 at Test and Training Range Road	Surrounding lands (IV)
29	U.S. Highway 95 north of Goldfield	Surrounding lands (IV)
30	U.S. Highway 95 at north end of Goldfield	Surrounding lands (IV)
31	Where rail line would cross U.S. Highway 95 south of Goldfield	Surrounding lands (IV)
32	U.S. Highway 95 at State Route 266	Surrounding lands (IV), State Route 266 (III), Stonewall Mountain (II)
33	U.S. Highway 95 at State Route 267	Surrounding lands (IV), State Route 267 (III)
34	U.S. Highway 95 (typical cut)	Surrounding lands (IV)
35	U.S. Highway 95 north of Oasis Valley (typical landscape)	Surrounding lands (IV)
36	U.S. Highway 95 and Beatty Wash access road	Surrounding lands (IV)
37	U.S. Highway 95 at proposed Maintenance-of-Way Headquarters Facility	Surrounding lands (IV)

a. Appendix D contains photographs taken from each key observation point.
b. Sources: DIRS 155970-DOE 2002, pp. 3-158 and 3-159; DIRS 173224-BLM 1997, pp. 6, 7, and 27, and Map 8; DIRS 103079-BLM 1998, Map 2-9; DIRS 101811-DOE 1996, pp. 4-152 to 4-154; DIRS 174518-BLM 2005, Map 2.4-5.

Following BLM guidance, DOE selected most key observation points along travel routes or at use or potential use areas, and included critical viewpoints and typical views. DOE also selected multiple points within Garden Valley, along county roads used primarily by a small number of residents, for two reasons: (1) During the scoping period for this Rail Alignment EIS, commenters expressed concern about visual impacts in Garden Valley because of *City*, a large outdoor complex of sculptural and architectural forms on private land, currently under construction; (2) Garden Valley is considered a special recreation management area for visual values under multiple alternatives of the Draft Ely Resource Management Plan (DIRS 174518-BLM 2005, all). Section 3.2.3.3.2 highlights areas of high visual value and other special areas, and identifies key observation points from which DOE analyzed impacts to these areas.

3.2.3.3.2 Specific Visual Settings and Characteristics along Alternative Segments and Common Segments

3.2.3.3.2.1 Alternative Segments at the Interface with the Union Pacific Railroad Mainline. The Caliente rail alignment would begin in or near the City of Caliente with either the Caliente or the Eccles alternative segment. The Caliente alternative segment would begin in a Class II area around the City of Caliente, while the Eccles alternative segment would begin in a Class III area farther east. Big Hogback, a Class II visual resource, would be visible from either alternative segment but would be more than 4 kilometers (2.5 miles) in the background of views across the alternative segments from the U.S.

Highway 93. The Caliente and Eccles alternative segments would approach within 6.1 kilometers (3.8 miles) of the southern boundary of Cathedral Gorge State Park, a Class II special area.

The Caliente alternative segment would cross or be very near Class III lands for approximately 4 to 5 kilometers (2.5 to 3.1 miles) and would cross approximately 1.1 kilometers (0.7 mile) of Class II lands north of the City of Caliente. The Eccles alternative segment would cross approximately 4 to 5 kilometers of Class III lands and would approach within approximately 400 meters (1,300 feet) of Class II lands for approximately 1 to 2 kilometers (0.6 to 1.2 miles).

Key observation points (indicated in parentheses) for the Caliente and Eccles alternative segments provide a view of where the rail line would cross under U.S. Highway 93 (6); views from the intersection of U.S. Highway 93 and State Route 319 toward Big Hogback and Cathedral Gorge (8); a view from Cathedral Gorge toward the alignment (9); and views of the Caliente-Upland and Caliente-Indian Cove options for the Staging Yard (5 and 2, respectively). In addition, a key observation point (3) provides a view of the place where a conveyor would cross U.S. Highway 93 to the Staging Yard Caliente-Indian Cove option if DOE developed potential quarry CA-8B (see Figure 2-25) as a source of ballast. Another key observation point (4) provides a view of the place where a conveyor would cross U.S. Highway 93 to the south of the Staging Yard Caliente-Upland option.

3.2.3.3.2.2 Caliente Common Segment 1 (Dry Lake Valley Area). Caliente common segment 1 would cross through the pass between the Highland Range and the Chief Range, through Dry Lake Valley, through the North Pahroc and Seaman Ranges, and on to the Golden Gate Range. Part of the Highland Range is Class II. Much of the Seaman Range falls into the Weepah Springs Wilderness, a Class I area; two areas are Class II, including Timber Mountain; while the north and south ends of the Seaman Range are Class III or IV.

As shown in Figure 3-58, Caliente common segment 1 would cross Class II lands in the area of the Highland and Chief Ranges, and Class IV land in Dry Lake Valley. Caliente common segment 1 would be approximately 2 kilometers (1.2 miles) north of the Class II lands of the Pahroc Range and would cross Class III lands between the Pahroc Range and Timber Mountain. The segment would approach within a few hundred meters of the northeastern point of Weepah Springs Wilderness, but would not cross any Class I land. It would also approach within a few hundred meters of the Class II slopes of Timber Mountain, at the north end of the Seaman Range, but remain in Class III and IV lands. Finally, Caliente common segment 1 would cross Class IV and then Class III lands from Timber Mountain to Garden Valley.

A key observation point on State Route 318 provides a view of the location where the Caliente rail alignment would cross the highway (10). A key observation point on a county road just off State Route 318 provides a view over the rail alignment on the slopes of Timber Mountain (11), while another key observation point provides a view of the rail alignment crossing the county road on those slopes (12). Two key observation points provide views across Dry Lake Valley and toward the Chief and Highland Ranges (1 and 7, respectively).

3.2.3.3.2.3 Garden Valley Alternative Segments. The Garden Valley alternative segments would cross the Golden Gate Range and Garden Valley, and pass between the Worthington Mountains and the Quinn Canyon Range. The Golden Gate Range is a Class III area. The portion of the Quinn Canyon Range that bounds Garden Valley on the northwest is managed by the U.S. Forest Service. The Quinn Canyon Range is generally considered Class III in this evaluation, with the exceptions of the Quinn Canyon and Grant Range Wilderness Areas (approximately 8 kilometers [5 miles] from Garden Valley alternative segment 3 at their closest) which are analyzed as Class I. The Worthington Mountains include the Class I Worthington Mountains Wilderness, and lower slopes that are Class III or Class IV. As shown in Figure 3-58, the valley floor and the hills and lower slopes of ranges around Garden Valley are considered Class II. The Draft Ely Resource Management Plan proposes Garden Valley as a Class II Special Recreation Management Area for visual values (DIRS 174518-BLM 2005, p. 2.5-111).

City is a complex of abstract sculptural and architectural forms made from earth, rock, and concrete extending over 2.4 kilometers (1.5 miles) on private land in Garden Valley. The largest feature to date is approximately 21 to 24 meters (70 to 80 feet) high and 0.4 kilometer (0.25 mile) long. *City* is designed in five phases and could be completed by 2010 supported by private funding.

Several key observation points (13 to 18) both inside and outside the sculpture provide views across one or more of the Garden Valley alternative segments. The DOE selection of key observation points within the sculpture area and along lightly traveled county roads is more conservative than standard BLM methodology for areas of low visual sensitivity, which calls for viewpoints at locations where a significant number of viewers are expected. There are no public roads within the sculpture area, and views from key observation points on county roads outside the sculpture area do not include the sculpture. DOE selected the additional key observation points to better inform decisionmakers about managing for the visual values in the Class II lands and Special Recreation Management Area, and to provide data to address concerns about visual impacts in Garden Valley raised in public comments offered during the scoping period for this Rail Alignment EIS.

3.2.3.3.2.4 Caliente Common Segment 2 (Quinn Canyon Range Area). Caliente common segment 2 would run to the north of the Worthington Mountains, pass within 8.4 kilometers (5.2 miles) of the Class I Worthington Mountains Wilderness and travel through the Class IV land in the south end of the Quinn Canyon Range. The segment would continue through Class IV land but would come within 6.6 kilometers (4.1 miles) of the Class II slopes of the southern end of the Reveille Range, and 9.2 kilometers (5.7 miles) of the Class I South Reveille Wilderness Study Area. A key observation point provides views from State Route 375 across common segment 2 near the highway crossing and a proposed construction camp (19).

3.2.3.3.2.5 South Reveille Alternative Segments. The South Reveille alternative segments would begin near Cedar Pipeline Ranch, between the Reveille and Kawich Ranges, and extend northwest through Class IV lands. The Reveille Range is a Class II area and includes the Class I South Reveille Wilderness Study Area. The more northerly South Reveille alternative segment 2 would approach within about 5 kilometers (3.1 miles) of the Wilderness Study Area and come within 1.3 kilometers (0.8 mile) of the Class II land at the base of the range, while South Reveille alternative segment 3 would pass farther south from these areas. The Kawich Range is Class II in the area of these alternative segments, although the range would be more than 10 kilometers (6.2 miles) away at its closest point. Key observation point 20 is near Cedar Pipeline Ranch.

3.2.3.3.2.6 Caliente Common Segment 3 (Stone Cabin Valley Area). Caliente common segment 3 would extend north up Reveille Valley and pass through the Kawich Range at Warm Springs summit. It would then proceed through Stone Cabin Valley and around the Nevada Test and Training Range to the Goldfield area. As previously mentioned, the Kawich Range is a Class II area. Caliente common segment 3 would be at least 5 kilometers (3 miles) away from the Class II portions of the Kawich Range as it crossed the Class IV portion of the valley, except near Warm Springs summit, where it would approach within 1 or 2 kilometers (0.6 to 1.2 miles) of the Class II area. The Kawich Range also contains the Class I Kawich Wilderness Study Area to the west of common segment 3. The segment would be within approximately 0.5 kilometer (0.31 mile) of the Wilderness Study Area boundary for approximately 2 kilometers in the Class IV land between the Reveille and Kawich Ranges. This portion of the common segment would also come within approximately 7.9 kilometers (4.9 miles) of the southern edge of the Rawhide Mountains Wilderness Study Area, which is north of Warm Springs. As common segment 3 passed Warm Springs summit and headed southwest and then west along the boundary of the

Nevada Test and Training Range, it would cross Class IV lands exclusively. Key observation points provide views from State Route 375 and U.S. Highway 6 across Caliente common segment 3 (21 through 23) on the east side of Warm Springs summit, views at Warm Springs summit and approaching it from the west (24 and 25), and views across common segment 3 from U.S. Highway 6 (28) and from the road leading into the Nevada Test and Training Range (26 and 27).

3.2.3.3.2.7 Goldfield Alternative Segments. The Goldfield alternative segments would pass through the Class IV hills northwest of Stonewall Mountain, which is a Class II area. Key observation points include a view across all three Goldfield alternative segments toward potential quarry NS-3A (29), a view across Goldfield alternative segment 4 from north Goldfield (30), a view of the place Goldfield alternative segment 4 would cross U.S. Highway 95 at the south end of Goldfield (31), and a view of the proposed Maintenance-of-Way Headquarters Facility from U.S. Highway 95 (37).

3.2.3.3.2.8 Caliente Common Segment 4 (Stonewall Flat Area). Caliente common segment 4 would begin south of Goldfield and proceed past Stonewall Mountain and beyond the intersection of U.S. Highway 95 and State Route 266. Caliente common segment 4 would be in Class IV land and would never pass closer than 6.9 kilometers (4.3 miles) of the Class II Stonewall Mountain area. The BLM manages State Route 266 west of U.S. Highway 95 as a Class III area. Lida Junction, the intersection of U.S. Highway 95 and State Route 266, is a key observation point for the view toward Stonewall Mountain (32).

3.2.3.3.2.9 Bonnie Claire Alternative Segments. The Bonnie Claire alternative segments would cross Class IV lands to the southwest of the Nevada Test and Training Range and past Scottys Junction at the intersection of U.S. Highway 95 and State Route 267, which the BLM manages as a Class III area west of U.S. Highway 95. A key observation point at Scottys Junction provides a view northeast toward the alternative segments (33).

3.2.3.3.2.10 Common Segment 5 (Sarcobatus Flat Area). Common segment 5 would cross Class IV land between the Bonnie Claire area and the Oasis Valley area. There are no visual resources of concern along this common segment and, therefore, no key observation points.

3.2.3.3.2.11 Oasis Valley Alternative Segments. The Oasis Valley alternative segments would cross Class IV areas through Oasis Valley. Key observation point (35) is north of Springdale, looking east over the Oasis Valley, showing a typical landscape. Key observation point (34) provides a view of a typical ***cut***.

3.2.3.3.2.12 Common Segment 6 (Yucca Mountain Approach). Common segment 6 would pass from the Oasis Valley area, near Beatty and across Beatty Wash, through the Nevada Test Site to the Yucca Mountain Site. State Route 374, entering Beatty, is a Class III area. Common segment 6 would cross approximately 10 kilometers (6.2 miles) of Class III lands before it entered the Nevada Test Site, but the segment would be more than 15 kilometers (9.3 miles) from U.S. Highway 95 in this area. Land on the Nevada Test Site is not under BLM jurisdiction. Land on the Nevada Test Site that is visible from U.S. Highway 95 and that the rail line would cross is considered Class IV in this evaluation. Key observation point (36) is north of Beatty, with views from U.S. Highway 95 over the Class IV lands surrounding the access road to Beatty Wash. The viewshed within the wash is considered a contributing element to cultural resources within the wash that are important to American Indians (DIRS 174205-Kane et al. 2005, p. 17). Beatty Wash and the rail line through it would not be visible from the highway. Therefore, DOE did not select key observation points in this area.

3.2.4 AIR QUALITY AND CLIMATE

This section describes the present air quality and climate characteristics along the Caliente rail alignment and summarizes information from ***ambient air*** monitoring and meteorological data collection in the region. Section 3.2.4.1 describes the region of influence for air quality and climate, Section 3.2.4.2 describes general air quality characteristics in the Caliente rail alignment region of influence, and Section 3.2.4.3 describes the climate characteristics in the Caliente rail alignment region of influence.

3.2.4.1 Region of Influence

The region of influence for air quality and climate along the Caliente rail alignment is the air basins in Lincoln, Nye, and Esmeralda Counties. Historic data on pollutant emissions inventories and compliance status for the State of Nevada are calculated at the county level, and these data provide a basis for determining existing air quality in the region of influence for use in analyzing potential impacts to air quality (see Section 4.2.4).

However, air-emissions fixed-point sources such as quarries and linear sources such as operating railroads can subject certain locations (for example, population centers) to higher localized levels of pollutants than a regional analysis would suggest. Therefore, DOE also selected more focused study locations within the region of influence in which to model air quality impacts on specific receptors. These locations are the two largest population centers near the Caliente rail alignment (the City of Caliente in Lincoln County and Goldfield in Esmeralda County), and potential quarry sites northwest of the City of Caliente (CA-8B) and in South Reveille Valley (NN-9B).

3.2.4.2 Existing Air Quality

Air quality is determined by measuring concentrations of certain pollutants in the atmosphere. The U.S. Environmental Protection Agency designates an area as being ***in attainment*** for a particular pollutant if ambient concentrations of that pollutant are below the National ***Ambient Air Quality Standards***. The pollutants regulated under the State of Nevada and National Ambient Air Quality Standards are ***ozone***, ***carbon monoxide***, ***nitrogen dioxide***, ***sulfur dioxide***, ***particulate matter*** with an aerodynamic diameter less than or equal to 10 micrometers (***PM_{10}***) and particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers (***$PM_{2.5}$***), and lead. Collectively, these pollutants are referred to as ***criteria air pollutants***. Table 3-15 lists the National Ambient Air Quality Standards for both the primary public health standard and the secondary public welfare standards in comparison to State of Nevada Ambient Air Quality Standards.

Areas in violation of one or more of these standards are classified as ***nonattainment areas***. If there is not enough air quality data to determine the status of a remote or sparsely populated area, then the U.S. Environmental Protection Agency lists the area as unclassifiable. However, for regulatory purposes, unclassifiable areas are considered to be in attainment. All portions of the Caliente rail alignment would be within areas classified as in attainment for all National Ambient Air Quality Standards.

The most comprehensive source of representative data on ambient concentrations of gas-phase air pollutants for the region of influence is a special study at Yucca Mountain covering a 4-year period from October 1991 to September 1995 (DIRS 102877-CRWMS M&O 1999, all). The limited amount of air quality data reflects choices made by national and state agencies to focus monitoring resources either on population centers or pristine areas such as national parks. Additional data on particulate matter are available based on monitoring at three sites in the vicinity of Yucca Mountain from 1989 to 1997 (DIRS 102877-CRWMS M&O 1999, all; DIRS 102876-CRWMS M&O 1997, all; DIRS 147777-SAIC 1992, all; DIRS 147780-SAIC 1992, all), from three sites from 1998 to 2001 (DIRS 173738-DOE

Table 3-15. State of Nevada and National Ambient Air Quality Standards[a] (page 1 of 2).

Pollutant[b]	Average time[c]	Nevada standards concentration[b]	National primary standards[b]	National secondary standards[b]	Notes regarding the air quality standard
Ozone	1 hour	0.12 ppm (235 μg/m^3)	None	Same as primary	The expected number of days per calendar year with a maximum hourly average concentration above the standard is less than or equal to 1.
	8 hour	None	0.08 ppm (195 μg/m^3)	Same as primary	The 3-year average of annual fourth-highest daily maximum.
Ozone, Lake Tahoe Basin	1 hour	0.10 ppm (195 μg/m^3)	None	None	The expected number of days per calendar year with a maximum hourly average concentration above the standard is less than or equal to 1.
Carbon monoxide	8 hours	9 ppm (10,500 μg/m^3) for elevations less than 1,500 meters[d] above mean sea level	9 ppm (10,500 μg/m^3) at any elevation	None	Not to be exceeded more than once per year.
		6 ppm (7,000 μg/m^3) for elevations greater than 1,500 meters above mean sea level			
Carbon monoxide (at any elevation)	1 hour	35 ppm (40,500 μg/m^3)	35 ppm (40,500 μg/m^3)		
Nitrogen dioxide	Annual arithmetic mean	0.053 ppm (100 μg/m^3)	0.053 ppm (100 μg/m^3)	Same as primary	Not to be exceeded.
Sulfur dioxide	Annual arithmetic mean	0.03 ppm (80 μg/m^3)	0.03 ppm (80 μg/m^3)	None	Not to be exceeded.
	24 hours	0.14 ppm (365 μg/m^3)	0.14 ppm (365 μg/m^3)		Not to be exceeded more than once per year.
	3 hours	0.5 ppm (1,300 μg/m^3)	None	0.5 ppm (1,300 μg/m^3)	
Particulate matter as PM	Annual arithmetic mean	50 μg/m^3	Revoked[e]	Revoked[e]	The 3-year average of the weighted annual mean concentration at each monitor within an area.
	24 hours	150 μg/m^3	150 μg/m^3		Not to be exceeded more than once per year.[f]

Table 3-15. State of Nevada and National Ambient Air Quality Standards[a] (page 2 of 2).

Pollutant[b]	Average time[c]	Nevada standards concentration[b]	National primary standards[b]	National secondary standards[b]	Notes regarding the air quality standard
Particulate matter as $PM_{2.5}$	Annual arithmetic mean	None	15 μg/m^3	Same as primary	The 3-year average of the weighted annual mean concentration from single or multiple community-oriented monitors.
	24 hours	35 μg/m^3	35 μg/m^3		The 3-year average of the 98th percentile of 24-hour concentrations at each population-oriented monitor within an area.[g]
Lead [h]	Quarterly arithmetic mean	1.5 μg/m^3	1.5 μg/m^3	Same as primary	Not to be exceeded.
Hydrogen sulfide[h]	1 hour	0.08 ppm (112 μg/m^3)	None	None	Not to be exceeded.

a. Sources: Nevada Administrative Code Section 445B.22097 and 40 CFR 50.4 through 50.11.
b. PM_{10} = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers; ppm = parts per million; μg/m^3 = micrograms per cubic meter.
c. Time over which pollutant is measured.
d. To convert meters to feet, multiply by 3.2808.
e. The U.S. Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006 (71 FR 60853, October 17, 2006).
f. The 24-hour state standard is attained when the expected number of days per calendar year with a 24-hour average concentration above the standard is equal to or less than 1. The expected number of days per calendar year is based on an average of the number of exceedances per year for the last 3 years.
g. The 24-hour state standard is attained when the second highest of a 3-year rolling average of the 24-hour concentration at each monitor is less than the standard.
h. The proposed railroad would not emit lead or hydrogen sulfide; they are included here for completeness.

2002, p. 42), and from two sites from 2002 through 2005 (DIRS 168842-DOE 2003, p. 42; DIRS 173740-DOE 2004, p. 36; DIRS 176801-Wills 2005, p. 38; DIRS 179948-DOE 2006, p. 40). While these data sets pertain to locations more than 160 kilometers (100 miles) from the easternmost part of the Caliente rail alignment, DOE believes they are representative of the ambient air quality along most of the Caliente rail alignment, because neither area has large emission sources or metropolitan areas that would otherwise affect air quality. However, local natural sources of particulate matter, such as barren land or dry lake beds, could generate higher localized concentrations of particulate matter.

In the vicinity of the eastern portion of the Caliente rail alignment, the closest location for which there are recorded air quality data is Mesquite, Nevada, at which ozone and particulate matter measurements are taken. However, because Mesquite is outside the air quality and climate region of influence (Mesquite is in Clark County) and is more than 100 kilometers (65 miles) from its closest point to the Caliente rail alignment, and because there has been substantial construction activity and population growth in Mesquite in recent years, Mesquite's air quality is not representative of the area of the Caliente rail alignment.

In the vicinity of the western portion of the Caliente rail alignment, the closest location (other than the Yucca Mountain Site) for which there are recent air quality data is Pahrump, Nevada. However, Pahrump, which is in the extreme southern tip of Nye County, is 65 kilometers (40 miles) southeast of the rail alignment, and only monitors particulate matter. In recent years there have been exceedances of the National Ambient Air Quality Standards for particulate matter in Pahrump because there has been substantial construction activity and population growth in the Pahrump Valley. In September 2003, Pahrump entered into a Memorandum of Understanding (DIRS 178128-Nevada Division of Environmental Protection 2003, p. 5) with the U.S. Environmental Protection Agency, the State of Nevada, and Nye County to develop an air quality improvement plan, with quantified emission-reduction measures so that the emission reduction strategies will be adequate to ensure the area stays in attainment of the particulate matter standards and with the objective that the area would be in attainment by 2009. Pahrump has a background monitoring site intended to represent natural background concentrations of the northern Mojave Desert; however, some disturbed land in the vicinity of the monitor makes the site only representative of the local background in the Pahrump Valley. Because of Pahrump's distance from the Caliente rail alignment and heavy construction activity and population growth, its air quality is not representative of the area of the Caliente rail alignment.

The DOE Environmental Safety and Health Department began air quality monitoring in the Yucca Mountain vicinity in 1989. Figure 3-59 shows station locations. The air quality network originally consisted of Sites YMP1 and YMP5; DOE added sites YMP6 and YMP9 in 1992.

DOE designed the air quality and meteorological monitoring program to comply with the U.S. Environmental Protection Agency's *On-Site Meteorological Program Guidance for Regulatory Modeling Applications* (DIRS 101822-EPA 1987, all) and *Ambient Monitoring Guidelines for Prevention of Significant Deterioration (PSD)* (DIRS 108989-EPA 1987, all), and with U.S. Nuclear Regulatory Commission meteorological monitoring guidance (ANSI/ANS-2.5-1984, *Standard for Determining Meteorological Information at Nuclear Power Sites* and Regulatory Guide 1.23, Rev. 0, *Onsite Meteorological Programs*).

DOE monitored the criteria gaseous pollutants of carbon monoxide, nitrogen dioxide, ozone, and sulfur dioxide at YMP1 from October 1991 through September 1995. DOE also monitored the concentration of PM_{10} at YMP1; the ambient air quality monitoring program included sampling of PM_{10} every sixth day, based on the U.S. Environmental Protection Agency's representative schedule of sampling.

YMP5, the second site measuring PM_{10}, represented background conditions away from site activities at Yucca Mountain. Measurements at YMP5 began in April 1989 and continued until 2002.

In October 1992, DOE added two sites to measure PM_{10}:

- YMP6, along the western border of the Nevada Test Site where the Test Site meets the U.S. Air Force land in upper Yucca Wash, measured particulate matter that might be transported from Midway Valley toward the northwest through Yucca Wash (discontinued September 1999).
- YMP9, at Gate 510 on the southern border of the Nevada Test Site, north of Amargosa Valley.

Tables 3-16 and 3-17 summarize the results of the particulate-matter air quality monitoring programs. More information on the results of the sampling program is available in *Environmental Baseline File for Meteorology and Air Quality* (DIRS 102877-CRWMS M&O 1999, all); *Meteorological Monitoring Program Particulate Matter Ambient Air Quality Monitoring Report January through December 1996* (DIRS 102876-CRWMS M&O 1997, all); *Particular Matter Ambient Air Quality Data Report for 1989 and 1990* (DIRS 147777-SAIC 1992, all); and *Particular Matter Ambient Air Quality Data Report for 1991* (DIRS 147780-SAIC 1992, all).

Between 1989 and 1997, the highest 24-hour PM_{10} measurement was 67 micrograms per cubic meter. This measurement, made at Site YMP5 in 1995, is approximately 45 percent of the regulatory standard of 150 micrograms per cubic meter (40 CFR 50.4 through 50.11).

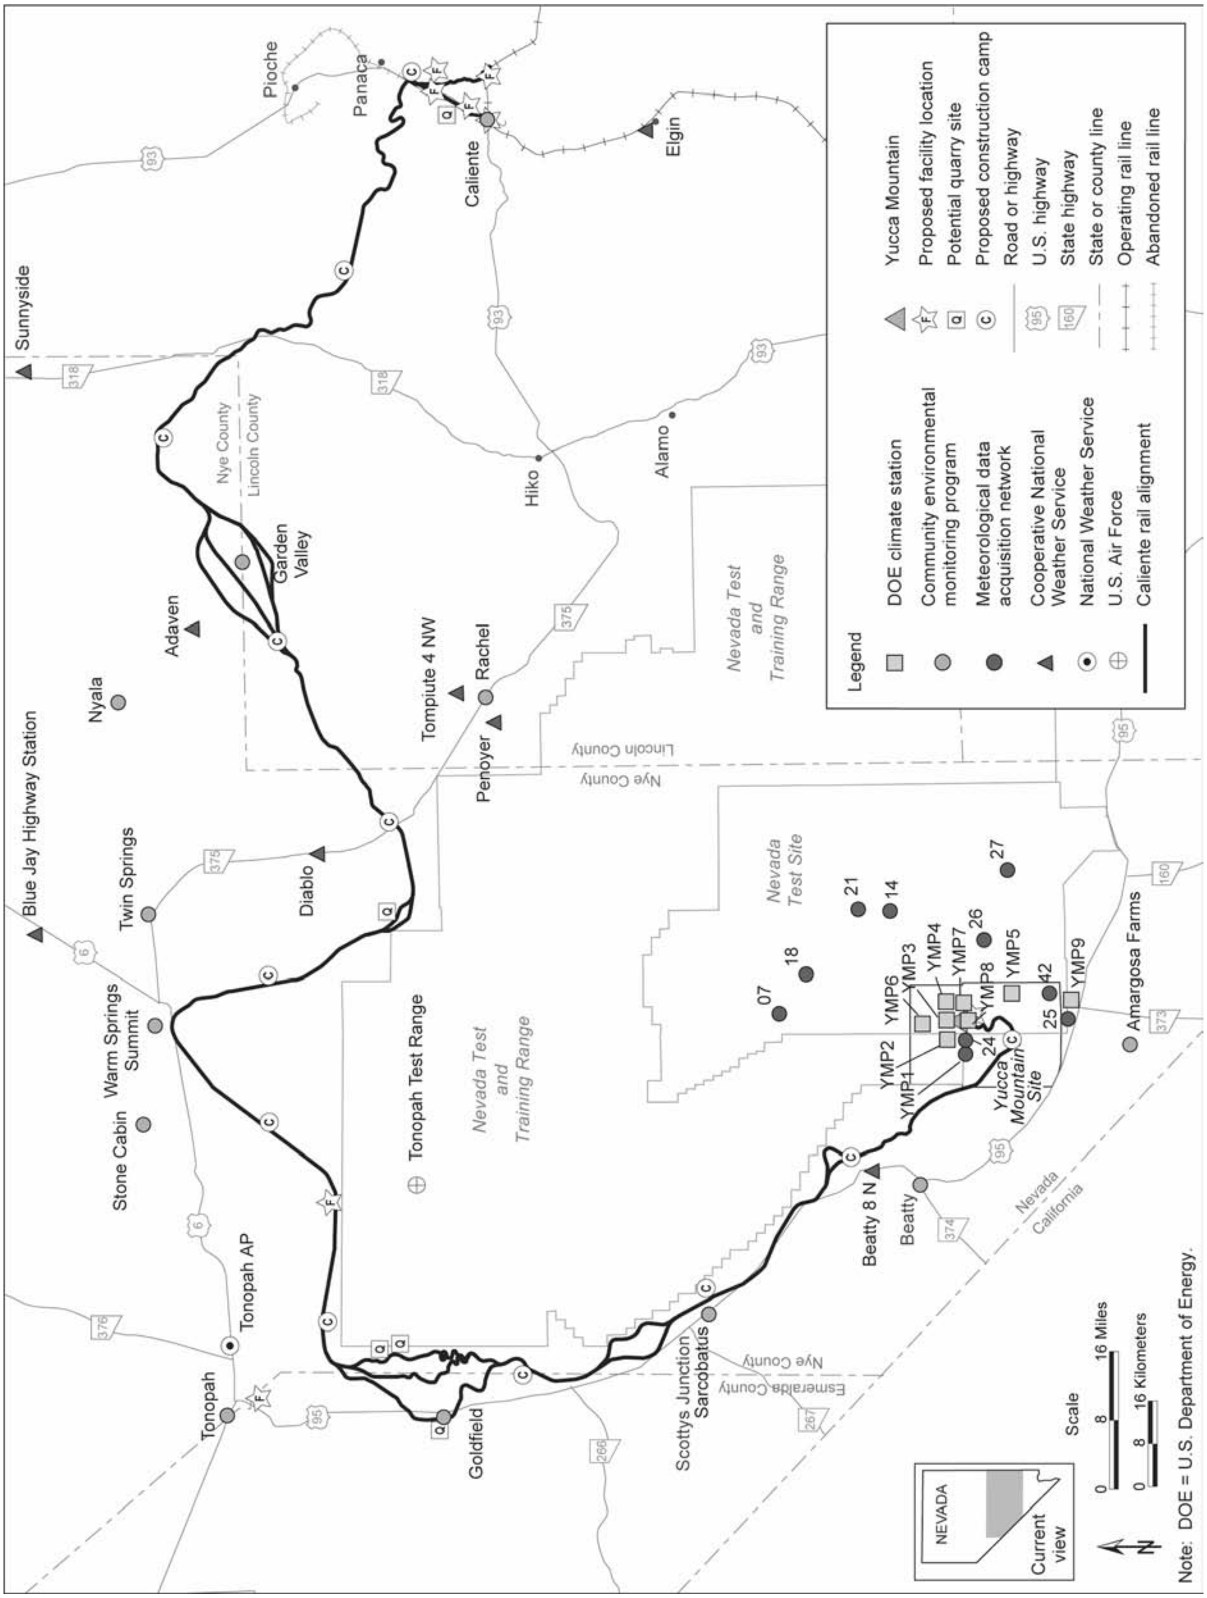

Figure 3-59. Air quality and climate stations along the Caliente rail alignment.

Table 3-16. Summary of PM_{10} concentrations at sites in the vicinity of Yucca Mountain (1989 to 1997).[a,b,c]

Sampler[d]	Averaging time	1989	1990	1991	1992	1993	1994	1995	1996	1997	High
Site YMP1	24-hour highest	41	62	33	30	30	39	21	60	31	62
	Second highest	27	49	25	24	22	26	20	23	21	49

	Second highest	NA	NA	NA	31	21	19	14	28	19	31
	Annual average	NA	NA	NA	NA	9	8	7	10	8	10

a. Sources: DIRS 102877-CRWMS M&O 1999, p. 13; DIRS 102876-CRWMS M&O 1997, p. 13; DIRS 147777-SAIC 1992, p. 13; DIRS 147780-SAIC 1992, p. 13.
b. Concentrations are shown in micrograms per standard cubic meter ($\mu g/m^3$).
c. PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; NA = samples were not taken during the corresponding monitoring period.
d. YMP = Yucca Mountain Project.

The second-highest value at any monitoring site, which is the basis for a violation of the ambient air quality standard, was 49 micrograms per cubic meter at Site YMP1 in 1990, which is 33 percent of the PM_{10} standard.

The annual averages were between 6 and 13 micrograms per cubic meter (Site YMP9 [1998] and Site YMP5 [1989], respectively), which is less than 30 percent of the historical annual standard (50 micrograms per cubic meter).

Table 3-17 lists the annual highest and second-highest 24-hour concentrations, and the annual average PM_{10} concentration for the period 1998 to 2005 for YMP1, YMP5, and YMP9, and shows the measured levels of ambient particulate matter were well below the Nevada particulate-matter standards. Table 3-18 lists Site YMP1 results for monitoring of gaseous criteria pollutants (carbon monoxide, nitrogen dioxide, ozone, and sulfur dioxide) for each year of the 4-year monitoring period (1991 to 1995); for comparison, the National Ambient Air Quality Standards are also shown.

Ambient concentrations of carbon monoxide and sulfur dioxide were below the threshold of reliable detection of the instrument. Nitrogen dioxide occasionally registered values of a few hundredths of parts per million by volume, typically associated with nearby vehicle activity. The number of hours per operating quarter with measurements above the threshold was between 1 and 161, which occurred from October through December 1993. The results listed in Table 3-18 are expressed in the units of the applicable standard (for example, annual average of nitrogen dioxide), and the listed values are based on the threshold of reliable detection for that instrument.

Table 3-17. Summary of PM_{10} concentrations at sites in the vicinity of Yucca Mountain (1998 to 2005).[a,b,c]

Sampler	Averaging time	1998	1999	2000	2001	2002	2003	2004	2005	High

Table 3-18. Site YMP1 maximum observed ambient gaseous air quality concentration in comparison to the Nevada Standards for Air Quality and the National Ambient Air Quality Standards (in parts per million by volume).[a]

Pollutant	Nevada and NAAQS[b]	Year 1 (10/91 to 9/92)	Year 2 (10/92 to 9/93)	Year 3 (10/93 to 9/94)	Year 4 (10/94 to 9/95)
Carbon monoxide	35 (1 hour)	0.2	0.2	0.2	0.2
	9[c] (8 hour)	0.2	0.2	0.2	0.2
Nitrogen dioxide	0.053 (annual)	0.0020	0.0020	0.0021	0.0021
Ozone[d] (for Nevada ambient air quality only)	0.12 (1 hour) 0.08 (8 hour)	0.096 (1 hour)	0.093 (1 hour)	0.081 (1 hour)	0.083 (1 hour)
Sulfur dioxide	0.5 (3 hour)	0.002	0.002	0.002	0.002
	0.14 (24 hour)	0.002	0.002	0.002	0.002
	0.03 (annual)	0.002	0.002	0.002	0.002

a. Source: DIRS 102877-CRWMS M&O 1999, p. 14; 40 CFR 50.4 through 50.11.
b. NAAQS = National Ambient Air Quality Standards.
c. Nevada Standards for Air Quality: less than 5,000 feet above mean sea level.
d. The 1-hour ozone standard of 0.12 parts per million, in place during the listed years, was phased out in 2005 and replaced with an 8-hour ozone standard of 0.08 parts per million.

DOE believes these measurements of particulate matter, carbon monoxide, nitrogen dioxide, and sulfur dioxide are representative of the air quality along the Caliente rail alignment because the region of influence has no large emission sources or metropolitan areas that would otherwise affect its air quality. However, in areas close to barren land or dry lake beds, there could be higher particulate-matter concentrations.

Ozone was the only gaseous criteria pollutant to routinely register ambient levels above the instrument threshold. Ozone levels never exceeded the regulatory limit for the 1-hour average standard (0.12 parts per million by volume). The highest 1-hour average was 0.096 parts per million. Note that the 1-hour average standard was withdrawn in 2005, and has now been replaced with an 8-hour average standard (0.08 parts per million). Ozone is formed in the atmosphere under the presence of sunlight, ***nitrogen oxides***, and ***volatile organic compounds***. Ozone typically has the highest concentrations during warm weather because strong sunlight and high temperatures are more conducive to higher ambient concentrations. Approximately 90 percent of the warm-season hours had concentrations between 0.020 and 0.060 parts per million; only 44 hours had concentrations in excess of 0.080 parts per million.

Available data for Death Valley National Park (for 1995 to 2004), 50 kilometers (31 miles) west of the westernmost portion of the Caliente rail alignment, reported a highest 1-hour average ozone concentration of 0.095 parts per million (DIRS 176115-EPA 2005, all), which is similar to the ozone values measured at Yucca Mountain. Ozone concentrations along more eastern parts of the Caliente rail alignment are anticipated to be even lower because of their greater distance from emission sources.

No ambient monitoring data were available for lead. However, DOE expects concentrations of lead to be far below the regulatory standard because there are no industrial sources in the region of influence (or near enough to transport this ***contaminant*** into the region of influence), and lead-based gasoline, previously the principal source of lead in the air, has been phased out.

No ambient monitoring data were available for $PM_{2.5}$; however, because $PM_{2.5}$ is a subset of PM_{10}, $PM_{2.5}$ can be estimated from measurements of ambient PM_{10}. In the region of influence, nearly all PM_{10} would be generated from the resuspension of surface-level soil and mineral materials. A U.S. Department of Agriculture study on wind erosion in the western United States found that over all soils, the fraction of PM_{10} as $PM_{2.5}$ was about 15 percent, ranging from 10 to 30 percent (DIRS 173838-Hagen 2001, p. 1). To be conservative, DOE applied the upper end of this range (30 percent) to the ambient PM_{10} data collected at Yucca Mountain (Sites YMP1, YMP5, and YMP9) over the past 8 years (1998 through 2005), and the resulting data indicated the highest expected 24-hour concentration of $PM_{2.5}$ would be 16 micrograms per cubic meter, and the highest expected annual average concentration would be 4 micrograms per cubic meter. These figures are 46 and 26 percent of the standards for $PM_{2.5}$. Table 3-19 summarizes these results and indicates that $PM_{2.5}$ would be well below the National Ambient Air Quality Standards at all locations along the Caliente rail alignment.

3.2.4.3 Climate

The Caliente rail alignment would cross ***desert*** and ***semi-desert*** areas that generally have abundant hours of cloud-free days, low annual precipitation, and large daily ranges in temperature.

To characterize the existing climate, DOE collected meteorological data from 41 meteorological monitoring stations within the Caliente rail alignment region of influence (see Figure 3-59 and Table 3-19).

The following four groups operated these stations:

- National Oceanic and Atmospheric Administration
- Community Environmental Monitoring Program
- DOE Environment, Safety and Health Programs Department Network
- U.S. Air Force

The Meteorological Data Acquisition Network is a network of meteorological stations operated by the National Oceanic and Atmospheric Administration, Air Resources Laboratory/Special Operations and Research Division.

Table 3-19. Maximum observed ambient air quality concentrations at sites in the vicinity of Yucca Mountain (1998 to 2005) compared to the National Ambient Air Quality Standards for particulate matter.[a,b,c]

Sampler	Nevada and NAAQS[d]	1998	1999	2000	2001	2002	2003	2004	2005	High

b. PM_{10} = particulate matter with an aerodynamic diameter equal to or less than 10 micrometers; $PM_{2.5}$ = particulate matter with an aerodynamic diameter equal to or less than 2.5 micrometers.
c. Concentrations are shown in micrograms per standard cubic meter.
d. NAAQS = National Ambient Air Quality Standards.
e. The U.S. Environmental Protection Agency revoked the annual PM_{10} standard effective December 18, 2006. (71 Federal *FR* 60853, October 17, 2006).
f. Estimated based on upper-end range of PM_{10} data assuming 30 percent of PM_{10} is $PM_{2.5}$ (DIRS 173838-Hagen 2001, p. 1).

The Community Environmental Monitoring Program is a joint effort between the DOE Nevada Operations Office, the University of Nevada Desert Research Institute, and the Community College System of Nevada, and is a network of monitoring stations in communities surrounding the Nevada Test Site that check the ***environment*** for ***radioactivity*** and check a variety of meteorological parameters. The U.S. Air Force has historically operated a meteorological station from time to time on the Nevada Test and Training Range at the Tonopah Test Range and archives this data with the Air Force Combat Climatology Center.

DOE acquired data not directly available through these programs through the Western Regional Climate Center (DIRS 165987-WRCC 2002, all), which maintains historical climate databases for most of the climate and operational National and Military Weather Service stations throughout the western United States, including a network of stations that collect daily climate observations.

Table 3-20 lists the station operators and their respective elevations in the Caliente rail alignment air quality and climate region of influence. All stations collected temperature and precipitation data, and Table 3-20 also identifies those stations that collected wind speed and direction data. The range of elevations over which weather data were collected is approximately the same as the elevation range of the Caliente rail alignment – from 746 meters (2,450 feet) at the Amargosa Farms Station to 2,293 meters (7,520 feet) at the Warm Springs Summit Station.

The Caliente rail alignment would cross a variety of topographic features, ranging from mountain passes to sage-covered deserts. Alignment elevations range from 1,341 meters (4,400 feet) near the City of Caliente in Lincoln County to 2,293 meters (7,520 feet) at the Warm Springs Mountain Summit in Nye County and back down to 1,080 meters (3,540 feet) near the end of the Caliente rail alignment at Yucca Mountain. These elevation changes drive a wide variation in temperature and precipitation.

From east to west, the Caliente rail alignment would lie within and be exposed to the climatic conditions of the Nevada counties of Lincoln, Nye, and Esmeralda, as described in Sections 3.2.4.3.1 through 3.2.4.3.3.

3.2.4.3.1 Lincoln County

In Lincoln County, the Caliente rail alignment would cross two mountain ranges and cross the Dry Lake Valley, representing an elevation range of approximately 1,200 to 2,000 meters (3,900 to 6,600 feet),

Table 3-20. Meteorological stations in the Caliente rail alignment air quality and climate region of influence[a,b] (page 1 of 2).

and would pass through another portion of Lincoln County from approximately Garden Valley to near the Quinn Canyon Range. Annual average temperatures along the rail alignment through Lincoln County range from approximately 13° Celsius (55° Fahrenheit) at lower elevations to approximately 7° Celsius (45° Fahrenheit) at higher elevations. Because of the arid climate, it is common for strong daytime heating and rapid nighttime cooling to result in large variations in temperature, particularly during the summer months. Daily temperature variations are smaller during winter months, and less pronounced at higher elevations. At the lower elevations, summertime mean maximum temperatures are approximately 35° Celsius (95° Fahrenheit), and are accompanied by low relative humidity (commonly less than 10 percent). Winter mean minimum temperatures are around minus 8° Celsius (18° Fahrenheit) in December and January (DIRS 165987-WRCC 2002, all).

In the eastern portion of Lincoln County, maximum precipitation occurs during the winter months (January through March), and a secondary peak occurs during July through September, associated with occasional thunderstorms. At higher elevations, annual average precipitation is greater than 250 millimeters (10 inches); at lower elevations, average precipitation is 250 millimeters or less. Daily precipitation levels can be high, and historical maximums have exceeded 76 millimeters (3 inches) per day in the vicinity of the Caliente rail alignment. These maximums have historically occurred during the winter months, and could cause localized flooding, particularly if the ground has been saturated by recent rainfall. The occasional summer thunderstorms can produce heavy rains that can cause flash floods.

The western portion of Lincoln County is drier, averaging closer to 130 millimeters (5 inches) of precipitation per year, primarily occurring January through April.

From November through April, precipitation in Nye County along the Caliente rail alignment might fall as snow. Mean average snowfall in the lower valleys is about 250 millimeters (10 inches). At higher elevations, the average snowfall is between 500 and 1,000 millimeters (20 and 40 inches) per year.

Local topography strongly influences winds in Lincoln County along the Caliente rail alignment. Local winds are generally channeled by topography, with prevailing wind direction oriented along valley axes. Wind speeds are highest in the spring and occasionally generate dust storms. The extreme highest wind speeds are along ridgetops and mountain summits. Annual average wind speeds in the valleys range from 1.3 meters per second (2.9 miles per hour) at the Caliente station to about 2.2 meters per second

(4.9 miles per hour) at the Garden Valley station. Calm conditions (wind speeds of less than 0.6 meter per second [1.3 miles per hour]) are most frequent at the Caliente station, and characterize slightly more than one-third of all hours; the Garden Valley station has calm conditions about 15 percent of the time.

3.2.4.3.2 Nye County

Through southern Nye County, the Caliente rail alignment would lie to the east of the southern Sierra Nevada Range, a large mountain ***barrier*** that prevents much of the moist Pacific Ocean air from reaching the area. The result is lower-elevation areas that are largely desert or semidesert. The Caliente rail alignment would cross a variety of topographic features within the region, from mountain passes to sage-covered deserts. Elevations range from 2,293 meters (7,520 feet) at the Warm Springs Mountain Summit to 1,080 meters (3,540 feet) near the end of the Caliente rail alignment at Yucca Mountain, and present a wide variation in temperature and precipitation. In general, the climatic features can be described as abundant hours of cloud-free days, low annual precipitation (less than 250 millimeters [10 inches] per year), and large daily ranges in temperature.

In Nye County, the mean annual temperature along the Caliente rail alignment ranges from approximately 16° Celsius (61° Fahrenheit) at lower elevations to approximately 10° Celsius (50° Fahrenheit) at the highest elevations. Because of the arid climate, it is common for strong daytime heating and rapid nighttime cooling to result in large variations in temperature, particularly during the summer months. Daily temperature variations are smaller during winter months, and less pronounced at higher elevations. At the lowest elevations along the Caliente rail alignment, summertime maximum temperatures frequently exceed 38° Celsius (100° Fahrenheit), and are accompanied by low relative humidity (commonly less than 10 percent).

Annual precipitation averages less than 250 millimeters (10 inches) per year at all locations across southern Nye County, and most precipitation occurs during the winter. Along the Caliente rail alignment, precipitation is lowest from the Sarcobatus Flat station to the Beatty station, averaging just 75 to 100 millimeters (3 to 4 inches) per year because of the ***rain shadow*** effects from the Sierra Nevada and Amargosa Range. At higher elevations, a secondary peak in rainfall (associated with increased thunderstorm activity) occurs during the late summer months; at lower elevations, this precipitation often evaporates before reaching the ground. The thunderstorms occasionally produce heavy rains that can cause flash floods. Daily precipitation levels can be high, and historical maximums have reached 60 millimeters (2.4 inches) at the Sarcobatus Flat station, with a number of locations exceeding 40 millimeters (1.6 inches).

From November through April, precipitation in Nye County along the Caliente rail alignment might fall as snow. Mean average snowfall in the lower valleys is about 50 to 130 millimeters (2 to 5 inches). At higher elevations, the average snowfall is between 130 and 380 millimeters (5 and 15 inches) per year.

Local topography in Nye County strongly influences winds along the Caliente rail alignment. Local winds are generally channeled by topography, with prevailing wind direction oriented along valley axes. Wind speeds are highest in the spring, and occasionally generate dust storms at playas. The extreme highest wind speeds are along ridgetops and mountain summits. The maximum wind speed recorded at Warm Springs Summit was 34 meters per second (76 miles per hour), and winds of more than 40 meters per second (90 miles per hour) have been recorded along ridgetops at the Nevada Test Site station. Annual average wind speeds are much lower – from 5.4 meters per second (12 miles per hour) at the Warm Springs Summit station to 1.7 meters per second (3.8 miles per hour) at the Stone Cabin station. Along the Caliente rail alignment through southern Nye County, calm conditions (wind speeds of less than 0.6 meter per second [1.3 miles per hour]) are most frequent at the Stone Cabin station, and characterize wind conditions in the area about 12 percent of the time. In southern Nye County, annual average wind speeds are much lower, with annual average speeds of 2.4 meters per second (5.4 miles per hour) at Sarcobatus Flat and 2.2 meters per second (4.9 miles per hour) at Beatty. Through southern Nye County, calm conditions are most frequent at Sarcobatus Flat station, and characterize wind conditions in the area about 7 percent of the time.

3.2.4.3.3 Esmeralda County

The Caliente rail alignment would cross through a small portion of Esmeralda County near the Goldfield station and would be east of the high peaks of the Sierra Nevada and White Mountain ranges, at an elevation of around 1,700 meters (5,500 feet). This area experiences abundant hours of cloud-free days, low annual precipitation (less than 250 millimeters [10 inches] per year), and large daily ranges in temperature.

Within Esmeralda County, the mean annual temperature along the Caliente rail alignment is approximately 10° Celsius (50° Fahrenheit). Because of the arid climate, it is common for strong daytime heating and rapid nighttime cooling to result in large variations in temperature, particularly during the summer months. Summertime mean maximum temperatures are approximately 32° Celsius (90° Fahrenheit), and are accompanied by low relative humidity (commonly less than 10 percent). Winter mean minimum temperatures are approximately minus 7° Celsius (20° Fahrenheit) in December and January.

Annual precipitation in this part of Esmeralda County averages less than 180 millimeters (7 inches) per year, and is heaviest during the winter. During the summer, occasional thunderstorms can produce heavy rains and cause flash floods. Daily precipitation levels occasionally exceed 50 millimeters (2 inches), but on average only 1 day per year has more than 25 millimeters (1 inch) of rain. Precipitation from October through April might fall as snow. Snowfall averages are around 380 millimeters (15 inches).

Local topography in Esmeralda County strongly influences winds along the Caliente rail alignment. Local winds are generally channeled by topography, with prevailing wind direction oriented along valley axes. Highest wind speeds occur in the spring, and occasionally generate dust storms. Annual average wind speeds at the Goldfield station are around 2.7 meters per second (6 miles per hour); slightly more than 5 percent of the time the area experiences calm conditions.

3.2.5 SURFACE-WATER RESOURCES

This section describes surface-water resources along the Caliente rail alignment. Surface-water resources include streams, washes, playas, ponds, wetlands, floodplains, and springs. Section 3.2.5.1 describes the region of influence for surface-water resources along the Caliente rail alignment; Section 3.2.5.2 is a general overview of surface-water features along the rail alignment; and Section 3.2.5.3 describes specific surface-water features for the rail alignment alternative segments and common segments. Sections 3.2.5.2.3 and 3.2.5.2.4 describe wetlands and floodplains, respectively, from a regulatory perspective; Section 3.2.7, Biological Resources, describes wetlands from a habitat perspective. Appendix F (Floodplain and Wetlands Assessment) addresses compliance with Executive Orders 11988, *Floodplain Management*, and 11990, *Protection of Wetlands*, in more detail.

3.2.5.1 Region of Influence

The Caliente rail alignment region of influence for surface-water resources is limited in most cases to the nominal width of the construction right-of-way. Because of the types of land-disturbing activities that would take place during rail line construction, the construction right-of-way would be susceptible to erosion and changes in surface-water flow patterns. Spills (of, for example, fuel, paint, or lubricants) during the railroad construction and operations phases could also affect this area.

In some cases, the region of influence for surface water extends beyond the construction right-of-way. In places where surface-water flow patterns (including floodwaters) could be modified or surface-water drainage could carry eroded soil, sediment, or spills downstream, the region of influence extends beyond the construction right-of-way. Within the region of influence, there could be impacts to floodwaters such that they would back up on the upstream side of the rail line, while there could be impacts to water quality pollutants traveled downstream during a storm event without precipitating out (soils from erosion) or becoming too dilute (petroleum-based lubricants or fuels) to detect. For purposes of analysis, DOE screened the area within 1.6 kilometers (1 mile) of the centerline of the rail alignment for surface-water resources that could be indirectly affected.

Surface-Water Terms

An **ephemeral stream** or ephemeral drainage has a channel bed above the normal water table and only flows in direct response to precipitation or snowmelt within its drainage basin.

An **intermittent stream** or intermittent drainage has a channel bed that fluctuates above or below the normal water table along its length, and might or might not have flow within it during any particular time or at any particular location. The presence of flow within the channel is determined by its channel elevation in relation to the water table, precipitation events, or snowmelt within its drainage basin.

A **wash** or drainage in the western United States generally refers to the dry streambed of an intermittent or ephemeral stream. In this Rail Alignment EIS, wash is used interchangeably with intermittent and ephemeral streams.

A **perennial stream** or perennial drainage receives groundwater into its channel and its stream bed is normally below the water table. During years with normal precipitation, a perennial stream will have constant flow.

A **playa** is normally a dry lake bed that can contain water in response to seasonally high runoff.

Evapotranspiration is a combination of processes through which water is transferred to the atmosphere from evaporation from open water and bare soil, and transpiration from vegetation.

3.2.5.2 General Environmental Setting and Characteristics

Important characteristics of hydrologic systems in the region of influence include ***ephemeral streams*** and playas. Ephemeral surface-water features can be dry over multiple seasons or even years during droughts, but can have multiple periods of flow or standing water during wet periods, as during the winter of 2004-2005. Central and southern Nevada are characterized by low precipitation and high annual ***evapotranspiration*** rates typical of desert climates, as described in Section 3.2.4, Air Quality and Climate. Because of the arid climate and the terrain (that is, north-south trending, parallel mountain ranges with broad, intervening valleys) in this area, surface water generally evaporates before it can flow out of the drainage basin. Typically, surface drainage in this area remains within its topographically defined water basin; that is, surface water generally flows to low areas such as lakes, flats, or playas.

Surface-water systems are typically defined in terms of watersheds (or basins). For water planning and management purposes, the State of Nevada is divided into discrete hydrologic units delineated by 14 major hydrographic regions that are subdivided into 256 hydrographic areas (DIRS 103406-Nevada Division of Water Planning 1992, all). In this Rail Alignment EIS, watersheds (or basins) are referred to as hydrographic regions. A region is defined as a geographic area drained by a single major stream or an area consisting of a drainage system comprised of streams and often natural or manmade lakes.

Overall, most surface-water features described in this section are ephemeral drainage features that intermittently contain flowing water. Meadow Valley Wash and portions of Clover Creek at the beginning of the Caliente rail alignment are the exceptions, where surface-water flow is perennial or more consistently present. This section describes surface-water features in relation to the hydrographic regions in which they are located. Figure 3-60 shows the hydrographic regions within Nevada and the boundaries for the three hydrographic regions the Caliente rail alignment would cross. These regions include the Colorado River Basin, the Central Region, and the Death Valley Basin.

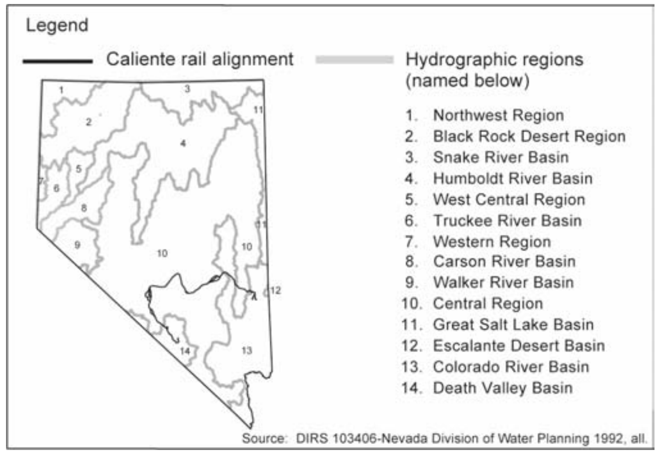

Figure 3-60. Nevada hydrographic regions crossed by the Caliente rail alignment.

3.2.5.2.1 Surface Drainage Features (Streams and Playas)

As described in Section 3.2.1, Physical Setting, the Caliente rail alignment would pass through numerous valleys and over or around numerous mountain ranges. The need for relatively gentle curves and gradients sets physical limitations on the design of the rail line that would require the alignment to follow valley floors that go around mountain ranges, or parallel the mountain ranges in transition zones to change elevation gradually (DIRS 180916-Nevada Rail Partners 2007, Appendix B). Within the valley floors, the rail alignment could parallel predominant drainage channels and cross through or near flats and playas. Some streams within low areas are braided channels where stream flow is divided among multiple channels, which the rail alignment could cross in several locations. Near or within mountain ranges, the alignment typically would be perpendicular to the predominant drainage direction. Therefore, the Caliente rail alignment would encounter a wide variety of surface drainage features.

Drainage features have been classified using Strahler's stream order system (DIRS 176728-Goudie et al., ed. 1981, pp. 50 and 51), which is a method of classifying stream segments based on the number of upstream tributaries. Stream order ranks the size and potential power of streams. Orders range from small streams with no branches (1st Order) up to streams the size of the Mississippi River, which is a 10th Order stream. As two 1st Orders come together, they form a 2nd Order stream. Two 2nd Order streams converging form a 3rd Order stream. Streams of lower order joining a higher order stream do not change the order of the higher order stream.

DOE used stream order to define ***notable drainage channels*** and as a method to select the number of ephemeral washes shown on figures in Section 3-62. To improve the readability of these figures and provide a means to prioritize the drainage features, the figures depict only rivers, streams, and washes the rail alignment would cross that are 2nd Order streams or higher. Figures in Section 3-62 do not show all the washes and drainages the rail alignment would cross, but provide enough information to support the analysis of potential impacts to surface-water resources. Section 4.2.5 identifies the estimated number of drainage channels the rail alignment would cross by alternative segment and common segment.

> **Notable drainage channels,** as referenced in the text and shown on figures in Section 3.2.5.3, were determined by choosing those channels with a stream order of 2 or greater based on Strahler's ordering system, with the National Hydrography Dataset as a base map.

3.2.5.2.1.1 Surface-Water Quality. Because of the ephemeral nature of surface water in the southern part of Nevada, water-quality data for the region of influence are limited. The State of Nevada does not formally monitor surface water in the Caliente rail alignment region of influence.

Water-quality data for the State of Nevada are available through the Nevada District of the U.S. Geological Survey and the Nevada Division of Environmental Protection. Surface water samples are collected from several major river basins in the state and then analyzed for physical and chemical parameters. The routine water-quality monitoring network includes the following river/basin systems: Walker River, Humboldt River, Colorado River, Lake Tahoe Tributaries, Snake River, Truckee River, Carson River, and Steamboat Creek. The Colorado River Basin is the only hydrographic region in the Nevada Division of Environmental Protection's monitoring system within the region of influence for the Caliente rail alignment (DIRS 176306-NDEP 2005, all).

In accordance with federal regulations, each state is required to submit a report on overall water-quality conditions to the U.S. Environmental Protection Agency every 2 years. According to the Nevada Division of Environmental Protection report for 2005 (DIRS 176306-NDEP 2005, all), agriculture and grazing have the greatest impacts on Nevada's waters, mainly because of ***nonpoint source pollution*** (such as irrigation, grazing, and flow-regulation practices). Flow reductions have a great impact on streams, limiting dilution of salts, minerals, and pollutants. Temperature, ***pH***, dissolved oxygen, nutrients, and suspended solids are the main pollutants of concern in the state. Agricultural sources generate large sediment and nutrient loads. Surface-water quality in Nevada varies greatly from location to location and from month to month with change of flow. In general, concentrations of dissolved solids are higher in the southern part of the state than in the northern part, depending largely on water discharge (DIRS 176316-Bostic et al. 2004, all). Because of dilution by precipitation or snowmelt, dissolved solids concentrations are usually highest during periods of low stream flow and lowest during periods of high stream flow.

No site-specific water chemistry data are available for streams or washes the Caliente rail alignment would cross. No streams the alignment would cross are known to be impaired. DOE previously collected and analyzed surface-water samples for chemical characteristics in the Yucca Mountain region. These analytical data are provided in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, p. 3-40).

3.2.5.2.1.2 Stream Flow. The U.S. Geological Survey has stream-gaging stations (many of which have been discontinued) throughout Nevada. Stream-flow data from these monitoring stations are available through the Geological Survey Nevada District. Table 3-21 lists the range of peak discharges for typical or major streams along the Caliente rail alignment. DOE cross-referenced peak discharge measurements at and near the Nevada Test Site with a Geological Survey fact sheet that discusses significant flooding events in the Amargosa River drainage basin in 1995 and 1998 (DIRS 159895-Tanko and Glancy 2001, Table 2).

Table 3-21. U.S. Geological Survey annual peak flow measurements for selected sites in streams of hydrographic areas along the Caliente rail alignment (page 1 of 3).[a]

Hydrologic unit gaging station (station number)	Drainage area (square kilometers)[b]	Annual peak flow range (cubic meters per second)[c]	Typical peak flow month(s)	Years of record (number of counts)
Areas in the Nevada Test Site				
Meadow Valley Wash (Eccles alternative segment, Caliente alternative segment, Caliente common segment 1)				
Meadow Valley Wash near Caliente (09418500)	4,300	0.12 to 68	February and March	1951-2004 (53)
Caselton Wash near Panaca (09418150)	180	0.11 to 48	July through August	1963-1981 (19)
Meadow Valley Wash at Eagle Canyon near Ursine (09417500)	760	0.62 to 20	January and February	1963-2003 (14)
Dry Lake Valley (Caliente common segment 1)				
Dry Lake Valley tributary near Caliente (10245270)	28	0 to 4.4	July	1967-1981 (15)
White River (Caliente common segment 1)				
White River near Lund (09415550)	1,800	0 to 1.3	March	1991-2003 (8)
Crystal Spring near Hiko (09415590)	No data	0.37 to 0.57	June through October	1986-2001 (11)
White River tributary near Sunnyside (09415560)	52	0 to 17	August and September	1966-1982 (15)
Sand Spring-Tikaboo Valleys (Caliente common segment 1; Garden Valley alternative segments 1, 2, 3, and 8; Caliente common segment 2)				
Penoyer Valley tributary near Tempiute (10247860)	3.8	0 to 3.7	July through September	1964-1981 (18)
Hot Creek-Railroad Valleys (Caliente common segment 2; South Reveille alternative segments 2 and 3; Caliente common segment 3)				
Big Creek near Warm Springs (10247200)	31	0.14 to 0.62	May	1991-1994 (4)
Hot Creek tributary near Warm Springs (10247010)	5.4	0.03 to 2.8	August	1964-1981 (17)
Ralston-Stone Cabin Valleys (Caliente common segment 3; Goldfield alternative segments 1, 3, and 4)				
Ralston Valley tributary near Tonopah (10249140)	0.52	0 to 1.4	July and August	1961-1981 (21)
Cactus-Sarcobatus Flats (Goldfield alternative segments 1, 3, and 4; Caliente common segment 4; and common segment 5)				
Stonewall Flat tributary near Goldfield (10248970)	1.4	0 to 4.3	June through August	1964-1985 (20)
Upper Amargosa (Oasis Valley alternative segments 1 and 3; common segment 6)				
Pah Canyon Wash above Fortymile Wash confluence (102512495)	16	2.6	February	1998 (1)

Table 3-21. U.S. Geological Survey annual peak flow measurements for selected sites in streams of subbasins along the Caliente rail alignment (page 2 of 3).[a]

Hydrologic unit gaging station (station number)	Drainage area (square kilometers)[b]	Annual peak flow range (cubic meters per second)[c]	Typical peak flow month(s)	Years of record (number of counts)
Areas in the Nevada Test Site				
Upper Amargosa (Oasis Valley alternative segments 1 and 3; common segment 6) (continued)				
Unnamed tributary to Fortymile Wash north of Delirium Canyon (102512496)	2.9	5.1	February	1998 (1)

b. To convert square kilometers to square miles, multiply by 0.3861.
c. To convert cubic meters per second to cubic feet per second, multiply by 35.3.

Most of the drainage channels the Caliente rail alignment alternative segments and common segments would cross typically flow only during significant (heavy) rainfall events, which generally occur only a few times a year. In many years, most of the streams listed in Table 3-21 have little or no flow. From late spring to early fall, precipitation patterns are dominated by convective, short-duration, high-intensity thunderstorms. From late fall to early spring, precipitation patterns are dominated by long-duration, low-intensity, general storm events with both rain and snow possible throughout the area. These two types of precipitation events result in runoff that differs between smaller watersheds (up to 520 square kilometers [200 square miles]) and larger watersheds (greater than 520 square kilometers). For smaller watersheds, the summer thunderstorm events dominate the peak runoff rates, which occur in the tributary channels and washes. However, as watershed size increases, the general storm events eventually dominate the peak rates of runoff. In addition, for all watersheds, the volume runoff is generally greater for the general (winter) storm events than for the thunderstorm (summer) events (DIRS 182755-Parsons Brinckerhoff 2005, p. 12).

In general, stream discharge in Nevada is low in late summer, and then increases through the autumn and winter until the snow melts in the spring. Maximum discharge for the year normally can be expected in May and June, although rain or snow has caused floods from November through March (DIRS 176325-USGS 2006, all). As shown in Table 3-21, the more significant peak-flow scenarios relevant to the Caliente rail alignment occur within the Meadow Valley Wash and Upper Amargosa hydrologic units. The highest peak flows for these hydrographic regions generally occur during late winter due to snowmelt and late summer due to intense precipitation.

The washes that drain the Yucca Mountain Site discharge into the Amargosa River. This ephemeral drainage typically sees very low runoff rates due to minimal precipitation in its basin and is usually dry (DIRS 159895-Tanko and Glancy 2001, p. 1). Precipitation is least along the Caliente rail alignment in this area, from Sarcobatus Flat to Beatty, averaging just 75 to 100 millimeters (3 to 3.9 inches) per year. Most of the annual precipitation typically occurs in late spring to early fall. Fortymile Wash and Topopah Wash are significant tributaries draining the Nevada Test Site area into the Amargosa River with maximum peak flows of 94 cubic meters (3,300 cubic feet) per second and 42 cubic meters (1,500 cubic feet) per second, respectively, during late winter to late summer (see Table 3-21). Section 3.2.5.2.4 describes two significant flooding events (March 1995 and February 1998) in the Amargosa River drainage basin on and near the Nevada Test Site.

3.2.5.2.2 Waters of the United States

Some of the surface-water features along the Caliente rail alignment, such as ephemeral drainages, streams, ponds, and lakes, are considered waters of the United States, especially if there is an interstate connection to commerce. Section 404 of the Clean Water Act (33 U.S.C. 1344) and implementing regulations (33 CFR Part 323) require the U.S. Army Corps of Engineers to regulate discharges of dredge or fill material into waters of the United States. Discharges of dredge or fill material essentially includes all land-disturbing activities accomplished via the use of mechanized equipment.
The placement of structures, such as bridge embankments, bridge piers and abutments, and culverts, would be activities potentially discharging fill materials into waters of the United States. Chapter 6 of this Rail Alignment EIS discusses compliance with Section 404 of the Clean Water Act in more detail.

DOE surveyed all drainages within 400 meters (0.25 mile) of the Caliente rail alignment that are within interstate hydrologic basins to determine if those drainages could be classified as waters of the United States (DIRS 180914-PBS&J 2006, p. 1). This survey also identified and delineated wetlands along the Caliente rail alignment. The alignment-specific discussions in Section 3.2.5.3 detail the results of the survey. Subsequent to DOE surveys performed along the rail alignment, the U.S. Environmental Protection Agency and U.S. Army Corps of Engineers released new guidance to be used when making determinations of waters of the United States subject to jurisdiction under the Clean Water Act.
This guidance provides criteria for making these determinations for adjacent wetlands and non-navigable tributaries of waters of the United States, particularly in relation to ephemeral waters. As a result of this guidance, it is likely that many of the drainages along the rail alignment would not be considered waters of the United States (see Section 4.2.5.2.1 for further discussion).

The U.S. Army Corps of Engineers is responsible for determining whether drainages and wetlands along the rail alignment are regulated under Section 404; therefore, all conclusions in this analysis about the classification of washes and wetlands as waters of the United States are tentative. If DOE pursued the Caliente rail alignment for construction of the proposed railroad, the Department would request that the U.S. Army Corps of Engineers determine the limits of jurisdiction under Section 404 along the alignment before beginning construction.

> The term **waters of the United States** is defined in 33 CFR 328.3a. The U.S. Army Corps of Engineers and U.S. Environmental Protection Agency regulate the placement of dredged or fill material into these waters. The definition incorporates channels with ephemeral and intermittent flow that exhibit specific physical features, including channel shape and surrounding vegetation that would provide indications of an ***ordinary high water mark***.
>
> **Ordinary high water mark** means that line on the shore established by the fluctuations of water and indicated by physical characteristics such as clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas (33 CFR 328.3e).

3.2.5.2.3 Wetlands

Generally, wetlands are lands where saturation with water is the dominant factor that determines how soil develops and the types of plant and animal communities living in the soil and on its surface (DIRS 178724-Cowardin et al. 1979, p. 3). Wetlands can support both aquatic and terrestrial species. The prolonged presence of water creates conditions that favor the growth of specially adapted plants and promote the development of characteristic wetland (***hydric***) ***soils***.

According to the U. S. Environmental Protection Agency and the U. S. Army Corps of Engineers, the regulatory definition of a Section 404 jurisdictional wetland is (33 CFR 328.3b) "those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions." The U.S. Department of Agriculture Natural Resources Conservation Service and U. S. Fish and Wildlife Service define wetlands somewhat differently, but all four agencies include three basic elements for identifying wetlands: ***hydrology***, soils, and vegetation. Wetland communities are recognized as providing many valuable functions that improve the human environment. Wetlands that have surface-water connections to or are adjacent to (bordering, contiguous, neighboring) other waters of the United States are regulated under Section 404 of the Clean Water Act. Wetlands that are isolated – that is, they have no permanent or temporary surface-water connections to interstate water bodies or are not considered adjacent – are not typically regulated under Section 404 unless the use of these isolated wetlands could affect interstate commerce.

Surveys in support of this Rail Alignment EIS have identified wetlands along the Caliente rail alignment (DIRS 180914-PBS&J 2006, all). Tables in Section 3.2.5.3 list wetlands identified during these surveys. Appendix F discusses wetlands along the Caliente rail alignment in more detail, and Section 3.2.7, Biological Resources, discusses wetlands from a habitat perspective.

3.2.5.2.4 Floodplains

The presence of floodplains in the Caliente rail alignment region of influence largely depends on the meteorology and hydrology of the area. Much of the rail alignment would be in areas that are subject to intense rainfall over a short duration (1 to 3 hours), which typically occurs in late spring to early fall. Precipitation in late fall to early spring is dominated by low-intensity rainfall or snow over a long duration (2 to 4 days). In both cases, precipitation has the potential to produce flooding (DIRS 182755-Parsons Brinckerhoff 2005, pp. 12 to 14). Evapotranspiration rates throughout the region of influence are high; therefore, most of the rainfall from summer storms is lost relatively quickly unless a storm is intense enough to produce runoff, or unless there are more storms before the water evaporates (DIRS 182755-Parsons Brinckerhoff 2005, p. 18). Evapotranspiration rates are lower during the winter, and water from precipitation or melting snow has a better chance of resulting in streamflow, thereby increasing the chances of flooding. Much of the runoff quickly infiltrates into rock fractures or into the dry soils, some is carried down alluvial fans in arroyos, and some drains onto dry lakebeds where it might stand for weeks as a lake (DIRS 182755-Parsons Brinckerhoff 2005, p. 18).

Although flow in most washes is rare, the area is subject to flash flooding from intense summer thunderstorms and sustained winter precipitation. When it occurs, intense flooding can include mud and debris flows in addition to water runoff. Thunderstorms in the area can be local and intense, creating runoff in one wash while an adjacent wash receives little or no rain. In rare cases, however, storm and runoff conditions can be extensive enough to result in flow being present throughout the drainage systems. For example, conditions recorded during March 1995 and February 1998 at the Amargosa River and its tributaries indicated that the channels all flowed simultaneously along its primary stream channels to Death Valley. The 1995 event was the first documented case of this flow condition. During the 1995 event, the peak flow near the location where the existing Yucca Mountain access road crosses Fortymile Wash was approximately 100 cubic meters (3,500 cubic feet) per second (DIRS 182755-Parsons Brinckerhoff 2005, p. 18).

In accordance with the requirements of 10 CFR Part 1022, DOE reviewed available authoritative information to determine whether the Caliente rail alignment would be located in wetlands or floodplains. The results of that effort (DIRS 182755-Parsons Brinckerhoff 2005, p. 10) indicated that the only flood map or flood studies available for the areas of the Caliente rail alignment were those completed by the Federal Emergency Management Agency in the form of Flood Insurance Rate Maps. Furthermore, and consistent with the remoteness of the project area, DOE found that Federal Emergency Management Agency maps cover only about 45 percent of the rail alignment (see Appendix F, Table F-1). DOE completed flood studies for several washes on the eastern slope of Yucca Mountain at the repository site in support of the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Figure 3-12 and pp. 3-37 to 3-39).

In accordance with 10 CFR Part 1022, DOE prepared a floodplain and wetland assessment (see Appendix F) for the Caliente rail alignment. Appendix F provides a detailed discussion of the floodplains the Caliente rail alignment would cross, including figures of the relevant floodplains identified on Federal Emergency Management Agency maps and those identified near the repository site.

3.2.5.2.5 Springs

Springs are the only natural source of perennial surface water throughout the Caliente rail alignment region of influence. Typically, these springs flow year round. The springs often infiltrate naturally into the ground or undergo evapotranspiration, or are captured near the source for local use (such as irrigation). DOE used the U.S. Geological Survey Geographic Names Information System, the National Hydrologic Dataset, and several DOE field studies completed in support of this Rail Alignment EIS to identify springs along the Caliente rail alignment (DIRS 180914-PBS&J 2006, all; DIRS 182755-Parsons Brinckerhoff 2005, all).

3.2.5.3 Surface-Water Features along Alternative Segments and Common Segments

DOE compiled this information using the National Wetland Inventory database, a U.S. Geological Survey dataset of hydrologic features known as the National Hydrological Dataset (DIRS 177714-MO0607NHDFLM06.000), a dataset from the U.S. Geological Survey Geographic Names Information System (DIRS 176979-MO0605GISGNISN.000), and DOE wetland surveys conducted in support of this Rail Alignment EIS (DIRS 180914-PBS&J 2006, all). Specific hydrologic features are divided into two categories: those within 150 meters (500 feet) of the rail alignment centerline and those between 150 meters and 1.6 kilometers (1 mile) from the rail alignment centerline. Both of these categories fall within the region of influence for surface-water resources. The first category is also within the nominal width of the rail line construction right-of-way.

Sections 3.2.5.3.1 through 3.2.5.3.12 describe surface-water resources for each Caliente rail alignment alternative segment and common segment moving along the rail line from east to west (from Caliente, Nevada, to Yucca Mountain). Tables in these sections provide summaries of surface-water features identified in the Caliente rail alignment region of influence. Figures in these sections show the proposed rail line location as it crosses Nevada's physiographic features. A key for these map areas is provided in Chapter 2, Figure 2-4.

3.2.5.3.1 Interface with Union Pacific Mainline Railroad

DOE is considering two alternative segments to connect the rail line to the existing Union Pacific Railroad Mainline: the Caliente alternative segment and the Eccles alternative segment (Figure 3-61). DOE would construct an Interchange Yard at the beginning of either of these two alternative segments. There are two options for siting the Staging Yard along the Caliente alternative segment (Caliente-Upland and Caliente-Indian Cove) and one potential site for the Staging Yard along the Eccles alternative segment (Eccles-North). Potential quarry CA-8B would be to the west of the Caliente alternative segment approximately 4.8 kilometers (3 miles) north of Caliente (see Figure 3-61).

3.2.5.3.1.1 Caliente Alternative Segment. The Caliente alternative segment would originate in the City of Caliente, near the junction of Clover Creek and Meadow Valley Wash. For nearly its entire length, the Caliente alternative segment would be constructed along an abandoned rail ***roadbed***.

From Caliente, the alternative segment would run north across Meadow Valley for approximately 16 kilometers (10 miles) running parallel to and crossing Meadow Valley Wash (Table 3-22 and Figure 3-61).

Both Meadow Valley Wash and Clover Creek are part of the interstate tributary system of the Colorado River, a navigable waterway. The Caliente alternative segment would cross several stream channels and washes. DOE field surveys identified nine of these drainage channels that classify as waters of the United States under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, Figure 3A and Table 3), including Clover Creek, Meadow Valley Wash, Bennett Springs Wash, and unnamed washes flowing toward Meadow Valley Wash from side canyons. Construction camp 1 would be in Meadow Valley approximately 2.5 kilometers (1.6 miles) south of the beginning of Caliente common segment 1 (DIRS 180922-Nevada Rail Partners 2007, Figure 4-A). Potential quarry CA-8B would be approximately 2 kilometers (1.2 miles) west of the Caliente alternative segment. The siding that would be constructed to support the proposed quarry would cross three unnamed washes identified as waters of the United States. The Upland option for the Staging Yard would cross one water of the United States within the Staging Yard area.

According to the U.S. Geological Survey, Meadow Valley Wash near Caliente (at gaging station 09418500) has a drainage area of 4,300 square kilometers (1,660 square miles) (see Table 3-21). The Geological Survey collected 53 years of streamflow data (1951 through 2004); the annual peak flow range for streamflow was 0.11 cubic meter (3.9 cubic feet) per second to 68 cubic meters (2,400 cubic feet) per second (see Table 3-21). The maximum discharge of 68 cubic meters per second was recorded on March 5, 1978. There are several irrigation diversions upstream of the gaging station. There are no gaging stations within the region of influence for the Caliente alternative segment (DIRS 176325-USGS 2006, all). No water-quality data are available for drainage channels along the Caliente alternative segment.

There is a relatively large extent of wetlands in the southern portion of the Caliente alternative segment. This segment would be constructed on or adjacent to an existing rail roadbed that runs adjacent to or across DOE-delineated wetland areas for approximately 9.2 kilometers (5.7 miles) along Meadow Valley Wash (see Figures 3-62 and 3-63). DOE delineated all wetlands within 61 meters (200 feet) of the alignment (DIRS 180914-PBS&J 2006, p. 1). The Department did not examine a larger area because it would limit rail line construction activities in this area as much as possible and maintain disturbances within wetlands to an area within 30 meters of the rail alignment centerline. In those areas where the rail line would cross wetlands, the rail line would be constructed along an existing, rail roadbed on upland fill raised above the wetlands in width from about 7 to 16 meters (23 to 52 feet) (DIRS 180914-PBS&J 2006, Figure 4A). The Indian Cove option for the Staging Yard would be in a wetland (DIRS 180914-PBS&J 2006, Figure 4A). Based on field observations, the wetlands extend beyond the rail alignment DOE surveyed. The entire meadow is assumed to be a wetland area. There are no wetlands associated with the Upland option for the Staging Yard. The Interchange Yard would not be in wetlands. Appendix F of this Rail Alignment EIS provides additional information about wetlands.

The Federal Emergency Management Agency has mapped floodplains only for the very southern portion of the Caliente alternative segment. This mapping shows that the alternative segment would cross 100-year floodplains at its starting point in Clover Creek and within Meadow Valley Wash north of the City of Caliente (see Figure 3-64). Based on the topography of these areas, it is reasonable to assume that the portions of Meadow Valley Wash farther upstream to the north would have similar flood levels to the mapped areas. The southern end of the Indian Cove option for the Staging Yard would lie in the mapped 100-year floodplain. Appendix F further describes the floodplains associated with the Caliente alternative segment.

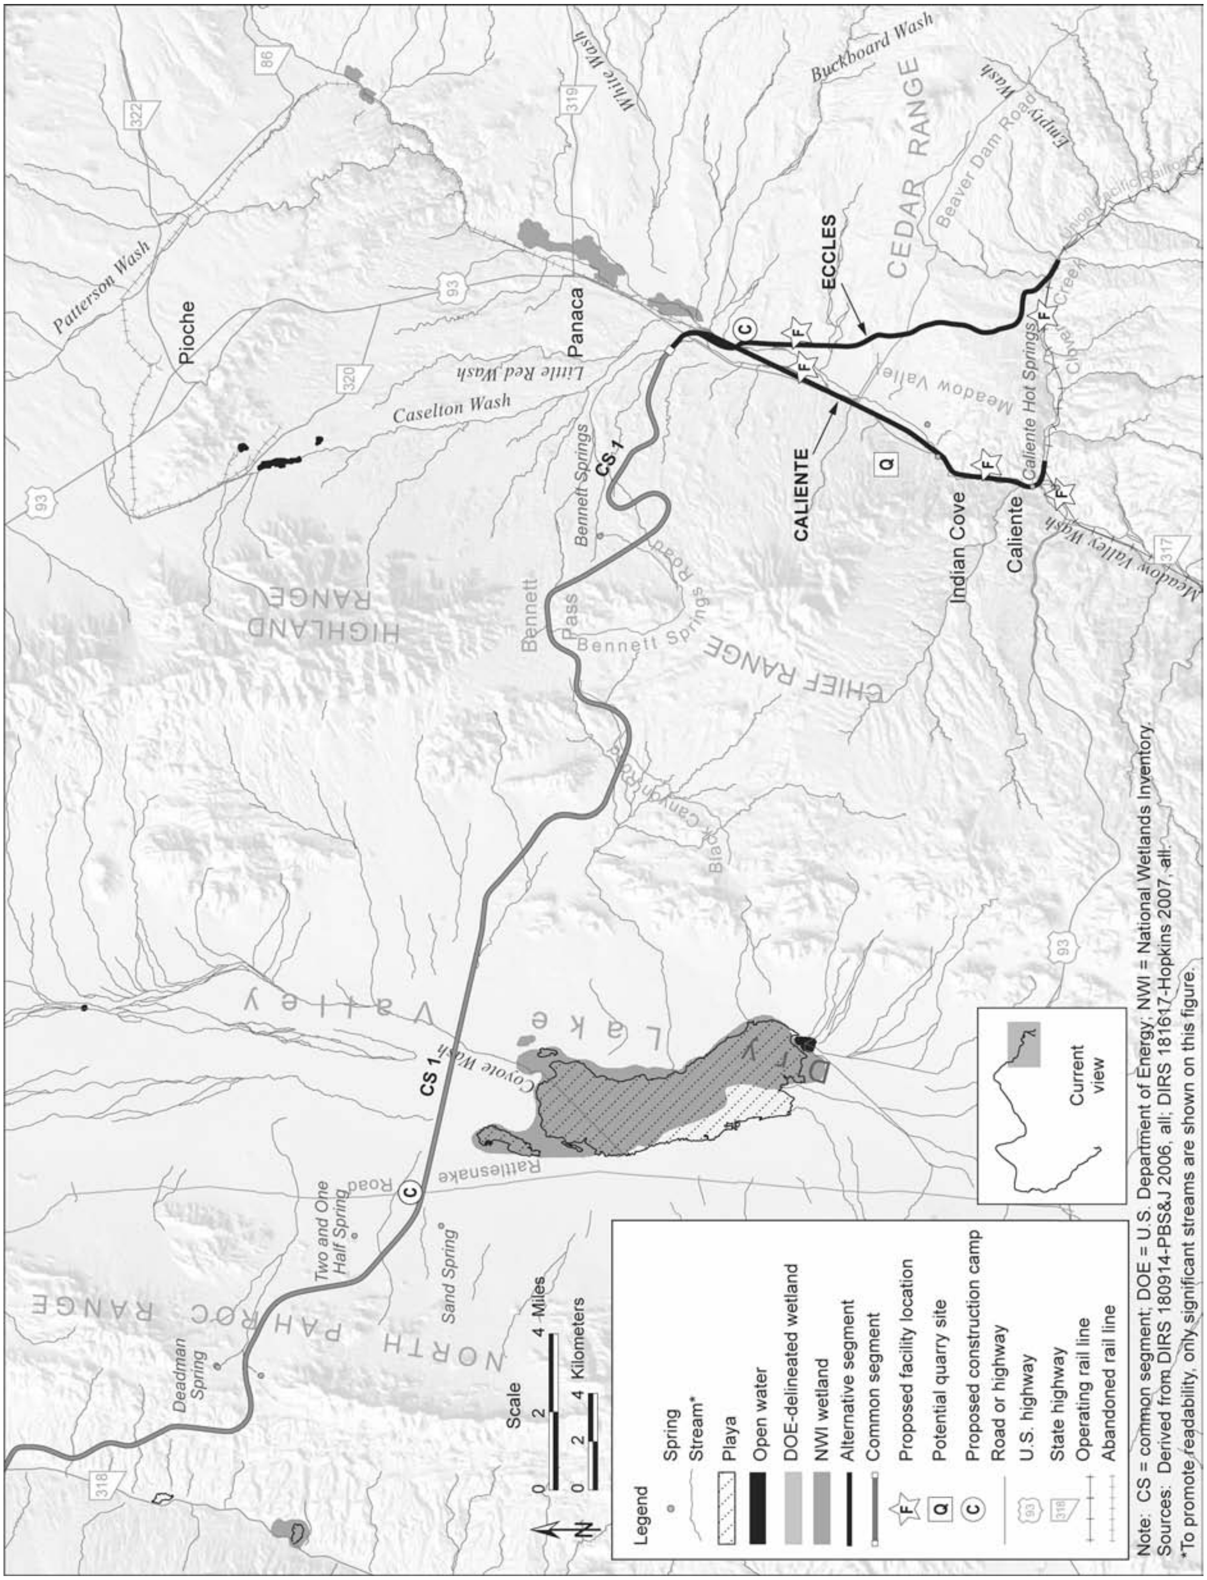

Figure 3.-61. Surface drainage within map area 1.

Table 3-22. Hydrologic features potentially relevant to the Caliente alternative segment.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from the Delmar Mountain Range, the Clover Mountains, the Chief Range, and the Cedar Range down to Meadow Valley through Meadow Valley Wash, Clover Creek, and Miller Spring Wash.	The alignment would run along the Meadow Valley Wash for nearly 16 kilometers and cross Meadow Valley Wash three times. The alignment would cross 12 tributaries leading into Meadow Valley Wash, including Bennett Springs Wash, Cobalt Canyon Wash, Miller Spring Wash, Clover Creek, and White Wash. The alignment would run adjacent to or across wetland areas for approximately 9.2 kilometers of DOE-delineated wetlands within Meadow Valley Wash. Indian Cove option for the Staging Yard would be in a wetland. Caliente Hot Springs 0.02 kilometer east. Unnamed spring 0.1 kilometer northwest.	The alignment would be within 1.6 kilometers of Casselton Wash, Little Red Wash, and 18 unnamed tributaries. Ponds/reservoirs along valley floor. Unnamed spring 0.71 kilometer southeast. Unnamed spring 0.83 kilometer southeast. Unnamed spring 0.75 kilometer southwest.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 63.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

There are two springs within the Caliente alternative segment construction right-of-way: Caliente Hot Springs is 16 meters (52 feet) east and there is an unnamed spring 0.1 kilometer (0.06 mile) northwest of the alternative segment. There are three other unnamed springs at distances of 0.71 kilometer (0.44 mile) southeast, 0.83 kilometer (0.52 mile) southeast, and 0.75 kilometer (0.47 mile) southwest of the alternative segment. See Table 3-22 for a list of springs.

3.2.5.3.1.2 Eccles Alternative Segment. The Eccles alternative segment would start at the Eccles Siding of the Union Pacific Railroad at Dutch Flat, which is within the Clover Creek drainage, approximately 8 kilometers (5 miles) east of the City of Caliente. Dutch Flat is basically a wide area in an otherwise relatively narrow, east-west oriented canyon where Clover Creek, an ephemeral stream at that location, parallels an existing rail line. The Eccles alternative segment would cross the bed of Clover Creek to connect to the Union Pacific Railroad Mainline in this location. Proceeding north from the Eccles/Dutch Flat area, the Eccles alternative segment would cross Meadow Valley Wash upstream of Caliente and downstream of Panaca, just before joining with Caliente common segment 1 (Table 3-23 and Figure 3-61). The Interchange Yard location proposed for the Eccles alternative segment would be adjacent to and extend into Clover Creek. There are no potential quarry sites along this alternative segment (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

Clover Creek is part of the interstate tributary system of the Colorado River, a navigable waterway. All of the washes along this segment are characterized by ephemeral flow. There are no gaging stations within the region of influence for the Eccles alternative segment (DIRS 176325-USGS 2006, all). There are no water-quality data available for drainage channels along this alternative segment.

Of the washes or drainage channels the Eccles alternative segment would cross, DOE field surveys identified 11 stream segments that are designated as waters of the United States under Section 404 of the

Table 3-23. Hydrologic features potentially relevant to the Eccles alternative segment.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from the Delmar Mountain Range, the Clover Mountains, the Chief Range, and the Cedar Range down to Meadow Valley through Meadow Valley Wash, Clover Creek, and Miller Spring Wash.	The segment would cross Meadow Valley Wash, Clover Creek, and unnamed tributaries leading into Meadow Valley Wash, and Clover Creek. Notable crossings would include Bennett Springs Wash, Miller Spring Wash, Empty Wash, and White Wash. Alignment would cross a total of 15 washes. The segment would cross DOE-delineated wetlands along Meadow Valley Wash just south of the end of the segment. The Interchange Yard would extend into Clover Creek.	The segment would lie within 1.6 kilometers of Casselton Wash, Little Red Wash and many unnamed tributaries. DOE-delineated wetlands within 1.2 kilometers of the origin of the Eccles alternative segment. DOE-delineated wetlands within 0.4 kilometer.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 63.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Clean Water Act (DIRS 180914-PBS&J 2006, Figures 3A and 3B, and Table 3), including Clover Creek, Meadow Valley Wash, Miller Spring Wash, Empty Wash, White Wash, and Bennett Springs Wash. The proposed Interchange Yard for the Eccles alternative segment would cross Clover Creek, which is classified as a water of the United States (DIRS 180914-PBS&J 2006, Figure 3A). The Eccles-North Staging Yard would cross one wash identified as a water of the United States. There are no water-quality data available for drainage channels along this alternative segment.

DOE delineated five wetland areas within 1.2 kilometers (0.8 mile) of the origin of the Eccles alternative segment, one of which is associated with a spring. Although these wetlands would be outside the rail line construction right-of-way, two of them would be within the construction footprint for the Interchange Yard (see Figure 3-65). DOE delineated another wetland area within 0.4 kilometer (0.25 mile) of this alternative segment approximately 1.8 kilometers (1.1 miles) south of where the Eccles alternative segment crosses the Caliente alternative segment as shown on Figure 3-62. The alternative segment would also cross wetlands associated with the Meadow Valley Wash just to the south of the end of the segment. Appendix F provides additional information about these wetlands.

The Federal Emergency Management Agency has no published flood maps for the area of the Eccles alternative segment. Existing flood maps of Clover Creek near Caliente indicate the floodplain associated with Clover Creek terminates before it reaches the Eccles alternative segment. However, flooding that occurred in 2005 in and around Clover Creek, Meadow Valley Wash, and Muddy River washed out and undermined portions of an existing rail line in this area. Rail line construction would require encroachment into Clover Creek. The Interchange Yard along the Eccles alternative segment would cross Clover Creek and be in the floodplain. Appendix F provides more information on floodplains.

3.2.5.3.2 Caliente Common Segment 1 (Dry Lake Valley Area)

From Meadow Valley, Caliente common segment 1 would pass through Bennett Pass, Black Canyon, and Dry Lake Valley (Table 3-24 and Figures 3-61 and 3-66). The common segment would then cross State Highway 318 and the White River Valley before passing around the northern end of the Seaman Range and terminating in Coal Valley. Construction camp 2 would be adjacent to Caliente common segment 1 approximately 37 kilometers (23 miles) northwest of the beginning of the common segment. Construction camp 3 would be directly adjacent to the common segment approximately 15 kilometers (9.3 miles) northeast of the junction of common segment 1 with the Garden Valley alternative segments. There are no potential quarry sites along this common segment (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

Common segment 1 would run 1.4 kilometers (0.87 mile) to the north of an unnamed playa in Dry Lake Valley that is 47 square kilometers (18 square miles) in size. During periods of heavy rainfall, runoff from the Highland, Chief, North Pahroc, and Seaman Ranges can produce ephemeral lakes in this playa. There is no flow data available indicating the seasonal duration of the ephemeral lakes. There is ephemeral flow from streams draining upland areas such as Coyote Wash. Flow data for a Dry Lake Valley tributary indicates an annual peak flow range of 0 to 4.4 cubic meters (160 cubic feet) per second (see Table 3-21).

Caliente common segment 1 would continue northwest from Dry Lake Valley, where it would cross State Highway 318 and the White River. The White River Valley hydrographic area has a drainage area of 1,800 square kilometers (700 square miles) (see Table 3-22) The closest U.S. Geological Survey gaging station to common segment 1 is on the White River near Lund, Nevada, approximately 51 kilometers (32 miles) north (upstream) of common segment 1. At the station near Lund, the river's drainage basin is 1,800 square kilometers (700 square miles); annual mean streamflow was 0.79 cubic meter (28 cubic feet) per second recorded in 1993, and 1.3 cubic meters (44 cubic feet) per second in 2001 (DIRS 176325-USGS 2006).

From White River Valley, common segment 1 would pass around the northern end of the Seaman Range and then down into Coal Valley. Coal Valley contains a large playa approximately 30 kilometers (19 miles) long and 8 kilometers (5 miles) wide, with its northern tip reaching the termination of common segment 1. The National Wetlands Inventory dataset identifies Coal Valley Playa as a wetland; however, DOE field studies in support of this Rail Alignment EIS confirmed that there are no hydric soils, plant species indicative of wetlands, or other indicators of wetlands on or adjacent to the playa near the alignment (DIRS 180696-Potomac Hudson Engineering 2007, p. 3).

Caliente common segment 1 would cross 17 stream channels or washes designated as waters of the United States tributaries of the Colorado River (a navigable river) along its route, as classified by DOE field studies completed in support of this Rail Alignment EIS (DIRS 180914-PBS&J 2006, Figure 3C). DOE also surveyed the White River and its associated drainages and determined that even though the White River drained into the Colorado River in the past, there is no surface-water connection between the two drainage systems. Drainages associated with the White River have been altered over time by changes in topography and geological conditions.

DOE determined that the bottom of the White River Valley is flat and has no discernable channel bed and bank (indicators used to identify waters of the United States) in the area where the rail alignment would cross. At that location, and at other locations to the south, sediment deposited from channels flowing into the valley have blocked downstream flow. Additional field observations within the White River Valley south of the rail alignment (historically downstream) confirmed the lack of a discernable channel bed and bank. Because there are no physical indicators of a stream channel in this portion of the White River Valley, it has been determined that the White River and associated tributaries do not have connectivity to the Colorado River system. Because they have no connectivity to the Colorado River system and do not appear to have a connection with interstate or foreign commerce, they are not considered waters of the United States in this analysis (DIRS 180914-PBS&J 2006, p. 7).

No water-quality data are available for drainage channels along Caliente common segment 1.

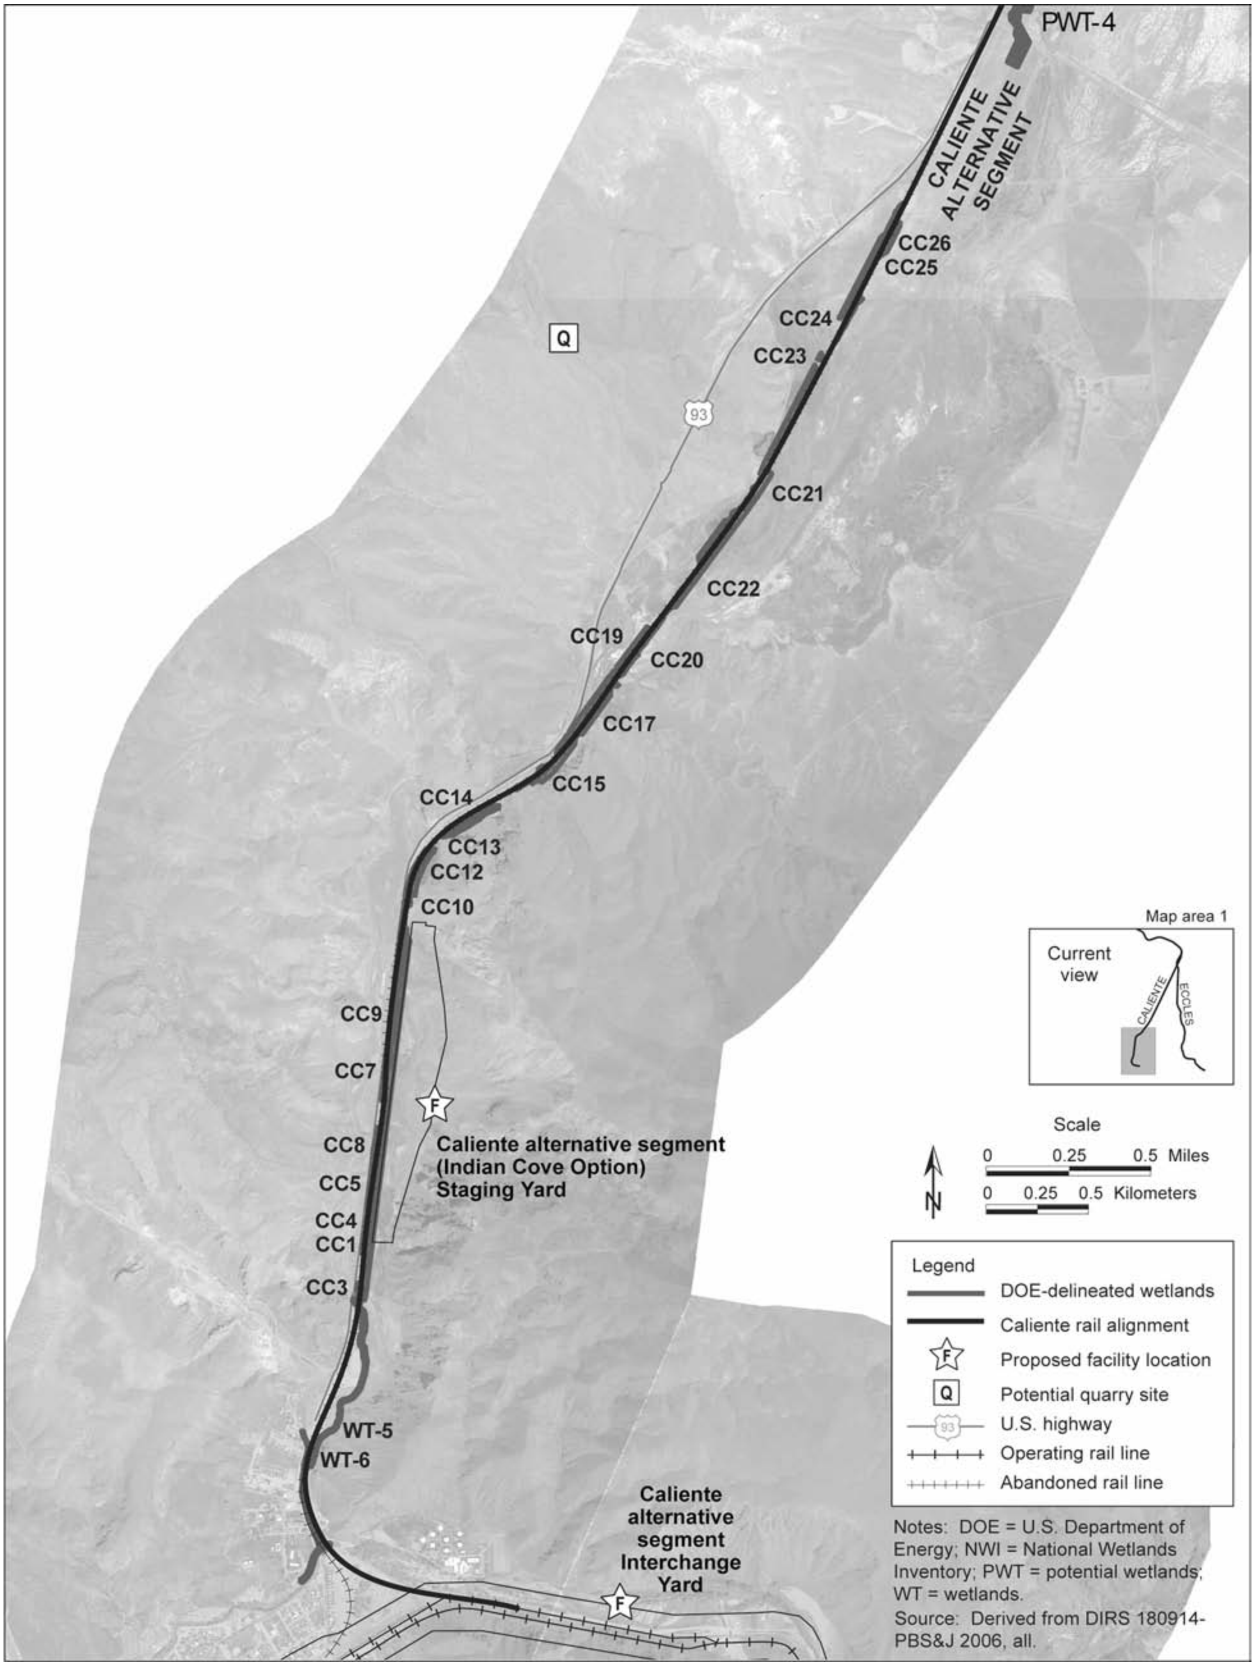

Figure 3-62. Wetlands along the southern portion of Caliente alternative segment.

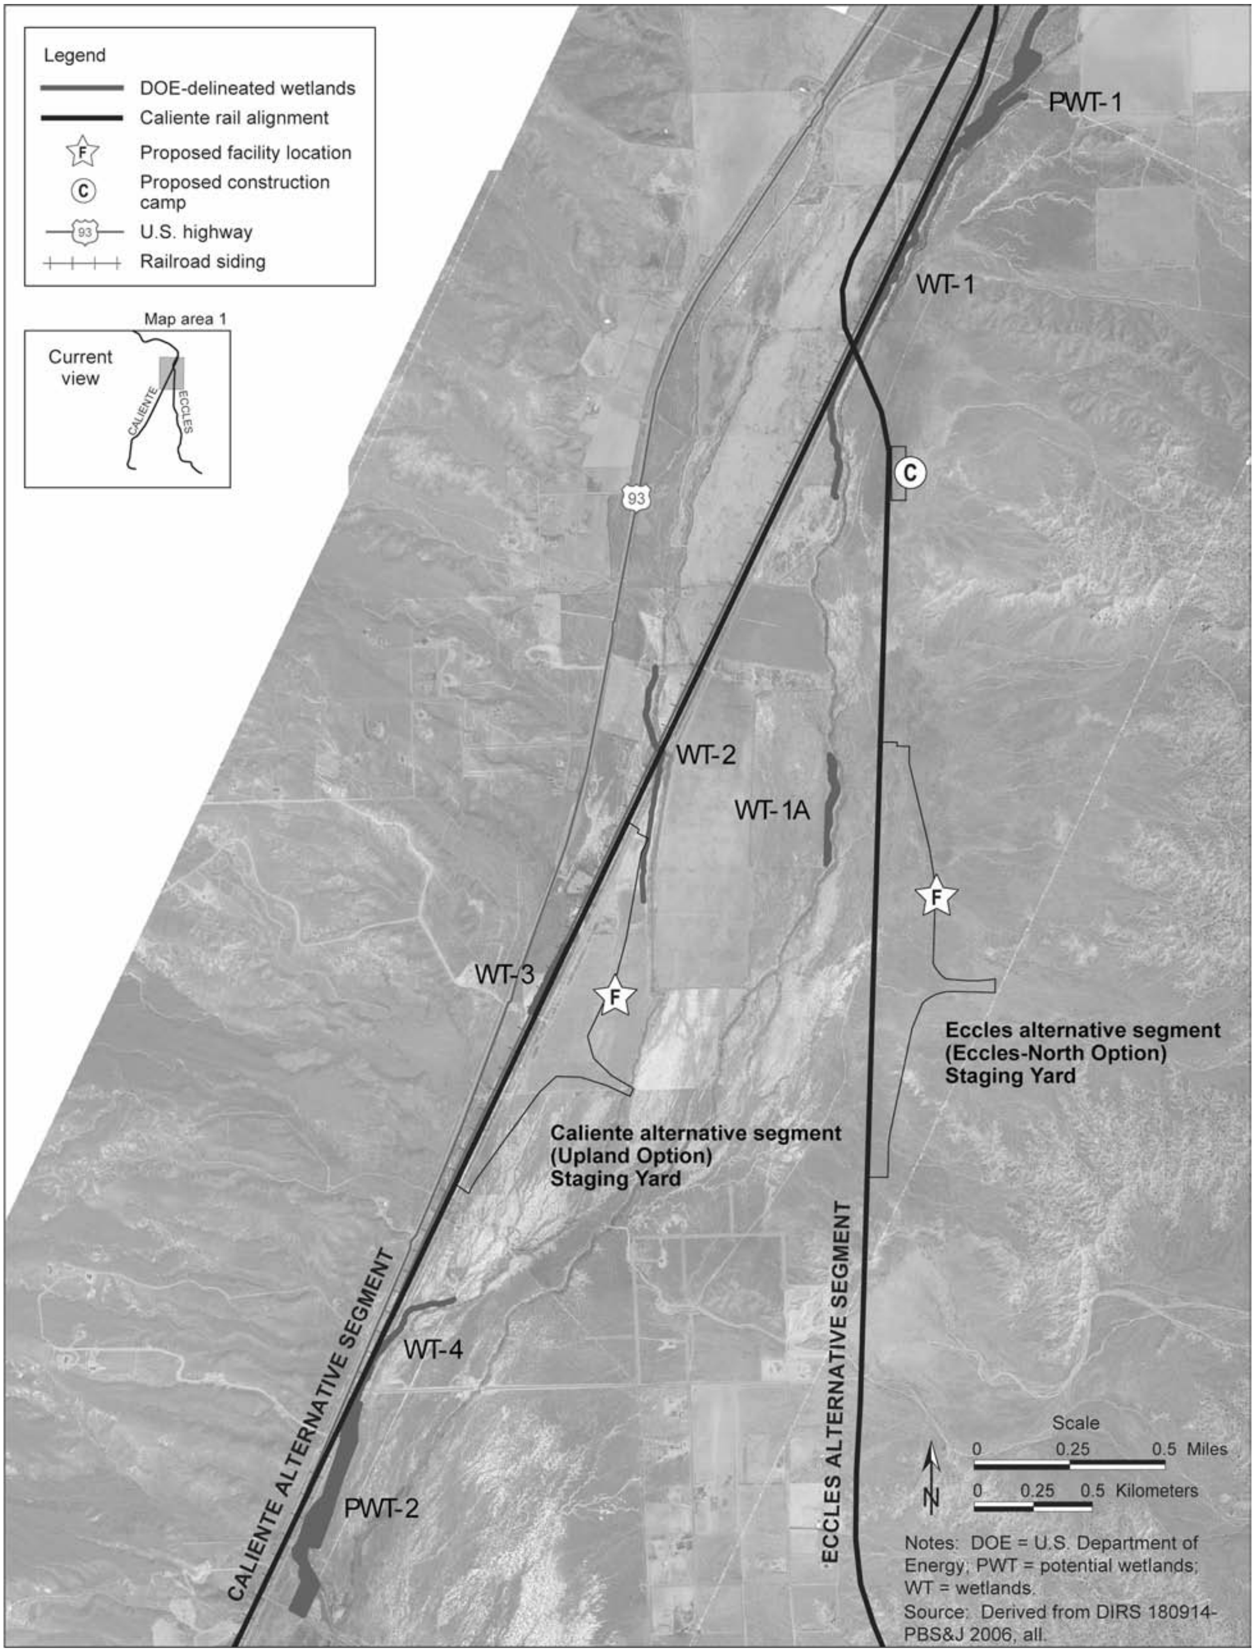

Figure 3-63. Wetlands along northern portion of Caliente alternative segment.

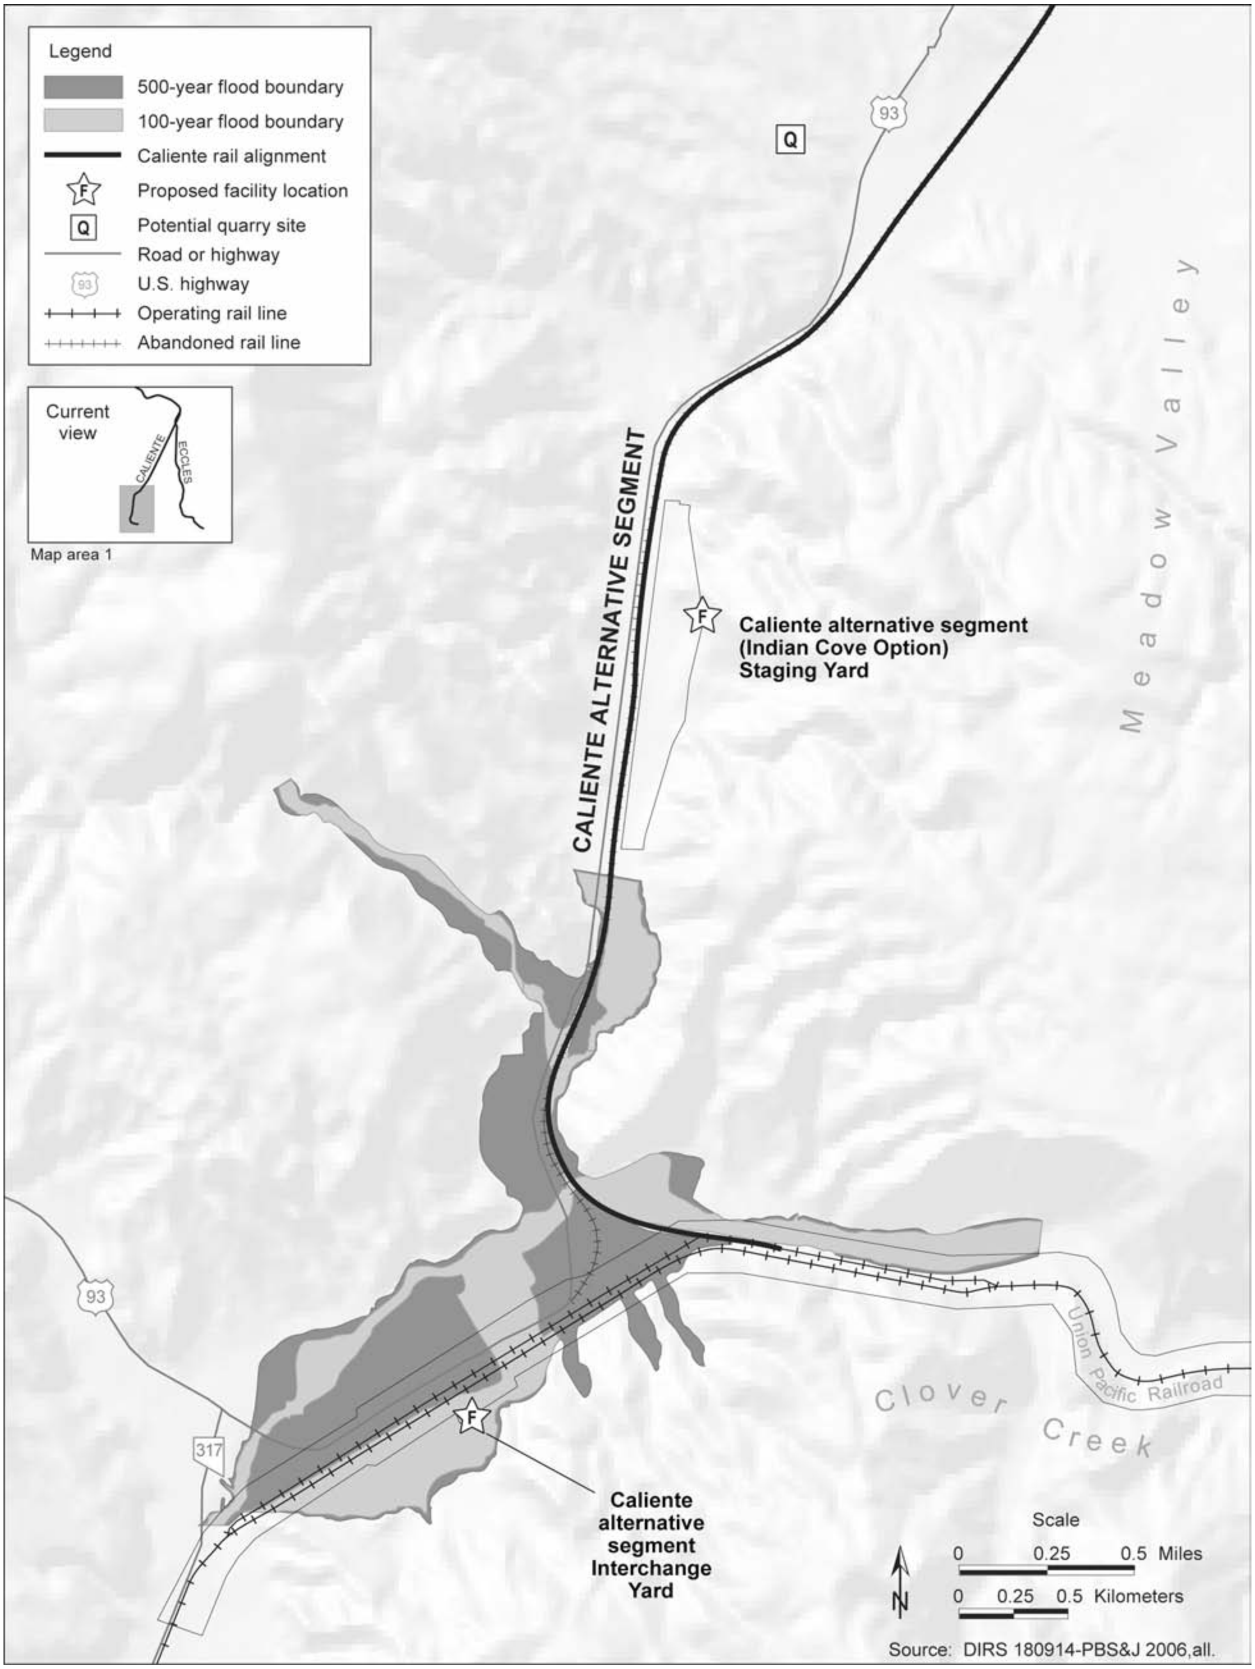

Figure 3-64. FEMA floodplain map for Caliente alternative segment.

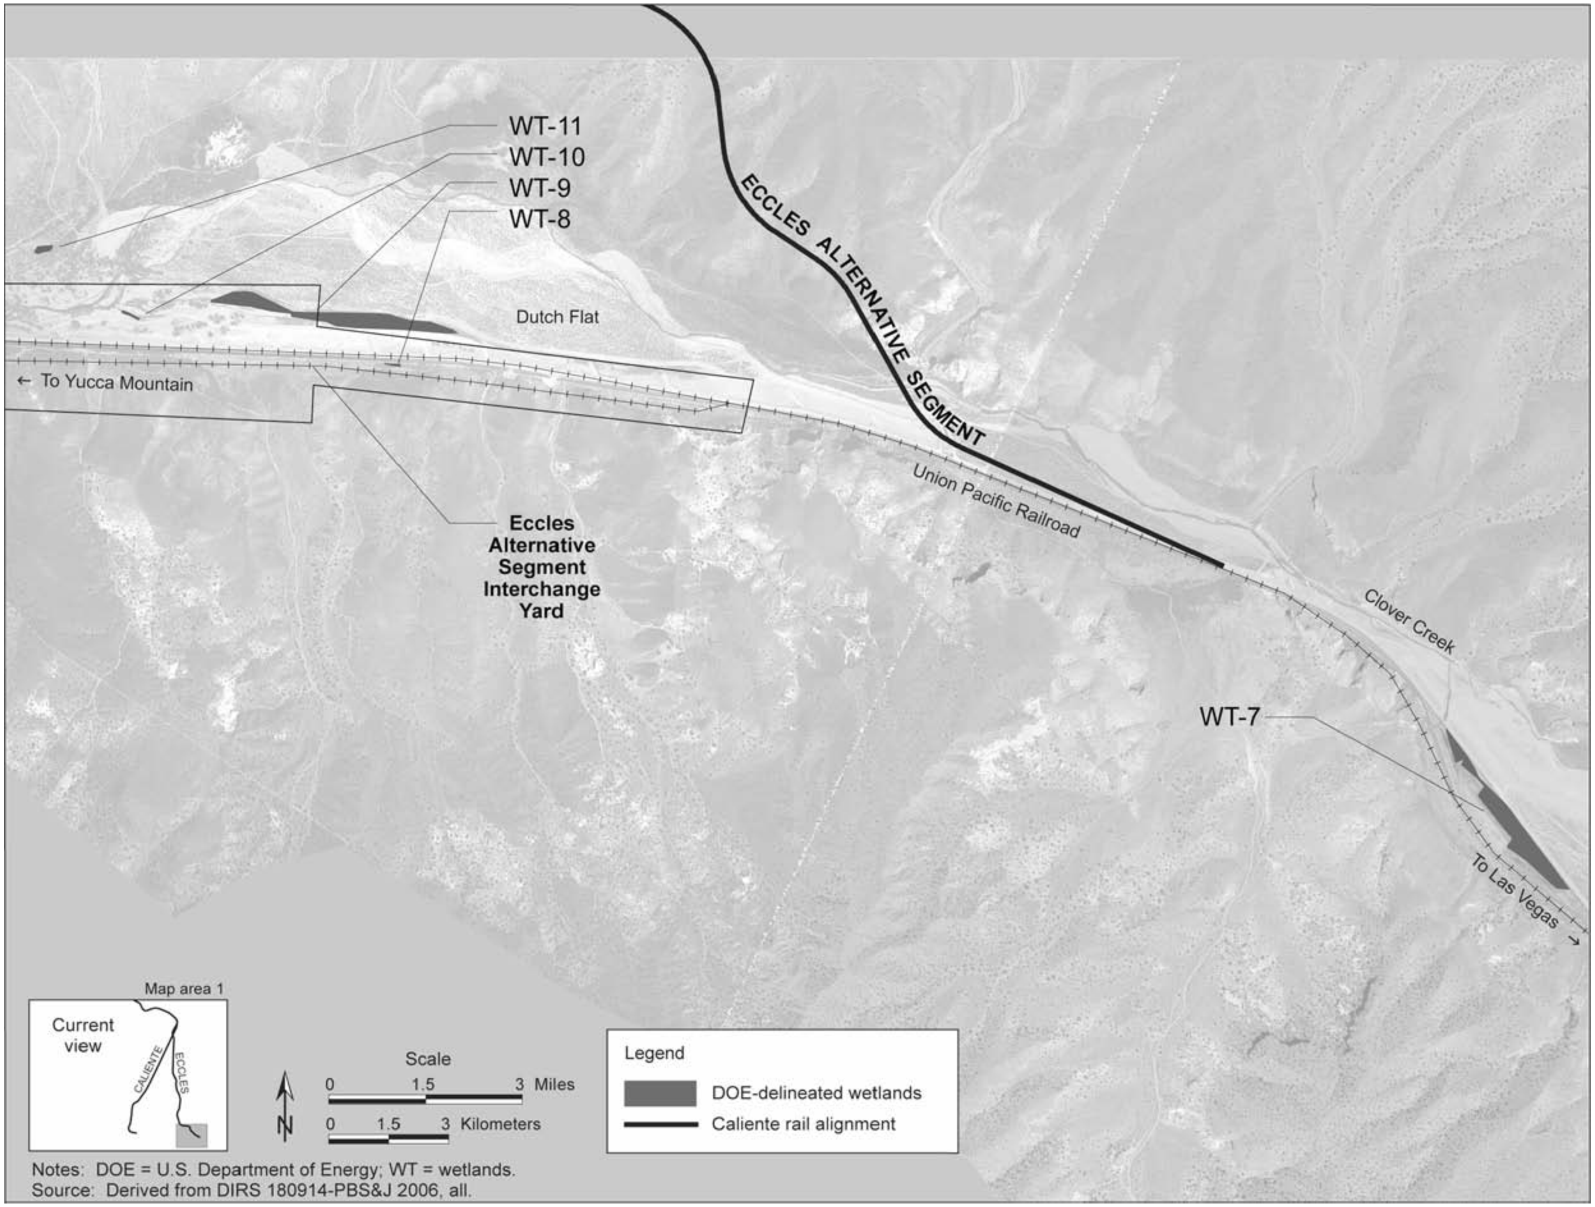

Figure 3-65. Wetlands in vicinity of Eccles Interchange Yard.

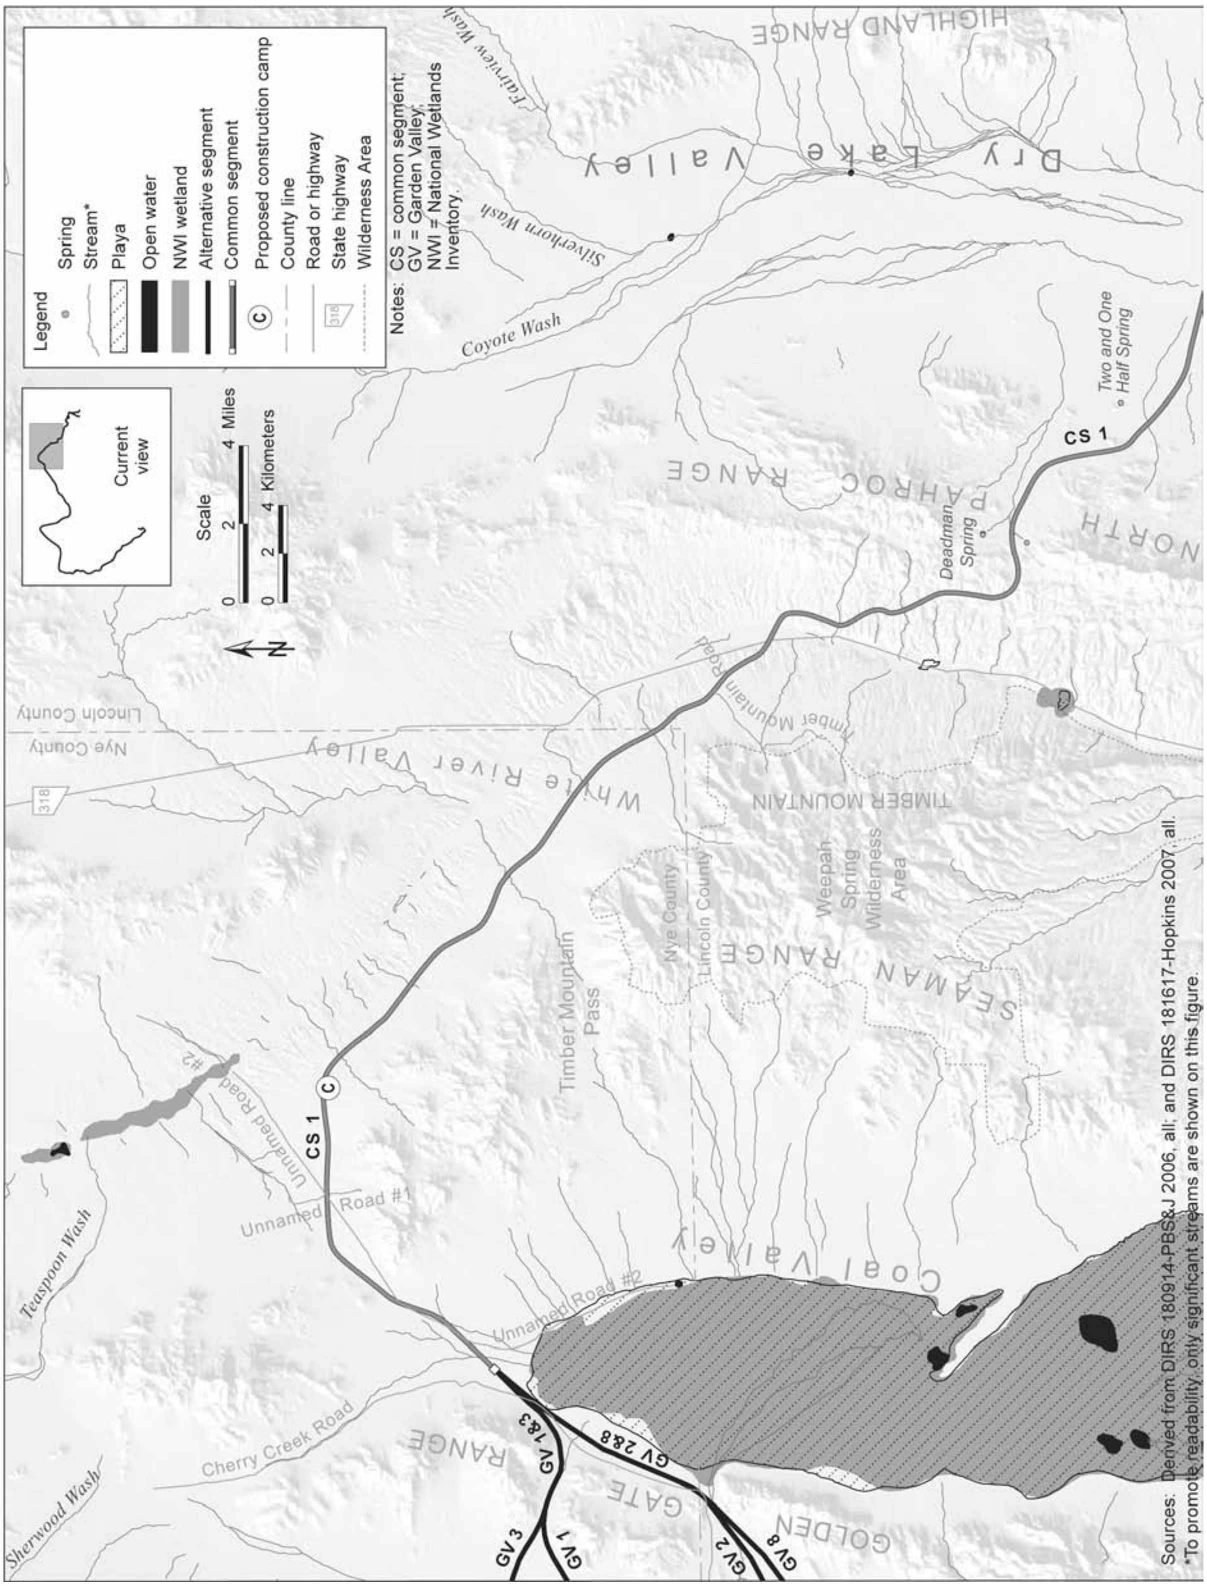

Figure 3.-66. Surface drainage within map area 2.

Table 3-24. Hydrologic features potentially relevant to Caliente rail alignment common segment 1.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from the Highland Range and the Chief Range. On the east side of these mountain ranges, flow travels down to Meadow Valley Wash. On the west side, the flow travels down through Bennett Pass and Dog Hollow to Coyote Wash and farther to Dry Lake Valley and Cliff Reservoir. Drainage from the east side of the North Pahroc Range to Dry Lake Valley Playa and Cliff Reservoir. Drainage from the Seaman Range and the North Pahroc Range to White River. Drainage from the western side of the Seaman Range to Coal Valley and on to Coal Valley Reservoir.	Segment would cross headwater tributaries of Bennett Springs Wash, Coyote Wash, and 20 unnamed tributaries. Alignment would cross seven of the unnamed tributaries multiple times. Alignment would cross White River and 54 unnamed tributaries, and two unnamed tributaries to the Coal Valley Playa. Alignment would cross a total of 144 washes.	Alignment would be within 1.6 kilometers of Casselton Wash and Little Red Wash. Alignment would cross within 1.2 kilometers of Dry Lake Valley Playa. White River Reservoir, Rye Patch Reservoir, pond/reservoir in the foothills of the Seaman Range. Three DOE-delineated isolated wetlands within 0.63 kilometer. Bennett Springs 1.1 kilometers north. Black Rock Spring 1.2 kilometers south. Deadman Spring 1.1 kilometers north. Sand Spring 1.2 kilometers south. Two and One Half Spring 1.4 kilometers north. Unnamed spring 0.63 kilometer south.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 62-63.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

In the North Pahroc Range pass (between White River Valley to the west and Dry Lake Valley to the east), Caliente common segment 1 would pass within 600 meters (2,000 feet) of a small group of three isolated wetlands. DOE delineated these isolated, non-jurisdictional (not regulated under Section 404 of the Clean Water Act), wetlands during the field survey in support of this Rail Alignment EIS (DIRS 180914-PBS&J 2006, Figure 4S). Appendix F provides additional information on these wetlands.

The Federal Emergency Management Agency has published one flood map for part of the area that Caliente common segment 1 would cross. This map covers a portion of land in White River Valley and the adjacent north end of the Seaman Range. According to this flood map, common segment 1 would not cross any floodplains, but the map does show a floodplain approximately 2 kilometers (1.2 miles) northeast of the rail alignment along the White River. It is reasonable to assume that the White River channel is a floodplain. It is also reasonable to assume that the playas of the Dry Lake Valley have associated floodplains. Appendix F provides additional information on floodplains.

There is a series of springs that would be outside the construction right-of-way but within 1.6 kilometers (1 mile), near the summit of the North Pahroc Range pass. Table 3-24 lists these springs. Bennett Springs is on private land in the general area of the eastward approach to Bennett Pass.

3.2.5.3.3 Garden Valley Alternative Segments

In Garden Valley, the Caliente rail alignment has four alternative segments (Table 3-25 and Figure 3-67). The four alternative segments that would cross Garden Valley are designated Garden Valley 1, Garden Valley 2, Garden Valley 3 (the northernmost route) and Garden Valley 8 (the southernmost route).

Table 3-25. Hydrologic features potentially relevant to the Garden Valley alternative segments (page 1 of 2).[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Garden Valley alternative segment 1		
Drainage from the Quinn Canyon Range, the Grant Range, and the Worthington Mountains across Garden Valley and through the Golden Gate Range to join drainage from the Seaman Range and flow farther to Coal Valley and to Coal Valley Reservoir. Alternative segment encompasses a small headwater section of the Sand Spring Valley drainage system.	Segment would cross Cottonwood Creek, Pine Creek, Cherry Creek, Bruno Creek, Sand Creek, and 20 other tributaries. Coal Valley Playa.	30 unnamed washes/tributaries for described drainage systems. Ponds/reservoirs. Modes Hole Spring 1.3 kilometers north.
Garden Valley alternative segment 2		
Drainage from the Quinn Canyon Range, the Grant Range, and the Worthington Mountains across Garden Valley and through the Golden Gate Range to join drainage from the Seaman Range and flow farther to Coal Valley and to Coal Valley Reservoir. Alternative segment encompasses a small headwater section of the Sand Spring Valley drainage system.	Segment would cross Cottonwood Creek, the Golden Gate Range water gap, and 17 other tributaries. The segment would follow the drainage of Garden Valley down though the Golden Gate Range Water Gap and cross the drainage system in multiple places. Coal Valley Playa.	22 unnamed washes/tributaries for described drainage systems.
Garden Valley alternative segment 3		
Drainage from the Quinn Canyon Range, the Grant Range, and the Worthington Mountains across Garden Valley and through the Golden Gate Range to join drainage from the Seaman Range and flow farther to Coal Valley and to Coal Valley Reservoir. Alternative segment encompasses a small headwater section of the Sand Spring Valley drainage system.	Segment would cross Cottonwood Creek, Pine Creek, Cherry Creek, Bruno Creek, Sand Creek, and 23 other tributaries. Coal Valley Playa.	Pond/reservoir. Modes Hole Spring 1.3 kilometers east.

Table 3-25. Hydrologic features potentially relevant to the Garden Valley alternative segments (page 2 of 2).

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Garden Valley alternative segment 8		
Drainage from the Quinn Canyon Range, the Grant Range, and the Worthington Mountains across Garden Valley and through the Golden Gate Range to join drainage from the Seaman Range and flow farther to Coal Valley and to Coal Valley Reservoir. Alternative segment encompasses a small headwater section of the Sand Spring Valley drainage system.	Segment would cross Cottonwood Creek, the Golden Gate Range Water Gap, and 16 other tributaries. Coal Valley Playa.	Ponds/reservoirs. Put Back Spring 0.42 kilometer west.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 61-62.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Construction camp 4 would be along Joe Barney Pass Road, approximately 4.8 kilometers (3 miles) northeast of the junction any of the Garden Valley alternative segments with Caliente common segment 2 (Figure 3-63). There are no potential quarry sites along the Garden Valley alternative segments (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

All four of the Garden Valley alternative segments would cross through the Golden Gate Range, but at two different locations. The southerly alternative segments (Garden Valley 2 and 8) would pass through the topographic feature designated as Water Gap and the northerly alternative segments (Garden Valley 1 and 3) would cross an unnamed pass approximately 7.2 kilometers (4.5 miles) north of Water Gap. In Garden Valley, intermittent surface water from the Quinn Canyon Range, the Grant Range, and the Worthington Mountains drains via Cottonwood Creek and its tributaries through the Golden Gate Water Gap. After the Garden Valley alternative segments pass through the Golden Gate Range, they would cross Garden Valley at different locations on their way to a common point on the north end of the Worthington Mountains. Along Garden Valley alternative segments 1 and 3, surface water flows from the Quinn Canyon Range, the Grant Range, and Worthington Mountains via Cottonwood Creek, Bruno Creek, Sand Creek, Pine Creek, Cherry Creek, and unnamed tributaries through the Golden Gate Water Gap to join drainage from the Seaman Range and flow farther to Coal Valley. In Coal Valley, the water from Garden Valley seeps into basin fill sediments. Garden Valley alternative segment 3, which would loop a bit farther to the north, would cross these drainage features closest to their source in the Quinn Canyon Range. There are no streamflow or water-quality data available for the ephemeral washes the Garden Valley alternative segments would cross.

The Garden Valley alternative segments would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin. Therefore, there are no stream channels or washes identified along the proposed segments designated as waters of the United States, as regulated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, p.7).

The National Wetlands Inventory dataset identifies Coal Valley Playa as a wetland; however, DOE field studies in support of this Rail Alignment EIS confirmed that there are no hydric soils, plant species indicative of wetlands, or other indicators of wetlands on or adjacent to the playa near the rail alignment (DIRS 180696-Potomac Hudson Engineering 2007, p. 3). Garden Valley alternative segment 2 would skirt (within 1 kilometer [0.62 mile]) Coal Valley Playa. Coal Valley Playa is an area expected to be susceptible to flooding and standing water.

The Federal Emergency Management Agency has not published flood maps of this region; however, it is likely that areas in Garden Valley experience periodic flooding. Garden Valley alternative segment 2 would cross the drainage feature designated as Water Gap, which is described as a topographically constricted area through which several small drainage channels run. Although the area is normally dry, Water Gap must be considered a suspect area for flooding. Appendix F discusses floodplains and wetlands.

There are two springs within the region of influence for the Garden Valley alternative segments. Modes Hole Spring is 1.3 kilometers (0.78 mile) east of Garden Valley alternative segments 1 and 3 and Put Back Spring is 0.42 kilometer (0.26 mile) west of Garden Valley alternative segment 8 (see Figure 3-63).

3.2.5.3.4 Caliente Common Segment 2 (Quinn Canyon Range Area)

Leaving the west end of Garden Valley, Caliente common segment 2 would cross west along the northern edge of Sand Spring Valley, skirting the Quinn Canyon Range, before it crossed into Railroad Valley, and then Reveille Valley (Table 3-26 and Figures 3-67 and 3-68). Construction camp 5 would be along Caliente common segment 2 approximately 11 kilometers (6.5 miles) east of the junction of Caliente common segment 2 and the South Reveille alternative segments. There are no potential quarry sites along common segment 2 (DIRS 180922-Nevada Rail Partners 2007, Figure 3-D).

Caliente common segment 2 would cross several stream channels or washes, as listed in Table 3-26. The segment would run perpendicular to drainage flow from the Quinn Canyon Range to a playa in Sand Spring Valley. After crossing Sand Spring Valley, Caliente common segment 2 would enter Railroad Valley and cross State Highway 375. After crossing State Highway 375 in Railroad Valley, Caliente common segment 2 would cross unnamed washes that originate in the northern tip of the Belted Range (Gray Top Mountain) and drain to the northeast and north in Railroad Valley toward a playa area. Caliente common segment 2 would terminate south of the Reveille Range. There is a notable unnamed wash less than 0.8 kilometer (0.5 mile) to the north of the end of Caliente common segment 2.

Caliente common segment 2 would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin. Therefore, there are no stream channels or washes identified along the segment designated as waters of the United States, as regulated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, p. 7). There are no streamflow or water-quality data available for the streams and washes Caliente common segment 2 would cross.

The National Wetlands Inventory dataset does not indicate the presence of wetlands along Caliente common segment 2. Appendix F provides additional information on wetlands along the Caliente rail alignment.

Federal Emergency Management Agency flood maps cover only the west end of Caliente common segment 2 in Railroad and Reveille Valleys. The maps show that Caliente common segment 2 would not cross any floodplains. Appendix F provides additional information on floodplains along the Caliente rail alignment.

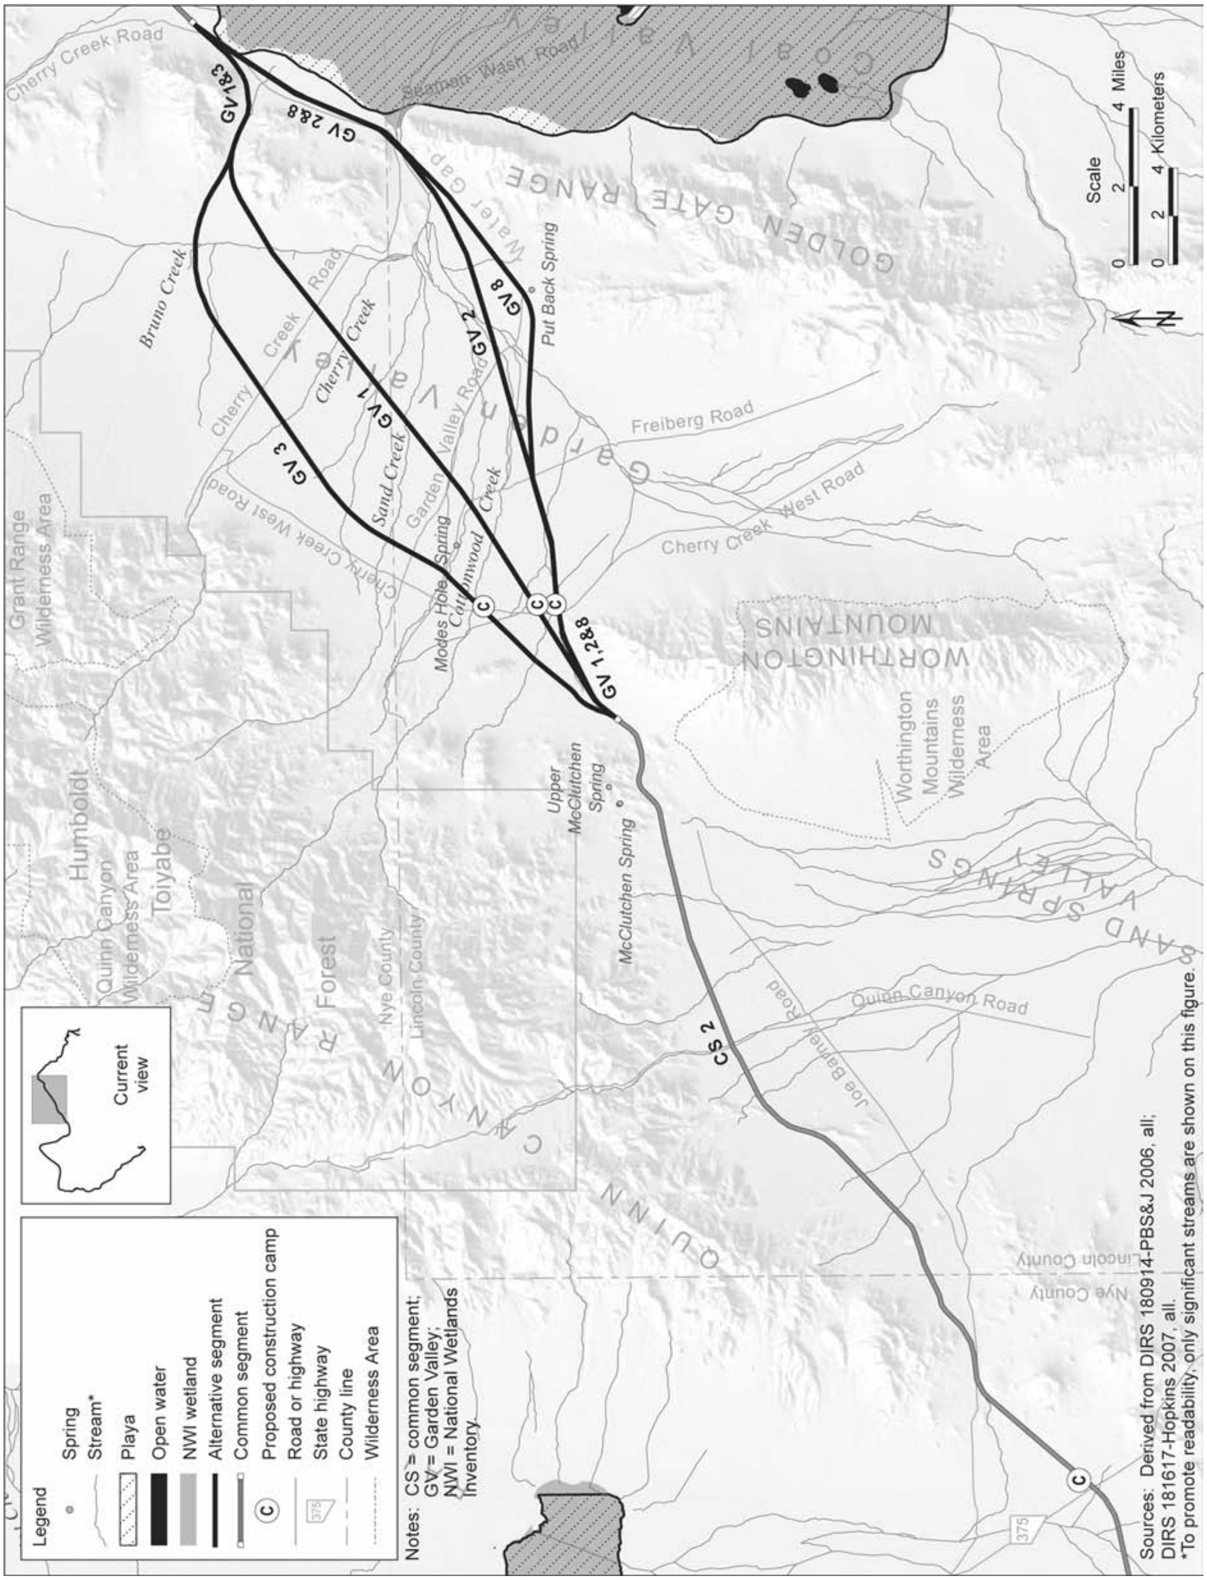

Figure 3-67. Surface drainage within map area 3.

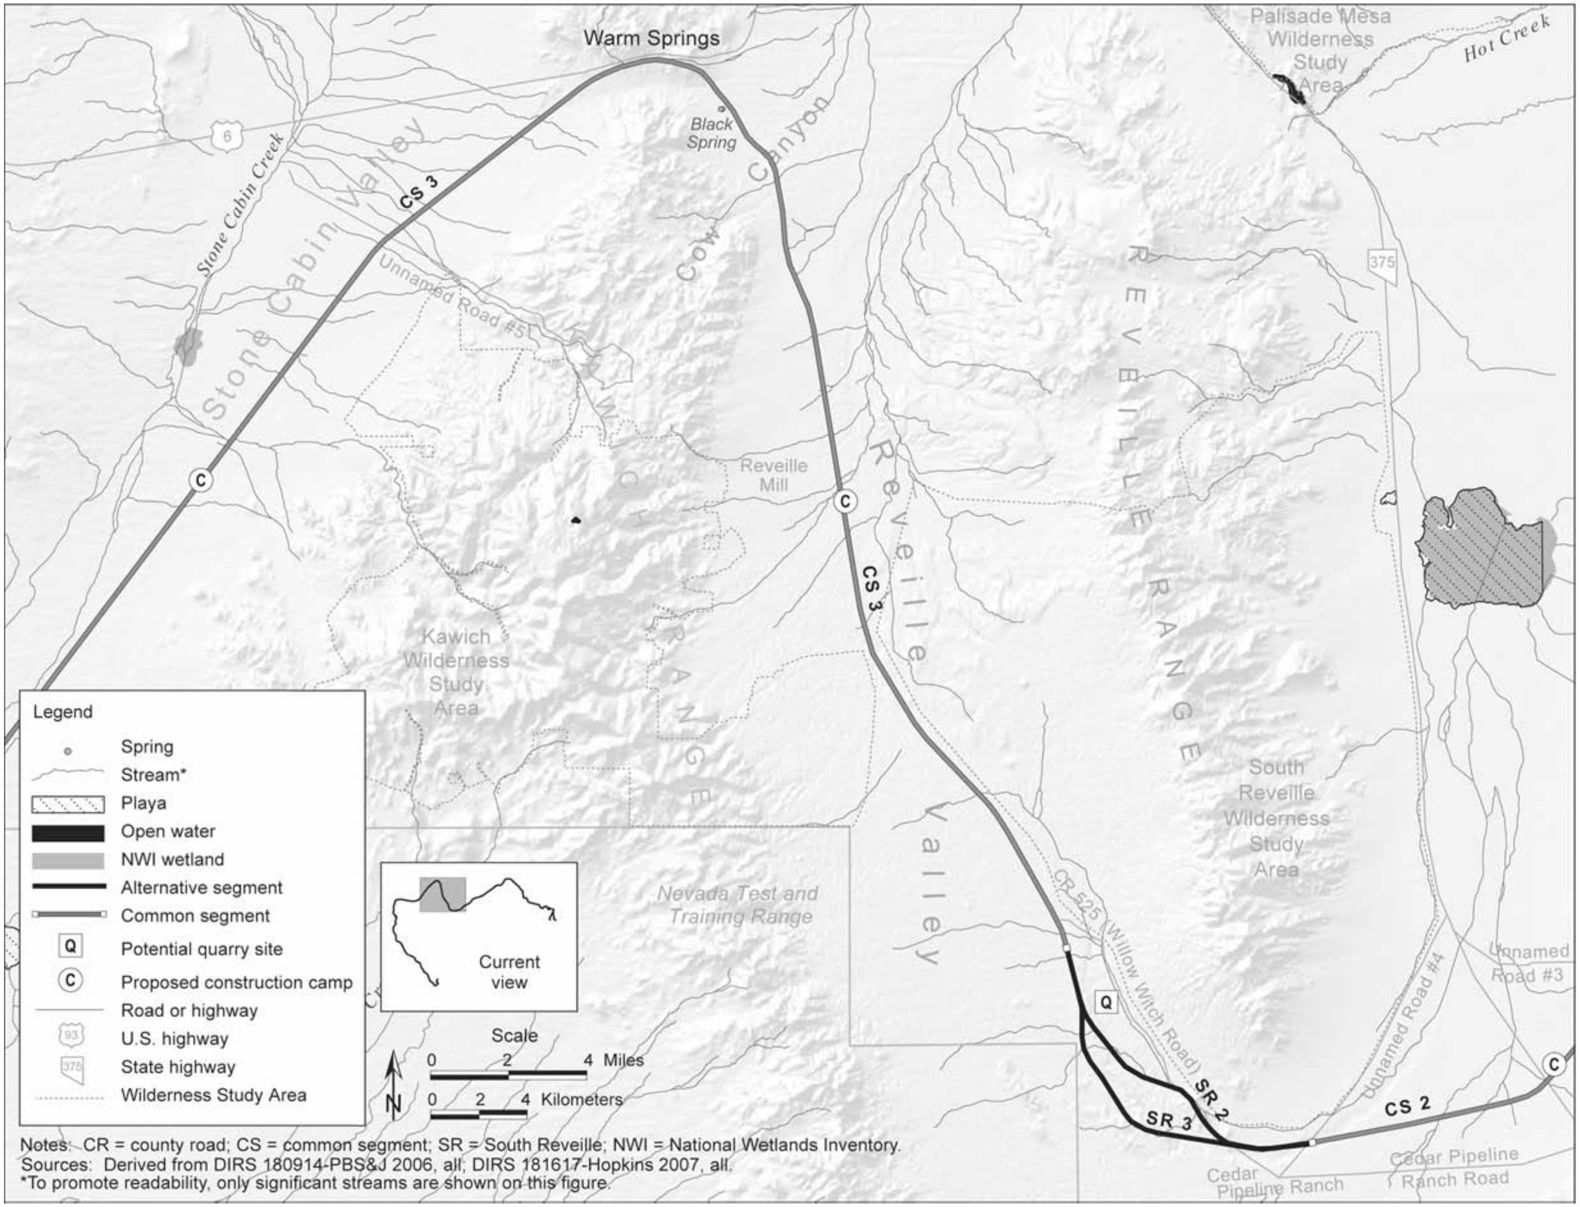

Figure 3-68. Surface drainage within map area 4.

Table 3-26. Hydrologic features potentially relevant to Caliente rail alignment common segment 2.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from the Worthington Mountains and the southern tip of the Quinn Canyon Range to playas in Sand Spring Valley and Railroad Valley, respectively. Drainage from southern end of Reveille Range and northern tip of the Belted Range (Gray Top Mountain) to Railroad Valley.	Segment would cross 27 unnamed tributaries and 8 tributaries to Railroad Valley Wash.	McCutchen Spring 1 kilometer north. Upper McCutcheon Spring 1.2 kilometers north. Cedar Pipeline Ranch Spring 1.6 kilometers south.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 61.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

McCutchen Spring would be 1 kilometer (0.65 mile) north and Upper McCutcheon Spring would be 1.2 kilometers (0.76 mile) north of Caliente common segment 2.

3.2.5.3.5 South Reveille Alternative Segments

Caliente common segment 2 would end near the south end of the Reveille Range where DOE is considering two short alternative segments (South Reveille 2 and 3) (Table 3-27 and Figure 3-68). There are two potential quarry sites, NN-9a and NN-9b, in Reveille Valley to the east of the junction of the South Reveille alternative segments and Caliente common segment 3. Potential quarry site NN-9A would be about 490 meters (1,600 feet) east of where the South Reveille alternative segments converge (as shown on Figure 3-26) before joining Caliente common segment 3. Quarry site NN-9B would be within 300 meters (1,000 feet) north of South Reveille alternative segment 2 (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

Both alternative segments would be within areas that receive drainage from the Kawich Range and the Reveille Range, which then flows into Railroad Valley. South Reveille alternative segment 2 would proceed north up Reveille Valley, along a notable unnamed braided wash, crossing it several times. South Reveille alternative segment 3 would run farther west before proceeding up Reveille Valley, thus avoiding the wash in this area. Both alternative segments would cross tributaries associated with this braided channel. There are no washes within the areas of the two potential South Reveille quarry sites. However, potential quarry NN-9A would overlie an unnamed tributary of the braided channel.

South Reveille alternative segments 2 and 3 would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin. Therefore, there are no stream channels or washes identified along the alternative segments that are designated as waters of the United States, as regulated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, p. 7). There are no streamflow or water-quality data available for the streams and washes these alternative segments would cross.

The National Wetlands Inventory dataset does not indicate the presence of wetlands along either of the South Reveille alternative segments. Appendix F provides additional information on wetlands located along the Caliente rail alignment.

Table 3-27. Hydrologic features potentially relevant to the South Reveille alternative segments.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
South Reveille alternative segment 2		
Drainage from the Kawich Range and the Reveille Range to Reveille Valley and on to Railroad Valley.	Segment would cross tributaries to the unnamed notable braided wash running from Reveille Valley into Railroad Valley. Segment would run along and cross the same notable braided wash from Reveille Valley into Railroad Valley for approximately of 3.1 kilometers. Segment would cross a total of 9 washes.	None.
South Reveille alternative segment 3		
Drainage from the Kawich Range and the Reveille Range to Reveille Valley and on to Railroad Valley.	Segment would cross tributaries to unnamed braided wash running from Reveille Valley into Railroad Valley. Segment would cross a total of 11 washes.	None.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 61.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Federal Emergency Management Agency flood maps cover all of the land area of these two short alternative segments. Although South Reveille alternative segment 2 would run alongside a notable unnamed braided wash, it would not cross it. South Reveille 2 would run through a 3.1-kilometer (1.9-mile) stretch of the 100-year floodplain associated with five of the tributaries that drain to the notable unnamed braided wash. South Reveille alternative segment 3, farther away from the wash, would not cross any 100-year floodplains. Appendix F provides additional information on the floodplains South Reveille alternative segment 2 would encounter.

There are no springs within the South Reveille alternative segments regions of influence.

3.2.5.3.6 Caliente Common Segment 3 (Stone Cabin Valley Area)

Caliente common segment 3 would run northward through the Reveille Valley (Table 3-28 and Figures 3-68 and 3-69) and then skirt the western side of the Kawich Range in a southerly direction approximately 3.2 to 4.8 kilometers (2 to 3 miles) from and parallel to Stone Cabin Valley. DOE would construct the Maintenance-of-Way Trackside Facility in the southwestern portion of Stone Cabin Valley near the northern boundary of the Nevada Test and Training Range. The Maintenance-of-Way Trackside Facility would be on the north side of the common segment approximately 26 kilometers (16 miles) east of its junction with the Goldfield alternative segments (Figure 3-65). ***Construction camps*** 6, 7, and 8 would be along Caliente common segment 3. There are no surface-water features at or near the proposed locations of the Maintenance-of-Way Trackside Facility or construction camps. There are no potential quarry sites along this common segment (DIRS 180922-Nevada Rail Partners 2007, Figure 3-F).

Table 3-28. Hydrologic features potentially relevant to Caliente common segment 3.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from the Kawich Range and the Reveille Range to Reveille Valley and on to Hot Creek Valley.	36 tributaries/washes, 33 flowing toward Reveille Valley and on to Hot Creek Valley; the other 3 unnamed washes flowing toward a playa in Railroad Valley.	Mud Lake Playa. Black Spring 0.31 kilometer east.
Drainage from the Kawich Range and the Reveille Range to Stone Cabin Valley and Reveille Valley, respectively. Drainage from the west side of the Kawich Range flows to Stone Cabin Valley. Drainage from the east side of the Kawich Range flows to Reveille Valley and on to Hot Creek Valley.	Segment would cross 6 tributaries of Stone Cabin Creek/Willow Creek and 15 tributaries of Hot Creek, including Cow Canyon Wash. Segment would run parallel to drainage running to the Reveille Range.	
Drainage from the west side of the Kawich Range, Monitor Range, Monitor Hills, San Antonio Mountains to Stone Cabin Valley and Ralston Valley and on to Mud Lake Playa and Cactus Flats.	Segment would cross Ralston Valley Wash, Saulsbury Wash, and Willow Creek (also referred to as Stone Cabin Creek), and 32 unnamed tributaries. Maintenance-of-Way Trackside Facility would cross one notable drainage.	

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 54-55, 59, 61.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Drainage from the east side of the Kawich Range and drainage from the Reveille Range flows to Reveille Valley and on to Hot Creek Valley. Drainage from the west side of the Kawich Range flows down to Stone Cabin Valley. Common segment 3 would cross three tributaries to the unnamed braided channel that flows toward Railroad Valley, tributaries that flow on to Hot Creek Valley, including Cow Canyon Wash, and tributaries of Willow Creek in Stone Cabin Valley. The Cow Canyon wash drains northeast to a notable north-flowing wash on the floor of the Reveille Valley.

After crossing Warm Springs Summit, Caliente common segment 3 would turn to the southwest and proceed through Stone Cabin Valley skirting the western side of the Kawich Range in a southerly direction generally parallel to Stone Cabin Valley. Closer to the northern boundary of the Nevada Test and Training Range, common segment 3 would turn west and cross the braided drainage path designated as Willow Creek. Willow Creek provides drainage for the southern end of the Monitor Range (including Monitor Hill) and the western portion of the Kawich Range. Tributaries such as Saulsbury Wash feed into this drainage from north of U.S. Highway 6, and the drainage terminates at Mud Lake Playa, approximately 5.1 kilometers (3.2 miles) south of the termination of common segment 3. It is joined by a second notable tributary of Mud Lake Playa flowing north to southwest out of the central portion of Ralston Valley. A large portion of Mud Lake Playa is within the Nevada Test and Training Range. Common segment 3 would skirt along the northern and western boundaries of this large playa, approximately 1.4 kilometers (0.89 mile) away from the playa.

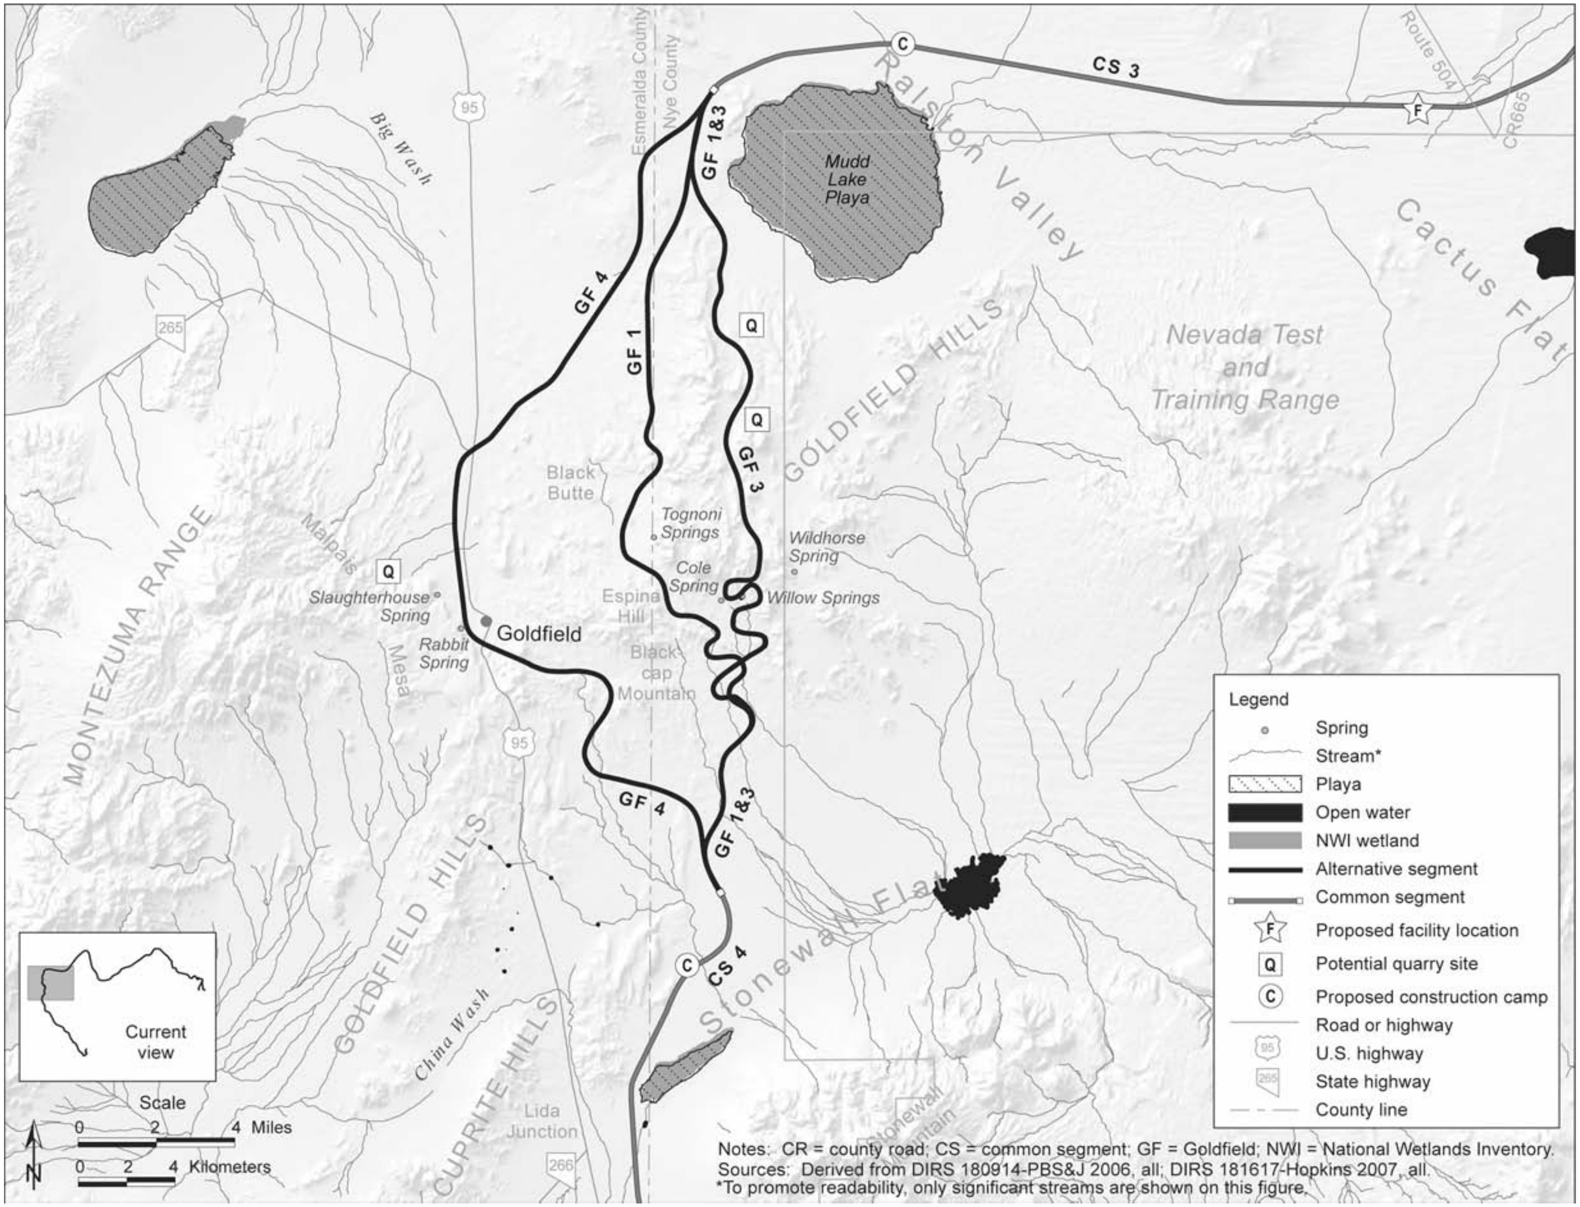

Figure 3-69. Surface drainage within map area 5.

Caliente common segment 3 would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin (DIRS 180914-PBS&J 2006, p. 7). No streamflow or water-quality data are available for the streams and washes common segment 3 would cross.

The National Wetlands Inventory map classifies Mud Lake Playa as a wetland; however, field studies conducted in support of this Rail Alignment EIS confirmed that there are no hydric soils, plant species indicative of wetlands, or other indicators of wetlands on or adjacent to the playa near the rail alignment (DIRS 180696-Potomac Hudson Engineering 2007, p. 3). DOE did not identify any other wetlands along common segment 3. Appendix F provides additional information on wetlands along the Caliente rail alignment.

Most of common segment 3 would cross land that has Federal Emergency Management Agency flood map coverage. According to these maps, common segment 3 would not cross floodplains until it neared the vicinity of Mud Lake Playa and its tributaries. From the east, common segment 3 would first encounter a floodplain associated with Stone Cabin Creek and Saulsbury Wash as they converge on the area of the playa. The segment would then cross the floodplain of a notable wash draining the central Ralston Valley and finally cross through two legs of a drainage system coming down from western Ralston Valley. Appendix F provides more information on the floodplains common segment 3 would cross.

Black Spring is within the Caliente common segment 3 region of influence, approximately 0.31 kilometer (0.19 mile) east of the common segment.

3.2.5.3.7 Goldfield Alternative Segments

Turning south at Mud Lake Playa, the Caliente rail alignment has three proposed alternative segments: the western alternative segment (Goldfield 4), a central alternative segment (Goldfield 1), and an eastern alternative segment (Goldfield 3) (Table 3-29 and Figure 3-69). From the point where Caliente common segment 3 would end, Goldfield alternative segment 4 would proceed toward the southwest, passing around the west side of the community of Goldfield. Goldfield alternative segment 1 would pass southward through the center of the Goldfield Hills, first generally along the boundary between Esmeralda and Nye Counties, along the eastern side of Goldfield, and then winding southeastward toward a point beyond which the alternative segment would coincide with the southern portion of Goldfield alternative segment 3. The eastern alternative segment (Goldfield 3) would trend south-southeastward, in a meandering path, to the east of Goldfield and to the west of the western boundary of the Nevada Test and Training Range. The Goldfield alternative segments would end at the western part of Stonewall Flat, approximately 16 kilometers (10 miles) southeast of Goldfield.

There are three potential quarry sites along the Goldfield alternative segments – two along Goldfield alternative segment 3 and one that would be accessible from Goldfield alternative segment 4. Quarry sites NS-3A and NS-3B would be northeast of Goldfield 3 approximately 4 kilometers (2.5 miles) south of its junction with common segment 3. Quarry site ES-7 would be to the west of Goldfield 4 approximately 24 kilometers (15 miles) southwest of its junction with common segment 3 (DIRS 180922-Nevada Rail Partners 2007, Figure 3-F).

Generally, drainage within the area of the Goldfield alternative segments flows from the Goldfield Hills, the Montezuma Range, and the Chispa Hills to Mud Lake, Mud Lake Playa, Alkali Lake Playa, and Stonewall Flat. While still north of Goldfield, Goldfield alternative segments 1 and 4 would cross a notable tributary to Indian Springs Canyon Wash, which drains the northwestern side of the Montezuma Range. Indian Springs Canyon Wash merges with Big Wash along the east side of U.S. Highway 95 and then terminates approximately 10 kilometers (6.2 miles) west of U.S. Highway 95 at the Alkali Lake

Playa. As they passed through the community of Goldfield and the Chispa Hills, each alternative segment would cross numerous unnamed tributaries, as listed in Table 3-29.

Table 3-29. Hydrologic features potentially relevant to the Goldfield alternative segments.a

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Goldfield alternative segment 1		
Drainage from the Goldfield Hills and Chispa Hills to Mud Lake, Mud Lake Playa, Alkali Lake Playa, and Stonewall Flat.	Segment would cross tributary to Big Wash and unnamed tributaries that flow to Mud Lake, Stonewall Flat Playa, Mud Lake Playa, and Alkali Lake Playa. Segment would cross a total of 25 washes.	Mud Lake Playa 1.4 kilometers west. Cole Spring 1 kilometer east. Tognoni Springs 1.2 kilometers east.
Goldfield alternative segment 3		
Drainage from the Goldfield Hills and Chispa Hills; to Mud Lake, Mud Lake Playa, Alkali Lake Playa, and Stonewall Flat.	Segment would cross unnamed tributaries that flow to Mud Lake, Stonewall Flat Playa, and Mud Lake Playa. Segment would cross unnamed wash draining southeastern Goldfield Hills to Stonewall Flat. Segment would cross a total of 15 washes. Willow Springs 0.14 kilometer north.	Mud Lake Playa 1.4 kilometers west. Cole Spring 0.33 kilometer west. Wildhorse Spring 1.5 kilometers east.
Goldfield alternative segment 4		
Drainage from the Montezuma Range, Goldfield Hills, and Chispa Hills to Mud Lake, Mud Lake Playa, Alkali Lake Playa, and Stonewall Flat.	Segment would cross 26 unnamed tributaries that flow to Mud Lake, Stonewall Flat Playa, Alkali Lake Playa, and Mud Lake Playa.	Rabbit Spring 0.22 kilometer west. Slaughterhouse Spring 0.97 kilometer west.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 59.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

In the area where Goldfield alternative segments 1, 3, and 4 would end (just before the start of Caliente common segment 4), the alternative segments would cross another notable drainage – an unnamed wash that drains the southeastern Goldfield Hills and into Mud Lake. Goldfield 4 would actually cross this same drainage feature four times – twice at points farther up the hill, then again in the area where it would be the same as the other two Goldfield alternative segments. Goldfield alternative segments 1 and 3 and a small portion of Goldfield alternative segment 3 would skirt around the western end of Mud Lake Playa, approximately 1.3 to 1.5 kilometers (0.83 to 0.94 mile) away.

The Goldfield alternative segments would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin. Therefore, there are no stream channels or washes identified along the alternative segments designated as waters of the United States, as regulated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, p. 7). No streamflow or water-quality data are available for the stream channels and washes these alternative segments would cross.

The potential quarry sites to the northeast of the Goldfield alternative segments, NS-3A and NS-3B, would excavate and extract rock from two hills along the east side of Goldfield alternative segment 3 and a hill centered along Goldfield alternative segment 3. An unnamed wash that would run nearly parallel to Goldfield 3 flows between the two hills DOE would quarry as part of the NS-3A quarry site. This unnamed wash appears to originate from the hills that would be excavated and flows toward Mud Lake Playa. The proposed access road to potential quarry NS-3A would cross one unnamed wash that flows toward Mud Lake Playa. The NS-3B quarry site would not intersect any washes. The potential quarry site to the west of the Goldfield alternative segments, ES-7, would not intersect any surface-water features; however, the proposed access road to this quarry would run alongside and cross one unnamed wash draining this area and would cross another. The first half of this road would run along existing roads, while the final stretch would be newly constructed (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

The National Wetlands Inventory dataset does not indicate the presence of wetlands or identify any hydric soils along the Goldfield alternative segments. Appendix F provides additional information on wetlands along the Caliente rail alignment.

Federal Emergency Management Agency flood maps cover the northern and southern portions of the Goldfield alternative segments, but not the central area that includes the community of Goldfield. According to these maps, the alternative segments would cross a small portion of the floodplain associated with Mud Lake Playa and each alternative segment would cross a small portion of the floodplain associated with the notable drainage channel leading to Stonewall Flat Playa. Appendix F provides more information about this floodplain.

There are several springs in the region of influence for all three Goldfield alternative segments (see Table 3-29). Willow Springs would be within the rail line construction right-of-way 0.14 kilometer (0.09 mile) north of Goldfield alternative segment 3. Cole Spring would be 1 kilometer (0.63 mile) east and Tognoni Springs 1.2 kilometers (0.76 mile) east of Goldfield alternative segment 1. Wildhorse Spring would be 1.5 kilometers (0.91 mile) east and Cole Spring would be 0.33 kilometer (0.21 mile) west of Goldfield 3. Rabbit Spring would be 0.22 kilometer (0.14 mile) and Slaughterhouse Spring 0.97 kilometer (0.6 mile) west of Goldfield alternative segment 4.

3.2.5.3.8 Caliente Common Segment 4 (Stonewall Flat Area)

South of the Goldfield Hills, Caliente common segment 4 would run south, crossing Stonewall Flat and Alkali Flat (both within the Lida Valley) (Table 3-30 and Figures 3-65 and 3-66). Construction camp 9 would be alongside the common segment approximately 5 kilometers (3 miles) south of its junction with the Goldfield alternative segments. There are no potential quarry sites along this common segment (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

The U.S. Geological Survey has designated Stonewall Flat and Alkali Flat as playas. Common segment 4 would pass around the southwest end of Stonewall Flat Playa and then to the east of Alkali Flat Playa. Surface water from Stonewall Flat discharges to Lida Valley. The estimated runoff for Stonewall Flat is 490,000 cubic meters (17 million cubic feet) per year (DIRS 101811-DOE 1996, Section 4.2.5.1). Common segment 4 would cross this drainage path. There are no ***perennial streams*** in any of the surrounding basins; rather, the many washes that drain the upland areas convey ephemeral flow that ponds on the playas during periods of intense precipitation. Common segment 4 would cross 10 unnamed channels from Stonewall Mountain and the Cuprite Hills.

Caliente common segment 4 would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin.

Table 3-30. Hydrologic features potentially relevant to Caliente common segment 4.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from northwest side of Stonewall Mountain and the Cuprite Hills to Stonewall Flat Playa and Lida Valley Alkali Flat Playa.	Jackson Wash, China Wash, and seven unnamed washes.	Alkali Flat/Lida Valley Playa, Stonewall Flat Playa.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 59.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Therefore, there are no stream channels or washes identified along the segment designated as waters of the United States, as regulated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, p. 7). No streamflow or water-quality data are available for the stream channels and washes this common segment would cross.

The National Wetlands Inventory map identifies the playas associated with Stonewall Flat as wetlands; however, field studies conducted in support of this Rail Alignment EIS confirmed that there are no hydric soils, plant species indicative of wetlands, or other indicators of wetlands on or adjacent to the playa near the alignment (DIRS 180696-Potomac Hudson Engineering 2007, p. 6). There are no wetlands within the region of influence for common segment 4. Appendix F provides additional information on wetlands along the Caliente rail alignment.

Federal Emergency Management Agency flood maps provide coverage for a good portion of common segment 4. The maps show that the common segment would cross 1 kilometer (0.6 mile) of the 100-year floodplain associated with the drainage between Stonewall Flat Playa and Alkali Flat Playa in Lida Valley. Appendix F provides more information on this floodplain.

There are no springs identified within 1.6 kilometers (1 mile) of Caliente common segment 4.

3.2.5.3.9 Bonnie Claire Alternative Segments

Bonnie Claire alternative segment 2 would begin south of Stonewall Flat, exit Lida Valley, and turn to the east, entering Sarcobatus Flat, a large playa. Sarcobatus Flat is bounded by Pahute Mesa on the east and Gold Mountain on the west (Table 3-31 and Figure 3-70). There are no construction camps or quarries proposed for Bonnie Claire 2.

Bonnie Claire 2 would be in an area that receives drainage from Stonewall Mountain, the foothills of Gold Mountain, and Northern Pahute Mesa, which flows toward Lida Valley, Alkali Flat, and the Bonnie Claire area of Sarcobatus Flat. Unnamed washes run northeast to southwest, providing a path for overland flow from Pahute Mesa, including the south and southeast sides of Stonewall Mountain to Sarcobatus Flat. Bonnie Claire 2 would cross a notable braided wash at the north end of Sarcobatus Flat before running adjacent to the same wash for several kilometers. This braided wash flows from Stonewall Pass to the Bonnie Claire area of Sarcobatus Flat. There are no streamflow or water-quality data available for the stream channels and washes Bonnie Claire 2 would cross.

Bonnie Claire 2 would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin.

Table 3-31. Hydrologic features potentially relevant to the Bonnie Claire alternative segments.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Bonnie Claire alternative segment 2		
Drainage from Stonewall Mountain, the foothills of Gold Mountain, Stonewall Pass, and Northern Pahute Mesa to Lida Valley, Alkali Flat, and Bonnie Claire area within Sarcobatus Flat.	Segment would cross 31 unnamed washes, including an unnamed braided wash.	Alkali Flat/Lida Valley Playa.
Bonnie Claire alternative segment 3		
Drainage from the foothills of Gold Mountain, Stonewall Mountain, Stonewall Pass, and Northern Pahute Mesa to Lida Valley, Alkali Flat, and Bonnie Claire area within Sarcobatus Flat.	Segment would cross Alkali Flat/Lida Valley Playa. Segment would cross 23 washes.	None.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, pp. 59, 60, and 68.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Therefore, none of the washes along Bonnie Claire 2 qualify as waters of the United States, as regulated under Section 404 of the Clean Water Act, because there are no connections to surface-water bodies with a connection to interstate water (DIRS 180914-PBS&J 2006, p. 3).

There are no wetlands within the region of influence for Bonnie Claire 2.

Federal Emergency Management Agency flood maps cover most of Bonnie Claire 2, but do not include a portion of the land on the eastern side of the segment, which is shown on the maps as an old boundary of the Nevada Test and Training Range. Flood mapping does not extend east of this boundary. The flood maps also show a floodplain for an unnamed drainage feature from Pahute Mesa. The floodplain ends just south of Bonnie Claire 2 near one of the old Nevada Test and Training Range boundaries. It is possible that this floodplain would extend far enough to the northeast to be encountered by Bonnie Claire 2; however, the distance is too far to support such an assumption. In addition, Bonnie Claire 2 would run farther up in the foothill area where the wash would involve few tributaries. Appendix F provides additional information on this floodplain.

There are no springs identified within 1.6 kilometers (1 mile) of Bonnie Claire 2.

Bonnie Claire 3 would begin south of Stonewall Flat, exit Lida Valley, and continue south into Sarcobatus Flat, a large playa. Sarcobatus Flat is bounded by Pahute Mesa on the east and Gold Mountain on the west (Table 3-31 and Figure 3-66). There are no potential quarry sites or proposed construction camps along Bonnie Claire 3.

Bonnie Claire 3 would be in an area that receives drainage from Stonewall Mountain, the foothills of Gold Mountain, and the Northern Pahute Mesa, which flows toward the Lida Valley, Alkali Flat, and the Bonnie Claire area of Sarcobatus Flat. Unnamed washes run northeast to southwest, providing a path for overland flow from Pahute Mesa, including the south and southeast sides of Stonewall Mountain to Sarcobatus Flat.

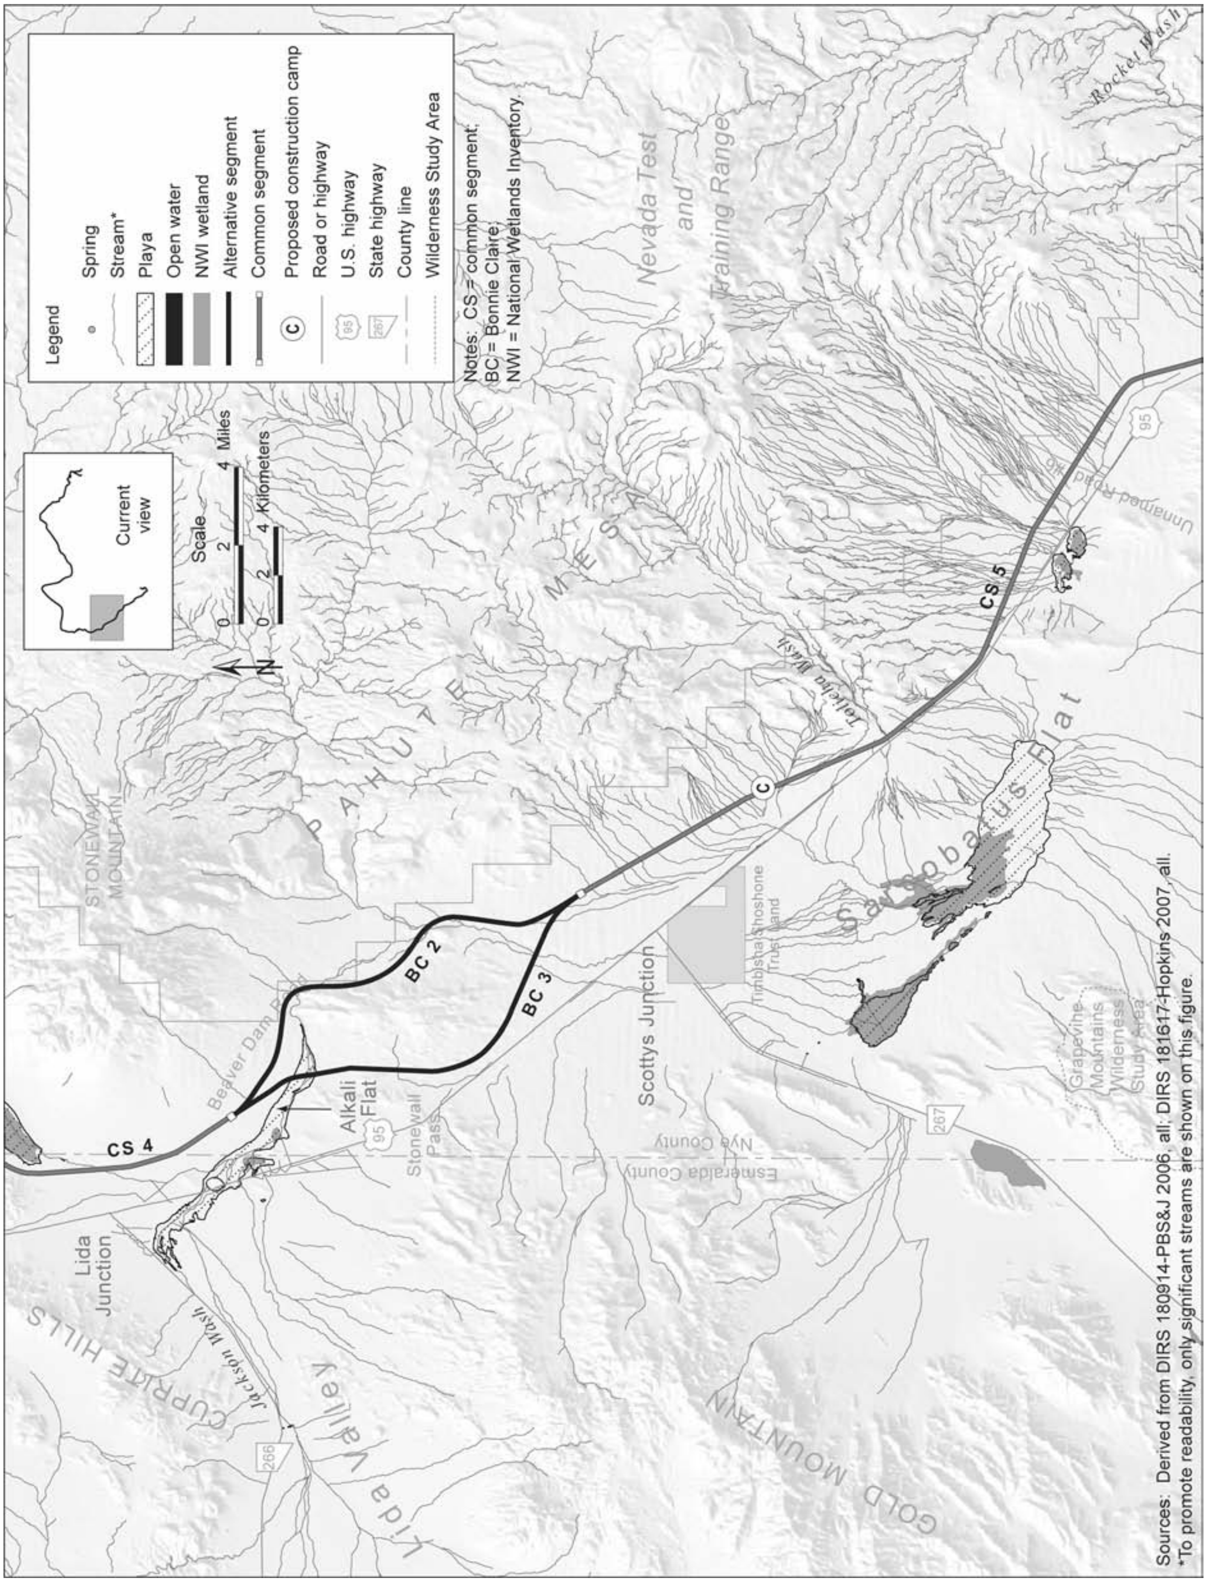

Figure 3-70. Surface drainage within map area 6.

Bonnie Claire 3 would pass through Alkali Flat Playa, a major playa shown in Figure 3-66, and cross a notable braided wash in Sarcobatus Flat. This braided wash flows from Stonewall Pass to the Bonnie Claire area of Sarcobatus Flat. There are no streamflow or water-quality data available for the stream channels and washes Bonnie Claire 3 would cross.

Bonnie Claire 3 would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin (DIRS 180914-PBS&J 2006, p. 3). Therefore, none of the washes along Bonnie Claire 3 qualify as waters of the United States, as regulated under Section 404 of the Clean Water Act because there are no connections to surface-water bodies with a connection to interstate water.

There are no wetlands within the region of influence for Bonnie Claire 3.

Federal Emergency Management Agency flood maps cover most of Bonnie Claire 3, but do not include a portion of the land on the eastern side of the segment, which is shown on the maps as an old boundary of the Nevada Test and Training Range. Flood mapping does not extend east of this boundary. Bonnie Claire 3 would cross a 100-year floodplain associated with Alkali Flat Playa. The flood maps also show a floodplain for an unnamed drainage feature from Pahute Mesa. The floodplain ends just south of Bonnie Claire 3 at one of the old Nevada Test and Training Range boundaries. The floodplain is close enough to Bonnie Claire alternative segment 3 that it is reasonable to assume it would be at a similar width if it extended farther up the wash to where Bonnie Claire 3 would cross. Appendix F provides additional information on this floodplain.

There are no springs identified within 1.6 kilometers (1 mile) of Bonnie Claire 3.

3.2.5.3.10 Common Segment 5 (Sarcobatus Flat Area)

Common segment 5 would begin approximately 3.1 kilometers (1.9 miles) east of U.S. Highway 95 and trend generally southeast, through the Sarcobatus Flat Area, and along the east side of U.S. Highway 95 (Table 3-32 and Figures 3-70 and 3-71). Common segment 5 would end approximately 6.4 kilometers (4 miles) north of Springdale. Construction camp 10 would be adjacent to the rail alignment and east of U.S. Highway 95. Numerous ephemeral washes draining downslope of Pahute Mesa would run through the construction camp. There are no potential quarry sites along common segment 5 (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

Common segment 5 would cross washes that drain the Tolicha Peak area of Pahute Mesa. Drainage from Pahute Mesa flows from the east into Sarcobatus Flat. The alluvial flat terrain between Tolicha Peak and U.S. Highway 95 is characterized by numerous braided washes. Although Sarcobatus Flat is an extensive topographic feature, there is only one portion designated as a minor playa that would be close to the rail alignment. The northern edge of this small playa is adjacent to U.S. Highway 95, and would be approximately 1.7 kilometers (1.1 miles) south of common segment 5 to the southeast of the point where Tolicha Wash crosses U.S. Highway 95. The segment would then cross surface drainage originating from Tolicha Peak and Springdale Mountain. No streamflow or water-quality data are available for the stream channels and washes common segment 5 would cross.

Common segment 5 would be in the Central Hydrographic Region of Nevada, which has surface hydrology characterized by internally draining sub-areas and is considered an intrastate basin (DIRS 180914-PBS&J 2006, p. 3). Therefore, none of the washes along common segment 5 qualify as waters of the United States, as regulated under Section 404 of the Clean Water Act, because there are no connections to surface water bodies with a connection to interstate water.

Table 3-32. Hydrologic features potentially relevant to common segment 5.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from Pahute Mesa and Bullfrog Hills flows to playas within Sarcobatus Flat and Bonnie Claire Lake within Sarcobatus Flat.	Segment would cross Tolicha Wash and 123 other washes. The alluvial flat terrain between Tolicha Peak and U.S. Highway 95 is characterized by numerous braided washes. Washes within this type of soil and terrain can shift in number and geography with a variation of precipitation intensity.	Dry lake bed 0.5 kilometer south.

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, pp. 59, 60, 64, and 68.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

The National Wetlands Inventory map identifies the playas associated with Sarcobatus Flat as wetlands, but field studies conducted in support of this Rail Alignment EIS confirmed that there are no hydric soils, plant species indicative of wetlands, or other indicators of wetlands on or adjacent to the playa near the rail alignment (DIRS 180696-Potomac Hudson Engineering 2007, p. 6). Appendix F provides more information about wetlands in this area.

Federal Emergency Management Agency flood maps provide coverage for almost all of common segment 5. The maps show that the segment would cross a 100-year floodplain associated with Tolicha Wash where it drains toward Sarcobatus Flat. Appendix F provides more information on this floodplain.

There are no springs identified within 1.6 kilometers (1 mile) of common segment 5.

3.2.5.3.11 Oasis Valley Alternative Segments

Oasis Valley alternative segment 1 would begin north of Oasis Mountain and would run southeast for approximately 9.8 kilometers (6.1 miles) before joining common segment 6 (Table 3-33 and Figure 3-71). Construction camp 11 would be along the west side of Oasis Valley 1 approximately 3.1 kilometers (1.9 miles) north of its junction with common segment 6. Several ephemeral washes flowing downslope from Bullfrog Hills and mountains to the east would run through the construction camp. There are no potential quarry sites along Oasis Valley 1 (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

Oasis Valley alternative segment 1 would cross the Amargosa River and its tributaries. Although referred to as a river, the Amargosa River and tributary branches and washes receive ephemeral flows from winter and summer storms, and perennial flows near springs and seeps. For most of the year, the tributaries carry no water. The Amargosa River has approximately 20 branches and 40 tributary washes in Oasis Valley. The main branch enters the valley from the north through Thirsty Canyon. Most of the drainage into Oasis Valley is from Pahute Mesa (including Oasis and Springdale Mountains to the north) and the Bullfrog Hills to the southwest. There are no streamflow or water-quality data available for this area; however, there is regional data for the Death Valley Basin (DIRS 176325-USGS 2006, all).

The Amargosa River interstate drainage system flows to Death Valley in California. A survey of washes along the Caliente rail alignment identified the Amargosa River and one tributary that Oasis Valley 1 would cross as waters of the United States, as regulated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, p. 7 and Figure 3D).

There are no wetlands identified within the region of influence for Oasis Valley 1.

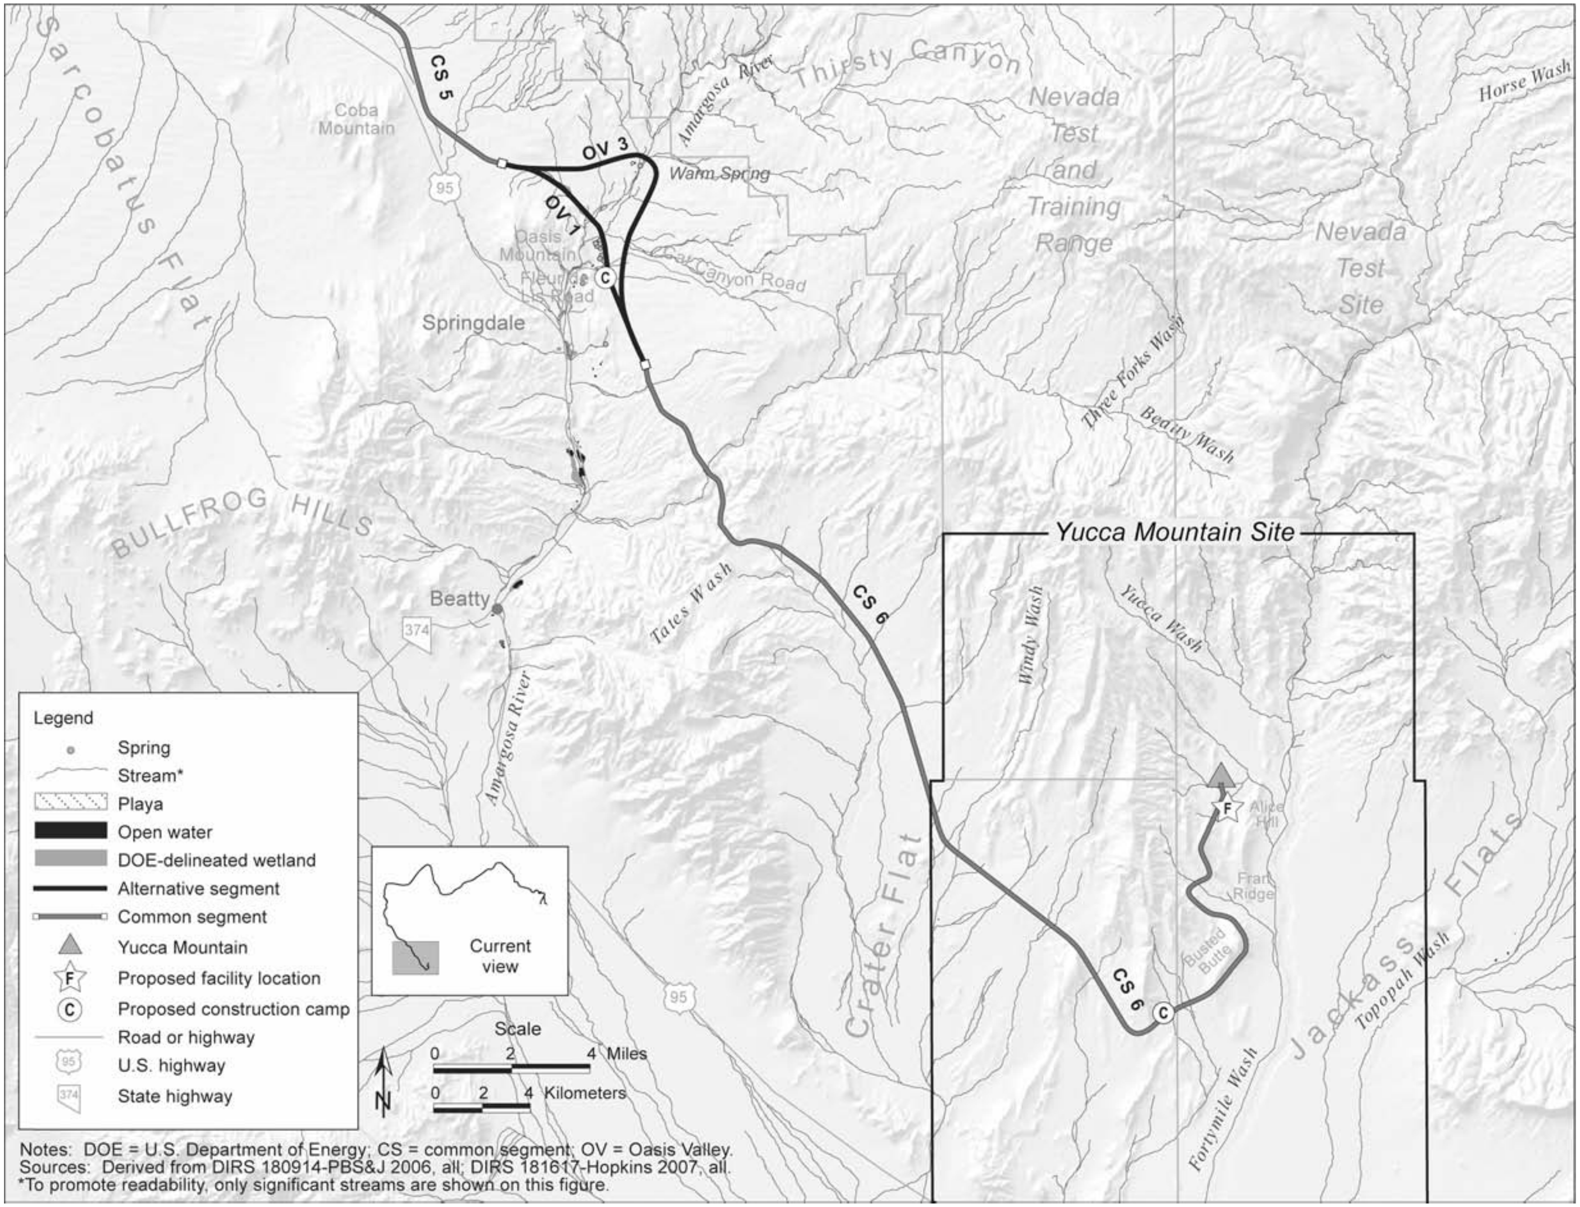

Figure 3-71. Surface drainage within map area 7.

Table 3-33. Hydrologic features potentially relevant to the Oasis Valley alternative segments.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Oasis Valley alternative segment 1		
Drainage from Bull Frog Hills and the Pahute Mesa, including the Amargosa River and Amargosa River tributaries.	Segment would cross the Amargosa River and 23 unnamed washes.	Unnamed springs: 1.5 kilometers west 0.53 kilometer west 0.74 kilometer west 0.69 kilometer west 0.47 kilometer west 0.59 kilometer west 0.46 kilometer west 0.59 kilometer west 0.67 kilometer west 0.54 kilometer west 0.48 kilometer west 1.4 kilometers west 1.5 kilometers west
Oasis Valley alternative segment 3		
Drainage from Bull Frog Hills and the Pahute Mesa, including the Amargosa River and Amargosa River tributaries.	Segment would cross the Amargosa River, and 27 washes/tributaries to the Amargosa River.	Colson Pond (spring fed) 0.24 kilometer southwest. Small wetland 0.5 kilometer from Colson Pond. Unnamed springs: 0.2 kilometer west 1.1 kilometers west 1.2 kilometers west 1.2 kilometers west 1.3 kilometers west 1.3 kilometers west 1.3 kilometers west 1.4 kilometers west 1.4 kilometers west 1.5 kilometers west 1.5 kilometers west 1.6 kilometers west

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, p. 64.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Federal Emergency Management Agency flood maps provide complete coverage for Oasis Valley 1. The maps show that the segment would cross a 100-year floodplain associated with the Amargosa River. Appendix F provides more information about this floodplain.

There are numerous springs in Oasis Valley and Thirsty Canyon near where Oasis Valley 1 would cross. Oasis Valley 1 would pass within 0.48 kilometer (0.30 mile) of several springs identified as the upper Oasis Valley Ranch Springs (DIRS 169384-Reiner et al. 2002, Figure 3). These springs are near the narrows through which the Amargosa River leaves Oasis Valley. Table 3-33 lists these springs. Oasis Valley alternative segment 3 would begin north of Oasis Mountain, generally run east and then south for approximately 14 kilometers (8.8 miles) and would cross Oasis Valley approximately 0.24 kilometer

(0.15 mile) northeast of Colson Pond before converging with common segment 6 (Table 3-33 and Figure 3-68). There are no potential quarry sites or proposed construction camps along Oasis Valley 3.

Oasis Valley 3 would cross the Amargosa River and its tributaries, as described above for Oasis Valley alternative segment 1.

A survey of washes along the Caliente rail alignment identified the Amargosa River, which Oasis Valley 3 would cross, as a water of the United States, as regulated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, p. 7 and Figure 3D).

DOE field surveys identified a small wetland associated with an unnamed seep approximately 0.5 kilometer (0.31 mile) from Colson Pond (DIRS 180914-PBS&J 2006, Figure 4T). Appendix F provides additional information about this wetland.

Federal Emergency Management Agency flood maps provide complete coverage for Oasis Valley 3. The maps show that the segment would cross a 100-year floodplain associated with the Amargosa River. Appendix F provides more information about this floodplain.

There are numerous springs in Oasis Valley and Thirsty Canyon near where Oasis Valley 3 would cross (see Table 3-33). Colson Pond is spring fed and would be within 0.24 kilometer (0.15 mile) of the alternative segment. This spring is commonly known as Colson Pond Spring (DIRS 169384-Reiner et al. 2002, Plate 2), but is also referred to as Warm Spring.

3.2.5.3.12 Common Segment 6 (Yucca Mountain Approach)

Common segment 6 would begin at the south juncture of the end of the Oasis Valley alternative segments and proceed to the southeast toward Yucca Mountain (Table 3-34 and Figure 3-71). The proposed location for construction camp 12 is adjacent to the rail line approximately 9.7 kilometers (6 miles) south of the ***geologic repository*** operations area. There are no potential quarry sites along common segment 6 (DIRS 180922-Nevada Rail Partners 2007, Figure 3-B).

Table 3-34. Hydrologic features potentially relevant to common segment 6.[a]

General hydrographic features/drainage	Hydrologic features within 150 meters[b] of the centerline of the rail alignment	Hydrologic features between 150 meters and 1.6 kilometers[c] of the centerline of the rail alignment
Drainage from northern Yucca Mountain Range, including Tram Ridge, and Timber Mountain. Drainage from Yucca Mountain Range to Crater Flat and Amargosa Valley.	Segment would cross Beatty Wash, Tates Wash, Windy Wash, Busted Butte Wash, and 39 unnamed washes.	Fortymile Wash Midway Valley Wash

a. Sources: DIRS 177710-MO0607NHDWBDYD.000; DIRS 177714-MO0607NHDFLM06.000; DIRS 176979-MO0605GISGNISN.000; DIRS 176730-DeLorme 1996, pp. 64 and 65.
b. To convert meters to feet, multiply by 3.2808.
c. To convert kilometers to miles, multiply by 0.62137.

Common segment 6 would cross terrain that drains from the southern end of Pahute Mesa and the Yucca Mountain Range to Crater Flat and the Amargosa River. The first significant tributary common segment 6 would cross is Beatty Wash and its tributaries, which provide drainage from Timber Mountain and Tram Ridge at the northern reaches of Yucca Mountain, to Oasis Valley and the Amargosa River at a point approximately 4.8 kilometers (3 miles) northeast of the community of Beatty. Beatty Wash is one of the largest tributaries of the Amargosa River. Common segment 6 would cross Beatty Wash at the north end of the Yucca Mountain Range, approximately 5.4 kilometers (3.4 miles) southeast of Oasis

Valley. After crossing Beatty Wash, common segment 6 would proceed to the southeast toward Yucca Mountain, where it would cross several tributaries of Tates Wash. Approximately 26 kilometers (16 miles) from the start of common segment 6, the segment would cross Windy Wash and unnamed washes carrying drainage from the eastern side of Yucca Mountain. The segment would then continue around the southern tip of the Yucca Mountain Range before turning northeast, skirting the eastern edge of Busted Butte and continuing between Bow and Fran Ridges.

Near the Yucca Mountain Site, Fortymile Wash, a major wash that flows to the Amargosa River, drains the eastern side of Yucca Mountain (DIRS 169734-CRWMS M&O 2004, p. 7.1-3). The tributaries draining into Fortymile Wash at Yucca Mountain include Yucca Wash to the north; Drill Hole Wash, which, together with a tributary in Midway Valley, drains most of the repository site; and Busted Butte Wash (also known as Dune Wash) to the south. Common segment 6 would cross Busted Butte Wash, some of its unnamed tributaries, and unnamed tributaries of Drill Hole Wash. The segment would not actually cross Drill Hole Wash, but the wash would be within the common segment 6 region of influence. Fortymile Wash runs parallel to the end of common segment 6 at the Yucca Mountain Site, but common segment 6 would not cross the wash. Fortymile Wash is the most prominent drainage through Jackass Flats to the Amargosa River (DIRS 155970-DOE 2002, p. 3-36, Figure 3-11).

All of common segment 6 is within the Amargosa River interstate drainage system in the Death Valley Basin. Of the numerous washes along common segment 6, 14 were identified as waters of the United States, as designated under Section 404 of the Clean Water Act (DIRS 180914-PBS&J 2006, Figures 3D and 3E). The Rail Equipment Maintenance Yard would be where the proposed rail line ends at Yucca Mountain. There are no perennial streams, natural bodies of water, or naturally occurring wetlands at Yucca Mountain (DIRS 155970-DOE 2002, p. 3-35). The facility would overlie an ephemeral stream but would not cross any waters of the United States.

No streamflow or water-quality data are available for drainage channels along common segment 6. There are no wetlands identified within the region of influence for common segment 6. Appendix F provides additional information on wetlands identified along the Caliente rail alignment.

Slightly more than half of common segment 6 has coverage on Federal Emergency Management Agency flood maps. These maps show that common segment 6 would cross a short span of the 100-year floodplain associated with Beatty Wash. Although the flood maps do not provide coverage for the area of the repository on the eastern side of Yucca Mountain, DOE has performed flood studies on several washes in that area, as addressed in the Yucca Mountain FEIS. An overlay of the Caliente rail alignment with Yucca Mountain FEIS Figure 3-12 indicates that common segment 6 would cross short stretches of 100-year floodplains associated with Busted Butte Wash and Drill Hole Wash. The rail line would terminate just before reaching a floodplain associated with Midway Valley Wash (also known as Sever Wash) (DIRS 155970-DOE 2002, pp. 3-38 and 3-39, and Figure 3-12). Appendix F further describes the floodplains associated with common segment 6.

There are no springs identified within 1.6 kilometers (1 mile) of common segment 6. Ute Springs, 270 meters (890 feet) west of U.S. Highway 95 in Oasis Valley, would be within about 0.6 to 0.88 kilometer (0.37 to 0.55 mile) of potential alternative well sites OV9 through OV12 (see Figure 3.7) near U.S. Highway 95 (DIRS 169384-Reiner et al. 2002, Plate 2).

3.2.6 GROUNDWATER RESOURCES

This section describes groundwater resources along the Caliente rail alignment. Section 3.2.6.1 describes the region of influence for groundwater resources; Section 3.2.6.2 is a general overview of groundwater features along the Caliente rail alignment; and Section 3.2.6.3 describes more specific features for each of the Caliente rail alignment alternative segments and common segments.

3.2.6.1 Region of Influence

The region of influence for groundwater resources along the Caliente rail alignment includes aquifers that would underlie areas of railroad construction and operations, portions of groundwater aquifers DOE would use to obtain water for construction and operations support and that would be affected by these groundwater withdrawals, and nearby springs that might be affected by such groundwater withdrawals. The horizontal extent of the region of influence varies depending on the particular aspects of the specific project activity, as follows:

- DOE used the nominal width of the rail line construction right-of-way and the footprints of construction and operations support facilities to define where there would be construction or other land disturbances. These areas could be susceptible to changes in groundwater ***infiltration***, discharge (for example, spring discharge), or quality. There could also be damage to, or loss of use of, an existing well (including potential need for well abandonment), if that well fell within the rail ***roadbed*** or was disturbed during construction activities. Review of the available information on the locations of existing wells indicates that rail roadbed construction would not disturb any existing wells. However, the precise locations of existing wells have not been field-verified and actual well locations might vary from the coordinates identified and cataloged for the wells in State of Nevada and U.S. Geological Survey (USGS) well databases (see Section 3.2.6.2.1).
- DOE used an initial screening-level distance of 1.6 kilometers (1 mile) on either side of the rail alignment centerline and an initial radius of 1.6 kilometers surrounding each proposed new well if that well would be outside of the nominal width of the construction right-of-way to define areas in the general vicinity of the rail alignment and proposed well locations that could also be affected by changes in groundwater discharge or quality at existing wells or springs. DOE used the same distance criteria to identify whether there could be damage to, or loss of use of, an existing well if that well fell within the rail roadbed or was disturbed during construction activities.
- DOE considered both the individual groundwater basins (hydrographic areas) that underlie the Caliente rail alignment and the railroad construction and operations support facilities and adjacent hydrographic areas for evaluating areas that might be affected by proposed groundwater withdrawals for construction or operations support. This would include areas that could be susceptible to changes in groundwater discharge or flow to an adjacent groundwater basin.

3.2.6.2 General Hydrogeologic Setting and Characteristics

This section is an overview of the general hydrogeologic setting and characteristics of groundwater underlying the area along the Caliente rail alignment. Water-resource features, primarily those associated with groundwater, are described primarily in relation to the hydrographic areas in which they lie.

Groundwater in central and southern Nevada is affected by low precipitation and high annual evaporation rates typical of desert climates. Most ***recharge*** to aquifers in the region of influence is derived from precipitation falling in the higher parts of the interbasin mountain ranges (DIRS 103136-Prudic, Harrilll, and Burbey 1993, pp. 2, 58, 84, and 88).

3.2.6.2.1 Groundwater Hydrographic Areas and Groundwater Use in Nevada

Acre-foot is a unit commonly used to measure water volume. It is the quantity of water required to cover 4,047 square meters (1 acre) to a depth of 0.3048 meter (1 foot), and is equal to 1,233.5 cubic meters (325,851 gallons). Section 3.2.6 lists perennial yields, committed groundwater resources, and consumptive use in acre-feet because it is the common unit used by industry and government agencies.

To classify hydrographic regions and areas and to facilitate the management of groundwater resources within the State of Nevada, the state has been divided into a series of groundwater basins (designated as hydrographic areas) (DIRS 176488-State of Nevada 2006, all; DIRS 177741-State of Nevada 2005, all; DIRS 106094-Harrill, Gates, and Thomas 1988, all).

A total of 260 hydrographic areas are recognized within the western United States Great Basin; all or parts of 232 hydrographic areas fall within Nevada (DIRS 106094-Harrill, Gates, and Thomas 1988, all; DIRS 177741-State of Nevada 2005, all).

Three types of aquifers are the principal sources of groundwater found in central and southern Nevada, as follows (DIRS 172905-USGS 1995, all):

- Alluvial valley fill: Composed primarily of unconsolidated alluvial sand and gravel. The distribution of sediment size is directly associated with distance from the mountains. In general, the coarsest materials (such as gravel and boulders) were deposited near the mountains, and the finer materials (such as sand, silt, and clay) were deposited in the central parts of the basins or in the lakes and playas. Alluvial fans are important hydrologic features within the hydrographic basins, sometimes serving as targets for groundwater development, and with alluvial valley-fill portions of the basins receiving some of their recharge through the coarse sediment deposits in the alluvial fans. Alluvial deposits consisting of alluvial sand and gravel are present along the courses of modern ephemeral streams or ancestral streams that generally parallel the long axes of the basins. Alluvial deposits underlie most of the Caliente rail alignment.
- Volcanic-rock aquifers: Composed primarily of tuffs (ash flows, ash falls), rhyolite, or basalt. Groundwater movement in these materials is often controlled by the number and degree of joint interconnections, ***fractures*** or faults, or vesicle (small cavities in minerals or rock) interconnection in lavas.
- Carbonate-rock aquifers: Composed primarily of limestones and dolomites. The carbonate rocks are commonly highly fractured and are locally fragmented. Groundwater flow in the carbonate rock aquifers is controlled by interconnected fractures.

Tectonic forces superimposed faulting on existing groundwater-bearing formations (aquifers) in this region. As a result, several aquifer units underlying the Caliente rail alignment are fractured and faulted in some locations. These faults and fractures locally can influence groundwater flow patterns within the affected aquifer areas, with such features being capable of acting as either barriers to, or conduits for, groundwater flow (see Appendix G).

Within the Basin and Range Province, any or all of the three basic aquifer types discussed above might be present within a particular area and might constitute three separate, hydraulically distinct, sources of groundwater. Alternatively, any or all of the three aquifer types might underlie an area but might be hydraulically connected to form a single groundwater source (DIRS 172905-USGS 1995, all).

Groundwater levels fluctuate seasonally and annually in response to changes in withdrawal (consumptive use) and climatic conditions, with levels generally rising from late winter to early summer and generally declining from summer to early winter (DIRS 172904-Berris et al. 2002, p. 6). In 2000, an estimated 1.75 billion cubic meters (1.42 million ***acre-feet***) of groundwater were pumped in Nevada (DIRS 175964-

Lopes and Evetts 2004, p. 7). Irrigation and stock watering was the primary groundwater use, accounting for approximately 46 percent of the total groundwater withdrawal, followed by mining (approximately 26 percent), drinking-water systems (approximately 14 percent), geothermal production (approximately 8 percent), self-supplied domestic (approximately 5 percent), and miscellaneous (1 percent) (DIRS 175964-Lopes and Evetts 2004, p. 7) (see Figure 3-72). Virtually all major groundwater development in Nevada has been in alluvial valley fill, with withdrawals from approximately the upper 460 meters (1,500 feet) of these aquifers. The carbonate rock aquifers in eastern and southern Nevada supply water to numerous springs (DIRS 106094-Harrill, Gates, and Thomas 1988, all).

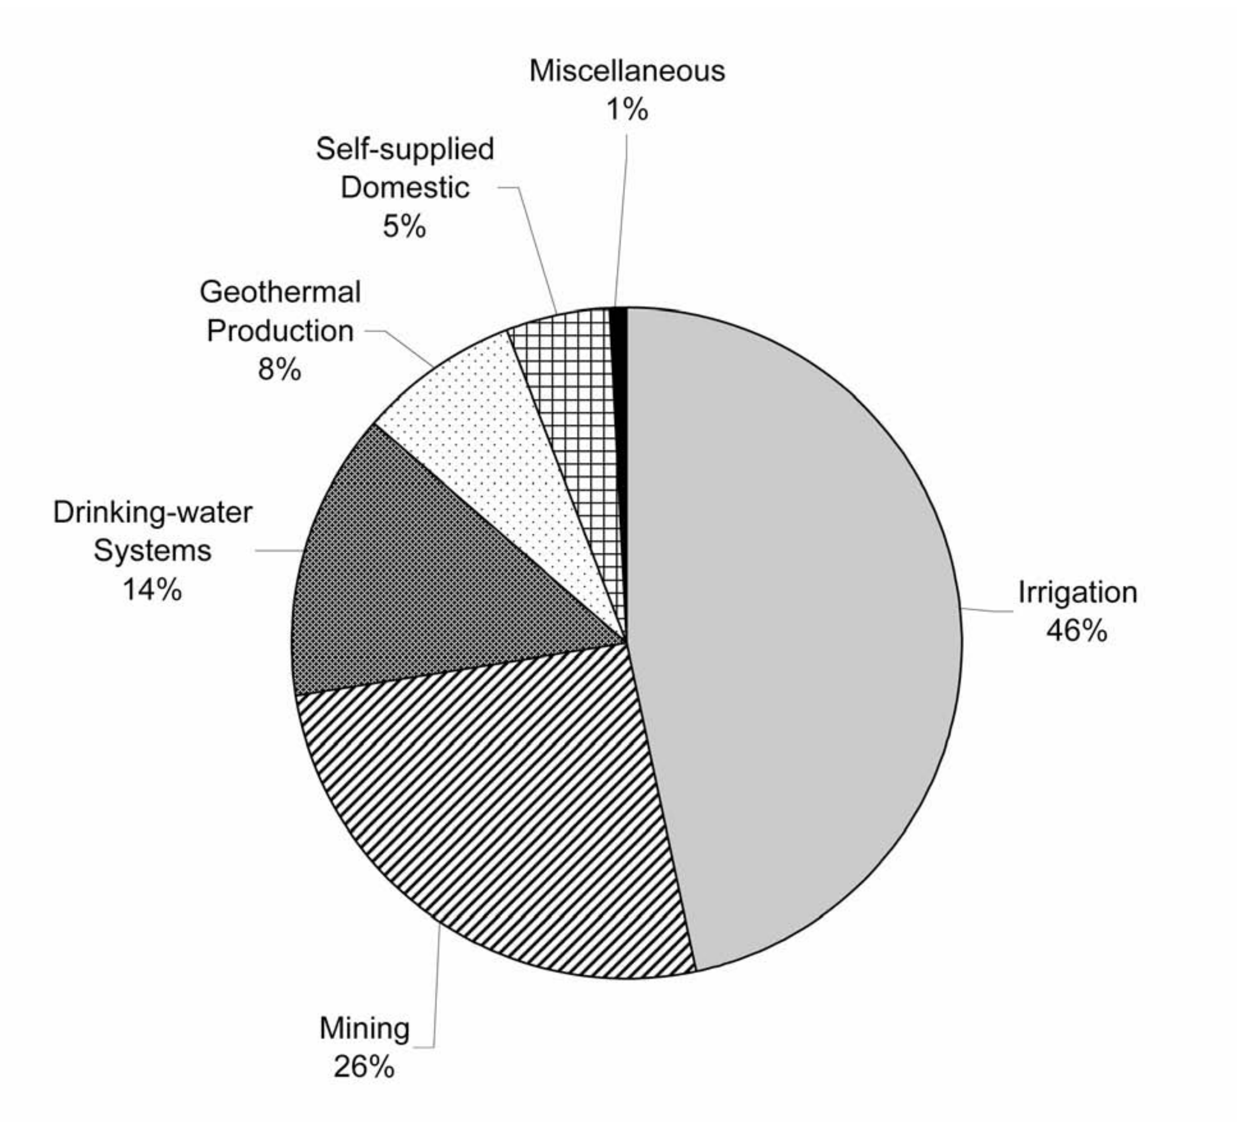

Figure 3-72. Groundwater usage in Nevada in 2000.
(Source: DIRS 175964-Lopes and Evetts 2004, p. 7).

Figure 3-73 shows generalized regional groundwater flow patterns in the vicinity of the Caliente rail alignment. Available information regarding groundwater "interbasin" inflow and outflow (groundwater flow across hydrographic area boundaries) characteristics for hydrographic areas (groundwater basins) within central Nevada (DIRS 177524-Anning and Konieczki 2005, pp. 10 and 11, and Plate 1) indicates interbasin groundwater outflow or groundwater inflow through alluvial valley-fill aquifer materials or through consolidated rock aquifers appears to occur at some locations; at other locations, there appears to be no substantial interbasin groundwater flow occurring through either or both of these aquifer units. The figure depicts generalized flow directions within alluvial valley-fill units and within consolidated rock aquifers, in areas where such flow is inferred to be occurring across hydrographic area boundaries.

Perennial yield is the amount of useable water from a groundwater aquifer that can be economically withdrawn and consumed each year for an indefinite period. It cannot exceed the natural recharge to that aquifer and ultimately is limited to the maximum amount of discharge that can be utilized for beneficial use.

The State of Nevada may identify a hydrographic area as a **designated groundwater basin** where permitted groundwater rights approach or exceed the estimated average annual recharge and the water resources are being depleted or require additional administration, including a state declaration of preferred uses (for example, municipal and industrial, domestic supply) (DIRS 103406-Nevada Division of Water Planning 1992, p. 18). Designated groundwater basins are also referred to as administered groundwater basins.

This section describes groundwater resources in relation to hydrographic areas. Figure 3-74 shows the 19 hydrographic areas the Caliente rail alignment could cross, depending on alternative segments selected. Table 3-35 lists the estimated annual ***perennial yields*** for the 19 hydrographic areas, and identifies which are State of Nevada-***designated groundwater basins***. The hydrographic areas are listed in the order the Caliente rail alignment would cross them, beginning near Caliente or Clover Creek Valley, moving westward across Nevada toward Goldfield, and then southward toward Yucca Mountain.

There are a number of published estimates of perennial yield for many of the hydrographic areas in Nevada, and those estimates often differ by large amounts. The perennial-yield values listed in Table 3-35 predominantly come from a single source, the Nevada Division of Water Planning (DIRS 103406-Nevada Division of Water Planning 1992, for Hydrographic Regions 10, 13, and 14); therefore, the table does not show a range of values for each hydrographic area. In the Yucca Mountain area, the Nevada Division of Water Planning identifies a combined perennial yield for hydrographic areas 225 through 230. DOE obtained perennial yields from *Data Assessment & Water Rights/Resource Analysis of: Hydrographic Region #14 Death Valley Basin* (DIRS 147766-Thiel 1999, pp. 6 to 12) to provide estimates for hydrographic areas the Caliente rail alignment would cross: 227A, 228, and 229. That 1999 document presents perennial-yield estimates from several sources. Table 3-35 lists the lowest (that is, the most conservative) values cited in that document, which is consistent with the approach DOE used in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, p. 3-136).

Table 3-35 also summarizes existing annual ***committed groundwater resources*** for each hydrographic area along the Caliente rail alignment. However, all committed groundwater resources within a hydrographic area might not be in use at the same time. Table 3-35 also includes information on pending annual duties within each of these hydrographic areas. A ***pending annual duty*** represents the amount of water for which an appropriation application has been submitted to the State Engineer for consideration and that the State Engineer has classified as a pending annual duty value within a hydrographic area in accordance with applicable state statutes. Unless otherwise noted, the source of data for pending annual duties in the hydrographic areas crossed by the alignment is the Water Rights Data Update (DIRS 182288-NDWR 2007, all). These data were acquired on May 30, 2007.

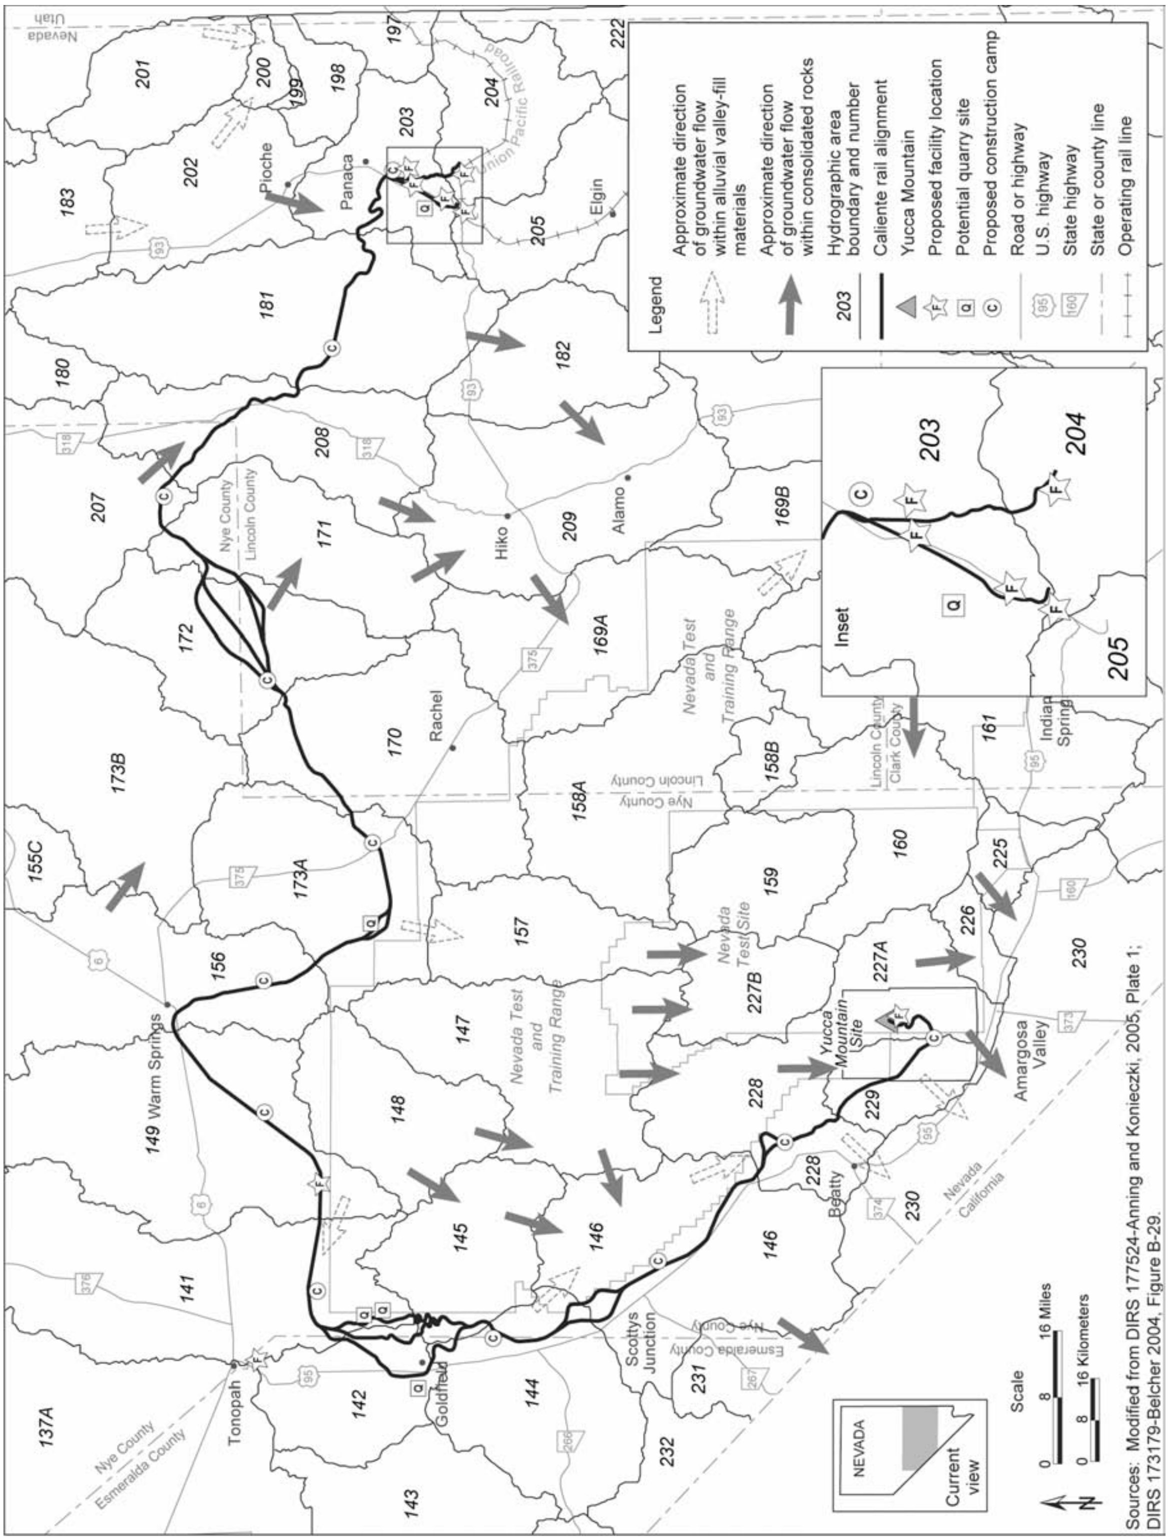

Figure 3-73. Generalized groundwater flow direction through alluvial valley-fill and consolidated rock aquifers in the vicinity of the Caliente rail alignment.

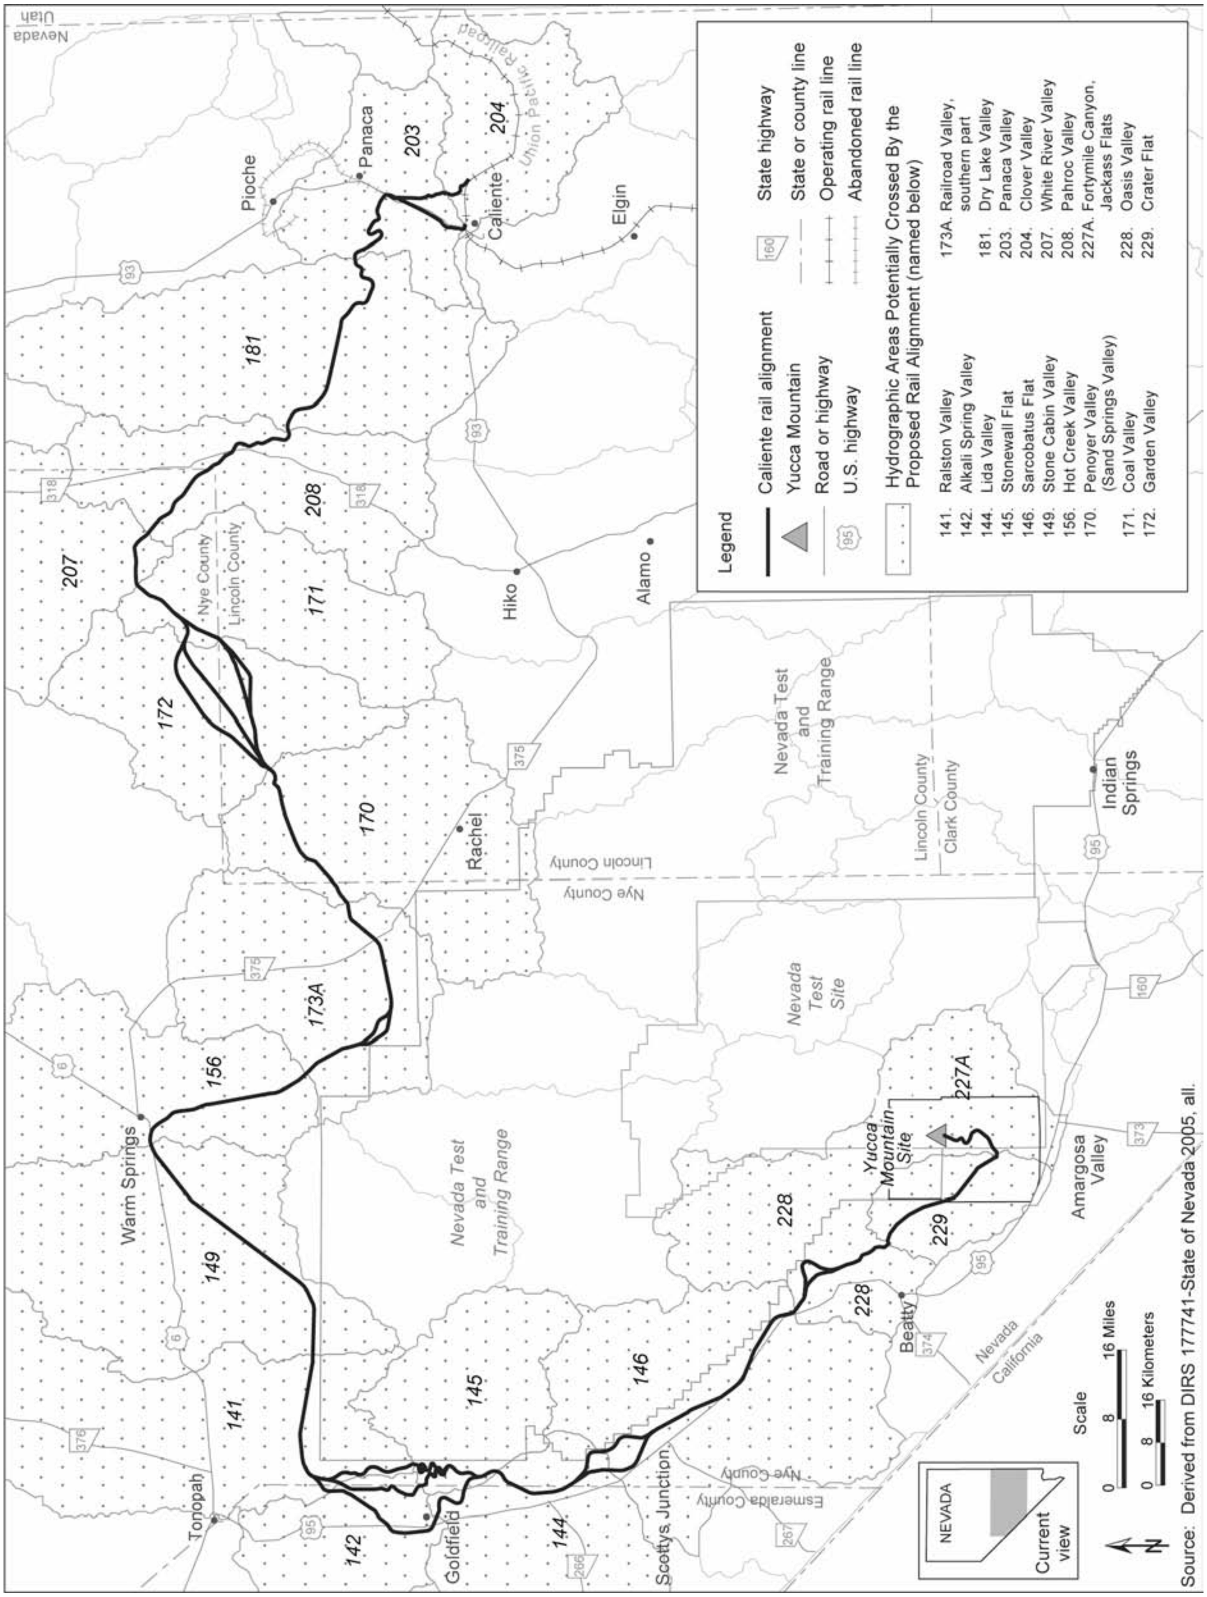

Figure 3-74. Hydrographic areas the Caliente rail alignment would cross.

Table 3-35. Perennial yield and annual committed groundwater resources of hydrographic areas the Caliente rail alignment would cross (page 1 of 2).

Rail line segment	Hydrographic area[a] number	Hydrographic area name	Perennial yield (acre-feet)[b,c]	Annual committed groundwater resources/pending annual groundwater duties (acre-feet)[d]	Designated groundwater basin[e,f]
Caliente alternative segment, Eccles alternative segment	204	Clover Valley	1,000	3,787/0	No
Caliente alternative segment, Eccles alternative segment, Caliente common segment 1	203	Panaca Valley	9,000	31,367/0	Yes
Caliente common segment 1	181	Dry Lake Valley	2,500	57/21,824	No
Caliente common segment 1	208	Pahroc Valley	21,000	30/0	No
Caliente common segment 1	207	White River Valley	37,000	31,819/42,512	No
Caliente common segment 1; Garden Valley alternative segments 1, 2, 3, and 8	171	Coal Valley	6,000	38/33,071	No
Garden Valley alternative segments 1, 2, 3, and 8; Caliente common segment 2	172	Garden Valley	6,000	559/12,224	No
Caliente common segment 2	170	Penoyer Valley (Sand Spring Valley)	4,000	14,461/11,888	Yes
Caliente common segment 2; South Reveille alternative segments 2 and 3; Caliente common segment 3	173A	Railroad Valley, Southern Part	2,800	3,867/0	No
Caliente common segment 3	156	Hot Creek Valley	5,500	4,231/0	No
Caliente common segment 3	149	Stone Cabin Valley	2,000	11,532/6,400	Yes
Caliente common segment 3; Goldfield alternative segments 1, 3, and 4	141	Ralston Valley	6,000	4,330/1	Yes
Goldfield alternative segments 1 and 4	142	Alkali Spring Valley	3,000	2,596/0	No
Goldfield alternative segments 1 and 3	145	Stonewall Flat	100	12/0	No

Table 3-35. Perennial yield and annual committed groundwater resources of hydrographic areas the Caliente rail alignment would cross (page 2 of 2).

Rail line segment	Hydrographic area[a] number	Hydrographic area name	Perennial yield (acre-feet)[b,c]	Annual committed groundwater resources/pending annual groundwater duties (acre-feet)[d]	Designated groundwater basin[e,f]
Goldfield alternative segments 1, 3, and 4; Caliente common segment 4; Bonnie Claire alternative segments 2 and 3	144	Lida Valley	350	72/0	No
Bonnie Claire alternative segments 2, 3, and 5	146	Sarcobatus Flat	3,000	3,591/0	Yes
Common segment 5; Oasis Valley alternative segments 1 and 3; common segment 6	228	Oasis Valley	1,000	1,299/0	Yes
Common segment 6	229	Crater Flat	220	1,147/82	No
Common segment 6	227A	Fortymile Canyon, Jackass Flats	880[g]	58[g] /5	No

a. Source: DIRS 106094-Harrill, Gates, and Thomas 1988, Summary, Figure 3, with the proposed rail alignment map overlay.
b. Source: DIRS 103406-Nevada Division of Water Planning 1992, Regions 10, 13, and 14, except hydrographic areas 227A, 228, and 229, for which the source is DIRS 147766-Thiel 1999, pp. 6 to 12. The perennial yield value shown for area 228 is the lowest value in range of estimated values (1,000 to 2,000 acre-feet per year) presented by Thiel Engineering Consultants 1999.
c. To convert acre-feet to cubic meters, multiply by 1,233.49. To convert acre-feet to gallons, multiply by 3.259×10^5.
d. Data for committed groundwater resources are current as of May 30, 2007 (DIRS 182288-NDWR 2007, all). Data for pending groundwater resources include underground duties but do not include duties for streams or springs. All values have been rounded to the nearest acre-foot.
e. Sources: DIRS 176488-State of Nevada 2006, Regions 10, 13, and 14; DIRS 177741-State of Nevada 2005, all.
f. Based on a 1979 Designation Order by the State Engineer; there are no committed resources in area 227A. However, water-rights information from the Nevada Department of Water Resources indicates there are 58 acre-feet in committed resources for this area. The discrepancy appears to be related to the location of the boundary between areas 227A and 230 (Amargosa Desert) (DIRS 176600-Converse Consultants 2005, p. 29 and Table 4-45). The perennial-yield value shown for area 227A is the lowest estimated value presented in *Data Assessment & Water Rights/Resource Analysis of: Hydrographic Region #14 Death Valley Basin* (DIRS 147766-Thiel 1999, p. 8) for the western two-thirds of hydrographic area 227A. The perennial yield estimate for area 277A is broken down into 300 acre-feet for the eastern third of the area and 580 acre-feet for the western two-thirds of the area.

As part of an effort to assess water resources in the vicinity of the Caliente rail alignment, DOE performed studies to identify groundwater conditions, the locations of springs, and the locations, use, and water rights status of groundwater-supply wells within 32 kilometers (20 miles) of either side of the centerline of the rail alignment. Information on groundwater characteristics in hydrographic areas the rail alignment would cross and identified groundwater uses and use types within the 62-kilometer (39-mile) search area are compiled in the *Water Resources Assessment Report, Caliente Rail Corridor, Yucca Mountain Project, Nevada, Task 3.4, Rev. 0* (the Water Resources Assessment Report, Caliente Rail Corridor) (DIRS 176600-Converse Consultants 2005, all). DOE reviewed several other published reports and maps providing information regarding hydrogeologic and groundwater characteristics in hydrographic areas the rail alignment would cross to obtain information to support the groundwater resources impacts assessment.

DOE reviewed several well and spring databases, including Nevada Division of Water Resources (NDWR) and U.S. Geological Survey National Water Information System (USGS NWIS) databases to identify existing wells and springs located within the potential region of influence of proposed new groundwater withdrawal wells. Unless noted otherwise, the sources for the spring and well data in this section are as follows: DIRS 176325-USGS 2006, all; DIRS 177712- MO0607NHDPOINT.000, all; DIRS 177710-MO0607NHDWBDYD.000, all; DIRS 182898-NDWR 2007,all; DIRS 177293-MO0607PWMAR06D.000, all; DIRS 177294-MO0607USGSWNVD.000; DIRS 176600-Converse Consultants 2005, all; and DIRS 176979- MO0605GISGNISN.000, all. An initial screening process identified existing wells within 1.6 kilometers (1 mile) of the centerlines of the respective alternative segments, or within 1.6 kilometers of DOE-proposed new wells. As described later in this section, before analyzing potential impacts to groundwater resources, DOE extended the search radius for identifying existing beneficial-use wells and springs up to 2.4 kilometers (1.5 miles) away from a proposed new well if the initial search for such wells or springs within 1.6 kilometers did not reveal the presence of any such wells or springs. Additionally, on a case-by-case basis (see Section 4.2.6 and Appendix G), for a selected set of new groundwater withdrawal wells specifically targeted for installation within a fault zone or an extensive fracture zone, DOE identified the locations of existing wells and springs up to 10 kilometers (6 miles) away from each such proposed well (to address the possibility of fault zones or extensive fracture zones acting as conduits for groundwater flow). The Department derived information for completing this compilation through a review of well-log data and water-rights information obtained from the NDWR. NDWR well-log database entries include a general and legal description of the location of existing wells, along with ***borehole*** and well completion information and well testing data (if available). The NDWR water-rights database includes data on the locations, manner of use, and appropriations status of wells having appropriated water rights in Nevada. The USGS website generally includes site information (for example, well location coordinates, elevation, depth) and water-level data. DOE eliminated from consideration in the impacts analysis wells in the NDWR well-log database and the NDWR water-rights database that did not have an appropriated water right or were not domestic wells (such as abandoned or plugged wells, monitoring wells, thermal gradient test wells, oil or gas exploration or groundwater investigation wells). DOE considered all USGS-identified wells.

The compiled well locations had varying levels of accuracy. For example, well locations recorded in the NDWR water-rights database are generally considered to be at the center of each 0.16-square-kilometer (40-acre) parcel representing each quarter-quarter section. Additionally, the well driller might have mapped the well incorrectly, or a well might have been inadvertently recorded in the NDWR water-rights database in the wrong hydrographic area (for example, for wells very near a hydrographic area boundary). Figures 3-75 through 3-82 identify well locations within 1.6 kilometers (1 mile) of the centerline of the Caliente rail alignment or proposed wells. As a result of the characteristics of the well location specifications, there might be more than one existing well at some locations on these figures. Table 3-36 lists hydrographic areas the Caliente rail alignment would cross and the corresponding number of

Totals		180	6	0	14	47	2	0	9	9	0	11

a. To convert kilometers to miles, multiply by 0.62137.
b. Source: DIRS 177293-DTN MO0607PWMAR06D.000.
c. NDWR=Nevada Division of Water Resources.
d. C = commercial; G = monitoring wells; H = domestic; I = irrigation; K = mining and milling; N = industrial (includes those designated in the database as N for "industrial" and as J for "industrial-cooling"); P = municipal or quasi-municipal; S = stock; X = test wells; Z = other (includes those designated in the database as Z for "other," R for "recreation," and U for "unused").
e. Proposed use categories are tabulated only for wells (98 of the 180 wells) listed as NDWR wells with water rights or NDWR domestic wells.
f. Includes total number of NDWR-documented existing wells with water rights, plus NDWR domestic wells, plus U.S. Geological Survey National Water Information System-listed wells within 1.6 kilometers from the centerline of the rail alignment or within 1.6 kilometers of any DOE-proposed new well. The number of NDWR wells listed by proposed use category applies only to NDWR wells with water rights and NDWR wells. U.S. Geological Survey wells are not included in the well counts; the Geological Survey database does not provide information regarding well use category.
g. Well locations have not been field-verified. Therefore, some of the identified wells might be farther than 1.6 kilometers from the centerline of the rail alignment or proposed new wells.

wells within 1.6 kilometers of the centerline of the rail alignment, as recorded by the NDWR and the USGS NWIS. Table 3-36 identifies the associated proposed use category of the NDWR-catalogued wells (as defined in the State of Nevada well-log database). The USGS NWIS database does not categorize wells according to their use.

The distance of 1.6 kilometers (1 mile) reflects the first two of three aspects considered in establishing the groundwater region of influence, as described in Section 3.2.6.1. Most of the wells shown in Figures 3-75 through 3-80 are along the easternmost extent of the Caliente rail alignment; a smaller number of wells are clustered in several groups along the western portion. Few existing wells are present elsewhere along the rail alignment. The wells identified in these figures were compiled from information in *Water Resources Assessment Report, Caliente Corridor* (DIRS 176600-Converse Consultants 2005, all) and databases administered by the NDWR and the USGS NWIS. DOE would field-verify the locations of wells that could be affected during rail line construction before starting construction activities.

DOE-compiled well data include data on well locations and uses as documented in the *Water Resources Assessment Report, Caliente Corridor*, and include well records coded as "new" or "replacement" wells in the Nevada well-log database. Because each entry in the well-log database represents an event at a well site (for example, installation, re-drilling, abandonment), there is a possibility that there is more than one record to represent a particular well. To preclude duplication, DOE summarized only records that identified wells as new or replacement.

As shown in Table 3-36, there are a total of 180 NDWR wells with water rights, NDWR domestic wells, and USGS NWIS wells within 1.6 kilometers (1 mile) of the centerline of the Caliente rail alignment or within 1.6 kilometers of proposed new wells. Most of these wells are in areas 203 and 204. Table 3-36 lists irrigation (41 of the 77 NDWR-listed wells with water rights and domestic wells in areas 203 and 204) as the predominant use category for those NDWR-listed wells that are within 1.6 kilometers of the centerline of the Caliente rail alignment or within 1.6 kilometers of any proposed new well.

3.2.6.2.2 Groundwater-Quality Characteristics

Water quality in aquifers in Nevada varies with location (DIRS 106094-Harrill, Gates, and Thomas 1988, all). In the Basin and Range, total dissolved solids concentrations can range from less than 500 to more than 10,000 milligrams per liter (DIRS 172905-USGS 1995, all). In general, at hydrographic area margins and on the slopes of alluvial fans, groundwater quality is good. In discharge areas (such as playas) and other selected areas, groundwater quality can be brackish. However, groundwater in deeper alluvial valley-fill units underlying some playa areas can be of better quality (DIRS 172905-USGS 1995, all). Groundwater quality in the carbonate aquifers in southern and central Nevada, including total dissolved solids concentrations, is generally more uniform in character and with depth within the aquifer (DIRS 101167-Winograd and Thordarson, 1975, p. C103). Total dissolved solids concentrations in alluvial valley fill underlying the Caliente rail alignment generally range from less than 500 to 1,000 milligrams per liter, or approximately 500 to 1,000 parts per million, but a few locations might be in the 1,000 to 3,000 milligrams per liter (approximately 1,000 to 3,000 parts per million) range (DIRS 172905-USGS 1995, Figure 7, with overlay of hydrographic area boundaries). The U.S. Environmental Protection Agency has set an aesthetic standard of 500 milligrams per liter of total dissolved solids for drinking water (40 CFR Part 143). Water with a total dissolved solids concentration of 500 milligrams per liter or less is regarded as acceptable and pleasing for general consumption. A secondary preferred drinking water standard for total dissolved solids concentrations of 500 milligrams per liter for public water supplies has been adopted for Nevada. If water supplies that meet the preferred standard are not available, the Maximum Contaminant Level of 1,000 milligrams per liter is enforceable by the State of Nevada. At higher concentrations, general consumption issues (pertaining to hardness, deposits, color, staining, and salty taste) could develop, but the water could be used for other purposes (for example, agriculture or earthwork compaction as part of embankment construction). Another parameter of interest for gauging the quality of groundwater in Nevada is arsenic. A revised drinking water standard for arsenic (for water systems meeting certain specified criteria) of 0.010 milligrams per liter became enforceable in January of 2006 (40 CFR 141.23).

3.2.6.3 Hydrogeologic Setting and Characteristics along Alternative Segments and Common Segments

3.2.6.3.1 Interface with the Union Pacific Railroad Mainline

The Caliente alternative segment and the Eccles alternative segment would both overlie a small portion of Clover Valley (hydrographic area 204) and would cross Panaca Valley (hydrographic area 203) (see Figure 3-75). The Caliente and Eccles alternative segments would predominately overlie alluvial valley fill (Table 3-37).

Groundwater quality underlying the areas of the Caliente and Eccles alternative segments varies according to location within the hydrographic areas the segments would cross. Table 3-37 summarizes the general groundwater-quality and aquifer characteristics of this area.

Table 3-37. General groundwater-quality and aquifer characteristics – Interface with the Union Pacific Railroad Mainline, Caliente and Eccles alternative segments.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
204 Clover Valley	Quaternary-age alluvial valley fill and volcanic rocks[e]	6 to 20	Upper 30 meters: 650,000[e]	Total dissolved solids: 30 to 350 mg/L[f]
203 Panaca Valley	Alluvial valley fill, carbonate and clastic rocks, volcanic rocks and other crystalline rocks, with some terraced areas comprised of fine-grained lakebed deposits[e]	12 to 30	Upper 30 meters: 1.4 million[f]	Total dissolved solids: 230 to 770 mg/L[e]

a. Source: DIRS 176600-Converse Consultants 2005, Plates 4-13a and 4-15. The listed depth ranges generally apply to areas underlying the alternative segments; groundwater is deeper in the southern part of area 204 beneath the Clover Mountains (DIRS 176600-Converse Consultants 2005, p. 93) and in some other parts of area 203 (DIRS 176600-Converse Consultants 2005, p. 88).
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1,233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.

Hydrographic area 204, Clover Valley, is not a designated groundwater basin (see Table 3-35). Committed groundwater resources exceed estimated perennial yield of 1.2 million cubic meters (1,000 acre-feet). However, as noted previously, all committed resources within a hydrographic area might not be in use at the same time. Groundwater depth throughout Clover Valley varies from less than 1 meter to 60 meters (2.5 to 200 feet). The depth at which groundwater occurs varies from 6 meters (20 feet) to 20 meters (60 feet) below ground along the short segments of the Caliente and Eccles alternative segments that would lie within area 204 (see Table 3-37). Groundwater is primarily produced from the alluvial valley fill. Geologic units encountered in boreholes drilled in the Clover Valley area include alluvial valley fill and volcanic rocks.

DOE determined that there are a total of 29 combined existing NDWR wells with water rights, NDWR domestic wells, and USGS NWIS wells in hydrographic area 204 within 1.6 kilometers (1 mile) of the centerlines of the Caliente and Eccles alternative segments. Figures 3-75 and 3-76 show the locations of these wells. The locations of existing wells are based on data on well locations as available in NDWR and USGS NWIS databases. Not all existing wells in area 204 that lie within 1.6 kilometers of the centerlines of the Caliente and Eccles alternative segments may be depicted on Figures 3-75 and 3-75 because some wells are at very nearly the same locations and cannot be shown at the scale used in these figures. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 204.

Hydrographic area 203, Panaca Valley, is a designated groundwater basin. Committed groundwater resources exceed the estimated annual perennial yield of 11.1 million cubic meters (9,000 acre-feet) (see Table 3-35). However, as previously noted, all committed resources within a hydrographic area might not be in use at the same time. The depth at which groundwater occurs ranges from above the ground surface to about 60 meters (200 feet) below ground, although in most areas, it is generally less than approximately 20 meters (60 feet) below ground. Along the Caliente alternative segment, the shallowest depth to groundwater in this basin is in its central portion, along U.S. Highway 93, where depth to groundwater is generally approximately 12 to 30 meters (40 to 100 feet) (see Table 3-37) (DIRS 176600-Converse Consultants 2005, Plate 4-13a). Groundwater is primarily produced from the alluvial valley fill, although some low-yielding wells have produced groundwater from thin sand beds in lakebed deposits of the Panaca Formation. Groundwater also occurs in fractured volcanic rocks and carbonate rocks (DIRS 176600-Converse Consultants 2005, pp. 86 and 87).

There are 60 wells (total number of NDWR wells with water rights, NDWR domestic wells, and USGS NWIS wells) in hydrographic area 203 within 1.6 kilometers (1 mile) of the centerlines of the Caliente and Eccles alternative segments. Figures 3-75 and 3-76 show the locations of these wells. As described above for the case of hydrographic area 204, not all existing wells in area 203 that lie within 1.6 kilometers of the centerlines of the proposed Caliente and Eccles alternative segments may be depicted on Figures 3-75 and 3-76 because some wells are at very nearly the same locations and cannot be shown at the scale used in these figures.

The predominant use categories for the NDWR wells with water rights within 1.6 kilometers (1 mile) of the centerlines of the Caliente and Eccles alternative segments in area 203 are irrigation, domestic municipal, or quasi-municipal, or other. Based on the information in Table 3-36, groundwater use associated with about 53 percent of NDWR wells with water rights or NDWR domestic wells in hydrographic areas 203 and 204 within 1.6 kilometers of the centerlines of those two alternative segments is categorized as irrigation; about 16 percent of those wells are listed as domestic wells; about 14 percent are listed as having other uses; about 8 percent are listed as municipal or quasi-municipal water-supply wells; about 6 percent are listed as commercial-use wells. Listed individual water-use types from other wells each represent 5 percent or less of the total well use.

The Panaca Valley area is underlain by alluvial valley fill, volcanic rocks and other crystalline rocks, and older carbonate and clastic rocks, with some terraced areas comprised of fine-grained lakebed deposits (DIRS 176519-Rowley and Shroba 1991, all; DIRS 176600-Converse Consultants 2005, pp. 86 and 87). Geologic materials present in the vicinity of the potential quarry site northwest of Caliente (west of proposed new well location PanV23) include lava flows; mudflow breccias; ash-flow tuffs; alluvium and alluvial fan materials; limestone and dolomite; and sandstone, mudstone, and conglomeratic rocks (DIRS 176947-Rowley et al. 1994, all; DIRS 176519-Rowley and Shroba 1991, all).

There is groundwater under both confined and unconfined conditions in the Meadow Valley Wash area (DIRS 176502-Rush 1964, p. 18), which generally includes the area between Caliente and Panaca. Groundwater storage values for the alluvial aquifers within the uppermost 30 meters (100 feet) of saturated material in Panaca Valley and Clover Creek Valley were previously estimated at 1.75 billion cubic meters (1.4 million acre-feet) and 802 million cubic meters (650,000 acre-feet), respectively (Table 3-37). Because most wells are no deeper than approximately 46 meters (150 feet), the total thickness of the alluvial aquifer groundwater reservoir is not known in many parts of the Meadow Valley Wash area (DIRS 176502-Rush 1964, p. 18). In this area, well-pumping rates on the order of 40 to 190 liters per minute (10 to 50 gallons per minute) to more than 4,000 liters per minute (1,000 gallons per minute) have been reported (DIRS 176502-Rush 1964, Table 15). NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 203.

Figures 3-75 and 3-76 show DOE-proposed wells for supplying water to support construction of the Caliente or Eccles alternative segment. In addition to construction within the nominal width of the rail line construction right-of-way, a potential quarry in this area would also require up to two new wells. Quarry wells proposed for the Caliente and Eccles alternative segments would be outside the nominal width of the construction right-of-way of either alignment. Although the potential quarry location and its associated new well(s) would be outside the construction right-of-way, they are described in this Rail Alignment EIS in the context of the rail alignment segment(s) with which they are most closely associated, because each quarry would be accessed in a generally perpendicular direction from the rail line. A well proposed to provide water to potential quarry CA-8B (PanV23 on Figures 3-75 and 3-76) is approximately 1.6 kilometers (1 mile) northwest of the proposed Caliente alternative segment, respectively, and would overlie hydrographic area 203.

3.2.6.3.2 Caliente Common Segment 1 (Dry Lake Valley Area)

Crossing from east to west, Caliente common segment 1 would overlie hydrographic areas Panaca Valley (203), Dry Lake Valley (181), Pahroc Valley (208), White River Valley (207), and Coal Valley (171) (see Figure 3-74). Caliente common segment 1 would predominantly overlie alluvial valley fill (DIRS 176600-Converse Consultants 2005, Plates 4-13a and 4-13b). The depth to groundwater underlying common segment 1 varies according to locale. Groundwater quality underlying common segment 1 varies according to location within the hydrographic areas the rail line would cross. Table 3-38 summarizes the groundwater-quality and aquifer characteristics in the hydrographic areas common segment 1 would cross.

Section 3.2.6.3.1 discusses hydrographic area 203, Panaca Valley, in detail. Two existing wells in areas 203, one NDWR well with a water right and one USGS NWIS well, are within 1.6 kilometers (1 mile) of the centerline of the rail alignment in area 203. One existing spring (Bennett Springs) is within 1.6 kilometers of the centerline of common segment 1. Figure 3-75 shows the locations of these wells and the spring.

Hydrographic area 181, Dry Lake Valley, is not a designated groundwater basin. Committed groundwater resources do not exceed its estimated perennial yield of 3.08 million cubic meters (2,500 acre-feet) (see Table 3-35).

The depth to groundwater depth in most parts of Dry Lake Valley generally exceeds 60 meters (200 feet), and in many places exceeds 240 meters (800 feet). Depth to groundwater underlying the common segment varies from 50 to 160 meters (160 to 520 feet) (Table 3-38). Groundwater is generally calcium–sodium–sulfate type (DIRS 101811-DOE 1996, Section 4.6.5.2). The primary source of groundwater in Dry Lake Valley is mountain front recharge. Geologic units in the Dry Lake Valley area include alluvial valley-fill deposits, volcanic rocks, clastic rocks, and older carbonate rocks.

Table 3-38. General groundwater-quality and aquifer characteristics – Caliente common segment 1.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
203 Panaca Valley	Alluvial valley fill, carbonate and clastic rocks, volcanic rocks and other crystalline rocks, with some terraced areas comprised of fine-grained lakebed deposits[e]	Less than 60	Upper 30 meters: 1.4 million[f]	Total dissolved solids: 230 to 8,770 mg/L
181 Dry Lake Valley	Alluvial valley fill deposits, volcanic rocks, and older carbonate rocks[e]	50 to 160	Upper 30 meters: for both aquifer types – *Alluvial valley fill*: 2.8 million[f] *Carbonate rock aquifer*: 800,000[f]	Total dissolved solids: 377 mg/L[e] Sulfate: 30 mg/L[e] Fluoride: Less than 1 mg/L[e]
208 Pahroc Valley	Alluvial sediments, carbonate rocks, quartzite, volcanics, and a clastic aquitard[e]	50 to 180	Upper 30 meters: for both aquifer types – *Alluvial valley fill*: 1.3 million[f] *Carbonate rock aquifer*: 325,000[f]	Total dissolved solids: 475 mg/L[e] Sulfate: Less than 30 mg/L[e]
207 White River Valley	Alluvial valley-fill and older carbonate rocks[e]	30 to 50	*Alluvial valley fill*: 4.9 million[f]	Total dissolved solids: 257 to 470 mg/L[e]
171 Coal Valley	Alluvial valley fill, volcanic rocks, clastic rocks, and older carbonate rocks[e]	50 to 90	Upper 30 meters: for both aquifer types – *Alluvial valley fill*: 1.5 million[f] *Carbonate rock aquifer*: 600,000[f]	Total dissolved solids: 200 to 300 mg/L[e]

a. The listed depth ranges generally apply to areas underlying the alternative segments (DIRS 176600-Converse Consultants 2005, Plates 4-10 through 4-13a); groundwater can vary over a wide range of depth depending on location in each hydrographic area (DIRS 176600-Converse Consultants 2005, pp.76, 78, 79, 83, and 88).
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1,233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.
e. Source: DIRS 176600-Converse Consultants 2005, pp. 75 to 90.
f. Sources: DIRS 180754-Rush et al. 1971, all; DIRS 176883-Brothers, Katzer, and Johnson 1996, pp. 27 and 28; DIRS 176851-Brothers, Bugo, and Tracy 1993, pp. 17 to 30; DIRS 176852-Drici, Garey, and Bugo 1993, p. 36.

Unconsolidated alluvial materials and older carbonate rock comprise the best aquifers in area 181 (DIRS 176600-Converse Consultants 2005, p. 83). Beneath Dry Lake Valley, the thickness of the alluvial materials varies from a few meters to more than 300 meters (1,000 feet) (DIRS 176883-Brothers, Katzer, and Johnson 1996, p. 15). There is an estimated 3.5 billion cubic meters (2.8 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer material within this basin, and there might be an additional 990 million cubic meters (800,000 acre-feet) of recoverable groundwater in the carbonate aquifer underlying the basin. There is one existing well (181M-1) and four springs in hydrographic area 181 within 1.6 kilometers (1 mile) of the centerline of common segment 1. Figures 3-75 and 3-77 identify the locations of this well and the springs. Well 181M-1 is shown on Figures 3-75 and 3-77 as the "SNWA well." This well is an exploration well drilled by the Southern Nevada Water Authority.

In addition to existing groundwater wells in hydrographic area 181 that have water-rights appropriations, NDWR data indicate that there are approximately 26.9 million cubic meters (22,000 acre-feet) of documented pending annual duties (see Table 3-35) in area 181. These total pending annual duties include 14.3 million cubic meters (12,000 acre-feet) for water-rights applications originally filed by the Las Vegas Valley Water District in 1989 to appropriate water at some future time from a series of proposed new wells in Dry Lake Valley (DIRS 177516-SNWA 2006, p. 3). Ownership of these water-rights applications was subsequently transferred to the Southern Nevada Water Authority. Caliente rail alignment common segment 1 would cross one of five different proposed groundwater exploration areas the Water Authority identified in area 181 (DIRS 176469-SNWA [n.d.], all) from which groundwater might be developed. The additional water-rights applications comprise pending annual duties of 12.6 million cubic meters (10,000 acre-feet) and were filed with the Nevada State Engineer by the Lincoln County Water District to appropriate water at some future time from a series of proposed new wells in Dry Lake Valley. Until the outcomes of agency and public scoping and the water-rights application process are known and the Nevada State Engineer makes permitting decisions, details about the specific future groundwater development in this valley pursuant to these applications (including final locations of any proposed new wells, or the precise timing of such development) are not known. However, according to the NDWR Water Rights Database, an application has been filed for a future irrigation well that would be within approximately 1.7 kilometers (1.1 miles) of a proposed new well location (DLV3) in Dry Lake Valley. The proposed production rate for the municipal well would be up to 17,000 liters (4,448 gallons) per minute and the well would operate year round. This water rights application is under protest. The potential for impacts associated with this well application, if it were to be approved and the well installed and used at the same time as proposed well location DLV3, is evaluated in Section 5.2.2.6. Chapter 5, Cumulative Impacts, includes additional information about these water-rights applications.

Hydrographic area 208, Pahroc Valley, is not a designated groundwater basin. Committed groundwater resources do not exceed its estimated perennial yield of 25.9 million cubic meters (21,000 acre-feet) (see Table 3-35). In addition to existing wells with water rights in area 208, Lincoln County and two other entities have filed water-rights applications with the Nevada State Engineer to possibly appropriate water at some future time from a series of proposed new wells in Pahroc Valley (DIRS 175909-Hafen et al. 2003, pp. 1 and 2, and Exhibit B). Pending the outcome of agency and public scoping and water rights permitted by the Nevada State Engineer, details pertaining to the specific future groundwater development in this valley pursuant to these applications (including final locations of any proposed new wells, or the precise timing of such development) are not known. However, according to the NDWR Water Rights Database, there are NDWR water-rights applications with "Ready for Action" (RFA) or "Ready for Protest" (RFP) status on file, and the most recent amended application applies to a proposed well location in Pahroc Valley that would be within approximately 1.7 kilometers (1.1 miles) of a proposed location (PahV9) for installation of up to two new withdrawal wells. This application has an RFA status, the proposed production rate for this municipal well would be up to 10,200 liters (2,690 gallons) per minute, and the well would operate year round. Water-rights applications have also been submitted for a proposed municipal well that would be approximately 1.5 kilometers (0.9 mile) northeast of the proposed PahV7 well location and a proposed municipal well that would be approximately 1 kilometer (0.6 mile) northeast of the proposed PahV8 well location. The potential for impacts associated with these well applications is evaluated in Section 5.2.2.6. Chapter 5, Cumulative Impacts, includes additional information pertaining to proposed future groundwater development projects in eastern Nevada.

The depth to groundwater beneath the Pahroc Valley hydrographic area generally exceeds 61 meters (200 feet) (see Table 3-38). Depth to groundwater underlying the rail alignment in Pahroc Valley ranges from 50 to 180 meters (160 to 600 feet). Available data regarding characteristics of the aquifers underlying area 208 indicate that approximately 1.6 billion cubic meters (1.3 million acre-feet) of recoverable groundwater might exist within the upper 30 meters (100 feet) of saturated aquifer material within this basin. It is also estimated that there could be an additional 400 million cubic meters (320,000 acre-feet) of recoverable groundwater in the carbonate aquifer underlying this area (Table 3-38). NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 208.

Geologic units underlying the Pahroc Valley hydrographic area include alluvial sediments, carbonate rocks, quartzite, volcanics, and an older clastic rock (rock formed from fragments of pre-existing rock) aquitard. Mountain front precipitation and inflow from adjacent valleys (primarily White River Valley to the north) provide most of the flow to Pahroc Valley.

There are no NDWR wells with water rights, no NDWR domestic wells, no USGS NWIS wells, and no springs in hydrographic area 208 within 1.6 kilometers (1 mile) of the centerline of Caliente common segment 1 (see Table 3-36).

Hydrographic area 207, White River Valley, is not a designated groundwater basin. Committed groundwater resources do not exceed its estimated perennial yield of 45.6 million cubic meters (37,000 acre-feet) (see Table 3-35). In addition to existing groundwater wells in hydrographic area 207 with water-rights appropriations, preliminary NDWR data indicate that that there are approximately 52.4 million cubic meters (42,500 acre-feet) of pending annual duties in area 207. None of the pending water-rights locations are within 1.6 kilometers (1 mile) of the centerline of the Caliente common segment 1.

Groundwater depth throughout White River Valley varies from above surface to 120 meters (–1 to 400 feet). In the portion of hydrographic area 207 the rail line would cross, groundwater is approximately 20 meters (60 feet) below ground surface (Table 3-38). Available data regarding characteristics of the aquifer underlying area 207 indicate that approximately 6.04 billion cubic meters (4.9 million acre-feet) of recoverable groundwater might exist within the upper 30 meters (100 feet) of saturated aquifer material within this basin. Groundwater is a calcium-bicarbonate type. Groundwater is primarily obtained from alluvial valley fill, but water does occur in carbonate rocks. The primary geologic units comprising White River Valley include alluvial valley fill and older carbonate rocks. There are no NDWR wells with water rights, USGS NWIS wells, or springs in hydrographic area 207 within 1.6 kilometers (1 mile) of the centerline of common segment 1 (see Table 3-36 and Figure 3-77).

Hydrographic area 171, Coal Valley, is not a designated groundwater basin. Committed groundwater resources do not exceed its estimated perennial yield of 7.4 million cubic meters (6,000 acre-feet) (see Table 3-35). Groundwater is primarily obtained from alluvial valley fill, but water does occur in fractured volcanic rocks and carbonate rocks. An oil exploration well in north-central Coal Valley penetrated 820 meters (2,700 feet) of alluvium. Depth to groundwater throughout Coal Valley varies from 30 meters to more than 240 meters (100 to more than 800 feet). Depth to groundwater along the rail alignment beneath area 171 varies from 50 to 90 meters (160 to 280 feet) (Table 3-38). It is estimated that there could be approximately 1.9 billion cubic meters (1.5 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer material within area 171. It is estimated that there could be an additional 740 million cubic meters (600,000 acre-feet) of recoverable groundwater in the carbonate aquifer underlying these two areas combined (DIRS 176851-Brothers, Bugo, and Tracy 1993, p. 29). NDWR data indicate that there are approximately 40.8 million cubic meters (33,100 acre-feet) of pending annual duties (see Table 3-35) in area 171.

There is one USGS NWIS well and no springs in hydrographic area 171 within 1.6 kilometers (1 mile) of the centerline of Caliente common segment 1. Figure 3-77 shows the location of the well. Table 3-36 lists two existing wells within 1.6 kilometers of the centerline of the rail alignment within hydrographic area 171. One of these wells are within 1.6 kilometers of the centerline of common segment 1; the other is within 1.6 kilometers of the centerline of the Garden Valley 2 alternative segment (Figure 3-77).

The predominant proposed use category for the existing NDWR wells with water rights that are within approximately 1.6 kilometers (1 mile) of the centerline of Caliente common segment 1 is irrigation. Table 3-36 (columns 4 through 13) summarizes the proposed use categories of these wells. Figures 3-75, 3-77, and 3-78 show DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of common segment 1. In addition to a series of new wells proposed for installation within the rail line construction right-of-way, DOE might install a series of additional wells at selected locations outside the construction right-of-way, either as alternative water wells or as alternative wells used in combination with other water wells installed within the construction right-of-way. These wells would be drilled in areas where groundwater resources within the construction right-of-way were not adequate to meet railroad construction or operations needs. No potential quarry sites have been identified along Caliente common segment 1. Proposed new wells that might be required outside the nominal width of the rail line construction right-of-way not related to water-supply requirements for potential quarries include:

- Location DLV5 (Figures 3-75 and 3-77) in the western part of Dry Lake Valley 1.1 kilometers (0.7 mile) northeast of the centerline of the rail alignment
- Locations PahV3, PahV4, and PahV8 (Figure 3-77) in southern, central, and western Pahroc Valley approximately 1.3 to 2.7 kilometers (0.8 to 1.7 miles) west to southwest of the centerline of the rail alignment

There are no known existing wells within 1.6 kilometers (1 mile) of proposed well site DLV5, and the closest existing springs are Deadman Spring and Black Rock Spring, about 2.4 kilometers (1.5 miles) northwest or west of this location (DIRS 176189-Converse Consultants 2006, Appendixes A and B). There are no known existing wells or springs within 1.6 kilometers of the proposed well locations at PahV3, PahV4, and PahV8.

3.2.6.3.3 Garden Valley Alternative Segments

Crossing from east to west, alternative segments Garden Valley 1, Garden Valley 2, Garden Valley 3, and Garden Valley 8 would overlie hydrographic areas 171 (Coal Valley) and 172 (Garden Valley) (see Figure 3-78). Areas 171 and 172 each have a perennial yield of 7.40 million cubic meters (6,000 acre-feet), and are not designated groundwater basins (see Table 3-35). Committed groundwater resources in these areas do not exceed estimated perennial yields. In addition to existing groundwater wells in hydrographic area 172 that have water-rights appropriations, NDWR data indicate that there are approximately 15 million cubic meters (12,200 acre-feet) in pending underground annual duties (see Table 3-35) in area 172. These pending annual duties applications correspond to water-rights applications filed with the Nevada State Engineer by the Las Vegas Valley Water District and Lincoln County to appropriate water at some future time from a series of proposed new wells within hydrographic area 172 (DIRS 175909-Hafen et al. 2003, all). According to the NDWR Water Rights Database, an application for a future municipal well has been filed by the Lincoln County Water District and by a private entity to appropriate groundwater from a location approximately 1.2 kilometers (0.8 mile) southwest of a proposed location (GV10) for up to two new withdrawal wells in Garden Valley. The potential for impacts associated with this well application is evaluated in Section 5.2.2.6.

Groundwater quality underlying the areas of the Garden Valley alternative segments varies according to location within the hydrographic areas the rail line would cross. Table 3-39 summarizes general groundwater-quality and aquifer characteristics in the two hydrographic areas underlying the Garden Valley alternative segments.

Along the Caliente rail alignment, depth to groundwater in Garden Valley varies from approximately 40 to 120 meters (120 to 400 feet) below ground (Table 3-39). Groundwater quality underlying the Garden Valley alternative segments varies according to location. Data from four wells in Garden Valley indicate the groundwater is a calcium-bicarbonate type. Table 3-39 summarizes generalized groundwater-quality characteristics in this area.

Table 3-39. General groundwater-quality and aquifer characteristics – Garden Valley alternative segments.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality [d]
171 Coal Valley	Alluvial valley fill, volcanic rocks, clastic rocks, and carbonate rocks[e]	50 to 80	*Alluvial valley fill*: 1.5 million[f] *Carbonate rock aquifer*: 600,000 (total for hydrographic areas 171 and 172)[f]	Total dissolved solids: 200 to 300 mg/L[e]
172 Garden Valley	Alluvial valley fill, with surrounding mountain ranges comprised of older carbonate and clastic rocks, and younger volcanic rock units[e]	40 to 120	*Alluvial valley fill*: 1.5 million[f] *Carbonate rock aquifer*: 600,000 (total for hydrographic areas 171 and 172)[f]	Total dissolved solids: 200 to 300 mg/L[e]

a. The listed depth ranges generally apply to areas underlying the alternative segments (DIRS 176600-Converse Consultants 2005, Plate 4-10); groundwater can vary over a wide range of depth depending on location in the hydrographic area (DIRS 176600-Converse Consultants 2005, pp. 74 and 76).
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1,233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.
e. Source: DIRS 176600-Converse Consultants 2005, pp. 73 to 77.
f. Sources: DIRS 180754-Rush et al. 1971, all; DIRS 176851-Brothers, Bugo, and Tracy 1993, pp. 29 and 30.

Geologic units in the Garden Valley area include primarily alluvial valley fill, with surrounding mountain ranges comprised mostly of carbonate rocks, rock units, and clastic rocks (Table 3-39). The Garden Valley alternative segments would predominantly overlie alluvial valley fill. It is estimated that there could be approximately 1.85 billion cubic meters (1.50 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer material within area 172. It is estimated that there could be an additional 740 million cubic meters (600,000 acre-feet) of recoverable groundwater (DIRS 176851-Brothers, Bugo, and Tracy 1993, p. 30) in the carbonate aquifer underlying these two areas combined (Table 3-39). Review of available data for existing wells and springs indicates the following (Figure 3-78):

- There is one existing USGS NWIS well and no springs in hydrographic area 171 within 1.6 kilometers (1 mile) of the Garden Valley 2 alternative segment.
- In hydrographic area 172, there are no NDWR wells with water rights, no NDWR domestic wells, six USGS NWIS wells, and one spring within approximately 1.6 kilometers of the centerline of Garden Valley alternative segment 3; no NDWR well with water rights or NDWR domestic wells,

one USGS NWIS well, and one spring within 1.6 kilometers of the centerline of Garden Valley alternative segment 1; no NDWR wells with water rights or NDWR domestic wells, no USGS NWIS wells, and no springs within 1.6 kilometers of Garden Valley alternative segment 2; and no NDWR wells with water rights or NDWR domestic wells, no USGS NWIS wells, and one spring within approximately 1.6 kilometers of the centerline of Garden Valley alternative segment 8.

Figure 3-78 identifies NDWR wells with water rights and USGS NWIS wells within approximately 1.6 kilometers (1 mile) of the centerlines of the Garden Valley alternative segments. As described above for the cases of hydrographic areas 203 and 204, all existing wells in areas 171 and 172 that lie within 1.6 kilometers of the centerlines of the proposed Garden Valley alternative segments may not be depicted on Figure 3-78 because some wells are at very nearly the same locations and cannot be shown at the scale used in the figure.

Figure 3-78 shows DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of the Garden Valley alternative segments. All proposed water wells would be within the construction right-of-way of the selected alignment alternative. There are no potential quarry sites along the Garden Valley alternative segments.

3.2.6.3.4 Caliente Common Segment 2 (Quinn Canyon Range Area)

Crossing from east to west, Caliente common segment 2 would overlie hydrographic areas 172 (Garden Valley), 170 (Penoyer Valley), and 173A (Railroad Valley) (Figures 3-78 and 3-79). Section 3.2.6.3.3 describes the hydrogeologic characteristics of area 172. Committed groundwater resources in areas 170 and 173A exceed estimated perennial yields, but not in area 172 (see Table 3-35). However, as previously noted, all committed resources within a hydrographic area might not be in use at the same time. Caliente common segment 2 would cross over a small portion of hydrographic area 172. Groundwater depth underlying the rail alignment in hydrographic area 172 varies from 50 to 90 meters (180 to 280 feet) (Table 3-40).

Groundwater quality underlying Caliente common segment 2 varies according to location within the hydrographic areas (172, 170, and 173A) the rail alignment would cross (Figures 3-78 and 3-79). Area 173A typically exhibits low dissolved-solids concentrations, with either bicarbonate with sodium or calcium as primary constituents. Table 3-40 summarizes general groundwater-quality and aquifer characteristics in this area.

Hydrographic area 170, Penoyer Valley, is a designated groundwater basin. Committed groundwater resources exceed the estimated perennial yield of 4.93 million cubic meters (4,000 acre-feet). However, as previously noted, all committed resources within a hydrographic area might not be in use at the same time. In addition to existing groundwater wells in hydrographic area 170 that have water-rights appropriations, preliminary NDWR data indicate that there are approximately 14.7 million cubic meters (11,900 acre-feet) of pending annual duties (see Table 3-35) in area 170. This pending water-right location is not within 1.6 kilometers (1 mile) of the centerline of Caliente common segment 2.

Groundwater in area 170 is produced primarily from valley fill, although consolidated rocks (including volcanic rocks) underlying and surrounding Railroad Valley and Penoyer Valley transmit water through fractures associated with faulting (DIRS 176848-Van Denburgh and Rush 1974, p. 11). Depth to groundwater throughout Penoyer Valley varies from approximately 5 to 100 meters (10 to 330 feet) (DIRS 176600-Converse Consultants 2006, p. 71). Depth to groundwater varies from 50 to 60 meters (160 to 200 feet) along common segment 2 (Table 3-40). It is estimated that there could be approximately 2.71 billion cubic meters (2.2 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer material within area 170. Figures 3-78 and 3-79 show wells within approximately 1.6 kilometers (1 mile) of common segment 2. There are no NDWR wells with water rights, no NDWR domestic wells, two USGS NWIS wells (classified as monitoring wells), and two springs in area 170 within 1.6 kilometers of the centerline of common segment 2 or within 1.6 kilometers of any DOE-proposed new well.

Hydrographic area 173A is not a designated groundwater basin. Committed groundwater resources exceed the estimated perennial yields of 3.45 million cubic meters (2,800 acre-feet) (see Table 3.2.6-1). Groundwater in area 173A is produced primarily from valley fill, although consolidated rocks (including volcanic rocks) underlying and surrounding Railroad Valley and Penoyer Valley transmit water through fractures associated with faulting (DIRS 176848-Van Denburgh and Rush 1974, p. 11). Depth to groundwater throughout hydrographic area 173A varies from 5 to 120 meters (17 to 400 feet). Depth to groundwater varies from 50 to 55 meters (160 to 180 feet) along common segment 2 (Table 3-40). It is estimated that there could be approximately 2.59 billion cubic meters (2.1 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer material within area 173A.

Table 3-40. General groundwater-quality and aquifer characteristics – Caliente common segment 2.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
172 Garden Valley	Alluvial valley fill, with surrounding mountain ranges comprised of older carbonate and clastic rocks, and younger volcanic rock units[e]	50 to 90	*Alluvial valley fill*: 1.5 million[f] *Carbonate rock aquifer*: 600,000 (total for hydrographic areas 171 and 172)[f]	Total dissolved solids: 200 to 300 mg/L[e]
170 Penover Valley	Alluvial valley fill, volcanic rocks, and older carbonate rocks[e]	50 to 60	2.2 million[f]	Total dissolved solids: 300 to 700 mg/L[e]
173A Railroad Valley (Southern Part)	Alluvial valley fill, volcanic rocks, and older carbonate rocks[e]	50 to 55	2.1 million[f]	Total dissolved solids: 253 to 409 mg/L; 2,790 mg/L in one well[e] Fluoride: more than 4 mg/L[e]

a. The listed depth ranges generally apply to areas underlying the alternative segments (DIRS 176600-Converse Consultants 2005, Plates 4-8 and 4-10); groundwater can vary over a wide range of depths depending on location in the hydrographic area (DIRS 176600-Converse Consultants 2005, pp. 64 and 71).
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1,233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.
e. Source: DIRS 176600-Converse Consultants 2005, pp. 63 to 75.
f. Sources: DIRS 180754-Rush et al. 1971, all; DIRS 176851-Brothers, Bugo, and Tracy 1993, pp. 29 and 30.

There are no NDWR wells with water rights, no USGS NWIS wells, and no springs in area 173A within 1.6 kilometers (1 mile) of the centerline of common segment 2. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 173A.

Geologic units in the Penoyer Valley (area 170) and the Railroad Valley South (area 173A) areas include alluvial valley fill, volcanic rocks, and older carbonate rocks (Table 3-40). Carbonate rocks make up part of the Reveille Range and a portion of the southern Quinn Canyon Range where common segment 2 would cross the east and west perimeters of Railroad Valley. Caliente common segment 2 would predominantly overlie alluvial valley fills.

Figures 3-78 and 3-79 show proposed well locations (see Section 4.2.6) for supplying water to support construction of Caliente common segment 2. New wells are proposed within and outside the rail line construction right-of-way. These wells would be drilled in areas where groundwater resources within the construction right-of-way would not be adequate to meet construction or operations needs. Up to two locations in the north-central portion of Penoyer Valley approximately 2.9 to 3.5 kilometers (1.8 to 2.2 miles) south of the rail alignment (locations PeV1, PeV2, and PeV3 on Figure 3-78) represent potential alternative new well locations. These two alternative well sites are within alluvial valley fill, and are proposed as alternative wells if needed, to allow for wells to be completed a greater distance from a geologic contact between alluvium and bedrock materials. There are no potential quarry sites along Caliente common segment 2.

3.2.6.3.5 South Reveille Alternative Segments

South Reveille alternative segments 2 and 3 would overlie the Railroad Valley Southern Part, hydrographic area 173A (Figure 3-79). Section 3.2.6.3.4 describes area 173A in detail. Table 3-40 summarizes generalized groundwater quality and aquifer characteristics in this area. Committed groundwater resources in this (designated) area exceed the estimated perennial yield (see Table 3-35). However, as previously noted, all committed resources within a hydrographic area might not be in use at the same time. There is one NDWR well with water rights, no NDWR domestic wells, and no USGS NWIS wells, and no springs in area 173A within 1.6 kilometers (1 mile) of the centerlines of the South Reveille alternative segments.

Geologic units in the general area of South Reveille alternative segments 2 and 3 include alluvial valley fill, with volcanic rocks primarily comprising the Kawich Range and older carbonate rocks and volcanic rocks comprising the Reveille Range adjacent to the alternative segments. About half of the total length of the South Reveille alternative segments would overlie alluvial valley fill. Groundwater is produced primarily from alluvial valley fill, although water does occur in fractured volcanic rocks. Based on data from six wells in the southern part of Railroad Valley, depth to groundwater ranges from approximately 5 to 120 meters (17 to 400 feet) (DIRS 176600-Converse Consultants 2006, p. 64). Near Caliente common segment 2 and the South Reveille alternative segments in the southern part of area 173A, the depth to groundwater could be more than 91 meters (300 feet) in some areas based on data from only two wells. Section 3.2.6.3.4 contains additional information on groundwater characteristics and groundwater availability in area 173A.

3.2.6.3.6 Caliente Common Segment 3 (Stone Cabin Valley Area)

Crossing from east to west, Caliente common segment 3 would overlie hydrographic areas 173A (Railroad Valley South), 156 (Hot Creek Valley), 149 (Stone Cabin Valley), and 141 (Ralston Valley) (Figures 3-79 and 3-80). Caliente common segment 3 would predominantly overlie alluvial valley fill. Depth to groundwater varies from approximately 24 to more than 90 meters (80 to more than 300 feet) along Caliente common segment 3 (Table 3-41). This range includes projected values in those areas where there are few or no wells.

Groundwater quality underlying Caliente common segment 3 varies according to location within the hydrographic areas the rail line would cross. Table 3-41 summarizes general groundwater-quality and aquifer characteristics in the three hydrographic areas underlying Caliente common segment 3.

Section 3.2.6.3.4 describes the hydrogeologic characteristics of area 173A. There is one USGS NWIS well in area 173A within 1.6 kilometers (1 mile) of the centerline of Caliente common segment 3 (Figure 3-79).

Area 156, Hot Creek Valley, is not a designated groundwater basin. Committed groundwater resources do not exceed the perennial yield of 6.8 million cubic meters (5,500 acre-feet). Geologic units in hydrographic area 156 (Hot Creek) include alluvial valley fill, volcanic rocks in the Kawich Range adjacent to Caliente common segment 3, and volcanic and older carbonate rocks comprising part of the Hot Creek Range, north of Warm Springs (see Figure 3-79). Groundwater is produced primarily from alluvial valley fill, although there is water in fractured volcanic rocks and in carbonate rocks in the Hot Creek Range. There is groundwater under both confined and unconfined conditions in area 156 (DIRS 176950-Rush and Everett 1966, p. 16). The thickness of underlying alluvium is not known; however, three wells in the area penetrated between 47 and 97 meters (150 and 320 feet) of alluvial materials (DIRS 176950-Rush and Everett 1966, p. 35). There could be approximately 2.8 billion cubic meters (2.3 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 156.

Table 3-41. General groundwater-quality and aquifer characteristics – Caliente common segment 3 and South Reveille alternative segments 2 and 3.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
173A Railroad Valley, Southern Part	Alluvial valley fill, volcanic rocks, and older carbonate rocks[e]	20 to 50	2.1 million[f]	Total dissolved solids: 253 to 409 mg/L; 2,790 mg/L in one well[e] Fluoride: more than 4 mg/L[e]
156 Hot Creek Valley	Alluvial valley fill, volcanic rocks in the Hot Creek and Kawich Ranges adjacent to common segment 3, and older carbonate rocks comprising part of the Hot Creek Range[d]	Less than 60	2.3 million[f]	Total dissolved solids: 176 to 2,500 mg/L[e] Fluoride: 5 to 30 mg/L[e]
149 Stone Cabin Valley	Alluvial valley fill, volcanic rocks, and carbonate rocks[e,g]	20 to 40	2.2 million[f]	Total dissolved solids: Less than 500 to 1,000 mg/L[h]
141 Ralston Valley	Alluvial valley fill, volcanic rocks, and older carbonate and clastic rocks[e,g]	50 to 70	2.7 million[f]	Total dissolved solids: 290 mg/L (in one well 3.2 kilometers [2 miles] northwest of Tonopah airport)[e]

a. The listed depth ranges generally apply to areas underlying the alternative segments (DIRS 176600-Converse Consultants 2005, Plates 4-6 to 4-8); groundwater can vary over a wide range of depths depending on location in the hydrographic area (DIRS 176600-Converse Consultants 2005, pp. 53 and 57.
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1,233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.
e. Source: DIRS 176600-Converse Consultants 2005, pp. 52 through 66.
f. Source: DIRS 180754-Rush et al. 1971, all.
g. Sources: DIRS 176600-Converse Consultants 2005, p. 55; DIRS 173179-Belcher 2004, Figure B-1.
h. Sources: DIRS 172905-USGS 1995, Figure 70; DIRS 177741-State of Nevada 2005, all, with overlay of hydrographic area boundaries.

Groundwater is reported to be a sodium-bicarbonate type. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 156.

There is one NDWR well with water rights, no NDWR domestic wells, and no USGS NWIS wells in area 156 within 1.6 kilometers (1 mile) of the centerline of Caliente common segment 3. One spring (Black Spring) in area 156 (Figure 3-79) is within 1.6 kilometers of the centerline of Caliente common segment 3.

Area 149, Stone Cabin Valley, is a designated groundwater basin with perennial yields of 2.5 million cubic meters (2,000 acre-feet). Committed groundwater resources in area 149 exceed the estimated perennial yield (see Table 3-35). However, as previously noted, all committed resources within a hydrographic area might not be in use at the same time. In addition to existing groundwater wells in hydrographic area 149 with water-rights appropriations, NDWR data indicate that there are approximately 7.9 million cubic meters (6,400 acre-feet) of pending annual duties (see Table 3-35) in area 149.

Groundwater in area 149 is produced primarily from alluvial valley fill, although there is water in fractured volcanic rocks and in carbonate rocks in the Hot Creek Range, north of Warm Springs (see Table 3-41). There could be approximately 2.71 billion cubic meters (2.2 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 149. Table 3-41 summarizes groundwater-quality characteristics in this area. Depth to groundwater throughout hydrographic area 149 varies from 5 to 120 meters (18 to 390 feet). Depth to groundwater underlying the rail alignment in this area ranges from 20 to 40 meters (80 to 120 feet) (Table 3-41). There are five NDWR wells with water rights, no NDWR domestic wells, six USGS NWIS wells, and no springs in area 149 within approximately 1.6 kilometers (1 mile) of the centerline of Caliente common segment 3 (Figures 3-79 and 3-80). The proposed use categories for the wells include irrigation and public supply–municipal. Figure 3-80 does not depict all existing wells in area 149 that lie within 1.6 kilometers of the centerline of Caliente common segment 3 because some wells are at very nearly the same locations and cannot be shown at the scale used in the figure.

Area 141, Ralston Valley, is a designated groundwater basin with perennial yields of 7.40 million cubic meters (6,000 acre-feet) (see Table 3-35). Committed groundwater resources do not exceed the estimated perennial yield. The thicknesses of underlying alluvium is not known; however, well logs for wells drilled in the area indicate alluvial materials up to at least 120 meters (380 feet) thick. Geologic units include alluvial valley fill, volcanic rocks in the central and southern parts of the basin, and older carbonate or clastic rocks in the northern part of the basin. Groundwater in area 141 is produced primarily from alluvial valley fill, with limited production from volcanic rocks where they are fractured and minor production from carbonate rocks in the northern part of the valley. Groundwater depths throughout hydrographic area 141 vary from less than 3 meters to 150 meters (less than 10 to 500 feet). Groundwater depth underlying the common segment 3 alignment in this area varies from 50 to 70 meters (Table 3-41). There could be approximately 3.33 billion cubic meters (2.7 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 141. Table 3-41 summarizes groundwater-quality characteristics in this area. There are no NDWR wells with water rights, no NDWR domestic wells, no USGS NWIS wells, and no springs in area 141 within 1.6 kilometers (1 mile) of the centerline of Caliente common segment 3 (see Figure 3-80). NDWR data indicate that there are approximately 1,230 cubic meters (1 ***acre-foot***) of documented pending annual duties (see Table 3-35) in area 141.

Figures 3-79 and 3-80 show DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of Caliente common segment 3. The potential quarry site east of Caliente common segment 3 in South Reveille Valley (see Figure 3-79) would overlie hydrographic area 173A. Host rock units in the vicinity of this potential quarry include basalt and lava flow rocks (DIRS 173842-Shannon &

Wilson 2005, Plate 2). Depth to groundwater in the area could be between 90 and 150 meters (300 and 500 feet) (DIRS 176189-Converse Consultants 2006, Appendix A).

3.2.6.3.7 Goldfield Alternative Segments

Crossing from north to south, Goldfield alternative segment 1 would overlie hydrographic areas 141 (Ralston Valley), 142 (Alkali Spring Valley), and 145 (Stonewall Flat); Goldfield alternative segment 3 would overlie areas 141 and 145; and Goldfield alternative segment 4 would overlie areas 141, 142, 144 (Lida Valley), and 145 (Figure 3-80).

Section 3.2.6.3.6 describes hydrographic area 141. There are no existing NDWR wells with water rights, USGS NWIS wells, or springs in area 141 within 1.6 kilometers (1 mile) of the centerlines of the proposed Goldfield alternative segments.

Depth to groundwater varies along the Goldfield alternative segments. However, based on projections from nearby areas, depth to groundwater could generally vary between approximately 15 and 90 meters (50 to 300 feet) (Table 3-42), but can locally be shallower, such as in areas where springs occur.

Groundwater quality underlying the Goldfield alternative segments varies according to location within the hydrographic areas the rail line would cross. Table 3-42 summarizes general groundwater-quality and aquifer characteristics in the three hydrographic areas underlying the Goldfield alternative segments.

Area 142, Alkali Spring Valley, is not a designated groundwater basin. Committed groundwater resources do not exceed the perennial yield of 3.7 million cubic meters (3,000 acre-feet) (see Table 3-35). Groundwater depth throughout area 142 varies from 15 to 40 meters (50 to 120 feet). There could be approximately 1.6 billion cubic meters (1.3 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 142. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 142.

Near the western edge of Goldfield, along Goldfield alternative segment 4, the depth to groundwater is approximately 15 to 40 meters (50 to 120 feet) (Table 3-42). Water quality varies in area 142 according to location. Water in Alkali Spring, in the southern portion of area 142 approximately 13 kilometers (8 miles) northwest of Goldfield is reported to be a sodium sulfate type that exhibits elevated total dissolved solids concentrations (DIRS 176849-Rush 1968, Plate 1). Analyses have shown that the quality of water from various groundwater wells in the basin is good (Table 3-42).

In area 142 (see Table 3-36), there is one NDWR well with water rights (municipal use), no NDWR domestic wells, four USGS NWIS wells, and two springs within approximately 1.6 kilometers (1 mile) of the centerline of Goldfield alternative segment 4, and one spring within approximately 1.6 kilometers of the centerline of Goldfield alternative segment 1. In area 141, there are no existing NDWR wells with water rights, no NDWR domestic wells, no USGS NWIS wells, and no springs within 1.6 kilometers of the centerline of Goldfield alternative segment 3.

Area 144, Lida Valley, is not a designated groundwater basin. Committed groundwater resources do not exceed the perennial yield of 430,000 cubic meters (350 acre-feet) (see Table 3-35). There could be approximately 1.85 billion cubic meters (1.5 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 142. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 144.

Depth to groundwater is uncertain along the Goldfield 4 alternative segment where it would cross area 144. However, based on projections from nearby areas, depth to groundwater could range from 50 to 90 meters (160 to 290 feet) (DIRS 176600-Converse Consultants 2005, pp. 46 and 47). There is one existing NDWR well with water rights, no NDWR domestic wells, no existing USGS NWIS wells, and no springs in area 144 within 1.6 kilometers (1 mile) of the centerline of Goldfield alternative segment 4.

Area 145, Stonewall Flat, is not a designated groundwater basin. Committed groundwater resources do not exceed the perennial yield of 124,000 cubic meters (100 acre-feet) (see Table 3-35). There could be approximately 1.01 billion cubic meters (820,000 acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 145. Depth to groundwater is uncertain along Goldfield alternative segment 3 where it would cross area 145. However, based on projections from nearby areas, depth to groundwater could be approximately 37 to 60 meters (120 to 200 feet) (Table 3-42). There are no existing NDWR wells with water rights and no NDWR domestic wells, no existing USGS NWIS wells, and one spring in area 145 within 1.6 kilometers (1 mile) of the centerline of Goldfield alternative segment 1, and no existing NDWR wells with water rights and no NDWR domestic wells, no existing USGS NWIS wells, and three springs in area 145 within 1.6 kilometers of Goldfield alternative segment 3. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 145.

There are two potential quarry sites (NS-3A and NS-3B) east of Goldfield alternative segment 3 (Figure 3-80). These potential quarry sites would overlie hydrographic area 141. Host rock units include

Table 3-42. General groundwater-quality and aquifer characteristics – Goldfield alternative segments.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
141 Ralston Valley	Alluvial valley fill, volcanic rocks, and older carbonate or clastic rocks[e]	43 to 67	2.7 million[f]	Total dissolved solids: 290 mg/L (in one well 3.2 kilometers [2 miles] northwest of Tonopah airport)[g]
142 Alkali Spring Valley	Alluvial valley fill deposits, volcanic rocks, and older sedimentary rocks[h]	15 to 40	1.3 million[f]	Total dissolved solids: Less than 500 to 1,000 mg/L[i]
144 Lida Valley	Alluvial valley fill, rhyolite, volcanic sediments (including tuffs of the Stonewall Flat and tuffs of the Thirsty Canyon Group), and older rock units including claystone, siltstone, and limestone[d]	50 to 85	1.5 million[f]	Total dissolved solids: 400 to 1,100 mg/L[g] Sulfate: 61 to 284 mg/L[g]
145 Stonewall Flat	Alluvial valley fill deposits, volcanic rocks, and older sedimentary rocks[h]	37 to 60	820,000[f]	Total dissolved solids: Less than 300 mg/L[g]

a. The listed depth ranges generally apply to areas underlying the alternative segments (DIRS 176600-Converse Consultants 2005, Plates 4-5 and 4-6); groundwater can vary over a wide range of depths depending on location in the hydrographic area (DIRS 176600-Converse Consultants 2005 pp. 41, 45 through 47, 49, and 51).
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.

alluvial fan deposits, and the targeted water production zones for wells at these potential quarry sites, if required, are an alluvial fan or the underlying fractured volcanic rocks. The estimated total depths of these new wells (RaV9/10/11) would be between 120 and 150 meters (400 and 500 feet), and the target aquifer would be an alluvial unit (DIRS 176189-Converse Consultants 2006, Appendixes A and B). A potential alternative groundwater-supply well location west of Goldfield alternative segment 4 (AsV6) would be installed if necessary to obtain adequate water to support operation of a quarry (ES-7) west of Goldfield alternative segment 4 and southwest of this proposed well (Figure 3-80). This potential quarry site would overlie the southern portion of hydrographic area 142. Up to two wells that might be installed at this location would have total depths of between about 30 and 60 meters (100 and 200 feet), with the target aquifer being a fractured volcanic rock unit (DIRS 176189-Converse Consultants 2006, Appendixes A and B). Host rock units for this potential quarry site include basalt (DIRS 175986-Shannon & Wilson 2005, Plate 2 and Figure 3, Sheet 21 of 94; DIRS 173842-Shannon & Wilson 2005, Plate 2).

Geologic units underlying hydrographic areas 142, 144, and 145 include alluvial valley-fill deposits, volcanic rocks, and older sedimentary rocks (DIRS 173179-Belcher 2004, p. 28). Goldfield alternative segments 1 and 3 would cross alluvial deposits, basalt flows, rhyodacite lava flow deposits, and ash-flow tuff deposits (DIRS 175986-Shannon & Wilson 2005, Figures 2 and 3, Sheets 23 to 26). Goldfield alternative segment 3 would cross near a small cinder cone west of Mud Lake Playa (DIRS 175986-Shannon & Wilson 2005, Plate 2 and Sheets 23 and 26). Portions of the three Goldfield alternative segments would overlie alluvial valley fill (DIRS 176189-Converse Consultants 2006, Maps 11a and 11b). About two-thirds of the total length of Goldfield alternative segment 4 would overlie alluvial valley fill, compared to approximately one-third for Goldfield alternative segments 1 and 3. Goldfield alternative segment 1 and, to a considerably lesser extent, Goldfield alternative segment 3, would pass close to mine shafts at one or more locations (for example, along a section of Goldfield alternative segment 1 near Black Butte in the immediate vicinity of the City of Goldfield) (DIRS 175986-Shannon & Wilson 2005, Figure 3, Sheets 24 and 25).

Within area 142 (Alkali Spring Valley), which portions of Goldfield alternative segments 1 and 4 would cross, groundwater production is generally derived from valley-fill alluvium. Groundwater production in area 144 is limited to a few domestic wells, a municipal well at Lida, and stockwater wells. There are a few small stockwater wells near the general area of the rail alignment in area 144. These wells produce from valley fill materials; however, no aquifer test data are available for these wells (DIRS 176189-Converse Consultants 2006, Appendix B).

Figure 3-80 shows DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of the Goldfield alternative segments. In addition to a series of new wells proposed for installation within the rail line construction right-of-way of the selected alternative segment, DOE might install a series of additional wells outside the nominal width of the rail line construction right-of-way, either as alternative water wells or as alternative wells used in combination with other water wells installed within the rail line construction right-of-way. These wells would be drilled in areas where groundwater resources within the construction right-of-way would not be adequate to meet construction or operations needs. Possible locations for wells in this category (Figure 3-80) include the following (locations used would depend on the alternative segment):

- Locations ASV1/2/3/4/5/8/9 in hydrographic area 142, approximately 3.5 kilometers (2.2 miles) west of the centerline of Goldfield alternative segment 4. Wells installed at this location would be expected to intercept alluvial valley fill deposits (alluvial fan), and could encounter groundwater at a depth of approximately 60 to 90 meters (200 to 300 feet) (DIRS 176189-Converse Consultants 2006, Appendixes A and B).
- Locations StF1/2/3/5/6/7 in hydrographic area 145, approximately 1.9 to 2.3 kilometers (1.2 to 1.4 miles) east of the centerline of Goldfield alternative segment 3. Wells installed at this location would be

expected to intercept alluvial valley fill deposits, and would have total depths of approximately 180 to 210 meters (600 to 700 feet) (DIRS 176189-Converse Consultants 2006, Appendixes A and B and Maps 12a and 12b).

- Locations LV1/2/3/4/9/10/11/12 in hydrographic area 144, approximately 4.6 to 5.0 kilometers (2.9 to 3.1 miles) west of the centerline of Goldfield alternative segment 4. Wells installed at this location would be expected to intercept alluvial valley fill deposits, and would have total depths of approximately 120 to 150 meters (400 to 500 feet) (DIRS 176189-Converse Consultants 2006, Appendixes A and B and Maps 12e and 12f).

3.2.6.3.8 Caliente Common Segment 4 (Stonewall Flat Area)

Caliente common segment 4 would overlie hydrographic area 144 (Figures 3-80 and 3-81). Section 3.2.6.3.7 describes the hydrogeologic characteristics of area 144. Committed groundwater resources in this area do not exceed the estimated perennial yield (see Table 3-35). As shown on Figures 3-80 and 3-81, there is one NDWR well with water rights, no NDWR domestic wells, two USGS NWIS wells, and no springs within approximately 1.6 kilometers (1 mile) of the centerline of Caliente common segment 4.

Geologic units that common segment 4 would cross include primarily alluvial valley fill deposits and some volcanic rocks (DIRS 173179-Belcher 2004, p. 28). Specific volcanic units the segment would cross include Stonewall Flat and tuffs of the Thirsty Canyon Group. The estimated depth to groundwater throughout hydrographic area 144 can vary from 8 to 110 meters (26 to 360 feet) depending on location (DIRS 176600-Converse Consultants 2005, p. 45). The depth to groundwater underlying the alignment varies from 50 to 85 meters (160 to 280 feet) (Table 3-43) (DIRS 176600-Converse Consultants 2005, Plate 4-5). Section 3.2.6.3.7 and Table 3-42 summarize general groundwater quality and aquifer characteristics in area 144.

Figures 3-80 and 3-81 show DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of Caliente common segment 4. All proposed water wells would be within the rail alignment construction right-of-way. There are no potential quarry sites along Caliente common segment 4.

3.2.6.3.9 Bonnie Claire Alternative Segments

From north to south, Bonnie Claire alternative segments 2 and 3 would cross hydrographic areas 144 (Lida Valley) and 146 (Sarcobatus Flat) (Figure 3-81). Section 3.2.6.3.7 describes hydrographic area 144. There are no existing NDWR wells with water rights, no NDWR domestic wells, no existing USGS NWIS wells, and no existing springs in area 144 within 1.6 kilometers (1 mile) of the centerlines of the proposed Bonnie Claire alternative segments. There are four NDWR wells with water rights, no NDWR domestic wells, no USGS NWIS wells, and no existing springs in area 144 within 1.6 kilometers of the centerlines of the proposed Bonnie Claire alternative segments.

The Bonnie Claire alternative segments would predominantly overlie alluvial valley fill deposits and some volcanic rocks (DIRS 173842-Shannon & Wilson 2005, p. 28). The primary volcanic unit encountered along Bonnie Claire alternative segments 2 and 3 is tuff of the Timber Mountain Group (DIRS 173842-Shannon & Wilson 2005, p. 30 and Plate 2).

Area 146, Sarcobatus Flat, is a designated groundwater basin, and has a perennial yield of 3.7 million cubic meters (3,000 acre-feet) (see Table 3-35). Committed groundwater resources in area 146 exceed the estimated perennial yield, but as previously noted, all committed resources within a hydrographic area might not be in use at the same time. There could be approximately 3 billion cubic meters (2.4 million acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 146. While the basin is primarily comprised of alluvial valley fill deposits, volcanic rocks make up the hills surrounding Sarcobatus Flat (Table 3-43). There are no existing water-supply wells or springs in area 146 within 1.6 kilometers (1 mile) of the centerlines of the Bonnie Claire alternative segments. Section 3.2.6.3.7 and Table 3-42 summarize general groundwater characteristics in area 144. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 146.

Groundwater in hydrographic area 146 contains elevated levels of sodium bicarbonate. Table 3-43 summarizes general groundwater-quality and aquifer characteristics in areas 144 and 146.

Most of the existing groundwater wells in area 146 are ***screened*** (installed with the well casing screened interval) in the alluvial valley fill; a few wells in the western portion of the basin are screened in volcanic rocks. The total volume of alluvial valley fill comprising the primary aquifer reservoir in area 146 is not known because of variations in the thickness of valley fill that result in variations in the surface of the underlying bedrock. However, Malmberg and Eakin (DIRS 106695-Malmberg and Eakin1962, pp. 13 and 19) suggested the maximum thickness of valley fill in area 146 could be as much as thousands of

Table 3-43. General groundwater-quality and aquifer characteristics – Caliente common segment 4 and Bonnie Claire alternative segments.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
144 Lida Valley	Alluvial valley fill, rhyolite, volcanic sediments (including tuffs of the Stonewall Flat and tuffs of the Thirsty Canyon Group), and older rock units including claystone, siltstone, and limestone[e]	50 to 85	1.5 million[f]	Total dissolved solids: 400 to 1,100 mg/L[g] Sulfate: 61 to 284 mg/L[g]
146 Sarcobatus Flat	Alluvial valley fill deposits and some volcanic rocks[f] (Volcanic units are tuff of the Timber Mountain Group)[h]	24 to 40	2.4 million[f]	Total dissolved solids: 540 mg/L[g]

a. The listed range of groundwater depths applies to the area underlying the proposed rail alignment (DIRS 176600-Converse Consultants 2005, Plates 4-4 and 4-5). The depth to groundwater can vary over a wide range of depths depending on location in a hydrographic area DIRS 176600-Converse Consultants 2005, pp. 41 and 45 through 47.
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1,233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.
e. Sources: DIRS 173842-Shannon & Wilson 2005, pp. 23 and 24, 29 and 30, 33 to 35, and Plate 2; DIRS 173179-Belcher 2004, Figure B-1.
f. Source: DIRS 176600-Converse Consultants 2005, pp. 42 and 47.
g. Source: DIRS 176600-Converse Consultants 2005, pp. 40 to 42, and Plates 4-4 and 4-5.
h. Source: DIRS 180754-Rush et al. 1971, all.

meters (several thousand feet). Figure 3-81 shows DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of the Bonnie Claire alternative segments. All proposed water wells would be within the nominal width of the construction right-of-way of the selected alternative segment. There are no potential quarry sites along Bonnie Claire alternative segments.

3.2.6.3.10 Common Segment 5 (Sarcobatus Flat Area)

Crossing from north to south, common segment 5 would overlie hydrographic area 146 (Sarcobatus Flat) and a small portion of hydrographic area 228 (Oasis Valley) (Figures 3-81 and 3-82). Section 3.2.6.3.9 describes the groundwater-quality and aquifer characteristics of area 146, which are summarized in Table 3-43. There are four NDWR wells with water rights, one NDWR domestic well, eight USGS NWIS wells, and no springs within approximately 1.6 kilometers (1 mile) of the centerline of common segment 5 within area 146. The use categories for the NDWR wells with water rights are irrigation, quasi-municipal and stock-watering (see Table 3-36). Most wells in area 146 are screened in alluvial valley fill; a few wells are screened in volcanic rocks on the west side of the basin.

Section 3.2.6.3.11 describes the hydrogeologic characteristics of area 228, including groundwater-quality and aquifer characteristics; Table 3-44 summarizes those characteristics. Committed groundwater resources in these areas exceed estimated perennial yields (see Table 3-35). However, as previously noted, all committed resources within a hydrographic area might not be in use at the same time. There are no NDWR wells with water rights, no USGS NWIS wells, and no springs within approximately 1.6 kilometers (1 mile) of the centerline of common segment 5, as shown in Figure 3-81.

Common segment 5 would predominantly overlie alluvial valley fill, with depth to groundwater generally approximately 3 to 55 meters (10 to 180 feet) in those portions of areas 146 and 228 the rail line would cross. Volcanic rocks are the predominant rock type comprising the hills surrounding the basin.

Figures 3-81 and 3-82 show DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of common segment 5. All proposed water wells would be within the rail line construction right-of-way. There are no potential quarry sites along common segment 5.

Table 3-44. General groundwater-quality characteristics – Oasis Valley alternative segments.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
228 Oasis Valley	Volcanic rocks clastic rocks, older carbonate rocks, and alluvial valley fill[e]	10 to 30	400,000[f]	Total dissolved solids: Less than 500 to 1,000 mg/L[g] Fluoride: 1 to more than 4 mg/L[h]

a. The listed depth to groundwater range applies to the area underlying the proposed Oasis Valley alternative rail alignments (DIRS 176600-Converse Consultants 2005, Plate 4-3). Depth to groundwater is much greater in the central and northern parts of area 228 (DIRS 176600-Converse Consultants 2005, p. 38).
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.

3.2.6.3.11 Oasis Valley Alternative Segments

Oasis Valley alternative segments 1 and 3 would cross hydrographic area 228 (Oasis Valley) (Figure 3-82). This area is a designated groundwater basin with an estimated perennial yield in the range of 1.2 to 2.5 million cubic meters (1,000 to 2,000 acre-feet) (DIRS 147766-Thiel 1999, pp. 6 to 12 and Table 3-35). Committed groundwater resources in area 228 total 1.6 million cubic meters (1,300 acre-feet) per year (see Table 3-35). However, as previously noted, all committed resources within a hydrographic area might not be in use at the same time. There could be approximately 490 million cubic meters (400,000 acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 228. NDWR data indicate that there are no documented pending annual duties (see Table 3-35) in area 228.

Geologic units Oasis Valley alternative segments 1 and 3 would cross include sedimentary rocks, small areas underlain by volcanic rocks, and some alluvial valley fill (Table 3-44). Depth to groundwater throughout Oasis Valley is generally 3 to 46 meters (10 to 150 feet), with the shallowest groundwater occurring along Oasis Valley alternative segment 1, northeast of Springdale. Depth to groundwater underlying the Oasis Valley alternative segments ranges from 10 to 30 meters (40 to 100 feet).

Oasis Valley has several springs and seeps. The locations of these springs and seeps are dictated by structurally controlled changes in rock unit lithology and thickness and conduits. The springs, seeps, and shallow groundwater in the valley are maintained primarily by groundwater flow moving into the area through a regional volcanic rock aquifer system (DIRS 169384-Reiner et al. 2002, p. 8). Most groundwater flowing south-southeastward into Oasis Valley through the ***welded tuff*** aquifer is diverted upward along faults where it either forms springs or flows laterally out of Oasis Valley as underflow, indicating a regional groundwater inflow component to the flow at the springs. Springs and seeps occur where upward diversion coincides with areas where the potentiometric surface is above the ground surface (DIRS 169384-Reiner et al. 2002, pp. 9 and 10). Most historical groundwater resource development in this area was from springs.

Available information indicates a non-welded confining volcanic tuff unit separates the alluvial aquifer from a regional welded tuff volcanic rock aquifer throughout much of Oasis Valley. This regional welded tuff aquifer has moderate fracture ***permeability*** (DIRS 169384-Reiner et al. 2002, p. 9).

Based on a review of the NDWR and USGS NWIS databases and other published information, Figure 3-82 identifies seven USGS NWIS wells, four springs, and one surface-water body within approximately 1.6 kilometers (1 mile) of the centerlines of the Oasis Valley alternative segments. As shown on the figure, there is a series of three springs (Upper Oasis Valley Ranch Springs) southwest of Oasis Valley alternative segment 1. Colson Pond and Colson Pond Spring are also near Oasis Valley alternative segment 3 (Figure 3-82).

There are no existing NDWR wells with water rights within 1.6 kilometers (1 mile) of the centerline of the Oasis Valley alternative segments. There is one cluster of three USGS-installed wells within approximately 0.64 kilometer (0.40 mile) of the centerline of Oasis Valley alternative segment 3 (wells ER-OV-01, ER-OV-06a, and ER-OV-06a2), and one USGS-installed well (ER-OV-02) within approximately 0.40 kilometer (0.25 mile) of Oasis Valley alternative segment 1 (DIRS 176600-Converse Consultants 2005, Plate 4-3 and Appendix A; DIRS 176325-USGS 2006, all; DIRS 177294-MO0607USGSWNVD.000; DIRS 169384-Reiner et al. 2002, Plate 2). The use category for these wells is monitoring. There are three additional shallow USGS-installed wells (the OVU-Dune Well, OVU-Middle ET Well, and the OVU-Lower ET Well), used for monitoring groundwater levels, within approximately 0.32 to 0.48 kilometer (0.20 to 0.30 mile) of Oasis Valley alternative segment 1 (DIRS 176600-Converse Consultants 2005, Plate 4-3 and Appendix A; DIRS 169384-Reiner et al. 2002, Plate 2). Figure 3-82 does not show all existing wells in area 228 that lie within 1.6 kilometers of the centerlines of Oasis Valley alternative segments because some wells are at very nearly the same locations and cannot be shown at the scale used in the figure.

Groundwater in much of Oasis Valley exhibits elevated levels of fluoride, in excess of the 4 milligrams per liter (approximately 4 parts per million) Nevada drinking water standard level (Table 3-44). Dissolved-solids concentrations in the alluvial valley fill are expected to be less than 500 milligrams per liter (approximately 500 parts per million) in the vicinity of the Oasis Valley alternative segments.

Figure 3-82 shows DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of the Oasis Valley alternative segments. In addition to a series of new wells proposed for installation within the construction right-of-way, DOE might install wells at other locations outside the construction right-of-way, and use them either as principal water wells or in combination with other water wells installed within the construction right-of-way. These wells would be drilled in cases where either groundwater resources within the construction right-of-way would not be adequate for meeting construction or operations needs, or groundwater withdrawals would need to be distributed to reduce potential impacts on existing groundwater resources (see Section 4.2.6). Possible locations for wells in this category that could be used to obtain water for constructing the Oasis Valley alternative segments include the following (Figure 3-82):

- Up to two locations in the Oasis Valley groundwater basin, approximately 5.6 to 5.8 kilometers (3.5 to 3.6 miles) southwest of the centerline of common segment 6 (locations OV6 and OV8, or OV14 and OV16, depending on alternative segment). The target water source at this location would be alluvial valley fill (DIRS 176189-Converse Consultants 2006, Appendixes A and B and Maps 14a and 14b).
- Locations in the southeastern part of Oasis Valley, approximately 0.8 kilometer (0.5 mile) west of common segment 6 (well location OV22 or OV23, depending on alternative segment). The target water source at this location would be a possibly water-bearing fault system (DIRS 176189-Converse Consultants 2006, Appendixes A and B and Maps 14a and 14b).

Review of NDWR and USGS database data and other published information (DIRS 169384-Reiner et al. 2002, Plate 2; DIRS 181909-Fridrich et al. 2007, all) on existing wells and springs indicates the following:

- There two existing NDWR wells with water rights, no NDWR domestic wells, and no USGS NWIS wells within 1.6 kilometers (1 mile) of locations OV6 and OV8, or OV14 and OV16. Two springs (Ute Springs and Manley Springs) lie within approximately 1.3 to 1.4 kilometers (0.8 to 0.9 mile) east of locations OV6 and OV8, or OV14 and OV16.
- There are no known existing wells or springs within 1.6 kilometers of the proposed alternative well location at OV22/OV23.

3.2.6.3.12 Common Segment 6 (Yucca Mountain Approach)

From north to south, common segment 6 would cross a portion of hydrographic area 228 (Oasis Valley), all of hydrographic area 229 (Crater Flat), and a portion of area 227A (Jackass Flats), as shown in Figure 3-82. Section 3.2.6.3.11 describes, and Table 3-44 summarizes groundwater-quality and aquifer characteristics of hydrographic area 228.

There are 14 USGS NWIS wells, no NDWR wells with water rights, no NDWR domestic wells, and no springs within approximately 1.6 kilometers (1 mile) of the centerline of common segment 6, as shown on Figure 3-82. The figure does not show all existing wells in area 227A that lie within 1.6 kilometers of the centerline of common segment 6 because some wells, particularly in area 227A, are at very nearly the same locations and cannot be shown at the scale used in this figure.

Geologic units that common segment 6 would cross include volcanic rocks and basin-fill alluvium (DIRS 173179-Belcher 2004, p. 28; DIRS 176600-Converse Consultants 2005, Plate 4-3). Specific volcanic rock units the segment would cross include volcanic rocks of the Crater Flat and Paintbrush Groups (DIRS 173842-Shannon & Wilson 2005, Plate 2).

Hydrographic area 228, Oasis Valley, is a designated groundwater basin and is described in Section 3.2.6.3.11.

Hydrographic area 229, Crater Flat, is not a designated groundwater basin. Committed groundwater resources exceed the estimated perennial yield of about 271,000 cubic meters (220 acre-feet) (see Table 3-35). As previously noted, all committed resources within a hydrographic area might not be in use at the same time. In addition to existing groundwater wells in hydrographic area 229 that have water-rights appropriations, preliminary NDWR data indicate that approximately 101,000 cubic meters (82 acre-feet) of pending annual duties (see Table 3-35) exist in area 229. The pending water right locations are not within 1.6 kilometers (1 mile) of the centerline of common segment 6. There could be approximately 430 million cubic meters (350,000 acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 229.

Table 3-45 summarizes groundwater-quality and aquifer characteristics of hydrographic area 229. Groundwater is typically very deep in area 229 beneath the rail alignment, generally 180 to 370 meters (600 to 1,200 feet) below ground. In the northwestern portion of area 229 and west of the rail alignment, groundwater occurs within two aquifers and the estimated depth to groundwater varies from 55 to 200 meters (180 to 650 feet). There are three USGS NWIS wells, one NDWR well with a water right, and no springs in area 229 within approximately 1.6 kilometers (1 mile) of the centerline of common segment 6, as shown on Figure 3-82.

Hydrographic area 227A, Jackass Flats, is not a designated groundwater basin. Committed groundwater resources do not exceed the total perennial yield value of 1.1 million cubic meters (880 acre-feet) per year estimated for the entire hydrographic area (see Table 3-35). For evaluation purposes, the perennial yield estimate for hydrographic area 227A is assumed to be approximately 720,000 cubic meters (580 acre-feet) per year, representing the western two-thirds of the area. The perennial yield estimate for the eastern one-third of this hydrographic area has been estimated at approximately 370,000 cubic meters (300 acre-feet) per year. The value of 720,000 cubic meters (580 acre-feet) per year is used as a basis for evaluating the potential impacts of groundwater withdrawals (Section 4.2.6) because the western two-thirds of the hydrographic area is most representative of the potential source area from which groundwater required to support the project might be obtained. There could be approximately 910 million cubic meters (740,000 acre-feet) of recoverable groundwater in the upper 30 meters (100 feet) of saturated aquifer materials within area 227A. NDWR data indicate that there are approximately 6,170 cubic meters (5 acre-feet) of documented pending annual duties (see Table 3-35) in area 227A.

Table 3-45 summarizes groundwater-quality and aquifer characteristics of hydrographic area 227A. In hydrographic area 227A, groundwater occurs in alluvial valley-fill deposits in the southern portion of the area and deeper in volcanic rocks in the central part of the basin. The depths to groundwater in wells throughout area 227A vary from approximately 12 to 650 meters (38 to 2,150 feet) (DIRS 176600-Conserve Consultants 2006, p. 31). Most groundwater storage in area 227A occurs toward the southern end of the basin, south of the rail alignment. Groundwater is typically very deep near the rail alignment, generally 180 to 370 meters (600 to 1,200 feet) below ground.

Most wells penetrating the volcanic rocks are monitoring wells used for monitoring groundwater conditions southwest, southeast, and south of the Yucca Mountain Site. Twelve of 15 NDWR existing new or replacement wells cataloged within all of hydrographic area 227A are groundwater monitoring wells; the others are listed as production wells. The volcanic rocks in this area generally have low porosity, and are not considered suitable for groundwater production except in major fractured areas.

Figure 3-82 shows DOE-proposed wells (see Section 4.2.6) for supplying water to support construction of common segment 6. All proposed water wells would be within the rail alignment construction right-of-way. There are no potential quarry sites along common segment 6.

Table 3-45. General groundwater-quality characteristics – common segment 6.

Hydrographic area number and name	Aquifer geologic characteristics	Depth to groundwater (meters)[a,b]	Estimated recoverable groundwater (acre-feet)[c]	Groundwater quality[d]
228 Oasis Valley	Volcanic rocks clastic rocks, older carbonate rocks, and alluvial valley fill [e]	10 to 30	400,000[f]	Total dissolved solids: Less than 500 to 1,000 mg/L[g] Fluoride: 1 to more than 4 mg/L[h]
229 Crater Flat	Volcanic rocks and alluvial valley fill[e]	180 to 370	350,000 [f]	Total dissolved solids: 270 mg/L[h]
227A Fortymile Canyon, Jackass Flats	Volcanic rocks and alluvial valley fill[e]	210 to 370	740,000 [f]	Total dissolved solids: Less than 500 to 1,000 mg/L[g]

a. The listed depth range for depth to groundwater generally applies to the area underlying the rail alignment (DIRS 176600-Converse Consultants 2005, Plates 4-1, 4-2, and 4-3). Depth to groundwater in each hydrographic area can vary over a greater range of depths depending on location (refer to text).
b. To convert meters to feet, multiply by 3.2808.
c. To convert acre-feet to cubic meters, multiply by 1233.49; unless otherwise specified, the groundwater quality refers to the upper 30 meters of the saturated alluvial valley-fill material in the hydrographic area.
d. mg/L = milligrams per liter.

3.2.7 BIOLOGICAL RESOURCES

This section describes the biological resources that could be affected by construction and operation of the proposed railroad along the Caliente rail alignment.

Biological resources include vegetation, wildlife, special status species, game species, and wild horses and burros within or near the construction right-of-way described in Section 3.2.7.1. This discussion of biological resources is based on the results of a review of available data from federal, State of Nevada, and local agencies, and data gathered during field investigations.

Section 3.2.7.2 provides a general overview of biological resources, including vegetation, wildlife, special status species, game species, and wild horses and burros along the Caliente rail alignment. Section 3.2.7.3 describes biological resources unique to each Caliente rail alignment alternative segment and common segment. Appendix H, Biological Resources, provides additional information regarding biological resources along the Caliente rail alignment.

Special Status Species

Endangered species are classified under the Endangered Species Act as being in danger of extinction throughout all or a significant part of their range.

Threatened species are classified under the Endangered Species Act as likely to become endangered species in the foreseeable future.

Proposed species are plants and animals for which the U.S. Fish and Wildlife Service has sufficient information on their biological status and threats and that are the subject of a Fish and Wildlife Service *Federal Register* rulemaking notice to list them as endangered or threatened.

Candidate species are plants and animals for which the U.S. Fish and Wildlife Service has sufficient information to support a proposal to list as endangered or threatened, but development of a listing regulation is precluded by other higher priority listing activities.

Endangered Species Act candidate species are plants and animals for which the U.S. Fish and Wildlife Service has sufficient information on their biological status and threats to propose them as endangered or threatened under the Endangered Species Act.

State protected plant and animal species. Wildlife species or subspecies are classified as protected under Nevada Administrative Code (NAC) Chapter 503 if one or more of the following criteria exists:

1. The wildlife is found only in the State of Nevada and its population, distribution, or habitat is limited.
2. The limited population or distribution within Nevada is likely to decline.
3. The population is threatened as a result of the deterioration or loss of its habitat.
4. The wildlife has ecological, scientific, educational, or other value that justifies its classification as protected.
5. The available data is not adequate to determine the exact status of the wildlife population, but does indicate a limited population, distribution, or habitat.
6. The wildlife is listed by the U.S. Fish and Wildlife Service as a candidate species, or it is classified as threatened or endangered in the federal Endangered Species Act.
7. Other evidence exists to justify classifying the wildlife as protected.

Under NAC Chapter 527, plants are classified as being in danger of extinction if their survival requires assistance because of overexploitation, disease, or other factors or because its habitat is threatened with destruction, drastic modification, or severe curtailment. There are no State of Nevada-listed endangered plants present in the areas of assessment.

BLM-designated sensitive species are species other than federally listed, proposed, or candidate species, and may include such native species as those that:

1. Could become endangered in or extirpated from a state or within a significant portion of their distribution in the foreseeable future;
2. Are undergoing a status review by the U.S. Fish and Wildlife Service to determine whether to list the species as a threatened or endangered species across all or a significant portion of its range under the Endangered Species Act;
3. Are undergoing significant current or predicted downward trends in habitat capability that would reduce their existing distribution;
4. Are undergoing significant current or predicted downward trends in population or density such that federally listed, proposed, candidate, or state listed status might become necessary;
5. Have typically small and widely dispersed populations;
6. Are inhabiting ecological refugia or specialized or unique habitats; or
7. Are state listed but might be better conserved through application of BLM sensitive species status. Such species should be managed to the level of protection required by State laws or under the BLM policy for candidate species, whichever would provide better opportunity for their conservation.

3.2.7.1 Areas of Assessment

DOE used two areas of assessment to describe the affected environment for biological resources: the greater study area and the construction right-of-way.

3.2.7.1.1 Construction Right-of-Way

The rail line construction right-of-way would be a nominal width of 300 meters (1,000 feet), which is 150 meters (500 feet) on either side of the rail alignment centerline. The footprint, which would be within the construction right-of-way, is the area that would involve clearing of vegetation, excavation, and filling for subgrade to support the rail line. This area would be directly affected, long term, by rail line construction activities. The footprint would fluctuate throughout the alignment due to topography, cut and fill requirements, and land use. The footprint could also vary based on land use and avoidance or minimization of impacts to other resources (for example, water or structures) but generally would be 300 meters or less. The area between the footprint and the outer edge of the construction right-of-way would be directly affected, short term, by construction-related activities such as construction staging, material laydown, and temporary access roads. DOE analyzed the area between the footprint and the outer edge of the construction right-of-way for short-term impacts even though the use of this area would be minimized and the area might not be disturbed. For purposes of this analysis, DOE has taken a conservative approach of potentially overstating the environmental impacts to biological resources. For facilities that would be outside the nominal width of the rail line construction right-of-way (such as quarries and other ***infrastructure***), the area DOE assessed as the affected environment is the maximum area or the footprint of the proposed facility.

3.2.7.1.2 Study Area

DOE identified a study area (16-kilometers [10-miles] wide, extending 8 kilometers [5 miles] on either side of the centerline of the rail alignment) for use in database and literature searches to ensure the identification of sensitive habitat areas near the Caliente rail alignment and transient or migratory wildlife, particularly special status species, that could pass through or along the construction right-of-way. Using the larger study area identifies special status species and/or habitat that could be present near the rail alignment to better describe the habitat value and species use within the construction right-of-way.

3.2.7.2 General Environmental Setting and Characteristics

This section describes the affected environment for biological resources that could be present or have the potential to occur within the construction right-of-way or the study area. DOE used the 2004 Southwest Regional Gap Analysis Project (DIRS 174324-NatureServe 2004, all), which the BLM currently uses in its conservation and management actions, to characterize the vegetation communities in the construction right-of-way and the study area.

As a starting point for classification, the 2004 Southwest Regional Gap Analysis Project divided the southwestern United States into general ***ecoregions*** (relatively discrete sets of ecosystems characterized by certain plant communities or assemblages) based on physical and biological similarities. Using satellite imagery and field data, the Project classified geographic areas or “mapping zones” within each ecoregion based on their land-cover types, and generated maps of these land-cover types. The project classified naturally vegetated types using the “ecological systems” and developed and described types based on dominant vegetation, physical characteristics of the land, hydrology, and climate in the area (DIRS 176369-Lowry et al. 2005, all; DIRS 173051-Comer et al. 2003, all). These mapping zones represent recurring groups of biological communities that are found in similar physical environments and are influenced by similar dynamic ecological processes, such as fire or flooding. As shown in Figure 3-83, the Caliente rail alignment would cross three mapping zones: the Pioche, the Mojave, and the Nellis. The land-cover types are grouped into land-cover classes. Eleven land-cover classes occur in this part of Nevada. To identify the land-cover types and classes within the construction right-of-way and the study area, digital maps of the land-cover types within the affected map zones were overlain (spatial analysis using the Geographic Information System) with the Caliente rail alignment construction right-of-way and operations support facilities.

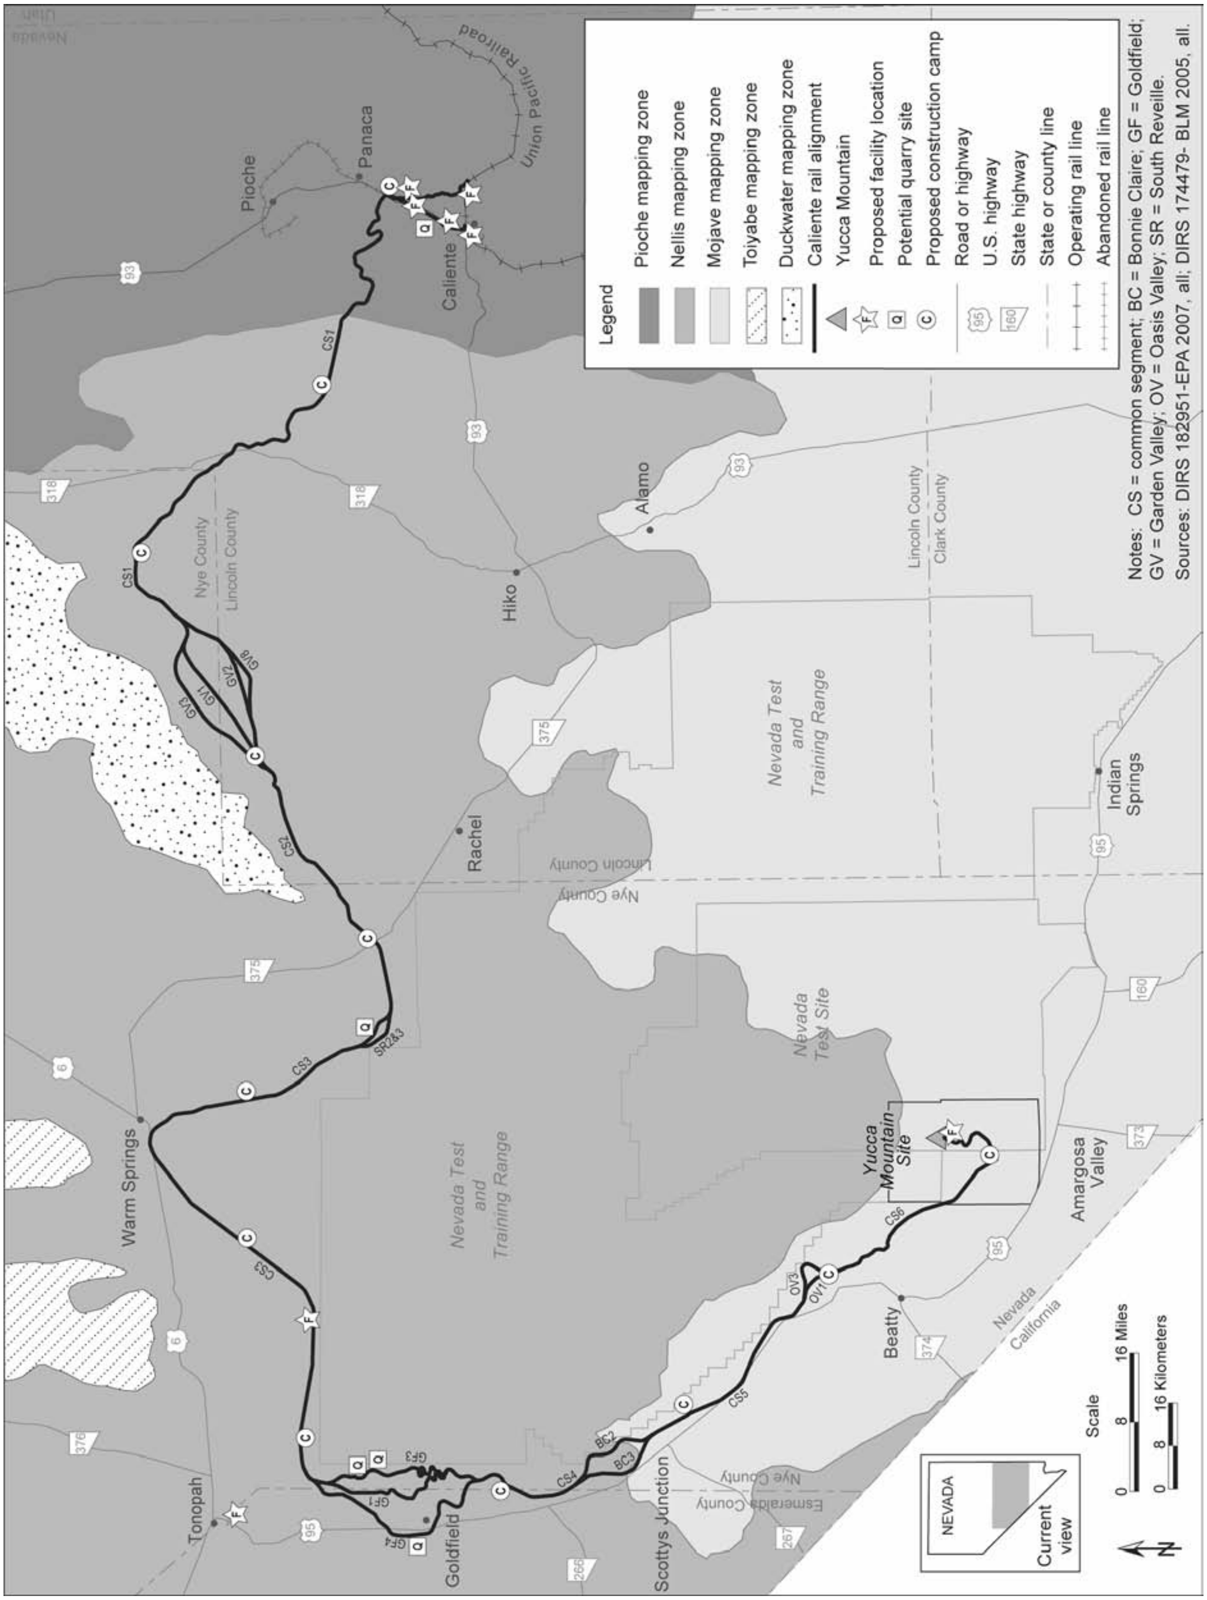

Figure 3-83. Mapping zones along the Caliente rail alignment.

The Caliente rail alignment construction right-of-way would cross nine of the eleven classes (DIRS 174324-NatureServe 2004). Table 3-46 lists classes and types and Figures 3-84 through 3-90 show the classes the rail alignment would cross.

To document additional site-specific information regarding vegetation and habitat, DOE performed literature and database searches, and consulted with land and resource management agencies and authorities, including the BLM, the U.S. Fish and Wildlife Service, the Nevada Natural Heritage Program, the Nevada Department of Wildlife, the University of Nevada–Reno, and the Nevada Division of Forestry.

In addition to the review of existing information, DOE conducted field surveys and gathered data to further characterize the mapping zones and associated vegetation communities, and to further characterize the habitats in the study area that might support special status species. DOE chose field survey locations to provide representative survey coverage of the different types of vegetation along the Caliente rail alignment, specifically in the construction right-of-way, but also in the larger study area. The field survey data DOE collected helped further characterize the types of habitats in the construction right-of-way and identified by the Southwest Regional Gap Analysis Project (DIRS 174324-NatureServe 2004, all). Appendix H describes the field survey methodology. The additional surveys and data searches are outlined in each specific resource area below.

3.2.7.2.1 Vegetation

The Caliente rail alignment is situated within two large deserts: the Great Basin and the Mojave. The Great Basin Desert is considered a cold desert and has been referred to as the Basin and Range region due to its parallel north-south trending ranges, or mountains, and intervening basins, or valleys. This region covers most of central and northern Nevada, with its southern extent ending roughly in southern Lincoln, Esmeralda, and Nye Counties. The Mojave Desert is considered a hot desert and covers most of southern Nevada and much of southeastern California (DIRS 174412-Ryser 1985). Just as the two deserts are distinguished from one another climatically, the predominant vegetation and vegetation communities also define each desert.

The Great Basin Desert is generally characterized by big sagebrush (*Artemisia tridentata*), which is mostly absent from the Mojave Desert except at moderate to high elevations in the mountains. Alternatively, the Mojave Desert is dominated by creosote bush (*Larrea tridentata*), which is mostly absent from the Great Basin Desert. There is a broad transitional zone where these two deserts meet, which exhibits characteristics of both regions.

Based on the spatial analysis described above, the Caliente rail alignment would intersect 25 land-cover types, which are listed in Table 3-46. The most common plant communities within the study area are the Inter-Mountain Basins Mixed Salt Desert Scrub and the Inter-Mountain Basins Big Sagebrush Shrubland. Appendix H, Table H-1, describes plant communities. The acreages in the table are representative of the total acreages in the mapping zones (the Pioche, the Mojave, and the Nellis) that intersect the Caliente rail alignment.

Undisturbed areas of winterfat, or whitesage (*Krascheninnikovia lanata*), are present, but uncommon, within the construction right-of-way. While they have no official protected status with any federal or state agency, the BLM has identified these vegetation communities as important and their conservation or protection should be considered during development of any projects.

Table 3-46. Land-cover classes and types in the mapping zones.

Class and type	Total amount of classes and land-cover types within the Pioche, the Mojave, and the Nellis mapping zones (square kilometers)[a]
Barren Lands	
Inter-Mountain Basins Playa	1,100
Inter-Mountain Basins Wash	1.6
Inter-Mountain Basins Cliff and Canyon	420
North American Warm Desert Playa	520
North American Warm Desert Bedrock Cliff and Outcrop	1,820
Evergreen Forest	
Great Basin Pinyon-Juniper Woodland	1,000
Scrub/Shrub	
Inter-Mountain Basins Mixed Salt Desert Scrub	26,000
Inter-Mountain Basins Big Sagebrush Shrubland	8,000
Sonora-Mojave Creosotebush-White Bursage Desert Scrub	19,000
Great Basin Xeric Mixed Sagebrush Shrubland	7,600
Mojave Mid-Elevation Mixed Desert Scrub	11,000
Sonora-Mojave Mixed Salt Desert Scrub	1,500
Grassland/Herbaceous	
Inter-Mountain Basins Semi-Desert Shrub Steppe	4,900
Inter-Mountain Basins Semi-Desert Grassland	100
Inter-Mountain Basins Montane Sagebrush Steppe	530
Woody Wetland	
Inter-Mountain Basins Greasewood Flat	1,440
Great Basin Foothill and Lower Montane Riparian Woodland and Shrubland	140
North American Warm Desert Lower Montane Riparian Woodland and Shrubland	30.8
Emergent Herbaceous Wetland	
North American Arid West Emergent Marsh	47.2
Altered or Disturbed	
Invasive Annual Grassland	51
Invasive Annual and Biennial Forbland	29
Developed and Agriculture

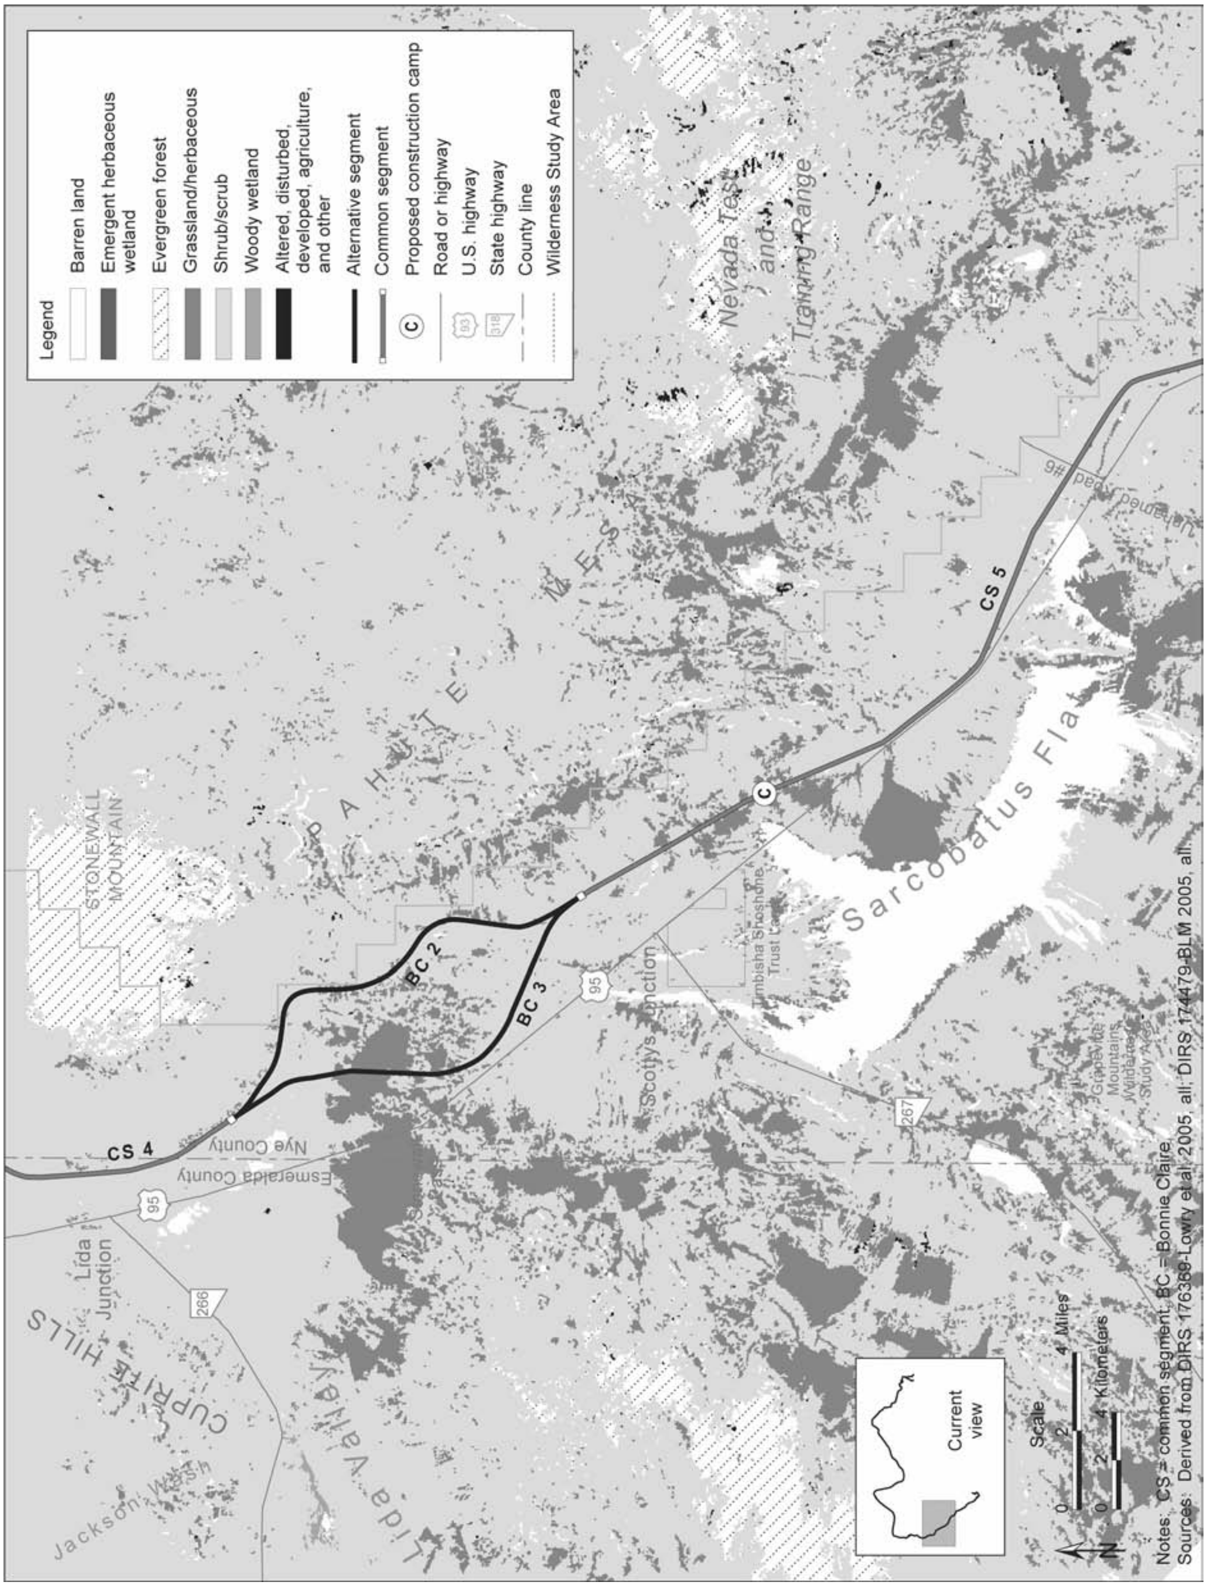

Figure 3-89. Land-cover classes the Caliente rail alignment would cross within map area 6.

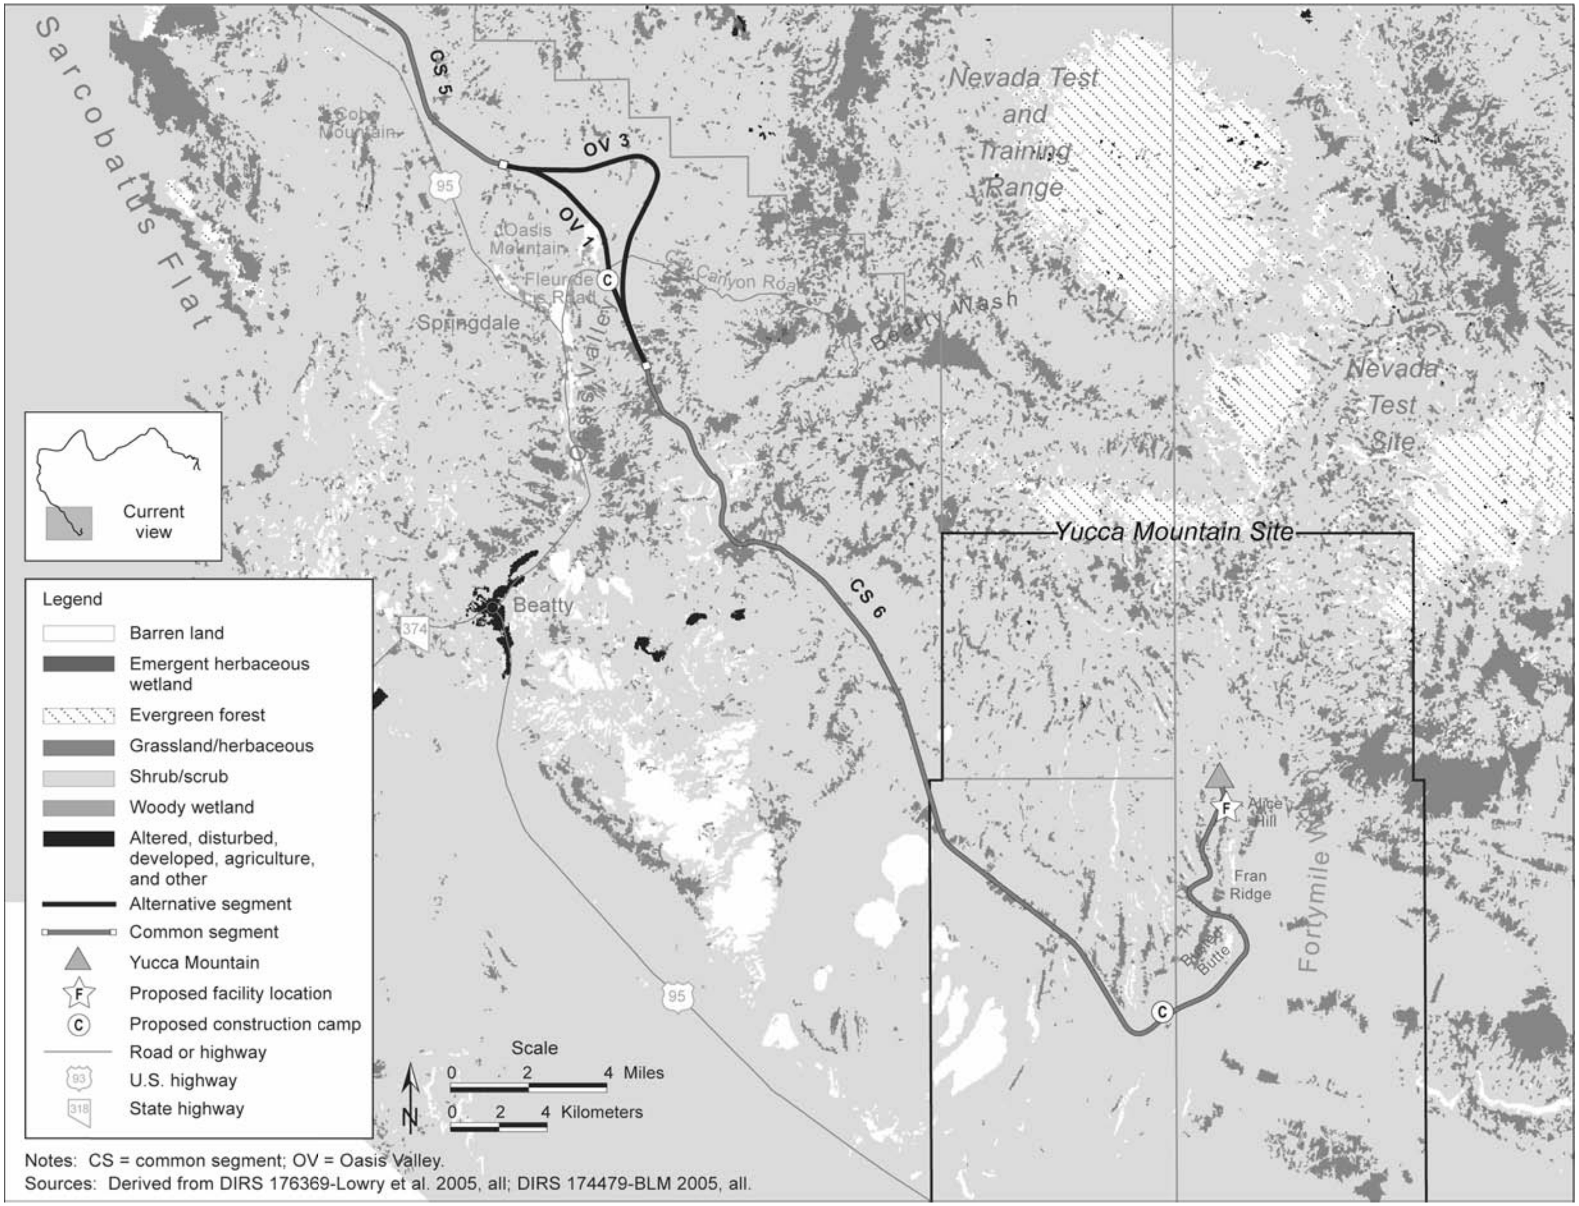

Figure 3-90. Land-cover classes the Caliente rail alignment would cross within map area 7.

In addition to shrubs and grasses, biological soil crusts are an important component to both the Mohave and Great Basin ecosystems. Biological crusts are comprised of multiple species of lichen, moss, cyanobacteria and algae which live on top of the soil surface, binding with soil particles and forming a cohesive mat or crust on the surface of arid landscapes (DIRS 181866-Belnap 2006, p. 1). Cyanobacteria is the dominant component of crusts in the Mojave Desert, while soil lichen and moss species tend to be limited. Biological crusts (if present) could play an important role in maintaining the health of some of the desert vegetation communities listed in Table 3-46, including but not limited to facilitating water infiltration, retaining soil moisture, and reducing soil loss from wind and water erosion (DIRS 181957-Kaltenecker and Wicklow-Howard 1994, p. 1-8). Crusts are highly sensitive to surface disturbance and are easily destroyed. Biological crusts likely occur within the region of influence in some areas where there has been no surface disturbance. Biological crusts are potentially present in areas where construction would occur, but because of insufficient data regarding the location and extent of biological crusts in the region of influence, Section 4.2.7 does not discuss impacts to biological crusts.

Nonnative plant species: A species found in an area where it has not historically been found.

Native plant species: With respect to a particular ecosystem, a species that, other than as a result of an introduction, historically occurred or currently occurs in that ecosystem (Executive Order 13112, *Invasive Species*).

Invasive plant species: An alien species whose introduction does or is likely to cause economic or environmental harm or harm to human health (Executive Order 13112, *Invasive Species*).

Noxious weeds: The BLM defines a noxious weed as: "A plant that interferes with management objectives for a given area of land at a given point in time." (DIRS 177037-BLM 1996, p. 3) The State of Nevada defines noxious weeds as: "Any species of plant which is, or liable to be, detrimental or destructive and difficult to control or eradicate" (Nevada Revised Statute 555.005).

Weeds can be native or nonnative, invasive or non-invasive, and noxious or not noxious. Invasive species include not only noxious weeds, but also other nonnative plants. The BLM considers plants invasive if they have been introduced into an environment where they did not evolve. As a result, invasive species usually have no natural enemies to limit their spread and can produce significant detrimental changes.

3.2.7.2.1.1 Noxious Weed and Invasive Species. The Great Basin-Mojave Desert region is threatened by a number of nonnative, invasive plant species that have displaced ***native plant species***. Invasive plant species, such as red brome (*Bromus rubens*), tamarisk (*Tamarix ramosissima*), and cheatgrass (*Bromus tectorum*), have the ability to out-compete individual species of native range plants, which results in extensive monocultures of the introduced species. ***Invasive species*** usually have little to no nutritional value for livestock and wildlife; some invasive species are toxic or physically injurious to animals, can increase the frequency of wildfires, and degrade wildlife habitat by reducing the diversity of native vegetation (DIRS 155925-Nevada Weed Action Committee 2000, p. 5).

Some plant species are considered ***noxious weeds***, an official designation used by federal and state authorities to identify species with a high likelihood of being very destructive or difficult to control or eradicate. Chapter 555.010 of the Nevada Administrative Code lists species designated as noxious. Chapter 555 of the Nevada Revised Statutes directs that designated noxious weeds are to be controlled on both public and private land, and provides for enforcement measures should the landowner or occupier fail to take corrective action. While many noxious species are invasive, invasiveness is not required for a species to be designated noxious. Some species managed as noxious weeds are not considered truly invasive because they cannot effectively out-compete healthy communities of native vegetation.

3.2.7.2.1.2 Wetlands and Riparian Habitats. Riparian habitats are transition areas from wetland or stream habitat to upland habitat. Wetlands are areas that are saturated by water for a sufficient amount of time to support vegetation that is adapted to saturated soil conditions. While wetland and riparian habitats in Nevada cover a very small percentage of the total area of the state, they support a comparatively high number and large diversity of species, many of which are locally ***endemic***. Wetland and riparian habitats have been reduced in the region over the years due in part to water removal and the presence of invasive species, such as tamarisk (DIRS 174518-BLM 2005, p. 3.5-9). Appendix F contains information on wetlands within the project area and Sections 3.2.5 and 4.2.5 discuss impacts in relation to Section 404 of the Clean Water Act and wetland fill permitting. This section discusses wetlands and riparian habitats that support terrestrial and aquatic species.

To maintain consistency within this section, DOE assessed the amount and types of wetland and riparian habitats utilizing the 2004 Southwest Regional Gap Analysis Project (DIRS 174324-NatureServe 2004, all). Section 3.2.5, Surface-Water Resources, utilizes National Wetlands Inventory maps (DIRS 176976-MO0605GISNWIDQ.000) and the results of the wetland delineations conducted during the field surveys in 2005 (DIRS 174040-PBS&J 2005, pp. 15 and 16) and 2006 (DIRS 180914-PBS&J 2006, pp. 11 and 12) to calculate the area of the wetlands. Therefore, the area totals differ between Sections 3.2.5 and 3.2.7 because Section 3.2.7 analyzes wetland and riparian habitat and Section 3.2.5 analyzes only the wetland areas.

According to the Southwest Regional Gap Analysis Project, there are three types of wetland or riparian habitats along the Caliente rail alignment and at locations of the proposed railroad construction and operations support facilities: North American Warm Desert Lower Montane Riparian Woodland and Shrubland; Great Basin Foothill and Lower Montane Riparian Woodland and Shrubland; and North American Arid West Emergent Marsh (Figures 3-91 to 3-94 and Table 3-46).

The North American Warm Desert Lower Montane Riparian Woodland and Shrubland is found along perennial and seasonally intermittent streams. Generally located in middle to low elevations and found in canyons and valleys, vegetation in this land-cover type depends on seasonal flooding and removal of sediment that occurs during these flood events. The vegetation is a mix of tree and shrub species including Fremont cottonwood (*Populus fremontii*) and willows, including sandbar willow (*Salix exigua*) and seep willows (*Baccharis salicifolia*) (DIRS 174324-NatureServe 2004. pp. 140 to 142).

The Great Basin Foothill and Lower Montane Riparian Woodland and Shrubland land cover occurs in the mountains of the Great Basin from middle to high elevations. This habitat requires flooding, and the scouring and subsequent deposition of soils that occurs during flood events, for maintenance and germination of vegetation. Vegetation typically associated with this type of riparian habitat includes Fremont cottonwood, willows, rushes (*Juncus* spp.), and sedges (*Carex* spp.) (DIRS 174324-NatureServe 2004, pp. 149 and 150).

The North American Arid West Emergent Marsh type occurs throughout the arid regions of the western United States. This land cover occurs along slow-moving streams, has soils that are able to accumulate organic material, and contains vegetation that is adapted to frequently or continually saturated soil conditions. Vegetation commonly found in marsh areas includes bulrushes (*Scirpus* spp.), cattails (*Typha* spp.), and rushes (DIRS 174324-NatureServe 2004, pp. 154 to 156).

3.2.7.2.2 Wildlife

As with the vegetation communities and wetland habitats, DOE gathered data on wildlife communities to identify existing information regarding the occurrence and distribution of wildlife, including mammals, birds, reptiles, and aquatic species, within the construction right-of-way.

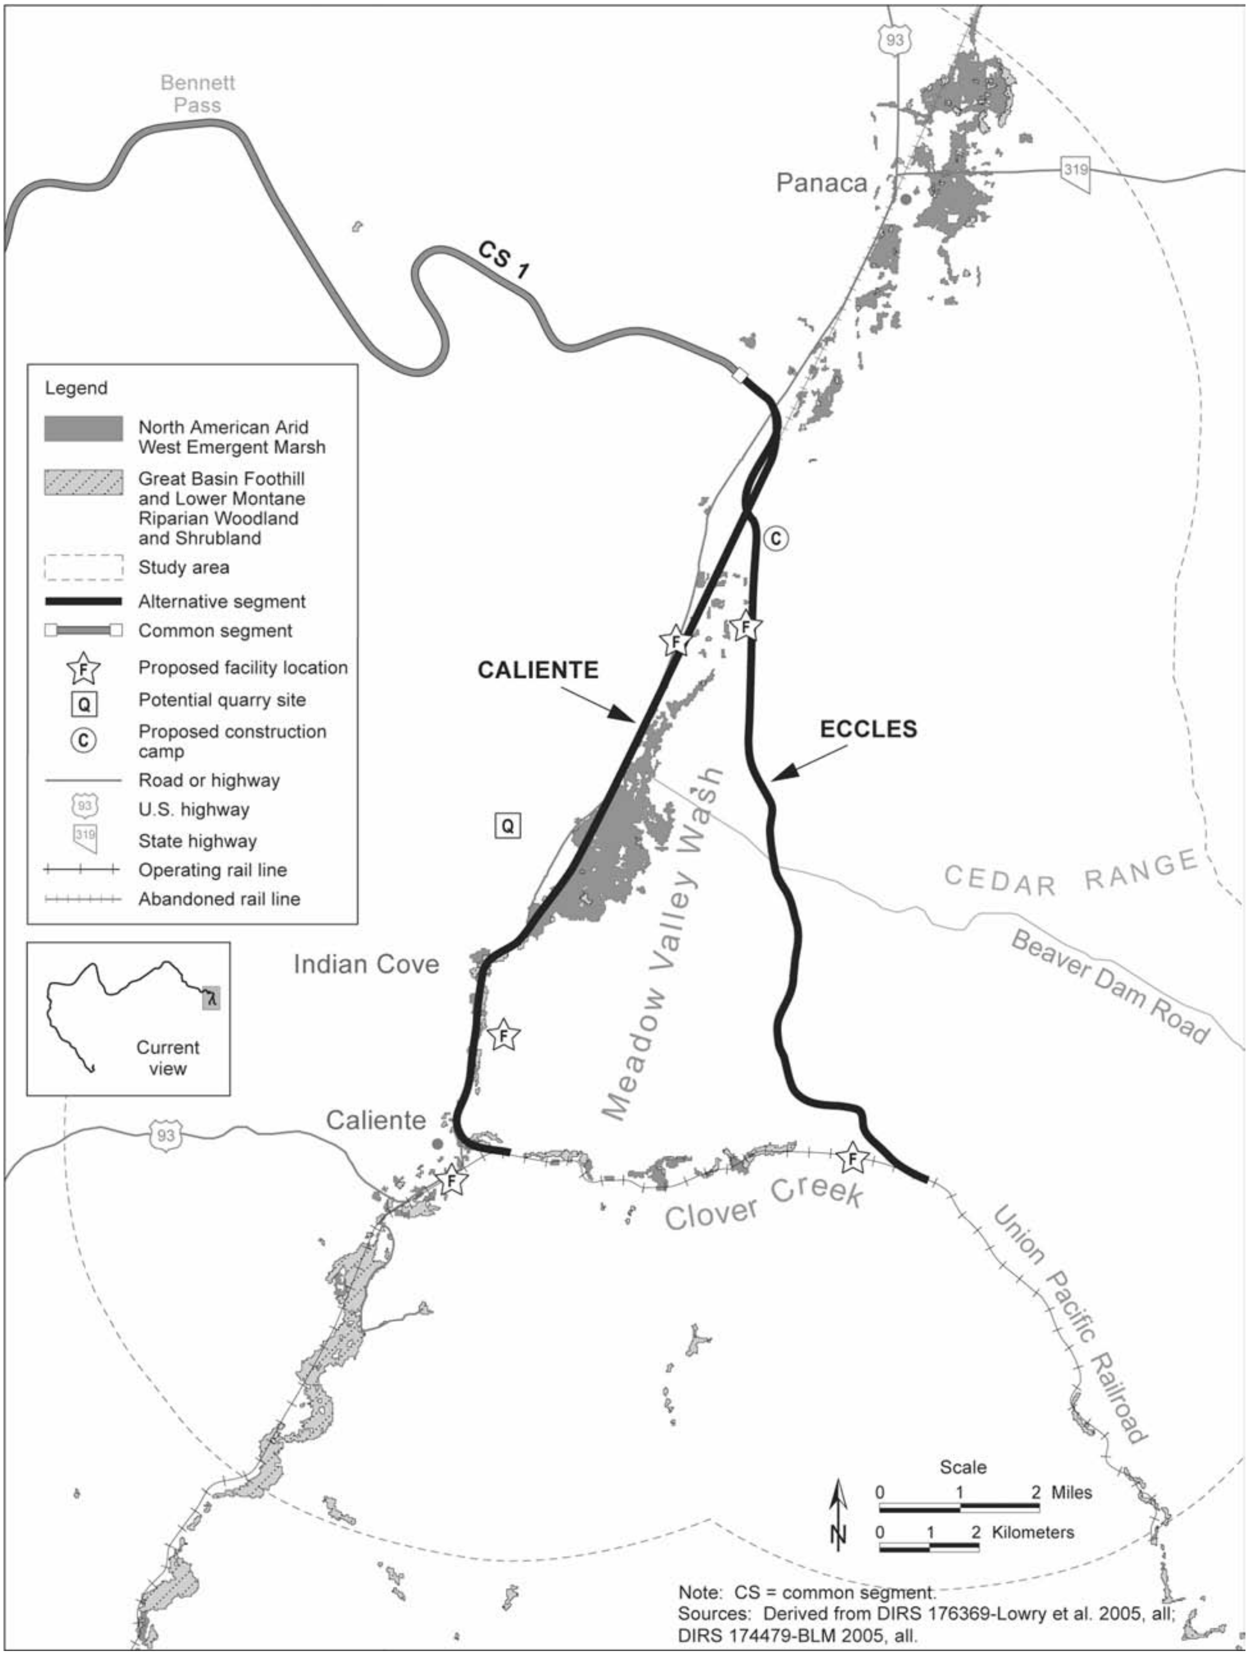

Figure 3-91. Wetland/riparian habitat within the study area near the Caliente and Eccles alternative segments.

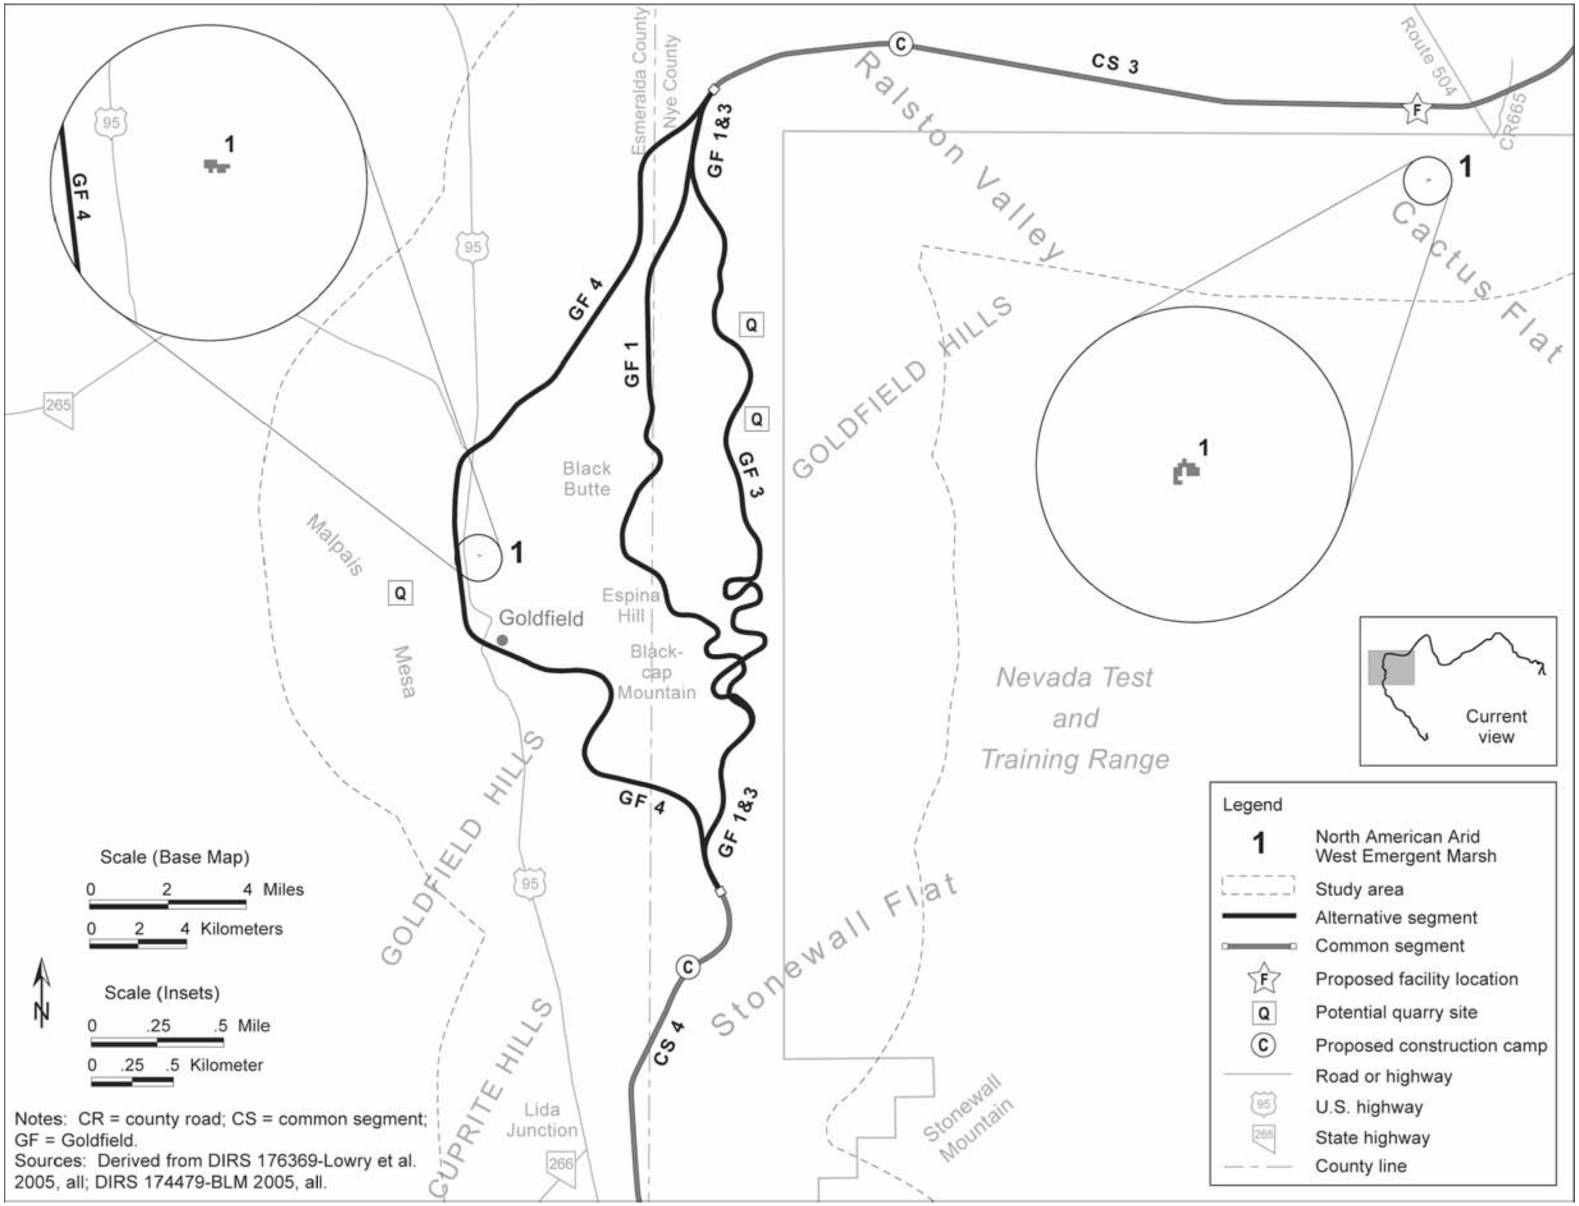

Figure 3-92. Wetland/riparian habitat within the study area adjacent to the Goldfield alternative segments.

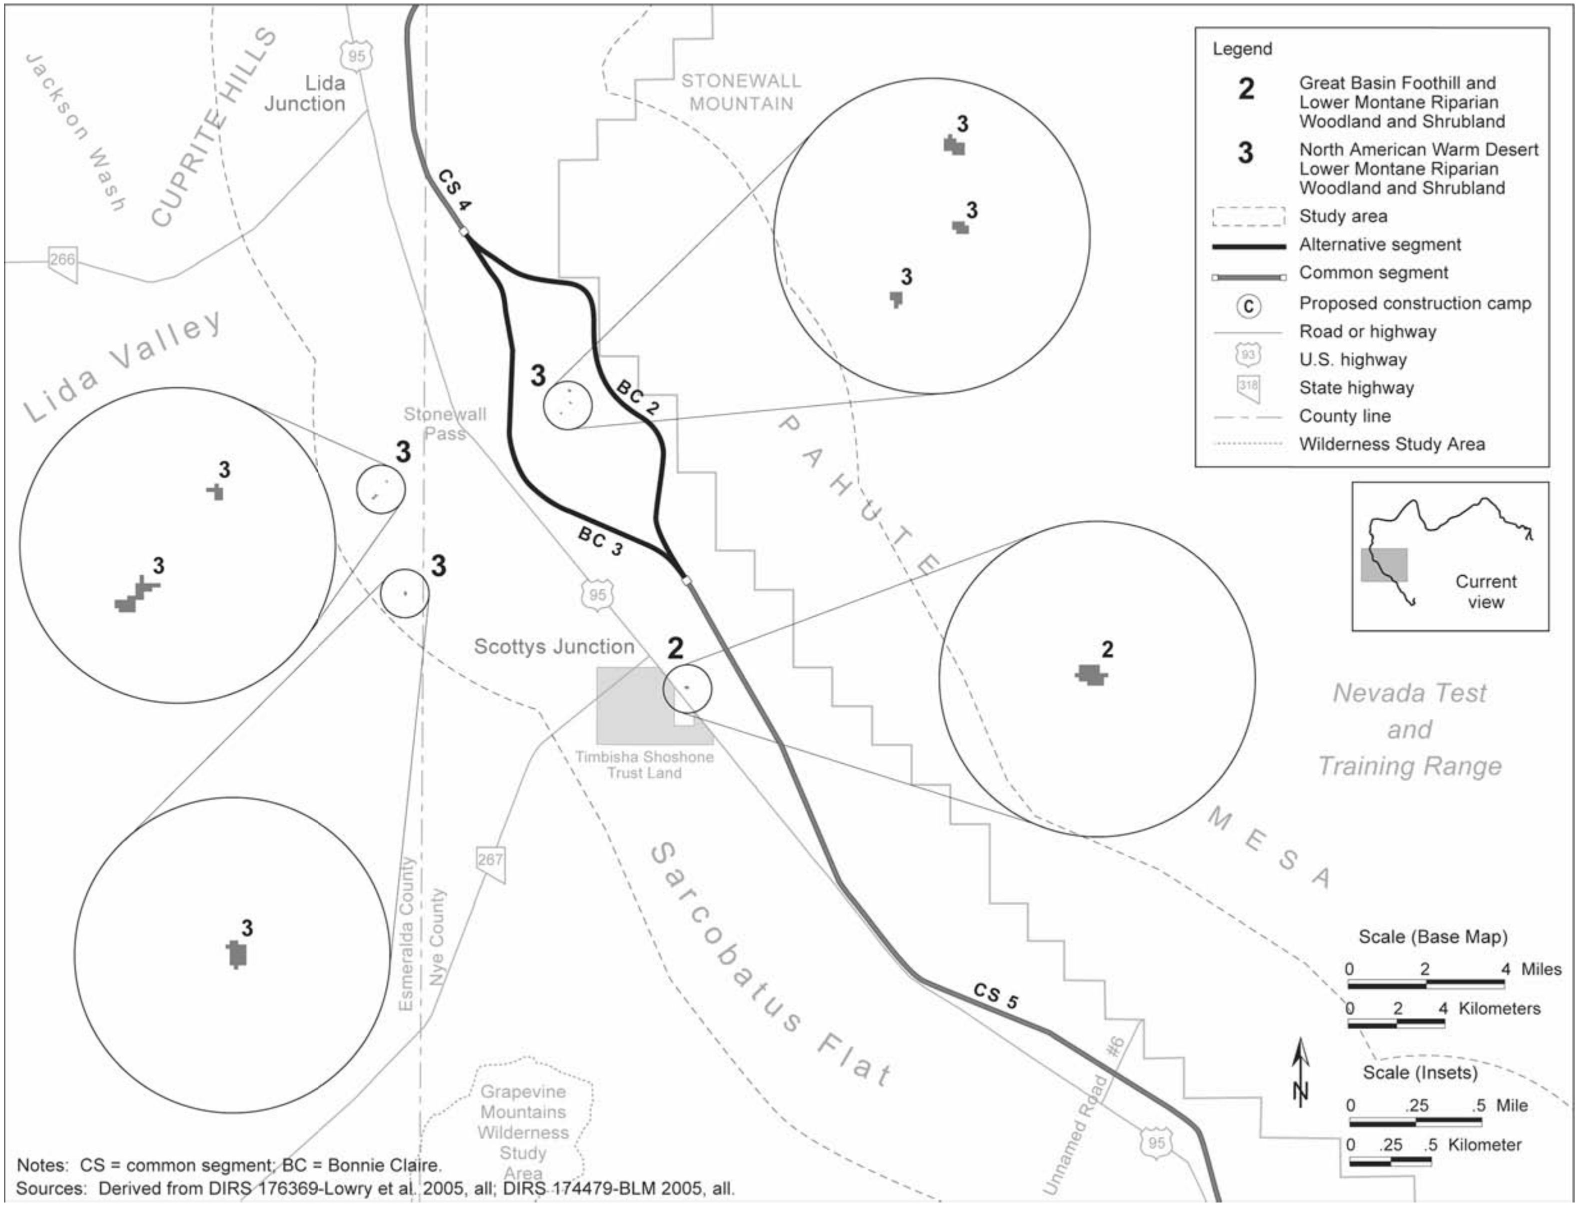

Figure 3-93. Wetland/riparian habitat within the study area near the Bonnie Claire alternative segments.

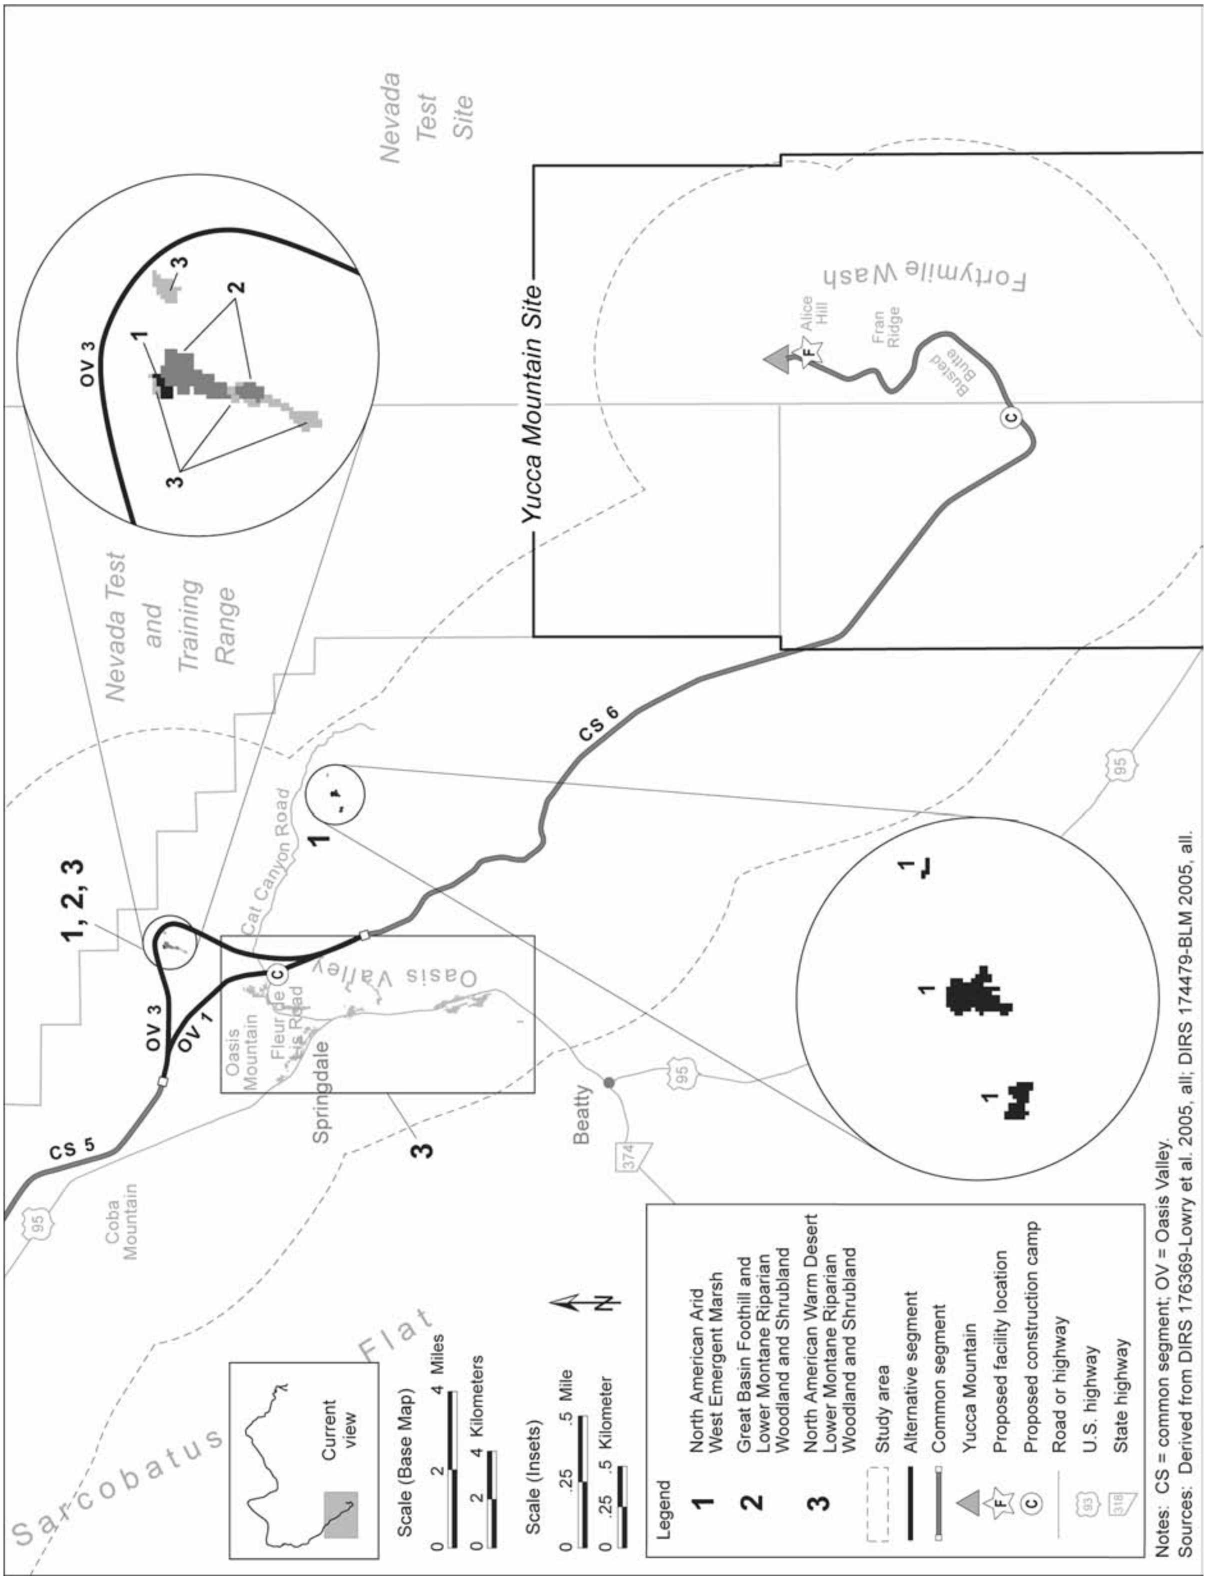

Figure 3-94. Wetland/riparian habitat within the study area near the Oasis Valley alternative segments.

These investigations incorporated literature and database searches and consultations with land and resource management agencies and authorities, including the BLM, the U.S. Fish and Wildlife Service, the Nevada Natural Heritage Program, and the Nevada Department of Wildlife. DOE also obtained information regarding Nevada game species from these agencies. Concurrent with other field surveys, the Department gathered information on field observations to identify the presence of wildlife within the construction right-of-way.

Wildlife abundance and diversity is related to habitat or land-cover types and quality. DOE mapped the wildlife and species synonymous with the habitat or land-cover types to the construction right-of-way. Appendix H contains a map detailing field survey locations.

3.2.7.2.3 Special Status Species

Special status species are plants, fish, and wildlife species that are afforded some level of protection or special management under federal or state laws or regulations. DOE contacted the U.S. Fish and Wildlife Service to obtain a list of species protected under the federal Endangered Species Act that are known to exist or could exist within the construction right-of-way or within the study area (DIRS 174439-Williams 2005, all). The Department assessed the potential for federally listed species to occur within the construction right-of-way by reviewing agency listings of known, or potentially occurring, listed species, and through a review of potential habitat for those species along the Caliente rail alignment. The Department also obtained location records for special status species from a statewide database managed by the Nevada Natural Heritage Program that contains records of incidental observations of rare or protected plants, fish, and wildlife species (DIRS 182061 2005, all). The special status species DOE selected for further consideration are one or a combination of the following:

- Special status species documented as occurring within the study area
- Special status species identified as potentially occurring in the study area by personnel affiliated with appropriate resource management agencies, including the BLM (DIRS 172900 BLM 2003, all), the U.S. Fish and Wildlife Service, the Nevada Department of Wildlife, or the Nevada Division of Forestry
- Special status species identified as potentially occurring in the study area because field personnel identified potentially suitable habitat during the field surveys

DOE used a Geographic Information System database to map the documented occurrences of special status plants and wildlife species within the study area in relation to the Southwest Regional Gap Analysis Project types. The Department then used these maps to identify and match areas of potential habitat and the presence of the documented special status species within those habitats. Through field surveys, the Department further evaluated areas that appeared to contain viable habitat for a special status species. Appendix H provides details on the survey methodology for special status species.

3.2.7.2.4 State of Nevada Game Species

Table 3-47 lists the game species identified in the Nevada Administrative Code Sections 503.020, 503.045, 503.060 that potentially occur in the study area. Game species identified in these sections of the Nevada Administrative Code that are absent from the study area are listed in Appendix H, Table H-5, and are not considered further in this Rail Alignment EIS. The greater sage-grouse *(Centerocercus urophasianus)* and pygmy rabbit *(Sylvilagus idahoensis)* are game species that are also BLM-listed sensitive and State of Nevada protected. The bighorn sheep is a BLM-listed sensitive species managed by the Nevada Department of Wildlife as a big game mammal.

Table 3-47. Nevada game species present or potentially present in the biological resources study area – Caliente rail alignment.[a]

Common name	Scientific name	Occurrence within the study area
Game mammals		
Pronghorn antelope	*Antilocapra americana*	Present
Mule deer	*Odocoileus hemionus*	Present
Mountain lion	*Felis concolor*	Present
Cottontail rabbit	*Sylvilagus* spp.	Present
Pygmy rabbit	*Sylvilagus idahoensis*	Present
Black-tailed jackrabbit	*Lepus californicus*	Present
Bighorn sheep	*Ovis canadensis*	Present
Elk	*Cervus elaphus*	Present
Upland and migratory game birds		
Greater sage-grouse	*Centrocercus urophasianus*	Potentially present
Chukar	*Alectoris chukar*	Present
Ring-necked pheasant	*Phasianus colchicus*	Present
Gambel's quail	*Callipepla gambelii*	Present
Wild turkey	*Meleagris gallopavo*	Present
American crow	*Corvus brachyrhynchos*	Present
Ducks, geese, and swans	Family *Anatidae*	Present only in wetland/marsh areas
Wild doves and pigeons	Family *Columbidae*	Present
Cranes	Family *Gruidae*	Present only in wetland/marsh areas
Rails, coots, and gallinules	Family *Rallidae*	Present only in wetland/marsh areas
Woodcocks and snipes	Family *Scolopacidae*	Present only in wetland/marsh areas

a. Source: Nevada Administrative Code Sections 503.020, 503.045, and 503.060.

DOE conducted surveys along the Caliente rail alignment to further characterize the presence or absence of game species. Observations included identification of tracks and fecal pellets, and direct observation of animals within the rail alignment study area. Results do not imply population level or habitat quality, only the presence or absence of game species and their approximate level of use.

3.2.7.2.5 Wild Horses and Burros

The BLM has delineated herd management areas within the wild horse herd areas. Each herd management area has an appropriate management level determined by the BLM through a rangeland assessment and a public review process. The appropriate management level is the number of wild horses and burros that the herd management area is managed for, and it is established to avoid the ecological degradation of the herd management area. DOE reviewed the Tonopah Resource Management Plan (DIRS 173224-BLM 1997, all), the Draft Ely District Resource Management Plan (DIRS 174518-BLM 2005, all), and herd management plans for the Ely and Battle Mountain BLM Districts to obtain current information on herd management areas. The Department contacted the BLM to obtain Geographic Information System data on management areas and to obtain data regarding the use of the herd management areas by wild horses and burros.

Concurrent with other field investigations, DOE performed observations for wild horses and burros, or signs of their presence. Section 3.2.2, Land Use and Ownership, describes the grazing allotment planning process.

3.2.7.3 Affected Environment along Alternative Segments and Common Segments

This section describes biological resources in the Caliente rail alignment construction right-of-way and study area. To avoid unnecessary repetition, this section discusses biological resources by resource type (vegetation, wildlife, special status species, migratory birds, State of Nevada game species, and wild horses and burros) rather than by alternative segment or common segment.

3.2.7.3.1 Vegetation

There are 25 different land-cover types within the construction right-of-way and multiple options for the proposed Caliente railroad construction and operations support facilities. Tables 3-48 through 3-50 list land-cover types along the rail alignment and the areas of proposed operations support facilities. The percentages disclosed are the percent of land-cover types that could be affected and these percentages relate to the total acreages in the Pioche, the Mojave, and the Nellis mapping zones (see Table 3-46). The land-cover types listed and the percentages that could be affected are based on the nominal width of the rail line construction right-of-way for the alternative segments and common segments and the footprint of each proposed operations support facility. Table 3-51 lists the land-cover types present in the areas of the potential quarry sites.

3.2.7.3.1.1 Noxious Weeds and Invasive Species. Cheatgrass is found along most of the Caliente rail alignment where it fills open space between shrubs. Red brome is also common, although it is generally confined to areas along the rail alignment that would cross the Mojave Desert region. These observations were made during the 2005 field surveys.

The BLM and the Nevada Department of Agriculture maintain databases identifying the locations of documented occurrences of noxious weeds and invasive species (DIRS 174479-BLM 2003, all). The databases identify the following noxious weeds and invasive species in the Meadow Valley Wash near the Caliente alternative segment:

- Dalmatian toadflax (*Linaria dalmatica*)
- Hoary cress (*Cardaria draba*)
- Spotted knapweed (*Centaurea maculosa*)
- Tall whitetop (*Lepidium latifolium*)
- Russian knapweed (*Acroptilon repens*)

These databases also identify tall whitetop along the Eccles alternative segment and Caliente common segment 1, and Scotch thistle (*Onopordum acanthium*) along the Eccles alternative segment.

3.2.7.3.1.2 Wetlands and Riparian Habitat. Before conducting field surveys, DOE reviewed pertinent maps, the 2004 Southwest Regional Gap Analysis Project (DIRS 174324-NatureServe 2004, all), and available state wetland and land-use inventories to identify the locations of possible wetland and riparian habitat within the rail line construction right-of-way and the study area.

DOE identified wetland and riparian habitat along the following portions of the Caliente rail alignment using a combination of fieldwork and the 2004 Southwest Regional Gap Analysis Project (see Figures 3-91 through 3-94):

- Caliente alternative segment
- Eccles alternative segment
- Caliente common segment 1
- Goldfield alternative segments
- Bonnie Claire alternative segments
- Oasis Valley alternative segment

This section discusses only portions of the Caliente rail alignment in which there are wetland and/or riparian habitats. Section 3.2.5, Surface-Water Resources, provides information on springs and their locations and specific information for function and value of wetlands for Section 404 permitting. This section discusses wetlands and riparian areas in relation to the vegetation and habitat that is supplied for terrestrial and aquatic species. Table 3-52 details the identified wetland and riparian types found in the construction right-of-way and the study area, along alternative segments and common segments of the Caliente rail alignment.

Plant species that are considered indicators of wetland conditions that were found along the Caliente alternative segment include bulrushes, sedges, Fremont cottonwood, willows (including sandbar willow), broadleaf cattail (*Typha latifolia*), Baltic rush (*Juncus balticus*), common reed (*Phragmites australis*), tamarisk, and Russian olive (*Eleagnus angustifolia*) (DIRS 174040-PBS&J 2005, p. 17).

The wetlands along the Eccles alternative segment at the Meadow Valley Wash were classified as emergent, emergent/rock bottom, and scrub-shrub/rock bottom wetlands (DIRS 174040-PBS&J 2005, p. 16).

In the North Pahroc Range pass (between White River Valley to the west and Dry Lake Valley to the east), Caliente common segment 1 would pass near an approximately 0.01-square kilometer (3-acre) wetland. This wetland is adjacent to a single, developed unnamed spring, approximately 440 meters (1,450 feet) outside the rail line construction right-of-way near Black Rock Spring (DIRS 174040-PBS&J 2005, p. 18 and Figure 5). The unnamed spring was likely developed to provide a stock watering area. The wetland area is classified as emergent/rock bottom/unconsolidated bottom and emergent wetlands. The Southwest Regional Gap Analysis Project (DIRS 174324-NatureServe 2004, all) lists the riparian habitat in this area as Great Basin Foothill and Lower Montane Riparian Woodland and Shrubland.

Table 3-52. Wetland and riparian land-cover types within the Caliente rail alignment construction right-of-way and study area.[a]

Segment/land-cover type	Amount in construction right-of-way (square kilometers)[b]	Amount in study area (square kilometers)

a. Source: DIRS 174324-NatureServe 2004.
b. To convert square kilometers to acres, multiply by 247.10.

Oasis Valley alternative segment 3 contains a small (approximately 0.02 square kilometer [5 acres]) wetland area that would be within the construction right-of-way. This wetland area contains willow and inland saltgrass (*Distichlis spicata*) (DIRS 174040-PBS&J 2005, Figure 4T).

See Section 3.2.5, Surface-Water Resources, for more specific information on wetlands.

3.2.7.3.2 Wildlife

> A **wildlife guzzler** is a water development for wildlife that relies on rainfall or snowmelt to recharge it, rather than springs or streams. Usually used where there are no other sources of water for wildlife.

This section describes the wildlife and wildlife communities potentially present in the Caliente rail alignment construction right-of-way. Figure 3-95 details the manmade wildlife water sources, also called ***wildlife guzzlers***, within the study area. There are three wildlife guzzlers within the study area: Scofield #3, and two guzzlers, both named Garden Valley (Figure 3-95 Scofield #3 is approximately 7.6 kilometers (4.7 miles) north of Garden Valley alternative segment 3. The first Garden Valley guzzler is approximately 1.8 kilometers (1.1 miles) south of Garden Valley alternative segment 8. The second Garden Valley guzzler is approximately 2 kilometers (1.2 miles) south of Garden Valley alternative segment 8. Section 3.2.5, Surface-Water Resources, provides information about and locations of other sources of water available to wildlife.

The following sections describe the most common species of mammals, birds, reptiles, amphibians, and fish potentially found within the Caliente rail alignment greater study area and potentially within the construction right-of -way. Section 3.2.7.3.3 provides information on federally listed threatened and endangered species, and federally and state-listed sensitive or protected species. Section 3.2.7.3.4 discusses migratory birds, Section 3.2.7.3.5 discusses Nevada game species, and Section 3.2.7.3.6 discusses wild horses and burros.

3.2.7.3.2.1 Mammals. Mammals are known to exist within the study area along the entire length of the Caliente rail alignment. The types of mammals found within the study area would depend on the vegetation communities. Mammals that could occur within the greater study area and the construction right-of-way of the Caliente rail alignment include:

- Mountain lion (*Felis concolor*)
- Bighorn sheep (*Ovis Canadensis*)
- Kit fox (*Vulpes macrotis*)
- Coyote (*Canis latrans*)
- Bobcat (*Lynx rufus*)
- Badger (*Taxidea taxus*)
- Cottontail rabbit (*Sylvilagus* spp.)
- Various rodents
- Elk (*Cervus elaphus)*
- Pronghorn antelope (*Antilocapra americana*)
- Grey fox (*Urocyon cinereoargenteus*)
- Mule deer (*Odocoileus hemionus*)
- Black-tailed jackrabbit (*Lepus californicus*)
- Ringtail (*Bassariscus astutus*)
- Various bats
- Various ground squirrel species

Mule deer, elk, pronghorn antelope, and bighorn sheep are Nevada game species and are discussed in Section 3.2.7.3.5.

Twenty-three species of bats have been observed in Nevada (DIRS 174474-NDOW 2002, p. 7-8). Bats, including resident, migrant, and transient species, are found throughout Nevada and in every type of habitat. Bats occupy a variety of habitats within the construction right-of-way, including mine shafts, caves, talus slopes with cracks and crevices, cliff faces, man-made structures, and pinyon-juniper and Joshua tree (*Yucca brevifolia*) forests. Bats often use different day and night roosting habitats, different nursery and non-breeding habitats, and different winter and summer habitats. Appendix H includes a list of bat species potentially found within the project area. Many of the bats along the rail alignment are special status species and are discussed further in Section 3.2.7.3.3.

3.2.7.3.2.2 Birds. A variety of bird species are commonly observed in central and southern Nevada, including year-round residents, summer residents, migratory species breeding in southern Nevada, winter residents that breed to the north, and seasonal migrants passing through central and southern Nevada en route to breeding ranges to the north and winter ranges to the south. Several federal laws and state statutes protect various groups of birds. Chapter 6 of this Rail Alignment EIS details these protections.

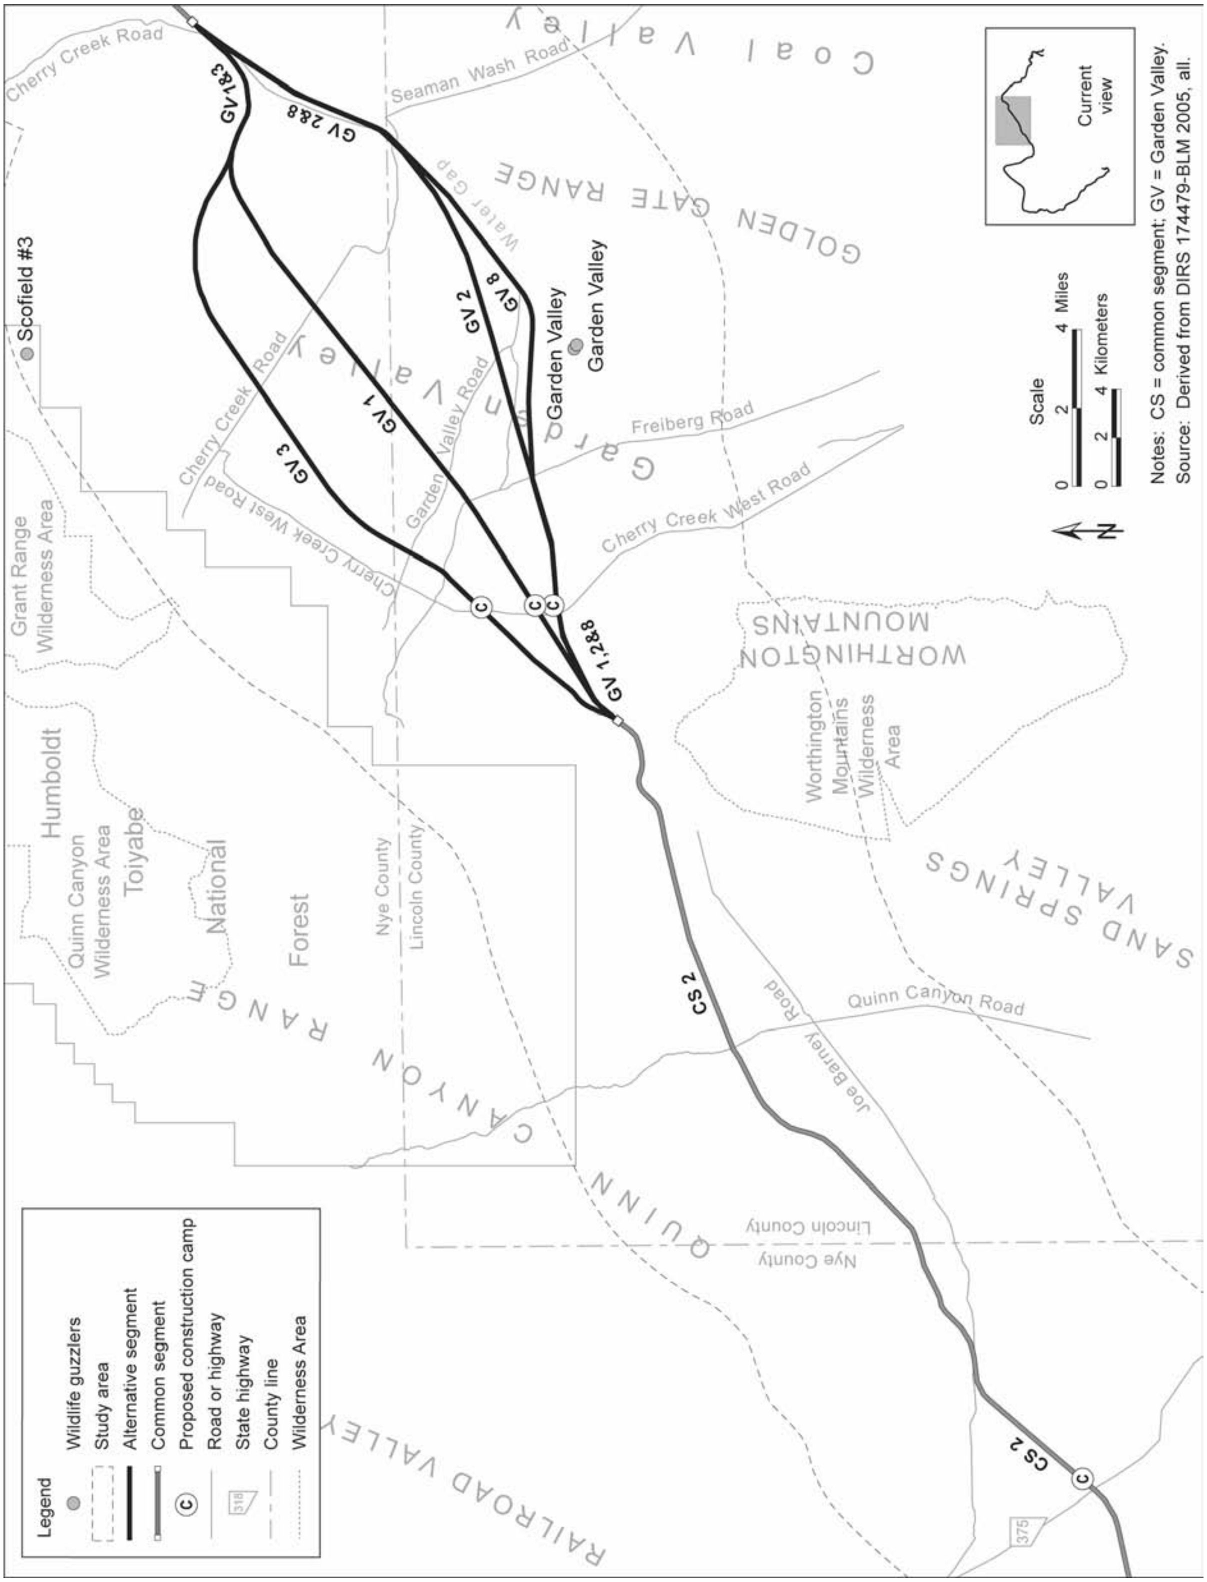

Figure 3-95. Wildlife guzzlers located along the Caliente rail alignment.

The Great Basin region of Nevada is an important migration route for waterfowl and other species of birds traveling between southern wintering areas and northern breeding territories; however, suitable habitat for waterfowl and shorebirds is extremely limited in the region and along the Caliente rail alignment. Portions of Meadow Valley Wash are considered to be waterfowl habitat (DIRS 101504-BLM 1979, pp. 2-35 and 2-36) and migrating birds might temporarily utilize any exposed surface-water areas. Waterfowl and shorebirds were observed during the 2005 field surveys in a few locations where there was standing surface water that supported aquatic vegetation.

Common species of resident and migrating birds observed along the Caliente rail alignment include:

- Common raven (*Corvus corax*)
- Horned lark (*Eremophila alpestris*)
- American pipit (*Anthus rubescens*)
- European starling (*Sturnus vulgaris)*
- American crow (*Corvus brachyrhynchos*)
- MacGillivray's warbler (*Oporonis tolmiei*)
- Loggerhead shrike (*Lanius ludovicianus*)
- Yellow warbler (*Dendroica petechia*)

Two upland game bird species are expected to occur within the Caliente rail alignment construction right-of-way: chukar (*Alectoris chukar*) and Gambel's quail (*Callipepla gambelii*). Two species of upland game birds, chukar and mourning dove, were observed during surveys conducted along the rail alignment. Chukars were recorded in cliff and talus habitat in the Beatty Wash area. Mourning doves are common and were observed at multiple locations along the rail alignment. The greater sage-grouse is an upland game bird that has historically occurred in low abundance near portions of the rail alignment and it could occupy suitable habitat along the northern sections of the rail alignment. The greater sage-grouse is a BLM-listed special status species and receives additional protection from the State of Nevada; it is discussed in more detail in Section 3.2.7.3.3.

Populations of raptors are typically low in numbers, and their occurrence in the rail line construction right-of-way would be very low due to the lack of roosting, nesting, and foraging potential along the alignment. Raptors observed during field surveys included prairie falcon (*Falco mexicanus*), red-tailed hawk (*Buteo jamaicensis*), rough-legged hawk (*Buteo lagopus*), northern harrier (*Circus cyaneus*), burrowing owl (*Athene cunicularia*), great-horned owl (*Bubo virginianus*), turkey vulture (*Cathartes aura*), and golden eagle (*Aquila chrysaetos)*. In addition, ferruginous hawks (*Buteo regalis*) have been reported to occupy, and in some cases nest in, areas with trees close to the construction right-of-way (DIRS 174519-Bennet 2005, Plate 5).

Populations of bird species that rely on sagebrush habitat in Nevada are declining because cattle grazing and the proliferation of nonnative weeds have degraded the native sagebrush habitat (DIRS 174518-BLM 2005, pp. 222-223). Sagebrush-dependent species that might occupy habitat along the proposed rail alignment could include sage thrasher (*Oreoscoptes montanus)*, sage sparrow (*Amphispiza belli*), Brewer's sparrow (*Spizella breweri*), and vesper sparrow (*Pooecetes gramineus*). The Caliente rail alignment would cross sagebrush habitat in Bennett Pass, Pahroc Pass, and the western and northern portions of Garden Valley, portions of western Sand Spring Valley, southeastern Railroad Valley, and Warm Springs Pass.

3.2.7.3.2.3 Reptiles. A variety of species of lizards and snakes are present throughout the southern Great Basin Desert and northern Mojave Desert and along the Caliente rail alignment. Appendix H, Table H-6, lists the reptiles that have the potential to occur along the Caliente alignment. The desert tortoise (*Gopherus agassizii*) is found within the proposed rail line construction right-of-way at its southern end, from the Beatty Wash area to Yucca Mountain.

This special status species is discussed in Section 3.2.7.3.3.1. The most common lizard species observed during the 2005 field surveys were:

- Western fence lizard (*Sceloporus occidentalis*)
- Western whiptail lizard (*Cnemidophorus tigris*)
- Long-nosed leopard lizard (*Gambelia wislezenii*)
- Side-blotched lizard (*Uta stansburiana*)
- Sagebrush lizard (*Sceloporus graciosus*)
- Desert horned lizard (*Phrynosoma platyrhinos*)

Other lizard species that were observed, but did not appear to be common, were:

- Zebra-tailed lizard (*Callisaurus draconoides*)
- Desert spiny lizard (*Sceloporus magister*)
- Desert iguana (*Dipsosaurus dorsalis*)

Great Basin collared lizards (*Crotaphytus bicinctores*) and desert night lizards (*Xantusia vigilis*) were not observed during field surveys, but probably occur in the study area and potentially in the construction right-of-way. Chuckwalla (*Sauromalus ater*) commonly occurs in land-cover types similar to those in the southern portion of common segment 6, although none were observed during field surveys. This species is found in rocky outcrops and is rarely seen above ground.

Two species of snakes were observed during field surveys performed in February, March, and May 2005: the coachwhip snake (*Masticophis flagellum*) and the gopher snake (*Pituophis catenifer*). Various other species of snakes are likely to occur in the study area and potentially in the construction right-of-way, but were not directly observed during field surveys.

3.2.7.3.2.4 Aquatic Species. Aquatic species are species that require wet environments for at least part of their life cycle. The only native fish species found within the Caliente rail alignment greater study area are special status species and include:

- Railroad Valley springfish (*Crenichthys nevadae*)
- Oasis Valley speckled dace (*Rhinichthys osculus* ssp. 6 [unnamed])
- Meadow Valley Wash speckled dace (*Rhinichthys osculus* ssp. 11 [unnamed])
- Meadow Valley Wash desert sucker (*Catostomus clarki* ssp. [unnamed])

Nine more species of amphibians can be found in the southern Great Basin Desert and northern Mojave Desert that are not present in the Caliente rail alignment study area or construction right-of-way and are listed in Appendix H. Potential amphibian habitat correlates with the riparian and wetland habitat found along the rail alignment. The only amphibian observed during field surveys was a possible Woodhouse's toad (*Bufo woodhousii*) at an unnamed spring approximately 760 meters (2,500 feet) downgradient of Caliente common segment 1 on Pahroc Pass, which would be outside of the construction right-of-way. A tadpole in the spring outflow and a brief vocalization are the only recorded evidence; there were no direct observations of adult individuals. The Amargosa toad (*Bufo nelsoni*) occurs only in Oasis Valley north of Beatty. The southwestern toad (*Bufo microscaphus*) has been reported to occur (DIRS 174048-Bennett and Thebeau 2005, all), and is assumed still to exist, at the confluence of Clover Creek and Meadow Valley Wash, although none were observed during field surveys. Nonnative bullfrogs (*Rana catesbeiana*) are also present in some waterways and water bodies in the Caliente rail alignment greater study area.

3.2.7.3.3 Special Status Species

Special status species are plants or wildlife species that are afforded some level of protection or special management under federal or state laws or regulations. The following sections describe two categories of special status species, including threatened or endangered species and BLM special status (designated sensitive) and State of Nevada protected species. Table 3-53 lists special status species, their BLM, state, and federal status, and their likely occurrence in the greater study area and potentially within the construction right-of-way. Figures 3-96 through 3-98 show documented locations of special status species in the study area from the Nevada Natural Heritage Program database. Not all special status species listed in Table 3-53 appear on the figures because DOE obtained the additional information in the table from personnel affiliated with appropriate resource management agencies, including the BLM, the U.S. Fish and Wildlife Service, the Nevada Department of Wildlife, or the Nevada Division of Forestry, and obtained the specific locations of the special status species from a review of the Natural Heritage Program database (DIRS 182061-NNHP 2005, all). The review of the Nevada Natural Heritage Program database for the study area revealed 24 special status species that have been documented as occurring within the study area.

3.2.7.3.3.1 Threatened and Endangered Species. Table 3-53 identifies six federally listed plant and wildlife species, or candidates for listing, with the potential to occur along the Caliente rail alignment, including one plant, one fish, one reptile, and three bird species. However, in 2007 the U.S. Fish and Wildlife Service delisted the bald eagle and the golden eagle. These two species are protected under the Bald and Golden Eagle Protection Act, but are no longer federally listed (See Section 3.2.7.3.3.2). There are no federally listed mammal species along the Caliente rail alignment.

Plants The threatened Ute ladies'-tresses orchid has the potential to occur in the area of the Caliente alternative segment. However, the alternative segment is within the southernmost extent of potential Ute ladies'-tresses habitat. A petition to delist the Ute ladies'-tresses was filed with the U.S. Fish and Wildlife Service in 2004. In its 90-day finding on this petition, the U.S. Fish and Wildlife Service stated that the petition presented substantial new information on the orchid, and that the Service was initiating a 5-year status review to determine if delisting of this species is warranted (50 CFR 17). Until this review is completed and the Service issues the 12-month finding, the Ute ladies'-tresses orchid will continue to be addressed as a ***threatened species***.

An historic observation of the Ute ladies'-tresses orchid was documented in 1936 approximately 8 kilometers (5 miles) north of the Caliente and Eccles alternative segments near Panaca Spring (Meadow Valley Wash watershed). Until recently, this species was believed to no longer exist in Nevada (*Endangered and Threatened Wildlife and Plants; Final Rule to List the Plant Spiranthes Diluvialis (Ute Ladies'-Tresses) as a Threatened Species* [57 *FR* 2048, January 17, 1992]). However, in July 2005, the population at Panaca Spring was rediscovered and included 80 to 100 individual plants (DIRS 176365-Fertig et al. 2005, p. 12). The Ute ladies'-tresses orchid is associated with moist soil conditions, which in the southwest can include perennial streams or washes, floodplains or spring-fed stream channels, or wetlands. There is no designated critical habitat for this species within the study area (DIRS 174439-Williams 2005). However, there is a potential for the Ute ladies'-tresses orchid to occur within Meadow Valley Wash between Panaca and Caliente, along the proposed Caliente alternative segment (DIRS 181606-Rautenstrauch 2007, all).

Fish The endangered Railroad Valley springfish was reportedly introduced into Warm Springs near the Warm Springs summit, north of U.S. Highway 6. The Nevada Natural Heritage Program documented the occurrence approximately 3.3 kilometers (2 miles) northeast of Caliente common segment 3 (see Figure 3-93). A survey of the springs in 1994 indicated that the springfish was no longer present in this area, and the Draft Ely District Resource Management Plan indicates that the introduction failed (DIRS 174518-BLM 2005, p. 3.7-5). This fish is typically found in warm spring pools, outflow streams, and adjacent marshes.

Figure 3-98. Occurrences of special status species documented in the Nevada Natural Heritage Program database adjacent to the Oasis Valley alternative segments and the Yucca Mountain Site.

Amphibians and Reptiles The desert tortoise, which is listed as threatened under the Endangered Species Act and by the State of Nevada (Mojave Desert population only), is found along the southern end of the Caliente rail alignment from approximately Beatty Wash to Yucca Mountain (DIRS 101830-Bury et al. 1994, pp. 57 to 72). The desert tortoise's range in this portion of Nevada extends approximately 16 kilometers (10 miles) north of Beatty near Springdale (DIRS 176649-FWS 2003, p. 7). About 48 kilometers (30 miles) of the rail alignment would be within potentially suitable desert tortoise habitat, including common segment 6 and the Rail Equipment Maintenance Yard (Figure 3-99). Mojave Desert tortoises are generally confined to warm, creosote bush and shadscale (*Atriplex confertifolia*) scrub habitats with well-drained sandy ***loam*** soils. These soils are composed of sand or sandy gravel that permit the tortoises to burrow and nest (DIRS 102475-Brussard et al. 1994, p. 15). The area through which common segment 6 would pass and the location of the Rail Equipment Maintenance Yard are not designated as critical habitat for the desert tortoise. This area is primarily considered low-density for the desert tortoise, with the population of tortoises at a low level in relation to other areas within the range of this species in Nevada.

Birds Until recently, the yellow-billed cuckoo, which is a federal ***candidate species*** under the Endangered Species Act, had been considered to no longer exist in Nevada; however, recent U.S. Fish and Wildlife Service survey data indicated that at least one nesting pair has been observed along the Meadow Valley Wash area in southeastern Nevada approximately 27 kilometers (17 miles) south of the City of Caliente (DIRS 173227-Micone and Tomlinson 2000; DIRS 173228-Gallagher et al. 2001, p. 10; DIRS 173229-Furtek et al. 2002, p. 13-21; DIRS 173230-Furtek et al. 2003, p. 18-23; DIRS 173231-Furtek and Tomlinson 2003, p. 16-22). Yellow-billed cuckoos nest in tall cottonwood trees and willow riparian woodlands in the West and require patches of an average of 0.17 square kilometers (42 acres) of dense riparian habitat with at least 0.03 square kilometers (7 acres) of it closed canopy (DIRS 175505-Laymon and Halterman 1987, pp. 19 to 25). There is no suitable breeding habitat for yellow-billed cuckoos within the Caliente rail alignment construction right-of-way (DIRS 182308-Rautenstrauch 2006, all). There is an area of marginally suitable migratory or non-nesting yellow-billed cuckoo habitat approximately 320 meters (1,050 feet) long on the northern border of the City of Caliente. This habitat is between U.S. Highway 95 and the Caliente rail alignment and outside the construction right-of-way. There is also a stand of riparian vegetation west of the Eccles Interchange Yard location along Clover Creek; although suitable for migratory or non-nesting yellow-billed cuckoos, this area is outside the Caliente rail alignment construction right-of-way. This area of riparian vegetation would not be disturbed during the construction of the Eccles Interchange Yard. The lack of confirmed records for this species throughout Nevada and the lack of sufficient breeding habitat within the Caliente rail alignment construction right-of-way suggest that it is highly unlikely that the yellow-billed cuckoo would occur within the project area.

The southwestern willow flycatcher, listed as endangered under the Endangered Species Act, is potentially present in Nevada from May through September and breeds in dense riparian habitat. This species' preferred habitat is typically dominated by willows, cottonwood, or invasive tamarisk. The southwestern willow flycatcher has been observed in dense stands of riparian vegetation in Meadow Valley Wash in Lincoln County. Potential habitat exists along Meadow Valley Wash; however, substantial flood events and recent construction efforts in the area have greatly reduced the amount of potential flycatcher habitat in this area. The closest recorded occurrence of this species within Meadow Valley Wash was approximately 12 kilometers (7.5 miles) from the beginning of the Caliente alternative segment, south of the City of Caliente (DIRS 182061-NNHP 2005, all). There is no suitable breeding habitat for southwestern willow flycatchers within the construction right-of-way (DIRS 182308-Rautenstrauch 2006, all). There is an area of marginally suitable migratory or non-nesting habitat for southwestern willow flycatchers approximately 320 meters (1,050 feet) long on the northern border of the City of Caliente to the confluence of Meadow Valley Wash and Antelope Canyon Wash.

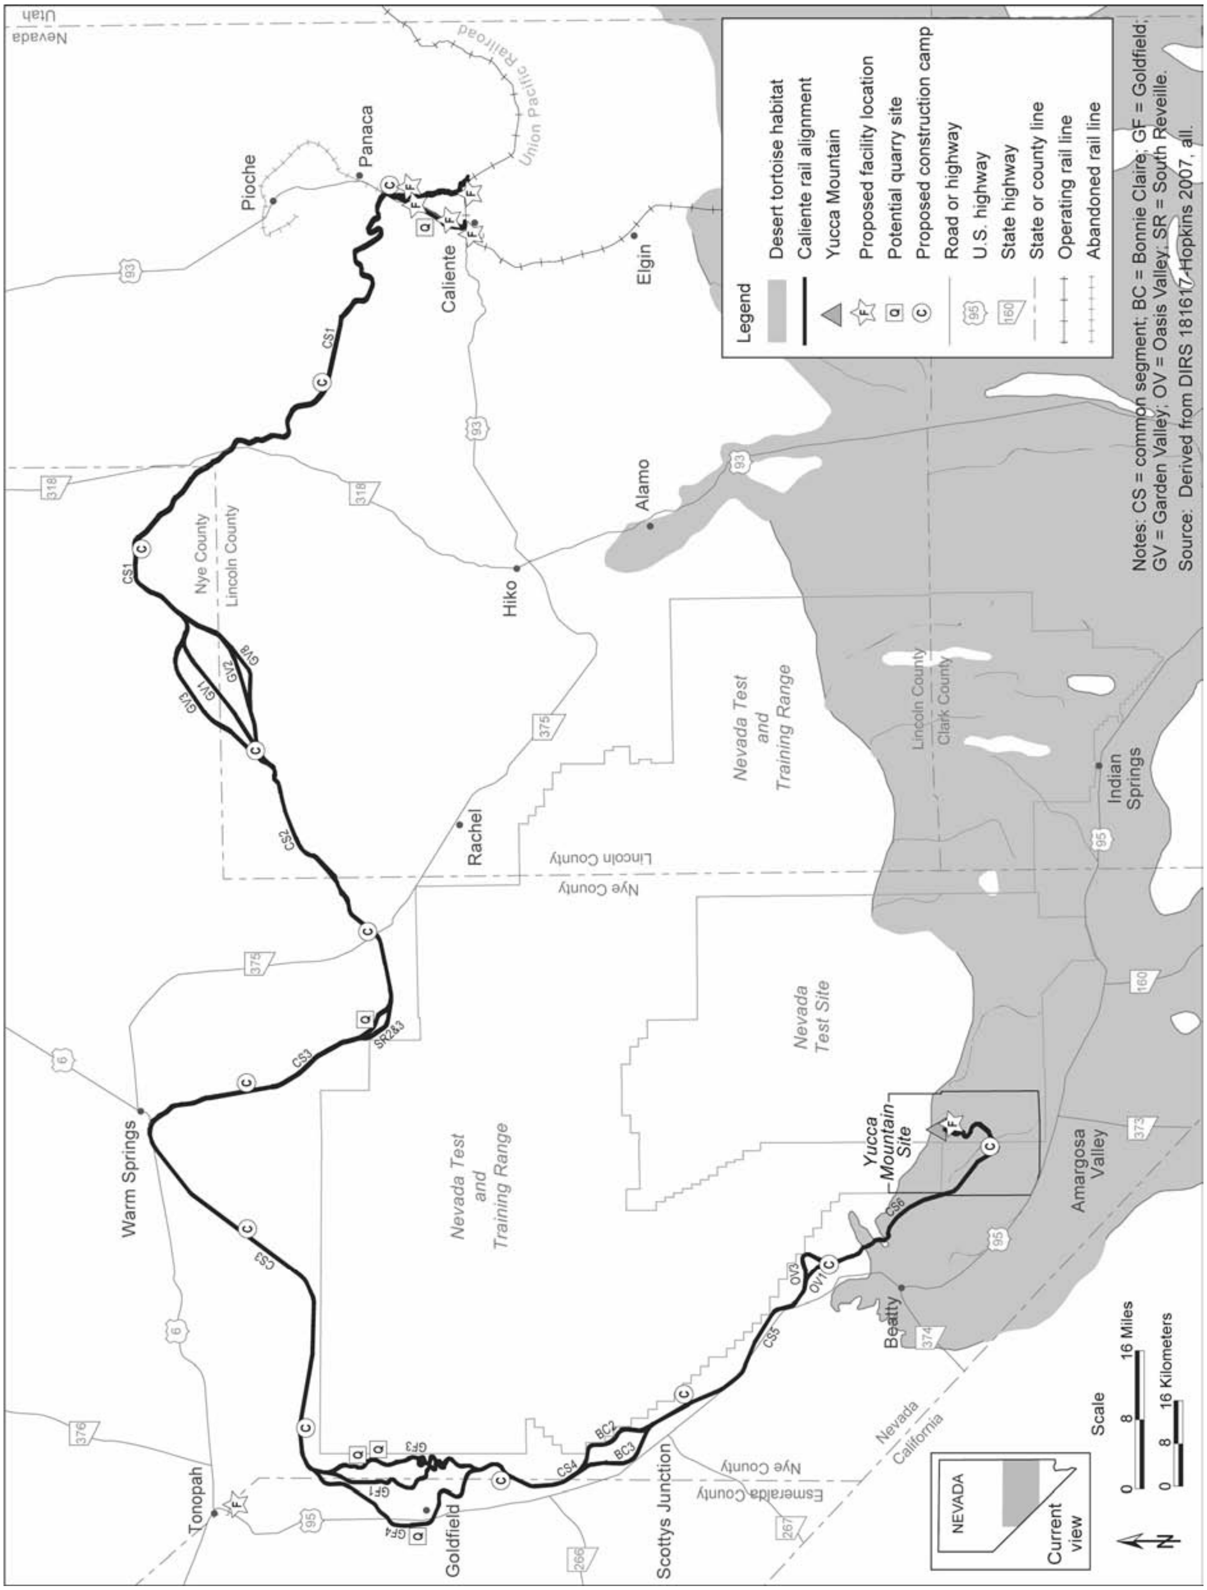

Figure 3-99. Estimated northern extent of potential desert tortoise habitat in relation to the Caliente rail alignment.

There are scattered occurrences of willows and cottonwoods within this stretch of riparian habitat and within the construction right-of-way but adjacent to the old rail roadbed where the new rail line would be constructed. There is a small amount, about 20 to 30 meters (66 to 98 feet), of riparian habitat to the north and west of the Antelope Canyon Wash bridge crossing. This area is between U.S. Highway 95 and the proposed construction right-of-way along the Caliente alternative segment. There is also a stand of riparian vegetation west of the proposed location of the Eccles Interchange Yard along Clover Creek, outside the construction right-of-way, which could be suitable for migrating and non-nesting southwestern willow flycatchers. This area of riparian vegetation would not be disturbed during construction of the Eccles Interchange Yard. Southwestern willow flycatchers have also been documented approximately 19 kilometers (12 miles) north of Beatty, near Oasis Valley (DIRS 182061-NNHP 2005, all). This recorded occurrence was approximately 4.4 kilometers (2.7 miles) southwest of Oasis Valley alternative segment 1 and well outside the Caliente rail alignment construction right-of-way.

3.2.7.3.3.2 BLM Special Status and State of Nevada Protected Species. The BLM State Office and the State of Nevada have identified a number of species as requiring conservation and protection. The BLM State Office designates species as sensitive and the State of Nevada designates species protected. Many of the species designated as sensitive by the BLM are also designated as protected by the State of Nevada. Additionally, a few BLM-designated sensitive species and State of Nevada-designated protected species are also listed as threatened, endangered, proposed, or candidate under the Endangered Species Act. Table 3-53 lists BLM-designated sensitive and State of Nevada-designated protected species and provides information on their status and known or potential locations along the Caliente rail alignment. These species are described below by plant and animal categories.

Plants DOE performed field surveys in May 2005 to confirm the presence of BLM-designated sensitive species and to identify potential habitat for such species along the Caliente rail alignment. Appendix H contains detailed survey information. In addition to location records for BLM-designated sensitive species obtained from the Nevada Natural Heritage Program (DIRS 182061-NNHP 2005, all), these species were passively observed during field surveys in other locations with habitat characteristics of the species. Because the field surveys did not cover the entire construction right-of-way, and there is both seasonality to the presence or absence of visible signs of plants and annual variability among plant species, the fact that a BLM-designated sensitive species was not documented at a specific location does not indicate a definitive absence of the species.

The Eastwood milkweed has been documented 140 meters (460 feet) west of Goldfield alternative segment 4, near Mud Lake. Surveys in May 2005 in this location documented an individual Eastwood milkweed plant within the construction right-of-way of Goldfield alternative segment 4. Typical habitat for this species consists of sandy soils in mixed desert shrub or salt desert scrub, including blackbrush (*Coleogyne ramosissima*) and sagebrush from 1,130 to 2,000 meters (3,700 to 6,500 feet) elevation (DIRS 176456-Welsh et al. 1993).

Needle Mountains milkvetch has been recorded in large populations within approximately 0.8 kilometer (0.5 mile) of the Eccles alternative segment (DIRS 182061-NNHP 2005, all). Field surveys identified this species in the gravelly, eroded sandstone badlands between the areas east of Bennett Pass to where the Caliente or Eccles alternative segment would join Caliente common segment 1, and continuing south along the Eccles alternative segment to the dirt road between U.S. Highway 93 and Beaver Dam State Park and outside the construction right-of-way. This species typically occurs in deep, sandy, gravelly, or clay soils and is frequently found in or along drainages. Although this species appears to be locally common, its distribution is patchy, and habitat outside this area is rare.

The black woollypod has been observed approximately 6 kilometers (4 miles) east of U.S. Highway 95 near Beatty Wash. Field surveys along common segment 6 in Beatty Wash confirmed the presence of this species in the study area but outside the construction right-of-way. This plant is common locally on very steep, gravelly slopes of light-colored volcanic tuff in the area where there is little competition from other species. Habitat for this species is characterized by open, talus, or gravelly slopes on alluvium soils composed of volcanic tuff around 975 to 2,340 meters (3,200 to 7,700 feet) elevation (DIRS 181872-NNHP 2001, all).

Long-calyx eggvetch has been recorded in the vicinity of the Highland Range, approximately 4.5 kilometers (2.8 miles) north of Bennett Pass, just west of Panaca within the study area but outside the construction right-of-way. There is very little information on the habitat of this species in Nevada. Typical habitat includes pinyon-juniper associations and other mixed-shrub communities (DIRS 176456-Welsh et al. 1993), which occur at elevations of 1,770 and 2,300 meters (5,800 and 7,550 feet) throughout the Great Basin.

White River catseye is known to occur in gravelly, eroded sandstone badlands between the areas east of Bennett Pass to where the Caliente or Eccles alternative segment would join Caliente common segment 1, and continuing south along the Eccles alternative segment to the dirt road between U.S. Highway 93 and Beaver Dam State Park. It has also been recorded in the Meadow Valley watershed near the Caliente alternative segment; however, the location description puts the species in a wet meadow, which is not typical habitat for the species. No White River catseye were observed in the construction right-of-way during field surveys; however, this species has been documented approximately 200 meters (660 feet) south of Garden Valley alternative segment 3.

Rock purpusia has been documented approximately 13 kilometers (8 miles) from common segment 6 within the study area but outside the construction right-of-way. No systematic surveys have been completed for this species; therefore, there is no habitat and range information. Studies at the Nevada Test Site show this species tends to occur in cliff crevices and boulders on volcanic and possibly carbonate rocks in the upper mixed-shrub, sagebrush, and pinyon-juniper zones (DIRS 180962-NatureServe Explorer 2007, all).

Pioche blazingstar is a newly described species that has been documented approximately 7.5 kilometers (4.7 miles) north of Bennett Pass, less than 1.6 kilometers (1 mile) east of Panaca. This species appears to be restricted to barren clay knolls and slopes between Panaca and the Patterson Wash area of southern Lake Valley and is known from only five reported occurrences in this area of Nevada (DIRS 181846-NatureServe 2007, all).

Tiehm blazingstar has been documented in the White River Valley, west of the White River approximately 1.6 kilometers (1 mile) from Caliente common segment 1. Field surveys conducted in May 2005 did not detect the presence of this species at the location described by the Nevada Natural Heritage Program (DIRS 182061-NNHP 2005, all). Additionally, no occurrences were documented along the Caliente rail alignment construction right-of-way in the White River Valley, although it is possible that the plant would not have matured enough to be identified. Other occurrences of this species were recorded approximately 40 kilometers (25 miles) to the north, near Sunnyside, in an area dotted with knolls of white, chalky soil, the type of habitat typically associated with this species. The area in White River Valley consists of a series of gravelly mesas separated by steep washes and lacks the white chalky soil found to the north.

A population of the Nevada dune beardtongue was documented during field surveys along the Caliente rail alignment within the Sarcobatus Flats area outside the construction right-of-way. This species is common locally in a sandy area along common segment 5 on both sides of a bisecting secondary road, but appears restricted to this area of deep, sandy soil. Typical habitat for this species consists of deep, loose sandy soils of valley bottoms, often in alkaline areas, sometimes on road banks and other previously disturbed areas with associated vegetation including shadscale, four-winged saltbush (*Atriplex canescens*), and rabbitbrush (*Chrysothamnus nauseosus* spp.) (DIRS 180960-NatureServe Explorer 2007, all).

Bashful beardtongue, also known as the Kawich Range beardtongue, has been documented along the Caliente rail alignment where it would pass through the Kawich Range at Warm Springs Summit. This species has a narrow distribution and is known from only five sites within the Kawich Range. Typical habitat for this species includes coarse rocky slopes in pinyon-juniper or mountain mahogany woodlands and sagebrush communities around 2,300 to 2,700 meters (7,500 to 8,900 feet) elevation (DIRS 181882-NNHP 2001, all).

Williams combleaf has been found within the Kawich Range approximately 10 kilometers (6 miles) south of the study area along Caliente common segment 3 but outside the construction right-of-way. This species has a small range in Nevada and is found in relatively barren sandy to sandy-clay soils associated with high elevation non-alkaline seasonal lakes in sagebrush, pinyon-juniper zones around 1,700 to 2,700 meters (5,700 to 8,900 feet) (DIRS 181881-NNHP 2001, all).

The Tonopah fishhook cactus has been recorded near the Caliente rail alignment in Reveille Valley. Only general locations of this species are included in the Nevada Natural Heritage Program database (DIRS 182061-Hopkins 2005) because of the risk of illegal collection. Field surveys consisting of two 1.6-kilometer (1-mile) transects perpendicular to the rail alignment in Reveille Valley did not locate any Tonopah fishhook cacti within the construction right-of-way. This species is typically found in dry, rocky soils or outcrops, or under shrubs in the upper salt desert and lower sagebrush zones (DIRS 181880-NNHP 2001, all).

A population of the Schlesser's pincushion was recorded 640 meters (2,100 feet) north of the Caliente rail alignment near the city of Panaca. The habitat for this species is typified by open, gravelly or sandy-clay soils, with dense shrubs or grass canopies dominated by shadscale shrubs (DIRS 181879-NNHP 2001, all). Surveys along the rail alignment nearest the recorded occurrence, east of Bennett Pass to where the Caliente or Eccles alternative segment would join Caliente common segment 1, found no Schlesser's pincushion.

As defined in Section 3.2.7.3.3, special status species are species that are afforded some level of protection or special management under federal or state laws or regulations. As such, all cacti and yucca are considered special status because they are protected by the State of Nevada and the BLM. All cacti, yucca, and Christmas trees have special consideration under Nevada Revised Statutes Section 527.050 and are protected from unauthorized removal. Removal or possession of any cactus, yucca, or Christmas tree for commercial purposes on any state, county, or privately owned land is regulated by the State Forester Fire Warden. Removal of such species from private lands would require a permit requisition from the State Forester Fire Warden. DOE would salvage minimal amounts of cacti and yucca within the construction right-of-way in accordance with this law and the requirements of applicable land management agencies during the construction phase. Stipulations for salvage are outlined in BLM Manual 6840, *Special Status Species Management* (DIRS 172901-BLM 2001, all).

Invertebrates The Oasis Valley pyrg, a snail, is known to occur in the Amargosa River drainage in Oasis Valley. Specifically, this snail has been observed in an unnamed spring near Fleur de Lis Spring 12 kilometers (7.5 miles) north-northeast of Beatty (DIRS 104593-CRWMS M&O 1999, p. K-6) and potentially inhabits other springs in the Amargosa River drainage. This snail inhabits small springs and stream outflows where it is typically found on stone, travertine, watercress, and plant debris (DIRS 175029-NatureServe Explorer 2007, all). There is no recorded occurrence of this snail in the construction right-of-way.

Fish The Meadow Valley Wash desert sucker is also found in Meadow Valley Wash (DIRS 104593-CRWMS M&O 1999, pp. E-2 and E-4) and in the White River drainage. This subspecies is typically found in small- to moderate-sized streams, often with pools and riffles or shallow areas, with mainly gravel-rubble, sandy silt substrates (DIRS 180964-NatureServe Explorer 2007, all).

The Meadow Valley Wash speckled dace has been historically observed in Meadow Valley Wash approximately 60 meters (200 feet) northwest of the Caliente rail alignment (DIRS 182061-NNHP 2005, all; DIRS 104593-CRWMS M&O 1999, pp. 3-23, E-2, and E-4). This subspecies has a very limited range and is only known within this watershed. Specific distribution of this fish varies within Meadow Valley Wash due to water availability within the wash.

The Oasis Valley speckled dace occurs in the Amargosa River drainage and Fleur de Lis Spring near the towns of Springdale and Beatty, less than 1.6 kilometers (1 mile) from Oasis Valley alternative segment 1. This subspecies has a very limited range and is only known from the watershed in Oasis Valley. Specific distribution of this fish varies with available water (DIRS 181847- NatureServe 2007).

Amphibians and Reptiles The Amargosa toad is found in or near riparian habitats associated with the Amargosa River drainage (Oasis Valley) and at Fleur de Lis Spring, Crystal Spring, Indian Spring, and other springs and seeps near the towns of Springdale and Beatty (DIRS 174414-Stebbins 2003, pp. 209 and 210; DIRS 104593-CRWMS M&O 1999, p. 3-20). Vegetation bordering this toad’s habitat includes cottonwood trees, cattails, and sedges. Adult toads hide and rest under bushes and in rodent burrows, and generally hibernate from November to March. In the late summer and fall, adult toads have been documented as traveling more than 183 meters (600 feet) from water sources. If moist soil is available, open water might not be necessary for the adult toad to survive (DIRS 176795-BLM [n.d.]).

The southwestern toad (also known as Arizona toad) has been documented in locations in Meadow Valley Wash near the City of Caliente, and also within Clover Creek (DIRS 174048-Bennett and Thebeau 2005). Specifically, this toad has been documented approximately 0.8 kilometer (0.5 mile) south of the Caliente alternative segment and approximately 4.8 kilometers (3 miles) south of the Eccles alternative segment in Clover Creek outside the construction right-of-way. This species can be found in cottonwood-willow associations, creeks, pools, irrigation ditches, flooded fields, and reservoirs. This toad normally breeds in low- to moderate-gradient streams and is not dependent on rainfall (DIRS 174414-Stebbins 2003, pp. 213 and 214; DIRS 175487-NatureServe Explorer 2007). There were no southwestern toads found within the Caliente rail alignment study area during the 2005 field surveys. However, the potential presence of this species cannot be discounted, because the survey of potentially suitable toad habitat was limited to areas that were accessible and along the construction right-of-way. Thus, the survey excluded large areas of potentially suitable habitat on private property to which DOE had no access.

Chuckwalla has been documented in the southeastern foothills of Yucca Mountain, adjacent to common segment 6 but outside the construction right-of-way. This area represents the chuckwalla’s northern-most range in southern Nevada. This large lizard is typically found among talus slopes, large rocky outcrops and boulders, which provide cover and basking sites (DIRS 174414-Stebbins 2003, pp. 269 and 270).

Birds Western burrowing owls are known to occur throughout the Mojave and Great Basin Deserts (DIRS 176455-Dickinson ed. 1999, p. 256). DOE identified one burrowing owl burrow, which appeared to be active, within the Caliente rail alignment study area in the vicinity of Yucca Mountain. Typical burrowing owl habitat is characterized by well-drained, level-to-gently sloping areas in arid or semi-arid environments. This species has been known to overwinter throughout Nevada; however, they are predominantly encountered during their breeding season from mid-March through September (DIRS 176361-Klute et al. 2003, p. 1-12).

The greater sage-grouse is a BLM-designated sensitive bird species that is also listed as a game species by the State of Nevada. Greater sage-grouse are found exclusively in sagebrush habitat. Although sage-grouse are sagebrush obligate species, they require a variety of habitats within the landscape throughout the year, including various conditions and communities of sagebrush, meadow, and riparian habitats. The Caliente rail alignment would cross the extreme southern portion of the range of the greater sage-grouse. Big sagebrush and other sagebrush species provide nesting, brood, fall/winter cover, and forage throughout the year for the greater sage-grouse. Suitable winter habitat for the greater sage-grouse consists of big sagebrush stands comprised of 10 to 30 percent horizontal sagebrush cover and a diversity of sagebrush heights that are generally tall enough to emerge through any accumulated snow, and ridges or canyons where sagebrush is exposed. Nesting habitat is characterized by big sagebrush communities that have 15 to 38 percent canopy cover and 10 to 15 percent grass. Nesting habitat is usually close to leks (communal courtship and breeding sites in open areas surrounded by sagebrush cover). Nesting and early brood rearing in Nevada usually occurs during April through June in habitat with nearby sagebrush cover and an abundance of grass and forbs to provide nutrition for chicks. After about 6 weeks, hens move chicks to summer habitat for the remaining brood rearing. Summer habitat for this species is characterized by mixed sagebrush with wet meadows and riparian habitat (DIRS 173575-NDOW 2004, Appendix E, p. 2-3). The 2004 Conservation Assessment for *The Greater Sage-Grouse Management Plan for Nevada and Eastern California* shows the largest populations of sage-grouse to inhabit most of Elko county and portions of Washoe, White Pine, Humboldt, Lincoln, and Nye counties (of these, the proposed Caliente rail alignment would pass through Lincoln and Nye Counties). Documented lek sites in Nye County are concentrated in the north-central portion of the county, outside the study area. However, there is suitable winter, year-round, and nesting habitat along Caliente common segment 3 outside of the construction right-of-way. There is suitable winter habitat within the construction right-of-way of all Garden Valley alternative segments and within the northern portion of Caliente common segment 1 and a portion of the Caliente common segment 3 construction right-of-way (Figure 3-100). There are documented lek sites within the construction right-of-way of Garden Valley alternative segment 3 (DIRS 173575 NDOW 2004, p. 12). No greater sage-grouse or sage-grouse leks were observed in the construction right-of-way during the field surveys of the Caliente rail alignment in the spring of 2005. Appendix H provides additional information on the greater sage-grouse surveys.

Bald eagles almost exclusively occupy habitat associated with large bodies of water during the breeding season, but occasionally use upland areas for food and roost sites. They usually nest in tall trees and feed opportunistically on fish, waterfowl and seabirds, various mammals, and carrion. In the winter, bald eagles preferentially roost in large, shelter-providing trees (DIRS 180967-NatureServe Explorer [n.d.], all). There is no nesting habitat for the bald eagle within the Caliente rail alignment study area. The marsh habitat in Indian Cove and Meadow Valley Wash provides potential foraging habitat for migrating eagles. However, the waterbodies are small and not used by enough fish and waterfowl to support wintering eagles. Any use of the study area by bald eagles would be transitory.

Ferruginous hawks have been reported to occupy and, in some cases, nest in areas adjacent to the Caliente rail alignment (DIRS 174519-Bennett 2005). The ferruginous hawk is a relatively rare breeding species in the study area. This species prefers to nest in trees; however, in Nevada tall trees are scarce, so the species is often found in pinyon-juniper associations or occasionally on shrubs or rocks on the ground. No ferruginous hawks or nests were observed during the 2005 field surveys, although they have been previously reported in the area.

Peregrine falcons are found in a wide variety of habitats during the breeding season, from tundra, moorlands, steppe, and seacoasts to mountains, open-forested regions, and human population centers. They typically nest on rocky cliffs.

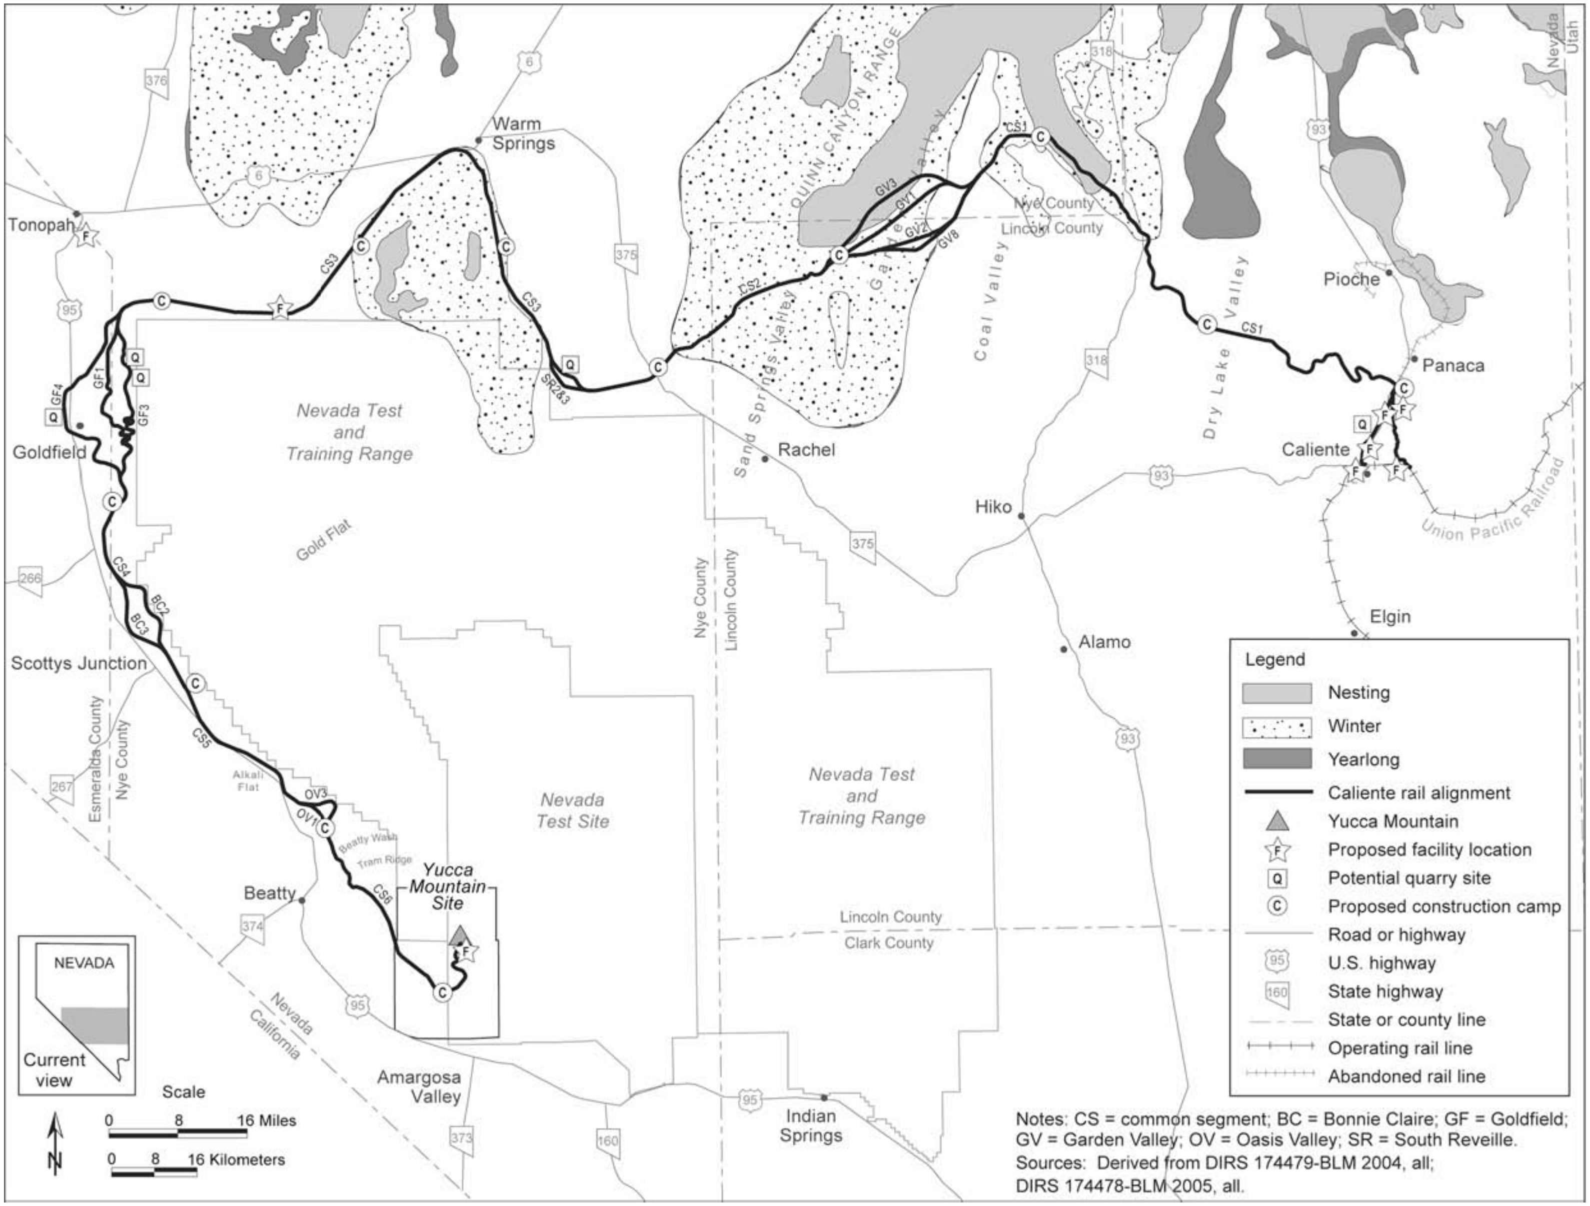

Figure 3-100. Potential greater sage-grouse habitat along the Caliente rail alignment.

Outside the breeding season, the falcons occur in areas where prey (primarily birds) concentrate, including farmlands, marshes, lakeshores, river mouths, tidal flats, dunes and beaches, broad river valleys, cities, and airports (DIRS 180966-NatureServe Explorer 2007, all). There is potential nesting habitat for peregrine falcons on cliffs within the Clover Creek area and near the City of Caliente.

Loggerhead shrikes have been documented along the Caliente rail alignment where suitable habitat is present. Habitat used by this species during the breeding season includes open country with scattered trees and shrubs, savanna, desert scrub (southwestern United States) and, occasionally, open woodlands (DIRS 180963-NatureServe Explorer 2007, all). They typically nest in thick brush, shrubs, or small trees in open areas. Potentially suitable habitat for loggerhead shrikes occurs along all segments of the Caliente alignment.

Sage thrashers are known to occur in sagebrush habitat within the Caliente rail alignment construction right-of-way. During Field surveys in May 2005, an individual was sighted near Pahroc Pass within the common segment 1 study area in the Highland Range. Habitat for this bird species is associated with large stands of sagebrush habitat, which can be found in areas where the rail alignment would cross mountain ranges, including the Highland, Reveille, and Kawich Ranges. There is potential sagebrush habitat near Bennett Pass, Pahroc Pass, the western and southern portions of Garden Valley, western Sand Spring Valley, southeastern Railroad Valley, and at Warm Springs Summit.

Brewer’s sparrows are strongly associated with sagebrush over most of their range, in areas with scattered shrubs and short grass (DIRS 180959-NatureServe Explorer 2007, all). Sagebrush habitat can be found in areas where the rail alignment would cross mountain ranges, including the Highland, Reveille, and Kawich Ranges. There is potential sagebrush habitat near Bennett Pass, Pahroc Pass, the western and southern portions of Garden Valley, western Sand Spring Valley, southeastern Railroad Valley, and at Warm Springs Summit. Brewer’s sparrows are likely to occur in sagebrush habitat within the Caliente rail alignment construction right-of-way.

Mammals The State of Nevada classifies desert bighorn sheep as a game species. As further discussed in Section 3.2.7.3.5, the State of Nevada manages the desert bighorn sheep as a game species throughout the state.

The pygmy rabbit (*Brachylagus idahoensis*), a small sagebrush-dependent rabbit, has been documented 7.5 kilometers (4.6 miles) northwest of Garden Valley alternative segment 3 (DIRS 174519-Bennett 2005, Plate 3). This species is well-distributed throughout the Great Basin; however, overall the populations tend to be locally clustered in areas of high-density sagebrush, which they use for both cover and food. DOE field surveys did not indicate the presence of pygmy rabbit habitat within the Caliente rail alignment construction right-of-way.

The dark kangaroo mouse and the closely related pale kangaroo mouse are known to occur in appropriate habitat from the Dry Lake Valley to Goldfield (DIRS 174519-Bennett 2005). Habitat for these two mouse species is characterized by alkali (salt) sinks and desert scrub dominated by shadscale or big sagebrush. These rodents usually prefer soft sand accumulated at bases of shrubs for burrow sites (DIRS 176370-O’Farrell and Blaustein 1974, p. 1-2; DIRS 176372-O’Farrell and Blaustein 1974, p. 1).

There are 23 species of bats in Nevada. In general, bats are highly mobile; all of the 23 species could at some time of the year fly over or, if appropriate habitat exists, roost and forage near the Caliente rail alignment. Twenty-one of the 23 species of bats in Nevada are BLM-designated sensitive (DIRS 172900-BLM 2003, p. 2) and nine are State of Nevada protected.

Of these bat species, seven have a strong probability of utilizing habitat along the rail alignment (DIRS 181865 Bradley et al. 2006), as follows:

- Pallid bat
- Townsend's big-eared bat
- Big brown bat
- California myotis bat
- Small-footed myotis bat
- Western pipistrelle bat
- Brazilian free-tailed bat

All of these bat species are commonly found throughout the Mojave and southern Great Basin Deserts. These species are known to roost in cliff faces, caves, rocky outcrops, and man-made structures where available. Bats are also known to forage over natural or artificial water sources.

3.2.7.3.4 Migratory Birds

More than 300 species of birds are commonly observed in southern Nevada, including year-round residents, seasonal migrants that breed in southern Nevada, winter residents that breed in the north, and seasonal migrants that pass through southern Nevada while traveling in spring and fall between breeding ranges to the north and winter ranges to the south. All of the migratory birds found along the Caliente rail alignment are protected under the Migratory Bird Treaty Act (16 U.S.C. 703 *et seq*.) and Executive Order 13186.

3.2.7.3.5 State of Nevada Game Species

The Caliente rail alignment would cross several areas designated as game habitat (DIRS 173224-BLM 1997, Maps 9-13; DIRS 174518-BLM 2005, Maps 3.6-1 through 3.6-4). As shown in Table 3-53, three game species that occur, or have the potential to occur, within or near the construction right-of-way are cross-listed as BLM-designated sensitive, are state protected, or both. The game species that are also BLM-designated sensitive include greater sage-grouse, pygmy rabbit, and desert bighorn sheep. Section 3.2.7.3.3.2 provides information on the greater sage-grouse and pygmy rabbit. The Nevada Department of Wildlife actively manages the desert bighorn sheep as a big game animal. Its distribution is shown on Figure 3-98. Other game species that could be affected by the proposed railroad construction and operation include mule deer, pronghorn antelope, elk, and mountain lion. Figures 3-101 to 3-104 indicate the general habitat locations for desert bighorn sheep, mule deer, pronghorn antelope, and elk. Mountain lions occur throughout the State of Nevada in canyon, mountain, and forested areas; therefore, no distribution map is included for this species. Sections 3.2.7.3.5.1 through 3.2.7.3.5.5 summarize game species information.

3.2.7.3.5.1 Desert Bighorn Sheep. Desert bighorn sheep are found predominantly in lower foothills and grasslands of mountain ranges, often where terrain is rough, rocky and steep, and broken up by canyons and washes. Desert bighorn sheep require access to freestanding water, especially during the summer, and distribution of water holes significantly influences patterns of home-range movement (DIRS 176363-Shackleton 1985, p. 4). Any natural or artificial water sources within this species' range could be subject to desert bighorn sheep use. Caliente common segment 1 would cross year-round desert bighorn sheep habitat near the Pahroc Range, and common segment 6 would cross a ***movement corridor***, or an area of high use at certain times of the year, in the Beatty Wash area (Figure 3-101). The Caliente rail alignment would not cross any crucial habitat for this species.

3.2.7.3.5.2 Mule Deer. Mule deer are fairly common in southern Nevada and throughout the western United States, and are found in a variety of habitats from coniferous forests at high elevations to desert shrub, chaparral, and grasslands at lower elevations (DIRS 176454-Whitaker 1992, p. 652). Mule deer are often associated with early transitional vegetation, especially near agricultural lands. Mule deer are found throughout the area the Caliente rail alignment would cross, but would most likely be encountered in the segments from Warm Springs Summit (Kawich Range) eastward. The eastern portion of Caliente common segment 1 would pass through year-round mule deer habitat. The western portion of Caliente common segment 1, Garden Valley alternative segments, much of Caliente common segment 2, and Caliente common segment 3 at the Warm Springs summit would cross mule deer winter habitat. Figure 3-102 details habitat for mule deer. The rail alignment would not cross any mule deer crucial habitat.

3.2.7.3.5.3 Pronghorn Antelope. Most of the Caliente rail alignment would cross year-round pronghorn antelope habitat from Dry Lake Valley west to Goldfield (Figure 3-103). Pronghorn antelope are generally found at lower elevations in open desert grasslands, salt desert scrub, or bunchgrass-sagebrush vegetation in the valleys and foothills throughout the western United States. This species also occurs in dense sagebrush communities at higher elevations during the breeding season (DIRS 176454-Whitaker 1992, pp. 662 and 663). NDOW has not identified any areas along the Caliente rail alignment as pronghorn antelope augmentation areas.

3.2.7.3.5.4 Elk. Elk are known to have summer, winter, and year-round ranges along portions of the Caliente rail alignment from Garden Valley and the Quinn Canyon Mountain Range eastward. Elk habitat is usually composed of moderate- to low-density conifer woodlands and open mountain grasslands (Figure 3-104). This species is migratory, moving to lower elevations with dense wooded slopes during the winter (DIRS 176454-Whitaker 1992, pp. 647 to 650).

3.2.7.3.5.5 Mountain Lion. Mountain lions occur throughout the State of Nevada in low numbers in canyon, mountainous, and forested areas (DIRS 103439-Hall 1995, pp. 269 to 271). They are known to occur within the study area and might move along the Caliente rail alignment construction right-of-way. This species is shy, solitary, secretive, and active mostly at night (DIRS 103439-Hall 1995, pp. 269 to 271).

3.2.7.3.6 Wild Horses and Burros

Wild horses are generally presumed to descend from horses that were released by, or escaped from, settlers of western North America, possibly dating as far back as Spanish settlers in the 1600s. The size, color, and confirmation of the horses depend on the type of stock or breed from which the wild horses descended (DIRS 174518-BLM 2005, p. 3.8-1).

Generally, burros live in the lower elevations year-round, while wild horses reside in the higher elevations in summer and migrate to the lower elevations in winter. Both wild horses and burros will travel as far as 16 kilometers (10 miles) away from permanent water sources. Their diets vary–burros prefer shrubs, horses tend to prefer grasses (DIRS 103079-BLM 1998, p. 3-48).

Wild horse herd areas were originally identified by federal agencies in 1971, with passage of Public Law 92-195, the Wild Free-Roaming Horses and Burros Act. The BLM has delineated herd management areas within the wild horse herd areas. Each herd management area has an appropriate management level determined by the BLM through a rangeland assessment and a public review process. The appropriate management level is the number of wild horses and burros the BLM has determined the herd management area can support, and it is established to avoid the ecological degradation of the herd management area and any riparian areas within each herd management area (DIRS 176364-State of Nevada [n.d.], all).

The Caliente rail alignment would cross approximately 13 designated wild horse and burro herd management areas (Figure 3-105). Appendix H provides detailed information on the individual herd management areas. Table 3-54 identifies each Caliente rail alignment alternative segment and common segment that would cross or lie within herd management areas and describes the location, size, and management level of each herd management area.

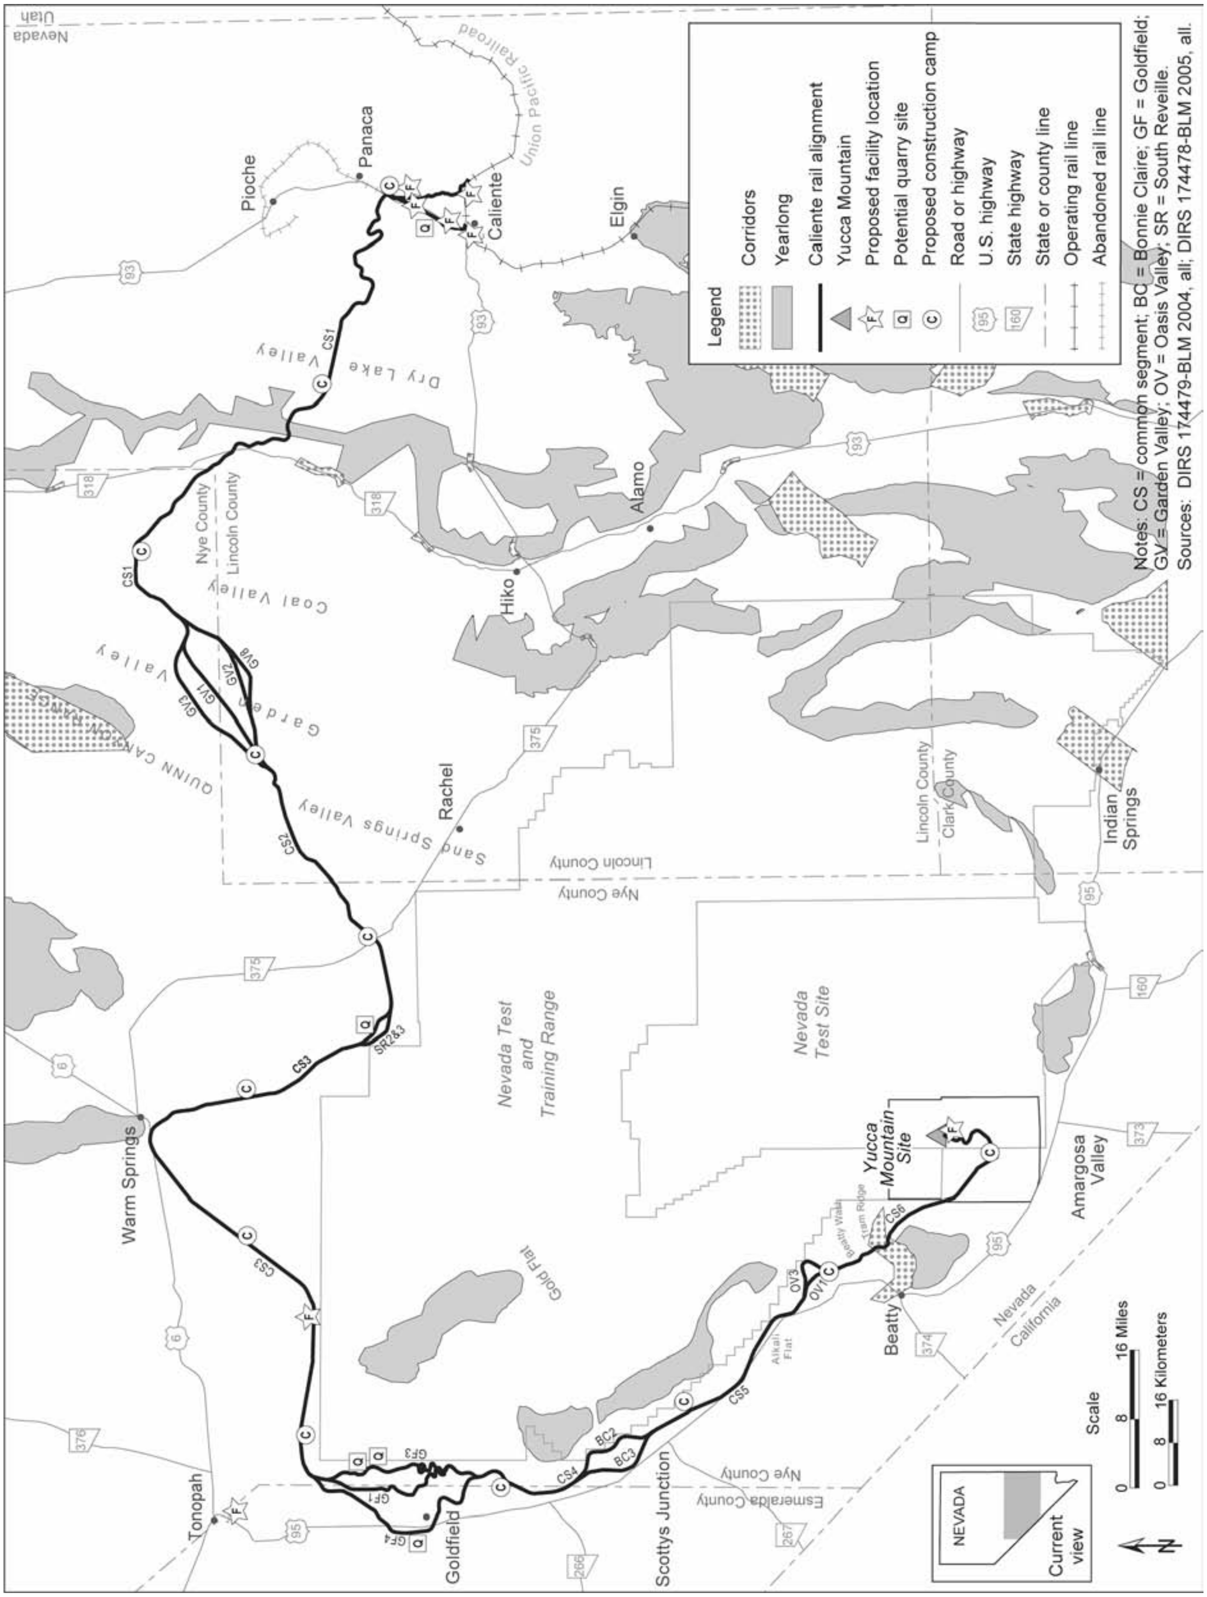

Figure 3-101. Desert bighorn sheep habitat along the Caliente rail alignment.

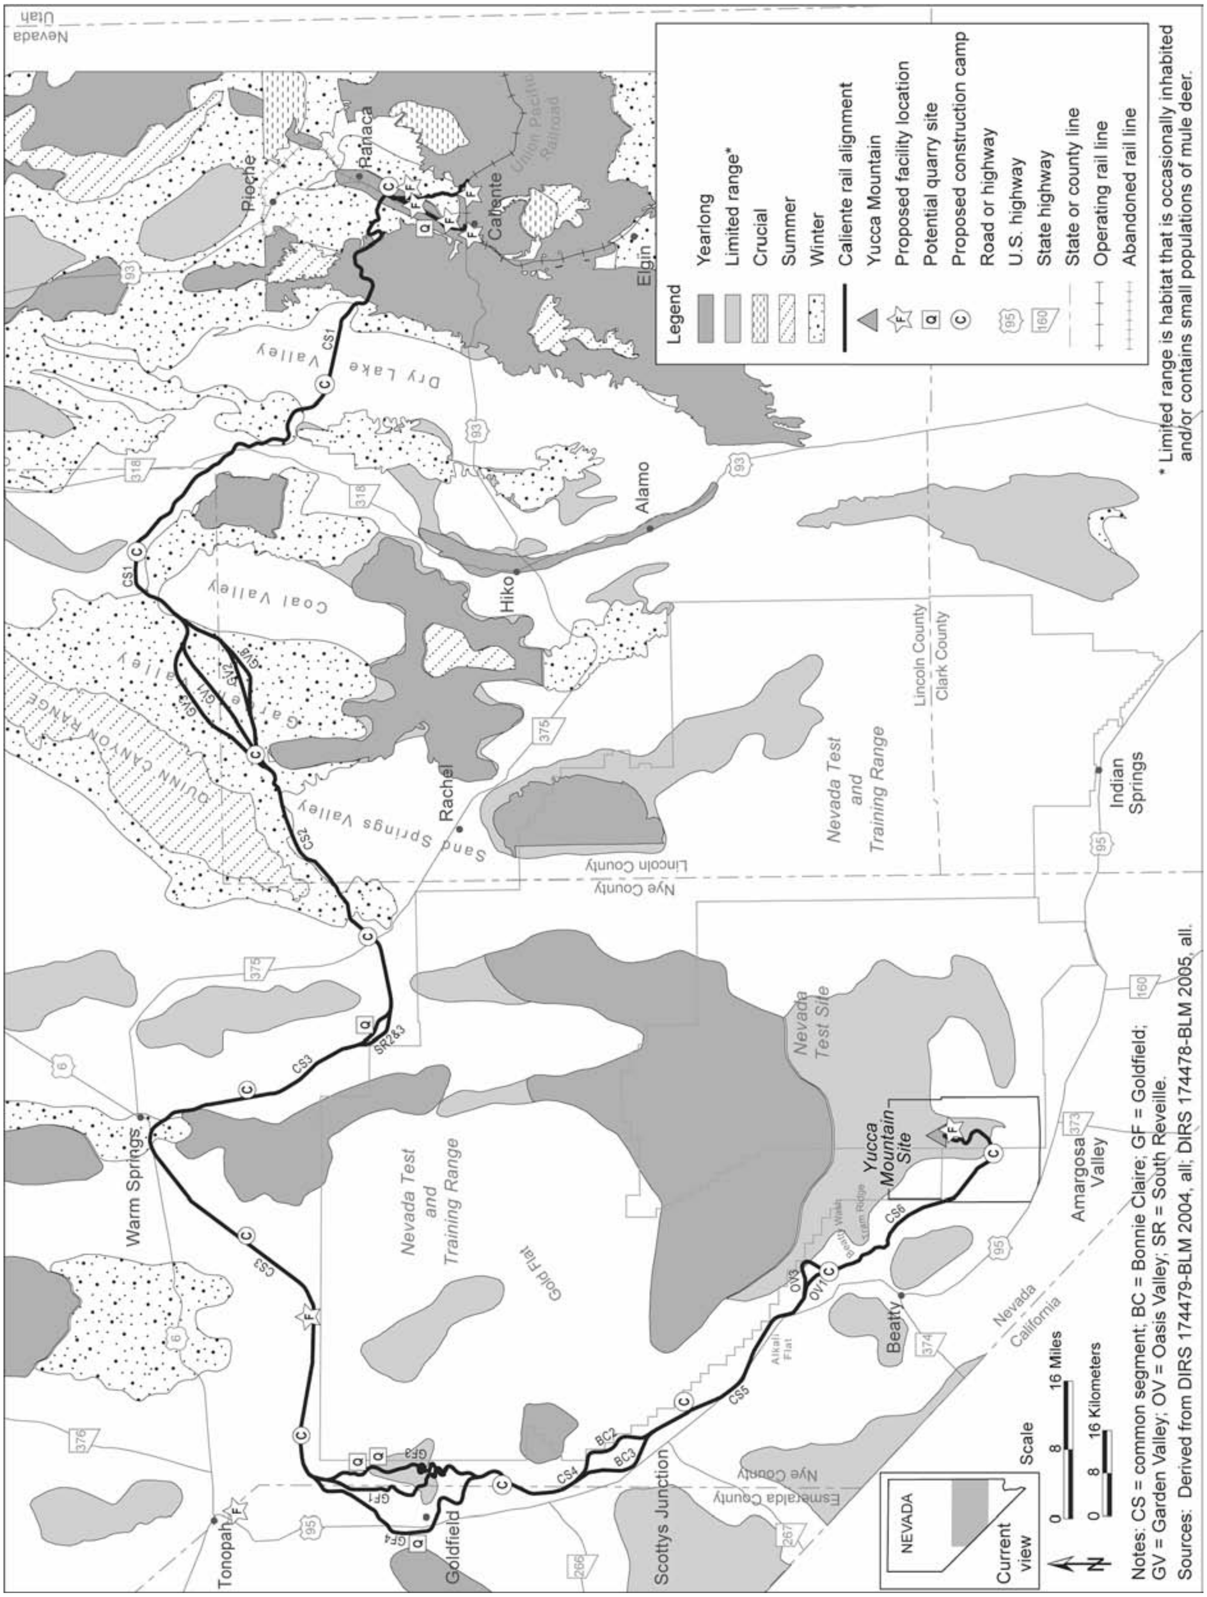

Figure 3-102. Mule deer habitat along the Caliente rail alignment.

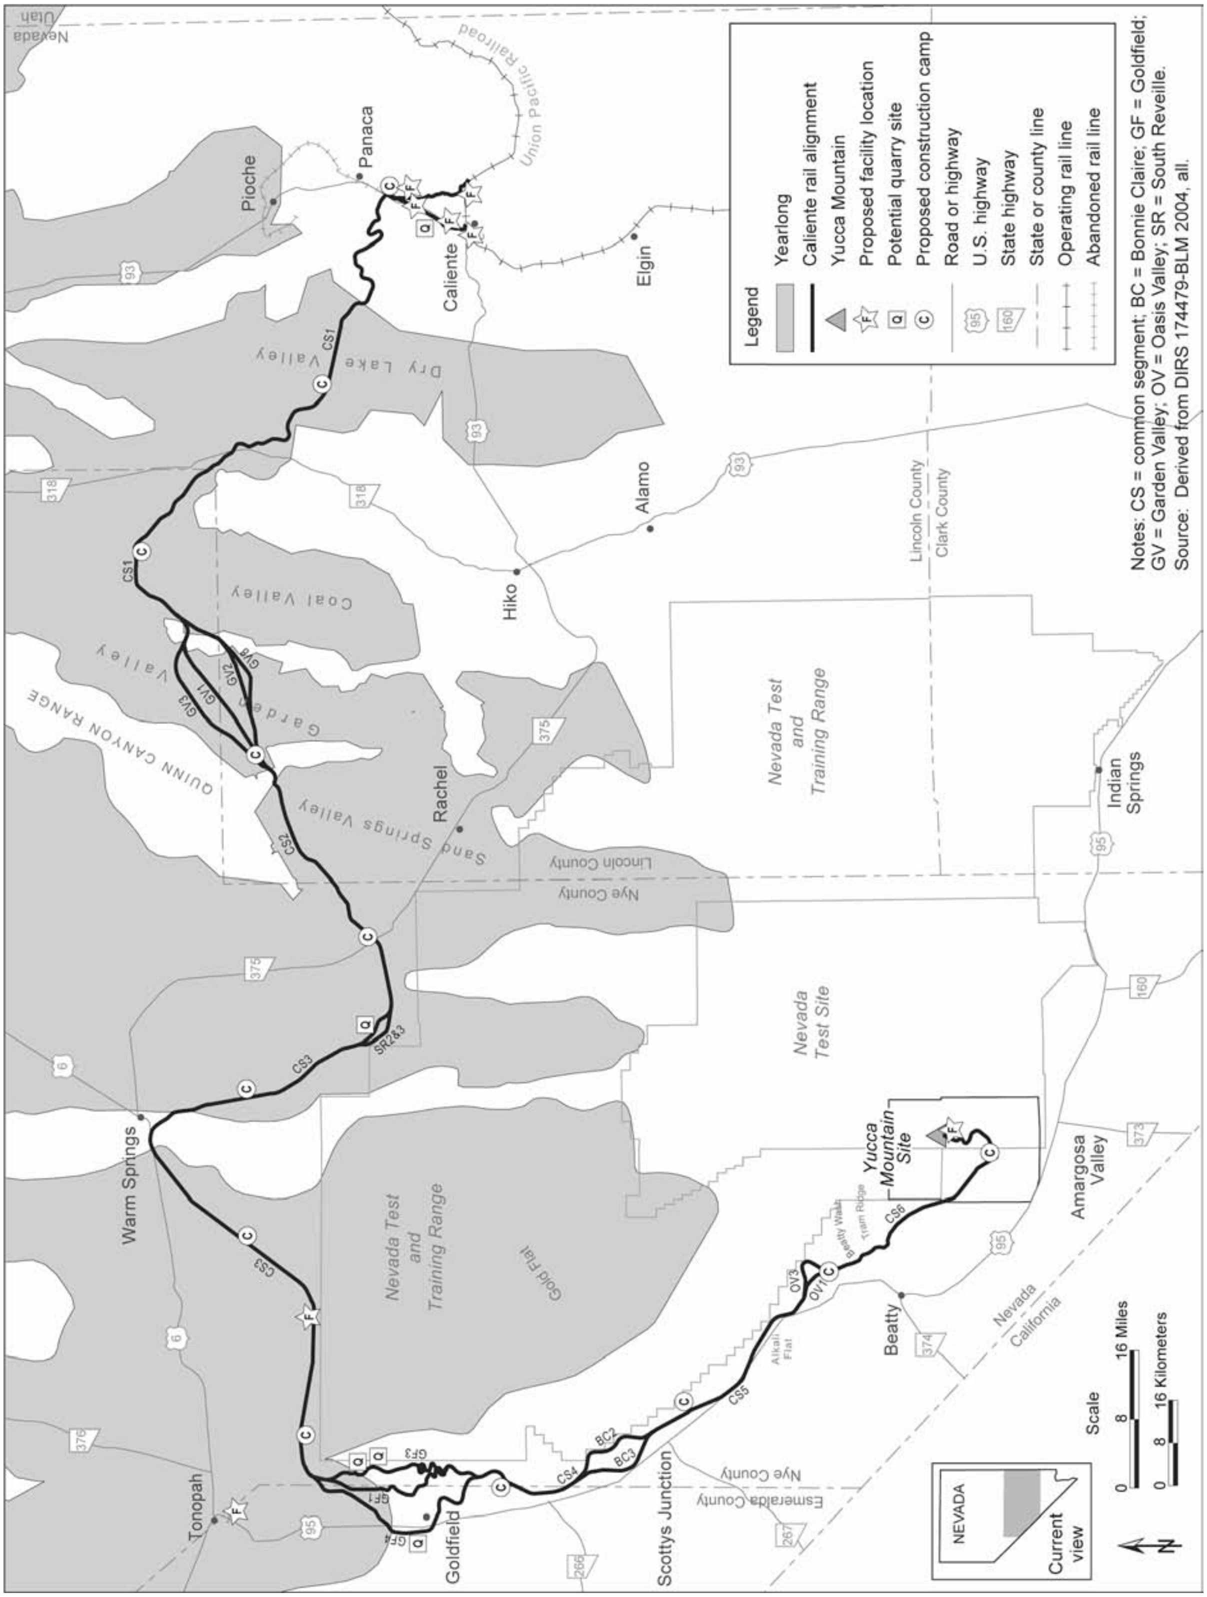

Figure 3.-103. Pronghorn antelope habitat along the Caliente rail alignment.

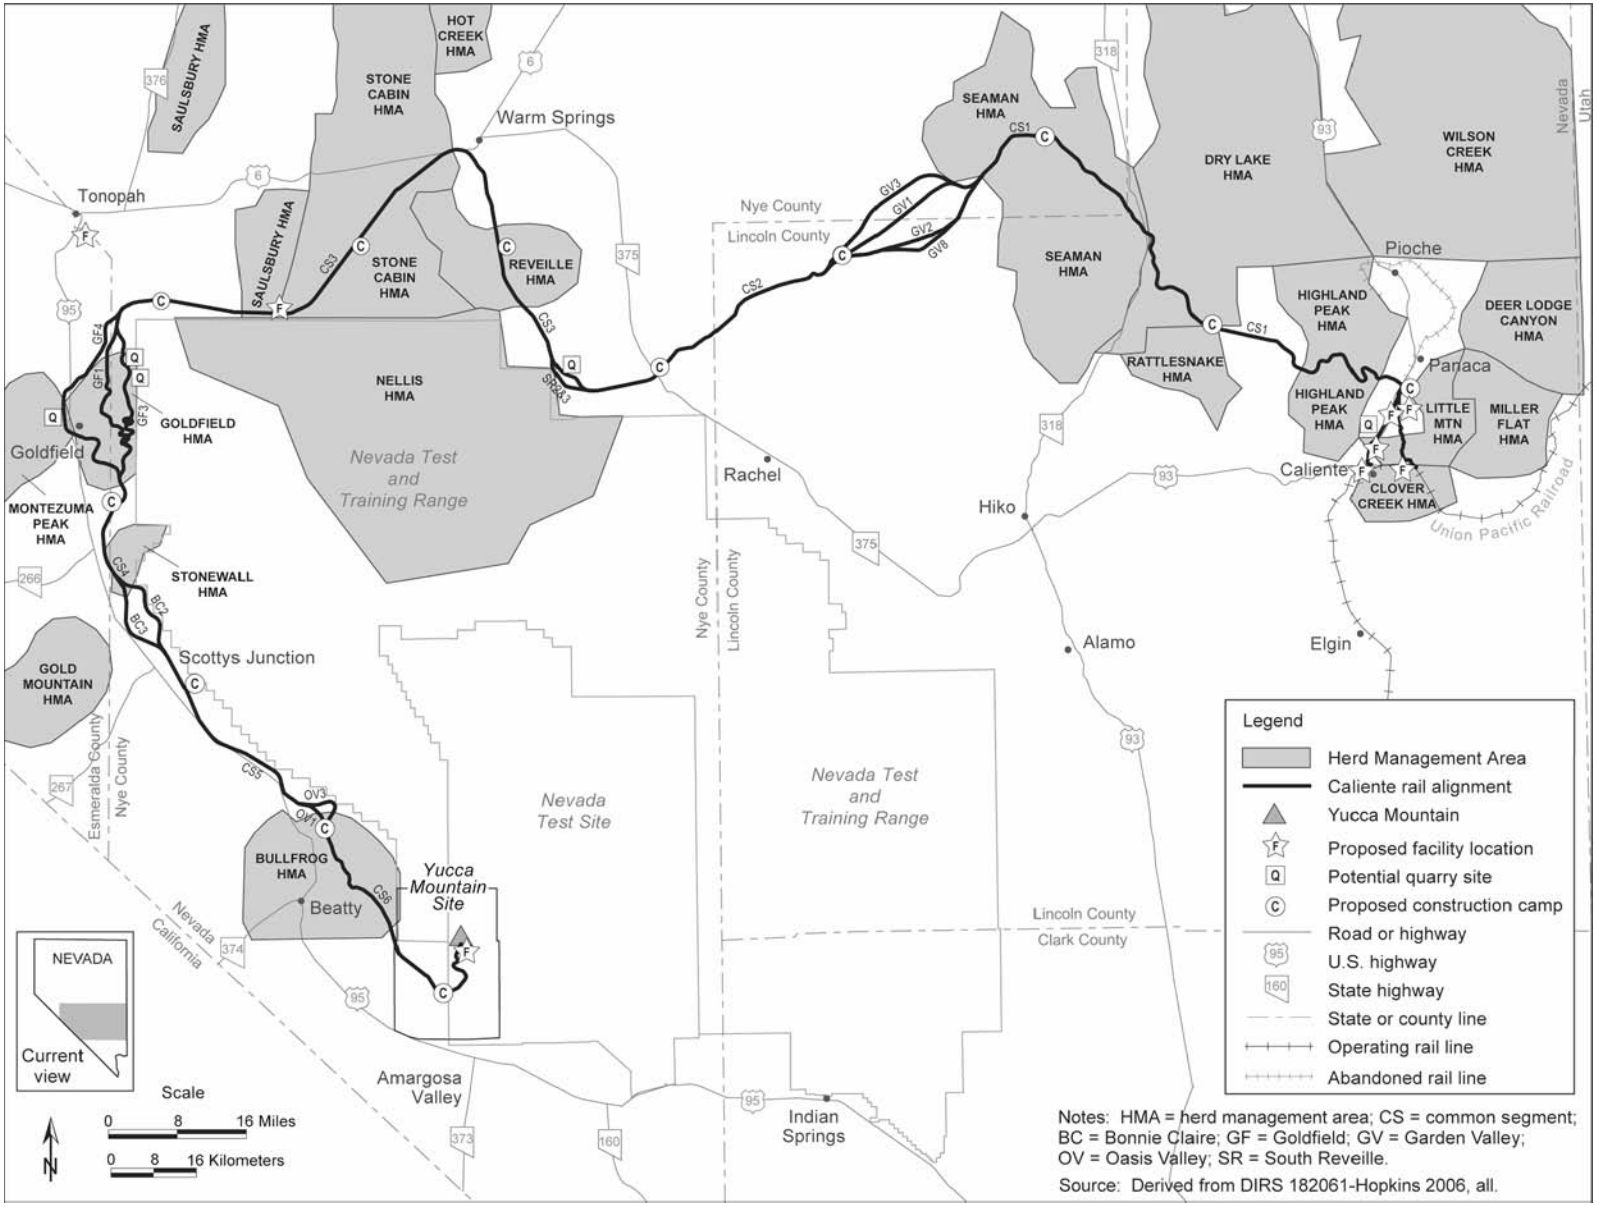

Figure 3-105. Herd management areas along the Caliente rail alignment.

Table 3-54. Herd management areas the Caliente rail alignment would cross.[a]

Herd management area	Location[b]	Area (square kilometers)[c]	Appropriate management level	Alternative segment or common segment that would cross area
Miller Flat	Lincoln County, northeast of Caliente	360	9 to 15 horses	Caliente and Eccles alternative segments
Little Mountain	Lincoln County, northeast of Caliente	210	9 to 15 horses	Caliente and Eccles alternative segments
Highland Peak	West of Panaca	550	20 to 33 horses	Caliente common segment 1
Rattlesnake	27 kilometers west of Caliente	290	1 horse	Caliente common segment 1
Dry Lake	West of Pioche	2,000	94 horses	Caliente common segment 1
Seaman	56 kilometers south of Lund	1,500	159 horses	Caliente common segment 1; Garden Valley alternative segments 1, 2, and 3
Reveille	80 kilometers east of Tonopah and 19 kilometers south of Warm Springs	510	138 horses	Caliente common segment 3
Stone Cabin	45 kilometers east of Tonopah	1,600	364 horses	Caliente common segment 3
Saulsbury	26 kilometers east of Tonopah	570	40 horses	Caliente common segment 3
Goldfield	East of Goldfield	260	125 horses 50 burros	Goldfield alternative segments 1, 2, and 3
Montezuma Peak	West of Goldfield	310	146 horses 10 burros	Goldfield alternative segment 4
Stonewall	West of Lida Junction and south of Goldfield	100	50 horses 25 burros	Caliente common segment 4; Bonnie Claire alternative segments 2 and 3
Bullfrog	Surrounds Beatty	520	12 horses 185 burros	Oasis Valley alternative segments 1 and 3; common segment 6

3.2.8 NOISE AND VIBRATION

This section describes existing noise and vibration in the Caliente rail alignment region of influence. Section 3.2.8.1 describes the region of influence; Section 3.2.8.2 describes general regional characteristics for noise and vibration; and Section 3.2.8.3 describes the existing environment for noise and vibration in more detail for Caliente rail alignment alternative segments and common segments.

Noise is considered a source of pollution because it can be a human health hazard. Noise effects on people range from hearing impairment at very high noise levels to annoyance at moderate to high noise levels. Sound waves are characterized by frequency and measured in ***hertz***; sound pressure is expressed as ***decibels*** (dB). Appendix I, Noise and Vibration Assessment Methodology, provides more information on the fundamentals of analyzing noise.

With the exception of prohibiting nuisance noise, neither the State of Nevada nor local governments have established numerical noise standards. Nevertheless, many federal agencies use the ***day-night average noise level*** (DNL) as a guideline for land-use compatibility and to assess the impacts of noise on humans.

Day-night average noise level (DNL): The energy average of A-weighted decibels (dBA) sound level over 24 hours; includes an adjustment factor for noise between 10 p.m. and 7 a.m. to account for the greater sensitivity of most people to noise during the night. The effect of nighttime adjustment is that one nighttime event, such as a train passing by between 10 p.m. and 7 a.m., is equivalent to 10 similar events during the day.

A-weighted decibels (dBA): A measure of noise level used to compare noise from various sources. A-weighting approximates the frequency response of the human ear.

For the operation of trains during proposed railroad construction and operations, DOE analyzed noise impacts under established STB criteria. The STB has environmental review regulations for noise analysis (49 CFR 1105.7e(6)), with the following criteria:

- An increase in noise exposure as measured by DNL of 3 ***A-weighted decibels*** (dBA) or more.
- An increase to a noise level of 65 DNL or greater.

If the estimated noise level increase at a location exceeds either of these criteria, the STB then estimates the number of affected noise-***sensitive receptors*** (such as schools, libraries, residences, retirement communities, nursing homes). The two components (3 dBA increase, 65 DNL) of the STB criteria are implemented separately to determine an upper bound of the area of potential noise impact. However, recent noise evaluations indicate that both criteria components must be met to cause an adverse impact from noise (DIRS 173225-STB 2003, p. 4-82). That is, noise levels would have to be greater than or equal to 65 DNL and increase by 3 dBA or more to cause an adverse impact.

There are three potential ground-borne vibration (vibration propagating through the ground) impacts of general concern: annoyance to humans, damage to buildings, and interference with vibration-sensitive activities. To evaluate potential impacts of vibration from construction and operations activities, DOE used Federal Transit Administration building vibration damage and human annoyance criteria. Under these criteria, if vibration levels exceeded human annoyance criterion for infrequent events 80 VdB (vibration velocity in decibels) or if the vibration levels (measured as ***peak particle velocity***) exceeded 0.20 inches per second for fragile buildings or 0.12 inches per second for extremely fragile historic buildings, then there could be an impact from vibration (DIRS 177297-Hanson, Towers, and Meister 2006, all). Appendix I provides more information on the vibration metrics used in this study.

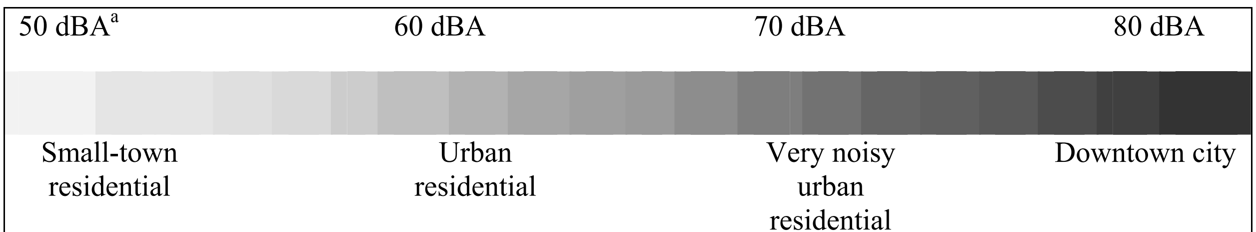
3.2.8.1 Region of Influence for Noise and Vibration

> **Ambient noise:** The sum of all noise (manmade and natural) at a specific location over a specific time is called ambient noise.

The region of influence for noise and vibration for construction and operation of a railroad along the Caliente rail alignment includes the construction right-of-way and extends out to variable distances, depending on several analytical factors (ambient noise level, train speed, number of trains per day, and number of railcars). Similarly, the region of influence for the railroad construction and operations support facilities depends on the magnitude of noise that would be generated and ambient noise levels, which would affect how far away the noise might be heard. In areas with low ambient noise conditions along the proposed rail alignment, project-related noise might be heard farther away. Therefore, the region of influence varies along the rail alignment. In addition, DOE has reviewed recent aerial photographs along the entire rail alignment to identify the locations of receptors in the region of influence that might be affected by noise, vibration, or both.

3.2.8.2 General Regional Characteristics for Noise and Vibration

The Caliente rail alignment is primarily in a quiet desert environment where natural phenomena such as wind, rain, and wildlife account for most of the ambient noise. Manmade noise in some areas of the region of influence is caused by vehicles traveling along public highways and an occasional low-flying military jet. At present, there is no train activity in the region of influence except in the City of Caliente. Historically, there was train activity in Goldfield, Nevada. Baseline sound conditions vary somewhat along the rail alignment and are site-specific. Most of the region of influence for the Caliente rail alignment is typical of other desert environments in which the DNL values range from 22 decibels on a calm day to 38 decibels on a windy day (DIRS 102224-Brattstrom and Bondello 1983, p. 170). Areas within the region of influence are sparsely populated and, in general, ambient noise levels are low. The noise level at a specific location depends on nearby and distant sources of noise. Noise levels in populated areas tend to be higher than in unpopulated areas because of human activity and higher levels of transportation noise (Figure 3-106).



a. dBA = A-weighted decibels.
b. Source: DIRS 101821-EPA 1974, p. 23.

Figure 3-106. Typical DNLs for residential areas.[b]

Ground-borne vibration occurs as a result of both natural phenomena (such as seismic activity) and manmade activities (such as construction and transportation activities). Human activities that can create perceptible levels of ground-borne vibration are important when sensitive sites, structures, or activities could be affected. Background vibration exists as a component of the overall effects of ground-borne vibration, higher in areas with more human activity, lower in areas more distant from human activities. Vibration levels in populated areas tend to be higher than in unpopulated areas because of human activity and higher levels of transportation vibration. Background levels of ground-borne vibration along the Caliente rail alignment are low.

3.2.8.3 Existing Environments for Noise and Vibration at Three Measurement Locations along the Caliente Rail Alignment

DOE evaluated existing noise and vibration conditions along the Caliente rail alignment and compiled the detected ranges of noise and vibration levels at different locations under different conditions. Most of the region of influence for the rail alignment is sparsely populated and, in general, ambient noise levels are low and there are no detectable vibrations. DOE measured ambient noise and vibration levels at three locations along the proposed rail alignment: in Caliente, in Garden Valley near *City* (a large complex of abstract sculptural and architectural forms made from earth, rock, and concrete), and in Goldfield. DOE selected these locations for ambient noise and vibration measurements because they are representative of the few populated areas or Special Recreational Management Areas within the region of influence. The ambient noise measurements at these representative locations along the rail alignment ranged from 47 to 62 DNL and ambient vibration levels ranged from 25 to 44 VdB. Table 3-55 summarizes the measured ambient noise levels in Caliente, Garden Valley, and Goldfield. Table 3-56 summarizes the measured ambient vibration levels in Caliente, Garden Valley, and Goldfield.

Table 3-55. Ambient noise measurements along the Caliente rail alignment.

Location	DNL dBA[a]
Caliente	53[b]
Garden Valley	62[c]
Goldfield	47[d]

a. DNL dBA = day-night average noise level in A-weighted decibels.
b. DNL measurements were taken on January 11, 2005 (with a result of 54 DNL), and February 9, 2005 (with a result of 53 DNL). To be conservative, DOE selected the lowest value because the relative difference between project noise levels and ambient noise levels could influence the potential impact.
c. DNL measurements were taken in Garden Valley on February 9, 2005.
d. DNL measurements were taken in Goldfield on January 12, 2005.

Table 3-56. Ambient vibration measurements along the Caliente rail alignment.

Location	VdB[a]
Caliente	44[b]
Garden Valley	29[c]
Goldfield	25[d]

a. VdB = vibration velocity in decibels with respect to 1 micro-inch per second.
b. Vibration measurements were taken in Caliente on January 11, 2005.
c. Vibration measurements were taken in Garden Valley on February 9, 2005.
d. Vibration measurements were taken in Goldfield on January 12, 2005.

3.2.8.3.1 Caliente

DOE took noise measurements for 24-hour periods in Caliente, Nevada, on January 11, 2005, and on February 9, 2005. The measurements were repeated on February 9 because there was a major flood in the area during the January 11 measurements, which could have affected measurement results. Train activity was halted during that period, and there was substantial helicopter activity associated with flood-relief efforts. However, the DNL did not vary much between the two sets of measurements. On January 11 the noise level was 54 DNL; on February 9 it was 53 DNL (see Table 3-55). Measured DNL noise levels at Caliente are consistent with the "small-town residential" category shown on Figure 3-106.

Hourly ***equivalent sound levels*** ranged from 32 to 62 dBA. Noise sources consisted of vehicular traffic on U.S. Highway 93, train horns, noise from nearby residential areas, and aircraft overflights. Figure 3-107 shows measured noise levels taken at the Agua Caliente Trailer Park over a 24-hour period. Figure 3-108 shows the location where DOE took the ambient noise measurements in Caliente.

Equivalent sound level (Leq): A single value of sound level for any desired duration (such as 1 hour), which includes all of the time-varying sound energy in the measurement period. Leq correlates reasonably well with the effects of noise on people, even for wide variations in environmental sound levels and time patterns. It is used when only the durations and levels of sound, and not their times of occurrence (day or night), are relevant.

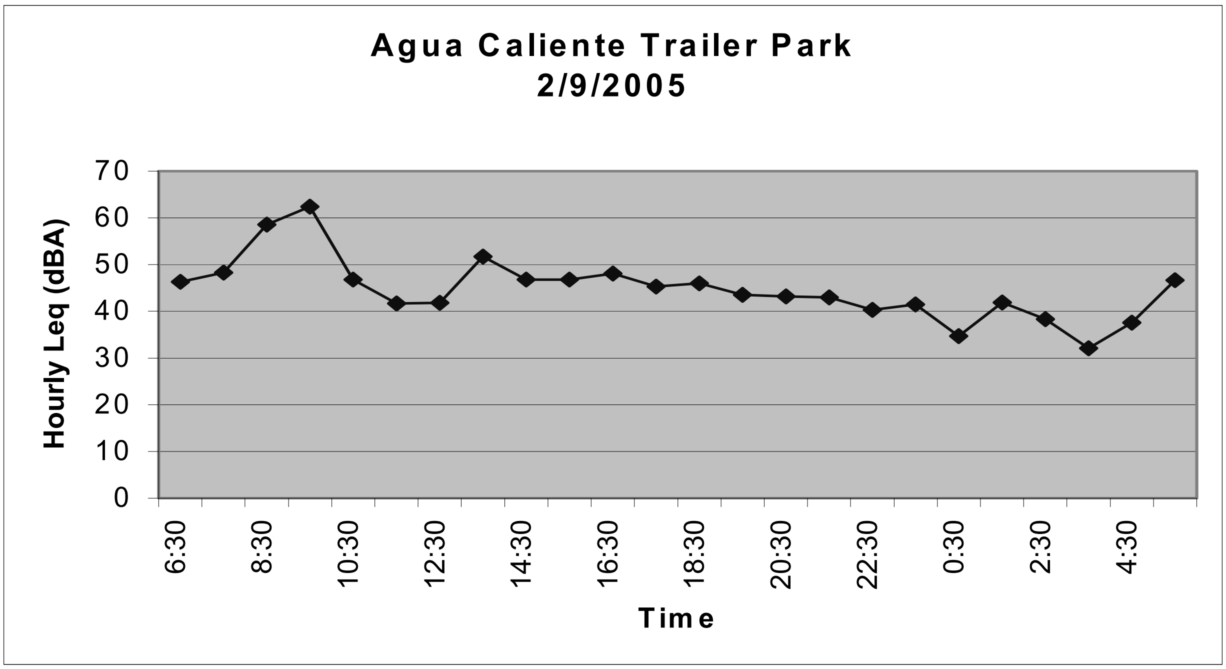


Figure 3-107. Measured noise levels over a 24-hour period in Caliente, Nevada.

Figure 3-109 shows modeled noise levels (65 DNL contour) for Union Pacific Railroad train activity in Caliente based on an average of 25 trains per day consisting of 2 locomotives and 60 railcars, and an operating speed of 64 kilometers (40 miles) per hour. The jagged shape and islands within the contour are caused by the shielding effects of buildings close to the grade crossing at South Spring Street.

DOE also took ambient ground-borne vibration measurements at the Agua Caliente Trailer Park on January 11, 2005. The vibration measurement was 44 VdB (see Table 3-56). Measured ambient vibration levels were low because of low population density and the resulting lack of vibration-producing activity. Ambient vibration levels of this magnitude are lower than human perception levels.

3.2.8.3.2 Garden Valley

DOE took noise measurements for 24 hours on February 9, 2005, near *City* in Garden Valley. Hourly equivalent sound level values ranged from 15 to 65 dBA, as shown on Figure 3-110. Figure 3-111 shows where DOE took the ambient noise measurements in Garden Valley. Two sonic booms from nearby U.S. Air Force jet activity or some other very loud-noise source occurred during the measurements,

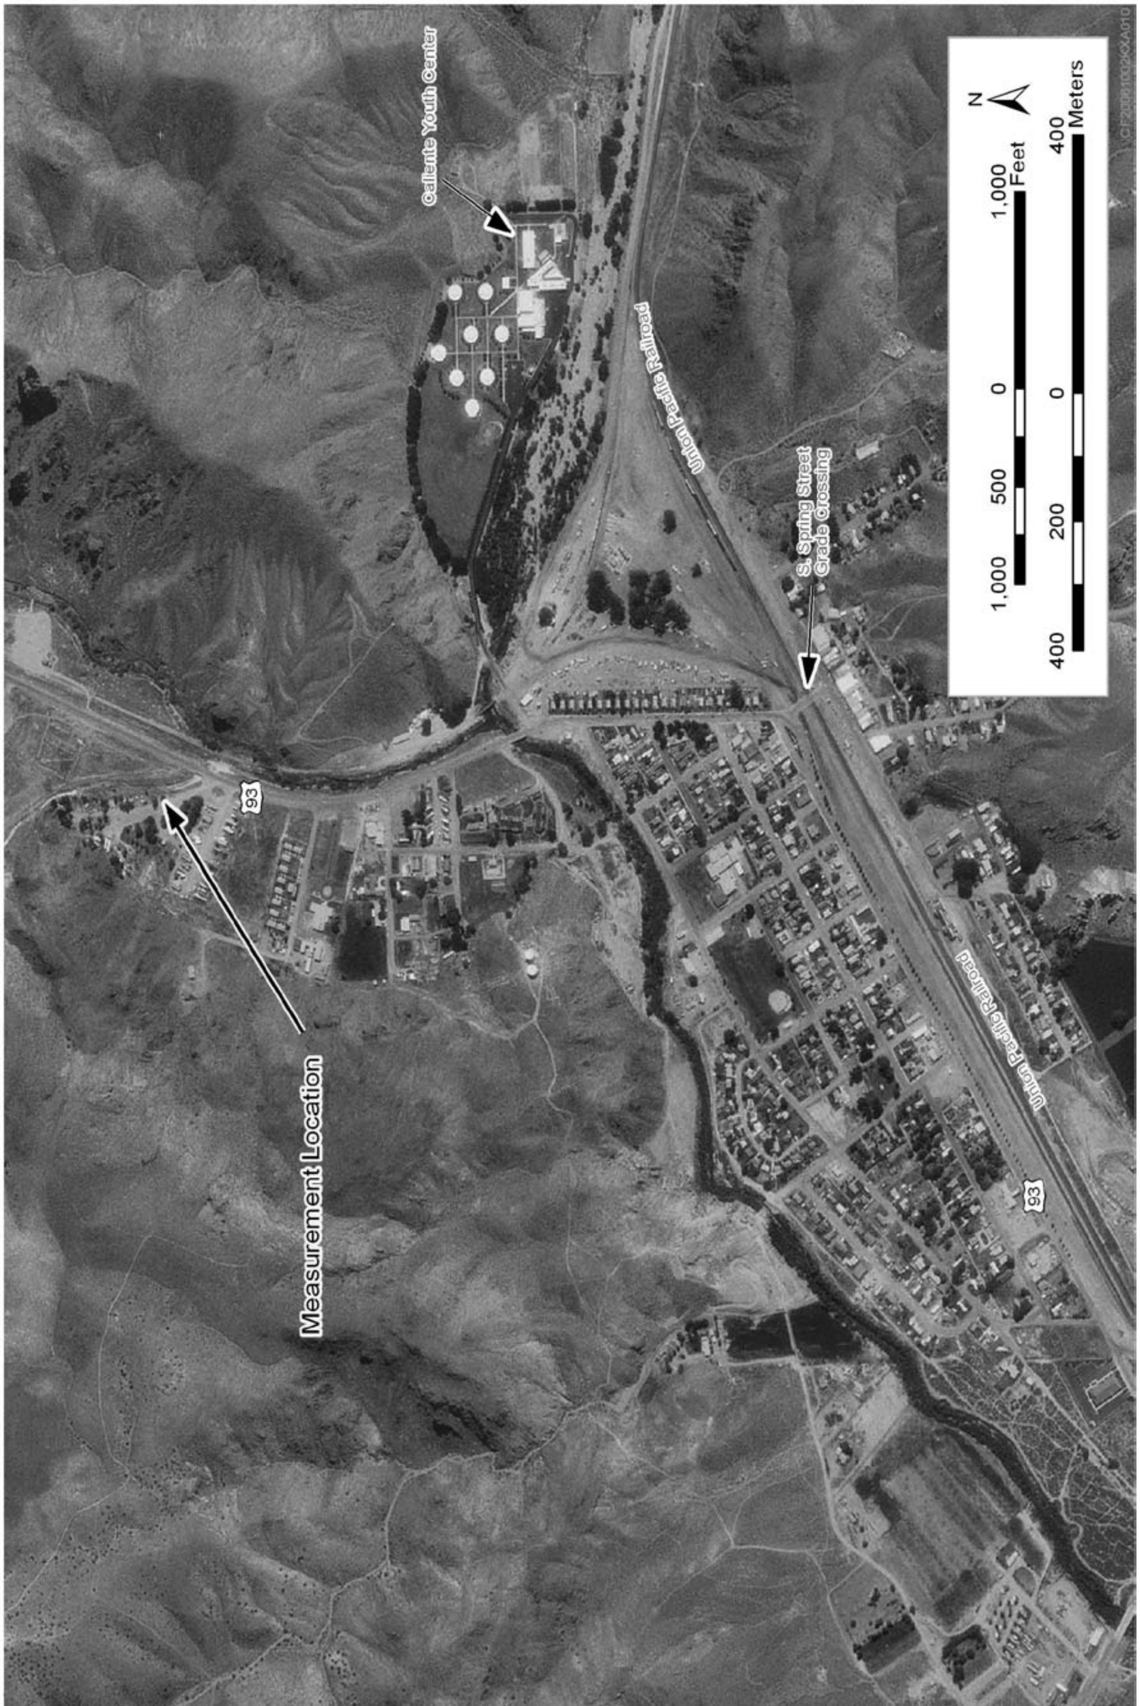

Figure 3-108. Ambient noise monitoring location at Agua Caliente Trailer Park, Caliente, Nevada.
(Source: Base map derived from DIRS 174497-Keck Library 2004, filename 37114E52.sid.)

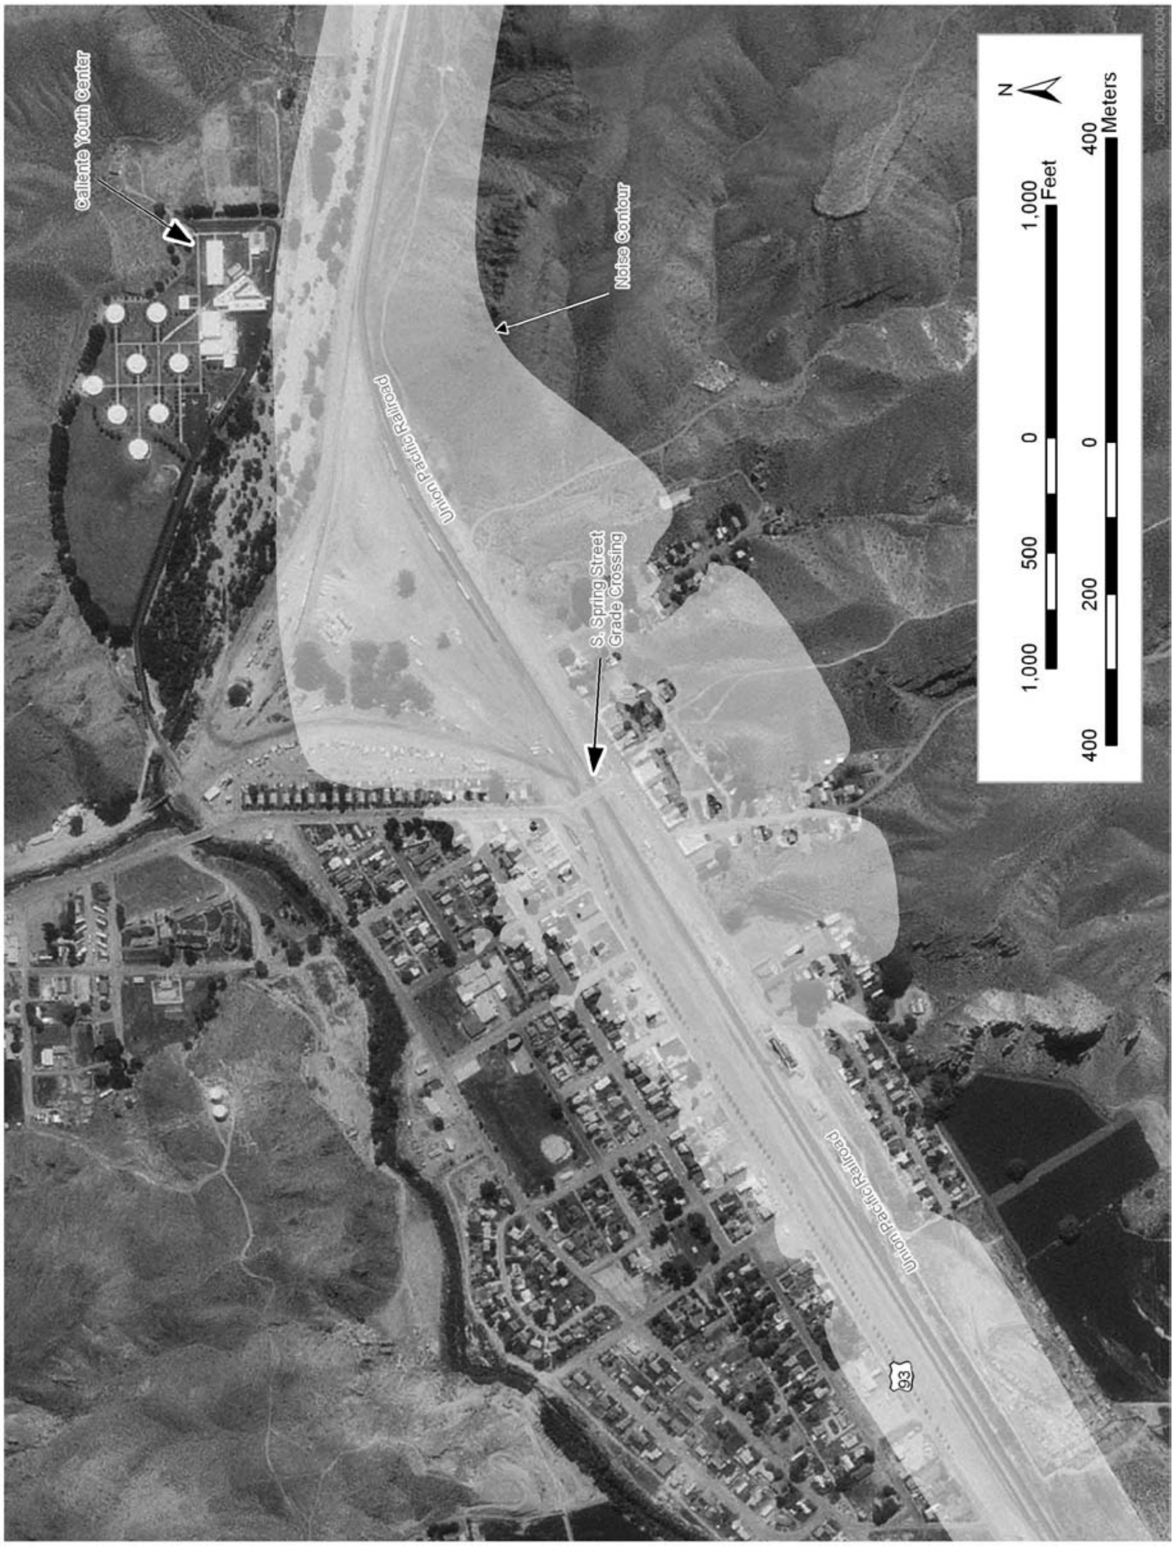

Figure 3-109. Union Pacific Railroad existing train activity in Caliente, Nevada, 65-decibel day-night average noise level contour.
(Source: Basemap derived from DIRS 174497-Keck Library 2004, filename 37114E52.sid.)

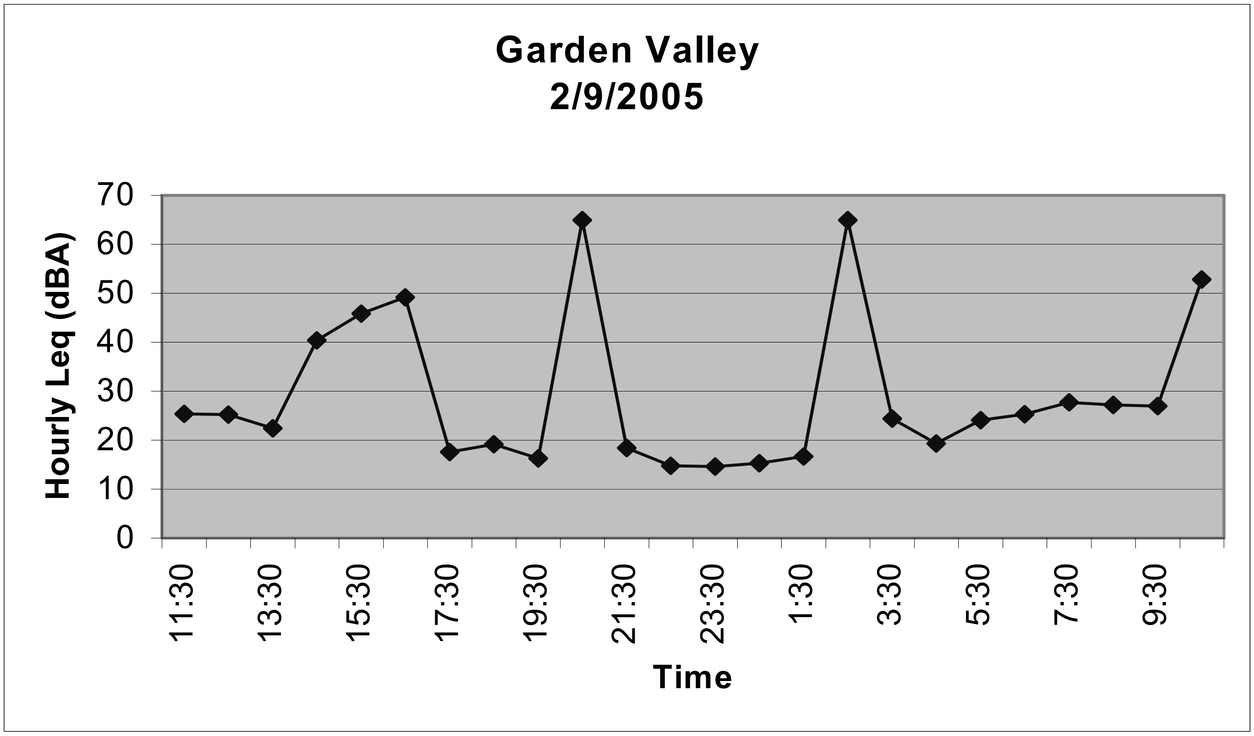

Figure 3-110. Measured noise levels over a 24-hour period in Garden Valley.

which resulted in two hourly equivalent noise level values of 65 dBA. Including these two loud noise events in the ambient noise results gives a noise level of 62 DNL (see Table 3-55). Excluding these two events, the noise level would have been 41 DNL. Measured noise levels at Garden Valley, excluding the two loud noise events, are consistent with the "small-town residential" category shown on Figure 3-106. Measured noise levels at Garden Valley, including the two loud noise events, are consistent with the "urban residential" category shown on Figure 3-106.

Noise levels varied dramatically at the Garden Valley location, from near the threshold of hearing to much higher levels. Military aircraft activity appears to be the cause of the high noise levels. While at this location, field personnel observed a substantial amount of military jet aircraft activity, some of which resulted in very high noise levels. U.S. Air Force noise data indicate that long-term noise levels associated with subsonic aircraft activity in this area range from 55 to 60 DNL (DIRS 174499-Frampton, Lucas, and Plotkin 1993, all). A separate U.S. Air Force report indicates that this Garden Valley location is within an area authorized for supersonic military training exercises to altitudes as low as 1,500 meters (5,000 feet) (DIRS 176798-Varnell et al. 1994, p. 2-5).

The measured DNL values confirm that ambient noise levels are high in this location. Noise sources consist of military aircraft and commercial aircraft. During the measurements, there were extended periods when there was no audible noise. Some construction equipment was operating at *City* during the measurements, but the noise monitor was sufficiently far away that the equipment had no effect on the measured noise level.

DOE also took ambient ground-borne vibration measurements at *City* on February 9, 2005. The vibration measurement was 29 VdB (see Table 3-56). Measured ambient vibration levels were low because of low population density and the resulting lack of activity that would produce vibration. Ambient vibration levels of this magnitude are lower than human perception levels.

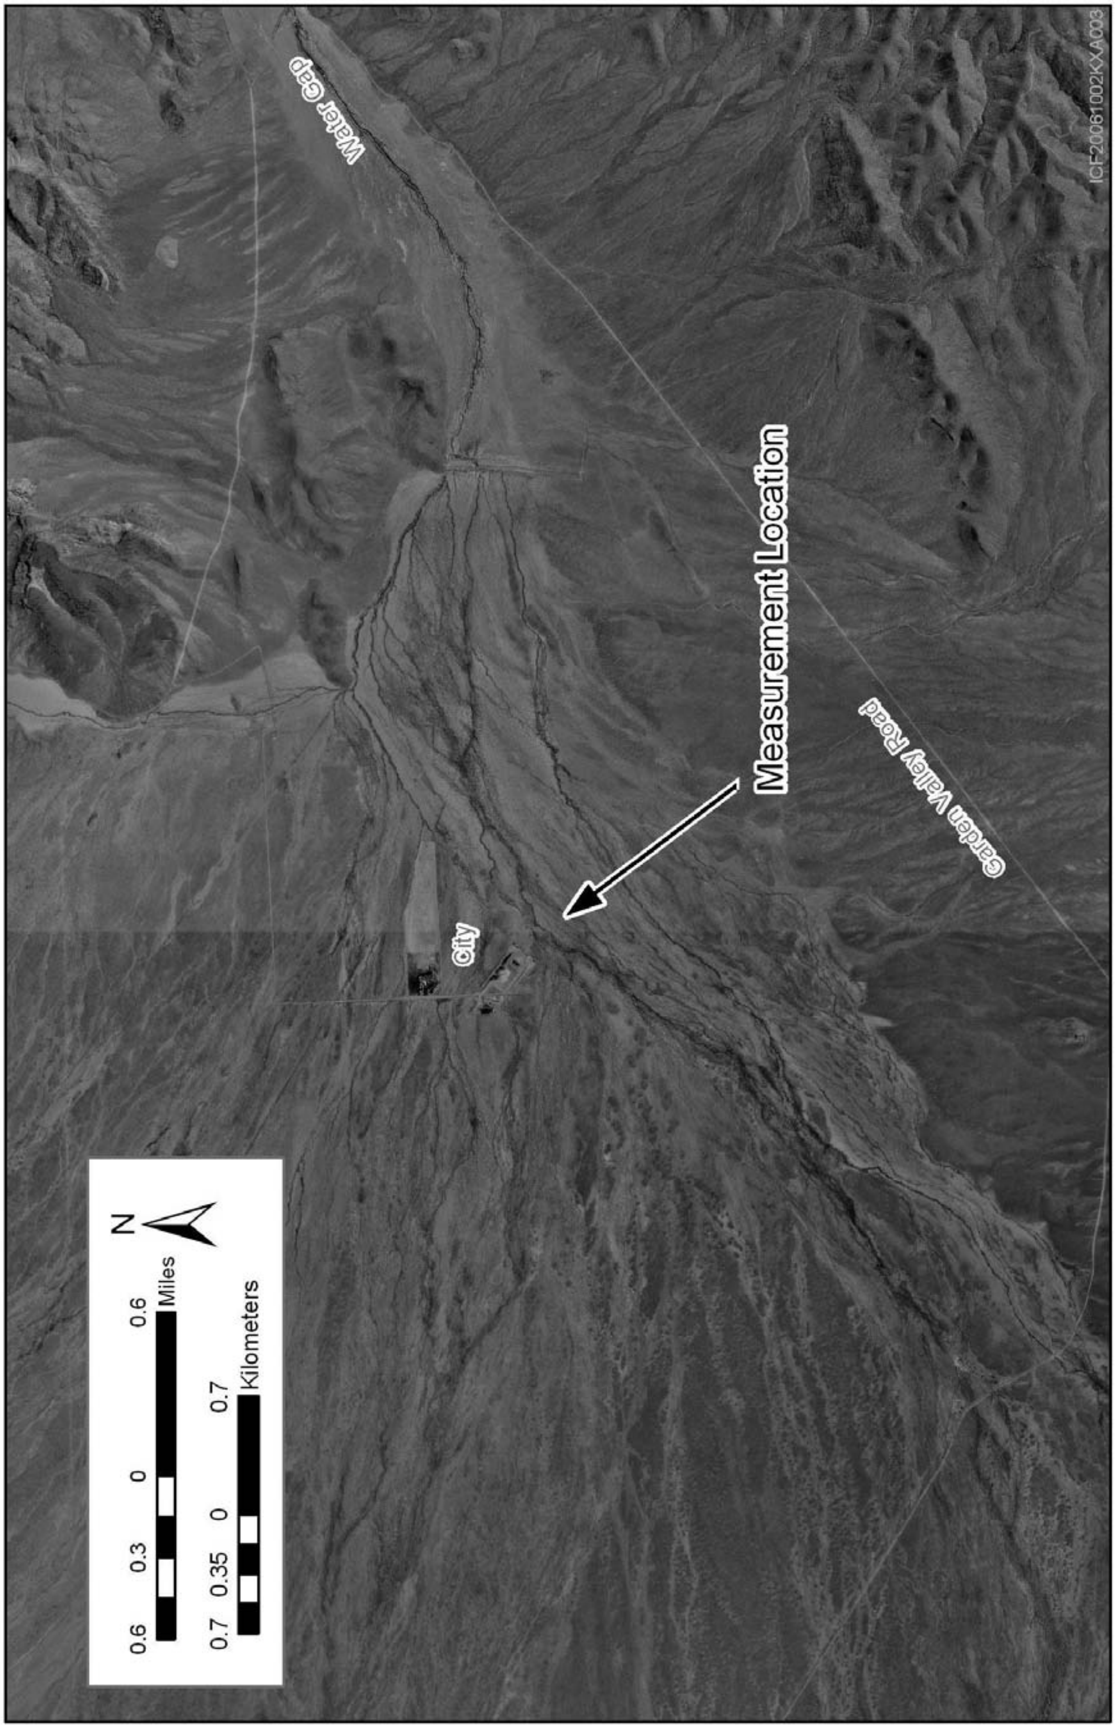

Figure 3-111. Ambient noise monitoring location in Garden Valley, Nevada.
(Source: Basemap derived from DIRS 174497-Keck Library 2004, filenames 381154A43.sid and 38115A44.sid.)

3.2.8.3.3 Goldfield

DOE conducted noise measurements for 24 hours in Goldfield on January 12, 2005. Hourly equivalent sound level values ranged from 30 to 44 dBA, as shown on Figure 3-112. The DNL at this location measured 47 dBA (see Table 3-55).

Noise sources included occasional vehicular traffic on U.S. Highway 95, barking dogs, wind, and occasional front-end-loader noise from the U.S. Department of Transportation maintenance station. Figure 3-113 shows where DOE took ambient noise measurements in the Goldfield area. Measured noise levels at Goldfield are lower than values associated with the "small-town residential" category, which is consistent with the low population density and desert environment (see Figure 3-104).

DOE also took ambient ground-borne vibration measurements at the Goldfield monitoring site on January 12, 2005. The vibration measurement was 25 VdB (see Table 3-56). Measured ambient vibration levels were low because of low population density and the resulting lack of ***ground vibration***-producing activity. Ambient vibration levels of this magnitude are lower than human perception levels.

3.2.9 SOCIOECONOMICS

This section describes the existing socioeconomic conditions (employment and income, population and housing, public services, and transportation) along the Caliente rail alignment. Section 3.2.9.1 describes the region of influence for socioeconomics; Section 3.2.9.2 summarizes the method DOE used to establish ***baseline*** socioeconomic conditions in the region of influence; and Section 3.2.9.3 describes general regional socioeconomic characteristics.

3.2.9.1 Region of Influence

The region of influence for the Caliente rail alignment socioeconomics analysis is Lincoln, Nye, Esmeralda, and Clark Counties and the Timbisha Shoshone Trust Lands. While the Timbisha Shoshone Trust Lands are included in the region of influence, they were not included in the socioeconomics analysis because no economic activity or growth is currently taking place or planned on these lands (Figure 3-114).

Construction and operation of a railroad along the Caliente rail alignment could affect social and economic activities and public services in these areas. This section examines baseline socioeconomic conditions for the counties and selected communities in the counties that would likely be affected during construction and operation of the proposed railroad. This analysis presents some socioeconomics detail for Clark County because, even though the rail line would not cross Clark County, construction workers for construction of the rail and associated facilities (except those in Nye County) are assumed to come from Clark County. This is because Clark is the only county with a sufficient workforce. Construction and operations workers for facilities located in Nye County are assumed to reside 80 percent in Clark County and 20 percent in Nye County, reflecting historical patterns. Operations workers for facilities outside Nye County are assumed to reside in the county of the facility. Furthermore, Clark County medical facilities could receive medical cases from the construction camps and construction sites.
The region of influence does not extend beyond these counties in Nevada because there is no indication of a regional or national socioeconomic effect from goods and services purchased outside the region of influence, and demand for goods and services would not be likely to adversely affect regional or national supplies of required goods and services. The Yucca Mountain FEIS examined the possibility that socioeconomic effects from purchasing construction materials could be felt beyond this four-county region and concluded that there would be little or no impact (DIRS 155970-DOE 2002, p. 4-77).

The region of influence for the analysis of transportation resources includes public roadways near the Caliente rail alignment, and the rail alignment itself.

During rail line construction, new access roads to construction camps, quarries, and water wells would originate from nearby intersections with existing public roadways. Most of the rail alignment would be within Nevada Department of Transportation District 1, crossing Lincoln, Nye, and Esmeralda Counties, with a small portion in District 3 near the State Route 318 crossing (along Caliente rail alignment common segment 1). There are no operating railroads along the Caliente rail alignment.

3.2.9.2 Methodology for Determining Existing Socioeconomic Conditions

DOE characterized socioeconomic activities and resources in the region of influence with a particular emphasis on community-level resources, as appropriate.

For this analysis, DOE used the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Chapter 3) as a basic source of data, and supplemented that data where possible with current community-level data for Lincoln, Nye, and Esmeralda Counties.

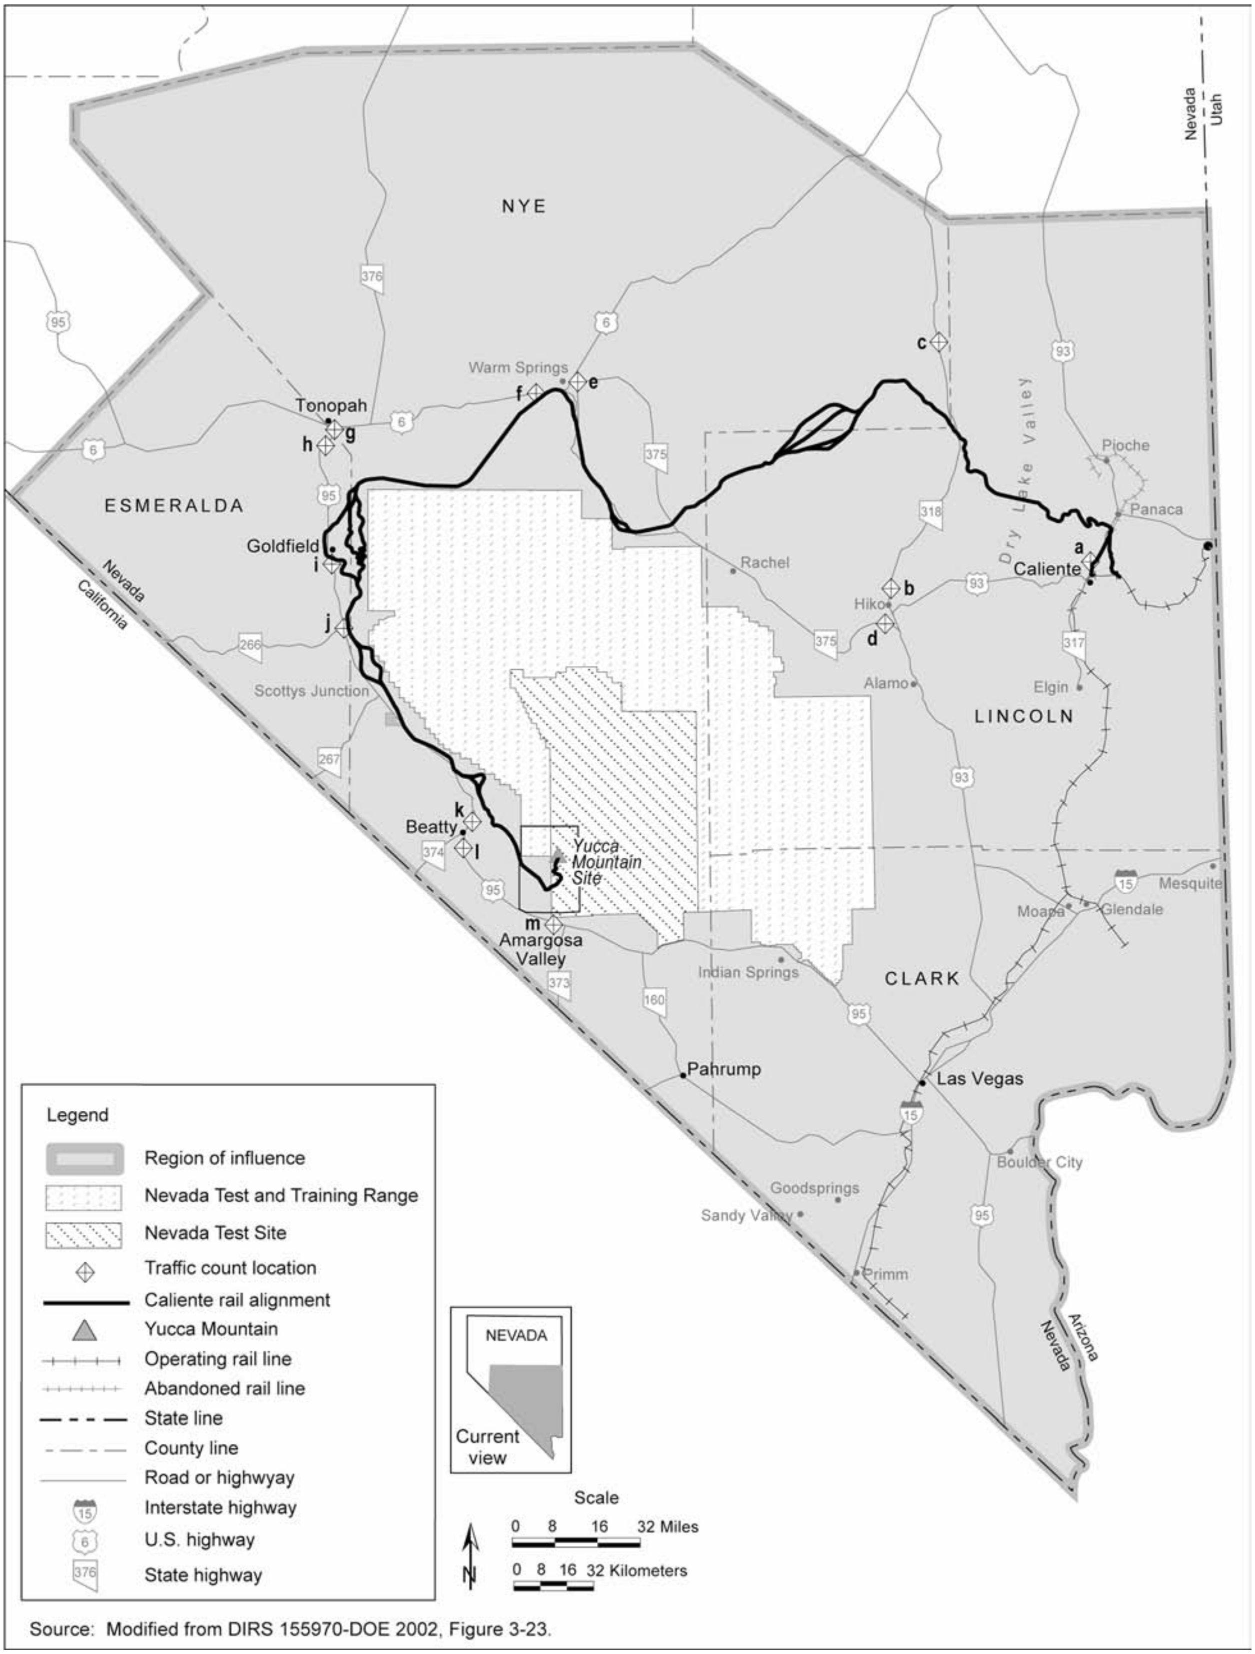

Figure 3-114. Socioeconomics region of influence – Caliente rail alignment.

> **Real disposable income** is the value of total income received after taxes; it is the income available for spending or saving.

DOE used an economic-demographic forecasting model known as *Policy Insight*, developed by Regional Economic Models, Inc. (DIRS 178610-Bland 2007, all), to generate employment, ***real disposable income***, and ***gross regional product*** data for Clark, Lincoln, Nye, and Esmeralda Counties. *Policy Insight* is an eight-region model, which includes Clark, Lincoln, Nye, Esmeralda, Mineral, and Lyon Counties, the joint area of Washoe County and Carson City, and one last region encapsulating the rest of Nevada. Appendix J, Socioeconomics, contains the results of the *Policy Insight* model runs.

The description of existing economic conditions in the Caliente rail alignment region of influence and the forecast values of populations, gross regional product, and real disposable income draw on data from *Policy Insight* version 9.0 (DIRS 182251-REMI 2007, all). The description includes revenue from DOE's Payments Equal to Taxes program, described in detail in the Yucca Mountain FEIS (DIRS 155970-DOE 2002, p. 3-90), and the Repository SEIS. Revenue from this program is not described separately. Because the model is based on nationally collected data for which there is a lag between collection and issuance by the national agencies, and another lag before the data are incorporated into the *Policy Insight* model, there is always a gap of approximately 2 to 3 years between the current year and the last history year. The year 2004 is the last history year for *Policy Insight* version 9.0 used in this baseline forecast. To compensate for this time lag, the model's employment update feature is specifically designed to accommodate new historical data provided by users, which update the model's growth-rate assumptions. *Policy Insight* version 9.0 uses an employment update module that relies on years 2004 to 2006 data from the Nevada Department of Education, Training, and Rehabilitation (DIRS 180712-NDETR 2006, all; DIRS 180740-DETR [n.d.], all; DIRS 180741-DETR 2005, all; DIRS 180742-DETR [n.d.], all). This version also incorporates information from the latest Clark County population projections prepared by the University of Nevada, Las Vegas (DIRS 178806-CBER 2006, all) and the latest population projections developed by the Nevada State Demographer (DIRS 178807-Hardcastle 2006, all).

Data for the affected environment (both those taken from the Yucca Mountain FEIS and supplemental information included here) come from various state, federal, community, and proprietary sources. DOE obtained current and historical population data from a report prepared for the Nevada Small Business Development Center (DIRS 177656-Nevada State Demographer's Office 2006, all). The Department obtained housing data, including information on housing stock, vacancy rates, median housing values, and gross rents, from the Nevada Small Business Development Center, which compiled the information from U.S. Census Bureau data (DIRS 173564-Nevada Small Business Development Center 2003, all; DIRS 173565-Nevada Small Business Development Center 2003, all; DIRS 173566-Nevada Small Business Development Center 2003, all; DIRS 173567-Nevada Small Business Development Center 2003, all). DOE uses the U.S. Census Bureau housing data because county-collected housing data can be inconsistent across counties due to unique county assessment practices. In addition, the Census Bureau's housing data contain characteristics that county housing data sources do not, such as whether a property is a rental property or owner-occupied, occupied, or vacant.

Income, poverty, and unemployment data come from the U.S. Census Bureau (DIRS 176856-U.S. Census Bureau 2003, all). DOE obtained current values for employment, real disposable income, and gross regional product for Lincoln, Nye, Esmeralda, and Clark Counties from the *Policy Insight* model, as previously described. DOE compiled business-establishment data from the *Nevada Workforce Informer, Data Analysis* (DIRS 173545-Nevada Department of Employment, Training & Rehabilitation 2005, all; DIRS 173542-Nevada Department of Employment, Training & Rehabilitation 2005, all; DIRS 173544-Nevada Department of Employment, Training & Rehabilitation 2005, all). The Department obtained data on public services mainly from interviews with county representatives in the region of influence and from the Yucca Mountain FEIS (DIRS 155970-DOE 2002, Chapter 3), augmented in some instances with information from other sources cited herein. Yucca Mountain Oversight Offices in Lincoln and Esmeralda Counties provided contact information for county agencies and suggested data sources for this section. The County Manager provided similar assistance for Nye County. DOE obtained health data from the Nevada State Health Division (DIRS 173560-State of Nevada [n.d.], all); education data from Nevada District Accountability Reports (DIRS 177758-Lincoln County School District [n.d.], all; DIRS 177759-Nye County School District [n.d.], all; DIRS 177760-Esmeralda County School District [n.d.], all); law enforcement data from the Department of Public Safety (DIRS 173399-State of Nevada 2004, all; DIRS 177747-State of Nevada 2005, all; DIRS 177748-State of Nevada 2006, all).

DOE based the description of the affected transportation environment on existing traffic volumes on the roadways (measured as average daily traffic counts), and obtained traffic volumes for roads from the Nevada Department of Transportation traffic report for 2005 (DIRS 178749-NDOT [n.d.], all). The Department then estimated levels of service on the affected roadways using guidelines in the Highway Capacity Manual (DIRS 176524-Transportation Research Board 2001, all).

3.2.9.3 General Regional Socioeconomic Characteristics

DOE examined baseline socioeconomic conditions for selected communities within the region of influence that would be likely to be affected by railroad construction and operations. These communities include Caliente in Lincoln County; Tonopah, Beatty, the Town of Amargosa Valley, and Pahrump in Nye County; and Goldfield in Esmeralda County. This section presents baseline conditions for Clark County at the county level, primarily in relation to economic measures and health-care capacity. DOE assumes that there would be an overall income effect on Clark County from the workers living there and commuting to work on the proposed railroad project, but because of the large population of Clark County, the effect would be small.

3.2.9.3.1 Employment and Income

According to the *Policy Insight* baseline projections listed in Table 3-57, Lincoln County's economy is substantially smaller than Nye County's. The three largest employment sectors in Lincoln County are state and local government (27 percent of the employed population), services (21 percent), and retail trade (11 percent). Mining is also an important employment sector, with 11 percent of the employed population. The county's largest employers include the Lincoln County School District; Lincoln County; and an engineering firm, DynCorp Technical Services, LLC (DIRS 173542-Nevada Department of Employment, Training & Rehabilitation 2005, all). Lincoln County's employment has been declining after growth during the 1980s (DIRS 155970-DOE 2002, p. 3-87). According to *Policy Insight* baseline projections, the gross regional product of the county in 2007 will be $93.6 million, and the real disposable income will be $93.6 million.

Nye County has the second largest economy in the region of influence. The largest employment sectors are services (44 percent of the employed population), followed by retail trade (12 percent), and then transportation warehousing, information, and finance and insurance (11 percent collectively). State and local government and construction are also important sectors. The importance of construction reflects the county's population growth from 1990 to 2003 because new residents and businesses require construction materials and labor, and a range of services. Large employers include National Security Technologies, LLC (NSTec), the management and operating contractor for DOE at the Nevada Test Site, which employs between 1,000 and 1,500 people in the area, although many Nevada Test Site employees live in Clark County (DIRS 173544-Nevada Department of Employment, Training & Rehabilitation 2005, all).

Table 3-57. Lincoln, Nye, Clark, and Esmeralda County employment by industry, 2007.[a]

Industry sector	County			
	Lincoln	Nye	Esmeralda	Clark
Private				
Forestry and fisheries	14	67	3	306
Mining	242	1,094	84	1,420

State and local government	576	1,792	101	83,135
Totals[b]	2,169	18,184	475	1,150,594

a. Source: DIRS 178610-Bland 2007, all.
b. Totals might differ from sums of values due to rounding.

Local government agencies such as the Nye County School District and Nye County, and mining companies such as the Round Mountain Gold Corporation, are also major employers (DIRS 173544-Nevada Department of Employment, Training & Rehabilitation 2005, all).

Nye County employment rebounded after a 15 percent decrease between 1990 and 1995 (DIRS 155970-DOE 2002, p. 3-87). According to *Policy Insight* baseline projections, the gross regional product of Nye County in 2007 will be $1.16 billion, and the real disposable income will be $1.12 billion.

Esmeralda has the smallest economy of the four counties. The county's three largest employment sectors are services, state and local government, and mining, which account for 24, 21, and 18 percent of the employed population, respectively. Employers include government agencies such as the State of Nevada and the Esmeralda County School District, and mining companies such as the Chemetall Foote Corporation, which runs Silver Peak Mine and Lode Star Gold, Inc. (DIRS 173545-Nevada Department of Employment, Training & Rehabilitation 2005, all).

According to *Policy Insight* baseline projections, the gross regional product of Esmeralda County in 2007 will be $25.7 million, and the real disposable income will be $29.3 million.

Clark County's economy dominates southern Nevada. The largest employment sectors are services (50 percent of the employed population; 46 percent of services employment is within the Accommodations and Food Services sectors); transportation warehousing, information, and finances and insurance (14 percent); construction (11 percent); and retail trade (11 percent). According to *Policy*

Insight baseline projections, Clark County surpasses the other counties with a gross regional product of $95.4 billion, which is more than 80 times that of Nye County. According to *Policy Insight* baseline projections, Clark County residents will have $60.7 billion in ***real disposable personal income*** in 2007.

3.2.9.3.1.1 Mining and Agriculture. This section describes existing conditions for mining and agricultural activities, because a railroad along the Caliente rail alignment would be likely to affect these interests more than other economic activities.

Mining At present, Lincoln, and Clark Counties have only industrial mines; Nye County has metallic and nonmetallic mines and oil production fields; and Esmeralda County has industrial and metallic mineral mines. In 2007, the mining industry employed 18 percent of the 475 workers in Esmeralda County and 6 percent of workers in Nye County (DIRS 178610-Bland 2007, all). Mining also constitutes a large part of the total personal income generated in the four-county region of influence. In Esmeralda County in 2002, almost 18 percent of personal income came from mining, making it the single largest source of personal income in the county (DIRS 173546-BEA 2004, Table CA05N). Almost 7 percent of personal income in Nye County came from the mining industry in 2002 (DIRS 173548-BEA 2005, Table CA05N).

Mined minerals in the region of influence include gold, silver, aggregate (consisting of crushed stone, natural sands, and gravel), salt, and a wide range of other non-metallic minerals. Gold is central to Nevada's mining industry, and at $2.4 billion in revenue (DIRS 169127-Driesner and Coyner 2003, all; DIRS 173554-Price and Meeuwig 2003, all), it brings in more revenue than any other type of mining. Silver production is also important and was Nevada's fourth leading mineral commodity in 2002, valued at $62 million.

The Caliente rail alignment would cross some mining areas and districts. Caliente common segment 1 would cross the northernmost portion of the Seaman Range Mining District. As discussed in Section 3.2.2.5.2, most of historic mining activity in this mining district occurred more than 5 kilometers (3 miles) south and southwest of Caliente common segment 1. The South Reveille alternative segments and common segment 3 would pass within 3 kilometers (2 miles) of the Reveille Valley Mining Area. A portion of common segment 3 would cross the Clifford Mining District, which is near Warm Springs. Goldfield alternative segments 1, 3, and 4 would cross the Goldfield Mining District; Goldfield alternative segment 1 also would cross the Diamondfield Mining District. A portion of Caliente common segment 4 would cross the westernmost portion of the Stonewell Mining District, although most of the historic mining activity in this district was approximately 5 kilometers (3 miles) east of the common segment. Finally, Caliente common segment 6 would cross the northeastern portion of the Bare Mountain Mining District, although most historical mining activity there occurred more than 3 kilometers (2 miles) south of this common segment.

Agriculture The primary agricultural activity the Caliente rail alignment would intersect would be grazing. As discussed in Section 3.2.2, Land Use and Ownership, there are 27 separate grazing allotments along the Caliente rail alignment, 24 of which are active. In Section 3.2.2, Land Use and Ownership, Tables 3-6 and 3-7 list and describe these grazing allotments, and Figures 3-26 through 3-33 show the locations of the allotments.

The permitted grazing operations support employment and provide income for ranchers and their workers, and income for the respective counties. BLM-issued grazing permits authorize these operations, and specify the total number of animal unit months apportioned (an animal unit month represents enough dry forage for one mature cow for 1 month). For those allotments for which information is available (see Table 3-6), animal unit months range from 118 to 48,250, and land area ranges from 17 to 4,363 square kilometers (4,200 to 628,000 acres). The BLM established the property base for each allotment based on land or water rights.
