

B. Georges Bank Haddock by Jon Brodziak, Michele Thompson and Russell Brown

1.0 Background

The Georges Bank haddock stock was last assessed at the Transboundary Resources Assessment Committee Meeting in 2001. Based on the 2001 assessment, spawning biomass was increasing (59,700 mt in 2000) from a near-record low of 11,400 mt in 1993 and fishing mortality was relatively low ($F=0.19$ in 2000). In this report, we update the Georges Bank haddock assessment using fishery data for 2001 and available survey data for 2001-2002. Updated estimates of spawning biomass and fishing mortality are used for stock status determination. Sensitivity of assessment results to survey trawl warp marking discrepancies during 2000-2002 is evaluated. An updated estimate of the fishing mortality required to rebuild the spawning biomass to B_{MSY} by 2009 ($F_{REBUILD}$) is provided.

2.0 Assessment for 2002

2.1 2001 Landings

US haddock landings were prorated into Georges Bank and Gulf of Maine stock components using a standard algorithm. US Georges Bank haddock landings totaled 4,637 mt in 2001, a 38% increase over 2000 (Table B1, Figure B1). Canadian landings totaled 6,712 mt in 2001, a 24% increase over 2000. US sea sampling data indicated discard rates of 0-5% in 2001 for primary fishing gears. There were no changes in regulatory measures which might have increased discarding. As a result, discards were assumed to be negligible as in the 2000 and 2001 assessments (Brown and Munroe 2000).

US Commercial fishery sampling increased in 2001 (Table B2) for total number of samples (+41%), fish lengths (+43%), and fish ages (+58%) over 2000 sampling. Commercial fishery sampling on western Georges Bank was adequate to compute US catch-at-age on a quarterly basis (Table B2). Sampling was not adequate on eastern Georges Bank to characterize fishery length compositions due to a lack of large and scrod haddock sampling in the second half of the year (Table B2). US Landings are relatively low on eastern Georges Bank (608 mt in 2001) versus western Georges Bank (4,028 mt in 2001). Fisheries in both areas use otter trawl gear and length selectivity is similar. As a result, US catch-at-age data for eastern Georges Bank was computed on a quarterly basis using the commercial fishery length composition of western Georges Bank landings with the addition of all US length samples from eastern Georges Bank (Table B2). Canadian commercial fishery age-length keys from eastern Georges Bank were used for quarters 2, 3, and 4, while the Canadian spring survey age-length key was used for quarter 1. Canadian commercial fishery length sampling ($n=67,905$ fish) was over 10-fold greater than US fishery length sampling ($n=5,276$ fish). Canadian commercial fishery age sampling ($n=1,393$ fish) was comparable to US fishery length sampling ($n=1,985$ fish). The US fishery catch-at-age data was combined with the Canadian fishery catch-at-age data to compute total catch at age (Table B3).

2.2 Survey Indices

US spring survey indices were computed for 2001-2002 (Table B4) and US autumn survey indices were computed for 2001 (Table B5) using standardized data. Canadian survey indices for 2001-2002 (Table B6) were provided by DFO, Canada (Stratis Gavaris, personal

communication). Canadian survey indices in 2001-2002 were lower than the record high 2000 index which included unusually large catches in stratum 5Z8. Survey maturity-at-age analyses from the 2001 assessment were used for computing spawning biomass.

3.0 Assessment Results

3.1 VPA Results

An updated VPA analysis for Georges Bank haddock was conducted. The VPA formulation was identical to that used for the 2001 assessment, with the exception that the US spring survey was used for tuning in the terminal year. The updated VPA had a total of 30 new survey index values for calibration. VPA diagnostics indicated a good fit to the survey data with maximal coefficients of variation of catchability ranging from 0.14 to 0.34 across surveys.

VPA results indicate that total stock size increased (Table B7) from 80.5 million fish in 2000 to 111.4 million fish in 2002 (+38%). Spawning biomass increased (Table B8, Figure B3) from 59,000 mt in 2000 to 74,400 mt in 2001 (+26%). Fishing mortality (average ages 4-7, unweighted) increased from 0.19 in 2000 to 0.22 in 2001 (+16%; Table B9, Figure B4). Results indicate that the 1998 (39.5 million) and 2000 (75.1) year classes are the strongest since 1978. Preliminary indications are that the 2001 year class may be well below average. Retrospective analysis suggests a random pattern of retrospective estimation errors (Figure B5). Bootstrap analysis indicates that estimates of spawning biomass and F in 2001 are relatively precise with coefficients of variation of 9-10%.

3.2 Sensitivity Analyses

3.2.1 Potential Survey Trawl Warp Inconsistencies during 2000-2002

Measurements of NEFSC survey trawl warps in autumn 2002 suggested that right and left warps may have been offset by up to several feet during winter 2000 through spring 2002 surveys. To evaluate the sensitivity of VPA results to potential undercapture of fish, NEFSC spring and autumn survey indices were arbitrarily adjusted upwards by 10%, 25%, and 100% for spring 2000 through spring 2002 (Figure B6). Results are summarized in Section 5.2 (Summary of Assessment Advice).

3.2.2 Influence of Survey Index Time Series Selection

VPA analysis for Georges Bank haddock includes three survey index time series (US spring, US fall, and Canadian spring). To evaluate sensitivity of baseline results to selection of survey index time series, VPA analyses were conducted using only one index for calibration. Results indicate that the baseline results are closely matched by one-index results for US spring and US fall indices while one-index results for the Canadian spring index produce higher spawning biomass and lower F estimates than the baseline.

4.0 Sources of Uncertainty

- US catch-at-age data for eastern Georges Bank haddock landings are less certain than for western Georges Bank haddock. Improved sampling of US landings from eastern Georges Bank haddock would improve precision of US catch-at-age data.
- Proration of landings are based on preliminary logbook data and are subject to change.

5.0 Summary Stock Status

5.1 Biological Reference Points

For Georges Bank haddock, spawning biomass (B_{MSY}) and the proxy fishing mortality (F_{MSY}) to produce MSY are $B_{MSY} = 250,300$ mt and $F_{MSY} = 0.263$ (NEFSC 2002). The overfished threshold ($B_{THRESHOLD}$) for Georges Bank haddock is $B_{THRESHOLD} = \frac{1}{2} B_{MSY} = 125,200$ mt. The overfishing threshold ($F_{THRESHOLD}$) for Georges Bank haddock is $F_{THRESHOLD} = F_{MSY} = 0.26$.

5.2 Stock Status in 2001

In 2001, spawning biomass was 74,400 mt (59% of $B_{THRESHOLD}$ and 30% of B_{MSY}). Therefore, the Georges Bank haddock stock was overfished in 2001. In 2001, the fishing mortality was 0.22 (85% of $F_{THRESHOLD}$). Therefore, overfishing was not occurring on the Georges Bank haddock stock in 2001.

5.3 Projections

Age-structured projections were conducted to compute $F_{REBUILD}$ for 2003-2009. A two-stage resampling model using the cumulative distribution function of observed recruitment with a cutoff spawning biomass value of 75,000 mt was updated using recruitment results from the baseline VPA and updated mean weights at age and selectivities based on 1999-2001 averages. The assumed value of fishing mortality in 2002 was $F_{2002} = 0.85 * F_{2001} = 0.19$. The assumed 15% reduction in F from 2001 to 2002 is based on environmental impact analyses of the probable impacts of implementing the Settlement Agreement for the Amendment 9 groundfish lawsuit during fishing year 2002.

Projection results indicate that $F_{REBUILD} = 0.197$ (Table B10, Figure B7). Median projected spawning biomass and landings in 2009 under $F_{REBUILD}$ are 250,300 mt and 38,300 mt. Median projected landings in 2002, 2003, and 2004 are 12,500 , 17,800 , and 19,400 mt, respectively. Average projected landings for fishing years 2002-2003 and 2003-2004 are 15,000 and 18,600 mt.

¹Data 1963-1979 from Clark et al. (1982); Data 1980-1981 from Overholtz et al. (1983); Data 1982-1990 from Hayes and Buxton (1992); data from 1991-1994 from O'Brien and Brown (1996); data from 1995-2001 from current assessment, Gavaris and Van Eekhaute (1999), and S. Gavaris (personal communication).

²Of this total, approximately 1.0 million fish were added to the catch at age to account for high discards in 1974.

³Of this total, approximately 12.8 million fish were added to the catch at age to account for high discards in 1977.

⁴Of this total, approximately 5.0 million fish were added to the catch at age to account for high discards in 1978.

⁵Of this total, approximately 20.0 million fish were added to the catch at age to account for high discards in 1980.

⁶Total includes discards resulting from trip limit regulations for most year classes.

Table B4. Stratified mean catch per tow (numbers) for haddock in NEFSC offshore spring research vessel bottom trawl surveys on Georges Bank (Strata 01130-01250, 01290-01300), 1968-2002. Indices have been corrected to account for changes in catchability due to changes in research vessels and doors.

Table B10. Input data and results for short-term (2002-2005) stochastic stock biomass and catch projections for Georges Bank haddock.

Input for Projections:

Number of Years: 3; Initial Year: 2002; Final Year: 2005
 Number of Ages : 9; Age at Recruitment: 1; Last Age: 9
 Natural Mortality is assumed Constant over time at: .200
 Proportion of F before spawning: .25
 Proportion of M before spawning: .25
 Last age is a PLUS group;

Age-specific Input data for Projection # 1

Age	Fish Mort Pattern	Nat Mort Pattern	Proportion Mature	Average Catch	Weights Stock
1	.0010	1.0000	.0400	0.579	0.395

Projections for 2002-2005; $F(2002)=0.19$; Basis: 85% of 2001 point estimate. Recruitment (age 1) 2002-2004 year classes derived from two-stage resampling of 1931-2001 stock-recruitment data excluding the 1963 year class with a 75,000 mt spawning biomass cutoff.

SSB was estimated to be 74,400 mt in 2001.
