Dear National Forest Planning Participant:

Enclosed is a copy of the Draft Environmental Impact Statement (DEIS) and Draft Revised Forest Plan for the Targhee National Forest. The primary purpose of these documents is to outline the proposed management of the Targhee National Forest for the next 10-15 years.

I appreciate all the assistance some of you in the community have provided as we developed these plans.

Your review and comments on the Draft EIS and Revised Forest Plan are important to the analysis process. In your review, I encourage you to pay particular attention to concerns you may have raised earlier in the process to see if the analysis is responsive. Comments on the DEIS should be as specific as possible and must be received no later than JUN 7 1996.

E-mail comments can be submitted to /s=drev/oui=r04f15a@mhs-fswa.attmail.com. It would be helpful to know the reasons for your comments, to help us make better informed decisions. Positive comments about portions that are acceptable to you would also be appreciated. After the comment period ends, the comments will be analyzed and the Final EIS and Record of Decision prepared.

If you have questions or comments please contact me or Carol Cushing, Forest Planner, at P.O. Box 208, St. Anthony, ID 83445 or call (208) 624-3151.

Sincerely,

JERRY B. REESE
Forest Supervisor

ABSTRACT: This Draft Environmental Impact Statement documents the analysis of seven alternatives, which were developed for possible management of the 1.8 million acres administered by the Targhee National Forest. Alternative 3-M is the Forest Service's preferred alternative.

The alternative ultimately chosen may change based on input from the public, other agencies, and this agency's own internal deliberative process. That alternative, selected by the Regional Forester, will be published in the final EIS, and will become the Forest Plan Revision, which will guide management of the Targhee National Forest in the future.

Date of transmission to the Environmental Protection Agency and the public is: MAR 1 1996.
Send comments regarding this Draft Environmental Impact Statement to the Forest Supervisor, Targhee National Forest, at the above address by JUN 7 1996.

The comment period of the draft EIS will be 90 days from the date the Environmental Protection Agency publishes the notice of availability in the Federal Register.

The Forest Service believes it is important to give reviewers notice of several court rulings related to *public participation in the environmental review process*. First, reviewers of draft EISs must structure their participation in the environmental review of the proposal so that it is meaningful and alerts an agency to a reviewer's position and contentions. (*Vermont Yankee Nuclear Power Corp. v. NRDC*, 435 U.S. 519, 553 (1978)) Also, environmental objections that could be raised at the draft EIS stage, but are not raised until after completion of the final EIS may be waived or dismissed by the courts. (*City of Angoon v. Hodel*, 803 F.2d 1016, 1022 (9th Cir. 1986) and *Wisconsin Heritages, Inc. v. Harris*, 490 F. Supp. 1334, 1338 (E D. Wis. 1980)) Because of these court rulings, it is very important that those interested in this proposed action participate by the close of the comment period so that substantive comments and objections are made available to the Forest Service at a time when it can meaningfully consider them and respond to them in the final EIS.

To assist the Forest Service in identifying and considering issues and concerns on the proposed action, comments on the draft EIS should be as specific as possible. It is also helpful if comments refer to specific pages or chapters of the draft EIS. Comments may also address the adequacy of the draft EIS *or the merits of the alternatives formulated and discussed in the statement*. Reviewers may wish to refer to the Council on Environmental Quality Regulations for implementing the procedural provisions of the National Environmental Policy Act at 40 CFR 1503.3 in addressing these points.

Please note that comments on the draft EIS will be regarded as public information.

The policy of the United States Department of Agriculture Forest Service prohibits discrimination on the basis of race, color, national origin, age, religion, sex, or disability, familial status, or political affiliation. Persons believing they have been discriminated against in any Forest Service related activity should write to: Chief, Forest Service, USDA, P.O. Box 96090, Washington, DC 20090-6090.

SUMMARY OF THE DRAFT ENVIRONMENTAL IMPACT STATEMENT FOR THE TARGHEE MANAGEMENT PLAN

The purpose of the summary of the Draft Environmental Impact Statement (DEIS) for the Forest Plan Revision is to provide the reader with a quick overview of the planning process, the issues, and the alternatives, including the preferred, that will affect the management of the Targhee National Forest for the next ten years and beyond.

The DEIS considers and evaluates an array of alternatives, identifying the preferred. This summary will not cover the Draft Revision (DREV). The DREV carries out the actions of the preferred alternative and provides key decisions for the long-term management of the Forest. The DREV summary is contained in a document called "The Executive Summary."

Readers wanting more in-depth information or who wish to comment on the DEIS and DREV may write or call the Targhee National Forest Supervisor's Office at P.O. Box 208, St. Anthony, Idaho 83445, (208) 624-3151.

Vicinity Map of Targhee National Forest on a National Scale

GENERAL INFORMATION: LOCATION AND SETTING FOR THE TARGHEE NATIONAL FOREST

The Targhee National Forest is an administrative unit of the Department of Agriculture, Forest Service, encompassing 1.8 million acres. Established by President Theodore Roosevelt in 1908, the Forest is named in honor of a Bannock Indian warrior. The Targhee Forest Supervisor's Office is located in St. Anthony, Idaho with District offices in Dubois, Island Park, Ashton, Idaho Falls, and Driggs. The Forest is bordered by six other National Forests.

The Forest lies almost entirely within the Greater Yellowstone Ecosystem, an area of 12 million acres and the largest remaining block of relatively undisturbed plant and animal habitat in the contiguous United States.

On a larger scale, the Forest lies along the Continental Divide, at the uppermost reaches of the Columbia River Basin, an ecosystem of 40 million acres extending from Western Washington to the Southeastern Idaho border and encompassing parts of Montana, Wyoming, Nevada and Utah. The Forest includes all or portions of several distinct mountain ranges, including the Lemhi, Beaverhead, Bitterroot, Centennial, Henry's Lake, Teton, Big Hole, Caribou, and Snake River Ranges. Elevations range from near 5,000 feet on the Snake River to over 12,000 feet on the Forest's western and easternmost reaches. The Forest contains the Island Park Caldera and several reservoirs. Topography ranges from rolling foothills to rugged, glaciated mountain peaks.

Although most of the land is dry and semi-arid, 190 stream headwaters situated on the Forest provide varied vegetation to support a multitude of uses. The area has cold, moist winters and hot dry summers. Average annual precipitation, most of which falls as snow, increases with elevation. As little as ten inches of precipitation falls in lower valleys and as much as forty inches occurs at the highest elevations. Wide temperature extremes exist, with summer temperatures at lower elevations exceeding 100 degrees Fahrenheit and winter temperatures at higher elevations falling to less than 40 degrees below zero Fahrenheit.

SUMMARY OF THE DRAFT ENVIRONMENTAL IMPACT STATEMENT (DEIS)

The 1985 Current Forest Plan emphasized an extensive salvage and reforestation program of dead lodgepole killed by a massive mountain pine bark beetle epidemic over the previous 3 decades. The 1996 DEIS recommends a preferred alternative that provides for sustainable management with a more balanced program for recreation, wildlife habitat, timber harvest, and other uses of the Forest.

Need for Change

Several reasons triggered the need to change from the old direction to a new one. In summary these were,

The salvage program was over, much of the remaining dead lodgepole was no longer marketable or accessible. An overabundance of old salvage roads was impacting wildlife and riparian habitat and soil productivity.

The recently adopted concept of Ecosystem Management by the Forest Service needed to become an integral part of the Forest's direction. A revision would require the Forest to be managed for sustainability of all ecologic and social components for the present and the future

New knowledge and findings for wildlife habitat management, unknown at the time of the 1985 Current Forest Plan, needed to be incorporated into a new Forest direction.

Results from monitoring data indicated that the Forest was not meeting all of the 1985 Current Forest Plan goals for some resources such as wildlife habitat, riparian areas, vegetation, and human access management.

Desired Future Condition for the Year 2010

Based on public and Forest Service employee comments received between 1991-1994, a set of goal statements, called the "Desired Future Condition for the Year 2010", emerged that collectively represent where the Forest would ideally like to be. The Desired Future Condition influenced the selection of the preferred alternative in the Draft EIS. These are described as follows:

Ecosystem Processes and Patterns Desired Future Condition:

A mosaic of age classes and types of vegetation are sustained through time and exist across the landscape. Natural disturbances such as insects, disease and fires continue their natural roles in the ecosystem. The Forest functions as an integral part of the Greater Yellowstone Ecosystem as well as adjacent systems, sustaining habitat and conditions necessary for free movement of wildlife.

Biological/Physical Desired Future Condition:

Riparian zones are healthy and productive. Aquatic systems are allowed to function naturally while protecting flows for downstream consumptive uses. Riparian area integrity contributes to productive fisheries and excellent water quality. Native plant and animal species are favored over undesirable nonnative species and sustained populations of all native and desirable species thrive. Habitat conditions contribute toward the recovery of Threatened, Endangered and Sensitive Species.

Forest Use and Occupation Desired Future Condition:

Growing and diverse recreational, cultural, visual, historical and prehistoric management, interpretive, and spiritual needs are accommodated based on the capability of the ecosystem to sustain these uses. Recreation use is managed to minimize conflicts between incompatible uses and provides high levels of satisfaction. Year-round human access is managed to provide both motorized and nonmotorized opportunities. A system of trails and support facilities exist which are compatible with resource capabilities. Roadless characteristics are preserved in the proposed wilderness areas and in existing Wildernesses.

Production of Natural Resources Desired Future Condition:

Commodity production, such as timber, firewood, mining, livestock forage; or outfitting and guide services are conducted at sustainable levels and maintain the capability of the land to produce an even flow and variety of goods and services for present and future generations. Timber harvest, prescribed fires and livestock grazing are used as tools to achieve desired ecological vegetation conditions. Forest products are provided to sustain social and economic values and needs of the local communities within limits which maintain ecosystem health.

Key Issues

Although there were over 70 issues and concerns identified by the public and Forest employees, seven Key Issues were the ultimate driving force for developing the alternatives and for the recommended direction of the Revised Forest Plan. The Key Issues had the most significance as variables between the alternatives and are points of conflict

Each Key Issue received an "Issue Indicator", a unit of measurement that showed how the issue was addressed in each alternative. The leadership team, consisting of the Forest Supervisor, District Rangers, Branch Chiefs and Public Affairs Officer, studied the issues and selected one major indicator for each issue that best reflected the variability for that issue between the alternatives.

Key Issue 1: Sustainability, Fire, and Natural Disturbances

An Ecosystem is a large, complex, integrated system of living and nonliving components that interact and change continually. Healthy ecosystems are those that retain all of their parts and functions for future generations even though vegetation patterns, human uses, or other conditions may change. Because ecosystem management is a new approach for the Forest Service, a variety of approaches are possible in working towards implementation. Issue 1 mainly focuses on determining actions needed for sustainability and maintenance of a healthy ecosystem, particularly as it relates to fire, insects and disease, collecting and monitoring data; and identifying the range of variability.

Issue 1 Indicator: Of all the indicators of ecosystem health, patch size limit (in acres) was selected. A patch is defined as an area of vegetation that is structurally and/or compositionally different from what surrounds it — for example, a clearcut of 40 acres within a lodgepole pine component is a patch. Patch size limit was selected because the forest has gathered some general information about the subject from old historical photos and maps. Changes in patch sizes from what existed historically, particularly as it relates to fire and other natural disturbances, may affect individual species or ecosystem sustainability. As our knowledge increases about the nature and magnitude of patch size limits, the Forest may be constrained in its ability to achieve desired patch sizes by the National Forest Management Act's harvest unit size limit or other species or resource considerations. At this time the Forest does not know the implications of historical changes in vegetation patch sizes for other resources such as animal populations.

Key Issue 2: Riparian

Riparian areas lie adjacent to water and are composed of vegetation communities dependent upon water near the ground surface. Riparian areas are associated with lakes, reservoirs, springs, bogs, wet meadows, and streams. Riparian areas are essential breeding, rearing and feeding grounds for many species of wildlife and all fish. They serve people as important sources for water and flood control and for recreational purposes such as camping, fishing, floating and aesthetics. Although riparian areas constitute less than 5 percent of the total land base, they are the most productive areas in terms of plant and animal species diversity and consumptive use. A healthy riparian area indicates that the aquatic, water and soil components are also healthy.

Issue 2 Indicator: The issue indicator showing the differences between the alternatives for riparian areas is Desired Vegetation Condition. The riparian area's health is indicated by the amounts and types of riparian vegetation along the streambanks, with highest preference to native deep-rooted grasses, shrubs and trees that maintain streambank stability and provide for a high rate of recovery following disturbance.

Key Issue 3: Security for Elk

Although the Forest provides habitat for a number of wildlife species (85 mammals, 301 birds, 17 reptiles and amphibians), for many there were only slight differences in the management of their habitat amongst the alternatives. Security for elk was chosen as a key issue relating to future hunting conditions and opportunities and cooperative relations with Fish and Game Departments. Observations and studies by agency and university scientists determined that, as motorized road and trail densities increase, elk security declines. Portions of the Forest have high densities of trails and roads open to motorized use due to the extensive road building associated with the salvage activity of removing the dead lodgepole.

Issue 3 Indicator: The best indicator showing the differences between alternatives for elk security is "the percentage of the Forest meeting State Fish and Game vulnerability thresholds for elk." Elk vulnerability is defined as a measure of elk susceptibility to being killed during the hunting season. As cross country off-highway vehicle travel and motorized road and trail densities increase, the security for elk decreases and mortality rate increases. The primary effect that the Forest Service has control over, related to elk vulnerability, is the density of open motorized roads and trails and the amount of area open to cross-country, off-highway vehicle travel.

Key Issue 4: Grizzly Bear Management Units

Portions of the Forest are within the Yellowstone Grizzly Bear Ecosystem which has been divided into Bear Management Units (BMU's). Portions of the Forest are within three BMU's and feature grizzly bear recovery. As with all threatened and endangered species, all alternatives must meet the stringent guidelines of the Endangered Species Act. The importance of managing motorized access is one of the most influential parameters affecting grizzly bear habitat security. New information accumulated over the last ten years provides better insight and direction regarding effective management of roads, timber and human activities in grizzly bear habitat.

Issue 4 Indicator: The indicator for the Bear Management Units issue is the Open Road and Open Motorized Trail Route Density. By managing motorized access, the Forest can minimize human interaction and potential grizzly bear mortality, displacement from important habitats, and habituation to humans.

Key Issue 5: Access

The Forest currently has 1,367 miles of open system road and 1,021 miles of open nonsystem roads; 433 miles of open system trail and 199 miles of open nonsystem trail. "Open" means road and trail miles without restrictions on motorized use. There are currently road and trail miles with restrictions on motorized use as follows: 633 miles of restricted system road (61 miles with seasonal restrictions and 572 miles with yearlong restrictions), 201 miles of restricted nonsystem road (24 miles with seasonal restrictions and 177 miles with yearlong restrictions); 597 miles of restricted system trail; 102 miles of restricted nonsystem trail.

Recreational motorized use has increased over the last decade. The current plan allows cross-country motorized travel across much of the Forest and does not establish road density standards. Road closures would provide more protection and fewer impacts upon wildlife, threatened, endangered, and sensitive species, soils and water, and fisheries; less visual, garbage and noise pollution; reduced maintenance, and more opportunity for escape and solitude. Open roads and trails would allow more access for hunting, fishing, berry-picking, developed camping, hiking and other recreational pursuits, increased opportunities for sightseeing, challenging cross-country travel for off-highway vehicles, and greater access for persons with disabilities and the elderly.

Issue 5 Indicator: The indicator that best showed differences between alternatives is the Number of Miles of Road/Trails Open to Summer (June-Sept) Motorized Use.

Key Issue 6: Management of Roadless Areas

The Forest has sixteen areas which qualify as roadless, totaling 841,000 acres. The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in the Wyoming Wilderness Act of 1984. Portions of three roadless areas in Idaho were recommended as wilderness in the current Forest Plan, but no legislative action has been taken to resolve the roadless areas question in Idaho. During the last planning period, some roadless areas were roaded as part of the salvage program. As motorized recreation demands increase, public debate increases over whether or not the Forest should maintain the roadless character of the remaining roadless areas. More acres of a Congressionally designated wilderness assures protection from resource uses and national recognition of wilderness character. Fewer acres in wilderness would allow more motorized access for recreation, oil and gas, timber and other industries.

Issue 6 Indicator: The indicator for Issue 6 is the Number of Acres Recommended for Wilderness. Prior to designation by Congress, recommended wilderness areas' roadless character is protected. Once a roadless area is designated as wilderness by Congress, it is managed in perpetuity for non motorized, scientific, and dispersed recreational purposes.

Key Issue 7: Timber Harvest

The three major timber species available for harvest on the forested areas of the Targhee are quaking aspen (15%), Douglas fir (15%), and lodgepole pine (60%). Previously, large scale salvage of dead and dying lodgepole pine timber was conducted at levels that could not be sustained. Since the harvest of dead timber has largely been completed, the Forest must now harvest at sustainable levels. The Endangered Species Act; Grizzly Bear Recovery Plan and Guidelines, Ecosystem Management principles, demise of availability of dead lodgepole, increased knowledge about the impacts of motorized use of roads and trails upon the Forest's resources, and other factors result in a greatly reduced availability of timber for harvest, called the allowable sale quantity (ASQ). The amount of firewood availability does not vary among the alternatives. A greater harvest of timber aids the local economy, better maintains the 25% payments to local governments, maximizes the removal of the remaining dead or mature wood, and assists in faster regeneration of the fire-dependent lodgepole pine. A reduction in timber harvest results in fewer impacts by motorized trail and road uses upon wildlife, riparian areas, soils and water, aesthetics and other resources.

Issue 7 Indicator. The key indicator for this issue is the Allowable Sale Quantity (ASQ). The ASQ does not include firewood and is defined as the quantity of timber that may be sold from the area of suitable land for a ten-year period specified in a Forest Plan.

The Alternatives

Before creating alternatives, the Forest and public put together an "Analysis of the Management Situation," (AMS) which looked at current conditions and direction of the Forest. Alternatives were developed by using the AMS data that identified problem areas that needed changing.

The alternatives reflected a range of options that responded to the issues, the desired future condition, and the need for change. The interdisciplinary team evaluated the significant physical, biological, economic and social effects of each alternative that was considered in detail. The evaluation included social and economic impacts, outputs of goods and services, and overall protection and enhancement of environmental resources.

The Forest analyzed in detail seven alternatives; the Forest Supervisor and Leadership Team recommended Alternative 3-Modified to the Regional Forester and the public for review.

The Alternative Continuum

The numbering scheme for alternatives ranges from 1-6, with alternative 3-M being the preferred Alternative and Alternative 1 being the No-Action or continue the Current Forest Plan Alternative. As the numbers increase from Alternatives 2 to 6, they move consistently towards.

- *Greater protection of wildlife habitat
- *Greater protection of riparian areas
- *More protection for Bear Management Units
- *More security for elk
- *More nonmotorized, dispersed recreation opportunities
- *More recommended wilderness
- *Less cross-country motorized use
- *Fewer open roads and trails
- *Reduced livestock grazing and timber harvest
- *Fewer lasting visual impacts from management activities

A Summary Description of the 7 Alternatives

ALTERNATIVE 1 = Continue the Current Forest Plan (No Action)

The purpose of Alternative 1 is to continue management of the Forest under the current Forest Plan, finalized in 1985, and updated with amendments, litigious concessions for the grizzly bear; and changes for new listings of sensitive wildlife species over the last ten years. Timber harvest occurs at the highest levels possible within the management constraints required for threatened and sensitive wildlife species like grizzly bears and goshawks. Vehicle access is slightly reduced over current levels due to the implementation of the interagency grizzly bear guidelines and better road management across the Forest. Cross-country, motorized access in summer and winter would continue close to current levels. Riparian, wildlife and recreation values are emphasized in specific areas of the Forest. Alternative 1 recommends portions of the Lionhead, Italian Peaks and Winegar Hole roadless areas for wilderness designation. Their roadless characteristics are maintained until Congress acts on the recommendation.

ALTERNATIVE 2

The purpose of Alternative 2 is to resolve the needs for change by emphasizing cross-country, winter access and timber production, while adding more restrictions to summer, cross-country access. Timber harvest occurs at the highest levels within the management constraints required for maintaining threatened, endangered and sensitive species habitat. Grazing continues at current levels. *Vehicle access is slightly reduced to meet requirements of the interagency grizzly bear guidelines.* Riparian, wildlife and heritage resource values are emphasized in specific areas of the Forest. Alternative 2 makes no recommendations to Congress for wilderness designation.

ALTERNATIVE 3

The purpose of Alternative 3 is to resolve the needs for change by emphasizing management of wildlife habitat and sustaining timber harvest levels within wildlife constraints. Grizzly bear recovery is enhanced with a reduction in motorized use allowed in each BMU. Grazing allotments continue at current levels and larger percentage of riparian areas meet the desired vegetation condition. Cross-country, summer, motorized vehicle use is restricted to specific areas. Lionhead, Palisades and

Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness are recommended to Congress for wilderness designation; until Congress acts on the recommendation, their roadless characteristics are maintained.

ALTERNATIVE 3-M = Alternative 3 Modified (Also the Proposed Programmatic Action and Preferred Alternative)

The purpose of Alternative 3-M is to resolve the needs for change by providing sustainable management with a balanced program among, wildlife habitat, timber harvest, recreation, and other uses and resources of the Forest. Alternative 3-M also provides increased emphasis for wildlife habitat management and allocates more core areas for grizzly bear. Motorized access, timber harvest levels and livestock grazing are all reduced from levels allowed in the current Forest Plan. Riparian areas with cutthroat trout are further protected with increased vegetation and reduced livestock grazing. Cross-country, summer, motorized vehicle use is restricted to specific areas. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness are recommended to Congress for wilderness designation; until Congress acts on the recommendation, their roadless characteristics are maintained.

All the alternatives respond to and incorporate the resource objectives set forth in the Recommended 1990 RPA Program. Alternative 3-M has been selected as the RPA Alternative because it represents the Forest's best attempt to simultaneously implement multiple-use management, ensure resource sustainability, emphasize the quality of resource outputs, and to provide for the economic well-being of rural communities.

ALTERNATIVE 4

Alternative 4 emphasizes watershed and wildlife habitat improvement and a reduction in timber harvest. Riparian areas receive increased emphasis. Motorized access is restricted to designated routes and more roads are closed in BMU's than in previous alternatives. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness and another 14,000 acres of roadless areas are recommended to Congress for wilderness designation; until Congress acts on the recommendation, their roadless characteristics are maintained.

ALTERNATIVE 5

The purpose of Alternative 5 is to meet the needs for change that reduce focus on human management and human disturbances of wildlife and riparian habitat. Motorized access is restricted to designated routes and more roads are closed in BMU's. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness and another 100,000 acres of presently roadless areas are recommended to Congress for wilderness designation, until Congress acts on the recommendation, their roadless characteristics are maintained.

ALTERNATIVE 6

The purpose of Alternative 6 is to meet the needs for change by de-emphasizing human management and human disturbance of wildlife and riparian habitat to the lowest level in all the alternatives. Timber harvest is not scheduled. All access is strongly restricted to designated routes and more roads are closed to reduce human disturbance than in any other alternative. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness and another 340,000 acres of presently roadless areas are recommended to Congress for wilderness designation. Almost all the roadless areas retain their roadless characteristics.

COMPARING THE ALTERNATIVES USING SOME ISSUE INDICATORS

This page contains a summary of the environmental effects of the seven alternatives. This summary is drawn from information in Chapters II and IV of the DEIS and Table II-1. M means that all acres are in the thousands (* are Key Issue Indicators)

	Exist Level	Alt #1	Alt #2	Alt #3	Alt #3-M	Alt #4	Alt #5	Alt #6
* M Acres restricted to openings < Range of Variability	NA	47	25	82	259	310	333	330
- M Acres where prescribed fire is allowed	1,282	1,282	1,401	1,302	1,232	1,223	1,202	1,256
- M Acres open to locatable and mineral entry	1,722	1,383	1,414	1,324	1,277	1,340	1,197	968

Alternatives Comparison Chart

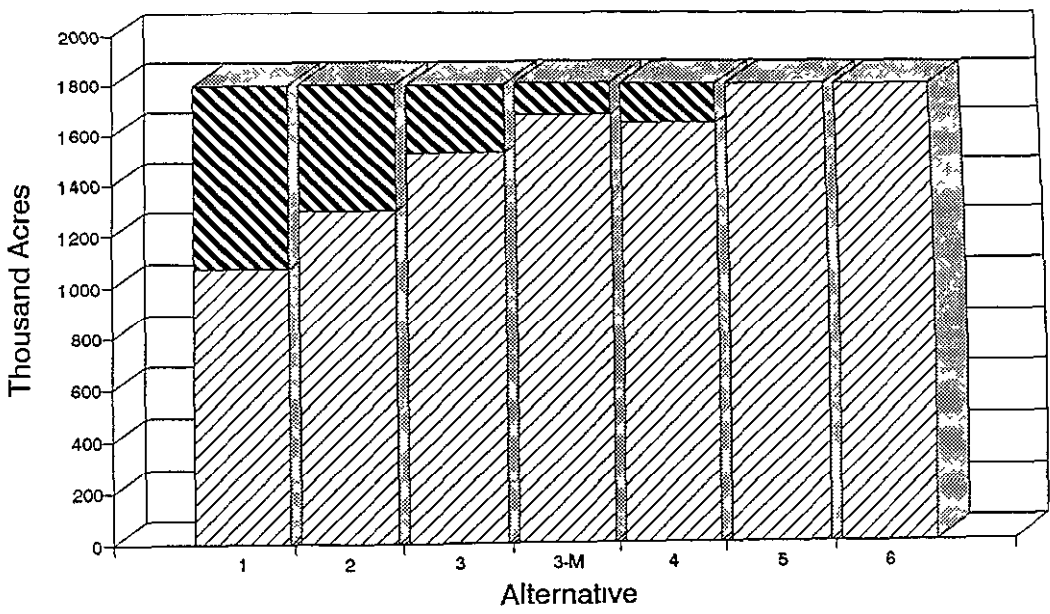

This chart shows how the alternatives compared, or stacked up against each other when the Key Issue indicators' differences were analyzed. The differences are determined by the alternative with the most advantages. For grizzly bear management, the alternative with the fewest number of open roads and motorized route density receives the highest rating. For the access issue, the alternative with the most numbers of trails and roads open per mile received the highest rating

All alternatives meet baseline State and Federal Standards; Grizzly Bear Recovery Plan Goals for Greater Yellowstone Ecosystem, Threatened and Endangered Species Act, Wilderness Act; Wild and Scenic Rivers Act, National Historical Act; NFMA, Native Americans Act; etc.

Livestock Grazing
 Thousand Animal Unit Months (MAUM's)

Elk Vulnerability
 State Thresholds Achieved/Not Achieved

Achieved
 Not Achieved

Bear Management Units (BMU's) Open Road/Motorized Trail Route Density

Purpose and Need for a Forest Plan Revision

CHAPTER I

PURPOSE AND NEED FOR A FOREST PLAN REVISION

READER'S GUIDE - In this chapter you will find:

General Information about the Targhee National Forest
Legal Background for Preparing Forest Plan Revisions
Decisions Based on this EIS
Decisions Made in a Revision
Background about the 1985 Targhee National Forest Management Plan
Reasons for Revising the Plan
Introduction to Issue Components
Introduction to Key Issues and Key Indicators Driving the Revision
Discussion of Key Issues and Key Indicators

GENERAL INFORMATION: LOCATION AND SETTING FOR THE TARGHEE NATIONAL FOREST

The Targhee National Forest (hereafter usually referred to as "the Forest") is an administrative unit of the Department of Agriculture, Forest Service, encompassing 1.8 million acres. Established by President Theodore Roosevelt in 1908, the Forest is named in honor of a Bannock Indian warrior. The Shoshone-Bannock Tribe, has ancestral Treaty Rights to uses of the Forest. The Targhee Forest Supervisor's Office is located in St Anthony, Idaho, with District offices in Dubois, Island Park, Ashton, Idaho Falls, and Driggs. The Forest is bordered by six other National Forests. Part of the Caribou National Forest is administered by the Targhee and part of the Targhee is administered by the Bridger-Teton National Forest.

The majority of the Forest lies in eastern Idaho and the remainder in western Wyoming (Figure I-1). Situated next to Yellowstone and Grand Teton National Parks, the Forest is home to a diverse number of wildlife and fish, including Threatened and Endangered species, wilderness, scenic panoramas and intensively managed forest lands.

The Forest lies almost entirely within "the Greater Yellowstone Area" or "the Greater Yellowstone Ecosystem," an area of 12 million acres and the largest remaining block of relatively undisturbed plant and animal habitat in the contiguous United States. The area continues to gain prominence for its ecological integrity. The United Nations has identified the area as a Biosphere Reserve.

On a larger scale, the Forest lies entirely within the Upper Columbia River Basin, an ecosystem of 40 million acres extending from Western Washington to the Southeastern Idaho border and encompassing parts of Montana, Wyoming, Nevada and Utah. The Forest includes all or portions of several distinct mountain ranges, including the Lemhi, Beaverhead, Bitterroot, Centennial, Henry's Lake, Teton, Big Hole, Caribou, and Snake River Ranges. Elevations range from near 5,000 feet on the Snake River to over 12,000 feet on the Forest's westernmost reaches. The Forest contains the Island Park Caldera and several reservoirs. Topography ranges from rolling foothills to rugged, glaciated mountain peaks.

Vicinity Map of Targhee National Forest
on a National Scale

Although most of the land is dry and semiarid, 190 stream headwaters situated on the Forest provide varied vegetation to support a multitude of uses. The area has cold, moist winters and hot, dry summers. Average annual precipitation, most of which falls as snow, increases with elevation. As little as ten inches of precipitation falls in lower valleys and as much as forty inches occurs at the highest elevations. Wide temperature extremes exist with summer temperatures at lower elevations sometimes exceeding 100 degrees Fahrenheit and winter temperatures at higher elevations falling to 40 degrees Fahrenheit below zero and lower.

LEGAL BACKGROUND FOR PREPARING FOREST PLAN REVISIONS

The National Forest Management Act (NFMA) of 1976 requires the Forest Service to develop 10-year integrated land management plans for units of the National Forest System within the framework of a public involvement process. NFMA directs the Forest Service to review and/or update forest plans every ten to fifteen years or more frequently when resource and management conditions have changed significantly. The plans must include management guidelines, an assessment of suitability of the lands, and consistency with the two other laws relating to the management of National Forests: The Multiple Use-Sustained Yield Act of 1960, and the Forest and Rangeland Renewable Resources Planning Act (RPA) of 1974. The Management Plan for the Forest was finalized in 1985. This is the first Revision of that plan.

DECISIONS BASED ON THIS EIS

An Environmental Impact Statement (EIS) is a document that proposes two or more alternatives to a proposed action of significance for public review and input. One alternative is always a 'No-Action' Alternative; the other is the proposed action or preferred alternative. In this Draft Environmental Impact Statement (DEIS), the No-Action is Alternative 1. Other alternatives are also considered and evaluated, according to the guidelines in the NFMA.

The DEIS explains the need for change; the proposed action; the issues and concerns; the alternatives considered during the decision making process; the consequences of implementing the alternatives; and the preferred alternative.

The proposed action and preferred alternative in this DEIS is 3-Modified (3-M). More discussion about its selection can be found in Chapter II.

DECISIONS MADE IN A FOREST PLAN REVISION

The Forest Plan Revision carries out the actions of the preferred alternative. It provides key decisions for the long-term management of the Forest. These decisions include:

- Forestwide multiple-use goals and objectives, including a description of the Desired Future Condition (DFC) for the Forest.
- Forestwide standards and guidelines.
- Direction and prescriptions.
- Land suitable for Resource Use and Production.
- Monitoring and evaluation requirements.
- Recommendations to Congress for Wilderness and Wild/Scenic and Recreational River Designations.

BACKGROUND ON THE 1985 CURRENT FOREST PLAN

The first and current Targhee Forest Plan was started in 1980, but was not finalized until 1985 due to national requirements by Congress in 1982 for reevaluations of roadless areas in forest plans. The 1985 Forest Plan remains the guiding document for the Forest until a Final EIS and plan are completed in 1996.

The Forest is 60% lodgepole pine, a fire-dependent, short-lived tree species with a mature "old-growth" lifespan of 100-160 years. It regenerates rapidly after most disturbances, allowing it to dominate forest composition. As forest succession advances, lodgepole pine tends to be gradually replaced by more shade adapted tree species in the absence of further disturbances. Beginning in the 50's and continuing to the early 1980's, an extensive mountain pine beetle infestation attacked 90% of the lodgepole pine forest. The natural beetle infestation was not outside the natural range of variation for such forests, nor were the subsequent large fires in the late 1980's. Mountain pine beetle epidemics and large fire events are characteristic of lodgepole pine forests. Hence these forests are subject to rapid changes in forest structures and vegetation patterns.

Because clearcutting can approximate the role of fire in the regeneration process of fire-dependent lodgepole, the final 1985 Forest Plan emphasized the continued cutting of lodgepole and regeneration in the clearcut areas. The plan also predicted an abrupt decline of a high level of lodgepole supply within the next decade.

REASONS FOR REVISING THE FOREST PLAN (Need for Change)

In 1992, in preparation for the 10-year required revision of the forest plan, the public and employees verified that resource and management conditions have changed significantly, pointing out the need for a revision. Significant triggers for the Revision are

- The advent of Ecosystem Management as a new concept, a new way of doing business, requiring that the Forest be managed for sustainability of all ecologic components for the present and the future. How to do this is still in its infancy, but the need for moving towards implementing this concept should start now.
- The need to review and incorporate new knowledge and techniques in wildlife habitat management. For example, recent studies indicate that road density plays a more crucial role in habitat management for elk and grizzly bears than was assumed earlier. Based on recent studies, standards are being developed for nesting and foraging habitat for goshawks and other raptors on the Forest. Results of studies analyzing fish habitat in the Upper Columbia River Basin are pointing out new ways of managing fisheries. None of these findings were taken into account in the 1985 Forest Plan.
- Results of the Forest monitoring data, signaled the fact that the Forest was not completely meeting all the 1985 plan goals for improving elk habitat; reducing human activities in grizzly bear habitat, improving the condition of riparian areas, maintaining sensitive wildlife and plant species, managing human access to the Forest, and balancing timber harvest with the needs of wildlife.

PUBLIC'S ROLE IN SCOPING AND ISSUES

The public and Forest employees played an important role in determining the context of management for the Forest over the next 10-15 years. Public involvement has taken place at every stage of the Revision process. A Process Paper describes the public involvement that occurred.

HOW THE KEY FOREST ISSUES WERE SELECTED

The Forest's approach to defining the Key Issues was a six step process:

- Compile a list of issues and concerns from the public, resulting in an issue paper released in November, 1992, listing over 70 issues and concerns.

- Simultaneously develop a compatible list of "Issue Questions" that needed to be addressed in the EIS alternatives and in the Revision, this list was also released in November, 1992 and was tied to the Issues and Concerns.

- Categorize issues and concerns into "Issue Components" or "Issue Areas," a planning approach to help with the development and structure of the EIS and Plan.

- Choose the "Issue Indicators," which are units of measurement tied to the Issues and Concerns.

- Review the alternatives, determining which Issue Indicators have the greatest variables and which Issue Indicators remain relatively constant or the same.

- Choose the "Key Issues" as those issues and concerns having the greatest and most significant variation among the alternatives.

ISSUE COMPONENTS USED TO ORGANIZE EIS AND PLAN

"Issue Components" are an organizational planning approach used to group similar Issues and Concerns. Key Issues, alternatives, the rest of the EIS, and the Revision are consistently divided into the following Issue Components, in this order:

- Issue Component 1 = Ecological Processes and Patterns
- Issue Component 2 = Physical Elements
- Issue Component 3 = Biological Elements
- Issue Component 4 = Forest Use and Occupation
- Issue Component 5 = Production of Natural Resources

KEY ISSUES THAT DROVE THE ALTERNATIVES

Although there were over 70 issues and concerns identified by the public and Forest employees, seven Key Issues were the ultimate driving force for deciding between the alternatives and for the recommended direction of the Forest Plan Revision. The Key Issues had the most significance as *variables between the alternatives and are points of conflict.*

WHAT IS AN ISSUE INDICATOR?

Each key issue received an "Issue Indicator," a unit of measurement that showed how the issue was addressed in each alternative. The leadership team, consisting of the Forest Supervisor and District Rangers studied the issues and selected one major indicator for each issue that best reflected the variability for that issue between the alternatives.

SUMMARY OF KEY ISSUES AND KEY INDICATORS

Key Issue 1. Sustainability, fire, natural disturbances
(Ecological Processes and Patterns Component)

Key Indicator. Percent of the Forest with limitations on the size of created openings or patches

Key Issue 2: Riparian
(Biological/Physical Component)

Key Indicator. Acres not meeting the Desired Vegetative Condition (DVC). DVC = riparian vegetation such as deep rooted grasses, shrubs and trees that maintain streambank stability

Key Issue 3: Security for Elk
(Biological Component)

Key Indicator. Percent of Forest meeting Elk Vulnerability Goals measured by the number of miles of open roads and open motorized trails

Key Issue 4 Grizzly Bear Management
(Biological Component)

Key Indicator. Open Road & Open Motorized Trail Route Density, measured in miles per square mile (for Bear Management Units)

Key Issue 5. Access
(Forest Use & Occupation Component)

Key Indicator. Roads/Trails open to motorized use

Key Issue 6. Management of Roadless Areas
(Forest Use & Occupation Component)

Key Indicator. Number of Acres Recommended for Wilderness

Key Issue 7: Timber Harvest
(Production of Natural Resources Component)

Key Indicator : Allowable Sale Quantity (ASQ)

KEY ISSUES

KEY ISSUE 1: Sustainability, Fire, and Natural Disturbances (Issue Component: Ecological Processes and Patterns)

Issue Discussion: An Ecosystem is a large complex, integrated system of living and nonliving components that interact and change continually. Healthy ecosystems are those that retain all of their parts and functions for future generations even though vegetative patterns, human uses, or other conditions may change. Understanding ecological processes (fire and other natural disturbances) and how these processes shaped vegetative patterns over time in a landscape are important steps towards implementing ecosystem management.

Ecosystem management is a new philosophy of management for the Forest Service, and different interpretations and approaches are possible in working towards implementation. The Targhee National Forest is the first forest in the Greater Yellowstone Area that is revising its Forest Plan and incorporating the Ecosystem Management principles in the Revision. Although many activities and projects are being studied towards the application and implementation of Ecosystem Management, their new information and conclusions lag far behind the need to meet the timeline for the revision of the Forest Plan.

The most pressing and debated questions are, 'What is the Forest's desired natural condition?' and 'How do we achieve sustainability incorporating fire and natural disturbances, to achieve that state?' As one Forest specialist noted about Ecosystem Management on the Forest, "We almost know enough to know what we don't know." While the reality exists that new Forest Plan direction is needed soon, the struggle continues over defining Ecosystem Management, sustainability, and a healthy ecosystem; collecting and monitoring data; and determining the range of variability.

For more discussion of the ecosystem management issue, refer to the Targhee National Forest process paper titled "Implementing Ecosystem Management in Forest Plan Revisions," September 23, 1994

Sustainability, Fire and Natural Disturbances Key Issue Indicator: Of all the indicators of ecosystem health, Patch Size Limit (in acres) was selected as the Key Issue Indicator for the Forest. Patch Size Limit was selected because the forest has gathered some general information about the subject from old historical photos and maps. Natural patch sizes relate to and are an indication of historic ecological processes (fire, insects, and disease) and resulting vegetation patterns which historically occurred in an area.

A patch is defined as an area of vegetation that is structurally and/or compositionally different from what surrounds it.

Managing within the range of variability for Patch Size Limits is important because it helps maintain conditions under which plants and animals evolved and is assumed to provide for ecosystem sustainability. Changes in patch sizes from what existed historically, particularly as it relates to fire and other natural disturbances, may affect individual species or ecosystem sustainability. Even though Patch Size Limits are the best general historical source of information to the Forest as an indicator for ecosystem management, the nature and magnitude of the

acreage limits are unknown at this time. As our knowledge increases about Patch Size Limits, the Forest may be constrained by National Forest Management Act's harvest unit size limit or other species or resource considerations. In addition, the Forest does not know how historical changes in vegetation patch sizes equates to other changes such as changes in animal populations. It is possible that some species may be more or less abundant today than they were historically.

KEY ISSUE 2: Riparian (Issue Component: Biological/Physical Elements)

Issue Discussion: Riparian areas lie adjacent to water and are composed of vegetation communities dependent upon or tolerant to the presence of free or unbound water near the ground surface. Riparian areas are associated with lakes, reservoirs, potholes, springs, bogs, wet meadows, and ephemeral, intermittent or perennial streams. Although riparian areas constitute less than 5 percent of the total land base, they are the most productive areas in terms of plant and animal species diversity and consumptive use.

Riparian areas are essential breeding, rearing and feeding grounds for many species of wildlife and all fish. They serve people as important sources for water and flood control and for recreational purposes such as camping, fishing, floating, and aesthetics. A healthy riparian area indicates that the physical, aquatic, water and soil components are also healthy. Because of the myriad of competing uses for these highly valuable pieces of land, the variability between the alternatives was considered significant.

Riparian Key Issue Indicator: The key indicator showing the differences between the alternatives for riparian areas is Desired Vegetation Condition (DVC). The riparian area's health is indicated by the amounts and types of vegetation along the banks, with highest preference to deep-rooted grasses, shrubs and trees that maintain streambank stability and that have a high rate of recovery. Riparian areas meeting Desired Vegetation Condition are currently meeting the Forest Plan Revision objective to maintain or enhance riparian vegetation, aquatic habitat, and water quality.

KEY ISSUE 3: Security for Elk (Issue Component: Biological Element)

Issue Discussion: Although the Forest provides habitat for a number of species (61 mammals, 156 birds, 8 reptiles and amphibians), there were no significant differences in the management of their habitat. For many of these species there was no information, or the best data and analysis existed for elk security, which had the highest wildlife variance amongst the alternatives. Security for elk was chosen as a key issue relating to future hunting conditions and opportunities and cooperative relations with Fish and Game Departments. Observations and studies by the Idaho Fish and Game Department, University of Idaho, and Forest Service scientists have determined that as motorized road and trail densities increase, elk security declines. Portions of the Forest have high densities of trails and roads open to motorized use due to the extensive road building associated with the salvage activity of removing the dead lodgepole. Now that the salvage activity is in decline and new knowledge about impacts of road densities upon wildlife are available, the Revision examines the range of management alternatives related to security for elk.

Security for Elk Key Issue Indicator: The best indicator for showing the differences between alternatives for elk security is "The percentage of the Forest meeting State Fish and Game Vulnerability thresholds for Elk." The primary effect that the Forest Service has control over related to elk vulnerability analysis is the density of open motorized roads and trails and the amount of area open to cross-country, off-highway vehicle travel.

Elk Vulnerability is defined as a measure of elk susceptibility to being killed during the hunting season. Elk Vulnerability models help managers predict elk mortality rates. As cross country off-highway vehicle travel and motorized road and trail densities (measured in miles per square mile on a watershed basis) increase, the security for elk decreases and the mortality rate increases

KEY ISSUE 4: Grizzly Bear Management Units (Issue Component: Biological Element)

Issue Discussion: Portions of the Forest are within the Yellowstone Grizzly Bear Ecosystem which has been divided into Bear Management Units (BMU's). Portions of the Forest are within three BMU's and feature grizzly bear recovery. As with all Threatened and Endangered Species, all alternatives must meet the stringent guidelines of the Endangered Species Act. The importance of managing motorized access is one of the most influential parameters affecting grizzly bear habitat security.

New information accumulated over the last ten years provides better insight and direction regarding effective management of roads, timber and human activities in grizzly bear habitat. The one variation between alternatives that makes the BMU issue significant is the density of open motorized roads and trails in BMU's. Which roads will be closed in BMU's, how many miles, and in what manner?

Grizzly Bear Key Issue Indicator: The Key Issue Indicator for BMU's is Open Road and Open Motorized Trail Route Density (OROMTRD). Studies are showing that the importance of managing access is one of the most influential components affecting habitat security for grizzly bears. By managing motorized access, the Forest can minimize human interaction and potential grizzly bear mortality; minimize displacement from important habitats; and minimize habituation to humans.

KEY ISSUE 5: Access (Issue Component: Forest Use and Occupation)

Issue Discussion: The Forest currently has 1,367 miles of open system road and 1,021 miles of open nonsystem roads; 433 miles of open system trail and 199 miles of open nonsystem trail. "Open" means road and trail miles without restrictions on motorized use. There are currently road and trail miles with restrictions on motorized use as follows: 633 miles of restricted system road (61 miles with seasonal restrictions and 572 miles with yearlong restrictions), 201 miles of restricted nonsystem road (24 miles with seasonal restrictions and 177 miles with yearlong restrictions); 597 miles of restricted system trail; 102 miles of restricted nonsystem trail.

Recreational motorized use has increased over the last decade. The current plan allows cross-country motorized travel across much of the Forest and does not establish road density standards. Access to the Forest during nonsnow months is a significant variable among the alternatives. Comments in the early planning stages were supportive of more or fewer road and trail closures depending on a variety of factors. Those supporting road and trail closures want more protection and fewer impacts upon wildlife, threatened, endangered, and sensitive species, soils and water, and fisheries; less visual, garbage and noise pollution; reduced maintenance and law enforcement costs and more opportunity for escape and solitude. Those supporting continued or more road and trail access want them for hunting, fishing, berry-picking, camping, hiking and other recreational pursuits, and increased opportunities for sight-seeing and challenging cross-country travel for off-highway vehicles. Motorized access is considered a key element for enjoyment and use of the Forest by persons with disabilities and the elderly. For more information on this issue, refer to Process Paper E.

Access Key Issue Indicator: The indicator that best shows differences between alternatives is the Number of Miles of Road/Trails Open to Summer Motorized Use. The greater the number of miles of roads and trails open to motorized use, the greater the increased recreational benefits and hunting/fishing access to users of motorized vehicles including persons with disabilities.

KEY ISSUE 6: Management of Roadless Areas (Issue Component: Forest Use and Occupation)

Issue Discussion: The Forest has sixteen areas which qualify as roadless, totaling 841,000 acres. The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in the Wyoming Wilderness Bill of 1984. Portions of 3 roadless areas in Idaho were recommended as Wilderness in the current Forest Plan, but no legislative action has been taken to resolve the roadless area question in Idaho. During the last planning period, some roadless areas were roaded as part of the salvage program. As motorized recreation demands increase, pressure increases to maintain the roadless character of the remaining roadless areas. The significant difference between alternatives in the management of roadless areas is in the amounts of acres recommended for Wilderness. Those arguing for more acres of Congressionally designated Wilderness want the assurance of preservation of biological diversity, protection from resource uses and national recognition of Wilderness character. Those opposed to more acres in Wilderness want roadless areas to be left as roadless or to be developed to allow motorized access for recreation and for oil and gas, timber and other industries requiring access.

Management of Roadless Areas Key Issue Indicator: The indicator best showing differences between alternatives related to the management of roadless areas is the number of acres Recommended for Wilderness. Once a roadless area is designated as Wilderness by Congress, it is managed in perpetuity for nonmotorized, scientific, dispersed recreational purposes. Roadless areas not recommended as Wilderness may be managed as roadless areas or for some other use during each planning cycle.

KEY ISSUE 7: Timber Harvest (Issue Component: Production of Natural Resources)

Issue Discussion: The three major timber species available for harvest on the Forest are aspen (15% forested area), Douglas fir (15% forested area), and lodgepole pine (60% forested area). Previously, large scale salvage of dead and dying timber was conducted under legal direction for temporary departure from sustained yield management. Since the goals of harvest of dead timber have largely been met, the Forest must now operate within sustained yield for the future.

Two local mills, once dependable bidders for salvage and other wood harvest, are now closed but local demand remains high. The Endangered Species Act; Grizzly Bear Recovery Plan and Guidelines, Ecosystem Management Principles, demise of availability of dead lodgepole, increased knowledge about the impacts of motorized use of roads and trails upon the Forest's resources, and other factors resulted in a greatly reduced availability of timber harvest, called the allowable sale quantity (ASQ). The issue of timber harvest does not include firewood, since the amount of firewood quantity does not vary between the alternatives. Some people desiring a greater harvest of timber from the Forest often cite the effects upon the local economy. Others have expressed a concern over the reduction in payments to local governments (25% of Forest receipts go to county treasuries) associated with the reduced harvest levels. They also want to maximize harvest of the remaining dead or mature wood. Some argue that small harvests in the fire dependent lodgepole are contrary to historic based ecosystem management principles. Those supporting a greater reduction in timber harvest are concerned about motorized trail and road uses that impact wildlife, reductions in the amount and distribution of late successional forest, fisheries, riparian areas, soils and water, aesthetics, and other resources.

Timber Harvest Key Indicator: The key indicator for timber harvest that portrays the differences between alternatives is the ASQ. The ASQ does not include firewood. The ASQ is defined as the quantity of timber that may be sold from the area of suitable land for a time period specified in a Forest Plan. This quantity is usually expressed on an annual basis as an "average" ASQ.

WHERE ARE ALL THE OTHER ISSUES AND INDICATORS?

Although most of Chapters I and II of the EIS are focused on the Key Issues and Key Indicators, most of the effects and consequences in Chapters III and IV and the Standards and Guidelines in the Forest Plan Revision address the remaining issues and indicators. For example, firewood availability is an issue. Although not a key issue, firewood is addressed in the Revision and the effects and consequences remains the same in all the alternatives.

Another confusion may exist over the noninclusion of significant resources such as water and soils as key issues. Why aren't these considered "Key Issues"? All the alternatives comply with state and federal quality standards, there was only a slight range of variability and the condition of soil and water is interconnected with the condition of riparian areas. The Key Issue of Riparian Areas became the symbol and captured the essence of the significance of differences for soil & water resources.

The selection of the 7 key issues has to do with the selection of the Preferred Alternative and the Forest Plan Revision. It does not mean that the other issues are not addressed or that they are not important. The table at the end of Chapter II lists most of the issue components and indicators. A Process Paper about public involvement refers to the complete list of issues published in the Analysis of the Management Situation document, November, 1992.

DESIRED FUTURE CONDITION FOR THE YEAR 2010

After issues are identified, one of the first steps in the revision process is to develop goals for the "desired" future condition of the Forest by the year 2010 and beyond.

Based on public and employee comments between 1991-1994, a set of goal statements emerged that collectively represent a new general management direction for the Forest. The goal statements were tied to the key issues driving the plan, evolving into a new Desired Future Condition (DFC) for the Forest. More specific DFC's for particular portions of the Forest are outlined in the Draft Forest Plan Revision, a separate companion document to this DEIS.

The DFC is described in terms of the Five Components: Ecological Processes and Patterns, Physical Elements, Biological Elements, Forest Use and Occupation, and Production of Natural Resources. The Biological and Physical are combined because of their interconnectivity. The DFC is broader than the 7 Key Issues that are driving the alternatives and the decisions. The DFC is where the Forest would ideally like to be someday and is described as:

Ecological Processes and Patterns Desired Future Condition:

A mosaic of age classes and types of vegetation are sustained through time and exist across the landscape. Natural disturbances such as insects, disease and fires continue their natural roles in the ecosystem. The Forest remains an integral part of the Greater Yellowstone Ecosystem as well as adjacent systems, sustaining habitat and conditions necessary for free movement of wildlife.

Biological/Physical Desired Future Condition:

Riparian zones are healthy and productive. Aquatic systems are allowed to function naturally while protecting flows for downstream consumptive uses. Riparian area integrity contributes to productive fisheries and excellent water quality. Native plant and animal species are favored over undesirable nonnative species and sustained populations of all native and desirable species thrive. Habitat conditions contribute toward the recovery of Threatened, Endangered and Sensitive Species.

Forest Use and Occupation Desired Future Condition:

Growing and diverse recreational, cultural, visual, historical and prehistoric management, interpretive, and spiritual needs are accommodated based on the capability of the ecosystem to sustain these uses. Recreation use is managed to minimize conflicts between incompatible uses and provides high levels of satisfaction. Year-round human access is managed to provide both motorized and nonmotorized opportunities. A system of trails and support facilities exist which are compatible with resource capabilities. Roadless characteristics are preserved in the proposed wilderness areas and in existing Wildernesses

Production of Natural Resources Desired Future Condition:

Commodity production, such as timber; firewood; mining; livestock forage; or outfitting and guide services are conducted at sustainable levels and maintain the capability of the land to produce an even flow and variety of goods and services for present and future generations. Timber harvest, prescribed fires and livestock grazing are used as tools to achieve desired ecological vegetation conditions. Forest products are provided to sustain social and economic values and needs of the local communities within limits which maintain ecosystem health.

THE PREFERRED ALTERNATIVE**Alternative 3-M**

The purpose of Alternative 3-M is to resolve the needs for change by providing sustainable management with a balanced program among, wildlife habitat, timber harvest, recreation, and other uses and resources of the Forest. Alternative 3-M also provides increased emphasis for wildlife habitat management and allocates more core areas for grizzly bear. Motorized access, timber harvest levels and livestock grazing are all reduced from levels allowed in the current Forest Plan. Riparian areas with cutthroat trout are further protected with increased vegetation and reduced livestock grazing. Cross-country, summer, motorized vehicle use is restricted to specific areas. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness are recommended to Congress for wilderness designation; until Congress acts on the recommendation, their roadless characteristics are maintained.

All the alternatives respond to and incorporate the resource objectives set forth in the Recommended 1990 RPA Program. Alternative 3-M has been selected as the RPA Alternative because it represents the Forest's best attempt to simultaneously implement multiple-use management, ensure resource sustainability, emphasize the quality of resource outputs, and to provide for the economic well-being of rural communities.

Chapter

Alternatives Including the Proposed Programmatic Action (Preferred Alternative)

CHAPTER II

ALTERNATIVES INCLUDING THE PROPOSED PROGRAMMATIC ACTION (PREFERRED ALTERNATIVE)

READER'S GUIDE - In this chapter you will find:

- How the Alternatives Were Formulated
- Explanation about Issues That Are Treated the Same or Vary Slightly in All Alternatives
- The Alternative Continuum
- Descriptions of the Seven Alternatives
- Comparison Chart of the Key Issue Indicators of the Alternatives
- Alternatives Considered But Eliminated From Detailed Study
- A Table Comparing the Environmental Effects Depicted by Issue Indicators

HOW THE ALTERNATIVES WERE FORMULATED

In Chapter I, we discussed the issues, issue indicators, reasons for the need for change, and the Desired Future Condition. This chapter will explain how the alternatives were formulated and how each alternative addressed the issues.

Forestwide Standards and Guidelines specify management requirements that apply throughout the Forest. Management prescriptions say how different portions of the Forest will be managed differently from one another.

The lands of the Targhee meet many different needs. Some of these needs are mutually exclusive - a wilderness area is not set up to provide developed recreation sites for motorized users, e.g. It is more commonly the case though, that many uses coexist on the same land. A single piece of land may provide habitat for grizzly bear, security cover for elk, grazing for livestock, timber for harvesting and so on. This multiplicity of uses is built into the prescriptions. Land that provides crucial winter range for elk may address that need whether the land is placed in a Winter Range prescription, in a Recommended Wilderness prescription, or even in a Range Management prescription.

For purposes of managing the Forest though, people need to have ready access to the management direction that applies to any particularly piece of land. That would not be possible if they had to look up separate management prescriptions for grizzly bear habitat, elk security cover, livestock grazing, and timber harvesting and then face the question of which to apply.

The convention the Forest has adopted is that any single piece of land has only one prescription applied to it in any given alternative. That simplifies management, but it also means that people cannot just look at a given prescription acreage total and assume that it contains all the acreage on the Forest that could possibly fit there. For instance, there is more Elk and Deer Winter Range on the Forest than is allocated to that prescription.

For the most part, when there was a question as to which management prescription should be applied, that prescription was assigned which best described the area's intended future management. As an example, when an eligible wild scenic river was identified in an area recommended for wilderness, the river corridor was assigned an Eligible Wild River prescription, the surrounding recommended wilderness was assigned a Recommended Wilderness prescription.

Alternatives can be formulated simply by specifying a different mix of management prescriptions for a given area of the Forest. For instance, a given portion of the Forest could be designated for a Timber Management, Grizzly Bear Habitat, or Recommended Wilderness prescription.

The alternatives reflected a range of options open to management that responded to the issues, the desired future condition, and the need for change. The interdisciplinary team evaluated the significant physical, biological, economic and social effects of each alternative that was considered in detail. The evaluation included aggregate effects of social and economic impacts, outputs of goods and services, and overall protection and enhancement of environmental resources.

The Forest analyzed in detail seven alternatives. The Forest Supervisor and Leadership Team recommended Alternative 3-Modified to the Regional Forester and the public for review.

Consequences for nonkey issues are not included in Chapter II discussions, since many of them are addressed the same or with slight variation in every alternative. As an example, local communities are noticeably interested in firewood availability. Regardless of the alternative, a constant 3.8 million board feet will be available each year in some remaining dead lodgepole and aspen areas. Although discussed in Chapters III and IV, firewood was not a key issue and did not drive the selection of the preferred alternative. Therefore firewood is not discussed in the alternative summaries of Chapter II.

ISSUE INDICATORS THAT ARE THE SAME OR VARY SLIGHTLY IN ALL ALTERNATIVES

As the Interdisciplinary Team developed the alternatives with the public and Forest Service employees, certain needs for change had the same consequences or varied slightly in all alternatives. The following summarizes the issue indicators with consequences and effects that are the same or vary slightly in all alternatives. Details can be found in process papers.

Wild and Scenic Rivers Recommendations and Research Natural Areas
Water Quality, Visual Quality
Developed Recreation, nonmotorized
Archaeology/historical
Cave Management
Predator Control
Noxious Weeds
Outfitter and Guides
Summer Homes & Other Special Use Permits
Management of Existing Wilderness and Wilderness Study Areas

Firewood - All alternatives offer 3.8 MMBF
Bald Eagle - Forestwide Standards and Guides are the same in all alternatives
Peregrine Falcon - Forestwide Standards and Guides are the same in all alternatives

Sensitive Species (These include Three-Toed Woodpecker, Flammulated Owl, Boreal Owl, Great Gray Owl, Goshawk, Trumpeter Swan, Spotted Frog Habitat, Common Loon, Harlequin Duck) - Forestwide Standards and Guides are the same in all alternatives.

Sensitive Species (These include Wolverines, Lynx, Fisher) - Small variation in habitat quality or quantity (generally in the realm of 1-3% change from existing conditions).

THE ALTERNATIVE CONTINUUM

The numbering scheme for alternatives ranges from 1-6, with alternative 3-Modified being the preferred and Alternative 1 being the No-Action or continue the Current Forest Plan Alternative. As the numbers increase from Alternatives 2 to 6, they move consistently towards:

- *Greater protection of wildlife habitat
- *Greater protection of riparian areas
- *More protection for Bear Management Units
- *More security for elk
- *Nonmotorized, dispersed recreation opportunities
- *More recommended wilderness
- *Less cross-country motorized use
- *Fewer open roads and trails
- *Reduced livestock grazing and timber harvest
- *Less lasting visual impacts from management activities

ISSUE INDICATORS THAT ARE NOT "KEY"

In Chapter 1, Key Issues and Indicators were discussed in great detail. At that time, it was acknowledged that there were other issues and issue indicators important to the planning process. When the Forest was designing the alternatives around the issues, a number of issue indicators were created. Specialists analyzed the consequences for all the different alternatives. It soon became clear that most of the consequence indicators were either the same in all alternatives or had minor variations, making them less significant than the "Key Issue Indicators." Much of the discussion in Chapters III and IV discuss these issues, issue indicators and consequences in more detail. Most of the other indicators are listed in Table II-1.

DESCRIPTION OF ALTERNATIVES

All the alternatives comply with State and Federal law.

ALTERNATIVE 1 = Continue the Current Forest Plan (No Action)

The purpose of Alternative 1 is to continue management of the Forest under the current Forest Plan, finalized in 1985, and updated with amendments; litigious concessions for the grizzly bear, and changes for new listings of sensitive wildlife species over the last ten years. Timber harvest occurs at the highest levels possible within the management constraints required for threatened and sensitive wildlife species like grizzly bears and goshawks. Vehicle access is slightly reduced over current levels due to the implementation of the interagency grizzly bear guidelines and better road management across the Forest. Cross-country, motorized access in summer and winter would continue close to current levels. Riparian, wildlife and recreation values are emphasized in specific areas of the Forest. Alternative 1 recommends portions of the Lionhead, Italian Peaks and Winegar Hole roadless areas for wilderness designation. Their roadless characteristics are maintained until Congress acts on the recommendation.

How the Key Issues and Key Indicators are addressed in Alternative 1

1. Sustainability, Fire, and Natural Disturbances. Key Indicator Percent of the Forest with limitations on the size of created openings or patches.

Alternative 1 would limit size of patches to 40 acres or less on approximately 3% of the forest, or about 47,000 acres.

2. Riparian. Key Indicator. Acres not meeting DVC.

Approximately 342,000 aquatic influence zone (AIZ) acres would be managed to maintain or enhance riparian vegetation aquatic habitat, and water quality. At the end of the first decade, about 4,000 acres would not meet the DVC Fisheries habitat quality would continue at a moderate level. Live-stock grazing would occur at current levels. A mosaic of different species and size classes of vegetation would be provided. Season long, deferred rotation and rest rotation grazing systems would continue to be used on all allotments. There would be a slight increase in cattle AUM's. Timber harvest would be allowed within limits, and would contribute to the ASQ

3. Security for Elk. Key Indicator Percent of Forest meeting state elk vulnerability thresholds, measured by miles of open roads and open motorized trails.

In Alternative 1, 58% of the Forest (1,075,000 acres) would meet the state elk vulnerability thresholds. The greatest factors under control of the Forest Service that influence elk security are the miles of open roads and open motorized trails. Alternative 1 would reduce the number of open system roads by 47 miles (-3%) and open nonsystem roads by 457 miles (-45%). About 16 more miles (+4%) of system trail would be open to motorized use, but there would be a reduction of open nonsystem trails by 76 miles (-38%). The 58% of the Forest meeting state elk vulnerability standards is a 16 percentage points increase over the existing level of 42%, probably resulting in a potential for a slightly lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMU's). Key Indicator Open road and open motorized trail route density (miles per square mile).

The reduction in the average open road and motorized trail densities to an average ranging from 0.45 to 0.87 miles per square mile, in the bear management units (BMU's) would improve grizzly bear habitat. Off-highway vehicle (OHV) use would continue at current levels of use. Alternative 1 has no restrictions on cross-country snowmachine use, except on a small portion of the Plateau BMU. Sheep and cattle allotment grazing would continue at current levels. Timber harvest could occur with constraints and would contribute to the ASQ

5. Access. Key Indicator: Roads and trails per mile open to motorized use.

Alternative 1 would reduce the number of open system roads by 47 miles (-3%) and open nonsystem roads by 457 miles (-45%). About 16 more miles (+4%) of system trail would be open to motorized use, but there would be a reduction of open nonsystem trails by 76 miles (-38%). This alternative would allow the most camping, berry-picking, hunting, and sight-seeing activities that conventionally use road access. The decrease in numbers of open roads and trails would provide increased wildlife security, especially for elk and grizzly bears and protect other resources from damage. Acres available for summer OHV would also be the highest of the alternatives, allowing OHV use on approximately 960,000 acres, about a 15% reduction over the current 1,126,000 acres open to OHV use

6. Roadless Area Management. Key Indicator: Number of acres recommended for Wilderness

Alternative 1 would recommend 65,000 acres to Congress for Wilderness designation. These are the roadless areas recommended in the current forest plan (Italian Peak, Lionhead and Winegar Hole), although no Congressional action has been taken. This recommendation is about 7% of the total acres which presently qualify as roadless

7. Timber Harvest. Key Indicator: ASQ.

Alternative 1 would harvest timber at a sustainable level of a maximum 51 million board feet (MMBF) for the decade (approximately 5.1 MMBF per year) on an estimated 14,774 acres.

ALTERNATIVE 2

The purpose of Alternative 2 is to resolve the needs for change by emphasizing cross-country, winter access and timber production, while adding more restrictions to summer, cross-country access. Timber harvest occurs at the highest levels within the management constraints required for maintaining threatened, endangered and sensitive species habitat. Grazing continues at current levels. Vehicle access is slightly reduced to meet requirements of the interagency grizzly bear guidelines. Riparian, wildlife and heritage resource values are emphasized in specific areas of the Forest. Alternative 2 makes no recommendations to Congress for Wilderness designation

How the Key Issues and Key Indicators are addressed in Alternative 2

1. Sustainability, Fire, and Natural Disturbances. Key Indicator: Percent of the Forest with limitations on the size of created openings or patches.

Alternative 2 would limit size of patches to 40 acres or less on approximately 1% of the forest, or about 25,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC.

Approximately 325,000 AIZ acres would be managed to restore and maintain the health of aquatic influence zones in ways that also produce desired resource values, products, protection and enhancement of these areas. At the end of the first decade, about 2,500 acres would not meet the DVC.. Livestock grazing would occur at slightly reduced levels. Fisheries habitat quality would remain at a moderate level.

3. Security for Elk. Key Indicator: Percent of Forest meeting state elk vulnerability thresholds, measured by miles of open roads and open motorized trails.

In Alternative 2, 72% of the Forest (1,296,000 acres) would meet the state elk vulnerability thresholds. The greatest factors under control of the Forest Service that influence elk security are the miles of open system roads and open motorized trails. Alternative 2 would increase the number of open system roads by 44 miles (+3%), but reduce the open nonsystem roads by 586 miles (-56%). There would be a reduction in open system trails by 76 miles (-18%) and open nonsystem trails by 86 miles (-43%). The 72% of the Forest meeting state elk vulnerability standards is a 30 percentage points increase over the existing level of 42%, probably resulting in a potential for a slightly lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMU's). Key Indicator. Open road and open motorized trail route density (miles per square mile)

Alternative 2's reduction in the average open road and motorized trail densities to an average ranging from 0.37 to 1.03 miles per square mile in the BMU's would improve grizzly bear habitat. Cross-country snowmobile use would be restricted from December 15 to April 1 in all BMU's. Acres of summer cross-country, motorized access is significantly reduced from Alternative 1. Sheep and cattle allotment grazing would continue at current levels. Timber harvest that might occur to achieve grizzly bear habitat objectives would contribute to the ASQ.

5. Access. Key Indicator: Roads and trails per mile open to motorized use

Alternative 2 would increase the number of open system roads by 44 miles (+3%), but reduce the open nonsystem roads by 586 miles (-56%). There would be a reduction in open system trails by 76 miles (-18%) and open nonsystem trails by 86 miles (-43%). This alternative would allow more opportunities for dispersed camping, berry-picking, sight-seeing, and other activities that conventionally use road access. The decrease in numbers of open roads and trails is needed to meet guidelines for increased wildlife security, especially for elk and grizzly bears. Acres available for OHV would also be reduced over recent levels. Alternative 2 would allow OHV use on approximately 761,000 acres, about a 68% reduction over the current 1,126,000 acres open to OHV use. Winter OHV access would be increased, with an additional 210 miles of groomed trails for snowmobiles, for a total of 666 miles.

6. Roadless Area Management. Key Indicator: Number of acres recommended for Wilderness

Alternative 2 would not recommend any areas to Congress for Wilderness designation

7. Timber Harvest. Key Indicator: ASQ.

Alternative 2 would harvest timber at a sustainable level of a maximum 60 MMBF for the decade (approximately 6.0 MMBF per year) on an estimated 16,940 acres.

ALTERNATIVE 3

The purpose of Alternative 3 is to resolve the needs for change by emphasizing management of wildlife habitat and sustaining timber harvest levels within wildlife constraints. Grizzly bear recovery is enhanced with a reduction in motorized use allowed in each BMU. Grazing allotments continue at current levels and larger percentage of riparian areas meet the Desired Vegetation Condition. Cross-country, summer, motorized vehicle use is restricted to specific areas. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness are recommended to Congress for wilderness designation, until Congress acts on the recommendation, their roadless characteristics are maintained

How the Key Issues and Key indicators are addressed in Alternative 3:

1. Sustainability, Fire, and Natural Disturbances. Key Indicator: Percent of the Forest with limitations on the size of created openings or patches.

Alternative 3 would limit size of patches to 40 acres or less on approximately 5% of the forest, or about 82,000 acres..

2. Riparian. Key Indicator Acres not meeting DVC.

Alternative 3 would promote the health and function of riparian, wetland and aquatic ecosystems on approximately 448,000 AIZ acres. At the end of the first decade, about 2,500 acres would not meet the DVC. Fisheries habitat quality would be moderately high. Livestock grazing would be slightly reduced. Timber harvest could occur in riparian areas to attain the desired vegetation characteristics, but is not scheduled and would not contribute to the ASQ

3. Security for Elk. Key Indicator: Percent of Forest meeting state elk vulnerability thresholds, measured by miles of open roads and open motorized trails.

In Alternative 3, about 83% of the Forest (1,526,000 acres) would meet the state elk vulnerability thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open roads and open motorized trails. Alternative 3 would reduce the number of open system roads by 146 miles (-11%) and open nonsystem roads by 653 miles (-64%). There would be a reduction in open system trails by 96 miles (-22%) and open nonsystem trails by 101 miles (-51%) The 83% of the Forest meeting state elk vulnerability standards is almost twice the existing level of 42%, thereby greatly improving elk security and allowing a higher potential for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMU's). Key Indicator: Open road and open motorized trail route density (miles per square mile).

The reduction in the open road and motorized trail densities to an average ranging from 0.38 to 0.65 miles per square mile in the BMU's, would improve grizzly bear habitat. Almost no summer cross-country, motorized travel would be permitted in the BMU's. Snowmachine use is allowed on designated routes throughout the snow season. In 96% of the Henry's Lake BMU - Subunit 2, 20% of the Plateau BMU, and 3% Bechler/Teton BMU, cross-country snowmachine use is allowed only from December 15 to April 1. Some timber harvest could occur to improve bear habitat. Sheep and cattle allotment grazing would continue at existing levels.

5. Access. Key Indicator: Roads and trails per mile open to motorized use.

Alternative 3 would reduce the number of open system roads by 146 miles (-11%) and open nonsystem roads by 653 miles (-64%). There would be a reduction in open system trails by 96 miles (-22%) and open nonsystem trails by 101 miles (-51%). This would restrict dispersed camping, berry-picking, firewood gathering, sight-seeing, and other activities that conventionally use road access and it would concentrate these uses on the remaining open roads and trails. The decrease in numbers of open roads and trails would better meet goals for increased wildlife security, especially for elk and grizzly bears. Acres available for summer OHV use would also be reduced over current levels. Alternative 3 would allow OHV use on approximately 368,000 acres, about a 67% reduction from the current 1,126,000 acres open to OHV use. Besides providing wildlife security, summer OHV reductions would prevent other resource damages from OHV use.

6. Roadless Area Management. Key Indicator. Number of acres recommended for Wilderness.

Alternative 3 would recommend 125,000 acres to Congress for Wilderness designation. The 125,000 acres would include the 65,000 acres recommended by the current Plan in Italian Peak, Lionhead and Winegar Hole roadless areas, plus additional roadless acres in each of these areas and the Palisades. This recommended 125,000 acres is 15% of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator. ASQ.

Alternative 3 would harvest timber at a sustainable level of a maximum 50 MMBF for the decade (approximately 5.0 MMBF per year) on an estimated 14,230 acres.

ALTERNATIVE 3-M = Alternative 3 Modified (Also the Proposed Programmatic Action and Preferred Alternative)

The purpose of Alternative 3-M is to resolve the needs for change by emphasizing wildlife habitat management and allocating more core areas for grizzly bear. Motorized access, timber harvest levels and livestock grazing are all reduced from levels allowed in the current Forest Plan. Riparian areas with cutthroat trout are further protected with increased vegetation and reduced livestock grazing. Cross-country, summer, motorized vehicle use is restricted to specific areas. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness are recommended to Congress for wilderness designation; until Congress acts on the recommendation, their roadless characteristics are maintained.

All the alternatives respond to and incorporate the tentative resource objectives set forth in the Recommended 1990 RPA Program. Alternative 3-M has been selected as the RPA Alternative because it represents the Forest's best attempt to simultaneously implement multiple-use management, ensure resource sustainability, emphasize the quality of resource outputs, and to provide for the economic well-being of rural communities.

How the Key Issues and Key Indicators are addressed in Alternative 3-M:

1. Sustainability, Fire, and Natural Disturbances. Key Indicator: Percent of the Forest with limitations on the size of created openings or patches.

Alternative 3-M would limit size of patches to 40 acres or less on approximately 14% of the forest, or about 259,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC.

Approximately 512,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems under Alternative 3-M. At the end of the first decade, about 2,500 acres would not meet the DVC. Fisheries habitat quality would be moderately high, compared to the current moderate quality rating. There would be a moderately rapid rate of recovery of degraded habitats. Livestock grazing would be reduced more with this alternative than with Alternatives 1, 2, or 3. Timber harvest could occur in riparian areas to attain the desired vegetation characteristics, but is not scheduled and would not contribute to the ASQ.

3. Security for Elk. Key Indicator: Percent of Forest meeting state elk vulnerability thresholds, measured by miles of open roads and open motorized trails.

Over 91% of the Forest (1,673,000 acres) would meet the state elk vulnerability thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open roads and open motorized trails. Alternative 3-M would reduce the number of open system roads by 170 miles (-12%) and open nonsystem roads by 658 miles (-64%). There would be a reduction in open system trails by 93 miles (-22%) and open nonsystem trails by 101 miles (-51%). The 91% of the Forest meeting state elk vulnerability standards is more than twice the existing level of 42%, thereby greatly improving elk security. This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMU's). Key Indicator: Open road and open motorized trail route density (miles per square mile).

The reduction in the open road and motorized trail densities ranging from 0.29 to 0.56 miles per square mile in the BMU's, would improve grizzly bear habitat. Additional access restrictions to improve habitat security would be no summer cross country motorized vehicle use in any of the BMU's, except a small portion in the Bechler BMU. Domestic sheep grazing would be phased out over time. No timber harvest would be scheduled in the "core" or "secure" areas. Snowmachine use is allowed on designated routes throughout the snow season. Cross-country snowmachine use is allowed only from December 15 to April 1.

5. Access. Key Indicator: Roads and trails per mile open to motorized use.

Alternative 3-M would reduce the number of open system roads by 170 miles (-12%) and open nonsystem roads by 658 miles (-64%). There would be a reduction in open system trails by 93 miles (-22%) and open nonsystem trails by 101 miles (-51%). This would restrict dispersed camping, berry-picking, firewood gathering, sight-seeing, and other activities that conventionally use road access and it would concentrate these uses on the remaining open roads and trails. The increase in road closures and restrictions would provide increased wildlife security, especially for elk and grizzly bears, and would provide additional protection from other resource damage. Acres available for summer OHV use would be reduced allowing OHV use on approximately 121,000 acres, almost a 90% reduction from the current 1,126,000 acres open to OHV use.

6. Roadless Area Management. Key Indicator: Number of acres recommended for Wilderness

Alternative 3-M would recommend 125,000 acres to Congress for Wilderness designation. The 125,000 acres would include the 65,000 acres recommended by the current Plan in Italian Peak, Lionhead and Winegar Hole roadless areas, plus additional roadless acres in each of these areas and the Palisades. This recommended 125,000 acres is 15% of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator: ASQ.

Alternative 3-M would harvest timber at a sustainable level of a maximum 37 MMBF for the decade (approximately 3.7 MMBF per year) on an estimated 11,430 acres.

ALTERNATIVE 4

Alternative 4 emphasizes watershed and wildlife habitat improvement and a reduction in timber harvest. Riparian areas receive increased emphasis. Motorized access is restricted to designated routes and more roads are closed in some BMU's than in previous alternatives. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness and another 14,000 acres of roadless areas are recommended to Congress for wilderness designation; until Congress acts on the recommendation, their roadless characteristics are maintained.

How the Key Issues and Key Indicators are addressed in Alternative 4:

1. Sustainability, Fire, and Natural Disturbances. Key Indicator: Percent of the Forest with limitations on the size of created openings or patches

Alternative 4 would limit size of patches to 40 acres or less on approximately 17% of the forest, or about 310,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC.

Approximately 533,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems. At the end of the first decade, about 1,700 acres would not meet the DVC. Fisheries habitat quality would be high, compared to the current moderate quality rating. Degraded habitats would recover rapidly. Livestock grazing would be reduced by about 8,000 cattle AUM's. Timber harvest could occur in riparian areas to attain the desired vegetation characteristics, but is not scheduled and would not contribute to the ASQ.

3. Security for Elk. Key Indicator. Percent of Forest meeting state elk vulnerability thresholds, measured by miles of open roads and open motorized trails

About 89% of the Forest (1,640,000 acres) would meet the state elk vulnerability thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open roads and open motorized trails. Alternative 4 would reduce the number of open system roads by 295 miles (-22%) and open nonsystem roads by 722 miles (-71%). There would be a reduction in open system trails by 113 miles (-26%) and open nonsystem trails by 98 miles (-49%). The 89% of the Forest meeting state elk vulnerability standards is more than twice the existing level of 42%, thereby greatly improving elk security. This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMU's). Key Indicator: Open road and open motorized trail route density (miles per square mile).

The reduction in the open road and motorized trail densities to an average ranging from 0.33 to 0.50 miles per square mile in the BMU's, would improve grizzly bear habitat. Additional access restrictions to improve habitat security would be no cross-country motorized vehicle use in any of the BMU's, except a small portion of the Plateau and Bechler BMU's. Snowmachine use is allowed on designated routes throughout the snow season. Cross-country snowmachine use is allowed only from December 15 to April 1. Sheep grazing would be phased out.

5. Access. Key Indicator Roads and trails per mile open to motorized use.

Alternative 4 would reduce the number of open system roads by 295 miles (-22%) and open nonsystem roads by 722 miles (-71%). There would be a reduction in open system trails by 113 miles (-26%) and open nonsystem trails by 98 miles (-49%). This would restrict dispersed camping, berry-picking, firewood gathering, sight-seeing, and other activities that conventionally use road access and it would concentrate these uses on the remaining open roads and trails. The increase in closures and restrictions would provide increased wildlife security, especially for elk and grizzly bears, and protect other resources from damage. Alternative 4 would allow OHV use on approximately 79,000 acres, over a 90% reduction from the current 1,126,000 acres currently open to OHV use.

6. Roadless Area Management. Key Indicator: Number of acres recommended for Wilderness.

Alternative 4 would recommend 139,000 acres to Congress for Wilderness designation. These acres more than double the 65,000 acres recommended by the current Plan in Italian Peak, Lionhead and Winegar Hole roadless areas, plus additional roadless acres in each of these areas and the Palisades. This recommended 139,000 acres is 18% of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator: ASQ.

Alternative 4 would harvest timber at a sustainable level of 25 MMBF for the decade (approximately 2.5 MMBF per year) on an estimated 7,510 acres.

ALTERNATIVE 5

The purpose of Alternative 5 is to meet the needs for change that reduce focus on human management and human disturbances of wildlife and riparian habitat. Motorized access is restricted to designated routes and more roads are closed in BMU's. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness and another 100,000 acres of presently roadless areas are recommended to Congress for wilderness designation; until Congress acts on the recommendation, their roadless characteristics are maintained.

How the Key Issues and Key Indicators are addressed in Alternative 5:

1. Sustainability, Fire, and Natural Disturbances. Key Indicator: Percent of the Forest with limitations on the size of created openings or patches.

Alternative 5 would limit size of patches to 40 acres or less on approximately 18% of the forest, or about 333,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC.

Approximately 590,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems under this alternative. At the end of the first decade, about 1,700 acres would not meet the DVC. Fisheries habitat quality would be high, compared to the current moderate quality rating. Degraded habitats would recover rapidly. Livestock grazing would be reduced by about 8,000 cattle AUM's.

3. Security for Elk. Key Indicator. Percent of Forest meeting state elk vulnerability thresholds, measured by miles of open roads and open motorized trails.

In Alternative 5, about 98% of the Forest (1,802,000 acres) would meet the state elk vulnerability thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open roads and open motorized trails. Alternative 5 would reduce the number of open system roads by 395 miles (-29%) and open nonsystem roads by 740 miles (-73%). There would be a reduction in open system trails by 262 miles (-61%) and open nonsystem trails by 138 miles (-69%). The 98% of the Forest meeting state elk vulnerability standards is more than twice the existing level of 42%, thereby greatly improving elk security. This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMU's). Key Indicator: Open road and open motorized trail route density (miles per square mile).

The reduction in the open road and motorized trail densities to an average ranging from 0.37 to 0.49 miles per square mile in the BMU's, would improve grizzly bear habitat. Additional access restrictions to improve habitat security would be no cross country motorized vehicle use in any of the BMU's, a small portion of the Plateau and Bechler BMU's. Snowmachine use is allowed on designated routes throughout the snow season. Cross-country snowmachine use is allowed only from December 15 to April 1. Sheep grazing would cease.

5. Access. Key Indicator: Roads and trails per mile open to motorized use.

Alternative 5 would reduce the number of open system roads by 395 miles (-29%) and open nonsystem roads by 740 miles (-73%). There would be a reduction in open system trails by 262 miles (-61%) and open nonsystem trails by 138 miles (-69%). This would restrict dispersed camping, berry-picking, firewood gathering, sight-seeing, and other activities that conventionally use road access and it would concentrate these uses on the remaining open roads and trails. The increase in closures and restrictions would provide increased wildlife security, especially for elk and grizzly bears and protect other resources from damage. Alternative 5 would allow OHV use on approximately 50,000 acres, over a 95% reduction from the current 1,126,000 acres open to OHV use.

6. Roadless Area Management. Key Indicator. Number of acres recommended for Wilderness

Alternative 5 would recommend 226,000 acres to Congress for Wilderness designation. These acres more than triple the 65,000 acres recommended by the current Plan in Italian Peak, Lionhead and Winegar Hole roadless areas, plus additional roadless acres in each of these areas and the Palisades. This recommended 139,000 acres is 28% of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator: ASQ.

Alternative 5 would harvest timber at a sustainable level of 15 MMBF for the decade (approximately 1.5 MMBF per year) on an estimated 4,730 acres.

ALTERNATIVE 6

The purpose of Alternative 6 is to meet the needs for change by de-emphasizing human management and human disturbance of wildlife and riparian habitat to the lowest level in all the alternatives. Timber harvest is not scheduled. All access is strongly restricted to designated routes and more roads are closed to reduce human disturbance than in any other alternative. Lionhead, Palisades and Italian Peaks, plus the Idaho roadless portion adjacent to the Winegar Hole Wilderness and another 340,000 acres of presently roadless areas are recommended to Congress for wilderness designation. Almost all the roadless areas retain their roadless characteristics.

How the Key Issues and Key Indicators are addressed in Alternative 6.

1. Sustainability, Fire, and Natural Disturbances. Key Indicator: Percent of the Forest with limitations on the size of created openings or patches.

Alternative 6 would limit size of patches to 40 acres or less on approximately 18% of the forest, or about 330,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC.

Approximately 793,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems under this alternative. At the end of the first decade, about 1,700 acres would not meet the DVC. Fisheries habitat quality would be high, compared to the current moderate quality rating. Degraded habitats would recover rapidly. Livestock grazing would be reduced the same as Alternative 5.

3. Security for Elk. Key Indicator: Percent of Forest meeting state elk vulnerability thresholds, measured by miles of open roads and open motorized trails.

About 98% of the Forest (1,802,000 acres) would meet the state elk vulnerability thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open roads and open motorized trails. Alternative 6 would reduce the number of open system roads by 406 miles (-30%) and open nonsystem roads by 753 miles (-74%). There would be a reduction in open system trails by 405 miles (-94%) and open nonsystem trails by 145 miles (-73%). The 98% of the Forest meeting state elk vulnerability standards is more than twice the existing level of 42%, thereby greatly improving elk security. This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMU's). Key Indicator: Open road and open motorized trail route density (miles per square mile).

The reduction in the open road and motorized trail densities to an average ranging from 0.28 to 0.56 miles per square mile in the BMU's, would improve grizzly bear habitat. Additional access restrictions to improve habitat security would be no cross country motorized vehicle use in any of the BMU's, except in a small portion of the Plateau and Bechler BMU's. Snowmachine use is allowed on designated routes throughout the snow season. Cross-country snowmachine use is allowed only from December 15 to April 1. All domestic sheep grazing would be stopped immediately.

5. Access. Key Indicator: Roads and trails per mile open to motorized use

Alternative 6 would reduce the number of open system roads by 406 miles (-30%) and open nonsystem roads by 753 miles (-74%). There would be a reduction in open system trails by 405 miles (-94%) and open nonsystem trails by 145 miles (-73%). This would restrict dispersed camping, berry-picking, firewood gathering, sight-seeing, and other activities that conventionally use road access and it would concentrate these uses on the remaining open roads and trails. The increase of road closures and restrictions would provide increased wildlife security, especially for elk and grizzly bears, and protect other resources from damage. Acres available for OHV use would also be reduced over current levels. Alternative 6 would allow OHV use on approximately 34,000 acres, a 97% reduction from the current 1,126,000 acres open to OHV use. This approach is consistent with the minimum maintenance level of management emphasized in this alternative.

6. Roadless Area Management. Key Indicator: Number of acres recommended for Wilderness.

Alternative 6 would recommend 465,000 acres to Congress for Wilderness designation, more than seven times the 65,000 acres recommended by the current Plan in Italian Peak, Lionhead and *Winegar Hole* roadless areas, plus additional roadless acres in each of these areas and the *Pali-sades*. This recommended 465,000 acres is 55% of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator: ASQ.

Alternative 6 would not have a scheduled timber harvest. A limited harvest might occur, but not much, given the minimum level of human disturbance emphasis of this alternative.

Alternatives Comparison Chart

Figure II-1

Figure II-1 shows how the alternatives compared, or stacked up against each other when the Key Issue Indicators' differences were analyzed. The differences are determined by the alternative with the most advantages. For grizzly bear management, the alternative with the fewest number of open roads and motorized route density receives the highest rating. For the access issue, the alternative with the most numbers of trails and roads open per mile received the highest rating.

All alternatives meet baseline State and Federal Standards; Grizzly Bear Recovery Plan Goals for Greater Yellowstone Ecosystem; Endangered Species Act, Wilderness Act; Wild and Scenic Rivers Act; National Historical Act, NFMA; Native Americans Act; etc.

ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Several alternatives were considered but eliminated from detailed study and more information about these can be found in the process papers. These additional alternatives were not fully developed because they closely resembled alternatives that were considered in detail, they did not meet the needs for change; they were missing practical implementation components; or they were inappropriate for other reasons as follows:

Maximum Commodity Production and Motorized Access

This alternative called for more Forest land devoted to scheduled timber production than Alternative 1. It provided more designated open motorized routes, allowed less cross-country OHV access; recommended no wilderness designation; proposed elimination of the Palisades Wilderness Study Area; and recommended that eligibility determinations under the Wild and Scenic Rivers Act not be made.

Some portions of this proposal were incorporated into Alternative 2. Suggestions that could not be implemented without Congressional action (like those regarding the Palisades Wilderness Study Area and eligibility under the Wild and Scenic Rivers Act) were not included in any alternative. Because large portions of this proposal became part of Alternative 2, further detailed analysis did not occur.

Maximum Wilderness

During public involvement activities it was proposed that all of the Forest's inventoried roadless areas be recommended for wilderness designation. Alternative 6 was developed in response to the desire for additional recommended wilderness. After analysis, some inventoried roadless areas were not proposed for wilderness in any alternative because some areas did not exhibit sufficient wilderness qualities to warrant their inclusion into the wilderness system at this time. *The all-wilderness alternative was dropped.*

Range of Variability

Many members of the public and several Forest Service employees advocated the development of an alternative that would move the forest into its "range of variability." This would involve learning what ecological conditions existed on the Forest historically and managing for those same conditions. This was not developed as a separate alternative because the current information on the range of variability for the Forest is insufficient to formulate an alternative. Even with this information, ecological variability may be so broad as to provide inadequate direction for an alternative at this time. Finally, this type of alternative would not meet the National Forest Management Act Direction to formulate alternatives that incorporate social and economic conditions along with the ecological situation.

Original Forest Plan as Written

Alternative 1 reflects current management of the Forest and how it would continue in the future. It differs from the original 1985 Plan in some respects.

Some people have asked for an alternative that comes closer to the letter of the existing Forest Plan. The differences between Alternative 1 (which is modeled consistent with the intent of the 1985 Plan) and a strict reading of the 1985 Plan are summarized below. They could have been used to shape a separate alternative.

- The 1985 Plan called for the harvesting of timber from suitable lands at rates that could not be sustained. Because most of this material has already been logged or is no longer merchantable, and because some of it could not be logged because of other resource protection needs, the nonsustainable harvest schedule was not used.

- As a part of the Revision process, the Forest reassessed the eligibility of river segments for study as wild, scenic, or recreational rivers. That eligibility determination was made; and the Forest has moved to protect the outstandingly remarkable values of the eligible segments in all the alternatives. Some people have asked that an alternative be developed which does not include that protection. We did not do so because Forest Service policy is to protect the outstandingly remarkable values once eligibility is established

- The provisions of the Endangered Species Act (ESA) have not changed since the Forest Plan was put into effect in 1985. However, the understanding of the habitat needs of those species has changed substantially. Meeting the needs of these species, in particular the grizzly bear, has substantially changed management on a large portion of the Forest. We did not use the previously acceptable approaches for providing grizzly bear habitat because they are not generally accepted in today's scientific community.

- The Forest Service has greatly expanded its own list of sensitive species. In response to that expanded list, the Forest has had to change management practices to increase habitat protection. We have continued this level of protection because it is designed to prevent these species from being listed as threatened or endangered.

COMPARISON OF ALTERNATIVES

A summary of the environmental impacts and effects (called Indicators) for each alternative is provided in Table II-1. Due to the complexity of the consequences displayed in this table, cumulative impacts are not presented here. For a detailed discussion of the effects, consult Chapter IV, "Environmental Consequences."

**TABLE II-1
COMPARISON OF ENVIRONMENTAL EFFECTS**

The following pages contain a summary of the environmental effects of the alternatives. This summary is drawn from information in Chapter III and IV of the DEIS. The reader is referred to those Chapters for additional information.

The key issue indicators are displayed first for the components outlined in Chapter 1. Due to the complexity of the issues, there are other indicators that need to be evaluated to adequately address the environmental effects, and those are listed below the key indicators. Acronyms and abbreviations are defined at the end of this Table.

ECOLOGICAL PROCESSES AND PATTERNS

	Exist Level	Alt #1	Alt #2	Alt #3	Alt #3-M	Alt #4	Alt #5	Alt #6
Key Indicator - Sustainability and Patch Size Issue								
- M Acres restricted to openings < Range of Variability	NA	47	25	82	259	310	333	330

In addition to patch size, there are other ecosystem processes and patterns that we analyzed that contribute to ecologically sustainable ecosystems.

All alternatives were evaluated on the ability to use management practices such as prescribed fire and timber harvest to manipulate ecosystems. Aquatic connectivity was determined to be a good indicator of ecosystem patterns and opportunities to maintain or improve current connectivity were addressed.

Other Ecosystem Management Indicators

- M Acres where prescribed fire is allowed	1,282	1,282	1,401	1,302	1,232	1,223	1,202	1,256
- M Acres with less restrictions on timber harvest	0	262	275	132	132	0	0	0
- M Acres aquatic zones where connectivity is maintained	342	342	325	448	512	533	590	793

PHYSICAL

Most forest management activities impact the soil resource to some extent. These activities (recreation, timber harvesting, road building, grazing) were evaluated to determine what environmental effect they will have on the soil resource.

The only issue indicators used to evaluate physical elements are related to minerals and the ability to locate, or enter areas on the Forest.

Other Physical Component Indicators

- M Acres open to locatable and mineral entry	1,722	1,383	1,414	1,324	1,277	1,340	1,197	968

CHAPTER III AFFECTED ENVIRONMENT

READER'S GUIDE - In this chapter you will find:

A description of the following components of the Forest and Key Issues.

Ecological Processes and Patterns and Key Issue of Patch Sizes;
Physical Elements,
Biological Elements Component and Key Issues of Riparian Health, Elk Vulnerability and Grizzly Bear Habitat;
Forest Use and Occupation Component and Key Issues of Access Management and Wilderness,
Production of Natural Resources Component and the Key Issue of Timber Volume

This chapter describes the existing environment that will be affected by implementation of any of the alternatives. It describes the existing physical, biological and social environment of the Forest and the surrounding area. Information contained in this section appears in the same order as the key issues outlined in Chapter 1.

There were many other issues raised by publics and forest employees that were determined not to drive the development of alternatives. The Analysis of the Management Situation (USDA Forest Service, Targhee N.F., 1992) and process papers listed in section six in this document provide additional information about these issues (i.e. infrastructure, outfitter/guides).

I. ECOLOGICAL PROCESSES AND PATTERNS

INTRODUCTION

In recent years the Forest Service has embraced the concept of ecosystem management. This is an approach to natural resource management that strives to ensure healthy, productive, sustainable ecosystems by blending the needs of people and environmental values on a given area such as the Targhee National Forest. An ecosystem is a complex system of living and nonliving components that interact and change continually. Healthy ecosystems are those that retain all of their parts and functions for future generations even though vegetation patterns, human uses, or other conditions may change. Understanding ecological processes (fire and other natural disturbances) and how these processes shaped vegetative patterns over time in a landscape are important steps towards implementing ecosystem management.

An additional principle of ecosystem management is the quest for and application of new knowledge regarding ecosystems. Our understanding of ecosystems and the effects of various management activities is subject to change as new information becomes available. In order to accommodate and react to such change, the Forest Service has adopted an adaptive management approach. In adaptive management, monitoring and evaluation are used to assess the effects of management decisions and identify new information. Resource management may then be changed to reflect new understandings.

Another important ecosystem management principle is that different issues, components or effects may require description at different scales or levels. For example, economic issues are described at the county level, but fisheries are discussed by hydrologic unit. For economic and social issues political boundaries are more meaningful, while ecological units are used for resource discussions. In this document, we have addressed issues at many different scales and levels of specificity, depending on which is most relevant to the decisions being made.

Many resources are described in this chapter using the ecological units known as subsections (referred to as management areas in Chapter II). These units exhibit unique patterns in soils, landform, topography and potential natural vegetation, among other characteristics. The Forest encompasses part or all of seven subsections (Figure III-1).

- Lemhi/Medicine Lodge
- Centennial Mountains
- Island Park
- Madison Plateau
- Teton Range
- Big Hole/Palisades Mountains
- Caribou

To get a better understanding of each of the seven subsections that are being evaluated in this chapter, a brief description of each follows. Additional information on the subsections is available throughout this document, and in process papers or planning records.

Lemhi/Medicine Lodge - This subsection includes the Lemhi Mountains and the Medicine Lodge/Beaverhead Mountains. A variety of vegetation exists with dominant communities of mostly Douglas-fir and limber pine. Sagebrush/bunchgrass and mountain mahogany communities are common on the lower elevation and strong southerly exposures. Limber pine communities and alpine meadows exist at the high elevations. This subsection is rich in mining history with old mining sites and remnants of town sites. Located in the Birch Creek Valley are four preserved brick adobe Charcoal Kilns. Sixteen were originally built to furnish charcoal to the Nicholia Mine. This area also has a National Scenic Trail, a recommended wilderness (Italian Peaks) and most big game species.

Centennial Mountains - This subsection covers the Centennial Mountains between the east fork of Irving Creek and Reas Pass to the east. The Centennials, which form part of the Continental Divide, are a scenic mountain range with high mountain meadows scattered through spruce/fir and Douglas-fir forests. At lower elevations sagebrush/grasslands grade into Douglas-fir and lodgepole pine forests. Lionhead, in the northeast portion of the subsection, is a recommended wilderness in Montana. The major travel corridors are Highways 20 and 87, and a portion of Interstate 15. The Yale-Kilgore road is a secondary travel route connecting Island Park to Kilgore and Dubois. In the northeast portion of the subsection is Henry's Lake, a world renowned fishery. The western part is the Red Conglomerate range, home to at least one endemic sensitive plant species.

Island Park - This subsection includes the west half of Island Park, Ashton, and the northwest portion of Teton Basin Ranger Districts. The landscape of this subsection features a large caldera. Highway 20 is the only major highway that travels through this subsection. Among the many scenic attractions are Upper and Lower Mesa Falls, the last major undisturbed falls on the Columbia River system. The Mesa Falls Scenic Byway, established in 1989, provides motorists with a breathtaking view of the Teton Mountain Range and accesses the two falls. The Island Park subsection offers excellent trout fishing at Island Park Reservoir and along the Henry's Fork, Buffalo River, Warm River, Fall River and Bitch Creek. The Island Park subsection is also known for its snowmachine trails and cross-country ski trails and summer home concentrations. The area shows signs of large scale timber harvesting due to the mountain pine beetle epidemics in 1960's and 1970's. Harriman State Park lies in the heart of the Harriman Wildlife Refuge, with 16,000 acres of forest, meadows, lakes and streams.

Madison Plateau - The largest portion of the Madison Plateau Subsection is actually in Yellowstone National Park. The section on the Forest falls within the Island Park and Ashton Districts next to Yellowstone National Park. The Jedediah Smith and Winegar Hole Wildernesses lie within this subsection, as does the recommended Idaho wilderness portion of Winegar Hole. The Ashton-Flagg Ranch Road and Fish Creek Road are the major access routes in this area. Grassy Lake is a 320-acre lake created when a dam was built by the Bureau of Reclamation in 1937-1939. Grassy Lake as well as other lakes and

Subsection Overlay on the Targhee National Forest and the Surrounding Area

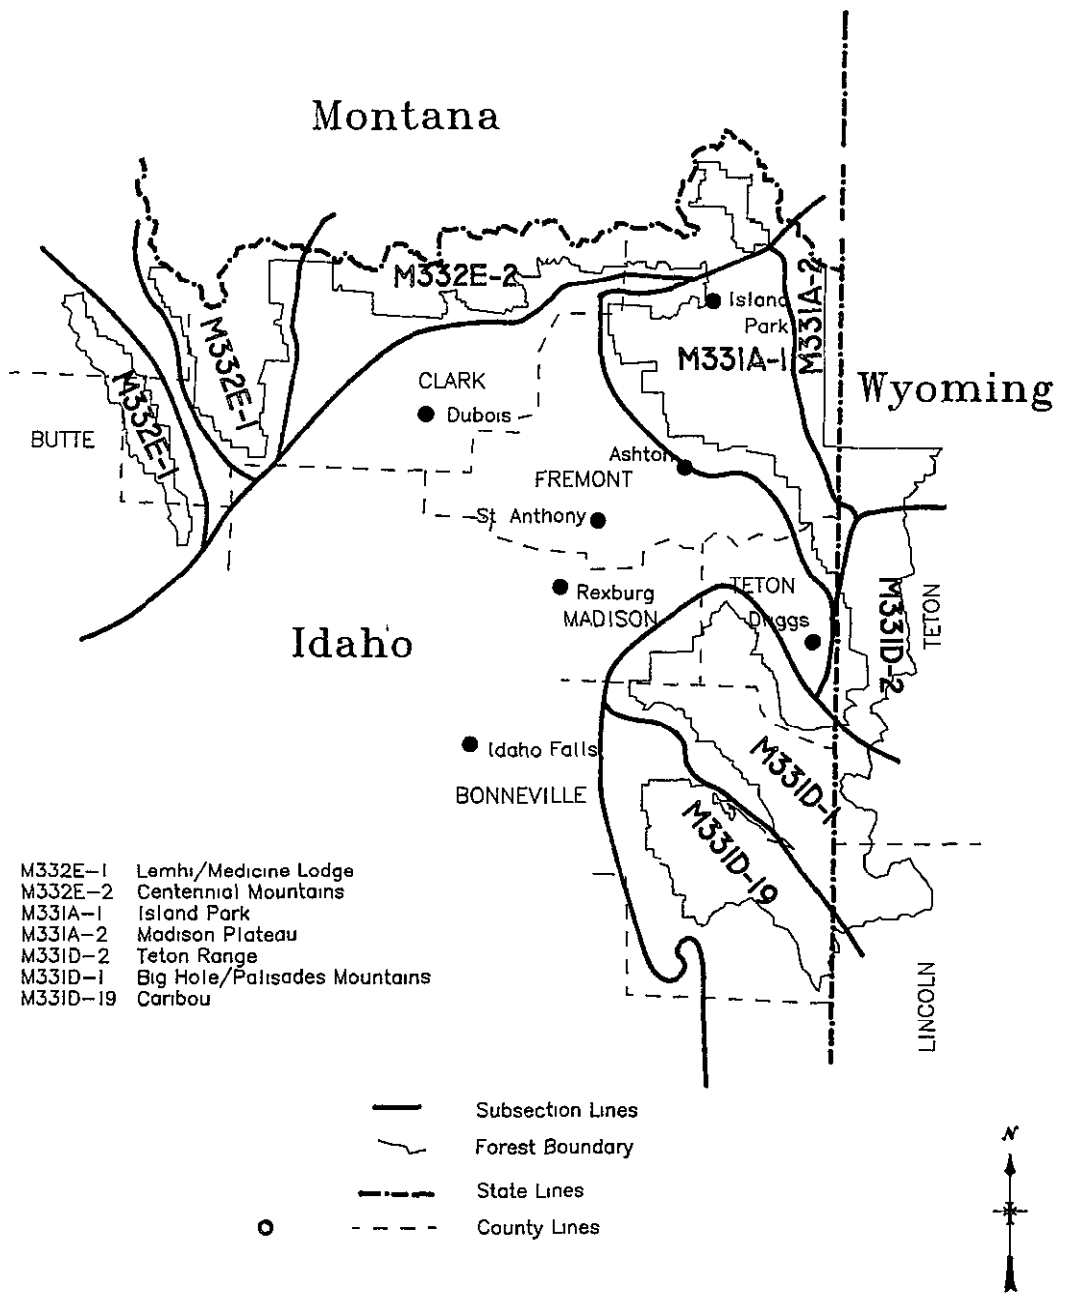

Figure III-1

streams in the area are popular fishing areas and are accessed by the Flagg Ranch road. Several organized youth camps exist throughout this subsection. The Cave Falls road is the only motorized access to the southwest portion of Yellowstone Park.

Teton Range - This area encompasses the west slope of the Teton Mountains. The Teton Range is a spectacular line of high peaks rising abruptly along the west side of Jackson Hole. The vegetation is a diverse mix of forested and nonforested plant communities. The Jedediah Smith Wilderness traverses the upper portions of the west slopes of the Teton Mountains. The Grand Targhee Ski Resort is a major tourist attraction within the subsection. Two organized youth camps are present. This area is known for its many backcountry trails which are accessible by horse or foot.

Big Hole/Palisades Mountains - This subsection takes in all National Forest lands between Highway 33 in Idaho and Highway 22 in Wyoming on the north and the South Fork of the Snake River to the south. Several major highways provide access: Idaho Highways 26, 31 and 33, and Highway 22 in Wyoming. Highway 31 is a State Scenic Byway over Pine Creek Pass. Vegetation consists of mountain brush, grass/forb openings, aspen, and forests of Douglas-fir and lodgepole pine. The area has a variety of recreational opportunities including Kelly Canyon Ski Resort and backcountry hiking. Palisades Reservoir and the South Fork of the Snake River are used by water sports enthusiasts.

Caribou - This subsection is the portion of the Caribou National Forest administered by the Forest. It lies south of the South Fork of the Snake River. Steep mountain slopes and canyons dominate the landscape. The Palisades Reservoir is shared by this subsection and the Big Hole/Palisades Subsection. Vegetation in this subsection forms a patchwork of tall sage/grass openings, aspen, and mixed Douglas-fir/lodgepole pine forests. Recreation use is very similar to the Big Hole/Palisades Subsection with high trail and backcountry use as well as hunting, fishing and water sports both on the reservoir and the Snake River. This area has several summer home divisions and two organizational camps.

RANGE OF VARIABILITY

The phrase "range of variability" refers to the composition, structure and dynamics of ecosystems through time. By understanding how ecosystems have functioned in the past and successfully maintained themselves, we may gain insight into how to keep the systems healthy and resilient into the future. The range of variability provides information, usually through analysis of vegetation patterns, about conditions under which plant and animal species evolved. Sustaining healthy plant and aquatic systems is an important part of ensuring that all ecosystem components, from wildlife and fish to microbes and fungi, are maintained.

The Forest is in the process of analyzing historical maps, photographs and literature to better understand the range of variability, both natural and human-caused, for the Forest. In addition, a cooperative project between the Forest, the Gallatin National Forest, and Montana State University is underway to increase our understanding of historical vegetation patterns and watershed function.

Information is limited, especially prior to 1900, but we do have some knowledge of how the Forest has changed over recent history. We expect to have more complete and quantifiable information available for the Final Environmental Impact Statement.

Both ecosystem processes, and the patterns created by those processes, have a range of variability. The next two sections discuss our current understanding of the range of variability for the disturbance regimes (processes) and landscape patterns of the Forest.

ECOLOGICAL PROCESSES AND DISTURBANCES

Ecosystems constantly change across both time and space. Change is brought about by many different processes and disturbances that occur over varying time frames and spatial scales. For example, fire is a disturbance process that can burn thousands of acres of forestland within a matter of hours. On the other hand, it may take millions of years for a stream to carve a canyon through the process of erosion. Some disturbances are relatively predictable, while others happen in utterly unpredictable, random ways. Humans can have a great impact on some of these processes, as discussed below. Ecosystem processes and disturbances are never independent from one another. Any given process will change resource conditions, which then sets the stage for some other agent to act.

While there are innumerable processes occurring in an ecosystem, we have focused on only a few that are most likely to be affected by the alternative management schemes being analyzed in this DEIS. This section will only examine "natural" disturbances, not those associated with human activities such as grazing, timber harvest and roading.

Succession - Scale: Community Type

Succession is the process by which plant communities change through time if they are undisturbed. This process usually begins with pioneer species invading bare ground. These early successional plants change the environment by their presence to the point where other more shade-tolerant plants can take over the site. These plants then modify conditions further by their leaf litter and shade, making the site more hospitable to yet another set of plant species which replaces them. The gradual progression from early to late successional communities continues unless interrupted by a disturbance such as wind or fire.

Due to the control of fire on the Forest since the early 1900's, succession has become a dominant ecosystem process in the unharvested portions of the Forest. Late successional communities are prevalent in herbaceous/shrub ecosystems as well as in most forest types.

Herbaceous/Shrub Communities - The process of succession in these areas generally begins following fire and is characterized by open grassland interspersed with a few shrub species. Mountain big sagebrush and other shrubs begin to dominate after five to ten years. As they compete with the grasses for water, the grasses lose vigor and die out. Sagebrush provides shade for Douglas-fir seedlings, which may take over the site as a dominant community type until fire sets it back to grassland. In the absence of a Douglas-fir seed source, the area may become a sagebrush-dominated community.

Fire suppression on the Forest has allowed a significant acreage of the herbaceous and shrub communities to convert to Douglas-fir or dense sagebrush. This varies from historical conditions where mosaics of different-aged sagebrush/grassland stands existed, and where stands dominated by herbaceous species were more common. Some high mountain meadows are also being reduced in size by conifers encroaching in from the edges.

Forest Communities - Succession can vary a great deal depending on climate and soils in forested systems, but it generally begins with early successional species such as aspen and lodgepole pine, then progresses to shade-tolerant climax species. Aspen is a relatively short-lived tree which may give way to lodgepole pine or Douglas-fir communities after approximately 100 years. The mountain pine beetle commonly attacks lodgepole pine after 80 to 120 years, allowing more shade tolerant species to take over. Douglas-fir will likely then dominate on warmer, drier sites, while subalpine fir and Engelmann spruce dominate in colder areas. Douglas-fir, subalpine fir or Engelmann spruce generally form long-lived climax communities until a disturbance occurs.

Much of the aspen acreage that was present historically on the Forest has been converted to Douglas-fir through the succession process. In addition, aspen stands are overwhelmingly in the mature or older age classes. These conditions have resulted from fire suppression. Succession at higher elevation sites has resulted in subalpine fir and Engelmann spruce becoming intermixed with whitebark pine. With continued absence of fire, the whitebark pine will likely give way to the spruce and fir.

Currently 79.6 percent of the forested land is in the mature age class. This is primarily a result of fire suppression. Historically fire produced a greater variety of age classes over the landscape. Mature age classes provide important wildlife habitat for some species. They are also more susceptible to stand-replacing fires and mortality from insects than most early-successional communities.

Fire - Scale: Vegetative Community and Subsection

Historically fire has played a significant role in the Greater Yellowstone Area. Some plants have evolved with fire and have adapted to it in various ways. Fires occurred naturally at certain average time intervals, which varied by vegetation and climatic conditions. Fires were also set by humans on a fairly regular basis, particularly in the sagebrush/grass and aspen communities. These fires created mosaic patterns of different successional stages of vegetation across the landscape.

In the early 1900's public concern for protecting the forests from fire ushered in a period of aggressive fire suppression which has continued to the present. With these suppression strategies and the lack of a prescribed fire program, the fire intervals which occurred historically have been altered. Due to the absence of fire, much of the forest vegetation has reached the mature age class and herbaceous/shrub types are in the later stages of succession. The mosaic patterns in the landscape are not as prevalent as before. These conditions increase the potential for fires of higher intensity which may be detrimental to species that evolved with frequent, low intensity burns.

There are no approved fire management plans on the Forest. All previous fire management plans were suspended as a result of the 1988 Yellowstone fires.

Fire frequency intervals and behavior vary widely among the different vegetation communities, so each is described separately in the following discussion.

Douglas-fir Fire Regimes - It appears that Douglas-fir forests in this area historically had a fire interval of 20-50 years. These fires were generally low ground fires which tended to thin the stands, favoring large, older Douglas-fir trees with thick bark. Fire suppression has led to conditions on the Forest where most Douglas-fir stands have multiple stores and dense stocking (many trees per acre). Trees of various heights provide a "ladder" for fire, allowing it to reach the tree crowns. Absence of frequent ground fires can cause dead fuels to build up over time. Fires which start under these conditions are much more severe than ground fires and tend to replace the Douglas-fir with earlier successional species such as aspen or lodgepole pine. (Bradley et al. 1992)

Lodgepole Pine Fire Regimes - In this area between the years 1200 and 1700, major fires occurred in the lodgepole pine component approximately every 100 years. Stand-replacement fires in lodgepole pine are closely tied to epidemics of the mountain pine beetle. Tree mortality caused by the beetle creates massive amounts of fuel. Fires which start under such conditions are likely to be severe. This cycle of beetles, fire and stand replacement is part of lodgepole pine's evolutionary history in the Rocky Mountains. We witnessed this cycle on the Forest beginning with beetle epidemics in the 1960's and ending with huge fires such as the North Fork Fire in 1988. Conditions for these large fires still exist in much of the Forest's mature lodgepole pine.

Most lodgepole pine, with the exception of that on cool moist sites, historically also experienced low intensity fires every 40-60 years. Fire suppression has interrupted this portion of the lodgepole fire cycle on the Forest. The effects of this are likely not too serious, since conditions created by the mountain

pine beetle are similar to those created by light ground fires (stands are thinned and regeneration may fill in the understory). (Personal comm., Brown 1993; Bradley et al. 1992; USDI National Parks Service 1993; Management of Lodgepole Pine Ecosystems 1973)

Aspen Fire Regimes - The average fire-free period historically was 40 years or longer for pure aspen stands. Fire in aspen has been reduced in size and frequency throughout the West due to fire control and the cessation of intentional burning. On the Forest fire suppression has resulted in many aspen stands that are now mixed with, or almost overtaken by, conifers such as Douglas-fir or lodgepole pine. If left undisturbed for long periods of time, conifers can change the soil characteristics so that aspen is less likely to survive (Cryer & Murray 1992) Mixed conifer/aspen stands are conducive to large stand-replacing fires. If such fires were allowed to occur, they would likely lead to pure aspen regeneration providing the fires weren't so severe as to destroy the aspen root systems. Moderate severity fires result in better aspen sprouting than either high or low severity fires (Bradley et al. 1992)

Subalpine Fir Fire Regimes - Subalpine fir forests generally occupy cool, moist habitats and are therefore common at higher elevations. Because of this fire is relatively infrequent in this type, occurring every 50-350 years depending on aspect, elevation and other factors. Large fires generally occur only during drought conditions and periods of high winds. Ladder fuels are common in this type, so fires can spread easily between tree crowns and burn large acreages. (Bradley et al. 1992)

Sagebrush/Grassland Fire Regimes - Historically, fires likely occurred every 10 to 25 years in the Forest's sagebrush communities (Clark and Starkey 1990, Houston 1973, Winward 1987). These fires created a mosaic of vegetation conditions across the landscape. In the absence of fire, these communities tend to progress toward stands of Douglas-fir or dense sagebrush. Dense sagebrush stands are less diverse than sagebrush/grasslands, and more susceptible to soil erosion, because the herbaceous vegetation is lacking. Much of the sagebrush/grassland on the Forest and throughout the west is in advanced successional stages due to the absence of fire (Winward 1992).

Whitebark Pine Fire Regimes - Fires are important to the survival and regeneration of whitebark pine. This species can survive surface fires which kill other tree species that compete with it. Since whitebark pine reproduces on fire-prepared sites, stand-replacing fires help perpetuate the species. Historically, fire occurred in whitebark pine communities every 30-300 years. Suppression of fires has favored subalpine fir and Engelmann spruce over whitebark pine. Other disturbance agents affecting whitebark pine are white pine blister rust and mountain pine beetle, which are discussed in the insect and disease section. (Morgan et al. 1994)

Fire Risks

The Forest has experienced large fires in five of the past twenty years; three of those were within the last eight years. Two fires have exceeded 5,000 acres. One was a prescribed natural fire that was allowed to burn until it exceeded the prescription parameters of the High Country Fire Plan. That fire was the Gallagher Peak Fire of 1979. The other was the North Fork Fire, one of the Greater Yellowstone Fires of 1988. Approximately 17,691 acres of the 507,580-acre North Fork Fire burned on the Forest. The size or scale of historic fires on the Forest is unknown at this time, but it is likely that the North Fork Fire emulated the size of fires that historically occurred in the lodgepole pine types.

Development of private lands adjacent to the Forest has made a significant increase in the wildland/urban interface. To deal with the threat of a wildland fire within or adjacent to these areas Emergency Evacuation Plans are being developed such as the one for the North Fire Zone in Island Park. All wildland fires, including natural ignitions, receive the appropriate suppression response of contain, confine or control. The following section briefly summarizes fuels and other conditions which contribute to fire hazard.

Lemhi/Medicine Lodge and Centennial Mountains - These subsections are dominated by sagebrush/grasslands and Douglas-fir communities. The Centennial Mountain Subsection has had substantial timber management activities, which have reduced fuels on some areas. Also in the Centennial Mountains the wildland/urban interface has significantly increased due to the development of the private lands within the Forest protection boundary. This increases the risk of a fire spreading between the Forest and private lands.

Island Park - The vegetation in this subsection is primarily lodgepole pine. This area also has heavy recreation use during all seasons, which can increase the likelihood of human-caused fires. Timber management activities have reduced much of the natural fuel loadings, but there are still some lodgepole pine stands with heavy accumulations of dead material. These stands are generally isolated by the surrounding young stands from timber harvest activities. This subsection has seen an increase in the wildland/urban interface with the development of private land. Areas with high summer home densities also present fire risks in this subsection.

Madison Plateau - The dominant vegetation is lodgepole pine. Timber activities have been widespread, significantly reducing fuel loadings. There are still high concentrations of dead fuels in stands not treated, but these areas are generally adjacent to young stands created by clearcuts. This subsection includes 17,691 acres burned over by the North Fork Fire. The Winegar Hole Wilderness is located in the southern portion of this subsection. Natural and human ignited fires in this wilderness have been suppressed.

Teton Range - A large portion of this subsection is grass forb vegetation, with forests of Douglas-fir, lodgepole pine and mixed conifers also being common. The Jedediah Smith Wilderness covers a major portion of the subsection. Since 1988 natural and human caused fires have not been allowed to burn in the Wilderness.

Big Hole/Palisades - The primary vegetation types are mixed conifer and mountain brush. Most of this subsection is roadless and primarily used for grazing and recreation. The recreation use may increase the likelihood of human-caused fires.

Caribou - Mixed conifers and sagebrush/grass communities dominate the subsection. Some timber management has occurred in the Engelmann spruce/subalpine fir type, and subsequent fuel treatments have reduced fuel loading and rate of fire spread for the short-term. Recreation use here may increase the chance for human-ignited fires.

Insects & Diseases - Scale: Forestwide and Subsection

Insects and diseases play important roles in ecosystems, even those often considered "destructive." Many of these organisms serve as food sources for a variety of wildlife species, ranging from birds to grizzly bears. In addition they are change agents, causing death, decay or damage to vegetation. This latter function is closely intertwined with the processes of succession and fire. The change from one species community to another on a site is often brought about by insects and diseases, particularly when fire is absent. For example, aspen is eventually killed by fungal diseases which may then allow Douglas-fir to dominate. Insects can change forest structure by killing all trees of a particular size or species. *Insect-killed trees contribute to fuel conditions and thereby help determine the severity, size and patterns of fires in the landscape.*

Most native insects and diseases are opportunistic, taking their toll on weakened or aged individuals. However, under some conditions these organisms may build up high populations that also overwhelm healthy, young vegetation. Trees and plants are usually adapted to insects and diseases, having evolved with them. The exception to this is when damaging agents are introduced from another continent and the plants have not had time to adapt genetically. This can often lead to disastrous consequences for a tree species, such as the American chestnut which fell victim to an introduced fungus. A concern about

whitebark pine exists currently on the Forest and throughout the range of this tree. Whitebark pine is dying off at an alarming rate due to an introduced disease known as white pine blister rust. Although there is genetic resistance to this disease, the number of whitebark pine trees is expected to decrease significantly in the short term.

Native insects of importance on the Forest include the mountain pine beetle, Douglas-fir beetle, western balsam bark beetle and western spruce budworm. Mountain pine beetle populations have remained at low levels since 1983. Between 1981 and 1987 western spruce budworm was active in the Douglas-fir on the Forest. This insect stressed the trees to the extent that Douglas-fir beetles were able to kill many Douglas-fir between 1988 and 1992. Additional information on these insects may be found in the Analysis of the Management Situation for the Forest (USDA Forest Service, Targhee N.F. 1992). Stalactiform rust, gall rust and various root rots are common fungal diseases. Dwarf mistletoes (parasitic plants) are present on lodgepole pine across the Forest and Douglas-fir in more isolated pockets. Important existing insect and disease conditions for each subsection are briefly covered in the Vegetation section of forest ecosystems.

ECOLOGICAL PATTERNS

The ecosystem disturbances and processes discussed above contribute to patterns of vegetation across the landscape. Other factors such as climate, topography and soils also help determine vegetation patterns. The patterns themselves are important to other components of the ecosystem such as wildlife species and humans. Vegetation patterns have a range of variability which the Forest is seeking to more fully understand. We have chosen to analyze four measures of ecosystem patterns that we believe are most important on the Forest. A brief discussion of each follows.

Patch Sizes - Scale: Subsection

Natural and human disturbances tend to break up large tracts of similar forest habitat into smaller blocks separated by openings, different vegetation types, or different age classes. Patch sizes varied historically based on topography, soils and the scale of disturbances. On the Forest they are affected by all these factors, plus human activities such as roading and clearcutting. Patch size is important since some wildlife species are adapted to using extensive forested areas.

Current conditions on the Forest vary by subsection. The Caribou, Big Hole/Palisades and Lemhi/Medicine Lodge Subsections have historically exhibited small patch sizes due to their physiographic conditions. This continues to be the case. Clearcutting over the past decade in the Island Park and Madison Subsections has created smaller patch sizes than occurred historically. The Teton Range and Centennial Mountains Subsections are likely exhibiting larger patch sizes than they did historically due to fire suppression and the current predominance of forests in mature age classes.

Vegetation Types - Scale: Subsection

The distribution of community types and age classes by subsection is displayed in Table III-1. Studies to date show that the Forest's vegetation has changed in some significant ways over the past century. Preliminary analysis indicates that some vegetation conditions are different than what occurred historically on the Forest. These situations are discussed below.

In some subsections aspen has declined by up to 80%, while in others aspen acreage has increased in the past two decades due to clearcutting (USDA Forest Service, Targhee N.F. 1994). Aspen decline is most serious in the Lemhi/Medicine Lodge, Centennial Mountains, Big Hole/Palisades and Caribou Subsections.

The amount of whitebark pine has been reduced over the past 30 years as a result of mountain pine beetle, white pine blister rust and succession. The seeds of this tree are an important food source for grizzly bears, some birds and small mammals.

Table III-1 Existing Forested Conditions within Subsections								
Subsection	Community Type	Total Forested Acres	Percent Non-stock	Percent Seedling	Percent Sapling	Percent Pole	Percent Mature 1/	Percent Mature Prev Harv 2/
Lemhi/Medicine Lodge	Aspen	335	00	00	00	00	100 0	00

	Spruce/Subalpine Fir	793	00	17 1	26 9	00	56 0	00
	All Forested Acres	122,495	0 6	0 3	0 2	0 4	98 5	00

1/ The mature category incorporates all older age classes, including noncommercial

2/ Includes acres of mature forest that have had harvest treatments such as commercial thinning or shelterwood seed tree cuts, but the harvest did not result in reclassifying the acres to a different age class

Shrublands and grasslands are less prevalent than in the past due to fire suppression. This indicates a habitat loss for species dependent on these communities and a habitat gain for species adapted to forested areas. The greatest changes have occurred in the Lemhi/Medicine Lodge, Centennial Mountains, Big Hole/Palisades and Caribou Subsections.

Stand structures, particularly in the Douglas-fir forests, have changed as a result of fire suppression. Compared to structures in the past, these stands are now denser and more multi-storied. This has increased the likelihood of severe fires, increased the susceptibility to insects and diseases, and altered the type of habitat provided by Douglas-fir forests. These conditions are common in all subsections.

The Forest currently has much more area in mature age classes than the historical record indicates. Of particular significance are the high percentages of mature or older mountain mahogany, mountain big sagebrush, aspen, cottonwood and Douglas-fir. Mosaics of different age classes were more common in the past.

Connectivity - Scale: Forestwide and Subsection

Connectivity between habitat areas involves the linkage of similar habitat patches such as water courses, natural openings, or as most commonly studied, vegetation. The maintenance of connectivity is needed to ensure proper levels of nutrient cycling, hydrologic function, and species survival. If the level of connectivity is maintained over time and space, then processes such as predation, dispersal, and gene exchange continue even though habitat areas may be separated from each other. Species differ in their need for corridors between blocks of habitat, with some moving freely through the landscape while others tend not to cross openings between habitat areas. Specific habitat linkage requirements for various species have not been determined. However, species evolved to function within certain limits of connectivity shaped by natural disturbances. Maintenance of vegetation patterns with which plant and animal species evolved is an accepted measure of ecosystem health

Connectivity is influenced by access routes and clearcuts, as well as by historic vegetation patterns. Connectivity in the Caribou, Big Hole/Palisades and Lemhi/Medicine Lodge Subsections is likely similar to what existed historically based solely on the vegetation patterns. However, human access routes may have reduced the ability of species to move between habitat blocks. Clearcutting and roading over the past decade in the Island Park and Madison Subsections have altered vegetation patterns and connectivity from what existed historically. Although leave strips have provided continuity of mature forest habitat, these links are much narrower and more randomly distributed across the landscape. Based on vegetation patterns alone, the Teton Range and Centennial Mountains Subsections are likely exhibiting similar or greater connectivity than historically due to fire suppression and the current predominance of forests in mature age classes. However, the presence of roads and trails in the subsections may have reduced some species ability to move between habitat blocks.

Connectivity is important in aquatic, as well as forested ecosystems. Natural disturbance forms patterns of habitat patches, which in turn control aquatic ecosystem processes and functions (see "aquatic ecosystem" section). Natural and human-induced disturbances affect the connectivity of riparian areas and the linkages between aquatic and forested ecosystems. Where road crossings and concentrated human activity exist in aquatic ecosystems, it can be assumed that some level of connectivity has been lost compared to what existed historically.

Adjacent Land Use Patterns - Scale: Forestwide

Lands adjacent to the Forest are part of the ecosystem. Uses of these lands affect the Forest, and management of the Forest likewise affects adjacent ownerships. This all plays into the larger social and ecological context in which the Forest is managed. Lands next to the Forest represent many different owners and management strategies. Adjacent entities include private landowners, Harriman State Park, Idaho Department of Lands, Yellowstone and Grand Teton National Parks, John D. Rockefeller

Memorial Parkway and the U.S. Sheep Experiment Station. In addition, several National Forests and Bureau of Land Management (BLM) Districts lie adjacent to the Forest.

Dominant land use patterns on adjacent private lands involve farming and ranching. These activities have occurred since the 1800's in this area. The past decade has brought a trend toward subdivision developments, particularly in Teton Valley, Island Park and Swan Valley. On lands administered by the Idaho Department of Lands, other National Forests and the BLM, management tends to be oriented toward use of resources, with timber harvest, livestock grazing and recreation being common activities. National Parks are governed by the principles of preservation and noninterference with natural processes, but have intensive recreation management in some areas.

The Adjacency Study contained in process papers shows how the Forest fits into the management of neighboring lands. For the most part there is a sense of continuity across the borders of the Forest into adjoining National Forest, BLM, and National Park Service (NPS) lands. Probably the single most visible discontinuity lies along Yellowstone National Park's western boundary where evidence of the Forest's intensive timber management can be seen in sharp contrast to the Park's unmanaged forest. That apparent discontinuity will continue until the young regeneration grows and blends with older surrounding vegetation.

There are other land management practices on the Forest which might appear to be incongruent to some people, and understandable to others. The Grand Targhee Ski Resort, an area of concentrated recreation development, shares much of its boundary with the congressionally-proclaimed Jedediah Smith Wilderness. The ski resort and the wilderness uses remain in effect in all the alternatives. Likewise, some people view the presence of a road alongside a wilderness as being incongruent. Others accept the fact that roads, as an exclusionary feature in a wilderness, will frequently end up being used to define its boundaries.

From the point of view of the Forest, management of adjacent lands seems to have more of an impact on Forest management than vice versa. As the human population of the area of influence has grown so has their use of the Forest - in particular their recreational use. The Forest has had to respond to those changes by hardening recreation sites to prevent damage to the resource.

II. PHYSICAL ELEMENTS OF THE ENVIRONMENT

Soils and Geology - Scale: Subsection

Lemhi/Medicine Lodge - This subsection consists of fault block mountains, which exhibit a northwest-southeast trend. The dominant rock types are limestone and sandstone. The landscape is dissected by parallel drainage systems.

Soils on these landscapes are greater than 60 inches to bedrock, having gravelly medium textured surface layers and extremely gravelly medium textured subsurface layers. These soils have a low to moderate inherent fertility, are droughty, are high in carbonates, and have a high erosion hazard.

Principal ecological concerns affecting soil quality in the subsection are as follows: the expansion of conifers into sagebrush/grass and riparian communities has changed some sites, the area's susceptibility to fires has increased the risk of losses in soil productivity associated with such events, and canopy density of sagebrush communities and subsequent loss of understory vegetation has led to declining watershed conditions.

The principal management activity affecting soil quality is roads and OHV use. Secondary management activities affecting soil quality include grazing concerns along incised drainages and water developments, and mining impacts which have not been reclaimed.

Centennial Mountains - This subsection consists of a fault block mountain range, which exhibits an east-west trend along the Continental Divide. The dominant rock types are rhyolite, sandstone and shale. The landscape is dissected by dendritic and parallel drainage systems.

Soils on these landscapes are greater than 60 inches to bedrock, having nongravelly to gravelly medium to medium-fine textured surface layers and gravelly to extremely stony medium to medium-fine subsurface layers. These soils have a moderate to moderately high inherent fertility, are susceptible to compaction and puddling, have a moderate to high erosion hazard, exhibit plant competition concerns, and demonstrate slumping hazards on mountain side-slopes and escarpments at higher elevations.

Principal ecological concerns affecting soil quality include conifers expanding into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes; increased risk of losses in soil productivity associated with fire events; canopy density of sagebrush communities and subsequent loss of understory vegetation which is causing declining watershed conditions; and slumping potentials. Principal management activities that are concerns affecting soil quality include roads and OHV use, dispersed recreation impacts, grazing concerns along drainages and water developments. Secondary management activities that are affecting soil quality include mining impacts which have not been reclaimed, past timber and firewood harvest which have resulted in roads, compaction, organic matter removal or displacement, and loss of woody residue.

Island Park - The Island Park Caldera was formed by the collapse of a large rhyolite shield volcano. After the collapsing of the caldera, volcanic activity continued, resulting in basalt flows covering much of the caldera floor. The entire subsection has been overlain by wind blown silts (loess). The dominant rock types are rhyolite and basalt. The landscape is dissected by dendritic and parallel drainage systems on the caldera rim and associated tablelands. The caldera floor has very little dissection.

Soils on these landscapes are greater than 60 inches to bedrock, having nongravelly to gravelly medium textured surface layers and medium fine to extremely cobbly medium textured subsurface layers. These soils have a moderately low to moderate inherent fertility. Soils on the caldera floor have plant competition concerns on deeper soils, reforestation concerns on shallower soils, and a moderate susceptibility to compaction. Soils on the caldera rim have a moderate susceptibility to compaction, moderate to high erosion hazard, low bearing strength, and plant competition concerns.

A principal ecological concern affecting soil quality (limited to the caldera rim) is the expansion of conifers into aspen, sagebrush/grass, riparian and mountain meadow communities and resulting site changes

Principal management activities affecting soil quality (caldera rim) are roads and OHV use, and extensive past timber and firewood harvest which have resulted in roads, compaction, organic matter removal or displacement, and loss of woody residue.

Principal management activities (caldera floor) are the same as for the rim, plus dispersed recreation, which is especially heavy near summer home areas, and grazing along certain riparian areas and meadow complexes.

Madison Plateau - This subsection consists of a large consolidated ash flow that came out of Yellowstone Park and overtopped the east rim of the Island Park Caldera. The landscape is dissected by dendritic and parallel drainage systems.

The soils in the northern part are greater than 60 inches to bedrock, having medium textured surface layers and stratified gravelly coarse textured to extremely gravelly coarse textured subsurface layers. The soils in the southern part are greater than 60 inches to bedrock, having gravelly medium textured surface layers and very gravelly to extremely cobbly medium textured subsurface layers. These soils have a moderately low inherent fertility, are droughty, and have windthrow hazards. They are highly erodible if the subsoil is exposed, as it is in the northern part of this subsection due to the North Fork Fire.

A principal ecological concern affecting soil quality (southern portion) is the susceptibility to fires, increasing the risk of losses in soil productivity associated with such events, including areas on the 1988 North Fork Burn that have not recovered yet.

Principal management activities affecting soil quality include roads and OHV use, dispersed recreation, effects associated with timber harvest which have resulted in roads, compaction, organic matter removal or displacement, and loss of woody residue.

Teton Range - The Teton Range is a north-south trending mountain range. The dominant rock types are granite, limestone, sandstone, dolomite, slate, gneiss and quartzite. The landscape is dissected by parallel drainage systems.

This subsection consists of two primary landscape settings. These include foothills on lower to mid elevations and mountain side-slopes at mid to high elevations. Soils on these landscapes are 40 to greater than 60 inches to bedrock, having nongravelly to very gravelly medium textured surface layers and gravelly to extremely stony medium textured subsurface layers. These soils have low to moderately low inherent fertility, low to moderate compaction hazard, moderate to high erosion hazard, reforestation concerns and low to high mass instability hazards.

Principal ecological concerns affecting soil quality in this subsection include conifer expansion into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes, and the area's susceptibility to fires with increased risk of losses in soil productivity associated with such events.

Principal management activities affecting soil quality include roads and OHV use, and dispersed recreation. Secondary management activities affecting soil quality include grazing along drainages, and the effects of timber harvest which have resulted in roads, compaction, organic matter removal or displacement, and loss of woody residue.

Big Hole/Palisades Mountains - This subsection consists of a mountain range of multiple, parallel overthrusts (faults) and benches of mixed rocks and eolian material that have been modified by thrust faulting.

Soils on these landscapes are greater than 60 inches to bedrock, having gravelly medium textured surface layers and very gravelly moderately coarse to moderately fine textured subsurface layers. These soils have a moderate to high inherent fertility, moderate compaction and rutting hazard, moderate to high erosion hazard, moderate to high slumping and earthflow hazard, plant competition concerns, and areas of low bearing strength.

Principal ecological concerns affecting soil quality include conifer expansion into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes, increased risk of losses in soil productivity associated with fire events, canopy density of sagebrush communities and subsequent declining watershed conditions, and slumping/earth flows.

Principal management activities affecting soil quality are roads and OHV use, dispersed recreation, and grazing along drainages. Secondary management activities affecting soil quality include erosion along sheep driveways, effects resulting from timber harvest in the Big Hole Mountains, and big game feeding areas along Rainey Creek.

Caribou - The Caribou Subsection is a southeast to northwest trending overthrust (multiple faults) mountain range. The northeast side of the range is moderate relief mountains on mixed sediments. The southwest side of the range is low relief foothills and basins on fine textured marine sediments. The dominant rock types are a mix of sedimentary materials with a loess influence. The landscape is dissected by dendritic drainage systems.

Soils on these landscapes are greater than 60 inches to bedrock, having medium textured surface layers and moderately-coarse to fine textured subsurface layers. These soils have a moderate to high inherent fertility, moderate compaction and rutting hazard, moderate to high erosion hazard, moderate to high slumping and earthflow hazard, plant competition concerns, and areas of low bearing strength.

Principal ecological concerns affecting soil quality include conifer expansion into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes, increased risk of losses in soil productivity associated with fire events, and canopy density of sagebrush communities and subsequent loss of understory vegetation resulting in a decline in watershed conditions and slumping/earthflows. Principal management activities affecting soil quality include roads and OHV use, dispersed recreation, and grazing along drainages. Secondary management activities affecting soil quality includes erosion along sheep driveways, and effects from timber harvest.

Air Quality - Scale: Forestwide

The United States Environmental Protection Agency (EPA), in conjunction with the states of Idaho and Wyoming, have established National Ambient Air Quality Standards for pollutants to protect the public health and welfare. These standards relate to PM10 particles, which are particles with an aerodynamic diameter of 10 microns or less.

National Ambient Air Quality Standards require that PM10 remain below 50 micrograms per cubic meter when averaged over a year. PM10 must generally remain below 150 micrograms per cubic meter averaged over a 24-hour period, however, this standard can be exceeded up to one time per year.

Class I airsheds have the highest air quality standards, and Class II have a moderate level of protection. The entire Forest, including the Jedediah Smith and Winegar Hole Wildernesses, is a Class II airshed. Yellowstone and Grand Teton National Parks, adjacent to the Forest's eastern boundary, are Class I airsheds. The Forest must ensure that its activities do not reduce air quality in these Class I airsheds.

In general, the area's air quality is very good. The primary sources of PM10 on the Forest are wildfire, prescribed fire, and dust generated from road traffic. The major source of PM10 from outside the Forest is dust generated by wind and agriculture. Agricultural burning and mechanical disturbance such as plowing, planting and harvesting crops reduce air quality.

Currently there are no air quality monitoring stations located on the Forest. The closest air quality monitoring station is located in Jackson, Wyoming. This station has measured PM10 since 1986. During the analysis period the highest 24-hour average PM10 reading recorded was 124 micrograms per cubic meter in 1992. This is 26 micrograms per cubic meter less than the allowable standard. One short term value of 248 micrograms per cubic meter was recorded in 1988 during the Yellowstone wildfire situation. Annual averages have ranged from a high of 39.8 micrograms per cubic meter in 1988 (Yellowstone Fire influenced) to a minimum of 25.5 grams per cubic meter in 1993.

Caves - Scale: Subsections

Caves are present primarily in two subsections on the Forest, as discussed below.

Lemhi/Medicine Lodge - This area contains numerous small caves in limestone cliffs. Many have been identified during heritage resource inventories. Large caves in this area contain evidence of Native American habitation in the form of pictographs and cave fills with stratified cultural deposits. Few caves in this area have sufficient depth to provide recreational opportunities.

Teton Range - The Teton Range has numerous caves but most are small and have little recreational interest to spelunkers. The Fossil Mountain Ice Cave and Wind Cave, however, have high recreational interest for exploration. Both caves are identified on Forest maps and have access trails and signs from Darby Canyon. These caves probably qualify as "significant caves" under the Federal Cave Resources Protection Act of 1988, but they have not yet been inventoried or nominated. A thorough inventory of caves in this area has not been completed, and new significant caves with high public interest may be discovered.

Lands - Scale: Forestwide and Subsections

The Lands program includes the adjustment of land ownership patterns, land acquisition, granting of rights-of-way, identification and resolution of trespasses, and property boundary management.

Land Ownership Adjustments

Land ownership within the administrative Forest boundary is displayed in Table III-2. Land ownership adjustments have enabled the Forest to acquire lands that meet specific needs, goals, and objectives. These are valuable for recreation, wildlife habitat, riparian areas, and historical resources. These also enabled us to consolidate land ownership to improve operating efficiency. Ownership adjustments reduce the miles of private/Forest Service property lines that need to be surveyed, posted and maintained. Adjustments can also reduce special use permit administration and resolve trespass and title claims.

The Congressionally mandated Land and Water Conservation Fund can be used to purchase land interests for the Federal Government. Although the Forest has submitted yearly requests for one to fifteen such purchases, the last funded project was in 1962.

Land adjustments may also occur through donation of land or partial land interest. Proponents in land transactions have been approached and encouraged to donate lands or interests in lands.

Land Exchanges have been the most effective tool in completing the objectives for land adjustments. Through eight land exchanges important wildlife and wetland habitats, scenic and historical sites, a needed gravel source, and six inholdings were acquired. Lands disposed of have been, for the most part, those that have lost their Forest characteristics, are difficult to manage, or consolidated Forest holdings. The Forest is presently pursuing five land exchange cases.

Land ownership adjustment on the Forest has emphasized the transfer of both surface and subsurface rights. This has resulted in very little reserved or outstanding mineral ownership. Currently nonfederal minerals consist of only about 5,000 acres out of a total of about 1.8 million Forest acres.

Ownership	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Range	Big Hole/ Palisades	Caribou	Totals*
NFS Land Acres	279,655	319,248	296,482	196,424	160,806	350,222	204,949	1,808,175
Private Acres	1,883	7,559	9,986	815	963	7,661	8,364	59,840
State Acres	637	5,886	15,060	637	0	0	0	
BLM Acres	0	0	389	0	0	0	0	389
Total Acres	282,175	332,693	321,917	197,876	161,769	357,883	213,313	1,868,015

* Figures in this column are the figures of record. Differences in sums of prior columns are due to measurement method.

Right-of-Way Acquisition

Right-of-way acquisition is driven by the need to provide land managers and the public access to National Forest System lands. With private lands changing hands, many roads that have been open to the public are now being closed. There is a need to gain legal access through the acquisition of rights-of-way. Eight right-of-way cases have been completed and 91 rights-of-way been identified for acquisition (see Table III-3).

Table III-3 Land Adjustments, 1985-1995 1/							
	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Range	Big Hole/ Paisades	Caribou

1/ These figures are updated yearly. Current figures are on file at the Forest office.							

Minerals - Scale: Subsections

No specific proposals for mineral development have been addressed in this Revision. The role of the Forest Service is to manage the surface resources to minimize adverse environmental impacts, and to provide mitigation direction.

The issue of oil and gas development on the Forest is being addressed in a separate EIS. The current status of oil and gas production is included briefly here to give the reader an overall picture of the mineral, oil, gas and hard rock situation on the Forest.

Lemhi/Medicine Lodge - During the mid and late 1800's lead and copper, and to a lesser extent silver and gold, were mined extensively in this subsection. Since then there has been no activity and none is predicted. There are no oil and gas leases currently, although during the 1980's there were numerous leases generating rental income. In a recent study by the BLM the area has been rated as having a low potential for the discovery of oil and gas resources.

Centennial Mountains - During the late 1950's and early 1960's phosphate was mined near Mt. Taylor in the eastern Centennials from two of the three phosphate leases located in the area. Since then no mining has occurred, but the leases still remain. Should phosphate production resume, 50 percent of all revenues generated from leasing return to the State of origin for use as the legislature may direct.

Oil and gas leases blanketed the area in the mid 1980's, but none exist today. Even though the potential for discovery of oil and gas is rated low in this area, an exploration well was drilled in the late 1980's, but came up dry.

Northeast of Dubois, gold exploration is currently taking place and has been for several years. In the event of development and production the local communities would experience a boost in their economies.

Also, northeast of Dubois are several mining claims where the exploration, development and production of opal has been conducted for the past 30 years. One particular claim has exhibited most of this activity and has been patented (private ownership). The site is known as the Spencer Opal Mine and has operated commercially as a public digging site since 1968. Current activity on surrounding nonpatented claims consists mainly of exploration.

Island Park & Madison Plateau - Oil and gas and geothermal leases blanketed the area in the mid 1980's, but none exist today. The area is rated as having no potential for the discovery of oil and gas. Congress has effectively prohibited geothermal development in this area through legislation prohibiting the leasing of lands in the Island Park geothermal area (Geothermal Steam Leasing Amendments Act of 1988). There are no other mineral resources in this area of economic importance.

Teton Range - Oil and gas leases were scattered through the area in the mid-1980's, but none exist today. The area is rated as having no potential for the discovery of oil and gas. There are no other mineral resources of economic importance in this area.

Big Hole/Palisades - Oil and gas leases blanketed the area in the mid-1980's, generating rental income. Fifty percent of this money returned to the State of origin for use as the legislature directed. There are no oil and gas leases currently, pending the completion of an oil and gas EIS. A couple of exploratory wells were drilled during the 1980's, but were dry holes. The potential for discovery of oil and gas is rated as moderate in the north half of the subsection and high in the south.

Caribou - Oil and gas leases blanketed the area in the mid-1980's, generating rental income. Fifty percent of this money returned to the State of origin. There are no oil and gas leases currently, pending the completion of an oil and gas EIS. The potential for discovery of oil and gas is rated as moderate in this subsection.

There are four phosphate leases located in the northern part of the subsection, which are currently inactive. Last reported activity was in the 1960's and consisted primarily of exploration. Activity is not expected on these leases for the next three or four decades.

Travertine, a marble-like building stone product, is mined in the northern part of the area and is the only active mine of economic importance on the Forest.

In the southern portion of the subsection, McCoy Creek has long been the center for recreational placer gold dredging, sluicing and panning. Mining claim activity has also occurred with limited commercial success.

III. BIOLOGICAL ELEMENTS OF THE ENVIRONMENT

This section is divided into various types of ecosystems so that the relationships between biological elements within the same system can be better understood. Aquatic and riparian ecosystems, and terrestrial ecosystems (upland forested and upland nonforested) will be considered.

AQUATIC AND RIPARIAN ECOSYSTEMS

Riparian - Scale: Subsection

Riparian areas lie adjacent to water and are composed of vegetation communities influenced by water. Though riparian areas constitute only a fraction of the total land area, they are more productive in terms of both plant and animal species diversity and biomass per unit area than the remainder of the land base. Riparian areas are essential breeding, rearing and feeding grounds for many species of wildlife and they directly correlate to the quality of the aquatic habitat (fisheries). Often these key areas visibly reflect the quality and success of land management activities in tributary watersheds. Riparian areas are extremely important for flood control and hydrologic function. These systems are very important to the human environment from ecological, aesthetic, recreational and economic points of view.

Grazing is considered to have shifted the species composition on 8,988 (32%) acres of riparian communities across the forest. Under current range management 5,338 acres of these acres are moving toward higher ecological conditions with increasing plant biodiversity. Some 3,650 acres are remaining in less stable, lower ecological conditions, with lower plant biodiversity (Table III-4). Where grazing decreases the species diversity, shallow, fine rooted species such as Kentucky Bluegrass (*Poa pratensis*) become dominant and replace the deeper, thicker-rooted native herbaceous species, decreasing the potential of stream stability.

Biodiversity and sometimes stream stability are also affected by riparian community succession. Riparian areas with closed shrub canopies have little understory vegetation due to shading and may have low overall species diversity. This can negatively affect stream stability on some streams. Spruce forest riparian communities also have low species diversity due to shading, and low vegetative cover to protect streambanks from erosive events unless armored by large rock.

Additional information may be found in the water quality, fisheries and riparian wildlife sections. Table III-4 summarizes riparian conditions by subsection.

Lemhi/Medicine Lodge - The principal ecological concern affecting riparian quality in this subsection is that upland vegetation has expanded into riparian zones due to past over-utilization and/or a drop in the water table levels. A secondary ecological concern affecting riparian quality in this subsection is that within some riparian areas willows are dying out and are not being replaced by willow regeneration.

Principal management influences affecting riparian quality include past overuse by ungulates (domestic and wild), dispersed recreation and OHV use, and roads in or adjacent to riparian areas and associated stream crossings.

Centennial Mountains - Principal ecological concerns affecting riparian quality includes the expansion of upland vegetation into riparian zones due to past over-utilization and/or a drop in the water table levels, and some areas of fine textured subsoils which have a moderate to high slumping potential. A secondary ecological concern affecting riparian quality is that within some riparian areas willows are dying out and are not being replaced by willow regeneration.

Principal management concerns affecting riparian quality are overuse in some areas by ungulates (domestic and wild), dispersed recreation and OHV use, and roads in or adjacent to riparian areas and associated stream crossings. Secondary management concerns affecting riparian quality include past mining sites that have not been rehabilitated, past timber harvest that left inadequate buffers, and fuel wood gathering.

Table III-4 Aquatic and Riparian Conditions by Subsection							
Parameter	Lemhi/ Medicine Lodge	Centennia Mountain	Island Park	Madison Plateau	Teton Range	Big Holes/ Palisades	Caribou

Island Park - The principal ecological concern affecting riparian quality is that there are areas where willows are dying out and not being replaced by willow regeneration.

Principal management concerns affecting riparian quality include high use recreation areas (including summer home, dispersed and developed recreation areas), OHV use, roads in or adjacent to riparian areas and associated stream crossings, past timber harvest which left inadequate buffers, and fuel wood gathering. A secondary management concern affecting riparian quality is overuse in some areas by ungulates (domestic and wild).

Madison Plateau - The principal ecological concern affecting riparian quality is in the area of the North Fork Burn. Principal management concerns affecting riparian quality include dispersed recreation and OHV use, roads in or adjacent to riparian areas and associated stream crossings, past timber harvest which left inadequate buffers, and fuel wood gathering. A secondary management activity affecting riparian quality is overuse in some areas by ungulates (domestic and wild).

Teton Range - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, horse use and OHV use, trails in close proximity to or within riparian areas and associated crossings, isolated areas of overuse by ungulates (domestic and wild), and roads in or adjacent to riparian areas and associated stream crossings. Secondary management activities affecting riparian quality include past timber harvest which left inadequate buffers, and fuel wood gathering.

Big Hole/Palisades - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, horse use and OHV use, trails in close proximity to or within riparian areas and associated crossings, and areas of overuse by ungulates (domestic and wild). Secondary management activities affecting riparian quality include sheep driveways, past timber harvest which left inadequate buffers (Big Hole Mountains), fuelwood gathering (Big Holes Mountains), and Idaho Fish and Game Department feeding grounds in Lower Rainey Creek.

Caribou - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation and OHV use, trails in close proximity to or within riparian areas and associated crossings, areas of overuse by ungulates (domestic and wild), sheep driveways, and roads in and adjacent to riparian areas and associated crossings.

Water - Scale: Subsection

Subsection boundaries are used for analysis and description, although this means that some streams are split between two subsections. Channel stability information dates primarily from inventories completed in the mid-1970's to early 1980's. More current information does exist on some portions of the Dubois and Teton Basin Ranger Districts (1989-1993). It is important to determine which streams are naturally "unstable" (i.e., dynamic) due to landforms, bed and bank materials, etc., and which ones have instability induced by management practices. An attempt is made in the text to make this determination where possible. In discussions of channel stability the "good" and "fair" categories were further split into (+) and (-) to indicate better or poorer stability respectively.

Water Yield

Total water yield on the Forest is about 1.4 million acre-feet. Water is lost or used in many ways, including evaporation, infiltration, use by plants and animals, and diversion ditches from stream channels. Because of these factors and many others, the amount of water reaching the Forest boundary will be less than what is produced. Table III-5 shows water yield by subsection across the Forest.

Management activities have the potential to change the timing and amount of water delivered to stream channels. As an example, timber harvest, especially in headwater areas, may allow more snow to accumulate in created openings. This may result in higher flood peaks and possible impacts to streams. Currently there are approximately 22,000 acres in headwaters that have been altered by timber harvest (out of a total of approximately 239,000 headwater acres in those watersheds that have much harvest), which includes stands in seedling, sapling and unregenerated categories. While this is approximately 9 percent on a Forestwide basis, the amount of actual headwater harvest varies widely between subwatersheds.

Subsection	Annual Water Yield for Subsection (ac-ft)	Unit Water Yield (ac-ft per acre)
Lemhi/Med Lodge	96,400	0.34
Centennial Mountains	134,300	0.42
Island Park	125,600	0.42
Madison Plateau	186,400	0.95
Teton Range	405,300	2.52
Big Holes/ Palisades	299,100	0.85
Caribou	169,600	0.83

Water Quality

The biggest pollutant on the Forest is excess sediment, derived from within-channel erosion and upland erosion reaching stream channels. The main source of sediment is roads, specifically those segments within riparian areas, including stream crossings. Forest roads generally contribute an estimated 85 to 90 percent of the sediment reaching streams in disturbed Forest land (Burroughs, 1990). This is likely the case on the Forest, too. Currently there are 5,680 stream crossings and 670 miles of road in riparian areas. The amount of water meeting State water quality goals on the Forest is unknown. Idaho Code Section 39-3601 et seq. (effective July 1, 1995) approved adoption of new water quality standards. Streams targeted for the new regulations are those listed as "Water Quality Limited" under section 303(d) of the Clean Water Act. These are to receive priority for monitoring so they may be removed from the list if water quality is good. If it isn't, special BMP's and pollutant limits must be established.

Lemhi/Medicine Lodge - Major streams in this subsection are Medicine Lodge Creek and its tributaries. There are many perennial streams that have their headwaters in the Bitterroot and Beaverhead Ranges, that eventually flow through broad valleys. Their flows are mostly the result of snowmelt runoff and baseflow from groundwater sources. The rest of the streams in the subsection are mostly intermittent spring or snowmelt fed streams that eventually lose flow to deep sediments in valleys. The streams fed by snowmelt generally only flow for a few months of the year.

Channel stability ranges from fair (-) to good (+). This subsection has generally declining trends in channel stability, sometimes even where grazing has been excluded.

Idaho Division of Environmental Quality (DEQ) sampled sites on streams in this subsection to assess changes in water quality from management. On Irving, Edie, and Fritz Creeks water quality was similar on National Forest System lands and below where Forest Service management was occurring. All sites showed impacts from grazing at the time of the survey. Water Quality Limited streams here include Edie, Irving, Fritz, Warm, and Warm Springs Creeks. Monitoring of water quality on these streams was conducted during 1995. Nutrients were listed as a concern on all these streams. There are no standards for nutrients, nor any clear direction as to what forms of nitrogen and phosphorus are to be monitored, so recommendations from researchers were used. None of these streams directly enter lakes, so a recommended maximum phosphate level of 0.1 mg/l was used in lieu of a standard. All of the streams phosphate concentrations were lower than this value. Nitrate/nitrite recommendations vary widely, from 10mg/l for drinking water to 0.3 mg/l for prevention of algal growth. Fritz, Warm and Edie Creeks showed an increase in nitrate/nitrite in late July and early August, to a maximum of 0.43 on Fritz and 0.44 on Warm Creek. Divide Creek, a tributary to Warm Creek, was also sampled from July to early September, and showed nitrate/nitrite levels ranging from 0.49 to 0.73 mg/l. All levels dropped below 0.1 in September, except on Divide Creek. Temperature was listed as a concern on Fritz and Warm Creeks. Warm Creek is fed by a warm-water spring source, so temperature is an erroneous concern here. Temperature was not continually monitored on Fritz Creek, but spot measurements ranged from 20°F in June to 6°F in September. State Water Quality Standards state that, for cold water biota, temperatures are not to exceed 22°F, with a maximum daily average of no greater than 19°F, so Fritz Creek may have temperature concerns. More monitoring is needed to determine this.

Centennial Mountains - Streams having headwaters along the front of the Centennial Mountains generally flow south and their water comes from both snowmelt and spring sources. The influence of springs increases moving east, providing these streams with more constant streamflow through the year. Major streams in the western part of the subsection include Beaver, Camas, Sheridan, Icehouse, and Willow Creeks. Some streams in the western part of the subsection (e.g., Beaver and Camas Creeks) generally subside into deep valley sediments or areas of volcanic rock before they reach Mud Lake. The rest of the streams (Sheridan, Icehouse, Willow, etc.) flow through the meadows of Shotgun Valley and eventually add flow to Island Park Reservoir.

The eastern part of the subsection includes the headwaters of the Henry's Fork of the Snake River (Henry's Lake and the headwater streams) as well as the upper part of the Henry's Fork itself. It also includes Big Springs, a major tributary of the Henry's Fork that has a flow of approximately 180 cubic feet per second at its source year-round. Spring-controlled streams are prevalent here, having relatively low variation in flow throughout the year, but also having less ability to flush excess sediments than snowmelt streams.

Channel stability ratings generally range from fair (-) to good (+) with stable or declining trends throughout most of the subsection. The only standout is a poor rating on part of West Dry Creek, though there is no apparent management-related reason. Some portions of the Henry's Fork Headwaters rated as excellent. The most frequent management problems are livestock damage and roads. Specific locations of road and cow impacts are Disaster Creek, Kay Creek, Corral Creek, Dairy Creek, Long Creek, West Rattlesnake Creek, Sheep Creek, Middle and West Threemile Creek, and Jesse Creek. Other streams may also have these impacts, but comments were missing from survey forms. Sedimentation below clearcuts on Bear Gulch Creek and in-stream deflectors on Willow Creek are two other management impacts. The greatest impact from timber harvest in this area appears to be related to roads. Data is not available to assess cumulative effects to streamflows from tree removal.

Sampling at Big Springs in 1994 found water quality to be excellent and water temperatures consistently low. Monitoring by the State of Idaho in the Henry's Fork headwaters showed limited impacts to beneficial uses. Duck Creek has been found to be one of the major contributors of sediment and nutrients to Henry's Lake, however it has not been determined if the source is on private or public land. Targhee Creek was also found to be a major source of sediment and nutrients, but a survey of the Forest portion of the watershed could only find natural sources of sediments (old slumps, for example). DEQ has

determined that more than 60% of the phosphorus going into Henry's Lake is natural, and is from National Forest System lands. Bacterial levels were found to be high on Hope, Duck, Meadow, and lower Jesse Creeks downstream of National Forest System lands. Henry's Lake Outlet meets all water quality criteria, however there have been some instances of temperature exceeding State standards for salmonid spawning. Siltation and dewatering have been described as limiting factors. In general, it appears that while there is some degradation of water quality on the Forest, it does not appear to be significant as a result of management activities.

Island Park - Many streams here show a strong influence from groundwater, having relatively low variation in flow throughout the year. The major stream is the middle section of the Henry's Fork of the Snake River. Other drainages in the subsection are Fish, Robinson, Rock, Squirrel, Conant, Bitch, and South Badger Creeks. The portions of the Buffalo and Warm River in this subsection are low-gradient, spring-controlled streams that show little variation in flow. Fall River shows more snowmelt influence and flows through a narrow canyon, unlike the other streams. While the Henry's Fork is a spring-fed system, Island Park Dam controls its flow to a large extent, providing peak flows not just when Island Park Reservoir fills in spring, but also when irrigation and other downstream needs dictate. The western side of the subsection is fairly dry, with little surface runoff.

Channel stability ratings range from fair(-) to excellent. Management impacts stem from roads, livestock and recreation, which vary in significance in different places. The greatest impact from timber harvest in this area appears to be related to roads. No data are available to assess cumulative effects to streamflows from tree removal. Data are very scattered, but Conant Creek (upper and near the Forest boundary), one section of Buffalo River, and portions of Rock Creek were specific areas of concern while the Henry's Fork and most of Buffalo River were in good to excellent condition.

Zimmer (1981) reported occasional high levels of fecal coliform in Island Park Reservoir, probably due to inadequately treated sewage at local recreational facilities. Phosphorus levels in the reservoir were also reported to be high, especially in areas of groundwater discharge along the reservoir shoreline. The source of the phosphorus could not be identified. Nuisance levels of algal blooms have been reported in the Henry's Fork upstream of Osborne Bridge, possibly due to nutrient contributions from upstream developments. High stream temperatures have also been reported in this reach as this section of the stream is wide, shallow, and unshaded. The Buffalo River was sampled in the late 1970's, and water quality was found to be good. The Henry's Fork, from Buffalo River to Riverside, is listed as a Water Quality Limited segment.

Madison Plateau - Surface drainage here is not very well-developed, due to the underlying volcanic rocks which allow more water to percolate than to run off. These streams originate in or near Yellowstone National Park and exhibit strong groundwater influence. Major streams include the upper sections of tributaries to the Henry's Fork that were discussed under the Island Park Subsection. Main drainages within this subsection include Thirsty Creek, North Fork, Middle Fork and South Fork of Split Creek, and the upper reaches of Moose, Partridge, Snow, Conant and Boone Creeks. There are numerous small lakes in this subsection.

Channel stability ranges from fair(+) to excellent. The North Fork Fire in 1988 caused major changes in channel stability to Moose Creek. Road systems were a watershed concern in this area even before the fire. After the fire, erosion from uplands accelerated due to loss of vegetation and burning effects on soils, which caused more water to run off slopes. The result was a dramatic increase in the amount of sediment moving off slopes and into stream channels. Increases of fine material and channel scour were noted in the lower reaches of the stream after the fire. Since 1991, however, the cross-sectional area and substrate size distribution have come to more closely resemble pre-fire values. Standards and Guidelines will not be able to mitigate impacts to acceptable levels. Current conditions do not reflect watershed objectives. Logging, roads, livestock use and recreation impacts exist in this subsection.

The greatest impact from timber harvest appears to be associated with roads. No data are available to assess cumulative effects to streamflows from tree removal. Possible channel impacts in the Falls River subwatershed are due to dewatering by irrigation withdrawals.

Five of the streams in the subsection (Rock Creek, Robinson Creek, Fish Creek, Porcupine Creek, and Warm River) had been named by Idaho as Stream Segments of Concern before this designation was eliminated in 1995. Water quality has been generally good on these streams. The only variation from State standards has been in temperature on some of the streams which have experienced extremely low flows due to drought (Porcupine and Rock). Water temperatures on Moose Creek are consistently low. Turbidity increases, sometimes significantly, during and after rainstorms in the drainage. Hidden Lake, Loon Lake and Grassy Lake Reservoir were sampled as part of the Western Lakes Survey in 1985. All had good water quality, though Hidden Lake's total phosphorus was high.

Teton Range - Streams in this subsection originate along the west slope of the Teton Mountains. They are steep, dynamic and characterized by coarse substrate (up to boulders in size) due to the proximity of this material to the stream channel. Glaciation has been an important influence on stream systems here. Not only did glaciers shape the major valleys, they also brought the sediment and rock material in which stream channels subsequently developed. Present-day forces such as avalanches and various types of mass failure bring not just rock but also trees and other debris to the streams, causing them to adjust to accommodate the load. These streams respond to snowmelt, having high spring peak flows which drop to their low flow levels in late summer. Major streams here include Badger, Leigh, Teton, Darby, Fox, Game, Trail, and Moose Creeks

Channel stability ranges from fair(-) to good(+). Impacts to channels stem mostly from natural causes such as avalanche debris, unstable bank materials and failed beaver dams. Localized management effects are related to roads, recreation and livestock

Water quality sampling has been extremely limited in this subsection. Most of the available information is from the Alaska Basin Water Study conducted by the Teton Science School in 1989. The two lakes studied (Two Island Lake and Mirror Lake) were found to be slightly acidic. There was only one sample for alkalinity in each lake, and both were extremely low. This indicates a low ability to buffer changes to pH (e.g., changes from acid rain), probably due to the geology of the area. The Teton River (headwaters to Trail Creek) is listed as a Water Quality Limited segment.

Big Hole/Palisades - Streams here contribute to either the Teton River or the South Fork Snake River. They are generally confined within steep-sided valleys or canyons, and are high-energy systems, able to move a considerable amount of sediment. Snowmelt is important in these streams, so they have high spring peak flows which later drop to their late summer levels. Major streams in this subsection include Indian, Big Elk, Palisades, Rainey, Big Burns, Pine, Canyon, Moody, Horseshoe, Mahogany and Packsaddle Creeks. Packsaddle Lake, Upper and Lower Palisades Lakes, and the Palisades Reservoir are also important hydrological features in this subsection.

Channel stability ranges from poor to good(+). Impacts exist in most drainages from recreation use, especially trails along the streams and dispersed camping. Management impacts associated with cattle and roads are also very common. The Teton River subwatershed has impacts from mining (channel alteration) and loss of riparian vegetation due to lowering of water tables and channel incision. Problems in Rainey Creek are primarily associated with grazing by wildlife and cattle. In 1994, there was a fire in the headwaters of Palisades Creek, but it was generally a light burn and did not adversely affect water resources.

In-depth water quality sampling was conducted on Big Elk Creek in the late 1970's. Water temperatures were consistently good, and turbidity was consistently low. Little Elk Creek was sampled once, and had readings similar to Big Elk. Stream temperatures on Rainey and Palisades Creeks were measured on a regular basis in 1994, and all met State standards. Upper Palisades Lake was sampled during the

Western Lakes Survey in 1985, and was in very good condition. Canyon Creek was intensively sampled in the mid-1970's, and once in 1994, all samples met State standards. In general, it appears that stream channel stability is a concern in many places, but (based on available data) water quality impacts are not evident. Teton River (headwaters to Trail Creek), Packsaddle, and Horseshoe Creeks are listed as Water Quality Limited segments.

Caribou - Geology has played an important role in this subsection. The underlying geology of folded and faulted sedimentary rocks has produced perpendicular drainages, and the streams follow the weaknesses in the rocks. Valleys are bounded by steep slopes, with the width of the valleys varying depending on the distance that streams could laterally migrate. Snowmelt is important here, and streams have distinct flow peaks in spring. Water generally flows to the South Fork Snake River. Major streams include Fall, Pritchard, Bear, Beaver, Brockman, Indian, Corral and McCoy Creeks. The western portion of Palisades Lake falls within this subsection.

All reaches rated from fair(-) to good(+) in channel stability. Grazing, powerline clearing, roads in riparian areas, and heavy recreational use are all listed as problems in the Fall Creek drainage. Brockman Creek shows impacts from grazing (bank trampling). Antelope Creek is heavily impacted (both on private and on Forest lands) by roads, recreation, and bank trampling by cattle. Channel stability was lowest on Fall, Bear, Brockman, and Antelope Creeks, with almost all of Fall Creek in the "fair" category, as well as half the reaches on Bear. Most streams here have not been surveyed. Antelope, McCoy, Tex, Brockman, Corral, and Sawmill Creeks are listed as Water Quality Limited.

Idaho DEQ sampled several streams in 1994. Antelope, Sawmill, Lava, Hell, Willow, and Brockman Creeks. Conclusions cannot be drawn from their data, however.

Fisheries - Scale: Hydrologic Unit

Streams delineated as "fish-bearing" are those stream segments that are used by any fish species to satisfy all or a portion of their requirements such as spawning, rearing of young, adult feeding, and winter survival. Information on the miles of fish-bearing streams and acres of fish-bearing lakes and impoundments is broken out by subsection in Table III-4. Existing watershed, water quality, and riparian conditions are more fully described in the Riparian and Water sections of this chapter.

Fisheries resources and habitat conditions are best assessed by hydrologic unit, which is a portion of a watershed with common characteristics.

The land area immediately surrounding the various water types is referred to as the aquatic influence zone. These zones control the biological diversity and integrity of the aquatic environment. It is within these zones that the ecological functions and processes necessary for the maintenance of healthy fisheries habitat take place. Aquatic habitat conditions are expressed in terms of water quality, quantity, and timing of flow, conditions within the stream channel (pools, woody material, etc.), and health of associated plant communities. Since the hydrologic, geomorphic and ecological processes that shape the various water types differ by hydrologic unit, the sensitivity of fisheries habitat to disturbances also varies by hydrologic unit. Human-induced disturbances within the aquatic influence zone, including streamflow diversion, livestock grazing, road construction, timber harvesting, and recreation use, can disrupt natural processes and functions. Where these are intense or prolonged, fisheries distribution, abundance, and productivity may be impaired.

Yellowstone cutthroat trout (large-spotted form and fine-spotted form) is selected to represent the many species of fish occupying the Forest. This species requires high water quality and high habitat diversity for survival. Since these conditions are indicative of healthy aquatic ecosystems, with associated healthy riparian plant communities and functioning watersheds, it is assumed that by providing for these habitat needs, the habitat needs of all other aquatic life would be provided as well.

A complete list of the fish species by hydrologic unit is shown on Table III-6. Descriptions of the condition and trends of aquatic and riparian habitats are shown on Table III-4.

Birch, Medicine Lodge, and Beaver-Camas Hydrologic Units - These hydrologic units are assessed together because of similarities in fisheries resources and conditions. All drainages originate along the eastern aspect of the Lemhi Range or the southern aspect of the Beaverhead Mountains. As they flow onto the Upper Snake River Plain, these waters "sink" and flow underground. Recent studies document that these subterranean flows reach the lower Snake River at Thousand Springs, 48 miles away. Fish populations within the Birch, Crooked, Medicine Lodge and Beaver-Camas Creek systems are now physically and genetically isolated from the Snake River system and from each other.

Fish-bearing streams on National Forest System lands are small, steep to moderate-gradient, and fed by snowmelt runoff and baseflow from groundwater sources. The natural capabilities of this area to produce abundant or diverse fisheries resources is relatively limited.

Upper Henry's Hydrologic Unit - All drainages flow into Henry's Lake or the Henry's Fork of the Snake River above the confluence of Fall River. Spring creeks provide an environment capable of producing abundant aquatic insect and plant biomass. Where fisheries life history requirements are met, these streams are among the most productive trout fisheries in the world.

The primary natural disturbances shaping and controlling fisheries habitat are high intensity summer rains and fire. Natural processes of overland flow, slumping and tree windthrow bring organic matter, soil, rocks, and nutrients into streams.

Fisheries resources in this hydrologic area are very productive and varied. Duck and Targhee Creeks are important economically and scientifically as they provide key spawning habitats for the Henry's Lake native cutthroat trout fisheries and associated Idaho Department of Fish and Game (IDFG) managed hatchery.

Lower Henry's Hydrologic Unit - All drainages flow into the Henry's Fork of the Snake River near the confluence of Falls River. Many are similar to those of the Upper Henry's Hydrologic Unit but tend to be more strongly influenced by groundwater. Falls River is a medium to large, low-gradient system which is predominately spring-controlled.

The primary natural disturbances shaping and controlling fisheries habitat are high intensity summer rains and fire. Natural processes of overland flow, slumping and tree windthrow bring organic matter, soil, rocks, and nutrients into streams.

The fisheries resources of importance within this area are primarily small headwater streams and alpine lakes spread across a small portion of the landscape.

Teton Hydrologic Unit - This area drains the western aspect of the Teton Mountains and the northern aspect of the Big Hole Mountains. Fish-bearing streams originating in the Teton Mountains are steep, dynamic, and strewn with large boulders. Stream channels developed from the sediment and rock that was delivered through glaciation. Within the Big Hole Mountains, fish-bearing streams are relatively small, moderate-gradient, and fed by snowmelt runoff and baseflow from groundwater sources.

The primary natural disturbance shaping and controlling fisheries habitat in the Teton Mountains is rapid snowmelt. Natural processes of mass failure and avalanches recruit organic matter, large woody debris, soil, rock and nutrients into streams. In the Big Hole Mountains, rapid snowmelt initiates overland flow and slumping which contribute organic matter, soil, rock, and nutrients to fish habitats.

Palisades Hydrologic Unit - All drainages originate along the south aspect of the Big Hole Mountains and the north aspect of the Caribou Mountains and are tributary to the South Fork of the Snake River.

The primary natural disturbances shaping and controlling fisheries habitat are high intensity summer rains and fire. Natural processes of overland flow, slumping, and tree windthrow move organic matter, soil, rock and nutrients into streams.

The fisheries resources found here are very productive and varied. Many of the streams flowing into Palisades Reservoir, and Palisades and Rainey Creeks, provide key spawning and rearing habitats for the native cutthroat trout fisheries.

1/ Includes only fish species known to occur within Forest System Lands.
2/ Denotes nonindigenous species known to be introduced by European man

Cutthroat Trout

Cutthroat trout is a sensitive species and has been selected as a management indicator. Table III-7 illustrates cutthroat trout population status and distribution on the Forest by hydrologic unit.

The only indigenous trout within the Forest is the Yellowstone cutthroat (*Oncorhynchus clarki bouvieri*). Scientific information to date indicates that this subspecies consists of two forms the fine-spotted Snake River and the large-spotted. Scientists are continuing research to determine if the fine-spotted Snake River cutthroat trout is a separate subspecies (Behnke 1992).

The Forest Service in Regions 1 and 4 have prepared a draft Habitat Conservation Assessment (HCA) for Yellowstone cutthroat trout, including the big-spotted and the fine-spotted Snake River forms. The HCA is directed at defining habitat conditions necessary for the long term persistence of Yellowstone

cutthroat trout. In addition, the assessment correlates habitat conditions to population distribution and species management activities within the historic range of the species. Yellowstone cutthroat trout currently occupy 41% of their historic habitat. Within Idaho, approximately 45% of the historic habitat is presently occupied. German brown, rainbow, and brook trout have been stocked into many drainages and compete with cutthroat trout (see Table III-6). Rainbow trout have been introduced into every hydrologic unit on the Forest and are likely to hybridize with cutthroat trout, causing genetic contamination of cutthroat trout populations.

Table III-7 Population Status of Cutthroat Trout by Hydrologic Unit								
Population Status 1/	Hydrologic Unit							
	Birch	Medicine Lodge	Beaver - Camas	Upper Henrys	Lower Henrys	Teton	Paisades	Average
Large-spotted Cutthroat Trout								
% strong/healthy	0	9	0	0	0	74	54	20
% depressed at risk	6	23	10	19	37	26	37	23
% extinct	94	54	90	68	52	0	9	52
% status unknown	0	14	0	13	11	0	0	5
Fine-spotted Cutthroat Trout								
% strong/healthy	-	-	-	-	-	100	0	50
% depressed at risk	-	-	-	-	-	0	37	18
% extinct	-	-	-	-	-	0	63	32
% status unknown	-	-	-	-	-	0	0	0
<p>1/ These values represent the status of that portion of the population occupying Forest Service lands within each of seven Hydrologic Units. The population status categories were adapted from assessment protocol developed by the Upper Columbia River Basin Assessment Team.</p> <p>A "-" means the fine-spotted cutthroat trout was never present in the hydrologic unit.</p> <p>"Strong/healthy" denotes populations with the following characteristics: 1) all major life-history forms that historically occurred are still present, 2) numbers appear to be stable or increasing and the population is at least half of the historic number or density, and 3) the population within the watershed or within the larger metapopulation of which the population is a part, contains at least 5000 fish or 500 adults.</p> <p>"Depressed/at risk" denotes populations with at least one of the following characteristics: 1) a major life-history component has either been eliminated or is remnant, 2) the population within the sixth order watershed has a declining trend in abundance, or the population occurs in less than half of the habitat thought to historically support the species, or numbers are less than half of what the watershed supported historically; and 3) total abundance for the whole metapopulation of which this watershed is a part is lower than 5000 total fish or 500 adults.</p> <p>"Extinct" denotes the species is not present and there is evidence that the species was historically present or could conceivably have had natural access to a watershed even though landscape/habitat characteristics might be outside the range deemed suitable for supporting populations.</p> <p>"Status unknown" denotes that reliable information was not available by which to make a judgement about current presence or absence.</p>								

Wildlife Associated with Aquatic and Riparian Habitats

Wildlife management indicator species include bald eagles, trumpeter swans, spotted frogs, common loons, and harlequin ducks. Monitoring and analysis emphasizes habitat conditions to evaluate potential changes in the status or sustainability of these species. Table III-8 illustrates the distribution of these habitats by subsection. A brief overview of these species and habitats follows. Additional information is available in Process Paper D.

Table III-8 Distribution of Wildlife Management Indicator Species Associated with Riparian and Aquatic Habitats, Including Endangered, Threatened, Candidate, and Sensitive Wildlife Species on the Targhee National Forest within the Seven Subsections								
Management Indicators	Subsections 1/							
	Status 2/	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Range	Big Hole/ Palisades	Caribou
Riparian and Aquatic Habitats								
Bald Eagle Nesting Habitat	T	N	Y	Y	N	N	Y	Y
Trumpeter Swan Nesting Habitat	C2/S	N	N	Y	Y	N	N	S
Spotted Frog Habitat	C1/S	Y	Y	Y	Y	Y	S	S
Common Loon Habitat	S	N	N	Y	Y	N	Y	Y
Harlequin Duck Habitat	C2/S	N	N	N	N	Y	Y	Y

1/ Letters used for distributions among subsections are as follows
 Y = Species presence and/or suitable habitat has been documented on the Forest. For the grizzly bear, Y = areas within the recovery line
 N = Species presence has not been documented on the Forest, suitable habitat has not been documented
 U = Unverified but reliable sightings exist on the Forest, suitable habitat probably exists
 S = Suitable habitat probably exists, but there have been no documented nor unverified sightings on the Forest.

2/ Letters used for Status are as follows: E = endangered, T = Threatened, NE = Nonessential Experimental, C1 = Category 1 Candidate Species, C2 = Category 2 Candidate Species, S = Sensitive species, '-' = no formal status

Sources of information for this table include: Targhee National Forest AMS, 1992, Personal communication with K Johnson, Feb 8, 1995, B Aber, M Oechsner; B Alford, D Welch, R Newton

Bald Eagle Nesting Habitat - Scale Forestwide

This species has for some years been listed as endangered under the Endangered Species Act. In August of 1995 the U.S. Fish & Wildlife Service downlisted the bald eagle to the threatened status.

The data we have been able to compile on bald eagle nesting populations in SE Idaho dates back to 1972 (USDA Forest Service, Targhee N.F. AMS, 1992). In 1972, there was one recorded bald eagle nest along the South Fork of the Snake River, which was not on the Forest. The first recorded bald eagle nest on the Forest was noted in 1975, along Palisades Reservoir. From 1975 to 1995, the bald eagle nesting population on the Forest has increased to 17 nesting pairs. In addition to these nesting pairs on the Forest, there are 9 nesting pairs adjacent to the Forest with some portion of the nesting territory within the Forest. Depending upon food supply and tolerance of bald eagle pairs to nest in proximity to other pairs, the existing number of nesting pairs on the Forest may be near the habitat capacity.

Trumpeter Swan Nesting Habitat - Scale Forestwide

Trumpeter swans on the Forest are part of the Rocky Mountain Population (RMP) of trumpeter swans (Shea 1994). The RMP comprises the nonmigratory resident Tri-state (Idaho, Montana, Wyoming) flocks.

(which includes the Forest) and the migratory Canadian flocks. From less than 200 birds in 1930, the RMP increased to about 2,526 birds by 1994 (this includes about 275 Tri-state summer residents; 2,150 migratory birds from Canada, and about 100 birds transplanted to Oregon and Nevada). (Shea 1994) Process Paper D provides more information on the swan population.

For the period 1982 to 1994, 31 lakes and ponds on the Forest have been used at least during one or more summers; 17 of these 31 have had at least one nesting attempt, 11 of these 31 have successfully produced young during one or more years. Table III-8 shows the distribution of nesting habitat within subsections. Process Paper D provides more information on swan nesting habitat.

Spotted Frog Habitat - Scale Forestwide

Spotted frogs are most likely found near permanent water such as marshy edges of ponds or lakes, in algae-grown overflow pools of streams, or in wet areas with emergent vegetation (Gomez 1994) They may move considerable distances from permanent water after breeding, often frequenting mixed conifer and subalpine forests, grasslands, and brushlands of sage and rabbitbrush if puddles, seeps or other water is available. (Gomez 1994) Spotted frogs are thought to hibernate in holes near springs or other areas where water remains unfrozen and is constantly renewed. A muddy or soupy substrate in rivers or ponds is preferred by the spotted frog for hibernation. (Gomez 1994)

A spotted frog inventory/study has been in progress on the Forest for several years, at this time, spotted frogs have been documented in all subsections except the Big Hole/Palisades Subsection and the Caribou Subsection (Table III-8). A recent progress report stated the following:

"All frogs were always within two meters of water. None left riparian habitats and almost all were associated with ponds until September when they left the ponds for nearby streams. Ponds within 50 m of permanent streams were an important combination of habitat characteristics for them." (Bartelt and Peterson 1993)

Common Loon Habitat - Scale: Subsections

For nesting and brood rearing, common loons need lakes large enough to provide adequate runways for flight (greater than 9 acres in size), deep enough to sustain fish populations, and clear enough for them to see their prey (they rely on their sight for foraging). Loons avoid lakes with high levels of human activity, fluctuating water levels, turbid water, and no protected coves. Common loons have been observed on five subsections, as discussed below.

Centennial Mountains - Common loons have been observed on Henry's Lake, but no nesting or brood rearing has been documented

Island Park - Common loons have been observed on Island Park Reservoir, but no nesting or brood rearing has been documented. This reservoir probably does not provide suitable breeding habitat due to significant drawdowns during the summer months.

Madison Plateau - Common loons have been documented at Thompson Hole, Grassy Lake Reservoir, Lake of the Woods, Loon Lake, Moose Lake, Indian Lake and Bergman Reservoir (Atkinson 1991). Successful reproduction has been documented at Indian Lake, Thompson Hole and Bergman Reservoir.

Big Hole/Palisades and Caribou - Common loons have been observed in these subsections, but no nesting or brood rearing has been documented.

Harlequin Duck Habitat - Scale. Forestwide

For nesting and brood rearing, these ducks require relatively undisturbed, low-gradient, meandering mountain streams with dense, shrubby riparian areas, and woody debris for nesting and brood rearing. They also need log jams, and overhanging vegetation for cover and loafing areas. Specific habitat requirements include streams with gradients less than 3 degrees, greater than 50 percent streamside shrub cover, and at least 3 loafing sites (midstream boulders or log jams) per 33 feet of stream. Successful reproduction has been documented at only three locations: Big Elk Creek, Teton Creek, and Darby Creek. Sightings have been made at McCoy Creek, but these sightings have not indicated successful reproduction.

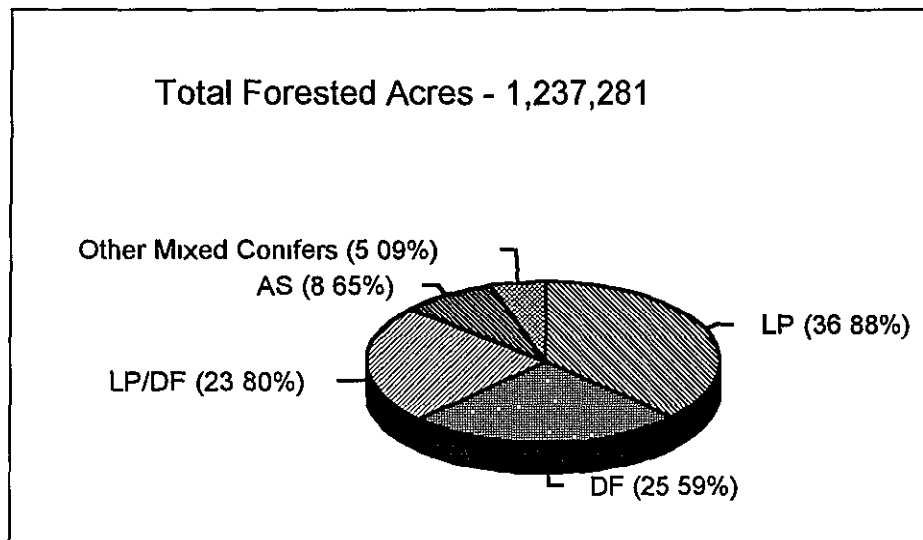

TERRESTRIAL ECOSYSTEMS

Upland Forested Ecosystems - Scale: Subsections

Sixty-eight forest community types currently occur on the Forest. One sensitive plant species, *Astragalus paysonii*, occurs in forest ecosystems and is a Federal Candidate species for listing as threatened or endangered. This plant is found within disturbed or open areas in lodgepole pine and mixed Douglas-fir/lodgepole pine communities. Fire suppression has been attributed to the decline of this species over its range (Fertig et al 1993).

The community types and age classes present on the Forest are displayed by subsection in Table III-1. Major community types are shown in Figure III-2. Minor community types include whitebark pine, limber pine, and Engelmann spruce/subalpine fir. Two community types of cottonwoods occur on the Forest, primarily on the Snake River and lower elevational portions of the Henry's Fork of the Snake River

Figure III-2
Major Forest Types on the Targhee National Forest

Lemhi/Medicine Lodge - Although only 37 percent of this subsection is forested, this is more forest land than occurred historically. Information from the early 1900's indicates that Douglas-fir has expanded onto lands that were formerly dominated by grasses and sagebrush. Some riparian communities also appear to have more conifers than they did historically.

Approximately 90 percent of the forested land is in the mature age class, indicating a lack of age class diversity in the subsection. With 90 percent of the forests in Douglas-fir there is also a lack of tree species diversity. Many of the Douglas-fir stands are densely stocked. The uniformity of tree species and age classes, as well as the dense stocking, make this area's forests more susceptible to ecosystem disturbances such as insects, diseases and large fires. An example of the latter was the Gallagher Peak Fire which burned 37,230 acres in 1979. This was the largest fire in the last twenty years on the Forest.

Limber pine occurs in the subsection, but is not differentiated as a community type since it occurs as a scattered tree in predominantly Douglas-fir stands. The intermingling of forestland with nonforested communities provides most of the vegetative diversity in this subsection.

Centennial Mountains - The landscape is dominated by forested communities which cover 71 percent of the subsection. Approximately 51 percent of the forested acres are Douglas-fir. Lodgepole pine (21%) is found in pockets on low-productivity soils. Mixed lodgepole pine/Douglas-fir (13%) and other mixed conifers (10%) are also well-represented. The presence of mixed stands indicates that species such as Douglas-fir and subalpine fir are becoming established as stands move toward mature stages through succession. Aspen comprises 4 percent of the forested acres, which is less than was historically present. Fire suppression has allowed conifers to take over areas that were previously aspen, through the process of succession. Some riparian and mountain meadow communities also appear to have more conifers than they did historically.

Mature forests cover 79 percent of the forested acres, indicating a lack of diversity in age classes. Decreasing diversity however is associated with the loss of aspen over time. Potential for severe fires, insects and diseases are concerns in this subsection, mainly because of the large component of mature forests. Western balsam bark beetle has been active in this area in recent years. Douglas-fir beetle caused losses in Douglas-fir from the late 1980's through 1992 and could again reach destructive levels. Pockets of root rot are common in the subsection, associated with partial cutting of Douglas-fir which occurred in the 1950's.

Past Douglas-fir shelterwood regeneration methods implemented on dry south and west slopes of the Centennials have failed, requiring planting to reforest the sites. Similar treatments on north-facing slopes have tended to regenerate naturally.

Island Park - The landscape is dominated by forested community types, which blanket 93 percent of the area. Forested areas are primarily lodgepole pine types (70%) that contain small pockets of aspen, sagebrush/grass, grass meadows and mountain brush. Douglas-fir (10%) and mixed lodgepole pine/Douglas-fir (15%) community types provide diversity in the area. Lodgepole pine occupies the floor of the Island Park Caldera and Douglas-fir cover types are concentrated on the Caldera rim. On the Caldera rim, aspen and sagebrush areas are evolving towards the Douglas-fir type through the process of succession.

Salvage harvesting has shifted 46 percent of the lodgepole pine into the nonstocked, seedling and sapling classes. Active management of aspen, as well as aspen sprouting in lodgepole pine clearcuts, has moved 34 percent of the aspen into these young classes. Other community types are concentrated in the mature age group.

Many lodgepole pine clearcuts in this subsection have not regenerated naturally and have required planting to restock the stands. The process of planting these sites is expected to continue through the year 2000.

Mature Douglas-fir on the caldera rim experienced outbreaks of spruce budworm and Douglas-fir beetle in the past decade. These problems have now subsided, but could easily recur given the mature condition of the Douglas-fir and the presence of multiple-storied stands. Due to fuel reductions and young age classes associated with harvest, fire is less of a concern here than in most other subsections.

Madison Plateau - The landscape is dominated by forests, which comprise 97 percent of the area. Lodgepole pine is the most common forested community type (76%), with mixed stands of lodgepole pine and Douglas-fir running a distant second place (14%). Relatively minor amounts of aspen and various mixed conifers provide some diversity. The southern portion of the subsection is unique in that there are many wet meadows and small lakes intermingled with the forests.

The 1988 North Fork Fire burned some 17,700 acres in the northern part of this subsection. Past timber harvesting also occurred primarily in the north half of the subsection. These two events have shifted 39 percent of the lodgepole pine into the nonstocked, seedling and sapling age classes. Active management of aspen has also provided some age class diversity.

Most areas of the North Fork Burn regenerated naturally following the fire. Approximately 1,360 acres are being planted in portions of the burn that did not reforest.

Due to fuel reductions and young age classes associated with past harvest and the North Fork Burn, fire is less of a concern here than in many areas. However, conditions in the southern portion of the Madison Subsection are presenting some fire risks as mixed aspen and lodgepole pine stands convert to Douglas-fir through succession. Mature subalpine fir and Douglas-fir in this southern area experienced outbreaks of western balsam bark beetle and Douglas-fir beetle in the past decade. These conditions have subsided, but could easily recur since vegetation conditions have not changed.

Teton Range - The landscape is a diverse mix of forested (57%) and open (43%) community types. Lodgepole pine occurs on poorer soils at lower to middle elevations. Lodgepole is mixed with Douglas-fir in 31 percent of the forested area, indicating that the pine is converting to Douglas-fir through succession. Open Douglas-fir forests, mountain brush, aspen, and sagebrush pockets are found predominately on south and west aspects. Aspen is becoming mixed with conifers as succession proceeds, and the amount of aspen has likely declined compared with historic levels due to fire suppression. Upper elevations are characterized by dense mixed conifer forests, open grass/forb meadows, and talus slopes. Conifers are moving into riparian areas and mountain meadows due to fire suppression over time.

Since much of the Teton Range Subsection is designated wilderness, timber harvest has been limited. Because of this and fire suppression, only one percent of the forested acres are in the nonstocked, seedling or sapling age classes. The large percentage of mature or older forests make this area ripe for insect infestations, diseases and large-scale fires. In recent years western balsam bark beetle has been active in the subalpine fir. Douglas-fir beetle has killed pockets of Douglas-fir in the past decade, but beetle populations have declined since 1992.

Big Hole/Palisades - The landscape is a combination of community types, with 65 percent of the landscape forested and 35 percent in nonforested. The most common forested community type by far is mixed lodgepole pine and Douglas-fir, comprising 47 percent of the forested acres. Aspen, pure Douglas-fir and pure lodgepole pine each account for roughly 15 percent of the forests. Mountain brush is common, consisting of mountain mahogany on south slopes and hawthorn, chokecherry, serviceberry, antelope bitterbrush and Rocky Mountain maple on various slopes depending on elevation. Grass/forb meadows and sagebrush are also present in significant amounts. The northwestern boundary of the subsection extends into the cottonwood type along the Snake River.

Only 4 percent of the forested stands are in the nonstocked, seedling or sapling age category. These are concentrated in the north end of the subsection where timber harvest has occurred. The Snake River cottonwood stands and most of the shrublands are also in late age classes. This creates hazards for large fires, insect infestations and disease problems. In the north end of the subsection Douglas-fir beetle and western balsam bark beetle caused damage in the late 1980's and early 1990's, but tapered off in 1994. Insect information is not available for the southern portion. Due to fire suppression and lack of disturbance over the years, conifers have taken over some sites that were historically nonforested. This has likely reduced overall vegetative diversity in the subsection.

In the Big Hole Mountains, natural regeneration has been difficult to obtain where Douglas-fir was harvested. In the Palisades area, harvest in both lodgepole pine and Douglas-fir have failed to reforest naturally. This has resulted in the need to plant most of these areas.

Caribou - The Caribou Subsection is similar to the Big Hole/Palisades in its overall vegetation characteristics. This subsection is 40 percent nonforested and 60 percent forested. The primary forest types are aspen (31%) and mixed lodgepole and Douglas-fir (47%). The interspersions of forests with sagebrush, grass/forb meadows and mountain brush provides for good diversity of plant species. The northeastern boundary area of the subsection includes cottonwood forests along the Snake River.

Age class diversity is limited, as in many other areas of the forest. Because virtually no vegetation management has taken place in this subsection and fires have been suppressed for many years, only one percent of the forests are in young age classes. Most of the shrublands are also in late age classes. Risks of large fires, insects and diseases are high due to these vegetative conditions. The insect situation in recent years has been similar to that in the Big Hole/Palisades Subsection. Douglas-fir is becoming more predominant as it mixes with stands of lodgepole pine, aspen or shrubs. It is likely that there is more Douglas-fir here now, and less aspen, lodgepole pine and shrubland, than existed historically. The Snake River cottonwood stands are also uniformly in the mature age class due to lack of disturbance which they need in order to regenerate.

Establishing natural regeneration of both Douglas-fir and lodgepole pine following harvest has been a problem in this subsection, and most sites have required planting.

Upland Nonforested Ecosystems - Scale: Subsections

Table III-9 illustrates the acres of nonforested community types by subsection throughout the Forest. Herbaceous and shrub ecosystems dominate the landscape in the Lemhi/Medicine Lodge Subsection and are significant in the Centennial, Big Hole/Palisades and Caribou Subsections.

Fire suppression has modified the historical 10-25 year frequency of fire in the low to mid elevation areas. Fire suppression coupled with grazing and drought cycles has increased shrub canopy cover and decreased herbaceous species composition within the sagebrush/grass and mountain brush community types. These communities are shifting from a low risk of stand-replacing fires to a high risk of stand-replacing fires over broad areas. A trend is also occurring whereby the historically high percentage of early and mid seral stages is moving toward a predominance of mid and late seral stages.

Table III-9 Acres of Nonforested Community Types by Subsection								
Herbaceous/Shrub Communities	Lemhi/Medicin Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Range	Big Holes/Palisade	Caribou	Forest Total
Herbaceous	11,610	13,626	4,180	2,472	45,902	35,711	9,330	122,831

Total Acres	175,772	94,110	20,265	6,157	68,645	122,853	82,456	570,256
% of Subsection	63	29	7	3	43	35	40	32

HERBACEOUS- Includes grass, sedge/forb, and grass/forb communities on all landscapes from low elevations to alpine
SAGEBRUSH/GRASS- Low sagebrush, black sagebrush, Wyoming big sagebrush and mountain big sagebrush community types
MOUNTAIN BRUSH - Includes chokecherry, mountain lover, mountain big sagebrush, serviceberry, antelope bitterbrush, curl-leaf mountain mahogany, hawthorn, snowberry and snowbrush ceanothus in mixed communities
AQUATIC - Includes lake, river and riparian vegetation
ROCK/BARREN/TALUS - Includes rock outcrops, bare and rocky windswept ridges, talus slopes and boulder fields from lowlands to alpine
UNDESIGNATED - open areas of unknown composition

Fourteen sensitive plant species have been identified to occur or are suspected to occur on the Forest within a broad range of herbaceous and shrub habitats (Process Paper F). Nine of these species are Federal candidate species for listing as threatened or endangered. Thirty-one additional plant species are rare in Idaho and Wyoming and are indicators of biodiversity and unique habitats on the Forest (Process Paper G) Diversity of community types in a range of seral stages is important in maintaining these species on the Forest.

The nonforested vegetation on the Forest is grouped into two broad plant communities, riparian and upland vegetation Forestwide the ecological status of these communities occur in various seral stages that meet, move toward meeting or do not meet desired vegetation conditions (see Table III-4 for riparian conditions and Table III-10 for upland conditions). Desired vegetation condition is a plant community in satisfactory ecological condition. Satisfactory ecological condition is defined as being in mid-seral stage or higher ecological status and having a stable or upward trend in soil and vegetation condition.

High density of mountain big sagebrush (> 30% canopy cover), undesirable herbaceous plants in the understory and other indicators of downward trend in vegetation are characteristics of unhealthy rangeland in unsatisfactory ecological condition. For example, on the Dubois Ranger District, there are approximately 42,310 acres in less than satisfactory condition because of high density of mountain big sagebrush.

Table III-10 Acres of upland vegetation meeting, moving toward or not meeting desired vegetation conditions Existing situation by subsection 1/								
Plant Community 3/	Subsection

2/ Includes acres of undetermined status								
3/ DVC = Desired Vegetation Condition								

Noxious weeds are undesirable plants designated by federal or state law. They generally possess one or more of the following characteristics: aggressive and difficult to manage; parasitic; carrier or host of serious insects or diseases; nonnative, new to the United States, or common in the United States. Soil-disturbing activities encourage the establishment and spread of noxious weeds. They can be spread by the use of weed infested hay, routine road maintenance, and lack of weed control on adjacent lands. Introduction (seeding) and invasion of aggressive species such as timothy and smooth brome have further decreased biodiversity by out-competing native species along roadways and in riparian communities. Nine different species of noxious weeds occupy approximately 19,000 acres of forest and rangeland on the Forest (see Table III-11). The Forest uses biological, chemical, and mechanical treatments to control the spread of noxious weeds. Presently, the Forest does not apply chemical herbicides by aerial applications, and only ground application is approved for use on the Forest.

1/ Letters used for distributions among subsections are as follows

Y = Species presence and/or suitable habitat has been documented on the Forest For the grizzly bear, Y = areas within the recovery line

N = Species presence has not been documented on the Forest, suitable habitat has not been documented

U = Unverified but reliable sightings exist on the Forest, suitable habitat probably exists

S = Suitable habitat probably exists, but there have been no documented nor unverified sightings on the Forest

2/ Letters used for Status are as follows. E = endangered, T = Threatened, NE = Nonessential Experimental, C1 = Category 1 Candidate Species, C2 = Category 2 Candidate Species, S = Sensitive species, '-' = no formal status

3/ It is generally assumed that since conifer and/or aspen and/or cottonwood habitats exist in every subsection of the Forest, then habitat for most of these cavity nesting species occurs in each subsection

Sources of information for this table include Targhee National Forest AMS, 1992, Personal communication with K Johnson, Feb 8, 1995, B Aber, M Oechsner, B Alford, D Welch, R Newton

Elk Vulnerability (EV) - Scale Principal Watershed

Elk Vulnerability (EV) is defined as a measure of elk susceptibility to being killed during the hunting season. (Lyon and Christensen 1992, IDFG letter May 12, 1995). EV models (Unsworth et al 1993) have been proposed as a predictive tool that managers can use to predict mortality rates and monitor elk vulnerability (IDFG letter May 12, 1995)

For the Idaho portion of the Forest, this EV analysis is used to predict percent mortality of bull elk during the general antlered elk rifle hunting season, which usually occurs in the month of October. For the Wyoming portion of the Forest, this EV analysis is used to predict percent mortality of bull elk during the general license any elk rifle hunting season, which usually occurs during the months of September and October.

Research conducted by the Idaho Department of Fish and Game and the University of Idaho provides the basis for this EV analysis (Unsworth et al, 1993) For the Forest Plan Revision, two parameters were determined to be most important for EV analysis.

1. Hunter-day densities (measured in total hunter-days per square mile on a watershed basis)
2. Motorized road and trail densities (measured in miles per square mile on a watershed basis).

EV is an important component of the State Fish and Game Departments' management goals and objectives. The following briefly describes the Idaho and Wyoming goals as related to EV.

Idaho Department of Fish and Game (IDFG)

Game Management Units 60, 61, 62, 62A, 64, 65, 66, 69 (Figure III-3). These game management units are known as "Ready Access Units." For these units, the IDFG goal for the post hunting season population is ≥ 15 bulls per 100 cows. This equates to a maximum of 60 percent bull elk mortality. (IDFG letter, May 12, 1995)

Game Management Units 58, 59, 59A, 67 (Figure III-3). These game management units are known as "Front Range Units." For these units, the IDFG goal for the post hunting season population is ≥ 20 bulls per 100 cows. This equates to maximum of 50 percent bull elk mortality (IDFG letter, May 12, 1995).

Wyoming Game and Fish Department (WGF):

Elk Hunt Areas 73 and 85 (Figure III-3): The WGF goal for the post hunting season population is ≥ 20 bulls per 100 cows. This equates to a maximum of 50 percent bull elk mortality

The mortality percentages indicate threshold levels, which if exceeded would likely require additional management actions to be initiated by the State Fish and Game Departments. (IDFG letter, May 12, 1995) These management actions could include such items as shorter hunting seasons, restrictions on the type and number of animals to be harvested, restrictions on the number of hunters, more controlled hunts and less opportunity for general hunts, etc. The estimated current bull elk mortality varies from a low of 23 percent mortality near Palisades Creek to 97 percent mortality in the Buffalo River watershed. At the present time, 42 percent of the Forest meets State Fish and Game thresholds for EV.

IDFG Game Management Units
WGF Elk Hunt Areas

Figure III-3

Not To Scale

Elk Habitat Effectiveness (EHE) - Scale. Principal Watersheds

EHE is defined as the percentage of available habitat that is usable by elk outside the hunting season. (Lyon and Christensen 1992) For this EHE analysis, it is the spring, summer, and early fall habitat that is usable by elk outside the general elk rifle hunting seasons. EHE is not a measure of elk populations and it is not a measure of habitat carrying capacity. (Lyon and Christensen 1992) Two habitat parameters were determined to be most important for EHE analysis

1. Motorized road and trail densities (measured in miles per square mile on a watershed basis). As motorized road and trail densities increase, EHE declines. This relationship is based on research by Dr. L. Jack Lyon (Lyon 1983)

2. Elk hiding cover (measured as a percentage of a watershed in hiding cover) Hiding cover is defined as vegetation capable of hiding 90 percent of a standing adult elk from the view of a human at a distance equal to or less than 200 feet (Lyon and Christensen 1992) Optimum habitat exists when 50 to 60 percent of a watershed is in hiding cover; this is based on the judgement of professional biologists involved in elk workshops on the Forest

An EHE of 100% (usually displayed as 1.0) would require no motorized roads and trails within a watershed, and 50 to 60 percent of the watershed being in hiding cover. The existing values for EHE range from a low of 0.46 in the north end of the Big Hole Mountains to a high of 0.76 near the Fall River in Wyoming; an average forestwide EHE value is 0.56.

Elk & Deer Winter Range - Scale Forestwide

Generally, elk and deer winter range areas are those areas, usually at lower elevations with lower snow accumulations, used by elk and deer during the winter months (Lyon and Christensen 1992). Figure III-4 displays these winter ranges on the Forest.

The winter range areas on the Forest are the upper elevational limits of elk and deer winter ranges; more winter range acres exist at lower elevations on BLM, State, and private lands. Some elk and deer which summer on the Forest winter on ranges in Montana and Wyoming. The distribution and number of wintering deer and elk on the Forest depends on winter severity. Generally a higher proportion of deer and elk winter at lower elevations on BLM, State and private lands. Development on private lands is a concern as it can adversely affect areas historically used by wintering deer and elk

There are 321,264 acres of crucial mid-to-late elk and deer winter range on the Forest. These winter range areas on the Forest have a wide range of vegetation types, with some of the areas mostly in mature forest and some predominantly in tall sagebrush/grass habitats. Some winter range shrub communities (such as mountain mahogany) are in overmature or decadent condition due primarily to historical fire suppression

Currently, 12 percent of the winter range acres are closed to livestock grazing. On the winter range acres open to livestock grazing, there are 6,352 AUM's of domestic sheep grazing, and 26,423 AUM's of cattle grazing.

Currently, 78 percent of the winter range acres are meeting desired vegetation conditions (DVC's) for range condition, 13 percent of the winter range acres are improving and moving toward DVC's, and 9 percent of the winter range acres are not improving.

Targhee National Forest Elk & Deer Winter Range

Figure III-4

About 38 percent of the winter range acres are capable of being used for cross-country snowmachine use (capable of being used for cross-country snowmachine use means slopes less than 50 percent and open vegetation conditions and types) Some winter range areas have been historically popular snow-machine use areas, and in these areas the Forest has implemented restrictions on cross-country snow-machine use. Currently 22 percent of the winter range acres are closed to cross-country snowmachine use.

Currently there is one feed ground for wintering deer and elk on the Forest, this is in Rainey Creek, within the South Fork/Palisades winter range area. The number of animals fed at this site varies each winter, primarily based on the severity of the winter. The following information from the IDF&G illustrates what has occurred from 1978 to 1995.

Winter Season	Number of Elk Fed	Number of Deer Fed
1978-79	<i>no recorded number</i>	<i>no recorded number</i>

Grizzly Bear - Scale Bear Management Unit

Portions of the Forest are within the Yellowstone Grizzly Bear Ecosystem (YGBE). The YGBE has been divided into Bear Management Units (BMU's). Portions of the Forest are within the following BMU's: Henry's Lake BMU (Subunits 1 and 2), Plateau BMU (Subunits 1 and 2), and Bechler/Teton BMU (Figure III-5).

Recovery goals for the YGBE are (U.S. Fish and Wildlife Service 1993):

"15 females with cubs over a running 6-year average both inside the recovery zone and within a 10-mile area immediately surrounding the recovery zone, 16 of 18 bear management units (BMU's) occupied by females with young from a running 6-year sum of observations, no two adjacent BMU's shall be unoccupied, and known, human-caused mortality not to exceed 4 percent of the population estimate based on the most recent 3-year sum of females with cubs. Furthermore, no more than 30 percent of this 4 percent mortality limit shall be females. These mortality limits cannot be exceeded during any two consecutive years for recovery to be achieved."

Targhee National Forest Bear Management Units

Figure III-5

Not To Scale

Table III-13 presents grizzly bear population data for the YGBE for the years 1987-1994 (from personal communication with Dr. Chris Servheen, USDI Fish and Wildlife Service, 1995). As of 1994, the status of the grizzly bear population in relation to the recovery goals was as follows

- The running 6-year average for unduplicated females with cubs was 21, compared to the recovery goal of 15.
- Average annual human-caused mortality was 4.5 bears (2 2% of the population estimate), compared to the recovery goal mortality limit which is to be ≤ 8 2 bears ($\leq 4\%$ mortality limit of the population estimate).
- Average annual human-caused female mortality was 2.0 bears (24% of the mortality limit), compared to the recovery goal mortality limit which is to be ≤ 2.5 bears ($\leq 30\%$ of the mortality limit).
- The distribution of females with young was 17 of 18 BMU's, compared to the recovery goal of 16 of 18 BMU's

Within the Plateau and Henry's Lake BMU's, a study was initiated in 1993 to determine the capability of these BMU's to support females with young. As of 1995, two of the BMU's (Plateau, Bechler/Teton) had sightings of females with cubs.

Process Paper D presents an overview of food habitats, cover requirements, denning habitat, home ranges, and motorized access effects for the grizzly bear.

To aid in the following discussions of each BMU, the following definitions are important to understand:

Habitat Value (HV): This is a measure of habitat quality for the grizzly bear derived from values for vegetation plus fish plus ungulates as measured by the Grizzly Bear Cumulative Effects Model. The higher the HV the better the habitat quality is for the grizzly bear. HV does not include any effects of human activities. HV helps answer the question, how good is the habitat for grizzly bears?

Habitat Effectiveness (HE): This value includes the HV plus all of the effects from human activities. Increasing amounts of human activity result in lower HE values which means lower habitat quality for the grizzly bear. HE helps answer the question, how much impact is human activity having on the quality of the habitat for grizzly bears?

HE/HV Index: This is a mathematical expression which shows how much of a decline there has been in habitat quality due to human activities. An index of 1.0 would mean that there has been no decline in habitat quality. An index of 0.5 means there has been a 50% decline in habitat quality.

Table III-14 presents an overview of existing habitat conditions for the Targhee portion for each of the BMU's. A brief summary from the grizzly bear cumulative effects model (CEM) for the existing conditions illustrates the following:

The Henry's Lake Subunit 1 has the highest HV of all BMU's on the Forest; followed by the Henry's Lake Subunit 2, then the Bechler/Teton BMU, and then the Plateau BMU.

The Henry's Lake Subunit 1 has the highest HE of all BMU's on the Forest, followed by the Henry's Lake Subunit 2, then the Bechler/Teton BMU, and then the Plateau BMU.

The HE/HV Index is highest for the Henry's Lake Subunit 1, followed by the Bechler/Teton BMU, then the Henry's Lake Subunit 2, and then the Plateau BMU.

Table III-13 Annual Yellowstone Grizzly Bear Population and Known Human Caused-Mortality Data

Based on 1993 Grizzly Bear Recovery Plan Criteria Data From Known, Human-Caused Mortalities, Minimum Unduplicated Counts of Females With Cubs, and Distribution of Females With Young

Year	Annual Undup FWC's	Annual Adult Female Mortality	Annual All Female Mortality	Annual Total Mortality	4% Total Mortality Limit 1/	30% All Female Mortality Limit	Annual Total Mortality 6yr avg	Annual Female Mortality 6yr avg

Notes For Henry's Lake BMU, Subunit 1, all of the analysis (beginning with Motorized Road and Trail Density down through the Cumulative Effects Model Ratings) applies only to the National Forest acres which are in Management Situation 2 habitat

Gray Wolf - Scale: Forestwide

Possible sightings of gray wolves have occurred on the Forest, and are summarized in the Analysis of the Management Situation (AMS). There have been no reported sightings of packs or evidence of successful breeding. In April, 1994 the USDI Fish and Wildlife Service approved the Final EIS for The Reintroduction of Gray Wolves to Yellowstone National Park and Central Idaho (USDI Fish and Wildlife Service 1994a). In November of that year final rules were issued for the establishment of a nonessential experimental population of gray wolves in Yellowstone National Park, central Idaho, and southwestern Montana (USDI Fish and Wildlife Service 1994b). As a result of these actions, the following conditions exist

The portion of the Forest west of Interstate 15 is within the Central Idaho Nonessential Experimental Population Area. The portion of the Forest east of Interstate 15 is within the Yellowstone Nonessential Experimental Area. (See Figure III-6) All wolves found in the wild within the boundaries of these management areas, after the first wolf releases, will be considered nonessential experimental animals (USDI Fish and Wildlife Service 1994a and b)

This gray wolf reintroduction does not conflict with existing or anticipated Federal agency actions or traditional public uses of park lands, wilderness areas, or surrounding lands (USDI Fish and Wildlife Service 1994b). Land use restrictions may be temporarily used by land or resource managers to control intrusive human disturbance, primarily around active den sites between April 1 and June 30, when there are five or fewer breeding pairs of wolves in a recovery area. After six or more breeding pairs become established in a recovery area, land-use restrictions would not be needed (USDI Fish and Wildlife Service 1994a).

The ability of individuals holding grazing permits on public land to harass adult wolves in an opportunistic, noninjurious manner will become part of their permit conditions so it is clearly understood exactly what can occur. There is a seven day reporting requirement for any such incident (USDI Fish and Wildlife Service 1994a).

The following conditions and criteria will apply in determining the problem status of wolves (USDI Fish and Wildlife Service 1994a). Livestock in this context refers to only cattle, sheep, horses or mules.

Wounded livestock or some remains of a livestock carcass must be present with clear evidence that wolves were responsible for the damage. Also there must be reason to believe that additional losses would occur if the problem wolf or wolves were not controlled. Such evidence is essential since wolves may simply feed on carrion they have found while not being responsible for the kill

Artificial or intentional feeding of wolves must not have occurred. Livestock carcasses not properly disposed of in an area where depredations have occurred will be considered attractants. On federal lands, removal or resolution of such attractants must accompany any control action. Livestock carrion or carcasses on federal land, not being used as bait in an authorized control action (by agencies), must be removed, buried, burned, or otherwise disposed of such that the carcass(es) will not attract wolves.

On federal lands, animal husbandry practices identified in existing approved allotment plans and annual operating plans for allotments must have been followed.

If additional livestock depredations were likely, proper animal husbandry practices were employed (proper disposal of livestock carcasses, etc.), artificial feeding did not take place, and federal grazing allotment plans were followed, agencies would harass, capture, more, or kill wolves that attacked livestock (defined as cattle, sheep, horses, or mules only) on public or private land. Females with pups on public land would be released on site before October 1.

Central Idaho Nonessential Experimental
Population Area and Yellowstone Nonessential
Experimental Population Area for Gray Wolf.
(USDI Fish and Wildlife Service 1994 b)

Figure III-6

Wolf recovery will not result in wolf travel corridors or linkage zones being established. The size and proximity of the areas where wolves will be managed for recovery are large enough, close enough, and have enough public land between them that additional areas are not required in the foreseeable future to maintain a viable wolf population after the three subpopulations become established (USDI Fish and Wildlife Service 1994a).

Primary Cavity Nester Habitat - Scale Forestwide and Watersheds

Distribution maps and other sources of literature indicate there are eight species of primary cavity nesters (Table III-12), that is they create their own nesting holes in dead and defective trees. Four of these primary cavity nesting species (hairy woodpecker, northern flicker, yellow-bellied sapsucker, Williamson's sapsucker) require larger size snags and provide larger nesting cavities which are important for several other species of animals.

We analyzed overall biological potential for the primary cavity nesting species as a group, and a biological potential analysis was done for the four species which require larger size snags. These biological potential analyses are based on existing snag densities. Currently, the biological potential for the primary cavity nesting species as a group is 0.61, and the biological potential for the larger cavity nesting species is 0.47.

Forest Owl Habitat - Scale: Subsection

Flammulated & Boreal Owls - Flammulated owls are known to be present on the Island Park, Teton Range, Big Hole/Palisades and Caribou Subsections. Boreal owls have been documented on all but the Lemhi/Medicine Lodge and Caribou Subsections. The habitat components considered most important for the flammulated and boreal owls are a) the amount of mature and older Douglas-fir, mixed conifer, and aspen; b) primary cavity nesting habitat for the larger woodpeckers (hairy woodpecker, northern flicker, yellow-bellied sapsucker and Williamson's sapsucker). Thirty acres encompasses the entire home range of a flammulated owl pair during the breeding/nesting period. Thirty acres encompasses the largest size nest stands recorded in the literature for boreal owls. Approximately 3,600 acres encompasses the winter home range of a boreal owl. Summer home ranges are slightly smaller. (USDA Forest Service 1994a)

Great Gray Owl - The Forest has documented the presence of great gray owls in all seven subsections. The habitat components considered most important for this species are: a) mature or older forest habitat to provide suitable nesting sites; and b) suitable foraging habitat which includes nonstocked and seedling forests and nonforested habitats. Great gray owl nest sites average 143 meters from nearest opening; a 143 meter radius circle is about 16 acres. The largest home ranges recorded for great gray owls is 6.5 sq. km., which is 1,622.4 acres. All of the subsections have suitable foraging habitat. (USDA Forest Service 1994a)

Furbearer Habitat - Scale: Subsection

Wolverine - In 1985 a wolverine survey was done in Idaho to determine the location and status of populations (Groves 1987). Results of the survey indicated that three areas of the State had wolverine populations, however, the Forest was not within one of these areas. However, documented observations of wolverine on the Forest have occurred in the Centennial, Island Park, Madison, Teton Range and Caribou Subsections. Respectively, there have been 18, 1, 3, 7, and 1 observations between 1961 and 1995.

North American Lynx - Historically, lynx populations were minimal in the contiguous United States due to a lack of suitable habitat (U.S. Fish and Wildlife Service 1994c). Favorable habitat conditions for the lynx dissipate with decreasing latitude. Thus, the lynx is restricted to higher elevations the more southern the latitude (U.S. Fish and Wildlife Service 1994c).

The only documented reports of lynx on the Forest occur in the Wyoming portion of the Big Hole/Palisades Subsection (USDA Forest Service 1994b). Based on current knowledge, it is unlikely that the Forest historically or currently provides habitat for a viable resident lynx population.

Fisher - Historically, fisher were never known to occur in the Idaho portion of the Greater Yellowstone Area (Clark, et al 1989). However, one fisher was trapped in the Island Park Subsection at Warm River Butte in 1978. Also, fisher tracks were observed in the Teton Range Subsection near North and South Leigh Creeks during the winter of 1995 by a research team studying furbearers on the Forest. At this time, there is uncertainty about both the historical and current status of fisher populations on the Forest

American Marten - Marten sightings have been documented within all subsections except Lemhi/Medicine Lodge (Table III-12).

We are not sure about the presence of American marten in the Lemhi/Medicine Lodge subsection. Suitable habitat exists for marten, however, conifer forests only make up 37 percent of this subsection, and the forests are not connected to other forested habitats with known marten populations. Therefore, there is uncertainty about marten populations and habitat in this part of the Forest

There is a furbearer study in progress in the Island Park, Madison Plateau, and Teton Range subsections. Preliminary observations indicate marten are abundant

Northern Goshawk Habitat - Scale Forestwide

The goshawk is a forest habitat generalist that uses a variety of forest types, forest ages, structural conditions, and successional stages (Reynolds et al. 1992). It preys on small to medium sized birds and mammals (robins and chipmunks to grouse and hares), which it captures on the ground, in trees, or in the air (Reynolds et al. 1992). Forests within goshawk nesting home ranges should be an interspersed mosaic of structural stages - young to old forests - to increase the diversity of habitat for goshawks and their many prey species (Reynolds et al. 1992). Goshawk monitoring on the Forest has identified 49 goshawk territories, some of these territories are historic and some active. Not all of the Forest has been inventoried or monitored for goshawks, therefore additional goshawk territories probably exist. Northern goshawks have been documented in all seven subsections. These range from a high of 13 territories in the Centennial Mountains Subsection to a low of one territory in the Teton Range Subsection. Trends are unknown at this time.

Nest Areas - Nest areas include one or more forest stands, several nests, and several landform characteristics. Nest areas are occupied by breeding goshawks from early March until late September, and are the focus of all movements and activities associated with nesting. The size (20-25 acres) and shape of nest areas depend on topography and the availability of patches of dense, large trees (Reynolds et al. 1992)

Nest areas are often used more than one year, and some are used intermittently for decades. Many pairs of goshawks have two to four alternate nest areas within their home range. All previously occupied nest areas may be critical for maintaining nesting populations because they contain the habitat elements that attracted the goshawks originally. Additionally, replacement nest areas are required because goshawk nest stands are subject to loss from catastrophic events and natural decline. (Reynolds et al. 1992)

Goshawk nest stands have a relatively high tree canopy cover and a high density of large trees. Studies suggest that the dense vegetation in these stands provide relatively mild and stable microenvironments, as well as protection from predators of goshawks. Nest areas are usually classified as mature and older forest stands. (Reynolds et al. 1992)

Post-Fledging Family Area (PFA) - PFA's include the area used by the adults and young from the time the young leave the nest until they are no longer dependent on the adults for food. The PFA surrounds the nest area and, although it generally includes a variety of forest conditions, the vegetation structure resembles that found within nest stands. PFA's vary in size from 300 to 600 acres (mean = 415 acres). PFA's provide the young hawks with cover from predators, and sufficient prey to develop hunting skills and feed themselves in the weeks before juvenile dispersal. Forests in the PFA's should contain overstories and habitat attributes critical in the life-histories of goshawk prey species. (Reynolds et al 1992)

Foraging Area - Goshawks prey on birds and mammals in the larger body-size classes available to forest-dwelling hawks. Generally speaking, because of larger species of vertebrates have less dense populations than smaller species, predators of large prey must hunt over large areas in order to meet their energy requirements. Goshawk foraging areas are about 5,000 to 6,000 acres. (Reynolds et al. 1992)

Limited radiotelemetry evidence suggests that goshawks prefer mature forests for foraging. Additional information on the composition and structure of goshawk foraging habitat was gleaned from information on the habitat requirements of goshawk prey species. Raptor populations are often limited by prey populations, and choice of foraging habitat by goshawks is predicted, at least in part, on habitats where prey are abundant and accessible. (Reynolds et al 1992)

The foraging area comprises the largest portion of the goshawk nesting home range and therefore typically includes a greater diversity of landforms, forest cover types, and vegetation structural stages. Important habitat components include snags, downed logs, woody debris, openings, large trees, herbaceous and shrubby understories, and interspersed vegetation structural stages (forest successional stages) (Reynolds et al. 1992)

Red Squirrel Habitat - Scale: Subsections

Red squirrels are so strongly associated with the conifer forests that their population densities fluctuate with cone crops. (Smith 1968, Gurnell 1983, Halvorson and Engeman 1983) Since red squirrels are so strongly dependent upon conifer seeds as a food supply, conifer forests must be of seed-producing age before red squirrels will make significant use of them. Habitat quality is also related to nesting cover and food-caching sites. Natural cavities are preferred by red squirrels as nest sites. (Hamilton 1939, Layne 1954) However, underground nests and external tree nests are more commonly used where cavities are not available. (Fancy 1980) Large diameter trees, large standing snags, and fallen trees are important sites for cone storage. (Vahle and Patton 1983)

Suitable habitat for red squirrels exists in all subsections. At the present time, about 80% of the forested acres are of cone bearing age (about 928,000 acres)

Peregrine Falcon - Scale: Subsection

Table III-8 indicates the distribution of the peregrine falcon across the Forest within the seven subsections. Process Paper D includes information on sightings and habitat preferences of peregrine falcons.

The peregrine falcon has been listed as an endangered species under the Endangered Species Act. However, in June of 1995, the U S. Fish & Wildlife Service proposed removing this species from the list of endangered and threatened wildlife. (USDI Fish and Wildlife Service, 1995)

Lemhi/Medicine Lodge and Madison Plateau - No peregrine falcon habitat has been identified. Other subsections are discussed below.

Centennial Mountains - Efforts to establish successful peregrine falcon eyries have occurred at three general areas in this subsection: Targhee Creek, Sawtell Peak and Henry's Lake Flat. The Henry's Lake Flat area is not National Forest land. At the present time, the Targhee Creek and Sawtell areas are not being used by peregrines.

Island Park - One historic peregrine falcon eyrie occurs in this subsection along the Henry's Fork (upstream from the confluence with Warm River). This site has not been used by peregrines in recent years.

Teton Range - Two eyries occur in Teton Canyon.

Big Holes/Palisades - Three peregrine falcon eyries occur in this subsection in the following general locations: South Fork of the Snake River (above Heise), Sheep Creek (near Palisades Dam), and Alpine. The Sheep Creek and Alpine eyries have been productive in recent years, but the South Fork of the Snake River eyrie has not.

Caribou - One peregrine falcon eyrie occurs in this subsection in the general vicinity of Swan Valley.

Unique Ecosystems

Research Natural Areas - Scale: Forestwide

Research Natural Areas (RNA's) are part of a national network of field ecological areas designated for research and education and/or to maintain biological diversity on National Forest System lands. RNA's are used for nonmanipulative research, observation and study. They also may serve to carry out provisions of special acts, such as the Endangered Species Act and the monitoring provisions of the National Forest Management Act.

The Forest currently has six established RNA's, each having unique features representing some of the Forest's diversity. In addition, three areas are being evaluated for designation and one RNA is awaiting final approval.

IV. FOREST USE AND OCCUPATION

ACCESS MANAGEMENT

Road System - Scale: Forestwide

The Forest road system provides access to the National Forest for recreation, industry and administration. Land transportation by motorized vehicles is the main means of travel on the Forest. Seven major highways run through the Forest and all primary access to the Forest begins from one of these highways. Average daily traffic counts collected by the Idaho State Highways Department (Gillespie 1994) suggest the heaviest traffic occurs on the highways between Idaho Falls and the northeast part of the Forest (Figure III-7). Many of the Forest's roads were constructed in the mid-1970's as part of the timber salvage program and provided access to recreationists, firewood gatherers and hunters. The roads have also proved useful for fire suppression activities. Currently there are 1,367 miles of open system roads plus 1,021 miles of open nonsystem roads. Motorized use is currently restricted on some roads as follows: 61 miles of system roads have seasonal restrictions; 572 miles of system roads have yearlong restrictions, 24 miles of nonsystem roads have seasonal restrictions, and 177 miles of nonsystem roads have yearlong restrictions.

Targhee National Forest

Average Daily Traffic (ADT) at Selected Locations

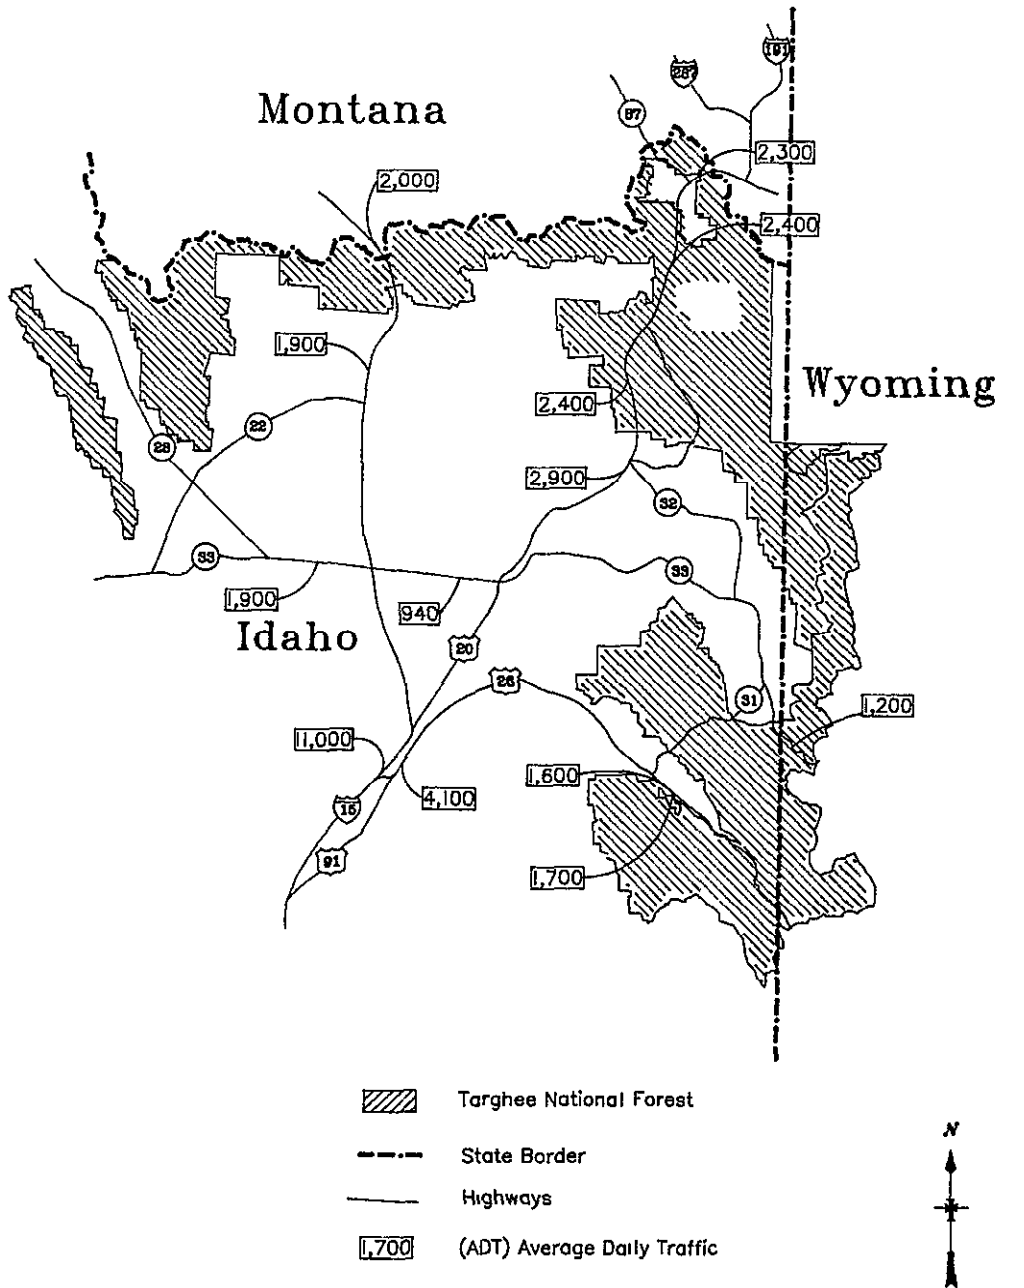

Figure III-7

Not To Scale

The present Forest road system is essentially in good shape, with maintenance being done yearly on arterial and collector roads, and some local roads, depending on resources needs. Further information on the present Forest Development Road System can be found in the Transportation section of the Analysis of the Management Situation (AMS).

The road system now in existence has created some resource conflicts with wildlife, fish and watersheds. Road restrictions or reclamations have been requested by agencies, groups, and individuals to reduce resource conflicts. Law enforcement problems have also increased over the years because of the need to enforce road restrictions

The Forest has begun restricting and/or reclaiming roads to reduce resource conflicts. Many of the spur roads built during the salvage program are now restricted. A total of 377 miles of road were obliterated from 1981 to 1991. An additional 1,245 miles of road were obliterated in 1992-93.

There are approximately 2,000 miles of existing system roads (Table III-15). Of these, 10 percent are classified as arterials. They are often two-lane and paved or have a good gravel surface and can handle unrestricted traffic at moderate speeds. Branching from the arterial roads are the collectors. Collector roads are medium standard roads that constitute about 25 percent of the mileage in the transportation system. Collector roads are stable enough for most traffic during normal season of use. Small single-lane roads, known as local roads, are found throughout the Forest and make up 65 percent of the road system. These minimum standard roads provide access for specific purposes, such as conducting a timber sale, maintaining an electronic communication station, or reaching a trailhead. They allow limited passing, but the road conditions require that vehicles move slowly. Many of the local roads are currently restricted to vehicular traffic much of the time.

Other two-track roads exist that are referred to as nonsystem roads (sometimes called "ghost roads"). These isolated roads were not designed or maintained for public use; they are created by repeated use by the public. Some vehicles cannot travel on these roads. Road surfaces are generally rough and irregular with no drainage. Some of these roads are currently restricted to motorized use. There are 1,222 miles of these roads on the Forest (Table III-15).

Table III-15 Existing Road and Trail Access

Collector	504	*0	*0
Local	667	*61	*572
Total	1367	61	572
* Open to snowmobile travel if designated			

There are 235 existing and 109 potential/needed materials sources for gravel, rock riprap, and earth borrow sites. This should serve the Forest's needs for the planning period. The 1993 Compendium of Material Sources is available for further information.

The National Forest Scenic Byways Program was developed to increase public awareness and understanding of the National Forest and State activities and recreation opportunities. Presently there are two Scenic Byways that pass through the Forest, the Mesa Falls Scenic Byway and the Teton Scenic Byway. The Mesa Falls Scenic Byway follows old State Highway 47 from Ashton to where it ties back to US Highway 20. About 20 of the total 29 miles are located on the Forest. The Teton Scenic Byway Route travels east from Idaho Falls to Swan Valley along Highway 26, then north to Victor on Highway 31, from Victor to Tetonia on Highway 33 to the intersection of Highway 32, and then to Ashton on Highway 32.

Summer Access for Off-Highway Vehicles (OHV)

Approximately 61 percent of the Forest (1,126,000 acres) is currently open for summer cross-country motorized and mechanized vehicle access. There are 1,367 miles of open system road, 1,021 miles of open nonsystem road, 433 miles of open system trails, and 199 miles of open nonsystem trails (Table III-15 and III-17). The Forest conducted an analysis of motorized access and road/trail density in the spring of 1995 to accurately inventory these opportunities. This analysis is documented in Process Paper E.

There are no trails designed specifically for motorized OHV's or mountain bikes, although some are suitable in their present condition. There is a significant increase in demand for such opportunities. Both types of use are increasing at a rate of five to ten percent per year on the Forest and adjacent lands. The highest concentration of these activities are in the Big Hole/Palisades and Caribou Subsections, where there is significant use by motorcycles and mountain bikes. As noted in the Soil and Riparian section there are areas of concern for OHV effects on soil and vegetation. There are no serious widespread adverse consequences as a result of this use. However, it is possible that motorized use is affecting some big game wildlife habitat potential or vulnerability to hunting pressure.

Winter Access

There are over 450 miles of winter trails that are groomed on the Forest (as shown in Table III-17) and 1,511,000 acres open to cross-country snowmobiling. Groomed snowmachine and cross-country ski trails and their use are most numerous in the Island Park and Big Hole/Palisades Subsections (Table III-16). The Centennial Mountains, Madison Plateau, and Caribou Subsections surrounding these two hub areas also provide many winter opportunities. In contrast, the most undeveloped backcountry opportunities and the least used by both skiers and snowmachiners are found in the Lemhi/Medicine Lodge, and Teton Range Subsections. Within the Teton Range Subsection, the Jedediah Smith Wilderness is closed to snowmobiling.

Special use permits for outfitter-guide operations for snowmobiling, dog sledding, and skiing are scattered across the Forest, but are most numerous in the Madison Plateau subsection where there are six commercial snowmachine operations. This is due to attractions such as the Two-Top National Snow-machine Trail near west Yellowstone, the Mesa Falls Scenic Area, and an excellent grooming program by Fremont County, Idaho. Growth in snowmobiling has been increasing at 5-10 percent per year annually across the Forest. As a result, the Forest constructed one new parking area and day lodge for winter users at Big Springs, in Island Park. This winter activity has resulted in some concerns regarding conflicts with wintering wildlife, and several travel access closures have been implemented to reduce conflicts.

Activity	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Range	Big Hole/ Palisades	Caribou	Forest Total 1/
# Outfitters Permitted (summer and winter use)	5	11	11	5	30	18	3	83

WILDERNESS AND RECREATION RESOURCES

Wilderness and Recommended Wilderness

There are currently two designated wilderness areas on the Forest. These are the Jedediah Smith Wilderness (123,451 acres) and the Winegar Hole Wilderness (10,715 acres). The Jedediah Smith is mostly in the Teton Range Subsection with the balance in the Madison Plateau Subsection. Winegar Hole is totally within the Madison Plateau Subsection. Winegar Hole is largely primitive with very little recreational use. This is mostly due to access difficulty, since there are only four miles of trail in the area. Use of this area is mostly for hunting big game. The Jedediah Smith is intensively used in the summer with approximately 60,000 visits for hiking, backpacking and horseback riding. This is a spectacular mountainous area on the west slope of the famous Teton Mountain Range. These wilderness areas are two of twelve designated in the Greater Yellowstone Area which total 3.8 million acres.

The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in 1984. The Study Area contains approximately 129,100 acres. Of these acres, over 79,800 are administered by the Bridger-Teton National Forest and 49,300 acres are administered by the Targhee. In addition, there are 110,520 acres of this roadless area in Idaho which have had no action or recommendation taken on them. The studies on the Wyoming portion have not been conducted, and are planned to be done with the Bridger-Teton as the lead forest at the time of their plan revision.

Portions of Italian Peak, Lionhead, and Winegar Hole Roadless Areas (65,000 acres) were recommended wilderness in the current Forest Plan, but no legislative action has been taken to date.

Roadless Areas

There are sixteen areas on the Forest which qualify as roadless or roadless adjacent to designated wilderness. These areas total about 841,000 acres. Within these roadless areas, some 243,000 acres are closed to summer OHV use. The majority of the roadless acres are contained in the Lemhi/Medicine Lodge, Centennial Mountains, Big Holes/Palisades, and Caribou Subsections. The 1993 roadless inventory showed a net increase in qualifying acres over the inventory in the current Forest Plan. This is because several of the roading and timber harvest projects proposed in the Plan were never completed. These areas were added to the previously inventoried areas. In contrast, the Signal Peak, Warm River South and East, and Moody Creek areas did incur enough development to require them to be removed from the inventory. In 1990, the Centennial Mountains Wilderness Suitability Study EIS (Mt. Jefferson) was completed, and none of the Targhee portion was recommended wilderness. The Mt. Jefferson area was thereby released for management according to Forest Plan direction.

Wild, Scenic, and Recreational Rivers

In November, 1994, an eligibility inventory was completed for the entire Forest, and approximately 249 miles of rivers and streams were determined eligible (Table III-17). The largest mileage of eligible stream segments is in the Island Park Subsection, and the Big Hole/Palisades Subsection has the second highest. The remaining subsections (excluding the Lemhi/Medicine Lodge) all have a lesser mileage ranging from 17 to 35 miles.

The largest potential classification mileage is for Wild, followed by Recreational and Scenic which are almost equal. Suitability studies have not been completed for any of these streams, and none are scheduled for funding until 1996.

Visual Resources

The Forest has some very unique and outstanding scenery. It encompasses peaks over 10,000 feet, arid lands, timbered highlands, lakes and waterfalls.

During the past decade, the greatest change in visual resources occurred among the vast expanses of mature lodgepole pine found in the Madison Plateau and Island Park Subsections. Large portions of this mature timber were clearcut. Some of this timber harvest occurred near major travel routes and use areas such as campgrounds, resorts, summer home areas and private lands. This changed many of the solid timbered areas to open meadow-like mosaics of scattered timber stands. Even though this was a drastic change from the past, it also provided variety in terms of scenic views and vistas. In some instances, this type of harvest enhanced areas from a visual standpoint.

The following chart shows the acres which currently meet each visual quality objective.

<u>Visual Quality Objective</u>	<u>Acres</u>
Preservation	137,761
Retention	226,882
Partial Retention	804,784
Modification	519,184
Maximum Modification	148,189

Most of the Preservation acreage falls within the Jedediah Smith and Winegar Hole Wildernesses, which are in the Teton Range and Madison Plateau Subsections. Most of the Modification and Maximum Modification acres are in the Island Park and Madison Plateau Subsections. The other classifications are scattered throughout the subsections.

Developed Recreation Sites - Scale: Forestwide

Demand for new types of specialized facilities such as trailheads, mountain biking trails, boat ramps, fishing access and snowmachine facilities is increasing at five to ten percent annually. A strong increase in demand for group camping sites is an example of this type of specialized recreation facility need.

As shown in Table III-17, there are 61 developed recreation sites with facility investments over \$50,000 on the Forest. This figure includes both existing and planned sites. These sites, which include facilities such as campgrounds and boat ramps, have a total capacity of 8,890 persons at one time (PAOT). These sites receive approximately 608,000 visits and result in 703,000 12-hour recreation visitor days (RVD's) annually. Use is increasing approximately 2 percent per year. The Big Hole/Palisades Subsection has the most sites (19), and the Island Park Subsection has the next largest number (18). The remaining subsections each have seven sites or less. Utilization rates for these sites range from low (<20%) to high (60%) across the Forest, with highest rates in the Warm River/Island Park, and Palisades areas.

Developed recreation facilities are in fair to good condition across the Forest, but there is a significant backlog in heavy maintenance and reconstruction needs. The Forest has been able to reconstruct a few of the major sites. Because many of our campgrounds and other developed facilities are adjacent to or along travel routes to Grand Teton and Yellowstone National Parks, use patterns on the Forest are affected by management actions and physical attractions of these parks.

Dispersed Recreation

The largest number of dispersed activity and camping sites are in the Caribou and western Centennial Mountains Subsections as shown in Table III-17. The next largest numbers of sites are in the Lemhi/Medicine Lodge and Big Hole/Palisades Subsections. These sites receive approximately 1,147,000 visits and result in 992,000 RVD's annually. Dispersed sites have few or no structural facilities for recreation. They are used for general camping and to provide access to fishing, hunting, OHV areas, and trails. Some of these sites have received increased use and number of camping spots, such as at Horseshoe Lake which has increased from three to seven sites in the last decade. Many dispersed activity uses are increasing at a rate of approximately 4 percent.

The capacity in PAOT of these sites is greater than the developed sites on the Forest. There are 106 heavy use dispersed sites on the Forest, and some of these dispersed campsites are showing damage to vegetation and soils. Many sites are in need of management actions to stabilize or minimize such impacts.

There are approximately 1,029 miles of system and 229 miles of nonsystem trails for motorized and nonmotorized use on the Forest. Summer use trails are most abundant in Big Hole/Palisades, Caribou, Teton Range, and Centennial Mountains Subsections (Table III-17).

Outfitters and Guides

There are 83 permitted outfitter/guide operations on the Forest at the present time (Table III-17). Outfitted activities are most numerous in the Teton Range and Big Holes/Palisades Subsections. The Centennial Mountains and Island Park Subsections also have a moderate number of permitted operations.

Forestwide, the largest number of these permits is for summer activities. These permits are for guided activities such as hunting, horseback riding, river trips, fishing, wagon rides, backpacking, horsepacking, etc. These activities represent a commercial industry with an annual income estimated at over 1.8 million dollars, and fees to the government of over \$53,000. There is continuing interest in new permits, however capacity determinations and commercial allocations have only been made for a few parts of the Forest. Therefore, a moratorium was recently initiated on the Forest to deny any new applications for permits, except in areas where capacity had been determined to be available through environmental analysis and documentation.

Special Uses

Excluding outfitter-guide permits, there are 267 other recreation special use permits on the Forest (Table III-17). These are issued for summer homes, organization camps, special events, ski areas, etc. The highest number of these are located in the Island Park and Caribou Subsections where there are large numbers of summer homes. There are moderate numbers of permitted activities in the Centennial Mountains and Big Holes/Palisades Subsections. The Forest administers permits for 203 summer homes, 32 recreation special events, 14 organization camps, and 2 regional-sized ski resorts. These permits are the major portion of the activity and result in returns to the treasury in the hundreds of thousands of dollars annually.

There are over 200 nonrecreation uses authorized by special use permit on the Forest. Uses authorized include roads; water transportation systems such as ditches, canals and pipelines, hydropower, communication sites; municipal watersheds; telephone, telegraph and power transmission lines, uses related to agriculture and industry; and uses related to research, training, cultural and historic resources.

ECONOMIC AND SOCIAL ENVIRONMENT - Scale: Region, County, and Forestwide

Figure III-1 shows how area population centers and county lines rest relative to the subsection boundaries outlined for the Forest. The area primarily affected by the Forest in terms of economic and social concerns comprises Bonneville, Clark, Fremont, Jefferson, Madison, and Teton counties in Idaho. Together these counties make up the great majority of the Forest's total administrative area and account for the largest part of Forest-related employment, personal income, and revenues for local governments. These counties are recognized as being the Area of Primary Forest Economic Influence (APFEI) (Table III-18).

Table III-18 Population Density and Unemployment					
				Unemployment Rate

* Area of Primary Forest Economic Influence -- APFEI
1/ US Bureau of the Census, County and City Data Book, 1988 US Government Printing Office. 1988
2/ US Bureau of the Census, 1990 Census of Population and Housing Summary Population and Housing Characteristics Idaho, Montana, Wyoming US Government Printing Office. 1991.
3/ US Bureau of the Census, County and City Data Book, 1994 US Government Printing Office. 1994.

The Forest is of lesser economic importance to other area counties including Teton and Lincoln counties in Wyoming and the Idaho counties of Bannock, Bingham, Butte, and Lemhi. Bannock and Bingham counties have no lands administered by the Forest. The Forest does manage significant amounts of land in Butte, Lemhi, Lincoln, and Teton (Wyoming) counties. Management of the Forest as depicted in the various alternatives under consideration is not expected to have significant effects on these counties.

Even though these counties are not included in the APFEI they still have important links to the Forest. The Grand Targhee Ski Resort, for instance, is located in Teton County, Wyoming. It is an important source of income and employment. Services and supplies for the facility must come through Teton County, Idaho, however.

People from outside this area also have strong ties to the Forest. Besides Idaho, Wyoming and Montana the Forest receives many visitors from Utah, California, and the rest of the nation. The designation of an area of influence does not diminish the interests others have in the area or the attention paid to their input.

Most of the area's population lives in cities like Idaho Falls, Blackfoot and Rexburg. The area's population is relatively small and concentrated in Bonneville County which contains Idaho Falls, the area's largest city with a population in excess of 42,000. It regularly ranks as Idaho's second- or third-largest city.

Perhaps the most striking characteristic of the area's population is the growth that has occurred in Bonneville and Madison counties during recent decades. Since 1950 the population within the APFEI has more than doubled, from 63,334 in 1950 to 137,991 in 1994. Bonneville and Madison counties have increased over 2.5 times during that same period.

Table III-18 displays the relatively low population density of the six counties making up the Area of Primary Forest Economic Influence at about 17 people per square mile.

Employment and Income

Although information is presented herein by county, by economic sector, or by other grouping it is important that the associations among the various components not be overshadowed. Area barley farmers support the Anheuser-Busch barley malting facility in Idaho Falls. Idaho's largest potato farm is located in the area and potato growers support a wide-ranging potato industry including fertilizer, irrigation equipment, storage and packing facilities, equipment manufacture and repair, and other agricultural support activities. Some 10,000 workers at the Idaho National Engineering Laboratory (INEL) live throughout the area and thus contribute to the well-being of a number of local communities.

The entire area benefits from its proximity to Yellowstone and Grand Teton National Parks. Recreationists travelling through the area use the lodging and retail sectors of the economy. Perhaps more importantly, many of those recreationists have bought summer homes in the area. With improvements in roads and vehicles, more and more people are locating in areas which were previously considered inaccessible during the winter months.

The presence of large numbers of recreationists drawn to a permanent world-class attraction like Yellowstone National Park has made the area attractive for other types of spin-off recreation. Examples are the grizzly bear theme park in West Yellowstone, Montana, just outside the Area of Primary Forest Economic Influence, and fishing on the Henry's Fork and South Fork of the Snake River.

The Grand Targhee Ski Resort has emerged as a destination resort. Although it is located in Wyoming, all traffic into it flows through the APFEI. The resort has been successful in establishing itself as a year-round facility with attendant increases in the numbers of people employed and the seasons during which they are employed. Grand Targhee employs 166 people on a full-time equivalency basis on the site. Another 23 people are employed off-site. (USDA Forest Service, Grand Targhee DEIS 1992)

Unusual associations have developed as the area's economy has grown and evolved in different ways. The Sand Dunes in Fremont County draw large crowds of recreationists, but much of the economic activity associated with the Dunes is associated with Madison County which offers a greater variety of retail services and the nearest hospital. On the other hand, the recently-closed Louisiana-Pacific lumber mill in the Madison County seat of Rexburg formerly employed a great many people who live in Fremont County.

Major employment in the Area of Primary Forest Economic Influence (APFEI) comes from the services, wholesale and retail trade, and government sectors (Table III-19). The Service sector includes a wide range of activities such as automobile repair, funeral services, lodging, health care, legal services, engineering services, amusement and miscellaneous repair shops

* APFEI--Area of Primary Forest Economic Influence
The sources of data on this page are tables provided by the Idaho Department of Employment, Research & Analysis and the 1989-1990 Annual Covered Employment for the State of Wyoming issued by the Wyoming Department of Employment, Division of Research and Planning
D -- To avoid disclosing information on individual firms no number is shown for some entries Total figures for those rows and columns are therefore underestimated
** -- Food Processing and Lumber Manufacturing are not displayed as separate Manufacturing categories They are here included in Other Manufacturing
1/ Includes logging

The respective counties' economies differ greatly. Clark, Fremont, Jefferson, and Teton Counties rely heavily on agriculture and related activities for their economic bases. Bonneville and Madison Counties both rely heavily on the services sector (most notably the Idaho National Engineering Laboratory and Ricks College) for their economic bases. Madison county until recently hosted a Louisiana-Pacific green Douglas-fir sawmill at Rexburg. That mill operated on a seven-month season, and employed about sixty people directly. Another one hundred people are estimated to have been employed on a seasonal basis doing logging, road work and hauling Most of these workers live in adjoining Fremont county

The economy of Bonneville county is much larger than those of the other counties in the APFEI and thus tends to overwhelm the statistics. The primary economic driver of Bonneville county is the Idaho National Engineering Laboratory (INEL) which accounts for the large showing of service sector employment.

Changes continue to occur in the local area's economy. Coors Brewing, long a purchaser of locally grown barley, pulled out of the market. Canola is being grown on larger acreages of area farms. Idaho Forest Industries, long a major employer in Fremont County, closed its sawmill in St. Anthony in 1992. The INEL has scheduled thousands of jobs for elimination. Snowmachine activity has blossomed to the point that anticipated restrictions on their use in Yellowstone National Park seems likely to spur increased use on the Targhee and other lands surrounding the Park. Jet ski use on area waterways is another recent development in area recreation.

Many people in the local area rely on Forest commodity production for their livelihoods to some extent. Loggers, mill workers, ranchers, outfitters, guides, and truckers fall into this category. Area mills relying in part on timber from the Forest include numerous smaller mills producing posts, poles, house logs and dimension lumber. Before its closure in 1992, the large stud mill in St. Anthony (Fremont County) received about 80% of its raw material from the Forest. About half of the material processed at the Rexburg mill before its closure in 1995 likewise came from the Forest. The Forest is a significant supplier to the smaller facilities in the APFEI as well. Dead timber serves as an important fuel supply for home heating in the local area thereby providing a source of income for some and a source of heat for others.

Some area residents rely on Forest rangeland as a source of seasonal forage for their livestock. Normally this forage is an integral part of the ranch's overall operations. Alternative sources of supply suitable for the permittees' needs are difficult to come by.

Recreation is an important part of the local economy and one with significant growth potential. It includes readily-identifiable recreation resources like the Grand Targhee Ski Resort, Kelly Canyon Ski Resort, outfitters and guides, and snowmachine rental. Other related activities include sales at area restaurants, motels and retail establishments. Harriman State Park and private facilities located off-Forest also rely on the Forest for an expanded range of activities for their visitors.

Another recreation-related economic spin-off has been the proliferation of summer home residences in the area. This has increased the local tax base without increasing demands on area schools.

Some area residents have noticed an increasing level of recreation use which they attribute to overcrowding in the adjacent Yellowstone and Grand Teton National Parks which are attracting record numbers of visitors.

The Forest Service employs some 140 workers to manage the Targhee National Forest. The Forest Service is a major employer in the area and the great bulk of its annual budget (Table III-20) goes to salaries of Forest employees living in the local area. Additional background information on the local area is available in the Forest's Analysis of the Management Situation (AMS).

1993	12.2
1992	14.0
1991	11.9
1990	11.6
1989	12.0
1988	16.3
1987	9.0
1/ Excludes firefighting costs averaging about \$1 million annually.	

Payments to Counties

The Forest also plays a role in the area economy by generating funds which are returned to local governments. These funds result from the Payment in Lieu of Taxes (PILT) program administered by the U.S. Department of the Interior and from Payments to Local Governments known as the 25% Fund (Table III-21). The "25% Fund" is the common nomenclature used for payments made under the National Forest Revenue Act of 1908, as amended. The payments are to be used as directed by the respective state legislatures for the benefit of roads and schools in the local area. Twenty-five Percent Fund payments are calculated based on Forest receipts. The Forest's timber program accounts for the largest part of these payments. PILT payments are calculated based on the amount of acreage held by the federal government, the area's population, and other federal receipts. Unlike 25% Fund payments, PILT payments may be used for any governmental function.

Amenity Interests

Many people in the area, and outside the area, enjoy the Forest for the recreational opportunities it provides, for the scenic vistas it offers, for its aesthetic values, for its importance to wildlife and fish, and for the contributions it makes to the greater ecosystem. Interests include those associated with the effects of clearcutting on the visual landscape and on area plants, fish, and wildlife, spiritual concerns; land ethics; and environmental concerns in general

Many people value the Forest even though they have never been here. They recognize its place and importance in the larger ecosystem. The large clearcuts of lodgepole pine that began in the 1960's have been photographed extensively from the air and have been widely published. People have commented, favorably and unfavorably, about this activity. The photographs have heightened the level of public consciousness of clearcutting on the Forest

Understandably enough, most of the recreation that occurs on the Forest is associated with people who live in close proximity to it. Out-of-area recreationists, with the exception of hunters and anglers, are more likely to focus their recreational activities on the big-name attractions like Yellowstone and Grand Teton National Parks. Local people have often grown up in the area, experiencing the Forest from the

time of their youth, and enjoy the greater sense of freedom associated with the less-restrictive recreational experience available on the Forest compared to the Parks. Big game hunting, particularly elk hunting, is a fall experience of extreme importance to those who enjoy it.

Within the Forest boundaries are wildernesses, big-game herds, two ski resorts, waterfalls, a world-class fishery, and the kind of scenery associated with the adjacent Yellowstone and Grand Teton National Parks. These features give rise to a great deal of recreational use by those from outside the immediate area. Big-game hunting, camping, hiking, skiing, and recreational driving are major attractions for this group. Most of the big-game hunters are from other parts of Idaho. Residents of the adjoining states and California are the most common out-of-area users of the Forest.

Products such as timber, firewood, and grazing that the Forest provides are obviously important to the local communities. Less obvious are the plant products that individuals collect (commercially or for personal use) for food, medicinal purposes, mushrooms, dried flowers/plants, trees and shrubs for landscaping, and huckleberries and chokecherries (plus other berries) are yearly utilized by people both locally and from other areas. These products also have cultural significance to local American Indian tribes who utilize a wide variety of plants from the many habitat types on the Forest as shown in Table III-22.

Habitat	# of Species
Douglas-fir	50
Lodgepole Pine	42
Spruce/Fir	34
Limber Pine	9
Whitebark Pine	8
Mixed Conifer	54
Aspen	34
Sagebrush/Grass	70
Grass/Forbs	57
Mountain Brush	99
Alpine	21
Riparian/Aquatic	102
Rock/Barren/Talus	17

Tribal Interests

The Forest lies within the aboriginal territory of the Shoshone-Bannock Tribes. The Tribes collectively comprise a single, federally recognized Indian tribe with a governing body, the Fort Hall Business Council, which is duly recognized by the Secretary of the Interior. Tribal members are successors-in-interest of Indian signatories to the Fort Bridger Treaty. In part, that treaty led to the creation of the Fort Hall Indian Reservation in the Idaho Territory as a permanent tribal homeland. The 544,000-acre reservation lies generally between Blackfoot and American Falls, Idaho.

Article 4 of said treaty secured for the Tribes in perpetuity the continuation of a wide variety of "use rights" to off-Reservation lands. More specifically, by virtue of Article 4 of the treaty, the Tribes expressly reserved the right to hunt "on the unoccupied lands of the United States so long as game may be found thereon" including such lands owned by the federal government outside the boundaries of the Reservation. The courts decided in the Tinno decision (State v. Tinno 1972) that the right to hunt also included a right to fish (Shoshone-Bannock Tribes 1992b).

The Tribes have historically used the Targhee for hunting, fishing and gathering. Native Americans historically used at least 838 species of plants on the Forest, covering virtually every type of plant community. These activities are important economically as well as socially and culturally. Part of the economic importance to the Tribes lies in their use of hunted meat to provide food for the elderly and the disabled. "The philosophy and management direction from the Tribes has always been for subsistence hunting and this is reflected in the Tribes Big Game Regulations." (Shoshone-Bannock Tribes 1992a)

Rights to believe, express, and exercise traditional religions are protected by various federal laws, including the American Indian Religious Freedom Act of 1978. This includes, but is not limited to, access to sites, the use and possession of sacred objects, and the freedom to worship through ceremonial and traditional rites. Additionally, rights reserved under treaty may possess an inherent measure of resource protection. (U.S. v. Washington (759 F.2d 1353, 1985) in Shoshone-Bannock Tribes 1992b)

The Forest has worked with representatives of the Tribes to coordinate the Revision with them. Representatives of the Tribes have stressed the following points.

Treaties are the supreme law of the land (U.S. Constitution, Article 6, Clause 2). Treaty rights cannot be negotiated at the Department level of the United States government. Consultations with the Tribes are on a government-to-government basis.

The multiple jurisdictions they have to work with make any attempts at working with the Forest an extremely frustrating exercise. Their territory lies within the boundaries of many National Forests, on lands administered by the Bureau of Land Management, on state lands, and on lands privately held. This complicates even relatively simple matters like interpretive signs.

The processes the Forest uses to handle archaeological sites and cultural values do not fully address the Tribes' concerns. It is important to protect sites, to keep them unpublished, and to recognize that providing access to sites invites vandalism. It is important for the Forest to consult with the Tribes on a case-by-case basis when providing protection to sites. It is important that vandalism of sites be vigorously prosecuted to serve as a deterrent.

The Revision must recognize the:

- sacredness of the land
- need for protection
- obligation to consult with the Tribes as outlined in the American Indian Religious Freedom Act, the National Environmental Policy Act, and the National Forest Management Act.
- many aspects of reserved rights including, but not limited to, the priority nature of rights reserved under the treaty, as well as an inherent measure of resource protection to satisfy these rights.

The Forest must be recognized for its religious and spiritual significance to the Tribes. That significance is not limited to vision quest sites or traditional camp sites. The Forest and even the lands beyond its borders are important in their entirety. As with many other religions, tribal members are not free to share all the dimensions of their faith.

The Tribes also have a significant economic interest in the Forest. These include subsistence activities like hunting, fishing and gathering. They also include important aspects of Tribal life like sharing the fruits of the land. Riverine ecosystems are important to the Tribes not only for their resources but also for the role they play in the Tribes' religion.

Heritage Resources

Scale: Subsection

Lemhi/Medicine Lodge - This area contains over 200 heritage resources of predominately Native American sites including habitation sites and rock art. The aboriginal settlement pattern for the area is related to scarce perennial water sources in generally high altitude settings. Archaeological excavations in the area indicate that high altitude hunting camps were used primarily for hunting mountain sheep.

European-American settlement in this area was focused on homesteading and lead mining in the late 19th century. The Birch Creek Charcoal Kilns is the most significant site relating to this period of settlement and is a major tourist attraction. The remains of ancillary sites associated with the lead mining industry are found in several canyons. The Worthing Cabins also have interpretive potential for late 19th century homesteading.

Impacts to heritage resources, such as prehistoric Native American lithic scatters associated with hunting camps, are occurring from livestock grazing and antelope hunting blind construction. Construction of hunting blinds involves digging a hole up to two feet deep, which can disturb cultural deposits. Since permanent water sources in this area are scarce, most springs have evidence of prehistoric Native American occupations. Livestock tend to congregate at these springs, trampling surface cultural deposits. Soil erosion from lack of vegetation in these areas exposes buried cultural deposits.

Centennial Mountains - The Centennial Mountains contain the highest frequency of heritage resource sites on the Forest. Over 400 heritage resources of predominately Native American sites have been identified. The aboriginal settlement pattern for the area is seasonal occupations for the extraction of obsidian and collecting camas plants for medicinal use. Site types include base camps, obsidian workshops, quarry sites and hunting camps. The most significant archaeological site in this area is the Big Table Mountain Obsidian Source. Monida Pass and Targhee Pass provided natural travel routes across the Continental Divide into the buffalo hunting grounds of Montana. These passes were also utilized extensively during the 19th century by fur trade companies and later as stagecoach routes.

European-American settlement of the area is in the form of late 19th and early 20th century homesteads along the Forest fringe bordering the upper Snake River Plain.

Some prehistoric Native American sites, such as lithic scatters associated with hunting camps and lithic workshops, have been affected by logging. Monitoring following timber harvest in this subsection showed that all heritage resource sites located in cutting units were damaged by logging. Site avoidance recommendations discussed in Heritage Resource Survey Reports were not followed during timber sale administration. State authorities are aware of these, and the situation has been corrected.

Island Park - Heritage resources in the Island Park area are primarily related to the Tie Hack Period (cutting trees for railroad ties) and early Forest Service history. The 140 sites identified are composed primarily of tie hack camps associated with the Yellowstone Railroad, Forest Service administrative sites such as guard stations, ranger stations, and fire lookouts, and recreational cabins dating to the early 1900's. Social patterns in this area are closely related to the logging industry, Forest Service management and tourism. Few Native American sites have been identified.

The most significant heritage resources in this area are Mesa Falls Lodge, Bishop Mountain Lookout, Squirrel Meadows Guard Station, and Warm River Fish Hatchery. These sites receive high public visitation and have economic values associated with tourism.

Heritage resources in this area have been impacted by logging, road construction, historic building removals, and the North Fork Fire.

Madison Plateau - The Madison Plateau contains one of the lowest frequencies of heritage resource site on the Forest. Relatively extensive inventory has identified only 25 sites. The majority of these are tie hack sites associated with the Yellowstone Railroad. Native American sites are few and seem to be related to transitory movements through the area. The only site identified as suitable for enhancement and interpretation is the Big Springs Fire Lookout.

Teton Range - The Teton Range has high frequencies of Native American sites in the upper reaches of the drainages. Over 79 heritage resource sites have been identified. The vast majority are associated with high altitude adaptations by Native Americans. This area may also contain spiritual sites important to local tribes. Historic Euro-American sites are generally related to early 1900's ranching.

This area has high economic values for heritage resource tourism with an emphasis on high altitude adaptations.

Big Hole/Palisades - This area contains over 100 heritage resource sites with most sites located along the northwestern edge of the Big Hole Mountains. The majority of these sites are Native American hunting camps and lithic workshops. Historic Euro-American sites are associated with early 20th century mining and ranching. The Palisades Mountains area is one of the least inventoried areas of the Forest. Site types and frequencies are relatively unknown.

There is potential to enhance and interpret early 20th century limekiln and mining sites. Interpretation of a National Register-eligible Native American site at Table Rock Campground also has potential.

Caribou - The Caribou Range is one of the least inventoried areas of the Forest, however, 50 heritage resources have been identified. All but two sites are Native American hunting camps, lithic workshops and volcanic glass quarry sites. This area also contains the Currant Creek and Brockman Guard Stations, Forest Service administrative sites eligible for the National Register of Historic Sites. Potential exists for interpretation of the guard stations as early 20th century Forest Service sites.

Quality of Life

The Center for Business Research and Services of Idaho State University has conducted recent surveys of Quality of Life perceptions among area residents in Fremont County and the City of Idaho Falls. These two areas are vastly different in terms of population, income structure, employment opportunities, and other demographic characteristics. In both surveys, many of the questions relate to concerns people have with regard to their everyday lives—things like shopping and local government services. The amount of information presented which relates to the Forest is limited. The surveys do provide some insight into how area residents perceive their living environments.

Fremont County

Air Quality and "Open Spaces and Green Spaces" were the quality of life attributes respondents were most satisfied with. Employment opportunities and the Availability of Retail Shopping were the attributes with the least amount of satisfaction. Among respondents, 43% felt that Tourism was the type of ideal business they would like to see locate in Fremont county. Some 34% felt the same way about General Manufacturing. Employment Opportunities, Level of Individual Well-Being, and Public Education were identified as being the most important in determining quality of life.

City of Idaho Falls

Favorable characteristics of life in Idaho Falls included a Low Local Tax Rate, Medical Services, and Salary and Wage Levels. In making choices among conflicting alternatives, respondents found these selections to be the most acceptable. Limit Economic and Population Growth (32%) and Increase Taxes and the Local Cost of Living (31%). The least acceptable choices were to Permit Degrading of the Environment (30%) and Increase Taxes and the Local Cost of Living (27%).

Minorities and Women

Various programs have been implemented on the Forest to focus the resources of these group members on Forest activities to the benefit of both the Forest and the individuals. This effort is reflected in Forest Service hiring, supervising and contracting procedures. Under authority of a number of civil rights and equal employment opportunity acts and executive orders the Forest intends to continue

- ◆ Eradication of all forms of illegal discrimination from facilities, programs, activities, contracting, and hiring practices.
- ◆ Positive action in helping to provide developmental opportunities for the disabled, minorities, women, and all other employees
- ◆ Providing coordinators for the Equal Employment Opportunity, Federal Women's, and Hispanic programs
- ◆ Civil Rights Action Team activities.
- ◆ Civil rights training for all employees.

Coordination with Other Agencies

The importance of coordinating management within the Greater Yellowstone Ecosystem has been recognized by the public land management agencies. To that end, the Greater Yellowstone Coordinating Committee was established in the early 1960's. This group consists of National Park and National Forest managers who meet twice yearly to discuss issues and improve coordination between the two agencies.

There are many examples of how the various National Forests and Parks of the Greater Yellowstone Ecosystem have coordinated management across jurisdictional boundaries. The agencies have an ecosystem-wide Grizzly Bear Recovery Plan. Changes in these uniform guidelines for grizzly bear management are coordinated among the Forests and Parks. Uniform regulations for recreation use in the area have been initiated for the 1995 summer season. Federal and state agencies in the GYE are implementing coordinated guidelines for management of noxious weeds and exotic plants. Fire management is another area where resources and policies are shared across Forest and Park boundaries. Currently the Forest is participating in the integrated winter sports planning taking place throughout the ecosystem. As the Revision for the Forest is implemented, coordination with fellow managers in the ecosystem will continue.

V. PRODUCTION OF NATURAL RESOURCES

TIMBER

Timber - Scale: Forestwide and Subsection

The amount of forested land by tree species group and age class on the Forest was displayed earlier in Table III-1.

Table III-23 displays the total gross volume growing on the Forest by species and by subsection.

Table III-23 Merchantable Volume in Thousands of Board Feet (MBF) by Species 1/								
	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Range	Big Holes/ Palisades	Caribou	Total

1/ MBF per acre (LP=6 1, DF=9 0, Mixed LP/DF=7 9, Other Mixed Conifer = 12 4, Spruce/Subalpine Fir=13 9, Aspen=3 2) x 57
 (About 57% of the forested land is tentatively suitable)
 LPP = Lodgepole pine, DF = Douglas-fir, MX = Douglas-fir/Lodgepole pine, MX3 = three or more conifer species mixed,
 S/F = Englemann Spruce/Subalpine fir, AS = Aspen

Tentatively Suitable Forest Land

While the volumes shown in Table III-23 exist on the Forest, not all acres are available for timber harvest. In order to determine which land can be managed for timber production a Tentatively Suitable Forest Land Classification process is used.

Tentatively suitable forest land is defined as land that is producing or is capable of producing crops of industrial wood and meets the following criteria

- (a) Has not been withdrawn by Congress, the Secretary of Agriculture, or the Chief of the Forest Service.
- (b) Existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions.
- (c) Existing technology and knowledge provides reasonable assurance that it is possible to restock adequately within 5 years after final harvest.
- (d) Adequate information is available to project responses to timber management activities.

Tentatively suitable acres for the Forest have been determined and the process is displayed in Process Paper C. This amounts to 703,100 acres or approximately 57 percent of the total forested land on the forest. Table III-24 below displays Tentatively Suitable Acres by Ranger District and Ecological Sub-section.

	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Range	Big Hole/ Palisades	Caribou	Total
Dubois	13,040	79,700	0	0	0	0	0	92,740
Island Park	0	91,100	64,000	47,640	0	0	0	202,740
Ashton	0	0	151,070	107,230	3,330	0	0	261,630
Palisades	0	0	0	0	0	33,580	30,730	64,310
Teton Basin	0	0	31,090	0	17,710	32,880	0	81,680
Total	13,040	171,800	246,160	154,870	21,040	66,460	30,730	703,100

The 703,100 acres shown above is 249,300 less than the 952,400 acres identified in the 1985 Land and Resource Management Plan. The primary difference between the two analyses is associated with the amount of nonforest acres. The 1985 analysis identified 390,300 acres of nonforest lands and the current analysis identifies 681,079 acres, a difference of 290,779 acres.

The current analysis utilizes more up-to-date data than in 1985. The Forest has more stand exam information than previous and land-sat data was used in areas where stand exam data did not exist. A comparison of the two analyses is found in Process Paper C.

Similarly, Table III-25 displays tentatively suitable acres by species and age class.

Table III-25 Timber Information by Subsections									
	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison Plateau	Teton Basin	Big Holes/ Palsades	Caribou	Total

Future Supply and Demand

The projected demand-supply situation in the United States implies rising prices for timber. In the U S. economy, demand and supply for market commodities are equated through price adjustments and the workings of the market. When demand increases faster than supply, price brings the two together by reducing demand and/or by inducing supply increases (USDA Forest Service, 1990 RPA Assessment).

In general, it is expected that the price of softwood roundwood will follow the historic trend and continue to increase faster than the rate of inflation for at least the next 50 years (USDA Forest Service, 1990 RPA Assessment), an indicator that demand from an increasing population will rise faster than supply can respond.

Supply

The local demand-supply situation generally reflects the national and regional trend. The following is a brief analysis of supply and demand for our area.

Table III-27 displays sources of timber that have been available in the past. The volumes shown, (except for private land which is an estimate) are averages from the past 4-year (FY 92-95) sell program from the agencies listed. While the actual amounts available in the future are unknown, all sources (except for the Targhee National Forest) are assumed to be constant for at least the next 3-5 years. Of the total, 15.1 MMBF or 51 percent historically came from the Forest. This includes sawtimber, roundwood, commercial and personal use firewood.

Table III-27. Average Volume per year available in local demand area.

Source	Total Annual Quantity (MMBF)	Sawtimber	Products
Targhee N.F.	15.1	8.8	6.3
Caribou N.F.	1.6	1.2	0.4
Bridger-Teton N.F.	0.2	0.0	0.2
Bureau of Land Mgmt.	3.2	3.0	0.2
State of Idaho	4.3	4.1	0.2
Private Land	5.0	5.0	0.0
Total	29.4	22.1	7.3

Demand

Table III-28 below displays the expected demand for wood products in our area from all users. It does not include previous demand from Louisiana-Pacific as they have announced they are closing their Rexburg mill. It also assumes the present number and mix of large and small timber operators will remain fairly constant.

Table III-28 Total Demand for all Mills and Users (MMBF)

Present Level	Survival Level	Maximum Efficiency Level
35.7	31.0	36.0

The current demand for wood in our area, all operators, large and small (including personal use firewood), is about 35.7 MMBF annually. The minimum level of timber demand, from all operators, necessary to meet the survival needs of timber industry and personal use in this area is 31.0 MMBF. This level of harvest will just barely provide for the existence of the current number of operators at their minimum operating level, plus meet the current demand for "walk-in-the door" products and personal use firewood. To provide for maximum efficiency of mill operation and meet all demands for wood products that small operators receive and meet the current demand for personal use firewood and walk-in traffic, the level of timber offer should be approximately 36.0 MMBF.

Reforestation/Timber Stand Improvement

Table III-29 indicates past levels of reforestation (Artificial and Natural) and Timber Stand Improvement (Thinning) Activities that have occurred on the Targhee National Forest.

Table III-29 Levels of Past Reforestation and Timber Stand Improvements Activities

	Reforestation Acres	TSI Acres

1991	3,152	1,210
1992	2,874	397
1993	3,163	759
1994	4,361	493
1995	2,753	111

LIVESTOCK GRAZING

Livestock Grazing - Scale: Forestwide and Subsection

Approximately 79 percent of the Forest's 1.88 million acres are in range allotments. An estimated 67 percent of this area is suitable for grazing. Areas suitable for grazing have been determined by field range surveys. There are 154 allotments (76 cattle, 78 sheep) on the Forest where livestock grazing occurs. Of these 154 allotments, 15 sheep allotments are vacant and no grazing presently occurs. The current livestock use on the Targhee is 148,065 Animal Unit Months (AUM's). Permitted livestock consists of 21,696 cattle and 72,005 sheep. A summary of grazing activity by subsection is displayed on Table III-30.

Currently, 182 permittees hold 201 grazing permits which authorize grazing on the Forest. Nearly all of the permittees are dependent on National Forest grazing privileges to sustain all or part of their livelihood. The fee paid to graze their livestock is based on a grazing fee formula established by Congress.

Livestock grazing has been a use of both forested and nonforested plant communities throughout the Forest since before 1900. Effects of grazing, coupled with fire suppression, over time have promoted changes in species composition and biodiversity within grazed areas. Although effects are noticeable in sagebrush, aspen and grazed forest communities, they are especially critical in riparian communities. For additional information see the herbaceous/shrub vegetation section.

Chapter

IV

Environmental Consequences

CHAPTER IV ENVIRONMENTAL CONSEQUENCES

READERS'S GUIDE - In this chapter you will find:

A description of the Consequences of implementing the alternatives with respect to the following components and key issues:

- Ecological Processes and Patterns and Key Issue Patch Size;
- Physical Elements Component;
- Biological Elements Component and Key Issues Riparian Health, Elk Vulnerability and Grizzly Bear Habitat;
- Forest Use Occupation and Key Issues Access and Wilderness;
- Production of Natural Resources and Key Issue Timber Volume.

The consequences are described in terms of Consequences Common to All Alternatives, Consequences Which Vary by Alternative, and Cumulative Effects

I. ECOLOGICAL PROCESSES AND PATTERNS

This component is described in two parts. "Ecological Processes" discusses the effects of each of the alternatives on the natural causal agents of fire, insects, and disease. "Ecological Patterns" discusses the effects of the alternatives on several important parameters which describe ecosystem conditions and spatial relationships.

The key issue element for this component is patch size. The indicator for this element is the area restricted to opening sizes smaller than the range of variability. A full discussion can be found at the beginning of the "Ecological Patterns" section in this component. Briefly, patch sizes would be smaller than the historic range under all alternatives in the Centennial Mountains, Island Park, Madison Plateau, and Teton Range subsections, largely due to implementation of the standards and guidelines to protect goshawks. Each alternative also has some restrictions to protect visual quality or grizzly bear habitat; these additional restrictions are greatest in Alternatives 3-M through 6. However, since timber harvest is scheduled on less than 15 percent of the forested lands in these subsections, the scope of adverse effects deriving from smaller patch sizes is expected to be minor.

ECOLOGICAL PROCESSES

Fire

The role of fire as an ecosystem disturbance agent has been greatly diminished by fire suppression since the early 1900's. To sustain healthy ecosystems on the Forest it is important to reestablish fire as a disturbance agent. This can be done by allowing lightning-caused fires to burn (prescribed natural fires) or by intentionally setting fires (prescribed management-ignited fires) to achieve specific management goals. Using prescribed fire in concert with silvicultural treatments to reestablish historic fire intervals should reduce the suppression costs and resource losses caused by severe wildfires. The following indicators measure how likely the Forest is to use prescribed fire as a tool in the next decade, given the risks and costs involved.

Indicators

- 1 Acres where use of prescribed fire is allowed, with few restrictions.
- 2 Acres where timber harvest is allowed with few restrictions This tends to reduce the risks associated with using prescribed fire.
3. Miles of motorized road and trail access. Access can reduce the risks and costs associated with prescribed fire.

Consequences Common to All Alternatives - Fire management plans are required for portions of the Forest that will receive prescribed burning To date, only one such plan has been written, the Jedediah Smith Wilderness Fire Plan This fire plan has not been approved, it is estimated that this fire plan would be approved at about the same time as the FEIS for the Revision. This fire plan applies to all alternatives except Alternative 1. This plan will result in increased natural fire ecology within the Wilderness, with the most potential for stand replacing fires in the northern portion. Stand replacing fires would only occur under drought conditions. In the southern part of the wilderness, fires would be expected to remain small and burn in isolated groups of trees.

Forestwide it is estimated that some 11,000 to 21,000 acres of the sagebrush/grass type will be burned in the first decade in all alternatives, which amounts to about 4 to 8% of this type on the Forest. The effect of this will be to move acres with dense sagebrush canopies to earlier seral stages where sagebrush is less dominant This will create more of a mosaic of age classes than currently exists, thereby improving diversity by reestablishing grasses and forbs on these sites. However, the magnitude of this program is not sufficient to significantly alter the seral class distribution of sagebrush/grassland overall. Although the existing seral class distribution of this type is unknown, preliminary studies indicate the Forest supports a higher percentage of mid- and late-seral stages than existed historically

All alternatives allow the use of prescribed fire to some extent. Acreages of other vegetation communities to be treated with fire are unknown in any alternative, but the likelihood that management will use this tool varies by alternative.

Consequences Which Vary by Alternative - Some restrictions are placed on the use of prescribed fire in all alternatives Reasons for the restrictions vary, but are primarily concerned with maintaining existing wildlife habitat and visual quality. Table IV-1 shows, by alternative, the number of acres where prescribed fire is allowed without significant restrictions on its use. Alternative 2 allows the most use of prescribed fires, and Alternative 5 the least. However, the differences among alternatives based on this indicator are not large.

The inability to use timber harvest or other methods to manipulate fuels and stand structures prior to a fire can significantly increase the risk of prescribed burning in the older age class forested stands Managers are less likely to use fire as a tool when the risk of escape is higher. Table IV-1 shows the number of acres where timber harvest is allowed with few restrictions for each alternative. Alternatives 1 and 2 allow the most fuel manipulation via harvest, Alternatives 3 and 3-M a significantly lower amount, and in Alternatives 4, 5 and 6 harvest is very restricted.

Motorized road and trail access to prescribed burn areas can be important for reducing risks and costs associated with prescribed fire. Roads and trails can serve as containment lines and provide escape routes Motorized access route mileage is summarized by alternative in Table IV-1. Motorized roads and trails generally decrease from Alternative 2 through Alternative 6. Alternative 1 falls between Alternatives 2 and 3 on this factor

Based on the three indicators, Alternatives 1 and 2 would allow for the highest use of prescribed fires, Alternatives 3 and 3-M significantly lower amounts, and Alternatives 4, 5 and 6 the least.

Cumulative Effects - Overall, the low number of acres scheduled for timber harvest and the restricted motorized access across the Forest will limit the use of prescribed fire for all alternatives, especially in the forested types. Alternative 2, with the highest number of acres scheduled for harvest, only harvests 1.7% of the existing mature-or-older forested acres over the next ten years. Additional vegetation manipulation will occur via nonscheduled harvest (including unsuited lands) such as firewood removal, but this small amount of fuel manipulation is not enough to allow managers to restore fire over large acreages with acceptable risks. For community types where fire intervals are outside their historic range, all alternatives are expected to delay a return to more natural fire regimes for at least the next decade. A discussion of these effects by community type follows.

Indicator	Alternatives						
	1	2	3	3-M	4	5	6
Prescribed Fire							
Prescribed Fire Allowed with Few Restrictions 1/ (Thousand Acres)	1,282	1,401	1,302	1,232	1,223	1,202	1,256

Connectivity							
Acres of Aquatic Zones where Connectivity is Maintained (thousands of acres)	342	325	448	512	533	590	793
Forested Acres In Mature-or-Older Age Classes 3/	903,800 78.3%	901,000 78.2%	908,800 78.5%	906,600 78.7%	910,500 79.0%	913,100 79.2%	918,000 79.6%
1/ Prescriptions 3 1.1, 3 1.2, 3 2, 5 1, 5 1.3, 5 1.4, 5 1.5, 5 2.1, 5 4, 5 9.1, 6 1, 2 1.1, 2 2, 2 7, 1 1.6, 1 1.7, 1 1.8, 1.2, and 1.3. 2/ Includes all forested lands within prescriptions 5 1 and 5.1 3 3/ Assumes all harvest leads to reduction of mature component. Also assumes no ingrowth into the mature category in the first decade. Percents are percentages of total forested acres. 4/ The word "open" means the roads and trails do not have any restrictions on motorized use.							

Sagebrush/Grass Ecosystem - With the removal of several fire cycles from these ecosystems, the preponderance of big sagebrush stands fall within the moderate to dense canopy coverage class (greater than 15% canopy coverage). Under all alternatives, only approximately 4 to 8% of the Forest sagebrush/grass acres are projected to be manipulated during the first decade. As a result, the majority of the big sagebrush acres will continue to decline in overall watershed conditions (loss of understory vegetation resulting in increased susceptibility to erosion, reduced water infiltration and decreased organic matter recruitment).

As these ecosystems simplify, becoming a homogeneous dense canopy of dense sagebrush, they become increasingly susceptible to fires of higher severity and intensity than what historically occurred. Implications of such fires include

1. Potential for loss of species not adapted to these "altered" fire regimes (e.g., Idaho fescue),
2. Loss of nutrients and a lowering of site productivity potential (more nutrients being stored within the dense overstory versus within the soil profile as historically - thus being more susceptible to loss through ignition),
- 3 Higher potential for having more acres severely burned with subsequent chances for altering the soils physical and chemical properties,
- 4 Alteration of the natural resistance and resiliency of the soils

Lack of management within the sagebrush/grass ecosystem will also result in more acres which historically supported sagebrush/grass being converted to conifers and subsequent decrease in overall inherent site productivity

Aspen Ecosystem - Aspen is mainly found on soils that have a high inherent productivity due to the nutrient cycling (leaf fall) that occurs within healthy stands. Over time as conifers invade these sites the soils begin to acidify and nutrients are leached out of the productive surface layers to lower depths within the soil profile. If left unchecked, these soils will mature and develop into soils more suitable for conifers and less likely to support healthy vibrant aspen communities. This will reduce future options or making future options more at risk for success

Currently 93% of the aspen on the Forest is mature or at pathological rotation age. Inability to regenerate significant amounts of aspen by fire will maintain most of this type in the mature class, and will result in aspen's being replaced by conifers in many cases. Where this occurs, the ability of the soils to support aspen may be lost due to changes in soil chemistry or due to loss of clone root vitality. Severe fires are more likely to occur where conifers have become mixed with aspen, which would tend to regenerate aspen as long as fires are not so hot that they destroy the aspen root systems (most root nodes for sprouting are 3-6 mm below the surface).

Dry and Moist Douglas-fir, and Mid and Lower Elevation Subalpine Forest Fire Groups - These fire groups occur within all subsections. Mean fire intervals within these fire groups indicates that one or more fire cycles may have been removed from these areas mainly through fire suppression. Results of altering the fire regimes in these fire groups include the following:

1. Thickening of the forest - potential loss of certain habitats (e.g., aspen stands, wet/dry meadows, riparian areas etc.) due to encroachment
- 2 Accumulation of more large organic materials on the forest floor. As organic matter accumulates, decomposition rates decline and nutrient cycles stagnate. Nitrogen mineralization rates decline.

3. Decrease in stream flow and on-site water balance. Increase in interception, evaporation and transpiration Available water is less.

4 Development of ladder fuels

Implications if fires of higher intensity and severity were to occur are as follows:

1. The potential increases for the loss of species not adapted to these "altered" fire regimes (e g., old, past fire-resistant Douglas-Fir).

2. Loss of nutrients and a lowering of site productivity potential. Storing more nutrients above ground in the denser (more stems per acre) forest canopy instead of the soil profile as was historically the case makes them more susceptible to loss through fire

3 There is a higher potential for having more acres severely burned with subsequent chances for altering the soils' physical and chemical properties or of developing water-repellant layers with subsequent sensitivity to increased overland flows and erosion.

4. The natural resistance and resiliency potential for the soils would be altered, requiring longer recovery time and thus a longer risk period for resource damage.

Historic forest structures of large, widely spaced Douglas-fir trees would not be restored during the first decade. Susceptibility to Douglas-fir beetle and western spruce budworm are expected to remain high due to dense stocking and multiple-storied structure.

Due to the long fire intervals (50-350 years) in the subalpine fir type, the historic fire patterns most likely have not been significantly changed due to fire suppression. Failure to reintroduce fire in subalpine fir within the next decade is not expected to cause important impacts to this community type.

Lodgepole Pine - Historic fire regimes in the lodgepole pine community type have not been seriously disrupted on the Forest. Significant lodgepole pine acreages have been returned to early age classes by past timber management, and within the Greater Yellowstone Ecosystem a large proportion of this type was affected by the fires of 1988. Although the possibility of severe stand-replacing fires still exists within this type, such fires are in line with what historically occurred The consequences of not reintroducing fire to this type are expected to be insignificant over the first decade.

High Elevation Whitebark Pine - Lack of fire reintroduction at high elevations where whitebark pine is found may contribute to the decline of this species. Newly burned areas which provide seedbeds will continue to be lacking. Since much of the whitebark pine is mixed with subalpine fir, fires would likely be of high intensity leading to loss of mature whitebark pine trees. Both these conditions would reduce opportunities in this species for improved genetic resistance to white pine blister rust via gene recombination.

Insects and Disease

The environmental consequences discussed here focus primarily on pest management through forest vegetation manipulation. Forest management on timberlands provides the best opportunity to prevent or reduce the amount and impact of pest-related damage, although direct actions against pests may be necessary in specific (small scale) situations, as it relates to forest vegetation. With greater opportunity to manage forest vegetation, less damage would be anticipated. Areas managed intensively for timber would present the greatest opportunity to reduce or prevent timber losses, while areas managed nonintensively for timber production would have anticipated higher timber losses. Another method in treating insects and disease is the use of baiting or trap trees. Prescribed fire may be an appropriate tool in managing insects and disease, under some conditions.

Reducing competing vegetation in plantations increases available soil moisture and available light, and is essential for acceptable seedling survival and growth. Controlling tree densities in timber stands improves tree health and vigor and greatly increases their resistance to insect attack. Replacing existing stands which contain a component of overmature, decadent trees with young trees reduces mortality caused by insects and disease.

Indicators - Amount of treated acres of mature and older age classes

Consequences Common to All Alternatives - All alternatives allow some treatment of insects and disease, including vegetation manipulation. However, the intensity of application and opportunities for managing pests will vary according to the kinds and intensities of resource management planned for each alternative. Plantations of seedling, sapling and pole-size stands existing from previous vegetation manipulations will be treated during this planning period in order to enhance vigor and growth. The amount of treatment in these stands will be about the same for all alternatives.

All alternatives allow insects and disease to play their natural role in ecological succession in one or more management prescription areas. Endemic levels of insects and disease are natural and should be expected.

Vegetation management in developed recreation areas should result in improved health of the vegetation, decreased tree mortality, and fewer hazardous trees. Vegetation management in developed recreation areas should remain about the same as the current situation assuming the same level of funding as in the past.

Consequences Which Vary by Alternative - The amount of forested vegetation manipulation varies in each alternative. The alternatives with the most acres in the 5-series prescriptions allow for the most vegetation management. Alternative 2 allows the most forest management and Alternative 6 the least (see Table II-1 & Table IV-22). While the level of insects and disease activities expected from each alternative is difficult to measure, the amount of vegetation manipulation in each alternative is not significantly different.

Cumulative Effects - All alternatives provide a low level of vegetation management, and will not affect levels of insect and disease activity significantly from past forest plan activities. While the levels of vegetation management are lower than the previous planning period, treatment of mature stands at any level is beneficial in reducing insect and disease conditions.

Under all the alternatives pest-caused mortality would be expected to increase as mature timber stands continue to become overmature. This could result in both an increased level of annual losses, and the increased possibility of large periodic losses from insect and disease epidemics. Pest-caused mortality would likely increase as vegetation management decreased, though the differences between alternatives are not likely to be significant.

ECOLOGICAL PATTERNS

Patch Size

Key indicator - Area restricted to opening sizes smaller than the range of variability.

Consequences Common to All Alternatives - The size of forested patches in the Centennial Mountains, Island Park, Madison and Teton Range Subsections were relatively large historically, based on preliminary analysis. All alternatives will limit portions of these subsections to small opening sizes of one-half to 40 acres. This has the effect of creating patch sizes smaller than what historically existed. For all alternatives this situation is the result of implementing goshawk standards and guidelines. Within 5,400-acre foraging areas around each goshawk nest, opening size is limited to 40 acres or less (required by

Forestwide Standards and Guidelines) The four subsections having historically larger patch sizes contain 29 known goshawk nests. This translates to 156,600 acres where management will result in patch sizes smaller than what occurred historically. It is expected that more goshawk nests will be discovered as surveys continue, which would expand the area limited to 40-acre openings.

Consequences Which Vary by Alternative - Each alternative has some restrictions on the size of created openings which will move the Centennial Mountains, Island Park, Madison and Teton Range Subsections toward smaller patch sizes than existed historically. These limitations are generally included to protect visual quality or maintain grizzly bear habitat. Table IV-1 shows how many acres in these four subsections are placed under management prescriptions with opening sizes smaller than the range of variability. Alternatives 1, 2 and 3 have low acreages of restricted opening sizes, while in alternatives 3-M, 4, 5 and 6 these acreages are significant. However, since scheduled timber harvest in alternatives 3-M, 4, 5 and 6 occurs on less than 1.5 percent of the forested lands in the four subsections, any adverse effects on overall patch size are expected to be minor.

Cumulative Effects - The effect of small opening size requirements is to move outside the range of variability on portions of four subsections on the Forest. Past clearcutting, even while allowing up to 100-acre openings, has already created smaller patch sizes than existed historically in the Madison and Island Park Subsections. The situation could be exacerbated, particularly in alternatives 3-M, 4, 5 and 6, by requiring small opening sizes. However, since scheduled timber harvest in these four alternatives over the entire coming decade would occur on less than 1.5 percent of the forested lands in the four subsections, any adverse effects on overall patch size are expected to be minor.

Changes in patch sizes from what existed historically may affect individual species or ecosystem sustainability; however, the nature and magnitude of such effects on the Forest are not known at this time.

Connectivity

Indicators

1. Acres where aquatic connectivity is improved or maintained
2. Open motorized road & trail miles, which decrease connectivity
3. Percent of forested acres in mature or older age classes.
4. Patterns of mature forests

Consequences Which Vary by Alternative

Aquatic Influence Zone - Buffers intended to protect the entire aquatic influence zone and retain abundant riparian vegetation are utilized in Alternatives 4, 5, and 6. It is anticipated that these alternatives will restore natural levels of connectivity at a relatively rapid rate (10-30 years). Alternative 3-M, which protects the entire aquatic influence zone but retains less riparian vegetation, will eventually restore natural levels of connectivity but at a much slower rate than Alternatives 4, 5 and 6. Alternatives 2 and 3 employ narrower buffers and less protective standards and guides. It is expected that these alternatives will not restore natural levels of connectivity as effectively as alternatives 3-M, 4, 5, and 6. Alternative 1 provides the narrowest buffers and the least protective standards and guides. This alternative is expected to be the least effective in restoring natural levels of connectivity. Alternatives 1, 2, and 3 would not fully restore many stream reaches. Further information on aquatic ecosystems is shown in Table II-1 and under Aquatic and Riparian Resources in the Biological Elements section of this chapter.

Terrestrial Zone - Since open motorized roads and trails can interrupt wildlife movement and plant dispersal, the miles of such roads can be used as an inverse measure of connectivity. This is displayed for each alternative in Table IV-1. All alternatives show a gradually decreasing number of open motorized access miles. All alternatives are expected to reduce open road mileages from the existing conditions, thereby providing benefits to connectivity.

The amount and pattern of mature or older age classes across the Forest can also indicate levels of connectivity for species requiring this type of habitat. Higher amounts of mature age classes would likely provide greater connectivity. The percentage of forested acres in mature or older age classes is shown by alternative in Table IV-1. Across all alternatives the mature forested acres exhibit very little variation, ranging from 78.2% to 79.6%. Alternative 2, with the highest potential timber harvest acreage, would harvest 17,000 acres in the first decade, which translates to 1.4% of the forested land. This is not expected to create adverse effects on connectivity. Patterns of mature forest distribution do not vary by alternative. There is nothing in any alternative that would prevent managers from providing for connectivity by spatially arranging site-specific projects to approximate historic vegetation patterns.

Cumulative Effects - Clearcutting over the past decade in the Island Park and Madison Subsections has altered vegetation patterns and connectivity from what existed historically in some watersheds. Since no harvest of these watersheds is planned in any alternative within the next decade, there is little likelihood that these areas will move further from their historic patterns, nor will they be restored to historic patterns. Connectivity based solely on vegetation patterns has not been significantly changed by past timber harvest in other subsections.

Current levels of motorized road and trail density have reduced connectivity from historic levels Forest-wide. Reductions in motorized roads and trails proposed under all alternatives will eliminate some of these past effects. Road restrictions which occur near adjacent ownerships are expected to increase habitat connectivity over the current situation between Forest lands and those of its neighbors.

Along the western border of Yellowstone National Park, connectivity is significantly increased by road reclamation and restrictions in Alternatives 4, 5 and 6. More moderate gains are realized in Alternatives 1, 2, 3, and 3-M.

Changes in connectivity from what existed historically may have already affected individual species or ecosystem sustainability; however, the nature and magnitude of such effects on the Forest, and whether they exist, are not known at this time.

Adjacent Land Use Patterns

Land uses occurring adjacent to the Forest may or may not be consistent with management being proposed for the Forest. How the Forest fits within the context of its neighbors is an important factor in understanding the broad ecosystem patterns that result when the various alternatives are implemented. The appendices have information on current management of lands adjacent to the Forest.

Consequences Common to All Alternatives - For the most part, management of the Forest is expected to be compatible with adjacent land uses occurring on both public and private lands. However, there are some cases where conflicts may arise.

In all alternatives, the existence and effectiveness of winter ranges for elk, deer and antelope may be affected by activities on private land. Subdivision of agricultural lands for homes and businesses is expected to reduce winter range on private lands, thereby increasing pressure on the Forest's winter range. This is a concern especially in the Teton Range and Big Hole/Palisades Subsections, where housing developments are increasing rapidly in key winter range in the Teton Basin and Swan Valley areas.

Other inconsistencies between Forest management and adjacent jurisdictions exist where there is a strong commodity emphasis next to designated or recommended wilderness. Intensive management activities can detract from the wilderness character and experience by creating noise or visual impacts that are not consistent with wilderness. The most obvious example of this lies along the western boundary of Yellowstone National Park where the Forest's past intensive timber management ends in a sharp, straight line against the wilderness emphasis of the Park. In all alternatives this will remain visible for several decades.

Another situation that creates inconsistency is managing for nonmotorized recreation or wilderness adjacent to developed private lands. Private development and associated activities can detract from the intended nonmotorized experience by creating noise or visual impacts that do not appear natural.

In addition, keeping motorized vehicles off Forest lands is extremely difficult when individual homes have direct access to the Forest. This inconsistency exists in every alternative to some extent.

Consequences Which Vary by Alternative - Conflicts between grizzly bears and humans may become a problem where bear habitat exists next to private ranches or housing developments. Any conflicts that may arise would likely be tied to higher grizzly bear occupation of Forest habitat than currently exists. Although Grizzly Bear Management Units on the Forest do not change between alternatives, the likelihood of conflicts may be greater in alternatives which provide for better habitat effectiveness if there is a resultant increase in grizzly bear occupancy on Forest lands adjacent to other public and private lands (see the Biological Elements section of this chapter). Such problems would also be more prevalent in years when grizzly bear food sources are scarce. Adjacent lands most likely to experience conflicts between bears and ranching operations are in the Henry's Lake area, where grizzly bear habitat lies directly adjacent to active ranches. Private developments in Island Park, Henry's Lake Flat, Shotgun Valley and Robinson Creek/Fall River are those most likely to experience conflicts with grizzly bears.

There is an area of discontinuity between the Forest and the Gallatin National Forest in Alternative 2. The Lionhead area has been proposed as wilderness on both the Forest and Gallatin National Forests in all alternatives except Alternative 2. The Forest portion in Alternative 2 would have a commodity emphasis which would not match well with the Gallatin's proposal for wilderness. In addition, current management on the Gallatin is for intensive range management adjacent to a portion of Targhee land proposed for the Lionhead wilderness area. This creates a management inconsistency in Alternatives 1, 3, 3-M, 4, 5 and 6.

Except for Alternative 2, all the alternatives recommend the Lionhead Roadless Area for wilderness. The Lionhead recommended wilderness lies next to private lands which are rapidly being developed in Henry's Lake Flat.

Private developments in the Swan Valley area abut small portions of the Forest proposed for nonmotorized recreation or wilderness in Alternatives 1, 2, 3, 3-M and 4. Major portions of the Big Hole/Palisades Subsection will have this problem in Alternative 6 where proposed wilderness adjoins developments in Swan Valley and southwest of Driggs. The Big Bend Ridge area near Ashton is proposed for nonmotorized management in Alternatives 5 and 6. This is inconsistent with development that is beginning to occur on private lands in this area.

Cumulative Effects - The distribution and number of wintering deer and elk on the Forest depends on winter severity. The elk and deer winter range areas on the Forest are the upper elevational limits for these ranges. Generally, more winter range acres exist at lower elevations on BLM, State, and private lands, and a higher proportion of deer and elk winter at these lower elevations during most winters.

As a result, subdivision and loss of agricultural lands adjacent to the Forest and increasing pressure on winter range may trigger reductions in herd size over the long term. National Forest winter ranges cannot compensate for the loss of winter range acres at lower elevations on adjacent lands. If big game populations outstrip winter range capacity, winter range on the Forest could become degraded. The greatest impacts to the Forest from adjacent land uses are expected to result from conversion of agricultural lands to housing and businesses. Agricultural lands provide some habitat for a variety of species, and much of this habitat could be lost as development continues. Development may also create significant impacts on the Forest by increasing recreation pressures.

II. PHYSICAL ELEMENTS

Soils and Geology

Indicators

1. Miles or acres of road construction
2. ASQ (Allowable Sale Quantity)
3. Firewood and Products Volume
4. Roads Open, Restricted, Reclaimed/Obliterated (miles or acres)

Consequences Common to All Alternatives - Soil disturbances related to developed recreation sites, unmanaged dispersed (including OHV) recreation, concentrated developed areas (e.g. electronic sites, administrative sites, etc.), potential acres severely burned through prescribed fires within the sagebrush/grass and forested ecosystem, and fuelwood harvest would be similar under all alternatives.

Soil disturbance would continue to occur across approximately 350 acres within developed recreation sites and special use recreation sites. Soil disturbance would mainly be the result of maintenance or reconstruction activities, vehicles, and foot traffic in and between facilities. Such activities would have an effect on the soil's hydrologic function (e.g. through compaction and/or puddling) and site productivity (e.g. erosion).

Soil disturbance from unmanaged dispersed recreation and OHV use will be one of the main challenges to soil quality management. Demand for these uses will continue to escalate with corresponding concerns. At this time, it is difficult to project which of the alternatives would present more concerns to soil quality.

Soil disturbance would continue to occur across approximately 110 acres of concentrated developed areas. Soil disturbance would be the result of construction/reconstruction/maintenance activities and vehicular/foot traffic. Areas of disturbance would be susceptible to being eroded, with a subsequent loss in site productivity.

Severely burned conditions have the potential of occurring across 560 acres (5% of the area) where prescribed fire is used within the mountain big sagebrush/grass ecosystem. If areas of severely burned conditions occur in larger patches (acre or more), these areas would be more susceptible to erosion and would require a longer recovery period, thus presenting a longer risk period.

Approximately 38 million board feet of personal use fuelwood would be removed within the first decade. Areas designated for personal use and commercial fuelwood gathering would be susceptible to reductions in soil quality through such detrimental disturbances as displacement, compaction, puddling and removal of large woody debris necessary for maintenance of long term site productivity. The development of random skidding and access roads is also a concern within fuelwood areas since there is a tendency to drive up to each log or snag harvested.

Consequences Which Vary by Alternative (Refer to Table II-1)

Scheduled Timber Harvest (ASQ Lands) - Land surface disturbed by a variety of logging systems (tractor/cable) and cutting prescriptions (primarily shelterwood harvests) was evaluated. Under Alternative 6 no scheduled timber harvest would occur, thus no surface disturbance. Of the remaining alternatives, Alternative 5 would result in the least acres disturbed i.e., 675 acres over the coming decade. Using Alternative 5 as a base, the remaining alternatives (in ascending order) would expose twice as much (Alternative 4); three times as much (Alternatives 1, 3 and 3-M); and four times as much (Alternative 2) the amount of bare soil as Alternative 5. Areas of bare soil could be either compacted, displaced or puddled or a combination of these detrimental conditions. These areas would be susceptible to erosion and subsequent loss in site productivity. Disturbed areas would be the result of timber

harvesting practices such as skidding, skid trail networks, landings, etc. Ground based harvesting techniques may approach or exceed the 15% soil disturbance threshold but should be held to acceptable levels by adhering to the Soil Quality Standards and Guidelines.

Nonscheduled Timber Harvest - Timber harvesting would also occur on nonASQ Lands (unsuitable lands). Timber removal on nonASQ Lands would be in response to other resource needs, for instance, to remove hazard trees from developed recreation areas, to improve visibility along roadways, wildlife needs etc.

It is possible, though currently unplanned, for substantially greater volumes of material to be harvested to meet ecosystem management objectives than has been the case in the past. Volumes of timber to be removed would, in all likelihood, vary with each alternative but the actual amounts that might occur are not known. Concerns to the soil resource would be similar to those expressed above on ASQ lands with the added concerns of a large number of these acres occurring on steep slopes (greater than 40 percent) and/or not being readily accessible.

Roads - Land removed from the productive land base due to existing and proposed roads would be least under Alternative 6 (4,978 acres). Using Alternative 6 as a basis for comparing the remaining alternatives, Alternative 5 would remove 4 percent more acres from the productive land base, Alternative 4 would remove 18 percent more, Alternative 3 and 3-M would remove 42 percent more, Alternative 2 would remove 57 percent more, and Alternative 1 would remove 78 percent more than Alternative 6. Presently, there are 11,424 acres removed from the productive land base from roads, which is higher than any of the proposed alternatives. These lands would be effectively removed from the Forest's total productive land base for the life of the road and would be susceptible to erosion/sediment. A high percentage of these acres occur within the aquatic influence zone, thus have a short delivery distance to a stream channel. One objective under the watershed activity schedule is to inventory roads, trails, culverts, fords and stream crossings within the aquatic influence zone by the year 2000. This inventory will identify problem areas and suggest remedial actions.

Miles of roads transecting soil types having mass instability concerns is least under Alternatives 6 (356 miles, of which 42 miles occur on slopes over 40%). The highest number of miles crossing sensitive soil types occurs within Alternative 2 (three times the miles within Alternative 6, 13% of which occur on slopes over 40%). The remaining alternatives (1, 3, 3-M, 4 and 5) have twice the miles of Alternative 6, and 14% of their miles occurring on slopes greater than 40%. These road segments would be susceptible to mass erosion (especially those slopes greater than 40%) and to being major sediment producers—depending on their drainage systems.

Although Alternatives 1 and 2 allow the most access (open roads) and acres available to cross-country motorized summer use (53% and 42% of the Forest available), it is difficult to predict if dispersal of increasing numbers of recreationists would result in more or less damage to the soil resource. Similarly, Alternatives 5 and 6 allow the least access (open roads) and acres available to cross-country motorized summer use (3% and 2% of the Forest available). It likewise is difficult to predict whether concentrating recreationists into less area would result in more or less damage to the soil resource. In all cases, administration, monitoring and enforcement would be key in limiting damage to the soil resource. Alternatives 3, 3-M and 4 are intermediary (in descending order) to the above alternatives with respect to access and area open to summer cross-country travel.

Acres placed back into productivity (stabilized and revegetated) through road reclamation/obliteration would be highest under 6 (6,446 acres) and least under Alternative 1 (2,616 acres). Alternatives 2, 3 and 3-M, 4, and 5 would be intermediary, in ascending order, as to the number of acres placed back into production. Obliterated roads would have a lower inherent site productivity than adjacent undisturbed sites but overall benefits from obliteration is beneficial to soil and watershed conditions.

Range - Soil disturbance (areas with inadequate ground cover having exposed soil or areas where soil conditions are in a downward trend, e.g. eroding) would be least under Alternatives 4, 5, and 6. Alternatives 2, 3, 3-M would be intermediary Soil disturbance would be highest under Alternative 1 These areas would be susceptible to erosion and decreasing site productivity.

Dispersed Recreation - Land surface disturbance within areas managed for dispersed recreation would be potentially greatest under Alternatives 1, 5 and 6 because they have the fewest acres on which dispersed recreation sites would be more strictly managed. Alternatives 2, 3, 3-M, and 4 would place more dispersed sites under management and potentially result in less soil damage. Foot traffic and vehicles would be the main source of soil disturbance resulting in compaction, displacement, or puddling. These areas would be susceptible to erosion and have lower productivity potentials than adjacent undisturbed areas.

Cumulative Effects Common to All Alternatives - Based on the level of activities being projected within the various ecosystems, some cumulative impacts will be similar across all the alternatives. The ecological cumulative impacts to soils are described in the Ecological Processes and Patterns section

Because all of these alternatives call for management outside the historical range of mean fire intervals thus perpetuating altered ecosystems, it is very important to mitigate, protect or intensively manage these ecosystems to achieve and maintain the desired future condition These ecosystems are susceptible to fires of higher intensity/severity.

It is anticipated that dispersed recreation may increase over the current situation by 40% over the next decade thus having the greatest potential increase in relation to other Forest uses. Demands and potential conflicts by this group of users will continue to escalate in the future. Potential cumulative impacts from this use could be very similar under all alternatives (e.g., compaction/displacement, loss of vegetation ground cover, increased erosion potential, rutting, rill/gully formation, etc.).

Cumulative Effects Which Vary by Alternative

Management-Induced - Open roads also have the potential to produce continued cumulative impacts on soil quality (erosion and sedimentation) and overall watershed values. As mentioned previously, of particular concern is the potential for mass erosion occurring along roads that pass through soils having mass instability concerns (especially on those where side slopes are greater than 40%) Greatest potential for cumulative impacts (negative) from roads is under Alternative 2; continuing in descending order of impacts—1, 3 & 3-M, 4, 5, 6.

During the next decade, Camas Creek (Watershed 025) is the only watershed scheduled to have timber harvesting (in all alternatives except Alternative 6) that has 20% or more of the area in a hydrologically disturbed condition

Cumulative Effects Summary - Overall, soil quality on the Forest should improve over the existing situation under all alternatives. Soil quality standards and guidelines have been established to help direct soil quality improvement, maintenance, and/or enhancement within managed portions of the Forest. These standards and guidelines have been incorporated within the Revision.

Management-induced cumulative impacts (acres disturbed compared to total acres/alternative open for multiple use management) to the soil resource would be greatest under Alternatives 1 & 3-M (6%), Alternatives 2, 3, 6 (5%) and Alternatives 4 & 5 (4%).

Ecological cumulative impacts to the soil resource are very similar under all alternatives, especially within the sagebrush/grass and aspen ecosystems and within the Dry and Moist Douglas-Fir; and Mid and Lower Elevation Subalpine Forest Fire Groups.

There is a risk to soil quality within unmanaged portions of the Forest as mentioned under the previous section entitled "Ecological Processes." Because all the alternatives manage these ecosystems outside of their historic mean fire intervals then plans need to be formulated to mitigate, protect or intensively manage these ecosystems/fire groups to maintain the desired future conditions. Because this has not yet been done, there is a risk within these ecosystems/fire groups of having adverse effects take place to the soil resource through the occurrence of fires of higher severity and intensity than what historically happened.

Air Quality

Indicator - Potential to exceed Idaho or Wyoming Ambient Air Quality Standards.

Consequences Which Vary by Alternative - Alternative 1 allows the most activities on forest lands; this would subject air quality to more degradation from management activities than the other alternatives. Alternative 6 allows the least activities on forest lands—thus would be less likely to cause air quality degradation from management activities. An exception to these consequences would be the effects on air quality caused by catastrophic wildfire. Those effects are discussed in the cumulative effects section.

Cumulative Effects - Severe wildfire would be the primary event that would cause air quality degradation. Although there is risk of severe wildfire with all the alternatives, the risks would be higher with alternatives which limit the use of management activities the most. Activities such as prescribed fire (natural and management-ignited), timber harvest, or other vegetation manipulation methods used to reduce fuel loadings and modify stand structure, could decrease the risks of deteriorating air quality caused by wildfires on the Forest. Short-duration smoke events that meets state smoke management guidelines during early or late seasons could reduce the visual and health impacts caused by a high severity wildfire during the high visitor use season.

Caves

Impacts on cave resources would be the same for all alternatives. These would result from normal recreational use of the caves. Obtaining management funding for cave inventories, nominations, etc may be more limited under Alternatives 4-6 than in higher activity alternatives (1, 2, 3, 3-M).

Lands

There would be no impacts on lands from any alternative.

The following plans are incorporated in the Revision by reference.

- Land Adjustment Plan
- Right-of-Way Acquisition Plan
- Encroachment Plan

All three plans will be located in the landline section office on the Forest. These plans will subject to yearly updating by the landline section.

Minerals

Indicators

- 1 Area Open to Mineral Leasing
- 2 Area Open to Locatable Mineral Entry
- 3 Area Open to Mineral Material Entry

Consequences Common to All Alternatives - Under all alternatives mineral resources will be available for extraction. However, access and availability of lands for exploration and development will vary by alternative as indicated by Table IV-2.

The Forest Oil and Gas Leasing EIS will make the availability decision (acres available for oil and gas leasing) and will be coordinated with the Revision.

Consequences Which Vary by Alternative - Alternatives reflecting more developed recreation sites and facilities, more roadless areas which are to remain undeveloped, and more acres recommended for wilderness designation than in Alternative 1 will reduce the availability of lands for mineral exploration and development. As displayed in Table IV-2, Alternatives 1 and 2, in which no additional lands are recommended for wilderness classification than currently exist, provides the most land available for mineral exploration and development. Alternative 6, which has the most acres recommended for wilderness, provides the least amount of land available for mineral exploration and development.

Cumulative Effects - Alternatives which limit development activities on the Forest will have a tendency to also limit the utilization of mineral resources by restricting access and availability of lands for mineral extraction. Conversely, alternatives which provide opportunities for development activities will also provide opportunities for the utilization of mineral resources. Thus, cumulative effects of development activities in the long-run is beneficial to the utilization of mineral resources.

Table IV-2. Comparison of Minerals Effects (Acreages are in thousands)							
	Alternative						
	1	2	3	3-M	4	5	6
Acres Open to Locatable and Mineral Entry	1,383	1,414	1,324	1,277	1,340	1,197	968

The area analyzed in the Oil and Gas Leasing EIS is 1,102,828 acres, which excluded the existing wilderness and Island Park areas of the Forest. Thus, the actual available acreage figure for oil and gas leasing will be less than that shown for all alternatives. However, the acres by alternative are accurate for other leasables including phosphate and coal.

Historically discovery of valuable minerals in economic quantities to warrant development and production have been relatively infrequent on the Forest when compared to other forests in the region. The probability of mineral resource development is marginal given the current geologic knowledge of the Forest. The only current mineral activity of consequence is the extraction of travertine on the Palisades Ranger District. Before that, in the mid-to-late 1800's, the mining of lead in the western portion of the Forest was significant.

III. BIOLOGICAL ELEMENTS

Two parts make up the description of the Biological Component. These two parts are Aquatic and Riparian Ecosystems; and Terrestrial Ecosystems (upland forested and upland nonforested). Under each of these a key indicator is discussed first, with other indicators described subsequently.

AQUATIC AND RIPARIAN ECOSYSTEMS

Riparian

Key Indicator - Riparian acres not meeting DVC due to continual grazing and introduction of nonnative species (including acres in undetermined status)

The riparian vegetation along some streams would not be expected to improve to a desired condition within 10-15 years, even in the absence of livestock grazing. Under Alternative 1, riparian forage utilization would be managed to retain a specified percentage of plant material at the end of the grazing season rather than retaining a specified stubble height at the end of the grazing period. All other alternatives employ specified stubble heights

Compared to the existing situation; all alternatives close an additional 98,214 acres to grazing. Alternatives 3-M and 4 "phase out" grazing on an additional 172,186 acres and Alternatives 5 and 6 immediately close the same acres identified in Alternatives 3-M and 4. These acres that will be closed will show improvements in vegetation composition in the riparian communities faster than those acres with grazing.

Under Alternative 1, riparian vegetation trends will show slow improvements in species composition from fine-rooted species like Kentucky bluegrass, to coarse-rooted species like beaked sedge, on allotments with rotation grazing systems. Approximately 18,810 acres (68%) of the riparian vegetation will meet DVC, while 4,945 acres (18%) are predicted to move slowly towards DVC. Allotments with season-long grazing will tend to remain in their current condition (static); or as stream systems and water tables are lowered, the riparian communities will change to dryer upland species, lower successional riparian species, or introduced and weedy species. Loss of habitat for riparian sensitive plant species are greatest in this alternative. Compared to the existing situation, riparian acres not meeting DVC will increase from the current 3,650 acres to 3,963 acres during the first decade (Table II-1). Fish habitat conditions, and bank stability, would improve slowly to a moderate level commensurate with improved riparian vegetation. (Definitions and measurement protocol from Quigley et al , 1989.)

Compared to the existing situation, Alternatives 2, 3, and 3-M increase the riparian acres meeting DVC from 68% to 72%, while 19% will move toward DVC with the 4" HGL stubble height grazing requirement. Streamside *Carex* species will increase along streamsides and will better retain yearly sediments, increasing the habitat diversity, water-holding capabilities and hydrological conditions of the system. Sensitive plant habitats and biodiversity will increase moderately with these alternatives. Compared to the existing situation, riparian acres not meeting desired vegetation conditions will decrease from 3,650 acres to 2,476 acres (9%) during the first decade (Table II-1). This would result in a moderate rate of recovery and moderately high level of fisheries habitat quality commensurate with improved riparian vegetation and streambank conditions.

Compared to the existing situation, Alternatives 4, 5, and 6 increase the riparian acres meeting DVC from 68% to 76%, while 18% will move toward DVC, with the 6" HGL stubble height grazing requirements. Increased vegetation cover will hold greater amounts of sediment, accelerating changes over those in Alternatives 2, 3, and 3-M. These alternatives also have the greatest potential to improve riparian sensitive plant habitats and improve biodiversity by increasing habitat diversity. Compared to the existing situation, riparian acres not meeting DVC will decrease from 3,650 acres to 1,744 acres (6%) during the first decade (Table II-1). This would result in a rapid rate of recovery of degraded habitats and a high level of fisheries habitat quality commensurate with improved riparian vegetation and streambank conditions.

Alternative 1 will have 3,963 acres (14%), Alternatives 2,3, and 3-M will have 2,476 acres (9%), and Alternatives 4, 5, and 6 will have 1,744 acres (6%) of the riparian vegetation in undesirable, shallow rooted species. Plant communities with a high percentage of shallow-rooted species increase the risk

of flood events lowering stream channels, increasing bank-cutting, changing stream gradients, and changing riparian communities to upland communities with lowering of water tables.

Alternatives 2, 3, 3-M, 4, 5, and 6 will all show an increase in *Carex* complexes along stream edges that have a greater chance of trapping sediment and improving the vegetation diversity of the riparian areas

Water

Indicators

1. Number of stream crossings
2. Acres of timber harvest in headwaters
3. Miles of native cutthroat trout stream with at least 6" HGL (Hydric Green Line) stubble height remaining at the end of the grazing period
4. Miles of fish-bearing stream habitat with at least 4" HGL stubble height remaining at the end of the grazing period
5. Acres impacted by developed recreational sites in the aquatic influence zone as defined by the buffers described in prescription 2 8.3
6. Acres roaded in the aquatic influence zone

Consequences Common to All Alternatives - Land disturbance and impacts to riparian areas will take place under all alternatives, the magnitude of these effects will vary by alternative. Closure of roads and trails within the aquatic influence zone would create new sediment sources due to ground disturbance under all alternatives. This would be a short-term impact to riparian areas and water bodies, lasting a maximum of approximately three years (until the disturbed sites were stabilized) These closures would, however, provide a long-term benefit to aquatic and riparian resources once they became effective (i.e., when the vegetation was established). If road prisms are not removed where they exist in floodplains, even with road closure, floodplain and stream functions could be adversely affected by the confinement presented by these features.

There will be no difference between alternatives in the amount of water diverted from streams on National Forest System lands by private parties, for use under special use permits. There will also be no difference in the amount of water (instream flow and consumptive uses) claimed for National Forest purposes through the Snake River Basin Adjudication: no new uses after 1987 are claimed. There may be a difference between alternatives in the amount of water under application and license for consumptive use (e.g., for livestock watering), but the differences should be small. Compliance with legal requirements, such as meeting State water quality standards, will not differ between alternatives

Acres affected by developed recreational sites and special use permit recreation sites within the aquatic influence zone would vary little by alternative. All alternatives would have approximately 1,100 acres of disturbance associated with these sites within the aquatic influence zone. Impacts from dispersed recreation are discussed in the recreation section.

Consequences Which Vary by Alternative

Direct Impact - See Table II-1. Direct impacts to streams and riparian areas on National Forest System lands are of three general types.

1. Change in streambank, riparian soil, and riparian vegetation characteristics,
2. Direct in-channel alteration,
3. Change in the amount of sediment delivered to streams, and therefore the load that the stream must transport

Change in Riparian Soils, Vegetation, and Streambanks - Damage of riparian soils by compaction, displacement, rutting, or puddling can reduce riparian soil productivity through changes in infiltration characteristics and a reduction in the ability of soils to support desirable riparian vegetation. Changes in

the composition of riparian vegetation communities and loss of plant vigor result from such adverse impacts to soils, as well as from direct impacts from overuse by wildlife, livestock, or people. Refer to the key indicator discussion under Aquatic and Riparian Resources

Direct In-Channel Alteration - These actions include putting a structure into a stream and changing channel hydraulics, or changing some aspect of the stream's geometry (e.g., increasing its gradient) by mechanical alteration

Potential for direct impacts associated with road crossings would vary by alternative. The greatest potential would exist under Alternative 1, gradually decreasing until Alternative 6, which has approximately 2,200 fewer crossings than Alternative 1. This could be a tangible difference Forestwide, even between consecutive alternatives (e.g., Alternative 2 has about 400 fewer crossings than Alternative 1)

Change in Sediment Delivery and Load - Natural events, such as high spring runoff, may lead to both increased sediment delivery to streams and increased erosive energy to move the sediment. Roads are major sources of sediment, especially when they are near streams or cross them. Since forest roads contribute an estimated 85-90% of the sediment reaching streams in disturbed forest land (Burroughs, 1990), the amount of roads within the aquatic influence zone and number of stream crossings are used as indicators of sediment delivered to streams.

Many roads and trails located within the aquatic influence zone would be closed in all alternatives. Acres of open roads within the aquatic influence zone steadily decreases from a high of 9,552 acres under Alternative 1 to a low of 4,787 acres under alternative 6, which is half the acres affected under Alternative 1. Such a decrease in roads within the aquatic influence zone means a proportional decrease in the potential for sediment delivery to streams, for delivery of other pollutants, and for detrimental impacts to riparian areas. The influence of road prisms would still exist if they were not removed. Differences in impacts from road crossings would be the same as discussed under section 2, above (direct in-channel alteration). An inventory of roads will determine where there are problems and provide recommendations to reduce impacts to acceptable levels

Cumulative Effects

Hydrologic Effects - Manipulation of vegetation has the potential to alter streamflow regimes. Researchers have shown that creation of large openings, especially in small (i.e., headwater) watersheds allows for increased snow accumulation and more exposure to the sun. This results in higher peak flows that occur earlier than under preexisting conditions, having the potential to deliver more sediment to streams and destabilize channels. The increase in sediment delivery due to changes in peak flows cannot be calculated nor estimated

The highest potential for cumulative impacts from vegetation manipulation in headwater areas would exist under Alternative 2. Alternatives 1 and 3 have the next highest potential, and 3-M, 4, and 5 have the lowest, for alternatives having vegetation manipulation. There would be no impact under Alternative 6. From a watershed perspective, watersheds 10 (Buffalo River) and 12 (Warm River) appear to have potential for adverse cumulative impacts under all alternatives due to past activities. No additional harvest is planned in these watersheds. These are watersheds that would have approximately 30% of their headwaters in a hydrologically disturbed state for the decade, having stands that have already been manipulated and which would still be unrecovered by the end of the planning decade.

Although it is unlikely that any of the proposed alternatives would threaten the population viability of native cutthroat trout over the planning period, differences in rate of recovery of degraded habitats and overall habitat quality would result from implementation of various alternatives. Alternatives 1, 2, and 3 would protect the fewest acres within aquatic influence zones and would allow the greatest amount of potentially harmful activities associated with livestock grazing, timber harvest, riparian recreational use,

and roads and trails as displayed in Table II-1. Fisheries habitat quality, including that for native cut-throat trout, would be the lowest of any alternative under Alternative 1. Alternatives 1, 2, and 3 would result in a slow rate of recovery of degraded habitats, reduced water quality, and less habitat quality. Refer to Table II-1 for a quantitative view of riparian habitat change. Since alternatives 4, 5, and 6 would emphasize more protection of aquatic influence zones, they would result in a rapid rate of recovery of degraded habitats and the highest levels of water quality and fish habitat quality. Alternative 3-M would result in a moderate rate of recovery of degraded habitats and intermediate levels of water quality and fish habitat quality. All alternatives would meet State water quality standards.

Nearly all of the environmental consequences described for each alternative are cumulative in the sense that they reflect the environmental and management impacts of an accumulation of management actions that would occur under each alternative and that have occurred in the past. Many of these impacts have occurred over the last 100 years; some would cease with implementation of certain alternatives while others would continue over the planning period (10 to 15 years).

Wildlife Associated with Aquatic and Riparian Ecosystems

The effects of implementing the alternatives are displayed in terms of consequences to the following:

- Bald Eagle Nesting Habitat
- Trumpeter Swan Nesting Habitat
- Spotted Frog Habitat
- Common Loon Habitat
- Harlequin Duck Habitat

Bald Eagle Nesting Habitat

Table IV-3 displays the consequences of each alternative for bald eagle nesting habitat.

Consequences Common to All Alternatives - Forestwide standards and guidelines establish habitat management direction for all occupied bald eagle nesting territories, and any new territories which may become established. All recovery goals have been exceeded. Nesting habitat for all existing pairs and any new pairs will be maintained in all alternatives. This management direction will continue to have beneficial effects for the bald eagle populations on the Forest.

Management Indicator	Existing	1	2	3	3M	4	5	6
Bald Eagle Nesting Habitat								
# of Nest Sites on Forest	17	17	17	17	17	17	17	17
# of Territories on Forest	26	26	26	26	26	26	26	26
Trumpeter Swan Habitat	Forest-Wide Standards and Guidelines protect all nesting areas in all alternatives							
Spotted Frog Habitat (disturbance)	Most	Most	Moder	Moder	Moder	Least	Least	Least
Common Loon Habitat	Monitoring and Habitat Evaluation to be done in all alternatives							
Harlequin Duck Habitat	Forest-Wide Standards and Guidelines protect all nesting areas in all alternatives							

Cumulative Effects - Bald eagle nest zones and primary use areas occur on adjacent National Forests, BLM lands, State and private lands. Along the South Fork of the Snake River, a "Snake River Activity/Operations Plan" was approved by the BLM and the Forest Service in 1991. Bald eagle habitat management was a key component of that Plan.

Management actions of other agencies, such as management of fishing and fish populations by the State Fish and Game agencies, and management of river flows by the Bureau of Reclamation and the SE Idaho irrigators, may have positive or negative effects on the bald eagle population.

However, according to records which we have been able to compile from 1972 to the present, the bald eagle population has increased in southeastern Idaho.

Trumpeter Swan Nesting Habitat

Table IV-3 displays the consequences of each alternative for trumpeter swan nesting habitat.

Forestwide standards and guidelines for trumpeter swan nesting habitat apply in all alternatives.

Consequences Common to All Alternatives - Suitable habitat will be maintained for all existing nesting pairs plus any new nesting pairs which may become established.

Cumulative Effects - Many of the lakes and ponds historically used by trumpeter swans are naturally filling in with sediment and are becoming too shallow for swan use. Active management will be needed to help maintain suitable water depths for swans, or the lakes and ponds will not be usable.

Spotted Frog Habitat

Table IV-3 displays the consequences of each alternative for spotted frog habitat.

Consequences Which Vary by Alternative - Five aquatic influence zone management prescriptions have been developed for the seven alternatives. We evaluated how each alternative may affect spotted frog habitat as follows.

Influence of Buffer Widths - Bartelt and Peterson (1993) noted that spotted frogs were always within 2 meters of water, none left riparian habitats, almost all were associated with ponds until September when they left the ponds for nearby streams, and ponds within 50 m of permanent streams were an important combination of habitat characteristics. Based on this, the different buffer widths in each of the management prescriptions all appear to be adequate.

Some literature indicates that spotted frogs may move considerable distances after breeding; in these cases, the movements would be farther than any of the buffer widths in the management prescriptions. In these cases, we doubt there is much of a measurable difference in effect due to different buffer widths.

Timber Harvesting/Management - There is no data in the literature to suggest that spotted frogs are dependent upon a particular forested vegetation condition. Therefore, there is no difference between the alternatives in terms of effects from changes in forest vegetation due to timber harvesting. However, there may be a disturbance effect from the presence of human activity associated with timber harvesting. Therefore, Alternatives 1 and 2 which allow scheduled timber harvesting in the aquatic influence zones may have site-specific, short-term impacts on spotted frog populations and habitat.

Livestock Grazing - A recent conservation assessment for spotted frogs (USDA Forest Service, 1994b) listed concerns about possible threats to spotted frogs and habitat from livestock or grazing. (Concerns included such things as reduced vegetation in riparian areas, potential increases in water temperature, trampling, etc.) However, no documented studies were cited in support for these concerns.

In studies done on the Forest, Clark et al (1993 and 1994 plus errata page) reported there appeared to be no significant relationship between spotted frog occurrence and evidence of grazing. They stressed however, that no controlled study was performed investigating the effects of grazing on spotted frogs, and therefore appropriate caution should be exercised when evaluating the importance of the results.

Using an assumption that less grazing activity may result in potentially less effect on spotted frog habitat, Alternatives 4, 5, and 6 will have the least amount of potential disturbance; Alternatives 2, 3 and 3-M will have intermediate amounts of potential disturbance, and Alternative 1 the most amount of potential disturbance.

Recreation and Other Activities - Using an assumption that less recreation activity and other human activities in spotted frog habitat may result in less potential effects on their habitat, Alternatives 4, 5, and 6 will have the least amount of potential disturbance; Alternatives 2, 3 and 3-M will have intermediate amounts of potential disturbance; and Alternative 1 the most amount of potential disturbance.

Riparian Habitat Condition and Trend - In Alternative 1, 86% of the riparian acres are meeting DVC's or will be improving towards DVC's. In Alternatives 2, 3, and 3-M, 90% of the riparian acres are meeting DVC's or will be improving towards DVC's. In Alternatives 4, 5, and 6, 93% of the riparian acres are meeting DVC's or will be improving towards DVC's.

All alternatives are expected to maintain the current spotted frog distribution on the Forest. General habitat conditions are expected to improve with all alternatives, with the most improvement occurring in Alternatives 4, 5, and 6.

Common Loon Habitat

Consequences Common to All Alternatives - The Forest has an objective to evaluate the potential to provide and maintain suitable breeding habitat for common loons at the sites mentioned in Chapter III. If this evaluation proves that these sites are suitable breeding habitat for common loons, the Forest is to develop common loon management plans for these sites. Current habitat conditions will be perpetuated at these sites in all alternatives.

Harlequin Duck Habitat

Consequences Common to All Alternatives - There is no scheduled timber harvesting adjacent to any of the streams with documented breeding activity. Livestock grazing, existing recreation activity (existing trails, recreation facilities, dispersed use, etc.), and other human activities are not measurably different among the alternatives for the sites with documented reproduction. Existing habitat conditions will be maintained in all alternatives.

TERRESTRIAL ECOSYSTEMS

Upland Forested Ecosystems

Indicators - Acres and percent change in age classes of forested community types.

Consequences Common to All Alternatives - Potential for loss of individuals or populations, and suitable habitat for Payson's milkvetch *Astragalus paysonii* (sensitive species) is the same for Alternatives 1-6. Fire is thought to be an important part of this species' life cycle, as it inhabits lodgepole pine and lodgepole pine/Douglas-fir mixed forests in the seedling to pole age classes; and in disturbed areas and openings in mature age classes. (Fertig et al 1993)

Consequences Which Vary by Alternative - Table IV-4 shows the amount of change in percent of mature forest with timber harvest for each subsection, by alternative. Changes in the mature forest acres do not necessarily reflect a change to a lower age class. The range of management methods, from clearcutting to thinning, and use of prescribed fire, will create a variety of changes in the vegetation composition in the mature forest. Changes will range from conversion to grass/forb communities with seedlings, to open stands of mature trees with different understory species, resulting from different light and moisture conditions.

Alternatives 1 through 5 have various harvest rates in each of the subsections. Changes in the mature stands range from 0% to a maximum of 3.4% in these alternatives which is not a significant change of mature forests in any of the subsections. Forests in the mature age class will continue to dominate the landscapes in all alternatives.

Management for white bark pine is possible in all alternatives but timber harvest is limited in BMU's, Alternatives 5 and 6, and in wilderness. Fire as a tool is available in all alternatives.

Management acres in mature aspen stands is shown in Table IV-5. Management levels for all alternatives are insignificant in changing the age classes in aspen. Stands will continue to change to coniferous forest types, as Douglas-fir and subalpine fir trees increase and dominate the aspen stands. Disease and insects common within mature age classes of aspen will accelerate the change to coniferous forest types.

Table IV-4. Change in Percent of Mature Age Class Forest Due to Scheduled Timber Harvest Over the Coming Decade

	Lemhi/ Mecidine Lodge	Centennials	Island Park/ Madison	West Slope Tetons	Big Hole Palisades	Caribou	Forest Total
Current % Mature total forested ac	90 103,887	79 225,012	62 466,489	97 92,182	95 227,216	99 122,495	79.6 1,237,281

Alternative 6 % Harvest 1/ % Mature	0 0 90	0 0 79	0 0 62	0 0 97	0 0 95	0 0 99	0 0 79.6

1/ The percent change from a mature age class, undisturbed forest, to an early age class or mature forest with previous harvest.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Current Acres	106,193	106,193	106,193	106,193	106,193	106,193	106,193
% Mature	92.3	92.3	92.3	92.3	92.3	92.3	92.3
Managed Acres	3,250	5,590	3,840	3,200	1,500	760	0
% Change to Low Age Class	3.1	5.3	3.6	3.1	1.4	0.7	0
% Left in Mature Class	89.2	87.0	88.7	89.2	90.9	91.6	92

Cumulative Effects - Mature forest community types will continue to dominate the landscapes Forest-wide Aspen stands for all alternatives will continue to be converted to coniferous forests as Douglas-fir and subalpine fir increase within the aspen stands. Aspen across the forest will decrease as a component of the landscape, which decreases the total biodiversity of the landscape. Aspen stands provide natural wildfire buffers that change the fire rates and intensities across the landscape. Loss of aspen stands to conifers creates larger continuous stands that can have high fire intensities that increases the severity of wildfire on the landscape.

Coniferous forests will continue to mature increasing biomass, canopy cover and fuel loading within the stands. The understory will change to shade-tolerant species and also decrease in the number of species as the forest habitat becomes more uniform. As mature conifer forests continue along current trends, insects and disease will increase creating areas of dead trees and greater fuel loads, increasing the risk of large and intense wildfire. Open areas created by dead trees will provide sites for early seral species to establish and will increase the habitat and species diversity within large stands. Absence of periodic low impact fires will put most of the mature forest in jeopardy of stand-replacing fires over large areas due to fuel loading.

Coniferous forest species, especially Douglas-fir will continue to encroach into sagebrush/grass, mahogany, grass/forb meadows, riparian and mountain brush communities throughout the forest. Conversion of herbaceous and shrub communities decrease the biodiversity and habitat diversity of the mid-elevation and high elevation areas of the Forest. As forests mature, water requirements also increase which decrease water availability to wet meadows and riparian areas.

Whitebark pine stands will continue to decline across the Forest. Regeneration in most stands is low due to encroachment of other coniferous species and lack of fire.

Upland Nonforested Ecosystems

Indicators - Acres (and percent) meeting desired vegetation conditions (DVC).

Consequences Common to All Alternatives - Potential for loss habitat, individual plants or populations of upland sensitive plant species is dependent on projects, locations, and slopes. About 12,555 acres of sagebrush/grass community type are planned to be burned (10,755 ac.), sprayed (500 ac.) or rotobeat (1,300 ac.) to improve vegetation conditions over the coming decade. Management on these sites will account for a change in species cover type and composition. To achieve the 10,755 acre burning goal, an additional 10,000 acres may be partially burned. Acres scheduled for burning would be predominantly in late-seral sagebrush with canopy cover greater than 30%. Some acres of mid-seral sagebrush with canopy cover of 15-30% could be affected depending on burn design. Partially burned acres are assumed to be converted from late-seral to mid-seral. Management of the 12,555 to 22,555 acres of sagebrush/grass community type represents 4 to 8% of the acres that will move towards meeting DVC's over the next decade.

Cumulative Effects - A predominance of acres in high-seral and mid-seral stages will continue to dominate the landscapes under all alternatives. As shrub cover increases, productivity and biodiversity will decrease and potential for wildfires will increase. Lack of fire has decreased habitat potential for plant species that prefer early seral stage habitats such as *Penstemon lemhiensis* (sensitive species)

Canopy cover over 15% in sagebrush significantly impacts herbaceous species productivity and ability to reestablish over time. About 65% of the Forests range land is currently in late-seral stage due primarily to lack of fire in these communities. Resting or eliminating grazing will not show significant improvements over time in understory herbaceous species when high canopies of sagebrush occur (Winward 1991). These communities increase the risk of large acres wildfires that are of higher intensity and severity than was historically present under 12-40-year fire cycles. These unnaturally hot fires could alter subsequent plant diversity by destroying existing soil seed banks, burning deeper into crowns of bunchgrasses and perennial forbs (and subsequently killing these plants) and changing the physiology of the soils by changing soil conditions and productivity.

Upland and riparian communities will continue to decrease with encroachment of coniferous forest species. Mahogany stands are all in the high-seral stage and are becoming decadent due to lack of fire, and an increase in Douglas-fir establishment. Increases of spruce and subalpine fir along mid- and high-elevation riparian areas has decreased willow and other shade-intolerant riparian species within the riparian zone and increased the susceptibility of these sites to erosion.

Wildlife Associated with Terrestrial Ecosystems

Key indicator - Elk Vulnerability (EV)

Consequences Which Vary by Alternative - Table IV-6 displays the percent of the Forest which meets the EV threshold levels of the State Fish and Game Departments. (Process Paper D displays the details of this analysis on a watershed basis for each alternative).

The primary effect (that the Forest Service has control of) in this EV analysis is the density of open motorized roads and trails, and the amount of area open to cross-country OHV travel. Since Alternative 1 has the highest density of open motorized roads and trails, and the most area open to cross-country OHV travel, this alternative has the highest EV and the potential for a higher proportion of the bulls to be harvested, thus the lowest percentage of the Forest meeting State EV thresholds. Since Alternatives 5 and 6 have the lowest density of open motorized roads and trails, and the least area open to cross-country OHV travel, these alternatives have the lowest EV and the potential for the lowest proportion of the bulls to be harvested, thus the highest percentage of the Forest meeting State EV thresholds.

In Alternatives 2 and 3-M, within certain management prescriptions, use of all-terrain vehicles (ATV's) is permitted cross-country and on restricted roads and trails during the big game hunting season for retrieval of legally harvested big game animals. Before hunters can use ATV's to do this, certain conditions must be complied with (see specific management prescriptions). There has been no research or monitoring on how this provision might affect elk vulnerability. There is concern from some agencies and individuals that this provision might result in higher EV.

Cumulative Effects - All roads and trails receiving motorized use, and cross country motorized use, are incorporated into the EV analysis. Hunter-day densities were provided by the State Fish and Game Departments (see Process Paper D). If hunter-day densities change in the future, due to changes in hunting seasons, motorized access restrictions, or human populations, then this analysis will need to be updated.

Table IV-6 Consequences of each Alternative for Terrestrial Ecosystems - Wildlife Management Indicators Species and Habitats								
Management Indicator	Existing	1	2	3	3-M	4	5	6
Elk Vulnerability % of Forest meeting State Fish and Game thresholds 2/	42	58	72	83	91	89	98	98
Elk Habitat Effectiveness 1/	0.56	0.60	0.62	0.63	0.64	0.66	0.69	0.70
Elk and Deer Winter Range

% of acres meeting DVC	78	81	82	82	82	84	84	84
% of acres moving toward DVC	13	11	11	11	11	10	10	10
% of acres not improving	9	8	7	7	7	6	6	6
% of acres capable of being used for cross-country snowmachine use	38	38	38	38	38	38	38	38
% of acres closed to cross-country snowmachine use	22	22	21	23	34	28	42	62
Gray Wolf	Protected as a nonessential experimental population in all alternatives							
Primary Cavity Nesting Habitat 3/ All Primary Cavity Nesters Four Large Species	0.61 0.47	0.61 0.47	0.61 0.47	0.61 0.47	0.61 0.47	0.61 0.47	0.61 0.47	0.61 0.47
Forest Owl Habitat (Acres) 4/ Percent of All Forested Acres	985,000 79.6	970,000 78.4	968,000 78.2	971,000 78.5	974,000 78.7	977,000 79.0	980,000 79.2	985,000 79.6
Furbearer Habitat (Acres) 4/ Percent of All Forested Acres	985,000 79.6	970,000 78.4	968,000 78.2	971,000 78.5	974,000 78.7	977,000 79.0	980,000 79.2	985,000 79.6
Goshawk Habitat	Forest-wide S&G's provide the same protection in all alternatives							
Red Squirrel Habitat (Acres) 5/ Percent of All Forested Acres	928,000 80.0	938,000 81.0	936,000 81.0	938,000 81.0	942,000 82.0	945,000 82.0	948,000 82.0	953,000 83.0
Peregrine Falcon Habitat	Forest-wide S&G's provide the same protection in all alternatives							
<p>1/ Elk habitat effectiveness is based on open motorized road and trail densities during the spring, summer, and fall season, and hiding cover. A perfect rating would be 1.0, which would require no motorized access and 50 to 60 percent hiding cover. The numbers in the table are a weighted average for the entire Forest based on watershed analysis.</p> <p>2/ Elk vulnerability is based on motorized access density during the general elk hunting season and hunter-day densities. The numbers in the table are the percent of the Forest meeting elk vulnerability threshold levels set by the State Fish and Game Departments.</p> <p>3/ The numbers in the table are an index of biological potential for primary cavity nesting species. An index of 1.0 would mean that enough snags of the right sizes exist on every forested acre of the Forest to meet 100 percent of the habitat requirements for all primary cavity nesting species. The four large species are Williamson's sapsucker, northern flicker, hairy woodpecker, and rednapped sapsucker.</p> <p>4/ These are acres of mature and older forested habitat.</p> <p>5/ These are conifer acres with trees old enough to bear cones. Cone-bearing ages were defined as pole, mature, and older size classes and age classes.</p>								

Elk Habitat Effectiveness (EHE)

Consequences Which Vary by Alternative - Table IV-6 displays how EHE changes on a forestwide basis for each of the alternatives. (Process Paper D displays EHE analysis in more detail on a watershed basis for each of the alternatives)

The primary factor in EHE analysis is the density of open motorized roads and trails. Since Alternative 1 has the highest density of open motorized roads and trails, it has the lowest EHE value. Since Alternative 6 has the lowest density of open motorized roads and trails, it has the highest EHE value.

A lesser factor in EHE analysis is the amount of hiding cover. In all alternatives, the amount of hiding cover improves slightly as new seedlings grow into sapling stands in previously logged areas of the Forest. The amount of timber harvesting proposed in all alternatives is less than the number of acres growing into better hiding cover.

The overall effect from improving EHE (which ranges from .60 in Alternative 1 to .70 in Alternative 6) is a probable wider distribution of elk into areas previously under utilized because these areas had high motorized access densities and densities are now reduced. Improving EHE does not mean elk populations will increase.

Cumulative Effects - All roads and trails receiving motorized use are incorporated into EHE analysis. All previous timber harvesting, plus all future proposed timber harvesting are incorporated in EHE analysis.

Elk and Deer Winter Range

Consequences Common to All Alternatives - The feed ground in Rainey Creek would be phased out in all alternatives, within five years of the Record of Decision. Research studies have shown that deer and elk have high fidelity to winter range areas. Even though it would be the intent of the Forest Service and the Idaho Department of Fish and Game to encourage these animals to winter on adjacent natural winter ranges, this may not be successful. If not successful, there could be a reduction in the deer and elk population in this area with the phaseout of the winter feed ground.

Consequences Which Vary by Alternative - The amount of winter range acres meeting desired vegetation conditions increases from existing levels as follows: +3% in Alternative 1, +4% in Alternatives 2, 3, and 3-M; +6% in Alternatives 4, 5, and 6 (Table IV-6).

The amount of winter range acres closed to cross-country snowmachine use changes from existing levels as follows: no change in Alternative 1; -1% in Alternative 2; +1% in Alternative 3; +12% in Alternative 3-M; +6% in Alternative 4; +20% in Alternative 5; +40% in Alternative 6 (Table IV-6).

The majority of the deer and elk that summer on the Forest do not winter on the Forest. The number of deer and elk wintering on Forest winter ranges depends on the severity of the winter. As far as we know, no alternative would decrease the suitability of winter ranges on the Forest for deer and elk from existing habitat conditions. Improvements in the number of acres meeting DVC's, and increased restrictions on cross-country snowmachine use will result in improved winter range conditions for deer and elk, but populations may not increase over existing levels.

Cumulative Effects - Development on private lands is a concern as it can adversely affect areas historically used by wintering deer and elk.

Key Indicator - Grizzly Bear Habitat

Key Indicator - Open Road and Open Motorized Trail Route Density (OROMTRD)

Tables IV-7, IV-8, IV-9, and IV-10 present an overview of future OROMTRD and other habitat conditions for the Forest portion of each of the BMU's for each of the alternatives.

Other Indicators

1. Total Motorized Access Route Density (TMARD)
2. Cross-country OHV
3. Forest Acres in Core Areas
4. Winter Snowmachine Use
5. Livestock Grazing
- 6 Timber Harvest

Consequences Common to All Alternatives (within the BMU's) -

1. The size of each BMU remains the same in all alternatives.
2. Acres within designated Wilderness remains the same in all alternatives.
3. Acres within inventoried roadless areas remains the same in all alternatives.
4. There is no timber harvesting proposed in the Henry's Lake BMU, Subunit 2.
- 5 The number of cattle allotments remains the same in all alternatives.

All developed and undeveloped recreation sites (also known as "point sources" in the grizzly bear cumulative effects model) remain the same in all alternatives (Some additional analysis may indicate that road restrictions and reclamations in some alternatives may create a change in use at some of the point sources, but at this time no changes have been made for the alternative analysis)

Consequences Which Vary by Alternative (within the BMU's) - The importance of managing motorized access, one of the most influential parameters affecting habitat security, has been emphasized for grizzly bears. (Interagency Grizzly Bear Committee 1994). By managing motorized access on the landscape, the following grizzly bear management objectives can be met (Interagency Grizzly Bear Committee 1994):

- Minimize human interaction and potential grizzly bear mortality.
- Minimize displacement from important habitats.
- Minimize habituation to humans.
- Provide relatively secure habitat where energy requirements can be met

Important elements of motorized access include. open road and open motorized trail density, total motorized access route density, and the amount of core areas. (Interagency Grizzly Bear Committee 1994). We analyzed how each of these elements of motorized access change in each BMU for each of the alternatives. In addition, we also analyzed how spring/summer/fall cross-country motorized access changes in each BMU, and winter snowmachine use. This information is presented in Tables IV-7, IV-8, IV-9, and IV-10 The following briefly summarizes the information from the tables.

Total Motorized Access Route Density (TMARD) and Open Road and Open Motorized Trail Route Density (OROMTRD) -

In the Henry's Lake BMU, Subunit 1, TMARD ranges from 0.99 in Alternative 1 (a 52 percent reduction from existing conditions) to 0.47 in Alternative 6 (a 77 percent reduction from existing conditions) OROMTRD ranges from 0.60 in Alternative 1 (a 60 percent reduction from existing conditions) to 0.35 in Alternative 4 (a 77 percent reduction from existing conditions).

In the Henry's Lake BMU, Subunit 2, TMARD ranges from 0.66 in Alternative 1 (a 48 percent reduction from existing conditions) to 0.38 in Alternative 6 (a 70 percent reduction from existing conditions). OROMTRD ranges from 0.45 in Alternative 1 (a 54 percent reduction from existing conditions) to 0.28 in Alternative 6 (a 71 percent reduction from existing conditions).

In the Plateau BMU, Subunits 1 and 2, TMARD ranges from 1.74 in Alternative 1 (a 41 percent reduction from existing conditions) to 0.70 in Alternative 4 (a 76 percent reduction from existing conditions). OROMTRD ranges from 1.03 in Alternative 2 (a 20 percent reduction from existing conditions) to 0.49 in Alternative 5 (a 61 percent reduction from existing conditions).

In the Bechler/Teton BMU, TMARD ranges from 1.10 in Alternative 1 (a 31 percent reduction from existing conditions) to 0.49 in Alternative 6 (a 69 percent reduction from existing conditions). OROMTRD ranges from 0.59 in Alternative 2 (a 23 percent reduction from existing conditions) to 0.39 in Alternatives 4, 5, and 6 (a 49 percent reduction from existing conditions)

Cross-Country Off-Highway Vehicle (OHV) Use -

In the Henry's Lake BMU, Subunit 1, most of the Forest acres are currently closed to OHV use; only 6.2 percent of the acres are currently open and suitable for OHV use. The alternatives range from 6.2 percent of the acres being open and suitable for OHV use (Alternative 1) to 0 percent of the acres being open and suitable for OHV use (Alternatives 3, 3-M, 4, 5, and 6).

In the Henry's Lake BMU, Subunit 2, most of the Forest acres are currently closed to OHV use, only 7.1 percent of the acres are currently open and suitable for OHV use. The alternatives range from 7.1 percent of the acres being open and suitable for OHV use (Alternative 1) to 0 percent of the acres being open and suitable for OHV use (Alternatives 3, 3-M, 4, 5, and 6).

In the Plateau BMU, Subunits 1 and 2, 69.2 percent of the Forest acres are currently open and suitable for cross-country OHV use. The alternatives range from 69.2 percent of the acres being open and suitable for OHV use (Alternative 1) to 0 percent of the acres being open and suitable for OHV use (Alternative 3-M)

In the Bechler/Teton BMU, most of the Forest acres are currently closed to OHV use, only 8.7 percent of the acres are currently open and suitable for OHV use. The alternatives range from 8.7 percent of the acres being open and suitable for OHV use (Alternative 1) to 0.2 percent of the acres being open and suitable for OHV use (Alternatives 3-M, 4, 5, and 6)

Forest Acres Within Core Areas -

In the Henry's Lake BMU, Subunit 1, 32.2 percent of Forest acres currently meet core area standards. Core areas in the alternatives range from 65.6 percent of the BMU in Alternative 2 to 82.8 percent of the BMU in Alternative 4.

In the Henry's Lake BMU, Subunit 2, 45.1 percent of Forest acres currently meet core area standards. Core areas in the alternatives range from 74.9 percent of the BMU in Alternative 1 to 92.2 percent of the BMU in Alternative 6.

In the Plateau BMU, Subunits 1 and 2, 0 percent of Forest acres currently meet core area standards. Core areas in the alternatives range from 33.1 percent of the BMU in Alternative 2 to 70.9 percent of the BMU in Alternative 5

In the Bechler/Teton BMU, 47.6 percent of Forest acres currently meet core area standards. Core areas in the alternatives range from 47.6 percent of the BMU in Alternative 1 to 70.6 percent of the BMU in Alternative 5.

Winter Cross-Country Snowmachine Use -

Snowmachine use is primarily a concern because of the potential to displace bears before they hibernate or after they emerge from their dens in the spring. We are not aware of specific problems or

incidents occurring on the Forest, but the alternatives do prescribe different cross-country snowmachine use dates as follows in an effort to be sensitive to potential future effects.

In the Henry's Lake BMU, Subunit 1, there are no cross-country snowmachine use restrictions in Alternatives 1, 2, and 3. About 85 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1 in Alternatives 3-M, 4, 5 and 6

In the Henry's Lake BMU, Subunit 2, about 46 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1 in Alternative 1. There are no cross-country snowmachine use restrictions in Alternative 2. In Alternatives 3, 3-M, 4, 5 and 6, an additional 50 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1.

In the Plateau BMU, Subunits 1 and 2, about 8 percent of the BMU has cross-country snowmachine use dates of December 1 to June 1 in Alternative 1. There are no cross-country snowmachine restrictions in Alternative 2. About 20 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1 in Alternative 3. In Alternatives 3-M, 4, 5, and 6 all of the BMU has cross-country snowmachine use dates of December 15 to April 1.

In the Bechler/Teton BMU, about 34 percent of the BMU is closed to all snowmachine use in all alternatives in the Winegar Hole and Jedediah Smith Wilderness Areas. In Alternatives 1 and 2, there are no cross-country snowmachine use restrictions outside of wilderness. In Alternative 3, an additional 3 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1. In Alternatives 3-M, 4, 5, and 6, an additional 56 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1.

Cross-country snowmachine use dates of December 15 to April 1 are considered to have no adverse effect for the grizzly bear because most bears are in their winter dens by December 15, and most bears do not emerge from their dens until after April 1.

Livestock Grazing -

There is a well documented history of grizzly bears preying on domestic sheep when there were sheep allotments in Management Situation 1 areas of the Forest in the 1970's and 1980's (Orme and Williams 1985). All of the sheep allotments in Management Situation 1 areas have already been closed. There are 11 sheep allotments currently in use in Management Situation 2 areas (9 allotments in the Henry's Lake BMU, Subunit 1, and 2 in the Bechler/Teton BMU). There have been no grizzly bear/sheep conflicts in the Henry's Lake BMU, Subunit 1, but there have been two bear/sheep conflicts (identified as grizzly bear) in the southern portion of the Bechler/Teton BMU.

In Alternatives 1, 2, and 3, the sheep allotments are allowed to remain. In Alternatives 3-M and 4, the sheep allotments would be phased out over time on an opportunity basis. In Alternatives 5 and 6, the sheep allotments would be closed immediately upon completion and approval of the Forest Plan.

Timber Harvesting -

In the Henry's Lake BMU, Subunit 1, 90 percent of the forested acres are currently classified as mature and older. The highest amount of timber harvesting would occur in Alternative 1, with 87.0 percent of the forested acres remaining as mature and older by the end of the 1st decade. All other alternatives would have between 88.5 to 90 percent of the forested acres remaining as mature and older by the end of the first decade.

In the Henry's Lake BMU, Subunit 2, some 87.6 percent of the forested acres are currently classified as mature and older. There is no timber harvesting scheduled in any of the alternatives.

In the Plateau BMU, Subunits 1 and 2, about 50.7 percent of the forested acres are currently classified as mature and older. Only Alternative 1 has scheduled timber harvesting; in this alternative, about 49.8 percent of the forested acres would be mature and older by the end of the first decade.

In the Bechler/Teton BMU, some 81.4 percent of the forested acres are currently classified as mature and older. The highest amount of timber harvesting would occur in Alternative 2, with 80.0 percent of the forested acres remaining as mature and older by the end of the first decade. All other alternatives would have between 80.1 and 81.4 percent of the forested acres remaining as mature and older by the end of the first decade.

Cumulative Effects - To measure the cumulative effects from the items listed above, the grizzly bear cumulative effects model (CEM) was used to measure how impacts would change for each alternative. Tables IV-7, IV-8, IV-9, and IV-10 display the results of the CEM. For all of the BMU's, the dominant factor in differences in CEM outputs between the alternatives is the difference in motorized road and trail densities between the alternatives. A brief summary of the results follows

Henry's Lake BMU, Subunit 1 - The HE/HV index is lowest for Alternative 1 (annual average of 0.65) and is highest for Alternative 6 (annual average of 0.70)

Henry's Lake BMU, Subunit 2 - The HE/HV index is lowest for Alternative 1 (annual average of 0.52) and is highest for Alternative 6 (annual average of 0.62).

Plateau BMU, Subunits 1 and 2 - The HE/HV index is lowest for Alternative 1 (annual average of 0.49) and is highest for Alternatives 5 and 6 (annual average of 0.65).

Bechler/Teton BMU - The HE/HV index is lowest for Alternative 1 (annual average of 0.59) and is highest for Alternative 5 (annual average of 0.71).

At this time, no definitive statement can be made for a "threshold" number for TMARD, OROMTRD, amount of core area, or CEM outputs, in order to achieve a certain number of grizzly bears using a specific area. Analysis on female home ranges is currently being done by the Interagency Grizzly Bear Study Team, which may help define threshold levels in the future. Generally, the lower the TMARD and OROMTRD, the higher amount of core area and the higher HE/HV CEM output, the better the habitat conditions are for grizzly bears. The Yellowstone grizzly bear population has been increasing, and all demographic recovery targets are currently being met.

Gray Wolf

Consequences Common to All Alternatives - Application of the Forestwide standards and guidelines is expected to allow wolf pairs to establish dens on the Forest if they choose to do so, and to receive the protection of the nonessential experimental population rule (USDI Fish and Wildlife Service, 1994b).

Primary Cavity Nesting Habitat

An overall biological potential for the primary cavity nesting species as a group was analyzed for each alternative. In addition, a biological potential analysis was done for four of the species which require larger size snags (red-napped sapsucker, Williamson's sapsucker, hairy woodpecker, northern flicker). These biological potential analyses are based on existing snag densities and projected changes in snag densities due to management activities as specified in the management prescriptions.

Consequences Common to All Alternatives - All of the management prescriptions which allow scheduled timber harvesting and fuelwood harvesting (with the exception of management prescription 5.2.2) require the retention of snags and green replacement trees. The snag and green replacement tree requirements vary in these management prescriptions, ranging from > 40 percent of biological potential to 100 percent of biological potential for primary cavity nesters.

In addition to the management prescriptions which allow scheduled timber harvesting, snag and green replacement trees requirements are also contained in other motorized management prescriptions where fuelwood harvesting could be permitted based on the presence of roads for access and management prescription direction which allows fuelwood harvesting. The snag and green replacement tree requirements vary in these management prescriptions, ranging from > 40 percent of biological potential to 100 percent of biological potential.

There is no snag and green replacement tree requirements in the management prescriptions which are nonmotorized, wilderness, wilderness study areas, proposed wilderness, research natural areas, wild/scenic/recreational rivers, or special management areas. In these management prescriptions, timber harvesting is not scheduled, and primary cavity nesting habitat will evolve with natural processes.

There is no snag and green replacement tree requirements in the recreation and concentrated development management prescriptions. In these management prescriptions, public safety and protection of facilities is the paramount importance, therefore snags and other hazard trees are generally removed from these sites. The total acres in these sites is less than one-half of one percent of the total acres on the Forest.

Table IV-6 displays the biological potential for the primary cavity nesting species for each alternative on a Forestwide basis (Process Paper D displays the biological potential on a watershed basis for each alternative) In all alternatives, the biological potential for all primary cavity nesting species is 0.61, and the biological potential for the larger cavity nesting species is 0.47. As a result of the snag and green replacement tree requirements in the management prescriptions, there is no measurable difference in biological potential for primary cavity nesting species between the alternatives due to scheduled timber harvest activities.

Cumulative Effects - The analysis for future biological potential does not include possible future effects of natural disturbances. Future natural disturbances may have a greater effect on the biological potential for primary cavity nesting species habitat than vegetation management activities proposed for each alternative. Generally, natural disturbances such as fire, insects and disease create additional snags in the short term.

Forest Owl Habitat

Consequences Common to All Alternatives - Proposed management activities are not expected to change habitat conditions for these species regardless of the alternative.

Flammulated Owl - All known nest sites, whether or not they are active, will be protected in all alternatives

Boreal Owl and Great Gray Owl - All known nest sites, whether or not they are active, will be protected in all alternatives. Within home ranges, $\geq 40\%$ of the forested acres will be maintained in late successional stages.

Furbearer Habitat

Furbearers include the American marten, fisher, lynx and wolverine. These species require late successional forest habitats (mature and older forests) for some or all of their habitat requirements. Snags and down woody debris are also important components of their habitat.

Consequences Which Vary by Alternative - Table IV-6 displays how the quantity of late successional forest habitat is expected to change due to scheduled timber management activities in each alternative. The amount of late successional forest habitat changes by alternative according to the amount of timber harvesting proposed in that alternative. Alternative 2 has the largest potential change in habitat (-1.4%), and Alternative 6 the least potential change (0%)

Goshawk Habitat

Consequences Common to All Alternatives -

Nest Areas - Three suitable nest areas and three replacement nest areas (≥ 30 acres in size each) are to be provided for all goshawk territories. Where possible, these six areas are to be managed in a ≥ 180 acre contiguous area. The suitable nest areas are to be mature and older stands of trees, with numerous snags (80 to 100 percent biological potential for cavity nesting species). Any vegetation management within nest areas is to occur during the months of October to February. There are to be no new system roads.

Post-Fledging Family Area - This area is ≥ 420 acres in size. A variety of forest successional stages can be present, but ≥ 40 percent of the forested acres must be in mature and older size/age classes. Any created opening must be ≤ 40 acres in size. Numerous snags are to be present (80 to 100 percent biological potential for cavity nesting species). Any vegetation management within this area is to occur during the months of October to February. There are to be no new system roads.

Foraging Area - This area is $\geq 5,400$ acres in size. A variety of forest successional stages can be present, but ≥ 40 percent of the forested acres must be in mature and older size/age classes. Any created opening must be ≤ 40 acres in size. Numerous snags are to be present (80 to 100 percent biological potential for cavity nesting species). Vegetation management within this area can occur any-time during the year. Road densities are to be \leq the density required by the management prescription.

Since this goshawk management direction applies to all alternatives, there is no measurable difference between the alternatives in terms of goshawk habitat. This management direction applies to all known territories, whether or not they are active.

Red Squirrel Habitat

Consequences Which Vary by Alternative - Table IV-6 displays the acres of conifer cone-bearing habitat in each alternative. All remaining alternatives result in an increase in cone-bearing habitat from 1 to 3 percent. The increase is the result of some previously harvested acres coming of cone-bearing age during the decade. The number of acres coming of cone-bearing age is larger than the number of acres proposed for timber harvesting in any of the alternatives.

Peregrine Falcon Habitat

Consequences Common to All Alternatives - Forestwide Standards and Guidelines for peregrine falcon habitat apply in all alternatives. Suitable habitat will be maintained for all existing nesting pairs plus any new nesting pairs which may become established.

IV. FOREST USE AND OCCUPATION

This component is described in four parts: Access Management, Wilderness, Recreation, and Social and Economic. Under the first two parts, key indicators are discussed first, with subsequent discussion of other indicators. No key indicators are associated with the third and fourth parts.

ACCESS MANAGEMENT

Road and Trail System and Motorized Access

Consequences are presented in the winter and summer access sections which follow. In summary, winter motorized access will be monitored in most alternatives, and summer motorized transportation system and access will be reduced in all alternatives.

Summer Access

Key Indicators

1. Miles of road open to summer motorized
2. Miles of trail open to summer motorized
3. Acres open to summer cross-country OHV

Consequences Common to All Alternatives - There will be some reduction from current levels in miles of road and trail open to motorized use in all alternatives. This would result in increased needs and costs for law enforcement and signing to manage the system of restricted roads and trails. Another consequence common to all alternatives is the routine reconstruction of roads and structures.

The Forestwide Guidelines concerning trail condition surveys and restricting OHV use on slopes 25-40 percent and greater should help meet the Revision goals of sustaining OHV opportunities and sustaining trails in good condition while minimizing effects to other resources.

Consequences Which Vary by Alternative - Table IV-11 shows a comparison of roads and trails by alternative that will be open to motorized use, restricted, or reclaimed. Compared to existing conditions, changes in open roads and trails in the alternatives are as follows.

- open system roads range from an increase of 44 miles (+3%) in Alternative 2 to a reduction of 406 miles (-30%) in Alternative 6
- open nonsystem roads range from a reduction of 457 miles (-45%) in Alternative 1 to a reduction of 253 miles (-74%) in Alternative 6.
- open system trails range from an increase of 16 miles (+4%) in Alternative 1 to a reduction of 405 miles (-95%) in Alternative 6.
- open nonsystem trails range from a reduction of 76 miles (38%) in Alternative 1 to a reduction of 145 miles (73%) in Alternative 6.

In the preferred alternative (3-M), most of the system roads proposed for reclaiming/obliteration, are located within the grizzly bear BMU's

In most all cases, the system roads that have been identified to be reclaimed/obliterated are roads that are currently restricted, and were originally constructed in conjunction with timber sales.

Roads closed for resource management purposes limit opportunities for dispersed camping, berry-picking, sight-seeing, and other activities that conventionally depend on road access. The amount of opportunities available with the various alternatives is varied, according to the programmed amount of new or existing road development and resource management activities, particularly timber harvesting.

Table IV-11 Road and Trail Access

<p>1/ System roads and trails comprise the official Forest Transportation Management System. Nonsystem roads and trails (sometimes called ghost roads and trails) are not part of the official Forest Transportation Management System.</p> <p>2/ Miles - Open means road and trail miles without restrictions on motorized use.</p> <p>3/ Miles - Seasonal Restriction means road miles on which motorized use is restricted for only a portion of the spring/summer/fall seasons.</p> <p>4/ Miles - Yearlong Restriction means road miles on which motorized use is restricted for the entire spring/summer/fall seasons.</p> <p>5/ Miles - Restricted means trail miles on which motorized use is restricted either for a portion of the spring/summer/fall seasons or yearlong (as in designated wilderness areas).</p> <p>* This table refers to present time. It does not take into account the 1,622 miles of roads that were reclaimed/obliterated between 1981 and 1993.</p>								

Acres open to cross-country OHV travel decrease significantly from present levels in all alternatives. The decrease from present levels ranges from approximately 172,000 acres (15%) in Alternative 1 to over 1 million acres (97%) in Alternative 6. However, it should be recognized that many of these acres are in terrain and vegetative cover which do not actually permit cross-country travel. So, the decrease in acreage may not be as significant as it appears at first glance.

Costs for signing designated routes, rehabilitation of old alignments, and providing law enforcement will increase significantly, especially for Alternatives 3 through 6. Trail reconstruction and maintenance costs will also be much higher to meet soil and water standards and guides and to accommodate the higher use levels with motorized and mechanized equipment.

Most foot and horse trails would not be affected by any of the alternatives. However, under the alternatives with more motorized restrictions there would be some benefit to the nonmotorized user in terms of relief from interaction with motorized users. Some of the impacts to trails, such as rutting or displacement of soils, being caused by OHV use would also be removed.

Cumulative Effects - As acres and roads/trails open to motorized access decrease from Alternatives 1 through 6, the density of OHV users on designated routes will increase on the routes remaining open. In addition, some loop trails will be eliminated, along with current access to some of the more spectacular scenic vistas. The increased interaction may result in increased user or resource conflicts and additional resource impacts. This could have an overall effect of loss of enjoyment of the recreation activity for some people in some of the areas. In other areas, it may be possible to develop "play areas" that become favorites of those who like a "social experience," or who enjoy the spectator opportunity.

A secondary effect of decreasing motorized access areas would be reduction of hunting and fishing opportunities for those requiring motorized access. This might not be too significant except in Alternatives 5 and 6.

An additional effect of decreasing motorized access would be decreased trail maintenance. A good portion of our trail maintenance work is performed by motorized users and the state of Idaho's Trail Ranger program which uses trail bikes for its maintenance crew. Motorized users and trail maintenance funding from the State would naturally decline as restrictions on motorized access increase, unless some type of reconstruction program can be initiated to improve trails for motorized use.

Overall, it is questionable whether there will be enough designated routes and cross-country areas open to travel to meet the needs of increasing motorized access demand in any alternative, but especially in Alternatives 5 and 6. Much of the cross-country use that is presently occurring would be eliminated by Alternatives 3-6. Therefore, the actual and apparent loss of OHV access and recreation opportunities may be of concern to some OHV users.

Winter Access

Indicators

1. Acres open to winter cross-country snowmachines
2. Miles of groomed trails for snowmachines

Consequences Common to All Alternatives - Management direction such as establishing linear capacities for snowmachine trails; providing networks of groomed trails, providing winter users with educational information and signing about wildlife needs; and prohibiting snowmachines and other equipment from groomed cross-country ski trails, should minimize adverse consequences on users and wildlife.

Consequences Which Vary by Alternative - Acreage open to cross-country snowmachine use (Table II-1) is maintained or increased for Alternatives 1-4, decreases slightly in Alternative 5, and significantly decreases (400,000 acres) in Alternative 6. These decreases are due to increases in winter range and recommended wilderness prescription allocations.

Miles of designated, groomed, or marked snowmachine trails increases 150-200 miles over current levels in Alternatives 2-4. Alternative 5 maintains existing levels of trails. Alternative 6 would result in a significant decrease in designated snowmachine routes from current levels. This decrease is due to increased wildlife winter range and recommended wilderness allocations.

Cumulative Effects - Winter recreation use opportunities would in large part be maintained in all alternatives. However, Alternatives 5 & 6 would have more restrictions on winter motorized use, and therefore, some reduction in those opportunities and use would be possible. Potential effects on wintering wildlife would be minimal in all alternatives.

WILDERNESS AND RECREATION RESOURCES

The following topics present the effects and consequences of the alternatives on the various wilderness and recreation resources. Key alternative comparison indicators for these resources are displayed in Table II-1. Overall, total recreation use would not change much between alternatives, but the types of use probably would. The trend from Alternative 1 to 6 would be away from semi-primitive motorized (SPM) and roaded natural appearing (RNA) recreation opportunities to an increase in primitive (P) and semi-primitive nonmotorized (SPNM), although some semi-primitive motorized (SPM) opportunities would remain. *This overall trend would be due to the reduction in motorized access and increase in recommended wilderness from Alternatives 4 through 6.* Such a trend would also support of a shift from currently evolving tourism/rural development to a slower developing, eco-tourism pattern.

Wilderness and Recommended Wilderness

Key Indicator - Acres of recommended wilderness

Other Indicator - Acres of management opportunity classes for the Jedediah Smith Wilderness

Consequences Common to All Alternatives - Designated wilderness and wilderness study acres remain the same in all alternatives. Quality and character of designated wilderness would not be degraded by any alternative. All action alternatives include a wilderness implementation schedule (WIS) and monitoring plan for the Jedediah Smith Wilderness and a WIS for the Winegar Hole Wilderness Plan. The Revision prescriptions; monitoring plans; and the implementation schedules will become the wilderness management plan for each wilderness. These plans provide direction for management and monitoring of resource and social conditions and to address any changes which may result. These plans would maintain wilderness resources and recreation opportunities at approximately current levels and conditions.

Consequences Which Vary by Alternative

Recommended Wilderness - With the exception of Alternative 2 which has no recommended wilderness, the acreage of recommended wilderness increases from Alternative 1 to Alternative 6, with the largest increases in Alternatives 5 and 6 (Table II-1). Motorized OHV travel would be impacted by Alternatives 3-6, and significant Forestwide reductions in summer, cross-country OHV travel would result from Alternatives 5 and 6 to be consistent with the 1.3 prescription access table.

Existing Designated Wilderness - The main difference in designated wilderness would be in the Opportunity Class I-III allocations (Table IV-12). Opportunity Class I, II, and III areas are represented by prescriptions 1.1.6, 1.1.7, and 1.1.8 respectively. Alternative 1 (No-Action) contains prescriptions to match the current management situation. Alternatives 2-6 contain a variety of applications of the new prescriptions based on the Limits of Acceptable Change (LAC) opportunity classes developed by the Jedediah Smith Project Team as documented in a process paper on file in the Supervisor's Office. These Opportunity Classes involve levels of recreation, research and maintenance, and potential resulting changes in resource or social impacts. Generally, Alternatives 2 and 3 would have the highest social

interaction effects among recreationists and the greatest chance for disturbance of wildlife. Alternatives 3-M and 4 would have less chance of social interaction or wildlife disturbance impacts. Alternatives 5 and 6 would have the least chance of user conflicts or impacts to the resources, since these two alternatives do not contain any Class III (highest recreation level) areas.

Cumulative Effects - Alternative 1 (No-Action) has the highest probability of potential adverse impacts to wilderness character over time. This is because it lacks a management and monitoring process to measure change in wilderness values. All other alternatives should have little cumulative impact or secondary effects, since the LAC monitoring process should allow adverse interactions or impacts to be noted, and a management response applied to appropriately deal with problems if they arise.

Mgmt. Rx	Opportunity Class	Alternative (Thousand Acres)						
		#1	#2	#3	#3-M	#4	#5	#6
1.1.1	NA 2/	40	0	0	0	0	0	0
1.1.2	NA 2/	11	0	0	0	0	0	0
1.1.3	NA 2/	32	0	0	0	0	0	0
1.1.4	NA 2/	25	0	0	0	0	0	0
1.1.5	NA 2/	27	0	0	0	0	0	0
1.1.6	I	0	83	83	102	102	115	115
1.1.7	II	0	39	39	20	20	19	19
1.1.8	III	0	13	13	13	13	0	0

1/ Opportunity Class - Class I is lowest recreation use level, and Class III is highest use level.

2/ Prescriptions 1.1.1 - 1.1.5 are for the Current Forest Plan, which does not use LAC/Opportunity Class.

Roadless Areas

Indicators - Acres of roadless.

Consequences Which Vary by Alternative - As shown in Table II-1, the acres of roadless area would decrease from Alternative 1 to Alternative 2, and then increase again through Alternative 6. Alternative 6 would have the highest amount, which approximates the existing inventory. Roadless areas receive the highest level of management protection in Alternative 6 because of the recommended wilderness (1.3 prescription) allocation, which increases significantly between Alternatives 1 and 6 and because of lower motorized road and trail density standards. Alternative 2 is an exception, in that it has no recommended wilderness acres in it. As a result, cross-country summer OHV travel opportunities become significantly reduced between Alternatives 2 and 6. Table II-1 shows another example of the increasing restriction to OHV activity within the indicator entitled "acres roadless closed to summer OHV." This acreage increases from 243,000 acres in Alternative 1 to 378,000 acres in Alternative 5 and takes a sharp rise to 614,000 acres in Alternative 6. This pattern is similar to and verifies the recommended wilderness indicator discussed previously.

Cumulative Effects - Potential effects from timber harvest and roading would be highest under Alternative 1, with approximately 5,600 acres of roadless area possibly impacted during the next decade. However, this represents potential impact of only 1% or less to the inventoried roadless acres. This potential impact declines to 4,500 acres in Alternative 2, 3,500 acres in Alternative 3, 1,650 acres in Alternative 3-M, to 1,800 acres in Alternative 4, to 1,350 acres in Alternative 5, and no acres in Alternative 6.

Wild, Scenic, and Recreational Rivers

Consequences Common to All Alternatives - The eligibility of these rivers is not affected by the alternatives. Suitability studies need to be completed for all of these segments. This would need to be done on a priority basis for approximately one-third of the streams at a time, starting with those in the South Fork-Snake River Basin because of a current cooperative agreement with the State of Idaho. These studies would be done in coordination with the State of Idaho's studies and legislative recommendations. The remaining streams would probably be done in two additional studies - one for those in the Henry's Fork basin and a second for those in the Teton River basin, and probably in that order of priority.

Visual Resources

Indicator

Visual Quality Objectives (VQO)—Acres by VQO Class and associated ranges of VQO.

Consequences Which Vary by Alternative - With the exception of Alternative 2, the alternatives generally trend toward larger allocations of VQO's for Preservation, Retention, and Partial Retention going from Alternative 1 to Alternative 6 (Table II-1).

It should be noted that the VQO data in Table II-1 is mostly displayed as a range of VQO, such as retention to partial retention. This was necessary because the alternative prescriptions are described as a range, rather than with a single VQO. Therefore, the analysis could not be done in a comparative manner to the existing VQO's shown in Chapter III.

Alternatives 1-3 could result in some reduction in visual quality in areas of additional intensive timber harvest activity where VQO's of Modification and Maximum Modification are higher than in Alternatives 3-M through 6. Alternatives 5 and 6 would tend to maintain and could improve existing visual quality except in areas of management needs. For example, there are areas along major travel routes and use areas where greater restrictions on timber harvesting might prevent maintaining existing natural or created openings for scenic vistas over extended time periods. Such restrictions could preclude enhancement of some landscapes in thick monotonous timber stands.

Developed Recreation

Consequences Common to All Alternatives - Consequences will basically be the same for all alternatives (see Forest Plan Implementation Schedule for capital investments) because developed recreation facility construction and reconstruction will be about the same in all alternatives. This will include heavy maintenance and some reconstruction of recreation facilities, but little new site development. However, there may be some tendency for higher demand for developed recreation facilities in Alternatives 1-2, with decreasing demand in Alternatives 3-6.

Consequences Which Vary by Alternative - Generally, the higher the overall development and management activity levels, the higher the recreation use potential and associated development. This is due to user response to higher amounts of available opportunities and road and trail access. In Alternatives 1-2, there would be continuing diversity of opportunities with considerable motorized access. As the alternatives (3-6) increase in motorized restrictions for wildlife protection the need for developed facilities may decline somewhat. However, it is possible that the need for development of facilities such as

trailheads to access wilderness, rivers, etc. may increase over time even in these lower-scale development alternatives. This increase might offset the projected decline in amount of developed facilities

Cumulative Effects - As the alternatives become more restrictive in terms of motorized access and opportunity (i.e., Alternatives 3-6), there would likely be some displacement of recreationists from areas now being used. This could place a heavier burden on existing developed facilities, and create a need for new ones in a more concentrated geographic area. Furthermore, as recreation demand continues to increase, displacement and crowding could have a negative effect on recreation and social experiences. Additional displacement from adjacent heavy use areas such as Yellowstone National Park could further increase these effects.

Dispersed Recreation

Indicators - Acres allocated to dispersed camping prescription.

Consequences Common to All Alternatives - Approximately the same number of road-accessed, dispersed campsites (293) would continue to be used on the Forest in all alternatives. The number of sites would probably stay the same, because existing sites that would become unavailable due to new management allocations would simply be relocated to sites in other adjacent areas. Approximately one-third of these are heavy-use sites used by large groups (35+) during most days of the summer. Summer-use trail mileage of nonmotorized system trails would also remain constant across all alternatives.

Consequences Which Vary by Alternative - In the mapping of alternatives, a varying number of heavy-use dispersed campsites was allocated to the 4.3 dispersed campsite management prescription. Alternative 1 was given the least allocation for heavy-use dispersed sites (Table II-1) because very little management of dispersed sites is being done at present. Alternatives 2-4 have the most acres allocated (approx. 2,800 each), and Alternatives 5-6 were designed with 1,500 acres each of dispersed site prescription (Prescription 4.3) because the latter two are intended as less management intensive alternatives. The intent of this prescription allocation was to recognize the heavy public interest in these sites for camping, and to place a management emphasis on maintaining them while also maintaining soil resources and aquatic and riparian habitat. Provided funding for monitoring and management of these sites is available, alternatives with the highest acreage allocation should provide a better chance of maintaining recreation settings and opportunities, reducing or minimizing impacts to soils and vegetation; and maintaining or improving aquatic habitat. This is because restrictions on use of open fires, tents, and hardening of sites, etc. could be put into effect to reduce impacts to vegetation and soils in or near aquatic zones.

Cumulative Effects - It is possible in Alternatives 1-3 that some existing, dispersed camping sites and trails would need to be moved or closed to resolve conflicts with wildlife or aquatic management standards and guidelines. In Alternatives 3-M through 6, displacement or closure of such areas would be more likely to occur because there is less access and because aquatic buffer restrictions are greater. This could have an adverse impact on recreation experiences, due to having to add more facilities elsewhere, or due to crowding/congestion in smaller geographic areas. This could result in a need for increased monitoring, law enforcement, and management costs to prevent unacceptable impacts to soil, vegetation, aquatic, or wildlife resources.

Outfitters and Guides

Consequences Which Vary by Alternative - The number of new outfitter and guide permits issued would probably be less in Alternatives 3-M through 6 than in 1-3. Overall activity and amount of outfitted use would also be less in Alternatives 3-M through 6. The type of activities outfitted in Alternatives 3-M through 6 would be more related to backcountry, nonmotorized uses, due to increased restrictions on motorized and mechanized equipment in roadless, recommended wilderness and designated wilderness areas.

Cumulative Effects - Cumulative impacts would be higher in Alternatives 1-3 than in 3-M through 6 due to the higher demand for and access to recreation opportunities

Special Uses (Recreation)

Consequences Common to All Alternatives - Requests for special use permits for activities such as special events (e.g., races, group activities, etc.) and outfitting and guiding will likely increase gradually for all alternatives. At some point of saturation, the permitted activities would reach a plateau and level off.

Consequences Which Vary by Alternative - The trend for special uses in response to alternatives would be similar to that for developed sites. In Alternatives 1-3, there would be more increase in demand for special events and motorized access permits such as guided snowmachine or OHV trips. However, in Alternatives 4-6, the trend would be more towards undeveloped, backcountry experiences such as mountain biking, backpacking, horsepacking, hunting, and similar opportunities. The number of new special use permits would probably be less in Alternatives 3-M through 6 than in 1-3 and overall recreation use under permitted activities would also be less.

Cumulative Effects - Cumulative impacts of actual recreational use would likely be higher in Alternatives 1-3 than in Alternatives 3-M through 6, but those impacts would tend to be in the more easily accessed areas and closer to existing developed areas or special interest roads, trails, or attractions. In Alternative 3-M through 6, the additional cumulative impacts of recreation use would tend to be in more undeveloped, backcountry areas with a more primitive experience level. These, too, could have a measurable effect on wildlife, etc.

SOCIAL AND ECONOMIC EFFECTS

Indicators - The indicators used are jobs, employee compensation, payments to local governments (from both the 25% Fund and the Payments in Lieu of Taxes program), the Forest budget, population characteristics, land use patterns, effects on American Indians, and civil rights concerns. The factors are all discussed under the larger categories of life-styles, attitudes-beliefs-values, and social organization. Background information on these indicators is contained in Chapter III and in the Analysis of the Management Situation (AMS).

Consequences Common to All Alternatives

Population Characteristics - As discussed in Chapter III, the area is experiencing significant population increases. This rate of increase is not expected to be significantly affected by any of the alternatives.

The proportion of the area's population which is interested in the Forest for its recreational uses is expected to increase as recreational use continues to grow. The proportion of the area's population which is interested in the Forest for timber production or for livestock production is expected to decline.

Land Use Patterns - Lands adjacent to and within the Forest are increasingly passing from traditional uses like ranching to new uses like subdivisions. Forest management has to consider these new neighbors when deciding how best to manage Forest resources with particular attention being devoted to fire protection, visual quality and recreation opportunity. This challenge can be expected to continue to increase under all alternatives as the human population of the area increases.

Some newcomers to the area have deviated from long-held local custom by closing off access through their property to Forest lands. Their focus on having a Forest in a more natural condition has also been at odds with those who see the Forest as being a resource to be used. These sorts of conflicts can be expected to continue, if not worsen, under all the alternatives due to continuing in-migration.

American Indians - Input from the Shoshone-Bannock tribes indicates their strong concern for continuing the viability and abundance of plants, fish and wildlife on the Forest for the use of their members consistent with their treaty rights. Some of that input has focused on project-specific needs like providing designated routes for motorized access during the tribes' hunting season. The tribes have also commented on their need to have the public and the Forest Service respect their rights to practice their native religion. All the alternatives are structured so as to afford tribal members the rights guaranteed them by treaty.

Heritage Resources - No significant differences in alternatives would likely exist. However, there would be more risk of disturbance of sites in Alternatives 1 through 3-M than in 4-6. This would be only a slightly higher risk due to potential for ground-disturbing activities being somewhat higher. Also, there may be a little more likelihood of discovering new heritage resource sites during project-specific site surveys for Alternatives 1 through 3-M than in the lower-activity alternatives.

Lifestyles - The overall level of recreational use is expected to continue to increase along with its associated income and employment opportunities. Increased recreation use means more people from outside the immediate local area visiting, spending money, and in some cases investing in local property. The overall increase in recreation is expected to occur regardless of which alternative is selected. A certain percentage of the people visiting Yellowstone National Park can be expected to visit Forest attractions like Mesa Falls, for instance.

As Yellowstone and Grand Teton National Parks become more crowded the Forest can also expect to accommodate more of that spillover traffic. For instance, because snowmachining in Yellowstone National Park is reaching saturation levels, the Targhee is expected to receive more of that traffic—regardless of which alternative is selected.

The area also provides opportunities for further development of recreational activities. The recently opened Grizzly Bear Theme Park just outside Yellowstone's boundaries is an example of the kind of development which might occur regardless of which alternative is selected for the Revision.

Civil Rights - No civil rights effects associated with the alternatives have been identified. The contraction in the local timber industry is not expected to have disproportionate effects on women or minority groups. No civil rights effects have been identified as varying across the alternatives.

It is possible that with reduced budgets it will be more difficult for the Forest to achieve its affirmative action objectives. Some have speculated that reductions in the Forest budget might disproportionately affect women and minorities. The recent downsizing which occurred on the Forest did not have that effect. Future downsizing efforts are not expected to have disproportionately negative effects on women or minorities.

Consequences Which Vary by Alternatives

American Indians - Tribal members use the Forest in many different ways. Some of these uses are identical to those of the general population and are described elsewhere herein. Other interests may be unique to tribal members. For instance, gathering Forest products is an important part of the culture of some tribal members. Those who rely on open roads or motorized trails to access favorite spots may have to find alternative sites if motorized access is restricted. It is also possible that closing motorized access to some areas may effectively deny access to the infirm.

Discussions with the tribes to date have not revealed a preference for more or less roading per se. Concerns have been voiced about closing roads during the tribe's hunting season - something that needs to be addressed on a continuing, site-specific basis. In general though, as the alternatives reduce the amount of roads and trails available for motorized use, the time and effort involved in hunting is expected to increase. That also applies to other tribal activities which require access to the land. The

tribes have indicated that the game retrieval provision in some alternatives is not expected to significantly benefit tribal hunters who generally lack the resources to afford high-flotation cross-country motorized vehicles. Reducing motorized use may improve the suitability of the land for vision quest and various other cultural activities.

Each alternative maintains large areas of the Forest in both motorized and nonmotorized use but it is unclear whether one alternative meets overall Tribal needs better than another.

The Forest recognizes the rights afforded the tribes by treaty and by law as outlined in Chapter III of this document. All the alternatives comply with these requirements.

Lifestyles - Under Alternative 1 the trend of reducing Forest timber harvests would continue. This would mean that more of those people whose livelihoods depend on timber harvesting would lose those jobs and the associated income. Because access to fuelwood is frequently aided by timber harvests, people are likely to find it more difficult to get fuelwood for home use.

Those whose livelihoods are affected by the availability of Forest forage for domestic livestock would not expect to see their use of that resource significantly change in terms of overall use. Area livestock producers would however, have to invest more resources into the improvement of range allotments without necessarily seeing any increased use of available forage.

In terms of the way the Forest looks, people are likely to be generally pleased as young trees continue to reestablish in the large clearcuts of the Caldera and Plateau areas near Yellowstone National Park.

What this all means is that more people will be relying on the Forest as a recreation resource rather than as a provider of timber or livestock forage. It also means that area schools and roads will be receiving less money from Forest activities that generate receipts—principally timber management—through the 25% Fund. Payments in Lieu of Taxes would likely rise slightly, as shown in Table IV-13, for all alternatives. Likewise the budget for the Forest (and its associated local expenditures for payroll and supplies) will be reduced.

What Table IV-13 shows in its entirety is that the Forest's primary effect on the local economy derives from the recreational activity it provides. And no alternative is expected to significantly change the overall level of use - though usage is expected to shift over the landscape and by type. That comes as small consolation to those who have lost a livelihood in the timber industry.

Attitudes, Beliefs, Values - Many people believe the Forest should be used to produce timber products in conjunction with other Forest uses. Alternative 1 allocates the same amount of land to intensive timber production as the existing Forest Plan. It does not, however, continue timber harvests at the levels of the past. Instead the Forest would continue the recent trend toward very low timber harvests. This is because the potential yields identified in the current Forest Plan for timber are not sustainable.

The Forest will be stepping up its enforcement efforts to ensure that roads and trails closed to motorized traffic are not used by motorized vehicles. Even though in Alternative 1 these efforts are focused only on enforcing existing motorized use restrictions, many people will see them as Forest Service efforts to lock up the Forest. Others who see the Forest as being over-roaded are not likely to accept Alternative 1's proposal to substantially reduce motorized use through increased enforcement, more effective closures, or an improved public involvement program. There is great skepticism as to whether the road closures can be effectively implemented without the support of the local citizenry. The likelihood exists that there will be an increased level of conflicts between Forest Service personnel working to effectively close roads and trails and those who have grown accustomed to using them.

Table IV-13. Summary of Forest Effects on the Local Economy
(Dollar figures are expressed as Million Dollars)

	Recent Levels 1/	Average Annual Figures for Decade 1 of Implementation						
		1	2	3	3-M	4	5	6

PRESENT NET VALUE 7/		2,097	2,095	2,089	2,092	2,098	2,104	2,113

1/ Figures shown in this column are estimates of actual production or use during the period shown. Figures for livestock reflect actual forage consumption rather than permitted levels, some of which might not have been used

2/ Source: Forest IMPLAN model. Full-time and part-time employment. Recent Levels are based on 1995 levels for livestock, and an average of 1991-1993 for the other job categories shown.

3/ Source: Forest IMPLAN model. Wages and salaries plus the value of benefits and any contributions to social security and pension funds by the employer and the employee. Recent Levels are based on 1995 levels for livestock, and an average of 1991-1993 for Recreation and Timber.

4/ Payments to Local Governments come from two different programs, the 25% Fund and Payments in Lieu of Taxes. Recent Levels are for the period of 1992-1994. Payments from the 25% Fund result from Forest gross receipts whereas Payments in Lieu of Taxes derive from the population of the local government, the amount of its land under federal ownership, and other federal receipts, such as those received from the 25% Fund.

5/ Recent Levels are an average of the period 1991-1993, expressed in 1992 \$ terms. Includes the full range of Forest costs usually accounted for in the budget including Monitoring and Evaluation, Road Restriction, and Road Reclamation/Obliteration

6/ Recent Levels are an average of the period 1991-1993, expressed in 1992 \$ terms. Includes firefighting and law enforcement expenditures not tracked in the budget.

7/ Dollar-valued benefits less dollar-valued costs discounted at a 4% annual rate over the 150 year period of analysis.

The motorized access situation is particularly troublesome in that for a number of years, roaded access on the Forest was continually increasing—largely as a consequence of logging activity. People had come to expect more and more motorized access. In recent years, that access has been decreasing in order to provide better habitat for wildlife.

Alternative 1 would also likely not be acceptable to those whose belief systems are more tuned to nonconsumptive use of the Forest. That is due in large part to the fact that in the past Alternative 1 called for scheduling timber harvests at such high levels that they could not be continued into the future. Thus, the frame of reference people have for logging on the Forest is that areas entered for logging are logged very heavily - not harvested at rates that are sustainable.

As currently formulated, Alternative 1 would not continue the practice of logging at levels that cannot be continued into the future. But it is unlikely that those whose value systems were offended by Alternative 1's high harvest rates of the past could come to accept this identical land allocation even without the high harvest levels.

Big game hunting, and in particular elk hunting, is a major event on the Forest. Participants eagerly await the season's arrival. The success they have enjoyed in recent years would not be expected to change with the selection of Alternative 1, although with continuing growth in the previously clearcut areas and more effective road closures, hunter success may be more difficult to achieve.

Sense of Control, Sense of Self-Sufficiency - The financial, social and psychological insecurity associated with lost jobs and reduced incomes associated with lower timber harvests would be evident in Alternative 1. Businesses that could not make up this loss of raw material supply from other sources would likely shut their doors or continue operations at reduced levels. Employees would need to find other jobs or to relocate. The effect is more pronounced on the local economy because jobs in the timber industry tend to be better-paying. And while the existing Forest Plan did acknowledge that harvest levels would have to be reduced, the levels of reduction described in that document were nowhere near as severe as is now indicated.

There is no reason to expect that those who lose their jobs in the local timber sector will be able to find comparable-paying jobs in the local area. They will be faced with the prospect of getting along with a lower income, working multiple jobs, relocating, or reducing expenditures.

At the same time though, these job reductions are consistent with a trend that has been recognized for some time. Timber-related jobs have been on the decline. For some there is a grudging recognition that even things like personal use fuelwood are not going to be as readily available in the future as they have been in the past.

People whose livelihoods or recreation-based activities (like fuelwood gathering) are associated with timber harvesting are likely to feel their sense of control and sense of self-sufficiency diminished because they will suffer a loss in earnings or in the use of a recreation opportunity. People whose primary interest on the Forest is on nonconsumptive use would likely have a mixed response to the Forest's management under Alternative 1. Many of the Forest's watersheds that were previously heavily logged would be left largely undisturbed in Alternative 1—including much of the area in the highly visible US Highway 20 corridor used by so many people heading into Yellowstone National Park. The timber harvest would, however, be moved into other areas to which a different set of recreationists might object.

Local governments receive payments associated with the Forest from the 25% Fund, which remits to local governments 25% of Forest gross receipts; and from the Payments in Lieu of Taxes program, which bases payments to local counties based on their human population, their area under federal ownership, and their receipts from other federal sources. Area counties receive substantially more from the latter program than from the former. It would not be expected to change significantly based on the alternative selected. Payments from the 25% Fund are expected to change substantially as shown in Table IV-13. Money from these funds help compensate the local governments for expenses they incur relative to the federally-owned lands within their jurisdiction.

Social Organization: Community Cohesion - Selecting the Continue the Forest Plan Alternative (Alternative 1) would likely have no perceptible effect on community cohesion.

Social Organization: Community Stability - People involved in the timber industry and its related industries would continue to lose their jobs. More jobs will become available in the sectors serving recreationists. The livestock industry would see little change other than the need to invest more money into permitted use areas. For some who are operating on the margin, that could be the difference between maintaining an operation and getting out of the business, but overall use of the Forest forage resource by livestock is expected to change very little. Those trends have been in place in the local area for some time. They will continue under Alternative 1.

Economic Efficiency - The primary measure of economic efficiency used in the analysis is Present Net Value (PNV). Present Net Value is, "The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area." (36 CFR 219.3)

Dollar values were identified for recreation, timber, livestock grazing, and water. Costs included in the analysis included all costs of managing the Forest, including firefighting, law enforcement, and monitoring.

As shown in Table IV-13, the range of the PNV's is quite small, the overall range varying less than two percent. The predominant reason for this small range is that recreation and water benefits, which comprise the great bulk of dollar-valued benefits, are not expected to vary by alternative. Changes in recreation use may occur, such as concentration of use in smaller areas or movement of recreationists from one type of recreation to another. The overall level of recreation is expected to be the same for all alternatives. Likewise, no changes in water flows from the Forest are anticipated by alternative. Changes in benefits thus derive from changes in the range and timber programs.

Variations in costs do occur across the alternatives and over time. These are associated with reduced timber harvests, increasing road restrictions and law enforcement, and increasing costs of firefighting.

Alternatives 2-6

Lifestyles - The numbering scheme of these alternatives stretches from 2 to 6. As the numbers assigned to the alternatives increase, the alternatives move consistently toward:

- Less opportunities to make a living off the Forest by producing timber products or raising livestock.
- Restricting those management activities which leave lasting visual reminders.
- Increasing the possibility of lasting visual reminders due to unmanaged occurrences like wildfires.
- Reduced incidence of livestock grazing.
- Fewer roads and trails.
- Fewer roads and trails open to motorized use.
- Less cross-country motorized use.
- More nonmotorized recreation opportunities.
- Greater protection of wildlife habitat.
- More recommended wilderness.

Timber-related employment would be expected to vary directly and proportionally to the projected ASQ.

Reductions in domestic livestock grazing, while substantial (especially in Alternatives 3-M, 4, 5, and 6), are not nearly so severe as those associated with the timber industry. The economic viability of grazing operations is likely to diminish though as restrictions are placed on the allotments to improve resource conditions.

Aesthetically, those desiring a more natural appearing landscape will see the heavily logged areas of the Forest coming back in new growth in all the alternatives. The alternatives with higher levels of ASQ will harvest larger amounts of timber in other less-logged or nonlogged watersheds around the Forest. Those areas will show the effects of humans working on the land, building roads, removing timber, and establishing new timber stands in direct proportion to the amount of ASQ.

Those alternatives with fewer miles of road and trail open for motorized use (as shown in Chapter II) would likely see increased concentrations of motorized use on the miles remaining open, reductions in recreation dependent on motorized use, increases in nonmotorized recreation, or some combination thereof. The way people recreate on the Forest will definitely change. People will not have the same type of hunting experience in every alternative. Opportunities for solitary experiences on the Forest will change as well

Attitudes, Beliefs, Values - The numbering scheme of the action alternatives stretches from 2 to 6. As the numbers assigned to the alternatives increase, the alternatives move consistently toward:

- Greater accommodation of those who feel the Forest's resources should be left to change without human intervention
- Less accommodation of those who feel the Forest's resources should be used for the benefit of humans.
- Greater trust that developments which occur without human intervention will benefit the ecosystem.

Social Organization (Community Cohesion and Stability) - Any of the alternatives would create stress on the local social organization. The most stressful would likely be those alternatives near the extremes of the spectrum—1 and 2, 5 and 6—because they respond more clearly to the needs of one group rather than those of another. For instance, Alternatives 5 and 6 recognize the needs of those favoring increases in nonmotorized recreation and protection of wildlife habitat as being more important than the needs of those who favor motorized recreation use and timber harvest on the Forest

In order for the local communities to come together in a positive manner, some sense of a new social order must emerge on the local scene that integrates the diverse views held on how the Forest should be managed. Otherwise the tensions and stresses associated with an un-networked leadership are likely to continue. The Forest can also work constructively in this area by maintaining its efforts in public involvement.

To the extent that new social order is not achieved, there will likely be progressively more vandalism and trespass associated with the alternatives as they decrease motorized access to the Forest.

Facilities

Consequences Common to All Alternatives - The individual facilities are not anticipated to have any major effects on environmental components beyond those existing today. The Forest Service may alter and repair such facilities as administrative sites and other structures on the land owned by the federal government, as necessary to carry out its mission. Any proposed facilities will be subject to environmental analysis to verify the need for the proposal, to review alternatives, and to determine site-specific effects and mitigation measures as needed. Decisions on proposals will be based on in separate environmental assessments or impact statements.

Non-Recreational Special Uses

Consequences Common to All Alternatives - There are approximately 204 existing special use permits, in addition to recreation special use permits on the Forest. Ditches, canals, fences, power plants, powerlines, telephone lines, fences, roads, electronic sites, communication sites, and dams are all examples of these uses.

Any new proposed special use permits will be subject to environmental analysis to verify the need for the proposal, to review alternatives, and to determine site-specific effects and mitigation measures as needed. Decisions on proposals will be based on in separate environmental assessments or impact statements.

Consequences Which Vary by Alternative - Alternative 2 identifies two potential communication sites. One site is on the Island Park Ranger District, located on Two Top Mountain. The other is located on Palisades Ranger District on Big Elk Mountain. The other alternatives are unchanged.

V. PRODUCTION OF NATURAL RESOURCES

Timber

Key Indicator - Volume Harvested, Allowable Sale Quantity (ASQ)

Other Indicators

1. Acres Harvested
2. Unscheduled Timber Harvested
3. Firewood/Product Volume
4. Suitable Timber Acres
5. Harvest Volume as a percent of Long Term Sustained Yield
6. Noninterchangable component (NIC)
7. Harvest Acres by Harvest System
8. Supply and Demand for wood products
9. Reforestation
10. Timber Stand Improvement (TSI)

Consequences Common to All Alternatives

Unscheduled Timber Harvest - All alternatives allow unscheduled timber harvesting for the following purposes:

- Public safety;
- Visual quality;
- Long term maintenance of vegetation conditions,
- Commercial, personal use and camp firewood,
- Commercial and administrative post and pole cutting;
- Administrative use;
- Achieve mature growth standards;
- To meet specific recreation objectives;
- Attain desired vegetation characteristics;
- Improve wildlife habitat; and
- Where needed to meet management prescription goals.

The volume and acres associated with unscheduled timber harvest are currently unknown but treatments will occur to implement ecosystem management and to meet the various prescription goals and objectives

Firewood/Product Volume - All alternatives allow harvest of wood products other than ASQ volume. A goal of the Revision is to conduct an inventory for determining a sustainable level of firewood and then offer that level. A current estimate of volume (firewood and products) that would be available from the forest annually during this planning period (the first decade of revision implementation) is 3.8 MMBF. This compares to approximately 4.6 MMBF that was sold during Fiscal Year 95 and 6.3 MMBF which is a four-year average for the years of 1992-95

All alternatives harvest less firewood and product volume compared to the levels associated with the past planning period. Demand for firewood is down, due to a decreased supply and the quality of offered material, over the past 4-5 years. The anticipated supply level is below the expected demand. This will result in more competition for sales and therefore, increased cost to purchasers. Demand for product volume (post and poles) is increasing within the planning area. There will be a decrease in availability of personal use post and poles for farm and ranch use and a move toward competitive bids as demand will exceed supply. The supply of poles may be augmented by precommercial thinning material as thinning opportunities will increase during this planning period.

Harvest System - The ASQ acres for all alternatives will be harvested using even-aged silvicultural systems (clearcut, commercial thinning, seed tree, shelterwood and overstory removal) and where appropriate, and to a lesser degree, uneven-aged systems (group selection, individual tree selection and commercial thinning). Specific direction regarding appropriate harvest systems for each species is found in the Forestwide Standards and Guides and will be applied on a site-specific basis.

Timber Stand Improvement (TSI) - During the planning period it is estimated that there will be 34,841 acres of regenerated forest stands that will need to be thinned. Of the total 17,812 acres are planned to be treated this decade. Some 24,111 acres of the total acres available are within BMU's. Some 17,029 acres (71%) of the 24,111 acres in BMU's are located within core areas and by prescription cannot be treated.

Consequences Which Vary by Alternative

Timber Prescription Areas - Table IV-14 below displays the total number of acres within each alternative which are allocated to timber management activities (ASQ). The display represents total acres within timber management prescription boundaries (includes forested and nonforested).

Table IV-14. Total Acres Within Timber Management Prescriptions							
	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Timber Prescription Ac.	795,600	857,300	663,800	585,800	523,600	272,300	0

Suitable Timber Acres - All seven alternatives have different amounts of acres suited for timber management. Table IV-15 below displays the numbers of acres of available suitable timber by alternative. Total tentatively suitable acres for the Forest are 703,100. The process used to determine total suitable acres is found in Process Paper C

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Suitable Acres	591,420	598,830	549,010	487,000	421,510	208,810	0

Total suitable acres shown above reflect forest acres within the timber management prescription acres shown in Table IV-14. The difference between total tentatively suitable acres (703,100) and those shown in Table IV-15 above, reflect specific constraints within the prescription mix in each alternative. The alternatives with the largest acreages of suitable forest land will have the most effect on forested vegetation.

Acres Harvested - Table IV-16 displays harvest acres for each alternative. Harvest acres are determined by the number of suitable acres within management prescriptions that allow timber harvest activities. The differences between the acres shown below and the suitable acres shown above is due to specific constraints within each prescription area, past timber activities in that area, and the fact that suitable acres shows the area harvested over an entire 150-year period of analysis rather than the first decade. Process Paper B provides information on the constraints used for this analysis.

Alternative 2 harvests the most acres during the decade followed by 1, 3, 3-M, 4, and 5. There are no ASQ harvest acres associated with Alternative 6. All alternatives harvest 1.4% or less of the total forested acres and 2.4% or less of total suitable acres.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Harvest Ac (Yr)	1,477	1,694	1,423	1,143	751	473	0
Harvest Ac. (Dec)	14,764	16,940	14,230	11,430	7,510	4,730	0
% of Total Forested Acres	1.2	1.4	1.2	0.9	0.6	0.4	0.0
% of Total Mature Forested Acres	1.5	1.7	1.4	1.2	0.8	0.5	0.0
% of Forest Suitable Acres	2.1	2.4	2.0	1.6	1.1	0.7	0.0
% of Alternative Suitable Acres	2.5	2.8	2.6	2.1	1.8	2.3	0.0
Aspen Harvest Ac.	325	559	384	320	150	76	0
% of Ac. Treated	22	22	27	28	20	16	0.0
LPP Harvest Ac.	561	644	597	457	368	184	0
% of Ac. Treated	38	38	42	40	49	39	0.0
Other Conifer Ac.	591	491	440	366	233	213	0
% of Ac. Treated	40	29	31	32	31	45	0.0
% Tractor Logging	86	88	87	90	90	84	0.0
% Cable Logging	14	12	13	10	10	16	0.0

Except for Alternative 1, lodgepole pine (38-40%) is the species that is harvested the most. This was the case in the existing Forest Plan except that the percentage of lodgepole pine to the total harvest was about 90%. Aspen harvest (16-28%) makes up a larger percent of harvest as compared to the existing Plan as is the case with Douglas-fir and the mixed conifer groups (29-45%)

The use of all logging systems to harvest timber would continue under all alternatives. Selection of appropriate systems would be made at the project level and would be based on silvicultural needs, watershed protection, operational feasibility and costs.

Noninterchangeable Component (NIC) - Table IV-17 below displays the number and percent of suitable acres by alternative that fall into a NIC. NIC acres are ASQ acres associated with aspen, forested slopes between 40-60%, specific prescriptions (5 3 2 - 5 3.5, 5.7, 5.8, and 5 9 2), and areas designated as roadless. This component basically indicates that the volume from these acres, if lost to harvesting opportunities, will not be made up elsewhere. As an example, if aspen cannot be harvested in the amounts shown above because of lack of market, the volume lost is not required to be made up with additional harvest of another species. Another example would be volume from a roadless area. If an alternative not to harvest timber is selected in a future site specific project analysis, the volume would not be made up from other lands.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
NIC Acres (Total)	352,486	237,137	312,387	256,162	210,755	67,377	0
% of Suitable Ac.	60	40	57	53	50	18	0 0
Ac Aspen (1st Decade)	3,250	5,590	3,840	3,200	1,500	760	0
Ac 40-60 % slopes (1st Decade)	2,067	2,033	1,850	1,143	750	757	0

Alternative 1 has the largest amount of NIC acres followed by Alternatives 3, 3-M, 4, 2, and 5. Alternative 5 also has the least amount of suitable acres of any alternative with a scheduled timber harvest.

Harvest Volume - Harvest volume data is shown in Table IV-18 below. ASQ is the amount of timber volume that each alternative allows to be harvested based on the number of suitable acres, average volume per acre and management direction within each prescription area.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Annual (ASQ)	5,116	5,963	5,007	3,698	2,457	1,487	0
Decade (ASQ)	51,160	59,629	50,073	36,979	24,578	14,866	0
Average Vol/Ac. MBF	3,465	3,520	3,519	3,235	3,273	3,143	0
% of Total Forest Vol.	1.0	1.0	1.0	0.6	0.7	0.3	0.0
% of Suitable Vol.	1.4	1.6	1.4	1.0	0.7	0.4	0.0
Aspen Volume	2,404	2,297	1,576	1,315	616	312	0
% of Total Vol.	30	39	31	36	25	21	0.0
LPP Volume	3,690	2,327	2,158	1,652	1,330	665	0
% of Total Vol	47	39	43	45	54	45	0.0
Other Conifer	1,801	1,339	1,273	731	511	510	0
% of Total Vol	23	22	25	19	21	34	0.0

Alternative 2 provides the most volume harvested during the decade, followed by Alternatives 1, 3, 3-M, 4 and 5. Alternative 6 does not provide any volume from ASQ harvest. All alternatives harvest 1.0% or less of total forested volume and 1.6% or less of total suitable volume.

In comparison to the existing Forest Plan, lodgepole volume will again provide the largest amount of volume but only about 40-50% to the total. Aspen volume provides 20-40% of the total volume which is a significant increase from past management. Douglas-fir and the mixed conifer group also increase significantly comprising 20-35%.

Volumes per acre are shown above in Table IV-18. The average volume per acre across the alternatives is about 3.4 MBF. During the previous planning period (1981 - 1990) the planned volume per acre averaged around 5.0 MBF and the actual sawtimber volume per acre was 6.2 MBF. The planned volume per acre is less than the previous planning period due to two wildlife constraints. The first requires 20 logs per acre in each decomposition class be left on-site. These logs should be a minimum of 7" in diameter (average 9.5" in diameter) and be 20' long. This would equate to about 0.75-1.0 MBF per acre left on the ground if adequate down and woody material is not available. The second wildlife constraint that affects volume per acre is a snag per cavity nesting requirement for leaving snags and snag recruitment trees. For a 100 percent biological potential at the high end, 10 snags per acre and 25 snag recruitment trees per acre (half in the 7.0"-9.9" diameter class) would have to be left. This would also equate to 0.65-1.25 MBF per acre being left standing.

Long Term Sustained Yield Capacity (LTSYC) - LTSYC is the highest uniform wood yield from lands being managed for timber production that may be sustained, under a specified management intensity, consistent with multiple use objectives. Table IV-19 below displays the LTSYC on an annual basis for each alternative. LTSYC generally shown in MCF (thousand cubic feet) is also displayed in MBF (thousand board feet) (estimate) terms for ease in comparing the alternatives.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
LTSYC (MCF/Yr)	7,144	7,271	7,451	6,155	5,772	2,801	NA
LTSYC (MBF/Yr.)	32,065	32,635	33,442	27,626	25,907	12,572	NA
Harvest Volume as a % of LTSYC	16	18	15	13	10	11	NA

For clarification, LTSYC indicates the amount of volume that is produced annually from the suited acres shown for each alternative in the long term. This includes growth from all trees and does not necessarily mean total merchantable volume that is available for harvest. By law, harvest levels cannot exceed LTSYC. Alternative 2 comes the closest to meeting its LTSYC but only utilizes 18 percent in decade 1, less than 1/5 the annual growth predicted in the long term. Alternative 2 is followed by Alternatives 1, 3, 3-M, 5 and 4 respectively.

Supply and Demand - Chapter III displays information on the current supply for sawtimber and wood products and the predicted demand from operators in our area. Table IV-20 below displays how the volume available from each alternative meets the demand.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
ASQ	31	36	31	23	15	9	0
Firewood/Products	23	23	23	23	23	23	23
% Total	54	59	54	46	38	32	23
% Present Demand	25	27	25	21	18	15	11
% Survival Level	29	31	28	24	20	17	12

Alternative 2 provides the most volume in terms of past supply and present demand but falls well short of historical levels provided by the Forest. Even during recent years (1991 - 1994) the Forest provided 54.4% of the volume available to the local demand area. Under Alternative 2, the Forest will supply about 59% of the volume available to the local market. This total would be less than half of what the local area demands. Following Alternative 2, Alternatives 1, 3, 3-M, 4, 5 and 6 provide decreasing amounts. Survival level is the minimum level of timber demand, from all operations, necessary to meet the needs of timber industry and personal use.

Future Harvest Levels - Table IV-21 below displays future levels of harvest.

Decade	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
2	5,158	6,060	5,504	3,692	3,281	1,425	0
3	15,197	13,400	12,346	9,708	4,693	3,457	0
4	14,063	13,187	13,435	10,377	6,048	4,037	0
5	15,810	13,443	13,100	10,619	6,642	4,204	0
6	14,429	14,474	21,916	15,609	7,186	6,281	0

Reforestation - Table IV-22 below displays the level of reforestation activities expected during the planning period.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Ac of Reforestation	25,190	27,360	24,650	21,850	17,930	15,150	10,420
Minimum Ac. of Planting	10,420	10,420	10,420	10,420	10,420	10,420	10,420
Ac. of Reforestation in BMU's	1,975	1,975	1,975	1,975	1,975	1,975	0

About 10,420 acres of the total reforestation needs shown above will be planted in all alternatives. Additional amounts in Table IV-22 come from planned harvest during the planning period and will be a mixture of artificial and natural regeneration. The amount of each will depend on the species harvested, harvest system used, and suitability for natural regeneration during the planning period. This will be determined through site-specific analysis.

Cumulative Effects

Silvicultural Systems - Even-aged management systems will continue to be used resulting in even-aged stands. Uneven-aged systems will be used to a lesser degree, but will have very little cumulative effect as the successional stage generally does not change when activities occur.

Fuelwood - The recent levels of fuelwood will continue to decrease due to the low number of acres treated under any alternative. Requirements for more down and woody vegetation and maintaining snags within harvest units will also reduce available fuelwood material offered in slash piles.

Use of aspen for firewood material could increase due to the increased aspen acreage that is available for treatment. Aspen firewood is not part of the ASQ.

Fire - The hazard from wildfire on the suited lands should remain about the same as in the past because the acres available to harvest, once harvested, will not reduce the composition of the mature component significantly. The hazard on the nonsuited lands should remain constant or slightly increase as the stands continue to mature and no activities are initiated to reduce fuel loading.

Insects and Disease - Insects and disease will continue to be present in both the suited and nonsuited lands. Vegetation management activities planned during this period will decrease in amount on the suited acres, but even a 2% or less reduction in mature stands provides some benefit in reducing insects and disease problems. On the unsuited lands, insect and disease could build up to epidemic proportions.

Growth on the managed stands would increase with management intensity. As more lands are developed, total growth would increase. Growth on the nonsuited lands would remain constant or decrease as the stands increase in age and are past culmination in the later successional stages.

Livestock Grazing

Indicators - The "Production" indicators for "Livestock Grazing" that will be covered in this portion of chapter 4 are:

1. Amount of permitted AUM's and livestock.
2. Number of grazing permittees and permits
3. Amount of acres open to grazing.
4. Number of allotments open to grazing

Consequences Common to All Alternatives - Three vacant sheep allotments on the Island Park Ranger District and four vacant sheep allotments on the Ashton Ranger District will be closed to sheep and cattle grazing to better manage grizzly bear habitat. One vacant sheep allotment on the Dubois Ranger District and another vacant sheep allotment on the Palisades Ranger District will be closed to sheep and cattle grazing to improve watershed and soils conditions. This is a reduction of 5,648 sheep AUM's, reduces the number of open sheep allotments from 78 to 69 and closes an additional 98,214 acres to grazing of domestic livestock. Since these allotments are currently vacant, this reduction in a real sense has already occurred.

All reconstruction of existing range improvements and all proposed new improvements will be needed equally with each alternative. These improvements are needed to: 1) arrest deteriorated range conditions and improve rangeland health, 2) maintain or implement improved grazing systems and Allotment Management Plans, and 3) mitigate site specific situations identified in previously completed NEPA documents. All proposed new nonstructural improvements (burns, spray, seedings, etc.) and noxious weed control will be implemented to improve ecological conditions. No increase in AUM's or livestock carrying capacity is anticipated.

Consequences Which Vary by Alternative - Unless otherwise specified, all environmental consequences are calculated to occur by the end of the first decade. The effects of implementation on indicators for all alternatives is shown in Table IV-23.

With the existing Forest Plan (Alternative 1), livestock management (grazing) systems are primarily utilized to maintain or improve forage outputs for livestock and wildlife and to protect and improve watershed conditions. Direction is not given to sustain livestock use at any specified level. The direction is to "Obtain optimum use of all suitable grazing lands on the Forest consistent with other resource needs." Information about this direction and how well the existing Forest Plan met objectives can be found in the "Range Section" of the Analysis of the Management Situation (AMS).

Riparian utilization in Alternative 1 is expressed as a percentage of forage utilized and ranges between 30% and 65% for herbaceous vegetation and 20% and 40% for browse, depending on the type of grazing system and "range" condition. There is a 100-foot buffer zone along each side of all perennial streams. Compared to the existing situation, Alternative 1 maintains the existing number of grazing permits, permittees, sheep, sheep AUM's, and cattle allotments open to grazing. Alternative 1 projects a slight increase in cattle numbers and AUM's.

Alternatives 2-6 express riparian forage utilization in terms of HGL "stubble height" and have wider buffer zones. With Alternatives 2-6, livestock management (grazing) systems are primarily utilized to maintain or improve forage outputs for livestock and wildlife and to protect and improve watershed conditions. The amount of protection varies among alternatives. Direction is not given to sustain livestock use at any specified level.

Alternative 2 implements the Aquatic Influence Zone Prescription which provides for a 4" HGL stubble height for all riparian areas either at the end of the grazing period or for all pastures grazed after September 1 and has buffer widths ranging from 100 feet to 200 feet on each side of all fish bearing

streams. Compared to the existing situation, Alternative 2 maintains the existing number of grazing permits, permittees, and cattle allotments open to grazing. Alternative 2 projects decreases for sheep and cattle numbers and AUM's.

Alternative 3 is similar to Alternative 2 except for a slight difference in cattle AUM's (88 AUM difference). Like Alternative 2, Alternative 3 implements a 4" HGL stubble height for utilization on riparian forage.

Alternative 3-M implements the Aquatic Influence Zone Prescription which provides for a 4" HGL stubble height for all riparian areas either at the end of the grazing period or for all pastures grazed after September 1 and has buffer widths ranging from 150 feet to 300 feet on each side of all fish bearing streams.

Compared to the existing situation, the Alternative 3-M implementation of the "phaseout" of sheep grazing to better manage grizzly bear and big horn sheep habitat will reduce sheep grazing by 8,995 active AUM's (18%). The reduction sustained as a result to improve grizzly bear habitat amounts to 5,446 AUM's (10.9%) and will eliminate (phaseout) all sheep grazing (100% of the sheep AUM's) on the Island Park Ranger District and portions (21% of the sheep AUM's) on the Teton Basin Ranger District. The reduction associated with improved big horn sheep habitat amounts to 3,549 AUM's (7.1%) and will reduce (phaseout) sheep grazing (51% of the sheep AUM's) on the Teton Basin Ranger District. As a result of providing improved riparian management, and additional projected reduction of 845 active sheep AUM's (1.7%) will occur on the Dubois Ranger District.

Compared to the existing situation, Alternative 3-M reduces livestock and AUM's, grazing permits and permittees, and the number of allotments and acres open to grazing.

Compared to the existing situation and Alternatives 1 through 3-M, Alternative 4 will achieve better riparian conditions in the shortest amount of time. This will result in a 12% Forestwide reduction of cattle AUM's. Alternative 4 implements the Aquatic Influence Zone Prescription which provides for a 6" HGL stubble height for riparian forage utilization at the end of the grazing period or for all pastures grazed after September 1 and has buffer widths ranging from 150 feet to 300 feet on each side of all fish-bearing streams. The most significant reductions in cattle AUM's will occur on the Dubois, Palisades, Teton Basin, and Ashton Ranger Districts with projected reductions of 7,986 AUM's (20%), 1,770 AUM's (10%), 486 AUM's (8%), and 925 AUM's (6%) respectively.

Alternative 4 implements the phaseout of sheep grazing in grizzly bear habitat and bighorn sheep habitat the same as in Alternative 3-M. The reduction in sheep AUM's on the Dubois Ranger District is also the same as Alternative 3-M.

Compared to the existing situation, Alternative 4 decreases livestock and AUM's, grazing permits and permittees, and the number of allotments and acres open to grazing.

Alternatives 5 and 6 are identical to Alternative 4, except that termination of sheep grazing in grizzly bear habitat will occur immediately.

Cumulative Effects - Because livestock operations and allotment conditions vary across the Forest, it is difficult to determine how each individual allotment or permittee will respond to implementation of the standards, guidelines and prescriptions associated with each alternative. For example, a change in AUM's can be the result of changes in the number of livestock, permitted season, or a combination of both. As demonstrated by traditional and nontraditional range management practices, the loss of AUM's (except those associated with grizzly bear habitat or bighorn sheep habitat) can often be mitigated while improvement in other resources such as fish and wildlife habitat and other "nonproduction" indicators occur. An actual change in AUM's can only occur with a site-specific analysis of each grazing allotment. The projected effects on the indicators associated with AUM's, livestock numbers, permits, and permittees are the Forest's best estimate of the potential impacts (Table IV-23).

Compared to the existing situation, implementation of Alternatives 1, 2, or 3 are not likely to significantly or adversely affect the majority of livestock grazing permittees with grazing privileges on the Targhee National Forest. However, depending on future site-specific analysis for each allotment, some allotments may be affected

Table IV-23. Comparison of Indicators by Alternative by the End of Decade 1								
Indicator	Existing Level	1	2	3	3-M 1/	4 1/	5	6
AUM's Sheep Cattle	55,749 92,316	50,101 93,517	49,801 89,110	49,801 89,022	40,261 89,022	40,261 81,083	40,261 81,083	40,261 81,083
Livestock 2/ Sheep Cattle	72,005 21,696	72,005 21,896	71,605 20,646	71,605 20,646	58,045 20,646	58,045 18,846	58,045 18,846	58,045 18,846
Permittees Sheep Cattle	33 142	33 142	33 142	33 142	25 142	25 132	25 132	25 132
Permits Sheep Cattle	76 201	76 201	76 201	76 201	63 201	63 187	63 187	63 187
Acres (MM) Open Closed	1 498 391	1 400 489	1.400 .489	1.400 .489	1.228 .661	1.228 .661	1.228 661	1.228 .661
Allotments 3/ Sheep Cattle	78 76	69 76	69 76	69 76	54 76	54 76	54 76	54 76
1/ These figures implement the "phase out" of sheep. 2/ These figures are the midpoint of the ranges described in Chapter III 3/ Allotments open to grazing.								

Compared to the existing conditions, implementation of Alternatives 3-M, 4, 5 or 6 will affect livestock permittees on all ranger districts. The largest significant impacts will occur to cattle permittees with grazing privileges on the Dubois and Palisades Ranger Districts, and to sheep permittees grazing sheep on the Island Park and Teton Basin Ranger Districts.

VI. IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

Irreversible commitment of resources refers to a decision that disturbs or reduces a nonrenewable resource, or a renewable resource to the point that renewal can only occur over a long period of time and/or at a great expense. Examples are minerals extraction, loss of cultural resources, and construction of major roads or hydroelectric projects

Irretrievable commitment of resources refers to lost production or use of renewable resources due to land use decisions. This represents the opportunities foregone for the period of time that the resource is unavailable.

Mineral extraction activities will require site-specific environmental analysis that explores the extent and consequences of irreversible commitments. To lessen the irreversible commitment of resources, it is the Forest manager's job to provide mitigation that will minimize adverse environmental impacts. The Forest has about 3300 miles of open or restricted roads. Table IV-12 shows what will happen to that figure over the coming decade. Open and restricted road miles may be regarded as being effectively withdrawn from vegetation production. Roads reclaimed or obliterated may be regarded as beginning to regain their capability to produce vegetation.

There would be some irreversible losses to soil hydrologic function and site productivity in areas where management activities are directed. Adherence to soil quality standards and guidelines, which are designed to reduce adverse impacts to an acceptable level, should allow soils to recover their natural properties for resiliency (e.g., soil organic matter in both surface and subsoil layers, available water holding capacity, etc.).

Road construction, timber harvest, grazing, dispersed recreation and motorized recreation (OHV's) have the highest likelihood of producing irreversible damage to the soil resource. Wildfires within the Cool, Dry Douglas-Fir Forests, Moist Douglas-Fir Forest, and Mid and Lower Elevation Subalpine Forests, where one or more fire cycles has elapsed due to fire suppression, might result in fires having a higher severity and intensity, resulting in irreversible losses (e.g., changes in the soils' chemical and physical properties or in the development of hydrophobic layers with subsequent increased overland flows and accelerated erosion) to the soil resource.

The portions of the inventoried roadless areas that are developed by roading and timber harvest will be lost for future wilderness consideration. Estimated acres that would be developed at some point during the next 150 years range from 40,000 acres in Alternative 6 to 148,000 acres in Alternative 2. Activities that are not scheduled by the Revision or are unforeseen, such as those external to the Forest Service (mining, power transmission lines), may also be regarded as an irreversible or irretrievable commitment of resources. See Table II-1 for a summary of wilderness and undeveloped acreage by alternative.

Adverse Environmental Effects that Cannot be Avoided - Adverse effects on some components of the environment cannot be avoided by actions proposed under the alternatives. Actions to benefit one component may have at least temporary adverse effects on another. A broad range of alternatives have been formulated, each with its own resource or environmental emphasis. Alternatives include management standards and guidelines, along with mitigation measures, to avoid or reduce adverse environmental effects. Monitoring will be used to measure how effective the standards and mitigation measures are in reducing adverse effects.

Some of the adverse effects that cannot be avoided in all alternatives include

- Forest management activities frequently result in impacts upon the visual resource. These changes in the landscape, although usually temporary, are often objectionable to some observers.
- A short-term increase in fire hazard will occur due to waste material, limbs, and tops left on the ground during and following timber harvest operations.
- A long-term increase in fire hazard will occur because actions are not being taken to reduce fuel loadings which are judged to be in excess of the range of variability.
- Intermittent and localized decrease in air quality may result due to dust from road construction, road maintenance and use, and due to smoke from wildfires, prescribed burns, and campfires.

- Short-term localized increases in soil erosion, vegetation degradation, and stream sedimentation may occur due to land-disturbing activities.
- Elimination of small areas from vegetation production will occur due to construction of permanent physical developments.
- Potential for additional conflicts between recreation use and other land use activities will increase in some alternatives.
- Temporary disturbance of wildlife and their habitat conditions in localized areas may result from increased human activity and changed vegetation conditions.
- Energy will be used to manage and provide goods and services.
- Increased soil compaction may occur on activity sites such as timber harvest areas and recreation areas

Many of these adverse effects are temporary, occurring during the site-specific activity, or transitional as forest vegetation progresses through successional stages

Short-term Uses of the Human Environment and the Maintenance of Long-term Productivity - Short-term uses are those that generally occur on a yearly basis, such as livestock grazing of forage or recreation site irrigation as a use of water. Long-term productivity refers to the capability of the land to provide for future generations. The quality of life for future generations is determined by the capability of the land to maintain its productivity.

Alternatives that have the greatest amount of timber harvest activity will result in the most short-term and continuing activity that may have an effect on the long-term productivity. Alternative 2 has the most potential for long-term effects, while Alternative 6 has the least. Other alternatives present middle range effects.

LIST OF PREPARERS

The following is a list of the current Forest Leadership Team (FLT) and Forest Interdisciplinary Team (IDT) members and others who developed the Targhee National Forest Plan, Draft Environmental Impact Statement, and supporting documents

A. Current Forest Leadership Team

Carol Cushing
Branch Chief for Land Management Planning

Ron Dickemore
District Ranger, Palisades Ranger District

Dave Dillard
District Ranger, Ashton Ranger District

Brad Exton
District Ranger, Teton Basin Ranger District

Larry Gorringer
Branch Chief for Engineering, Lands, and Minerals

Adrienne Keller
District Ranger, Island Park Ranger District

Ann Matejko
Public Affairs Officer

Mac Murdock
District Ranger, Dubois Ranger District

Jerry Reese
Forest Supervisor

Ric Rine
Branch Chief for Ecosystems

Chuck Sorenson
Administrative Officer, Branch Chief for Fire Management, Acting Forest Supervisor

B Forest Interdisciplinary Team (Present Members)

B Lynn Ballard

Natural Resource Specialist

Education B.S , Forest Resource Management
Experience U S. Forest Service
Timber Management - 14 years
Winter Sports Planning - 6 years
Function. Core Team Member, Timber, and Insect & Disease

Leon Bleggi

Transportation Planner

Education. Associate Degree, Engineering, Utah Valley Community College
Wildlife Management, University of Southern Utah
Experience. Bureau of Reclamation
Engineering Design and Inspection
Underwater Inspector (SCUBA Diver) - 8 Years
U.S. Forest Service
Engineering Design and Inspection - 11 years
Forest Transportation Planner - 12 years
Function: Core Team Member, Engineering, Access Management, Facilities.

Carol Cushing

Planning Branch Chief

Education. B.S., Forest Management
Experience. U S Forest Service - 16 years
Function: Planning Staff

Katina Harrison

Office Automation Clerk

Experience U S Forest Service - 5 years
Function: Document Preparation

Mark Orme

Wildlife Biologist

Education: B S , Forestry, University of Idaho
M S., Wildlife Management, University of Idaho
Experience. U.S. Forest Service - 14.5 years
University of Idaho - 2 years
Idaho Department of Fish and Game - 2 years
Function Wildlife Section

Dale Pekar

Team Leader, Forest Plan Revision

Education B.A , Economics and Sociology
M S , Economics
Experience U.S Army Corps of Engineers
U.S Forest Service
Land Management Planning, Economic & Social Analysis -
19 years
Function Economic and Social Analysis

Alan R. Silker

Recreation Staff Officer

Education. B.S., Forest Management
M S., Forest Recreation Management
Experience U.S Forest Service
Recreation Management - 25 years
Winter Sports Planning - 20 years
Function Developed and Dispersed Recreation, Roadless, Wilderness,
and Wild, Scenic, and Recreational Rivers analysis.

Fred Straus

GIS Coordinator, Analyst

Education B A , Forest Management
Experience: Peace Corps
U.S. Forest Service
Timber Management - 17 years
Function GIS, FORPLAN, Data Management, and Analysis.

C. Others Providing Substantial Contributions

Kendall Adams

Forest Land Surveyor

Education. Cert. Civil Technology
Experience: Bureau of Reclamation
Surveyor - 5 years
U.S. Forest Service
Engineering - 9 years
Lands - 9 years
Function Lands

Bart Andreasen

Landscape Architect

Education. B.S , Landscape Architecture and Environmental Planning
Experience: Bureau of Land Management
Visual Resources, Recreation Management - 1 year
U S Forest Service
Visual Resources, Recreation Management - 16 year
Function: Visual Resources, Off-Highway Vehicles, and ROS

David Betz

Data Base Manager

Education

Experience

Function

GIS Analysis

Keith Birch

Forest Aviation and Fire Management Officer

Education:

B S , Forest/Range Management, Idaho State University

Experience

U.S Forest Service

Forest Engineering - 8 years

Range Management - 8 years

Recreation Management - 8 years

Fire Management - 7 years

Function

Air Quality, and Fire

Brannon Bleggi*

Function

Visual Resources

Bob Boyles

GIS/CEM Specialist

Education

B S., Information Systems/Accounting, University of Nevada

Experience

U.S Army, Dept. of Vetrans Affairs

U.S Forest Service

Function

GIS and CEM Analysis

Dan Delany

Forest Fisheries Biologist

Education

B.S , Wildlife Management

Experience:

Bureau of Land Management

Range Management - 2 years

Fisheries and Wildlife Management - 14 years

U.S Forest Service

New Perspectives - 1 year

Fisheries and Wildlife Management - 5 years

Function

Fisheries and Aquatic Ecology

Kris Drewes

Forestry Technician

Function:

GIS Analysis

Rod Dykehouse

Forest Fuels Specialist

Education

A.A S , Forest Technology, Michigan Technology University

Experience

U.S. Forest Service

Fire Management - 17 years

Function:

Fire, Air Quality, Jedediah Smith Wilderness Fire Management Plan

Ed Fischer
Assistant Forest Planner

Education. B.S., Forest Management, Michigan State University
Course work completed toward M.S. in Silviculture at Oregon State
University and University of Washington

Experience. U.S. Forest Service
Forestry - 12 years
Planning - 5 years

Function: Chapter 1; Wild and Scenic Rivers

Jim Gerber *

Function: Timber

Kevin Greenwood
Island Park Ranger District

Function Range

Walt Grows
Range Management Specialist

Education. B.S., Forest Recreation (major)
B.S., Range Management (minor)

Experience U.S. Forest Service
Resource Management - 20 years
Forest Planner, Range Sub-Staff, District Ranger,
Resource Officer
(Assistant District Ranger), and Range Conservationist

Function: Range, Acting Forest Planner

Jack Haddox
Natural Resource Specialist
Island Park Ranger District

Education: B.S., Range and Forest Management, Colorado State University

Experience U.S. Forest Service
Range Management - 10 years
Recreation Management - 8 years

Function: Recreation and Lands

Lynn Hansen

Function Lands

Gene Hardin
Forester
Island Park Ranger District

Education: B.S., Forest Management, Clemson University
Region 6 Silviculture Institute Oregon State University of Washington
Wilderness Management, Colorado State University

Experience U.S. Forest Service - 19 years

Function: Roadless Areas

James F. Hayes*

Operations Research Analyst

Prospect Ranger District, Rogue River National Forest

Education B.A , Mathematics

Graduate work in Systems Science and English Literature

Experience: Southern Oregon Regional Services Institute

Urban Planning - 3 years

U S. Forest Service

Land Management Planning - 11 years

Project Planning - 3 years

Function: FORPLAN Modelling, Writer/Editor (Process Paper B)

Sue Heald*

Forest Silviculturist

Education B.S , Forestry

Experience U S Forest Service - 12 years

Function. Ecosystem Management Analysis, and Writer/Editor

Dusty Hincks

Palisades Ranger District

Function Range

Robin Jenkins

Island Park Ranger District

Function. Wild, Scenic, and Recreational Rivers

Bill Kirchhoff *

Function. GIS Analysis

Bob Kirkpatrick *

Function Facilities

Julie Lehmann

Cartographic Technician

Function GIS Analysis

Bill LeVere*

Lilly Mayer *

Function Threatened, Endangered and Sensitive Species

Maureen McBrien*, Past Forest Planner

Martha Merrill
Natural Resources Assistant
Ashton Ranger District

Education: B.S , Forest Management
A.S , Forestry Technician
Experience: U S. Forest Service
Recreation, Wilderness, Lands, Minerals, Reforestation,
Stand Improvement, Timber Sale Planning, Special Uses - 14 years
Function District Representative, Wilderness Specialist

Kaylene Monson
Rangeland Management Specialist
Palisades Ranger District

Education. B S., Range Science
Experience. U S Forest Service - 5 years.
Function. Range Management

Duane Monte
Soil Scientist

Education. B S , Natural Resource Management/Biology - UWSP
Post Graduate Work - Soil Science - UWSP
University of Wisconsin - Stevens Point
Experience. U.S. Soil Conservation Service - 4 Years
U.S Forest Service -16 Years
Function Riparian, Wetlands, Aquatic Infln, and Soils section

Ronna Simon Monte
Hydrologist

Education B S., Geology
M.S., Geography
M.S., Watershed Management
Experience U.S. Forest Service
Watershed Management - 6 years
U S. Geological Survey
Water Resource Monitoring, Quality Assurance - 1 year
Function: Water section and assistance on Wetlands section

Craig Morris *

Function: FORPLAN

Brent Porter
Recreation Forester
Palisades Ranger District

Education. B S., Utah State University, 1972
Experience: U S. Forest Service since 1972
Recreation, Lands, and Trails - 20 years
Timber - 16 years
Minerals - 20 years
Function Recreation, Recreation Special Uses

Cheryl Probert
Dubois Ranger District

Function. Range

John Pruess
Minerals Specialist

Education B A., Liberal Arts, Gettysburg College
M F , Timber Management, Duke University
Experience U.S Forest Service - Timber - 16 years
Minerals - 16 years
Lands - 5 years
Function Minerals and Lands sections

Betsy Rickards *

Function: NFMA and NEPA Compliance

Dee Sessions
Forest Silviculturist

Function. Public Involvement

Bill Shands *

Function Public Involvement

Greg Sorensen
Teton Basin Ranger District

Function Range

Bob Specht

Forest Botanist

Education:

B S , Botany

Experience:

Bureau of Land Management

Botanist - 1 year

Range Technician - 2 years

Range Conservationist - 1 year

Soil Conservation Service

Soil Conservationist - 1 1/2 years

Range Conservationist - 6 years

District Conservationist - 4 years

U S. Forest Service

Botanist - 3 years

Function.

Vegetation

Gretchen Straus *

Function:

Adjacency Analysis

Keith Tweedie

Dubois Ranger District

Function

Range

Skip Willingham

Forest Archaeologist

Education

B.A., Anthropology and Philosophy, University of Alabama

Experience.

U S. Forest Service

Heritage Resource Management - 13 years

Office of Archaeological Research, University of Alabama - 4 years

Function.

Heritage Resources

* - Not affiliated with the Targhee National Forest

**List of
Process
Papers**

Process Papers

Process Paper A - Issue Identification and Public Involvement

Process Paper B - Forplan Analysis

Process Paper C - Tentatively Suitable Timber Analysis

Process Paper D - Wildlife Analysis for the Forest Plan Revision

Process Paper E - Access Working Paper

Process Paper F - Sensitive Plant Species

Process Paper G - Idaho and Wyoming Rare Plant Species

Other Process Papers

- Implementing Ecosystem Management in Forest Plan Revisions (Sept. 23, 1994)
- Adjacent Land Use Patterns Analysis
- Roadless Areas
- Wild, Scenic, and Recreational Rivers Eligibility Determination
- Recreation Use Projection Process for Targhee National Forest Plan Revision
- Jedediah Smith Wilderness Environmental Assessment for Forest Plan Amendment

Draft Forest Plan Revision

Targhee National Forest

DRAFT FOREST PLAN REVISION
for the
TARGHEE NATIONAL FOREST
Intermountain Region R-4
January 1996

Lead Agency:	Forest Supervisor Targhee National Forest P.O. Box 208 St. Anthony, ID 83445
Responsible Official:	Dale N. Bosworth Intermountain Region USDA Forest Service 324 25th Street Ogden, UT 84401
For Further Information Contact:	Jerry B. Reese Targhee National Forest P.O. Box 208 St. Anthony, ID 83445 (208) 624-3151 (208) 624-4049 (fax)

This Draft Forest Plan Revision was prepared according to Secretary of Agriculture regulations (36 CFR 219), which are based on the Forest and Rangeland Renewable Resources Planning Act (RPA) as amended by the National Forest Management Act of 1976 (NFMA). This Draft Forest Plan Revision was developed in accordance with regulations (40 CFR 1500) for implementing the National Environmental Policy Act (NEPA). A detailed Draft Environmental Impact Statement (DEIS) has been prepared as required by NEPA and 36 CFR 219, because the Draft Forest Plan Revision is considered a major federal action significantly affecting the quality of the human environment.

If any particular provision of this Revision, or the application of the action to any person or circumstances, is found to be invalid, the remainder of the proposed action and the application of that provision to other persons or circumstances shall not be affected.

The United States Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, and marital or familial status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (braille, large print, audiotope, etc.) should contact the USDA Office of Communication at (202) 720-7808 (TDD).

To file a complaint, write the Secretary of Agriculture, U.S. Department of Agriculture, Washington, D.C. 20250, or call (202) 720-7327 (voice) or (202) 720-1127 (TDD). USDA is an equal opportunity employer

Chapter

Forest Plan Revision Introduction

CHAPTER I

FOREST PLAN REVISION INTRODUCTION

PURPOSE OF THE LAND AND RESOURCE MANAGEMENT PLAN (FOREST PLAN REVISION)

The Revision guides all natural resource management activities and establishes management standards for the Targhee National Forest (hereafter referred to as "the Forest"). The Revision embodies the provisions of the Resources Planning Act (RPA) as amended by the National Forest Management Act (NFMA), Endangered Species Act (ESA), and other guiding documents. The Forestwide Standards and Guidelines and management prescriptions state the Revision's management direction; however, the project outputs, services, and rates of implementation are dependent on the annual budgeting process.

The Forest Plan will be revised every 10-15 years, or sooner should conditions or demands significantly change

Development of the Revision occurs within the overall framework of both National and Regional Planning. The Revision and accompanying Environmental Impact Statement (EIS) are "tiered" to the Intermountain Regional Guide. Regional planning is a two-way street that helps convey direction from National to the Forest level, and helps transmit information from the Forest to the National level. The Regional Guide establishes standards and guidelines, and resolves Regional issues

During the Revision process, alternatives were developed, analyzed, compared, and a preferred alternative selected. This Revision is based on the "preferred alternative" displayed in the accompanying Draft Environmental Impact Statement (DEIS). The planning process and analysis procedures used in developing this Plan, as well as the other management alternatives that were considered, are described or referenced in the DEIS. In the development of the alternatives, estimates were made based on broad averages, as to the various activities and resulting outputs of implementing that alternative. These estimates were used to compare alternatives and to arrive at the preferred alternative. Actual outputs may vary slightly from those displayed in the preferred alternative, however, the intent of the preferred alternative will be met.

Forest Plan direction serves as an "umbrella" for the environmental analysis for proposed projects at the Forest and Ranger District levels. Future environmental analyses documented in environmental assessments (EA's) and EIS's will refer to this Plan, the accompanying EIS, and related documents wherever possible (except for the travel plan which will be implemented based on the Final EIS (FEIS) associated with this plan). EA's will be developed for project level activities not specifically described in this Plan and will concentrate on issues unique to the project.

The Revision does not give specific "how-to's" of project implementation. Many implementation plans will be developed during the life of the plan that will provide this operational direction. These plans will be adapted as new scientific principles and methods become available to improve resource management activities. The Revision does provide Wilderness Plan direction in the form of prescriptions, Standards and Guidelines, Implementation Schedules, and Monitoring Plans for the Jedediah Smith and Winegar Hole Wildernesses. In addition, the Revision contains detailed guidance for implementing Travel Management Plan Maps for all Districts on the Forest. A fire management plan for the Jedediah Smith Wilderness has recently been completed which outlines operational direction for that portion of the forest.

The Revision replaces previous resource management plans. Upon final approval of the Revision, all Forest activities, including budget proposals, will conform to it. All permits, contracts, and other uses of Forest lands must also conform with the Revision. But some existing permits and leases are already committed. In this case, existing contracts will remain in effect until they can be adjusted to accommodate Revision direction.

PLAN STRUCTURE

The Revision provides the long-term direction for managing the Forest. The Revision contains the overall direction when implemented to achieve the desired condition of the Forest.

The Forest Plan is organized into five chapters and two appendices:

Chapter I Forest Plan Revision Introduction

Discusses the general purpose of the Forest Plan, the relationship of the Plan to other documents, and the Plan structure. Includes a brief description of the Forest.

Chapter II Summary of the Analysis of the Management Situation (AMS)

Summarizes the key information contained in the AMS and describes the need to revise the Targhee National Forest Management Plan.

Chapter III Forest Management Direction

Presents the Forestwide Management Direction, provides ecological subsection descriptions, lists the management prescriptions, and presents the direction, standards and guides for management of the Forest.

Chapter IV Implementation of the Forest Plan

Displays the major activities required to meet the Desired Future Conditions (DFC) set forth in the EIS.

Chapter V Monitoring and Evaluation

Shows how the Forest will monitor compliance with, and performance of, critical standards and guidelines in the Revision. In this sense it is only a part of a larger range of project level monitoring activities which take place on the Forest.

Appendix

Summary of National Goals Relevant to Land and Resource Management.

Glossary

Defines technical terms used throughout the document

Index

LOCATION OF THE FOREST

The Forest contains approximately 1,810,000 acres of National Forest System land located in south east Idaho and western Wyoming. Parts of the Forest lie in Idaho counties of Bonneville, Butte, Clark, Fremont, Jefferson, Lemhi, Madison, Teton, and Wyoming counties of Lincoln and Teton. The Forest is bordered on the east by Yellowstone and Grand Teton National Parks and the Bridger-Teton National Forest, south by the Caribou National Forest, west by the Challis and Salmon National Forests, and north by the Beaverhead and Gallatin National Forests. Figures I-1 and I-2 display the location of the Forest on a National and local scale.

The Forest has five administrative Districts.

<u>District</u>	<u>Net Acres</u>
Dubois D-1	458,080
Island Park D-2	345,518
Ashton D-3	357,350
Palisades D-4	472,315
Teton Basin D-5	267,632

The Forest Supervisor's office is located in St. Anthony, Idaho.

Chapter

Summary of the Analysis of the Management Situation

CHAPTER II

SUMMARY OF THE ANALYSIS OF THE MANAGEMENT SITUATION

I. Introduction

This chapter summarizes the key information contained in the AMS and describes the need to revise the Targhee National Forest Land Management Plan.

II. Purpose of Preparing an AMS

The Revision process began by completing an AMS in 1992. A comprehensive review of the existing Plan identified changed conditions and new information, including new public issues and changed public attitudes and awareness, which affected the appropriateness of continuing with the management direction in the Plan.

A comprehensive review of the existing Plan is included in the AMS. This analysis: 1) described the present Forest condition, 2) defined the progress that has been made in implementing the Plan with respect to accomplishment of goals and objectives set forth in the Plan; and 3) showed how effective standards and guides were in achieving the desired future conditions described in the Plan.

III. Primary Emphasis of the Plan

A primary goal of the existing Plan was to harvest and reforest the thousands of acres of lodgepole pine that had been killed or damaged by the mountain pine beetle. To achieve this goal, species/product mix objectives were established. The objective for a mix of species was about 10 percent of the acres harvested were to be Douglas-fir and about 90 percent lodgepole pine. Another objective was to provide a product mix that was 40 percent sawtimber and 60 percent other products, such as posts, poles and firewood. A third objective limited the percent or number of acres within each Management Area that would be harvested.

IV. Results of Monitoring

The results of monitoring indicate the volume of timber actually harvested, for both lodgepole pine and Douglas-fir, is near planned levels. This volume was achieved from only 58% of the acres originally considered for harvest.

It was expected that standards and guidelines could be followed while operating at the Allowable Sale Quantity (ASQ) level. The Forest experienced difficulty in meeting many of the standards and guidelines. According to Forest Service direction, the ASQ is to be adjusted if standards and guidelines cannot be met.

The species mix objective was reached with the harvest of 11% Douglas-fir and 89% lodgepole pine. The product mix objective was not met. The product mix was 76% sawtimber and 24% other products which exceeded the 20% allowance set forth in the Plan.

Habitat effectiveness for big game and grizzly bear has been reduced through increases in road density and reduction of cover.

The standards and guidelines in the Plan have resulted in improvement of some degraded riparian habitats.

The Regional Forester and the U.S. Fish and Wildlife Service have increased the number of plant and animal species found on the Forest, listed as threatened and endangered, or sensitive from a total of 12 to 26.

V. Public Interaction and DFC

Social needs and desires have changed, as evidenced by the number of administrative appeals and lawsuits that challenge the application of current Forest management. The proposals most frequently challenged in the last four years have been timber harvests. Issues have centered on impacts to wildlife and, to a lesser extent, recreation and scenic values.

The existing Plan was designed by focusing primarily on capabilities of the land to produce commodities such as timber, recreation days, or livestock forage. The advent of ecosystem management (EM) requires that the Forest be managed for sustainability of all ecosystem components, many of which were not adequately addressed in the existing Plan (e.g., riparian systems).

Public comments and ideas received through scoping identified new public expectations as to what uses and benefits the Forest should provide. The new DFC which emerged could not be achieved under the existing Plan direction. They are grouped into ecologic, social, and economic components as described below.

Ecologic Component

- ◆ A mosaic of age classes and different types of vegetation, which can be sustained through time, exists across the landscape. Insects, disease, fires, plants, and animals are allowed to play their natural role in ecosystem dynamics to the extent compatible with other resource objectives.
- ◆ Native plant and animal species are favored and habitats are managed with the goal of delisting threatened and endangered species.
- ◆ The Forest serves as an important link within the Greater Yellowstone Ecosystem as well as to adjacent ecosystems, allowing free movement of wildlife.
- ◆ Aquatic and riparian ecosystems are healthy and productive. Aquatic systems are allowed to function naturally while protecting flows for downstream consumptive uses. Riparian area integrity contributes to productive fisheries and excellent water quality.

Social Component

- ◆ Growing and diverse recreational and cultural needs are accommodated within the capability of the ecosystem to sustain these uses. Increased recreation opportunities are managed to minimize conflicts with other forest uses and provides high levels of satisfaction.
- ◆ Year-round human access is managed to provide both motorized and nonmotorized recreation opportunities. A system of trails and support facilities exists which is compatible with resource capabilities.
- ◆ Roadless characteristics are preserved in existing roadless areas and proposed wilderness.
- ◆ Recreation sites, facilities and trails are well-maintained. Campgrounds provide an appropriate level of service.

- ◆Heritage resources are identified and protected. Enhancement and interpretation of historic properties takes place where appropriate.
- ◆The Forest features landscapes with a natural appearance.

Economic Component

- ◆Commodity production activities, such as timber harvest and livestock grazing, are conducted at sustainable levels and maintain the capability of the land to produce an even flow and variety of goods and services for future generations
- ◆Logging and grazing are tools used to achieve desired sustainable vegetation conditions.
- ◆The Forest provides economic opportunities, such as timber harvesting, mining, livestock grazing and recreation, to protect the social and economic values of local communities.
- ◆Forest products (e.g., firewood) are provided to address local community needs within limits which maintain ecosystem health.

VI. New Information

Another reason for embarking on the Revision is the need to review and incorporate new knowledge and techniques to improve sustainability of ecosystems. Recent studies and publications indicate, for example, that road density plays a more crucial role in habitat management for elk and grizzly bears than was assumed in the Plan. Much work has been done to develop standards for nesting and foraging habitat for goshawks and other raptors. EM efforts analyzing fish habitat in the Upper Columbia River Basin have suggested new ways of managing fisheries and aquatic ecosystems. These findings and other information have been reviewed for their applicability to habitat management on the Forest and incorporated where appropriate.

VII. Needs for Change

In total, the DFC, issues, and new information previously described provide the basis for revising the Plan. These needs for change are described below.

Ecologic Component

- ◆Manage to reduce elk vulnerability.

This need for change is prompted by new research indicating that motorized access density and hunter density are important factors contributing to elk vulnerability (EV). State Fish and Game Departments manage hunter densities, while the Forest Service manages motorized access. The accelerated timber harvest over the past decade has created many roads, and clearcutting in the lodgepole pine component has reduced cover. This combination resulted in high vulnerability for elk in some parts of the Forest. EV on winter range has also increased due to development on private lands adjacent to the Forest boundary and increasing levels of recreation use.

- ◆Encourage grizzly bear recovery.

During the last planning period, the Forest was charged with managing habitat to promote recovery of grizzly bear while implementing a large timber salvage program. The Forest complied fully with

the grizzly bear guidelines within the framework of habitat management as it was understood at the time. Direction from the U.S. Fish and Wildlife Service regarding management of grizzly bear habitat has changed since the Plan was developed. New information, accumulated over the last ten years, provides new insight and direction regarding effective management of access, vegetation manipulation, and human activities in grizzly bear habitat.

◆ **Improve the condition of riparian areas. Manage for more resilient riparian systems.**

New information developed in the last decade more precisely defines healthy, resilient riparian systems and indicates new approaches to management of aquatic influence zones. Stream channel stability and healthy riparian vegetation have become more important to the public in general, partly in the context of overall ecosystem health and resilience.

◆ **Manage for sensitive wildlife and plant species.**

Since the Plan was adopted/implemented, many species of wildlife and plants have been added to the sensitive species list. Management direction needs to be developed for these species. Also, additional information has become available regarding most of these sensitive species, and that knowledge may indicate new directions for management of the Forest.

Social Component

◆ **Manage human access to the Forest, integrating the needs of wildlife with the needs of people.**

The Plan allows cross-country motorized travel across much of the Forest and does not establish road density standards for any portion of the Targhee. New research indicates that many species of wildlife, including grizzly bear and elk, may require reduced motorized and nonmotorized human access. Recreational use of the Targhee has increased since the Plan was developed. For these two reasons, the Plan revision needs to address and balance the management of access to provide both secure habitat for wildlife and opportunities for human enjoyment of the Forest. In addition, questions have arisen about the appropriate mix of motorized versus nonmotorized access.

◆ **Protect the unroaded characteristics of existing roadless areas**

This need for change from current management is based on a shift away from lodgepole pine salvage toward less intensive management. During the last planning period some roadless areas were allowed by the Plan to be roaded as part of the salvage program. Some forest users are now calling for maintaining the roadless character of the remaining roadless areas on the Forest.

Economic Component

◆ **Harvest timber at or below sustainable levels. Balance timber harvest with the needs of wildlife.**
In the last planning period, large-scale salvage of dead and dying timber was conducted at levels that were outside of sustainable levels. During the planning period the Forest operated within legal direction that provided for departure from sustained-yield timber management to accomplish urgent salvage needs. Since the goals for the harvest of dead and dying timber have largely been met, the Forest will operate within the legal requirements for sustained-yield timber management in the next planning period.

In the Plan, timber production was emphasized over fisheries and wildlife habitat management. Now that the lodgepole pine salvage is completed, there is a need to provide for timber production while conserving biodiversity within all forest ecosystems.

INTRODUCTION

The Forestwide Standards and Guidelines are organized by ecological groupings, as shown in the table of contents. These standards and guidelines for the management of the different forest resources apply to all or most areas of the Forest, and are used in conjunction with additional standards and guidelines included within each management prescription.

Goal, a concise statement that describes a DFC which normally is expressed in broad, general terms that are timeless, in that there is no specific date by which each goal is to be achieved.

Objective, a concise, typically time-specific statement of a condition, outcome, or purpose. Objectives are often measurable planned results that respond to goals.

Standards, describes a condition of land, normally a maximum or minimum condition, that is measurable. A standard can also be expressed as a constraint on management activities or practices. Standards are established on a forestwide, subsection, and management prescription area basis to promote achievement of the DFC and objectives. Deviation from compliance with a standard requires a Forest Plan amendment (except for emergency situations as explained below). (USDA Forest Service, 1993)

Guidelines, represent a preferred or advisable course of action that is generally expected to be carried out. Deviation from compliance with a guideline does not require a Forest Plan amendment, but the rationale for such a deviation shall be documented in the project decision document. Guidelines are established on a forestwide, subsection, and management prescription area basis to promote achievement of the desired future condition and objectives in an operationally flexible manner that responds to such variations as changing site conditions or changed management circumstances (USDA Forest Service, 1993)

The standards and guidelines in this section of the document are common to the entire Forest. Forestwide goals and (in some cases) objectives are provided for each resource area and/or activity. Following the goals and objectives, the specific standards and guidelines are presented. A standard is identified with an (S), and a guideline is identified with a (G). A diligent effort has been made to make these goals and objectives, and standards and guidelines specific to the Forest. This set of standards and guidelines is the result of many suggested changes made by our publics and employees.

These standards and guidelines are to be used in conjunction with Forest Service policy and direction from Forest Service Manuals and Handbooks. A summary of National program and regional policy and goals can be found in Appendix A

If an emergency event occurs on the Forest, deviation from these standards and guidelines may occur in order to protect human life, property values and structures, and forest resources. Activities in response to emergency events include such things as law enforcement, search and rescue, and fire.

ECOLOGICAL PROCESSES AND PATTERNS

Biodiversity

Goals

1. Biodiversity is maintained or enhanced by managing as much as possible for a "diverse" array of habitats tied to the natural occurrence and distribution of plant communities.

2. The biological diversity elements of structure, composition, and function are provided at appropriate landscape scales.

Objectives

1. By 2007, determine the range of natural variability of vegetation conditions by subsection for the Forest
2. Regenerate and maintain plant associations within the range of natural variability for each ecological subsection or watershed.
3. Provide dead and down woody material to meet habitat requirements for those species of wildlife, insects, fungi, and other microscopic plant and animal species associated with this type of habitat (see the Soils and the Wildlife Sections and standards and guidelines below for specific standards).
4. Obtain and document historical information on mountain mahogany communities.
5. Treat aspen plant communities to reduce encroaching conifers and maintain a balance of age classes for these communities.

Standards and Guidelines

1. Sagebrush/grassland habitats. Within big sagebrush (*Artemisia tridentata* & varieties)/grassland habitats strive for canopy coverage distributions on a subwatershed (generally 2,000 to 6,000 acres in size) basis of (G):

- Less than 5 percent of a subwatershed in a less than 5 percent canopy coverage class.
- 75 percent of a subwatershed in a well distributed mosaic of canopy coverage ranging from 5-30 percent
- 20 percent of a subwatershed in a greater than 30 percent canopy coverage class.

2. Forested successional stages. At this time, the range of natural variation is not known. Until more information is obtained, these guidelines will be applied. Maintain > 20% of the forested acres in a late successional stage in each ecological subsection. For the conifer forest types, the acres in late successional stages should be in blocks > 300 acres in size (a block can be comprised of a combination of late successional forest types). (G)

Forest Type	Age of Dominant Overstory Trees
Lodgepole Pine	80+
Douglas-fir	100+
Mixed Conifer	90+
Spruce/Fir	100+
Aspen	40+
Cottonwood	50+
Juniper/Mahogany/Mtn Brush	20+

3. Maintain, and where possible, increase unique or difficult-to-replace elements or habitats [such as whitebark pine and areas of high species diversity (e.g., aspen, riparian zones, etc.)]. (G)

4. **Dead and Down Material.** No more than 40 percent of the forested portion of an analysis area should fall below the Forestwide standards for down woody material (see Forestwide Soils and Wildlife). If more than 40 percent is below, then retain twice the amount of down woody material as required in the Forestwide standards in any new harvest units. Forested areas include regenerating stands, but exclude meadows, rock and water. Data may be lacking for this analysis, so managers can assume that any unmanaged stand meets Forestwide standards for down woody material. The analysis can be done in either of two ways. 1) Make sure that no more than 40 percent of each habitat type in the analysis area meets the standard. OR 2) Discern the dominant habitat type for the analysis area and ensure that no more than 40 percent of the analysis area falls below the standard. (S)

5. **Emphasize methods of vegetation treatment that emulate natural ecological processes and restore functioning ecosystems.** (G)

Insects and Disease

Goal

Insects and disease are allowed to play their natural role in ecosystem dynamics to the extent compatible with other resource objectives

PHYSICAL ELEMENTS

Soils

Goal

Long-term soil productivity is sustained by retaining fine organic matter and woody residue on activity areas.

Standards and Guidelines - Soil Quality (applicable only to current activity areas):

1. **Fine Organic Matter -** meets soil cover requirements. Generally strive to maintain fine organic matter over at least 50 percent of the area. The preference is for fine organic matter to be undisturbed, but if disturbed, it should be of sufficient quantity and quality to avoid detrimental nutrient cycle deficits. If the soil and potential natural plant community are not capable of producing fine organic matter over 50% of the area, adjust minimum amounts to reflect potential soil and vegetation capability. (G)

2. **Woody Residue Requirements.** Sustain site productivity by providing the following minimum amounts of woody residue dispersed on the site: (G)

Woody Residue Requirement (tons/acre) 1/	Forest Habitat Type	
3-5	Limber pine/curl-leaf mountain mahogany (Pifl/Cele) Douglas-fir/common juniper (Psmc/Juco)	Douglas-fir/mountain snowberry (Psmc/Syor) Lodgepole pine/heartleaf arnica (Pinc/Arco)
5-10	Douglas-fir/ninebark (Psmc/Phma) Douglas-fir/mountain maple (Psmc/Acgl) Douglas-fir/blue huckleberry (Psmc/Vagl) Douglas-fir/grouse whortleberry (Psmc/Vasc) Douglas-fir/common snowberry (Psmc/Syal) Douglas-fir/white spirea (Psmc/Spbe) Douglas-fir/pine grass (Psmc/Caru) Alpine fir/white spirea (Abla/Spbe)	Alpine fir/pine grass (Abla/Caru) Alpine fir/heartleaf arnica (Abla/Arco) Whitebark pine/ross sedge (Pial/Caro) Lodgepole pine/blue huckleberry (Pico/Vagl) Lodgepole pine/grouse whortleberry (Pico/Vasc) Lodgepole pine/white spirea (Pico/Spbe) Lodgepole pine/pine grass (Pico/Caru) Lodgepole pine/elk sedge (Pico/Cage)
10-15	Douglas-fir/mountain sweetroot (Psmc/Osch) Engelman spruce/softleaved sedge (Pien/Cadi) Alpine fir/ninebark (Abla/Phma) Alpine fir/blue huckleberry (Abla/Vagl) Alpine fir/grouse whortleberry (Abla/Vasc)	Alpine fir/mountain arnica (Abla/Aria) Alpine fir/common snowberry (Abla/Syal) Alpine fir/western meadow-rue (Abla/Thoc) Alpine fir/oregon grape (Abla/Bere)
15-20	Engelman spruce/sweetscented bedstraw (Pien/Gatr)	Alpine fir/baneberry (Alba/Acru) Alpine fir/mountain sweetroot (Abla/Osch)
1/ Woody residue for long-term site productivity includes all woody materials greater than or equal to 3" in diameter		

3. During site preparation treatments strive to avoid disturbing concentrated areas of soil wood. (G)

Standards and Guidelines - Slope Stability for Mineral Activities:

1. In areas of high mass instability, that have been ground verified, occupancy shall not be allowed. (S)
2. In areas identified as having a moderate rating of instability, and that are ground verified, occupancy would be allowed provided that it could show that the project design can prevent unacceptable resource damage. (G)

Caves

Standards and Guidelines

1. Restrict logging, road construction, and other uses of heavy equipment above or in the vicinity of a cave with a thin roof, or the course of such a cave, if there is a potential for damage. (G)
2. Retain vegetation in the vicinity of a cave or cave course if it is required to protect the cave's microenvironment. (G)
3. Fell trees away from the cave and its course if timber harvesting is permitted in the vicinity of a cave. (G)
4. Cave entrances will not be altered or used as disposal sites for slash, spoils, or other refuse and no action will be taken to prevent or hinder ingress or egress of cave-dependent wildlife. Gating of cave entrances will be allowed as long as physical alteration of the entrance is not needed to construct the gate. Wilderness values will also be considered prior to installing such structures. (S)

5. Management activities will not be permitted within any area draining into a cave if they are likely to affect the cave ecosystem through sedimentation, soil sterilization, the addition of nutrients or other chemicals (including pesticides, herbicides, and fertilizers) or by changing the cave's natural hydrology. (S)

6. Surface drainage will not be diverted into caves. (S)

Lands

Goal

The National Forest System lands set aside for utility corridors would be minimized to reduce fragmentation and minimize acres set aside to that use

Objectives

1. Locate new applications for utility corridors in existing corridors.
2. Remove utility facilities which are presently in avoidance or exclusion areas as it becomes practical to do so.

Minerals

Objectives

1. Oil and gas pipelines and other related utilities should be constrained to one utility corridor except as needed to meet other resource objectives.
2. Leasing decisions including identification of lands available for leasing will be made in the Forest Oil and Gas Leasing EIS and its associated Record of Decision.

Standards and Guidelines—Locatable and Mineral Materials

1. Common Minerals. Give priority to use of currently developed common mineral (natural gravel and hard rock) material sources over undeveloped sources. Exceptions should be made when existing sources are unable to economically supply the quality and quantity of material needed or when conflicts with other resource uses are found to be unacceptable. (G)
2. The Forest is open to exploration and development and production of locatable, leasable, and mineral material resources unless otherwise specified in the management prescriptions

BIOLOGICAL ELEMENTS

Aquatic, Riparian Resources, and Watersheds

Goals

1. For individual streams, channel stability would be rated at good to excellent, except where instability is due to natural causes (e.g., avalanche) and therefore unavoidable

2. Desirable habitat conditions, connectivity, biodiversity, and viable populations of native cutthroat trout would be achieved primarily as a result of the maintenance and restoration of natural ecological functions and processes.

3 Water quality would have improved on streams identified by the State of Idaho as having water quality concerns and they would be removed from the Water Quality Limited list

Objectives

1. By 2007, watershed improvement needs backlog would be completed in the Lemhi/Medicine Lodge, Big Hole/Palisades Mountains, Caribou Range Mountains Subsections. Watershed improvement needs identified in the Teton Basin Study would be verified. Watershed improvement needs would be inventoried on the Centennials, Madison Plateau, and Teton Subsections.

2. By 1998, all streams supporting native cutthroat trout would be inventoried, classified, and delineated in GIS database. Restoration activities would be planned and scheduled for stream reaches found to be in unsatisfactory condition.

Standard and Guideline - Watershed, General

Not more than 30 percent of any of the 39 principal watersheds and their subwatersheds should be in a hydrologically disturbed condition at any one time. (G)

Standards and Guidelines - Municipal Watersheds

1 Use fertilizers and pesticides (chemical or biological) only in emergency situations, and then only following close coordination with the municipality involved. (G)

2. Avoid use of fire retardants when other effective measures of fire control are available. When the use of fire retardants within domestic supply watersheds is necessary, all reasonable efforts will be made to avoid direct application into live streams Only fertilizer-based retardants will be used. (G)

3 Locate fire camps outside municipal supply watersheds. When timber sales or other operations are located within a municipal supply watershed, wastes (including domestic, human, oil from machinery, etc.) will be transported outside the watershed for disposal. (G)

Standards and Guidelines - Aquatic Resources

1 New special use permits or new Forest Service projects involving instream facilities, exclusive of facilities retrofitted to existing dams, must maintain Forest-specified minimum instream flows and, on fish-bearing streams, provide for fish passage and include screening devices to prevent accidental loss of fish. (S).

2. When reauthorizing existing special use permits or existing Forest Service projects involving instream facilities, exclusive of facilities retrofitted to existing dams, where feasible provide for Forest-specified minimum instream flows and, on fish-bearing streams, where feasible provide for fish passage and include screening devices to prevent accidental loss of fish (G).

Vegetation

Objective

Preserve unique formations within a landscape such as cliffs, bogs, talus slopes, warm or alkaline springs, pot holes, and rock outcroppings that provide habitat to plant species not common to the overall landscape, and contribute to the species diversity within the landscape.

Standard and Guideline - Plant Species Diversity

Native plant species from genetically local sources will be used to the extent practicable for erosion control, fire rehabilitation, riparian restoration, forage enhancement, road right-of-way seeding, and other revegetation projects. (G)

A. Areas planned for nonnative seedings or plantings of nonnative woody species need to be evaluated to determine the impacts to the native flora within the planning area and habitats adjacent to the planning area. (G)

B. Introduced species should be utilized in project seedings where native species would not meet the objectives of erosion control, such as in high use or impact areas, and where the effects on local, native flora is minimal; sites that are currently dominated by introduced species and use of nonnative species has not degraded the adjacent native flora; and sites where the management objectives is to utilize nonnative species in one area to prevent degradation of other natural areas. (G)

Objectives - Special Forest Products

1. Establish guidelines for commercial harvesting of special forest product species.
2. Provide for the historical, cultural, and recreational uses, as well as rights and privileges afforded Native Americans under treaties and agreements, before commercial uses of special forest products are allowed.

Wildlife

Goals

1. Wildlife biodiversity is maintained or enhanced by managing for a diverse array of habitats tied to the natural occurrence and distribution of plant communities.
2. Provide habitat to support the wildlife and hunting goals of the States of Idaho and Wyoming.

Standard and Guideline - General Habitat

1. Dead and Down Material. Provide dead and down woody material in activity areas by doing the following:
 - A. An average total of at least 20 logs per acre in decomposition classes 1, 2, and 3 (USFS, 1979) shall be retained in all project activity areas (e.g , timber harvest units). (S) Retain decomposition classes 4 and 5 where they occur. (G)

1. An average of 7 logs per acre should be maintained in each decomposition class 1, 2, and 3. If logs are not present in a given decomposition class, logs from lesser decomposition classes should be retained to substitute, e.g., classes 1 and 2 can substitute for class 3. (G)

2. Logs should be at least 7 inches in diameter at the small end, be at least 20 feet long, and have a volume of at least 10 cubic feet, e.g., a log averaging 9.5 inches in diameter and 20 feet long. (G)

a. Tree tops are not included in this volume estimate.

b. Smaller size logs may only be used in meeting this volume criteria if the area is incapable of producing larger trees, or the stand is too young to have 12" DBH trees. In these cases, logs representing the largest tree diameter class present in the stand should be retained and at least 200 cubic feet per acre of down logs shall be retained. This equals about 2.3 tons per acre.

c. For every area 2 acres in size, capable of growing sufficient trees, there should be at least 2 logs.

2. Raptor Nest Sites. Raptor Nest Sites in use should be protected by providing a minimum 2-tree height buffer around the nest area unless otherwise specified. (G)

3. Winter Feeding of Big Game. Allow no new permanent feed grounds for wintering big game animals. (S)

Objective - Snag/Cavity Nesting Habitat

Determine the biological potential for cavity nesting habitat on a watershed basis to enable management of some areas at higher levels of biological potential and some at lower levels of biological potential and meet the overall management prescription objectives.

Standards and Guidelines - Snag/Cavity Nesting Habitat

1. Retain snags within all management prescription areas allowing timber harvest (refer to the following Tables 1 & 2 for snag requirements of cavity nesting species; refer to the wildlife standards and guidelines in each management prescription for the specific biological potential to be achieved) (G)

Table 1. Snag requirements for 100 percent biological potential for woodpecker populations.

Species	Range in Snag DBH (inches)	Range in Snag Height (feet)	No of Snags per 100 Forested Acres for 100 Percent Biological Potential			
			Aspen	Cottonwood	Doug-fir Spruce/Fir	Lodgepole
Lewis's Woodpecker	12 to 27	5 to 170	101	101	101	NA
Yellow-bellied Sapsucker	9 to 47	15+	150	150	150	150
Williamson's Sapsucker	12 to 37	15+	NA	NA	150	150
Downy Woodpecker	6 to 14	6 to 50	300	300	300	300
Hairy Woodpecker	9 to 29	15+	180	180	180	180
Three-toed Woodpecker	7 to 19	15+	59	NA	59	59
Black-backed Woodpecker	8 to 17	6+	NA	NA	59	59
Northern Flicker	10 to 51	6+	38	38	38	38
Total Hard Snags per 100 acres			828	769	1037	936
NA indicates the species does not use this forest type.						

Table 2. Snag requirements for maintaining various percentages of biological potential for woodpecker populations (refer to Table 1 for snag dbh, snag height, and individual species requirements).

Percent of Biological Potential	Number of Hard Snags per 100 Forested Acres			
	Aspen	Cottonwood	Doug-fir Spruce/Fir	Lodgepole
100	828	769	1037	936
80	662	615	830	749
60	497	461	622	562
40	331	308	415	374
20	166	154	207	187

2. Retain live trees for future snag recruitment using the following guidelines to achieve various percentages of biological potential' (G)

Percent of Biological Potential	Number of Live Trees per Forested Acre				Total Tree/Acre
	>= 10 in dbh	>= 7 0-9 9 in dbh	>= 5 0-6 9 in dbh	< 5 0 in. dbh	
100	8	5	5	7	25
80	6	4	4	6	20
60	5	3	3	4	15
40	3	2	2	3	10
20	2	1	1	1	5

3. In analysis areas where snag numbers are low (at or approaching management minimums), no dead standing trees should be harvested. (G)

Goals - Grizzly Bear Habitat

1. Habitat conditions will be sufficient to sustain a recovered population of grizzly bears
2. Allow for uninhibited movement of bears (continuity with Yellowstone National Park and adjacent bear management units).

Objectives - Grizzly Bear Habitat

1. Meet recovery criteria in the Grizzly Bear Recovery Plan.
2. Implement guidelines developed by the Interagency Grizzly Bear Committee
- 3 Provide safe, secure sites for bears in trouble.
4. Implement the road density standards in the Bear Management Units (BMU's) within 3 years of the signing of the ROD in coordination with USFWS and State Wildlife agencies.

Standard and Guideline - Grizzly Bear Habitat

The grizzly bear education program will focus on; residents in residential and summer home areas, developed recreation site users, wilderness users, and hunters. (G)

Standards and Guidelines - Bald Eagle Habitat

In Occupied Nesting Zones (Zone I) and Primary Use Areas (Zone II) apply the following.

- A. Minimize all human activities from February 1 to August 1. (G)
- B. No new roads in Zone I. (S) Avoid building new roads in Zone II. (G)
- C. Manage human use on existing roads at levels which do not adversely affect use and productivity of the nest site. (G)

D. No new developed recreation sites or facilities in Zone I. (S) Avoid building new recreation sites or facilities in Zone II. (G)

E. Manage existing recreation use at levels which do not adversely affect use and productivity of the nest site. (S)

F. Use the "No Surface Occupancy" stipulation for all minerals activities. (S)

G. If eagles choose to establish new nest sites and use areas in an area already receiving human use, the human activities may be restricted or modified. Expanded human activity, however, should be discouraged. (G)

H. Use silvicultural techniques which maintain or promote mature and old growth timber stand characteristics in both the short and long term, but reduce the risks of insects and disease epidemics. (S)

I. Vegetation management can only occur between September 1 and January 31. (S)

J. Use "control" as the appropriate suppression response for wildfires to minimize loss of habitat. (G)

K. Allow no new structures that have the potential to cause direct mortality to bald eagles (e.g. power lines). (S)

L. Historic levels of livestock use are permitted as long as no adverse impacts (such as abandonment of nest territory or reproduction failures) occur related to this activity. Manage livestock to allow successful reproduction of cottonwood where applicable. (G)

M. Allow no wildlife management or predator control activity with the potential to cause mortality to bald eagles (e.g. exposed traps). (S)

N. Within Home Ranges (Zone III) follow existing site-specific management plans for each bald eagle territory (S)

Objective - Gray Wolf Habitat

All wolves found in the wild on the Forest will be considered nonessential experimental animals as defined in the FEIS for The Reintroduction of Gray Wolves to Yellowstone National Park and Central Idaho. (USDI Fish and Wildlife Service 1994 a and b)

Standards and Guidelines - Gray Wolf Habitat

1. Restrict intrusive human disturbances (motorized access, vegetation management, livestock grazing, etc.) within 1 mile around active den sites and rendezvous sites between April 1 and June 30, when there are 5 or fewer breeding pairs of wolves in the Yellowstone Nonessential Experimental Population Area (applies to the portion of the Forest east of Interstate 15) or the Central Idaho Nonessential Experimental Population Area (applies to the portion of the Forest west of Interstate 15). After 6 or more breeding pairs become established in each experimented population Area, land-use restrictions will not be needed. (USDI Fish and Wildlife Service 1994 a and b) (S)

2. The ability of individuals holding grazing permits on public land to harass adult wolves in an opportunistic, noninjurious manner will become part of their permit conditions so it is clearly understood exactly what can occur. There is a 7 day reporting requirement. (USDI Fish and Wildlife Service 1994 a and b) (S)

3. The following conditions and criteria will apply in determining the problem status of wolves. (USDI Fish and Wildlife Service 1994 a and b) (S)

A. Wounded livestock or some remains of a livestock carcass must be present with clear evidence that wolves were responsible for the damage and there must be a reason to believe that additional losses would occur if the problem wolf or wolves were not controlled. Such evidence is essential since wolves may simply feed on carrion they have found while not being responsible for the kill.

B. Artificial or intentional feeding of wolves must not have occurred. Livestock carcasses not properly disposed of in an area where depredations have occurred will be considered attractants. Removal or resolution of such attractants must accompany any control action. Livestock carrion or carcasses not being used as bait in an authorized control action (by agencies), must be removed, buried at least 2 feet underground, burned, treated with an acceptable chemical repellent, or methods approved by the District Ranger, such that the carcass(es) will not attract wolves.

C. Animal husbandry practices previously identified in existing approved Allotment Management Plans and annual operating plans for allotments must have been followed.

4. If additional livestock depredations are likely, proper animal husbandry practices are employed (proper disposal of livestock carcasses, etc.), artificial feeding does not take place, and AMP's are followed, the Forest may implement procedures to harass, capture, move, or kill wolves that attacked livestock (defined as cattle, sheep, horses, or mules only) on National Forest land. (G) Females with pups on National Forest land will be released on site before October 1. (USDI Fish and Wildlife Service 1994 a and b) (S)

Objective - Peregrine Falcon Habitat

Plan project activities to avoid adverse impacts to falcons and their habitats.

Standards and Guidelines - Peregrine Falcon Habitat

1. For proposed projects within 2 miles of known falcon nests consider such items as: 1) human activities (aircraft, ground and water transportation, high noise levels, and permanent facilities) which could cause disturbance to nesting pairs and young during the nesting period April 15 to August 31; 2) activities or habitat alterations which could adversely affect prey availability. (G)
2. Within 15 miles of all known nest sites, prohibit all use of herbicides and pesticides which cause egg shell thinning as determined by EPA labeling. (S)
3. Restrict climbing and other human disturbances when necessary to avoid adverse impacts at known falcon nest sites. (S).

Sensitive Species Habitat

Objective - Goshawk Habitat

Manage for all active and historic goshawk nesting territories.

Standard and Guideline - Goshawk Habitat

Management standards and guidelines for all forest types within active and historic goshawk nesting territories follow.

Attribute	Nest Area	Post-Fledging Family Area	Foraging Area
Number of areas (S) Suitable areas Replacement areas	6 Total 1/ 3 3	1	1
Size of each area (acres) (G)	>= 30 ea	>= 420	>= 5,400
Size-Class Distribution (%) (G) nonstocked/seedling sapling pole mature/old growth 2/	0 0 0 100	<= 20 <= 20 <= 20 >= 40	<= 20 <= 20 <= 20 >= 40
Rotation age (years) (G)	140 to 420	60 to 240	60 to 240
Maximum created opening (acres) (G)	0	<= 40	<= 40
Snags and Reserve Trees 3/ (G)	80-100 % of potential	80-100 % of potential	80-100 % of potential
Downed logs (average/acre) (G)	Forestwide S&G's	Forestwide S&G's	Forestwide S&G's
Management Season (S)	Oct-Feb	Oct-Feb	Year-long
Thinning (S)	Non-uniform 4/	Non-uniform	Non-uniform
Open Road Density 5/ (G)	No new system roads	No new system roads	<= Management Rx Density
<p>1/ Where possible, manage the 6 nest sites in a 180 acre contiguous area (G) 2/ Mature and old growth canopy closure for nest sites and post-fledging family areas should range between 75-100 percent (G) 3/ Refer to previous section on snag/cavity nesting habitat for explanation of biological potential 4/ Maximize diversity of structure 5/ Open roads in goshawk territories will be given priority for closure to meet management prescription (Rx) road density standards First priority will be to close roads in nest areas, second priority in post-fledging family areas; third priority in foraging areas Where possible, open road density should be zero in the nest areas and the post-fledging family areas.</p>			

Standard and Guideline - Flammulated Owl Habitat

Do not manipulate vegetation within a 30 acre area around all flammulated owl active and historic nest sites. (S)

Standards and Guidelines - Boreal Owl Habitat

1. Do not manipulate vegetation within a 30 acre area around all boreal owl active and historic nest sites. (S)

2. Maintain > 40 percent of the forested acres in late age classes within a 3,600 acre area around all boreal owl nest sites. (G)

Standards and Guidelines - Great Gray Owl Habitat

1. Do not manipulate vegetation within a 20 acre area around all great gray owl active and historic nest sites. (S)
2. Maintain > 40 percent of the forested acres in late age classes within a 1,600 acre area around all great gray owl nest sites. (S)
3. Do not allow the use of strychnine poison to control pocket gophers within a 1/2 mile buffer around all active great gray owl nest sites. (S)

Objective - Trumpeter Swan Habitat

1. Maintain habitat to support \geq 10 breeding pairs on the Forest.
2. Protect emergent vegetation along shorelines. Maintain riparian vegetation in desired vegetative condition.

Standard and Guideline - Trumpeter Swan Habitat

Maintain suitable trumpeter swan nesting habitat conditions including (but not limited to) the following lakes and ponds. Boundary Pond, Swan Lake, Lily Pond, Hatchery Butte, Railroad Pond, Mesa Marsh, Bear Lake, Upper Goose Lake, Long Meadows, Thompson Hole, Twin Lakes, Chain Lakes, Widgit Lake, Rock Lake, Indian Lake, Putney Meadows, Unnamed Pond (Sec. 19, T9N, R46E). (S)

- A. Change livestock grazing through management or fencing when grazing is adversely affecting trumpeter swan use or productivity. (G)
- B. No vegetation management will occur within 300 feet of the lake or pond shoreline unless necessary to improve riparian habitat conditions favorable for trumpeter swans. Management may occur after the swans have left the lake or pond. (S)
- C. Maintain constant water levels; allow no drawdowns from May 1 to September 30 when not in conflict with preexisting water rights. (G)
- D. Discourage dispersed recreation activity at these lakes and ponds between April 1 and September 30. Close these areas to recreation activity if this activity is adversely affecting trumpeter swan use or productivity. (G)
- E. Implement habitat improvement projects at these lakes and ponds, such as dredging to maintain proper water depths and aquatic vegetation control. (G)

Objective - Spotted Frog Habitat

Maintain riparian vegetation in desired vegetative condition.

Objectives - Common Loon Habitat

1. Evaluate the potential to provide and maintain suitable breeding habitat for common loons at these sites: Indian Lake, Thompson Hole, Bergman Reservoir, Junco lake, Fish Lake, Loon Lake, Moose Lake, Unnamed Pond (Sec. 9, T47N, R118W).
2. Develop common loon management plans for the above sites if the evaluation indicates there is potential to provide and maintain suitable breeding habitat.

Standard and Guideline - Harlequin Duck Habitat

Avoid establishing new trails, new roads, or new recreation facilities within 300 feet of any stream reach with documented harlequin duck breeding activity. (G)

Objective - Spotted Bat and Western Big-eared Bat Habitat

Develop management plans for any caves, mine shafts, and other suitable habitats where these bat species are found to be present.

FOREST USE AND OCCUPATION

Access

Goal

Road density standards in each area would be emphasized in grizzly bear habitat, and big game management prescriptions.

Objectives

1. Provide a cost effective road system that integrates human needs with needs for wildlife specifically elk and grizzly bear, and other resource values
2. Decrease elk vulnerability and increase bear security through effective road closures.
3. The net Forest Development road mileage will not increase.
4. Road density standards in each management prescription will be achieved as soon as practicable. (See grizzly bear habitat objective in the preceding section)
 - A. Three years for BMU's
 - B. Ten years for all other areas.

Standards and Guidelines

1. Road Closure

- A Road closures will be located and designed to effectively control use. (S)
- B. Restrict or reclaim roads not needed for future management as determined in site-specific analysis, at the end of project use Consider historic recreation use before closure (G)

2. Administrative Use on Restricted Roads, Trails and Areas

- A. The Open Road and Open Motorized Trail Route Density (OROMTRD) Standards prescribed for each prescription area are not intended to place restrictions on being able to respond to emergency events to protect human life, property values and structures, and forest resources Responses to emergency events include law enforcement, search and rescue, and fire suppression. (S)

B. Other administrative uses (such as planned project work) on restricted roads, trails or areas will only be allowed with the following standards (S)

1. Any motorized vehicle access on a restricted road or trail or area will be for official administrative business only, and approved by the Forest Supervisor or District Ranger.

2. When motorized vehicle access on a restricted road or trail or area is necessary, a sign will be posted while project work is being accomplished.

3. Motorized vehicle access on a restricted road or trail or area will be allowed by permit under the following conditions when approved by the Forest Supervisor or District Ranger:

a. Project work is 1 mile or 30 minutes walk or greater.

b. Equipment is being used that is unreasonable to carry to the project work site.

c. Contract inspectors working with contractors who have motorized equipment and vehicles which are necessary for the contract work.

C. During the big game hunting seasons, persons with disabilities may be permitted to use motorized vehicles, if needed for mobility, on restricted roads and trails which are authorized for such use, with an authorized Motor Vehicle Hunting Permit. These persons must have a Disabled Hunting Permit issued from the State Fish and Game Departments. (G)

Recreation

Goal - Winter Recreation

Provide a quality winter recreation experience while minimize impacts of winter recreation use on wintering big game.

Objectives - Winter Recreation

1. Establish a linear capacity for two-way snowmachine trails for purposes of safety and quality of the recreation experience.

2. Provide networks of marked, designated, and groomed snowmachine, cross-country ski, and other winter travel routes and trailhead facilities.

3. Provide winter recreation user information to educate users of wildlife needs and promote snowmachine safety.

4. Promote opportunities for backcountry winter recreation.

Objective - Wild, Scenic, and Recreation Rivers

The 249 miles of inventoried, eligible streams of the Forest will have suitability studies done by 2002 (based on funding). This would be done on a priority basis for approximately one-third of the streams at a time, starting with those in the South Fork-Snake River Basin. The remaining streams would probably be done in two additional studies - one for the Henry's Fork Basin, and a second for those streams in the Teton River Basin or watershed, and probably in that order of priority.

Objective - Visual Quality

Manage the visual landscape in accordance with the planned visual quality objective, as mapped in the Geographic Information System.

Standard and Guideline - Visual Quality

Timber

Harvest.

A. Lodgepole pine Slash not needed to meet other resource objectives should be disposed of by a combination of piling, firewood gathering, and burning in areas up to 200-250 feet either side of primary travelways, trails, and use areas which have high public concern for scenic quality as soon after harvest as possible. (G)

B. Lodgepole pine. Slash not needed to meet other resource objectives should be disposed of by piling, firewood gathering, or burning for 150-200 feet on either side of roads, trails, and areas which have moderate public concern for scenic quality. (G)

Standards and Guidelines - Winter Recreation

1. Develop or provide trailhead facilities to match the desired trail capacity. These facilities may be public or private depending on location. (G)
- 2 Management of winter trails should be done where feasible by cooperative agreements with agencies and groups (G)
3. Snowmachine, snowshoes, and dogsleds are prohibited within designated groomed cross-country ski trails Snowmachines and dogsleds are prohibited within designated cross-country ski areas. (S)

Objective - OHV

Provide a network of OHV trails while minimizing the effects of OHV use on soils.

Standards and Guidelines - OHV.

1. Discourage OHV use on slopes greater than 40%, except on designated routes and except for snowmachine use. Roads and trails, however, may cross slopes that exceed 40 percent. (G)
- 2 Areas with slopes of 25-40 percent may require travel restrictions if soil erosion factors warrant them. (G)
- 3 Restrict OHV use on identified areas of unstable soils (except for snowmobiles). (G)
4. No motorized vehicles > 50 inches wide are allowed on trails unless the trails are specifically designed for such vehicles. (S)

Objective - Developed Facilities

Maintain or slightly increase the Forest's developed site capacity.

Standards and Guidelines - Developed Facilities

1. Expand existing developed facilities to meet public needs. (G)

2. Phase out low use developments that have high operation and maintenance (O&M) costs consistently exceeding \$1 50 per Persons-at-one-time (PAOT) per day. (G)

3. Rehabilitate or provide heavy maintenance to facilities in Maintenance Class Two (MC 2) and Maintenance Class Three (MC 3) which cannot be brought up to Maintenance Class One (MC 1) through general maintenance. (G)

A. Developed facilities receiving heaviest use should receive first priority for maintenance (G)

B. Facilities that cannot be maintained to acceptable health and safety requirements will be closed until they can be brought up to standard. (S)

Objective - Dispersed Recreation Use

By 2007, address soil, water, and vegetation impacts to maintain the desirable recreation setting on approximately 100 campsite areas of the 300 identified dispersed recreation sites on the Forest, which are in greatest need of restoration. These sites would have limited developed facilities.

Standards and Guidelines - Dispersed Recreation Use

1. Dispersed Camping. Unless otherwise posted, motorized access is allowed for dispersed camping within 300 feet of roads and trails which are open for motorized use. (S)

2. Dispersed Camp Site Condition. Dispersed campsites should be managed according to the Frissell Condition Classification System. Actions (close, protect, or restore) should be taken to restore campsites that do not meet Class 3. In some areas, where it is necessary to prevent resource damage and protect public health, scale 2 facilities may be provided. (G)

3. Dispersed Use Area. Low-development-level facilities should be provided at undeveloped concentrated-use areas to prevent resource damage and protect public health and safety. (G)

Goal - Trails

1. Trails for motorized/mechanized use would be sufficient to sustain use over long periods of time and minimize requirements for maintenance or reconstruction. These conditions would be achieved within subsections in the following sequence: Big Hole/Palisades Mountains, Caribou Range Mountains, Lemhi-Medicine Lodge, Centennial Mountains, Madison-Pitchstone Plateaus, Island Park, and Teton Range.

2. Trails for nonmotorized/mechanized use would be sufficient to sustain use over long periods of time with minimal requirements for maintenance or reconstruction. These conditions would be achieved within subsections in the following sequence: Teton Range, Big Hole/Palisades Mountains, Centennial Mountains, and Caribou Range Mountains.

Objective - Trails

Complete an IDT review of 5-10% of the system trails each year to determine rehabilitation needs.

Objective - Outfitters and Guides

Establish use capacities using the process outlined in the AMS for outfitter and guide recreation opportunities prior to issuing new permits.

Standard and Guideline - Outfitters and Guides

Outfitter and guide facilities in dispersed nonwilderness areas should be built in less-frequented areas and be temporary. To prevent unacceptable resource damage or sanitation problems, facilities may be allowed at more heavily used locations. Only essential facilities should be provided at commercial outfitter camps in accordance with Greater Yellowstone Area Outfitter Policy camp standards (G)

Wilderness

The following goals, standards and guidelines apply to all congressionally designated Wilderness on the Forest. Presently that includes the Jedediah Smith and Winegar Hole Wilderness Areas.

Goal

Desirable wilderness conditions for the Jedediah Smith and Winegar Hole Wilderness would be within the Limits of Acceptable Change (LAC) process, as specified in the management prescriptions, which when implemented in accordance with the Wilderness Implementation Schedules and Monitoring Action Plan, constitute the complete Wilderness Management Plans.

Standards and Guidelines

1. Outfitter/Guide - Allow no new outfitter camps (i.e. hunter, fisherman, etc) until studies have been completed to determine site suitability and carrying capacity. (S)
2. Recreation - ROS Manage for a primitive to semi-primitive nonmotorized classification. (G)
3. Recreation - VQO. Manage for preservation. (S)

PRODUCTION OF NATURAL RESOURCES

Range

Goals

1. Upland and riparian plant communities meet desired vegetation conditions for site-specific areas.
2. Domestic livestock grazing is managed to promote the desired conditions of various resources including maintenance of adequate plant and litter ground cover, nutrient recycling, forage for wildlife species, seed production, and the restoration and maintenance of riparian communities.

Objectives

1. By 2007, improve the ecological status of 1,200 acres of riparian habitat presently reported as early seral stage to mid- or late-seral stage.
2. By 2007, improve 26,400 acres of uplands (nonriparian and nontimber plant communities) currently reported as unsatisfactory ecological condition to satisfactory condition.
3. By 2007, grazing systems will be implemented on all grazing allotments to meet range goals #1 and #2 above.

4. Within five years after the signing of the Record of Decision, establish a stream bank stability (trampling disturbance) standard correlated to stubble height at the hydric greenline (HGL)

Standards and Guidelines

1. Upland Forage Utilization Apply upland forage utilization standards to all allotments and/or management areas as shown in Table 1. These standards provide for maximum utilization levels regardless of which species of animal uses the forage or browse (S)

Table 1 Upland Rangeland Ecosystems - Percent Forage Utilization 1/				
	Season-long Grazing		Rotation Grazing	
	Unsatisfactory Condition	Satisfactory Condition	Unsatisfactory Condition	Satisfactory Condition
Grasses and Herbaceous Species	40%	50%	50%	60%
Shrubs	25%	35%	35%	35%

1/ The figures shown represent the best estimate of acceptable use levels which will provide for maintenance or improvement of these ecosystems. They shall be used as maximum use levels unless there is site specific information to show that these levels are incorrect. Percent use is based on a dry weight percentage.

2. Riparian Forage Utilization.

A. Riparian Woody Plant Utilization. No more than 30 percent use on riparian woody plant species (current year's growth) is allowed. Thirty percent is the maximum allowed use as recorded at the end of the grazing period. (S)

B. Riparian Vegetation Stubble Height Standard (these apply to all grazing systems). (S)

1. At the HGL, there will be at least 4 inches of stubble height remaining at the end of the grazing period, unless determined otherwise through the Interdisciplinary team process. A written rationale for any deviation is required. This standard applies to native and desirable nonnative hydric vegetation.

2. Away from the HGL, at least 3 inches of stubble will be left on the remainder of the herbaceous riparian vegetation at the end of the grazing period.

3. Allotment Management Planning (AMP)

A. Salt should be placed greater than 1/4 mile from water, or as far from water as practicable. Salting will also be placed at least 100 feet away from aspen regeneration and conifer plantations that are 5 years old or less. (G)

B. Allow no livestock grazing for at least two growing seasons after prescribed or natural fires and rangeland planting or seeding, or at least until vegetation is established. (G)

C. Allow livestock conversions based on resource needs (such as topography, water distribution, vegetation, wildlife, and recreation), capability, and management objectives and not solely based on the desires of the permittee (G)

1. Conversions may be made in accordance with an AMP, and current range analysis, and when all necessary range improvements structures are in place. (G)

2. All range improvements necessary for the conversion will be financed and constructed by the permittee. Construction will be in accordance with Forest Service standards. (S)

3. Do not convert from a cattle allotment to a sheep allotment within bighorn sheep habitat. (S)

4. All proposed livestock conversions will be evaluated by a qualified cadre of IDT Specialists including a hydrologist, fisheries biologist, wildlife biologist, range specialist, and soils scientist. Only those conversions meeting Forest Plan Objectives and desired vegetation conditions will be approved. (S)

D. Forest Service administrative site livestock pastures will comply with the Forestwide standards and guidelines for forage utilization and riparian management. (S)

E. All structural improvements directly required to implement the AMP will be installed and financed whereby the Forest Service provides approximately 50% of the cost and the permittee provides the remaining 50%. (G)

F. Permittees are allowed motorized access to maintain facilities. AMP's and annual operating plans will include direction that motorized access must be less than 1 to 2 vehicles per week. (This permitted access is not included in the OROMTRD.) (S)

G. Until a Memorandum of Agreement is developed between the Southern Idaho Forests and the Idaho State Historic Preservation Office, follow the process outlined in the National Programmatic Agreement, Option 2 (Criteria and standards for independent management).

Timber Management

Goal - General

Silvicultural techniques will be used as a tool to manage or manipulate vegetation for the purpose of achieving Forest Plan resource objectives. Emphasis will be placed on restoration of ecological function, structure and composition.

Standards and Guidelines

1. ASQ and Long Term Sustained Yield

A. Estimates of ASQ and long term sustained yield timber supply capacity are themselves based on estimates of volume available on timbered acres scheduled for harvest. Acres harvested are estimated to be 11,430 for the decade. The volumes are an estimated outcome of harvesting those acres. In the event volume estimates prove to be inaccurate, acreages harvested will not be adjusted to make up the difference. Total harvested acres for the decade may vary and will depend on site-specific project implementation to meet plan goals and objectives.

B. ASQ will not exceed 37 million board feet (MMBF) for the plan decade. (G)

2. Silvicultural System Guideline

Silvicultural System Guideline. The appropriate silvicultural systems to use, by forest cover type, are.
(G)

Forest Cover Type	Even-aged (1 or 2 age classes)	Uneven-aged (3+ age classes)
Lodgepole pine	CC, SW, OR, CT	GS <2 acre, CT
Douglas-fir	CC (mistletoe-infected stands only; <i>Hawksworth Class 4, 5, or 6</i>), ST, SW, OR, CT	GS, ITS, CT
Mixed Conifer	CC, ST, SW, OR, CT	GS, ITS, CT
Spruce-fir	SW, OR, CT	GS, ITS, CT
Aspen	CC, CT	
Abbreviations used in the Table:		
CC = Clearcut OR = Overstory Removal CT = <i>Commercial Thin</i> GS = <i>Group Selection</i> ST = Seed Tree ITS = Individual Tree Selection SW = Shelterwood		

3 Rotation Age Guideline. Following are the earliest rotation ages of each species group beginning at culmination of mean annual increment (G)

Species	Earliest Rotation Age (years)
Lodgepole Pine	60
Douglas-fir	100
Mixed Conifer 1/	80
Spruce-fir	100
Aspen	60
1/ Includes both MX (DF/LP) and MX3 (DF/LP with ES/AF).	

4. Minimum Stocking Guideline. Following is the minimum stocking allowed to occur before an area can be certified as stocked. (G)

Species	Minimum Stocking (Trees/Acre) 1/	Percent of Area Meeting Minimum Stocking
Lodgepole Pine	170	70
Douglas-fir	140	70
Mixed Conifer 2/	200	70
Spruce-fir	200	70
Aspen	300	70
1/ Aspen counts toward stocking 2/ Includes both MX (DF/LP) and MX3 (DF/LP with ES/AF)		

Goal - Precommercial Thinning

Thinning results in restoration of ecological structure, function and composition.

Objectives - Precommercial Thinning

1. Mimic tree densities and patch sizes within the range of variability over a landscape.
2. Provide for a variety of future resource products.

Goal - Slash Treatment

Fuel loading on activity areas meet site productivity for wildlife and fire objectives.

Objective - Slash Treatment

Slash treatment reduces fuels less than 3 inches in diameter and retain larger diameter fuels needed for sustaining soil productivity and providing for wildlife habitat needs.

Standards and Guidelines - Slash Treatment Guideline. 1/ 2/

Predicted and existing fuel loading under 3 inches dbh	Minimum Treatment	Maximum Fuel Patch Size
Under 5 Tons/Acre	No treatment necessary for fire hazard reduction	160 ac under 40% slope 100 ac. over 40% slope
5 to 10 Tons/Acre	Lop or crush to Regional Lopping Specifications	80 ac < 40% 40 ac > 40%
11 - 25 Tons/Acre	<u>Alternatives</u>	
	1 Reduce single entry loading to 10 tons/ac. or less by multiple entry thinnings Follow lopping stds above according to loading	Single entry loading < 5 Ton/Ac , use above stds for < 5 tons Loading 5-10 use above std for 5-10 T/Ac
	2 Reduce slash < 3 in to < 5 tons per ac by burning or chipping	160 Ac < 40% 100 Ac > 40%
	3 Reduce loading of lopped or crushed fuel < 3 in to 5 - 10 ton per acre by burning or chipping	80 Ac < 40% 40 Ac > 40%
	4 Rehabilitate by piling, burning, and reforestation	160 Ac < 40% 100 Ac > 40%
5 No treatment	N/A	
1/ When down woody fuels constitute 30% or more of the total loading under 3 inches, the values in this column may be increased by 3 tons per acre		
2/ Make sure mechanical treatments meet Forestwide soils standards		

Objective - Size of Harvest Units and Adjacent Leave Blocks/Strips

Design timber management projects to simulate the range of natural variation for patch sizes, patch shapes, connectivity, and species composition and age class diversity.

Standard and Guideline

Created Opening. A harvested area of commercial forest land will not be considered a created opening for silvicultural purposes when stocking surveys indicate that minimum stocking is achieved and at least 7 feet high. When other resource management considerations (such as wildlife habitat, watershed needs, or visual requirements) prevail, a created opening will no longer be considered an opening when the vegetation in it meets a particular management objective stated in the applicable *management prescription*. (S)

Standards and Guidelines - Logging Systems

1 Slopes 40 percent or less will normally be harvested using ground-based logging equipment (tractors, rubber-tired skidders, low ground pressure equipment, etc). Slopes greater than 40 percent, but less than 60%, will normally be harvested using advanced logging systems like shortspan cable systems, longspan cable systems, or aerial systems. (G)

2. Rutting in skid trails should not exceed 6 to 8 inches in depth (wet condition) over more than 10 percent of a designated skid trail system. No yarding operations should take place when ground conditions are wet enough that there is a risk of such rutting. (G)

Goal - Fuelwood

A sustainable level of fuelwood would be available.

Objective - Fuelwood

Conduct inventory for determining sustainable level of fuelwood.

Standards and Guidelines - Fuelwood

1. Allow permitted fuelwood gathering in designated areas only. (S)

2. Select designated fuelwood areas that have an excess of dead and down woody material which is in excess of that required for ecological function, structure and composition. (G)

SUBSECTION DESCRIPTIONS

The ECOMAP unit of the Forest Service has developed a National Hierarchical Framework of Ecological Units to improve consistency in developing and sharing resource data and information at multiple geographic scales and across administrative and jurisdictional boundaries

An Ecological Unit is defined as "A mapped landscape unit designed to meet management objectives, comprised of one or more ecological types." (FSM 2060.05) These ecological units are designed to exhibit similar patterns in: Potential Natural Communities; Soils; Hydrologic Function; Landform and Topography, Lithologies; Climate, Air Quality; and Natural Processes for Cycling Plant Biomass and Nutrients

As of this writing, ECOMAP has described four levels in the National Hierarchy of Ecological Units: Domains, Divisions, Provinces, and Sections. A map of the United States (1:7,500,000 scale) has been developed displaying these four levels. The land area of the Forest falls within three of those sections. The National Hierarchical Framework of Ecological Units is shown below in its particular application to the Forest, as adjusted by Revision and Ecological Unit Inventory personnel.

Domain - Described by broad climatic zones or groups. The Forest is within the Dry Domain (which covers most of the Intermountain Region). This is an area of water deficit where the potential annual water losses through evaporation exceed annual water gains through precipitation.

Division - Described by regional climatic types, vegetation affinities, soil order. The Forest is within the Temperate Steppe Regime Mountains Division (M330).

Province - Described by potential natural vegetation, highlands or mountains with complex vertical climate-vegetation-soil zonation. The Forest is within two Provinces:

- M331 - Southern Rocky Mtn. Steppe - Open Woodland - Coniferous Forest - Alpine Meadow
- M332 - Middle Rocky Mtn. Steppe - Coniferous Forest - Alpine Meadow

Sections - Described by geomorphic province, geologic age, stratigraphy, lithology; regional climatic data; phases of soil orders, suborders or great groups; potential natural vegetation (PNV); potential natural communities (PNC). The Forest lies within three Sections:

- M331A - Yellowstone Highlands Section
- M331D - Overthrust Mountains Section
- M332E - Beaverhead Mountains Section

Subsections - Described by geomorphic process, surficial geology, lithology; phases of soil orders, suborders or great groups; subregional climatic data; PNC - formation or series. The Forest lies within seven Subsections:

- M332E-1 - Lemhi/Medicine Lodge (Subsection comprising two noncontiguous parts)
- M332E-2 - Centennial Mountains
- M331A-1 - Island Park
- M331A-2 - Madison Plateau
- M331D-2 - Teton Range
- M331D-1 - Big Hole/Palisades Mountains
- M331D-19- Caribou

Figure III-1 displays the locations of the seven subsections. Figure III-2 displays watershed boundaries on the Forest. Following these figures are individual descriptions and maps of each subsection.

Subsection Overlay on the Targhee National Forest and the Surrounding Area

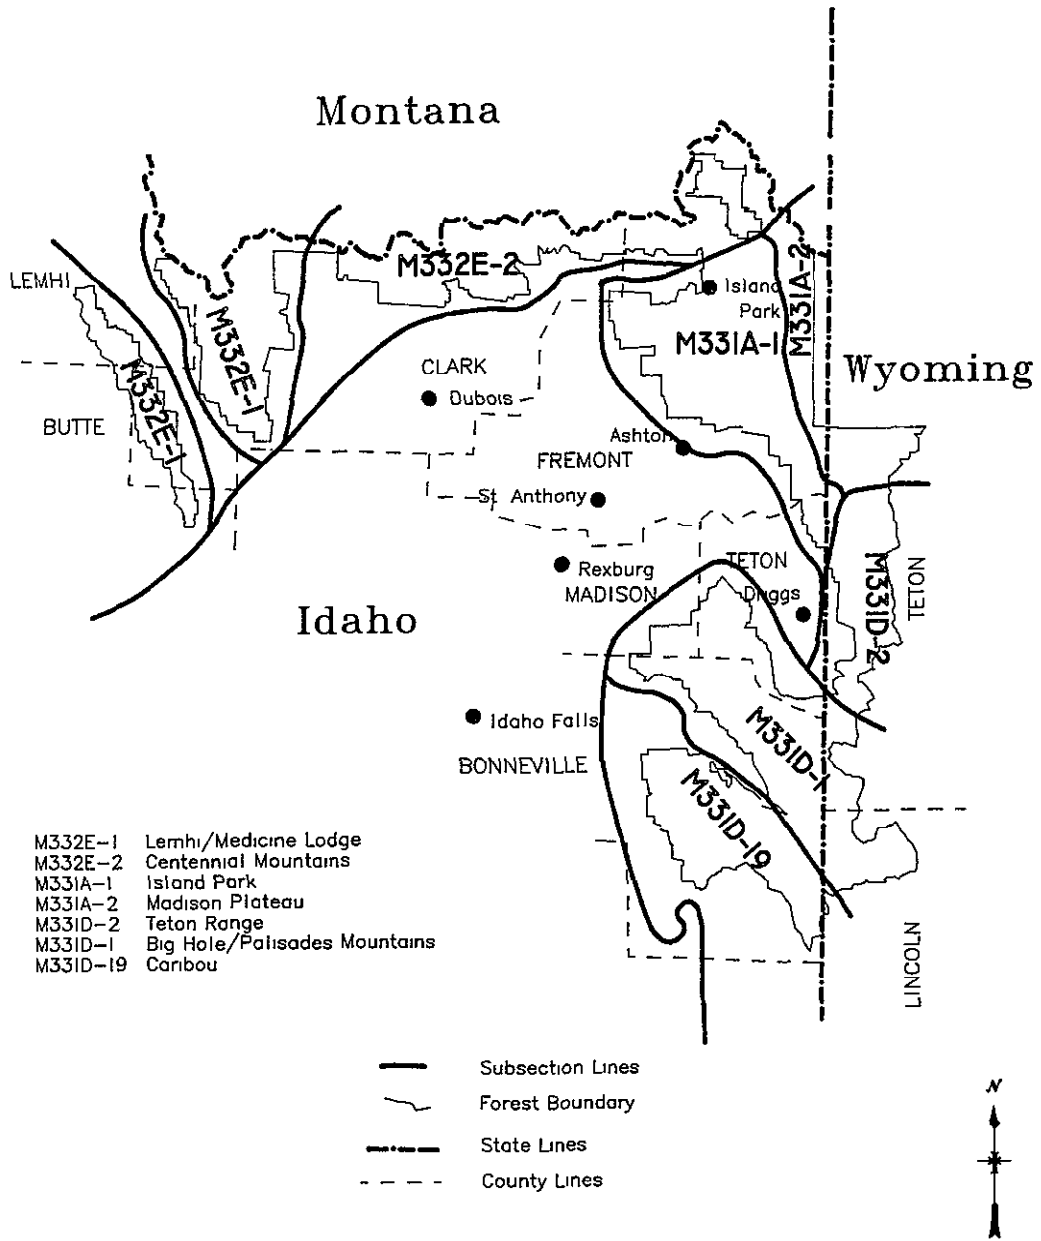

Figure III-1

Targhee National Forest Principal Watersheds

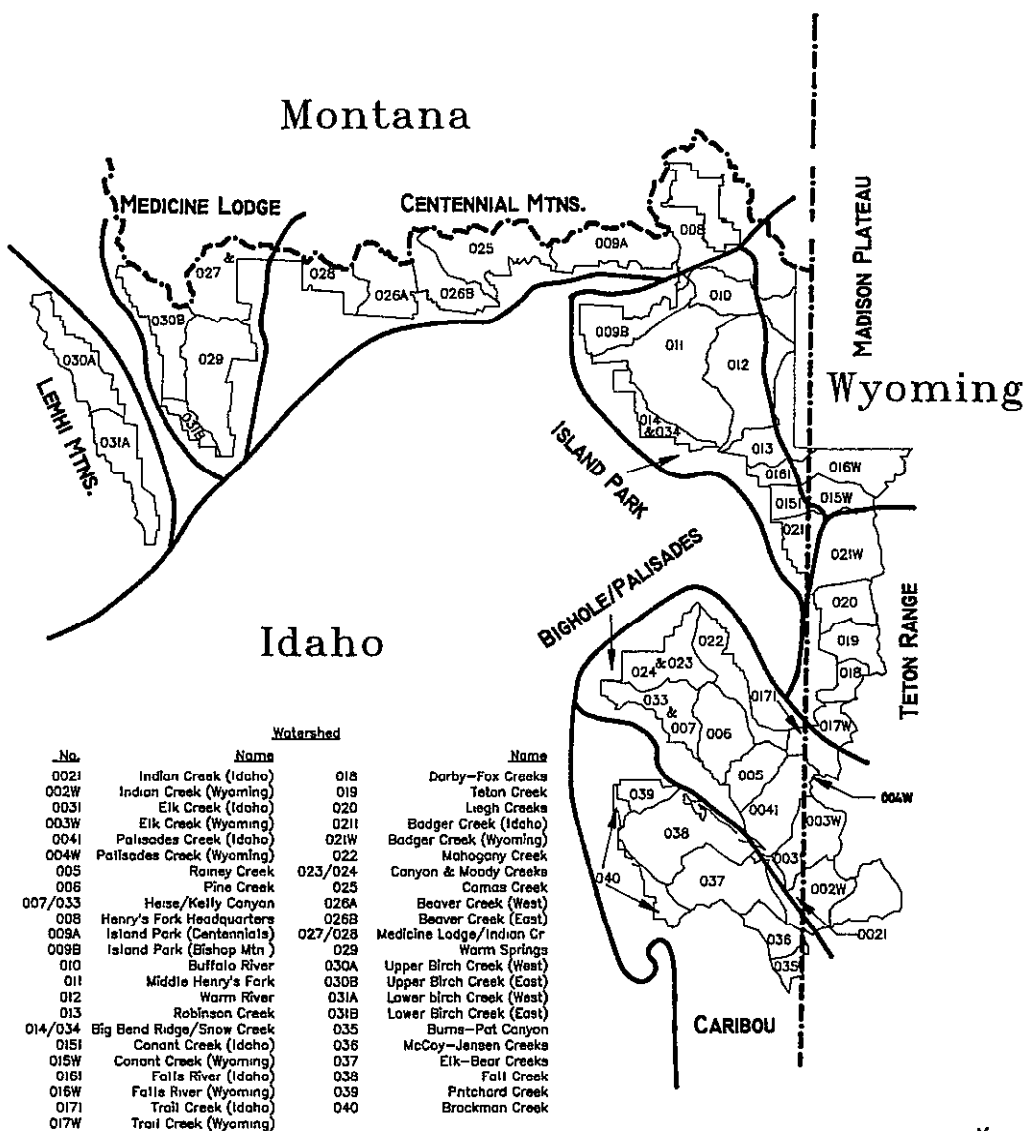

Figure III-2

Not To Scale

LEMHI/MEDICINE LODGE SUBSECTION (M332E-1A/M332E-1B)

SETTING

This subsection includes the Lemhi Mountains and the Medicine Lodge/Beaverhead Mountains. A variety of vegetation exists with forested communities dominated by Douglas-fir and limber pine. Sagebrush/bunchgrass and mountain mahogany communities are common on the lower elevation and strong southerly exposures. Limber pine communities and alpine meadows exist at the high elevations. This subsection is rich in mining history with old mining sites and remnants of town sites. Located in the Birch Creek Valley are four preserved brick adobe Charcoal Kilns. Sixteen were originally built to furnish charcoal to the Nicholia Mine. This area contains some of the most significant Native American sites on the Forest. This area also contains the Continental Divide National Scenic Trail, a recommended wilderness (Italian Peaks) and most big game species.

Although only 37 percent of this subsection is forested, this is more forest land than occurred historically. Information from the early 1900's indicates that in some areas Douglas-fir has become established on lands that were formerly dominated by grasses and sagebrush. Some riparian communities also appear to have more conifers than they did historically.

Approximately 90 percent of the forested land is in a mature age class, indicating a lack of age class diversity in the subsection. With 90 percent of the forests in Douglas-fir there is also a lack of tree species diversity. Many of the Douglas-fir stands are densely stocked. The uniformity of tree species and age classes, as well as the dense stocking, make this area's forests more susceptible to ecosystem disturbances such as insects, diseases and large fires. An example of the latter was the Gallagher Peak Fire which burned 37,230 acres in 1979. This was the largest fire in the last twenty years on the Forest.

Aspen acreage has declined since the early twentieth century due to fire suppression. This is of concern since aspen provides important habitat for many wildlife species, and is a critical factor in the scenic beauty of the Forest. Aspen is declining in this Subsection.

Existing biological potential for woodpeckers is 26 to 34 percent. This indicates that larger size snags are not abundant nor well distributed in this subsection at this time, even though a very high percentage of the forests are in mature and older successional stages.

Figure III-3 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

This area provides quality motorized and nonmotorized dispersed recreation, livestock forage, elk and deer winter range, and Italian Peaks is managed as a proposed wilderness.

Ecological conditions include social and economic requirements associated with hunting big game.

GOALS AND OBJECTIVES

Biodiversity - Objective

Manage where possible for a diverse array of habitats tied to the natural occurrence and distribution of plant communities. Regenerate and maintain plant associations within the range of variability.

Aquatic & Riparian Ecosystems - Objective

Improve stream channel stability ratings to good or excellent by 2007 on Divide Creek and Webber Creek.

Lemhi/Medicine Lodge Subsection (M332E-1)

RX	Lemhi M332E-1A	Med Lodge M332E-1B	TOTAL

Figure III-3

Recreation - Objective

Provide increased designated motorized road and trail access in a managed low impact method.

Heritage Resources - Objective

Provide opportunities for scientific studies of significant archaeological sites

STANDARDS AND GUIDELINES

Recreation

Restrict motorized use to designated routes only, except for snowmobiles. (G)

CENTENNIAL SUBSECTION (M332E-2)

SETTING

This subsection covers the Centennial Mountains between the east fork of Irving Creek and Reas Pass to the east. The Centennials, which form part of the Continental Divide, are a scenic mountain range with high mountain meadows scattered through spruce/fir and Douglas-fir forests. At lower elevations sagebrush/grasslands grade into Douglas-fir and lodgepole pine forests. Lionhead, in the northeast portion of the subsection, is a recommended wilderness in Montana. The major travel corridors are Highways 20 and 87, and a portion of Interstate 15. The Yale-Kilgore road is a more minor travel route connecting Island Park to Kilgore and Dubois. In the northeast portion of the subsection is Henry's Lake, a world-renowned fishery.

This subsection is dominated by sagebrush/grasslands and Douglas-fir communities. The Centennial Mountain Subsection has had substantial timber management activities. Also in the Centennial Mountains the wildland/urban interface has significantly increased due to the development of the private lands within the forest protection boundary. This increases the risk of a fire spreading between the forest and private lands.

The landscape is dominated by forested communities which cover 71 percent of the subsection. Approximately 51 percent of the forested acres are Douglas-fir. Lodgepole pine (21%) is found in pockets on low productivity soils. Mixed lodgepole pine/Douglas-fir (13%) and other mixed conifers (10%) are also well-represented. The presence of mixed stands indicates that later successional species such as Douglas-fir and subalpine fir are becoming established as stands move toward later seral stages through succession. Aspen comprises 4% of the forested acres, which is less than was historically present. Fire suppression has allowed conifers to take over areas that were previously rangeland, tall forb communities, and aspen. Conifers have also encroached into riparian areas through the process of succession.

Mature forests cover 79 percent of the subsection, indicating a lack of diversity in age classes. Diversity of tree species appears to be high as forests move from early to later successional species. In this transition phase both early and late successional tree species are present. Decreasing diversity however is associated with the loss of aspen over time. Severe fires, insects and diseases are concerns in this subsection, mainly because of the large component of mature forests.

The subsection contains portions of two subunits within the Henry's Lake BMU.

Existing biological potential for larger woodpeckers is 33 to 52 percent. Larger size snags are not abundant nor well distributed in this subsection either, even though 79% of the forests are in mature and older successional stages.

Figure III-4 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

This subsection is one of the most diverse and complex subsections on the Forest. It offers the greatest opportunity for vegetation treatments. This opportunity will be to move the landscape toward the range of variation while reducing the risk of catastrophic incidents outside the range of natural variation.

The interaction between dispersed motorized recreation and the Lionhead roadless area will be managed to still maintain access for snowmobiles while recommending the core area for wilderness.

Any activities will need to address concerns associated with grizzly bear management and big game management as well as reducing the risks with insects, disease, and fire.

Centennial Mountain Subsection (M332E-2)

Figure III-4

GOALS AND OBJECTIVES

Biodiversity - Goal

Move the spatial distribution patterns and ages of vegetation toward sustainable conditions based on the range of variation.

Biodiversity - Objective

Develop a fire plan which allows for prescribed natural and management ignited fire, where compatible with other resource objectives.

Aquatic & Riparian Ecosystems - Objective

Improve stream channel stability ratings to good or excellent by 2007 on Allan Canyon Creek, McGarry Canyon Creek, Moose Creek, Dairy Creek, Long Creek, E. Rattlesnake Creek, E. Three-mile Creek and W. Dry Creek.

Wild and Scenic River - Objective

Complete the suitability studies for rivers that are eligible for wild and scenic river designation.

STANDARDS AND GUIDELINES

Lands (Special Uses)

The Leon Petersen cabin and associated facilities will be treated as an isolated cabin rather than a recreation residence, since the cabin is not within an approved recreation residence tract. The permit will be changed to a "life tenure" permit by 1998. This cabin permit will not be transferable. Upon the expiration of the permit, the cabin will be evaluated and its historical qualifications determined. If the cabin is found to have historic value, it may be moved from the site, or the Forest may issue a special use permit to a Historical Association for maintenance of the cabin. (S)

Range

Domestic sheep grazing will be phased out over time on an opportunity basis. An opportunity is defined as a suitable or favorable time to abolish or close an allotment because of nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit. If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas. (G)

ISLAND PARK SUBSECTION (M331A-1)

SETTING

This subsection includes the west half of Island Park, Ashton, and the northwest portion of Teton Basin Ranger Districts. The dominant landscape feature of this subsection is a large caldera. Highway 20 is the only major highway that travels through this subsection. Among the many scenic attractions are Upper and Lower Mesa Falls, the last major undisturbed falls on the Columbia River system. The Mesa Falls Scenic Byway, established in 1989, provides motorists with a breathtaking view of the Teton Mountain Range and accesses the two falls. The Island Park Subsection offers excellent trout fishing at Island Park Reservoir and along the Henry's Fork, Buffalo River, Warm River, Fall River and Birch Creek. The Island Park subsection is also known for its many snowmobile and cross-country ski trails. The area shows signs of large scale timber harvesting due to salvage efforts following the mountain pine beetle epidemics in the 1960's and 1970's. Harriman State Park lies in the heart of the Harriman Wildlife Refuge, with 16,000 acres of forest, meadows, lakes and streams.

A small portion of the Winegar Hole recommended wilderness falls along the eastern border of this subsection.

The landscape is dominated by forested cover types, which blanket 93% of the area. Forested areas are primarily lodgepole pine types (70%) that contain small pockets of aspen, sagebrush/grass, grass meadows and mountain brush. Douglas-fir (10%) and mixed lodgepole pine/Douglas-fir (15%) cover types provide some diversity in the area. Lodgepole pine occupies the floor of the Island Park Caldera and Douglas-fir cover types are concentrated on the Caldera rim. On the Caldera rim, aspen and sagebrush areas are being encroached upon by Douglas-fir, through the process of succession.

Currently 61 percent of the forests are in a mature or older age class provide suitable nesting sites. Since 93 percent of this subsection is forested, creation of young forest age classes probably increases the amount of suitable foraging habitat. Currently 26 percent of the forested acres are in nonstocked and seedling conditions which provide foraging habitat.

Salvage harvesting has shifted 46 percent of the lodgepole pine into the nonstocked, seedling and sapling classes. Active management of aspen, as well as aspen sprouting in lodgepole pine clearcuts, has moved 34 percent of the aspen into these young classes. Other cover types are concentrated in the mature age group.

Mature Douglas-fir on the caldera rim experienced outbreaks of spruce budworm and Douglas-fir beetle in the past decade. These have now subsided, but could easily occur again given the mature condition of the Douglas-fir and the presence of multiple-storied stands. Due to fuel reductions and young age classes associated with timber harvest, fire is less of a concern here than in most other subsections.

Figure III-5 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

Forested conditions and roading densities will support the Forestwide objectives for grizzly bear management and elk vulnerability. This will include road closures and vegetation treatments aimed at improving cover and maintaining forest health.

This area will have improved recreation access and quality, particularly in the Highway 42-Mesa Falls Scenic byway and for snowmobile use linked to West Yellowstone.

Island Park Subsection (M331A-1)

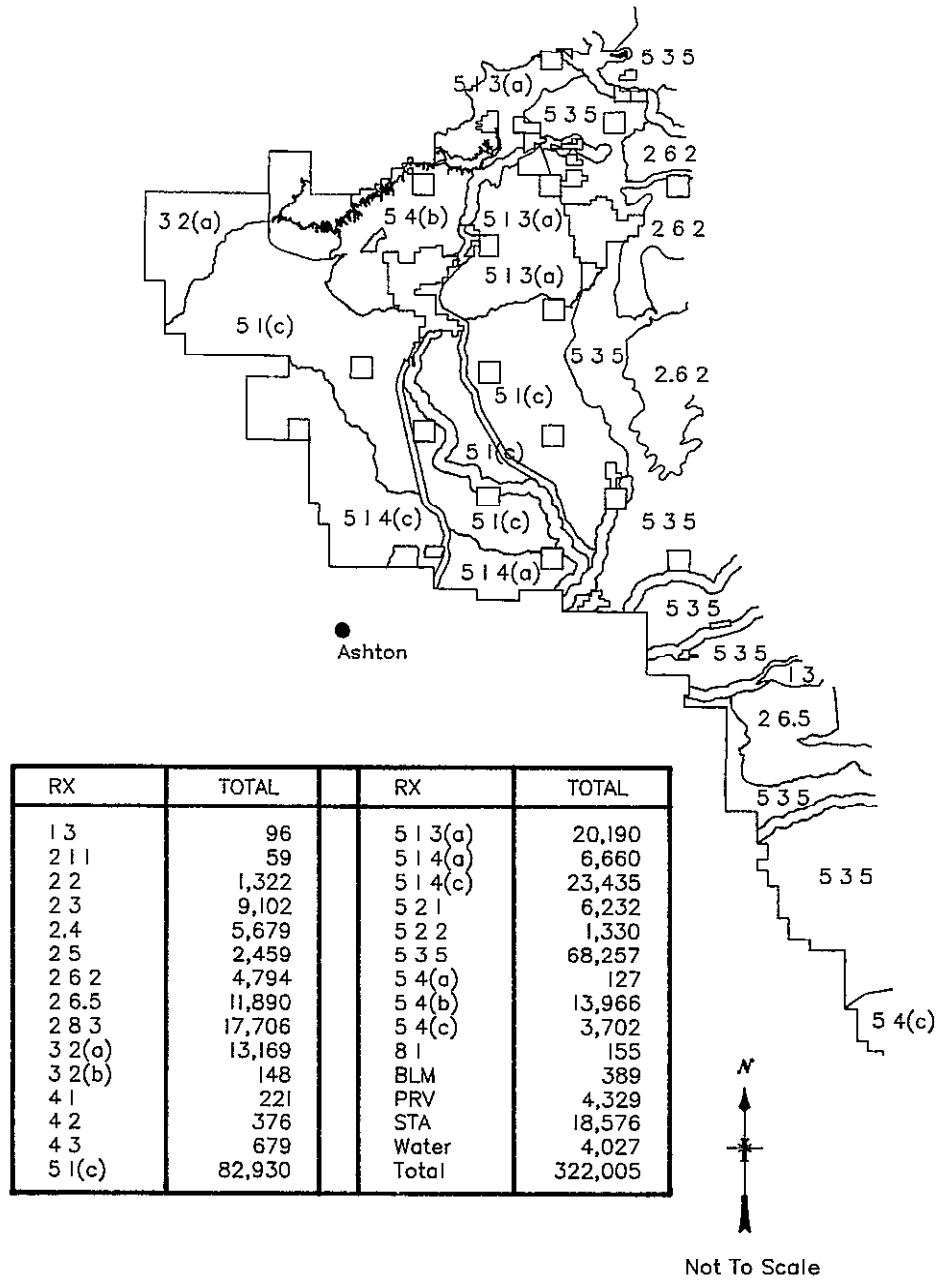

Figure III-5

GOALS AND OBJECTIVES

Biodiversity - Goal

Move toward patch sizes that better reflect historical patterns and frequencies of disturbance. Manage forest structure to reflect historic patterns.

Fire - Objective

Use management-ignited fire where possible to meet resource objectives.

Recreation - Objectives

Maintain visual quality and visitor interpretation facilities along the Highway 47 Mesa Falls byway.

Wild and Scenic River - Objective

Complete the suitability studies for rivers that are eligible for wild and scenic river designation.

STANDARDS AND GUIDELINES

Waterfowl Nesting Areas

Goose Neck Bay on Island Park Reservoir. Area closed to motorized vehicle-use April 1 to June 15; open to motorized vehicle use remainder of the year. (S)

MADISON PLATEAU SUBSECTION (M331A-2)

SETTING

The largest portion of the Madison Plateau Subsection is actually in Yellowstone National Park. The portion on the Forest lies within the Island Park and Ashton Districts next to Yellowstone National Park. The Winegar Hole Wilderness is within this subsection and portions of the Jedediah Smith Wilderness and the recommended wilderness portion of Winegar Hole in Idaho. The Ashton-Flagg Ranch Road and Fish Creek Road are the major access routes in this area. Grassy Lake is a 320-acre lake created when a dam was built by the Bureau of Reclamation in 1937-1939. Grassy Lake, as well as other lakes and streams in the area, are popular fishing areas and are accessed by the Flagg Ranch road. Several organized youth camps exist throughout this subsection. The Cave Falls road is the only motorized access to the southwest portion of Yellowstone Park.

The landscape is dominated by forests which comprise 97% of the area. Lodgepole pine is the most common forested cover type (76%), with mixed stands of lodgepole pine and Douglas-fir making up the remaining forested area (24%). Relatively minor amounts of aspen and various mixed conifers provide some diversity. The southern portion of the subsection is unique in that there are many wet meadows and small lakes intermingled with the forests.

The 1988 North Fork Fire scorched 17,700 acres in the northern part of this subsection. In numerous locations, the fire stimulated aspen suckering. Past timber harvesting also occurred primarily in the north half of the subsection. These two events have shifted 39% of the lodgepole pine into the nonstocked, seedling and sapling age classes. Active management of aspen has also provided some age class diversity.

Due to fuel reductions and young age classes associated with past harvest and the North Fork Burn, fire is less of a concern here than in many other areas. However, conditions in the southern portion of the Madison Subsection are presenting some fire risks as conifers become mixed with aspen and lodgepole pine stands convert to Douglas-fir through succession. Mature subalpine fir and Douglas-fir in this southern area experienced outbreaks of western balsam bark beetle and Douglas-fir beetle in the past decade. These conditions have subsided, but could easily occur again since vegetation conditions have not changed.

Currently 63 percent of the forests are in a mature or older age classes and provide suitable nesting sites. Since 97 percent of this subsection is forested, creation of young forest age classes increases the amount of suitable more open, foraging habitat. Currently 23 percent of the forested acres are in nonstocked and seedling conditions which provide foraging habitat.

There are currently two designated wilderness areas on the Forest. These are the Jedediah Smith Wilderness (123,451 acres) and the Winegar Hole Wilderness (10,715 acres). The Jedediah Smith is mostly in the Teton Range Subsection with the balance in the Madison Plateau Subsection. Winegar Hole is totally within the Madison Plateau Subsection. Winegar Hole is largely primitive with very little use. This is mostly due to access difficulty, since there are only four miles of trail in the area. Use of this area is mostly for hunting big game. The Jedediah Smith is intensively used in the summer with approximately 60,000 visits (hiking, backpacking and horseback riding). This is a spectacular mountainous area on the west slope of the famous Teton Mountain Range. These wilderness areas are two of twelve designated in the greater Yellowstone Area; which totals 3.8 million acres.

Figure III-6 displays this subsection along with the major prescription areas

DESIRED FUTURE CONDITION

Because of the intensive timber salvage efforts in the past, plus the North Fork Burn, there is limited opportunity for vegetation treatment in this area while still meeting grizzly bear management and elk vulnerability objectives. This subsection will be managed to provide for grizzly bear management objectives, primitive to semi-primitive recreation opportunities, and vegetation management to reduce insect and disease, and fire threats to remaining habitat. Roads will be closed to improve security for grizzly bears and other wildlife.

GOALS AND OBJECTIVES

Aquatic Ecosystem - Goal

Effective rehabilitation of the North Fork Fire burn area to stabilize slopes and reduce sediment delivery to streams

Biodiversity - Goal

Bring the area back toward the range of variability with a full mix of age classes, larger patch sizes and connectivity between stands

Fire - Goal

Use management-ignited and natural fire to meet resource objectives. Comply with the Jedediah Smith Wilderness Fire Management Plan.

Wild and Scenic River - Objective

Complete the suitability studies for rivers that are eligible for wild and scenic river designation.

STANDARDS AND GUIDELINES

Wilderness

Implement the Winegar Hole Wilderness Plan, which consists of the specific wilderness prescription management direction and the Wilderness Implementation Schedule. (G)

TETON RANGE SUBSECTION (M331D-2)

SETTING

This area encompasses the west slope of the Teton Mountains. The Teton Range is a spectacular line of high peaks rising abruptly along the west side of Jackson Hole. The landscape is a diverse mix of forested and open vegetation. The Jedediah Smith Wilderness traverses the upper portions of the west slopes of the Teton Mountains. The Grand Targhee Ski Resort is a major tourist attraction within this subsection. Two organized youth camps are present. This area is known for its many backcountry trail systems, which are accessible by horse or foot. Highway 22 runs along the southern boundary and is a popular route for visitors crossing Teton Pass.

The landscape is a diverse mix of forested (57%) and open (43%) community types. Lodgepole is mixed with Douglas-fir in 31 percent of the forested area, indicating that the pine is converting to Douglas-fir through succession. Open Douglas-fir forests, mountain brush, aspen, and sagebrush pockets are found predominately on south and west aspects. Aspen is being encroached upon by conifers as succession proceeds, and the amount of aspen has declined compared with historic levels due to fire suppression. Upper elevations are characterized by dense mixed conifer forests, open grass/forb meadows, and talus slopes. Conifers are moving into riparian areas and mountain meadows due to fire suppression.

Since much of the Teton Range Subsection is designated wilderness, timber harvest has been limited. Because of this and fire suppression, only 1% of the forested acres are in the nonstocked, seedling or sapling age classes. The 97 percent of mature or older forests make this area susceptible to insect infestations, diseases and large-scale fires. In recent years western balsam bark beetle has been active in the subalpine fir. Douglas-fir beetle has killed pockets of Douglas-fir in the past decade, but beetle populations have declined since 1992.

The Jedediah Smith Wilderness (123,451 acres) is mostly in the Teton Range Subsection with the balance in the Madison Plateau Subsection. The Jedediah Smith is intensively used in the summer with approximately 60,000 visits for hiking, backpacking and horseback riding.

The Bechler - Teton BMU is also partially within the subsection.

Teton Valley has been experiencing a development boom recently and urban interface is a growing concern for the forest.

Figure III-7 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

The Teton Range Subsection is dominated by the lands inside the Jedediah Smith Wilderness. Over 73% of the subsection is wilderness where the focus is to provide Opportunity Class I wilderness experiences. The description of the potential experience is described in prescriptions 1.1.7 and 1.1.8.

The Grand Targhee Ski Area, provides a safe and enjoyable winter sports experience.

The Bechler - Teton BMU provides for a high degree of security for grizzly bear.

The remaining lands in the subsection provide for motorized recreation and big game winter range improvement. Management of these lands reduces or eliminates conflicts with adjacent wilderness.

Teton Range Subsection (M331D-2)

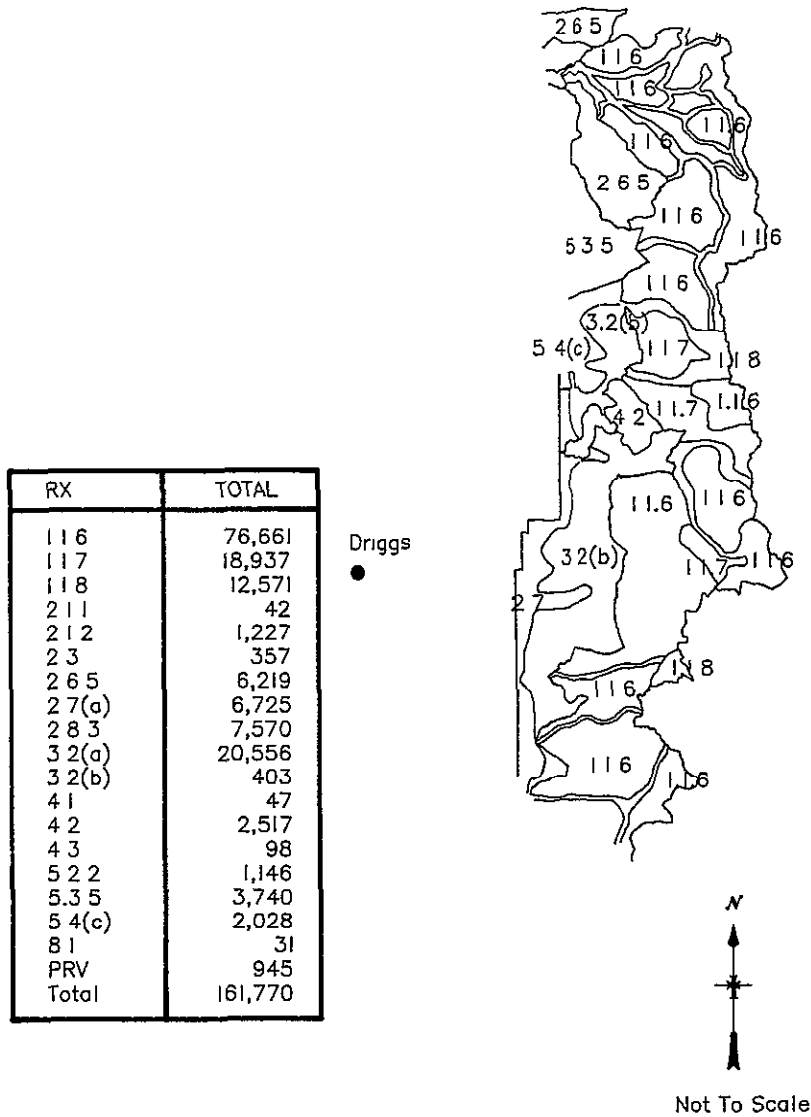

Figure III-7

Of critical importance to this subsection is the high amount of mature and over-mature vegetation. Careful treatment will be required to achieve the conditions for all of the management prescriptions since little of this area will be available for silvicultural treatment.

GOALS AND OBJECTIVES

Aquatic - Objective

Improve stream channel stability ratings to good or excellent by 2007 where natural conditions allow on Teton Creek, N. Leigh, S. Leigh, Moose Creek, Trail Creek, Fox Creek, and Kiln Creek where instability is management-caused.

Wildlife - Objective

Maintain or improve big game winter range.

Recreation - Objective

Maintain remaining roadless areas in their roadless condition.

Wild and Scenic River - Objective

Complete the suitability studies for rivers that are eligible for wild and scenic river designation.

STANDARDS AND GUIDELINES

Wilderness

I. Implement the Jedediah Smith Wilderness Management Plan which consists of the specific wilderness prescription management direction and the Wilderness Implementation Schedule and Monitoring Action Plan.(G)

II. Implement the Jedediah Smith Wilderness Fire Management Plan.(G)

Range

Domestic sheep grazing will be phased out over time on an opportunity basis. An opportunity is defined as a suitable or favorable time to abolish or close an allotment because of nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit. If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas. (G)

Restrict domestic sheep bands to not closer than 3 miles of bighorn sheep range in the Fossil Mountain, Mount Jedediah Smith, and Darby Creek area (these areas are used by bighorn sheep in the spring, summer, and fall). (G)

BIG HOLE/ PALISADES SUBSECTION (M331D-1)

SETTING

This subsection takes in all National Forest lands between Highway 33 in Idaho and Highway 22 in Wyoming on the north and the South Fork of the Snake River to the south. Several major highways provide access: Idaho Highways 26, 31 and 33, and Highway 22 in Wyoming. Highway 31 is a State Scenic Byway over Pine Creek Pass. Vegetation consists of mountain brush, grass/forb openings, aspen, and forests of Douglas-fir and lodgepole pine. The area has a variety of recreational opportunities including Kelly Canyon Ski Resort and backcountry hiking. Palisades Reservoir and its many boat ramps are used by water sports enthusiasts.

The landscape is a combination of community types, with 65% of the landscape forested and 35% nonforested. The most common forest type is mixed lodgepole pine and Douglas-fir, comprising 47% of the forested acres. Aspen, pure Douglas-fir and pure lodgepole pine each account for roughly 15% of the forest. Mountain brush is common; consisting of mountain mahogany on south slopes and hawthorne, chokecherry, serviceberry, antelope bitterbrush and Rocky Mountain maple on various slopes/aspects depending on elevation. Grass/forb meadows and sagebrush are also present in significant amounts. The northwestern boundary of the subsection extends into the cottonwood type along the Snake River.

Only 4% of the forested stands are in the nonstocked, seedling or sapling age category. These are concentrated in the north end of the subsection where timber harvest has occurred.

Most of the shrublands are also in late age classes or seral stages. There is concern about the lack of cottonwood regeneration along the Snake River, due to a lack of historic river flood levels.

Currently 95 percent of the subsection is in a mature age class which provides suitable habitat for a variety of interior wildlife species. This creates hazards for large fires, insect infestations and disease problems. In the north end of the subsection Douglas-fir beetle and western balsam bark beetle caused damage in the late 1980's and early 1990's, but tapered off in 1994. Insect information is not available for the southern portion. Due to fire suppression and lack of disturbance over the years, conifers have encroached into some sites that were historically nonforested. This has reduced overall vegetative diversity in the subsection.

The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in 1984. The Study Area contains 132,000 acres. Of these acres, over 79,800 are administered by the Bridger-Teton National Forest. In addition, there are 110,520 acres of this roadless area in Idaho which have had no action or recommendation taken on them. The studies on the Wyoming portion have not been conducted, and are planned to be done with the Bridger-Teton as the lead Forest at the time of their Plan Revision.

Figure III-8 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

This subsection will be managed to provide high quality motorized recreation opportunities both summer and winter with a signed system of roads and trails for OHV and full-sized vehicles while protecting resources.

On suitable lands silvicultural management will focus on reducing the risks of insect and disease while improving big game security and summer range. Prescribed fire will be used on the remainder of the subsection to help obtain healthy ecosystems and improve wildlife winter ranges.

The recreational use on the South Fork of the Snake River will continue but be balanced with the needs of wildlife

This subsection has similar ecosystem management conditions, but has two different management goals and objectives. The Big Hole portion of the subsection will be managed to provide a wide variety of resources and recreation opportunities. This area will have special management emphasis to provide *quality motorized recreation opportunity with signed system of roads and trails for motorized use*. Resource protection will be planned and accomplished by restricting motorized use to designated routes and by locating routes along planned and selected routes.

The Palisades subsection portion will be managed for more primitive motorized and nonmotorized recreation opportunities. Emphasis will be placed on quality backcountry experience for these type users along appropriate designated trails. The Forest will recommend the Idaho portion of the Palisades roadless area for wilderness designation and maintain the wilderness area status for the Wyoming portion.

GOALS AND OBJECTIVES

Biodiversity - Objective

1. Continue cooperation with other agencies in conducting research and implementing management actions to regenerate cottonwood along the South Fork of the Snake River.
2. Develop a fire management plan which considers summer home development and risk around the Palisades Reservoir.

Aquatic & Riparian Ecosystems - Objective

1. Improve stream channel stability ratings to good or excellent by 2007 where natural conditions allow on South Fork, Packsaddle, Horseshoe, Superior, North Fork Mahogany, Main Mahogany, Henderson, Patterson, and Murphy Creeks.
2. Channel stability would be rated at good to excellent for individual streams.

Recreation - Objective

1. Continue to place emphasis on winter recreation for the Big Hole portion of the subsection by continuing a grooming program for snowmachines, which is orientated towards family opportunities; continuing to work with user groups for X-country skiing opportunities in the Kelly area.
2. Continue to improve the quality of the summer time OHV use in the Big Hole area and protect resource values by locating and maintaining trails on suitable locations.

Heritage - Resources

Complete heritage resources inventory of this subsection by 2010.

Wild and Scenic River - Objective

Complete the suitability studies for rivers that are eligible for wild and scenic river designation.

Visuals - Objective

Manage the Pine Creek Scenic Byway (Highway 31) and Highway 22 over Teton Pass for visual quality.

Range - Objectives

Continue to recognize the value of grazing on the Kelly Ski hill for forage control and fire protection. Coordination for grazing timing and duration will continue to be coordinated between grazing permittees, ski hill permittee and Forest Service.

STANDARDS AND GUIDELINES

Winter Feeding of Big Game

Phase out Rainey Creek feed grounds for big game animals in cooperation with the State Fish and Game Departments within 5 years of the Record of Decision for the Forest Plan Revision. (S)

Access

In the Table Rock area, the OROMTRD standard of ≤ 2.0 mi./sq.mi. does not apply (S)

Winter Recreation

Kelly Canyon/Hawley/Buckskin-Morgan Ridge. This area is closed to snowmachines except on designated routes. (S)

Lands (Special Uses)

The Therold Buckland isolated cabin will continue as a life tenure permit and will not transferred. Upon the expiration of the permit, the cabin will be evaluated and its historical qualifications determined. If the cabin is found to have historic value, it may be moved from the site, or the Forest may issue a special use permit to a Historical Association for maintenance of the cabin. If no historical value is found the cabin will be removed. (S)

CARIBOU SUBSECTION (M331D-19)

SETTING

This subsection is the portion of the Caribou National Forest administered by the Targhee. It lies south of the South Fork of the Snake River. Steep mountain slopes and canyons dominate the landscape. The Palisades Reservoir is shared by this subsection and the Big Hole/Palisades Subsection. Vegetation forms a patchwork of tall sagebrush/grass openings, aspen, and mixed Douglas-fir/lodgepole pine forests. Recreation use is very similar to the Big Hole/Palisades Subsection with high trail and backcountry use as well as hunting, fishing and water sports both on the reservoir and the Snake River. This area has several summer home divisions and two organizational camps. Forest lands are visible from U.S Highway 26, the major travel corridor before Idaho Falls, Idaho and Jackson, Wyoming. Only very limited logging has occurred in the past. Both cattle and sheep are grazed.

Mixed conifers and sagebrush/grass communities dominate the subsection. Minimal timber management has occurred in the Engelmann spruce/subalpine fir type. Recreation use here may increase the chance for human-ignited fires.

The Caribou Subsection is 60% forested and 40% nonforested. The primary forest types are aspen (31%) and mixed lodgepole and Douglas-fir (47%). The interspersion of forests with sagebrush, grass/forb meadows and mountain brush provides for good diversity of plant species. The northeastern boundary area of the subsection includes cottonwood forests along the Snake River.

Age class diversity is limited, as in many other areas of the forest. Because virtually no vegetation management has taken place in this subsection and fires have been suppressed for many years, only 1% of the forests are in young age classes. Most of the shrublands are also in late age classes or seral stages. Risks of large fires, insects and diseases are high due to these vegetative conditions. The insect situation in recent years has been similar to that in the Big Hole/Palisades Subsection. Douglas-fir is becoming more predominant as it encroaches on stands of lodgepole pine, aspen or shrubs. It is likely that there is more Douglas-fir here now, and less aspen, lodgepole pine and shrubland, than existed historically. The Snake River cottonwood stands are also uniformly in the mature age class due to lack of disturbance, which they need in order to regenerate, caused by flooding control by Palisades Dam.

Establishing natural regeneration of both Douglas-fir and lodgepole pine following harvest has been a problem in this subsection, and most sites have required planting.

Currently 99 percent of the conifer forests are in a mature or older age class, and the biological potential for woodpecker populations ranges from 59 to 74 percent.

Figure III-9 displays this subsection along with the major prescription areas

DESIRED FUTURE CONDITION

This subsection will be managed to provide high quality nonmotorized and dispersed camping recreation opportunities.

On suitable lands silvicultural management will focus on reducing the risks of insect and disease while improving big game winter range conditions. Prescribed fire will be used on the remainder of the subsection to help obtain healthy ecosystems

The recreational use around Palisades Reservoir and the South Fork of the Snake River will continue but be balanced with the needs of wildlife.

Caribou Subsection (M331D-19)

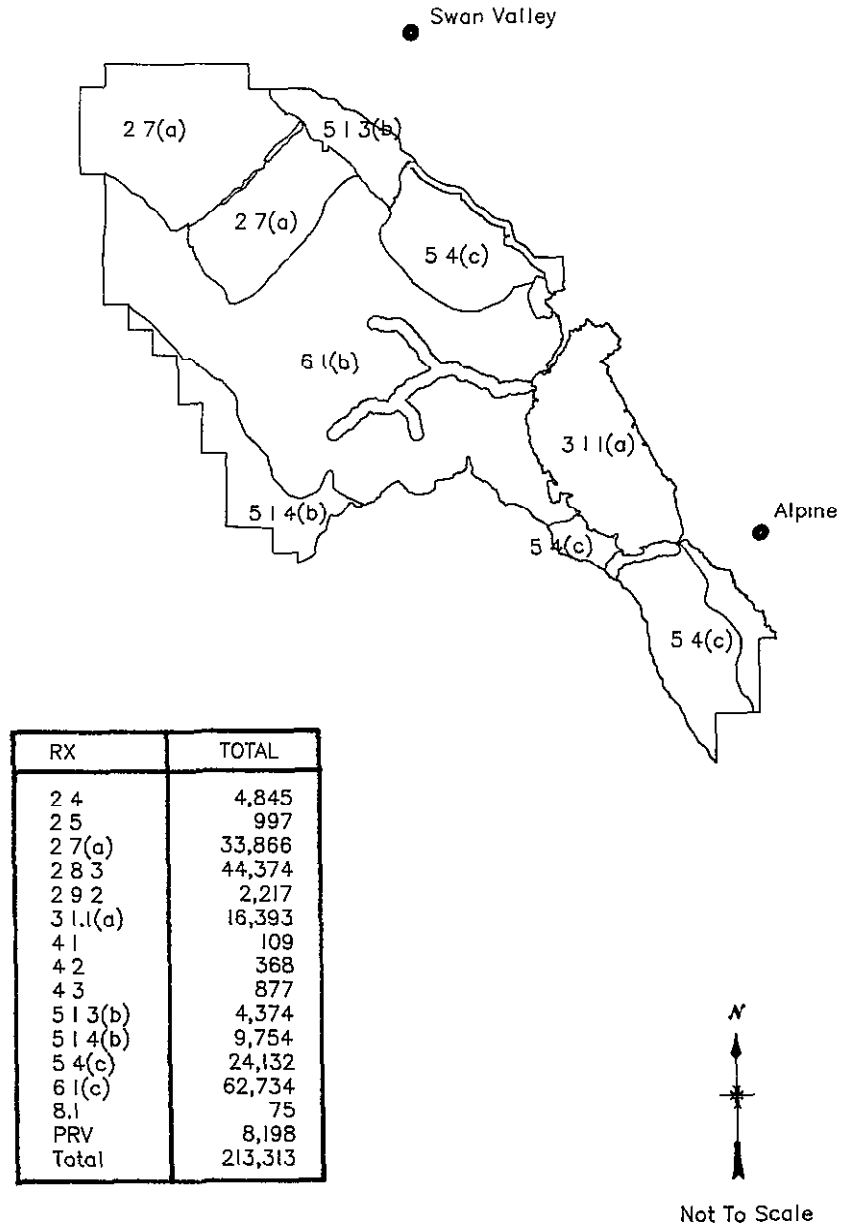

Figure III-9

This subsection will be managed to provide a variety of resource opportunities for the permitted and general public. Quality range management practices will continue on this subsection. Protection of high valued big game winter range in the Fall Creek area will be maintained or improved. Recreational opportunities with emphasis on dispersed recreation opportunities with a quality motorized opportunity on designated trails

GOALS AND OBJECTIVES

Biodiversity - Objective

1. Continue cooperation with other agencies in conducting research and implementing management actions to regenerate cottonwood along the South Fork of the Snake River
2. Develop a fire plan which allows for prescribed natural fire
3. Develop a fire management plan which allows for natural fire and which considers summer home development and risk around the Palisades Reservoir.

Heritage Resources

Complete heritage resource inventory of this subsection by 2010.

Recreation

1. Continue to improve the quality of the summer time OHV use in this Subsection and protect resource values by locating and maintaining trails on suitable locations.
2. Continue to place emphasis on winter recreation for this subsection by continuing a grooming program for snowmachines which is orientated towards family opportunities, and providing shelter facilities (warming huts) continuing to work with user group for X-country skiing opportunities in the Kelly area.

Wild and Scenic River Objective

Complete the suitability studies for rivers that are eligible for wild and scenic river designation.

STANDARDS AND GUIDELINES

Waterfowl Nesting Areas

Salt River on Palisades Reservoir. Area closed to snowmachines from December 1 to March 31.
Area closed to all wheeled vehicles March 15 to July 31 except on designated routes

INTRODUCTION

A management prescription is a composite of the specific multiple-use direction applicable to all or part of a management area that generally includes, but is not limited to, goals, objectives, standards and guidelines, and probable management practices.

The terms goals, objectives, standards and guidelines were defined in the Introduction of this Chapter. The goals, objectives, standards and guidelines in this section are specific to each management prescription.

This set of management prescriptions is the result of many suggested changes made by our publics and employees to previous sets.

Each management prescription has a motorized access density standard established for it. Roads or trails are frequently used as a convenient geographic feature to identify management prescription area boundaries. When roads or trails are used to identify a management prescription area boundary where the TMARD (Total Motorized Access Route Density) or OROMTRD (Open Road and Open Motorized Trail Route Density) is 0.0 miles/square mile, the road or trail miles are not counted in the TMARD or OROMTRD for that particular prescription area. The road and trail miles are included in the TMARD and OROMTRD calculations in the adjacent management prescription areas. The road and trail miles are included when calculating environmental effects, such as elk vulnerability, grizzly bear cumulative effects, etc.

1.1.6 DESIGNATED WILDERNESS - OPPORTUNITY CLASS I

Description

This prescription applies to the Winegar Hole Wilderness and areas of the Jedediah Smith Wilderness, which are managed as Opportunity Class I.

The effects of human activities are not noticeable to most visitors. Camping activities are not evident, although facilities may be present to assist recovery of T&E species (e.g., bearproof storage boxes). User-created routes and nonsystem trails may exist but they appear as game trails and are not shown on maps or trail guides.

Opportunities exist for individuals or small groups to experience a high quality wilderness dependent education experience. A low level of recreation use occurs in these remote areas which often contain rugged terrain. There is a lack of system trails, a lack of signing, and information about the area is not distributed. Trailhead facilities for these areas are minimally developed to encourage low levels of use. There is a low level of outfitter/guide use.

Low use levels allow for meeting the user's expectations of finding a climbing or caving experience with a high degree of solitude. Evidence of the user's passing are not evident. Opportunity for discovery may exist.

Goals

1. The maintenance of the natural diversity of wildlife species is given the highest priority and is dominant over other uses. There is no great alteration of wildlife behavior or use of crucial habitat by wildlife as a result of human activities.
2. Human activities are managed so there is no appreciable modification of natural succession. Any vegetation loss resulting from camping recovers within one growing season

3. There is no measurable downward trend in plant species composition and plant diversity due to livestock grazing. Utilization levels are compatible with maintaining or enhancing ecological condition. The range is managed so that plant communities are at or trending towards potential natural community status except where natural disturbance, and not livestock or recreation use, determines the lower seral condition.

4. There are outstanding opportunities for solitude, self-reliance, and challenge. Users do not normally see or hear other users.

5. A very minor amount of human-caused bare soil persists from year-to-year in localized areas. No great human-caused soil erosion occurs.

6. Opportunities are provided for research that do not require permanent instrumentation or direct contact with visitors.

Objectives

1. Cooperate with the State Game and Fish Departments to prepare a Wilderness fishery management plan by the year 1999, with consideration of the State's existing fishery management plan for wilderness fisheries.

2. Implement a wilderness education program for all users, which could include. yearly contacts with local schools; yearly programs with organizational camps; information available at Forest and District offices for distribution to the public, periodic contacts at trailheads by Forest Service personnel with Wilderness users; ethics orientation for Wilderness use presented to permittees and Forest Service personnel; and information about grizzly bears.

3. Cooperate with the Wyoming Game and Fish Department in the annual census of bighorn sheep, including lamb survival and ram harvest.

4. Cooperate with other agencies to determine if the Teton Crest bighorn sheep population should be augmented to improve genetic heterogeneity.

5. Reduce competition, disease and parasite exchange potential between domestic and wild sheep by lessening the overlap of their ranges. Phase out domestic sheep grazing within 3 miles of bighorn sheep habitat.

6. Natural and manager-ignited fires are allowed to burn under predetermined prescriptive conditions as described in the Fire Management Action Plan.

7. Manage as trailless areas. Any existing trails will be abandoned and allowed to regress to a natural state unless needed to prevent resource damage.

8. Manage for a low level of outfitter/guide use.

9. Within the grizzly bear recovery zone, domestic sheep grazing will be phased out over time on an opportunity basis.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is as follows:

Physical Elements

Heritage Resources

Evaluate and protect these resources in the context of a setting where there is little public visibility. (G)

Biological Elements

Fish and Other Aquatic Resources

Fish stocking for recreational fishing is permitted with species native to the Wilderness in waters previously stocked (prior to Wilderness designation) by the Game and Fish Department. (G)

Fish stocking for reestablishment of native species may occur. (G)

Wildlife

Grizzly Bear - No new trails or campsites will be developed within the grizzly bear recovery zone within Opportunity Class I areas. (S)

Harlequin Duck - No new trails or campsites should be developed within 300' of streams which provide harlequin duck habitat (G)

Peregrine Falcon - Restrict recreational climbing activities in Teton Canyon (or any other cliff occupied by nesting peregrines) from March 15 through July 31, should a conflict arise between nesting peregrine falcons and recreational climbers. (G)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	No
	Horse/Pack Stock	Yes	No
	Mtn Bike/Mechanized	No	No
	Motorized, <50" wide	No	No
	Motorized, >50" wide	No	No
	OROMTRD 2/	N/A	0.0 mi/sq.mi.
	Winter Nonmotorized	Yes	No
	Snowmachine	No	No
<p>1/ These areas are managed as trailless; there are no maintained trails. Motorized use is prohibited, except for emergencies or valid uses specified in the law.</p> <p>2/ OROMTRD = Open road and open motorized trail route density' includes all open roads and open motorized trails. (See Roads in Glossary for more information)</p>			

Recreation

Dispersed - No dispersed facilities are provided, except facilities may be present for recovery of T&E species. Existing bear-proof food storage boxes in Opportunity Class I zones installed prior to 1993 may remain, but no additional boxes or other facilities will be installed in these areas. (S)

- No signing. (S)

- No distribution of information about these areas (S)

ROS - Manage for a primitive classification. (S)

VQO - Manage for a preservation classification. (S)

Trails/Bridges - Trailhead facilities for these areas are minimally developed to encourage low levels of use. (G)

Production of Natural Resources

Range

Opportunities to resolve domestic sheep/grizzly bear and domestic sheep/bighorn sheep conflicts over time are defined as a suitable or favorable time to abolish or close an allotment because of nonuse violations, term permit waivers where the permit is waved back to the government, resource protection, or permit actions resulting in cancellation of the permit. If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas (G)

1.1.7 DESIGNATED WILDERNESS - OPPORTUNITY CLASS II

Description

This prescription applies to the portions of Jedediah Smith Wilderness which will be managed as Opportunity Class II.

The effects of human activities are somewhat evident to visitors. Camping activities are set back from trails and water. Trail treads are evident but the trail may be brushy and its location blends well with the natural topography. Trails are maintained to protect the resource.

Opportunities exist for individuals and moderate sized groups to experience a quality wilderness related educational experience.

A moderate level of recreation use occurs. Bridges generally are not provided except where needed for resource protection. Directional and resource protection signs may be provided. Campsite facilities may be present for recovery of T&E species. Trailheads used by those accessing these areas contain bulletin boards and may provide undeveloped areas for overnight camping. There may be a high level of outfitter/guide use.

There is a moderate to high opportunity for solitude during July-September. Opportunities for solitude are high at other times. Users may experience a moderate degree of self-reliance and challenge. Users normally do not see other users but may occasionally hear other groups.

Moderate use levels may result in other users seeing or hearing some evidence of caving and climbing activities. Fixed anchors at rappel stations, impacts on approach and descent routes, and some protection left by previous parties notifies users that others have gone before.

Goals

1. The maintenance of the natural diversity of wildlife species is given high priority. There is no displacement of wildlife during critical periods (winter and birthing), and only temporary displacement during noncritical periods.
2. Human activities are managed so there is only limited modification of natural succession at campsites, trails, and grazed areas. Some vegetation loss persists from year-to-year at identified campsites.
3. There is no measurable downward trend in plant species composition and plant diversity due to livestock grazing. Utilization levels are compatible with maintaining or enhancing ecological condition. The range is managed so that plant communities are at or trending towards potential natural community status except where natural disturbance, and not livestock use or recreation use, determines the lower seral condition.
4. Some bare soil persists from year-to-year due to human activities. Human-caused soil erosion may occur.
5. Research opportunities may include a minor amount of instrumentation and only occasional contact with visitors.

Objectives

In addition to the Objectives 1-6 and 9 in opportunity Class I (1.1.6), also add the following

1. Install signs at Wilderness portals advising users they may encounter a variety of other legitimate wilderness uses including sheep and cattle grazing and llama trekking.
2. Natural and manager ignited fires are allowed to burn under predetermined prescriptive conditions as described in the Fire Management Action Plan.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below:

Physical Elements

Heritage Resources

Evaluate and protect these resources in the context of a setting where there is some public visibility. (G)

Biological Elements

Fish and Other Aquatic Resources

Same as 1.1 6 Designated Wilderness Opportunity Class I.

Wildlife

Grizzly Bear - In the event future trails or campsites are developed within the grizzly bear recovery zone, avoid locations within 1/2 mile of key habitat areas such as white bark pine stands, huckleberry patches, riparian areas and wet meadows, avalanche chutes, seasonal insect feeding sites. (G)
Harlequin Duck - Avoid locating new trails or campsites within 300' of streams which provide harlequin duck habitat. (G)

Peregrine Falcon - Restrict recreational climbing activities in Teton Canyon (or any other cliff occupied by nesting peregrines) from March 15 through July 31, should a conflict arise between nesting peregrine falcons and recreational climbers. (G)

Forest Use and Occupation

Access (S)

(FSM 2326.03)</p> <p>2/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information)</p>			

Recreation

Dispersed - Additional food storage boxes may be provided in Opportunity Class II zones for protection of the grizzly bear. (G)

- Directional and resource protection signs may be provided. (G)

Trails/Bridges

Trails have evident tread but may be brushy. Bridges generally are not provided except where needed for resource protection. (G)

Trailhead facilities contain bulletin boards and may provide undeveloped areas for overnight camping (G)

ROS - Manage for a primitive to semi-primitive nonmotorized classification. (G)

VQO - Manage for a preservation classification. (S)

Production of Natural Resources

Range

Same as 1.1.6 Designated Wilderness - Opportunity Class I.

1.1.8 DESIGNATED WILDERNESS - OPPORTUNITY CLASS III

Description

This prescription applies to areas of the Jedediah Smith Wilderness which will be managed as Opportunity Class III.

The effects of human activities are evident to most visitors but blend in with the natural setting. Camping is set back from trails and water. Trail treads are very evident.

Education Opportunities exist for individuals and large groups to experience a quality educational experience.

Recreation use is relatively high. Bridges are provided where needed for resource protection or visitor safety. Directional, informational and regulatory signs may be provided. Campsite facilities may be present for recovery of T&E species. Trailheads used by those accessing these areas may contain information stations, undeveloped and developed areas for overnight camping and stock facilities. There may be a moderate level of outfitter/guide use.

There is a low to moderate opportunity for solitude during July-September. Opportunities are high at other times. Users may experience a low to moderate degree of challenge and self reliance. Users may see or hear other groups especially during July-September.

High use levels at peak times may result in other users seeing and hearing climbers. Cavers and climbers may encounter other groups, which may slow their progress and may impact their solitude expectations. Fixed anchors at rappel sites are evident. Approach and descent trails are evident, and their impacts are managed to control erosion. Fixed protection anchors on climbs may be evident to hikers at the base of cliffs, but not those on system trails.

Goals

1. The maintenance of the natural diversity of wildlife species is given high priority but does not dominate other uses except where measures are needed to recover T&E species. Temporary displacement of non-T&E species may occur except on crucial ranges but there is no permanent displacement. Some habituation of species may be evident. Opportunities exist for "Watchable Wildlife" program in wilderness setting.

2. Human activities are managed so that modification of natural succession only occurs at campsites, trails, and grazed areas. Moderate vegetation loss persists from year-to-year at identified campsites.

3. There is no measurable downward trend in plant species composition and plant diversity due to livestock grazing. Utilization levels are compatible with maintaining or enhancing ecological condition. The range is managed so that plant communities are at or trending towards potential natural community status except where natural disturbance, and not livestock or recreation use, determines the lower seral condition.

4. A moderate amount of bare soil may persist from year-to-year due to human activities. A moderate amount of human-caused soil erosion may occur.

5. Research opportunities may include some instrumentation and moderate contact with visitors.

Objectives

In addition to the Objectives 1-6 and 9 in Opportunity Class I (1.1.6), also add the following.

1. Signs will be installed at Wilderness portals advising users they may encounter a variety of other legitimate wilderness uses including sheep and cattle grazing and llama trekking.
2. Natural and manager ignited-fires are allowed to burn under predetermined prescriptive conditions as described in the Fire Management Action Plan.
3. Manage for a moderate level of outfitter/guide use.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Physical Elements

Heritage Resources

Evaluate, protect and interpret these resources in the context of a setting where there is moderate human influence and public visibility. (G)

Biological Elements

Fish and Other Aquatic Resources

Stocking of native and nonnative fish is permitted only in waters previously stocked by Game and Fish Department. (S)

Fish stocking for reestablishment of native species may occur. (G)

Wildlife

Grizzly Bear - In the event future trails or campsites are developed within the grizzly bear recovery zone, avoid locations within 1/2 mile of key habitat areas such as white bark pine stands, huckleberry patches, riparian areas and wet meadows, avalanche shoots, seasonal insect feeding sites (G)

Harlequin Duck - Avoid locating new trails or campsites within 300' of streams which provide harlequin duck habitat. (G)

Peregrine Falcon - Restrict recreational climbing activities in Teton Canyon (or any other cliff occupied by nesting peregrines) from March 15 through July 31, should a conflict arise between nesting peregrine falcons and recreational climbers. (G)

Forest Use and Occupation

Access(s)

Same as 1.1.7 Designated Wilderness Opportunity Class II

Recreation

Dispersed - Food storage boxes may be provided in Opportunity Class III zones for protection of the grizzly bear. (G)

- Directional, informational, regulatory and resource protection signs may be provided. (G)

Trails/Bridges - Trails are well defined and brushed out. Bridges are provided where needed for resource protection and visitor safety. (G)

Trailhead facilities contain information stations, undeveloped and developed areas for overnight camping and stock facilities. (G)

ROS - Manage for a primitive to semi-primitive nonmotorized classification. (G)

VQO - Manage for a preservation classification (S)

Production of Natural Resources

Range

Same as 1.1.6 Designated Wilderness Opportunity Class I.

1.2 WILDERNESS STUDY AREA

Description

This prescription applies to the Wyoming portion of the Palisades and Teton Basin Ranger Districts, which was designated as a Wilderness Study Area by the Wyoming Wilderness Act of 1984.

The 1984 Act provided the area be administered to "maintain its present existing wilderness character and potential for inclusion in the National Wilderness Preservation System." (AMS, Roadless Areas, Page 7) The Act provided that oil and gas exploration and development be allowed in accordance with laws and regulations generally applicable to nonwilderness lands in the National Forest system, and that snowmobiling should continue to be allowed in the same manner and degree as was occurring prior to the date of enactment of the Act

This is a mostly pristine area of the Forest where you find little sign of people away from trails or camping areas. They are undeveloped lands retaining their primeval character and influence, and are managed so as to preserve their natural condition. They generally appear to be have been affected primarily by the forces of nature and therefore offer an excellent opportunity for solitude or a primitive and unconfined type of recreation. Occasionally, however, a visitor may see effects of human activity such as primitive campsites, rustic bridges, trails, signs, or primitive roads. A visitor may also encounter livestock, mining, or a snowmobile.

You may find areas of the forest where recent burns, insect activity, or blowdowns dominate the landscape. You would not expect to encounter mechanized equipment, except snowmobiles.

Goal

Protect and perpetuate wilderness character.

Objectives

1. Insects and disease are allowed to play, as nearly as possible, their natural ecological role in the environment.
2. Trails and bridges are constructed/maintained to a level to accommodate heavy foot and horse traffic.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

Minimum Impact Suppression Tactics will be employed to the maximum extent possible. (G)

Allow prescribed fires from both natural and management-ignition when they meet the objectives of the Wilderness Study Area. (G)

Insects and Disease

Insect and plant disease epidemics may be controlled to prevent unacceptable damage to resources on adjacent lands or an unnatural loss to the Wilderness Study Area resource due to exotic pests. (G)

Physical Elements

Soil and Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans, or where their influences create a serious threat or loss of the Wilderness Study Area values (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within the Wilderness Study Area are not imminent; or where natural vegetation would return in a reasonable time. (G)

Use indigenous species to reestablish vegetation as the first choice. Where native species are unlikely to succeed, use appropriate self-extirpating naturalized species. (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of wilderness-like resources or to protect life, property, and other resource values outside the Wilderness Study Area. (S)

Maintenance or reconstruction of existing water development structures is allowed if it does not change the location, size, or type, or which does not increase the storage capacity of a reservoir. (G)

Minerals/Geology

Locatable - Withdraw from mineral entry, or remove from mineral entry through the notation rule, subject to valid existing rights (G)

Mineral Material - This area is not available for mineral material entry. (S)

Heritage Resource

Remove structures that do not qualify for the National Register of Historic Places, or allow them to deteriorate naturally unless they are: (G)

1. Deemed necessary to support public purposes of the Wilderness Study Area, or
2. Serve administration purposes.

Interpretation of cultural resources located in the Wilderness Study Area shall be done outside the area. (S)

Biological Elements

Fish and Other Aquatic Resources

Fish stocking of nonexotic species is allowed where it existed prior to establishment of the Wilderness Study Area. Stocking will normally be accomplished by nonmotorized means, such as horse or mule. (G)

Wildlife

Reintroduce wildlife species only if the species was once indigenous to the area and was eliminated by human-induced events. (S)

Wildlife habitat manipulation can only occur if: (S)

- 1 The condition needing change is a result of abnormal human influence.
2. The project can be accomplished with assurance that there will be no serious or lasting damage to wildernesslike value
3. There is reasonable assurance that the project will accomplish the desired objectives.

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
	Motorized, <50" wide Motorized, >50" wide OROMTRD 4/	No 2/ No 2/ N/A	Yes 3/ No 0.0 mi/sq.mi. 3/
	Winter Nonmotorized Snowmachine	Yes Yes 3/	Yes Yes 3/

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Motorized use is prohibited, except for emergencies or valid uses specified in the law.

3/ Indian Creek. Open to motorized vehicles < 50 inches wide on designated routes, and snowmachines anywhere.

4/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information)

Roads

Roads are allowed only to the extent they already exist. (S)

Recreation

ROS - Manage for primitive or semi-primitive nonmotorized classification. (G)

VQO - Manage for a preservation classification. (S)

Production of Natural Resources

Timber

Trees may be cut only for valid mining claims under specific conditions, when emergency conditions such as fire, insect and disease arise, for protecting public safety, or when administrative use make it necessary. (G)

1.3 RECOMMENDED/PROPOSED WILDERNESS

Description

This prescription applies to areas that are recommended for addition to the Wilderness Preservation System. They will be managed in their present condition (including existing road use and snowmachine use, as long as existing uses will not degrade Wilderness resources) until Congress takes action on that recommendation.

These are mostly pristine areas of the Forest where you find little sign of people away from trails or camping areas. They are undeveloped lands retaining their natural condition. They generally appear to have been affected primarily by the forces of nature and therefore offer an excellent opportunity for solitude or a primitive and unconfined type of recreation. Occasionally, however, a visitor may see effects of human activity such as primitive campsites, rustic bridges, trails, signs or primitive roads. A visitor may also encounter livestock or mining activity.

You may also find areas of the forest where recent burns, insect activity, or blowdowns dominate the landscape. You may encounter mechanized equipment on designated trails during the summer or snow-machine use during the winter.

Goal

Protect and perpetuate wilderness character.

Objective

Within the grizzly bear recovery zone, an active education program will be implemented each year, including patrols during the fall hunt. (S)

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

The Standards and Guidelines for this prescription are the same as 1 2 (Wilderness Study) except: Recreation. (Developed and Education). Differences are shown as follows:

Forest Use and Occupation

Access (S)

Same as 1.2 Wilderness Study Area, except motorized use.

2/ Motorized use is controlled as follows:

Idaho Portion of Winegar Hole: Motorized use will be managed according to direction in adjacent management prescription areas.

Lionhead. Closed to all motorized vehicles, except snowmachines are allowed during the period Dec. 15 to April 1.

Italian Peak: Open to two wheeled motorized vehicles only on designated routes, and snowmachines anywhere.

Palisades. The Idaho portion is open to snowmachines, but closed to all other forms of motorized use, except for Indian Creek which is as follows:

Indian Creek. Open to motorized vehicles < 50 inches wide on designated routes, and snowmachines anywhere.

Recreation

Developed - Developed, hardened campsites are generally not allowed. (G)

2.1.1 SPECIAL MANAGEMENT AREAS

Description

This management prescription applies to areas with unique cultural, geologic, botanical, or zoological resource values, and sites which are listed or eligible for the National Register of Historic Places.

Vegetation will vary depending on the objectives of each special area. A mix of age class distributions, openings, and horizontal/vertical diversity may be present. In general, vegetation will appear natural in the special management areas; however, exceptions may exist for some areas, and some human-caused vegetation manipulation will occur depending on the objectives of each special area.

Facilities may or may not be present to manage the special areas. Access will range from black top roads, to trails, to no access at all. Administrative sites could have a variety of facilities such as buildings, roads, trails, microwave towers, boat ramps and pasture for the livestock used by Forest Service personnel to manage the Forest.

The amount of human activity apparent in special areas will vary, depending upon the management objectives of each area.

Special management areas may provide some forage for livestock. Timber harvest may be rare or not at all. Restricted livestock grazing and timber activities can be expected to provide additional protection to the special values in the area. Surface facilities for leasable minerals, such as oil and gas, will not be found within a special management area. To protect the values within a special management area, restrictions can be expected for valid existing rights to develop locatable minerals, such as precious metals and high value industrial minerals.

Because of the unique characteristics of these special management areas, these lands may provide economic opportunities for outfitter and guides, educational opportunities for the public and research opportunities for resource managers and academia. These areas will provide a spectrum of recreational opportunities from developed sites containing comfort facilities and visitor centers in a natural setting to sites with no access at all in a pristine setting

Goal

Manage and protect the unique cultural, historic, botanical, geological, and/or zoological resources.

Objectives

1. Maintain or enhance the inherent values associated with each special interest area.
2. Allow insects and disease to play their natural role in ecological succession, except where resource values will be adversely affected.
3. Maintain or enhance the inherent wildlife habitat values associated with each special management area

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

Prescribed fire, utilizing both management-ignited and natural ignitions, may be used to maintain fire-dependent characteristics of the area (G)

Physical Elements

Soil & Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans. (G)

Promote natural healing where natural vegetation would return in a reasonable time. (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing. (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of resources (S)

Lands

Establish exterior boundaries of sites when necessary for protection (G)

Minerals/Geology

Same as 1.2 Wilderness Study Area.

Heritage Resource

Multiple user interpretive sites may be provided Avoid indoor interpretative sites unless warranted by special circumstances. (G)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes 2/ Yes 2/ No	Yes Yes Yes
	Motorized, <50" wide Motorized, >50" wide OROMTRD 3/	No No N/A	Yes Yes <= 0.5 m/sq.mi.
	Winter Nonmotorized Snowmachine	Yes 2/ Yes 2/	Yes Yes
<p>1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.</p> <p>2/ There may be site-specific exceptions.</p> <p>3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails In 2.1.1 prescription areas <= 1 sq mi. in size, OROMTRD does not apply. (See Roads in Glossary for more information)</p>			

Roads

New road construction may occur if needed to meet the management objectives for the special management area. (G)

Recreation

Dispersed - Minimal recreation facilities may be provided (such as trails, board walks, toilets, etc). Generally, such recreation facilities are not encouraged, and are only provided to protect resource values. (G)

ROS - Primitive to roaded natural. (G)

VQO - Retention to partial retention. (G)

Production of Natural Resources

Timber

These areas are removed from the suitable timber base. They are not part of the ASQ (S)

Generally, no timber harvesting will be allowed in special management areas. Exceptions to this may occur on a site-specific basis for such things as public safety, visual quality, long term maintenance of vegetation conditions, etc. (G)

Range

Livestock grazing and associated developments (such as fencing) are permissible as long as they do not adversely affect the unique resources of the special management area (G)

2.1.2 VISUAL QUALITY MAINTENANCE

Same as 5.2.2 - Visual Quality Maintenance, except: No motorized cross country travel, No ASQ.

2.2 RESEARCH NATURAL AREAS

Description

These management prescription areas are important ecological or natural areas established for non-manipulative research, education, and to maintain natural diversity on National Forest system lands. They also may assist in carrying out provisions of special acts, such as the Endangered Species Act and the monitoring provisions of the National Forest Management Act. Research natural areas are identified and recommended by a steering committee.

These areas are good examples of physical or biological units in which current natural conditions are maintained insofar as possible. These conditions are ordinarily achieved by allowing natural physical and biological processes to prevail without human intervention. (FSM 4063.05).

Nonmanipulative research activities occur in these areas. Some scientific instrumentation may be present. Since these areas are also used for education purposes, occasional groups of people may be present observing and being instructed about the area.

Generally, there are no developed facilities on site. Interpretation of special features will generally be done off site. A road or trail may be present to provide access primarily for research and education purposes. Recreation use is not promoted in these areas, and may be reduced or eliminated if adverse impacts are occurring.

Generally, timber harvesting and other vegetation manipulation is not done. Livestock grazing may occur if not detrimental to the ecological processes of the area. There is no mineral activity.

Goal

Maintain the natural ecological processes inherent in each research natural area.

Objectives

1. Allow insects and disease to play their natural role in ecological succession, except where resource values will be adversely affected.
2. In cooperation with the Intermountain Research Station, develop a research plan and monitoring plan for each research natural area.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed as follows:

Ecological Processes

Fire/Fuels

Use Minimum Impact Suppression Tactics (MIST) as appropriate (G)

Prescribed fire, utilizing both management-ignited and natural ignitions, may be used to maintain fire dependent ecological processes and to provide for a natural range of fuels, understory vegetation, and successional stages. (G)

Physical Elements

Soil & Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans. (G)

Promote natural healing where natural vegetation would return in a reasonable time (G)

Use indigenous species to reestablish vegetation where there is no reasonable expectation of natural healing. (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of resources. (S)

Lands

Establish exterior boundaries of research natural areas when necessary for management/protection purposes. (G)

Minerals/Geology

Same as 1.2 Wilderness Study Area.

Biological Elements

Fish and Other Aquatic Resources

Fish habitat will exist/evolve with natural ecological processes No fish habitat improvements allowed. (S)

Wildlife

Wildlife habitat will exist/evolve with natural ecological processes. No wildlife habitat improvements allowed (S)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes 2/	Yes
	Horse/Pack Stock	Yes 2/	Yes
	Mtn Bike/Mechanized	No	Yes
	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 3/	N/A	3/
	Winter Nonmotorized	Yes 2/	Yes
	Snowmachine	Yes 2/	Yes
<p>1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.</p> <p>2/ There may be site-specific exclusions</p> <p>3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. The acres in this prescription area and the OROMTRD will be included in the calculations with the acres and OROMTRD in adjacent prescription areas. (See Roads in Glossary for more information)</p>			

Roads

No new road construction. (S)

Recreation

Dispersed - These activities will be managed, and if necessary restricted, to maintain natural ecological processes. (G)

- No bear baiting. (S)

Trails - No new trails. (S)

ROS - Primitive to semi-primitive motorized. (G)

VQO - Preservation. (S)

Outfitter/Guide

No outfitter/guide campsites allowed. (S)

Production of Natural Resources

Timber

These areas are removed from the suitable timber base. They are not part of the ASQ. (S)

No timber harvesting of any kind will be allowed in research natural areas. (S)

Range

Existing livestock grazing permits and fencing are permissible as long as they do not adversely affect the ecological processes of the research natural area. No salting, water developments, vegetation manipulation, or other range improvements are allowed. (S)

2.3 ELIGIBLE WILD RIVER

Description

The purpose of this prescription is to maintain and protect the free-flowing character and the "outstandingly remarkable" values which qualify the river to be considered eligible as a Wild River in the National Wild and Scenic Rivers System pending a suitability determination. This prescription shall also be applied to a river determined to be suitable as a Wild River and to a river designated as a Wild River until such time as a Wild River Management Plan can be adopted.

Wild Rivers are intended to remain as a "vestige of primitive America" with the river corridor, within at least 1/4 mile of the ordinary high water mark on each side of the river, essentially natural and unmodified. Management maintains or improves this undeveloped character, and prevents the degradation or loss of the fish and wildlife, scenic, recreational, cultural, historic, ecologic, or other values which are determined to be outstandingly remarkable. This management prescription provides recreation opportunities that afford a high degree of independence, closeness to nature and self-reliance in an unmodified natural setting.

Interaction between users is infrequent and evidence of resource management activities and other users is minimal. Motorized use within the area is generally not compatible with this designation. Access is usually cross-country or on constructed trails.

The forest presents a natural appearance. A variety of forest successional stages may be present, ranging from areas with recent wildfires to old growth habitat. Firewood is available for camping, but is not available for home use. Outfitter and guiding activity may be present. Domestic livestock grazing may be present in some areas, and you may see limited range improvements such as fencing. A variety of nonforested rangeland successional stages may be present.

Goal

Maintain and protect the free flowing character and the outstandingly remarkable values of the river and corridor which qualify it as a wild river.

Objective

Insects and disease are allowed to play, as nearly as possible, their ecological role in the environment.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Elements

Fire/Fuels

Employ Minimum Impact Suppression Tactics to the maximum extent possible. (G)

Insects & Disease

Insect and plant disease epidemics may be controlled to prevent unacceptable damage to resources on adjacent lands or an unnatural loss to the wild river resource due to exotic pests. (G)

When control is necessary, it shall be carried out by measures that have the least adverse impact on the wild river resource and are compatible with wild river management objectives. (S)

Physical Elements

Soil & Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or loss of wild river resource values. (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within this prescription area are not imminent; or where natural vegetation would return in a reasonable time. (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing. (S)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of wild river resource values, or to protect life, property, and other resource values outside the area. (S)

Lands

Retain National Forest lands. Acquire private inholdings as opportunities arise. (G)

Minerals/Geology

Locatable - These areas are recommended for withdrawal from mineral activity, or, should be removed from mineral entry through the Notation Rule, subject to valid existing rights. For valid existing claims, design mineral exploration, and development activities to be compatible with this prescription. Apply the following management practices to reduce resource impacts: (G)

1. Design mineral management activities to maintain the present and continued productivity of fish habitat.
2. Take maximum advantage of topographic and vegetation screening when locating mining facilities and equipment.
3. Haul away, bury, burn, or scatter vegetation removed from the project area when vegetation is located adjacent to sensitive travel routes.
4. Minimize the scale of spoil/disposal areas in relation to the surrounding landscape as seen from sensitive viewpoints.
5. Use colors that simulate those found in the characteristic landscape. Avoid use of reflective materials in project facilities.
6. Apply timing restrictions to instream construction as needed to protect fisheries habitat and mitigate adverse disturbance of stream sediments.
7. Use sedimentation traps as needed to mitigate adverse stream sedimentation and meet State and Federal water quality regulations.
8. Design reclamation plans so minerals activities leave a natural appearing condition.
9. Shape landform modifications to simulate naturally occurring forms.

10. Revegetate disturbed areas in accordance with project plans.

Mineral Material - These areas are not available for mineral material entry.

Heritage Resource

Remove structures that do not qualify for the National Register, or allow them to deteriorate naturally unless they are' (G)

1. Deemed necessary to support public purposes of wild rivers, or
2. Serve administration purposes.

Interpretation of heritage resources located in wild river corridors shall be done outside the corridor. (S)

Biological Elements

Fish and Other Aquatic Resources

Fish habitat will exist/evolve with natural ecological processes. Fish habitat manipulation can only occur if: (S)

1. The condition needing change is a result of abnormal human influence.
2. The project can be accomplished with assurance that there will be no serious or lasting damage to wild river values.
3. There is reasonable assurance that the project will accomplish the desired objectives.

Fish stocking of nonexotic species is allowed where it existed prior to establishment of the Wild River. (S)

Stocking will normally be accomplished by nonmotorized means, like horse or mule. (G)

Wildlife

Reintroduce wildlife species only if the species was once indigenous to the area and was eliminated by human-induced events. (S)

Wildlife habitat will exist/evolve with natural ecological processes. Wildlife habitat manipulation can only occur if: (S)

1. The condition needing change is a result of abnormal human influence.
2. The project can be accomplished with assurance that there will be no serious or lasting damage to wild river values
3. There is reasonable assurance that the project will accomplish the desired objectives.

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	No	Yes
	Motorized, <50" wide	No	No 2/
	Motorized, >50" wide	No	No 2/
	OROMTRD 3/	N/A	0.0 mi/sq.mi.
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes 4/	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ This use may be allowed where currently existing and it does not degrade the outstandingly remarkable river values.

3/ OROMTRD = Open road and open motorized trail route density. includes all open roads and open motorized trails. (See Roads in Glossary for more information)

4/ Within grizzly bear BMU's, cross-country snowmachine travel is only allowed from December 15 to April 1.

Recreation

Dispersed - Recreation facilities will be of a very primitive nature, using a pack-it-in, pack-it-out philosophy. (G)

ROS - Primitive to semi-primitive nonmotorized. (G)

VQO - Retention. (S)

Outfitter/Guide

Permanent caches or nonnative improvements are not allowed unless they existed prior to the establishment of the wild river and have not been phased out. Upon designation of a Wild River, any existing caches will be phased out within two years. (S)

Production of Natural Resources

Timber

Lands are removed from the suitable timber base. No ASQ is calculated from these lands. (S)

Cutting of trees will not be allowed except when needed in association with a primitive recreation experience (such as clearing for trails and protection of users) or to protect the environment (such as control of fire). (S)

Range

Minimize conflicts with recreation use. (G)

Range developments (water tanks, fences, etc) that do not detract from the overall objectives of the area are acceptable. (G)

Manage allotments at FRES levels A , B, C, or D. (G)

2.4 ELIGIBLE SCENIC RIVER

Description

The purpose of this prescription is to maintain and protect the free-flowing character and the "outstandingly remarkable" values which qualify the river to be considered eligible as a Scenic River in the National Wild and Scenic Rivers System pending a suitability determination. This prescription shall also be applied to a river determined to be suitable as a Scenic River and to a river designated as a Scenic River until such time as a Scenic River Management Plan can be adopted.

Proposed Scenic Rivers are managed to protect and enhance the outstandingly remarkable fish and wildlife, scenic, recreational, historic, cultural or other values identified for the river, within, as a minimum, 1/4 mile of the ordinary high water mark on each side of the river. Moderate levels of existing development, including roads which cross the river but are generally screened from the river banks, are allowed. New development and uses must not degrade the values which qualify the river for consideration as eligible. Recreation facilities of a rustic design, including boat access, cabins, access roads leading to the river and trails are appropriate. The area is managed to provide a waterway and associated shorelines where activities are not visually evident to the casual observer. The Scenic River management prescription may provide recreation opportunities which meet high expectations for scenic quality associated with an essentially natural appearing environment and a free flowing river.

Administrative and recreation facilities are screened from the river. Nonrecreation special use structures may occur if they meet visual quality objectives and do not degrade the outstandingly remarkable values. Recreation facilities are designed to be compatible with the visual quality objectives of the river and corridor. Recreation opportunities range from roaded natural to primitive. Outfitter and guiding activity may be present.

No development of hydroelectric power facilities is permitted. New structures that would have a direct adverse effect on river values are not authorized.

Lands are open to mineral entry subject to regulations prescribed by the Secretary of Agriculture to protect the free-flowing character and outstandingly remarkable values of the river. Existing and new activity must minimize surface disturbance, sedimentation, air pollution, visual impairment, and meet applicable State Water Quality Standards. Reasonable access is permitted.

Fish and wildlife habitat improvement may occur and is designed to be visually compatible with the scenic qualities of the river and corridor.

Roads are generally screened from the river and infrequent road and trail crossings (bridges) may be present. Trails paralleling the river are acceptable.

Domestic livestock grazing may be present in some areas. Range improvements may occur and are designed to be visually compatible with the scenic qualities of the river and corridor.

Forested lands are classified as unsuitable; no scheduled timber harvesting is allowed. Personal use wood cutting is compatible with this land use designation provided that management objectives are met

Goal

Maintain and protect the free flowing character and the outstandingly remarkable values of the river and corridor which qualify it as a Scenic River.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

Employ Minimum Impact Suppression Tactics to the maximum extent possible. (G)

Insects & Disease

Allow sanitation and salvage of infested timber as long as such practices are carried out in such a way that there is no substantial adverse effect on the river and its immediate environment. (G)

Physical Elements

Soil & Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or loss of Scenic River resource values. (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within this prescription area are not imminent, or where natural vegetation would return in a reasonable time. (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing. (S)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of Scenic River resource values, or to protect life, property, and other resource values outside the area. (S)

Lands

Retain National Forest lands. Acquire private inholdings as opportunities arise. (S)

Minerals/Geology

Same as 2.3 Eligible Wild River

Biological Elements

Wildlife

Other - Reintroduce wildlife species only if the species was once indigenous to the area and was eliminated by human-induced events. (S)

Wildlife habitat will exist/evolve with natural ecological processes. Wildlife habitat manipulation can only occur if generally (S)

1. The condition needing change is a result of abnormal human influence
2. The project can be accomplished with assurance that there will be no serious or lasting damage to Scenic River values.
3. There is reasonable assurance that the project will accomplish the desired objectives.

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
	Motorized, <50" wide Motorized, >50" wide OROMTRD 3/	No No N/A	Yes 2/ Yes 2/ 3/
	Winter Nonmotorized Snowmachine	Yes Yes 4/	Yes Yes
<p>1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.</p> <p>2/ Motorized use is allowed unless it needs to be prohibited or restricted to protect the river values</p> <p>3/ OROMTRD = Open road and open motorized trail route density does not apply to this prescription area.</p> <p>4/ Within grizzly bear BMU's, cross-country snowmachine travel is only allowed from December 15 to April 1.</p>			

Roads

No new roads may be constructed or road improvements made that would change or modify the classification for which the river was designated. (S)

Recreation

Dispersed - Comfort and convenience facilities, such as fireboxes and shelters may be provided as necessary within the river area. These should harmonize with the surroundings and be managed so they do not adversely affect spawning grounds. (G)

Maintain existing dispersed campsites that do not degrade the outstandingly remarkable values. (G)

Trails - Trails and bridges paralleling or crossing the river are acceptable, provided VQO and ROS objectives for the river and corridor are maintained. (G)

No new trails may be constructed or trail improvements made that would change or modify the classification for which the river was designated (S)

ROS - Primitive to semi-primitive motorized. (G)

VQO - Retention. (S)

Outfitter/Guide

Permanent caches or improvements are allowed if they meet the visual quality management objectives for the river and corridor and are within the Greater Yellowstone Area Outfitter Plan. (G)

Production of Natural Resources

Timber

Lands are not included in the suitable timber base. They do not contribute toward the ASQ. (S)

Personal use wood cutting is allowed with restrictions to protect the outstanding remarkable values. (G)

Range

Range management is permitted to the extent it is currently practiced and does not degrade river values. (G)

Range developments (water tanks, fences, etc.) that do not detract from the overall objectives of the area are acceptable. (G)

Manage allotments at FRES levels B, C, or D. (G)

2.5 ELIGIBLE RECREATION RIVER

Description

The purpose of this prescription is to maintain and protect the essentially free-flowing character and the outstandingly remarkable values which qualify the river to be considered eligible as a Recreational River in the National Wild and Scenic Rivers System pending a suitability determination. This prescription shall also be applied to a river determined to be suitable as a Recreation River and to a river designated as a Recreation River until such time as a Recreation River Management Plan can be adopted.

Proposed Recreational Rivers are managed to protect the outstandingly remarkable fish and wildlife, scenic, recreational, historic, cultural or other values identified for the river, within, as a minimum, 1/4 mile of the ordinary high water mark on each side of the river. The area may include significant human development, residences, roads and highways, and minor existing modifications to the waterway, including diversion dams. Major water resource projects are not authorized. The area may include landscapes in a variety of visual conditions. Activities and structures may be dominant in some areas, but harmonize and blend with the generally natural-appearing environment to provide a pleasing setting for recreation activities. This management area prescription may provide recreation opportunities where the interaction between users may be moderate-to-high with evidence of current and past use prevalent. Roads are designed for conventional motorized vehicles. Facilities may exist for boat or aircraft use.

Allowed motorized use within the area may include boats, aircraft, snowmachines, construction and maintenance of needed facilities. Motorized land travel for recreation purposes may be restricted. All scheduled resource management activities are integrated in such a way that the recreation and water quality values remain paramount.

Administrative and recreation facilities are located and designed to complement and facilitate area management. Recreation opportunities range from semi-primitive nonmotorized to rural Outfitter and guiding activity may be present.

To the extent of Forest Service authority, no development of hydroelectric power facilities is permitted. New structures that would have a direct adverse effect on river values are not authorized.

Lands are open to mineral entry subject to regulations prescribed by the Secretary of Agriculture. Existing and new activity must minimize surface disturbance, sedimentation, air pollution, visual impairment, and meet applicable State Water Quality Standards. Reasonable access is permitted.

Forested lands are classified as unsuitable; no scheduled timber harvesting is allowed. Personal use woodcutting is compatible with this land use designation provided that management objectives are met.

Design and location of roads and facilities provide for conventional motorized use. User safety and opportunities for nonmotorized recreation activities may be provided by restricting motorized use to designated routes and areas. Both motorized and nonmotorized trail opportunities may be provided.

Fish projects may be identified and implemented which create or improve fishing opportunity. Wildlife habitat emphasis is on maintaining healthy and productive habitat conditions for indigenous species and improving wildlife viewing opportunities.

Domestic livestock grazing may be present in some areas. Range improvements may occur and are designed to be compatible with the recreational qualities of the river and corridor.

Goal

Maintain and protect the outstandingly remarkable values of the river and corridor which qualify it as a Recreational River.

Objectives

1. Maintain or improve forest health through silvicultural activities to protect the values of Recreational Rivers.
2. Fish habitat improvement projects will emphasize recreational fishing opportunities

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

All activity fuels will be treated to meet the partial retention VQO in foreground within one season following timber harvest. (G)

Insects & Disease

Encourage hazard tree management in high use areas. (G)

Physical Elements

Soil & Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or loss of Recreational River resource values. (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within this prescription area are not imminent; or where natural vegetation would return in a reasonable time. (G)

Consider the use of indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing. (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of Recreational River resource values, or to protect life, property, and other resource values outside the area. (S)

Lands

Retain National Forest lands. Acquire private inholdings as opportunities arise. (G)

Minerals/Geology

Same as in 2.3 Eligible Wild River.

Biological Elements

Fish and Other Aquatic Resources

Fish stocking of nonexotic species is allowed where it existed prior to establishment of the Recreational River. (S)

Forest Use and Occupation

Access(S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
	Motorized, <50" wide Motorized, >50" wide OROMTRD 3/	No No N/A	Yes 2/ Yes 2/ 3/
	Winter Nonmotorized Snowmachine	Yes Yes 4/	Yes Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Motorized use is allowed unless it needs to be prohibited or restricted to protect the river values.

3/ OROMTRD = Open road and open motorized trail route density does not apply to this prescription area.

4/ Within grizzly bear BMU's, cross-country snowmachine travel is only allowed from December 15 to April 1.

Recreation

Dispersed - All forms of recreation facilities may be provided, such as boat access points, trails, toilets, fire rings, grills, garbage collection, etc. Facilities are designed to be compatible with the ROS and VQO of the river and corridor and should be managed so they do not adversely affect spawning grounds. (G)

Trails - Trails and bridges paralleling or crossing the river are acceptable, provided VQO and ROS objectives for the river and corridor are maintained. (G)

- Both motorized and nonmotorized trail opportunities may exist. (G)

- New trails could be constructed on one or both river banks. There can be several bridge crossings and numerous river access points. (G)

ROS - Semi-primitive nonmotorized to urban. (G)

VQO - Partial retention VQO in the foreground as seen from the river, roads, trails and recreational facilities. (S)

- Modification to maximum modification for all other areas within the corridor (G)

Outfitter/Guide

Permanent caches or improvements are allowed if they meet the visual quality management objectives for the river and corridor and are within the Greater Yellowstone Area Outfitter Plan. (G)

Production of Natural Resources

Timber

Lands are not included in the suitable timber base. They do not contribute toward the ASQ (S)

Personal use wood cutting is allowed with restrictions to protect the outstandingly remarkable values. (G)

Range

Range developments (water tanks, fences, etc.) that do not detract from the overall objectives of the area are acceptable (G)

Manage allotments at FRES levels B, C, or D. (G)

2.6.1 (a-b) GRIZZLY BEAR HABITAT (NO ASQ, NO CROSS-COUNTRY, NO SHEEP)

Same as 5.3 5 except:

Production of Natural Resources

Timber

Lands are not included in the suitable timber base. They do not contribute toward the ASQ. (S)

Range

No domestic sheep grazing. (S)

2.6.2 GRIZZLY BEAR - PLATEAU BMU DIRECTION - CORE AREA

Description

The core area is defined as an area that provides a predictable refuge in space and time for a bear population segment or family unit. This area is consistently available and provides for use by wary bears while activities occur elsewhere. The core area contains moderate to high quality bear foods, provides predictable and consistently available space to meet seasonal bear habitat needs, and achieves the lowest mortality risk possible due to human activities for a period not less than 11 years. Management activities shall follow established rules, and in general, do not occur during the period of time that grizzly bears are active (outside dens). The primary emphasis for this area is on providing secure habitat for grizzly bears.

This is a refugium of high quality habitat available to bears where management activities do not occur during the period bears are active. Habitat conditions provide space that is consistently available and predictably locatable to bears. This area provides a portion of the foraging requirement for a reproductive female and a female offspring for spring, summer, and fall foraging away from human activities. Secure habitat exists, and mortality risk to bears is low.

Objectives

1. A fire management plan will be developed (and will be coordinated with any adjacent wilderness fire plans) to address wildfires.
2. Insects and diseases are allowed to play their natural role in ecosystem development.
3. Any nonfederal lands within this area will be a high priority for acquisition.
4. Manage dispersed recreation to minimize grizzly conflicts with humans.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

The Interagency Grizzly Bear Guidelines for Management Situation 1 Habitat apply to this management prescription.

Ecological Processes

Fire/Fuels

No prescribed fire is allowed. (S)

In the event of a fire that warrants suppression, only minimum impact suppression techniques will be allowed. (S)

Physical Elements

Lands

Activities which adversely affect grizzly bear populations and/or their habitat will not be allowed. (S)

No special use permits or operating plans are allowed. (S)

Minerals/Geology

Same as 2 3 Eligible Wild River.

Heritage Resource

No new interpretation/enhancement of cultural sites. (S)

Biological Elements

Wildlife

No wildlife habitat improvement projects are allowed (S).

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/

(See Roads in Glossary for more information)</p> <p>3/ Cross-country snowmachine use is only allowed from Dec. 15 to April 1.</p>			

Roads

All roads will be reclaimed, as soon as possible. (S)

Recreation

Special Uses - No special uses are allowed from April 1 to December 15. (S)

Trails - No new trails. (S)

ROS - Primitive to semi-primitive nonmotorized (G)

VQO - Retention. (S)

Outfitter/Guide

No outfitter and guide permits are allowed from April 1 to December 15 (S)

Production of Natural Resources

Timber

Lands are not included in the suitable timber base. They do not contribute toward the ASQ. (S)

No vegetation management of any kind will occur. (S)

Range

No livestock grazing permits of any kind are allowed. (S)

2.6.5 GRIZZLY BEAR - SECURITY AREA

Description

This area is consistently available and provides for use by wary bears while activities occur elsewhere. This area contains moderate to high quality bear foods, provides predictable and consistently available space to meet seasonal bear habitat needs, and achieves the lowest mortality risk possible due to human activities for a period not less than the planning period. Management activities shall follow established rules, and in general, do not occur during the period of time that grizzly bears are active (outside dens). Emphasis for this area is on providing secure habitat for grizzly bears.

This is an area of high quality habitat available to bears where management activities are limited during the period bears are active. Habitat conditions provide space that is consistently available and predictably locatable to bears. This area provides a portion of the foraging requirement for a reproductive female and a female offspring for spring, summer, and fall foraging.

Objectives

1. A fire management plan will be developed (and will be coordinated with any adjacent wilderness fire plans) to address wildfires.
2. Insects and diseases are allowed to play their natural role in ecosystem development.
3. Any nonfederal lands within this area will be a high priority for acquisition.
4. Activities which adversely affect grizzly bear populations and/or their habitat will not be allowed.
5. No new special use permits.
6. Wildlife habitat improvement projects will maintain or improve grizzly bear habitat.
7. Manage dispersed recreation to minimize grizzly conflicts with humans.
8. Domestic sheep grazing will be phased out over time on an opportunity basis.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

The Interagency Grizzly Bear Guidelines for Management Situation 1 Habitat apply to this management prescription.

Ecological Processes

Fire/Fuels

Prescribed fire is not usually allowed. (G)

Physical Elements

Minerals/Geology

Same as 2 3 Eligible Wild River

Heritage Resource

No new interpretation/enhancement of cultural sites. (S)

Biological Elements

Wildlife

Activity Areas - Inventory, monitoring, and short duration activities such as trail maintenance, spraying weeds, range maintenance activities, wildlife habitat improvement, etc., should be concentrated in time and space. Activities should be concentrated in one consecutive 30-day period each year, between April 1 and September 15. (G)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No	No
	Motorized, >50" wide	No	No
	TMARD 2/	N/A	0.0 mi/sq.mi 2/
	OROMTRD 2/	N/A	0.0 mi/sq.mi 2/
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes 3/	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ TMARD = Total motorized access route density; includes all open and restricted roads and motorized trails. (See Roads in Glossary for more information)

OROMTRD = Open road and open motorized trail route density; includes all open roads and open motorized trails. (see Roads in Glossary for more information).

Two roads are designated open through this prescription area: the Ashton/Flagg Ranch Road (#261) and the Jackass Loop Road (#264).

3/ Cross-country snowmachine use is only allowed from Dec. 15 to April 1.

Roads

No new roads. (S)

All nondesignated roads will be reclaimed by year 2000. (S)

Recreation

Special Uses - No new special uses are allowed from April 1 to December 15. (S)

Trails - No new trails. (S)

ROS - Primitive to semi-primitive motorized. (G)

VQO - Retention. (S)

Outfitter/Guide

No new outfitter and guide permits are allowed from April 1 to December 15 (S)

Production of Natural Resources

Timber

Lands are not included in the suitable timber base. They do not contribute toward the ASQ. (S)

Range

Opportunities to phase out domestic sheep grazing are defined as a suitable or favorable time to abolish or close an allotment because of nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit. If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas. (G)

Cattle grazing is allowed. Allotment Management Plan will specify measures to meet agency grizzly goals and objectives. (S)

Permittee's full compliance in meeting grizzly bear management goals and objectives for grizzly bear habitat will be a condition of the permit. In addition, the following will be required: (S)

1. Temporary cessation or modification of permitted livestock grazing activities will occur to resolve grizzly bear conflicts with humans or livestock.
2. Livestock carcasses will be disposed of or rendered unattractive to bear within 24 hours after they are discovered. Disposal may include removing the carcass from the area, burying it at least 2 feet underground, burning, using an acceptable chemical repellent, or other methods approved by the District Ranger. Disposal shall be in accordance with other governing agencies (e.g., Wyoming Department of Fish and Game) in order to determine cause of death for reimbursement purposes.
3. Human food, refuse, and prepared livestock/pet foods associated with the livestock operation will be made unavailable to grizzlies through proper storage, handling, and disposal. Proper storage includes a) inside a bear-proof container, b) suspended horizontally from adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger. The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported. Unburned human foods, garbage or other refuse will be carried off the Forest as often as practical.
4. High quality food production areas for grizzlies (i.e. wet alpine and subalpine meadows, stream bottoms, aspen groves, and other riparian areas) will receive special grazing direction such as light, once-over grazing, special utilization standards, or complete closure. These sites and their corresponding direction will be identified in the Annual Operating Plan.

5. Livestock depredation believed to be associated with bears will be reported within 24 hours after they are discovered to the District Ranger and the proper State agencies.

6. Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical.

7. Any action taken by the permittee or their agents which violates the Endangered Species Act will be grounds for cancellation of their grazing permit.

2.7 (a-b) ELK & DEER WINTER RANGE

Description

This management prescription emphasizes management actions and resource conditions which provide quality elk and deer winter habitat. Habitats are managed for multiple land use benefits, to the extent these land uses are compatible with maintaining or improving elk and deer winter habitat.

These areas are "crucial mid-to-late" natural winter ranges for deer and elk. These are the winter range areas which are considered to be the determining factor in a population's ability to maintain itself at a certain level over the long term. Moose and antelope may also be present.

Vegetation management occurs to maintain or improve winter habitat conditions. Winter range forage is abundant, includes a good mixture of grasses, forbs, and shrubs, and is well distributed throughout the area. Cover is maintained and distributed within the range of natural variability which historically occurred in the area.

Access is managed or restricted to provide security for wintering elk and deer. Area closures are emphasized where terrain and vegetation allow OHV use, with motorized use occurring only on designated routes.

Livestock grazing, timber management, recreation, and other resource management activities can occur as long as good winter range conditions are being maintained.

Goal

Provide quality elk and deer winter range.

Objectives

1. Minimize forage use conflicts between big game and livestock on the winter range.
2. Forested vegetation is managed to maintain or improve cover or forage conditions needed for wintering deer and elk.
3. Nonforested vegetation is managed to maintain or improve forage production needed for wintering deer and elk.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed as follows.

Ecological Processes

Fire/Fuels

Prescribed fire is allowed to maintain or improve winter habitat and enhance ecological conditions (G)

Physical Elements

Heritage Resource

No new interpretation/enhancement of cultural sites. (S)

Forest Use and Occupation

Access (S)

2.7 (a)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	No 2/	Yes
	Horse/Pack Stock	No 2/	Yes
	Mtn Bike/Mechanized	No 2/	Yes
	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 3/	N/A	<= 2.0 mi/sq.mi.
	Winter Nonmotorized	No	Yes 4/
	Snowmachine	No	Yes 4/

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ These uses are generally allowed from April 1 through Dec. 15, except where noted on annual Forest Travel Plan Maps.

3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails (See Roads in Glossary for more information)

In 2 7 (a) prescription areas <= 4.0 sq.mi. in size, OROMTRD does not apply.

In the Table Rock area (Palisades Ranger District), OROMTRD does not apply.

4/ Snowmachines, cross-country skiing, dogsleds, etc., will be restricted to 50 feet on either side of a designated road or trail.

2.7 (b) - The (b) access standards are the same as (a) above, except that cross country travel is allowed without seasonal restrictions for pedestrians, horse/pack stock, mountain bikes/mechanized Only snowmachine use is restricted to 50 feet on either side of a designated road or trail

Game Retrieval - Use of All Terrain Vehicles (ATV's) is permitted cross-country and on restricted roads and trails during the big game hunting seasons for retrieval of legally harvested big game animals (G)

The following guidelines should be followed. (G)

1 An ATV is defined as three or four wheeled vehicles (< 50" wide) that have low tire pressure (less than 10 psi) and large tire surface on the ground This does not include motorcycles, dirt bikes or conventional 4-wheel drive vehicles.

2 A permit to retrieve the legally harvested big game animal (s) must be obtained from a Ranger District Office.

3. Use of the ATV to retrieve the animal (s) must occur between noon and dark.

4. No firearms are allowed on ATV's while retrieving legally harvested big game animals

Recreation

Dispersed - Manage recreation sites to maintain winter habitat conditions. Minimal recreation facilities may be provided (such as hitch rack, rudimentary toilets, etc.). Generally, recreation facilities are not encouraged. (G)

ROS - Semi-primitive nonmotorized to roaded natural. (G)

VQO - Retention to modification (G)

Production of Natural Resources

Timber

These areas are not part of the suitable timber base. They are not part of the ASQ. (S)

2.8.3 AQUATIC INFLUENCE ZONE

Description

This prescription applies to the aquatic influence zone associated with lakes, reservoirs, ponds, perennial, and intermittent streams, and wetlands (e.g., wet meadows, springs, seeps, and bogs). These areas control the hydrologic, geomorphic, and ecological processes that shape the various water types mentioned above and directly affect aquatic life. They also provide unique habitat characteristics which are important to those plant and animal species which rely on aquatic, wetland, or riparian ecosystems for all or a portion of their life cycle. Many such habitats are locally rare or are sensitive to disturbance (e.g. fens and thermal springs). Overall, these areas serve as important reservoirs of biodiversity; critical linkages for the interchange of plant and animal genetic material, and specialized areas of nutrient cycling and freshwater filtration, storage, and transport.

Management emphasis is directed at the application of ecological knowledge to restore and maintain the health of these areas in ways that also produce desired resource values, products, protection, restoration, enhancement, interpretation, and appreciation of these areas.

These aquatic influence zones provide a high level of aquatic protection and maintain ecological functions (e.g., sediment transport, micro-climate control, nutrient regulation, and connectivity within the watershed) and processes (e.g., stream channel formation, plant community development, recruitment of organic material including large wood, and hydrologic cycles) necessary for the restoration and maintenance of habitat for aquatic and riparian dependent organisms. They also maintain future management options.

This Management Prescription is defined on the ground using boundary widths which may vary by water type, and geographic characteristics. The actual boundaries of the aquatic influence zone, as determined by a person having current knowledge of fluvial geomorphology of stream-riparian ecology, or both, could be narrower or wider than the prescribed boundary widths.

The five basic water types found on the Forest are:

- 1 Fish-bearing Stream Reaches,
2. Perennial Non-fish-bearing Stream Reaches,
3. Lakes,
4. Reservoirs, Ponds and Wetlands Greater than One Acre,
5. Intermittent Streams, and Wetlands Less Than One Acre

Goals

- 1 *Riparian, wetland and aquatic ecosystems are managed to promote their health and function within the range of variation, where feasible.*
2. Minimize adverse effects to aquatic and riparian dependent species from past, existing and proposed management activities.
3. Endemic levels of insects and disease are allowed to play their natural role in ecological succession, compatible with other resource objectives.

Objectives

1. Within three years of the Record of Decision, all existing roads, trails, culverts, fords and stream crossings within these lands will be inventoried and evaluated as to whether they meet management prescription goals. Those that do not meet management prescription goals will be scheduled for restoration.
2. Establish the range of variability for aquatic influence zone characteristics.
3. Manage wood residue (natural and human-made), including fuelwood, to maintain or restore ecological health and function.
- 4 Coordinate with Idaho Fish and Game, Wyoming Game and Fish, and other interested individuals or groups, to identify and evaluate potential beaver re-introduction sites. Support re-introductions into areas that would benefit from beaver activity and where conflicts with other uses have been resolved.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Boundary widths for the five water types apply until a site-specific analysis is completed. The slope distances specified for boundary widths in the five water types will vary by ecological subsection. Following are the slope distances of boundary widths, in feet, by ecological subsection. (G)

BOUNDARY WIDTHS OF WATER TYPES, BY SUBSECTIONS

Water Type	Subsections*		
	3;4	2	1;5;6;7
Fish-bearing Stream Reaches 1/	150	200	300
Perennial Nonfish-bearing Stream Reaches 1/	75	75	150
Lakes 2/	150	200	300
Reservoirs, Ponds, Wetlands Greater than One Acre 3/	75	75	150
Intermittent Streams, Wetlands Less Than One Acre 4/	75	75	100
<p>*Subsections 1 - Lemhi/Medicine Lodge 2 - Centennial Mountains 3 - Island Park 4 - Madison Plateau 5 - Teton Range 6 - Big Hole/Palisades Mountains 7 - Caribou</p>			
<p>1/ The boundary width is the slope distance on both sides of the stream, in feet, measured from the edge of the stream, or the area from the edge of the active stream channel to the outer edges of the riparian vegetation, whichever is greater.</p> <p>2/ The boundary width is the slope distance specified, in feet, measured from the high water mark of the lake; or the area from the high mark of the lake to the outer edge of the riparian vegetation or seasonally saturated soil, whichever is greater.</p> <p>3/ The boundary width is the slope distance specified, in feet, measure from the edge of the body of water (edge is defined as the maximum pool elevation of the water body); or the wetland area to the outer edges of the riparian vegetation, whichever is greater.</p> <p>4/ The boundary width is the slope distance on both sides of the intermittent stream, in feet, measured from the edge of the stream; or the wetland area to the outer edges of the riparian vegetation, whichever is greater.</p>			

Ecological Processes

Fire and Fuels

Avoid locating bases, camps, helibases, staging areas, helispots, hazardous material storage facilities, and other centers for incident activities within these lands. If the only suitable location for such activities is within this area, an exception may be granted following a review and recommendation by a resource advisor. The resource advisor will prescribe the location, use conditions, and rehabilitation requirements. (G)

Avoid application of chemical retardant, foam, or additives in these areas. Exceptions may be warranted in situations where over-riding safety situation exist, or following a review and recommendation by a resource advisor, when an escape would cause more long-term damage. (G)

Prescribed fire activities on adjacent lands must be compatible with management prescription goals (S)

Use minimum impact suppression methods (G)

Insects and Disease

Where catastrophic insect and disease damage results in degraded riparian conditions, unscheduled timber harvest (salvage and commercial fuelwood cutting) is allowed where needed to attain the Goals of this Management Prescription providing other Goals of this Management Prescription are not adversely affected (G)

Physical Elements

Minerals/Geology

Adequate reclamation plans and bonds are required in mining plans of operation. These bonds must cover the full costs of removing facilities, equipment, and materials; recontouring disturbed areas to near pre-mining topography; isolating and neutralizing or removing toxic or potentially toxic materials; salvaging and replacing topsoil; and preparing seedbeds and revegetating to meet Management Prescription Goals. (S)

Do not locate permanent structures or facilities within these lands (S)

Do not locate waste dumps, leaching pads, and other facilities within these lands where other alternatives are available. If no other alternative exists, ensure that safeguards are in place to prevent release or drainage of toxic or other hazardous materials onto these lands. (S)

Discourage mineral material extraction (subject to valid permitted rights, or where permitted by plans of operation). (G)

Plans of operation will be consistent to the extent possible with management prescription goals. (G)

Biological Elements

Wildlife

Strive to maintain dead and defective tree habitat at a level capable of supporting 100% potential populations of the management indicator species for primary cavity excavators. (G)

	Motorized, >50" wide	No 4/	Yes
	OROMTRD 3/	N/A	3/
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes 5/	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ When cross country travel is found to result in soil displacement in excess of 15 percent of an activity area, or alternation of natural stream channel morphology, reduce impacts through education, use limits, more intensive maintenance, facility modification, and/or closures

3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. The acres in this prescription area and the OROMTRD will be included in the calculations with the acres and OROMTRD in adjacent upland prescription areas. (See Roads in Glossary for more information)

4/ Motorized access to dispersed campsites and for picnicing is allowed

5/ Within grizzly bear BMU's, cross-country snowmachine travel is only allowed from December 15 to April 1.

Roads and Trails

No new roads, trails, or landings will be constructed within these lands until appropriate standards for construction, maintenance, and operations are in place. (G)

Improve; seasonally close; close and relocate and stabilize; or obliterate roads and trails that have been identified as posing a high risk of causing unnaturally high levels of sediment input into fish spawning areas. Action to be taken will be determined based upon travel management needs, terrain, the need for the road or trail, and resource priorities. (G)

Roads and trails or sections of them that have been identified as inhibiting riparian, wetland or aquatic ecosystem processes and/or functions (e.g., plant community development, sediment transport, and stream channel development) will be improved, relocated, or obliterated. The decision to improve, relocate, or obliterate will be based on the potential environmental impact, the ecological condition of the riparian, wetland and aquatic resources affected, and the need for the road or trail. (G)

Culverts and stream crossings found to pose a risk to riparian, wetland or aquatic conditions will be improved to accommodate at least a 50-year flood, including associated bedload and debris (G)

New stream crossings will be constructed and maintained to prevent diversion of streamflow out of the channel and down the road in case of failure. In locations found to have high potential for failure, the roadway will be hardened to further lessen the chance of roadway failure or severe erosion should the crossing over-top (G)

Constructed temporary stream crossings, such as log and culvert installations, may be allowed if temporary crossings will be constructed and used in such a way as to minimize sediment input and to provide for fish passage. They will be maintained during use and removed and rehabilitated as soon as they are no longer needed. (G)

Construct, reconstruct, and maintain all road crossings of streams which currently or historically bear fish to provide for fish passage. Exceptions are allowed where it is necessary to restrict fish movements in order to protect native or desirable nonnative fish populations. (G)

During construction and maintenance activities, sidecast loose material away from these lands or transport it to a suitable disposal site if on-site disposal is not practical. (G)

Recreation and Outfitter/Guide

When dispersed recreation is found to result in displacement in excess of 15 percent of an activity area, or alteration of natural stream channel morphology, address impacts through education, use limits, more intensive maintenance, facility modification, and /or closures. (G)

Recreational grazing must meet Range Standards for utilization of riparian vegetation. (S)

Permitted stock holding, watering, and handling facilities within riparian vegetation (does not include the entire boundary) are allowed only if appropriate mitigation measures are implemented to reduce negative impacts. (S)

ROS - Primitive to urban (G)

VQO - Retention to modification. (G)

Production of Natural Resources

Timber

These lands are not included in the suitable timber base. They are not part of the ASQ. (S)

Where needed to attain Management Prescription Goals, design silvicultural prescriptions and allow prescribed burning and stocking control, as well as the re-establishment and culturing of stands to attain desired vegetation characteristics. (G)

Fell hazard trees that pose an unacceptable safety risk and leave on site unless adequate levels of woody debris already occur on site. (G)

Mechanized treatment of wood residue is minimized. (G)

Burning of mechanized treated wood residues within the bankfull channel is prohibited. (S)

Where catastrophic events such as fire or windstorms result in degraded riparian conditions, unscheduled timber harvest (salvage and commercial fuelwood cutting) may be selected as the most desirable management practice (G)

Range

Incorporate into AMP's, objectives for attainment of desired vegetation conditions for riparian plant community seral stage development and stream channel condition. (G)

Proposed livestock watering facilities, corrals, and holding pastures within these lands are allowed only if appropriate mitigation measures are implemented to reduce negative impacts. (S)

Existing livestock watering facilities, corrals, and holding pastures within these lands are allowed at permit issuance only if mitigation measures are implemented to reduce negative impacts. (G)

2.9.1 SOUTH FORK ELIGIBLE SCENIC RIVER

Description

This prescription applies to the portion of the South Fork of the Snake River that has been determined to be an eligible scenic river, consisting of the water surface, islands, sand bars, riparian vegetation, and adjacent uplands.

Within this corridor are campgrounds, picnic sites, boating sites/ramps, and other facilities such as trailheads, scenic and wildlife viewing areas, fishing access points and inventoried National Forest Recreation sites selected for potential development. Development ranges from native material roads and campsites, with nonflush toilets, to a high degree of site modification with comfort and convenience facilities including paved roads, water systems, flush toilets, and boat launches.

Overall, you notice signs of people, generally oriented toward water use. Beginning at Palisades Dam in a boat and drifting downstream, you notice roads, buildings, picnic tables, camping spots and, occasionally, people fishing along the river bank. You hear sounds of vehicles and other human activity. You will see powerlines across the river from time to time. Other stretches of river have few roads or developments and provide a relatively quiet, peaceful, natural setting.

As you float you often see stands of cottonwood, most of them mature. In and around these cottonwood stands you may see bald eagles or peregrine falcon perched in trees, or great blue heron on the ground. During the winter you may see elk, moose, and deer on adjacent slopes.

During the summer, livestock may be seen grazing next to the river and on nearby slopes.

The management direction contained in the Snake River Activity/Operations Plan, as developed between the U. S. Forest Service and the Bureau of Land Management and signed in February 1991, applies to this area. This management direction will be adjusted (if necessary) to reflect direction from the required suitability study, which will not be done until after completion of the Forest Plan Revision

Goals

1. Maintain the river's scenic values, particularly in the South Fork Canyon from Conant Valley powerline to Riley Diversion.
2. Maintain or enhance critical nesting, foraging and wintering areas for bald eagles, maintain big game winter range and improve unsatisfactory big game habitat. Maintain heron rookeries and improve goose nesting opportunities.

Standards and Guidelines

Manage this area according to the standards and guidelines established in the Snake River Activity/ Operations Plan (U.S. Forest Service & Bureau of Land Management, February 1991), except for the access direction shown below. (S)

Physical Elements

Minerals/Geology

Same as 2.3 Eligible Wild River.

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	2/
	Winter Nonmotorized	Yes	Yes
	Snowmachine	No	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ OROMTRD = Open road and open motorized trail route density does not apply to this prescription area.

2.9.2 SOUTH FORK ELIGIBLE RECREATION RIVER

Description

This prescription applies to the portion of the South Fork of the Snake River that has been determined to be an eligible recreation river, consisting of the water surface, islands, sand bars, riparian vegetation, and adjacent uplands.

The rest of the description is the same as the scenic portion of the river (2.9.1).

Goal

Goals are the same as the scenic portion except:

Maintain the river's recreation values, from Palisades Dam to Conant Valley Powerline

Standards and Guidelines

Same as 2.9.1 S. Fork Eligible Scenic River

3.1.1 (a) NONMOTORIZED

Description

This management prescription identifies areas where semi-primitive nonmotorized recreation use, like hiking and horse-back riding, will occur during the summer months. The experience is similar to a primitive experience, but does allow some motorized use, like chainsaws for summer trail maintenance, snowmachines during the winter, and helicopters. Groomed snowmachine trails are not allowed

These areas are accessible by trails or cross-country; you find no usable roads. All-terrain vehicles and motorcycles cannot use the area. Encounters with other people diminish as you move away from nearby roads and trailheads. Generally, you experience a backcountry setting with a high likelihood of solitude. However, you may occasionally meet large groups.

You may find oversnow vehicles; helicopter use; stock tanks; or fences. Otherwise, the forest generally presents a natural appearance. A variety of forest successional stages may be present, ranging from areas with recent wildfires to old growth habitat. Firewood is available for camping, but is not generally available for home use. Outfitter and guiding activity may be present. Domestic livestock grazing may be present in some areas, and you may see range improvements such as fencing and stock tanks. *A variety of nonforested rangeland successional stages may be present.*

Goal

Maintain or enhance semi-primitive nonmotorized dispersed recreation opportunities.

Objectives

- 1 Prescribed natural fire and management ignited fire will be managed to maintain fire's ecological role and to enhance habitat.
2. Allow insects and disease to play their natural role in ecological succession, compatible with other resource objectives.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

The emphasis will be on prescribed natural fire whenever conditions permit. (G)

Employ Minimum Impact Suppression Tactics (MIST) to the maximum extent possible.(G)

Physical Elements

Soil & Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or loss of resource values. (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within this prescription area are not imminent; or where natural vegetation would return in a reasonable time. (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing. (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of semi-primitive nonmotorized resources or to protect life, property, and other resource values outside the area. (S)

Minerals/Geology

Same as 1.2 Wilderness Study Area.

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No	No 2/
	Motorized, >50" wide	No	No 2/
	OROMTRD 3/	N/A	0.0 ml/sq.mi. 3/
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Motorized use is not allowed, except that motorized equipment is allowed for trail construction/maintenance. Motorized transport of Forest Service employees is not allowed except on contracts where motorized maintenance equipment is being used.

3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information)

Roads

Existing system or nonsystem roads will be closed as soon as practicable. (S)

No new road construction. (S)

Recreation

Dispersed - Minimal recreation facilities may be provided (such as hitch rack, rudimentary toilets, etc) not to exceed Development Level I (see Glossary). Generally, recreation facilities are not encouraged (G)

High impact campsites should be restored to meet Frissell Condition Class 3 (see Glossary). (G)

Trails - Trails and bridges are constructed/maintained to a level to accommodate heavy foot and horse traffic, where allowed. (G)

- Motorized/mechanized trail maintenance and construction equipment may be used. (G)

ROS - Primitive to semi-primitive nonmotorized. (G)

VQO - Retention to partial retention. (G)

Production of Natural Resources

Timber

These areas are removed from the suitable timber base. They are not part of the ASQ.(S)

No timber harvesting, except for 'minor' forest products such as camp firewood, posts and poles for fencing on Forest only, administrative use, etc. Harvesting does not trigger the need for reforestation. Chainsaws are allowed. (S)

Range

Livestock Grazing - Range developments (water tanks, fences, etc.) that do not detract from the overall objectives of the area are acceptable. (S)

Manage allotments at FRES levels A, B, C, or D. (G)

3.1.2 NONMOTORIZED

Description

This management prescription identifies areas where semi-primitive nonmotorized recreation use, like hiking and horseback riding, will occur during the summer months. The experience is similar to a primitive experience, but does allow some motorized use, like chainsaws for summer trail maintenance, snowmachines during the winter, and helicopters. Groomed snowmachine trails are not allowed

These areas are accessible by trails or cross-country; you find no usable roads. All-terrain vehicles and motorcycles cannot use the area. Encounters with other people diminish as you move away from nearby roads and trailheads. Generally, you experience a backcountry setting with a high likelihood of solitude. However, you may meet large groups occasionally.

You may find oversnow vehicles, helicopter use, stock tanks, and fences. Otherwise, the forest presents a natural appearance. A variety of forest successional stages may be present, ranging from areas with recent wildfires to old growth habitat. Firewood is available for camping, but is not available generally for home use. Outfitter and guiding activity may be present. Domestic sheep grazing is greatly reduced or absent to provide better management in grizzly bear management. Cattle grazing may be present in some areas, and you may see range improvements such as fencing and stock tanks. A variety of nonforested rangeland successional stages may be present

Goal

Maintain or enhance semi-primitive nonmotorized dispersed recreation opportunities.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

Wildfire will be managed using the appropriate suppression response. The emphasis will be on prescribed natural fire whenever conditions permit. (S)

Employ Minimum Impact Suppression Tactics (MIST) to the maximum extent possible. (S)

Use management-ignited fire to maintain fire's ecological role and to enhance habitat. (G)

Insects & Disease

Allow insects and disease to play their natural role in ecological succession, compatible with other resource objectives. (G)

Physical Elements

Soil & Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or loss of resource values. (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside this prescription area are not imminent, or where natural vegetation would return in a reasonable time (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing. (S)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of semi-primitive nonmotorized resources or to protect life, property, and other resource values outside and within the area. (G)

Minerals/Geology

Same as 1.2 Wilderness Study Area.

Air Quality

Protect air quality in conformance with Class II standards specified in Forestwide standards and guidelines. (S)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/

Roads

Existing system or nonsystem roads will be closed as soon as practicable. (S)

No new road construction. (S)

Recreation

Dispersed - Minimal recreation facilities may be provided (such as hitch rack, rudimentary toilets, etc.) not to exceed Development Level I. Generally, recreation facilities are not encouraged. (G)

- High impact campsites should be restored to meet Frissell Condition Class 3 (G)

Trails - Trails and bridges are constructed/maintained to a level to accommodate heavy foot and horse traffic, where allowed. (S)

- Motorized/mechanized trail maintenance and construction equipment may be used (G)

ROS - Primitive to semi-primitive nonmotorized. (S)

VQO - Preservation to partial retention. (G)

Production of Natural Resources

Timber

These areas are removed from the suitable timber base. They are not part of the ASQ (S)

No timber harvesting, except for 'minor' forest products such as camp firewood, posts and poles for fencing on Forest only, administrative use, etc. Harvesting does not trigger the need for reforestation. Chainsaws are allowed. (S)

Range

Domestic sheep grazing will be phased out over time on an opportunity basis due to conflicts with grizzly bear. An opportunity is defined as a suitable or favorable time to abolish or close an allotment because of nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit. If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas. (G)

Cattle grazing is allowed. (S)

Allotment Management Plans will specify measures to meet agency grizzly goals and objectives. (S)

Permittee's full cooperation in meeting grizzly bear management goals and objectives for Situation 2 grizzly bear habitat will be a condition of the permit. In addition, the following will be required: (S)

a Temporary cessation or modification of permitted livestock grazing activities may occur to resolve grizzly bear conflicts with humans or livestock

b Livestock carcasses will be disposed of or rendered unattractive to bear within 24 hours after they are discovered. Disposal may include removing the carcass from the area, burying it at least 2 feet underground, burning, using an acceptable chemical repellent, or other methods approved by the District Ranger. Disposal shall be in accordance with other governing agencies (such as the Wyoming Department of Fish and Game) in order to determine cause of death for reimbursement purposes.

c. Human food, refuse, and prepared livestock/pet foods associated with the livestock operation will be made unavailable to grizzlies through proper storage, handling, and disposal. Proper storage includes a) inside a bear-proof container, b) suspended horizontally between adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger. The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported.

d. High quality food production areas for grizzlies (i.e. wet alpine and subalpine meadows, stream bottoms, aspen groves, and other riparian areas) will receive special grazing direction such as light, once-over grazing, special utilization standards, or complete closure. These sites and their corresponding direction will be identified in the Annual Plan of Use.

e. Livestock depredation believed to be associated with bears will be reported within 24 hours after they are discovered to the District Ranger and the proper State agencies.

f. Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical

g. Any action taken by the permittee or their agents which violates the Endangered Species Act will be grounds for cancellation of their grazing permit

Range developments (water tanks, fences, etc) that do not detract from the overall objectives of the area are acceptable. (S)

3.2 (a,b,c,d,f,g) SEMI-PRIMITIVE MOTORIZED

Description

This management prescription identifies areas with a semi-primitive backcountry recreation experience, associated with some motorized vehicle use. These areas are accessible by roads, trails or cross-country. Motorized vehicle use is allowed, except on steep slopes or unstable soils. Roads and trails are designed and maintained to allow easy passage. You will find occasional to frequent encounters with trail users. You may meet large groups occasionally.

Generally, the forest presents a natural appearance. A variety of forest successional stages may be present, ranging from areas with recent wildfires to late successional habitat. Firewood is available for camping and home use. Outfitter and guiding activity may be present. Domestic livestock grazing may be present in some areas, and you may see range improvements such as fencing and stock tanks. A variety of nonforested rangeland successional stages may be present.

Goal

Maintain or enhance semi-primitive motorized dispersed recreation opportunities.

Objective

Prescribed natural fire and management-ignited fire will be managed to maintain fire's ecological role and to enhance habitat.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Insects and Disease

Allow insects and disease to play their natural role in ecological succession.

Fire/Fuels

The emphasis will be on prescribed natural fire whenever conditions permit. (G)

Employ Minimum Impact Suppression Tactics (MIST) to the maximum extent possible (G)

Biological Element

Wildlife

Maintain snags at 60 percent of biological potential for woodpeckers. (G)

Forest Use and Occupation

Access (S)

3.2 (a)

Access standards for 3.2 (a)-(d) and (f) and (g) are shown in two charts based on differences in motorized cross country travel, season of use and size of areas where road and trail density does not apply.

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
	Motorized, <50" wide Motorized, >50" wide OROMTRD	Yes 2/ Yes 2/ N/A	Yes Yes <= 1.0 m/sq.mi. 3/
	Winter Nonmotorized Snowmachine	Yes Yes	Yes Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Motorized use is allowed (except on slopes > 40%, on unstable soils, or during the period from September 1 to December 30).

3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information) In the Spring Mtn. Canyon area (Lemhi Mtns., Dubois R D.) OROMTRD is <= 1.3 miles/square mile

3.2 (b)

The same as 3.2 (a) (see Table above) except cross-country motorized use is allowed, (except on slopes > 40%, on unstable soils, or during the period from Oct. 1 to Dec. 30).

3.2 (f)

The same as 3.2 (a) (see Table above) except in 3.2 (f) prescription areas ≤ 2 5 square mile in size, OROMTRD does not apply, and there are no seasonal restrictions on cross-country motorized use.

3.2 (g)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
	Motorized, <50" wide Motorized, >50" wide OROMTRD 2/	No No N/A	Yes Yes <= 1.0 mi/sq.mi. 2/
	Winter Nonmotorized Snowmachine	Yes Yes 3/	Yes Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails (See Roads in Glossary for more information) In 3.2 (g) prescription areas which are narrow linear road corridors (i.e. Pass Creek and Eightmile Creek, Irving Creek, East Dry Creek, and Keg Springs), OROMTRD does not apply.

3/ In grizzly bear BMU's, cross-country snowmachine use is only allowed from Dec. 15 to April 1.

3.2 (c)

The same as 3.2 (g), except in 3.2 (c) prescription areas ≤ 1.0 mi/sq.mi. in size, OROMTRD does not apply.

3.2 (d)

The same as 3.2 (g) except in 3.2 (d) prescription areas ≤ 3.5 mi./sq.mi. in size, OROMTRD does not apply.

Game Retrieval

Same as 2.7 a, b Elk and Deer Winter Range except in Henry's Lake BMU - Subunits 1 and 2

Roads

Generally, no new road construction. (G)

Recreation

Dispersed - Dispersed recreation facilities may be provided to reduce adverse resource impacts at heavily used sites (G).

- Development level shall not exceed Level 2 (see Glossary) (S)

- High impact campsites should be restored to meet Frissell Condition Class 3 (see Glossary). (G)

Trails - Trails and bridges are constructed/maintained to a level to accommodate heavy foot, horse, and motorized vehicle traffic, where allowed. (G)

ROS - Semi-primitive motorized and roaded natural. (G)

VQO - Retention to partial retention. (G)

Production of Natural Resources

Timber

These areas are removed from the suitable timber base They are not part of the ASQ (S)

Timber management is allowed for such products as camp firewood, home use firewood, posts and poles for fencing on Forest, Christmas trees, wildlife habitat, administrative use , etc Harvesting generally does not trigger the need for reforestation (G)

Commercial post and pole sales are allowed provided no new temporary or system road construction occurs (G)

Range

Range developments (water tanks, fences, etc.) that do not detract from the overall objectives of the area are acceptable. (G)

Manage allotments at FRES levels A, B, C, or D. (G)

4.1 DEVELOPED RECREATION SITES

Description

This prescription applies to existing campgrounds, picnic areas, boating sites/ramps, and other facilities such as trailheads, snow parks, scenic and wildlife viewing areas, fishing access points, and inventoried National Forest Recreation sites selected for potential development located throughout the Targhee National Forest Development ranges from native material roads and campsites, with nonflush toilets, to a high degree of site modification with comfort and convenience facilities including paved roads, water systems, mobility impaired access, flush toilets and boat launches. See recreation facility Development Levels 1-5 in the Glossary.

Overall, you find many signs of people. You see little or no evidence of resource development except for recreation. Picnic tables, roads, buildings, and camping spots are obvious. You often hear sounds of vehicles and other human activity. Signs advise that off-highway vehicle use is not allowed except to enter and depart the site on roads

You can gather down firewood for camping, but you cannot gather it for home use. Access to fishing may be rather easy if the facility is near a stream or river, but the fishing may be less satisfactory than in more remote areas

You generally will not find livestock within campgrounds, but they may be visible nearby. Signs and sounds of logging may also be apparent from time to time.

Wildlife, in the form of chipmunks, squirrels, birds, and occasional big game may be seen.

Generally you will find a variety of vegetation conditions from sagebrush to forested land within these areas. The forest cover will vary from mature trees to young seedling and sapling trees. The forest will generally be in a healthy, vigorous condition to provide for safety and provide for a friendly, relaxed outdoor experience. The area around the campground will generally exhibit a variety of visual conditions, depending on past insect, disease, and fire activity and management's response to those disturbances.

Goals

1. Provide for a variety of concentrated public recreation uses in a roaded-natural setting based on the character of the areas and visitors' needs.
2. Protect and enhance a natural appearing environment within and adjacent to the existing sites to the extent possible while maintaining the existing array of developed recreation sites.

Objectives

1. Natural fuels will be reduced or otherwise treated so the potential fireline intensities will not exceed 100 BTU per second per foot on 90% of the days during the regular fire season (Burning Index \leq 40)
2. Promote "Watchable Wildlife" when compatible with developed recreation use.
3. Provide an appropriate mix of reservation and nonreservation sites in campgrounds.
4. Provide short trails to facilities and opportunities for interpretation.
5. Manage aspen for its value in providing seasonal color.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

All wildfires that threaten these areas will be aggressively suppressed. (S)

Prescribed fire generally will not apply here. It may be used, however, to obtain natural regeneration in preference to soil-disturbing techniques. (G)

Insects and Disease

Control insects and disease consistent with recreational objectives. (S)

Physical Elements

Soil and Water

Where standards are not being met, actively rehabilitate these areas. Use rehabilitation techniques that do not detract from the recreation opportunity. (S)

Avoid new construction on unstable or highly erosive soil. (G)

On new developments provide adequate vegetation filters to maintain and/or enhance riparian-dependent resources. (G)

Lands

Corridor rights-of-way should avoid campgrounds and other facilities. (G)

Minerals/Geology

Same as 1.2 Wilderness Study Area.

Biological Elements

Wildlife

Animal Damage Control - Animal damage control generally will not be done in campgrounds and other developed sites because of potential conflicts with recreation users and their pets, except for control of problem bears, beavers, porcupines, etc. (G)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	No	Yes
	Mtn Bike/Mechanized	No	Yes
	Motorized, <50" wide	No	Yes 2/
	Motorized, >50" wide	No	Yes 2/
	OROMTRD 3/	N/A	N/A
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Motorized use is allowed only on existing roads and is limited to entering, leaving, and visiting other sites within the facility.

3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails (See Roads in Glossary for more information)

Recreation

Developed - Campgrounds and picnic areas that have a seasonal use level of 40 percent or higher should be managed at the Standard Service Level (see Glossary). (G)

- Campgrounds and picnic areas that have a season-long use level of 20 to 40 percent should be managed at less than the Standard Service Level. (G)

- Those with less than 20 percent average season-long use may require closure of sites first and then, if needed, closure of the entire facility. (G)

- Campground use will be limited to no more than two vehicles per family unit, unless posted as a multi-family unit. (S)

Development Level Guideline. Developed sites should be built, improved, and maintained in accordance with the established Recreation Opportunity Spectrum (ROS) classification for the Management Prescription Area and the development standards as follows: (G)

<u>ROS Class</u>	<u>Recreation Development Level</u>
Primitive	None
Semi-primitive Nonmotorized	Not to exceed 1
Semi-primitive Motorized	Not to exceed 2
Roaded Natural	Not to exceed 3
Urban	Not to exceed 4

ROS - Semi-primitive motorized to urban. (G)

VQO - Manage for a full range from retention to modification. Facilities are often evident but harmonize and blend with the natural setting. (G)

Production of Natural Resources

Timber

Developed recreation sites are removed from the suitable timber base. No ASQ is provided from these lands. (S)

Range

Exclude grazing of recreational stock and livestock in developed recreation sites during the managed recreation use season. (S)

Grazing at trailheads may be allowed when developments or recreation use is not adversely affected. (G)

4.2 SPECIAL USE PERMIT RECREATION SITES

Description

This prescription applies to ski areas, resorts, summer home sites and organization camps (e.g., Boy and Girl Scouts of America) that are allowed under a special use permit

The emphasis is on providing privately operated types of recreation on National Forest land for large concentrated groups of people. Overall, you find many signs of people. You see little or no evidence of resource development except for recreation. Cabins and buildings used by permittees are visible but blend into the surroundings. Roads are generally gravelled, but may be paved in higher use areas. OHV use is limited to entry and departure routes and for administrative purposes. In some areas you may see extensive development associated with ski areas or resorts—for example, buildings, ski lifts, maintenance equipment, etc. Many pedestrians and cars may be seen in these areas.

You generally will not find livestock within these areas, but they may be visible nearby. Signs and sounds of logging may also be apparent from time to time.

Wildlife, in the form of chipmunks, squirrels, birds, and occasional big game may be seen. Generally you will find a variety of vegetation conditions from sagebrush to forested land within these areas. The forest cover will vary from mature trees to young seedling and sapling trees. The forest will generally be in a healthy, vigorous condition to provide for safety and provide for a friendly, relaxed outdoor experience. The area around the special use facility will generally exhibit a variety of visual conditions, depending on past insect, disease, and fire activity and management's response to those disturbances.

Goals

1. Provide for privately operated recreation use.
2. Protect and enhance a natural appearing environment to the extent possible while providing for private and group recreation opportunities.
3. Strive to incorporate opportunities for watchable wildlife.

Objectives

1. Natural fuels will be reduced or otherwise treated so the potential fireline intensities will not exceed 100 BTU per second per foot on 90 percent of the days during the regular fire season (Burning Index ≤ 40). (S)
2. Implement the Big Springs Summer Home Agreement.
3. Implement decision of June 14, 1949 for Lot 2 Block G in the Buffalo Summer Home Area.

Require existing cabin to be removed from National Forest System lands by May 2, 1997, as specified in existing permit. No set-back lot will be provided and Lot 2 Block G will not be considered for exchange in the Buffalo Summer Home Area. (S)
4. Additional objectives for recreation residences

New recreation residence tracts (summer homes) will not be established. No new residences will be permitted on vacant lots that are no longer leased unless necessary to replace lots damaged by landslides at the Hoffman site or to implement the Big Springs court order. (S)
5. Provide short trails providing access to facilities and opportunities for interpretation.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

All wildfires that threaten these areas will be aggressively suppressed. (S)

Prescribed fire generally will not apply here. It may be used, however, to achieve resource objectives. (G)

Insects and Disease

Control insects and disease consistent with visual objectives. (S)

Physical Elements

Soil and Water

Use rehabilitation techniques that do not detract from the recreation opportunity (G)

Avoid new construction on unstable or highly erosive soils (G)

On new developments provide adequate vegetation filters to maintain and/or enhance riparian-dependent resources. (G)

Lands

Corridor rights-of-way will avoid summer homes and group facilities. (G)

Minerals/Geology

Locatable - Locatable mineral entry is allowable, but will be mitigated to the greatest extent possible to protect the recreation experience. (G)

Mineral Material - No entry for mineral materials. (S)

Biological Elements

Wildlife

Projects that allow selected wildlife species to be more visible to recreation users may be allowed when compatible with special use permit recreation sites. (G)

Animal Damage Control - Animal damage control generally will not be done on these sites because of potential conflicts with recreation users and their pets. (G)

Plants

Projects or events that focus on the identification and/or uses of plants are allowed where compatible with special use permits and the activities do not degrade the vegetation at the facility.

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	No 2/	Yes
	Mtn Bike/Mechanized	No	Yes
	Motorized, <50" wide	No	Yes 3/
	Motorized, >50" wide	No	Yes 3/
	OROMTRD 4/	N/A	not applicable
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes 5/	Yes 5/

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Horse/pack stock is not allowed cross-country, except as noted in the special use permit

3/ Motorized use is allowed only on existing roads and is limited to entering, leaving, and visiting other sites within the facility, except as guided by the special use permit.

4/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information)

5/ Except within designated downhill ski area boundaries.

Recreation

Developed - Natural vegetation should be favored around facilities. However, mowing natural vegetation around facilities may be allowed. (G)

Trails - Trails may be allowed for the convenience of people using these sites (G)

ROS - Roaded natural to urban. (G)

VQO - Manage for a full range from partial retention to maximum modification. Facilities are often evident, but harmonize and blend with the natural setting. (G)

Production of Natural Resources

Timber

Developed recreation sites are removed from the suitable timber base. No ASQ is provided from these lands (S)

All vegetation treatment options are available, but only as required to meet specific recreation objectives (G)

Stipulate removal of unsafe and/or dead trees in the special use permit. Native species may be planted to provide cover when naturally-occurring vegetation is inadequate (G)

Range

Unless grazing activities are needed to meet recreation objectives, or unless authorized by special use or grazing permit, grazing of recreation stock and other livestock will not be allowed in special use recreation sites. (G)

Grazing activities may be allowed in and around facilities designed for livestock use. (G)

4.3 DISPERSED CAMPING MANAGEMENT

Description

The purpose of this prescription is to maintain a quality dispersed recreation experience for the public and still protect other resource values that occur in the same area. This prescription applies to highly attractive and desirable, heavy, summer use areas such as around lakes or reservoirs, along roads and streams; or at trailheads where there are multiple campsites accessed by conventional wheeled vehicles (> 50" wide) or boat. Included would be heavy use areas where dispersed camping occurs in potential conflict with other resources or where site damage is occurring or likely to occur

While dispersed recreation is the main theme, protecting the resource values of the area is also critical. Therefore this prescription is intended to create a balance between the users and the resource they came to enjoy. This prescription is intended to be applied in those areas where special concerns or consideration must be given to dispersed recreation use in order to maintain the recreation opportunities.

This prescription includes areas not considered developed, but which are used by the public on a recurring basis. They include sites where developed status does not fit, but use by the public is more than occasional use during the recreation use period. These sites may have some limited developed facilities which may include one or two, but not the majority of the following: fire-rings, tables, toilet facilities, signs, and/or water. These sites are not fee areas and have very limited capital investment (<\$50M).

Management emphasis is directed at managing dispersed or undeveloped type camping opportunities, such that other resources are not unacceptably affected. Minor development is allowed to protect the site or prevent resource damage, but development should not put sites into a developed site management emphasis. Restrictions may be placed on camping locations to allow used areas to recover or to protect natural resources

Goals

1. Provide facilities to a level only to meet resource protection needs.
2. Provide a balance between recreation use and other resource needs so that those resources which provide attractions to the area are protected to a point they continue to be important recreational attractions.
3. Maintain or improve the quality of the dispersed camping sites that now exist in the area

Objective

Avoid allowing heavy build-up of fuels in these areas to reduce risk of accidental fire ignition.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire and Fuels

Avoid application of chemical retardant, foam, or additives in these areas. Exceptions may be warranted in situations where over-riding safety situations exist, or following a review and recommendation by a resource advisor, when an escape would cause more long-term damage (G)

Use minimum impact suppression methods. (G)

Physical Elements

Minerals/Geology

Adequate reclamation plans and bonds are required in mining plans of operation. These bonds include costs of removing facilities, equipment, and materials; recontouring disturbed areas to near pre-mining topography; isolating and neutralizing or removing toxic or potentially toxic materials; salvaging and replacing topsoil; and preparing seedbeds and revegetating to meet Management Prescription Goals. (G)

Avoid locating permanent structures or facilities within these lands. Limit road construction to the minimum necessary for the approved activity. (G)

Avoid locating waste dumps, leaching pads, and other facilities within these lands or within the viewshed where other alternatives are available. If no other alternative exists, ensure that visual mitigation such as screening are in place to prevent degradation of visual quality on these lands. (G)

For leasable minerals, avoid surface occupancy for exploration and development activities where leases do not already exist. (G)

Mineral material extraction should be discouraged (subject to valid permitted rights, or permitted plans of operation as allowed by Law). (G)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No 2/	Yes
	Motorized, >50" wide	No 2/	Yes
	OROMTRD 3/	N/A	N/A
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Cross-country travel is allowed only to access the campsite unless the surrounding prescription area is open for cross-country travel, or as described in the Management Plan for this prescription area.

3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails (See Roads in Glossary for more information)

Roads and Trails

No new roads, trails, or landings will be constructed within these lands until appropriate standards for construction, maintenance, and operations are in place. (G)

Improve, seasonally close, close and relocate and stabilize, or obliterate roads and trails (or sections of them) that have been identified as posing a high risk of causing unnaturally high levels of sediment input into fish spawning areas. Action to be taken will be determined based upon travel management needs, terrain, the need for the road or trail, and resource priorities (G)

Roads and trails that have been identified as inhibiting riparian, wetland or aquatic ecosystem processes and/or functions (e.g., plant community development, sediment transport, and stream channel development) will be improved, relocated, or obliterated. The decision to improve, relocate, or obliterate will be based on the potential environmental impact, the ecological condition of the riparian, wetland and aquatic resources affected, and the need for the road or trail. (G)

Culverts and stream crossings found to pose a risk to riparian, wetland or aquatic conditions will be improved to accommodate at least a 50-year flood, including associated bedload and debris. (G)

New stream crossings will be constructed and maintained to prevent diversion of streamflow out of the channel and down the road in case of failure(s). In locations found to have high potential for failure, the roadway will be hardened to further lessen the chance of roadway failure or severe erosion should the crossing over-top. (G)

Constructed temporary stream crossings, such as log and culvert installations, may be allowed. Temporary crossings will be constructed and used in such a way as to minimize sediment input and to provide for fish passage. They will be maintained during use and removed and rehabilitated as soon as they are no longer needed. (G)

Construct, reconstruct, and maintain all road crossings of streams which currently or historically bear fish to provide for fish passage. Exceptions are allowed where it is necessary to restrict fish movements in order to protect native or desirable nonnative fish populations. (G)

During construction and maintenance activities, sidecast loose material away from these lands or transport it to a suitable disposal site if on-site disposal is not practical (G)

Recreation and Outfitter/Guide

When dispersed recreation is found to result in soil displacement in excess of 15 percent of an activity area (e.g., aquatic influence zone, riparian areas, dispersed campsites, etc), or alteration of natural stream channel morphology, address impacts through education, use limits, more intensive maintenance, facility modification, and/or closures. (G)

Recreational grazing must meet Range Standards for utilization of riparian vegetation. (S)

Permitted stock holding, watering, and handling facilities within riparian vegetation (does not include the entire aquatic influence zone) are only allowed if appropriate and mitigation measures are implemented to reduce negative impacts. (S)

Road surfacing or hardening should be encouraged in areas of high use and evident resource damage. Both parking location and access roads should be considered. (G)

Fire circles created by the public, should not exceed one per site. Where more than one circle is inventoried, action should be taken to reduce the number to one. Action could include education, signing, facility installation closure order, surfacing, etc. Restrictions to require use of fire pans or contained fires may be necessary and should be considered in the area management plan. (G)

Boat launching along streams, river sections, lakes or reservoirs should be restricted to developed sites or if no sites exist, consideration should be made to develop a facility to meet the public needs. (G)

For all groups in excess of 20 persons, the site should have toilet facilities. Where facilities do not exist, portable toilet units should be provided by groups of 20 or more persons. (G)

When portable toilet units are used, they shall be placed away from water and must be packed out when use has ended. (S)

Solid waste disposal will be accomplished using the Pack In-Pack Out program. (G)

ROS - Primitive to urban. (G)

VQO - Retention to modification. (G)

Production of Natural Resources

Timber

These lands are not included in the suitable timber base. They are not part of the ASQ. (S)

Where needed to attain Management Prescription Goals, design silvicultural prescriptions and allow prescribed burning and stocking control, as well as the re-establishment and culturing of stands to attain desired vegetation characteristics (G)

Range

Incorporate into AMP's, objectives for attainment of site-specific DFC's for riparian or wetland plant community seral stage development and stream channel condition. (G)

Proposed livestock watering facilities, corrals, and holding pastures within these lands are allowed only if appropriate, and mitigation measures are implemented to reduce negative impacts (S)

Existing livestock watering facilities, corrals, and holding pastures within these areas are allowed at permit issuance only if mitigation measures are implemented to reduce negative impacts. (G)

Salting sites should be placed 1/4 mile from dispersed sites. (G)

5.1 (b-c) TIMBER MANAGEMENT

The purpose of this prescription is to provide commodity resource development with moderate accommodation of other resources

Description

The emphasis is on scheduled wood-fiber production and use, on livestock production, and on other compatible commodity outputs, and consideration for long-term forest health.

Overall, you notice many signs of people. You see a fairly extensive roading system and timber harvest activity in some areas. The main road system is gravel-surfaced and well maintained, with gentle grades well suited for sedan travel. You may see timber harvest equipment at roadside and meet logging traffic along the roadway. You will see other people driving for pleasure or hauling out a load of firewood. Driving a sedan you can travel about two-thirds of the main road system. About one-third of the main road system is closed for wildlife security or roadway protection.

You notice frequent low-standard branch roads with native and gravel surfaces. Most of these low-standard roads are closed annually or seasonally to vehicle access. Some branch roads remain open for public access, for commodity production and for Forest Service administration.

The forest is a mosaic of different sizes, ages and heights. Older, taller trees tend to dominate the landscape, but openings with smaller trees are obvious. Recently cut areas show tree stumps, slash and disturbed soil. Recently cut areas have a partial canopy of older trees. Older clearcut areas have seedlings, saplings, poles, and older trees up to 35 feet tall and have a less disturbed appearing forest floor. Dead trees from the mountain pine beetle infestation are seen in older stands and scattered throughout the rest of the forest

Firewood is available, by permit, from dead trees, designated aspen areas, and from slash and logs decked for that purpose.

If you watch wildlife, you will see a variety of species, particularly those which prefer young stages of forest succession to those which prefer late stages of forest succession. Elk and deer numbers have generally increased somewhat in recent years. However, in areas of active timber harvest activity, some elk and other big-game species may have been displaced to areas with greater security. Because of the setting, outfitted hunting may not be as common as it is in less-developed areas.

During the summer and fall you encounter cattle or sheep and notice signs of intensive management practices, such as burning, spraying, seeding, fences, cattleguards, water developments and gates. You see some cattle within streamside riparian areas and on nearby slopes. Away from the streams, you see scattered groups of livestock. You may find traffic delays when livestock is being moved.

You find such nonmotorized activities as hiking, biking and horse-back riding along roads closed to vehicle traffic. Some roads and areas are available for snowmobile, motorcycle, and 4-wheel-drive vehicle use.

Goal

These would be managed to promote the production of commodity and noncommodity resources.

Objectives

1. Establish fire protection objectives for the area and desired fuel conditions.
2. Fire management strategies emphasize preservation and protection of timber and range values scheduled for current use.
3. Effectively control the insects and disease and sustain forest growth.
4. Provide a wide array of dispersed recreation opportunities.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

Wildfires will normally be suppressed using control strategies during the fire season. Pre- and post-fire season strategies may include containment, confinement, or control. (G)

Prescribed fire may be used to reduce fuel loading; obtain natural regeneration; improve livestock forage conditions, for wildlife habitat improvement, and for other purposes that meet the needs of this prescription. (G)

Insects and Disease

Practices to prevent or control insects and disease through direct control or silvicultural practices may be considered. (G)

Biological Elements

Wildlife

Maintain snag habitat at > 40 percent of the biological potential for woodpeckers (G)

Forest Use and Occupation

Access (S)

The only difference in access standards between 5.1 (b) and (c) is open road and open motorized trail route density.

5.1 (b)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	<= 3.0 mi /sq.mi.
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ OROMTRD = Open road and open motorized trail route density. includes all open roads and open motorized trails. (See Roads in Glossary for more information)

5.1 (c) same as 5.1 (b) above except OROMTRD is <= 1.5 miles/square mile.

Game Retrieval

Same as 2.7 a, b Elk and Deer Winter Range.

Recreation

Trails - Motorized trails should be developed using primarily local roads and trails not being actively used for commodity recovery. (G)

ROS - Recreation is managed to provide a combination of semi-primitive nonmotorized to roaded natural opportunities. (G)

VQO - The VQO is generally Partial Retention to Modification. In visually sensitive foreground areas, the VQO is Retention. (G)

Production of Natural Resources

Timber

Lands are included in the suitable timber base They contribute toward the ASQ. (S)

Regeneration systems should rely on natural regeneration to the greatest extent possible. (G)

Reforested sites may be protected from rodent and livestock damage to encourage the greatest possible survival and growth over time, consistent with other resource needs. (G)

Harvest and treatment residues should be made available for firewood and other products in a manner compatible with site preparation, productivity, and restocking requirements. Designated aspen areas should be made available for firewood. (G)

Range

Livestock grazing may be allowed on transitory forage produced following timber harvest where and when that use will not conflict with regeneration efforts or other concerns. (G)

**5.1.3 (a-b) TIMBER MANAGEMENT
(NO CLEARCUTTING, URBAN INTERFACE FUELS MANAGEMENT)**

The purpose of this prescription is to provide timber management with no clearcutting, and to provide fuels management within and adjacent to urban areas of the Forest.

Description

The emphasis is on scheduled wood-fiber production and use, on fuels management within and adjacent to urban areas of the Forest, on livestock production, and on other compatible commodity outputs, with consideration for long-term forest health.

Overall, one would notice the same conditions as in Management Prescription 5 1 (b) and (c)

Goal

Manage vegetation and fuels to minimize fire risk for urban facilities within the interface.

Standards and Guidelines

Forestwide standards and guidelines apply. The same standards and guidelines apply as 5 1 except

Forest Use and Occupation

Access(S)

5.1.3 (a) is the same as 5.1 (b) except cross country motorized access for vehicles < 50" is permitted and prescription areas < 2.5 square miles in size, OROMTRD does not apply..

5.1.3 (b) is the same as 5.1 (b) except prescription areas < 2.5 square miles in size, OROMTRD does not apply.

Game Retrieval

Same as 2 7 a,b Elk and Deer Winter Range

Production of Natural Resources

Timber

No clearcutting allowed

5.1.4 (a-c) TIMBER MANAGEMENT (BIG GAME SECURITY EMPHASIS)

The purpose of this prescription is to provide commodity resource development with special emphasis on big game security.

Description

The emphasis is on scheduled wood-fiber production and use, big game security, other compatible commodity outputs, and consideration for long-term forest health. It combines the forested security block emphasis of 5.4 with cross-country motorized use allowed in 5.1, but restricts that motorized use during the big game hunts.

This management prescription emphasizes management actions and resource conditions which provide increased security for big game species, and hunting opportunities with limited access. Habitats are managed for multiple land use benefits, but these are managed over time and space to provide security and cover for hunted big game species.

Spring, summer, and fall forage is abundant and well distributed throughout the area. Hiding and thermal cover is abundant and in large patches to provide security for big game throughout the spring, summer, and fall seasons. Big game movements and migrations are facilitated due to well distributed forage and cover.

Timber management emphasizes providing a variety of forested successional stages, with large blocks of forested vegetation providing hiding cover. Security areas are provided adjacent to areas where timber harvesting is occurring.

Motorized access is managed to provide big game security. You notice frequent low-standard branch roads with native and gravel surfaces. Most of these low-standard roads are closed annually or seasonally to vehicle access. Some branch roads remain open for public access, for commodity production and for Forest Service administration.

Hiking off-road conditions, forest stand conditions, ability to view wildlife, presence of cattle and sheep, and nonmotorized activities are the same as 5.1.

Goal

Protect the long-term productivity of the land and meet areawide standards that protect resource values such as fisheries, water quality, wildlife habitat (including big game security areas) and visual quality.

Objective

Manage for big game security in > 250 acre forested blocks.

Standards and Guidelines

Forestwide standards and guidelines apply. The same standards and guidelines apply as 5.1 except:

FOREST USE AND OCCUPATION

Access (S)

5.1 4 (a)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
	Motorized, <50" wide Motorized, >50" wide OROMTRD 3/	Yes 2/ No N/A	Yes Yes <= 1.5 mi/sq mi. prior to and after the fall big game hunt
	OROMTRD 3/	N/A	<= 1.0 mi/sq.mi. during the fall big game hunt. 3/
	Winter Nonmotorized Snowmachine	Yes Yes	Yes Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps

2/ Open to travel from June 15 to just prior to the Idaho and Wyoming big game hunt.

3/ OROMTRD = Open road and open motorized trail route density* includes all open roads and open motorized trails. (See Roads in Glossary for more information)

5.1.4 (b) is the same as 5 1.4 (a) above except no cross country motorized travel by vehicles <50" wide and OROMTRD is < 1.5 without seasonal road restrictions.

5.1.4 (c) is the same as 5 1 4 (a) except cross country snowmachine use is only allowed from Jan. 1 to April 30

Game Retrieval

Same as 2 7 a, b Elk and Deer Winter Range, except not allowed in 5 1.4 (c).

Production of Natural Resources

Timber

For the forested component within the prescription area, no more than 20 percent of the acres will be in a created opening at any point in time (a created opening is defined as: a) clearcuts (nonstocked and seedling stages); b) seed cuts of a shelterwood (nonstocked and seedling stages); or c) group selection (nonstocked and seedling stages). (S)

Naturally occurring forested blocks less than 250 acres in size, may have 20 acre harvest units, with no more than 20% of the block in the created opening category at one time. (G)

For scheduling harvest activities, adjacent big game security areas will be provided. Security should provide the following conditions:

1. Security areas will be > 250 acres in size, or depending on the size of the timber sale area boundary, as large as necessary to meet big game security needs (G)
2. Within the security area, OROMTRD must be ≤ the density established for this management prescription.
3. No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated as a security area.

5.2.1 VISUAL QUALITY IMPROVEMENT

Description

This prescription emphasizes improving or maintaining visual opportunities for visitors along major travel corridors through heavily timbered areas, while allowing livestock production, timber harvest, and other compatible commodity outputs. The purpose of this prescription is to maintain or create openings in timber stands to provide scenic vistas.

Overall you may notice signs of people camping by the roadside or as part of a commercial timber harvest.

As you drive, you see occasional timber harvest activity in some areas. The main road system is paved or gravel-surfaced and well maintained, with gentle grades suited for sedan travel. Clearcuts and harvest areas have been designed and located to provide vistas of the surrounding area.

There will be occasional places to pull off the road and have a picnic, read an interpretative sign or photograph a pleasing landscape.

The road side area is dominated by a mix of older stands of trees, young stands, and created openings to provide scenic vistas. A few areas show tree stumps, hand-piled slash, and disturbed soil. Occasionally, older cut areas show tree seedlings, saplings and poles up to 35 feet tall and have a less-disturbed appearing forest floor. Scattered dead trees are seen throughout the forest, but generally it appears healthy and vigorous.

If you watch for wildlife, you may occasionally see an elk, deer or moose in a natural opening or alongside the road, but generally these are hidden from view by the trees. During the summer and fall, you may encounter cattle or sheep grazing in openings. Signs of intensive management practices, such as burning, spraying, seeding, fences, water developments and gates are normally visually compatible.

Nonmotorized activities, such as hiking, biking or horse-back riding may originate from trail or road points along the main road. Some roads and nearby areas are available for year-around snowmobile, motorcycle, and 4 wheel-drive vehicle use.

Goals

1. Manage these major travel corridors to improve or maintain their visual quality.
2. Manage these lands in an environmentally sensitive manner to promote the production of commodity and noncommodity resources at varying levels through a variety of silvicultural prescriptions.

Objectives

1. Establish fire protection objectives for the area and desired fuel conditions
2. Fire management strategies emphasize preservation and protection of timber and range values scheduled for current use.
3. Effectively control the insects and disease and sustain forest growth.
- 4 Provide a wide array of dispersed recreation facilities.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

Wildfires will normally be suppressed using control strategies during the fire season. Pre- and post-fire season strategies may include containment, confinement, or control. (G)

Prescribed fire may be used to reduce fuel loading; obtain natural regeneration, improve livestock forage conditions; for wildlife habitat improvement; and for other purposes that meet the needs of this prescription. (G)

Insects and Disease

Practices to prevent or control insects and disease through direct control or silvicultural practices may be considered. (G)

Biological Elements

Wildlife

Maintain snag habitat at > 40 percent of the biological potential for woodpeckers (G)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	Yes	Yes
	Motorized, >50" wide	Yes	Yes
	OROMTRD 2/	N/A	N/A
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes
<p>1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.</p> <p>2/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information)</p>			

Game Retrieval

Same as 2.7 a,b Elk and Deer Winter Range.

Roads

Management of the area does not require an extensive road system, and will consist of short spurs from the main travel routes (G)

Recreation

Trails - Motorized trails should be developed using primarily local roads and trails not being actively used for commodity recovery. (G)

ROS - Recreation is managed to provide a combination of semi-primitive nonmotorized to roaded natural opportunities. (G)

VQO - The Visual Quality Objective (VQO) is Retention to Maximum Modification. (G)

Production of Natural Resources

Timber

Lands are included in the suitable timber base. They contribute toward the ASQ. (S)

Any silvicultural system may be used, depending on the visual quality that is being emphasized. (G)

Regeneration systems should rely on natural regeneration to the greatest extent possible. (G)

Reforested sites may be protected from rodent and livestock damage to encourage the greatest possible growth over time, consistent with other resource needs. (G)

Maximum created opening size could be 40 acres, but will generally be 1 to 5 acres in size to create scenic vistas. (G)

Harvest and treatment residues should be made available for firewood and other products in a manner compatible with the visual quality objective. Designated aspen areas should be made available for firewood to ensure the color provided by these stands is maintained over time (G)

Range

Livestock grazing may be allowed on transitory forage produced following timber harvest where and when that use will not conflict with regeneration efforts or other concerns. (G)

5.2.2 VISUAL QUALITY MAINTENANCE

Description

This prescription emphasizes maintaining the existing visual quality within major travel corridors with high quality natural vistas, while allowing livestock production, limited timber harvest, and other compatible commodity outputs.

Overall you may notice signs of people camping by the roadside. Signs of commercial timber harvesting will generally not be evident.

The roadside area is dominated by a wide variety of vegetation and landscape forms (e.g. mountain peaks, valleys, meadows, streams, etc.) that are easily observed from natural vistas and openings along the road. Occasionally, older cut areas show tree seedlings, saplings and poles up to 35 feet tall and have a less-disturbed appearing forest floor. Scattered dead trees are seen throughout the forest, but generally it appears healthy and vigorous.

Other signs of activity are the same as 5.2.1.

Goal

Manage these travel corridors to protect their visual quality.

Objectives

1. Silvicultural practices are designed to emphasize or maintain visual quality of the area.
2. Lands are included in the suitable timber base. They contribute toward the ASQ (S)
3. Regeneration systems should rely on natural regeneration to the greatest extent possible. (G)
4. Reforested sites may be protected from rodent and livestock damage to encourage the greatest possible survival and growth over time, consistent with other resource needs. (G)
5. Maximum created opening size shall generally be less than 5 acres (G)
6. Harvest and treatment residues should be made available for firewood and other products in a manner compatible with the visual quality objective. Designated aspen areas should be made available for firewood to ensure the color provided by these stands is maintained over time. (G)

Standards and Guidelines

Forestwide standards and guidelines apply. The Standards and Guidelines are the same as 5.2 1 except:

Biological Elements

Wildlife

No assigned snag habitat biological potential for woodpeckers.

Forest Use and Occupation

Access (S)

The access Standard is the same as 5.2.1 except cross country motorized travel is allowed for all vehicles unless visual features are degraded by disturbances to vegetation or soils, and summer cross country motorized travel is prohibited where this prescription is used in the Centennial Subsection.

Game Retrieval

Same as 2 7 a, b Elk and Deer Winter Range

Recreation

VQO - The Visual Quality Objective (VQO) is Retention to Partial Retention. (G)

5.3.5 GRIZZLY BEAR HABITAT (NIC FOR ASQ, NO CROSS-COUNTRY, PHASE OUT SHEEP)

Description

This management prescription emphasizes a high degree of security and resource conditions which contribute toward the conservation and recovery of the grizzly bear, and benefits to other wildlife. Habitats will be managed to meet the goals of grizzly bear recovery. Other uses may be allowed when compatible with these goals.

Grizzly habitat maintenance and improvement, and grizzly-human conflict minimization will receive the highest management priority. Management decisions will favor the needs of the grizzly bear when grizzly habitat and other land use values compete. Land uses which can affect grizzlies and/or their habitat will be made compatible with grizzly needs or such uses will be disallowed or eliminated. Grizzly-human conflicts will be resolved in favor of grizzlies unless the bear involved is determined to be a nuisance bear. (IGBC, 1986)

The abundance and distribution of natural food sources (such as huckleberry habitats, whitebark pine, etc.) are maintained or improved by natural events such as fire and insect disturbances, or by designed vegetation management activities. A variety of forested successional stages are present, and are the result of natural disturbances such as fire and insects or by designed vegetation management activities. Habitat conditions which contribute to the movement of bears to adjacent bear management units are maintained. Human activities are managed or restricted so that human conflicts with grizzlies are unlikely; this includes restricting human activities and generally reduced public access.

Objectives

1. Develop a fire management plan (coordinated with adjacent wilderness fire plans) within 1 year of ROD.

2. Any nonfederal lands within this area will be a high priority for acquisition
3. Maintain grizzly bear security through a low density of open, motorized roads and trails.
4. Manage recreation to minimize grizzly conflicts with humans.
5. Domestic sheep grazing will be phased out over time, on a opportunity basis.
6. Vegetation manipulation will be designed to maintain or improve grizzly habitat
7. Effects analysis will be analyzed at multiple scales. Analysis areas will follow ecological boundaries, watersheds, and topographic breaks. Cumulative effects will be analyzed on no less than a BMU subunit scale.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

The Interagency Grizzly Bear Guidelines for Management Situation 1 Habitat apply to this management prescription.

Ecological Processes

Fire/Fuels

Prescribed fire is allowed to maintain or improve grizzly habitat. (G)

Insects & Disease

Insects and diseases are allowed to play their natural role in ecosystem development, unless this conflicts with the maintenance of grizzly bear habitat. (G)

Physical Elements

Lands

Lands activities which adversely affect grizzly bear populations or their habitat will not be allowed (S)

Heritage Resource

No new interpretation/enhancement of cultural sites. (S)

Biological Elements

Wildlife

Maintain snag habitat at > 60 percent of the biological potential for woodpeckers. (G)

Analysis areas for EA purposes will be at least 7,000 acres in size. (G)

Number, Size and Location - Timber sales, prescribed burns, road reclaiming, tree thinning, and trail construction must be concentrated in activity areas on an annual basis between April 1 and September 15. Each activity area shall not exceed 7,000 acres in size. (S).

Not more than 3 activity areas may exist within each bear management unit in any given year. (S)

Activity areas should generally follow ecological boundaries, watersheds and topographic breaks. Activity areas should be distributed such that no less than 7,000 acres exists between them. (G)

Inventory, monitoring, and short duration activities (generally 10 days or less) such as trail maintenance, spraying weeds, range maintenance activities, should be concentrated in time and space. Activities should be concentrated in one consecutive 30-day period each year, between April 1 and September 15 (G)

Management activities may take place during winter (December 15 to April 1) and shall be addressed on a case-by-case basis. The primary concern during the winter will be the changes the activity may have on habitat quality and quantity. (G)

Administrative Responsibilities - Emergency cessation or modification of activities will occur when those activities are in conflict with grizzly bear management objectives. Scheduled activities will not occur during the season of bear use in areas where foraging opportunities are limited in their availability, in area, or time. (S)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	TMARD 2/	N/A	<= 0.8 mi/sq.mi.
	OROMTRD 2/	N/A	<= 0.6 mi/sq.mi.
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes 3/	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ TMARD = Total motorized access route density: includes all open and restricted roads and motorized trails. (See Roads in Glossary for more information)

OROMTRD = Open road and open motorized trail route density. includes all open roads and open motorized trails. (See Roads in Glossary for more information)

3/ Cross-country snowmachine use is only allowed from Dec 15 to April 1.

Roads

New or relocated roads will meet the following guidelines' (G)

1. Avoid high quality (such as whitebark pine habitat) grizzly bear habitat.
2. Minimize sight lines on temporary roads and skid trails.

3 Revegetate temporary roads following use

4. Minimum required construction standards will be followed.

Motorized administrative use on restricted roads and restricted motorized trails by personnel of resource management agencies is acceptable at low intensity levels as defined in existing cumulative effects analysis models. This includes contractors and permittees in addition to agency employees. (See Roads and Trails in the Glossary for definitions) (S)

Recreation

Special Uses - Special Use Activities which adversely affect grizzly bear populations or their habitat will not be permitted. (S)

Trails - New or relocated trails will meet the following

1. Avoid high quality grizzly bear habitat (G)

2. Locate so as to minimize the risk of human/bear interactions (for example, do not place trails along roaring streams where bears cannot hear humans approaching). (G)

ROS - Primitive to semi-primitive motorized. (G)

VQO - Retention to partial retention. (G)

Production of Natural Resources

Timber

These lands are included in the suitable timber base. They contribute toward the ASQ, but are a NIC. (S)

There will be no vegetation manipulation in riparian areas in the spring or in whitebark pine areas in the fall (except in years of poor cone crops). (G)

Scarification is limited to ≤ 15 percent of an area where soil disturbance impedes the re-establishment of grizzly bear foods (for example: where berry producing shrubs are present such as blue huckleberry, mtn. ash, chokecherry, buffaloberry, grouse whortleberry, etc.; where wet site species are present such as horsetail, cow parsnip, camas, wet-site carex spp, etc.) (S)

Scarification of *Carex geyeri* and *Carex rossii* is allowed at levels above 15 percent since these species readily re-establish following scarification. (G)

Cover - Maintain > 70 percent of the forested acres in each analysis area in vegetation that provides security cover for the grizzly bear. Where security cover is below 70 percent, no treatments are allowed which would further reduce the number of acres meeting security cover. (S)

Security cover is defined as forested acres (all tree species) which have not been managed or burned in the last 20 years, and managed or burned forested areas within the last 20 years which meet the following criteria (G)

Overstory Basal Area of trees 5.0"+	Understory Trees/ac. 0-4 9" and 7'+	Acreage Multiplier
130+ sq. ft. per acre	250+	1.0 (Good)
80-129 sq. ft. per acre	150-249	0.7 (Medium)
30-79 sq. ft. per acre	50-149	0.4 (Poor)

The overstory and understory categories for security cover are to be considered separately. A stand having either 130 sq. ft. of basal area per acre or 250 understory trees per acre over 7 ft. tall would meet the requirements for full security cover. Both live and dead tree basal areas are used for overstory calculations. (S)

Maintain > 20 percent thermal cover in each analysis area. Where thermal cover is below 20 percent, no treatments are allowed which would further reduce the number of acres meeting thermal cover criteria. Thermal cover is defined as forest stands with >80 sq. ft. of basal area per acre (live and dead trees), >45 percent canopy closure, and >40 ft tall trees. (S)

Maximum distance to security cover will be 300 feet, which translates to a maximum created opening width of 600 feet. (S)

Created openings will be located at least 1500 feet from open roads. A clearcut and seedtree cut result in created openings. Final removal of a shelterwood or an overstory removal result in a created opening if the stand is less than 7 feet tall or less than stocking standards. (S)

No new created openings are allowed adjacent to existing openings (including meadows and created openings). Maintenance of natural openings is allowed. (S)

Leave strips between openings will be the larger of 600 feet or 3 times the sight distance (the distance needed to hide 90% of a grizzly bear). (S)

Dead & Down Component - If available, leave at least 2 pieces per acre over 12 inches in diameter. Woody material should be in various stages of decay if possible. If a treatment area is below Forestwide standards, use the treatment to increase down woody material to recommended amounts. (G)

Security Areas - Maintain a minimum 7,000 acre security area adjacent to each timber sale area. (S)

Security areas must provide the following conditions: (S)

1. Within the security area, TMARD (8 mi/sq.mile) and OROMTRD (.6 mi/sq mile) must be < the density established for this management prescription.
2. Within the security area, security cover must be greater than or equal to the amount established for this management prescription.
3. No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated as a security area.

Range

Opportunities to resolve domestic sheep and grizzly bear conflicts over time are defined as a suitable or favorable time to abolish or close an allotment because of nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit. If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas. (G)

Cattle grazing is allowed. Allotment Management Plans will specify measures to meet agency grizzly goals and objectives. (S)

Permittee's full compliance in meeting grizzly bear management goals and objectives for grizzly bear habitat will be a condition of the permit. In addition, the following will be required: (S)

1. Temporary cessation or modification of permitted livestock grazing activities will occur to resolve grizzly bear conflicts with humans or livestock.
2. Livestock carcasses will be disposed of or rendered unattractive to bear within 24 hours after they are discovered. Disposal may include removing the carcass from the area, burying it at least 2 feet underground, burning, using an acceptable chemical repellent, or other methods approved by the District Ranger. Disposal shall be in accordance with other governing agencies (e.g., the Wyoming Department of Fish and Game) in order to determine cause of death for reimbursement purposes.
3. Human food, refuse, and prepared livestock/pet foods associated with the livestock operation will be made unavailable to grizzlies through proper storage, handling, and disposal. Proper storage includes a) inside a bear-proof container, b) suspended horizontally from adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger. The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported. Unburned human foods, garbage or other refuse will be carried off the Forest as often as practical.
4. High quality food production areas for grizzlies (i.e. wet alpine and subalpine meadows, stream bottoms, aspen groves, and other riparian areas) will receive special grazing direction such as light, once-over grazing, special utilization standards, or complete closure. These sites and their corresponding direction will be identified in the Annual Operating Plan.
5. Livestock depredation believed to be associated with bears will be reported within 24 hours after they are discovered to the District Ranger and the proper State agencies.
6. Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical.
7. Any action taken by the permittee or their agents which violates the Endangered Species Act will be grounds for cancellation of their grazing permit.

5.4 (a,b,c) ELK AND DEER SUMMER RANGE

Description

This management prescription emphasizes management actions and resource conditions which provide increased security for big game species, and hunting opportunities with limited access. Habitats are managed for multiple land use benefits, but these uses are managed over time and space to provide security and cover for hunted big game species.

Spring, summer, and fall forage is abundant and well distributed throughout the area. Hiding and thermal cover is abundant and in large patches to provide security for big game throughout the spring, summer, and fall seasons. Big game movements and migrations are facilitated due to well distributed forage and cover.

Timber management emphasizes providing a variety of forested age classes, with large blocks of forested vegetation providing hiding cover. Security areas are provided adjacent to areas where timber harvesting is occurring.

Motorized access is managed to provide security for big game. Motorized summer use will occur only on designated routes.

Livestock grazing exists in some areas; forage utilization, water developments, grazing systems, and other livestock management actions are managed to be compatible with big game habitat needs.

Dispersed recreation, mining activity, and other multiple uses are managed in time and space to help provide security habitat for big game animals.

Goal

Provide big game security areas while allowing for other resource activities.

Objective

Utilize silvicultural techniques which prevent or lessen insect and disease epidemics to maintain cover values for elk.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

Use prescribed fire to improve forage production, assist in forest regeneration and enhance ecological conditions. (G)

Biological Elements

Wildlife

Maintain snag habitat at > 60 percent of the biological potential for woodpeckers. (G)

Forest Use and Occupation

Access (S)

5 4 (a)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	No	Yes
	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	<= 0.5 m/sq.mi.
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes 3/	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ OROMTRD = Open road and open motorized trail route density; includes all open roads and open motorized trails. (See Roads in Glossary for more information)

In 5.4 (a) prescription areas <= 5 0 sq mi. in size, OROMTRD does not apply.

3/ Cross-country snowmachine use is only allowed from Dec 1 to April 30.

5 4 (b) The same as (a) above, except No Motorized trail and road travel is allowed, the OROMTRD is 0.0 miles/square mile, and snowmachine use is not allowed.

5 4 (c) The same as (a) above, except Mountain Bike/Mechanized is allowed for cross country travel and the OROMTRD is < 1.25 miles/square mile.

Game Retrieval

Same as 2 7 a, b Elk and Deer Winter Range except. not allowed in 5.4b.

Recreation

ROS - Primitive to urban. (G)

VQO - Retention to partial retention. (G)

Production of Natural Resources

Timber

These lands are part of the suitable timber base. They contribute toward the ASQ. (S)

Manage for big game security in forested blocks > 250 acres (a forested block is defined as adjacent stands of saplings, pole, mature and old growth trees). (S)

For the forested component within the prescription area, no more than 20 percent of the acres will be in a created opening at any point in time (a created opening is defined as a) clearcuts (nonstocked and seedling stages); b) seed cuts of a shelterwood (nonstocked and seedling stages); or c) group selection (nonstocked and seedling stages). (S)

Naturally occurring forested blocks less than 250 acres in size, may have 20 acre harvest units, with no more than 20% of the block in the created opening category at one time (G)

For scheduling harvest activities, adjacent big game security areas will be provided. Security areas must provide the following conditions: (S)

1. Security areas will be > 250 acres in size, or as large as the timber sale area boundary, whichever is greater.
2. Within the security area, OROMTRD must be \leq the density established for this management prescription.
3. No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated as a security area.

Range

Allotments are managed at FRES levels A , B, C or D. (G)

6.1 (b) RANGE MANAGEMENT

Description

The purpose of this management prescription is to achieve and maintain healthy nonforested rangelands for livestock forage production and good watershed condition.

Forage is provided on a sustained-yield basis that protects rangeland values, including domestic livestock grazing and wildlife habitat. Cattle, sheep, horses, and perhaps other domestic livestock can often be seen. Important seasonal ranges for big game animals exist in many of these areas. Not all areas are grazed by domestic livestock, some areas may be reserved for wildlife and watershed restoration work. Range improvements, such as fencing, corrals, and water developments, are present. Roads, trails, and stock driveways exist, as needed, to provide access for livestock management. Vegetation manipulation (with the use of fire, mechanical means, or herbicides) may occur to achieve or maintain healthy rangeland conditions. A variety of rangeland vegetation successional stages can be observed. Herders, range riders, camps, and transport vehicles may be seen at various times and places. Dispersed recreation activity generally occurs throughout these areas.

Goal

Provide forage on a sustained-yield basis that protects rangeland values, including domestic livestock grazing, and wildlife habitat.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed as follows.

Ecological Processes

Fire/Fuels

Prescribed fire is allowed to achieve desired forage or ecological condition (G)

Forest Use and Occupation

Access (S)

6.1 (b)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	<= 2 mi/sq.mi. 2/
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information)

In 6.1 (b) prescription areas <= 40 sq. mi in size, OROMTRD does not apply.

Game Retrieval

Same as 2.7 a,b Elk and Deer Winter Range.

Outfitter/Guide

Outfitter/Guide stock are allowed; AUM's are specified in outfitter/guide permits and RPD's. (G)

Recreation

Dispersed - Limited recreation facilities, which are not detrimental to intensive range management, and other resources may be provided in this prescription. (G)

Opportunities may exist for some interpretative signs for public education. (G)

ROS - Semi-primitive nonmotorized to roaded natural. (G)

VQO - Retention to modification. (G)

Production of Natural Resources

Timber

These areas are removed from the suitable timber base. They are not part of the ASQ. (S)

Timber may be harvested to improve wildlife habitat and to provide miscellaneous products (such as posts & poles, firewood, etc.) as long as the harvest does not trigger the need for reforestation. (G)

Range

Allotments are managed at FRES levels A, B, C & D. (G)

7.1 (b) INTERMINGLED PUBLIC/PRIVATE LANDS

The purpose of this prescription is to provide fuels management within and adjacent to urban areas of the Forest. Timber management will only be done with selective or patch cut harvest methods, and will not contribute toward the ASQ.

Description

The emphasis is on fuels management within and adjacent to urban areas of the Forest, nonscheduled wood-fiber production and use, livestock production, and on other compatible commodity outputs, consistent with adequate protection of all resource values and consideration for long-term forest health and biodiversity.

Overall, you notice many signs of people. You see a fairly extensive roading system and timber harvest activity in some areas. The main road system is gravel-surfaced and well maintained, with gentle grades suited for sedan travel. You may see timber harvest equipment at roadside and meet logging traffic along the roadway. You will see other people driving for pleasure or hauling out a load of firewood. Driving a sedan you can travel about two-thirds of the main road system. About one-third of the main road system is closed for wildlife security or roadway protection.

You notice some low-standard branch roads with native and gravel surfaces. Most of these low-standard roads are closed annually or seasonally to vehicle access. About two-thirds of the closed roads are blocked seasonally by gates, and about one-third are blocked year-round by semi-permanent barricades and gates. Some branch roads remain open for public access, for commodity production and for Forest Service administration.

The forest is a mosaic of different sizes, ages and heights. Older, taller trees tend to dominate the landscape, but small, patch openings with smaller trees are obvious. Recently cut areas have a partial canopy of older trees and no new clearcuts have been made since implementation of the Revision. Older clearcut areas have seedlings, saplings, poles, and older trees up to 35 feet tall and have a less disturbed appearing forest floor. Dead trees from the mountain pine beetle infestation are seen in older stands and scattered throughout the rest of the forest.

Firewood is available, by permit, from dead trees, designated aspen areas, slash and logs decked for that purpose.

If you watch wildlife, you will see an increase in the early seral species like the snowshoe hare, mountain bluebird, and ruffed grouse with a corresponding reduction in such mature-growth-dependent species as the martin, red-breasted nuthatch, and goshawk. Elk and deer numbers have generally increased somewhat in recent years. However, due to human activity, increased hunting pressure, and reduced wildlife security some elk and other big-game have been displaced to areas with greater security. Over time, big-game seasons may have been shortened or restricted. Because of the setting, outfitted hunting may not be as common as it is in less-developed areas.

During the summer and fall you encounter cattle or sheep and notice signs of intensive management practices, such as burning, spraying, seeding, fences, cattleguards, water developments and gates. You see some cattle within streamside riparian areas and on nearby slopes. Away from the streams, you see scattered groups of livestock. You may find traffic delays when livestock is being moved.

You find such nonmotorized activities as hiking, biking and horse-back riding along roads closed to vehicle traffic. Some roads and areas are available for snowmobile, motorcycle, and 4-wheel-drive vehicle use.

Goals

1. Manage vegetation and fuels to minimize fire risk for urban facilities within the interface.
2. Manage these lands in an environmentally sensitive manner to promote the production of commodity and noncommodity resources.

Standards and Guides and Objectives

Same as 5.1.3 (and 5.1) except.

1. OROMTRD does not apply to prescription areas less than or equal to 1.0 square miles. (S)
2. No Game Retrieval Access is Allowed. (S)
3. No ASQ. (S)
4. VQO's of Maximum Modification are allowed. (G)

8.1 CONCENTRATED DEVELOPMENT AREAS

Description

This prescription applies to all existing concentrated developments including active mines, borrow pits, gravel pits, electronic sites, utility corridors, and administrative sites (including guard stations and rental cabins). Concentrated development is normally small, but may be extensive on occasion. A wide variety of vegetation and landtypes may be present. This category is often surrounded by other management areas.

These are generally highly developed areas with much evidence of people, structures, roads, and often disturbed ground. High noise levels sometimes emanate from these sites due to the use of heavy equipment or blasting at various times. Other sites are collections of buildings and storage structures from which the administration of the National Forest is carried out. Some closed gates and restrictions on travel may be present in order to protect equipment and developments.

Goal

Allow concentrated development in small areas for mineral development and infrastructure needs.

Objectives

- 1. Restrict development of concentrated development sites to the smallest area possible.
- 2. Develop new communication sites when existing site capacity has been reached, or when new technologies require new locations, or to meet public needs when alternative sites on other lands are not suitable or available
- 3. Obtain materials from commercial sources or borrow sites identified in the Forest "Compendium".

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes

Fire/Fuels

All wildfire will be aggressively suppressed. (S)

Insects & Disease

Attempt to control epidemics at small outbreak sizes. Salvage of dead and dying trees of commercial value is possible. (G)

Forest Use and Occupation

Access (S)

		Cross Country Travel	Road and Trail Travel 1/
	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
	Motorized, <50" wide	No 2/	Yes
	Motorized, >50" wide	No 2/	Yes
	OROMTRD 3/	N/A	N/A
	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the annual Forest Plan Travel Maps.

2/ Motorized use is not allowed, except as authorized in a site specific analysis.

3/ OROMTRD = Open road and open motorized trail route density: includes all open roads and open motorized trails. (See Roads in Glossary for more information)

Recreation

Dispersed - Do not encourage use of areas in proximity to these sites. (G)

Trails - Protect existing trails and wherever possible avoid development of trails in or near concentrated development sites. Where feasible move existing trails away from these areas. (G)

ROS - Semiprimitive nonmotorized to urban. (G)

VQO - The Visual Quality Objective (VQO) is generally Partial Retention to Maximum Modification (G)

Production of Natural Resources

Timber

These lands are removed from the suitable timber base. They do not contribute to the ASQ. (S)

Chapter

IV

Implementation Schedules

CHAPTER IV IMPLEMENTATION SCHEDULES

Implementation of the Revision occurs through identification, selection, scheduling and execution of management practices to meet management direction in the Revision. A list of activities that the Forest has decided to complete in the future that tie to decisions is provided below. This list is not inclusive of all the activities and projects the Forest will undertake in the coming decade, but rather those activities that will aid in implementation.

These listing will routinely change as projects get completed or are removed from the lists for other reasons, and new projects take their place. Projects will be implemented in response to public demand, planned outputs of goods and services in this Revision and the annual budgeting process and resource concern priorities.

Categories are listed by issue group, as identified in the DEIS

ECOLOGICAL PROCESSES

Objective

By 2007, establish the range of natural variability of vegetation conditions by subsection for the Forest.

BIOLOGICAL ELEMENTS

AQUATIC AND RIPARIAN RESOURCES, AND WATERSHEDS

Objectives

1 By 2017, watershed improvement needs backlog would be completed in the Lemhi/Medicine Lodge, Big Holes/Palisades, Caribou Subsections. Watershed improvement needs identified in the Teton Basin Study would be verified. Watershed improvement needs inventories would be completed on the Centennials, Madison Plateau, and Teton Subsections.

2. By 1998, all streams supporting native cutthroat trout would be inventoried, classified, and delineated. Restoration activities would be planned and scheduled for stream reaches found to be in unsatisfactory condition.

2.8.3 AQUATIC INFLUENCE ZONE

Objectives

1. Within three years of the Record of Decision, all existing roads, trails, culverts, fords and stream crossings within these lands will be inventoried and evaluated as to whether they meet management prescription goals. Those that do not meet management prescription goals will be scheduled for restoration.

2. Establish the range of variability for aquatic influence zone characteristics.

WILDLIFE

Objective - Snag/Cavity Nesting Habitat - Determine the biological potential for cavity nesting habitat on a watershed basis to enable management of some areas at higher levels of biological potential and some at lower levels of biological potential and meet the overall management prescription objectives.

Road Density - Implement the road density standards in the bear management units within 3 years of the signing of the ROD in coordination with USFWS and State Wildlife agencies. Complete the balance of the road density standards in the remainder of the decade.

Common Loon Habitat - Evaluate the potential to provide and maintain suitable breeding habitat for common loons at these sites: Indian Lake, Thompson Hole, Bergman Reservoir, Junco lake, Fish Lake, Loon Lake, Moose Lake, Unnamed Pond (Sec. 9, T47N, R118W).

Develop common loon management plans for the above sites if the evaluation indicates there is potential to provide and maintain suitable breeding habitat.

Spotted Bat and Western Big-eared Bat Habitat - Develop management plans for any caves, mine shafts, and other suitable habitats where these bat species are found to be present

2.3.5 GRIZZLY BEAR HABITAT

Objective - Fire/Fuels - Develop a fire management plan (coordinate with any adjacent wilderness fire plans) within 1 year of ROD.

NONFORESTED VEGETATION

Objectives

1. By 2007, improve the ecological status of 1,200 acres of riparian habitat presently reported as early seral stage to mid-/ late-seral stage.
2. By 2007, improve 26,400 acres of uplands (nonriparian and nontimber plant communities) currently reported as unsatisfactory ecological condition to satisfactory condition.
3. By 2007, grazing systems will be implemented on all grazing allotments to meet Range Goals I and II.
4. Within five years after the signing of the Record of Decision establish stream bank stability (trampling disturbance) standards correlated to stubble height at the hydric greenline.

FOREST USE AND OCCUPATION RECREATION

Objective - Dispersed - By 2007, stabilize soil, water, and vegetation conditions to maintain the desirable recreation setting on approximately 100 of the 300 identified dispersed recreation sites in greatest need of restoration. These sites would have limited developed facilities.

Trails - Complete a review of 5-10% of the system trails each year to determine rehabilitation needs.

Wild, Scenic and Recreation Rivers - By 2002, the 249 miles of inventoried eligible streams will have suitability studies completed. Priority would be on the South Fork of the Snake River Basin, approximately one-third of the streams would be done at a time.

8.1.6 DESIGNATED WILDERNESS - OPPORTUNITY CLASS I

Objective

Cooperate with the State Game and Fish Departments to prepare a Wilderness fishery management plan by the year 1999.

Forest Plan Revision - Capital Improvements Projects (CIP) List By Approximate Year of Construction			
Year	Project	Locations	Cost
1996	SST's -- 4 doubles	Stoddard, Upper Coffee, Big Elk, Teton Canyon Campground Rehabilitation and new group site	\$129M
1996	Buttermilk/Calamity		\$252M
1997	Water Systems	Warm River, Big Elk, Cave Falls, (Mike Harris and Steel Creek if \$ will stretch)	\$159M
1998	Reunion Flat rehabilitation		\$193M
1998	Blowout CG rehab/const (8-10 new units)		\$216M
1999	Trail Facilities (GWT, mtce - some new construction of TH's)		\$219M
1999	Buffalo CG rehabilitation		\$275M
2000	Cottonwood Boat Ramp (some new construction)		\$168M
2000	Charcoal Kilns (protective covers)		\$132M
2001	Water systems	Stoddard, Big Elk	\$244M
2001	Warm River CG Rehab, and SST		\$202M
2002	Big Falls Inn		
2002	Upper Coffee Pot rehabilitation		
2003	Water systems	Mike Harris, Box Canyon, Steel Creek, Alpine Alpine, Mike Harris	\$200M
2003	SST's		\$200M
2004	McCrea rehabilitation		
2004	Riverside rehabilitation/ramp		
2005	Big Elk rehabilitation		
2005	Palisades TH/bridge (some new construction)		
2006	Howard Springs picnic rehabilitation		
2006	Wilderness TH's (some new construction)		
2007	Lower Mesa parking, etc.		
2007	Webber Creek relocation		
<p>AS POSSIBLE - projects of construction/reconstruction <\$100M will be funded out of Forest Budget as funding is available. Projects to be selected by Forest Recreation Committee and Rangers from a priority list established by the committee. ANNUALLY - 4-6 miles of trail construction/reconstruction to be submitted \$60M</p>			
CG = Campground, SST = Sweet Smelling Toilet, TH = Trail Head			

JEDEDIAH SMITH WILDERNESS
Wilderness Implementation Schedule
October 1, 1997 - September 30, 2001

FY98 Schedule of Activities			
Activity	Due Date Priority	Responsibility	Cost Expanded Budget Line Item
Ecosystem Management			
Maintain signs at trailheads that address various users of the Wilderness	9/98 2	Recreation	\$ 500 NFWM
Coordinate management of wilderness with both districts	9/98 1	Recreation	
Coordinate recreation and wildlife planning	9/98 1	Recreation Wildlife	
Develop Watershed Improvement Needs Inventory	9/98 1	Resources	\$ 3,500 NFSO/SI
Develop Air Quality Monitoring Plan	12/98	Resources	\$ 2,500 NFSO
Develop Baseline Water Quality Monitoring Plan	9/98	Resources	\$ 2,000 NFSO
Continue plant surveys for noxious, t, e, and s species	9/97	Resources	\$ 3,000 NFWM
Recreation			
Continue monitoring based on Forest Plan	9/98 1	Recreation	\$ 2,000 NFWM
Update baseline data with Grand Targhee Ski Resort coordination	9/98 1	Recreation	\$10,000 NFWM
Continue evaluation and inventory of intruding manmade features	9/98 2	Recreation	\$ 3,000 NFWM
Education			
Develop education plan for local schools	9/98 1	Recreation	\$ 2,000 NFWM
Develop ethics orientation plan for permittees	9/98 1	Recreation	\$ 2,000 NFWM
Develop ethics orientation plan for internal employees	9/98 1	Recreation	\$ 2,000 NFWM
Develop education plan for organizational camps	9/98 1	Recreation	\$ 2,000 NFWM
Provide information on wilderness ethics to frontliners for public	5/98 1	Recreation	\$ 500 NFWM
Continue contact with users of mountain bikes, motor bikes, game carts	5/98 1	Recreation	
Lands			
Continue boundary survey	9/98 1	Lands	\$30,000 NFLA
Sign portions of boundary requiring identification	9/98 1	Recreation	\$ 2,000 NFWM

FY98 Schedule of Activities			
Activity	Due Date Priority	Responsibility	Cost Expanded Budget Line Item
Law Enforcement			
Revise winter law enforcement plan to protect wilderness boudary	9/98 1	Law Enforcement	\$70,000 NFWM
Revise MOU with NPS for winter law enforcement	9/98	Law Enforcement	
Wildlife/Fisheries			
Develop MOU for fish stocking with F&G	9/98 1	Wildlife	
Develop Wilderness Fish Management Plan with F&G	9/98	Wildlife	
Develop monitoring plan with F&G for bighorn sheep	9/98	Wildlife	\$ 3,000 NFWL

FY99 Schedule of Activities			
Activity	Due Date Priority	Responsibility	Cost Expanded Budget Line Item
Ecosystem Management			
Coordinate management of wilderness with both districts	9/99 1	Recreation	
Coordinate recreation and wildlife planning	9/99 1	Recreation Wildlife	
Watershed Improvement Projects from WINI	9/99 1	Resources	\$ 6,000 NFSO/SI
Air Quality Monitoring Scheme Developed	12/99	Resources	\$ 3,500 NFSO
Continue Baseline Water Quality Monitoring	9/99	Resources	\$ 3,500 NFSO
Continue plant surveys for noxious, t, e, and s species	9/99	Resources	\$ 3,000 NFWM
Recreation			
Continue monitoring based on Forest Plan	9/99 1	Recreation	\$ 3,000 NFWM
Update baseline data with Grand Targhee Ski Resort coordination	9/99 1	Recreation	\$10,000 NFWM
Continue evaluation and inventory of intruding manmade features	9/99 2	Recreation	\$ 3,000 NFWM
Education			
Continue education plan for local schools	9/99 1	Recreation	\$ 2,000 NFWM
Continue ethics orientation plan for permittees	9/99 1	Recreation	\$ 2,000 NFWM
Continue ethics orientation plan for internal employees	9/99 1	Recreation	\$ 2,000 NFWM
Continue education plan for organizational camps	9/99 1	Recreation	\$ 2,000 NFWM
Provide information on wilderness ethics to frontliners for public	5/99 1	Recreation	\$ 500 NFWM
Lands			
Continue boundary survey	9/99 1	Lands	\$30,000 NFLA
Sign portions of boundary requiring identification	9/99 1	Recreation	\$ 2,000 NFWM

FY99 Schedule of Activities			
Activity	Due Date Priority	Responsibility	Cost Expanded Budget Line Item
Law Enforcement			
Update winter law enforcement plan to protect wilderness boudary	9/99 1	Law Enforcement	\$50,000 NFWM
Revise MOU with NPS for winter law enforcement	9/99	Law Enforcement	
Wildlife/Fisheries			
Continue MOU for fish stocking with F&G	9/99 1	Wildlife	\$ 3,000 NFWL
Continue Wilderness Fish Management Plan with F&G	9/99	Wildlife	\$ 3,000 NFWL
Continue monitoring plan with F&G for bighorn sheep	9/99	Wildlife	\$ 3,000 NFWL

FY00 Schedule of Activities			
Activity	Due Date Priority	Responsibility	Cost Expanded Budget Line Item
Ecosystem Management			
Coordinate management of wilderness with both districts	9/00 1	Recreation	
Coordinate recreation and wildlife planning	9/00 1	Recreation Wildlife	
Watershed Improvement Projects from WINI	9/00 1	Resources	\$ 6,000 NFSO/SI
Air Quality Monitoring Scheme Developed	12/00	Resources	\$ 3,500 NFSO
Continue Baseline Water Quality Monitoring	9/00	Resources	\$ 3,500 NFSO
Continue plant surveys for noxious, t, e, and s species	9/00	Resources	\$ 3,000 NFWM
Recreation			
Continue monitoring based on Forest Plan	9/00 1	Recreation	\$ 3,000 NFWM
Update baseline data with Grand Targhee Ski Resort coordination	9/00 1	Recreation	\$10,000 NFWM
Continue evaluation and inventory of intruding manmade features	9/00 2	Recreation	\$ 3,000 NFWM
Education			
Continue education plan for local schools	9/00 1	Recreation	\$ 2,000 NFWM
Continue ethics orientation plan for permittees	9/00 1	Recreation	\$ 2,000 NFWM
Continue ethics orientation plan for internal employees	9/00 1	Recreation	\$ 2,000 NFWM
Continue education plan for organizational camps	9/00 1	Recreation	\$ 2,000 NFWM
Provide information on wilderness ethics to frontliners for public	5/00 1	Recreation	\$ 500 NFWM
Lands			
Continue boundary survey	9/00 1	Lands	\$30,000 NFLA
Sign portions of boundary requiring identification	9/00 1	Recreation	\$ 2,000 NFWM

Chapter

Monitoring and Evaluation

CHAPTER V

MONITORING AND EVALUATION

INTRODUCTION

In the preceding chapters of the Revision, the Forest Service has identified general management direction in terms of goals and objectives, and committed itself to carry out that direction. Monitoring and evaluation provides an opportunity for the agency to demonstrate how it is complying with the standards and guidelines, and whether or not the standards and guidelines are performing in the predicted manner. In essence, it answers the question, "Are we doing what we said we would do?", and "Are our assumptions that we based decisions and allocations on correct?"

A monitoring and evaluation plan is required by Forest Service planning regulations, which stipulate a report will be issued at the mid-point of the planning cycle. The Forest plans to issue a monitoring report annually, to better demonstrate progress toward meeting goals and objectives, and to identify as early as possible any needed changes to the Revision.

RELATIONSHIP TO OTHER MONITORING ACTIVITIES

This plan shows how the Forest will monitor compliance with, and performance of, standards and guidelines and assumptions in the Revision. The monitoring activities listed in this plan are only a part of a larger range of monitoring activities which take place on the Forest.

Often additional specific monitoring requirements are determined in planning and analysis which support specific projects (known as the NEPA process). Though these monitoring activities are conducted independently of Revision monitoring, there will often be an overlap between the two in that project monitoring can give some indication of how Revision standards and guidelines are working, or accomplishment of Revision goals and objectives. Monitoring of randomly-selected projects for compliance with Revision standards and guides is also conducted.

The Forest conducts some monitoring which is required by law or regulation and which may not necessarily demonstrate how the Revision is working. An example of this type of monitoring is regeneration surveys which are done in timber harvest units. Additionally, some contract administration provides information on how Revision goals and objectives are being met, and provides information on compliance with standards and guides.

The research branch of the Forest Service conducts a wide range of trials and experiments to determine the causes of resource problems, or to improve resource management. The results of these scientifically-rigorous experiments are documented in research technical reports and serve to validate current goals, objectives, standards and guidelines, or to recommend changes to them. This type of monitoring is crucial to the adaptive management approach the Forest has taken.

Collectively, all of the above-mentioned efforts, and other day-to-day work not discussed here, comprises a large body of monitoring work of which Revision monitoring is an important part. While not all of the items monitored by these other efforts are expressly listed in the Revision Monitoring Plan, there is often much overlap between them and they are closely related.

TYPES OF MONITORING

Three levels of feedback can be had regarding performance of the Revision. A type of monitoring is associated with each level. The three types of monitoring are implementation, effectiveness and validation.

Implementation monitoring answers the question, "Are projects and activities being implemented in compliance with the standards and guidelines?" Implementation monitoring forms the basis for the other types of monitoring, since those cannot be conducted unless projects and activities comply with Revision standards and guidelines. Thus this may be the most important of the three types, and needs to be conducted most often.

Effectiveness monitoring answers the question, "Is implementation of the standards and guidelines giving us the results we expected?" Effectiveness monitoring often means quantitatively assessing the effects of management actions. Since this may require quite a bit of data, effectiveness monitoring is generally conducted on a limited basis dealing with sensitive areas and activities that pose higher risks of adverse effects on Forest resources, or address items of high public interest. Once the question of whether effects are as expected is answered, then implementation monitoring is sufficient.

Validation monitoring answers the questions, "Are these results what we really want? Are there better ways to meet the Revision goals and objectives?" Validation monitoring is usually conducted when there is reason to question basic assumptions or coefficients, such as when these are not reasonably supported by existing research. Monitoring focuses on items of strong public interest, agency concern, diversity of opinion, or those that have the potential to be unduly lax or restrictive. This type of monitoring may require a partnership with the Research branch and long-term investigations. Once an item is validated, as with effectiveness monitoring, then implementation monitoring is sufficient.

WHAT ITEMS WILL BE MONITORED?

To maximize the efficiency of the overall monitoring effort, the Forest has focused on certain critical items, identified partners, and will measure as many items as possible with the least number of indicators. The items selected for Revision monitoring met these important criteria, among others.

- * critical planning assumptions;
- * activities with the greatest risk to resources;
- * most potentially constraining on outputs.

The items are listed in brief in the accompanying Monitoring Item Summary, and in greater detail in the individual Monitoring Item Descriptions on the following pages.

MONITORING AND THE BUDGET

The monitoring program outlined here is the optimal level, assuming the Revision is fully-funded. It is unlikely that annual budgets will fully fund the monitoring effort shown here. Priorities for the annual monitoring effort will be based on annual budgets and program direction, and on the priority of the item, in descending order, from Forest Priority Group 1 to Forest Priority Group 3.

The cost of annually monitoring the items in Priority Groups 1, 2 and 3 is as follows:

<u>Priority Group</u>	<u>Cost for Entire Group</u>
1 (5 items):	between \$ 14,270 and \$ 17,770;
2 (9 items):	between \$131,650 and \$141,650;
3 (13 items):	between \$114,850 and \$129,350;
Total Program Cost (27 items):	between \$260,770 and \$288,770.

MONITORING ITEM SUMMARY

Monitoring Item	Forest Priority Group	Page
PHYSICAL ELEMENTS		
Air Quality		
Long-term visual in Class I, II	3	V-5
Soils		
Hydrologic Disturbance in Watersheds	1	V-6
Woody Residue Needs (Soil/Wildlife)	1	V-6
Detrimental Soil Disturbance	2	V-8
Fine Organic Matter Retention	3	V-8
BIOLOGICAL ELEMENTS		
Aquatic/Riparian		
Improvement of WQL Streams	2	V-9
Application of BMP's	3	V-10
Wildlife		
Goshawk Habitat Standards	1	V-11
Grizzly Bear Habitat Improvement	1	V-12
Biological Diversity Study	3	V-13
Standing Dead Tree Habitat	3	V-14
FOREST USE AND OCCUPATION		
Forest Users		
User Satisfaction	2	V-16
Recreation		
Seasonal Trail Use Impacts to Soil + Veg	2	V-17
Recreation/Wildlife Conflicts	2	V-17
Dispersed Campsite Soil Displacement	3	V-18
Jedediah Smith Wilderness LAC	3	V-19
Roads and Trail Access		
Authorized Use/Game Retrieval Use Level	2	V-23
Road Closure Effectiveness	2	V-23
Achievement of Road Density Standards	2	V-25
PRODUCTION OF NATURAL RESOURCES		
Range		
Riparian Plant Use/Trampling	2	V-26
Riparian Forage Utilization	2	V-26
Upland Forage Utilization	3	V-27
AMP Planning/Admin Site Use	3	V-28
Upland Forage Utilization	3	V-29
Sage/Grassland Canopy Coverage	3	V-29
Timber		
Changes to Land Suitability	1	V-30
Maximum Created Opening Size	3	V-30
Security Cover Retention	3	V-31
Large Forested Block Retention	3	V-32

HOW WILL THE MONITORING INFORMATION BE USED?

The results of annual monitoring activities **will** be evaluated to either verify that the current actions and standards are correct; or to determine the **need** to change actions and standards. This evaluation will be assembled into an annual report and **made** available to Forest stakeholders

Based on the information included in the **annual** reports the Forest will identify any changes needed to actions or standards. Depending on the **magnitude** of the change required the Forest may amend the Revision with either a minor (**nonsignificant**) amendment, or a major (**significant**) amendment. If the changes needed are of such a **large magnitude** that it is not feasible to amend the Plan, a Revision Revision may be called for.

The Monitoring Item Descriptions contain **certain** information categories about each item. These categories are briefly explained below.

Monitoring Item - What is the subject **of the** monitoring? This will often tie back to a particular Revision standard or guideline.

Type of monitoring - Implementation, **Effectiveness** or Validation. The item may feature more than one type of monitoring, such as **effectiveness** and validation.

Priority - The Forest assigned each **monitoring** item to one of three group priorities **first, second** or third.

Where Applies - This targets those **areas of** the Forest where the monitoring would occur.

Indicator - This is the parameter(s) that **will be** used to show compliance or change For example, trails meeting acceptable standards **could be** measured in miles; area meeting standards for down woody residue might be measured in **acres**.

Method - How will the monitoring **be done**? This could be line transects for vegetation condition monitoring; or user surveys for recreation use. If partnerships can be developed for doing the monitoring, that should be mentioned **here**.

Expected Precision and Reliability

- **Precision** - How accurately can we **measure** the true conditions?
- **Reliability** - How reproducible are the **monitoring** results on repeated measurements?

Tolerance, or Variability Indicating Action - At what point will further action or a change in management be required?

Frequency of Monitoring - How often **will** monitoring be conducted?

Lead Responsibility - Who on the Forest **will see** that this gets done?

Estimated Annual Cost - What will it **cost the** Forest to do the monitoring?

MONITORING AND EVALUATION STRATEGY
Monitoring Item Description

PHYSICAL

Air Quality

Monitoring Item - Impairment of long-term visual range in Class I and Class II wilderness airsheds.

Type of monitoring - Implementation monitoring. The standards have not been quantified so there is also a need to establish a baseline.

Priority - Forest Priority Group 3.

Where Applies - Monitoring should be conducted in designated wilderness on the Forest; and other nonwilderness areas upwind from and adjacent to Class I airsheds and Class II wilderness airsheds managed by other entities.

Indicator - Visibility in miles.

Method - The following methods will be used.

1. Mounted, timed-exposure camera(s) established at fixed photopoint(s). The exposures should be evaluated periodically by density-monitoring devices in addition to ocular means.
2. Aerosol particle evaluation, to supplement information gathered by photographic means on days not meeting visual standards. These devices gather and evaluate information at the site only, not at remote locations on the visual evaluation track, and can help determine the particulate components of air not meeting standards to help discover the cause.

There appears to be ample opportunity for partnerships in this effort. Other federal agencies such as EPA, the U. S. Fish and Wildlife Service, and the National Park Service are already engaged in efforts of this type. The adjacent national parks, especially Grand Teton National Park, have been conducting some of this type of monitoring for some time, most recently in conjunction with their own prescribed burning activities which have increased since the 1988 Yellowstone fires. Within the Forest Service, the Bridger-Teton National Forest has conducted air quality monitoring for years in connection with oil and gas development activities. The Rocky Mountain Regional Office and Rocky Mountain Research Station both have shown interest in, and have expertise in, air quality monitoring

Expected Precision and Reliability

- Precision — High.
- Reliability — High.

Tolerance, or Variability Indicating Action — Reference standards.

Frequency of Monitoring - This will depend on local activities. Initially the frequency should be higher, until a baseline is established, perhaps at intervals of two to three times a week. After ambient conditions are determined frequency could be relaxed and targeted toward times when conditions exceed naturally-occurring ambient conditions, or the Forest is planning and conducting activities which threaten to exceed standards.

Lead Responsibility - The Forest fire management shop should take the lead responsibility for this monitoring.

Estimated Annual Cost

- * Installation of camera: \$2,000 per unit, or \$200/year;
- * Annual operation and evaluation cost: \$1,500 per unit;
- * Installation of aerosol monitoring unit: \$5,000 per unit, or \$500/yr ;
- * Annual operation and evaluation cost: \$1,500 per unit.

TOTAL COST: \$3,700/year

There has been money allocated at the national level to conduct some of this type of monitoring.

Soils

Monitoring Item - Watersheds which are 30% or more hydrologically disturbed.

Type of monitoring - Implementation, Validation

Priority - Forest Priority Group 1.

Where Applies - Watersheds 10, 11 and 12 (currently at or above the 30% level), and watersheds 13 and 25 (which are approaching the 30% level).

Indicator - Bank instability (natural versus management-induced) along representative stream reaches within the above-mentioned watersheds

Method - Rosgen stream-typing and Intermountain Region streambank stability ratings.

Expected Precision and Reliability

- Precision - Moderate.
- Reliability - Moderate.

Tolerance, or Variability Indicating Action - Determine if bank instability is occurring within the watersheds currently exceeding the 30% guideline Determine the sufficiency of the 30% guideline.

Frequency of Monitoring - Annually, until the 30% figure is validated or changed by appropriate study.

Lead Responsibility - Integrated effort lead by watershed specialists and aquatic scientists.

Estimated Annual Cost - \$4,500.

Monitoring Item - Dead and Down material for meeting soil and wildlife requirements on Forest.

Type of monitoring - Effectiveness/Validation

Priority - Forest Priority Group 1.

Where Applies - Subsection, Watershed, Stand (~25 acres), Site

Indicator -

A. size class, length, composition class to meet standards

1. logs of ≥ 7 " diameter @ small end and $\geq 20'$ length
2. ≥ 7 logs/acre in each of decomp classes 1,2,3.

B. acre or # acres (patch) dependent upon analysis approach and area size, species or life form (e.g. cavity-nesters) of interest.

C distribution/condition/availability

- 1 stand
2. subwatershed or watershed
3. landscape (incl. species type and sere(s))
4. subsection

D. follow "Woody Residue Requirements" incorporated within the Revision Standards and Guidelines package for the Revision (Soils, Item II).

Method - sampling in project or analysis areas by subsection by watershed/subwatershed, by type, elevation, and soil productivity class (IRI inventory).

Also, follow procedures outlined within "Guidelines for Sampling Some Physical Conditions of Surface Soils", by Steve Howes, John Hazard, and J. Michael Geist, Pacific Northwest Region, July 1983 (R6-RWM-146-1983). Sampling would be on line transects.

Role of partners will depend on the availability of funds and relation of partner skills to task needs.

Expected Precision and Reliability

- Precision - variable by type but generally high
- Reliability - high

Tolerance, or Variability Indicating Action - Changes in management will be necessary as:

- A. baseline studies (inventory) refine dead/down needs in varied forest types for species needs;
- B. monitoring of projects and comparison of results among treated areas demonstrate that current guidelines are in need of change.

Measures and need for change in both (a) and (b) should be determined through evaluations of site, stand and landscape conditions coupled with baseline forestwide (systematic) species inventories and improved knowledge of regional life history characteristics and requirements for various species of wildlife that use dead and down logs.

Frequency of Monitoring - (Soils) Prior to and following project analyses for each subsection. Analyses and evaluations should include site, stand and landscape conditions. For soils, monitoring would be conducted annually, until an adequate determination can be made for ground-disturbing resource management practices.

Lead Responsibility - (Soils) Monitoring teams including soils, vegetation and wildlife/ecology specialists.

Estimated Annual Cost - Will vary by the number of projects anticipated and planned to affect the distribution and abundance of dead and down material. Per analysis and project costs will vary, but will likely range from \$2,000 to \$4,000, depending on size of analysis area and levels of previous and expected disturbance. Costs do not include baseline inventories nor NEPA preparation.

Monitoring Item - Compliance with draft policy of 15% detrimental soil disturbance in activity areas.

Type of monitoring - Implementation and Effectiveness.

Priority - Forest Priority Group 2

Where Applies - Forestwide (select representative sites where various land treatments have occurred).

Indicator - At least 85% of the total area within an activity area must have soil in satisfactory condition, or, no more than 15% of an activity area may have detrimentally-disturbed soil. Detrimentially-disturbed soil is soil that has been displaced, compacted, puddled, or severely burned.

Method - Follow procedures in "Guidelines for Sampling Some Physical Conditions of Surface Soils", by Steve Howes, John Hazard, and J. Michael Geist, Pacific Northwest Region, July 1983 (R6-RWM-146-1983). Sampling would be done on line transects.

Expected Precision and Reliability

- Precision - Moderately high.
- Reliability - Moderately high.

Tolerance, or Variability Indicating Action - For those resource practices consistently exceeding the 15% threshold, determine if techniques can be improved or another method found. Evaluate areas with greater than 15% soil disturbance for rehabilitation opportunities.

Frequency of Monitoring - Annually, until an adequate determination can be made for various resource practices that are ground-disturbing.

Lead Responsibility - Forest or District soil scientist.

Estimated Annual Cost - \$5,000

Monitoring Item - Compliance with standard for retaining 50% of the fine organic matter (duff layer) in activity areas.

Type of monitoring - Implementation and Effectiveness.

Priority - Forest Priority Group 3.

Where Applies - Forestwide (select representative sites, or habitat types, where various land treatments have occurred)

Indicator - At least 50% (evenly distributed) of the total area within an activity area must retain its fine organic matter (duff layer plus materials less than 3-inches in diameter) within forested ecosystems; provide for a minimum of 65 percent ground cover (plants, litter and rock - greater than 3/4 inch in diameter) on rangeland ecosystems; or, in both ecosystems, an equivalent percentage if the site cannot naturally attain the minimum percentages mentioned above.

Method - Follow procedures outlined within "Guidelines for Sampling Some Physical Conditions of Surface Soils" by Steve Howes, John Hazard, and J. Michael Geist, Pacific Northwest Region, July 1983, (R6-RWM-146-1983). Sampling would consist of line transects and 1/10th acre plots.

Expected Precision and Reliability

- Precision - Moderately high to high.
- Reliability - Moderately high to high.

Tolerance, or Variability Indicating Action - For those resource practices consistently exceeding the threshold, determine if techniques can be improved or another method found. Evaluate areas exceeding the standard for rehabilitation opportunities.

Frequency of Monitoring - Annually, until an adequate determination can be made for various ground-disturbing resource management practices.

Lead Responsibility - Forest or District soil scientist.

Estimated Annual Cost - \$1,000.

BIOLOGICAL ELEMENTS

Aquatic/Riparian

Monitoring Item - Verification of Water Quality Limited Streams. Specifically, is water quality in these streams improving to the point they can be delisted?

Type of monitoring - Validation monitoring

Priority - Forest Priority Group 2.

Where Applies - First on streams listed as Water Quality Limited, and then, if necessary, monitoring will be extended to their tributaries and watersheds.

Indicator - Depends on the reason for listing, e.g , on streams listed for nutrient concerns, nitrate + nitrite and orthophosphate are used as indicators. If monitoring of streams for the specific compound or component turns up concerns, monitoring would be extended to find the source of the concern.

Method - Approved protocols for the constituent of concern. Procedures include those used by the U.S. Geological Survey, or in publications such as "Monitoring Protocols to Evaluate Water Quality Effects of Grazing Management on Western Rangeland Streams" by Stephen Bauer and Timothy Burton, October 1993 (EPA 910/R-93-017).

Expected Precision and Reliability

- Precision - Depends on the parameter/constituent being measured (e.g , nutrients may be in mg/l, but sediment measurements vary widely)
- Reliability - If conditions remain constant, should be able to reproduce. Some constituents, though, vary with streamflow. There are some things that are difficult to reproduce when dealing with a fluid medium.

Tolerance, or Variability Indicating Action - When it can be reliably determined that water quality standards are being violated, or that the stream cannot be removed from the WQL list because of deteriorated conditions.

Frequency of Monitoring - Depends on the constituent being monitored. Generally, one can expect to have to visit sites several times during the summer

Lead Responsibility - Forest hydrologist.

Estimated Annual Cost - Assuming that we would be monitoring all WQL streams, estimated annual cost would be approximately \$15,000. This would include a full-time person to do the monitoring at the GS-5 level

**** Note:** an item not on the form is the consequence of not doing the monitoring. Although details are not anywhere near finalized, it has been suggested that for any stream that cannot be removed from the WQL list (i.e., for any stream that we cannot prove is meeting water quality goals), total maximum daily loads (TMDL's) of the constituent of concern would have to be established for the stream. This would be an enormous task, and, in fact, one that is widely thought to be impossible for the nonpoint pollutants that come from National Forest activities

Monitoring Item - Monitoring of application of Best Management Practices (BMP's) related to maintaining and improving water quality.

Type of monitoring - Implementation and Effectiveness.

Priority - Forest Priority Group 3.

Where Applies - Project areas where BMP's are applied (such as timber sale areas, new roads, etc.)

Indicator - Variable, depending upon the BMP which was applied.

Method - For implementation monitoring, reviews would be conducted of projects by teams including the project planner, administrator, and interested specialists. For effectiveness monitoring, water quality, soil characteristics (such as erosion), and fish habitat would be monitored for selected projects

Expected Precision and Reliability

- Precision - Variable, depending on the project and the impacts being measured.
- Reliability - Results should be reasonably reproducible, unless conditions change between monitoring times.

Tolerance, or Variability Indicating Action — If BMP's are not being applied in situations which call for their use, a review would be conducted to determine the reasons. If instream beneficial uses may be put at risk, or if unacceptable soil degradation is occurring, a review would be conducted to determine the reasons.

Frequency of Monitoring -

Implementation monitoring: Once after projects are finished.

Effectiveness monitoring: Variable. Water quality monitoring might be conducted several times per year. Monitoring for changes in soils, fish habitat or channel condition may be conducted once per year.

Lead Responsibility - Soil scientist, fisheries biologist, hydrologist.

Estimated Annual Cost - Average cost would be between \$2,000 and \$10,000 per year, depending on what's being monitored.

Wildlife

Monitoring Item - Forestwide habitat conditions for the northern goshawk.

Type of monitoring - Effectiveness/Validation

Priority - Forest Priority Group 1

Where Applies - Subsection, Watershed, Stand

Indicator - Numbers for the respective indicators can be found in the wildlife standards and guides for the revised Revision

- A. Number of nesting areas within a goshawk territory
- B. Respective size of the nesting area (30 acres), Post fledgling family area (PFA)(420 acres), and foraging area (5400 acres) that comprise a portion of a goshawk territory.
- C. Size class distribution
- D. Rotation age
- E. Maximum created opening size
- F. Snags and reserve trees
- G. Downed logs
- H. Management season
- I. Thinning
- J. Open road density

Factors to be considered include but not limited to:

- A. Forest inventories that reveal species occupancy of mature stands (or other) that may compete with goshawks for available habitat or nesting areas;
- B. Size of female home range and breeding area requirements with representative habitat characteristics for successful breeding and fledging of young;
- C. Existing landscape, stand, and site conditions and characteristics within analysis and treatment areas as determined by inventories prior to project implementation (biological potential of existing conditions prior to treatment or activity);

D. distribution and dispersion of appropriate size mature or late succession forest stands as related to stands of immature and nonstocked forest stands and nonforest areas at the following scales.

1. stand
2. subwatershed or watershed
3. landscape (incl. species type and sere(s)).

Method - systematic sampling, evaluation, and documentation of pre- and post-vegetation treatment conditions in project or analysis areas by landscape X watershed/subwatershed X forest type (cover and habitat type) X elevation X soil productivity class (IRI inventory). Role of partners will be systematic inventories of habitat conditions and species occurrences prior to and after vegetative treatments.

Expected Precision and Reliability

- Precision - variable by species and forest (condition, characteristics) type but generally high
- Reliability - high

Tolerance, or Variability Indicating Action - Changes in management will be necessary as

A. baseline studies (inventory) refine or replace available guidelines for managing northern goshawk habitat (forest structure/composition);

B. monitoring of projects and comparison of results among treated areas demonstrate that current guidelines are in need of change.

Measures and need for change in both (a) and (b) should be determined through evaluations of site, stand and landscape conditions coupled with baseline forestwide (systematic) species inventories, productivity, and improved knowledge of regional life history characteristics and requirements for northern goshawks

Frequency of Monitoring - Prior to and following project analyses for each subsection. Analyses and evaluations should include site, stand and landscape conditions.

Lead Responsibility - Wildlife/Ecology specialists

Estimated Annual Cost - Will vary by the number of projects anticipated and planned to affect the distribution and abundance of dead and down material. Per analysis and project costs will vary, but will likely range from \$1500 to \$3000 depending on size of analysis area, levels of previous disturbance, and expected disturbance. Costs do not include baseline inventories nor NEPA preparation

Monitoring Item - Improvement in the quality of grizzly bear habitat on the Forest, and the contribution of the Forest to total grizzly bear habitat quality in the Greater Yellowstone Area.

Type of monitoring - Implementation, Effectiveness

Priority - Forest Priority Group 1.

Where Applies - Applies to all prescription areas within designated Bear Management Units (BMU's) on the Forest.

Indicator - The primary indicators of trend in grizzly bear habitat are habitat effectiveness, habitat value; and bear displacement. These three are described in detail in the documentation for the grizzly bear cumulative effects model. (IGBC 1990)

In addition to the above, indicators will be used from the Interagency Grizzly Bear Committee Taskforce Report on Motorized Access Management. (IGBC 1994)

Method - Each management unit of the Greater Yellowstone Area, including the Targhee National Forest, will annually submit data on changes in road and trail access, and vegetation, to the USDA-Forest Service Intermountain Regional Office. That office will compile the data, develop a data set fixed in time, and issue this in electronic digital form (CD-ROM). This data will then be forwarded to individual management units for on-site use and runs.

On the Targhee National Forest, individual ranger districts will track changes in road and trail access and vegetation. These will be submitted to the Forest GIS shop for assembly into a Forest data package

Expected Precision and Reliability

- Precision - Very high.
- Reliability - Results will be reproducible with the same data set.

Tolerance, or Variability Indicating Action - Refer to the item on achievement of road density standards.

Frequency of Monitoring - Annually.

Lead Responsibility - Forest wildlife biologist.

Estimated Annual Cost - On each of the three ranger districts with grizzly bear habitat, one person (GS-9 wildlife biologist) will need two weeks to put together the input data required. On receipt of the CD-ROM data from the Regional Office, the Forest GIS shop will need one person (GS-7 tech) for one day to run the cumulative effects model on each of the seven subunits.

GS-9 biologist: 3 districts, two weeks each @ \$150/day	\$4,500
GS-7 GIS technician: 7 subunits, one day each @ \$110/day	\$ 770
TOTAL:	\$5,270

Monitoring Item - Biological Diversity

Type of monitoring - Implementation

Priority - Forest Priority Group 3.

Where Applies - Subsection, Landscape, Watershed, Subwatershed

Indicator -

- A. alpha diversity for species richness (within area of selection) diversity (rarity)
- B. beta diversity (area changes/differences among areas of selection)

C. Presence of and rate of increase by nonnative species.

Method - Standard measures for diversity of species according to and compared by ecological subsection, forest vegetation type characterizations/ classifications (e.g. occurrence and distribution of upland/ grass, coniferous, riparian), forest seres, disturbance regime, watershed type(s))

Measures for species richness and dominance are described by Magurran (1988) and Krebs (1989). Combinations of indicators, as suggested by Magurran, as being further explored for their utility on the Targhee Forest

Role of partners will be systematic inventories of habitat conditions and species occurrences prior to and after vegetative treatments.

Expected Precision and Reliability

- Precision - generally high
- Reliability - generally high if used and interpreted appropriately

Tolerance, or Variability Indicating Action - Changes in management will be necessary as

A. baseline studies (inventory) identify species changes resulting in a change in index values at representative scales of application.

B. research improves upon measures for understanding and managing for retaining biological diversity.

C. monitoring of projects and generation of comparative indices result in detectable species changes or trends as a result of natural or human-induced changes at landscape, watershed, or subwatershed level.

Measures and need for change in both (a) and (b) should be determined through evaluations of site, stand and landscape conditions coupled with baseline forestwide (systematic) species inventories and improved knowledge of regional life history characteristics and requirements for various species of wildlife that use a variety of patch or larger landforms.

Frequency of Monitoring - Variable. annually to every third year depending on the baseline inventory information, number, size, and distribution of projects, and unpredictable events such as fire.

Lead Responsibility - Ecologist or individual skilled in collecting information and applying techniques.

Estimated Annual Cost - \$15,000 per year. Costs do not include baseline inventories nor NEPA preparation.

Monitoring Item - Dead Standing (plus green trees for replacement) for meeting wildlife requirements on Forest.

Type of monitoring - Effectiveness/Validation

Priority - Forest Priority Group 3.

Where Applies - Subsection, Watershed, Stand (~25 acres), Site

Indicator -

- A. diameter size
- B. tree species
- C. tree height
- D. composition (dead tree hardness/class)
- E. dispersion of dead standing and replacement trees (distribution=)
- F. evenness and clumpiness of dead and green replacement trees)

Factors to be considered include but not limited to

- A. Forest inventories for species that use dead standing trees
- B. Number of species, species group or life form (e.g. cavity nesters, forest raptors, songbirds, furbearers) with potential to occur according to species distribution and available habitat characteristics (Note. Guidelines do not assume that requirements for one species meet the needs for another where overlap in size and placement characteristics exist.)
- C. Size of female home range and breeding area requirements with representative habitat characteristics for successful breeding and fledging of young according for species of interest or concern.
- D. Existing landscape, stand, and site conditions and characteristics within analysis and treatment areas as determined by inventories prior to project implementation.
- E. Distribution/condition/availability:
 - 1. stand
 - 2. subwatershed or watershed
 - 3. landscape (incl. species type and sere(s).
 - 4. subsection
- F. Distribution of natural opening sizes, shapes and structural characteristics of forest seres comparing natural disturbance types to human-induced.
- G. Occurrence and distribution of forest types and effective conditions at landscape, stand and site relative to potential for species occurrence, distribution and reproduction.

Method - systematic sampling in project or analysis areas by subsection by watershed/subwatershed, forest type, elevation, and soil productivity class (IRI inventory). Role of partners will be systematic inventories of habitat conditions and species occurrences prior to and after vegetative treatments.

Expected Precision and Reliability

- Precision - variable by species and forest (condition, characteristics) type but generally high
- Reliability - high

Tolerance, or Variability Indicating Action - Changes in management will be necessary as:

- A. baseline studies (inventory) refine or replace dead standing and green replacement trees in varied forest types and conditions for species needs;

B. monitoring of projects and comparison of results among treated areas demonstrate that current guidelines are in need of change.

Measures and need for change in both (a) and (b) should be determined through evaluations of site, stand and landscape conditions coupled with baseline forestwide (systematic) species inventories and improved knowledge of regional life history characteristics and requirements for various species of wildlife that use dead standing and green replacement trees.

Frequency of Monitoring - Prior to and following project analyses for each subsection. Analyses and evaluations should include site, stand and landscape conditions.

Lead Responsibility - Monitoring teams including soils, vegetation and wildlife/ecology specialists

Estimated Annual Cost - Will vary by the number of projects anticipated and planned to affect the distribution and abundance of dead and down material. Per analysis and project costs will vary, but will likely range from \$1500 to \$3000 depending on size of analysis area, levels of previous disturbance, and expected disturbance. Costs do not include baseline inventories nor NEPA preparation.

FOREST USE AND OCCUPATION

Forest Users

Monitoring Item - Forest customer satisfaction with the direction, progress, and administration, of the Revision.

Type of monitoring - Implementation, Effectiveness

Priority - Forest Priority Group 2

Where Applies - Forestwide.

Indicator - Comments, both written and oral, approving or disapproving of the direction of Forest management and the rate of progress in implementing it.

Method - Forest User mailing lists would be used to periodically build random samples. Individuals and groups on this list would then be sampled using methods such as phone surveys or mailings. These samples would be conducted by organizations or academic institutions with sampling expertise, under contract to the Forest. Informal, optional, person-to-person user surveys would be conducted of trail users, campers, and sport recreationists by field-going Forest personnel. Records and notes would be kept of public meetings held by the Forest. Forest employees would be encouraged to record and submit informal notes of opinions and suggestions of friends and family for consideration by the Forest.

Expected Precision and Reliability

- Precision - Samples designed with statistical principles could be quite accurate. Otherwise it would still provide a reasonable indication to managers
- Reliability - The results should be reasonably reproducible.

Tolerance, or Variability Indicating Action - This would have to be determined by Forest line officers based on the issue.

Frequency of Monitoring - Annually or as needed

Lead Responsibility - Forest Public Affairs Officer

Estimated Annual Cost - Working with a survey organization would require three weeks per year for the Public Affairs Officer. Helping to assess the surveys would require GS-9 employees. To conduct field surveys of recreationists would require two weeks for two GS-9 employees

GS12 PAO, three weeks @ \$1,000/wk	\$3,000
GS9 45 hours at \$18/hr.	\$ 810
<u>GS9 (field survey), 4 wks. @ \$18/hr</u>	<u>\$2,880</u>
TOTAL:	\$6,690

RECREATION

Monitoring Item - Impacts to on-trail and off-trail soils and vegetation from impacts from hiking, horse use and OHV use, for compliance with the 15% soil disturbance policy.

Type of monitoring - Implementation and Effectiveness.

Priority - Forest Priority Group 2.

Where Applies - System trail and off-trail areas.

Indicator - Soil displacement on the trail or within the adjacent meadow or basin area.

Method - Visual and photo documentation and trail condition surveys.

Expected Precision and Reliability

- Precision - 60-75%
- Reliability - 60-75%

Tolerance, or Variability Indicating Action - When condition surveys show that use is impacting the trail tread or adjacent soils and vegetation such that significant resource damage, health, and safety, or trail maintenance are at risk

Frequency of Monitoring - Annually on approximately 5-10% of the system trail areas (60-120 miles) and adjacent off-trail areas. (Priority areas initially are the Big Holes/Palisades,, Plateau, Caribou, and Medicine Lodge subsections.)

Lead Responsibility - Recreation and Engineering Staffs

Estimated Annual Cost - \$25,000-35,000.

Monitoring Item - Conflicts between all forms of recreation and wildlife.

Type of monitoring - Implementation and Effectiveness.

Priority - Forest Priority Group 2.

Where Applies - Forestwide.

Indicator - Number of violations of closure areas, observed wildlife disturbances; and diminishing wildlife populations or signs of stress.

Method - Field and aerial observations, photography. This item will depend partially on the results of monitoring of the effectiveness of road closures, which is another Priority Group 2 item

It is expected that partnerships can be developed with State game and fish agencies, State recreation agencies, and possibly recreation user groups to monitor this item.

Expected Precision and Reliability

- Precision - 50-75%
- Reliability - 50-75%

Tolerance, or Variability Indicating Action - When evaluation of wildlife populations indicates they are beginning to falter or seek out other areas for security and solitude, then an evaluation of recreation use levels will take place. Evaluation of other uses of the area may also be appropriate.

Frequency of Monitoring -

- Winter, in prescription areas emphasizing winter range values: weekly in 10% of winter range per year for 3-4 months,
- Summer, in prescription areas emphasizing big game security or summer range values: weekly for 3 to 4 months, especially in the early summer.

Lead Responsibility - District Rangers

Estimated Annual Cost - \$30,000.

Monitoring Item - Soil displacement in heavy-use dispersed campsites, for compliance with the 15% soil disturbance policy.

Type of monitoring - Implementation, Effectiveness.

Priority - Forest Priority Group 3.

Where Applies - 4.3 prescription areas.

Indicator - Displaced soil.

Method - Frissell Condition Class method.

Expected Precision and Reliability

- Precision - 75%+
- Reliability - Very Good, 75%+

Tolerance, or Variability Indicating Action - Significant or consistent violation of the 15% soil disturbance policy in 4.3 prescription areas will be cause to re-examine campsite use. This may also trigger validation monitoring of the propriety of applying the policy in these areas.

Frequency of Monitoring - Annually, within approximately 10% of the 100 4.3 prescription areas. (Medicine Lodge and Caribou subsections will receive top priority for this monitoring initially.)

Lead Responsibility - Forest Recreation Staff

Estimated Annual Cost - \$40,000

Monitoring Item - Impacts from wilderness use on wilderness quality (from the wilderness Limits of Acceptable Change plan for Jedediah Smith Wilderness).

Type of monitoring - Implementation and Effectiveness

Priority - Forest Priority Group 3.

Where Applies - Jedediah Smith Wilderness.

Indicator - see The Jedediah Smith monitoring plan which follows.

Method - see The Jedediah Smith plan which follows.

Expected Precision and Reliability

- Precision - 75%
- Reliability - 75%

Tolerance, or Variability Indicating Action - If it is determined that impacts from use of the Wilderness are exceeding those limits shown, then an evaluation will be made of the possible causes and potential remediations identified.

Frequency of Monitoring - Annually.

Lead Responsibility - Teton Basin Ranger District, and Forest Recreation Staff.

Estimated Annual Cost - \$15,000-20,000

Monitoring Item - Jedediah Smith Wilderness Monitoring Plan.

INDICATORS AND STANDARDS

Indicators and standards will be monitored yearly and may require adjustment if on site administration indicates resources or social conditions are deteriorating beyond an acceptable level. These measurements relate only within each specific zone of the Wilderness and not all of one type of zone lumped together. In other words, for Class 1, if the standard is exceeded in a particular Class 1 zone, then management action will be taken. Following each indicator is a list of management actions which could be used to bring the indicator back to the identified standard for its class. The order of the actions shown does not indicate priority.

Indicator #1	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of occupied campsites users may see from their site	0	2	3	1, 2, 4

Possible Management Actions - If number of visible campsites is approaching or exceeds standards:

1. Remove campsite(s) and restore the area to as near natural condition as possible.
2. Relocate campsite(s) to more suitable location and restore to as near natural condition as possible.
3. Talk with users and suggest other camping possibilities.

Indicator #2	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Condition of individual campsites	vegetation flattened, not permanently injured	vegetation worn away at center of activity	vegetation lost around center of activity	1, 2, 5

Possible Management Actions - If condition of campsite is approaching or exceeds standards:

1. Rehabilitate the site, sign it for restoration, and/or close it.
2. Talk with users about minimum impact camping techniques.
- 3 Relocate site to a more durable location and restore the vacated campsite to as near natural condition as possible.
4. Visit local schools, organizational groups to discuss wilderness ethics, regulations, minimum impact practices.

Indicator #3	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Condition of user-created routes and trail segments	game trail	18" to 42" wide, brush, rock, litter present	42" wide, brushed out along edge	1, 2, 4

Possible Management Actions - If user-created route or trail is approaching or exceeds standard:

1. Talk with users about trail conditions and experiences.
2. Ensure trail crews and maintenance volunteers are aware of standards and do not exceed them.
3. Rehabilitate trail sections that exceed standards.
4. Relocate trail segments to more suitable locations.
5. Encourage use on other trails.
6. Limit number of users on trail.
7. Visit local schools, organizational groups to discuss wilderness ethics, regulations, minimum impact practices.

Indicator #4	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of encounters per mile with other parties along a user created route or trail	0*	3*	5*	1, 2, 3, 4, 5
* Encounters may be higher within first mile of trail from trailhead.				

Possible Management Actions - If number of encounters is approaching or exceeds standards:

1. Encourage users to vary starting times.
2. Lower party size and stock limits.
3. Monitor user acceptance of trail use levels.
4. Encourage users to go to other places.

Indicator #5	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of substantiated complaints about outfitters and grazing permittees from the public and other permittees	2	5	10	3, 5

Possible Management Actions - If the number of complaints concerning permittees is approaching or exceeds standards:

1. Increase permit administration on the ground.

2. Require wilderness ethics education as a condition of permit issuance.
3. Restrict the number of permits issued.
4. Bring parties together to discuss issue(s).

Indicator #6	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of violations of regulations by type	5	10	15	1, 3, 5
1/ See process paper for Jedediah Smith Wilderness				

Possible Management Actions - If the number of violations is approaching or exceeding standards

1. Increase presence of uniformed Forest Service personnel
2. Visit local schools, organizational groups to discuss wilderness ethics, regulations, minimum impact camping techniques.
3. Review regulations for appropriateness.
4. Increase posting of regulations at trailheads.

MONITORING

Air Quality

1. Monitor acid deposition in Wilderness lakes. Specifically, Two Island Lake is extremely sensitive to acid deposition; and Middle Granite Lake is more typical of Wilderness lakes with some buffering capacity. Reference for more information the water quality survey conducted in 1992 by personnel from the Targhee and Bridger-Teton National Forests

2. Monitor visual air quality by means such as periodic photography. Consider establishing a monitoring station at the Grand Targhee ski area or other location which would permit observation of air quality in both the Wilderness and Grand Teton National Park.

Wildlife and Fish

1. Monitor human/grizzly interactions (confrontations and movements) to determine any change in the known range of the bear, and which management actions are needed if any.
2. Monitor grizzly bear activity and movement relevant to domestic sheep grazing to determine which management actions are needed if any.
3. Continue annual population censusing of bighorn sheep including lamb survival and ram harvest (Wyoming Game and Fish Department).

Cultural Resources

Monitor cultural resource sites in high public use areas annually to assess potential and actual effects. Formulate mitigations in conjunction with the Wyoming State Historic Preservation Officer when effects are adverse.

Roads and Trails Access

Monitoring Item - Amount of authorized motorized use including permitted game retrieval on closed roads and trails, to determine if a route or area is effectively open.

Type of monitoring - Implementation monitoring.

Priority - Forest Priority Group 2

Where Applies - This item is most important in prescriptions which feature the following.

- * elk and deer habitat values—5.1.4, 5.4, 2.7;
- * grizzly bear habitat values—5 3.5, 2.6.1, 2.6.2, 2.6.5;

Indicator - The number of motorized trips per week per route.

Method - The districts will keep a record of administrative motorized use allowed on each route by date. This record could be maintained by the district ranger, and could be supported by an entry of dates and trips made per road, returned gate permits, or other means. At reporting time this record would be totalled and an evaluation made whether or not the number of trips throughout the summer effectively opened the road. Those roads opened would be noted to the GIS shop.

Expected Precision and Reliability

- Precision - Precision could be high depending on the accuracy of the record keeping.
- Reliability - The results would be wholly dependent on the records kept.

Tolerance, or Variability Indicating Action - Reference prescription standards.

Frequency of Monitoring - Annually.

Lead Responsibility - The district ranger would keep records of allowed entries onto closed routes for administrative purposes, and evaluate the data. The Forest GIS shop would display any resultant roads which are effectively opened.

Estimated Annual Cost

- * Two days per district per GS-9 biologist: 5 (\$450)
- * Two days for one GS-5 GIS technician. \$240

TOTAL: \$2,500

Monitoring Item - Effectiveness of road and trail closures.

Type of monitoring - Effectiveness monitoring

Priority - Forest Priority Group 2

Where Applies - This item is most important in prescriptions which feature the following

- * elk and deer habitat values—5.1.4, 5.4, 2.7;

- * grizzly bear habitat values—5.3.5, 2.6.1, 2.6.2, 2.6.5;
- * any 1.series prescriptions where motorized route densities exceed the target;
- * those areas where roads and/or trails were closed to stop direct resource damage.

Indicator - The units of measure to be used are:

- * direct encounter of a prohibited use in a restricted area;
- * evidence of prohibited use such as tire tracks

Method - Several methods would be used, in a rough stratified sampling approach. Visual checks of access points to closed road systems would be performed. Ocular check information from incidental employee observations would also be used. On the basis of evidence such as use encounters or tire tracks, roads would be placed into strata of confirmed-use, suspected-use and no-use. Each of these strata would then be sampled with mounted cameras activated by motion sensors. Although we might not be able to obtain a scientifically- valid number of samples due to cost, the data would help to refine our estimates of use and target areas of greatest concern.

There is an opportunity to develop partnerships with several entities, including State fish and game departments and the U. S. Fish and Wildlife Service. It is possible that user groups would be interested in assisting with this as well, though this would have to be done carefully because of possible information leakage.

Expected Precision and Reliability

- Precision - We can measure presence or absence of prohibited use with some accuracy. We will not be able to measure the number of offenses accurately.
- Reliability - Evidence of recent use at one point in time should be reliable. This data cannot be used reliably by itself to judge the frequency of prior use or predict future use since this will depend to some extent on the individual violators. The data could be entered into a predictive model if one is available and accepted.

Tolerance, or Variability Indicating Action - Reference the standards in the Roads section of the Forest-wide Standards and Guidelines (page 33). Briefly, the point at which some action would be required is when use exceeds 1-2 trips per week during the majority of the weeks during the spring/summer/fall period.

Frequency of Monitoring - The visual checks would be performed three times during the spring/summer/fall seasons, to incorporate at least one holiday weekend and the fall hunting season. Due to the limited number of cameras and personnel costs, we may wish to target only one or two districts per year, or only portions of certain districts. Complete Forest coverage would take several years.

Lead Responsibility - Forest law enforcement officer.

Estimated Annual Cost - Assume we will monitor one district per year. Assume one GS-5 tech can visually monitor ten roads per day, or thirty roads per sampling round of three days. Assume one GS-9 camera tech can install, monitor and remove six cameras (six roads) per one-week sampling round. Also assume we will purchase two camera units @ \$800 (the Forest wildlife shop already has 4-6 of these, but some need repairs). Then:

For visual checks:

- * One GS-5 tech twice per summer @ three days \$ 750;
- * Rental vehicle @ \$15/day \$ 90;

For camera confirmations:

* two new camera units amortized over ten years	\$ 160/year;
* install and read cameras-one week per sampling round three times per summer for one GS-9 @ \$700/week	\$2,100;
* materials/incidentals-mounting hardware, film, developing of film, incidental repairs	\$ 500;
Analysis/evaluation - one GS11 for one week	\$ 800.
TOTAL:	\$4,400/year.

Monitoring Item - Achievement of standards in prescription areas for Total Motorized Access Route Density (TMARD), and Open Road and Open Motorized Trail Route Density (OROMTRD).

Type of monitoring - Implementation monitoring.

Priority - Forest Priority Group 2.

Where Applies - This item is most important in prescriptions which feature the following:

- * elk and deer habitat values-5.1.4, 5 4, 2.7;
- * grizzly bear habitat values-5.3.5, 2.6.1, 2.6 2, 2.6.5;

Indicator - Miles per square mile of open roads and open motorized trails (for OROMTRD); and open and restricted roads and motorized trails (for TMARD).

Method - The method is explained in more detail in the Forestwide Standards and Guides, Roads section. The Forest Geographic Information System (GIS) and associated database will be used. Highlights of the method include:

- * annually update the transportation database with road and trail closures and other pertinent data;
- * GIS calculate the contiguous area of each prescription polygon;
- * calculate the miles of routes that are open and seasonally open, and total these;
- * moving-window technology will be used.

No partners in this effort were identified.

Expected Precision and Reliability

- Expected precision is high.
- Expected reliability is high.

Tolerance, or Variability Indicating Action - Progress in achieving the TMARD and OROMTRD standards should follow an established activity schedule. At the end of the specified time period the standards should be met. If the standards are not met by the end of the time period a management review should be conducted to determine the cause.

Frequency of Monitoring - Annually.

Lead Responsibility - The district ranger will annually forward accomplishments toward meeting standards, and other pertinent data, to the Forest engineer. The GIS shop will do the calculations and produce the report.

Estimated Annual Cost

* One GS-7 biologist for two days on each district - 2 (\$180) (5)

* One GS-5 GIS technician for one week per district - 5 (\$600)

TOTAL: \$4,800

PRODUCTION OF NATURAL RESOURCES

Range

Monitoring Item - Streambank trampling damage correlated to riparian stubble height standard. Range Objective IV.

Type of monitoring - Validation.

Priority - Forest Priority Group 2.

Where Applies - Grazing allotments (key areas) - same as monitoring item for riparian stubble height.

Indicator - Percent of streambank damage in key riparian areas.

Method - Targhee monitoring protocol (to be developed). Monitoring will be done concurrently with the monitoring of riparian forage utilization.

Expected Precision and Reliability

- Precision - High.
- Reliability - The measurements can be reproduced once the key area is established.

Tolerance, or Variability Indicating Action - To be determined

Frequency of Monitoring - To be done concurrently with riparian utilization monitoring.

Lead Responsibility - District Range Specialist.

Estimated Annual Cost If this item is done concurrently with the riparian utilization monitoring item, there will be no additional cost.

Monitoring Item - Riparian Forage Utilization, Range Item III. 2. a and b; and Administrative Site Monitoring Standard, Range Item IV. E.

Type of monitoring - Implementation

Priority - Forest Priority Group 2; High Range Priority #1.

Where Applies - Grazing Allotment (Key Areas)

Indicator - Percent Utilization of browse and stubble height of herbaceous riparian vegetation in Riparian Areas (hydric greenline) in key areas.

Method - Short term monitoring methods FSH 2209.21 Ch.42.0 or Targhee Monitoring Protocol (to be developed). Partners include Fish & Game and grazing permittee.

Expected Precision and Reliability

- Precision - Highly accurate.
- Reliability - The measurements can be repeated once the key area is identified.

Tolerance, or Variability Indicating Action - When the Standard/Guideline is more than 5% outside the range.

Frequency of Monitoring - Annually at least once a year on priority allotments and perhaps twice a year if there are wildlife concerns Each allotment requires 2-3 readings per unit Each allotment has 1-6 units.

Lead Responsibility - District Range Specialist.

Estimated Annual Cost - 33% of all allotments on each District will be monitored yearly: 1 GS-9 @ \$150.00/day. Average allotment requires 5 days (4 field days, 1 office) yearly. 33% of 154 allotments = 51 allotments:

$$\begin{array}{r}
 (\$150.00) (5) = 750 \\
 \quad \quad \quad \underline{51} \\
 \quad \quad \quad \$38,250 \text{ yearly}
 \end{array}$$

Monitoring Item - Upland Forage Utilization, Range Standard II; and Administrative Site Monitoring, Range Standard IV. E.

Type of monitoring - Implementation.

Priority - Forest Priority Group 3; High Range Priority #1.

Where Applies - Grazing Allotment (key areas).

Indicator - Percent utilization of forage species in key areas.

Method - Short-term monitoring methods described in Forest Service directives system at FSH 2209.21, Ch. 42.0; or Targhee Monitoring Protocol (to be developed). Partners include State game and fish agencies, and grazing permittee.

Expected Precision and Reliability

- Precision - Highly accurate.

•**Reliability** - The measurements can be repeated once the key area is identified.
Tolerance, or Variability Indicating Action - When the Standard/Guideline is more than 5% outside the range.

Frequency of Monitoring - Once a year on priority allotments and perhaps twice a year if there are wildlife concerns. Each allotment requires 2-3 readings per unit. Each allotment has 1-6 units.

Lead Responsibility - District Range Specialist.

Estimated Annual Cost - One-third of all allotments on each District will be monitored yearly. One GS-9 at \$150.00/day. Average allotment requires 3 days (2 days field, 1 day office) yearly. One-third of 154 allotments = 51.

$$\begin{array}{r} (\$150.00) (3) = 450.00 \\ 51 \\ \hline \$22,650.00 \text{ yearly Forestwide} \end{array}$$

Monitoring Item - Allotment Management Planning, Range Standard I.; and Administrative Site Monitoring, Range Standard IV. E.

Type of monitoring - Implementation

Priority - Forest Priority Group 3, High Range Priority #1.
Where Applies - Grazing Allotment (Bench Marks or key areas).

Indicator - Acres of Riparian or upland areas meeting DFC's or objectives identified in Allotment Management Plans (AMP's).

Method - Long-term trend determination FSH 2209.21 Ch.44 or Targhee Monitoring Protocol (to be developed).

Expected Precision and Reliability

- Precision - Highly accurate.
- Reliability - The measurements can be repeated.

Tolerance, or Variability Indicating Action - When the trend changes or objectives have not been met after 2 grazing rotations.

Frequency of Monitoring - Each study needs to be read every 5-7 years.

Lead Responsibility - Range Specialist

Estimated Annual Cost - Ten percent of all allotments will be monitored yearly, each allotment will have 2-5 studies. One GS-9 @ \$150.00/day, 3 days per study (2 field, 1 office day).

$$\begin{array}{r} 10\% \text{ of } 154 \text{ allots.} = 15 \\ (\$150.00) (3) = 450 \\ .15 \\ \hline \$6,750 \end{array}$$

Monitoring Item - Allotment Management Planning, Range Standard I.; and Administrative Site Monitoring, Range Standard IV. E.

Type of monitoring - Implementation

Priority - Forest Priority Group 3; Moderate Range Priority #2.

Where Applies - Ranger District or Forest total.

Indicator - Number of allotments with and without rotation grazing

Method - No field work required. Will use FSRAMIS Data Base. No partners

Expected Precision and Reliability

- Precision - Highly accurate.
- Reliability - The measurements can be repeated.

Tolerance, or Variability Indicating Action - Mid point of Decade 1.

Frequency of Monitoring - Annually at the end of the fiscal year.

Lead Responsibility - Forest Range Specialist.

Estimated Annual Cost - GS-12 @ \$225/day for 1 day. Total: \$225.00

Monitoring Item - Biodiversity Guideline I. for sagebrush/grassland habitats.

Type of monitoring - Implementation.

Priority - Forest Priority Group 3, Moderate Range Priority.

Where Applies - Watershed.

Indicator - Acres of big sagebrush (*Artemesi tridentata*) canopy cover classes expressed as a percent of the entire watershed.

Method - Line Intercept Method for Crown Canopy Cover, described in the Forest Service directives system at FSH 2209.21, Ch.44.51. Potential partners include State game and fish agencies, and grazing permittees.

Expected Precision and Reliability

- Precision - Highly accurate.
- Reliability - The measurements can be repeated.

Tolerance, or Variability Indicating Action - When the Standard/Guideline is more than 1% outside the range.

Frequency of Monitoring - Once every 5-7 years.

Lead Responsibility - District Range Specialist.

Estimated Annual Cost

One GS-9 @ \$150.00/day for 30 days (25 days field, 5 days office). \$4,500.00/District, assume each district is monitored twice during the ten-year plan period. Total cost \$4,500/year.

Timber

Monitoring Item - Reevaluation of land tentative suitability by the aggregation of information from individual project analyses.

Type of monitoring - Validation of tentative suitability calls made in the Revised Revision.

Priority - Forest Priority Group 1

Where Applies - Applies primarily to lands in 5.series prescriptions, but could involve the review of projects anywhere on the Forest.

Indicator - Change in total acreage in tentatively suited and unsuited lands using the criteria in the regulations and directives system.

Method - Review project-level NEPA analyses for site-level confirmations of LMP tentative suitability calls. Changes to initial calls on either suited or unsuited lands would be documented on a hardcopy map maintained in the planning shop. This map would aggregate changes from various documents. Changes to the Forest tentative suited land base could be entered into the Forest GIS.

Expected Precision and Reliability

- Precision - Site-specific analysis should give a precise description of true conditions.
- Reliability - Using given parameters such as slope percent and soil stability, results should be reliable and reproducible.

Tolerance, or Variability Indicating Action - A significant overall change in tentatively suitable acres could trigger a revision of the ASQ.

Frequency of Monitoring - Annually.

Lead Responsibility - The Forest planning shop would aggregate the findings. Project ID teams would do the individual analyses.

Estimated Annual Cost - \$1,000

Monitoring Item - Maximum created opening size.

Type of monitoring - Implementation monitoring

Priority - Forest Priority Group 3.

Where Applies - This item needs to be monitored in the following prescription areas:

- Rx 5.2.1 - generally 1 to 5 acres, but less than 40,
- Rx 5.2.2, 2.1.2 - less than 5 acres;
- Rx 5.3.5 - less than 6 5 acres;
- Rx 2.6.1 - less than 20 acres,

Indicator - Size of created openings, in acres.

Method - Compliance with the standard would be described in environmental documents.

Expected Precision and Reliability

- Precision - High.
- Reliability - High.

Tolerance, or Variability Indicating Action - Proposals to exceed the respective area standard would need to be sound and ecologically-based, and would require a Revision amendment. If a trend is seen in legitimate proposals to exceed the respective standards the standards would need to be reviewed.

Frequency of Monitoring - In each decision document, where vegetation management is selected.

Lead Responsibility - IDT leader and line officer.

Estimated Annual Cost - \$1000 per year, primarily in incidental GIS and other analysis costs to display compliance with the standard.

Monitoring Item - Providing security cover for grizzly bears in vegetation management projects.

Type of monitoring - Implementation and effectiveness.

Priority - Forest Priority Group 3.

Where Applies - This item must be monitored in the following prescription areas:

- 2.6.1 — 70%.

Indicator - Percent cover in area (see prescriptions for specifics).

Method - During environmental analysis of specific project proposals, work will be done to display compliance with the respective standards. See prescriptions.

Expected Precision and Reliability

- Precision - High.
- Reliability - High.

Tolerance, or Variability Indicating Action - Proposals to exceed the standard will require a Revision amendment. If a trend is seen toward exceeding the standard in soundly-based ecological management proposals the standard will need to be reviewed. This may involve re-opening of formal consultation.

Frequency of Monitoring - Every decision document selecting vegetation management in BMU's.

Lead Responsibility - IDT leaders, District Biologists, line officers.

Estimated Annual Cost - \$2000, primarily in incidental GIS and other analysis costs to display compliance with the standard. If the information required to demonstrate security cover is not found in the Forest data base, then field survey may be required

Monitoring Item - Manage for greater than 250-acre forested blocks.

Type of monitoring - Implementation

Priority - Forest Priority Group 3.

Where Applies - This applies to prescription areas 5.1.4 a-c and 5 4

Indicator - Size of forested blocks within project areas.

Method - Timber sale environmental documents will disclose compliance with this measure. Additionally, follow-up activity reviews should review effectiveness of treatments.

Expected Precision and Reliability

- Precision - High.
- Reliability - High

Tolerance, or Variability Indicating Action - Any proposal to violate the standard requires a Revision amendment. If a trend develops of proposals citing ecologically-sound reasons to amend the Plan or change the standard, the standard needs to be reviewed.

Frequency of Monitoring - With every decision document selecting a vegetation management alternative

Lead Responsibility - IDT leaders and line officers

Estimated Annual Cost - \$1,000, primarily in incidental costs of GIS or other analysis to demonstrate compliance with the standard.

Appendix

National Goals Relevant to Land and Resource Management

APPENDIX A
NATIONAL GOALS RELEVANT TO LAND AND RESOURCE MANAGEMENT
(BASED ON FSM OBJECTIVE STATEMENTS)

American Indians * 1563

1. Maintain a governmental relationship with federally recognized tribal governments
2. Implement programs and activities honoring treaty rights and fulfill legally mandated trust responsibilities to the extent that they are determined applicable to National Forest System lands
3. Administer programs and activities to address and be sensitive to traditional native religious beliefs and practices
4. Provide research, transfer of technology and technical assistance to American Indian governments.

Solid Waste Management * 2130.2

1. Program objectives are to design, operate, and maintain all solid waste systems under Forest Service jurisdiction in such a manner so as to meet all federal, state, and local requirements, promote public health and safety, protect Forest resource and environmental qualities; and complement and support the total land-use management process.

Pesticide Management * 2150.2

1. To ensure the proper use of pesticides.

Energy Management * 2170.2

The objectives of energy management are to:

1. Conserve energy in the conduct of Forest Service programs and in the operation of Forest Service programs and in the operation of Forest Service facilities, and to improve efficiency in the production and use of wood products.
2. Minimize undesirable consequences associated with development of renewable and nonrenewable energy source extracted from Forest System lands.
3. Facilitate recovery of fuels from Forest System lands and implement programs to support production and use of alternative fuels
4. Provide leadership and support for environmentally acceptable and scientifically sound development, production, and use of all energy resources from lands.

Range Management * 2202.1

1. To manage range vegetation to protect basic soil and water resources, provide for ecological diversity, improve or maintain environmental quality, and meet public needs for interrelated resource uses.
2. To integrate management of range vegetation with other resource programs to achieve multiple-use objectives contained in Forest System land and resource management plans

3. To provide for livestock forage, wildlife food and habitat, outdoor recreation, and other resource values dependent on range vegetation.

4. To contribute to the economic and social well being of people by providing opportunities for economic diversity and by promoting stability for communities that depend on range resources for their livelihood

Grazing and livestock Use Permit System * 2230.2

1. To administer the grazing permit system consistent with range resource management objectives found in Forest land management plans, and to best serve the public's long-term economic and social needs

Range Improvements * 2240.2

1. Without impairing land productivity or water quality, implement and maintain range improvements to the extent benefits are commensurate with cost and demand for livestock forage.

2. Provide information and advice through the Range Technical Information System and the Vegetative Rehabilitation and Equipment Workshop to enhance restoration, improvement, and quality of ranges

Structural Range Improvement * 2242.02

1. Install structural range improvements to obtain proper livestock management and to meet objectives contained in Forest System land and resource management plans and allotment management plans

Maintenance of Improvement * 2244.02

1. To maintain in operable condition all range improvements on the National Forest System and other lands controlled by the Forest Service.

Range Improvement Investment * 2246.02

1. Invest in cost-effective range improvements to achieve objectives established in Forest System land and resource management plans and allotment management plans.

Recreation * 2302

1. To provide nonurbanized outdoor recreation opportunities in natural-appearing forest and rangeland settings.

2. To protect the long-term public interest by maintaining and enhancing open-space options, public accessibility, and cultural, visual, and natural resource values.

3. To promote public transportation and/or access to National Forest recreation opportunities.

4. To shift landownership patterns as necessary to place urbanized recreation setting into other ownerships to create more public open space and/or natural resource recreation values.

National Wilderness Preservation System * 2320.2

1. Maintain and perpetuate the enduring resource of Wilderness as one of the multiple uses of National Forest System land.

2 Maintain Wilderness in such a manner that ecosystems are unaffected by human manipulation and influences so that plants and animals develop and respond to natural forces.

3 Minimize the impact of those kinds of uses and activities generally prohibited by the Wilderness Act, but specifically exempted by the Act or subsequent legislation.

4 Protect and perpetuate Wilderness character and public values including, but not limited to, opportunities for scientific study, education, solitude, physical and mental challenges and stimulation, inspiration, and primitive recreation experiences.

Recreation in Wilderness * 2323.11

1. Provide consistent with management of the area as Wilderness, opportunities for public use, enjoyment, and understanding of the Wilderness, through experiences that depend on a Wilderness setting

2. Provide outstanding opportunities for solitude or primitive and unconfined type of recreation

Range in Wilderness * 2323.21

1. Manage Wilderness range in manner that utilizes the forage resource in accordance with established Wilderness objectives

Wildlife and Fish Management in Wilderness * 2323.31

1 Provide an environment where the forces of natural selection and survival rather than human actions determine which and what numbers of wildlife species will exist.

2 Consistent with objective #1, protect wildlife and fish indigenous to the area from human-caused conditions that could lead to federal listing as threatened or endangered.

3 Provide protection for known populations and aid recovery in areas of previous habitation, of federally listed threatened or endangered species and their habitats.

Stocking Methods *2323.34b

Stocking shall normally be done by primitive means, however, Regional Foresters may permit dropping of fish from aircraft for those waters where this practice was established before the area was designated a wilderness. Conduct aerial stocking pre- or post-visitor seasons. Landings are prohibited Specify mitigation for stocking methods in wilderness implementation schedules.

Stocking Policy *2323.34c

1. Do not stock exotic species of fish in wilderness. The order of preference for stocking fish species is:

- a Federally listed threatened or endangered, indigenous species.
- b. Indigenous species.
- c. Threatened or endangered native species if species is likely to survive and spawn successfully
- d. Native species if species is likely to survive and spawn successfully.

2. Stock barren waters only after determining that the scientific and research values of such barren waters will not be eliminated from a wilderness and documenting the desirability of such action in the forest plan.

3 Consider on a case-by-case basis presently unstocked waters that at one time supported an indigenous fish population and that could provide suitable habitat for an indigenous species with unusual wilderness appeal.

Soil and Water in Wilderness *2323.41

1. Maintain satisfactory natural watershed condition within Wilderness.

Forest Cover in Wilderness * 2323.51

1. Manage forest cover to retain the primeval character of the environment and to allow natural ecological processes to operate freely.

Air Resource in Wilderness * 2323.61

1. Protect air quality and related values, including visibility, on Wilderness land designated Class 1 by the Clean Air Act as amended in 1977.

2 Protect air quality in Wilderness areas not qualifying as Class 1 under the same objectives as those for other national Forest System lands.

Minerals in Wilderness * 2323.72

1. To preserve the Wilderness environment while activities for the purpose of gathering information about mineral resources

2. To ensure that mineral exploration and development operations conducted in accordance with valid existing rights for federally owned, locatable, and leasable minerals (FSM 2810 and FSM 2820) and for nonfederally owned minerals (FSM 2830) preserving the Wilderness resource to the extent possible.

3. To ensure the restoration of lands disturbed during exploration and development activities as nearly as practicable promptly upon abandonment of operations.

Insects and Disease in Wilderness * 2324.11

1. To allow indigenous insect and plant diseases to play, as nearly as possible, their natural ecological role within Wilderness.

2. To protect the scientific value of observing the effect of insects and diseases on ecosystems and identifying genetically resistant plant species.

3 To control insect and plant disease epidemics that threaten adjacent lands or resources.

Research in Wilderness * 2324.21

1. To provide appropriate opportunity for scientific studies that are dependent on a Wilderness environment.

Fire Management in Wilderness * 2324.21

1. Permit lightning-caused fires to play, as nearly as possible, their natural ecological role within Wilderness.

2 Reduce, to an acceptable level, the risks and consequences of wildfire within Wilderness or escaping from Wilderness

Structures and Improvements in Wilderness * 2324.31

1. To limit structures and improvements for administrative purposes or under special-use permit to those actually needed for management, protection, and use of the Wilderness for the purpose for which the Wilderness was established.

Motorized Equipment in Wilderness * 2326.02

1. To accomplish management activities with nonmotorized equipment and nonmechanical transport of supplies and personnel.

2. Exclude the sight, sound, and other tangible evidence of motorized equipment or mechanical transport within Wilderness except where they are needed and justified.

Public Managed Recreation Opportunities * 2330.2

1 To maximum opportunities for visitors to know and experience nature while engaging in outdoor recreation.

2. To develop and manage sites consistent with the available natural resources to provide a safe, healthful, aesthetic, nonurban atmosphere.

3. To provide a maximum contrast with urbanization at National Forest sites.

Privately Provided Recreation Opportunities * 2340.2

1 To provide, under special-use authorization, sufficient, suitable facilities and service that supplement or complement those provided by the private sector, state, and local government on private land and the Forest Service on National Forest System land to meet public needs, as determined through land and resource management planning.

2. To facilitate the use, enjoyment, understanding, and appreciation of the National Forest, natural resource, setting.

Concession Uses Involving Privately Developed Facilities * 2343.02

1 To provide a diversity of recreation activities that emphasize the Forest setting and rustic, natural-resource-based recreation opportunities

Group Use By Institutions or other Entities * 2345.02

1. To allow group recreation opportunities, facilities, and service at camps on National Forest System land when suitable private lands are not available.

Trail, River, and Similar Recreation Opportunities * 2350.2

1. Provide recreation opportunities for users of the general forest, water, and cave resources.

2. Provide opportunities for a variety of recreation pursuits with emphasis on activities that are in harmony with the natural environment and consistent with the recreation role of the National Forest.

3. Mitigate adverse impacts of users on the natural resources, cultural and historical resources, and on other users.

Forest Development Trails * 2353.02

1. Provide trail-related recreation opportunities that serve public needs and meet land management and recreation policy objectives
2. Provide trail recreation opportunities that emphasize the natural setting of the National Forest and are consistent with land capability
3. Provide trail access for National Forest management and protection.

Scenic and Historic Trails * 2353.41

- 1 To develop and administer National Scenic or National Historic Trails to ensure retention of the outdoor recreation experience for which the trail was established and continued production of maximum benefits from the land

National Wild and Scenic Rivers System * 2354.02

1. Provide river and similar water-recreation opportunities to meet the public needs in ways that are appropriated to the National Forest recreation role and are within the capabilities of the resource base. Protect the free-flowing conditions of designated Wild and Scenic Rivers and preserve and enhance the values for which they were established.

Off-Road Vehicle Management * 2355.02

1. Provide off-road vehicle recreation opportunities that are in concert with the environmental setting, minimize off-road vehicle effects on the land and resources, promote public safety, and control conflicts with other uses of National Forest System lands.

Cave Management * 2356.02

1. Provide cave-related recreational, cultural, educational, and scientific study opportunities that serve public need Balance surface resource management and cave use with the protection of cave values

Special Interest Areas * 2360.3

- 1 To protect and, where appropriate, foster public use and enjoyment of areas with scenic, historical, geological, botanical, zoological, paleontological, or other special characteristics. To classify areas that possess unusual recreation and scientific values so that these special values are available for public study, use, or enjoyment.

Cultural Resources * 2361.02

1. Complete an inventory of cultural resources on all National Forest System land by 1985 sufficient to provide a database for land management planning
2. Complete an inventory of all cultural resources on National Forest System land by 1990.
- 3 Until these inventories are complete, exercise caution to ensure cultural resources are not damaged, destroyed or transferred by meeting the coordination requirements outlined in FSM 2361.3
4. As part of the decision-making process, document inventory and evaluation procedures to ensure adequate participation by cultural resource professionals.

5 Perform inventories at appropriate levels prior to initiating project actions.

National Registry of National Landmarks * 2373.02

To cooperate with the U.S. Department of Interior National Park Service.

1. Encourage the preservation of sites illustrating the geological and ecological character of the United States.
2. Enhance the scientific and educational value of sites thus preserved.
3. Foster a greater concern in the conservation of the nation's natural heritage.

Visual Quality * 2380.2

1. To manage all National Forest System lands to attain the highest possible visual quality commensurate with other appropriated public uses, costs, and benefits.

Interpretive Services/Visitor Information * 2390.2

1. To assist those visitors in the National Forest, research projects, and state and private forestry locations in gaining a greater appreciation of the role of conservation in the development of the nation's heritage and culture.
2. To promote visitor understanding of the Forest Service, the National Forest System, forestry research, and state and private forestry programs.
3. To inform visitors of recreation opportunities and facilities on the National Forests.
4. To help visitors know and experience the natural environment.
5. To implement an interpretive program that helps solve management problems and aids in the development of public understanding of Forest Service management.
6. To expand the number of interpretive associations that contribute to public understanding of Forest Service practices, support interpretive services objectives, increase public awareness, and aid in management of National Forest resources.
7. To increase visitor understanding of natural and cultural history principals and their relation to land management techniques

Timber Management * 2402

1. Provide a continuous supply of National Forest timber for the use and necessities of the citizens on the United States.
2. To provide, as far as feasible, an even flow of National Forest timber in order to facilitate the stabilization of communities and opportunities for employment.
3. To cultivate and maintain tree stands in the manner that promotes and achieves a diverse pattern of vegetation that best meets the needs of people now and in the future.
 - a Manage and provide for regeneration of tree stands.

b. Maintain a diversity of forest vegetation types and resources consistent with the Forest Plan

Personal Use Firewood * 2409.18

1. To provide firewood and other wood for personal use in order to aid in the protection and silvicultural improvements of the National Forest.

Commercial Timber Sales * 2430.2

1. To provide an orderly program of timber sales from each National Forest in accordance with the Forest Plan or approved interim plans.

2. To offer for sale the ASQ and other sales specified in Forest Plans, subject to financing levels or other modification during their implementation.

3. To coordinate the timber sales program with planning, management, and use of other Forest resources

4 To provide a continuous flow of raw material to local forest industries

Salvage Sales * 2435.02

1. To manage the use of salvage sale fund to provide for the rapid optimum practical use of wood material damaged through natural event, such as insects, windstorms, wildfires, hurricanes, and tornadoes

Reforestation * 2470.02

1. To maintain all forest lands within the National Forest System in appropriate forest cover

2. Improve the quality and yield of new timber stands.

3. Achieve desired time and stocking level goals in a cost-efficient manner

Silvicultural Practices * 2470.2

1 To prescribe, implement, and monitor silvicultural practices that develop forest stand conditions, which meet land management objectives designated in Regional Guides and Forest Plans.

Harvest Cutting * 2471.02

1. To manage timber and other forest resources for protection, enhancement, and sustained yield of those resources through the sale or permitted use of forest products with the long-term intent to regenerate the stand.

Timber Stand Improvement * 2476.02

1. Maintain or increase the growth rate, health, species composition, and/or improve the quality of stands for timber or other resource uses according to direction in the Forest Plan.

Watershed Management * 2502

1. To protect and, where appropriate, enhance soil productivity, water quality and quantity, and timing of waterflows.

2. To maintain favorable conditions of streamflow and continuous production of resources from National Forest System watersheds.

Watershed Protection and Management * 2520.2

1 To protect National Forest watersheds by implementing practices designed to retain soil stability, improve or maintain site productivity, secure favorable conditions of water flow, and preserve or enhance aquatic values.

Watershed Improvement * 2522.02

1 Restore hydrologic balance of degraded watershed areas by stabilizing soil, controlling surface runoff and erosion, reducing flood potential, and improving long-term soil productivity.

2. Improve soil and water quality.

Burned Area Emergency Rehabilitation * 2523.02

1. To provide for immediate rehabilitation of watersheds following wildfire to help stabilize soil, control water, sediment, and debris movement

Riparian Areas * 2526.02

1. To protect, manage, and improve riparian areas while implementing land and resource management activities.

2. To manage riparian areas in the context of the environment in which they are located, recognizing their values.

Floodplain Management Wetland Protection * 2527.02

1. To reduce risk of flood loss

2 To minimize impacts of floods on human safety, health, and welfare

3. To minimize destruction, loss, and degradation of wetlands.

Water Quality Management * 2532.02

1. To protect and, when needed, improve the physical, chemical, biological, and aesthetic quality of the water resource consistent with the purposes of the National Forests and national water-quality goals.

2. To provide water of a quality suitable for the beneficial uses identified in the land and resource management planning process.

3 To ensure safe drinking water subject to public use on National Forests, whether the source is a natural or developed water supply. (When state standards do not exist, observe EPA water-quality criteria.)

Municipal Supply Watersheds * 2542.02

1 To manage National Forest System lands for multiple-use by balancing present and future resource use with domestic water-supply needs.

Soil Resource Improvement * 2553.02

1. To improve soil quality to selected levels for specific purposes by mechanical treatment, chemical, or other soil additives, irrigation, or vegetative manipulation
- 2 To rehabilitate soils that are in unsatisfactory condition

Air Quality * 2580.2

1. Protect air-quality-related values within Class 1 areas, as described in 42 U.S.C.7475 (d)(2)(b) and (c) and section 2580.5.
2. Control and minimize air-pollutant impact from land management activities.
3. Cooperate with air regulatory authorities to prevent significant adverse effects of air pollutants and atmospheric deposition on forest and rangeland resources.

Fish and Wildlife * 2602

1. Maintain ecosystem diversity and productivity by:
 - a Recovering threatened or endangered species.
 - b. Maintaining at least viable populations of all native and desired nonnative wildlife, fish, and plants in habitats distributed throughout their geographic range on National Forest System lands.
 - c. Producing habitat capability levels to meet sustained yield objectives relative to demand for featured management indicator species identified in RPA and Forest Plans.
2. Provide diverse opportunities for aesthetic, consumption, and scientific uses of wildlife, fish, and sensitive plant resources in accordance with national, regional, state and local demands.

Animal Damage Management * 2650.2

1. To protect resources and permitted livestock from animal damage on National Forest System lands and to protect human health and safety

Threatened and Endangered Species * 2670.21

1. Manage National Forest System habitats and activities for threatened and endangered species to achieve recovery objectives so that special protection measures provided under the Endangered Species Act are no longer necessary.

Sensitive Species * 2670.22

1. Develop and implement management practices to ensure that species do not become threatened or endangered because of Forest Service actions.
2. Maintain viable populations of all native and desired nonnative wildlife, fish, and plant species in habitats distributed throughout their geographic range on National Forest System lands.
3. Develop and implement management objectives for populations and/or habitat of sensitive species.

Special Uses * 2702

1. To authorize the use of National Forest System lands by federal, state, and local agencies, as well as private industry and individuals, in accordance with governing laws and regulations to best serve the interest of the public and the United States.

Special Use Authorization * 2710.2

1. To issue appropriate special-use authorizations according to the law, regulations, and policy for occupancy and use of land in a manner consistent with the purpose of the National Forest System and Forest Plans.

Special Use Administration * 2721.02

1. To issue and to administer special-use permits for recreation uses that serve the public, promote public health and safety, and protect the environment.

Special Uses Management * 2730.2

1 Provide rights-of-way for the public road system, including the federal-aid system, when such roads cross National Forest System lands or interest in lands.

2 Accommodate the access needs for the protection, development, and utilization of lands and resources owned by private interests or administered by public agencies when the planned Forest Development Road System and public road system do not meet those needs adequately

3. Protect and enhance the quality of air, water, soil, and natural beauty of Forest Service administered lands in the granting of any right-of-way.

4. Cooperate with intermingled and adjacent landowners in developing roads that serve the needs of both parties through the exchange of rights-of-way.

5. Provide access across National Forest System land to private land that is adequate to secure the owners thereof reasonable use and enjoyment of their land without unnecessarily reducing the management options of the Forest Service or damaging National Forest lands or resources.

Withdrawals * 2761.02

1. Protect the United States' improvements and other unique values that are subject to disposition or destruction under the public land laws.

2. Provide a consistent and efficient withdrawal program that meets land and resource management objectives.

3. Ensure cooperation and coordination with the Secretary of the Interior and the Bureau of Land Management.

4. Encourage mineral activity where mineral extraction is the best use of the site

Federal Power Act Projects * 2770.2

1 To ensure hydroelectric production where it is compatible with National Forest purposes. To ensure that planning, construction, and operation of hydroelectric projects are performed in such a manner to protect or effectively utilize National Forest System land and resources.

Minerals and Geology * 2802

1. Encourage and facilitate the orderly exploration, development, and production of mineral and energy resources within the National Forest System in order to maintain a viable, healthy minerals industry and to promote self-sufficiency in those mineral and energy resources necessary for economic growth and the national defense.
2. Ensure that exploration, development, and production of mineral and energy resources are conducted in an environmentally sound manner and that these activities are integrated with the planning and management of other National Forest resources
3. Ensure that lands disturbed by mineral and energy activities are reclaimed for other productive uses.

Minerals Reservations Outstanding Mineral Rights * 2830.2

1. To administer mineral reservations and outstanding mineral rights consistent with the rights reserved or outstanding and the acquired rights of the United States in a manner that minimizes damage to National Forest System resources.

Mineral Materials * 2850.2

1. To meet the demand for mineral materials consistent with the management of other surface resources.

Reclamation * 2840.2

1. Minimize the environmental impacts resulting from such activities.
2. Ensure that disturbed lands are returned to a use that is consistent with long-term Forest land and resource management plans

Rural Development * 3602

1. To utilize Forest Service programs and authorities to provide more jobs and income opportunities, to improve rural living conditions, to enrich the cultural life of rural America, and to maintain and protect the environment and natural resources of rural areas.
2. Participation in the Rural Conservation and Development Program (RC&D) is to improve the ability of state and local units of government and local sponsors to accelerate the conservation, development, and use of forest resources with the aim of improving the social, economic, and environmental conditions in an authorized RC&D area.

Rural Development * 3610.2

1. To protect and manage the natural resources including scenic, Wilderness, and other special values of forest and range environments in rural areas.
2. To promote research to expand the technological base for forestry and the use of forest products and to lend support for rural housing goals.
3. To encourage the development and transfer of technological improvements to protect and improve the quality of the rural environment, and to extend the supplies of natural resources
4. To maintain or increase the forest land base, improve its productivity, and improve forest landownership patterns.

5 To promote orderly development and wise use of forest resources consistent with sound stewardship to develop and increase rural employment and income with the aim of improving or stabilizing rural social and economic conditions

6. To expand public understanding of environmental conservation and natural resource planning, protection, and management and how stewardship is related to these activities.

7. To provide information and analysis for determining forest resource potentials and opportunities to enhance rural development

Resource Conservation and Development Program * 3620.2

1 To help provide the people of the area with employment and other economic opportunities through the orderly development, improvement, conservation, and utilization of forest land-related resources in the RC&D areas.

2. *To provide state and local leadership with the opportunity to coordinate and use the facilities and techniques available under current agricultural programs and any applicable new programs as may be instituted to aid in planning and carrying out a balanced program of development, conservation, and protection of natural resources to meet local, state, and national needs.*

3. To develop a level of state and local leadership that can assume independent programs in forest and related resource management and achieve state and local forestry and related resource goals and objectives.

Research Natural Areas * 4063.02

1 Preserve a wide spectrum of representative areas that typify important forest, shrubland, grassland, alpine, aquatic, geological, and similar natural situations that have special or unique characteristics of scientific interest and importance that in combination form a national network of ecological areas for research, education, and maintenance of biological diversity.

2. Preserve and maintain genetic diversity.

3. Protect against serious environmental disruption.

4 Serve as reference areas for the study of success.

5. Provide on-site and extension education activities.

6. Serve as baseline areas for measuring long-term ecological changes

7. Serve as control areas for comparing results from manipulative research

8. Monitor effects of resource management techniques and practices

Fire Management * 5102

1. To protect, maintain, and enhance the production and quality of National Forest resources through fire protection and use of prescribed fire.

Fire Suppression * 5130.2

1 To suppress wildfires at minimum cost consistent with land and resource management objectives and fire management direction as stated in fire management action plans.

Prescribed Fire * 5140.2

1. To use prescribed fires, from either management ignitions or natural ignitions, in a safe, carefully controlled, cost-effective manner as a means of achieving management objectives defined in the Forest Plan.

Fuel Management * 5150.2

1. To identify, develop, and maintain fuel profiles that contribute to the most cost-efficient fire protection and use program in support of land and resource management direction in the Forest Plan.

Landownership Adjustment * 5402

1. Achieve the optimum landownership pattern to provide for resource use to meet the needs of the people now and in the future.

2 Settle land title claims equitably and promptly

3. Provide resource administrators readily accessible and understandable title information affecting the status and use of lands and resources they administer.

Land Purchases and Donations * 5420.2

1. Enhance the multiple use and sustained yield of the goods and services from the National Forest System.

2. Protect and improve the quality of renewable resources

3 Protect and preserve important historic, cultural, and natural aspects of the national heritage.

4. Provide for access, use, and enjoyment of the forest resources by the public.

5. Improve administrative efficiency and effectiveness of the National Forest System.

Land Exchange * 5430.2

1. To implement land management and resource planning directions to attain an optimum National Forest System landownership pattern that provides for resource uses that best meet the present and future needs of the people.

Partial Interest Acquisition * 5440.2

1. Provide for acquisition of only those interests in land necessary to meet planned program objectives.

2. Provide for continuance of private land uses consistent with planned program objectives.

National Forest System Modification * 5450.2

1. The objectives of National Forest System modifications are to

- a. Obtain National Forest status for all appropriate land within the National Forest System.
- b. Modify existing National Forest System unit boundaries as needed to provide logical exterior boundaries.
- c. Establish purchase units as needed to meet program objectives.
- d. Establish National Forest or other boundaries as needed to facilitate management and administration.

2. The objectives of land transfer are to:

- a. Improve management efficiency of federal lands.
- b. Improve service to the public
- c. Result in net benefits to the government, to the public, or both.

Right-of-Way Acquisition * 5460.2

1. To acquire, across nonNational Forest System land, road and trail rights-of-way that are adequate for the protection, administration, and utilization of the National Forests. Where compatible with National Forest needs, the rights-of-way should also accommodate the utilization and development of resources in other ownerships upon which communities within or adjacent to the National Forest depend.
2. To acquire such rights-of-way in time to meet road and trail construction and resource development program schedules.
3. To acquire all interests to permit use of road and trails to meet the multiple use and sustained yield objectives of the National Forests.

Reservations and Outstanding Rights * 5470.2

1. To accomplish real property adjustments free of encumbrances that would detract from present or future uses of National Forest System land or that would needlessly restrict private land use and impose an unwarranted management obligation on the Forest Service.

Condemnation * 5480.2

1. To acquire real property by condemnation when all other methods of acquisition fail and the property or interest is required for the protection, administration, or utilization of National Forest System lands.

Land Surveying * 7151.02

1. Provide legal land surveys and related service to locate, mark, post, and maintain land corners, property corners, and property lines between National Forest System land and other ownerships for the protection and management of National Forest System lands and resources.

Landline Location Program * 7152.02

1. Provide the land manager and public with visible and legally defensible administrative and property boundary lines on the ground, and to accurately depict the location of landownership lines on administrative maps produced by the Forest Service.

Sign and Poster Program * 7160.2

1. Support accomplishment of management are a direction contained in the Forest Plan for the administration, protection, management, and use of National Forest System lands.
2. Provide information for the safety, enjoyment and convenience of National Forest and National Grassland visitors, users, cooperators, and employees.
3. Provide information about geographic and historical features, and the use, management, and research activities on the National Forest and National Grasslands.
4. Identify National Forests and National Grassland facilities and land.

Portable Water Supply * 7420.2

1. Protect the health of the public and Forest Service personnel Accomplishment of this objective requires that water provided by the Fores Service for human consumption at any administrative side or public use area must be both safe and protected.

Wastewater Collection Systems and Treatment Works * 7430.2

- a. Avoid creating health hazards or nuisance conditions.
 - b. Restore and maintain the chemical, physical, and biological quality of water resources.
 - c. Manage future pollution or degradation of surface or groundwaters
2. The objective of this program is to plan, design, construct, operate, and maintain wastewater disposal facilities and other effluent-disposal activities to ensure that discharge and/or infiltration of pollutants do not create health hazards or nuisance conditions, nor alter the quality or characteristics of either groundwater or surface water beyond applicable federal and/or state water-quality and effluent-discharge standards Where no standards exist, the quality of characteristics of surface and groundwater shall.
- a. Be maintained as near to their existing conditions as measurable.
 - b. Not be degraded to adversely affect either present or projected beneficial uses (FSH 7409 11 Ch 20).
 - c. Not be allowed to degrade the quality of subsequent ground- or surface-receiving waters beyond the standards when such have been established.

Transportation System * 7702

1. To plan, develop, and operate a network of transportation facilities and transportation modes that provide user safety, convenience, and efficiency of operations.
- 2 To provide access to National Forest System lands to accomplish management direction and protection objectives that is coordinated with national and state-wide transportation needs.
3. To minimize the total transportation present value cost including user, maintenance, construction, restoration, realignment, and betterment costs.

Transportation Planning * 7710.2

1. To efficiently provide facilities that will achieves Forest management direction and that are appropriate for this intended use.
- 2 To direct the orderly development and management of the transportation system and to ensure the documentation of decisions affecting the system.
3. Document desired future condition for highway corridors (existing and planned) across National Forest System lands.

Development * 7720.2

1. To locate, survey, design, and construct transportation facilities in accordance with FSM 7702.

Operation and Maintenance * 7730

- 1 Operate and maintain the Forest Development Transportation System in a manner to provide cost effective support of resource management direction and safe travel for users of the system while protecting the environment, adjacent resources and the public investment.

Highway Safety Program * 7733.02

1. Reduce traffic accident, deaths, injuries and the resulting property damage.

Federal Lands Highway Program * 7740

1. To assist the Federal Highway Administration with the administration of the Forest highway program to plan and develop access roads to:
 - a. Enhance the value of National Forest System resources.
 - b. Protect, develop, and use the National Forest System and its renewable resources.
 - c. Enhance economic development at the local, regional, and national levels
 - d. Serve local needs and communities dependent on the National Forest System activities.
 - e Provide for economy of operation and maintenance and the safety of the users.
 - f. Provide safe and adequate rural highways connection the National Forest System with major highway systems

AMERICAN INDIANS (FSM 1563)

1. On October 22, 1992, the United States Department of Agriculture issued a policy statement on Indian tribes. The outlined policies include:
 - a. Supporting the principles of self-governance delineated in the Indian Self-Determination Act and Education Assistance Act.
 - b. Consulting with tribal governments regarding the influence of USDA activities on water, land, forest, air and other natural resources of tribal governments

- c. Seeking input from tribes on USDA policies and issues affecting tribes and reconciling Indian needs with the principles of good resources management.
- d. Observing the American Indian Religious Freedom Act.
- e. Working with tribal governments, high schools and universities to encourage the development of agribusiness skills and sharing of information through exchange of technical staff and skills.
- f. Encouraging early communication and cooperation between agencies with responsibilities to tribal governments.
- g. Consistent with applicable law or regulation, facilitating tribal participation in program planning and activities

For more on American Indians, see Chapter 3 * Forestwide Standards and Guidelines.

BIOLOGICAL DIVERSITY (FSM 2670)

Sensitive Species

1. Manage sensitive species habitat as directed in interim directive 2600-93-1

For more on Biological Diversity, see Chapter 3 * Forestwide Standards and Guidelines.

CAVES (FSM 2356)

1. Caves will be protected and evaluated under provisions of the Federal Cave Resources Protection Act of 1988. Caves determined to be significant under the Act or being evaluated are exempt from locational disclosure under the Freedom of Information Act. The location of caves will be kept confidential when needed to protect important archeological resources, habitat for endangered wildlife, sensitive cave biota, and unique geological features.
2. Management plans will be prepared for caves determined to be significant
3. Coordinate the management of cave and surface resources.
 - a. Manage the cave resource in partnership with caving organizations, other governmental agencies, scientists, researchers, and outdoor recreationists.
 - b. Interpret cave resources and provide public evaluation for increased public understanding and awareness of the need to protect and preserve these unique ecosystems.
 - c. Provide for public health and safety while recognizing that no cave is completely safe and that risk-taking is part of the caving experience.
4. Adjust silvicultural prescriptions to protect caves.
 - a. Retain a vegetative buffer area around cave entrances.
 - b. Do not alter cave entrances with timber harvest activities.
 - c. Do not dispose of slash, refuse, or burn slash at cave entrances.

5. Road or trail signs should not direct public attention to wild caves.
6. Access for exploration and development of locatable mineral resources will be analyzed in response to a proposed operating plan.
7. Potential impacts to cave resources will be considered in reviewing any project.
8. The water, sediment, nutrient and temperature regimes of caves and karst features will be protected so these environments can function naturally.

DAMS (FSM 7500)

1. For administrative Class A, B, C and high hazard Class D dams located on National Forest System lands, annually update the National Inventory of Dams (PL99-662) in accordance with data elements required by the Federal Emergency Management Agency (FSM 7514).
2. Maintain a record for all dams on National Forest System lands over six feet high (vertical difference between the lowest point on the crest of the dam and the lowest point in the original stream bed). As a minimum, the record should include the dam identification, location, purpose, owner, administrative classification, hazard-potential classification, height, and maximum storage (FSM 7514).

FIRE AND FUELS (FSM 5100)

Fire Suppression

1. *Structural firefighting is the responsibility of local fire service agencies. Structural fire protection from advancing wildfire within the National Forest Protection Boundary is the responsibility of local fire service agencies and the Forest Service (FSM 5133.1).*

Fuel Treatment

2. Cooperate with state and local governments and fire protection districts in the development of fire hazard reduction plans and ordinances by providing technical assistance (FSM 3172, 3173, 3174).
3. Provide a level of protection from wildfire outside of incorporated towns that minimizes the risk of building damage or firefighter exposure. A fire management plan will be written for all facilities on National Forest lands and will be maintained in the Forest's Fire Management Action Plan. National Fire Protection Association (NFPA) standards will be used as guidelines for the development of individual plans. Each plan will provide guidance for structural, vegetative, and infrastructure management of the facilities on the Forest. Planning standards will be used to provide guidance for private landowners requesting direction for wildland fire-protection improvements

Prescribed Fire

4. Use prescribed fire to accomplish resource management objectives, such as reducing fuel load buildup, wildlife habitat improvement, etc. Identify objectives in conjunction with a burning plan approved by a line officer. Prescribed burns adjoining private or other federal or state lands will be coordinated with the adjoining landowner (FSM 5140).
5. Use prescribed fire where it will meet management objectives in the most economically and ecologically acceptable way (FSM 5140). For more on Fire and Fuels, see Chapter 3 * Forestwide Standards and Guidelines.

GEOLOGY (FSM 2800)

1. Permit appropriate prospecting and collecting proposals for fossils and minerals by noncommercial, scientific, and/or educational institutions, and provide appropriate opportunities for recreational collection of mineral and fossil materials, where consistent with Forest Plan goals and objectives FSM 2860.3).
2. Prevent unauthorized removal of fossil and mineral resources (FSM 5302).

3. Propose significant paleontologic sites for designation as special interest areas or geologic areas (FSM 2360, 2372, 4063).

4. Identify special geologic hazards and problems that affect land and resource management and encourage research in those areas (FSM 2880, 2883, 2884).

HERITAGE RESOURCES (FSM 2360)

1. Locate, evaluate, protect and foster public use and enjoyment of heritage resources.
 - a. Protect all heritage resources listed on or eligible for the National Register of Historic Places (NRHP).
 - b. Nominate all eligible heritage resources to the NRHP.
 - c. All projects will be reviewed by a Forest Service professional heritage resources specialist.
 - (1) Complete heritage resource inventories, evaluations and mitigation measures for a project's area of potential effect prior to issuing environmental decision notices (FSM 2361)
 - d. Avoid effects to heritage resources until evaluated and determined ineligible for the NRHP.
 - e. Implement appropriate mitigative measures in consultation with the State Historic Preservation Officer (SHPO) and/or the President's Advisory Council on Historic Preservation (ACHP) when eligible heritage resources will be affected.
 - f. Maintain, stabilize, or enhance all eligible heritage resources. <F2P8B>

For more on Heritage Resources, see Chapter 3 * Forestwide Standards and Guidelines.

INTEGRATED PEST MANAGEMENT (FSM 4500)

1. Use only chemicals registered with the Environmental Protection Agency and follow label instructions.

For more on Integrated Pest Management, see Chapter 3 * Forestwide Standards and Guidelines.

LANDS (FSM 5400)

Landownership Adjustments

1. Work with other federal agencies to consolidate ownership and propose jurisdictional transfers that achieve the following objectives.
 - a. Develop more effective and efficient work units.
 - b. Reduce administrative costs

- c. Improve, maintain and simplify user access to public lands.
- 2. Adjust National Forest System and private lands to create a landownership pattern that meets objectives of the Forest Service and other landowners.
- 3 Manage National Forest System lands identified for exchange or sale consistent with surrounding management area goals and in accordance with the following:
 - a Terminate special-use permits on an opportunity basis and in compliance with applicable regulations and Forest Service policy.
 - b. Renew or extend special-use permits on an annual basis only with specific notice of the potential sale or exchange included in the authorization
 - c. Do not authorize construction of additional permanent facilities.
 - d Do not adversely affect land values by management activities.
 - e. Do not adversely affect land values through issuance of special-use permits.
 - f. Acquire unrestricted rights-of-way whenever possible to maintain the value of the public land.
 - g. Ensure needed public rights-of-way are retained across all lands conveyed out of public ownership (FSM 5403.1).
- 4 Convey lands only if:
 - a. Flood hazards on and downstream from conveyed lands are not increased.
 - b. Natural and beneficial values of acquired wetlands equal or exceed those of conveyed wetlands.
 - c Natural water regimes in wetlands downstream from conveyed lands are not disrupted.
 - d. Lands have been evaluated for the presence of hazardous materials and known hazardous materials have been removed.
 - e. Lands do not contain habitat identified by the U.S. Fish and Wildlife Service as necessary for recovery of federally listed threatened and endangered species.
 - f. Lands do not contain unique resource characteristics (FSH 5409.13, Chapter 30).
- 5 Effect jurisdictional transfers that achieve the following objectives:
 - a Reduce duplication of efforts by users and agencies in terms of time, cost and coordination
 - b. Improve or maintain user access to the administrating agency.
 - c. Decrease travel and enhance management.
 - d. Improve public understanding of applicable laws, regulations, policies and procedures.
 - e. Develop more effective and efficient work units.

Property Boundary Administration (FSM 7150)

6. Locate, mark and post landlines according to the following priorities:

- a. Lines needed to meet planned activities;
- b. Lines needed to protect NFS lands from encroachment, and
- c. All other lines (FSM 7152).

For more on Lands, see Chapter 3 * Forestwide Standards and Guidelines.

MINERALS (FSM 2800)

General

- 1 Require an operating plan for each significant proposed mineral action that may disturb surface resources (FSM 2817, 2818, 2820).
2. In areas of actively producing sites or areas containing known reserves, consider only surface resource programs compatible with mineral activities.
3. Provide reasonable access to outstanding and reserved mineral rights (FSM 2830.5).
- 4 In designated Wilderness areas, provide for reasonable access to proposed operations and for restoration of disturbed lands as near as practical to their natural condition when they are no longer needed for operation.
5. Consider significant cave discoveries for mineral withdrawal and other protection measures (FSM 2761, 5302)
- 6 Deny drilling, mining or production on withdrawn lands, with the exception of valid existing rights at the time of withdrawal (FSM 2811, 2818, 2822, 2823).
7. Resolve suspected abuse of the mining laws such as occupancy of the land for purposes other than prospecting, mining and related operations.
8. Avoid placing or proposing capital investments or other surface resource activities in areas where they would interfere with operating sites or known mineral resources (FSM 2761).
9. Request mineral leasing withdrawals in situations, such as for classified lands.
10. Cover mining activity by an operating plan and performance bond of the appropriate amount.
11. Reclamation will return disturbed lands to the planned uses.

Leasable Minerals

12. Approve Surface Use Plan of Operation (36 CFR 228.107) in conformance with all stipulations included in the lease and necessary conditions of approval determined during review of the applications (FSM 2800).

Geophysical Operations

13. Permit geophysical operations on withdrawn, classified lands where the operations do not interfere with purposes for which the lands are withdrawn. Do not permit such operations if significant adverse effects cannot be prevented (FSM 2860).

Coal, Uranium and Non-Energy Common Materials

14. In designated Wilderness, Congressionally designated Wilderness study areas, and areas recommended for Wilderness in RARE II upon which Congress has not taken final action:

- a. Prospecting for and disposals of common varieties of mineral materials will not be authorized.
- b. Coal mining in the National Wilderness Preservation System is prohibited by the Coal Leasing Amendments Act of 1975.
- c. Unless there is statutory language to the contrary, in which case the statutory provisions control, recommend, or consent to BLM for issuance of leases or permits where operations, including surface-based access, product transportation and other necessary ancillary facilities, will not cause irreversible and irretrievable damage to surface resources and where the lands disturbed can be restored as near as practical to natural conditions

15. In classified lands other than Wilderness (Wild and Scenic River Systems, RARE II Further Planning areas, National Recreation Areas, National Historic Sites, Natural Areas, Special Areas*such as geological, scenic and zoological, and some other specific classifications):

- a. Authorize common variety exploration and disposals under terms and conditions to protect the purposes for which the lands were classified. The objective of reclamation requirements will be to return lands to a condition suitable for the purposes for which they were classified.

For special areas classified under 36 CFR 294 and 251.23 for specific management purposes, the regulatory provisions permit no use or occupancy inconsistent with the classification.

b. Coal mining is prohibited by the Coal Leasing Amendment Act of 1975, within the National System of Trails and the Wild and Scenic Rivers System, including study rivers designated by that Act.

c. Recommend or consent to BLM for issuance of leases permits or licenses only when terms and conditions can be applied that will protect the purposes for which the lands were classified. <F2P8B>

For more on Minerals, see Chapter 3 * Forestwide Standards and Guidelines.

RANGE (FSM 2200)

1. Allotment management plans (AMPs) need to provide for threatened, endangered and sensitive species (FSM 2203, 2211, 2212).

2. When updating AMPs, display forage utilization factors by type of management, the season of use, and the ecological type by condition and seral stage within the AMP (FSM 2210, 2211).

3. Construct structural improvements to maintain or improve rangeland conditions within classified Wilderness, consistent with Wilderness values (FSM 2323.26).

4. Riparian utilization or stubble-remaining standards are to be developed and included in AMPs. Consider season of use to minimize impacts on riparian zones (FSM 2211, 2212, 2526).

5. Give emphasis to developing livestock management strategies that are economically efficient, environmentally sound and compatible with other resources (FSM 2212.03 - 2212 8).

6. Structural and nonstructural improvements to maintain or improve rangeland conditions will be designed to benefit livestock and wildlife and minimize impacts on wildlife and recreation users (FSH 2209.22, 2209.23, FSM 2240).

For more on Range, see Chapter 3 * Forestwide Standards and Guidelines.

RECREATION (FSM 2300)

Developed

1. Where terrain allows and demand exists, facilities will be considered for development to accommodate people with disabilities. Different challenge levels will be planned, depending upon the nature of the improvement and the principal form of recreation being provided.

2. The customer will be recognized as a spectrum of our society interested in a wide array of dispersed, sedentary, adventure, developed, guided, self- determined, motorized and nonmotorized activities in controlled and uncontrolled environments. Potential customers will be recognized as those who might use National Forest resources if appropriate services and resources were available (FSM 2330)

3. Sites will be managed and maintained according to the needs of our customers using the site. Safety and cleanliness are of utmost importance. Remove hazardous and/or dead trees in developed sites (FSM 2331 R-2 Supplement #70, FSM 2332).

4. The type and level of development sophistication in developed sites may vary, depending upon the situation and need. They are developed by the Forest Service, concessionaires or cooperators and may be managed by any or a mix of these (FSM 2303).

Recreation Opportunity Spectrum

5. A recreation opportunity spectrum (ROS) table is included in Chapter 1 of this Forest Plan. A decision to change an ROS class will be documented in a NEPA decision document (FSM 1922.15, 2310.3).

For more on Recreation, see Chapter 3 * Forestwide Standards and Guidelines.

RESEARCH NATURAL AREAS (FSM 4060)

1. Discourage or prohibit any public use that contributes to impairment of research or natural values (FSM 4063.36)

2. Use special-use permits or cooperative agreements to authorize and document scientific activity (FSM 4063.37).

RIGHTS-OF-WAY (FSM 5460)

Acquisition

1. Acquire rights-of-way on existing and proposed Forest System roads and trails that cross other than National Forest System lands.

2. Acquire rights-of-way using the following criteria:

- a. Legal access for existing roads and trails that provide general access to the National Forest.
- b. Legal access to support planned projects and high priority activities at least two years prior to project implementation (FSM 5461.2).<F2P8B>

For more on Rights-of-Way, see Chapter 3 * Forestwide Standards and Guidelines.

SOILS (FSM 2550)

- 1 Soil should not be displaced more than a continuous area of 100 square feet or more (FSH 2509.18 R-2 Supplement).
2. Soils should not be compacted more than (FSM 2509 18 R-2 Supplement):
 - a A 15 percent increase in bulk density from the average undisturbed density, or
 - b. Bulk density values that exceed the following threshold values:
 - 1 25g/c * silt and clay
 - 1.30 g/cc * silty clay, silty clay loam and silt loam
 - 1.40 g/cc * loam and clay loam
 - 1.50 g/cc * sandy loam, sandy clay loam and sandy clay
 - 1.60 g/cc * sand and loamy sand
3. Maintain adequate plant cover to protect the watershed and maintain plant health consistent with the soil type.
4. Management practices will be designed and implemented to maintain or improve the long-term soil productivity potential of the National Forest (FSH 2509 R-2 Supplement).
5. Soil quality monitoring will be conducted to determine if soil management goals, objectives and standards are being achieved (FSH 2509 R-2 Supplement).
6. Monitoring results will be used to adjust management activities and mitigating measures where necessary to prevent significant impairment of the long-term soil productivity (FSH 2509 R-2 Supplement).

For more on Soils, see Chapter 3 * Forestwide Standards and Guidelines.

SPECIAL LAND USES (FSM 2700)

1. Act on special-use applications according to the following priorities:
 - a Those required by law or regulation, or national in scope.
 - b. Those in the public interest, mainly local or regional in nature.
 - c. All others
- 2 Do not approve any special-use applications that can be reasonably met on nonfederal or other federal lands unless it is clearly in the public interest (FSM 2703.2).
3. Do not approve special-use applications for areas adjacent to developed sites unless the proposed use is compatible with the purpose and use of the developed site.

4. Utilize approved electronic sites where feasible

5. Do not approve applications for use of federal land that involve any hazardous materials as defined in U.S.C. 9601 et seq., 40 CFR 261.30 and 40 CFR 302.4. The hazardous materials listed are individual chemicals. These references do not relate to hazardous waste dumps (FSM 2703).

TIMBER (FSM 2400)

General

1. *Forests are to be managed to provide net public benefits. Many different philosophies and strategies are used that provide benefits desired in the areas of urban interface, those areas used for recreation and viewing, for wildlife habitat, watershed protection, water-yield enhancement, and others, as well as for wood and fiber products. In most cases, these must be integrated. Managers are to develop and use a wide variety of prescriptions to meet these public priorities and to accept that traditional economic considerations must be supplemented with both the empirical and subjective ones (FSM 2470 3).*

2. Plan areas for timber harvest only if assured, based on existing technology and knowledge, that long-term soil productivity will not be degraded (FSH 2409.26 Chapter 10).

3. Provide for wildlife habitat improvement and enhancement of other renewable resources in sale area improvement plans.

Tree Stand Improvement (Precommercial Thinning)

4. Provide for accelerated growth, create specific stocking, and improve quality and vigor of timber stands.

Silvicultural Prescriptions

5. Silvicultural prescriptions for tree-stand improvement, including thinning, should evaluate the tradeoffs associated with alternative treatments in terms of increased timber yields, economic efficiency, enhanced wildlife habitat, increased wood-products yield and quality, improved long-term forest health, increased species and structural diversity and the desired future condition for the stand (FSH 2409.26c Chapter 10, FSH 2409 17 Chapter 6).

6. Silvicultural prescriptions will be prepared for all vegetation management activities proposing the management of forested vegetation to work toward achieving the desired future condition (FSH 2409).

7. Apply a variety of silvicultural systems and harvest methods that best meet resource management objectives.

8. Prepare individual silvicultural prescriptions for areas or site specific practices.

9. Use thinning practices that consider genetic diversity, competition among the trees for water, nutrients and light. *The frequency of thinning should depend upon the tree species, financial efficiency, and the site's growing conditions (as commonly measured by site index) (FSH 2409.17 Chapter 6)*

10. Where appropriate, reduce competition between desired trees and other vegetation (FSH 2409.17 Chapter 6)

11. If the silvicultural system being applied to a particular area of the landscape is uneven-aged, harvest trees designated for commercial timber production based on the desired density as determined by age class or size, and the objective for the area (FSH 2409.26).

12. In most circumstances, rely on or make primary use of these silvicultural systems that ensure regeneration of forest stands through natural seeding and suckering (FSH 2409 26b Chapter 70).

13. Use artificial regeneration methods when we cannot rely on the natural sequence of events and/or environmental conditions to regenerate the forests within five years or earlier (FSH 2409.26b Chapter 70).

14. Inventory improvement needs in sale areas during sale reconnaissance. Use KV funds as applicable after sale closure to accomplish needed improvements including education and interpretation (FSH 2409.12 Chapter 10).

For more on Timber, see Chapter 3 * Forestwide Standards and Guidelines.

TRANSPORTATION AND TRAVEL

Transportation System Management (FSM 7700)

1. Unless a proposed road is determined necessary as a permanent addition to the National Forest Transportation System, close it and revegetate it. Revegetation will be achieved within six months. Close or obliterate temporary roads immediately when use ends (FSM 7703.1).

2. Retain access rights (FSM 7712 31).

3. Establish the specific purpose and intended use for each existing and proposed road, based on management direction. Document this purpose by writing specific road management objectives, which include appropriate design, operation, and maintenance criteria. Employ traffic (travel) management strategies of encourage, accept, discourage eliminate, unrestricted, or prohibit on all roads (FSM 7712.31).

4. Develop road management programs to require commercial users to pay their share of road maintenance.

5. Propose state and county roads as Forest Highways where the use and development of National Forest System lands affect the public road system, thus necessitating federal investments to ensure that these roads are safe and adequate. Such designation identifies state and local government roads that qualify for construction and reconstruction funding under the Forest Highway program. Designate and develop Forest Development Roads as Forest Highways when use of the road meets requirements for Forest Highway designation (FSM 7740.3).

6. Coordinate Forest information and directional signs with appropriate transportation agencies (FSH 7109.11).

Trails (FSM 2300)

7. Provide for a wide range of recreational opportunities, both motorized and nonmotorized. The trail system on each National Forest will:

a. Consider barrier-free opportunities for all new construction or rehabilitation proposals.

b. Not be dedicated to single use unless clearly necessary to resolve conflicts or create unique opportunities.

c. Have documentation on the purpose and use of each trail (FSH 2309).

8. Trail systems will be integrated across administrative boundaries, including adjacent Forest Service units, other federal agencies, state, and municipal trails (FSM 2353).

9. Maintain each trail to the standard required for the intended user-types

10. The permanent Forest trail system will be determined and identified in the Forest Trail Development Plan. This plan will include the existing and future quality constraints as they apply to trail experiences (FSM 2353).

11. National Historic, Scenic, or Recreation Trails will receive higher priority than other trails for reconstruction, operation and maintenance (FSM 2353).

12. *Maintain all trails to established Forest standards.*

a. Maintain trails in accordance with standards in the Trail Handbook

b. Schedule trail maintenance in accordance with Regional acceptable work standards

13. Construct or reconstruct trails when needed as part of the transportation system.

For more on Transportation and Travel, see Chapter 3 * Forestwide Standards and Guidelines.

VISUAL QUALITY (FSM 2380)

1. Management activities must be consistent with the visual quality objectives (VQO) in this Forest Plan unless a decision is made to change the VQO. A decision to change the VQO will be documented in project NEPA decision documents (FSM 2382.21).

2. At the project implementation stage, the VQO should be refined to the project scale.

3. As new viewer platforms (such as roads, trails, recreation areas or major housing developments outside National Forests) are developed, the VQOs should be reassessed (FSM 2382.32).

4. For areas which do not currently meet the VQO, use landscape rehabilitation as a short-term alternative to restore landscapes containing undesirable-visual impacts to a desired visual quality (FSM 2383).

For more on Visual Quality, see Chapter 3 * Forestwide Standards and Guideline and Appendix G

WATER (FSM 2520)

Water Quality

1. Develop integrated soil/water/fishery improvement schedules for watersheds, coordinated with other resources. Coordinate with state wildlife agencies. Apply treatment and land-use controls as needed to restore soil productivity, water quality, channel stability and aquatic habitat (FSM 2522.03, 2522 2).

For more on Water, see Chapter 3 * Forestwide Standards and Guidelines.

WILD AND SCENIC RIVERS (FSM 2354)

The following guidelines set forth standards for determining the classification (wild, scenic, or recreational) and eventual management of designated Wild and Scenic Rivers (FSH 1909.12).

Wild Rivers

1 Cutting of trees will not be permitted except when needed in association with a primitive recreation experience (such as clearing for trails and protection of users) or to protect the environment (such as

control of fire) Timber outside the boundary but within the visual corridors will be managed and harvested in a manner to provide special emphasis to visual quality

2 All water supply dams and major diversions are prohibited.

3. No development of hydroelectric power facilities is permitted.

4 No flood control dams, levees, or other works are allowed in the channel or river corridor. The natural appearance and essentially primitive character of the river must be maintained.

5 New mining claims and mineral leases are prohibited within 1/4 mile of the river. Valid claims would not be abrogated Subject to regulation (36 CFR 228) that the Secretaries of Agriculture and Interior may prescribe to protect the rivers included in the National System, other existing mining activity would be allowed to continue. Existing mineral activity must be conducted in a manner that minimizes surface disturbance, sedimentation, and visual impairment. Reasonable access will be permitted.

6. No roads or other provisions for overland motorized travel would be permitted within a narrow incised river valley or, if the river valley is broad, within 1/4 mile of the river bank. A few inconspicuous roads leading to the boundary of the river area at the time of study will not disqualify wild river classification. Also, unobtrusive trail bridges could be allowed.

7. Agricultural use is restricted to a limited amount of domestic livestock grazing and hay production to the extent currently practiced. Row crops are prohibited

8. Major public use areas, such as large campgrounds, interpretive centers, or administrative headquarters are located outside the wild river area. Simple comfort and convenience facilities, such as fireplaces or shelters, may be provided as necessary within the river area. These should harmonize with the surroundings

9 A few minor existing structures could be allowed assuming such structures are not incompatible with the essentially primitive and natural values of the viewshed. New structures would not be allowed except in rare instances to achieve management objectives (i.e. structures and activities associated with fisheries enhancement programs)

10. New transmission lines, gas lines, water lines, etc. are discouraged Where no reasonable alternative exists, additional or new facilities should be restricted to existing rights-of-way. Where new rights-of-way are indicated, the scenic, recreational, and fish and wildlife values must be evaluated in the selection of the site.

11. Motorized travel on land or water could be permitted, but is generally not compatible with this classification.

Scenic Rivers

12. A wide range of silvicultural practices could be allowed provided that such practices are carried on in such a way that there is not substantial adverse effect on the river and its immediate environment. The river area should be maintained in its near-natural environment. Timber outside the boundary but within the visual scene-area should be managed and harvested in a manner that provides special emphasis on visual quality.

13. All water supply dams and major diversions are prohibited.

14 No development of hydroelectric power facilities is allowed

15. Flood control dams and levees would be prohibited

16. Subject to regulations at 36 CFR 228 that the Secretaries of Agriculture and the Interior may prescribe to protect the values of rivers included in the National System, new mining claims and mineral leases could be allowed and existing operations allowed to continue. However, mineral activity must be conducted in a manner that minimizes surface disturbance, sedimentation and pollution, and visual impairment.

17. Roads may occasionally bridge the river area and short stretches of conspicuous or longer stretches of inconspicuous and well-screened roads or screened railroads could be allowed. Consideration will be given to the type of use for which roads are constructed and the type of use that will occur in the river area.

18. A wider range of agricultural uses is permitted to the extent currently practiced. Row crops are not considered as an intrusion of the largely primitive nature of scenic corridors as long as there is not a substantial adverse effect on the natural like appearance of the river area

19 Larger scale public use facilities, such as moderate size campgrounds, public information centers, and administrative headquarters, are allowed if such structures are screened from the river. Modest and unobtrusive marinas also can be allowed

20 Any concentrations of habitations are limited to relatively short reaches of the river corridor. New structures that would have a direct and adverse effect on river values would not be allowed.

21. New transmission lines, gas lines, water lines, etc. are discouraged. Where no reasonable alternative exists, additional or new facilities should be restricted to existing rights-of-way. Where new rights-of-way are indicated, the scenic, recreational, and fish and wildlife values must be evaluated in the selection of the site

22. Motorized travel on land or water may be permitted, prohibited or restricted to protect the river values.

Recreational Rivers

23. Timber harvesting would be allowed under standard restrictions to protect the immediate river environment, water quality, scenic, fish and wildlife, and other values.

24. Existing low dams, diversion works, rip rap and other minor structures are allowed provided the waterway remains generally natural in appearance. New structures are prohibited.

25. No development of hydroelectric power facilities is allowed.

26 Existing flood control works may be maintained. New structures are prohibited.

27 Subject to regulations (36 CFR 228) that the Secretaries of Agriculture and the Interior may prescribe to protect values of rivers included in the National System, new mining claims and mineral leases are allowed and existing operations are allowed to continue. Mineral activity must be conducted in a manner that minimizes surface disturbance, sedimentation and pollution, and visual impairment.

28. Paralleling roads or railroads could be constructed on one or both riverbanks. There can be several bridge crossings and numerous river access points.

29. Lands may be managed for a full range of agricultural uses to the extent currently practices.

30. Campgrounds and picnic areas may be established in close proximity to the river. However, recreational classification does not require extensive recreation development.

31. Small communities as well as dispersed or cluster residential developments are allowed. New structures are allowed for both habitation and for intensive recreation use.

32. New transmission lines, gas lines, water lines, etc. are discouraged. Where no reasonable alternative exists, additional or new facilities should be restricted to existing rights-of-way. Where new rights-of-way are indicated, the scenic, recreational, and fish and wildlife values must be evaluated in the selection of the site.

33. Motorized travel on land or water may be permitted, prohibited or restricted. Controls will usually be similar to surrounding lands and waters.

For more on Wild and Scenic Rivers, see Chapter 3 * Forestwide Standards and Guidelines.

WILDLIFE AND FISH (FSM 2600)

1. Manage animal damage in cooperation with the state wildlife agencies and the Animal and Plant Health Inspection Service to prevent or reduce damage to other resources and direct control toward preventing damage or removing only the offending animal.

2. Provide forage for big game. Allocate forage to big game based on direction in management area prescriptions and FSM 2210, range analysis and allotment management planning.

Endangered or Threatened Species

3. Provide habitat for federally listed or proposed endangered or threatened species on National Forest System lands (FSM 2672.24, 2676).

4. Complete biological evaluations on actions authorized through NEPA decision documents, funded or carried out by the Forest Service to determine the effects on federally listed or proposed endangered or threatened species (FSM 2672.4).

5. Carry out consultation, informal or formal as appropriate, with the U.S. Fish and Wildlife Service when biological assessments determine that Forest Service actions may affect federally listed or proposed endangered or threatened species (FSM 2671.45).

For more on Wildlife and Fish, see Chapter 3 Forestwide Standards and Guidelines.

GLOSSARY

-A-

Abiotic - Nonliving substances or environmental factors.

Accelerated Soil Erosion - Erosion much more rapid than normal, natural, geological erosion, primarily as a result of the influence of the activities of man or, in some cases, of animals.

Acceptable Storage/Acceptably Stored - (a) stored in a bear resistant container or, (b) stored in a closed vehicle constructed of solid, nonpliable material or; (c) suspended at least 10 feet clear of the ground at all points and 4 feet horizontally from any supporting tree or pole.

Acre-foot - A measure of water or sediment volume equal to the amount which would cover an area of one acre to a depth of one foot (325,851 gallons).

Activity Area - A land area impacted by a management activity, excluding specified transportation facilities, dedicated trails, and mining excavations, and dumps. Activity areas include harvest units within timber sale areas, prescribed burn areas, and grazing areas within range allotments. Riparian and other environmentally sensitive areas may be monitored and evaluated as individual activity areas.

Adaptation - A change in either the genetic makeup or behavior of an organism that enhances its ability to cope with or survive in its environment.

Adaptive Management - A type of natural resource management that implies making decisions as part of an ongoing process. Monitoring the results of actions will provide a flow of information that may indicate the need to change a course of action. Scientific findings and the needs of society may also indicate the need to adapt resource management to new information

Adaptive Planning - A strategy whereby planning efforts are directed towards meeting temporary crises which arise in response to changing conditions.

Aerial Logging - Removing logs from a timber harvest area by helicopter. Fewer roads are required, so the impact to an area is minimized.

Affected Environment - The natural environment that exists at the present time in an area being analyzed.

Afforestation - The establishment of a tree crop on an areas from which it has always or very long been absent

Age Class - An age grouping of trees according to an interval of years, usually 20 years. A single age class would have trees that are within 20 years of the same age, such as 1-20 years or 21-40 years and so on.

Air Pollution - The undesirable addition to the atmosphere of substances (gases, liquids, or solid particles) that are either foreign to or are in quantities exceeding their natural concentrations.

Air Quality - The composition of air with respect to quantities of pollution therein; used most frequently in connection with "standards" of maximum acceptable pollutant concentrations.

Air Shed - A geographic area that because of topography, climate and meteorology share the same air mass.

All-Aged Stand - A portion of a forest or a stand that contains trees of all, or almost all, age classes.

Allocation - The assignment of management practices to specific land areas to achieve established goals and objectives; such as the allocation of a wilderness management zone to an opportunity class.

Allotment (range allotment) - The area designated for use by a prescribed number of livestock for a prescribed period of time. Though an entire Ranger District may be divided into allotments, all land will not be grazed, because other uses, such as recreation or tree plantings, may be more important at a given time.

Allotment Management Plan (AMP) - A document that specifies the program of action designated to reach a given set of objectives for a livestock allotment. It is prepared in consultation with the permittee(s) involved and prescribes the manner and extent to which the permittee's livestock operations will be conducted in order to meet multiple use, sustained yield, economic, and other needs and objectives as determined for the lands involved. It describes the type, location, ownership, and specifications for the range improvements in place or to be installed and maintained on the lands to meet the livestock grazing and other objectives for the land. It contains such other provisions relating to the permittee's livestock management responsibilities and other objectives as may be prescribed by the Forest Service.

Allowable Sale Quantity (ASQ) - The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan for a time period specified by the Plan. This quantity is usually expressed on an annual basis as the "average annual allowable sale quantity."

Allowable Use - The degree of utilization considered desirable and attainable on various specific parts of an allotment considering the present nature and condition of the resource, management objectives, and level of management.

Alternative - One of several policies, plans or projects proposed for decisionmaking.

AMP - Allotment Management Plan

Analysis - A detailed examination of anything complex in order to understand its nature or determine its essential features.

Analysis Area - A geographic area used for environmental analysis. Analysis areas will vary in size, depending on the type of activity and/or project being analyzed, and the associated issues, concerns and opportunities.

Anthropogenic - Involving the impact of humans on natural systems.

Animal Carcass - The dead body or parts thereof, of any mammal, bird, or fish, including domestic livestock.

Animal Unit - Considered to be one mature dry cow of approximately 1000 pounds based upon an average daily forage consumption of 26 pounds dry matter per day. (Abbr. A.U.)

Animal Unit Conversion Factor - A numerical figure expressing the forage requirements of a particular kind or class of animal relative to the requirement for an animal unit. A conversion factor is satisfactory with respect to the amount of forage required to maintain an animal, but may not be applicable in determining stocking rates for range use for particular kinds or classes of animals because of different grazing preferences.

Animal Unit Month (AUM) - The amount of feed or forage required by one mature (1,000 lb.) cow with calf, or equivalent, for 1 month; average daily forage consumption is 26 pounds per day. Each wildlife species will utilize some fraction of this as follows: Elk = 7, Deer = .3, and Antelope = .3.

Apparent Trend - An estimate of trend drawn from the presence or absence of indicators noted or measured during a onetime observation. Conclusion drawn from such a method can be borne out or refuted only by making additional observations or measurements over time. Apparent trend is described in the same terms as measured trend except that when no trend is apparent it shall be described as "not apparent."

Appeal - A request to a higher ranking Forest Service official for relief from a written decision.

Appropriate Suppression Response - The planned strategy for wildfire suppression action, in terms of kind, amount and timing, which most efficiently meets fire management direction under current and expected burning conditions. The response may range from a strategy of prompt control to one of containment, confinement or surveillance.

ASQ - Allowable Sale Quantity

Aquatic Connectivity - The level of connection between aquatic habitat patches. Aquatic ecosystems and species coevolved to function within certain limits of connectivity. When aquatic habitat patches are fragmented beyond natural limits, the key ecological linkages between the biological

(aquatic biota, soil microbes, riparian plants) and physical (water, parent material, gradient) elements are weakened and result in reduced aquatic ecosystem health.

Aquatic Influence Zone - Used in the context of a land management prescription, the area encompassing aquatic and riparian ecosystems and adjacent lands which directly affect the hydrologic, geomorphic, and ecological processes controlling aquatic and riparian ecosystem health and function.

Aquatic Ecosystem - Any body of water, such as streams, lakes, or springs, and all organisms and nonliving components within it, functioning as a natural system and interacting with associated terrestrial ecosystems.

Aquatic Macroinvertebrates - Invertebrates living within aquatic systems that are large enough to be seen with the naked eye, i.e. most aquatic insects.

Aquifer - A water-bearing geologic formation or structure that transmits water.

Artificial Regeneration - Replacement of forest stands by planting young trees or applying seed (direct seeding).

Aspect - The direction a slope faces. A hillside facing east has an eastern aspect.

Assessment - The Renewable Resource Assessment required by the Resources Planning act (RPA).

Associated Species - A species found to be numerically more abundant in a particular forest successional stage as compared to other stages.

Association - Any assemblage of populations living in a prescribed area or physical habitat; it is a loosely organized unit to the extent that it has characteristics additional to its individual components.

AUM - Animal Unit Month

Avoidance Areas - Areas having one or more physical, environmental, institutional or statutory impediments to corridor designation. These are two types of avoidance areas.

Discretionary - areas that may be crossed by corridors only if necessary and reasonable mitigation or avoidance of significant impacts can be obtained.

Nondiscretionary - areas that may not be crossed by corridors unless authorized by the appropriate official (for example, Governor, President, etc.)

-B-

BA - Biological Assessment

Background - The visible terrain beyond the foreground and middleground where individual trees are not visible but are blended into the total fabric of the stand. (See "Foreground" and "Middleground".)

Background Level (Background, Natural Background) - The ever-present environmental conditions or effects above which a phenomenon must manifest itself in order to be detected

Bark Beetle - An insect that bores through the bark of trees to eat the inner bark and lay its eggs. Bark beetles are important killers of forest trees.

Basal Area - The area of the cross section of a tree trunk near its base, usually 4.5 feet above the ground. Basal area is a way to measure how much of a site is occupied by trees. The term basal area is often used to describe the collective basal area of trees per acre.

Base Sale Schedule - A timber sale schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade and that this planned sale and harvest for any decade is not greater than the long-term sustained-yield capacity. This definition expresses the principle of nondeclining flow.

BE - Biological Evaluation

Bear Management Units - 18 land units delineated within the Yellowstone Grizzly Bear Recovery Zone. These units are used for grizzly bear population and habitat analysis. There are three bear management units which encompass portions of the Targhee National Forest.

Bear Resistant Container - A securable container constructed of solid nonpliable material capable of withstanding 200 foot-pounds of energy (using the approved bear-resistant container impact testing machine). When secured and under stress the container will not have any cracks, openings, or hinges that would allow a bear to gain entry by biting or pulling with its claws. Wood containers are not considered bear-resistant unless they are reinforced with metal

Benchmark - (1) A permanent reference point. (2) In range monitoring, it is used as a point where changes in vegetation through time are measured.

Best Management Practices (BMP's) - Practices which have been designed to prevent or reduce the amount of nonpoint pollution, to a level compatible with State water quality standards and quality goals. These practices may be determined by the State, the Forest, a designated area wide planning agency, or on a project level basis. Also referred to as Soil and Water Conservation Practices (SWCP's).

Big Game - Those species of large mammals normally managed for sport hunting.

Biodegradable - Chemicals or substances which can be readily broken down into their component parts by biological action.

Biodiversity - The distribution and abundance of different plant and animal species and communities within an area Diversity encompasses four levels: genetics, species, ecosystems and landscapes.

Biological - Relating to, or affecting life and living organisms.

Biological Assessment (BA) - A document that reviews and evaluates proposed actions of Federal agencies for possible effects on any species listed, or proposed to be listed, as threatened or endangered, and their designated or proposed critical habitat.

Biological Control - The use of natural means to control unwanted pests. Examples include introduced or naturally occurring predators such as wasps, or hormones that inhibit the reproduction of pests. Biological controls can sometimes be alternatives to mechanical or chemical means.

Biological Diversity - See Biodiversity.

Biological Evaluation (BE) - A document that reviews all Forest Service planned, funded, executed, or permitted programs and activities for possible effects on endangered, threatened, proposed, or sensitive plant and animal species.

Biological Potential - The maximum possible resource output limited only by inherent physical and biological characteristics.

Biomass - The total weight of the living organisms in some biological system.

Biosphere - That part of the earth's crust, waters and surrounding air-layer which is inhabited by living organisms.

Biota - The plants and animals of an area, taken collectively.

Biotic - All the living organisms in an areas and their life processes.

Biotic Climax - A climax caused by a permanent influence or culmination of influences caused by one or more kinds of organisms, including humans. See Climax.

Biotic Community - See Community.

Biotic Diversity - See Biodiversity.

BMP - Best Management Practices.

Board Foot - The amount of wood equivalent to a piece 1 foot long by 1 foot wide by 1 inch thick. Generally, five board feet log measure is approximately equivalent to 1 cubic foot of round wood.

Broadcast Burn - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for reduction of fuel hazard, improve forage for wildlife and livestock, or encourage successful regeneration of trees.

Browse - Twigs, leaves and young shoots of trees and shrubs that animals eat. Browse is often used to refer to the shrubs eaten by big game, such as elk and deer.

Brush - Stands of vegetation dominated by shrubby, woody plants or low growing trees.

Buffer - A designated land or water area, along the perimeter of some feature (e.g., a stream), whose use is regulated so as to resist, absorb or preclude unwanted effects to the protected feature.

Buffer Strip - A protective area adjacent to an area requiring special attention or protection.

Burning Index (BI) - A number related to the contribution of fire behavior to the effort of containing a fire. BI is represented in NFDRS by a calculation of flame length in feet multiplied by 10.

-C-

C&H Allotment - A cattle and horse allotment.

Cable Logging - Logging that involves the transport of logs from stump to collection points by means of suspended steel cables. Cable logging reduces the need for the construction of logging roads.

Candidate Species - A species being considered for listing as a federally threatened or endangered species.

Canopy - The more or less continuous cover of branches and foliage formed collectively by the crown of adjacent trees and other woody growth. It usually refers to the uppermost layer of foliage, but it can be used to describe lower layers in a multi-storied forest.

Canopy Closure - The degree to which the collective forest canopy, as projected onto the surface, occupies or covers that surface, i.e. the degree to which the sunlight is blocked or the sky obscured.

Canopy Cover - The percentage of ground covered by a vertical projection of the outermost perimeter of the natural spread of foliage of plants. Small openings within the canopy are included. The sum of canopy cover of several species may exceed 100 percent. (Syn. crown cover).

Capability - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices and at a given level of management intensity. Capability depends upon current

conditions and site conditions such as climate, slope, landform, soils and geology, as well as the application of management practices, such as silviculture or protection from fire, insects and disease.

Carnivore - A organism that feeds on animal substances.

Carrying Capacity - The number of organisms that the resources of a habitat can support. Usually used with respect to specific species even though the carrying capacity of a habitat depends on the interactions of both its abiotic and biotic components.

Catastrophic Condition - A significant change in forest conditions on the area that affects Forest Plan resource management objectives and their projected and scheduled outputs, uses, costs, and effects on local communities and environmental quality.

Catastrophic Event - A large-scale, high-intensity natural disturbance that occurs infrequently.

Cavity - The hollow excavated in trees by birds or other natural phenomena; used for roosting and reproduction by many birds and mammals.

CEM - Cumulative Effects Model (Bear)

Channel - A natural or artificial conduit which periodically or continuously contains moving water, such as a stream. A channel has defined bed and banks.

Chargeable Volume - All volume included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity, based on regional utilization standards.

Chemical Control - The use of pesticides and herbicides to control pests and undesirable plant species

Class I Areas (Airsheds) - Regarding air quality, an area designated for the most stringent degree of protection by the Clean Air Act. Included are National parks established before August 1977 and wildernesses designated by the 1964 Wilderness Act

Class II Areas (Airsheds) - The level of air quality protection assigned to areas other than Class I Areas.

Class of Livestock - Age and/or sex group of a kind of livestock. (cf. class of animal)

Classification - The forming, sorting, apportioning, grouping or dividing of objects into classes to form an ordered arrangement of items having a defined range of characteristics.

Clean Air Act - (42 U.S.C. 7609) Section 309 provides authority for the Environmental Protection Agency to review other agency environmental impact statements.

Clearcutting - The cutting method where merchantable trees are removed from a designated area during one operation.

Clearcutting with Reserves Regeneration Method - A variant of the Clearcutting Method in which varying numbers of reserve trees are not cut to attain goals other than regeneration. The method normally creates a two-aged stand.

Climate - The average course or condition of the weather at a particular place over a period of many years as exhibited in extremes, means, ranges and seasonal distributions

Climax - The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition.

Climax Community - The final stage in succession, its nature is determined largely by the climate and soil of a region.

Climax Species - Species that are self-perpetuating in the absence of disturbance.

Climax Vegetation - The pattern or complex of climax communities in a landscape corresponding to the pattern of environmental gradients or habitats.

Closed Allotment/Area - An allotment or area where livestock grazing is not permitted.

Coarse-filter analysis - An analysis of aggregates of elements such as cover type or plant community.

Coarse Filter Management - Land management that addresses the needs of all associated species, communities, environments, and ecological processes in a land area. (See fine filter management.)

Collector Roads - These roads serve small land areas and are usually connected to a Forest System Road, a county road, or a state highway.

Commercial Forest Land - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions; and (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be attained within 5 years after final harvesting.

Commercial Thinning - Selective cutting in immature stands in which all or part of the felled trees are extracted for useful products and designed to improve the quality and growth of the remaining trees.

Commodity - A resource product for which a monetary value has been established.

Community - All of the organisms inhabiting a common environment and interacting with one another, or an association of interacting populations usually defined by the nature of their interaction in the place in which they live.

Community cohesion - The degree of unity and cooperation within a community in working toward shared goals and solutions to problems.

Community stability - A community's capacity to handle change without major hardships or disruptions to component groups or institutions. Measurement of community stability requires identification of the type and rate of proposed change and an assessment of the community's capacity to accommodate that level of change.

Community type - An aggregation of all plant communities distinguished by floristic and structural similarities in both overstory and undergrowth layers. A unit of vegetation within a classification.

Compartment - A unit of forested land, usually between 1,000 and 3,000 acres in size, defined by natural and man-made features and used to facilitate timber planning.

Competition - The general struggle for existence and dominance in which living organisms compete for a limited supply of the necessities of life.

Composition - What an ecosystem is composed of. Composition could include water, minerals, trees, snags, wildlife, soil, microorganisms, and certain plant species.

Concern - (Also management concern.) An issue, problem or condition which constrains the range of management practices identified by the Forest Service in the planning process.

Confine - To limit fire spread within a predetermined area principally by use of natural or preconstructed barriers or environmental conditions. Suppression action may be minimal and limited to surveillance under appropriate conditions.

Conifer - A tree that produces cones, such as a pine, spruce, or fir tree.

Connected Actions - Closely related actions which automatically trigger other actions, cannot proceed unless other actions are taken previously or simultaneously, or are interdependent parts of a larger action and depend on the larger action for justification.

Connectivity (of habitats) - The linkage of similar but separated vegetation stands by patches, corridors or "stepping stones" of like vegetation. This term can also refer to the degree to which similar habitats are linked.

Connectivity - The condition in which the spatial arrangement of land or water habitats allows biological and ecological processes to function across the landscape. Connectivity is the opposite of fragmentation.

Constraint - A limitation; action which cannot be taken or must be taken.

Conservation - The careful protection, utilization and planned management of natural resources to prevent their depletion, exploitation, destruction, waste or neglect.

Consistency - All resource plans and permits, contracts and other instruments for the use and occupancy of National Forest System land must be consistent with the Forest Plan.

Consumer Organism - A organism which ingests other organisms or food particles, depending upon their position in the food chain.

Consumptive Use - A use of resources that reduces the supply, such as logging and mining (See also nonconsumptive use).

Contain - To surround a fire, and any spot fires therefrom, with control lines as needed, which can reasonably be expected to check the fire's spread under prevailing and predicted conditions.

Contingency Plan - A plan for providing timely recognition of approaching critical fire situations, priority setting, and deployment of forces and other action to resolve those situations.

Continuous Grazing System - Unrestricted grazing throughout the entire grazing season every year.

Contour - A line drawn on a map connecting points of the same elevation.

Contrast - The degree to which adjacent landscape elements differ from each other, with respect to species composition and physical attributes.

Control - To complete the control line around a fire, any spot fires therefrom, and any interior islands to be saved; burn out any unburned area adjacent to the fire side of the control line; and cool down all hot spots that are immediate threats to the control line, until the line can reasonably be expected to hold under foreseeable conditions.

Coordinated Resource Management (CRM) - The process whereby various user groups are involved in discussion of alternative resource uses and collectively diagnose management problems, establish goals and objectives, and evaluate multiple use resource management.

Core Area - A term used to describe a component of grizzly bear habitat. Core areas are free of motorized access during the nondenning period. Core areas must meet the following criteria:

No motorized use of roads and trails during the nondenning period. Within the core area, restricted roads require closure devices that are permanent such as tank traps, large boulders, dense vegetation, etc.

No roads or trails that receive nonmotorized, high intensity use as defined in established cumulative effects activity definitions.

Minimum of .3 miles from any open road or motorized trail. This will be accomplished by buffering all open roads and open motorized trails.

Consideration should be given to ensure that the core areas meet seasonal bear habitat needs by assuring that spring, summer, fall and denning habitat within the core areas are representative of these seasonal habitats in the entire analysis area.

Once core areas become established and effective, these areas should remain in place for at least 10 years. This duration is based upon the generation time for a female grizzly bear or the time it takes a female grizzly bear to replace herself.

Corridor - A linear strip of land managed for specific vegetational and other (roads) characteristics to allow the movement wildlife species between areas of suitable habitat. The landscape elements that connect similar patches through a dissimilar matrix or an aggregation of dissimilar patches.

Cost-efficiency - The usefulness of specified inputs (costs) to produce specified outputs (benefits). In measuring cost efficiency, some outputs, including environmental, economic, or social impacts, are not assigned monetary values but are achieved at specified levels in the least cost manner. Cost efficiency is usually measured using present net value, although use of benefit-cost ratios and rates-of-return may be appropriate.

Council of Environmental Quality (CEQ) - The Council issues regulations binding on all federal agencies, to implement the procedural provisions of the National Environmental Policy Act. The regulations address the administration of the NEPA process, including preparation of Environmental Impact Statements (EIS) for major federal actions which significantly affect the quality of the human environment.

Cover - Any feature that conceals wildlife or fish. Cover may be dead or live vegetation, boulders, or undercut streambanks. Animals use cover to escape from predators, rest or feed

Cover Class - Represents a percentage range for a fixed area covered by the crowns of plants. It is measured as a vertical projection of the outermost portion of the foliage. Cover Class A = <40% canopy cover; Cover Class B = 40-60% canopy cover; Cover Class C = >60% canopy cover.

Cover-forage Ratio - The ratio of hiding cover to foraging areas for wildlife species

Cover, Percent - The area covered by the combined aerial parts of plants and vegetative ground cover expressed as a percent of the total area.

Cover type (forested cover type) - Stands of a particular vegetation type that are composed of similar species. The aspen cover type contains plants distinct from the pinyon-juniper cover type.

Created Opening - An opening in the forest cover created by the application of even-aged silvicultural practices. (Clearcuts, seed chutes of a shelterwood, or group selection (nonstocked and seedling stages)).

Critical Area - A portion of rangeland which has a critical issue related to it, such as a threatened or endangered or sensitive species, a high use recreation area, or a key wildlife habitat. The area serves as a monitoring and evaluation site for the critical issue.

Critical Habitat - Specific area occupied by threatened or endangered species, on which are found those physical and/or biological features that are essential to the conservation of the species.

Crop Tree - A tree that forms, or is selected to form, a component of the final stand; specifically, one selected to be carried through to maturity. Also known as a final crop tree or growing stock tree.

Crown - The upper part of a tree or other woody plant carrying the main branch system and foliage above a more or less clean stem.

Crown Closure - See cover class.

Crown Cover - The amount of canopy provided by branches and foliage of trees, shrubs, and herbs in a plant community. May be specified by species, growth form or collectively.

Crown Fire - A fire that advances from top to top of trees or shrubs more or less independently of the surface fire. Sometimes crown fires are classed as either running or dependent, to distinguish the degree of independence from the surface fire.

Crown Height - The distance from the ground to the base of the crown of a tree.

CU Allotment - An allotment grazed by both sheep and cattle (common use)

Culmination of Mean Annual Increment - The age at which the average annual growth is greatest for a stand of trees. Mean annual increment is expressed in cubic feet measure and is based on expected growth according to the management intensities and utilization standards assumed in accordance with 36 CFR 219.16 (a)(2)(i) and (ii). Culmination of mean annual increment (CMAI) includes regeneration harvest yields and any additional yields from planned intermediate harvests.

Cultural Resource - The remains of sites, structures, or objects used by humans in the past - historical or archaeological.

Cultural Sensitivity - Refers to the likelihood of encountering significant cultural volumes (quantity and/or quality) that may affect and may be affected by ground-disturbing activities

Cumulative Actions - Actions which when viewed with other proposed actions have cumulatively significant impacts

Cumulative Effects or Impacts - The impact on the environment which results from the incremental impact of an action when added to other past, present and reasonably foreseeable future actions regardless of what agency or person undertakes such other action. Cumulative effects or impacts can result from individually minor but collectively significant actions taking place over a period of time.

Cumulative Effects Analysis - An analysis of the effects on the environment which results from the incremental impact of a proposed action when

added to other past, present and reasonably foreseeable future actions, regardless of what agency or person undertakes such other actions.

Cutting Cycle - The planned lapse of time between successive cuttings in a stand.

Cutting Method - Describes cuttings used either to help reproduce forest stands (reproduction or harvest cuttings) or to maintain their vigor and desired composition and structure in terms of tree species, ages, and size classes (intermediate cuttings).

Cycling - One of the ways functions are described; resources which are transported within the system (i.e., animal migration, nutrient cycling in a forest stand, snow melt becoming part of the surface or groundwater flow.)

-D-

Data - Any measurements, facts, evidence or observations reduced to a recorded and retrievable format.

DB - Database

DBH - Diameter at Breast Height

Decomposer - An organism, usually a bacterium or fungus, that breaks down the bodies or parts of dead plants and animals into simpler compounds.

Decomposition - The process of separating into constituent parts, elements, or simpler compounds. In biological systems, a process usually accomplished by fungi and bacteria.

Decomposition Class - Any of five stages of decomposition of logs left in the forest; stages range from essentially sound to almost total decomposition. (See end of glossary for additional information)

Defoliation - The removal of leaves from plants, especially by herbicides or plant eating animals.

Density. Numbers of individuals or stems per unit area. (Density does not equate to any kind of cover measurement.)

Dependent Species - A species for which a habitat element (e.g. snags) is deemed essential for the species to occur regularly or to reproduce.

Departure - A sale schedule that deviates from the principle of nondeclining flow by exhibiting a planned decrease in the sale schedule at any time during the planning horizon. A departure is characterized by a temporary increase, usually in the beginning decade(s) of the planning horizon, over the base sale schedule originally established. This increase does not impair the future attainment of the long-term sustained yield capacity.

Desired Condition (DC) - A portrayal of land or resource conditions which are expected to result if planning goals and objectives are fully achieved.

Desired Future Condition (DFC) - A description of the cumulative results of implementing the goals expressed in the Forest Plan.

Desired Future Condition - Rangelands - The specific future condition of rangeland resources that meets management objectives as identified in the Forest Plan and Allotment Management Plan. Desired future condition of rangelands can be expressed in terms of ecological status of the vegetation, it could include species composition, diversity of habitats, or age classes of species, desired soil protection, including conditions of soil cover, erosion, compaction, and loss of soil productivity; in riparian areas, it includes conditions of streambank and channel stability, stream habitat, streamside vegetation, stream sedimentation, and water quality.

Desired Future Vegetation - The future state of the plant community on a site or an ecological unit which meets forest plan or other management objectives

Desired Plant Community - A plant community which produces the kind, proportion, and amount of vegetation necessary for meeting or exceeding the Forest Land Management Plan or Allotment Management Plan objectives established for an ecological type(s). The desired plant community must be consistent with the type's capability to produce the desired vegetation through management, land treatment, or a combination of the two. The desired plant community must conserve to the extent practicable the long-term potential of the site to produce vegetation, and produce in the short-term those combinations of desired goods and service.

Desirable Plant Species - Species which contribute to the management objectives.

Desired Riparian Vegetation Conditions (DVC) - Those conditions resulting from meeting the Forest Plan objective to "maintain or improve riparian vegetation, aquatic habitat, and water quality." Achieving DVC on the Forest would result in a complex of native riparian plant communities, in predominately mid to late seral stages, with the potential to produce high plant species diversity.

Desired Soil Protection - Desired soil quality standards which meet forest plan or other management objectives for maintaining soil productivity potential, including thresholds for soil cover, erosion, compaction and soil displacement.

Developed Recreation Sites - Relatively small, distinctly defined and developed areas where facilities are provided for concentrated public use, (i.e., campgrounds, picnic areas, and swimming areas). These areas have more than \$50,000 of investment and two or more developed facilities are present.

Development Scale

1 Minimum site modification. Rustic or rudimentary improvements designed for protection of the site rather than comfort of the users. Use of synthetic materials excluded. Minimum controls are subtle. No obvious regimentation Spacing informal and extended to minimize contacts between users. Motorized access not provided or permitted.

2 Little site modification. Rustic or rudimentary improvements designed primarily for protection of the site rather than the comfort of the users. Use of synthetic materials avoided. Minimum controls are subtle. Little obvious regimentation. Spacing informal and extended to minimize contacts between users. Motorized access provided or permitted. Primary access over primitive roads Interpretive services informal, almost subliminal

3 Site modification moderate. Facilities about equal for protection of site and comfort of users Contemporary/rustic design of improvements is usually based on use of native materials. Inconspicuous vehicular traffic controls usually provided. Roads may be hard surfaced and trails

formalized. Development density about 3 family units per acre. Primary access may be over high standard roads. Interpretive services informal, but generally direct.

4 Site heavily modified. Some facilities designed strictly for comfort and convenience of users. Luxury facilities not provided. Facility design may incorporate synthetic materials. Extensive use of artificial surfacing of roads and trails. Vehicular traffic control usually obvious. Primary access usually over paved roads. Development density 3-5 family units per acre. Plant materials usually native. Interpretive services often formal or structured.

5 High degree of site modification. Facilities mostly designed for comfort and convenience of users and usually include flush toilets; may include showers, bathhouses, laundry facilities, and electrical hookups. Synthetic materials commonly used. Formal walks or surfaced trails. Regimentation of users is obvious. Access usually by high-speed highways. Development density 5 or more family units per acre. Plant materials may be foreign to the environment. Formal interpretive services usually available. Designs formalized and architecture may be contemporary. Mowed lawns and clipped shrubs not unusual.

Detrimental Compaction - Soil compaction is a reduction in soil volume, resulting in decreased porosity and increased bulk density. Soil compaction that adversely affects hydrologic function and site productivity is detrimental.

Detrimental Displacement - Soil displacement is the movement of soil from one place to another by mechanical forces such as blade, wheel slippage, and dragging logs. Displacement is detrimental if it adversely affects hydrologic function or site productivity.

Detrimental Disturbance - Refers to areas that have had detrimental compaction, detrimental puddling, detrimental displacement and/or which have been severely burned.

Detrimental Puddling - Soil puddling is a physical change in soil properties due to shearing forces that alter soil structure and reduce permeability and infiltration. Soil puddling that adversely affects hydrologic function and site productivity is detrimental.

tal. Clearly identifiable ruts or hoof prints in mineral soil, or in a horizon of an organic soil, are indicators of detrimental puddling.

Developed Recreation Sites - Relatively small, distinctly defined area where extensive facilities are provided for concentrated public use, (i.e., campgrounds, picnic areas, and swimming areas).

DFC - Desired Future Condition

Diameter at Breast Height (DBH) - The diameter of a tree measured 4 feet 6 inches above the ground.

Direct Effect - An effect that is caused by an action and occurs in [generally] the same time and place as the action.

Discount rate - An interest rate that represents the cost or time value of money in determining the present value of future costs and benefits. A "real" discount rate is one adjusted to exclude the effects of inflation.

Discounting - An adjustment, using a discount rate, for the value of money over time so that costs and benefits occurring in the future are reduced to a common time, usually the present, for comparison.

Dispersal - The movement of plants and animals away from their point of origin to another location where they subsequently get established and produce offspring.

Dispersed Recreation - Recreational activities that do not require developed facilities. These include undeveloped camping sites, hiking, fishing, hunting, biking, etc.

Dispersed Recreation Sites - Relatively small, undeveloped areas where public recreation use occurs. These areas have less than \$50,000 of investment in facilities such as toilets, tables, fencing, etc. These sites are generally adjacent to roads or trails and are used for dispersed recreation activities, such as camping, fishing, hunting, hiking, etc.

Dispersion - To spread out the impacts of timber harvest by distributing harvest units more or less uniformly throughout a drainage.

Distinctive (Class A) landscape - Areas where features of landform, vegetative patterns, water forms, and rock formations are of unusual or outstanding visual quality.

Disturbance - Any event, such as a forest fire or insect infestation that alters the structure, composition, or function of an ecosystem.

Disturbed Soil - see 'soil disturbance.'

Diversity - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan. See also "Edge," "Horizontal Diversity," and "Vertical Diversity."

Diversity - See Biodiversity.

Dominant - A taxon or group of taxa which by their collective size, mass, or numbers exert the most influence on other components of the ecosystem.

Drainage - A large area mostly bounded by ridges, encompassing part, most or all of a watershed.

Drought Index - A number representing net effect of evaporation, transpiration, and precipitation in producing cumulative moisture depletion in deep duff or upper soil layers.

Durability - The ability of resources to tolerate sustained use, without degradation of the resource base (i.e., productivity or quality).

Dwarf Mistletoe (*Arceuthobium* spp.) - Dwarf mistletoes are parasitic, seedbearing plants that attack most western conifers. Infected trees can be recognized by presence of witch's brooms, cankers, swellings, and other abnormalities. Economic losses can be heavy, as damage results in smaller trees, lower timber quality, and increased mortality.

-E-

EA - Environmental Assessment

Early Forest Succession - The biotic (or life) community that develops immediately following the removal or destruction of vegetation in an area. For instance, grasses may be the first plants to grow in an area that was burned

Ecocentric - A conservation strategy that focus on providing habitat patterns that are manifestations of ecological processes operating at several scales. Also, a philosophical viewpoint which emphasizes the maintenance of natural systems at the expense of commodity production and other human uses. The goal of this philosophy is to permit natural ecological processes to operate as freely as possible, because wild land values for society ultimately depend on the retention of naturalness.

Ecoclass - Classification system for the biological and earth sciences based on linking together existing disciplinary classifications of the major ecosystem components.

Ecology - The interrelationships of living things to one another and to their environment, or the study of these interrelationships.

Ecomap - This was the name given to the Forest Service workgroup that developed the National Hierarchy of Ecological Units for the United States.

Economic impacts -

direct economic impact - Effects caused directly by forest product harvest or processing or by forest uses.

indirect economic impact - Effects that occur when supporting industries sell goods or services to directly affected industries.

induced economic impact - Effects that occur when employees or owners of directly or indirectly affected industries spend their income within the economy.

Ecoregion. A continuous geographic area over which the macroclimate is sufficiently uniform to permit development of similar ecosystems on sites with similar properties. Ecoregions contain multiple landscapes with different spatial patterns of ecosystems.

Ecosystem - An arrangement of living and nonliving things and the forces that move among them. Living things include plants and animals. Nonliving parts of ecosystems may be rocks and minerals. Weather and wildfire are two of the forces that act within ecosystems.

Ecosystem composition - The constituent elements of an ecosystem.

Ecosystem function - The processes through which the constituent living and nonliving elements of ecosystems change and interact, including biogeochemical processes and succession.

Ecosystem Health - Ecosystem health is defined in terms of four major characteristics applicable to any complex system: sustainability, which is a function of activity, organization, and resilience. An ecological system is healthy and free from "distress syndrome" if it is stable and sustainable -that is, if it is active and maintains its organization and autonomy over time and is resilient to stress ("distress syndrome" refers to the irreversible process of system breakdown leading to collapse).

Ecosystem Management - The use of an ecological approach to achieve productive resource management by blending social, physical, economic and biological needs and values to provide healthy ecosystems.

Ecosystem pattern - The structure that results from the distribution of organisms in, and their interaction with their environment. Includes zonation, stratification, activity or periodicity, food-webs, reproductive, social and stochastic.

Ecosystem restoration - Returning an ecosystem from a nonsustainable to a sustainable condition.

Ecosystem Stability - When the ecosystem process and function are operating within the ecosystems historical operating range. The historical range of variability identifies the ecosystem amplitude of historical responses to perturbations and disturbances.

Ecosystem structure - The spatial arrangement of the living and nonliving elements of an ecosystem.

Ecosystem sustainability - The ability to sustain diversity, productivity, resilience to stress, health, *renew ability, and/or yields of desired values, resource uses, products, or services* from an ecosystem while maintaining the integrity of the ecosystem over time.

Edge - The margin where two or more vegetation patches meet, such as a meadow opening next to a mature forest stand, or a Douglas-fir stand next to an aspen stand

Edge Effect - The increased richness of plants and animals resulting from the mixing of two communities where they join.

Effects - Environmental consequences as a result of a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and are later in time or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air, water and other natural systems, including ecosystems.

Effects and impacts as used in this statement are synonymous. Effects include ecological (such as the effects on natural resources and on the components, structures and functioning of affected ecosystems), aesthetic quality, historic, cultural, economic, social or health whether direct, indirect or cumulative. Effects may also include those resulting from actions that may have both beneficial and detrimental effects, even if on balance the agency believes that the effects will be beneficial.

EHE - Elk Habitat Effectiveness

EIS - Environmental Impact Statement

Elk Habitat Effectiveness (EHE) - A measure of the quality of an area for elk during the spring/summer/fall seasons. Two habitat parameters are considered to be most important for EHE. 1) motorized road and trail densities (measured in miles/square mile, 2) elk hiding cover (measured as a percentage of an area in cover).

Elk Hiding Cover - Vegetation capable of hiding 90 percent of a standing adult elk from the view of a human at a distance equal to or less than 200 feet

Elk Vulnerability (EV) - The percent mortality of bull elk during the fall general rifle hunting season. Three parameters are considered to be most important for EV: 1) aspect variability; 2) hunter densities (measured in hunter-days/square mile); 3) motorized road and trail densities (measured in miles/square mile).

Emission - A release of air contaminants into the outdoor atmosphere.

Endangered Species - Any species of animal or plant that is in danger of extinction throughout all or a significant portion of its range. Plant or animal species identified by the Secretary of the Interior and endangered in accordance with the 1973 Endangered Species Act.

Endangered Species Act - The Act which requires consultation with U.S. Fish and Wildlife Service if practices on National Forest System lands may impact a threatened or endangered species (plant or animal).

Endemic - Restricted in distribution to a defined area. (Not epidemic)

Environment - The complex of climatic, soil and biotic factors that act upon and influence an ecosystem.

Environmental Analysis - An analysis of alternative actions and their predictable long and short-term environmental effects. Environmental Analyses include physical, biological, social and economic factors.

Environmental Assessment (EA) - A document providing evidence and analysis relating to a proposed action by a Federal Agency. It establishes whether an environmental impact statement (EIS) must be written, or a finding of no significant impact (FONSI) will be issued. It includes the proposed action and alternatives, and evaluates their potential environmental impacts.

Environmental Impact Statement (EIS) A statement of the environmental effects of a proposed action and alternatives to it. It is required for major Federal actions under Section 102 of the National Environmental Policy Act (NEPA) and released to the public and other agencies for comment and review. It is a formal document that must follow the requirements of NEPA, the Council on Environmental Quality (CEQ) guidelines, and directives of the agency responsible for the project proposal.

Ephemeral Streams - Streams that flow only as the direct result of rainfall or snowmelt. They have no permanent flow.

Erosion - The wearing away of the land surface by wind or water.

ESA - Endangered Species Act

Escaped Fire - A fire which has exceeded, or is anticipated to exceed, initial action capabilities or the fire management direction or prescription.

EV - Elk Vulnerability

Even-aged forest - A forest stand comprising trees with less than a 20-year difference in age.

Even-aged Management - Timber management actions that result in the creation of stands of trees in which the trees are essentially the same age. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands.

Even-aged Stand - A portion of a forest or a stand composed of trees having no, or relatively small, differences in age, although differences of as much as 30 percent are admissible in rotations greater than 100 years.

Even-aged System - A silvicultural system that produces stands in which all trees are about the same age; that is, the difference in age between trees forming the main crown canopy level will usually not exceed 20 percent of the rotation length.

EWU - Ecological Water Unit.

Exclusion Areas - Areas having a statutory prohibition to rights-of-way for lineal facilities or corridor designation

Extensive Management - The practice of forestry on a basis of low operating and investment costs per acre. Also known as extensive forestry.

Extinct - A species is extinct when it no longer exists.

Extinction - The process which results in the complete elimination of a species leaving no living descendants. Extinctions may be local or global.

Eyrie - A ledge along a cliff used for nesting peregrine falcons.

-F-

Fauna - The animal life of an area.

Facilities - Transportation planning, road management and operation, fleet equipment, and engineering services (for example, administrative buildings, water and sanitation systems, sanitary landfills, dams, bridges and communication systems).

Felling - Cutting down trees.

Final Cut - The removal of the last seed bearers or shelter trees after regeneration of new trees has been established in a stand being managed under the shelterwood system of silviculture.

Final Removal - All overstory trees are removed to release an adequately stocked salvageable understory.

Final Removal Cut - A type of cut that releases established regeneration from competition with seed trees under the Seed Tree and Shelterwood Regeneration Methods. Reserve trees may or may not be retained.

Fine Fuels - Fast drying fuels such as grass, leaves, draped pine needles, and small twigs that when dry ignite readily. Fine fuels are considered 1 hour timelag fuels (see timelag definition).

Fine Organic Matter - Organic material on top of mineral soil consisting of fallen vegetative matter in various stages of decomposition. Specifically referred to as horizons in soil descriptions. Fine organic matter includes woody material up to 3 inches in diameter.

Fines - waterborn particles the size of sand and smaller.

Fire - The rapid, persistent chemical reaction of a fuel and oxygen that releases heat, light and unburned particulate (smoke).

Fire Ecology - Area of study addressing the relationships among fire, the environment, and living organisms.

Fire Frequency - The number of wildland fires started in a given area over a given time.

Fire Group - A collection of similar habitat types and their associated fire ecology.

Fire Hazard - A fuel complex, defined by volume, type condition, arrangement, and location, that determines the degree of ease of ignition and of resistance to control.

Fire Management - All activities required for the protection of burnable wildland values from fire and the use of fire to meet land management goals and objectives

Fire Management Area - One or more parcels of land having a common set of fire management objectives.

Fire Occurrence - Number of fires per unit time in a specified area.

Fire Regime - The characteristic frequency, extent, intensity, severity and seasonality of fires in an ecosystem.

Fire Risk - The chance of fire starting, as affected by the nature and incidence of causative agents; an element of the fire danger in any area.

Fire Suppression - All work and activities associated with fire extinguishing operations beginning with discovery and continuing until the fire is completely extinguished.

Fireline Intensity - The amount of heat released in BTU's per foot of fire front per second. It is related to the difficulty of containment of a fire.

Fish - Any of numerous cold-blooded aquatic vertebrates having fins, gills and a streamlined body.

Fish-bearing Stream Reaches - Those portions of streams and rivers that support fish of any species during all, or a portion of, their life cycle.

Fisheries Habitat. Streams, lakes, and reservoirs that support fish, or have the potential to support fish.

Floodplain - The lowland and relatively flat area adjoining waters, including, at a minimum, the area subject to a one percent chance or greater chance of flooding in any given year (100 year recurrence).

Flora - The plant life of an area.

FOIA - Freedom of Information Act.

Food Chain - A series of spatially associated species, each of which lives as a predator, parasite or absorber of the next lower species down in the series.

FOR - FORPLAN or FORPLAN Alternative

Forage - All browse and herbaceous foods that are available to grazing animals. It may be grazed or harvested for feeding

Forb - A broadleaf plant that has little or no woody material in it.

Foreground - The part of a scene or landscape that is nearest to the viewer.

Forest - An ecosystem characterized by a more or less dense and extensive tree cover. Usually supporting or capable of supporting forests at a density of 10 percent crown closure or better

Forest and Rangeland Renewable Resources Planning Act (RPA) (1974) - This act requires the development of long term strategies for the management and inventory of the renewable forest and range resources of Forest Service lands.

Forest Health - A measure of the robustness of forest ecosystems. Aspects of forest health include biological diversity, soil, air, and water productivity, natural disturbances, and the capacity of the forest to provide a sustaining flow of goods and services for people.

Forest Land - See "Timber Classification."

Forest Plan - Source of management direction for an individual National Forest unit, specifying allowable activities, minimum requirements, expected outputs and land use allocations for a 10 to 15 year period.

Forest Roads and Trails - A legal term for Forest roads or trails that are under the jurisdiction of the Forest Service.

Forest Structure - Often divided into four conceptual aspects: age, species composition, horizontal or mosaic pattern, and vertical.

Forest Supervisor - The official responsible for administering National Forest lands on an administrative unit, usually one or more National Forests. The Forest Supervisor reports to the Regional Forester.

Forest Trees - Woody plants having a well-developed stem and usually more than 12 feet in height at maturity.

Forest Type - A descriptive term used to group stands of similar character of development and species composition by which they might be differentiated from other groups of stands.

Fragile - Those land or water areas containing ecosystems, possibly but not necessarily rare, that are sensitive to external stimuli which may disturb their balance, especially in an irreversible direction

Fragmentation - The splitting or isolating of patches of similar habitat, typically forest cover, but including other types of habitat. Habitat can be fragmented naturally or from forest management activities, such as clearcut logging.

Freedom of Information Act (FOIA) (1966) - The freedom of information act provides public access to records of the agencies and departments of the Executive Branch of the U.S. government.

Frequency - A quantitative expression of the presence or absence of individuals of a species in a population.

FRES - Forest Range Environmental Study.

Frissell Condition Classes - A classification system which rates the degree of man-caused change that a wilderness, dispersed campsite or concentrated-use area has undergone. There are 5 classes as follows:

Frissell Condition Class 1 - Visible Indicators: Ground vegetation flattened, but not permanently injured. Minimal physical change except for possibly a simple rock fireplace.

Frissell Condition Class 2 - Visible Indicators: Ground vegetation worn away around fireplace or center of activity.

Frissell Condition Class 3 - Visible Indicators
Ground vegetation lost on most of the site, but humus and litter still present in all but a few areas.

Frissell Condition Class 4 - Visible Indicators:
Bare mineral soil widespread. Tree roots exposed on the surface.

Frissell Condition Class 5 - Visible Indicators:
Soil erosion obvious. Trees reduced in vigor or dead.

Fuel Loading - The dry weight of fuels in a given area, usually expressed in tons per acre. Fuel loading may be referenced to fuel size and may include total biomass.

Fuel Management - The treatment of fuels that would otherwise interfere with effective fire management or control. For instance, prescribed fire can reduce the amount of fuels that accumulate on the forest floor before the fuels become so heavy that a natural wildfire in the area would be explosive and impossible to control

Fuel Model - Simulated fuel complex for which all fuel descriptors required for the solution of a mathematical rate of spread model have been specified.

Fuel Moisture Content - The quantity of moisture in fuel expressed as a percentage of the weight when thoroughly dried at 212 degrees F.

Fuels - Plants and woody vegetation, both living and dead, that are capable of burning.

Fuelwood - Wood that is round, split, or sawn and/or otherwise generally refuse material cut into short lengths or chipped for burning.

Function - All the processes within an ecosystem through which the elements interact, such as succession, the food chain, fire, weather, and the hydrologic cycle.

Functional Planning - Planning which focuses on a single aspect or resource of a total complex

Game Species - Any species of wildlife or fish that is harvested according to prescribed limits and seasons.

Geographic Information System (GIS) - A set of procedures and computer hardware and software for organizing, storing, retrieving, analyzing, and displaying data that includes a geographic position component.

GIS - Geographic Information Systems.

Goal - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad, general terms and may not have a specific date for accomplishment.

Goods and Services. The various outputs, including on-site users, produced from forest and rangeland resources.

Grassland - Plant communities whose potential natural and dominant vegetation is comprised of grasses and grasslike plants.

Grasslike Plant - A plant of the Cyperaceae or Juncaceae families which vegetatively resembles a true grass of the Gramineae family.

Grazing - Consumption of forage by animals.

Grazing Formula - The specific order of grazing or sequence within a grazing system.

Grazing period - The time period in which domestic livestock are permitted to graze a specific pasture and/or portion of an allotment.

Grazing Season - The total length of time which domestic livestock are permitted to graze all pastures and/or portions of an allotment

Grazing System - A specialization of grazing management which defines systematically recurring periods of grazing and deferment for two or more pastures or management units. (cf. deferred grazing, intermittent grazing, deferred-rotation grazing, and short-duration grazing.)

Greater Yellowstone Area - A term for 11.7 million acre area that makes up parts of six National Forests and two National Parks in northwest Wyoming, eastern Idaho, and southwest Montana.

Greenline - The first perennial vegetation from the waters edge. Riparian areas that are in late seral status with stable stream banks will exhibit a continuous line of vegetation at the bankfull discharge level. Rocky stream types may have a significant amount of rock causing breaks in the vegetation. This rock is considered part of the green line. Other breaks may occur in the first perennial band of vegetation (watercourses or bare ground). The amounts of these (perennial vegetation, rock, and bare ground) should be recorded.

Grizzly Bear Security Cover - Forested areas (all tree species) which have not been managed or burned in the last 20 years, and managed or burned forested areas within the last 20 years which meet the following criteria:

The overstory and understory categories are to be considered separately. A stand having either 130 sq. ft. of basal area per acre or 250 understory trees per acre over 7 ft. tall would meet the requirements for full security cover. Both live and dead tree basal areas were used for overstory calculations.

Ground Cover - The percentage of material, other than bare ground, covering the land surface. It may include live vegetation, standing dead vegetation, litter, cobble, gravel, stones and bedrock. Ground cover plus bare ground would total 100 percent.

Ground Fire. A fire that burns along the forest floor and does not affect trees with thick bark or high crowns

Ground Water - The supply of fresh water under the earth's surface in an aquifer or in the soil.

Group Selection - A method of tree harvest in which trees are removed periodically in small groups. This silvicultural treatment results in small openings that form mosaics of age class groups in the forest.

Group Selection Regeneration Method - A method of regenerating uneven-aged stands in which trees are cut, and new age classes are established, in small groups.

Growing Stock Trees - Live trees, meeting specified standards of quality or vigor, included in growth and yield projections to arrive at the allowable sale quantity.

Guideline - Guidelines represent a preferred or advisable course of action that is generally expected to be carried out. Deviation from compliance with a guideline does not require a Forest Plan amendment, but the rationale for such a deviation shall be documented in the project decision document.

Guilds - A group of organisms that share a common food resource.

-H-

Habitat - The area where a plant or animal lives and grows under natural conditions.

Habitat Capability - The ability of a land area or plant community to support a given species of wildlife.

Habitat Diversity - The number of different types of habitat within a given area.

Habitat Type - A way to classify land area. A habitat can support certain climax vegetation, both trees and undergrowth species. Habitat typing can indicate the biological potential of a site.

Harvest Activity - A reference to a specific type of cut applied under a regeneration or intermediate treatment method. Refer to FSH 2409.14, Chapter 78 for valid values.

Harvest Cutting - The felling of the final crop of trees either in a single cutting or in a series of regeneration cuttings. Generally, the removal of financially or physically mature trees, in contrast to cuttings that remove immature trees. Also referred to as main felling and major harvest.

Harvesting - A loose term for the removal of natural resource for human use or consumption.

Healthy ecosystem - An ecosystem in which structure and functions allow the maintenance of the desired condition of biological diversity, biotic integrity, and ecological processes over time

Herb - Any flowering plant except those developing persistent woody stems above ground.

Herbivore - Any animal (mammal, bird, insect, etc.) that consumes living plants or their parts.

HGL - Hydric Greenline.

Hiding Cover - Vegetation or other surface characteristics (rocks, downed logs, etc.) that will hide 90% of an animal from the view of a human at some distance that varies by species. For deer and elk that distance is 200 feet.

Hierarchical - A type of classification technique whose successively lower level units must fit entirely within the separate units delineated by the next higher level in that system.

Hierarchical approach - An analysis approach accounting for differences in space and time (USDA Forest Service 1994).

Historical variation - Range of the spatial, structural, compositional, and temporal characteristics of ecosystem elements during a period specified to represent natural conditions.

Home Range - The area in which an animal conducts its activities during a defined period of time

Horizontal Diversity - The distribution and abundance of plant and animal communities or different stages of plant succession across an area of land. The greater the numbers of communities in a given area, the higher the degree of horizontal diversity.

Human dimension - An integral component of ecosystem management that recognizes people are part of ecosystems, that people's pursuits of past, present, and future desires, needs, and values (including perceptions, beliefs, attitudes, and behaviors) have and will continue to influence ecosystems and that ecosystem management must include consideration of the physical, emotional, mental, spiritual, social, cultural, and economic well-being of people and communities.

Human impact or influence - A disturbance or change in ecosystem composition, structure, or function caused by humans.

Hydric Soil - A soil that is saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions that favor the growth regeneration of hydrophytic vegetation.

Hydric Greenline - A belt of perennial riparian vegetation found closest to the water's edge. It is the area where recovery of riparian and aquatic ecosystems is first expressed and, therefore, can be monitored to test the impacts of livestock grazing. It is also the area which approximates the geographic location (level) of the active floodplain, a feature otherwise difficult to locate.

Hydrologic Cycle - Also called the water cycle, this is the process of water evaporating, condensing, falling to the ground as precipitation, and returning to the ocean as runoff.

Hydrology - The science dealing with the study of water on the surface of the land, in the soil and underlying rocks and in the atmosphere.

Hydrologically Disturbed Condition - Changes in natural canopy cover (vegetation removal) or a change in surface soil characteristics (e.g., compaction) that may alter natural streamflow quantities and character.

-I-

Idaho Stream Segment of Concern - A specified stream segment or body of water that has been designated by the water Quality Advisory Working Committee or the Governor to receive priority for water quality monitoring and management by state and federal agencies.

Idaho and Wyoming Species of Concern - Plant or animal species which are officially listed by state agencies due to concerns for habitats and/or populations.

Igneous Rock - Rocks formed when high temperature, molten mineral matter cooled and solidified.

Implementation Schedules - The schedules of projects and specific actions to implement a Land and Resource Management Plan. Implementation schedules are normally revised annually. They include site-specific actions, responsibilities and target dates.

Improvement Cutting - The elimination or suppression of less valuable trees in favor of more valuable trees, typically in a mixed, uneven-aged forest.

Increaser - Plant species of the original vegetation that increase in relative amount, at least for a time, under overuse.

Index - A number derived from a formula to characterize a complex set of information.

Indicator - An organism or an ecologic community that is so strictly associated with particular environmental conditions, that its presence (or absence) is a fairly certain sign or symptom of the existence of these conditions.

Indicator Species - A plant or animal species adapted to a particular kind of environment. Its presence is sufficient indication that specific habitat conditions are also present.

Indigenous Species - Any species of flora or fauna that naturally occurs in an area and that was not introduced by man.

Indirect Effect - Those effects occurring at a later time or distance from the triggering action.

Individual (Single) Tree Selection - The removal of individual trees from certain size and age classes over an entire stand area. Regeneration is mainly natural, and an uneven-aged stand is maintained.

Individual Tree Selection Cutting - An uneven-aged cutting method in which selected trees from specified size or age classes are removed over the entire stand area to meet a predetermined goal of size or age distribution and species composition in the remaining stand.

Infrastructure - The foundation (transportation, communications, utilities, schools, etc.) underlying an area's economy.

Input - Broadly referring to anything thing that is taken in by or enters into the workings of a system.

Insect Pests - There are a variety of insects in the Intermountain Region that can impact forest health by damaging or killing trees. Insect population levels may also affect other forest resources and activities like wildlife habitat, visual quality and fire

management. Some of the important insects in the area include Douglas-fir beetle (*Dendroctonus pseudotsugae*), Douglas-fir tussock moth (*Orgyia pseudotsugata*), Fir engraver (*Scolytus ventralis*), Mountain pine beetle (*Dendroctonus ponderosae*), Spruce beetle (*Dendroctonus rufipennis*), Western balsam bark beetle (*Dryocoetes confusus*) and Western spruce budworm (*Choristoneura occidentalis*).

Instream Flows - The minimum water volume (cubic feet per second) in each stream necessary to meet seasonal streamflow requirements for maintaining aquatic ecosystems, visual quality, recreational opportunities, and other uses

Integrated Pest Management (IPM) - A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are considered, including: the impact of the unregulated pest population to resources, alternative regulation strategies, and benefit/cost estimates of these alternatives strategies.

Integrated Resource Management - A management strategy which emphasizes no resource element to the exclusion or violation of the minimum legal standards of others.

Interdisciplinary Team - A team of individuals with skills from different disciplines that focuses on the same task or project.

Intermediate Cut - The removal of trees from a stand sometime between the beginning or formation of the stand and the regeneration cut. Types of intermediate cuts include thinning, release, and improvement cuttings

Intermittent Stream - A stream that flows only at certain times of the year when it receives water, usually from a surface source such as melting snow. These streams have a defined bed and banks.

Intermountain Region - The portion of the USDA Forest Service, also referred to as Region Four, that includes National Forests in Utah, Nevada, southern Idaho and southwestern Wyoming.

Invader - Plant species that were absent in the original vegetation and will invade under disturbance or continued overuse

Inventoried Roadless Area. (West of the 100th meridian) An area which meets the statutory definition of wilderness, does not contain improved roads maintained for travel by standard passenger-type vehicles, and meets one or more of the following criteria:

- Contains 5,000 acres or more
- Contains less than 5,000 acres, but:
 - Due to physiography or vegetation, is manageable in a natural condition.
 - Is a self-contained ecosystem such as an island.
 - Is contiguous to existing wilderness, primitive area, Administration-endorsed wilderness, or roadless area in other Federal ownership, regardless of size.

Inventoried Roadless Area - (East of the 100th meridian) An area which contains no more than a half mile of improved road for each 1,000 acres, and the road is under Forest Service jurisdiction and:

- The land is regaining a natural, untrammelled appearance.
- Improvements existing in the area are being affected by the forces of nature rather than humans and are disappearing or muted.
- The area has existing or attainable National Forest System ownership patterns, both surface and subsurface, that could ensure perpetuation of identified wilderness values.
- The location of the area is conducive to the perpetuation of wilderness values, considering the relationship of the area to sources of noise, air and water pollution and other unsightly conditions that would have an effect on the wilderness experience.

Inventory - The gathering of data for future use.

Inversion - A condition in which air temperatures increase rather than decrease with height in the atmosphere. Vertical motion in the atmosphere is inhibited by this stratification and allows for pollutants to be trapped near the surface.

Irretrievable - Applies to losses of production, harvest or commitment of renewable natural resources. For example, some or all of the timber

production from an area is irretrievably lost during the time an area is used as a winter sports site. If the use is changed, timber production can be resumed. The production lost is irretrievable, but the action is not irreversible.

Irreversible - Applies primarily to the use of non-renewable resources, such as minerals or cultural resources, or to those factors that are renewable only over long time spans, such as soil productivity. Irreversible also includes loss of future options.

Issue - A point, matter or question of public discussion or interest to be addressed or decided through the planning process.

Preliminary issue is an issue identified early in the scoping phase and is sometimes referred to as a tentative issue.

Significant issue is an issue within the scope of the proposed action which is used to formulate alternatives in an Environmental Analysis (EA) or Environmental Impact Statement (EIS).

-K-

Key Area - A relatively small portion of rangeland which because of its location, grazing or browsing value, and/or use, serves as a monitoring and evaluation site. (A key area guides the general management of the entire area of which it is a part, and will reflect the overall acceptability of current grazing management over the range.)

Key Species - (1) Forage species whose use serves as an indicator to the degree of use of associated species. (2) Those species which must, because of their importance, be considered in the management program.

Key Summer Range - The portion of a wildlife species' summer range that is essential for the animal's pre, post, and reproduction cycles. Deer require "fawning areas" where does give birth and hide their fawns for an essential period of time in the spring

Key Winter Range - That portion of big game's range where the animals find food and cover during severe winter weather.

Kind of Livestock - Species of animal.

LAC - Limits of Acceptable Change

Ladder Fuels - Vegetation located below the crown level of forest trees which can carry fire from the forest floor to tree crowns. Ladder fuels may be low-growing tree branches, shrubs, or smaller trees

Land - A term denoting the entire complex of surface and near-surface attributes of the solid portion of the surface of the earth which are significant to mankind

Land Class - The topographic relief of a unit of land. Land classes are separated by slope. This coincides with the timber inventory process. The three land classes used in the Forest Plan are defined by the following slope ranges: 0 to 35%, 36-55%, and greater than 55%.

Landform - Any physical, recognizable form or feature of the earth's surface having a characteristic shape and produced by natural causes.

Landscape - A large land area composed of interacting ecosystems that are repeated due to factors such as geology, soils, climate, and human impacts. Landscapes are often used for coarse grain analysis

Landscape Ecology - The body of knowledge pertaining to the ecological effects of spatial patterns in ecosystems.

Landtype - A group of defined and named taxonomic soil units occurring together in an individual and characteristic pattern over a geographic region.

Land Unit - One of the hierarchy levels used for project planning, encompassing one to tens of acres.

Land Use Allocation - The committing of a given area of land or resources to one or specific uses, e.g., to campgrounds, wilderness, etc.

Large Woody Debris - Organic materials such as plant stems and branches with a diameter greater than 3 inches. Included are both natural materials and management induced post-harvest slash. Large trees, or parts of them, that accumulate in streams or other water bodies. This material is

important for aquatic habitat and stream channel stability, and in maintenance of on-site productivity.

Late-Successional Forests - Forest seral stages that include mature and old-growth age classes.

Legal Notice - A notice of a decision which can be appealed that is published in the Federal Register or in the legal notice section of a newspaper of general circulation.

Lentic - Relating to, or living in, still waters (as lakes, ponds and swamps).

Limiting Factor - Any environmental factor whose presence, absence or abundance is the main factor restricting the distribution numbers or condition of an organism.

Limits of Acceptable Change (LAC) - A planning framework that establishes explicit measures of the acceptable and appropriate resource and social conditions in wilderness settings as well as the appropriate management strategies for maintaining or achieving those desired conditions

Line Officer - The officer (District Ranger, Forest Supervisor, Regional Forester, etc.) that has authority for a specific district, forest, region, etc.

Litter (forest litter) - The freshly fallen or only slightly decomposed plant material on the forest floor. This layer includes foliage, bark fragments, twigs, flowers and fruit.

Long-term Sustained Yield Capacity (LTSYC) - The highest uniform wood yield from lands being managed for timber production that may be sustained, under a specified management intensity, consistent with multiple-use objectives.

Logging Residues - The residue left on the ground after timber cutting. It includes unused logs, up-rooted stumps, broken branches, bark, and leaves. Certain amounts of "slash" provide important ecosystem roles, such as soil protection, nutrient cycling, and wildlife habitat

LTSL - Less-Than-Standard Service Level

LTSYC - Long-term Sustained Yield Capacity.

-M-

M - Thousand Five thousand board feet of timber can be expressed as 5M board feet.

MAI - Mean Annual Increment

Maintenance Class -

Maintenance Class 1, Satisfactory. Facility is safe and sanitary. Annual maintenance will not exceed 10 percent of replacement cost.

Maintenance Class 2, Substandard. Facility is safe and sanitary, although substandard as to type, construction standard, or not in keeping with planned experience-level for the site. Annual maintenance will not exceed 10 percent of current replacement cost of standard type facility. May be scheduled for eventual elimination or replacement but will serve intended purpose for next 3-5 years.

Maintenance Class 3, Heavy Maintenance. Facility unsafe or otherwise unsatisfactory. May be put back in good condition at a cost not to exceed 50 percent of current replacement of like kind facility.

Maintenance Class 4, Replacement. Facility unsafe or otherwise unsatisfactory. To put back in good condition would cost more the 50 percent of the replacement cost. Replace with like kind and standard of facility. Cost includes both removal of old facility and replacement.

Management - To treat with care; handle or direct with skill.

Management Action - Any activity undertaken as part of the administration of the National Forest.

Management Area - Units of land small enough for Districts and the public to relate to, but large enough to provide for management flexibility. A desired future condition developed for the management area will assist in achieving the shared land expectations.

Management Concern - An issue, problem or a condition which constrains the range of management practices identified by the Forest Service in the planning process.

Management Direction - A statement of multiple-use and other goals and objectives, the associated management prescriptions, and standards and guidelines for attaining them.

Management Ignition - A fire started by a scheduled, deliberate management action.

Management Indicator Species - A wildlife species whose population and trend in a certain habitat type indicates the population and trend of other species that are also dependent upon the same habitat.

Management Intensity - A management practice or combination of management practices and associated costs designed to obtain different levels of goods and services.

Management Practice - A specific activity, measure, course of action or treatment.

Management Prescription - Management practices and intensity selected and scheduled for application on a specific area to attain multiple-use and other goals and objectives.

Management Situation 1 - Population and habitat conditions. The area contains grizzly population centers (areas key to the survival of grizzly where seasonal or yearlong grizzly activity, under natural, free-ranging conditions is common) and habitat components needed for the survival and recovery of the species or a segment of its population. The probability is very great that major Federal activities or programs may affect (have direct or indirect relationships to the conservation and recovery of) the grizzly.

Management Situation 2 - Population and habitat conditions Current information indicates that the area lacks distinct population centers, highly suitable habitat does not generally occur, although some grizzly habitat components exist and grizzlies may be present occasionally. Habitat resources in Management Situation 2 either are unnecessary for survival and recovery of the species, or the need has not yet been determined but habitat resources may be necessary. Certain management actions are necessary. The status of such areas is subject to review and change according to demonstrated grizzly population and habitat needs. Major Federal activities may affect the conservation of the grizzly bear primarily in that they may

contribute toward (a) human-caused bear mortalities or (b) long-term displacement where the zone of influence could affect habitat use in Management Situation 1.

Management Situation 3 - Population and habitat conditions. Grizzly presence is possible but infrequent. Developments, such as campgrounds, resorts, or other high human use associated facilities, and human presence result in conditions which make grizzly presence untenable for humans and/or grizzlies. There is a high probability that major Federal activities or programs may affect the species' conservation and recovery.

Market-Value Outputs - Goods and services valued in terms of what people are willing to pay for them rather than go without, as evidenced by market transactions.

Mass Movement/Wasting - The downslope movement of large masses of earth material by the force of gravity. Also called a landslide or earthflow.

Mature Forest - Generally used in an economic sense to indicate that a forest has attained harvest age.

Mature Timber - Trees that have attained full development, especially height, and are in full seed production.

Maximum Modification - See "Visual Quality Objectives."

MBF - Thousand board feet (See board feet.)

Mean Annual Increment - The average yearly growth of trees in a stand over a period of years, usually expressed in annual cubic feet of growth per acre.

Mean Annual Increment of Growth - The total increase in size or volume of individual trees. Or, it can refer to the increase in size and volume of a stand of trees at a particular age, divided by that age in years.

Mean Fire Interval - Arithmetic average of all fire intervals determined in years, in a designated area during a specified time period; the size of the area and the time period must be specified.

Micro climate - The climate of a small site. It may differ from the climate at large of the area due to aspect, tree cover (or the absence of tree cover), or exposure to winds

Microhabitat - A restricted set of distinctive environmental conditions that constitute a small habitat, such as the area under a log.

Microsite - A localized area in which environmental conditions differ in a significant or important way from those of the region outside the area.

Middleground - A term used in the management of visual resources, or scenery. It refers to the visible terrain beyond the foreground where individual trees are still visible but do not stand out distinctly from the stand.

Mineral Soil - Soil that consists mainly of inorganic material, such as weathered rock, rather than organic matter. Any soil composed chiefly of mineral matter (e.g., sand, silt, clay, rocks, etc.)

Minimum Streamflow - A specified minimum level of flow through a channel that must be maintained by the users of the stream for biological, physical, or other purposes.

MIS - Management Indicator Species.

Mitigate/mitigation. To lessen the severity. Actions taken to avoid, minimize or rectify the impact of a land management practice.

Mixed Stand - A stand of trees in which less than 80 percent of the trees in the main crown canopy are of a single species.

MM - Million

MMBF - Million board feet (See board feet.)

Modification - A visual quality objective; management activities may visually dominate the original characteristic landscape, but they must borrow from naturally established form, line, color or texture so that the activity blends with the surrounding area.

Monitoring - The determination of how well project or plan objectives have been met and how closely management practices should be adjusted. (See adaptive management.)

Mortality - Trees that were merchantable and have died within a specified period of time. The term mortality can also refer to the rate of death of a species in a given population or community.

Mountain Pine Beetle - A tiny black insect, ranging from 1/8 to 1/4 inch in size, that bores through a pine tree's bark. When trees are attacked by large numbers they have the ability to stop the tree's intake and transport of the food and nutrients, thus killing the tree.

Multiple-Use - The management of all the various renewable surface resources of the National Forest System lands for a variety of purposes such as recreation, range, timber, wildlife and fish habitat, and watershed.

-N-

National Environmental Policy Act (NEPA) (1970) - The basic national charter for the protection of the environment. It establishes policy, sets goals and provides means for carrying out the policy. The NEPA process helps public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore, and enhance the environment.

National Forest Management Act (NFMA) (1976) - This act amends the Forest and Rangeland Renewable Resources Planning Act of 1974, and lays out the process for developing, adopting and revising land and resource management plans of the National Forest System lands.

National Forest System (NFS) Land - Federal lands that have been designated by Executive Order or statute as National Forests, National Grasslands, Purchase Units, and other lands under the administration of the Forest Service, including Experimental Areas and Bankhead-Jones Title III lands.

Native - Species indigenous to an area of consideration.

Native organism - Animals or plants which originated in the area in which they are found, were not introduced and naturally occur in the area.

Native Species - Any species of flora or fauna that naturally occurs in the United States and that was not introduced by man.

Natural - Existing in, or formed by, nature; not artificial.

Natural Barrier - A natural feature, such as a dense stand of trees or downfall, that will restrict animal travel

Natural Catastrophic Condition - A significant change in forest conditions on the area that affects Forest Plan resource management objectives and their projected and scheduled outputs, uses, costs, and impacts on local communities and environmental quality.

Natural Ignition - A fire started at random by either natural or human causes, or a deliberate incendiary fire.

Natural Regeneration - Renewal of a tree crop by self-sown seed or from sprouts.

Natural Range of Variability - Applied to specific components or elements of an ecosystem there is a distinctive variation in the status of these components, measured at a sufficiently large geographic scale and over a given time period. For example, the total number of nesting owl pairs in a given river basin is expected to have varied around some average number over the last 200 years. The entire spread of owl numbers describes its NRV for the given area. NRV includes aboriginal influences on ecosystems.

Natural Range of Variability - See Range of variability.

Natural Resource - A feature of the natural environment that is of value in serving human needs.

Nest Survey - A way to estimate the size of a bird population by counting the number of nests in a given area.

Net Public Benefits. An expression used to signify the overall long-term value to the Nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or

index. The maximization of net public benefits to be derived from management of units of the National Forest System is consistent with the principle of multiple-use and sustained-yield.

NFRS - National Forest recreation sites that have been inventoried

No Action Alternative - The most likely condition expected to exist in the future if management practices continue unchanged

Nonchargeable Volume - All volume not included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity.

Noncommercial Vegetative Treatment - The removal of trees for reasons other than timber production

Nonconsumptive Use - The use of a resource that does not reduce its supply; for example, nonconsumptive uses of water include hydroelectric power generation, boating, swimming and fishing.

Noncontinuous Grazing System - Rotational and repeated seasonal grazing systems.

Nondeclining Flow - See base sale schedule.

Nondegradation - A policy of not allowing resources to deteriorate any further than what exists at a chosen point of time. The objective is to either maintain the status quo, or to improve resource conditions.

Nonforest Land - See "Timber Classification."

Nongame - Species of animals not managed for sport hunting.

Nonmarket-Valued Outputs - Goods and services not generally traded in the marketplace, but valued in terms of what reasonable people would be willing to pay for them rather than go without. Those obtaining the actual outputs do not necessarily pay what they would be willing to pay for them.

Nonnative species - A species introduced into an ecosystem through human activities

Nonpoint Source Pollution - Pollution whose source is not specific in location. The sources of discharge are dispersed, not well-defined, or constant. Rain storms and snow melt often make this type of pollution worse. Examples include sediments from logging activities, and runoff from agricultural chemicals.

Nonrenewable Resource. A resource whose total quantity does not increase measurably over time, so that each use of the resource diminishes the supply.

Notice of Intent. A notice printed in the Federal Register announcing that an Environmental Impact Statement (EIS) will be prepared.

Noxious plant - A plant specified by law as being especially undesirable, troublesome, and difficult to control.

Noxious weed - See Noxious plant.

Nutrient Cycle - The circulation of chemical elements and compounds, such as carbon and nitrogen, in specific pathways from the nonliving parts of ecosystems into the organic substances of the living parts of ecosystems, and then back again to the nonliving parts of the ecosystem. For example, nitrogen in wood is returned to the soil as the dead tree decays; the nitrogen again becomes available to living organisms in the soil, and upon their death, the nitrogen is available to plants growing in that soil

Nutrient Cycling - The path of an element through the ecosystem including its assimilation by organisms and its release in a reusable inorganic form.

-0-

Objective - A clear and quantifiable statement of planned results to be achieved within a stated time period. Something aimed at or striven for within a predetermined time period. An objective must be achievable, be measurable, have a stated time period for completion, be quantifiable, be clear, and its results must be described.

Off-Highway Vehicle (OHV) - Any motorized vehicle 50 inches or less in width, having a dry weight of 600 pounds or less (includes trail bikes, motor-

cycles, 3-wheelers, 4-wheelers, etc.; does not include snowmachines).

-P-

Off-Road Vehicles (ORV's) - Vehicles such as motorcycles, all-terrain vehicles, four-wheel drive vehicles and snowmobiles.

OHV - Off-Highway Vehicle.

Old Growth - Terrestrial ecosystems characterized by vegetation and associated animals requiring the most mature successional stages (seres). Old growth forests contain trees normally beyond the age of optimum maturity for economic harvest. The precise definition of old growth varies with the tree species comprising the stand.

Opportunities - Ways to address or resolve public issues or management concerns in the land and resource management planning process.

Optimum - A level of production that is consistent with other resource requirements as constrained by environmental, social, and economically sound conditions.

Organism - A plant or animal.

OROMTRD (Open Road and Open Motorized Trail Route Density) - Includes all open roads and open motorized trails. Density may be displayed as follows: 1) Density (miles/square mile) for an analysis area (such as a watershed or a management prescription area). 2) Density is displayed as a percentage of the analysis area in a defined density category (example. 20% >2.0 miles per square mile).

ORV's - Off-road vehicles.

Output - One of the ways functions are described; resources which leave a system, i.e., animals migrating out of an area, mass erosion, removal of commercial timber from an area.

Overmature Timber - Trees that have obtained full development, particularly in height, and are declining in vigor, health, and soundness.

Overstory - The upper canopy or canopies of plants. Usually refers to trees, tall shrubs, and vines.

Overstory Removal - The final harvest cut of the shelterwood method in which overstory trees are removed releasing the established regeneration.

Packing - A temporary influx of organisms of various sex and age classes into remaining suitable habitat as previously available habitat is changed to unsuitable conditions.

PAOT - Persons-At-One-Time.

Parasites - Organisms that absorb their nutrients from the body fluids of living hosts. Parasites may be fungal, bacterial, plant or animal, (e.g. braconid wasp that parasitizes the fir engraver beetle, or dwarf mistletoe).

Parent Material - The unconsolidated and more or less chemically weathered, mineral or organic matter from which soils developed by soil-forming processes.

Partial Retention - A visual quality objective which, in general, means human activities may be evident, but must remain subordinate to the characteristic landscape.

Particulates - Small particles suspended in the air and generally considered pollutants.

Partnership - A cooperative, working relationship between the Forest Service and individuals, corporations, organizations or public agencies to pool financial and human resources to complete projects on National Forest System lands.

Patch - A small (20-60 acres) part of the forest. An area of vegetation that is internally homogeneous, differing from what surrounds it (matrix).

Patch Cut - A clearcut that creates small openings in a stand of trees, usually between 15 and 40 acres in size. Patch cuts are used to provide the disturbance needed to regenerate aspen.

Payment in lieu of taxes (PILOT) - Payments to local or State governments based on ownership of Federal land and not directly dependent on production of outputs or receipt sharing. Specifically, they include payments made under the payments in Lieu of Taxes Act of 1976 by U.S. Department of the Interior.

Payments to Local Government - The portion of receipts derived from Forest Service resource management that is distributed to State and county governments such as the Forest Service 25 percent fund payments.

Percent Use - The percentage of current year's forage production that is consumed or destroyed by grazing animals. May refer to a single species or to the vegetation as a whole.

Percolation - Downward flow or infiltration of water through the pores or spaces of rock or soil.

Perennial Streams - Streams that flow continuously throughout most years. These streams have defined bed and banks.

Permitted Grazing - Grazing on a National Forest range allotment under the terms of a grazing permit.

Personal Use - Normally used to describe the type of permit issued for removal of wood products (firewood, posts, poles, and Christmas trees) from National Forest land when the product is for home use and not to be resold for profit.

Persons-At-One-Time (PAOT) - A recreation capacity measurement term indicating the number of people who can use a facility or area at one time.

Planning - The act of deciding in advance, what to do. A dynamic problem solving effort used to guide future actions and decisions.

Planning Area - The area covered by a Regional Guide or Forest Plan.

Planning Period - One decade. The time interval within the planning horizon that is used to show incremental changes in yields, costs, effects, and benefits.

Planning Regulations - The rules which guide land and resource management planning on the National Forests.

Plant Association - A potential natural plant community of definite floristic composition and uniform appearance. See Association.

Plantation - Clearcut harvested area that has regenerated with natural and/or planted seedlings.

Plant Community - An aggregation of plants that are similar in species composition and structure, and occupy similar habitats over the landscape. See Community.

Plant Vigor - Plant health. (cf. plant vigor index.)

PM-10 - Smoke and debris particles with an aerodynamic diameter smaller than or equal to a nominal ten micrometers.

PNV - Present net value or Potential Natural Vegetation.

Pole/sapling - The stage of forest succession in which trees are between 3 and 7 inches in diameter and are the dominant vegetation.

Pole Timber - Trees of at least 5 0 inches DBH, but smaller than 8 0 inches in DBH, (except lodgepole pine and aspen which includes trees up to 7.0 inches in DBH).

Policy - A guiding principle which is based on a specific decision or set of decisions.

Pollution - The presence of matter or energy whose nature, location or quantity produces undesired environmental effects.

Porosity - Pertaining to landscapes, the density of a particular type of patch within a matrix. Porous landscapes have many small patches of similar type contained within the matrix.

Potential Natural Community (PNC) - The biotic community that would become established on an ecological type if all successional sequences were completed without interference by man under the present environmental conditions. Natural disturbances, such as drought, floods, wildfire, grazing by native fauna, insects, and disease, are inherent in its development. The PNC may include acclimatized or naturalized nonnative species. (IREG)

Potential vegetation - Vegetation that would develop if all successional sequences were completed under present site conditions (e.g., habitat type).

Practice (Also Management Practice) - A specific activity, measure, course of action, or treatment.

Practicable - When funding is obtained or a project is initiated

Precommercial Thinning - Removal of trees from a young stand to promote increased growth on the remaining stems and maintain a specific stocking or stand density range, controlling species composition and stand quality through selection of trees that are to remain in the stand.

Predator - An animal (rarely a plant) that kills and eats animals. Sometimes used in the sense of an insect consuming a seed.

Preparatory Cut - The removal of trees near the end of a rotation, which opens the canopy and enables the crowns of residual trees to enlarge, to improve conditions for seed production and natural regeneration. Typically done in the shelterwood system.

Prescribed Fire - Controlled application of fire to wildland fuels in either their natural or modified state, under specified environmental conditions which allow fire to be confined to a predetermined area and at the same time to produce the intensity of heat and rate of spread required to attain planned resource management objectives.

Prescribed Fire or Burn - A wildland fire ignited by humans under pre-planned, specified conditions, to accomplish specific, planned resource management objectives. This practice is common in California and is also known as "controlled burning".

Prescribed Natural Fire - A wildland fire ignited by natural sources such as lightning or vulcanism. These fires are allowed to burn in designated areas under carefully established conditions to provide for safety and fire control. If these conditions are exceeded, or predicted to worsen, a fire is reclassified as a wildfire and suppressed.

Prescription - Management practices selected to accomplish specific land and resource management objectives.

Present Net Value - The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area.

Preservation - See "Visual Quality Objectives."

Presuppression - Activities organized in advance of fire occurrence to assure effective suppression action.

Prey - Animals eaten by predators.

Primary Succession - The concept in which there is a sequence of vegetation development initiated on newly formed soils or upon surfaces exposed for the first time (as by landslides) which have never borne vegetation before.

Primitive ROS (Recreation Opportunity Spectrum) - A classification of wilderness and recreation opportunity. It is characterized by an essentially unmodified environment, where trails may be present but structures are rare, and, where it is highly probable to be isolated from the sights and sounds of people. (See ROS.)

Probability of Ignition - A rating of the probability that a firebrand (glowing or flaming) will cause a fire, provided it lands on receptive fuels. It is calculated from air temperature, fuel shading, and fuel moisture.

Production - One of the ways functions are described, resource which are "manufactured" within the system (i.e., plant growth, animal reproduction, snags falling and becoming down woody material).

Productive - The ability of an area to provide goods and services and to sustain ecological values.

Productivity - The amount of material (wood, forage, meat, etc.) yielded by an ecosystem, or its inherent potential to yield such material.

Program - When capitalized, the Renewable Resource Program required by the RPA. Generally, sets of activities or projects with specific objectives, defined in terms of specific results and responsibility for accomplishment.

Project - A single activity or an integrated group of activities designed to accomplish a specific on-the-ground purpose or result.

Proposal - Exists at the stage in the development of an action when an agency is actively preparing to make a decision on one or more alternative means of accomplishing a goal and the effects can be meaningfully evaluated.

Proposed Action - A proposal by the Forest Service to authorize, recommend or implement an action.

Province - See Physiographic Province.

Public Issue - A subject or questions of widespread public interest relating to management of the National Forest System.

Public Land - Land for which title and control rests with a government - federal, state, regional, county or municipal.

Public Participation - Meeting, conferences, seminars, workshops, tours, written comments, responses to survey questionnaires, and similar activities designed and held to obtain comments from the public about Forest Service planning and decisionmaking.

Purpose and Need - A statement which briefly specifies the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action.

-R-

Raptor - A bird of prey; primarily meat eating birds with strong hooked bills and sharp talons. Includes but is not limited to members of the Strigidae (Owls), Cathartidae (New World Vultures), Accipitridae (Hawks and Eagles), Falconidae (Falcons), and shrikes.

Range (of a species) - The area or region over which an organism occurs.

Range - Land on which the principle natural plant cover is composed of native grasses, forbs, and shrubs that area available as forage for big game and livestock

Range Allotment - An area designated for the use of a prescribed number and kind of livestock under one management plan.

Range Analysis - Systematic acquisition and evaluation of rangeland resources data needed for planning allotment management and overall land management.

Range Inspection - A field inspection of rangeland to determine if the Forest Plan Standards and Guides, the Allotment Management Plan Goals and Objectives, and the Grazing Permit requirements are being met and followed.

Range of Natural Variation - The observed limits of change in composition, structure, and function of an ecosystem considering both temporal and spatial factors as influenced by frequency, magnitude, and pattern of disturbances (other synonymous terms include 'natural variation' and 'range of variability').

Rangeland - All land-producing or capable-of-producing native vegetation, and lands that have been revegetated naturally or artificially. It includes all grasslands, shrublands, and those forest lands which will continually or periodically, naturally or through management, support an understory of herbaceous or shrubby vegetation

Rangeland Condition - The state of vegetation, soil cover, and soils in relation to a standard or ideal for a particular ecological type. (See satisfactory rangeland and unsatisfactory rangeland condition.)

Range Management - The art and science of planning and directing range use intended to yield the sustained maximum animal production and perpetuation of the natural resources.

Range of Variability - (Natural Variability, Historical Variability.) The components of healthy ecosystems fluctuate over time. The range of sustainable conditions in an ecosystem is determined by time, processes such as fire, native species, and the land itself. For instance, ecosystems that have a 10-year fire cycle have a narrower range of variation than ecosystems with 200-300 year fire cycles Past management has placed some ecosystems outside their range of variability. Future management should move such ecosystems back toward their natural, sustainable range of variation.

Ranger District - The administrative subunit of a National Forest that is supervised by a District Ranger who reports directly to the Forest Supervisor.

Raptor - A bird of prey, such as an eagle or hawk.

RARE II - Roadless Area Review and Evaluation. The national inventory of roadless and undeveloped areas within the National Forests and Grasslands.

Reach - A continuous unbroken stretch of a stream, with homogeneous characteristics.

Real Dollar Value - A monetary value that compensates for the effects of inflation.

Recharge - The addition of water to ground water by natural or artificial processes

Record of Decision - An official document in which a deciding official states the alternative that will be implemented from a prepared EIS.

Recovery - The achievement of viable populations of threatened or endangered plant or animal species.

Recreation Capacity - The number of people that can take advantage of any supply of recreation opportunity at any one time without substantially diminishing the quality of the experience sought after.

Recreation Opportunity Spectrum (ROS) - Six categories have been defined as follows:

Primitive (P or Class I): Very high probability of experiencing solitude, freedom, closeness to nature, tranquility, self-reliance, challenge and risk. Unmodified natural or natural appearing environment. Very low interaction between users. Minimal evidence of other users. Restrictions and controls not evident after entry. Access and travel is nonmotorized on trails or cross country. No vegetative alterations. Access for people with disabilities can be most difficult and very challenging. No site modifications for facilities. Interpretation through self-discovery. No on-site facilities. No facilities for user comfort. Rustic and rudimentary ones for site protection only. Use undimensioned native materials. (USDA Forest Service 1994).

Semi-Primitive Nonmotorized (SPNM or Class II): High probability of experiencing solitude, closeness to nature, tranquility, self-reliance, challenge and risk. Natural appearing environment. Low interaction between users. Some evidence of other users. Minimum of

subtle on-site controls. Access and travel is nonmotorized on trails, some primitive roads or cross country. Vegetative alterations. sanitation salvage to very small units in size and number, widely dispersed and not evident. Access for people with disabilities is difficult and challenging. Rustic and rudimentary facilities primarily for site protection. No evidence of synthetic materials. Use undimensioned native materials. Interpretation through self-discovery. Some use of maps, brochures, and guidebooks. No on-site facilities.

Semi-primitive Motorized (SPM or Class III): Moderate probability of experiencing solitude, closeness to nature, tranquility. High degree of self-reliance, challenge and risk in using motorized equipment. Predominantly natural appearing environment. Low concentration of users but often evidence of others on trails. Minimum on-site controls and restrictions present but subtle. Vegetative alterations very small in size and number, widely dispersed and visually subordinate. Access for people with disabilities is difficult and challenging. Rustic and rudimentary facilities primarily for site protection. No evidence of synthetic materials. Use undimensioned native materials. Interpretation through very limited on-site facilities. Use of maps, brochures and guidebooks.

Roaded Natural (RN or Class IV): Opportunity to affiliate with other users in developed sites but with some chance of privacy. Self-reliance on outdoor skill of only moderate importance. Little challenge and risk. Mostly natural appearing environment as viewed from sensitive roads and trails. Interaction between users at camp sites is of moderate importance. Some obvious on-site controls of users. Access and travel is conventional motorized including sedan, trailers, RV's and some motor homes. Vegetative alterations done to maintain desired visual and recreational characteristics. Access for people with disabilities is of only moderate challenge. Rustic facilities providing some comfort for the user as well as site protection. Use native materials but with more refinement in design. Synthetic materials should not be evident. Moderate site modification for facilities. Interpretation through simple wayside exhibits. Use native-like materials with some refinement in design. Some casual interpretation by forest staff.

Rural (R or Class V): Opportunity to observe and affiliate with other users is important as is convenience of facilities. Self-reliance on outdoor skills of little importance. Little challenge and risk except for activities such as downhill skiing. Natural environment is culturally modified yet attractive. Backdrop may range from alterations not obvious to dominant. Interactions between users may be high as is evidence of other users. Obvious and prevalent *on-site controls*. *Access and travel facilities* are for individual intensified motorized use. Access for people with disabilities is easy and meets ADAAG standards. Some facilities designed primarily for user comfort and convenience. Some synthetic but harmonious materials may be incorporated. Design may be more complex and refined. Moderate to heavy site modification. Interpretation through more complex wayside exhibits including small lighted structures. Interpretive facilities such as kiosks and portals may be staffed part-time.

Urban (U or Class VI): Opportunity to observe and affiliate with other users is very important as is convenience of facilities and recreation opportunities. Outdoor skills, risk, and challenge are unimportant except for competitive sports. Urbanized environment with dominant structures, traffic lights and paved streets. May have natural appearing backdrop. Recreation places may be city parks and large resorts. Interaction between large numbers of users is high. Intensive on-site controls are numerous. Access and travel facilities are highly intense, motorized and often with mass transit supplements. Vegetation is planted and maintained. Access for people with disabilities is easy and meets ADAAG standards. Facilities mostly designed for user comfort and convenience. Synthetic materials are commonly used. Facility design may be highly complex and refined but in harmony or complimentary to the site. Heavy site modifications for facilities. Interpretation through very sophisticated exhibits in staffed visitor centers, wayside exhibits, etc.

Recreation Visitor Day (RVD) - Twelve visitor hours, which may be aggregated continuously, intermittently, or simultaneously by one or more persons.

Recruitment - The addition to a population from all causes, including reproduction, immigration and stocking.

Reforestation - The natural or artificial restocking of an area with forest trees.

Regeneration - The renewal of a tree crop, whether by natural or artificial means. Also, the young crop itself, which commonly is referred to as reproduction.

Regeneration Method - A harvest method by which a new age class is created. The major methods are clearcutting, Seed-Tree, Shelterwood, Selection, and Coppice Regeneration Methods and their variants).

Regional Forester - The official of the USDA Forest Service responsible for administering an entire region of the Forest Service.

Regulations - Generally refers to the Code of Federal Regulations, Title 36, Chapter II, which covers management of the Forest Service.

Rehabilitation - A short-term management activity used to return visual impacts in the natural setting to a desired visual quality.

Release - Freeing trees from competition for light, water, and nutrients by removing or reducing the vegetation growth that is overtopping or closely surrounding them.

Release Cutting - Removal of competing vegetation to allow desired tree species to grow

Release Treatment - A treatment designed to free young trees from undesirable, usually overtopping, competing vegetation. Treatments include: liberation, cleaning, and weeding.

Removal Cut - The removal of the last seed bearers or shelter trees after regeneration is established

Renewable Resource - Resources whose total physical quantity is replenished over time and is thus can sustain some rate of consumption.

Repeated Seasonal Grazing - A situation in which a pasture is grazed at the same time each year.

Research Natural Area (RNA) - Lands that are protected for the purpose of maintaining biological diversity, conducting nonmanipulative research and monitoring, and promoting education.

Reserve Trees - Deliberate retention of trees in a stand for a specific resource use.

Resident Fish - Fish that are not migratory and complete their entire life cycle in fresh water.

Resource - A broad term denoting anything that is useful for something

Resource Value - The value of an ecosystem for a particular use or benefit on an ecological type. This value may be expressed as the value amount or as a relative rating, when compared to the maximum value for an ecological type.

Responsible Official - The Forest Service employee who has been delegated the authority to carry out a specific planning action.

Restoration - Actions taken to modify an ecosystem in whole or in part to achieve a desired condition.

Restoration Ecology - The study of recreating entire communities of organisms closely modeled after communities that occur naturally.

Retention - A visual quality objective; management activities that are not visually evident; activities repeat form, line, color, and texture characteristics found in the landscape.

Revalidation - Pertaining to prescribed natural fire, the daily certification by the approving line officer that the fire is within prescription and will remain in prescription through the ensuing 24-hour period, given reasonably foreseeable weather conditions and fire behavior.

Revegetation - The reestablishment and development of a plant cover by either natural or artificial means, such as reseeding.

Right-of-Way - An accurately located strip of land with defined width, point of beginning, and point of ending. It is the area within which the user has authority to conduct operations approved or granted by the landowner in an authorizing document, such as a permit, easement, lease, license, or Memorandum of Understanding (MOU).

Riparian - Of, on, or relating to the bank of a natural course of water.

Riparian Area - Geographically definable area with distinctive resource values and characteristics that are comprised of the aquatic and transitional ecosystems. Riparian areas may be associated with lakes, reservoirs, potholes, springs, bogs, wet meadows, and ephemeral, intermittent, or perennial streams

RNA - Research Natural Area.

Road

All created or evolved travel routes that are greater than 500 feet long (minimum inventory standard for the Forest Service Route Management System), which are reasonable and prudently drivable with a conventional passenger car or pickup (vehicles greater than 50 inches wide and having a dry weight of 600 pounds or more).

System Road/Managed Road: A road which is part of the official Forest Transportation Management System; these roads usually have a number and a name; they are usually on the Forest travel plan maps.

Nonsystem Road/Unmanaged Road/Ghost Road: A road which is not part of the official Forest Transportation Management System; these roads usually do not have a number or a name; they are not on the Forest travel plan maps.

Open Road/Motorized Road: Any road without restriction on motorized vehicle use.

Restricted Road: Any road on which motorized vehicle use is restricted seasonally or yearlong. The road requires physical obstruction (generally gated) and motorized vehicle use is legally restricted. Motorized administrative use by personnel of resource management agencies is acceptable at low intensity levels as defined in existing cumulative effects analysis models. This includes contractors and permittees in addition to agency employees.

Reclaimed/Obliterated Road: Any road which has been treated in such a manner so as to no longer function as a road or trail. This can be accomplished through one or a combination of

several means including, recontouring to original slope, placement of logging, road, or forest debris, planting of shrubs or trees, etc.

TMARD (Total Motorized Access Route Density) Includes all open and restricted roads and motorized trails. Density may be displayed as follows: 1) Density (miles/square mile) for an analysis area (such as a watershed or a management prescription area). 2) Density is displayed as a percentage of the analysis area in a defined density category (example: 20% >2.0 miles per square mile)

OROMTRD (Open Road and Open Motorized Trail Route Density): Includes all open roads and open motorized trails. Density may be displayed as follows: 1) Density (miles/square mile) for an analysis area (such as a watershed or a management prescription area). 2) Density is displayed as a percentage of the analysis area in a defined density category (example: 20% >2.0 miles per square mile).

A. Calculating OROMTRD for elk habitat effectiveness (the spring/summer/fall period, but not including the general big game rifle seasons):

1. OROMTRD will be calculated on the basis of principal watersheds. The area in square miles of each principal watershed will be calculated, and the miles of open roads and open trails within that principal watershed will also be calculated to determine the OROMTRD (expressed as miles/square mile). The acreage and road and trail mileage included in the calculation will include all acres (NF and private) within the principal watershed.

a. Open roads includes: (a) all system (managed) roads which are open for motorized use on the Forest Plan Travel Maps; plus (b) all system (managed) and nonsystem (unmanaged) roads which have more than 1 to 2 motorized vehicle trips per week for the majority of the weeks during the spring/summer/fall period, even if they are designated closed on

the Forest Plan Travel Maps, plus (c) all highways and county roads and private roads which are open for motorized use

b. Open motorized trails includes: (a) all system (managed) trails which are open for motorized use on the Forest Plan Travel Maps; plus (b) all system (managed) and nonsystem (unmanaged) trails which have more than 1 or 2 motorized vehicle trips per week for the majority of the weeks during the spring/summer/fall period, even if they are designated closed on the Forest Plan Travel Maps.

c. Open roads and open motorized trails which are on the boundary of principal watersheds will be calculated as having one-half the total mileage of that road or trail in each of the watersheds it separates. Open roads and open motorized trails which form the Forest boundary will likewise have one-half of that boundary mileage counted as occurring within the Forest

B. Calculating OROMTRD for elk vulnerability (the general big game rifle seasons):

1. OROMTRD will be calculated on the basis of principal watersheds. The area in square miles of each principal watershed will be calculated. The miles of open roads and open motorized trails within the principal watershed will also be calculated. In addition, "infinitely open areas" will be determined and included in the calculation using a factor of 6 miles of open road per square mile of infinitely open area. Open road and open motorized trail density will be expressed as miles/square mile. The acreage and road and trail mileage included in the calculation will include all acres (NF and private) within a principal watershed.

a. Open roads includes: (a) all system (managed) roads which are open for motorized use on the Forest Plan Travel Maps during the general big

game rifle seasons; plus (b) all system (managed) and nonsystem (unmanaged) roads which have motorized vehicle use during the general big game rifle seasons, even if they are designated closed on the Forest Plan Travel Maps except game retrieval permits are not included; plus (c) all highways and county roads and private roads which are open for motorized use during the general big game rifle seasons.

b. Open motorized trails includes: (a) all system (managed) trails which are open for motorized use on the Forest Plan Travel Maps during the general big game rifle seasons; plus (b) all system (managed) and nonsystem (unmanaged) trails which have motorized vehicle use during the general big game rifle seasons, even if they are designated closed on the Forest Plan Travel Maps, except game retrieval permits are not included.

c. Infinitely open areas include: areas which have terrain and vegetation which allow OHV use and they are not closed to OHV use on the Forest Plan Travel Maps during the general big game hunting seasons. Game retrieval permits in areas which are closed to OHV use are not included in calculations of infinitely open areas. Calculate the total square miles for these areas, and use a factor of 6 miles of open road for each square mile of area.

d. Open roads and open motorized trails which are on the boundary of principal watersheds will be calculated as having one-half the total mileage of that road or trail in each of the watersheds it separates. Open roads and open motorized trails which form the Forest boundary will likewise have one-half of that boundary mileage counted as occurring within the Forest.

C. Calculating OROMTRD for Management Prescription Areas. Follow the same procedure as for elk habitat effectiveness, except the boundaries will be contiguous management prescription areas (and in some cases adjacent management prescription areas as directed in the management prescriptions).

D. Calculating OROMTRD for Grizzly Bear Management Units Follow the procedures outlined in the Interagency Grizzly Bear Committee Taskforce Report - Grizzly Bear/Motorized Access Management, Final, approved by the IFBC, July 21, 1994.

Roadless Areas - Areas of National Forest land which qualify for placement on the inventory of potential wilderness if, in addition to meeting the statutory definition of wilderness, they meet one or more of the following criteria:

- 1 They contain 5,000 acres or more.
2. They contain less than 5,000 acres but.
 - a. Due to physiography of vegetation, they are manageable in their natural condition.
 - b. They are self-contained ecosystems such as an island.
 - c. They are contiguous to existing wilderness, primitive areas, Administration-endorsed wilderness, or roadless areas in other Federal ownership, regardless of their size.
3. They do not contain improved roads maintained for travel by standard passenger-type vehicles, except as permitted in areas east of the 100th meridian.

ROD - Record of Decision

ROS - Recreation Opportunity Spectrum.

Rosgen Channel Types - A classification system developed by Dave Rosgen which places stream reaches into categories based on physical characteristics. This system is useful in comparing the existing classification (condition) of a stream to its natural potential.

Rotation - The number of years required to establish (including the regeneration period) and grow timber crops to a specific condition or maturity for regeneration harvest. Selected management prescriptions in the forest plan provide the basis for the rotation age.

Rotational Grazing System - Animals are moved from pasture to pasture on a scheduled basis

RPA - The Forest and Rangeland Renewable Resources Planning Act of 1974. Also refers to the National Assessment and Recommended Program developed to fulfill the requirements of this Act.

Runoff - The portion of precipitation that flows over the land surface or in open channels.

RVD - Recreation Visitor Day

RVR - Resource Value Rating.

-S-

S&G Allotment - A sheep and goat allotment.

Sale Schedule - The quantity of timber planned for sale by time period from the area of suitable land covered by a forest plan. The first period, usually a decade, of the selected sale schedule provides the allowable sale quantity. Future periods are shown to establish that long-term sustained yield will be achieved and maintained.

Salvage Cutting - The harvest of trees that are dead, dying, or deteriorating (because they are overmature or have been materially damaged by fire, wind, insects, fungi, or other injurious agencies) before their timber becomes worthless.

Salvage Harvest - Harvest of trees that are dead, dying, or deteriorating because they are overmature or have been materially damaged by fire, wind, insects, fungi, or other injurious agents before the wood becomes unmerchantable.

Sanitation Cutting - The removal of dead, damaged, or susceptible trees, done primarily to prevent the spread of pests and pathogens and so promote forest hygiene.

Sanitation Harvest - The harvest of dead, damaged or susceptible trees done primarily to prevent the spread of pests or disease and to promote forest health.

Sapling - A young tree larger than a seedling but smaller than a pole. Size is with the range of 1.0 to 4.9 inches DBH.

Satisfactory Condition - When the desired future rangeland condition is being met or short term objectives are being achieved to move the rangeland toward the desired future condition.

Sawtimber - Trees that are 9 inches in diameter at breast height or larger and can be made into lumber.

Scoping - The ongoing process to determine public opinion, receive comments and suggestions, and determine issues during the environmental analysis process. It may involve public meetings, telephone conversations or letters.

SDI - Stand Density Index.

Second Growth - Forest growth that was established after some kind of interference with the previous forest crop, such as cutting, fire, or insect attack.

Security Cover - See grizzly bear security cover.

Sediment - Solid material, both mineral and organic, transported from its site of origin by air, water, gravity or ice.

Sedimentation - The action or process of forming or depositing excessive amounts of sediment.

Seed cut - A type of cut that prepares the seed bed and creates a new age class in an even-aged or two-aged stand under the Seed-Tree or Shelterwood Regeneration Method. Reserve trees may or may not be retained.

Seed Tree Cutting - An even-aged cutting method in which most of the mature timber from an area is removed in one cut except for a small number of desirable trees retained to provide seed or shelter for regeneration.

Seed-Tree Regeneration Method - A method of regenerating a stand in which a new age class develops from seeds that germinate in a fully-exposed microenvironment after removal of the previous stand, except for a small number of trees left to provide seed. This method creates an even-aged stand.

Seedling - A young tree less than 0.9 inches DBH.

Seed Tree Cutting - Removal in one cut of the mature timber crop from an area, except for a small number of seed bearers left singly or in small groups

Seed Tree Harvest. Removal of the mature timber crop from an area in one cut, except for a small number of seed bearers.

Selection - See "Group Selection" and "Individual (Single) Tree Selection."

Selection Cutting - The annual or periodic removal of trees (particularly mature trees), individually or in small groups, from an uneven-aged forest, to realize the yield and to maintain age stratification.

Selection System - An uneven-aged silvicultural system in which trees are removed individually or in groups, from a large area on a set temporal cycle.

Sensitivity Level - A particular degree of measure of viewer interest in scenic qualities of the landscape. Three sensitivity levels are employed, each identifying a different level of user concern for the visual environment.

Level 1 - Highest Sensitivity

Level 2 - Average Sensitivity

Level 3 - Lowest Sensitivity

Sensitive Species - Those species that (1) have appeared in the Federal Register as proposed for classification and are under consideration for official listing as endangered or threatened species or (2) are on an official state list or (3) are recognized by the U.S. Forest Service or other management agency as needing special management to prevent their being placed on federal or state lists.

Seral - The stage of succession of a plant or animal community that is transitional. If left alone, the seral stage will give way to another plant or animal community that represents a further stage of succession.

Seral Stage - The series of relatively transitory planned communities that develop during ecological succession from bare ground to the climax stage. There are five stages:

Early seral stage - The period from disturbance to crown closure of conifer stands managed under the current forest management regime. Grass, herbs, or brush are plentiful.

Mid-Seral stage - The period in the life of a forest stand from crown closure to first merchantability usually ages 15-40. Due to stand density, brush, grass, or herbs rapidly decrease in the stand. Hiding cover may be present

Late seral stage - The period in the life of a forest stand from first merchantability to culmination of mean annual increment. This is under a regime including commercial thinning, or to 100 years of age, depending on wildlife habitat needs. During this period, stand diversity is minimal, except that conifer mortality rates will be fairly rapid. Hiding than thermal cover may be present. Forage is minimal.

Mature seral stage - The period in the life of a forest stand from culmination of mean annual increment to an old-growth stage or to 200 years. This is a time of gradually increasing stand diversity. Hiding cover, thermal cover, and some forage may be present.

Old-growth seral stage - This stage constitutes the potential plant community capable of existing on a site given the frequency of natural disturbance events. For forest communities this stage exists from approximately age 200 until when stand replacement occurs and secondary succession begins again. Depending on fire frequency and intensity, old growth forests may have different structures, species composition, and age distributions. In forests with longer periods between natural disturbance, the forest structure will be more even-aged at late mature or early old-growth stages

Series - An aggregation of taxonomically related plant associations which take the name of (climatic) climax species that dominate, or have the potential to dominate, the principal vegetative layer in a time frame appropriate to the vegetative or taxonomic group under consideration. See Subseries.

Severely Burned - The main effect of burning is organic matter and nutrient loss. Severely burned is detrimental if it adversely affects site productivity or hydrologic function

Shade-Tolerant Plants - Plants that grow well in shade.

Shelterwood Regeneration Method - A method of regenerating a stand in which a new age class develops beneath the partially-shaded microenvironment provided by the residual trees. The method creates an even-aged stand

Shelterwood Removal Cut - A type of cut that releases established regeneration from competition with seed trees while retaining some trees needed for shelter under the Shelterwood Regeneration Method. Reserve trees may or may not be retained.

Shrub - A plant that has persistent, woody stems and a relatively low growth habit, and that generally produces several basal shoots instead of a single bole. It differs from a tree by its low stature and nonarborescent form.

Sight Distance - The distance at which 90 percent or more of a deer or elk is hidden from an observer. Hiding cover exists when 90 percent or more of a standing deer or elk is hidden at a distance of 200 feet or less.

Significance - As used in NEPA, requires consideration of both context and intensity.

Silvicultural System - The cultivation of forests; the result is a forest of a distinct form. Silvicultural systems are classified according to harvest and regeneration methods and the type of forest that results

Silviculture - The art and science that promotes the growth of single trees and the forest as a biological unit.

Single-Tree Selection - See "Individual (Single) Tree Selection"

Site - A small area or parcel of land considered in terms of its environment

Site Development Scale:

Site Development Level 1: Minimum Site Modification - Rustic or rudimentary improvements designed for protection of the site rather than comfort of the users. Use of synthetic materials excluded. Minimum controls are subtle. No obvious regimentation. Spacing informal and extended to minimize contacts between users. Motorized access not provided or permitted.

Site Development Level 2. Little Site Modification - Rustic or rudimentary improvements designed primarily for protection of the site rather than the comfort of the users. Use of synthetic materials avoided. Minimum controls are subtle. Little obvious regimentation. Spacing informal and extended to minimize contacts between users. Motorized access provided or permitted. Permitted access over primitive roads. Interpretive services informal, almost subliminal.

Site Development Level 3: Site Modification Moderate - Facilities about equal for protection of site and comfort of users. Contemporary or rustic design of improvements is usually based on use of native materials. Inconspicuous vehicular traffic controls usually provided. Roads may be hard surfaced and trails formalized. Development density about 3 family units per acre. Primary access may be over high standard roads. Interpretive services informal, but generally direct

Site Development Level 4: Site Heavily Modified - Some facilities designed strictly for comfort and convenience of users. Luxury facilities not provided. Facility design may incorporate synthetic materials. Extensive use of artificial surfacing of roads and trails. Vehicular traffic control usually obvious. Primary access usually over paved roads. Development density 3 to 5 family units per acre. Plant materials usually native. Interpretive services often formal or structured.

Site Development Level 5: High Degree of Site Modification - Facilities mostly designed for comfort and convenience of users and usually include flush toilets; may include showers, bathhouses, laundry facilities, and electrical hookups. Synthetic materials commonly used. Formal walks or surfaced trails. Regimentation

of users is obvious. Access usually by high-speed highways. Development density 5 or more family units per acre. Plant materials may be foreign to the environment. Formal interpretive services usually available. Design formalized and architecture may be contemporary. Mowed lawns and clipped shrubs not unusual.

Site Preparation - The general term for removing unwanted vegetation, slash, roots, and stones from a site before reforestation. Naturally occurring wild-fire, as well as prescribed fire can prepare a site for natural regeneration.

Site Productivity - Production capability of specific areas of land.

Size Class - One of the three intervals of tree stem diameters used to classify timber in the Forest Plan data base. The size classes are: Seedling/Sapling (less than 5 inches in diameter); Pole Timber (5 to 7 inches in diameter), Sawtimber (greater than 7 inches in diameter)

Skidding - Hauling logs by sliding, not on wheels, from stump to a collection point.

Skid Trail - Narrow path on which logging equipment travels when moving logs from the forest to a designated landing location.

SL - Standard Service Level.

Slash - The residue left on the ground after timber cutting and/or accumulating there as a result of storm, fire, or other damage. It includes unused logs, uprooted stumps, broken or uprooted stems, branches, twigs, leaves, bark and chips.

Small Game - Birds and small mammals typically hunted or trapped.

Snag - A standing dead tree greater than 20 feet tall from which the leaves and most of the limbs have fallen

Snowmachine - Any motorized vehicle which is used for over snow travel

Soil - The unconsolidated mineral material on the immediate surface of the earth that serves as a natural medium for the growth of land plants.

Soil Compaction - The reduction of soil volume. For instance, the weight of heavy equipment on soils can compact the soil and thereby change it in some ways, such as its ability to absorb water. Compaction is generally evaluated from 5 to 30 centimeters below the mineral soil surface. Substantial compaction in any 5-centimeter increment in the top 30 centimeters of soil is considered to be detrimental. Compaction that doubles the soil strength or that decreases soil porosity by 10 percent or more from undisturbed values is considered to be substantial. In soils with sand or sandy loam textures and less than 50% very fine sand (0.05-0.10 mm) in the sand fraction (0.05-2.0 mm), the porosity must be reduced more than 12% to be considered substantial compaction. Infiltration is another alternative for determining compaction. Forests are encouraged to develop infiltration guidelines that relate to detrimental compaction.

Soil Displacement - Detrimental displacement is the loss of either 5 centimeters or one-half of the humus-enriched top soil A-horizon, whichever is less, from an area that is 1 meter by 1 meter or larger.

Soil Disturbance - Detrimentally disturbed soil is soil that has been detrimentally displaced, compacted, puddled, or severely burned. At least 85% of the total area within an activity areas must have soil that is in satisfactory condition. Stated another way, no more than a total of 15% of an activity area may have detrimentally disturbed soil. Some examples of management options limiting the effects of soil disturbance and mitigation measures are listed in Exhibit 1.

Soil and Water Conservation Practices (SWCPs) - See Best Management Practice.

Soil Cover - Refers to ground cover, which consists of vegetation, litter, and rock fragments larger than three-fourths inch in diameter in contact with the soil. Also, it includes perennial canopy cover that is within 3 to 30 feet of the ground.

Soil Disturbance/Disturbed Soil - Soil that has been detrimentally displaced, compacted, puddled, or severely burned. No more than 15% of an activity area may have disturbed soils.

Detrimentially displaced. the loss of either 2 inches or one-half of the humus-enriched top soil (A-horizon), or both, from an area of 1 square meter or larger.

Detrimental compaction/puddling. decreases in soil porosity by 10% or more from undisturbed values, or doubling of the soil strength, in any 2 inch increment in the top foot of soil.

Soil Hydrologic Function - Is the inherent capacity of a soil to intake, retain and transmit water.

Soil Organic Matter - Is the organic fraction of soil. Includes plant, animal and microbial residues, fresh and at all stages of decomposition, and the relatively resistant soil humus.

Soil Productivity - The capacity of a soil to produce a specific crop. Productivity depends on adequate moisture and soil nutrients, as well as favorable climate.

Soil Puddling - Puddling is generally evaluated at the mineral soil surface. Visual indicators of detrimental puddling include clearly identifiable ruts with berms or hoof prints in mineral soil, or in an Oa horizon of an organic soil. Detrimental puddling may occur in conjunction with detrimental compaction. The guidelines for soil compaction (section b) are to be used when this occurs. Detrimentially puddled soils are not always detrimentally compact. Infiltration and permeability are affected by detrimental soil puddling. Forests are encouraged to develop infiltration and/or permeability guidelines that relate to detrimental puddling.

Soil Quality - Refers to the maintenance or improvement of long term soil productivity and soil hydrologic function.

Soil Survey - The systematic examination of soils in the field and laboratory, including description, classification, interpretation of productivity and mapping.

Spatial scale - The level of resolution in space perceived or considered.

Special forest products - Nontimber renewable plant products (such as mushrooms, berries, flowers, etc.).

Special Use Permit - A permit issued to an individual or group by the USDA Forest Service for use of National Forest land for a special purpose. Examples might be a Boy Scout Jamboree or a mountain bike race.

Species - A fundamental category of plant or animal classification

Species Composition - The proportions of various plant or animal species in relation to the total on a given area. Plant species may be expressed in terms of cover, density, weight, and so on.

Stand - A community of trees or other vegetation sufficiently uniform in composition, constitution, age, spatial arrangement or condition to be distinguishable from adjacent communities and so form a silvicultural or management entity.

Stand Exam - The activity of looking at a stand in the field to obtain measure of stand conditions, physical site factors, and other environmental data to help determine future management of the stand.

Stand Replacement Fire - Fire which kills all or most living overstory trees in a forest and initiates regrowth at an earlier successional stage.

Standard - a condition of land, normally a maximum or minimum condition, that is measurable. A standard can also be expressed as a constraint on management activities or practices. Deviation from compliance with a standard requires a Forest Plan amendment.

Standard Service Level (SL) - Management level designed to enhance the recreation experience, ensure public safety, correct resource damage, and maximize the longevity and serviceability of recreation facilities

Standards and Guidelines - Requirements found in a Forest Plan which impose limits on natural resource management activities, generally for environmental protection.

State Air Quality Regulations - The legal base for control of air pollution sources in that State. Prescribed burning is generally covered under these regulations.

State Implementation Plan - A State plan that covers implementation, maintenance, and enforcement of primary and secondary standards in each air quality control Region, pursuant to section 110 of the Clean Air Act.

Stocking - A measure of the proportion of the area in a stand actually occupied by trees expressed in terms of stocked quadrats or percent of canopy closure (as distinct from their stand density).

Stocking level - The number of trees in an area as compared to the desirable number of trees for best results, such as maximum wood production.

Storage - One of the ways functions are described; resources which are conserved within the system (i.e., sediments and water retained in wetlands, carbon and other nutrient storage in down woody material).

Structure - How the parts of ecosystems are arranged, both horizontally and vertically. These parts include vegetation patches, edge, fragmentation, canopy layers, snags, down wood, steep canyons, rocks in streams, and roads. For example, structure might reveal a pattern, mosaic or total randomness of vegetation.

Subregion - One of the hierarchy levels used for RPA assessments and statewide planning, encompassing hundreds to thousands of square miles.

Subsection - An ecological unit of land that has uniform climatic and geologic characteristics. Seven subsections have been delineated within the Targhee National Forest.

Succession - The natural replacement, in time, of one plant community with another. Conditions of the prior plant community (or successional stage) create conditions that are favorable for the establishment of the next stage.

Succession, Plant - The process of vegetational development whereby an area becomes successively occupied by different plant communities of higher ecological order.

Successional Stage - See Seral Stage.

Suitability - The appropriateness of applying certain management practices to a particular area of land, as determined by an analysis of the economic and environmental consequences and the opportunity cost of uses foregone.

Suitability for Timber Production - Timber harvest, other than salvage sales or sales to protect other multiple-use values, cannot occur on lands not suited for timber production.

Suitable Forest Land - See Timber Classification

Suitable Habitat - The biological and physical components necessary to meet some or all of the life needs of a species.

Suitable Range - Rangeland that is accessible and used by grazing animals, that produces forage or has inherent forage producing capabilities, and that can be grazed on a sustained yield basis under reasonable management goals. (cf. unsuitable range.)

Suppression - The action of extinguishing or confining a fire.

Surface Resources - Renewable resources that are on the surface of the earth, such as timber and forage, in contrast to ground water and minerals which are located beneath the surface.

Sustainability - The ability of an ecosystem to maintain ecological processes and functions, biological diversity, and productivity over time.

Sustainable - The yield that a renewable resource can produce continuously at a given intensity of management is said to be sustainable.

Sustainable Development - The use of land and water so sustain production indefinitely without environmental deterioration, ideally without loss of native biodiversity.

Sustainable Ecosystem Management - Management directed towards developing or maintaining a synergistic complex of plants and animals which can be perpetuated indefinitely.

Sustained-Yield - The yield that a renewable resource can produce continuously at a given intensity of management.

Swing Allotment - Any cattle or sheep allotment without a permanent permittee, that is open and available for grazing on a temporary basis to existing Targhee permittees. The intent of a "swing" allotment is to provide a place for grazing animals that are moved from their "permanent" allotment because of unplanned events and situations. A "swing" allotment may or may not have an allotment management plan and usually is not grazed by the same permittee on a yearly basis. An example of a "swing" allotment is an allotment that is

grazed by a band of sheep, that had to be removed from their "permanent" allotment because of Grizzly Bear conflicts, for a portion or all of their permitted grazing season.

-T-

Target - A National Forest's annual goal for accomplishment for natural resource programs. Targets represent the commitment of the Forest Service has with Congress to accomplish the work Congress has funded, and are often used as a measure of the agency's performance.

Technically Suitable Forest Land - See Timber Classification.

Tentatively Suitable Forest Land - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary, or the Chief, (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions; and (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that it is possible restock adequately within 5 years after final harvest, and (d) adequate information is available to project responses to timber management activities.

Thermal Cover - Cover used by animals to moderate the effects of weather. Thermal cover may represent protection from heat or cold. Thermal cover requirements vary with species and the prevailing climate.

Thinning - An intermediate cutting made in an immature stand primarily to maintain or accelerate diameter increment and also to improve the average form of the remaining trees without permanently breaking the canopy. An intermediate cutting.

Threatened Species - Any species listed in the Federal Register which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

Timber Base - The lands within the Forest capable, available and suited for timber production.

Timber Classification - The classification of forested lands into land management alternatives according to how the land relates to management of the timber resource there.

Nonforest Land - Lands never having or incapable of having greater than 10 percent of the area occupied by forest trees and lands formerly forested and currently developed for nonforest use.

Forest Land - Land at least 10 percent occupied by forest trees of any size or formerly having had such tree cover and not currently developed for nonforest use. Lands developed for nonforest use include areas for crops, improved pasture, residential, or administrative areas, improved roads of any width and adjoining road clearing and powerline clearing of any width. The term occupancy when used to define forest land will be measured by canopy cover of live forest trees at maturity. The minimum area for classification of forest land is 1 acre. Unimproved roads, trails, streams and clearings in forest areas are classified as forest if they are less than 120 feet in width.

Suitable Forest Land - Land that is managed for timber production on a regulated basis.

Unsuitable Forest Land (Not Suited) - Forest land that is not managed for timber production because: (1) the land has been withdrawn by Congress, the Secretary or the Chief; (2) technology is not available to prevent irreversible damage to soils, productivity or watershed conditions; (3) there is not reasonable assurance that lands can adequately be restocked within 5 years after final harvest based on existing technology and knowledge; (4) there is at present, a lack of adequate information to responses to timber management activities; or (5) timber management is inconsistent with or not cost-efficient in meeting management requirements and multiple-use objectives specified in the Forest Plan.

Tentatively Suitable (Commercial Forest Land) - Forest Land which is producing or is capable of producing crops of industrial wood and (1) has not been withdrawn by Congress, the Secretary or the Chief; (2) existing technology and knowledge is available to ensure timber production without irreversible damage

to soils, productivity, or watershed conditions, and (3) existing technology and knowledge provides reasonable assurance that adequate restocking can be attained within 5 years after final harvesting.

Timber Harvest Schedule - See "Sale Schedule."

Timber Production - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees for cutting into logs, bolts, or other round sections for industrial or consumer use. For purposes of forest planning, timber production does not include fuelwood or harvests from unsuitable lands.

Timber Sale Program Quantity (TSPQ) - The volume of timber planned for sale during the first decade of the planning horizon. It includes the allowable sale quantity (chargeable volume) and any additional material (nonchargeable volume) planned for sale. The timber sale program quantity usually is expressed as an annual average for the first decade.

Timber Stand Improvement (TSI) - Measures such as thinning, pruning, release cutting, prescribed fire, girdling weeding, or poisoning of unwanted trees aimed at improving growing conditions of the remaining tree.

Timelag - An indication of the rate a dead fuel gains or loses moisture due to changes in its environment. The time necessary for a fuel particle to gain or lose approximately 63 percent of the difference between its initial moisture content and its equilibrium moisture content. Fuels are usually grouped into the following groups:

Classification	Diameter (Inches)
1 hour	0-1/4
10 hour	1/4-1
100 hour	1-3
1,000 hour	3-8

Total Motorized Access Route Density (TMARD) - Includes all open and restricted roads and motorized trails. Density may be displayed as follows: 1) Density (miles/square mile) for an analysis area (such as a watershed or a management prescription area). 2) Density is displayed as a percentage of the analysis area in a defined density category (example 20% >2.0 miles per square mile).

Tractor Logging - A logging method that uses tractors to carry or drag logs from the stump to a collection point.

Trail -

All created or evolved travel (access) routes that do not qualify as a road, they are used for both motorized and nonmotorized modes of travel. For motorized travel, they are generally routes for vehicles less than 50 inches wide and which have a dry weight of 600 pounds or less. They are not reasonably and prudently drivable with a conventional passenger car or pickup.

System Trail/Managed Trail: A trail which is part of the official Forest Transportation Management System; these trails usually have a number and a name; they are usually on the Forest travel plan maps.

Nonsystem Trail/Unmanaged Trail/Ghost Trail: A trail which is not part of the official Forest Transportation Management System; these trails usually do not have a number or a name; they are not on the Forest travel plan maps.

Open Motorized Trail: A trail without restriction on motorized use and is used by motorized vehicles. Trails used by 3-wheelers, 4-wheelers, and motorized trail bikes are examples of this type of access route.

Restricted Motorized Trail: A trail on which motorized use is restricted seasonally or yearlong. Motorized use is legally restricted. Motorized administrative use by personnel of resource management agencies is acceptable at low intensity levels as defined in existing cumulative effects analysis models. This includes contractors and permittees in addition to agency employees.

Trail Maintenance - There are five levels of trail maintenance which are defined as follows:

Level 1: Trails maintained for primitive experience level. Custodial care only. No tread maintenance. Drainage functional and not likely to fail. Trailsides not brushed but tread is kept passable. Small slides may remain except for those with erosion potential. Structures maintained as needed. Signing may be deferred.

Level II: Trails maintained for near-primitive experience level. Tread maintained for public safety. Logs or similar rustic structures may be provided at stream crossing. Drainage same as Level I. Signing at a minimum level commensurate with level of trail use

Level III: Trails maintained for intermediate experience level. Tread maintained for public safety and user convenience. Drainage same as level I. Trailsides brushed out at Handbook standards. Signing same as Level II.

Level IV Trails maintained at relatively high standards to provide for public safety and convenience. Tread relatively smooth, firm and may require stabilization. Signing at high level, all other elements same as Level III. These trails are generally maintained for family or senior citizen use.

Level V. Trails maintained for high use and experience levels, including special purposes such as VIS trails, bicycle trails, trails to major vista points, trails for the handicapped, etc. Basic care same as Level IV but patching of paved tread may be needed annually. Trailsides maintained to meet high visual quality standards by brushing and cleanup of debris beyond the trail limits. Vistas are maintained.

Transportation Analysis - Conduct a systematic analysis to determine the transportation facilities and management needed to meet land and resource management objectives.

Transportation System or Network - All existing and proposed roads, trails, airfields, and other transportation facilities wholly or partly within or adjacent to and serving the National Forests and other areas administered by the Forest Service or intermingled private lands.

Treatment Area - The site-specific location of a resource improvement activity.

Tree Opening - An opening in the forest cover created by even-aged silvicultural practices.

TSI - Timber Stand Improvement

TTS - Tentative Timber Suitability

Underburn - A burn by a surface fire that can consume ground vegetation and "ladder" fuels.

Understory - The trees and woody shrubs growing beneath the overstory in a stand of trees.

Uneven-aged - The condition of a forest, crop, or stand composed of intermingling trees that differ markedly in age. In practice a minimum age difference of 25 percent of the length of the rotation usually is used.

Uneven-Aged Management - Actions that maintain a forest or stand of trees composed of intermingling trees that differ markedly in age. Cutting methods that develop and maintain uneven-aged stands are single-tree selection and group selection.

Uneven-aged Stand - A stand of trees of three or more distinct age classes, either intimately mixed or in small groups.

Uneven-aged System - A planned sequence of treatments designed to maintain and regenerate a stand with three or more age classes (see Single-Tree Selection, and Group Selection Regeneration Methods).

Unregulated Harvest - Tree harvest that is not part of the allowable sale quantity (ASQ). It can include the removal of cull or dead material or non-commercial species. It also includes volume removed from nonsuitable areas for research, to meet objectives other than timber production (such as wildlife habitat improvement), or to improve administrative sites such as campgrounds.

Unsatisfactory Rangeland Condition - Unsatisfactory rangeland condition is when the desired future rangeland condition is not being met and short term objectives are not being achieved to move the rangeland toward the desired future condition. (cf. satisfactory range condition.)

Unsuitable Range - Rangeland which has no current value or which should not be used because of physical or biological restrictions, or lack of improvements that would allow use.

Unsuitable Forest Land (Not Suited) - See Timber Classification.

Use, allowable - An estimate of proper range use by grazing animals. It can also mean the amount of forage planned to be used to accelerate range rehabilitation.

Utility and Transportation Corridors - A strip of land, up to approximately 600 feet in width, designated for the transportation of energy, commodities, and communications by railroad, State highway, electrical power transmission (66 KV and above), oil and gas and coal slurry pipelines 10 inches in diameter or larger, and telecommunication cable and electronic sites for interstate use. Transportation of minor amounts of power for short distances, such as short feeder lines from small power projects including geothermal or wind, or to serve customer subservice substations along the line, are not to be treated within the Forest Plan effort.

-V-

Vacant Allotment - An allotment that is available for grazing but is not grazed.

Variability (Range of, Natural, Historic) - The spectrum of conditions possible in ecosystem composition, structure and function considering both temporal and spatial factors. Natural range of the spatial, structural, compositional and temporal characteristics of ecosystem elements specified to represent "natural" conditions. The flux in composition, structure, and function of an ecosystem over the long term in a landscape.

Vegetation - Collectively, the plants growing in a given area

Vegetation Management - Activities designed primarily to promote the health of forest vegetation for multiple-use purposes

Vegetative Structural Stage - A method of describing the growth stages of a stand of living trees. It is based on tree size (DBH = diameter at breast height) and total canopy cover. The stages are: Grass/forb/shrub (VSS 1) = 0-1 inch DBH; Seedling/sapling (VSS 2) = 1-5 inches DBH, Young Forest (VSS 3) = 5-12 inches DBH, Mid-aged Forest

(VSS 4) = 12-18 inches DBH, Mature Forest (VSS 5) = 18-24 inches DBH, Old Forest (VSS 6) = 24+ inches DBH.

Vegetation Type - A plant community with distinguishable characteristics. See Cover Type.

Viable Population - A number of individuals of a species sufficient to ensure the long-term existence of the species in natural, self-sustaining populations adequately distributed throughout their region.

Viewshed - An expansive landscape or panoramic vista seen from a specific viewpoint, such as a road.

Vigor - The relative robustness of a plant in comparison to other individuals of the same species. It is reflected primarily by the size of a plant and its parts in relation to its age and the environment in which it is growing.

Visual Quality Objectives (VQO's) - A set of measurable goals for the management of forest visual resources used to measure the amount of visual contrast with the natural landscape caused by human activities. The following are VQO's:

Preservation - Ecological change only here

Retention - Human activities should not be evident to the casual Forest visitor.

Partial Retention - Human activity may be evident but must remain subordinate to the characteristic landscape

Modification - Human activity may dominate the characteristic landscape but must, at the same time, follow naturally established form, line, color, and texture. It should appear as a natural occurrence when viewed in foreground or middleground.

Maximum Modification - Human activity may dominate the characteristic landscape but should appear as a natural occurrence when viewed as background.

Visual Resource - A part of the landscape important for its scenic quality. It may include a composite of terrain, geologic features, or vegetation.

-W-

Watershed - The area of land above a given point on a stream that contributes water to the streamflow at that point. Also the land that contributes water to a lake or reservoir.

Watershed Improvement Needs (WIN) Inventory - A broad, reconnaissance inventory oriented primarily to problem identification rather than specific project design. It forms the basis for identifying potential soil and water resource restoration project areas and assigning priority for detailed planning and treatment.

Watershed Information System (WIS) - Inventory of Forest Service water rights and uses. The inventory includes such information as location of water right or use, the amounts of water involved, status of the use or right, purpose, etc.

Water Table - The upper surface of groundwater. Below it, the soil is saturated with water.

Water Yield - The runoff from a watershed, including groundwater outflow.

Weeding - A release treatment in stands not past the sapling stage that eliminates or suppresses undesirable vegetation regardless of crown position.

Wet Areas - Often referred to as "moist sites," they are very important components of elk summer range. These sites, often occurring at the heads of drainages, may be wet sedge meadows, bogs, or seeps.

Wetlands - Areas that are inundated by surface or ground water with a frequency sufficient, under normal circumstances, to support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction. Wetlands include wet meadows, springs, seeps, bogs, etc.

Wild and Scenic River - Rivers and their immediate environs designated by congressional action that are managed to be free of impoundments, diversions and unpolluted

Wilderness - Areas designated by congressional action that are managed for primeval characteristics, solitude or unconfined primitive recreation,

natural conditions and where the imprint of man is substantially unnoticeable.

Wilderness Act (1964) - The Wilderness Act allows preservation of designated areas of federal land under the National Wilderness Preservation System for the benefit of present and future generations. The land must be primarily affected by the forces of nature (not man), have outstanding opportunities for solitude or primitive recreation, be at least 5000 acres in size, and may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

Wildfire - Any wildland fire not designated and managed as a prescribed fire within an approved prescription and occurring in natural fuels.

Wildlife - All undomesticated mammals, birds, reptiles and amphibians living in a natural environment. Does not include feral animals, such as wild horses and burros.

Wildlife Habitat Diversity - The distribution and abundance of different plant and animal communities and species within a specific area.

WIN - Watershed Improvement Needs Inventory.

Windthrow - Trees that have been uprooted by the wind.

WIS - Watershed Information System.

Wood Fiber Production - The growing, tending, harvesting and regeneration of harvestable trees.

Woody Plant - Perennial plants that have stems consisting of wood (shrubs, trees, and vines)

Woody Residue/Residue - Organic materials such as plant stems and branches having a minimum diameter of 3 inches (small end). Included are both natural materials and management induced post-harvest materials/slash.

-X-

Xeric - Refers to a habitat characterized by dry soil conditions.

-Y-

Yield - The amount of forest produce that may be harvested periodically from a specified area over a stated period in accordance with the objectives of management.

-Z-

ZOI (Zone of Influence) - The are influenced by Forest Service management activities.

Zoning - The demarcation of a planning area into zones, which the establishment of regulations to govern the types of activities and uses within each zone.

Zoological Area - A protective area designated for its authentic, significant and interesting evidence of important animals, animal groups and animal communities.

--

Decomposition Class (cont.)

Log Characteristics	Log decomposition class				
	1	2	3	4	5
Bark	intact	intact	trace	absent	absent
Twigs < 3 cm	present	absent	absent	absent	absent
Texture	intact	intact to partly soft	hard, large pieces	small, soft, blocky pieces	soft and powdery
Shape	round	round	round	round to oval	oval
Color of wood	original color	original color	original color to faded	light brown to faded brown or yellowish	faded to light yellow or gray
Portion of log on ground	log elevated on support points	log elevated on support points but sagging slightly	log is sagging near ground	all of log on ground	all of log on ground

ABSTRACT This Final Environmental Impact Statement documents the analysis of seven alternatives, which were developed for possible management of the 1.8 million acres administered by the Targhee National Forest in Idaho and Wyoming. Alternatives developed in detail are identified as 1, 2, 3, 3M, 4, 5 and 6. Alternative 3-M is the Forest Service's Selected Alternative.

This FEIS has been prepared following public review periods for the DEIS and Proposed Revised Land and Resource Management Plan, during which approximately 12,000 comments were received from 2,300 individuals or organizations.

The policy of the United States Department of Agriculture, Forest Service prohibits discrimination on the basis of race, color, national origin, age, religion, sex, or disability, familial status, or political affiliation. Persons believing they have been discriminated against in any Forest Service related activity should write to Chief, Forest Service, USDA, P O Box 96090, Washington, DC 20090-6090.

SUMMARY OF THE FINAL ENVIRONMENTAL IMPACT STATEMENT FOR THE TARGHEE MANAGEMENT PLAN

INTRODUCTION

The purpose of the summary of the Final Environmental Impact Statement (FEIS) for the Revised Forest Plan (Revision) is to provide the reader with a quick overview of the planning process, the issues, and the alternatives, including the Selected, that will affect the management of the Targhee National Forest (Forest) for the next ten years and beyond

The FEIS considers and evaluates an array of alternatives, identifying the Selected. This summary does not cover the Revision. The Revision carries out the actions of the Selected Alternative and provides key decisions for the long-term management of the Forest. Readers wanting more in-depth information on the FEIS and Revision may write or call the Targhee National Forest Supervisor's Office at P O Box 208, St Anthony, Idaho 83445, (208) 624-3151

LOCATION AND SETTING FOR THE FOREST

The Forest is an administrative unit of the Department of Agriculture, Forest Service, encompassing approximately 1.8 million acres. Established by President Theodore Roosevelt in 1908, the Forest is named in honor of a Bannock Indian warrior. The Supervisor's Office is located in St. Anthony, Idaho with District offices located in Dubois, Island Park, Ashton, Idaho Falls, and Driggs, Idaho. The Forest is bordered by six other National Forests.

The Forest lies almost entirely within the Greater Yellowstone Ecosystem, an area of 12 million acres and the largest remaining block of relatively undisturbed plant and animal habitat in the contiguous United States.

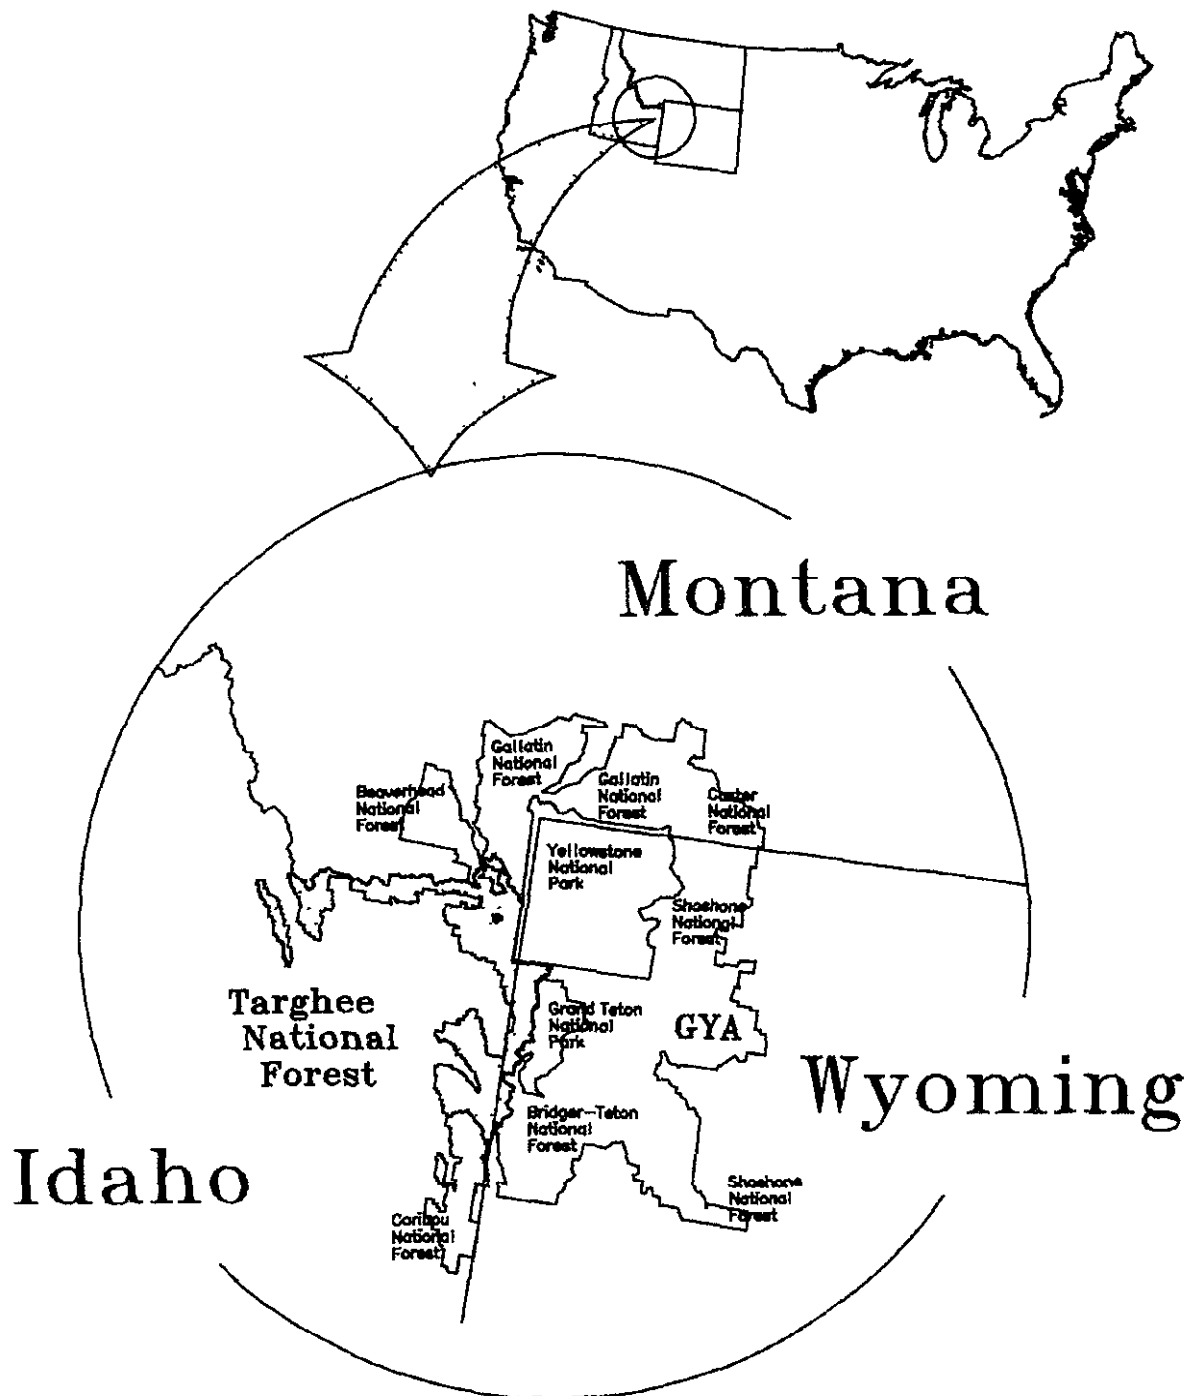

On a larger scale, the Forest lies along the Continental Divide, at the uppermost reaches of the Columbia River Basin, an ecosystem of 40 million acres extending from western Washington to the southeastern Idaho border and encompassing parts of Oregon, Montana, Wyoming, Nevada and Utah. The Forest includes all or portions of several distinct mountain ranges, including the Lemhi, Beaverhead, Bitterroot, Centennial, Henry's Lake, Teton, Big Hole, Caribou, and Snake River Ranges. Elevations range from near 5,000 feet on the Snake River to over 12,000 feet on the Forest's most western reaches. The Forest contains the Island Park Caldera and several reservoirs. Topography ranges from rolling foothills to rugged, glaciated mountain peaks.

Although most of the land is dry and semi-arid, 190 stream headwaters situated on the Forest provide varied vegetation to support a multitude of uses. The area has cold, moist winters and hot dry summers. Average annual precipitation, most of which falls as snow, increases with elevation. As little as ten inches of precipitation falls in lower valleys and as much as forty inches occurs at the highest elevations. Wide temperature extremes exist, with summer temperatures at lower elevations exceeding 100 degrees Fahrenheit and winter temperatures at higher elevations falling to less than 40 degrees below zero Fahrenheit.

NEED FOR CHANGE

The original Targhee Forest Plan, approved in 1985, emphasized an extensive salvage and reforestation program of dead lodgepole killed by a massive mountain pine beetle epidemic over the previous 30 years.

Figure S-1. Vicinity Map of Targhee National Forest on a National Scale

This rate of salvage caused, in effect, a departure from a sustained yield of timber harvest and could not be continued beyond the first decade (1985 - 1995) in an environmentally sound manner. Monitoring of activities during this time showed it was increasingly difficult to meet the standards and guidelines in the 1985 Plan. New information on resource needs and various management practices became evident during this time, and by 1990 it was apparent that a full revision was needed. More specific needs for change are as follows:

- The salvage program has ended. Use of the many roads built during salvage operations by increasing numbers of people is causing unwanted effects to wildlife, riparian areas, and soil productivity.
- The need to review and incorporate new knowledge and techniques continues, especially in wildlife habitat management. For example, recent studies indicate motorized road and trail densities play a crucial role in availability of suitable habitat for elk and grizzly bears. Standards for management activities near nesting and foraging habitat for goshawks and other raptors are needed to protect these crucial areas. Results of studies analyzing fish habitat in the Upper Columbia River Basin are pointing out new ways to manage fisheries. Some of these findings have widespread implications that the revision process was intended to address.
- Although much of the lodgepole pine component on the Forest has been salvaged, there is still a need to use timber harvest as a tool to reach ecosystem objectives, supply a variety of timber products for local use, deter other epidemics like the mountain pine beetle outbreak, and manage the potential for a devastating wildfire, like the Yellowstone Wildfires of 1988.

DESIRED FUTURE CONDITION FOR THE YEAR 2007 AND BEYOND

Based on public, other resource management agencies, and Forest Service employee participation between 1991-1994, a set of goal statements emerged that collectively represent what ideal conditions would be for the Targhee National Forest. These statements, called "Desired Future Conditions for the Year 2007 and Beyond" are the foundation for the goals, objectives, standards and guidelines developed in the Revised Forest Plan. They have changed from the desired future conditions (DFC) described in the 1985 Plan, reflecting changes in conditions and values of the local communities and knowledge gained over the decade. These titles of the DFCs also show how the analysis and documents are organized, and are described as follows:

Ecosystem Processes and Patterns DFC:

A mosaic of age classes and types of vegetation are sustained through time and exist across the landscape. Natural disturbances such as insects, disease and fires continue their natural roles in the ecosystem. The Forest functions as an integral part of the Greater Yellowstone Ecosystem as well as adjacent systems, sustaining habitat and conditions necessary for free movement of wildlife.

Biological and Physical DFC:

Riparian zones (aquatic influence zones) are healthy and productive. Aquatic systems are allowed to function naturally while protecting flows for downstream consumptive uses. Riparian area integrity contributes to productive fisheries and excellent water quality. Native plant and animal species are favored over undesirable non-native species and sustained populations of all native and desirable species thrive. Habitat conditions contribute toward the recovery of threatened, endangered and sensitive species.

Forest Use and Occupation DFC:

Growing and diverse recreational, cultural, visual, historical, and prehistoric management, interpretive, and spiritual needs are accommodated based on the capability of the ecosystem to sustain these uses. Recreation use is managed to minimize conflicts between incompatible uses and provide high levels of satisfaction. Year-round human access is managed to provide both motorized and nonmotorized opportunities. A system of trails and support facilities exist which are compatible with resource capabilities. Roadless characteristics are preserved in the proposed wilderness areas and in existing wildernesses.

Production of Commodity Resources DFC:

Commodity production, such as timber, firewood, mining, livestock forage, or outfitting and guide services are conducted at sustainable levels and maintain the capability of the land to produce an even flow and variety of goods and services for present and future generations. Timber harvest, prescribed fires and livestock grazing are tools used to achieve desired ecological vegetation conditions. Forest products are provided to sustain social and economic values and needs of the local communities within limits which maintain ecosystem health.

KEY ISSUES

Although there were over 70 issues and concerns identified by the public and Forest employees, seven key issues were the ultimate driving force for developing the alternatives and for the recommended direction of the Revised Forest Plan. The key issues address areas of controversy.

Key Issue 1: Sustainability, Fire and Natural Disturbances

An ecosystem is a large, complex, integrated system of living and nonliving components that interact and change continually. Healthy ecosystems are those that retain all of their parts and functions for future generations even though vegetation patterns, human uses or other conditions may change. Understanding ecological processes (fire and other natural disturbances) and how these processes shaped vegetation patterns over time in a landscape are important steps toward implementing Ecosystem Management (EM).

EM is a new philosophy of management for the Forest Service, and different interpretations and approaches are possible in working toward implementation. The Forest is the first in the Greater Yellowstone Area (GYA) to revise its Forest Plan and incorporate EM principles in the revision. Many activities and projects are being considered for the application and implementation of EM, new information and conclusions lag behind the need to meet the timeline for the revision of the Forest Plan.

Key Issue 2: Riparian

Riparian areas lie adjacent to water and are composed of vegetation communities dependent upon or tolerant to the presence of free or unbound water near the ground surface. Riparian areas are associated with lakes, reservoirs, potholes, springs, bogs, wet meadows, and ephemeral, intermittent or perennial streams. Although riparian areas constitute less than five percent of the total land base, they are the most productive areas in terms of plant and animal species diversity and consumptive use.

Riparian areas are essential breeding, rearing and feeding grounds for many species of wildlife and affect fish habitat. They serve people as important sources for water and flood control and for recreational

purposes such as camping, fishing, floating and aesthetics. A healthy riparian area indicates that most, if not all, of the associated water and soil components are also healthy. Because of the myriad of competing uses for these highly valuable pieces of land, the variability between the alternatives was considered significant.

Key Issue 3: Security for Elk

The Forest provides habitat for a number of species (a potential of 85 mammals, 300 birds, 17 reptiles and amphibians based on range maps). For most species there were no significant differences in the management of their habitat between alternatives. Rather, standards and guidelines were developed to maintain a variety of habitat conditions across the forest.

The best data and analysis existed for elk security, which had the highest wildlife variance among the alternatives. Elk are also wide-ranging animals, so their habitat encompasses virtually the entire Forest. Security for elk was chosen as a key issue relating to future hunting conditions and opportunities and cooperative relations with Fish and Game Departments. Observations and studies by the Idaho Department of Fish and Game (IDFG), University of Idaho, and Forest Service scientists have determined that as motorized road and trail densities increase, elk security declines. Portions of the Forest have high densities of trails and roads open to motorized use due to the extensive road building associated with the salvage of dead lodgepole. Salvage activity is largely completed and new knowledge about impacts of road densities upon wildlife is available. The Revision examines the range of management alternatives related to security for elk.

Key Issue 4: Grizzly Bear Management

Portions of the Forest are within the Yellowstone Grizzly Bear Ecosystem which has been divided into Bear Management Units (BMUs). Portions of the Forest are within three BMUs and feature grizzly bear recovery. As with all Threatened, Endangered and Sensitive (TES) species, all alternatives must meet the Endangered Species Act (ESA). The importance of managing motorized access is one of the most influential parameters affecting grizzly bear habitat security.

New information accumulated over the last 10 years provides better insight and direction regarding effective management of roads, timber and human activities in grizzly bear habitat. The one variation between alternatives that makes the BMU issue significant is the density of open motorized roads and trails in BMUs. Which roads will be closed in BMUs, how many miles and in what manner?

Key Issue 5: Access

The Forest currently has 1,985 miles of open road and 773 miles of open trail. "Open" means road and trail miles without restrictions on motorized use. There are currently road and trail miles with restrictions on motorized use as follows: 806 miles of restricted system road (73 miles with seasonal restrictions and 733 miles with yearlong restrictions) and 628 miles of restricted trail.

Recreational motorized use has increased over the last decade. The 1985 Plan allows cross-country motorized travel across much of the Forest and has no established road density standards. Access to the Forest during non snow months is a significant variable among the alternatives. Comments in the early planning stages were supportive of more or fewer road and trail closures depending on a variety of factors. Those supporting road and trail closures want more protection and fewer impacts upon wildlife, TES species, soils and water and fisheries, less visual, garbage and noise pollution, reduced maintenance and law enforcement costs, and more opportunity for escape and solitude. Those supporting continued or

more road and trail access want access for hunting, fishing, berry-picking, camping, hiking and other recreational pursuits, and increased opportunities for sight-seeing and challenging cross-country travel for off-highway vehicles. Motorized access is considered a key element for enjoyment and use of the Forest by persons with disabilities and the elderly.

Key Issue 6: Management of Roadless Areas

The Forest has 16 areas which qualify as roadless, totaling 841,000 acres. The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in the Wyoming Wilderness Bill of 1984. Portions of three roadless areas in Idaho were recommended as wilderness in the 1985 Forest Plan, but no legislative action has been taken to resolve the roadless area question in Idaho. During the last planning period, parts of some roadless areas were roaded as part of the salvage program. As motorized recreation demands increase, pressure also increases to maintain the roadless character of the remaining roadless areas. The significant difference between alternatives in the management of roadless areas is in the amounts of acres recommended for wilderness. Those arguing for more acres of Congressionally designated wilderness want the assurance of preservation of biological diversity, protection from resource uses and national recognition of wilderness character. Those opposed to more acres designated wilderness want roadless areas to be left as roadless or to be developed to allow motorized access for recreation, oil and gas, timber and other industries requiring access.

KEY ISSUE 7: Timber Harvest

Previously, large scale salvage of dead and dying timber was conducted as a temporary departure from sustained yield management. Since the goals of harvest of dead timber have largely been met, the Forest is returning to sustained yield management.

Two local mills, once dependable bidders for salvage and other wood harvest, are now closed but local demand remains high. The ESA, Grizzly Bear Recovery Plan and Guidelines, EM principles, increased knowledge about the impacts of motorized use of roads and trails upon the Forest's wildlife resources, and other factors have resulted in a greatly reduced availability of scheduled timber harvest, called the allowable sale quantity (ASQ). The issue of timber harvest does not include firewood, since the amount of firewood quantity does not vary between the alternatives. Some people desiring a greater harvest of timber from the Forest often cite the effects upon the local economy. Others have expressed a concern over the reduction in payments to local governments (25 percent of Forest receipts go to county treasuries) associated with the reduced harvest levels. They also want to maximize harvest of the remaining dead or mature wood. Some argue that small harvests in the fire dependent lodgepole are contrary to historically based EM principles. Those supporting a greater reduction in timber harvest are concerned about motorized trail and road uses that impact wildlife, reductions in the amount and distribution of late successional forest, fisheries, riparian areas, soil and water, aesthetics and other resources.

THE ALTERNATIVES

Before creating alternatives, the Forest put together an "Analysis of the Management Situation (AMS)," which looked at current conditions and direction of the Forest. Alternatives were developed by using the AMS data that identified problem areas that needed changing. All alternatives comply with applicable laws and regulations.

The alternatives reflected a range of options that responded to the issues, the DFCs and the need for change. The interdisciplinary team (IDT) evaluated the significant physical, biological, economic and social effects of each alternative that was considered in detail.

The Forest analyzed in detail seven alternatives, the Leadership Team (LST) recommended Alternative 3M to the Regional Forester and the public for review in the DEIS. Based on input received from the public, the Tribes, other government agencies and Forest Service personnel, Alternative 3M was revised. As shown in the FEIS, Alternative 3M is the Selected Alternative.

The Alternative Continuum

The numbering scheme for alternatives ranges from 1-6, with Alternative 3M being the Selected and Alternative 1 being the No Action, i.e. continue the Current Forest Plan Alternative. As the numbers increase from Alternative 2 through 6, they move generally toward

- *Greater protection of wildlife habitat
- *Greater protection of riparian areas
- *More protection for BMUs
- *More security for elk
- *More nonmotorized, dispersed recreation opportunities
- *More recommended wilderness
- *Less cross-country motorized use
- *Fewer open roads and trails
- *Reduced livestock grazing and timber harvest
- *Less lasting visual impacts from management activities

Alternative 1 (Continue the 1985 Forest Plan, No Action)

The purpose of Alternative 1 is to continue management of the Forest under the 1985 Forest Plan, updated since finalized with amendments, new direction, particularly the recent litigation for the grizzly bear, and, changes for new listings of sensitive wildlife species over the last ten years. Timber harvest occurs at the highest levels possible within the management constraints required for TES wildlife species like the grizzly bear and goshawk. Vehicle access is reduced from current levels due to the implementation of the Interagency Grizzly Bear Guidelines and better road management across the Forest. Cross-country, motorized access in summer and winter would continue close to current levels. Riparian, wildlife and recreation values are emphasized in specific areas of the Forest.

Alternative 2

The purpose of Alternative 2 is to resolve the needs for change by emphasizing cross-country and winter motorized access and timber production, while adding more restrictions to summer, cross-country access. Timber harvest occurs at the highest levels of any of the alternatives within the management constraints required for maintaining TES species habitat. Riparian, wildlife and heritage resource values are emphasized in specific areas of the Forest.

Alternative 3

The purpose of Alternative 3 is to resolve the needs for change by emphasizing management of wildlife habitat and sustaining timber harvest levels within wildlife constraints. Grizzly bear recovery affects motorized use allowed in each BMU. Cross-country, summer, motorized vehicle use is restricted to specific areas.

Alternative 3-Modified (3M), Selected Alternative

The purpose of Alternative 3M is to resolve the needs for change by emphasizing wildlife habitat management and providing a comprehensive habitat management strategy for the grizzly bear. Motorized access, timber harvest levels and livestock grazing are all reduced from levels allowed in the 1985 Forest Plan. Riparian areas with cutthroat trout are further protected. Cross-country, summer, motorized vehicle use is restricted to specific areas.

Alternative 4

Alternative 4 emphasizes watershed and wildlife habitat improvement and a reduction in timber harvest. Riparian areas receive increased emphasis. Motorized access is restricted to designated routes and summer motorized access is less than in previous alternatives.

Alternative 5

The purpose of Alternative 5 is to meet the needs for change by reducing the focus on human management and human disturbance of wildlife and riparian habitat. Motorized access is restricted to designated routes and more roads are closed in BMUs.

Alternative 6

The purpose of Alternative 6 is to meet the needs for change by de-emphasizing human management and human disturbance of wildlife and riparian habitat to the lowest level of all the alternatives. Timber harvest is not scheduled.

CHANGES BETWEEN DRAFT AND FINAL

This FEIS reflects many changes made since the Draft Environmental Impact Statement (DEIS) was issued. These changes were based on input received from the public and from Forest Service employees.

The great bulk of the changes that were made apply to Alternative 3M. As originally developed, Alternatives 2-6 could be viewed as lying along a continuum on which scheduled timber harvest gradually decreased, reliance on human management activity decreased, livestock grazing decreased and so on. With the changes that have been incorporated into Alternative 3M there now are exceptions to that continuum generalization. We considered the possibility of applying the changes made to Alternative 3M to other alternatives to maintain a certain logical consistency within the continuum. We ultimately rejected that idea because

- The continuum was a useful device for outlining how alternatives compared with one another—but it is not essential. All the information for the different alternatives is still presented.
- The recommendations adopted in Alternative 3M were still within the range of ideas previously identified in the other alternatives.
- Making a great many changes in other alternatives might make it harder for those familiar with the previous work to follow the final documents.

Most of the changes between the draft and final EIS were minor. The a summary of the changes of possible interest to a wide range of readers follows.

- Standards and Guidelines for Old Growth have been added
- Proper Functioning Condition (PFC) is now used instead of Patch Size Constraints as the primary measure of EM
- Direction has been added to both use more prescribed fire and to develop fire plans
- Objectives, standards and guidelines have been added to address the needs of cutthroat trout.
- New direction has been added to address bighorn sheep habitat needs
- The Game Retrieval provision has been eliminated from the Selected Alternative
- The direction to phase out the Rainey Creek feed ground has been eliminated
- Potential ground-disturbing acreages have increased
- Constraints used in formulating the scheduled timber harvest (Allowable Sale Quantity, ASQ) were reapplied so as to meet as fully as possible all constraint requirements on non-ASQ lands. This effectively increased the amount of timber that could be harvested ASQ's for all the alternatives increased accordingly
- Non-Interchangeable Component (NIC) volumes have been more explicitly identified
- The amount of harvest that can be conducted for EM purposes (outside the Forest's ASQ and fuelwood programs) has been capped at 20 MMBF per decade in all alternatives
- Numerous updates of information, inclusions of additional sources and clarifications have been incorporated
- Many changes have been made in the status of different roads and trails in the Selected Alternative
The net effect of these actions is an increase in motorized vehicle designated routes
- Protection for the Ute Ladies' Tresses (a threatened plant) has been added to all alternatives
- Cross-country snowmachine use in designated winter range areas has been prohibited in all alternatives
- Snowmachine date restrictions on large parts of the Forest have been removed or greatly reduced in Alternative 3M
- Planned additional snowmachine trail mileage has decreased to 93 in Alternative 3M.
- The contents and the priorities for Monitoring & Evaluation (M&E) were re-examined and modified
- Numerous changes were made to Forestwide Standards and Guidelines and individual prescriptions in response to public and employee input affecting things like goshawk management, grizzly bear management and range utilization
- Dates for application of the Snow Season travel map have been changed
- Many changes were made in terms of how different areas on the Forest would be managed in the Selected Alternative, including
 - Some 33,000 acres of the Diamond Peak area is now a recommended wilderness
 - Six acres of the recently-authorized Sheep Mountain RNA have been identified on the Forest
 - Approximately 13,000 acres have been added to the southern edge of the Italian Peaks recommended wilderness
 - The southern boundary of the Mt Jefferson Roadless Area has been adjusted to more accurately reflect the roadless area
 - A portion of the Forest near Heart Mountain has been moved into range management
 - A winter range prescription area in the Italian Peaks Recommended Wilderness has been re-assigned to the recommended wilderness prescription
 - A winter range prescription area north of Spencer has been changed to range management
 - The Davis Lakes area now has scheduled timber harvest
 - An area one quarter mile either side of Upper Mesa Falls on the Henry's Fork has been changed to eligible scenic river rather than eligible wild river
 - Approximately 1,500 acres of roadless area in Ruby Creek now has scheduled timber harvest
 - The area adjacent to the road to Grand Targhee is now non-ASQ Visual Quality Maintenance
 - The large intermingled public/private land area east of the Big Holes now has scheduled timber harvest
 - An area along the Pine Creek-Rainey Creek front has been changed to a winter range prescription
 - An area close to the Palisades Summer Home area is now a winter range prescription
 - An area in the northwest corner of the Caribou subsection is now range management
 - McCoy Creek has been deleted as an eligible wild, scenic, or recreational river
 - The Smokey Hollow area has been removed from scheduled timber harvest

Purpose and Need for a Forest Plan Revision

CHAPTER I

PURPOSE AND NEED FOR A FOREST PLAN REVISION

READER'S GUIDE - In this chapter you will find:

- General Information about the Targhee National Forest
- Legal Background for Preparing Forest Plan Revisions
- Decisions Made in an EIS
- Decisions Made in a Forest Plan Revision
- Summary of the 1985 Targhee National Forest Management Plan
- Reasons for Revising the Forest Plan (Need for Change)
- Public's Role in Scoping and Issues
- How the Key Forest Issues Were Selected
- Issue Components Used to Organize EIS and Plan
- Key Issues That Drove the Alternatives
- What is an Issue Indicator
- Summary of Key Issues and Key Indicators
- Issue Indicators That Are Not Key
- Desired Future Condition for the Year 2007

GENERAL INFORMATION: LOCATION AND SETTING FOR THE TARGHEE NATIONAL FOREST

The Targhee National Forest (hereafter usually referred to as "the Forest") is an administrative unit of the U.S. Department of Agriculture, Forest Service, encompassing approximately 1.8 million acres. Established by President Theodore Roosevelt in 1908, the Forest is named in honor of a Bannock Indian warrior. The Shoshone-Bannock Tribe has ancestral Treaty Rights to uses of the Forest. The Forest Supervisor's Office is located in St. Anthony, Idaho, with District offices located in Dubois, Island Park, Ashton, Idaho Falls and Driggs, Idaho. The Forest is bordered by six other National Forests (N.F.). Part of the Caribou N.F. is administered by the Forest and part of the Forest is administered by the Bridger-Teton N.F.

The majority of the Forest lies in eastern Idaho and the remainder in western Wyoming (Figure I-1). Situated next to Yellowstone National Park (the Park) and Grand Teton National Park (GTNP), the Forest is home to a diverse number of wildlife and fish, including TES species, wilderness, scenic panoramas and intensively managed forest lands.

The Forest lies almost entirely within "the Greater Yellowstone Area (GYA)" or "the Greater Yellowstone Ecosystem (GYE)," an area of 12 million acres which is the largest remaining block of relatively undisturbed plant and animal habitat in the contiguous United States. The area continues to gain prominence for its ecological integrity.

On a larger scale, the Forest lies entirely within the Upper Columbia River Basin (UCRB), an ecosystem of 40 million acres extending from western Washington to the southeastern Idaho border and encompassing parts of Montana, Wyoming, Nevada and Utah. The Forest includes all or portions of several distinct mountain ranges, including the Lemhi, Beaverhead, Bitterroot, Centennial, Henry's Lake, Teton, Big Hole, Caribou and Snake River Ranges. Elevations range from near 5,000 feet on the Snake River to over 12,000 feet on the Forest's most western reaches. The Forest contains the Island Park Caldera and several reservoirs. Topography ranges from rolling foothills to rugged, glaciated mountain peaks.

Vicinity Map of Targhee National Forest
on a National Scale

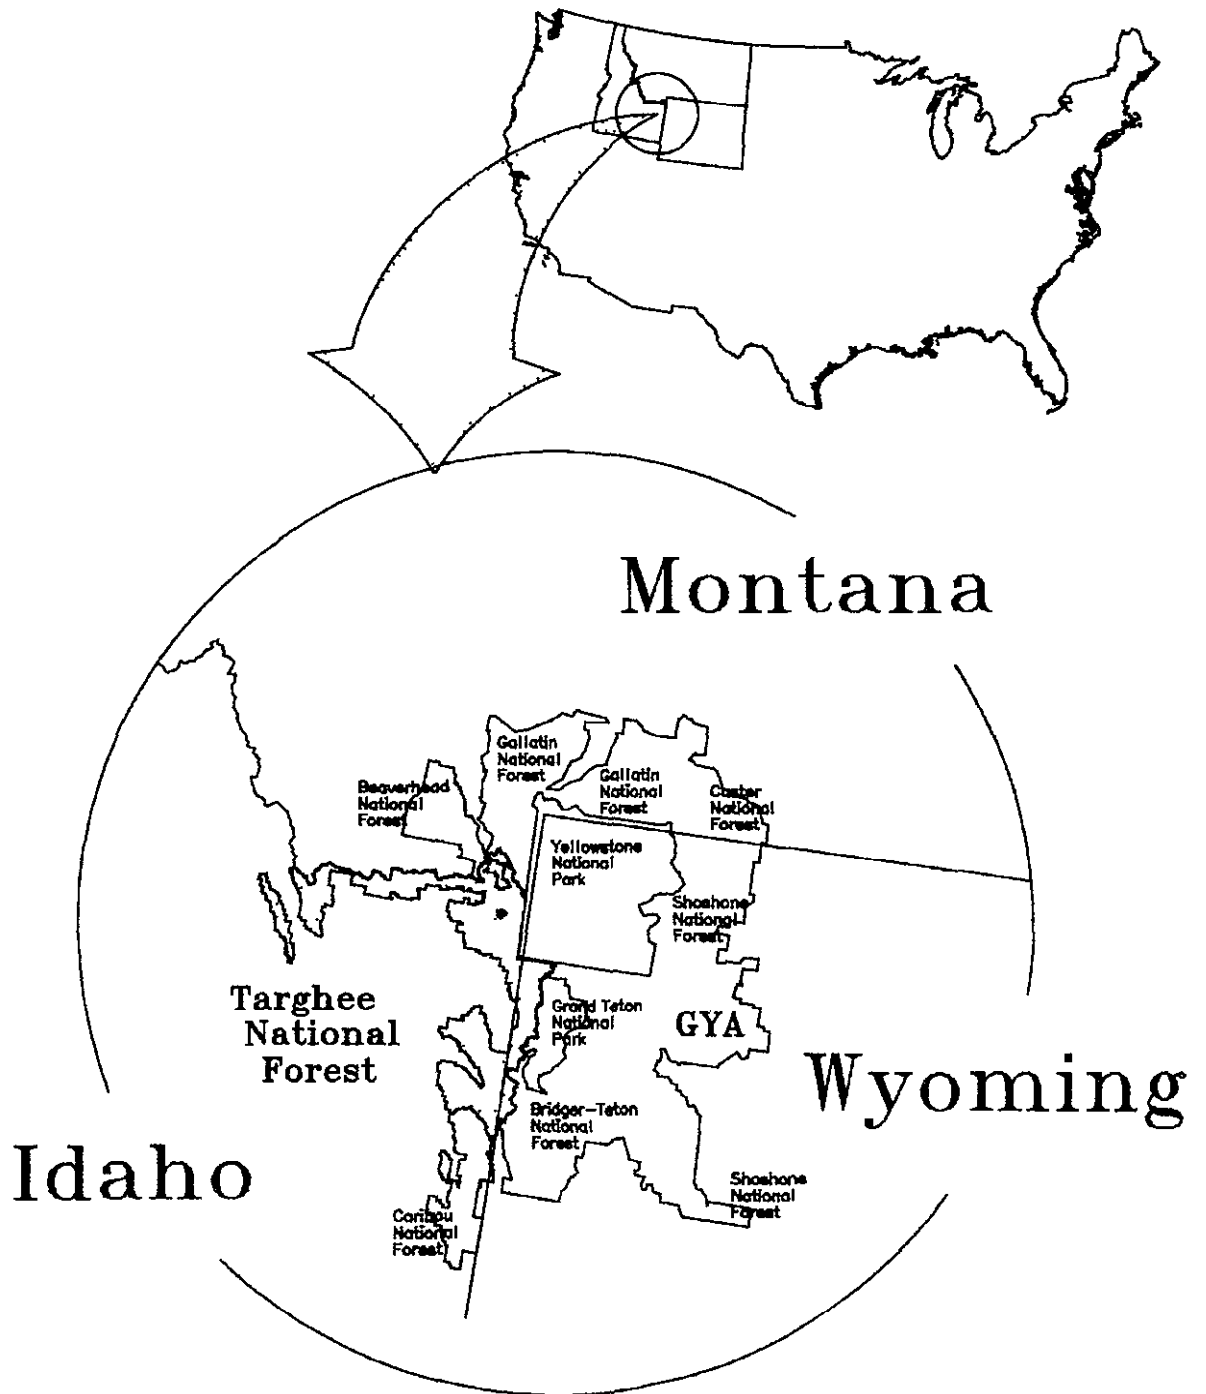

Figure I-1

Although most of the land is dry and semiarid, 190 stream headwaters situated on the Forest provide varied vegetation to support a multitude of uses. The area has cold, moist winters and hot, dry summers. Average annual precipitation, most of which falls as snow, increases with elevation. As little as 10 inches of precipitation falls in lower valleys and as much as 40 inches occurs at the highest elevations. Wide temperature extremes exist with summer temperatures at lower elevations sometimes exceeding 100 degrees Fahrenheit and winter temperatures at higher elevations falling to 40 degrees Fahrenheit below zero and lower.

LEGAL BACKGROUND FOR PREPARING FOREST PLAN REVISIONS

The National Forest Management Act (NFMA) of 1976 requires the Forest Service to develop 10 year integrated land management plans for units of the National Forest System within the framework of a public involvement process. NFMA directs the Forest Service to review and/or update forest plans every 10 to 15 years or more frequently when resource and management conditions have changed significantly. The plans must include management guidelines, an assessment of suitability of the lands, and consistency with the two other laws relating to the management of National Forests...The Multiple Use-Sustained Yield Act of 1960, and the Forest and Rangeland Renewable Resources Planning Act (RPA) of 1974. A Management Plan for the Forest was finalized in 1985. This is the first revision of that plan.

DECISIONS MADE IN AN EIS

An Environmental Impact Statement (EIS) is a document that proposes two or more alternatives to a proposed action of significance for public review and input. One alternative is always a 'No Action' Alternative, another is the proposed action or preferred alternative. In this FEIS, the No Action is Alternative 1. Other alternatives are also considered and evaluated, according to the guidelines in the NFMA.

The FEIS explains the need for change, the proposed action, the issues and concerns, the alternatives considered during the decision making process, the consequences of implementing the alternatives and the Selected Alternative.

The proposed action and Selected Alternative in this FEIS is 3-Modified (3M). More discussion about 3M can be found in Chapter II.

DECISIONS MADE IN A FOREST PLAN REVISION

The Forest Plan Revision carries out the actions of the Selected Alternative. It provides key decisions for the long-term management of the Forest. These decisions include:

- Forestwide multiple-use goals and objectives, including a description of the DFC for the Forest
- Forestwide standards and guidelines
- Management direction and prescriptions
- Land suitable for resource use and production
- Monitoring and evaluation requirements
- Recommendations to Congress for Wilderness and Wild/Scenic and Recreational River Designations

SUMMARY OF THE 1985 TARGHEE NATIONAL FOREST MANAGEMENT PLAN

The 1985 Forest Plan was started in 1980, but was not finalized until 1985 due to national requirements by Congress in 1982 for reevaluations of roadless areas in forest plans

The forest vegetation is approximately 37 percent lodgepole pine and 17 percent lodgepole/Douglas-fir mix (see Figure III-3), a fire-dependent, short-lived tree species with a mature "old-growth" lifespan of 100-160 years. It regenerates rapidly after most disturbances, allowing it to dominate forest composition. As forest succession advances, lodgepole pine tends to be gradually replaced by more shade-adapted tree species in the absence of further disturbances. Beginning in the 1950s and continuing to the early 1980s, an extensive mountain pine beetle infestation attacked 90 percent of the lodgepole pine forest. The natural beetle infestation was not outside the natural range of variation for such forests, nor were the subsequent large fires in the late 1980s. Mountain pine beetle epidemics and large fire events are characteristic of lodgepole pine forests. Hence these forests are subject to rapid changes in forest structures and vegetation patterns.

The 1985 Forest Plan emphasized the harvest of dead and dying lodgepole and artificial regeneration where applicable. The plan also predicted an abrupt decline from the high level of lodgepole supply within the next decade.

REASONS FOR REVISING THE FOREST PLAN (Need for Change)

The original Targhee Forest Plan, approved in 1985, emphasized an extensive salvage and reforestation program of dead lodgepole killed by a massive mountain pine beetle epidemic over the previous 30 years. This rate of salvage caused, in effect, a departure from a sustained yield of timber harvest and could not be continued beyond the first decade (1985 - 1995) in an environmentally sound manner. Monitoring of activities during this time showed it was increasingly difficult to meet the standards and guidelines in the 1985 Plan. New information on resource needs and various management practices became evident during this time, and by 1990 it was apparent that a full revision was needed. More specific needs for change are as follows:

- The salvage program has ended. Use of the many roads built during salvage operations by increasing numbers of people is causing unwanted effects to wildlife, riparian areas, and soil productivity.
- The need to review and incorporate new knowledge and techniques continues, especially in wildlife habitat management. For example, recent studies indicate motorized road and trail densities play a crucial role in availability of suitable habitat for elk and grizzly bears. Standards for management activities near nesting and foraging habitat for goshawks and other raptors are needed to protect these crucial areas. Results of studies analyzing fish habitat in the Upper Columbia River Basin are pointing out new ways to manage fisheries. Some of these findings have widespread implications that the revision process was intended to address.
- Although much of the lodgepole pine component on the Forest has been salvaged, there is still a need to use timber harvest as a tool to reach ecosystem objectives, supply a variety of timber products for local use, deter other epidemics like the mountain pine beetle outbreak, and manage the potential for a devastating wildfire, like the Yellowstone Wildfires of 1988.

PUBLIC'S ROLE IN SCOPING AND ISSUES

The public and Forest employees played an important role in determining the context of management for the Forest over the next 10-15 years. Public involvement has taken place at every stage of the revision process. Process Paper A describes the public involvement that occurred.

HOW THE KEY FOREST ISSUES WERE SELECTED

The following outlines the Forest's approach to defining the key issues:

- A list of issues and concerns from the public was compiled, resulting in an issue paper released in November 1992, listing over 70 issues and concerns.
- A compatible list of "Issue Questions" was simultaneously developed. These needed to be addressed in the EIS alternatives and in the Revision, this list was also released in November 1992 and was tied to the issues and concerns.
- Issues and concerns were then categorized into "Issue Components" or "Issue Areas," a planning approach to help with the development and structure of the EIS and Plan.
- The "Issue Indicators," the units of measurement tied to the issues and concerns, were chosen.
- The alternatives were reviewed to determine which issue indicators have the greatest variables and which issue indicators remain relatively constant or the same.
- The "Key Issues" were identified as those issues and concerns having the greatest and most significant variation among the alternatives.

ISSUE COMPONENTS USED TO ORGANIZE EIS AND PLAN

"Issue Components" are an organizational planning approach used to group similar issues and concerns. Key issues, alternatives, the rest of the EIS and the Revision are consistently divided into the following issue components, in this order:

- Ecological Processes and Patterns
- Physical Elements
- Biological Elements
- Forest Use and Occupation
- Production of Commodity Resources

KEY ISSUES THAT DROVE THE ALTERNATIVES

Although there were over 70 issues and concerns identified by the public and Forest employees, seven key issues were the ultimate driving force for alternative development and determining factors for alternative comparison in the Forest Plan Revision. The key issues had the most significance as variables between the alternatives.

WHAT IS AN ISSUE INDICATOR?

Each key issue received an "Issue Indicator," a unit of measurement that shows how the issue is addressed in each alternative. The LST, consisting of the Forest Supervisor, his primary staff and the District Rangers studied the issues and selected one major indicator for each issue that best reflected the variability for that issue between the alternatives.

SUMMARY OF KEY ISSUES AND KEY INDICATORS

Key Issue 1 Sustainability, Fire and Natural Disturbances

(Ecological Processes and Patterns Component)

Key Indicators Health of forest structure and composition, and prescribed fire

Key Issue 2 Riparian

(Biological/Physical Component)

Key Indicator Acres not meeting the DVC DVC = riparian vegetation such as deep rooted grasses, shrubs and trees that maintain streambank stability

Key Issue 3 Security for Elk

(Biological Component)

Key Indicator Percent of Forest meeting Elk Vulnerability (EV) thresholds measured by the number of miles of open roads and open motorized trails

Key Issue 4 Grizzly Bear Management

(Biological Component)

Key Indicator Open Road & Open Motorized Trail Route Density (OROMTRD), measured in miles per square mile for BMUs

Key Issue 5 Access

(Forest Use & Occupation Component)

Key Indicator Number of miles of roads/trails open to summer motorized use

Key Issue 6 Management of Roadless Areas

(Forest Use & Occupation Component)

Key Indicator Number of Acres recommended for wilderness

Key Issue 7 Timber Harvest

(Production of Commodity Resources Component)

Key Indicator ASQ

KEY ISSUE 1: Sustainability, Fire and Natural Disturbances (Issue Component: Ecological Processes and Patterns)

Issue Discussion: An ecosystem is a large, complex, integrated system of living and nonliving components that interact and change continually. Healthy ecosystems are those that retain all of their parts and functions for future generations even though vegetation patterns, human uses or other conditions may change. Understanding ecological processes (fire and other natural disturbances) and how these processes shaped vegetation patterns over time in a landscape are important steps toward implementing EM.

EM is a new philosophy of management for the Forest Service, and different interpretations and approaches are possible in working toward implementation. The Forest is the first in the GYA to revise its Forest Plan and incorporate EM principles in the revision. Many activities and projects are being studied toward the application and implementation of EM. Their new information and conclusions will be used to adaptively manage the Forest and modify direction in the Revised Plan, where needed.

The most pressing and debated question is, "How do we achieve sustainability incorporating fire and natural disturbances, to achieve healthy ecosystems?" This remains a very complex issue and we are just beginning to understand and experiment with some approaches to implementing EM. However, more information and research is emerging that provides a good foundation from which to begin. We are using adaptive management to monitor and test assumptions and strategies. And we will make course corrections as we conduct projects and evaluate results.

Sustainability, Fire and Natural Disturbances Key Issue Indicators: The primary indicator for this issue is health of forest structure and composition. This indicator is measured as the total acres where EM based activities will result in maintenance or improvement of forest structure and composition.

The secondary indicator is prescribed fire as measured by the number of acres where prescribed fire may be used to maintain or improve ecological sustainability.

The PFC (sustainability) of forested ecosystems can be assessed through an evaluation of four criteria, structure, composition, disturbance regime and pattern. Forest structure relates to the relative proportions of grasses, forbs, shrubs and trees, the relative ages of trees, the tree densities, etc. Forest composition relates to the relative proportions of tree species. The disturbance regimes affecting forested ecosystems are associated with fire (natural and prescribed), wind, insects, pathogens or flood and human induced disturbances, such as logging and grazing.

All four criteria are directly or indirectly affected by timber harvest and fire management practices. EM mandates that silvicultural activities, including timber harvest and prescribed fire, will contribute to maintaining or improving ecosystem sustainability.

KEY ISSUE 2: Riparian (Issue Component: Biological/Physical Elements)

Issue Discussion: Riparian areas lie adjacent to water and are composed of vegetation communities dependent upon or tolerant to the presence of free or unbound water near the ground surface. Riparian areas are associated with lakes, reservoirs, potholes, springs, bogs, wet meadows, and ephemeral, intermittent or perennial streams. Although riparian areas constitute less than five percent of the total land base, they are the most productive areas in terms of plant and animal species diversity and consumptive use.

Riparian areas are essential breeding, rearing and feeding grounds for many species of wildlife and affect fish habitat. They serve people as important sources for water and flood control and for recreational purposes such as camping, fishing, floating and aesthetics. A healthy riparian area indicates that most, if not all, of the associated water and soil components are also healthy. Because of the myriad of competing uses for these highly valuable pieces of land, the variability between the alternatives was considered significant.

Riparian Key Issue Indicator: The key indicator showing the differences between the alternatives for riparian areas is DVC. The riparian area's health is indicated by the amounts and types of vegetation along the banks, with highest preference to deep-rooted grasses, shrubs and trees that maintain

streambank stability and that have a high rate of recovery Riparian areas meeting DVC currently meet the Forest Plan Revision objectives to maintain or enhance riparian vegetation, aquatic habitat and water quality

KEY ISSUE 3: Security for Elk (Issue Component: Biological Element)

Issue Discussion: The Forest provides habitat for a number of species (a potential of 85 mammals, 300 birds, 17 reptiles and amphibians based on range maps) For most species there were no significant differences in the management of their habitat between alternatives Rather, standards and guidelines were developed to maintain a variety of habitat conditions across the forest The best data and analysis existed for elk security, which had the highest wildlife variance amongst the alternatives Elk are also wide-ranging animals, so their habitat encompasses virtually the entire Forest Security for elk was chosen as a key issue relating to future hunting conditions and opportunities and cooperative relations with Fish and Game Departments Observations and studies by the IDFG, University of Idaho and Forest Service scientists have determined that as motorized road and trail densities increase, elk security declines Portions of the Forest have high densities of trails and roads open to motorized use due to the extensive road building associated with the salvage of dead lodgepole Salvage activity is largely completed and new knowledge about impacts of road densities upon wildlife is available The Revision examines the range of management alternatives related to security for elk

Security for Elk Key Issue Indicator The best indicator for showing the differences between alternatives for elk security is, “the percentage of the Forest meeting State Fish and Game vulnerability thresholds for elk” The primary factors the Forest Service controls related to EV analysis, are the density of open motorized roads and trails and the amount of area open to cross-country, off-highway vehicle travel

EV is defined as a measure of elk susceptibility to being killed during the hunting season EV models help managers predict elk mortality rates As cross-country off-highway vehicle travel and motorized road and trail densities (measured in miles per square mile on a watershed basis) increase, the security for elk decreases and the mortality rate increases

KEY ISSUE 4: Grizzly Bear Management (Issue Component: Biological Element)

Issue Discussion: Portions of the Forest are within the Yellowstone Grizzly Bear Ecosystem which has been divided into BMUs Portions of the Forest are within three BMUs and feature grizzly bear recovery As with all TES species, all alternatives must meet the ESA The importance of managing motorized access is one of the most influential parameters affecting grizzly bear habitat security

New information accumulated over the last 10 years provides better insight and direction regarding effective management of roads, timber and human activities in grizzly bear habitat The one variation between alternatives that makes the BMU issue significant is the density of open motorized roads and trails in BMUs Which roads will be closed in BMUs, how many miles and in what manner?

Grizzly Bear Key Issue Indicator. The key issue indicator for BMUs is OROMTRD Studies show that the importance of managing access is one of the most influential components affecting habitat security for grizzly bears By managing motorized access, the Forest can minimize human interaction and potential grizzly bear mortality, minimize displacement from important habitats, and minimize habituation to humans

KEY ISSUE 5: Access (Issue Component: Forest Use and Occupation)

Issue Discussion: The Forest currently has 1,985 miles of open road and 773 miles of open trail "Open" means road and trail miles without restrictions on motorized use There are currently road and trail miles with restrictions on motorized use as follows 806 miles of restricted road (73 miles with seasonal restrictions and 733 miles with yearlong restrictions), 628 miles of restricted trail

Recreational motorized use has increased over the last decade The 1985 Plan allows cross-country motorized travel across much of the Forest and has no established road density standards Access to the Forest during non snow months is a significant variable among the alternatives Comments in the early planning stages were supportive of more or fewer road and trail closures depending on a variety of factors Those supporting road and trail closures want more protection and fewer impacts upon wildlife, TES species, soils and water, and fisheries, less visual, garbage and noise pollution, reduced maintenance and law enforcement costs, and more opportunity for escape and solitude Those supporting continued or more road and trail access want access for hunting, fishing, berry-picking, camping, hiking and other recreational pursuits, and increased opportunities for sight-seeing and challenging cross-country travel for off-highway vehicles Motorized access is considered a key element for enjoyment and use of the Forest by persons with disabilities and the elderly For more information on public comments, refer to Appendix A

Access Key Issue Indicator: The indicator that best shows differences between alternatives is the Number of Miles of Road/Trails Open to Summer Motorized Use The greater the number of miles of roads and trails open to motorized use, the greater the increased recreational benefits and hunting/fishing access to users of motorized vehicles including persons with disabilities

KEY ISSUE 6: Management of Roadless Areas (Issue Component: Forest Use and Occupation)

Issue Discussion: The Forest has 16 areas which qualify as roadless, totaling 841,000 acres The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in the Wyoming Wilderness Bill of 1984 Portions of three roadless areas in Idaho were recommended as wilderness in the 1985 Forest Plan, but no legislative action has been taken to resolve the roadless area question in Idaho During the last planning period, parts of some roadless areas were roaded as part of the salvage program As motorized recreation demands increase, pressure also increases to maintain the roadless character of the remaining roadless areas The significant difference between alternatives in the management of roadless areas is in the amounts of acres recommended for wilderness Those arguing for more acres of Congressionally designated wilderness want the assurance of preservation of biological diversity, protection from resource uses and national recognition of wilderness character Those opposed to more acres designated wilderness want roadless areas to be left as roadless or to be developed to allow motorized access for recreation, oil and gas, timber and other industries requiring access

Management of Roadless Areas Key Issue Indicator: The indicator best showing differences between alternatives related to the management of roadless areas is the number of acres recommended for wilderness Once a roadless area is designated as wilderness by Congress, it is managed in perpetuity for nonmotorized, scientific and dispersed recreational purposes Roadless areas not recommended as wilderness may be managed as roadless areas or for some other use during each planning cycle

KEY ISSUE 7: Timber Harvest (Issue Component: Production of Commodity Resources)

Issue Discussion Previously, large scale salvage of dead and dying timber was conducted as a temporary departure from long term sustained yield (LTSY) management. Since the goals of harvest of dead timber have largely been met, the Forest will return to management within LTSY for the future.

Two local mills, once dependable bidders for salvage and other wood harvest, are now closed but local demand remains high. The ESA, Grizzly Bear Recovery Plan and Guidelines, EM principles, availability of dead lodgepole, increased knowledge about the impacts of motorized use of roads and trails upon the Forest's wildlife resources and other factors have resulted in a greatly reduced availability of scheduled timber harvest, i.e. the ASQ. The issue of timber harvest does not include firewood, since the amount of firewood quantity does not vary between the alternatives. Some people desiring a greater harvest of timber from the Forest often cite the effects upon the local economy. Others have expressed a concern over the reduction in payments to local governments (25 percent of Forest receipts go to county treasuries) associated with the reduced harvest levels. They also want to maximize harvest of the remaining dead or mature wood. Some argue that small harvests in the fire dependent lodgepole are contrary to historically based EM principles. Those supporting a greater reduction in timber harvest are concerned about motorized trail and road uses that impact wildlife, reductions in the amount and distribution of late successional forest, fisheries, riparian areas, soils and water, aesthetics and other resources.

Timber Harvest Key Indicator: The key indicator for timber harvest that portrays the differences between alternatives is the ASQ. ASQ does not include firewood and is defined as the quantity of timber that may be sold from the area of suitable land for a time period specified in a Forest Plan. This quantity is usually expressed on an annual basis as an "average" ASQ.

ISSUE INDICATORS THAT ARE NOT KEY

When the Forest designed the alternatives around the issues, a number of issue indicators were created. Specialists analyzed the consequences for all of the different alternatives. It soon became clear that most of the consequence indicators were either the same in all alternatives or had minor variations, making them less significant than the key issue indicators.

Although most of Chapters I and II focus on the key issues and indicators, the remaining issues and indicators are addressed in Chapters III and IV and the standards and guidelines in the Forest Plan Revision. For example, firewood availability is an issue. Although not a key issue, firewood is addressed in the Revision and the effects and consequences remains the same in all the alternatives.

Confusion may exist over the lack of inclusion of significant resources such as water and soils as key issues. Why aren't these considered key issues? All the alternatives comply with state and federal quality standards, there was only a slight range of variability and the condition of soil and water is interconnected with the condition of riparian areas. The key issue of Riparian Areas became the symbol and captured the essence of the significance of differences for soil and water resources. Table II-1 lists most of the issue components and indicators. Process Paper A refers to the complete list of issues published in the AMS document, November, 1992. The following summarizes those indicators:

- Wild and Scenic Rivers Recommendations
- Research Natural Areas
- Visual Quality
- Developed Recreation, nonmotorized

- Heritage Resources
- Cave Management
- Predator Control
- Noxious Weeds
- Outfitter and Guides
- Summer Homes & Other Special Use Permits
- Management of Existing Wilderness & Wilderness Study Areas
- Firewood
- Old Growth Standards and Guidelines
- Unscheduled Harvest
- Bald Eagle - Forestwide standards and guidelines same in all alternatives
- Peregrine Falcon - Forestwide standards and guidelines same in all alternatives
- Ute Ladies' Tresses - Forestwide standards and guidelines same in all alternatives
- Sensitive Species (these include three-toed woodpecker, flammulated owl, boreal owl, great gray owl, goshawk, trumpeter swan, spotted frog habitat, common loon, harlequin duck) - Forestwide standards and guidelines same in all alternatives
- Sensitive Species (these include wolverines, lynx, fisher) - small variation in habitat quality or quantity, generally in the realm of one to three percent change from existing conditions
- Sensitive Species (plants listed in current Forest Sensitive Species plant list) - Forestwide standards and guidelines same in all alternatives

DESIRED FUTURE CONDITION FOR THE YEAR 2007 and BEYOND

After issues are identified, one of the first steps in the revision process is to develop goals for the DFC of the Forest by the year 2007 and beyond

The Forest plays an integral part in the GYA as well as in adjacent systems, observing the broad visions and principles in the Greater Yellowstone Coordinating Committee (GYCC) Framework document (GYCC, 1991) Habitat and conditions necessary for free movement of wildlife are sustained

Based on public and employee comments between 1991-1994, a set of goal statements emerged that collectively represent a new general management direction for the Forest. The goal statements were tied to the key issues driving the plan, evolving into a new DFC for the Forest. More specific DFCs for particular portions of the Forest are outlined in the Forest Plan Revision

The DFC is described in terms of the five components, Ecological Processes and Patterns, Physical Elements, Biological Elements, Forest Use and Occupation and Production of Commodity Resources. The Biological and Physical are combined because of their interconnectivity. The DFC is broader than the seven key issues that are driving the alternatives and the decisions

Ecosystem Processes and Patterns DFC:

A mosaic of age classes and types of vegetation are sustained through time and exist across the landscape. Natural disturbances such as insects, disease and fires continue their natural roles in the ecosystem. The Forest functions as an integral part of the Greater Yellowstone Ecosystem as well as adjacent systems, sustaining habitat and conditions necessary for free movement of wildlife

Biological and Physical DFC:

Riparian zones (aquatic influence zones) are healthy and productive. Aquatic systems are allowed to function naturally while protecting flows for downstream consumptive uses. Riparian area integrity contributes to productive fisheries and excellent water quality. Native plant and animal species are favored over undesirable non-native species and sustained populations of all native and desirable species thrive. Habitat conditions contribute toward the recovery of threatened, endangered and sensitive species.

Forest Use and Occupation DFC:

Growing and diverse recreational, cultural, visual, historical, and prehistoric management, interpretive, and spiritual needs are accommodated based on the capability of the ecosystem to sustain these uses. Recreation use is managed to minimize conflicts between incompatible uses and provide high levels of satisfaction. Year-round human access is managed to provide both motorized and nonmotorized opportunities. A system of trails and support facilities exist which are compatible with resource capabilities. Roadless characteristics are preserved in the proposed wilderness areas and in existing wildernesses.

Production of Commodity Resources DFC:

Commodity production, such as timber, firewood, mining, livestock forage, or outfitting and guide services are conducted at sustainable levels and maintain the capability of the land to produce an even flow and variety of goods and services for present and future generations. Timber harvest, prescribed fires and livestock grazing are tools used to achieve desired ecological vegetation conditions. Forest products are provided to sustain social and economic values and needs of the local communities within limits which maintain ecosystem health.

Chapter

Alternatives Including the Proposed Programmatic Action (Preferred Alternative)

CHAPTER II

ALTERNATIVES INCLUDING THE PROPOSED PROGRAMMATIC ACTION (SELECTED ALTERNATIVE)

READER'S GUIDE - In this chapter you will find:

How the Alternatives Were Formulated

The Alternative Continuum and Descriptions of the Seven Alternatives

Alternatives Considered but Eliminated from Detailed Study

Comparison of the Environmental Effects Depicted by Issue Indicators (Tables)

HOW THE ALTERNATIVES WERE FORMULATED

In Chapter I, we discussed the issues, issue indicators, reasons for the need for change and the DFCs. This chapter will explain how alternatives were formulated and how each alternative addressed the issues.

Forestwide standards and guidelines specify management requirements that apply throughout the Forest. Management prescriptions say how different portions of the Forest will be managed differently from one another.

Forest lands meet many different needs. Some of these needs are mutually exclusive, for example, a wilderness area is not set up to provide developed recreation sites for motorized users. It is more common that many uses coexist on the same land. A single piece of land may provide habitat for grizzly bear, security cover for elk, grazing for livestock, timber for harvesting and so on. This multiplicity of uses is allowed in the prescriptions. Land that provides crucial winter range for elk may address that need whether the land is placed in a winter range prescription, in a recommended wilderness prescription or a range management prescription.

For purposes of managing the Forest though, people need to have ready access to the management direction that applies to any particular piece of land. That would not be possible if they had to look up separate management prescriptions for grizzly bear habitat, elk security cover, livestock grazing, timber harvesting and then face the question of which to apply.

The Forest has adopted a convention that any single piece of land has only one prescription applied to it in any given alternative. This simplifies management, but it also means that people cannot just look at a given prescription acreage total and assume that it contains all the acreage on the Forest that could possibly fit there. For instance, there is more elk and deer winter range on the Forest than is allocated to that prescription.

For the most part, when there was a question as to which management prescription should be applied, that prescription was assigned which best described the area's intended future management by the LST. As an example, when an eligible wild scenic river was identified in an area recommended for wilderness, the river corridor was assigned an eligible wild river prescription, the surrounding recommended wilderness was assigned a recommended wilderness prescription.

Alternatives can be formulated simply by specifying a different mix of management prescriptions for a given area of the Forest. For instance, a given portion of the Forest could be designated for a timber management, grizzly bear habitat or recommended wilderness prescription.

The alternatives reflected a range of options open to management that responded to the issues, the DFC and the need for change. The IDT evaluated the significant physical, biological, economic and social effects of each alternative that was considered in detail. The evaluation included aggregate effects of social and economic impacts, outputs of goods and services and overall protection and enhancement of environmental resources.

Benchmarks were developed during the formation of the initial Forest Plans. Early indications were that additional benchmark work would not be needed for Forest Plan Revisions because the benchmark work had already been completed during the development of the initial Forest Plans.

Consequences for nonkey issues are not included in Chapter II discussions, since many of them are addressed the same or with slight variation in every alternative. As an example, local communities are noticeably interested in firewood availability. Regardless of the alternative, a constant 3.8 million board feet will be available each year in some remaining dead lodgepole and aspen areas. Although discussed in Chapters III and IV, firewood was not a key issue and did not drive the selection of the selected alternative. Therefore firewood is not discussed in the alternative summaries of Chapter II.

THE ALTERNATIVE CONTINUUM AND ALTERNATIVE DESCRIPTIONS

The numbering scheme for alternatives ranges from 1-6, with Alternative 3M being the Selected and Alternative 1 being the No-Action, or continue the 1985 Forest Plan Alternative. The continuum is not perfect, however, it helps to describe the changes which occur. As the numbers increase from Alternatives 2 to 6, they move generally toward

- *Greater protection of wildlife habitat
- *Greater protection of riparian areas
- *More protection for BMUs
- *More security for elk
- *More nonmotorized, dispersed recreation opportunities
- *More recommended wilderness
- *Less cross-country motorized use
- *Fewer open roads and trails
- *Reduced livestock grazing and timber harvest
- *Less lasting visual impacts from management activities

There are several exceptions to the general trends described above. The position of Alternative 3M on the continuum, for instance, could easily vary if one were to focus on certain factors. The continuum is presented only as an aid in understanding how the alternatives generally compare to one another. It is not correct to assume that these various factors or considerations are at odds with one another. Better performance in one category does not necessarily mean worse performance in another. For instance, moving acres between a recommended wilderness and nonmotorized prescriptions in a given alternative might have no other effect than a change in acres recommended for wilderness, because management under these prescriptions is otherwise quite similar.

All alternatives meet baseline State and Federal Standards, Grizzly Bear Recovery Plan Goals for Greater Yellowstone Ecosystem, ESA, Wilderness Act, Wild and Scenic Rivers Act, National Historical Act, NFMA, Native Americans Act, etc. All the alternatives respond to and incorporate the tentative resource objectives set forth in the Recommended 1990 RPA Program.

ALTERNATIVE 1 = Continue the 1985 Forest Plan (No Action)

The purpose of Alternative 1 is to continue management of the Forest under the 1985 Forest Plan, updated since finalized with amendments, new direction, particularly the recent litigation for the grizzly bear, and changes for new listings of sensitive wildlife species over the last 10 years. Timber harvest occurs at the highest levels possible within the management constraints required for TES wildlife species like the grizzly bear and goshawk. Vehicle access is slightly reduced from current levels due to the implementation of the Interagency Grizzly Bear Guidelines and better road management across the Forest. Cross-country, motorized access in summer and winter would continue close to current levels. Riparian, wildlife and recreation values are emphasized in specific areas of the Forest.

How the Key Issues and Indicators are addressed in Alternative 1

1. Sustainability, Fire and Natural Disturbances. Key Indicators: Health of forest structure and composition and prescribed fire

In Alternative 1, forest structure and composition would be maintained or improved on 48,530 acres. Prescribed fire could be used to maintain or improve ecosystem sustainability on 1,630,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC

Approximately 342,000 aquatic influence zone (AIZ) acres would be managed to maintain or enhance riparian vegetation, aquatic habitat and water quality. At the end of the first decade, about 4,000 acres would not meet the DVC. Fisheries habitat quality would continue at a moderate level. Livestock grazing would occur near current levels. There would be a slight increase in cattle Animals Unit Months (AUMs). Current levels of sheep grazing would be maintained, in spite of officially closing nine currently vacant sheep allotments and one vacant sheep permit. A mosaic of different species and size classes of vegetation would be provided. Timber harvest would be allowed within limits and would contribute to the ASQ.

3. Security for Elk. Key Indicator: Percent of Forest meeting state EV thresholds, measured by miles of open motorized roads and trails

In Alternative 1, 62 percent of the Forest (1,136,500 acres) would meet the state EV thresholds. The greatest factors under control of the Forest Service that influence elk security are the miles of open motorized roads and trails. Alternative 1 would reduce the number of open roads by 103 miles (5 percent). There would be a reduction of open trails by 201 miles (26 percent). The 62 percent of the Forest meeting state EV thresholds is a 14 percentage point increase over the existing level of 48 percent, indicating the potential for a slightly lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMUs). Key Indicator: OROMTRD in miles per square mile

Compared to the existing condition, OROMTRD is reduced 23 percent in Henry's Lake BMU Subunit 1, 40 percent in Henry's Lake BMU Subunit 2, and 22 percent in Bechler/Teton BMU. OROMTRD is increased 19 percent in Plateau BMU Subunit 1 and 8 percent in Plateau BMU Subunit 2. Off-highway vehicle (OHV) use would continue at current levels of use. Alternative 1 has no restrictions on cross-country snowmachine use, except on a small portion of the Plateau BMU. Timber harvest could occur with constraints and would contribute to the ASQ.

5. Access. Key Indicator Number of miles of roads and trails open to summer motorized use.

Alternative 1 would reduce the number of open roads by 103 miles (5 percent) There would be a reduction in open trails by 201 miles (26 percent) Acres available for summer OHV would also be the highest of the alternatives, allowing OHV use on approximately 960,000 acres, about a 15 percent reduction over the current 1,126,000 acres open to OHV use.

6. Roadless Area Management. Key Indicator Number of acres recommended for wilderness

Alternative 1 would recommend to Congress 65,000 acres for wilderness designation These are the roadless areas recommended in the 1985 Forest Plan (Italian Peak, Lionhead and Winegar Hole), although no Congressional action has been taken This recommendation is about seven percent of the total acres which presently qualify as roadless.

7. Timber Harvest. Key Indicator ASQ

Alternative 1 would harvest timber at a sustainable level of a maximum 110.7 million board feet (MMBF) for the decade (approximately 11.07 MMBF per year) on an estimated 28,380 acres

ALTERNATIVE 2

The purpose of Alternative 2 is to resolve the needs for change by emphasizing cross-country, winter access and timber production, while adding more restrictions to summer, cross-country access Timber harvest occurs at the highest levels within the management constraints required for maintaining TES species habitat Vehicle access is slightly reduced to meet requirements of the Interagency Grizzly Bear Guidelines Riparian, wildlife and heritage resource values are emphasized in specific areas of the Forest

How the Key Issues and Indicators are addressed in Alternative 2

1. Sustainability, Fire and Natural Disturbances. Key Indicators Health of forest structure and composition and prescribed fire

In Alternative 2, forest structure and composition would be maintained or improved on 58,580 acres Prescribed fire could be used to maintain or improve ecosystem sustainability on 1,750,000 acres

2. Riparian. Key Indicator Acres not meeting DVC

Approximately 325,000 AIZ acres would be managed to restore and maintain the health of AIZs in ways that also produce desired resource values, products, protection and enhancement of these areas At the end of the first decade, about 2,500 acres would not meet the DVC Cattle and sheep grazing are both slightly reduced from existing levels Fisheries habitat quality would remain at a moderate level

3. Security for Elk. Key Indicator Percent of Forest meeting state EV thresholds, measured by miles of open motorized roads and trails

In Alternative 2, 76 percent of the Forest (1,393,000 acres) would meet the state EV thresholds The greatest factors under control of the Forest Service that influence elk security are the miles of open

motorized roads and trails. Alternative 2 would reduce the number of open roads by 122 miles (6 percent). There would be a reduction in open trails by 303 miles (39 percent). The 76 percent of the Forest meeting state EV thresholds is a 28 percentage point increase over the existing level of 48 percent, probably resulting in a potential for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMUs). Key Indicator: OROMTRD in miles per square mile

Compared to the existing condition, OROMTRD is reduced 25 percent in Henry's Lake BMU Subunit 1, 45 percent in Henry's Lake BMU Subunit 2, and 17 percent in Bechler/Teton BMU. OROMTRD is increased 51 percent in Plateau BMU Subunit 1 and 25 percent in Plateau BMU Subunit 2. Acres of summer cross-country, motorized access is significantly reduced from Alternative 1. Timber harvest that might occur to achieve grizzly bear habitat objectives would contribute to the ASQ.

5. Access. Key Indicator: Number of miles of roads and trails open to summer motorized use

Alternative 2 would reduce the number of open roads by 122 miles (6 percent). There would be a reduction in open trails by 303 miles (39 percent). Acres available for OHV would also be reduced over recent levels. Alternative 2 would allow OHV use on approximately 761,000 acres, about a 32 percent reduction from the current 1,126,000 acres open to OHV use. Winter OHV access would be increased, with an additional 206 miles of groomed trails for snowmobiles, for a total of 666 miles.

6. Roadless Area Management. Key Indicator: Number of acres recommended for wilderness

Alternative 2 would not recommend to Congress any areas for wilderness designation.

7. Timber Harvest. Key Indicator: ASQ

Alternative 2 would harvest timber at a sustainable level of a maximum 129.0 MMBF for the decade (approximately 12.9 MMBF per year) on an estimated 33,080 acres.

ALTERNATIVE 3

The purpose of Alternative 3 is to resolve the needs for change by emphasizing management of wildlife habitat and sustaining timber harvest levels within wildlife constraints. Grizzly bear recovery is enhanced with a reduction in motorized use allowed in each BMU. The number of riparian areas meeting the DVC are slightly reduced. Cross-country, summer, motorized vehicle use is restricted to specific areas.

How the Key Issues and Indicators are addressed in Alternative 3

1. Sustainability, Fire and Natural Disturbances. Key Indicators: Health of forest structure and composition and prescribed fire

In Alternative 3, forest structure and composition would be maintained or improved on 52,930 acres. Prescribed fire could be used to maintain or improve ecosystem sustainability on 1,750,000 acres.

2. Riparian. Key Indicator Acres not meeting DVC

Alternative 3 would promote the health and function of riparian, wetland and aquatic ecosystems on approximately 448,000 AIZ acres. At the end of the first decade, about 2,500 acres would not meet the DVC. Fisheries habitat quality would be moderately high. Cattle and sheep grazing would occur at reduced levels compared to existing levels. Timber harvest could occur in riparian areas to attain the DVCs, but is not scheduled and would not contribute to the ASQ.

3. Security for Elk. Key Indicator Percent of Forest meeting state EV thresholds, measured by miles of open motorized roads and trails

In Alternative 3, about 83 percent of the Forest (1,521,500 acres) would meet the state EV thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open motorized roads and trails. Alternative 3 would reduce the number of open roads by 396 miles (20 percent). There would be a reduction in open trails by 338 miles (44 percent). The 83 percent of the Forest meeting state EV thresholds is a 35 percentage point increase over the existing level of 48 percent, thereby improving elk security and allowing a higher potential for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMUs). Key Indicator OROMTRD in miles per square mile

Compared to the existing condition, OROMTRD is reduced 24 percent in Henry's Lake BMU Subunit 1, 48 percent in Henry's Lake BMU Subunit 2, 7 percent in Plateau BMU Subunit 1, 22 percent in Plateau BMU Subunit 2, and 33 percent in Bechler/Teton BMU. Almost no summer cross-country, motorized travel would be permitted in the BMUs. Snowmachine use is allowed on designated routes throughout the snow season. In 96 percent of the Henry's Lake BMU - Subunit 2, 20 percent of the Plateau BMU, and 3 percent Bechler/Teton BMU, cross-country snowmachine use is allowed only from December 15 to April 1. Some timber harvest could occur to improve bear habitat.

5. Access. Key Indicator Number of miles of roads and trails open to motorized use

Alternative 3 would reduce the number of open roads by 396 miles (20 percent). There would be a reduction in open trails by 338 miles (44 percent). Acres available for summer OHV use would also be reduced over current levels. Alternative 3 would allow OHV use on approximately 368,000 acres, about a 67 percent reduction from the current 1,126,000 acres open to OHV use. Besides providing wildlife security, summer OHV reductions would prevent other resource damages from OHV use.

6. Roadless Area Management. Key Indicator Number of acres recommended for wilderness

Alternative 3 would recommend to Congress 125,000 acres for wilderness designation. The 125,000 acres would include the 65,000 acres recommended by the 1985 Plan in the Italian Peak, Lionhead and Winegar Hole roadless areas, plus additional roadless acres in each of these areas and the Palisades. These acres represent 15 percent of the total acres which presently qualify as roadless on the Forest.

7 Timber Harvest. Key Indicator ASQ

Alternative 3 would harvest timber at a sustainable level of a maximum 108.3 MMBF for the decade (approximately 10.83 MMBF per year) on an estimated 27,780 acres.

ALTERNATIVE 3M = Alternative 3 Modified (Also the Proposed Programmatic Action and Selected Alternative)

The purpose of Alternative 3M is to resolve the needs for change by emphasizing wildlife habitat management and providing a comprehensive habitat management strategy for the grizzly bear. Motorized access, timber harvest levels and livestock grazing are all reduced from levels allowed in the 1985 Forest Plan. Riparian areas with cutthroat trout are further protected with increased vegetation. Cross-country, summer, motorized vehicle use is restricted to specific areas.

Alternative 3M has been selected as the RPA Alternative because it represents the Forest's best attempt to simultaneously implement multiple-use management, ensure resource sustainability, emphasize the quality of resource outputs and to provide for the economic well-being of rural communities.

How the Key Issues and Indicators are addressed in Alternative 3M

1. Sustainability, Fire and Natural Disturbances. Key Indicators: Health of forest structure and composition and prescribed fire

In Alternative 3M, forest structure and composition would be maintained or improved on 45,170 acres. Prescribed fire could be used to maintain or improve ecosystem sustainability on 1,750,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC

Approximately 512,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems under Alternative 3M. At the end of the first decade, about 2,500 acres would not meet the DVC. Fisheries habitat quality would be moderately high, compared to the current moderate quality rating. There would be a moderately rapid rate of recovery of degraded habitats. Livestock grazing is reduced to the same levels described in Alternative 3, in addition, a program is initiated to phase out sheep grazing on an opportunity basis on portions of the Island Park and Teton Basin Ranger Districts. Timber harvest could occur in riparian areas to attain the DVCs, but is not scheduled and would not contribute to the ASQ.

3. Security for Elk. Key Indicator: Percent of Forest meeting state EV thresholds, measured by miles of open motorized roads and trails

About 89 percent of the Forest (1,631,500 acres) would meet the state EV thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open motorized roads and trails. Alternative 3M would reduce the number of open roads by 408 miles (21 percent). There would be a reduction in open trails by 233 miles (30 percent). The 89 percent of the Forest meeting state EV thresholds is a 41 percentage point increase over the existing level of 48 percent, thereby greatly improving elk security. This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMUs). Key Indicator: OROMTRD in miles per square mile

Compared to the existing condition, OROMTRD is reduced 34 percent in Henry's Lake BMU Subunit 1, 39 percent in Henry's Lake BMU Subunit 2, 36 percent in Plateau BMU Subunit 1, 25 percent in Plateau BMU Subunit 2, and 34 percent in Bechler/Teton BMU. Additional access restrictions to improve habitat secu-

ity would be no summer cross-country motorized vehicle use in any of the BMUs, except a small portion in the Bechler BMU. No timber harvest would be scheduled in the designated core or secure areas. Snowmachine use is allowed on designated routes throughout the snow season. Cross-country snowmachine use is allowed from Thanksgiving Day until June 1.

5. Access. Key Indicator: Number of miles of roads and trails open to motorized use

Alternative 3M would reduce the number of open roads by 408 miles (21 percent). There would be a reduction in open trails by 233 miles (30 percent). The increase in road closures and restrictions would provide increased wildlife security, especially for elk and grizzly bears, and would provide additional protection from other resource damage. Acres available for summer OHV use would be reduced allowing OHV use on approximately 121,000 acres, an 89 percent reduction from the current 1,126,000 acres open to OHV use.

6. Roadless Area Management. Key Indicator: Number of acres recommended for wilderness.

Alternative 3M would recommend to Congress 171,000 acres for wilderness designation. The 171,000 acres would include the 65,000 acres recommended by the 1985 Plan in Italian Peak, Lionhead and Winegar Hole roadless areas, plus additional roadless acres in each of these areas and the Palisades. Over 33,000 acres of the Diamond Peak Roadless area was added. Another 12,000 acres was added to the Italian Peaks area due to re-digitizing the southern boundary. This recommended 171,000 acres is 20 percent of the total acres which presently qualify as roadless on the Forest.

7 Timber Harvest Key Indicator: ASQ

Alternative 3M would harvest timber at a sustainable level of a maximum 80.0 MMBF for the decade (approximately 8.0 MMBF per year) on an estimated 20,520 acres.

ALTERNATIVE 4

Alternative 4 emphasizes watershed and wildlife habitat improvement and a reduction in timber harvest. Riparian areas receive increased emphasis. Motorized access is restricted to designated routes and more roads are closed in some BMUs than in previous alternatives.

How the Key Issues and Indicators are addressed in Alternative 4

1. Sustainability, Fire and Natural Disturbances. Key Indicators: Health of forest structure and composition and prescribed fire

In Alternative 4, forest structure and composition would be maintained or improved on 39,770 acres. Prescribed fire could be used to maintain or improve ecosystem sustainability on 1,750,000 acres.

2. Riparian. Key Indicator: Acres not meeting DVC

Approximately 533,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems. At the end of the first decade, about 1,700 acres would not meet the

DVC Fisheries habitat quality would be high, compared to the current moderate quality rating. Degraded habitats would recover rapidly. Sheep grazing is reduced compared to existing levels, and the program to phase out sheep grazing on an opportunity basis also occurs under this alternative. Cattle grazing levels would be reduced considerably (12 percent) from current levels. Timber harvest could occur in riparian areas to attain DVCs, but is not scheduled and would not contribute to ASQ.

3. Security for Elk. Key Indicator: Percent of Forest meeting state EV thresholds, measured by miles of open motorized roads and trails.

About 89 percent of the Forest (1,631,500 acres) would meet the state EV thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open motorized roads and trails. Alternative 4 would reduce the number of open roads by 613 miles (31 percent). There would be a reduction in open trails by 352 miles (46 percent). The 89 percent of the Forest meeting state EV thresholds is a 41 percentage point increase over the existing level of 48 percent, thereby greatly improving elk security. This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMUs). Key Indicator: OROMTRD in miles per square mile.

Compared to the existing condition, OROMTRD is reduced 47 percent in Henry's Lake BMU Subunit 1, 53 percent in Henry's Lake BMU Subunit 2, 31 percent in Plateau BMU Subunit 1, 32 percent in Plateau BMU Subunit 2, and 43 percent in Bechler/Teton BMU. Additional access restrictions to improve habitat security would be no cross-country motorized vehicle use in any of the BMUs, except a small portion of the Plateau and Bechler BMUs. Snowmachine use is allowed on designated routes throughout the snow season. Cross-country snowmachine use is allowed only from December 15 to April 1.

5. Access. Key Indicator: Number of miles of roads and trails open to motorized use.

Alternative 4 would reduce the number of open roads by 613 miles (31 percent). There would be a reduction in open trails by 352 miles (46 percent). Alternative 4 would allow OHV use on approximately 79,000 acres, over a 93 percent reduction from the current 1,126,000 acres currently open to OHV use.

6. Roadless Area Management. Key Indicator: Number of acres recommended for wilderness.

Alternative 4 would recommend to Congress 139,000 acres for wilderness designation. These acres more than double the 65,000 acres recommended by the 1985 Plan in Italian Peak, Lionhead and Winegar Hole roadless areas, plus additional roadless acres in each of these areas and the Palisades. This recommended 139,000 acres is 18 percent of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator: ASQ.

Alternative 4 would harvest timber at a sustainable level of 60.33 MMBF for the decade (approximately 6.033 MMBF per year) on an estimated 15,470 acres.

ALTERNATIVE 5

The purpose of Alternative 5 is to meet the needs for change that reduce focus on human management and human disturbances of wildlife and riparian habitat. Motorized access is restricted to designated

routes and more roads are closed in BMUs

How the Key Issues and Indicators are addressed in Alternative 5

1. Sustainability, Fire and Natural Disturbances. Key Indicators Health of forest structure and composition and prescribed fire

In Alternative 5, forest structure and composition would be maintained or improved on 29,840 acres Prescribed fire could be used to maintain or improve ecosystem sustainability on 1,750,000 acres

2. Riparian. Key Indicator Acres not meeting DVC

Approximately 590,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems under this alternative At the end of the first decade, about 1,700 acres would not meet the DVC Fisheries habitat quality would be high, compared to the current moderate quality rating Degraded habitats would recover rapidly Sheep grazing is reduced compared to existing levels, and the program to phase out sheep grazing on an opportunity basis also occurs under this alternative Cattle grazing levels would be reduced considerably (12 percent) from current levels

3. Security for Elk. Key Indicator Percent of Forest meeting state EV thresholds, measured by miles of open motorized roads and trails

In Alternative 5, about 95 percent of the Forest (1,741,500 acres) would meet the state EV thresholds The greatest factors under the control of the Forest Service and influencing this are the miles of open motorized roads and trails Alternative 5 would reduce the number of open roads by 748 miles (38 percent) There would be a reduction in open trails by 541 miles (70 percent) The 95 percent of the Forest meeting state EV thresholds is a 47 percentage point increase over the existing level of 48 percent, thereby greatly improving elk security This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season

4. Grizzly Bear Management (within the BMUs). Key Indicator OROMTRD in miles per square mile

Compared to the existing condition, OROMTRD is reduced 37 percent in Henry's Lake BMU Subunit 1, 45 percent in Henry's Lake BMU Subunit 2, 34 percent in Plateau BMU Subunit 1, 30 percent in Plateau BMU Subunit 2, and 45 percent in Bechler/Teton BMU Additional access restrictions to improve habitat security would be no cross-country motorized vehicle use in any of the BMUs, a small portion of the Plateau and Bechler BMUs Snowmachine use is allowed on designated routes throughout the snow season Cross-country snowmachine use is allowed only from December 15 to April 1 Sheep grazing would end immediately in BMUs and cattle grazing would be considerably reduced

5. Access. Key Indicator Number of miles of roads and trails open to motorized use

Alternative 5 would reduce the number of open roads by 748 miles (38 percent) There would be a reduction in open trails by 541 miles (70 percent) Alternative 5 would allow OHV use on approximately 50,000 acres, a 96 percent reduction from the current 1,126,000 acres open to OHV use

6. Roadless Area Management. Key Indicator Number of acres recommended for wilderness

Alternative 5 would recommend to Congress 226,000 acres for wilderness designation. These acres are more than triple the 65,000 acres recommended by the 1985 Plan in Italian Peak, Lionhead and Winegar Hole roadless areas. Also included in the total recommended wilderness are additional roadless acres in the Palisades and Garns Mountain areas. This recommended 226,000 acres is 28 percent of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator ASQ

Alternative 5 would harvest timber at a sustainable level of 35.1 MMBF for the decade (approximately 3.51 MMBF per year) on an estimated 9,000 acres.

ALTERNATIVE 6

The purpose of Alternative 6 is to meet the needs for change by de-emphasizing human management and human disturbance of wildlife and riparian habitat to the lowest level of all the alternatives. Timber harvest is not scheduled. All access is strongly restricted to designated routes and more roads are closed to reduce human disturbance than in any other alternative.

How the Key Issues and Key Indicators are addressed in Alternative 6

1. Sustainability, Fire and Natural Disturbances. Key Indicators Health of forest structure and composition and prescribed fire

In Alternative 6, forest structure and composition would be maintained or improved on 20,730 acres. Prescribed fire could be used to maintain or improve ecosystem sustainability on 1,750,000 acres.

2. Riparian. Key Indicator Acres not meeting DVC

Approximately 793,000 AIZ acres would be managed to promote the health and function of riparian, wetland and aquatic ecosystems under this alternative. At the end of the first decade, about 1,700 acres would not meet the DVC. Fisheries habitat quality would be high, compared to the current moderate quality rating. Degraded habitats would recover rapidly.

3. Security for Elk. Key Indicator Percent of Forest meeting state EV thresholds, measured by miles of open motorized roads and trails

About 95 percent of the Forest (1,741,500 acres) would meet the state EV thresholds. The greatest factors under the control of the Forest Service and influencing this are the miles of open motorized roads and trails. Alternative 6 would reduce the number of open roads by 757 miles (38 percent). There would be a reduction in open trails by 692 miles (90 percent). The 95 percent of the Forest meeting state EV thresholds is a 47 percentage point increase over the existing level of 48 percent, thereby greatly improving elk security. This means the potential would be for a lower proportion of bulls to be harvested during the general hunting season.

4. Grizzly Bear Management (within the BMUs). Key Indicator OROMTRD in miles per square mile

Compared to the existing condition, OROMTRD is reduced 34 percent in Henry's Lake BMU Subunit 1, 55 percent in Henry's Lake BMU Subunit 2, 19 percent in Plateau BMU Subunit 1, 32 percent in Plateau BMU Subunit 2, and 45 percent in Bechler/Teton BMU. Additional access restrictions to improve habitat security would be no cross-country motorized vehicle use in any of the BMUs, except in a small portion of the Plateau and Bechler BMUs. Snowmachine use is allowed on designated routes throughout the snow season. Cross-country snowmachine use is allowed only from December 15 to April 1. Sheep grazing would end immediately in BMUs and cattle grazing would be considerably reduced.

5. Access. Key Indicator Number of miles of roads and trails open to motorized use

Alternative 6 would reduce the number of open roads by 757 miles (38 percent). There would be a reduction in open trails by 692 miles (90 percent). Acres available for OHV use would also be reduced over current levels. Alternative 6 would allow OHV use on approximately 34,000 acres, a 97 percent reduction from the current 1,126,000 acres open to OHV use. This approach is consistent with the minimum maintenance level of management emphasized in this alternative.

6. Roadless Area Management. Key Indicator Number of acres recommended for wilderness

Alternative 6 would recommend to Congress 465,000 acres for Wilderness designation, more than seven times the 65,000 acres recommended by the 1985 Plan in Italian Peak, Lionhead and Winegar Hole roadless areas. Also included in the total recommended wilderness are additional roadless acres in the Palisades, Garns Mountain, Bear Creek and Poker Peak areas. This recommended 465,000 acres is 55 percent of the total acres which presently qualify as roadless on the Forest.

7. Timber Harvest. Key Indicator ASQ

Alternative 6 would not have a scheduled timber harvest. Harvest might occur on unscheduled lands, but would be very limited, given the minimum level of human disturbance emphasis of this alternative.

ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Several alternatives were considered but eliminated from detailed study. More information about these can be found in Appendix A - Response to Public Comments. These alternatives were not fully developed because they closely resembled alternatives that were considered in detail, they did not meet the needs for change, they were missing practical implementation components, or they were inappropriate for other reasons described below.

Maximum Commodity Production and Motorized Access

This alternative called for more Forest land devoted to scheduled timber production than Alternative 1. It provided more designated open motorized routes, allowed less cross-country OHV access, recommended no wilderness designation, proposed elimination of the Palisades Wilderness Study Area, and recommended that eligibility determinations under the Wild and Scenic Rivers Act not be made.

Some portions of this proposal were incorporated into Alternative 2. Suggestions that could not be implemented without Congressional action (like those regarding the Palisades Wilderness Study Area and

eligibility under the Wild and Scenic Rivers Act) were not included in any alternative. Because large portions of this proposal became part of Alternative 2, further detailed analysis was not necessary.

Maximum Wilderness

During public involvement activities, it was proposed that all of the Forest's inventoried roadless areas be recommended for wilderness designation. After analysis, some inventoried roadless areas were not proposed for wilderness recommendation in our selected Alternative 3M, because they did not score high enough in our rating of wilderness characteristics. The Roadless Areas Process Paper (Q) was reanalyzed and updated in response to public comments on the DEIS. The updated portion of the process paper is included in Appendix B of this FEIS. A maximum wilderness alternative was not developed. Alternative 6 was developed in response to the desire for additional recommended wilderness.

Range of Variability

Many members of the public and several Forest Service employees advocated the development of an alternative that would move the Forest into its "range of variability (ROV)." This would involve learning what ecological conditions existed on the Forest historically and managing for those same conditions. This alternative was not developed because the current information on the ROV for the Forest is insufficient. Even with this information, ecological variability may be so broad as to provide inadequate direction for an alternative at this time. Finally, this type of alternative would not meet NFMA direction to formulate alternatives that incorporate social and economic conditions along with the ecological situation.

Citizens for a User Friendly Forest (CUFF) Alternative

This alternative was proposed by a citizens group as public comments to the DEIS. The elements of their proposal include the following:

- amend summer OHV map for Alt. 2
- remove date restriction on snowmobile use
- increase ASQ to 20 MMBF with >12 MMBF live and 30 to 50 percent lodgepole
- change 20 percent nonstocked standard to 45 percent
- change mature percent stand from 40 to 30 percent
- define hydrologic disturbance at less than 20 years
- allow sustained harvest in roadless areas and no noninterchangeable component (NIC)
- allow harvest in all BMUs, NIC in Situation 1 habitat
- if 20 MMBF isn't possible, look at departure
- add two areas in Caribou subsection to suitable timber base
- change large 6 1(b) in Caribou subsection to 6 1(a)
- delete forestwide guideline restricting OHV use on slopes of 25-40 percent
- drop Targhee and Robinson Creeks from Wild and Scenic River (W&SR) eligibility
- reduce number of live snag retention trees per acre from 25 to 10
- change 5 1 4(a) to allow cross-country travel from June 15 to prior to big game rifle

We have considered but dismissed this proposal from detailed study for the following reasons. A few of the key components (which appear to be within the DFC and Purpose and Need) of this proposed alternative are already depicted by Alternative 2 as updated for ASQ at > 20 MMBF. We believe this proposed alternative is not substantially different from the Maximum Commodity Production and Motorized Access alternative presented earlier. Also, we believe most of the remaining components of this alternative as recommended above are not advisable because they are not within the DFC and Purpose and Need.

outlined in the FEIS Detailed rationale for dismissal of each element of this proposal can be found in Appendix A, Response to Public Comments of this document

Greater Yellowstone Coalition Alternative

Several groups who commented on the DEIS recommended consideration of an alternative with a mix of the attributes of Alternatives 3M, 5 and 6 that would

- maintain the AUMs of 3M,
- maintain as much of the ASQ of 3M as possible on a sustainable basis,
- recommend substantially more wilderness than even 5 or 6,
- modify 3M grizzly bear prescription in the Bechler area to provide harvest mitigation,
- create a wildlife linkage corridor in the Centennial Mountains with no ASQ

This alternative was considered but dismissed from detailed study for the following reasons which are further documented in Appendix A These proposals would potentially be within the Purpose and Need and DFC, with the exception of the amount of recommended wilderness The overall Forest DFC did not call for recommending such high levels of inventoried roadless as wilderness Furthermore, a "Maximum Wilderness" alternative was presented previously in this EIS and dismissed because it did not respond to the DFC and because not all of the roadless areas rated high enough in the analysis

Original Forest Plan as Written

Alternative 1 reflects current management of the Forest and how it would continue in the future It differs from the original 1985 Plan in some respects Some people have asked for an alternative that comes closer to the letter of the existing Forest Plan The differences between Alternative 1 (which is modeled consistent with the intent of the 1985 Plan) and a strict reading of the 1985 Plan are summarized below They could have been used to shape a separate alternative

- The 1985 Plan called for the harvesting of timber from suitable lands at rates that could not be sustained Because most of this material has already been logged or is no longer merchantable, and because some of it could not be logged because of other resource protection needs, the non-sustainable harvest schedule was not used

- As a part of the Revision process, the Forest reassessed the eligibility of river segments for study as wild, scenic or recreational rivers. That eligibility determination was made, and the Forest has moved to protect the outstandingly remarkable values of the eligible segments in all the alternatives Some people have asked that an alternative be developed which does not include that protection We did not do so because Forest Service policy is to protect the outstandingly remarkable values once eligibility is established

- The provisions of the ESA have not changed since the Forest Plan was put into effect in 1985 However, the understanding of the habitat needs of those species has changed substantially Meeting the needs of these species, in particular the grizzly bear, has substantially changed management on a large portion of the Forest We did not use the previously acceptable approaches for providing grizzly bear habitat because they are not generally accepted in today's scientific community and would not be successfully consulted upon with the United States Department of Interior Fish and Wildlife Service (USFWS)

- The Forest Service has greatly expanded its own list of sensitive species In response to that expanded list, the Forest has had to change management practices to increase habitat protection We have contin-

ued this level of protection because it is designed to prevent these species from being listed as threatened or endangered

COMPARISON OF ALTERNATIVES

A summary of the environmental impacts and effects (called Indicators) for each alternative and the acres of each prescription area are provided in Table II-1 and Table II-2. Due to the complexity of the consequences displayed in these tables, cumulative impacts are not presented here. For a detailed discussion of the effects, consult Chapter IV, "Environmental Consequences."

Acronyms and Abbreviations Used in Table II-1.	
AIZ	Aquatic Influence Zone
ASQ	Allowable Sale Quantity
BMU	Bear Management Unit
Sub	Subunit of a Bear Management Unit
C/H	Cattle/Horse
CEM	Cumulative Effects Model
DVC	Desired Vegetative Condition
FSRAMIS	Forest Service Range Analysis Management Information System
HE	Habitat Effectiveness
HE/HV Index	Percent of Annual Habitat Value
HGL	Hydric Greenline
HV	Habitat Value
FFF	Forest Fire Fighting
LE	Law Enforcement
M Acres	Thousand Acres
M AUM's	Thousand Animal Unit Months
M\$	Thousand Dollars
MM\$	Million Dollars
MMBF	Million Board Feet
Max Mod.	Maximum Modification
Mod	Modification
OHV	Off-Highway Vehicle
P R	Partial Retention
Reten	Retention
S/G	Sheep/Goat
VQO	Visual Quality Objective

**TABLE II-1
COMPARISON OF ENVIRONMENTAL EFFECTS**

The following pages contain a summary of the environmental effects of the alternatives. This summary is drawn from information in Chapter III and IV of the FEIS. Unless otherwise indicated, the information presented for the alternatives is reflective of conditions in the first decade of Revision implementation. Please see these chapters for additional information.

The key issue indicators are displayed first for the components outlined in Chapter 1. Due to the complexity of the issues, there are other indicators that need to be evaluated to adequately address the environmental effects, and those are listed below the key indicators.

ECOLOGICAL PROCESSES AND PATTERNS

	Exist Level	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Key Indicator - Sustainability								
- M Acres where forest structure and composition maintained or improved 1/	NA	48 5	58 6	52 9	45 2	39 8	29 8	20 7

1/ Estimated acres of silvicultural treatments for the first decade. In addition to forest structure and composition, there are other ecosystem criteria we analyzed that contribute to ecologically sustainable ecosystems.

All alternatives were evaluated on the ability to use prescribed fire to manipulate ecosystems. Aquatic connectivity was determined to be a good indicator of ecosystem pattern.

Other Ecosystem Management Indicators

- M Acres where prescribed fire is allowed	1,610	1,630	1,750	1,750	1,750	1,750	1,750	1,750
- M Acres aquatic zones where connectivity is maintained	342	342	325	448	512	533	590	793

PHYSICAL

Most forest management activities impact the soil resource to some extent. These activities (recreation, timber harvesting, road building, grazing) were evaluated to determine what environmental effect they will have on the soil resource.

The only issue indicators used to evaluate physical elements are related to minerals and the ability to locate, or enter areas on the Forest.

Other Physical Component Indicators

- M Acres open to locatable and mineral entry	1,722	1,384	1,415	1,326	1,295	1,348	1,200	965
---	-------	-------	-------	-------	-------	-------	-------	-----

BIOLOGICAL								
	Exist Level	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Key Indicator - Riparian Health Issue								
- Riparian M Acres meeting DVC 1/	18 7	18 8	20 0	20 0	20 0	21 1	21 1	21 1

- Bechler/Teton BMU	0 76	0 59	0 63	0 51	0 50	0 43	0 42	0 42

Many indicators can be used to evaluate effects management activities have on grizzly bears. In addition to open motorized roads and trails, total access, the percent of the BMU that is in a core area, and an overall habitat effectiveness/value are used.

1/ OROMTRD = Open Road and Open Motorized Trail Route Density

2/ TMARD = Total Motorized Access Route Density

3/ The cumulative effects model ratings are the daily per acre averages for Habitat Effectiveness divided by the daily per acre average for Habitat Value. A rating of 100 percent would mean no human activity during the spring, summer, fall period. The first rating is for the Targhee portion of the BMU/Subunit. The rating in parenthesis is for the entire BMU/Subunit. For Henry's Lake Subunit 1, the CEM model does not include the 35,170 acres on Henry's Lake Flat, therefore no ratings are shown in parenthesis for the entire BMU/Subunit.

Chapter

Affected Environment

CHAPTER III AFFECTED ENVIRONMENT

READER'S GUIDE - In this chapter you will find:

A description of the following components of the Forest and Key Issues

- Introduction to Ecosystem Management
 - Principles
 - Proper Functioning Condition
- Ecological Processes and Patterns
 - Ecological Processes and Disturbances
 - Ecological Patterns*
- Physical Elements of the Environment
- Biological Elements of the Environment
 - Aquatic and Riparian Ecosystems
 - Terrestrial Ecosystems
- Forest Use and Occupation
 - Access Management
 - Wilderness and Recreation Resource
 - Economic and Social Environment
- Production of Commodity Resources
 - Timber
 - Livestock Grazing

This chapter describes the existing environment that will be affected by implementation of any of the alternatives. It describes the existing physical, biological and social environment of the Forest and the surrounding area. Information contained in this section appears in the same order as the components outlined in Chapter 1.

INTRODUCTION TO ECOSYSTEM MANAGEMENT

PRINCIPLES

In recent years the Forest Service has embraced the concept of EM. This is an approach to natural resource management that strives to ensure healthy, productive, sustainable ecosystems by blending the needs of people and environmental values in a given area such as the Forest. An ecosystem is a complex system of living and nonliving components that interact and change continually. Healthy ecosystems are those that are in PFC. Ecosystems that are in PFC display resilience to disturbance to the structure, composition and process of their biological and physical components. They retain all of their parts and functions for future generations even though vegetation patterns, human uses or other conditions may change. Understanding ecological processes (fire and other natural disturbances) and how these processes shaped vegetation patterns over time in a landscape are important steps towards implementing EM.

Adaptive Management

An additional principle of EM is the quest for and application of new knowledge regarding ecosystems. Our understanding of ecosystems and the effects of various management activities is subject to change as new information becomes available. In order to accommodate and react to such change, the Forest Service has adopted an adaptive management approach. In adaptive management, monitoring and evalu-

ation are used to assess the effects of management decisions and identify new information. Resource management may then be changed to reflect new understandings.

Scale

Another important EM principle is that different issues, components or effects may require description at different geographic and time scales. For example, economic issues are described at the county level, but fisheries are discussed by hydrologic unit. For economic and social issues political boundaries are more meaningful, while ecological units are used for resource discussions. In this document, we have addressed issues at many different scales and levels of specificity, depending on which is most relevant to the decisions being made.

Subsections

Many resources are described in this chapter using the ecological units known as subsections. These units exhibit unique patterns in soils, landform, topography and potential natural vegetation, among other characteristics. The Forest encompasses part or all of seven subsections (Figure III-1)

- Lemhi/Medicine Lodge
- Centennial Mountains
- Island Park
- Madison-Pitchstone Plateaus
- Teton Range
- Big Hole Mountains
- Caribou Range Mountains

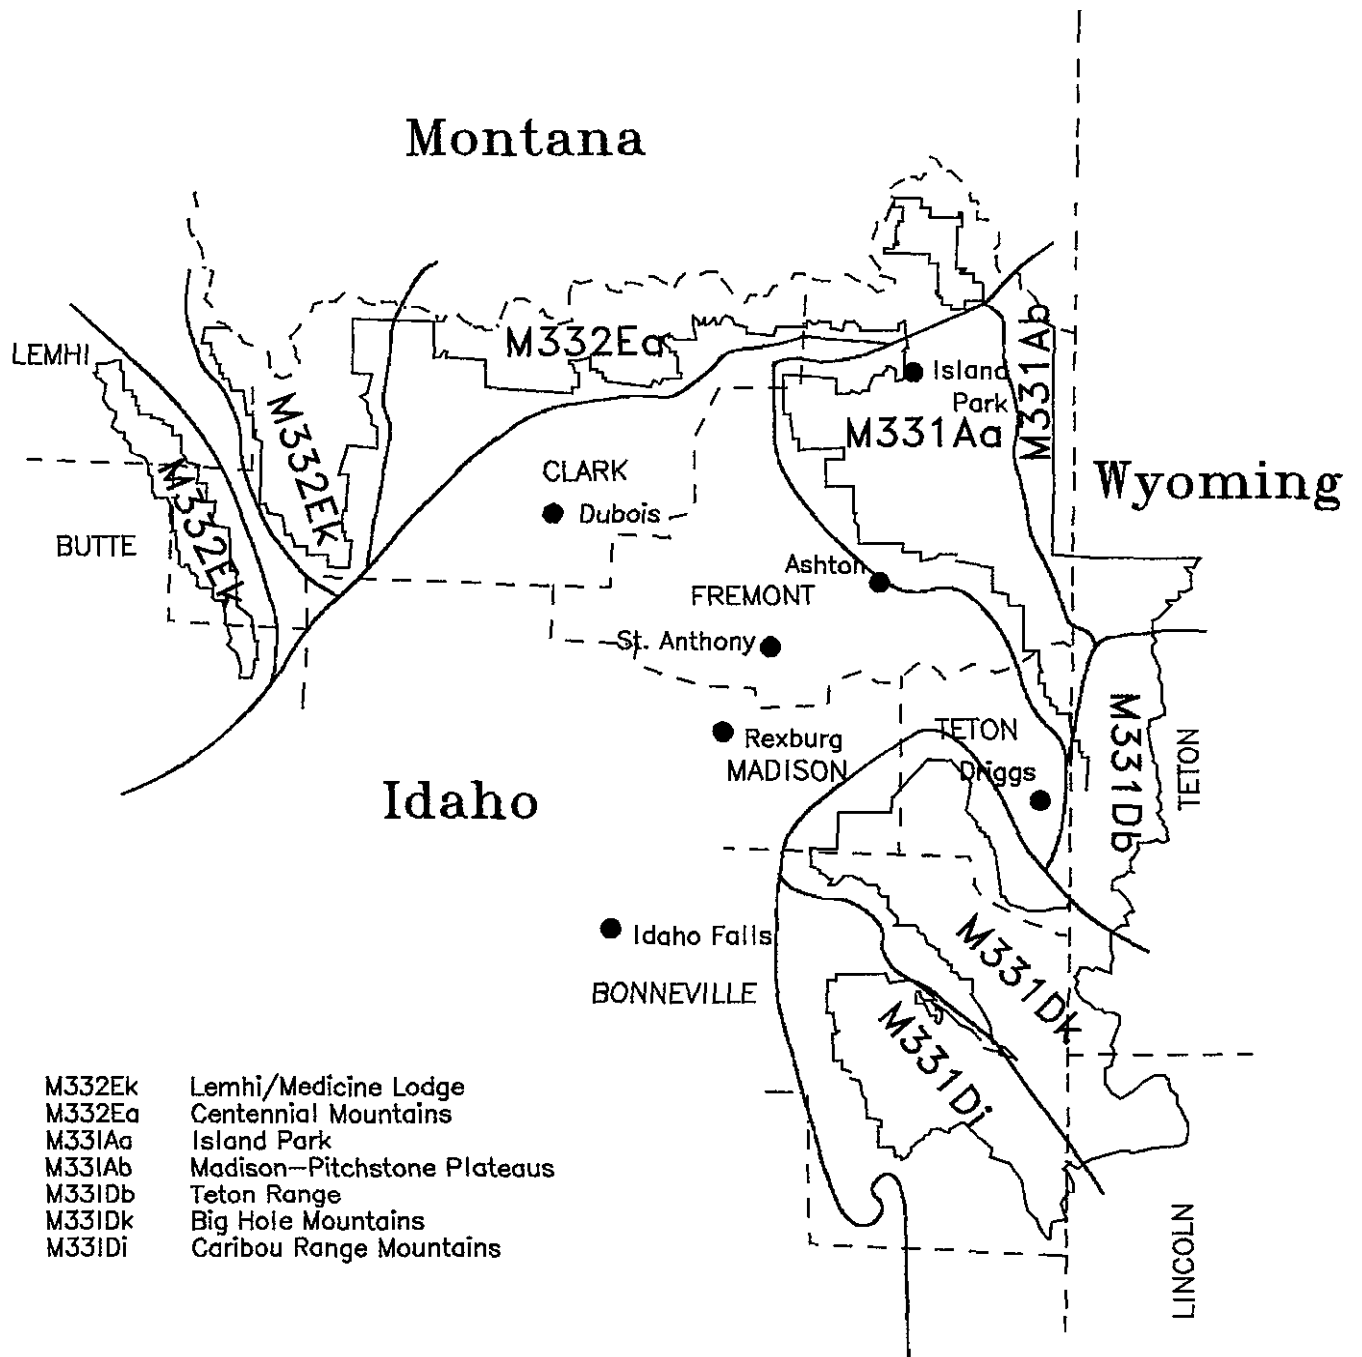

To get a better understanding of each of the seven subsections that are discussed in this chapter, a brief description of each follows. Additional information on the subsections is available throughout this document, and in process papers or planning records.

Lemhi/Medicine Lodge - This subsection includes the Lemhi and the Medicine Lodge/Beaverhead Mountains. A variety of vegetation exists with dominant communities of mostly Douglas-fir and limber pine. Sagebrush/bunchgrass and mountain mahogany communities are common on the lower elevation and strong southerly exposures. Limber pine communities and alpine meadows exist at the high elevations. This subsection is rich in mining history with old mining sites and remnants of town sites. Located in the Birch Creek Valley are four preserved brick adobe charcoal kilns. Sixteen were originally built to furnish charcoal to the Nicholia Mine. This area also has a National Scenic Trail, two recommended wilderness (Italian and Diamond Peaks) and most big game species. This section of the Forest is entirely on the Dubois Ranger District.

Centennial Mountains - This subsection covers the Centennial Mountains between the east fork of Irving Creek and Reas Pass to the east. The Centennials, which form part of the Continental Divide, are a scenic mountain range with high mountain meadows scattered through spruce/fir and Douglas-fir forests. At lower elevations sagebrush/grasslands grade into Douglas-fir and lodgepole pine forests. Lionhead, in the northeast portion of the subsection, is a recommended wilderness. The major travel corridors are Highways 20 and 87, and a portion of Interstate 15. The Yale-Kilgore road is a secondary travel route connecting Island Park to Kilgore and Dubois. In the northeast portion of the subsection is Henry's Lake, a world renowned fishery. The western part is the Red Conglomerate range, home to at least one endemic sensitive plant species. This section of the Forest falls within the Dubois and Island Park Ranger Districts.

Island Park - This subsection includes the west half of Island Park, Ashton and the northwest portion of Teton Basin Ranger Districts. The landscape of this subsection features a large caldera. Highway 20 is the only major highway that travels through this subsection and Highway 47, a state Scenic Byway also

Figure III-1

occurs in this subsection. Among the many scenic attractions are Upper and Lower Mesa Falls, the last major undisturbed falls on the Upper Columbia River system. The Mesa Falls Scenic Byway, established in 1989, provides motorists with a breathtaking view of the Teton Mountain Range and accesses the two falls. The Island Park subsection offers excellent trout fishing at Island Park Reservoir and along the Henry's Fork, Buffalo River, Warm River, Fall River and Bitch Creek. The Island Park subsection is also known for its snowmachine trails, cross-country ski trails and summer home concentrations. Large scale timber harvest activity is evident due to the mountain pine beetle epidemics in 1960s and 1970s. Harriman State Park lies in the heart of the Harriman Wildlife Refuge, with 16,000 acres of forest, meadows, lakes and streams.

Madison-Pitchstone Plateaus - The largest portion of this subsection is actually in the Park. The section on the Forest falls within the Island Park and Ashton Districts next to the Park. The Jedediah Smith and Winegar Hole Wildernesses lie within this subsection, as does the recommended Idaho wilderness portion of Winegar Hole. The Ashton-Flagg Ranch and Fish Creek roads are the major access routes in this area. Grassy Lake is a 320-acre lake created when a dam was built by the Bureau of Reclamation in 1937-1939. Grassy Lake as well as other lakes and streams in the area are popular fishing areas and are accessed by the Flagg Ranch road. Several organized youth camps exist throughout this subsection. The Cave Falls road is the only motorized access to the southwest portion of the Park.

Teton Range - This area encompasses the west slope of the Teton Mountains. The Teton Range is a spectacular line of high peaks rising abruptly along the west side of Jackson Hole. The vegetation is a diverse mix of forested and nonforested plant communities. The Jedediah Smith Wilderness traverses the upper portions of the west slopes of the Teton Mountains. The Grand Targhee Ski Resort is a major tourist attraction within the subsection. Two organized youth camps are present. This area is known for its many backcountry trails which are accessible by horse or foot. This section of the Forest falls within the Ashton and Teton Basin Ranger Districts.

Big Hole Mountains - This subsection takes in all Forest lands between Highway 33 in Idaho and Highway 22 in Wyoming on the north and the South Fork of the Snake River to the south. Several major highways provide access. Idaho Highways 26, 31 and 33, and Highway 22 in Wyoming. Highway 31 is a State Scenic Byway over Pine Creek Pass. Vegetation consists of mountain brush, grass/forb openings, aspen and forests of Douglas-fir and lodgepole pine. The area has a variety of recreational opportunities including Kelly Canyon Ski Resort and backcountry hiking. Palisades Reservoir and the South Fork of the Snake River are used by water sports enthusiasts. This section of the Forest falls within the Teton Basin and Palisades Ranger Districts.

Caribou Range Mountains - This subsection is the portion of the Caribou N.F. administered by the Forest. It lies south of the South Fork of the Snake River. Steep mountain slopes and canyons dominate the landscape. The Palisades Reservoir is shared by this subsection and the Big Hole Mountains Subsection. Vegetation in this subsection forms a patchwork of tall sage/grass openings, aspen and mixed Douglas-fir/lodgepole pine forests. Recreation use is very similar to the Big Hole Mountains Subsection with high trail and backcountry use as well as hunting, fishing and water sports both on the reservoir and the Snake River. This area has several summer home divisions and two organizational camps. This section of the Forest falls entirely in the Palisades Ranger District.

PROPER FUNCTIONING CONDITION (PFC)

Ecosystems at any temporal or spatial scale are in a PFC when they are dynamic and resilient to disturbances to structure, composition and processes of their biological or physical components. Ecosystems can be assessed as to the sustainability of their biological and physical components and the risks associated with ecosystems which are degraded beyond the point of resiliency and sustainability. These assessments evaluate the structure, composition, disturbance regime and patterns of ecosystems. When combined with assessments of social and economic conditions, they can provide a basis for making decisions on how to best maintain and restore ecosystem sustainability in ways that achieve social and

economic expectations. The USDA Forest Service, Intermountain Region developed a methodology of assessing ecosystems used on the Forest and is described in the draft document titled, Proper Functioning Condition Process - 1996 (Process Paper W). This document incorporates methodologies from Riparian Area Management, Process for Assessing Proper Functioning Condition (Bureau of Land Management, TR 1737-9, 1993, 52 pgs.)

Range of Variability (ROV)

One component of PFC is the historical ROV which refers to the range of conditions under which ecosystems evolved and function through time. By understanding how ecosystems have functioned in the past and successfully maintained themselves, we gain insight into characteristics of healthy ecosystems. The ROV provides information about conditions under which plant and animal species evolved. Sustaining healthy plant and aquatic systems is an important part of ensuring that all ecosystem components, from wildlife and fish to microbes and fungi, are maintained.

ROV is not a desired condition nor a target state for ecosystems. It encompasses the entire historic set of the many conditions that have existed on a given landscape during a given time period. Past conditions can provide reference points, like benchmarks, which can be used to predict successional development or the response of ecosystem elements, such as wildlife or plant communities, to management intervention. Understanding ROV helps us understand how systems will respond to different management options or no management action at all.

Information about ROV prior to 1900 is limited, but we do have some knowledge of how the Forest has changed over recent history. The Forest is in the process of analyzing historical maps, photographs and literature to better understand the ROV, both natural and human-caused. As part of assessing PFC, ROV of ecosystems will be identified for disturbance regimes, patterns, composition and structure. Cooperative projects with the scientific community will continue to be used to promote understanding of historical vegetation patterns and watershed function.

ECOLOGICAL PROCESSES AND PATTERNS

ECOLOGICAL PROCESSES AND DISTURBANCES

Ecosystems constantly change across both time and space. Change is brought about by many different processes and disturbances that occur over varying time frames and spatial scales. For example, fire is a disturbance process that can burn thousands of acres of forestland within a matter of hours. On the other hand, it may take millions of years for a stream to carve a canyon through the process of erosion. Some disturbances are relatively predictable, while others happen in utterly unpredictable, random ways. Humans can have a great impact on some of these processes, as discussed below. Ecosystem processes and disturbances are never independent from one another. Any given process will change resource conditions, which then sets the stage for some other agent to act.

While there are innumerable processes occurring in an ecosystem, we have focused on only a few that are most likely to be affected by the alternative management schemes being analyzed in this FEIS. This section will only examine "natural" disturbances, not those associated with human activities such as grazing, timber harvest and roading.

Succession - Scale: Community Type

Succession is the process by which plant communities change through time if they are undisturbed. This process usually begins with pioneer species invading bare ground. These early seral plants change the environment by their presence to the point where other more shade-tolerant plants can take over the site. These plants then modify conditions further by their leaf litter and shade, making the site more hospitable.

to yet another set of plant species which replaces them. The gradual progression from early to late seral communities continues unless interrupted by a disturbance such as wind or fire.

Due to the control of fire on the Forest since the early 1900s, succession has become a dominant ecosystem process in the unharvested portions of the Forest. Late seral communities are prevalent in herbaceous/shrub ecosystems as well as in most forest types.

Herbaceous/Shrub Communities - The process of succession in these areas generally begins following fire and is characterized by open grassland interspersed with a few shrub species. Mountain big sagebrush and other shrubs begin to dominate after five to ten years. As they compete with the grasses for water, the grasses lose vigor and die out. Sagebrush provides shade for Douglas-fir seedlings, which may take over the site as a dominant community type until fire sets it back to grassland. In the absence of a Douglas-fir seed source, the area may become a sagebrush-dominated community.

Fire suppression on the Forest has allowed a significant acreage of the herbaceous and shrub communities to convert to Douglas-fir or dense sagebrush. This varies from historical conditions where mosaics of different-aged sagebrush/grassland stands existed, and where stands dominated by herbaceous species were more common. Some high mountain meadows are also being reduced in size by conifers encroaching in from the edges.

Forest Communities - Succession can vary a great deal depending on climate and soils in forested systems, but it generally begins with early seral species such as aspen and lodgepole pine, then progresses to shade-tolerant climax species. Aspen is a relatively short-lived tree which may give way to lodgepole pine or Douglas-fir communities after approximately 100 years. The mountain pine beetle commonly attacks lodgepole pine after 80 to 120 years, allowing more shade-tolerant species to take over. Douglas-fir will likely then dominate on warmer, drier sites, while subalpine fir and Engelmann spruce dominate in colder areas. Douglas-fir, subalpine fir or Engelmann spruce generally form long-lived climax communities until a disturbance occurs.

Much of the aspen acreage that was present historically on the Forest has been converted to Douglas-fir through the succession process. In addition, aspen stands are overwhelmingly in the mature or older age classes. These conditions have resulted from fire suppression. Succession at higher elevation sites has resulted in subalpine fir and Engelmann spruce becoming intermixed with whitebark pine. With continued absence of fire, the whitebark pine will likely give way to the spruce and fir.

Eighty percent of the forested land is in the mature age class (the mature age class includes old growth and late seral forests). This is primarily a result of fire suppression. Historically fire produced a greater variety of age classes over the landscape. Mature age classes include old growth and late seral forests and provide important wildlife habitat for some species. They are also more susceptible to stand-replacing fires and mortality from insects than most early-seral communities.

Old Growth and Late Seral Forests - Scale: Vegetation Type, Subsection and Forestwide

OLD GROWTH

Old Growth Characteristics - In 1993, the Intermountain Region completed a report on the characteristics of old growth forests in the Intermountain Region (USDA Forest Service 1993). Table III-1 summarizes the characteristics of old growth forests as described in the 1993 publication. These characteristics are the old growth definitions for the Revised Plan. More description about old growth characteristics can be obtained from the complete report.

Old Growth Inventory and Analysis - The Forest does not have a complete old growth inventory. However, an analysis of 412 permanent forest inventory plots was completed to assess what percent of the forested acres meet the old growth characteristics and to gain an idea of the potential distribution of old growth.

Tabel III-1 Summary of Characteristics of Old Growth Forests in the Intermountain Region (USDA Forest Service 1993)

* All figures are less than or equal to, unless shown as a range of numbers

DBH = diameter at breast height, in inches

TPA = trees per acre

Age = years

6" DBH Classes = number of recognizable size classes that differ by at least 6 inches in diameter

Tree Decadence = tree decadence, number of trees per acre of a minimum DBH showing signs of disease or injury of some kind

Canopy Layers = number of recognizable canopy layers

Ht = height in feet

Dia = diameter of downed logs in inches

#/Acre = number of downed logs per acre

Length = minimum length (in feet) of downed logs

Evidence = some evidence of tree decadence but no minimum requirement for tpa or dbh

NA = information is not available for this parameter, or this parameter is not applicable for this old growth type

? = the old growth definitions are not clear on what this parameter should be

For this analysis, data from the 412 permanent forest inventory plots contained information on the old growth characteristics for live trees and standing dead trees. Data on downed dead trees was not available. If some of the plots were deficient in downed dead trees, then our calculation pertaining to the quantity of old growth will be high.

The 412 permanent inventory plots were measured in 1990 and 1991. Since the plots were measured in 1990 and 1991, we added five years to all of the tree ages to account for time. We also added 1-inch to all of the diameter at breast height (dbh) measurements to allow for growth. Adding 1-inch dbh is probably optimistic for old trees, but we did not want to eliminate plots which were close to the minimum required dbh.

In this examination, we did not include any plot which had less than 50 live trees per acre that were 1-inch dbh or larger. This was done to eliminate those stands which have had some kind of first entry logging, such as a seed tree cut. Also, it would be very difficult for any plot to qualify as having two canopy layers or two dbh size classes with less than 50 live trees per acre.

Further details of this analysis are described in Process Paper D.

Table III-2 displays the 36 plots (8.7 percent of the total 412 plots) which meet all of the old growth characteristics that could be determined from the permanent forest inventory plots. These plots were located in the Lemhi Mountains, Medicine Lodge, Centennial Mountains, Madison-Pitchstone Plateaus, Teton Range and Big Hole Mountains Subsections (Figure III-2). No old growth plots were found in the Island Park and Caribou Range Mountains Subsections.

LATE SERAL FOREST

Late Seral Forest Characteristics - Late seral forests meet some of the old growth characteristics as defined in Table III-1, but do not meet all of the characteristics. Late seral forests provide some of the structural and functional attributes of old growth forests. We characterized late seral forests in three categories as follows:

- 1) Forests which meet the live tree characteristics for old growth, but do not meet the standing dead tree characteristics for old growth.
- 2) Forests which partially meet the live tree characteristics for old growth, in that there are one or more live trees per acre that meet the minimum dbh and age requirement for old growth, but the number of live trees per acre is less than the old growth characteristic requirements.
- 3) Forests which have live trees which meet the minimum dbh requirements for old growth, but no live trees meet the age requirements for old growth.

Late Seral Forest Inventory and Analysis - The Forest does not have a complete late seral forest inventory. However, an analysis of 412 permanent forest inventory plots was completed to assess what percent of the forested acres meet late seral forest characteristics and to gain an idea on the potential distribution of late seral forests.

Further details of this analysis are described in Process Paper D.

The number of permanent forest inventory plots meeting the three categories of late seral forest is as follows:

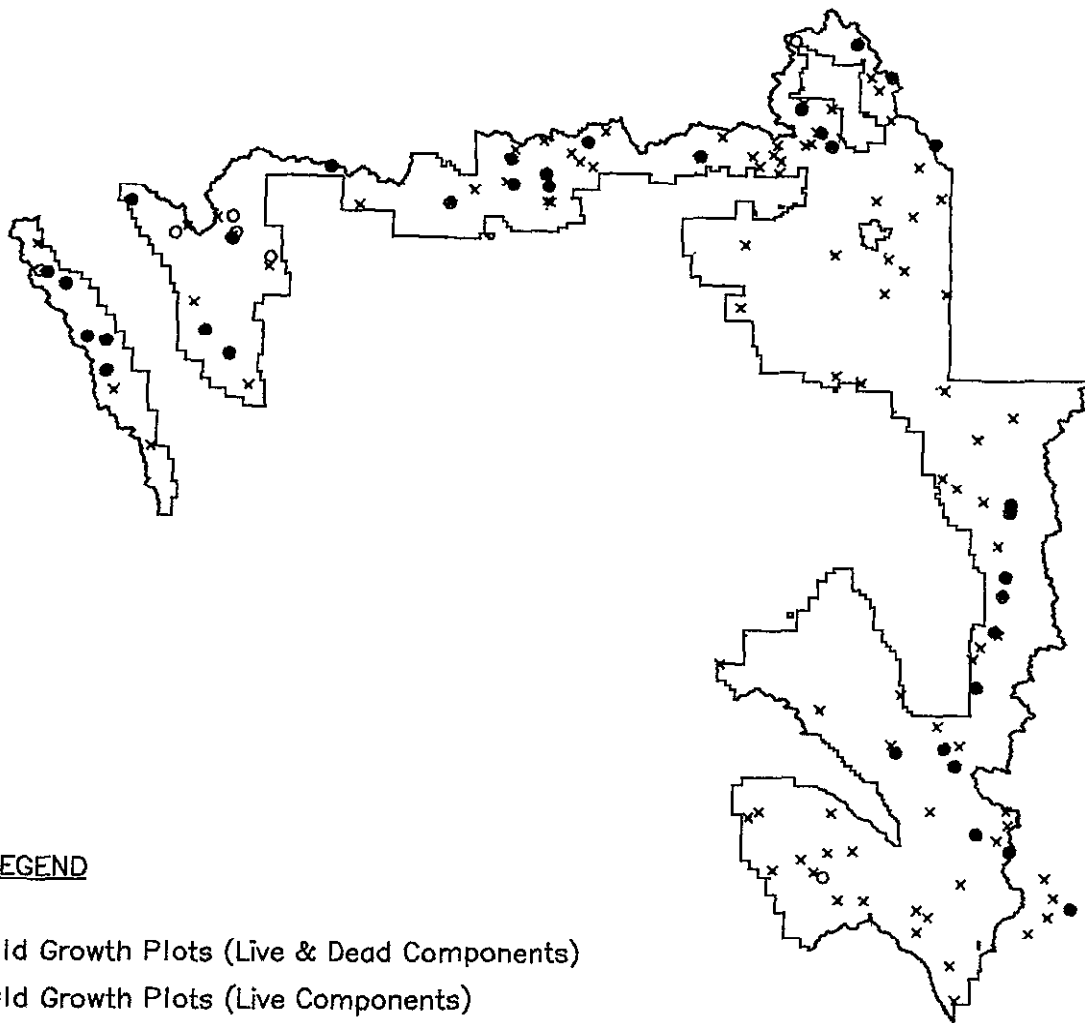

- 1) A total of seven plots (1.7 percent of the total 412 plots) meet the live tree characteristics for old growth, but do not have the required number of snags. These plots are located in the Lemhi Mountains, Medicine Lodge, Centennial Mountains and Caribou Range Mountains Subsections.
- 2) A total of 89 plots (21.6 percent of the total 412 plots) partially meet the live tree characteristics for old growth, in that there are one or more live trees per acre that meet minimum dbh and age requirements for old growth, but the number of live trees per acre is less than the old growth characteristic requirements. These plots are located in all subsections.
- 3) A total of 186 plots (45.1 percent of the total 412 plots) have live trees which meet the minimum dbh requirement for old growth, but no live trees meet the age requirements for old growth. These plots are located in all subsections.

In the previous section on Succession, it was stated that 79.6 percent of the forested acres are in the mature class. This analysis provides a further refinement of the mature age class as follows:

- 10.9 percent of the mature age class meets old growth characteristics for live trees and standing dead trees
- 2.1 percent of the mature age class meets live tree old growth characteristics
- 27.1 percent of the mature age class partially meets the live tree old growth characteristics
- 56.7 percent of the mature age classes have live trees that meet minimum dbh requirements, but do not meet the age requirements
- 3.2 percent of the mature age classes have mature trees with dbh smaller than old growth requirements

Subsection	Plot Number	SAF Cover Type
Lemhi Mountains	59	Douglas-fir, low productivity, also contains old growth limber pine trees
	60	Spruce/Fir - cold/dry, also contains old growth limber pine trees and Douglas-fir
	61	Spruce/Fir - cold/dry, also contains old growth limber pine trees and Douglas-fir
	62	Limber pine - lower timberline, also contains old growth spruce/fir trees
	64	Douglas-fir, low productivity
	359	Qualifies as both Douglas-fir - low productivity and Limber pine - lower timberline
Medicine Lodge	357	Douglas-fir - low productivity
	51	Douglas-fir - low productivity
	52	Spruce/Fir - cold/dry, also contains old growth limber pine trees and Douglas-fir
	46	Qualifies as both Spruce/Fir - cold/dry and Douglas-fir - low productivity
Centennials	39	Spruce/Fir - cold/dry, also contains old growth Douglas-fir trees
	34	Douglas-fir - low productivity
	26	Douglas-fir - low productivity
	28	Douglas-fir - low productivity
	16	Douglas-fir - low productivity
	18	Douglas-fir - low productivity, also contains old growth lodgepole pine and spruce/fir.
	12	Spruce/Fir - cold/dry
	88	Douglas-fir - low productivity
	79	Douglas-fir - low productivity
	221	Douglas-fir - low productivity
	69	Douglas-fir - low productivity
188	Spruce/Fir - cold/dry	
616	Qualifies as both Spruce/Fir - cold/dry and Douglas-fir - low productivity	
Madison Plateau	190	Spruce/Fir - cold/dry
Teton Range	343	Spruce/Fir - cold/dry, also contains old growth limber pine and Douglas-fir trees
	344	Spruce/Fir - cold/dry, also contains old growth lodgepole pine trees
	391	Aspen - mesic
	348	Spruce/Fir - cold/dry, also contains old growth Douglas-fir trees
	143	Spruce/Fir - cold/dry
	137	Spruce/Fir - cold/dry
Big Hole/Palisades	122	Spruce/Fir - cold/dry
	127	Spruce/Fir - cold/dry
	113	Spruce/Fir - cold/dry, also contains old growth Douglas-fir trees

Figure III-2

Fire - Scale: Vegetation Community and Subsection

Historically fire has played a significant role in the GYA. Some plants have evolved with fire and have adapted to it in various ways. Fires occurred naturally at certain average time intervals, which varied by vegetation and climatic conditions. Fires were also set by humans on a fairly regular basis, particularly in the sagebrush/grass and aspen communities. These fires created mosaic patterns of different seral stages of vegetation across the landscape.

In the early 1900s public concern for protecting the forests from fire ushered in a period of aggressive fire suppression which has continued to the present. With these suppression strategies and the lack of a prescribed fire program, the fire intervals which occurred historically have been altered. Due to the absence of fire, much of the forest vegetation has reached the mature age class (see Table III-3) and herbaceous/shrub types are in the later stages of succession. The mosaic patterns in the landscape are not as prevalent as before. These conditions increase the potential for fires of higher intensity which may be detrimental to species that evolved with frequent, low intensity burns.

There are no approved fire management plans on the Forest. All previous fire management plans were suspended as a result of the 1988 Yellowstone fires.

Fire frequency intervals and behavior vary widely among the different vegetation communities, so each is described separately in the following discussion.

Douglas-fir Fire Regimes - It appears that Douglas-fir forests in this area historically had a fire interval of 20-50 years. These fires were generally low ground fires which tended to thin the stands, favoring large, older Douglas-fir trees with thick bark. Fire suppression has led to conditions on the Forest where most Douglas-fir stands have multiple stories and dense stocking (trees/acre). Trees of various heights provide a "ladder" for fire, allowing it to reach the tree crowns. Absence of frequent ground fires can cause dead fuels to build up over time. Fires which start under these conditions are much more severe than ground fires and tend to replace the Douglas-fir with earlier seral species such as aspen or lodgepole pine (Bradley et al. 1992).

Lodgepole pine Fire Regimes - In this area between the years 1200 and 1700, major fires occurred in the lodgepole pine component approximately every 100 years. Stand-replacement fires in lodgepole pine are closely tied to epidemics of the mountain pine beetle. Tree mortality caused by the beetle creates massive amounts of fuel. Fires which start under such conditions are likely to be severe. This cycle of beetles, fire and stand replacement is part of lodgepole pine's evolutionary history in the Rocky Mountains. We witnessed this cycle on the Forest beginning with beetle epidemics in the 1960s and ending with large fires such as the North Fork Fire in 1988. Conditions for these large fires still exist in much of the Forest's mature lodgepole pine.

Most lodgepole pine, with the exception of that on cool moist sites, historically experienced low intensity fires every 40-60 years. Fire suppression has interrupted this portion of the lodgepole fire cycle on the Forest. The effects of this are likely not too serious, since conditions created by the mountain pine beetle are similar to those created by light ground fires (stands are thinned and regeneration may fill in the understory) (Personal comm., Brown 1993, Bradley et al. 1992, USDI National Park Service 1993, Management of Lodgepole Pine Ecosystems 1973).

Aspen Fire Regimes - The average fire-free period historically was 40 years or longer for pure aspen stands. Fire in aspen has been reduced in size and frequency throughout the West due to fire control and the cessation of intentional burning. Fire suppression on the Forest has resulted in many aspen stands that are now mixed, or overtaken by, conifers such as Douglas-fir or lodgepole pine. If left undisturbed for long periods of time, conifers can change the soil characteristics so that aspen is less likely to survive (Cryer & Murray 1992). Mixed conifer/aspen stands are conducive to large stand-replacing fires. If such fires were allowed to occur, they would likely lead to pure aspen regeneration providing the fires were not

1/ The mature category incorporates all older age classes, including old growth

2/ Includes acres of mature forest that have had harvest treatments such as commercial thinning or shelterwood seed tree cuts, but the harvest did not result in reclassifying the acres to a different age class

so severe as to destroy the aspen root systems. Moderate severity fires result in better aspen sprouting than either high or low severity fires (Bradley et al. 1992).

Subalpine Fir Fire Regimes - Subalpine fir forests generally occupy cool, moist habitats and are therefore common at higher elevations. Because of this, fire is relatively infrequent in this type, occurring every 50-350 years depending on aspect, elevation and other factors. Large fires generally occur only during drought conditions and periods of high winds. Ladder fuels are common in this type, so fires can spread easily between tree crowns and burn large acreages (Bradley et al. 1992).

Sagebrush/Grassland Fire Regimes - Historically, fires likely occurred every 10 to 25 years in the Forest's sagebrush communities (Clark and Starkey 1990, Houston 1973, Winward 1987). These fires created a mosaic of vegetation conditions across the landscape. In the absence of fire, these communities tend to progress toward stands of Douglas-fir or dense sagebrush. Dense sagebrush stands are less diverse than sagebrush/grasslands, and more susceptible to soil erosion because the herbaceous vegetation is lacking. Much of the sagebrush/grassland on the Forest and throughout the west is in advanced seral stages due to the absence of fire (Winward 1992).

Whitebark pine Fire Regimes - Fires are important to the survival and regeneration of whitebark pine. This species can survive surface fires which kill other tree species that compete with it. Since whitebark pine reproduces on fire-prepared sites, stand-replacing fires help perpetuate the species. Historically, fire occurred in whitebark pine communities every 30-300 years. Suppression of fires has favored subalpine fir and Engelmann spruce over whitebark pine. Other disturbance agents affecting whitebark pine are white pine blister rust and mountain pine beetle (Morgan et al. 1994), which are discussed in the insect and disease section.

Fire Risks

The Forest has experienced large fires in five of the past 20 years, three of those were within the last eight years. Two fires exceeded 5,000 acres. One was a prescribed natural fire that was allowed to burn until it exceeded the prescription parameters of the High Country Fire Plan. That fire was the Gallagher Peak Fire of 1979. The other was the North Fork Fire, one of the Greater Yellowstone Fires of 1988. Approximately 17,691 acres of the 507,580-acre North Fork Fire burned on the Forest. The size or scale of historic fires on the Forest is unknown at this time, but it is likely that the North Fork Fire emulated the size of fires that historically occurred in the lodgepole pine types.

Development of private lands adjacent to the Forest has made a significant increase in the wildland/urban interface. To deal with the threat of a wildland fire within or adjacent to these areas, Emergency Evacuation Plans are being developed such as the one for the North Fire Zone in Island Park. All wildland fires, including natural ignitions, receive the appropriate suppression response of contain, confine or control. The following briefly summarizes fuels and other conditions which contribute to fire hazard within the subsection.

Lemhi/Medicine Lodge and Centennial Mountains - These subsections are dominated by sagebrush/grasslands and Douglas-fir communities. The Centennial Mountain Subsection has had substantial timber management activities, which have reduced fuels on some areas. The wildland/urban interface in the Centennial Mountains has significantly increased due to the development of private lands within the Forest protection boundary. This increases the risk of a fire spreading between the Forest and private lands.

Island Park - The vegetation in this subsection is primarily lodgepole pine. This area has heavy recreation use during all seasons, which increases the potential of human-caused fires. Timber management activities has reduced much of the natural fuel loadings, but there are some lodgepole pine stands with heavy accumulations of dead material. These stands are generally isolated by the surrounding young stands.

from timber harvest activities. This subsection has seen an increase in the wildland/urban interface with the development of private land. Areas with high summer home densities also present fire risks in this subsection.

Madison-Pitchstone Plateaus - The dominant vegetation is lodgepole pine. Timber activities have been widespread, significantly reducing fuel loadings. There are still high concentrations of dead fuels in stands not treated, but these areas are generally adjacent to young stands created by clearcuts. This subsection includes the area burned by the North Fork Fire. The Winegar Hole Wilderness is located in the southern portion of this subsection. Natural and human-ignited fires in this wilderness have been suppressed.

Teton Range - A large portion of this subsection is grass forb vegetation, with forests of Douglas-fir, lodgepole pine and mixed conifers also being common. The Jedediah Smith Wilderness covers a major portion of the subsection. Since 1988 natural and human-caused fires have not been allowed to burn in the Wilderness.

Big Hole Mountains - The primary vegetation types are mixed conifer and mountain brush. Most of this subsection is roadless and primarily used for grazing and recreation. The recreation use can increase the potential of human-caused fires.

Caribou Range Mountains - Mixed conifers and sagebrush/grass communities dominate the subsection. Some timber management has occurred in the Engelmann spruce/subalpine fir type, and subsequent fuel treatments have reduced fuel loading and rate of fire spread for the short-term. Recreation use here can increase the potential for human-ignited fires.

Insects & Diseases - Scale: Forestwide and Subsection

Insects and diseases play important roles in ecosystems, even those often considered "destructive." Many of these organisms serve as food sources for a variety of wildlife species, ranging from birds to grizzly bears. In addition they are change agents, causing death, decay or damage to vegetation. This latter function is closely intertwined with the processes of succession and fire. The change from one species community to another on a site is often brought about by insects and diseases, particularly when fire is absent. For example, aspen is eventually killed by fungal diseases which may then allow Douglas-fir to dominate. Insects can change forest structure by killing all trees of a particular size or species. Insect-killed trees contribute to fuel conditions and thereby help determine the severity, size and patterns of fires in the landscape.

Most native insects and diseases are opportunistic, taking their toll on weakened or aged individuals. However, under some conditions these organisms may build up high populations that also overwhelm healthy, young vegetation. Trees and plants are usually adapted to insects and diseases, having evolved with them. The exception to this is when damaging agents are introduced from another continent and the plants have not had time to adapt genetically. This can often lead to disastrous consequences for a tree species, such as the American chestnut which fell victim to an introduced fungus. A concern about whitebark pine exists on the Forest and throughout its range. Whitebark pine is dying off at an alarming rate due to an introduced disease known as white pine blister rust. Although there is genetic resistance to this disease, the number of whitebark pine trees is expected to decrease significantly in the short term.

Native insects of importance on the Forest include the mountain pine beetle, Douglas-fir beetle, western balsam bark beetle and western spruce budworm. Mountain pine beetle populations have remained at low levels since 1983. Between 1981 and 1987 western spruce budworm was active in the Douglas-fir on the Forest. This insect stressed the trees to the extent that Douglas-fir beetles were able to kill many Douglas-fir between 1988 and 1992. Additional information on these insects may be found in the Analysis of the Management Situation for the Forest (USDA Forest Service, Targhee N.F. 1992). Stalactiform rust, gall rust and various root rots are common fungal diseases. Dwarf mistletoes (parasitic plants) are

present on lodgepole pine across the Forest and Douglas-fir in more isolated pockets. Important existing insect and disease conditions for each subsection are briefly covered in the Vegetation section of forest ecosystems.

ECOLOGICAL PATTERNS

The ecosystem processes and disturbances discussed above contribute to patterns of vegetation across the landscape. Other factors such as climate, topography and soils also help determine vegetation patterns. The patterns themselves are important to other components of the ecosystem such as wildlife species and humans. Vegetation patterns have a ROV which the Forest is seeking to more fully understand. We have chosen to analyze four measures of ecosystem patterns that we believe are most important on the Forest. A brief discussion of each follows.

Forest Structure and Composition - Scale: Subsection

Natural and human disturbances tend to break up large tracts of similar forest habitat into smaller blocks separated by openings, different vegetation types, or different age classes. Patch sizes varied historically based on topography, soils and scale of disturbances. Forestwide they are affected by all these factors, including human activities such as roading and clearcutting. Patch size is important since some wildlife species are adapted to using extensive forested areas.

Conditions on the Forest vary by subsection. The Caribou Range Mountains, Big Hole Mountains and Lemhi/Medicine Lodge Subsections have historically exhibited small patch sizes due to their physiographic conditions. This continues to be the case. Clearcutting over the past decade in the Island Park and Madison-Pitchstone Subsections has created smaller patch sizes than occurred historically. The Teton Range and Centennial Mountains Subsections are likely exhibiting larger patch sizes than they did historically due to fire suppression and the current predominance of forests in mature age classes.

Vegetation Types - Scale: Subsection

The distribution of forested community types and age classes by subsection is displayed in Table III-3. Studies to date show that the Forest's vegetation has changed in some significant ways over the past century. Preliminary analysis indicates that some vegetation conditions are different than what occurred historically on the Forest.

In some subsections aspen has declined by 80 percent, while in others aspen acreage has increased in the past two decades due to clearcutting (USDA Forest Service, Targhee N F 1994). Aspen decline is most serious in the Lemhi/Medicine Lodge, Centennial Mountains, Big Hole Mountains and Caribou Range Mountains Subsections.

The amount of whitebark pine has been reduced over the past 30 years as a result of mountain pine beetle, white pine blister rust and succession. The seeds of this tree are an important food source for grizzly bears, some birds and small mammals.

Shrublands and grasslands are less prevalent than in the past due to fire suppression. This indicates a habitat loss for species dependent on these communities and a habitat gain for species adapted to forested areas. The greatest changes have occurred in the Lemhi/Medicine Lodge, Centennial Mountains, Big Hole Mountains and Caribou Range Mountains Subsections.

Stand structures, particularly in the Douglas-fir forests, have changed as a result of fire suppression. Compared to past structures, these stands are now denser and more multi-storied. This has increased the likelihood of severe fires, increased the susceptibility to insects and diseases and altered the type of habitat provided by Douglas-fir forests. These conditions are found in all subsections.

The Forest has much more area in mature age classes than the historical record indicates. Of particular significance are the high percentages of mature or older mountain mahogany, mountain big sagebrush, aspen, cottonwood and Douglas-fir. Mosaics of different age classes were more common in the past.

Connectivity - Scale: Forestwide and Subsection

Connectivity between habitat areas involves the linkage of similar habitat patches such as water courses, natural openings or as most commonly studied, vegetation. The maintenance of connectivity is needed to ensure proper levels of nutrient cycling, hydrologic function and species survival. If the level of connectivity is maintained over time and space, then processes such as predation, dispersal and gene exchange continue even though habitat areas may be separated from each other. Species differ in their need for corridors between blocks of habitat, with some moving freely through the landscape while others tend not to cross openings between habitat areas. Specific habitat linkage requirements for various species have not been determined. However, species evolved to function within certain limits of connectivity shaped by natural disturbances. Maintenance of vegetation patterns with which plant and animal species evolved is an accepted measure of ecosystem health.

Connectivity is influenced by access routes and clearcuts, as well as by historic vegetation patterns. Connectivity in the Caribou Range Mountains, Big Hole Mountains and Lemhi/Medicine Lodge Subsections is likely similar to what existed historically based solely on the vegetation patterns. However, human access routes may have reduced the ability of species to move between habitat blocks. Clearcutting and roading over the past decade in the Island Park and Madison-Pitchstone Subsections have altered vegetation patterns and connectivity from what existed historically. Although leave strips have provided continuity of mature forest habitat, these links are much narrower and more randomly distributed across the landscape. Based on vegetation patterns alone, the Teton Range and Centennial Mountains Subsections are likely exhibiting similar or greater connectivity than historically due to fire suppression and the current predominance of forests in mature age classes. However, the presence of roads and trails in the subsections may have reduced some species' ability to move between habitat blocks.

Connectivity is important in aquatic, as well as forested ecosystems. Natural disturbance forms patterns of habitat patches, which in turn control aquatic ecosystem processes and functions (see "aquatic and riparian ecosystem" section). Natural and human-induced disturbances affect the connectivity of riparian areas and the linkages between aquatic and forested ecosystems. Where road crossings and concentrated human activity exist in aquatic ecosystems, it can be assumed that some level of connectivity has been lost compared to what existed historically.

Adjacent Land Use Patterns - Scale: Forestwide

Lands adjacent to the Forest are part of the ecosystem. Uses of these lands affect the Forest, and management of the Forest likewise affects adjacent ownerships. This all plays into the larger social and ecological context in which the Forest is managed. Lands next to the Forest represent many different owners and management strategies. Adjacent entities include private landowners, Harriman State Park, Idaho Department of Lands, the Park and GTNP, John D. Rockefeller Memorial Parkway and the U.S. Sheep Experiment Station. In addition, several N.F. and BLM Districts lie adjacent to the Forest.

Dominant land use patterns on adjacent private lands involve farming and ranching. These activities have occurred since the 1800s in this area. The past decade has brought a trend toward subdivision developments, particularly in Teton Valley, Island Park and Swan Valley. On lands administered by the Idaho Department of Lands, other N.F. and the BLM, management tends to be oriented toward use of resources, with timber harvest, livestock grazing and recreation being common activities. National Parks are governed by the principles of preservation and noninterference with natural processes, but have intensive recreation management in some areas.

An Adjacency Study (Process Paper P) shows how the Forest fits into the management of neighboring

lands For the most part there is a sense of continuity across the borders of the Forest into adjoining N F , BLM, and National Park Service lands Probably the single most visible discontinuity lies along the Park's western boundary where evidence of the Forest's intensive timber management can be seen in sharp contrast to the Park's unmanaged forest That apparent discontinuity will continue until the young regeneration grows and blends with older surrounding vegetation

There are other land management practices on the Forest which might appear to be incongruent to some people and understandable to others The Grand Targhee Ski Resort, an area of concentrated recreation development, shares much of its boundary with the congressionally-proclaimed Jedediah Smith Wilderness The ski resort and the wilderness uses remain in effect in all the alternatives Likewise, some people view the presence of a road alongside a wilderness as being incongruent Others accept the fact that roads, as an exclusionary feature in a wilderness, will frequently end up being used to define its boundaries

From a Forest point of view, management of adjacent lands seems to have more of an impact on Forest management than vice versa As the human population of the area of influence has grown so has their use of the Forest, particularly recreational use The Forest has had to respond to those changes by hardening recreation sites to prevent damage to the resource and developing reasonable restrictions on some uses

PHYSICAL ELEMENTS OF THE ENVIRONMENT

Soils and Geology - Scale: Subsection

Lemhi/Medicine Lodge - This subsection consists of fault block mountains, which exhibit a northwest-southeast trend The dominant rock types are limestone and sandstone The landscape is dissected by parallel drainage systems

Soils on these landscapes are greater than 60 inches to bedrock, having gravelly medium textured surface layers and extremely gravelly medium textured subsurface layers These soils have a low to moderate inherent fertility, are droughty, are high in carbonates and have a high erosion hazard

Principal ecological concerns affecting soil quality in the subsection are as follows the expansion of conifers into sagebrush/grass and riparian communities has changed some sites, the area's susceptibility to fires has increased the risk of losses in soil productivity associated with such events and canopy density of sagebrush communities and subsequent loss of understory vegetation has led to declining watershed conditions

The principal management activities affecting soil quality are roads, grazing concerns along incised drainages and OHV use Secondary management activities affecting soil quality include water developments and mining impacts which have not been reclaimed

Centennial Mountains - This subsection consists of a fault block mountain range, which exhibits an east-west trend along the Continental Divide The dominant rock types are rhyolite, sandstone and shale The landscape is dissected by dendritic and parallel drainage systems

Soils on these landscapes are greater than 60 inches to bedrock, having nongravelly to gravelly medium to medium-fine textured surface layers and gravelly to extremely stony medium to medium-fine subsurface layers These soils have a moderate to moderately high inherent fertility, are susceptible to compaction and puddling, have a moderate to high erosion hazard, exhibit plant competition concerns and demonstrate slumping hazards on mountain side-slopes and escarpments at higher elevations

Principal ecological concerns affecting soil quality include conifers expanding into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes, increased risk of losses in soil productivity associated with fire events, canopy density of sagebrush communities and subsequent loss of understory vegetation which is causing declining watershed conditions, and slumping potentials

Principal management activities that are concerns affecting soil quality include roads and OHV use, dispersed recreation impacts, grazing concerns along drainages and water developments. Secondary management activities that are affecting soil quality include mining impacts which have not been reclaimed, past timber/firewood harvest which have resulted in roads, compaction, organic matter removal or displacement and loss of woody residue

Island Park - The Island Park Caldera was formed by the collapse of a large rhyolite shield volcano. After the collapsing of the caldera, volcanic activity continued, resulting in basalt flows covering much of the caldera floor. The entire subsection has been overlain by wind blown silts (loess). The dominant rock types are rhyolite and basalt. The landscape is dissected by dendritic and parallel drainage systems on the caldera rim and associated tablelands. The caldera floor has very little dissection.

Soils on these landscapes are greater than 60 inches to bedrock, having nongravelly to gravelly medium textured surface layers and medium fine to extremely cobbly medium textured subsurface layers. These soils have a moderately low to moderate inherent fertility. Soils on the caldera floor have plant competition concerns on deeper soils, reforestation concerns on more shallow soils, and a moderate susceptibility to compaction. Soils on the caldera rim have a moderate susceptibility to compaction, moderate to high erosion hazard, low bearing strength and plant competition concerns.

A principal ecological concern affecting soil quality (limited to the caldera rim) is the expansion of conifers into aspen, sagebrush/grass, riparian and mountain meadow communities and resulting site changes and landscape patterns on structure and composition.

Principal management activities affecting soil quality (caldera rim) are roads, OHV use, and extensive past timber/firewood harvest which have resulted in roads, compaction, organic matter removal or displacement and loss of woody residue. Principal management activities (caldera floor) are the same as for the rim, plus dispersed recreation, which is especially heavy near summer home areas, and grazing along certain riparian areas and meadow complexes.

Madison-Pitchstone Plateaus - This subsection consists of a large consolidated ash flow that came out of the Park and overtopped the east rim of the Island Park Caldera. The landscape is dissected by dendritic and parallel drainage systems.

The soils in the northern part are greater than 60 inches to bedrock, having medium textured surface layers and stratified gravelly coarse textured to extremely gravelly coarse textured subsurface layers. The soils in the southern part are greater than 60 inches to bedrock, having gravelly medium textured surface layers and very gravelly to extremely cobbly medium textured subsurface layers. These soils have a moderately low inherent fertility, are droughty and have windthrow hazards. They are highly erodible if the subsoil is exposed, as it is in the northern part of this subsection due to the North Fork Fire.

A principal ecological concern affecting soil quality (southern portion) is the susceptibility to fires, increasing the risk of losses in soil productivity associated with such events, including areas on the 1988 North Fork Burn that have not recovered yet.

Principal management activities affecting soil quality include roads and OHV use, dispersed recreation, effects associated with timber harvest which have resulted in roads, compaction, organic matter removal or displacement and loss of woody residue.

Teton Range - North-south trending mountain range. The dominant rock types are granite, limestone, sandstone, dolomite, slate, gneiss and quartzite. The landscape is dissected by parallel drainage systems.

This subsection consists of two primary landscape settings. These include foothills on lower to mid elevations and mountain side-slopes at mid to high elevations. Soils on these landscapes are 40 to greater than 60 inches to bedrock, having nongravelly to very gravelly medium textured surface layers and gravelly to extremely stony medium textured subsurface layers. These soils have low to moderately low inherent fertility, low to moderate compaction hazard, moderate to high erosion hazard, reforestation concerns and low to high mass instability hazards.

Principal ecological concerns affecting soil quality in this subsection include conifer expansion into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes, and the area's susceptibility to fires with increased risk of losses in soil productivity associated with such events.

Principal management activities affecting soil quality include roads, grazing along drainages, OHV use and dispersed recreation. Secondary management activities affecting soil quality include the effects of timber harvest which have resulted in road construction, compaction, organic matter removal or displacement and loss of woody residue.

Big Hole Mountains - This subsection consists of a mountain range of multiple, parallel overthrusts (faults) and benches of mixed rocks and eolian material that have been modified by thrust faulting.

Soils on these landscapes are greater than 60 inches to bedrock, having gravelly medium textured surface layers and very gravelly moderately coarse to moderately fine textured subsurface layers. These soils have a moderate to high inherent fertility, moderate compaction and rutting hazard, moderate to high erosion hazard, moderate to high slumping and earthflow hazard, plant competition concerns and areas of low bearing strength.

Principal ecological concerns affecting soil quality include conifer expansion into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes, increased risk of losses in soil productivity associated with fire events, canopy density of sagebrush communities and subsequent declining watershed conditions and slumping/earth flows.

Principal management activities affecting soil quality are roads, OHV use, dispersed recreation and grazing along drainages. Secondary management activities affecting soil quality include erosion along sheep driveways, effects resulting from timber harvest and big game feeding areas along Rainey Creek.

Caribou Range Mountains - The Caribou Range Mountains Subsection is a southeast to northwest trending overthrust (multiple faults) mountain range. The northeast side of the range is moderate relief mountains on mixed sediments. The southwest side of the range is low relief foothills and basins on fine-textured marine sediments. The dominant rock types are a mix of sedimentary materials with a loess influence. The landscape is dissected by dendritic drainage systems.

Soils on these landscapes are greater than 60 inches to bedrock, having medium textured surface layers and moderately-coarse to fine textured subsurface layers. These soils have a moderate to high inherent fertility, moderate compaction and rutting hazard, moderate to high erosion hazard, moderate to high slumping and earthflow hazard, plant competition concerns and areas of low bearing strength.

Principal ecological concerns affecting soil quality include conifer expansion into aspen, sagebrush/grass, riparian and mountain meadow communities causing site changes, increased risk of losses in soil productivity associated with fire events, and canopy density of sagebrush communities and subsequent loss of understory vegetation resulting in a decline in watershed conditions and slumping/earthflows.

Principal management activities affecting soil quality include roads, OHV use, dispersed recreation and grazing along drainages. Secondary management activities affecting soil quality includes erosion along sheep driveways and effects from timber harvest.

Air Quality - Scale: Forestwide

(1) The United States Environmental Protection Agency (EPA), in conjunction with the states of Idaho and Wyoming, have established National Ambient Air Quality Standards for pollutants to protect the public health and welfare. These standards relate to PM₁₀ particles, which are particles with an aerodynamic diameter of 10 microns or less.

National Ambient Air Quality Standards require that PM₁₀ remain below 50 micrograms per cubic meter when averaged over a year. PM₁₀ must generally remain below 150 micrograms per cubic meter averaged over a 24-hour period, however, this standard can be exceeded up to one time per year.

(2) Class I airsheds have the highest air quality standards, and Class II have a moderate level of protection. The entire Forest, including the Jedediah Smith and Winegar Hole Wildernesses, is a Class II airshed. Yellowstone and GTNPs, adjacent to the Forest's eastern boundary, are Class I airsheds. The Forest must ensure that its activities do not reduce air quality in these Class I airsheds.

In general, the area's air quality is very good. The primary sources of PM₁₀ on the Forest are wildfire, prescribed fire and dust generated from road traffic. The major source of PM₁₀ from outside the Forest is dust generated by wind and agriculture. Agricultural burning and mechanical disturbance such as plowing, planting and harvesting crops reduce air quality.

Currently there are no air quality monitoring stations located on the Forest. The closest monitoring station is located in Jackson, Wyoming. This station has measured PM₁₀ since 1986. During the analysis period the highest 24-hour average PM₁₀ reading recorded was 124 micrograms per cubic meter in 1992. This is 26 micrograms per cubic meter less than the allowable standard. One short term value of 248 micrograms per cubic meter was recorded in 1988 during the Yellowstone wildfire situation. Annual averages have ranged from a high of 39.8 micrograms per cubic meter in 1988 (Yellowstone Fire influenced) to a minimum of 25.5 grams per cubic meter in 1993.

Caves - Scale: Subsections

Caves are present primarily in two subsections on the Forest, as discussed below.

Lemhi/Medicine Lodge - This area contains numerous small caves in limestone cliffs. Many have been identified during heritage resource inventories. Large caves in this area contain evidence of American Indian habitation in the form of pictographs and cave fills with stratified cultural deposits. Few caves in this area have sufficient depth to provide recreational opportunities.

Teton Range - The Teton Range has numerous caves but most are small and have little recreational interest to spelunkers. The Fossil Mountain Ice Cave and Wind Cave, however, have high recreational interest for exploration. Both caves are identified on Forest maps and have access trails and signs from Darby Canyon. These caves probably qualify as "significant caves" under the Federal Cave Resources Protection Act of 1988, but they have not been inventoried or nominated. Thorough inventory of caves in this area has not been completed, and new significant caves with high public interest may be discovered.

Lands - Scale: Forestwide and Subsections

The Lands program includes the adjustment of land ownership patterns, land acquisition, granting of rights-of-way, identification and resolution of trespasses and property boundary management.

Land Ownership Adjustments

Land ownership within the administrative Forest boundary is displayed in Table III-4. Land ownership adjustments have enabled the Forest to acquire lands that meet specific needs, goals and objectives.

Land ownership adjustments are valuable for recreation, wildlife habitat, riparian areas and historical resources, they also enabled us to consolidate land ownership to improve operating efficiency. Ownership adjustments reduce the miles of private/Forest Service property lines that need to be surveyed, posted and maintained. Adjustments can also reduce special use permit administration and resolve trespass and title claims.

Ownership	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison- Pitchstone Plateaus	Teton Range	Big Hole Mountains	Caribou Range Mountains	Totals*
NFS Land Acres	279,655	319,248	296,482	196,424	160,806	350,222	204,949	1,808,175
Private Acres	1,883	7,559	9,986	815	963	7,661	8,364	59,840
State Acres	637	5,886	15,060	637	0	0	0	
BLM Acres	0	0	389	0	0	0	0	389
Total Acres	282,175	332,693	321,917	197,876	161,769	357,883	213,313	1,868,015

* Figures in this column are the figures of record. Differences in sums of prior columns are due to measurement method.

The Congressionally mandated Land and Water Conservation Fund can be used to purchase land interests for the Federal Government. Although the Forest has submitted yearly requests for one to fifteen such purchases, the last funded project was in 1962. Land adjustments may also occur through donation of land or partial land interest. Proponents in land transactions have been approached and encouraged to donate lands or interests in lands.

Land Exchanges have been the most effective tool in completing the objectives for land adjustments. Through eight land exchanges important wildlife and wetland habitats, scenic and historical sites, a needed gravel source and six inholdings were acquired. Lands disposed of have been, for the most part, those that have lost their Forest characteristics, are difficult to manage or consolidated Forest holdings. Table III-5 displays past land adjustments (1985-1996).

	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison- Pitchstone Plateaus	Teton Range	Big Hole Mountains	Caribou Range Mountains
Purchased Acres							
Fee	2 40	-	2 76	160 59	-	-	-
Partial Land Interest	-	-	-	160 75	-	-	-
Donation Acres							
Fee	-	-	-	-	7 48	-	-
Land Exchanges Acres							
Acquired	-	640	511 65	-	-	319 94	6 5
Disposed	-	-	633 54	-	-	64 86	45
Right-of-Way Cases							
Acquired	-	1	1	-	1	2	3
Grants	-	1	-	1	1	13	4

1/ These figures are updated yearly. Current figures are on file at the Forest office.

Land ownership adjustment on the Forest has emphasized the transfer of both surface and subsurface rights. This has resulted in very little reserved or outstanding mineral ownership. Currently nonfederal minerals consist of only about 5,000 acres out of a total of about 1.8 million Forest acres.

Right-of-Way Acquisition

Right-of-way acquisition is driven by the need to provide land managers and the public access to National Forest System lands. With private lands changing hands, many roads that have been open to the public are now being closed. There is a need to gain legal access through the acquisition of rights-of-way. Eight right-of-way cases have been completed (see Table III-5) and 91 rights-of-way been identified for acquisition.

Minerals - Scale: Subsections

No specific proposals for mineral development have been addressed in this Revision process. The role of the Forest Service is to manage the surface resources to minimize adverse environmental impacts and to provide mitigation direction.

The issue of oil and gas development on the Forest is being addressed in a separate EIS. The following briefly discusses the current status of oil and gas production to give the reader an overall picture of the mineral, oil, gas and hard rock situation on the Forest.

Lemhi/Medicine Lodge - During the mid and late 1800s, lead and copper and to a lesser extent silver and gold, were mined extensively in this subsection. Since then there has been no activity and none is predicted. There are no current oil and gas leases, although during the 1980s there were numerous leases generating rental income. A recent BLM study rated the area as having a low potential for the discovery of oil and gas resources (USDI 1992).

Centennial Mountains - During the late 1950s and early 1960s phosphate was mined near Mt. Taylor in the eastern Centennials from two of the three phosphate leases located in the area. Since then no mining has occurred, but the leases still remain. Should phosphate production resume, 50 percent of all revenues generated from leasing return to the State of origin for use as the legislature may direct.

Oil and gas leases blanketed the area in the mid 1980s but none exist today. The potential for discovery of oil and gas is rated low in this area. An exploration well was drilled in the late 1980s which came up dry.

Northeast of Dubois, gold exploration is currently taking place and has been for several years. In the event of development and production the local communities would experience a boost in their economies.

Northeast of Dubois are several mining claims where the exploration, development and production of opal has been conducted for the past 30 years. One particular claim has exhibited most of this activity and has been patented (private ownership). The site is known as the Spencer Opal Mine and has operated commercially as a public digging site since 1968. Activity on surrounding nonpatented claims consists mainly of exploration.

Island Park & Madison-Pitchstone Plateaus - Oil and gas and geothermal leases blanketed the area in the mid 1980s, but none exist today. The area is rated as having no potential for the discovery of oil and gas. Congress has effectively prohibited geothermal development and mineral leasing in this area through legislation prohibiting the leasing of lands in the Island Park geothermal area (Geothermal Steam Leasing Amendments Act of 1988). There are no other mineral resources in this area of economic importance.

Teton Range - Oil and gas leases were scattered through the area in the mid-1980s, but none exist today. The area is rated as having no potential for the discovery of oil and gas. There are no other mineral resources of economic importance in this area.

Big Hole Mountains - Oil and gas leases blanketed the area in the mid-1980s, generating rental income. Fifty percent of this money is returned to the State of origin for use as the legislature directs. There are no oil and gas leases currently, pending the completion of an oil and gas EIS. A couple of exploratory wells were drilled during the 1980s, but were dry holes. The potential for discovery of oil and gas is rated as moderate in the north half of the subsection and high in the south.

Caribou Range Mountains - Oil and gas leases blanketed the area in the mid-1980s, generating rental income. Fifty percent of this money is returned to the State of origin. There are no oil and gas leases currently, pending the completion of an oil and gas EIS. The potential for discovery of oil and gas is rated as moderate in this subsection.

There are four phosphate leases located in the northern part of the subsection, which are currently inactive. Last reported activity was in the 1960s and consisted primarily of exploration. Activity is not expected on these leases for the next three or four decades.

Travertine, a marble-like building stone product, is mined in the northern part of the area and is the only active mine of economic importance on the Forest.

In the southern portion of the subsection, McCoy Creek has long been the center for recreational placer gold dredging, sluicing and panning. Mining claim activity has also occurred with limited success.

BIOLOGICAL ELEMENTS OF THE ENVIRONMENT

This section is divided into various types of ecosystems so that the relationships between biological elements within the same system can be better understood. Aquatic, riparian and terrestrial ecosystems (upland forested and upland nonforested) will be considered.

AQUATIC AND RIPARIAN ECOSYSTEMS

Riparian - Scale: Subsection

Riparian areas lie adjacent to water and are composed of vegetation communities influenced by water. Though riparian areas constitute only a fraction of the total land area, they are more productive in terms of both plant and animal species diversity and biomass per unit area than the remainder of the land base. Riparian areas are essential breeding, rearing and feeding grounds for many species of wildlife and they affect the quality of the aquatic habitat (fisheries). Often these key areas visibly reflect the quality and success of land management activities in tributary watersheds. Riparian areas are extremely important for flood control and hydrologic function. These systems are very important to the human environment from ecological, aesthetic, recreational and economic points of view. Additional information may be found in the water quality, fisheries and riparian wildlife sections. Table III-6 summarizes riparian conditions.

Grazing is considered to have shifted the species composition on 8,988 acres (32 percent) of riparian communities across the forest. Under current range management, 5,338 acres of these acres are moving toward higher ecological conditions with increasing plant biodiversity. Some 3,650 acres are remaining in less stable, lower ecological conditions, with lower plant diversity (Table III-6). Where grazing decreases the species diversity, shallow, fine-rooted species such as Kentucky bluegrass (*Poa pratensis*) become dominant and replace the deeper, thicker-rooted native herbaceous species, decreasing stream stability.

Biodiversity and sometimes stream stability are also affected by riparian community succession. Riparian areas with closed shrub canopies have little understory vegetation due to shading and may have low overall species diversity. This can negatively affect stream stability on some streams. Spruce forest riparian communities also have low species diversity due to shading and low vegetative cover to protect streambanks from erosive events unless armored by large rock.

Table III-6 Aquatic and Riparian Conditions by Subsection							
Parameter	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison- Pitchstone Plateaus	Teton Range	Big Holes	Caribou Range Mountains
Miles of Intermittent Streams	610	415	455	219	164	383	158

Lemhi/Medicine Lodge - The principal ecological concern affecting riparian quality in this subsection is that upland vegetation has expanded into riparian zones due to past over-utilization and/or a drop in the water table levels. A secondary ecological concern affecting riparian quality in this subsection is that within some riparian areas willows are dying out and are not being regenerated.

Principal management influences affecting riparian quality include past overuse by ungulates (domestic and wild), dispersed recreation, OHV use and roads in or adjacent to riparian areas and associated stream crossings

Centennial Mountains - Principal ecological concerns affecting riparian quality include the expansion of upland vegetation into riparian zones due to past over-utilization and/or a drop in the water table levels and some areas of fine-textured subsoils which have a moderate to high slumping potential. A secondary ecological concern affecting riparian quality is that within some riparian areas, willows are dying out and are not being regenerated.

Principal management concerns affecting riparian quality are overuse in some areas by ungulates (domestic and wild), dispersed recreation, OHV use and roads in or adjacent to riparian areas and associated stream crossings. Secondary management concerns affecting riparian quality include past mining sites that have not been rehabilitated, past timber harvest that left inadequate buffers and fuel wood gathering.

Island Park - The principal ecological concern affecting riparian quality is that there are areas where willows are dying out and not being regenerated.

Principal management concerns affecting riparian quality include high use recreation areas (including summer home, dispersed and developed recreation areas), OHV use, roads in or adjacent to riparian areas and associated stream crossings, past timber harvest which left inadequate buffers and fuelwood gathering. A secondary management concern affecting riparian quality is overuse in some areas by ungulates (domestic and wild).

Madison-Pitchstone Plateaus - The principal ecological concern affecting riparian quality is in the area of the North Fork Burn. Principal management concerns affecting riparian quality include dispersed recreation, OHV use, roads in or adjacent to riparian areas and associated stream crossings, past timber harvest which left inadequate buffers and fuelwood gathering. A secondary management activity affecting riparian quality is overuse in some areas by ungulates (domestic and wild).

Teton Range - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, horse and OHV use, trails in close proximity to or within riparian areas and associated crossings, isolated areas of overuse by ungulates (domestic and wild), roads in or adjacent to riparian areas and associated stream crossings. Secondary management activities affecting riparian quality include past timber harvest which left inadequate buffers and fuelwood gathering.

Big Hole Mountains - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, horse and OHV use, trails in close proximity to or within riparian areas and associated crossings and areas of overuse by ungulates (domestic and wild). Secondary management activities affecting riparian quality include sheep driveways, past timber harvest which left inadequate buffers, fuelwood gathering and IDFG feed grounds in Lower Rainey Creek.

Caribou Range Mountains - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, OHV use, trails in close proximity to or within riparian areas and associated crossings, areas of overuse by ungulates (domestic and wild), sheep driveways and roads in and adjacent to riparian areas and associated crossings.

Water - Scale: Subsection

Subsection boundaries are used for analysis and description, although this means that some streams are split between two subsections. Channel stability information dates primarily from inventories completed in the mid-1970s to early 1980s. More current information does exist on some portions of the Dubois and Teton Basin Ranger Districts (1989-1993). It is important to determine which streams are naturally "unstable" (i.e., dynamic) due to landforms, bed and bank materials, etc. and which ones have instability induced by management practices. An attempt is made in the text to make this determination where possible. In discussions of channel stability the "good" and "fair" categories were further split into (+) and (-) to indicate better or poorer stability respectively.

Water Yield

Total annual water yield on the Forest is about 1.4 million acre-feet. Water is lost or used in many ways, including evaporation, infiltration, use by plants and animals and diversion from stream channels. Because of these and many other factors, the amount of water reaching the Forest boundary will be less than what is produced. Table III-7 shows water yield by subsection across the Forest.

Subsection	Annual Water Yield for Subsection (ac-ft)	Unit Water Yield (ac-ft per acre)
Lemhi/Medicine Lodge	96,400	0.34
Centennial Mountains	134,300	0.42
Island Park	125,600	0.42
Madison-Pitchstone Plateaus	186,400	0.95
Teton Range	405,300	2.52
Big Hole Mountains	299,100	0.85
Caribou Range Mountains	169,600	0.83

Management activities have the potential to change the timing and amount of water delivered to stream channels. As an example, timber harvest, especially in headwater areas, may allow more snow to accumulate in created openings. This may result in higher flood peaks and possible impacts to streams. Currently there are approximately 22,000 acres in headwaters that have been altered by timber harvest (out of a total of approximately 239,000 headwater acres in those watersheds that have much harvest), which includes stands in seedling, sapling and nonstocked categories. While this is approximately 9 percent on a Forestwide basis, the amount of actual headwater harvest varies widely between subwatersheds.

Water Quality

The biggest pollutant on the Forest is excess sediment, derived from within-channel erosion and upland erosion reaching stream channels. The main source of sediment is roads, specifically those segments within riparian areas, including stream crossings. Forest roads generally contribute an estimated 85 to 90 percent of the sediment reaching streams in disturbed Forest land (Burroughs 1990). Currently there are 2,957 stream crossings and 323 miles of road in AIZs. The amount of water meeting State water quality goals on the Forest is unknown. Idaho Code Section 39-3601 et seq. (effective July 1, 1995) approved adoption of new water quality standards. Streams targeted for the new regulations are those listed as Water Quality Limited (WQL) under section 303(d) of the Clean Water Act. These are to receive priority for monitoring so they may be removed from the list if water quality is good. If it isn't, special Best Management Practices (BMPs) and pollutant limits must be established.

The Clean Water Act delegates authority for establishment of WQL priorities to the States (Idaho) Senate Bill 1284 (incorporated into Chapter 36, Title 39, Idaho Code) states that the water quality criteria that must be met consist of fully supporting existing beneficial uses (where there is no numeric water quality standard) or, where there is a numeric standard, meeting that standard. This applies to all water bodies, both those that are listed and those that are not. The bill goes on to describe the priority classifications of the WQL water bodies. "Low" priority bodies (all streams on the Forest are in this category) are those where limited data suggest that beneficial uses are not fully supported, but risks to humans and aquatic life are minimal. For streams listed in this category "such changes in permitted discharges from point sources on the water body or to the BMPs for nonpoint sources within the watershed deemed necessary to prohibit further impairment of the designated or existing beneficial uses" are to be undertaken.

In other words, these streams are to have monitoring of BMPs to ensure their effectiveness and monitoring of designated beneficial uses to ensure they are supported. There is no implication, or statement, in the bill that all management activities must cease in these watersheds, we are required to meet water quality standards and make sure BMPs are protecting beneficial uses. If our monitoring points out water bodies where are not meeting water quality standards, then we have to find the source for the water quality impairment and correct the problems.

WQL streams on the Forest (as of 1996) are listed under each subsection. While other streams in the vicinity of the Forest have been listed, the designated reaches are all downstream of the Forest boundary. The fact that these streams are listed for reaches downstream of National Forest System lands, suggests that the problems identified for the streams may originate on non-Forest (often private) lands.

The Forest is in the process of validating WQL streams to determine where we have water quality concerns, and if they exist, to find the source of the concerns. We have been working with the Idaho Department of Environmental Quality (DEQ) to develop suitable monitoring and assessment methods (including the state-approved Beneficial Use Reconnaissance Program protocols, to which we are tailoring our assessment efforts). We have coordinated our monitoring efforts with other state and federal agencies and have shared all our results with DEQ and EPA. Many of the water bodies currently listed have very limited data, so there is a great deal of speculation as to whether they should remain listed. A case in point is Warm Creek, which is listed for thermal concerns but which has as its source a warm spring having a constant temperature that is far above normal state standards for temperature. Changes in management would not correct this natural anomaly. Until we can verify the condition of these streams, particularly the condition of fish habitat and fish populations, the Forest is employing especially stringent management requirements in the WQL watersheds. We have begun baseline monitoring in at least one WQL watershed where new management activities are planned. Impacts to WQL streams are analyzed at the project level, where site-specific BMPs can be tailored to a given situation.

Lemhi/Medicine Lodge - Major streams in this subsection are Medicine Lodge Creek and its tributaries. There are many perennial streams that have their headwaters in the Bitterroot and Beaverhead Ranges, that eventually flow through broad valleys. Their flows are mostly the result of snowmelt runoff and baseflow from groundwater sources. The rest of the streams in the subsection are mostly intermittent spring or snowmelt-fed streams that eventually lose flow to deep sediments in valleys. The streams fed by snowmelt generally flow only for a few months of the year.

Channel stability ranges from fair (-) to good (+). This subsection has generally declining trends in channel stability, sometimes even where grazing has been excluded.

Idaho DEQ sampled sites on streams in this subsection to assess changes in water quality from management. On Irving, Edie and Fritz Creeks, water quality was similar above and below where forest management was occurring. All sites showed impacts from grazing at the time of the survey. WQL streams here include Edie, Irving, Fritz, Warm and Warm Springs Creeks. Monitoring of water quality on these streams was conducted during 1995. In 1996, Divide and Fritz Creeks were monitored for temperature. Nutrients were listed as a concern on all these streams. There are no standards for nutrients, or any clear direction

as to what forms of nitrogen and phosphorus are to be monitored, so recommendations from researchers were used. None of these streams directly enter lakes, so a recommended maximum phosphate level of 0.1 mg/l was used in lieu of a standard. All of the streams phosphate concentrations were lower than this value. Nitrate/nitrite recommendations vary widely, from 10mg/l for drinking water to 0.3 mg/l for prevention of algal growth. Fritz (1995), Warm and Edie Creeks showed an increase in nitrate/nitrite in late July and early August, to a maximum of 0.43 on Fritz and 0.44 on Warm Creek. Divide Creek, a tributary to Warm Creek, was also sampled from July to early September, and showed nitrate/nitrite levels ranging from 0.49 to 0.73 mg/l. All levels dropped below 0.1 in September, except on Divide Creek. Temperature was listed as a concern on Fritz and Warm Creeks. Warm Creek is fed by a warm water spring source, so temperature is an erroneous concern here. State Water Quality Standards state for cold water biota, temperatures are not to exceed 22°C, with a maximum daily average of no greater than 19°C. During 1996, Fritz Creek was continually monitored from July to October and the highest readings were approximately 18°C. Divide Creek was consistently cool.

Centennial Mountains - Streams having headwaters along the front of the Centennial Mountains generally flow south and their water comes from both snowmelt and spring sources. The influence of springs increases moving east, providing these streams with more constant streamflow through the year. Major streams in the western part of the subsection include Beaver, Camas, Sheridan, Icehouse and Willow Creeks. Some streams in the western part of the subsection (e.g., Beaver and Camas Creeks) generally subside into deep valley sediments or areas of volcanic rock before they reach Mud Lake. The rest of the streams (Sheridan, Icehouse, Willow, etc.) flow through the meadows of Shotgun Valley and eventually add flow to Island Park Reservoir.

The eastern part of the subsection includes the headwaters of the Henry's Fork of the Snake River (Henry's Lake and the headwater streams) as well as the upper part of the Henry's Fork itself. It also includes Big Springs, a major tributary of the Henry's Fork that has a flow of approximately 180 cubic feet per second at its source year-round. Spring-controlled streams are prevalent here, having relatively low variation in flow throughout the year, but also having less ability to flush excess sediments than snowmelt streams.

Channel stability ratings generally range from fair (-) to good (+) with stable or declining trends throughout most of the subsection. The only standout is a poor rating on part of West Dry Creek, though there is no apparent management-related reason. Some portions of the Henry's Fork Headwaters rated as excellent. The most frequent management problems are livestock damage and roads. Specific locations of road and cow impacts are Disaster, Kay, Corral, Dairy, Long, West Rattlesnake, Sheep, Middle and West Threemile and Jesse Creeks. Other streams may also have these impacts, but comments were missing from survey forms. Sedimentation below clearcuts on Bear Gulch Creek and in-stream deflectors on Willow Creek are two other management impacts. The greatest impact from timber harvest in this area appears to be related to roads. Data is not available to assess cumulative effects to streamflows from tree removal.

Sampling at Big Springs in 1994 found water quality to be excellent and water temperatures consistently low. Monitoring by the State of Idaho in the Henry's Fork headwaters showed limited impacts to beneficial uses. Duck Creek has been found to be one of the major contributors of sediment and nutrients to Henry's Lake, however it has not been determined if the source is on private or public land. Targhee Creek was also found to be a major source of sediment and nutrients, but a survey of the Forest portion of the watershed could only find natural sources of sediments (old slumps, for example). DEQ has determined that more than 60 percent of the phosphorus going into Henry's Lake is natural, and is from Forest lands. Bacterial levels were found to be high on Hope, Duck, Meadow and Lower Jesse Creeks downstream of Forest lands. Henry's Lake Outlet meets all water quality criteria, however there have been some instances of temperature exceeding State standards for salmonid (trout) spawning. Siltation and dewatering have been described as limiting factors. In general, it appears that while there is some degradation of water quality on the Forest, it does not appear to be significant as a result of management activities.

Island Park - Many streams here show a strong influence from groundwater, having relatively low variation

in flow throughout the year. The major stream is the middle section of the Henry's Fork of the Snake River. Other drainages in the subsection are Fish, Robinson, Rock, Squirrel, Conant, Bitch, and South Badger Creeks. The portions of the Buffalo and Warm River in this subsection are low-gradient, spring-controlled streams that show little variation in flow. Fall River shows more snowmelt influence and flows through a narrow canyon, unlike the other streams. While the Henry's Fork is a spring-fed system, Island Park Dam controls its flow to a large extent, providing peak flows not just when Island Park Reservoir fills in spring, but also when irrigation and other downstream needs dictate. The western side of the subsection is fairly dry, with little surface runoff.

Channel stability ratings range from fair (-) to excellent. Management impacts stem from roads, livestock and recreation, which vary in significance in different places. The greatest impact from timber harvest in this area appears to be related to roads. No data are available to assess cumulative effects to streamflows from tree removal. Data is very scattered, but Conant Creek (upper and near the Forest boundary), one section of Buffalo River, and portions of Rock Creek were specific areas of concern while the Henry's Fork and most of Buffalo River were in good to excellent condition.

Zimmer (1981) reported occasional high levels of fecal coliform in Island Park Reservoir, probably due to inadequately treated sewage at local recreational facilities. Phosphorus levels in the reservoir were also reported to be high, especially in areas of groundwater discharge along the reservoir shoreline. The source of the phosphorus could not be identified. Nuisance levels of algal blooms have been reported in the Henry's Fork upstream of Osborne Bridge, possibly due to nutrient contributions from upstream developments. High stream temperatures have also been reported in this reach as this section of the stream is wide, shallow, and unshaded. The Buffalo River was sampled in the late 1970s and water quality was found to be good. The Henry's Fork, from Buffalo River to Riverside, is listed as a WQL segment.

Madison-Pitchstone Plateaus - Surface drainage here is not very well-developed, due to the underlying volcanic rocks which allow more water to percolate than to run off. These streams originate in or near the Park and exhibit strong groundwater influence. Major streams include the upper sections of tributaries to the Henry's Fork that were discussed under the Island Park Subsection. Main drainages within this subsection include Thirsty, North Fork, Middle and South Forks of Split Creek and the upper reaches of Moose, Partridge, Snow, Conant and Boone Creeks. There are numerous small lakes in this subsection.

Channel stability ranges from fair (+) to excellent. The North Fork Fire in 1988 caused major changes in channel stability to Moose Creek. Road systems were a watershed concern in this area even before the fire. After the fire, erosion from uplands accelerated due to loss of vegetation and burning effects on soils, which caused more water to run off slopes. The result was a dramatic increase in the amount of sediment moving off slopes and into stream channels. Increases of fine material and channel scour were noted in the lower reaches of the stream after the fire. Since 1991, however, the cross-sectional area and substrate size distribution have come to more closely resemble pre-fire values. Current conditions do not reflect watershed objectives. Logging, roads, livestock use and recreation impacts exist in this subsection. The greatest impact from timber harvest appears to be associated with roads. No data is available to assess cumulative effects to streamflows from tree removal. Possible channel impacts in the Falls River subwatershed are due to dewatering by irrigation withdrawals.

Five of the streams in the subsection (Rock, Robinson, Fish and Porcupine Creeks and Warm River) had been named by Idaho as Stream Segments of Concern before this designation was eliminated in 1995. Water quality has been generally good on these streams. The only variation from State standards has been in temperature on some of the streams which have experienced extremely low flows due to drought (Porcupine and Rock). Water temperatures on Moose Creek are consistently low. Turbidity increases, sometimes significantly, during and after rainstorms in the drainage. Hidden Lake, Loon Lake and Grassy Lake Reservoir were sampled as part of the Western Lakes Survey in 1985. All had good water quality, though Hidden Lake's total phosphorus was high.

Teton Range - Streams in this subsection originate along the west slope of the Teton Mountains. They are

steep, dynamic and characterized by coarse substrate (up to boulders in size) due to the proximity of this material to the stream channel. Glaciation has been an important influence on stream systems here. Not only did glaciers shape the major valleys, they also brought the sediment and rock material in which stream channels subsequently developed. Present-day forces such as avalanches and various types of mass failure bring not just rock but also trees and other debris to the streams, causing them to adjust to accommodate the load. These streams respond to snowmelt, having high spring peak flows which drop to their low flow levels in late summer. Major streams here include Badger, Leigh, Teton, Darby, Fox, Game, Trail and Moose Creeks.

Channel stability ranges from fair (-) to good (+). Impacts to channels stem mostly from natural causes such as avalanche debris, unstable bank materials and failed beaver dams. Localized management effects are related to roads, recreation and livestock.

Water quality sampling has been extremely limited in this subsection. Most of the available information is from the Alaska Basin Water Study conducted by the Teton Science School in 1989. The two lakes studied (Two Island and Mirror) were found to be slightly acidic. There was only one sample for alkalinity in each lake, and both were extremely low. This indicates a low ability to buffer changes to pH (e.g., changes from acid rain), probably due to the geology of the area. The Teton River (headwaters to Trail Creek) is listed as a WQL segment.

Big Hole Mountains - Streams here contribute to either the Teton River or the South Fork Snake River. They are generally confined within steep-sided valleys or canyons, and are high-energy systems, able to move a considerable amount of sediment. Snowmelt is important in these streams, so they have high spring peak flows which later drop to their late summer levels. Major streams in this subsection include Indian, Big Elk, Palisades, Rainey, Big Burns, Pine, Canyon, Moody, Horseshoe, Mahogany and Packsaddle Creeks. Packsaddle Lake, Upper and Lower Palisades Lakes, and the Palisades Reservoir are also important hydrological features in this subsection.

Channel stability ranges from poor to good (+). Impacts exist in most drainages from recreation use, especially trails along the streams and dispersed camping. Management impacts associated with cattle and roads are also very common. The Teton River subwatershed has impacts from mining (channel alteration) and loss of riparian vegetation due to lowering of water tables and channel incision. Problems in Rainey Creek are primarily associated with grazing by wildlife and cattle. In 1994, there was a fire in the headwaters of Palisades Creek, but it was generally a light burn and did not adversely affect water resources.

In-depth water quality sampling was conducted on Big Elk Creek in the late 1970s. Water temperatures were consistently good, and turbidity was consistently low. Little Elk Creek was sampled once, and had readings similar to Big Elk. Stream temperatures on Rainey and Palisades Creeks were measured on a regular basis in 1994, and all met State standards. Upper Palisades Lake was sampled during the Western Lakes Survey in 1985, and was in very good condition. Canyon Creek was intensively sampled in the mid-1970s, and once in 1994, all samples met State standards. In general, it appears that stream channel stability is a concern in many places, but (based on available data) water quality impacts are not evident. Teton River (headwaters to Trail Creek), Packsaddle, and Horseshoe Creeks are listed as WQL segments.

Caribou Range Mountains - Geology has played an important role in this subsection. The underlying geology of folded and faulted sedimentary rocks has produced perpendicular drainages, and the streams follow the weaknesses in the rocks. Valleys are bounded by steep slopes, with the width of the valleys varying depending on the distance that streams could laterally migrate. Snowmelt is important here, and streams have distinct flow peaks in spring. Water generally flows to the South Fork Snake River. Major streams include Fall, Pritchard, Bear, Beaver, Brockman, Indian, Corral and McCoy Creeks. The western portion of Palisades Lake falls within this subsection.

All reaches rated from fair (-) to good (+) in channel stability. Grazing, powerline clearing, roads in riparian areas and heavy recreational use are all listed as problems in the Fall Creek drainage. Brockman Creek shows impacts from grazing (bank trampling). Antelope Creek is heavily impacted (both on private and on Forest lands) by roads, recreation and bank trampling by cattle. Channel stability was lowest on Fall, Bear, Brockman, and Antelope Creeks, with almost all of Fall Creek in the "fair" category, as well as half the reaches on Bear. Most streams here have not been surveyed. Antelope, McCoy, Tex, Brockman, Corral and Sawmill Creeks are listed as WQL.

Idaho DEQ sampled several streams in 1994, Antelope, Sawmill, Lava, Hell, Willow and Brockman Creeks. Conclusions have not yet been drawn from their data regarding support of beneficial uses.

Fisheries - Scale: Hydrologic Unit

Streams delineated as "fish-bearing" are those stream segments that are used by any fish species to satisfy all or a portion of their requirements such as spawning, rearing of young, adult feeding and winter survival. Information on the miles of fish-bearing streams and acres of fish-bearing lakes and impoundments is broken out by subsection in Table III-6.

Native trout watersheds are those primary watersheds identified as containing contiguous well conducted subwatersheds with high aquatic integrity and population strongholds of native cutthroat trout or have the capability to achieve this condition through recovery efforts. They have been determined to be necessary for species recovery. Of the 39 primary watersheds on the Forest, 17 have been designated as native trout watersheds, Elk Creek (003), Palisades Creek (004), Rainey Creek (005), Pine Creek (006), Heise (007), Henry's Fork Headwaters (008), Robinson Creek (013), Trail Creek (017), Mahogany Creek (022), Moody Creek (024), Bitch Creek (032), Burns-Pat Canyon (035), McCoy-Jensen Creeks (036), Elk-Bear Creeks (037), Fall Creek (038), Prichard Creek (039) and Brockman Creek (040).

Fisheries resources and habitat conditions are best assessed by hydrologic unit, which is a portion of a watershed with common characteristics.

The land area immediately surrounding the various water types is referred to as the AIZ. These zones control the biological diversity and integrity of the aquatic environment. It is within these zones that the ecological functions and processes necessary for the maintenance of healthy fisheries habitat take place. Aquatic habitat conditions are expressed in terms of water quality, quantity, and timing of flow, conditions within the stream channel (pools, woody material, etc.), and health of associated plant communities. Since the hydrologic, geomorphic and ecological processes that shape the various water types differ by hydrologic unit, the sensitivity of fisheries habitat to disturbances also varies by hydrologic unit. Human-induced disturbances within the AIZ, including streamflow diversion, livestock grazing, road construction, timber harvesting, and recreation use, can disrupt natural processes and functions. Where these are intense or prolonged, fisheries distribution, abundance and productivity may be impaired.

Yellowstone cutthroat trout (large-spotted and fine-spotted form) is selected to represent the many species of fish occupying the Forest. This species requires high water quality and high habitat diversity for survival. Since these conditions are indicative of healthy aquatic ecosystems, with associated healthy riparian plant communities and functioning watersheds, it is assumed that by providing for these habitat needs, the habitat needs of all other aquatic life would be provided as well.

A complete list of the fish species by hydrologic unit is shown on Table III-8. Descriptions of the condition and trends of aquatic and riparian habitats are shown on Table III-6.

Birch, Medicine Lodge and Beaver-Camas Hydrologic Units - These hydrologic units are assessed together because of similarities in fisheries resources and conditions. All drainages originate along the eastern aspect of the Lemhi Range or the southern aspect of the Beaverhead Mountains. As they flow onto the Upper Snake River Plain, these waters "sink" and flow underground. Recent studies document that these subterranean flows reach the lower Snake River at Thousand Springs, 150 miles away. Fish populations within the Birch, Crooked, Medicine Lodge and Beaver-Camas Creek systems are now physically and genetically isolated from the Snake River system and from each other.

Fish-bearing streams on Forest lands are small, steep to moderate-gradient and fed by snowmelt runoff and baseflow from groundwater sources. The natural capabilities of this area to produce abundant or diverse fisheries resources is relatively limited.

Upper Henry's Hydrologic Unit - All drainages flow into Henry's Lake or the Henry's Fork of the Snake River above the confluence of Fall River. Spring-fed creeks provide an environment capable of producing abundant aquatic insect and plant biomass. Where fisheries life history requirements are met, these streams are among the most productive trout fisheries in the world.

The primary natural disturbances shaping and controlling fisheries habitat are high intensity summer rains and fire. Natural processes of overland flow, slumping and tree windthrow bring organic matter, soil, rocks and nutrients into streams.

Fisheries resources in this hydrologic area are very productive and varied. Duck and Targhee Creeks are important economically and scientifically as they provide key spawning habitats for the Henry's Lake native cutthroat trout fisheries and associated IDFG managed hatchery.

Lower Henry's Hydrologic Unit - All drainages flow into the Henry's Fork of the Snake River near the confluence of Falls River. Many are similar to those of the Upper Henry's Hydrologic Unit but tend to be more strongly influenced by groundwater. Falls River is a medium to large, low-gradient system which is predominately spring-controlled.

The primary natural disturbances shaping and controlling fisheries habitat are high intensity summer rains and fire. Natural processes of overland flow, slumping and tree windthrow bring organic matter, soil, rocks and nutrients into streams.

The fisheries resources of importance within this area are primarily small headwater streams and alpine lakes spread across a small portion of the landscape.

Teton Hydrologic Unit - This area drains the western aspect of the Tetons and the northern aspect of the Big Hole Mountains. Fish-bearing streams originating in the Teton Mountains are steep, dynamic and strewn with large boulders. Stream channels developed from the sediment and rock that was delivered through glaciation. Within the Big Hole Mountains, fish-bearing streams are relatively small, moderate-gradient and fed by snowmelt runoff and baseflow from groundwater sources.

The primary natural disturbance shaping and controlling fisheries habitat in the Teton Mountains is rapid snowmelt. Natural processes of mass failure and avalanches recruit organic matter, large woody debris, soil, rock and nutrients into streams. In the Big Hole Mountains, rapid snowmelt initiates overland flow and slumping which contribute organic matter, soil, rock and nutrients to fish habitats.

Palisades Hydrologic Unit - All drainages originate along the south aspect of the Big Hole Mountains and the north aspect of the Caribou Mountains and are tributary to the South Fork of the Snake River.

The primary natural disturbances shaping and controlling fisheries habitat are high intensity summer rains and fire. Natural processes of overland flow, slumping, and tree windthrow move organic matter, soil, rock and nutrients into streams.

The fisheries resources found here are very productive and varied. Many of the streams flowing into Palisades Reservoir, and Palisades and Rainey Creeks, provide key spawning and rearing habitats for the native cutthroat trout fisheries.

Cutthroat Trout

Cutthroat trout is a sensitive species and has been selected as a management indicator. Table III-9 illustrates cutthroat trout population status and distribution on the Forest by hydrologic unit.

The only indigenous trout within the Forest is the Yellowstone cutthroat (*Oncorhynchus clarki bouvieri*). Scientific information to date indicates that this subspecies consists of two forms: the fine-spotted and large-spotted Snake River Yellowstone cutthroat. Scientists are continuing research to determine if the fine-spotted Snake River cutthroat trout is a separate subspecies (Behnke 1992).

The Forest Service in Regions 1 and 4 has prepared a draft Habitat Conservation Assessment (HCA) for Yellowstone cutthroat trout, including the large-spotted and the fine-spotted Snake River forms. The HCA is directed at defining habitat conditions necessary for the long term persistence of Yellowstone cutthroat trout. In addition, the assessment correlates habitat conditions to population distribution and species management activities within the historic range of the species. Yellowstone cutthroat trout currently occupy 41 percent of their historic habitat. Within Idaho, approximately 45 percent of the historic habitat is presently occupied. German brown, rainbow, and brook trout have been stocked into many drainages and compete with cutthroat trout (see Table III-8). Rainbow trout have been introduced into every hydrologic unit on the Forest and are likely to hybridize with cutthroat trout, causing genetic contamination of cutthroat trout populations.

Table III-9 Population Status of Cutthroat Trout by Hydrologic Unit								
Population Status 1/	Hydrologic Unit							
	Birch	Medicine Lodge	Beaver - Camas	Upper Henry's	Lower Henry's	Teton	Palisades	Average
Large-spotted Cutthroat Trout								
% strong/healthy	0	9	0	3	0	76	51	19
% depressed at risk	6	18	5	12	21	24	40	18
% extinct	94	64	95	85	68	0	9	59
% status unknown	0	18	0	0	11	0	0	4
Fine-spotted Cutthroat Trout								
% strong/healthy	-	-	-	-	-	0	0	0
% depressed at risk	-	-	-	-	-	46	42	44
% extinct	-	-	-	-	-	54	58	56
% status unknown	-	-	-	-	-	0	0	0
<p>1/ These values represent the status of that portion of the population occupying Forest Service lands within each of seven Hydrologic Units. The population status categories were adapted from assessment protocol developed by the Upper Columbia River Basin Assessment Team.</p> <p>A "-" means the fine-spotted cutthroat trout was never present in the hydrologic unit.</p> <p>"Strong/healthy" denotes populations with the following characteristics: 1) all major life-history forms that historically occurred are still present, 2) numbers appear to be stable or increasing and the population is at least half of the historic number or density, and 3) the population within the watershed or within the larger metapopulation of which the population is a part, contains at least 5,000 fish or 500 adults.</p> <p>"Depressed/at risk" denotes populations with at least one of the following characteristics: 1) a major life-history component has either been eliminated or is remnant, 2) the population within the sixth order watershed has a declining trend in abundance, or the population occurs in less than half of the habitat thought to historically support the species, or numbers are less than half of what the watershed supported historically, and 3) total abundance for the whole metapopulation of which this watershed is a part is lower than 5,000 total fish or 500 adults.</p> <p>"Extinct" denotes the species is not present and there is evidence that the species was historically present or could conceivably have had natural access to a watershed even though landscape/habitat characteristics might be outside the range deemed suitable for supporting populations.</p> <p>"Status unknown" denotes that reliable information was not available by which to make a judgement about current presence or absence.</p>								

Wildlife Associated with Aquatic and Riparian Habitats

Wildlife management indicator species include bald eagles, trumpeter swans, spotted frogs, common loons and harlequin ducks. Monitoring and analysis emphasizes habitat conditions to evaluate potential changes in the status or sustainability of these species. Table III-10 illustrates the distribution of these species and their habitats by subsection. A brief overview of these species and habitats follows. Additional information is available in Process Paper D.

Bald Eagle Populations - Scale GYA and Forestwide

GYA Overview - Bald eagles on the Forest are part of the GYA bald eagle population. A brief overview of the GYA population is presented to provide a proper context for bald eagle populations.

From 1960 to 1995, the bald eagle population in the GYA increased exponentially, from about 10 to 111 known breeding areas. In 1982 (the first year of comprehensive data), 49 breeding areas were known with 78 percent occupied by breeding pairs. An average of 0.61 young were fledged per occupied breeding area.

Table III-10 Distribution of Wildlife Management Indicator Species Associated with Riparian and Aquatic Habitats, Including Endangered, Threatened, Candidate and Sensitive Wildlife Species on the Forest within the Seven Subsections

Management Indicators, Species and Habitats	Subsections 1/							
	Status 2/	Lemhi/Medicine Lodge	Centennial Mountains	Island Park	Madison-Pitchstone Plateaus	Teton Range	Big Hole Mtns	Caribou Range Mtns
Riparian and Aquatic Habitats								
Bald Eagle Nesting Habitat	T	N	Y	Y	N	N	Y	Y
Trumpeter Swan Nesting Habitat	S	N	N	Y	Y	N	N	S
Spotted Frog Habitat	C/S	Y	Y	Y	Y	Y	S	S
Common Loon Habitat	S	N	N 3/	Y	Y	N	Y	Y
Harlequin Duck Habitat	S	N	N	N	N	Y	Y	Y

1/ Letters used for distributions among subsections are as follows

Y = Species presence and/or suitable habitat has been documented in the subsection

N = Species presence has not been documented in the subsection, suitable habitat has not been documented

U = Unverified but reliable sightings exist on the Forest, suitable habitat probably exists

S = Suitable habitat probably exists, but there have been no documented or unverified sightings on the Forest

2/ Letters used for Status are as follows E = endangered, T = threatened, NE = nonessential experimental, C= candidate for possible listing as endangered or threatened wildlife, S = sensitive species, '-' = no formal status

3/ Common loons have been observed on Henry's Lake, but this is not within the Forest

Sources of information for this table include Targhee National Forest AMS, 1992, Personal communication with K Johnson, Feb 8, 1995, B Aber, M Oechsner, B Alford, D Welch, R Newton, USFWS - Federal Register 61(40) 7613 (Feb 28, 1996)

and 23 young were produced. The number of known breeding areas had grown to 111 by 1995, with a mean annual occupancy rate of 91 percent, average number of young fledged per occupied breeding area 1.05, and average number of young produced per year of 80.8, over 14 years. Productivity has been well over that considered necessary for population maintenance (Greater Yellowstone Bald Eagle Working Group 1996).

Southeast Idaho and Forest Overview - The data we compiled on bald eagle nesting populations in southeast Idaho dates back to 1972. In 1972, there was one recorded bald eagle nest along the South Fork of the Snake River, which was not on the Forest. As of 1995, total known nesting territories in southeast Idaho numbered 42. The first recorded bald eagle nest on the Forest occurred in 1975, along the Palisades Reservoir. From 1975 to 1995, the bald eagle nesting populations on the Forest increased to 17 nesting pairs.

Bald Eagle Habitat - Scale Forestwide

Nesting habitat on the Forest is associated with large rivers (Henry's Fork and South Fork of the Snake River and Buffalo River), large lakes and reservoirs (Palisades and Island Park Reservoirs and Henry's Lake). Nests are commonly found in large trees, mainly conifers and cottonwoods. Because eagles need large trees to support their large nests, they are often found in multi-storied, late seral stands with open canopies.

During the breeding season, bald eagles eat mainly fish. They also eat waterfowl, shorebirds, upland birds and small mammals. Eagles are very opportunistic predators, especially during the winter. They will eat whatever is available including fish, waterfowl, small mammals and carrion.

Wintering bald eagles tend to congregate near bodies of water and roost communally. Major rivers and large lakes constitute the majority of winter habitats used, although temporary presence of high quality foods may entice eagles to areas far removed from aquatic zones.

Roost sites are usually located in stands of mature or old growth conifers or cottonwoods. For purposes of management, a communal roost is defined as an area usually less than 10 acres in size that contains

greater than or equal to six bald eagles on any given night Critical roost sites are defined as exhibiting traditional use for greater than or equal to five years and contain greater than or equal to 15 eagles per night for greater than or equal to 14 nights per season (USFWS 1983) No critical winter roost sites have been identified in GYA (Greater Yellowstone Bald Eagle Working Group 1996)

Bald Eagle Recovery Plan - The Forest is within the "Greater Yellowstone Bald Eagle Management Zone" as outlined in the Pacific States Bald Eagle Recovery Plan (USFWS 1986) The Recovery Plan established the following habitat and population goals for this management zone

- Habitat management goal - 65 nesting territories, which is considered the minimum number of territories needed to provide secure habitat for the recovered population
- Population management goal - 50 breeding pairs

For the portion of the Greater Yellowstone bald eagle management zone which includes the Forest, habitat management goals have been established for five areas as follows

Island Park/Henry's Fork	- 7 nesting territories
Big Springs	- 2 nesting territories
South Fork Snake River	- 8 nesting territories
Palisades	- 5 nesting territories
Henry's Lake	- 1 nesting territory
Total goal	23 nesting territories

All of these Recovery Plan goals have been exceeded with the current bald eagle populations

Prior to 1995, the bald eagle was listed as endangered under the ESA In August 1995, the U S Fish and Wildlife Service downlisted the improved bald eagle status to threatened

Trumpeter Swan Populations - Scale Rocky Mountain Population and Forestwide

Trumpeter swans on the Forest are part of the Rocky Mountain Population (RMP) (Shea 1994 and Maj and Shea 1996) The RMP comprises the nonmigratory resident tri-state (Idaho, Montana and Wyoming) flocks (including the Forest) and the migratory Canadian flocks From less than 200 birds in 1930, the RMP increased to about 2,500 birds by 1996, the highest in over a century (Maj and Shea 1996) About 80 percent of the RMP winters in southeast Idaho along the Henry's Fork of the Snake and southeast Montana along the Madison River The remaining 20 percent winter in western Wyoming and the Park

The following summarizes trumpeter swan population changes which have occurred from about 1932 to the present (from Maj and Shea 1996)

"From 1932 to the 1970s, the RMP grew from less than 200 birds (100 birds which summered in Canada and 100 birds from the tri-state area) to over 700 birds. Most of this increase was observed within the tri-state flock which had increased to over 500 birds by 1951 While the tri-state flock fluctuated between 450-650 birds (about 72 percent of the RMP) during the next 25 years, the Canadian flock increased to only 200 birds (about 28 percent of the RMP) During the 1970s, the Canadian flock started to grow, reaching 2,200 birds (86 percent of the RMP) by 1994 During the 1970s and 1980s, the tri-state flock continued to fluctuate between 400-600 birds (14 percent of the RMP) Since 1990, in an attempt to expand wintering and breeding distribution of the RMP, over 1,200 swans have been translocated from the tri-state wintering areas to southern Oregon, western Wyoming and other southeast Idaho areas Also, winter feeding at Red Rocks Lakes National Wildlife Refuge was terminated Due to translocation efforts and termination of winter feeding, the nonmigratory tri-state population has declined to less than 300 swans (239 adult birds counted in September 1994) This is the lowest number since 1945 "

Trumpeter Swan Habitat - Scale Forestwide

Nesting habitat occurs on large marshes which may be occupied by numerous breeding pairs, or on smaller lakes and beaver ponds, normally occupied by one pair

Preferred wintering sites in the tri-state area provide ice-free waters with slow current, extensive beds of aquatic plants and low levels of human disturbance. In the tri-state area during most winters, icing restricts swans to sites where geothermal waters, springs or outflows from dams maintain open water.

During the waterfowl hunting season in November and December, RMP swans concentrate in the less-disturbed habitats provided by the Park, Harriman State Park, Red Rock Lakes NWR, and the broad arms of Hebgen Lake, Montana. As these areas freeze and as human activity diminishes elsewhere, swans make greater use of other sites. About 80 percent of the RMP winters in southeast Idaho along the Henry's Fork of the Snake River and in southeast Montana along the Madison River. The remaining 20 percent winter in western Wyoming and the Park (Maj and Shea 1996).

For the period 1982 to 1994, 31 lakes and ponds on the Forest have been used at least during one or more summers, 17 of these 31 have had at least one nesting attempt, 13 of these 31 have successfully produced young during one or more years.

Spotted Frog Populations - Scale Forestwide

We do not know and are not able to provide a spotted frog population estimate for the Forest. An amphibian survey conducted on the Forest in 1992 and 1993 provides an overview on the distribution of spotted frogs on the Forest (Clark and Peterson 1994). This amphibian survey documented spotted frogs at 51 sites, distributed within five subsections, as shown in Table III-10. Ranger District records documented three additional sites with spotted frogs.

Results of the 1992 and 1993 amphibian survey, plus results of spotted frog research conducted in the Park (Turner 1960), illustrate that population detectability and abundance can vary widely between years. Turner (1960) documented that population size fluctuated greatly, depending upon breeding success, and breeding success was tied to the persistence of water at breeding sites, which was regulated by weather conditions. Clark and Peterson (1994) considered two factors, temperature and water availability, as the most important components of population detectability. They suggest these two factors may contribute to significant yearly variation in reproductive activity and foraging/dispersal patterns.

For lands adjacent to the Forest, spotted frogs have been documented in Yellowstone and GTNPs.

Spotted Frog Habitat - Scale Forestwide

Spotted frogs are most likely found near permanent water such as marshy edges of ponds or lakes, in algae-grown overflow pools of streams, or in wet areas with emergent vegetation. They may move considerable distances from permanent water after breeding, often frequenting mixed conifer and subalpine forests, grasslands, and brushlands of sage and rabbitbrush if puddles, seeps or other water is available. Spotted frogs are thought to hibernate in holes near springs or other areas where water remains unfrozen and is constantly renewed. A muddy or soupy substrate in rivers or ponds is preferred by the spotted frog for hibernation (Gomez 1994).

A spotted frog inventory/study has been in progress on the Forest for several years. A recent progress report stated the following:

All frogs were always within two meters of water. None left riparian habitats and almost all were associated with ponds until September when they left the ponds for nearby streams. Ponds within 50 m of permanent streams were an important combination of habitat characteristics for them (Bartelt and Peterson 1993).

Common Loon Populations - Scale Subsections

Common loon abundance on the Forest is highest during spring and fall migrations. Common loons have been documented using four reservoirs, nine lakes and an unnamed pond within five subsections as shown in Table III-10.

Nesting and rearing of young have only been documented at three sites: Indian Lake, Thompson Hole and Bergman Reservoir. Our records indicate only one pair uses each of these sites, and all sites are not used each year. Therefore, the total documented breeding population on the Forest ranges from one to three pairs.

In the GYA, loons nest on several lakes in the southwestern section of the Park, and on a few lakes throughout the rest of the Park, and in GTNP (Clark et al. 1989).

Common Loon Habitat - Scale Subsections

For nesting and brood rearing, common loons need lakes large enough to provide adequate runways for flight (greater than 9 acres in size), deep enough to sustain fish populations and clear enough for them to see their prey (they rely on their sight for foraging). Loons avoid lakes with high levels of human activity, fluctuating water levels, turbid water and unprotected coves.

The following lakes and ponds within the Island Park and Madison-Pitchstone Plateaus subsections have been identified as capable of providing suitable breeding habitat for common loons: Loon Lake, Moose Lake, Indian Lake, Thompson Hole, Junco Lake, Fish Lake, Bergman Reservoir and an unnamed pond. Only Indian Lake, Thompson Hole and Bergman Reservoir have documented nesting and rearing of young.

Common loon habitat on the Forest and in the adjacent National Parks occurs at the highest elevation of any other loon populations in North America (Atkinson 1991). Therefore, the time period for nesting and rearing of young is probably shorter than other areas in North America (Atkinson 1991 and Clark et al. 1989).

Harlequin Duck Populations - Scale Forestwide

Harlequin ducks have been observed along four creeks within three subsections on the Forest: Big Elk Creek, Teton Creek, Darby Creek and McCoy Creek. Successful reproduction has been documented at Big Elk Creek, Teton Creek and Darby Creek (IDFG 1992 - Idaho Conservation Data Center, Atkinson 1991, Atkinson and Atkinson 1990, Cassirer and Groves 1990 and 1991, Bud Alford, personal communication 1995). One to two pairs have been documented along each creek, therefore we estimate the breeding population on the Forest to be between three and six pairs. However, not all streams with potential suitable habitat have been surveyed, so this is considered a minimum estimate of breeding pairs.

The harlequin duck population on the Forest is part of the Pacific Northwest population. The estimated breeding population in the Pacific Northwest is as follows: Washington-274, Oregon-50, Idaho-50, Montana-110, Wyoming-40, Total-514. The documented breeding population on the Forest is part of the Idaho and Wyoming breeding populations. Monitoring of populations in Idaho and Wyoming indicate they are stable (Harlequin Duck Working Group 1993).

Harlequin Duck Habitat - Scale Forestwide

Harlequin ducks are only present on the Forest during the nesting and brood-rearing seasons; they migrate to the coasts of Oregon and Washington to winter. For nesting and brood rearing, these ducks require relatively undisturbed, low-gradient, meandering mountain streams with dense, shrubby riparian areas, and woody debris for nesting and brood rearing. They also need log jams and overhanging vegetation for

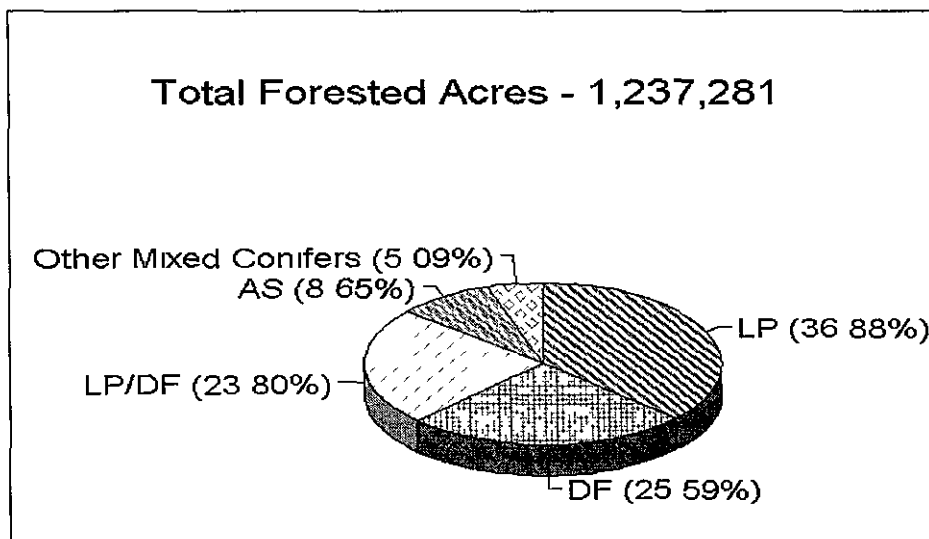

cover and loafing areas. Specific habitat requirements include streams with gradients less than three degrees, greater than 50 percent streamside shrub cover, and at least three loafing sites (midstream boulders or log jams) for every 33 feet of stream. Successful reproduction has been documented in only three locations: Big Elk, Teton and Darby Creeks. Sightings have been made at McCoy Creek, but these sightings have not indicated successful reproduction.

TERRESTRIAL ECOSYSTEMS

Upland Forested Ecosystems - Scale: Subsections

Sixty-eight forest community types currently occur on the Forest. The community types and age classes present on the Forest are displayed by subsection in Table III-3. Major forested community types are shown in Figure III-3. Minor forested community types include whitebark pine, limber pine and Engelmann spruce/subalpine fir. Two community types of cottonwoods occur on the Forest, primarily on the Snake River and lower elevational portions of the Henry's Fork of the Snake River.

Figure III-3
Major Forest Types on the Targhee National Forest

Lemhi/Medicine Lodge - Although only 37 percent of this subsection is forested, this is more forest land than occurred historically. Information from the early 1900s indicates that Douglas-fir has expanded onto lands that were formerly dominated by grasses and sagebrush. Some riparian communities also appear to have more conifers than they did historically.

Approximately 90 percent of the forested land is in the mature age class, indicating a lack of age class diversity in the subsection. With 90 percent of the forests in Douglas-fir there is also a lack of tree species diversity. Many of the Douglas-fir stands are densely stocked. The uniformity of tree species and age classes, as well as the dense stocking, make this area's forests more susceptible to ecosystem disturbances such as insects, diseases and large fires. An example of the latter was the Gallagher Peak Fire which burned 37,230 acres in 1979. This was the largest fire in the last 20 years on the Forest.

Limber pine occurs in the subsection, but is not differentiated as a community type since it occurs as a scattered tree in predominantly Douglas-fir stands. The intermingling of forest land with nonforested communities provides most of the vegetative diversity in this subsection.

Centennial Mountains - The landscape is dominated by forested communities which cover 71 percent of the subsection. Approximately 51 percent of the forested acres are Douglas-fir. Lodgepole pine (21 percent) is found in pockets on low-productivity soils. Mixed lodgepole pine/Douglas-fir (13 percent) and other mixed conifers (10 percent) are also well-represented. The presence of mixed stands indicates that species such as Douglas-fir and subalpine fir are becoming established as stands move through succession. Aspen comprises four percent of the forested acres, which is less than was historically present. Fire suppression has allowed conifers to take over areas that were previously aspen, through the process of succession. Some riparian and mountain meadow communities also appear to have more conifers than they did historically.

Mature forests cover 79 percent of the forested acres, indicating a lack of diversity in age classes. Decreasing diversity however is associated with the loss of aspen over time. Potential for severe fires, insects and diseases are concerns in this subsection, mainly because of the large component of mature forests. Western balsam bark beetle has been active in this area in recent years. Douglas-fir beetle caused losses in Douglas-fir from the late 1980s through 1992 and could again reach destructive levels. Pockets of root rot are common in the subsection, associated with partial cutting of Douglas-fir which occurred in the 1950s.

Past Douglas-fir shelterwood regeneration methods implemented on dry south and west slopes of the Centennials have failed, requiring planting to reforest the sites. Similar treatments on north-facing slopes have tended to regenerate naturally.

Island Park - The landscape is dominated by forested community types, which blanket 93 percent of the area. Forested areas are primarily lodgepole pine types (70 percent) that contain small pockets of aspen, sagebrush/grass, grass meadows and mountain brush. Douglas-fir (10 percent) and mixed lodgepole pine/Douglas-fir (15 percent) community types provide diversity in the area. Lodgepole pine occupies the floor of the Island Park Caldera and Douglas-fir cover types are concentrated on the Caldera rim. On the Caldera rim, aspen and sagebrush areas are evolving towards the Douglas-fir type through the process of succession.

Salvage harvesting has shifted 46 percent of the lodgepole pine into the nonstocked, seedling and sapling classes. Active management of aspen, as well as aspen sprouting in lodgepole pine clearcuts, has moved 34 percent of the aspen into these young classes. Other community types are concentrated in the mature age group.

Many lodgepole pine clearcuts in this subsection have not regenerated naturally and have required planting to restock the stands. The process of planting these sites is expected to continue through the year 2000.

Mature Douglas-fir on the caldera rim experienced outbreaks of spruce budworm and Douglas-fir beetle in the past decade. These problems have now subsided, but could easily recur given the mature condition of the Douglas-fir and the presence of multiple-storied stands. Due to fuel reductions and young age classes associated with harvest, fire is less of a concern here than in most other subsections.

Madison-Pitchstone Plateaus - The landscape is dominated by forests, which comprise 97 percent of the area. Lodgepole pine is the most common forested community type (76 percent), with mixed stands of lodgepole pine and Douglas-fir running a distant second place (14 percent). Relatively minor amounts of aspen and various mixed conifers provide some diversity. The southern portion of the subsection is unique in that there are many wet meadows and small lakes intermingled with the forests.

The 1988 North Fork Fire burned some 17,700 acres in the northern part of this subsection. Past timber harvesting also occurred primarily in the north half of the subsection. These two events have shifted 39 percent of the lodgepole pine into the nonstocked, seedling and sapling age classes. Active management of aspen has also provided some age class diversity.

Most areas of the North Fork Burn regenerated naturally following the fire. Approximately 1,360 acres are being planted in portions of the burn that did not reforest.

Due to fuel reductions and young age classes associated with past harvest and the North Fork Burn, fire is less of a concern here than in many areas. However, conditions in the southern portion of this subsection are presenting some fire risks as mixed aspen and lodgepole pine stands convert to Douglas-fir through succession. Mature subalpine fir and Douglas-fir in this southern area experienced outbreaks of western balsam bark beetle and Douglas-fir beetle in the past decade. These conditions have subsided, but could easily recur since vegetation conditions have not changed.

Teton Range - The landscape is a diverse mix of forested (57 percent) and open (43 percent) community types. Lodgepole pine occurs on poorer soils at lower to middle elevations. Lodgepole is mixed with Douglas-fir in 31 percent of the forested area, indicating that the pine is converting to Douglas-fir through succession. Open Douglas-fir forests, mountain brush, aspen, and sagebrush pockets are found predominantly on south and west aspects. Aspen is becoming mixed with conifers as succession proceeds, and the amount of aspen has likely declined compared with historic levels due to fire suppression. Upper elevations are characterized by dense mixed conifer forests, open grass/forb meadows, and talus slopes. Conifers are moving into riparian areas and mountain meadows due to fire suppression over time.

Since much of this subsection is designated wilderness, timber harvest and fire suppression has been limited, thus only one percent of the forested acres are in the nonstocked, seedling or sapling age classes. The large percentage of mature or older forests make this area ripe for insect infestations, diseases and large-scale fires. In recent years western balsam bark beetle has been active in the subalpine fir. Douglas-fir beetle has killed pockets of Douglas-fir in the past decade, but beetle populations have declined since 1992.

Big Hole Mountains - The landscape is a combination of community types, with 65 percent of the landscape forested and 35 percent nonforested. The most common forested community type by far is mixed lodgepole pine and Douglas-fir, comprising 47 percent of the forested acres. Aspen, pure Douglas-fir and pure lodgepole pine each account for roughly 15 percent of the forests. Mountain brush is common, consisting of mountain mahogany on south slopes and hawthorn, chokecherry, serviceberry, antelope bitterbrush and Rocky Mountain maple on various slopes depending on elevation. Grass/forb meadows and sagebrush are also present in significant amounts. The northwestern boundary of the subsection extends into the cottonwood type along the Snake River.

Only 4 percent of the forested stands are in the nonstocked, seedling or sapling age category. These are concentrated in the north end of the subsection where timber harvest has occurred. The Snake River cottonwood stands and most of the shrublands are also in late age classes. This creates hazards for large fires, insect infestations and disease problems. In the north end of the subsection Douglas-fir beetle and western balsam bark beetle caused damage in the late 1980s and early 1990s, but tapered off in 1994. Insect information is not available for the southern portion. Due to fire suppression and lack of disturbance over the years, conifers have taken over some sites that were historically nonforested. This has likely reduced overall vegetative diversity in the subsection.

Natural regeneration has been difficult to obtain in Douglas-fir stands. In the Palisades area, harvest in both lodgepole pine and Douglas-fir have failed to reforest naturally. This has resulted in the need to plant most of these areas.

Caribou Range Mountains - The Caribou Range Mountains Subsection is similar to the Big Hole Mountains in its overall vegetation characteristics. This subsection is 40 percent nonforested and 60 percent forested. The primary forest types are aspen (31 percent) and mixed lodgepole and Douglas-fir (47 percent). The interspersed forests with sagebrush, grass/forb meadows and mountain brush provides for good diversity of plant species. The northeastern boundary area of the subsection includes cottonwood forests along the Snake River.

Age class diversity is limited, as in many other areas of the forest. Because virtually no vegetation management has taken place in this subsection and fires have been suppressed for many years, only one percent of the forests are in young age classes. Most of the shrublands are also in late age classes. Risks of large fires, insects and diseases are high due to these vegetative conditions. The insect situation in recent years has been similar to that in the Big Hole Mountains Subsection. Douglas-fir is becoming more predominant as it mixes with stands of lodgepole pine, aspen or shrubs. It is likely that there is more Douglas-fir here now, and less aspen, lodgepole pine and shrubland, than existed historically. The Snake River cottonwood stands are also uniformly in the mature age class due to lack of disturbance which they need in order to regenerate.

Establishing natural regeneration of both Douglas-fir and lodgepole pine following harvest has been a problem in this subsection, and most sites have required planting.

TES and Biodiversity Indicator Plant Species - Scale: Forestwide

Fifteen sensitive plant species and one threatened plant species are currently listed on the Forest TES plant species list (Process Paper F) and occur in a broad range of habitats (Table III-11). Twenty-two rare Idaho and Wyoming plant species occur on the Forest and are indicator of biodiversity and unique habitats on the Forest (Process Paper G). Diversity of community types with a range of seral stages is important in maintaining these species on the Forest (Table III-12).

One sensitive plant species, *Astragalus paysonii*, occurs in forest ecosystems of lodgepole pine and mixed Douglas-fir/lodgepole pine communities. The plant is found in disturbed or open areas in mature stands or in early seral lodgepole pine stands following fire. Fire suppression has been identified as a cause of decline of this species over its range (Fertig et al. 1993).

One threatened plant species (Table III-11) is known to exist on the Forest. Listed in 1992 and discovered on the Forest 1996, the Ute ladies'-tresses (*Spiranthes diluvialis*) occurs on the Palisades Ranger District.

Upland Nonforested Ecosystems - Scale: Subsections

Table III-13 illustrates the acres of nonforested community types by subsection throughout the Forest. Herbaceous and shrub ecosystems dominate the landscape in the Lemhi/Medicine Lodge Subsection and are significant in the Centennial, Big Hole Mountains and Caribou Range Mountains Subsections.

Fire suppression has modified the historical 10-25 year frequency of fire in the low to mid elevation areas. Fire suppression coupled with grazing and drought cycles has increased shrub canopy cover and decreased herbaceous species composition within the sagebrush/grass and mountain brush community types. These communities are shifting from a low risk of stand-replacing fires to a high risk of stand-replacing fires over broad areas. A trend is also occurring whereby the historically high percentage of early and mid seral stages is moving toward a predominance of mid and late seral stages.

Livestock grazing has been a use of both forested and nonforested plant communities throughout the forest since before 1900. Effects of grazing, coupled with fire suppression, over time have promoted changes in plant species composition and biodiversity within grazed areas.

Typically, because cattle are grazers, upland areas used by cattle tend to become dominated by browse. Rangelands overgrazed by cattle typically become dominated by forbs, browse and other plants of low palatability and ecological status. Cattle by preference will excessively graze the gentle topography close to water before they move onto the slopes.

Sheep are both grazers and browsers. Over time, areas used by sheep tend to become dominated by grasses. Rangelands overgrazed by sheep typically become dominated by forbs and grasses of low palatability and ecological status. Sheep by preference prefer steeper slopes, do not require water as

Table III-11 Threatened and Sensitive Plants List for the Targhee National Forest				
Species	Occurrence 1/	Status R04	State	Habitat
<i>Agoseris lackschewitzii</i>	D	S	S1	Perennially wet montane and subalpine meadows
<i>Androsace chamaejasme</i> var. <i>carinata</i>	S	S	S1	Rock crevices and rocky soils of limestone and dolomite, 9,500+ft elev
<i>Astragalus amnis-amissi</i>	S	S	S3	Crevices and talus of limestone cliffs
<i>Astragalus aquilonius</i>	S	S	S3	Gravelly, sandy, clay or shale washes and bars at low elevations in sagebrush/ bunchgrass
<i>Astragalus diversifolius</i>	D	S	S1	Alkaline sedge/grass meadows and swales, in sagebrush valleys
<i>Astragalus leptaleus</i>	D	S	S1	Sedge grass meadows and streamsides
<i>Astragalus paysonii</i>	D	S	S1	Disturbed areas and openings in lodgepole pine and limber pine mixed forest
<i>Astragalus vexilliflexus</i> var. <i>nubilus</i>	S	S	S1	Sparsely vegetated open ridges and slopes, 8,000-9,600 ft, subalpine/alpine
<i>Chrysothamnus parryi</i> ssp. <i>montanus</i>	D	S	S1	Beaverhead Red Conglomerate rock and soils, Centennial Mountains
<i>Cymopterus douglassii</i>	D	S	S2	Limestone, subalpine and alpine grassy ridges and summits and meadows
<i>Draba apiculata</i> (<i>D. densifolia apiculata</i>)	S	S	S1	Most gravelly alpine meadows and talus slopes of 10,400-12,000 ft elevation
<i>Lesquerella paysonii</i>	D	S	S1	Rocky, sparsely vegetated slopes, on calcareous substrates
<i>Penstemon lemhiensis</i>	S	S	S1	Sagebrush/grass sites, Birch Creek Valley
<i>Primula alcalina</i>	D	S	S1	Wet, alkaline meadows and streamsides, Birch Creek Valley
<i>Saussurea weberi</i>	S	S	S2	Alpine talus and gravel fields, often limestone 10,000 + ft elevations
<i>Spiranthes diluvialis</i>	D	T		Herbaceous communities in perennially wet zones, between saturated Carex and aquatic habitats, and drier grass/ forb and shrub communities along streams, rivers and wetlands

often as cattle, like to bed on ridges, and because they often have a herder, they can be herded away from riparian zones more often

Although effects are noticeable in sagebrush, aspen and grazed forest communities, they are especially evident in riparian communities that have had a history of cattle overgrazing

Approximately 79 percent (1,466,475 acres) of Forest acres are identified as range allotments which are open to grazing. Approximately 400,640 acres are presently closed to grazing. There are 154 allotments (76 cattle and 78 sheep) on the forest

% of Subsection	63	29	7	3	43	35	40	32

HERBACEOUS- Includes grass, sedge/forb, and grass/forb communities on all landscapes from low elevations to alpine
 SAGEBRUSH/GRASS- Low sagebrush, silver sagebrush, black sagebrush, Wyoming big sagebrush and mountain big sagebrush community types
 MOUNTAIN BRUSH - Includes chokecherry, mountain clover, mountain big sagebrush, serviceberry, antelope bitterbrush, curl-leaf mountain mahogany, hawthorn, snowberry and snowbrush ceanothus in mixed communities
 AQUATIC - Includes lake, river and riparian vegetation
 ROCK/BARRENTALUS - Includes rock outcrops, bare and rocky windswept ridges, talus slopes and boulder fields from lowlands to alpine
 UNDESIGNATED - open areas of unknown composition

As documented in the Annual Operating Plan (AOP) and/or the Allotment Management Plan (AMP), all of the allotments have grazing systems in place which implement various grazing strategies (Process Paper K), and include grazing utilization standards. As previously mentioned, grazing and browsing of vegetation by wildlife and domestic livestock can have both positive and negative effects on many components of an ecosystem.

The nonforested vegetation on the Forest is grouped into two broad plant communities: riparian and upland vegetation. Forestwide, the ecological status of these communities occurs in various seral stages that meet, move toward meeting, or do not meet DVC (see Table III-6 for riparian conditions and Table III-14 for upland conditions).

The DVC for both riparian areas and nonforested uplands is defined as: The specific future condition of rangeland vegetation and other resources such as aquatic habitat and water quality that meet management objectives as identified in the Forest Plan, AMPs, or other documents. DVC can be expressed in terms of ecological status of the vegetation; it could also include species composition, diversity of habitats, or age classes of species, desired soil protection, including conditions of soil cover, erosion, compaction, and loss of soil productivity. In riparian areas, it includes conditions of streambank and channel stability, stream habitat, streamside vegetation, stream sedimentation, and water quality. DVC are those conditions resulting from meeting the Forest Plan objectives regarding the management of riparian and nonforested upland sites, aquatic habitat, and water quality. On a forestwide scale, achieving DVC would result in a mix of plant communities that meet management objectives.

On a forestwide scale, riparian and nonforested upland areas in PFC will meet DVC.

In order to achieve PFC objectives across the forest, it will be necessary to provide a mix of plant communities by moving vegetation from one seral stage to another seral stage and/or maintain some

vegetation communities in less than mid to late seral stages on a site specific basis. For example, Some small scale areas, less than 5,000 acres, of dense sagebrush with canopy cover greater than 30 percent, ranging from high mid to late seral stage, may be treated in order to meet landscape level (thousands to hundreds of acres by definition) PFC objectives. The result is the treated vegetation (burned, rotobeat, chemically treated, etc) would move from high seral stage to lower seral stage. Another example of where the Forest could make a decision to manage vegetation in less than mid to late seral status is where a substantial quantity of nonnative plants, plants of lower seral status or plants of lower seral status dominate the landscape and reintroduction or management of desirable native plants would not be practical.

High density of mountain big sagebrush (> 30 percent canopy cover), undesirable herbaceous plants in the understory and other indicators of downward trend in vegetation are characteristics of unhealthy rangeland in unsatisfactory ecological condition. For example, on the Dubois Ranger District, there are approximately 42,310 acres in less than satisfactory condition because of high density of mountain big sagebrush due to fire suppression.

Table III-14 Acres of upland vegetation meeting, moving toward or not meeting DVC Existing situation by subsection 1/								
Plant Community 2/	Subsection							
	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison- Pitchstone Plateaus	Teton Range	Big Hole Mtns	Caribou Range Mtns	Forest Total
Upland vegetation meeting DVC	228,284	187,027	196,721	22,939	49,499	230,399	113,520	1,028,389

2/ Includes acres of undetermined status.								

Noxious Weeds - Scale: Forestwide

Noxious weeds are undesirable plants designated by federal or state law. These plants in abundance are not part of a properly functioning ecosystem. They generally possess one or more of the following characteristics: aggressive and difficult to manage, parasitic, carrier or host of serious insects or diseases, nonnative, new to the United States or common in the United States. Soil-disturbing activities encourage the establishment and spread of noxious weeds. They are spread across the forest by a variety of natural and unnatural activities. Introduction (seeding) and invasion of aggressive species such as timothy and smooth brome have further decreased biodiversity by out-competing native species along roadways and in riparian communities. Nine different species of noxious weeds occupy approximately 19,000 acres of forest and rangeland on the Forest (see Table III-15). As per the existing approved forestwide direction for the control of noxious weeds, the forest uses an integrated pest management approach (biological, chemical and mechanical treatments) to control the spread of noxious weeds. This direction and the Affected Environment, Chapter III, of the 1987 forestwide EA are incorporated by reference into this analysis. Presently, the Forest does not apply chemical herbicides by aerial applications and only ground application is approved.

Wildlife Associated with Terrestrial Habitats

Distributions of wildlife management indicator species are displayed in Table III-16. Monitoring and analysis emphasizes habitat conditions to evaluate potential changes in the status or sustainability of these species. A brief overview of these species and habitats follows. Additional information for these species is available in Process Paper D.

Elk Populations - Scale Forestwide

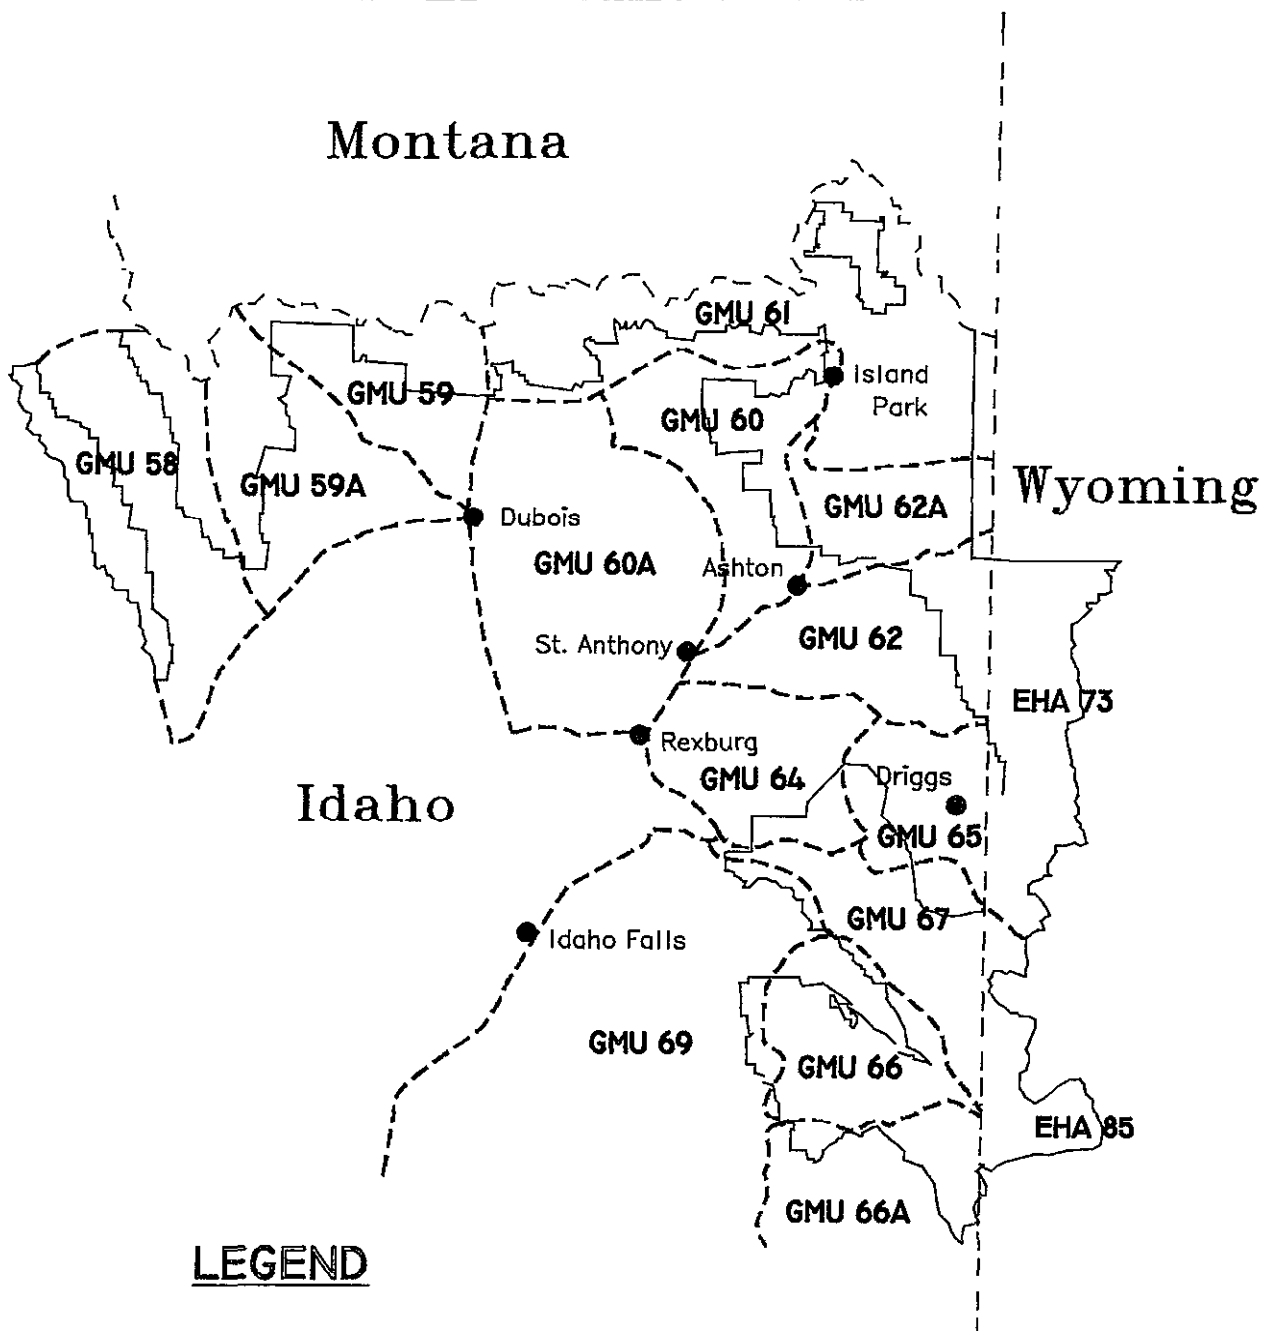

We do not know the total population of elk which use the Forest. The number of elk changes with seasons. Elk populations are lowest during the winter period because they migrate to lower elevation winter ranges. Many of the winter ranges occur off Forest lands. Elk populations on the Forest are highest during the spring, summer and fall periods, as elk migrate back from winter range areas. Some elk migrate through the Forest and summer in the Park.

For the Idaho Game Management Units which encompass the Forest (Figure III-4), elk populations have sustained annual harvests which have ranged between 940 to 3,111 animals harvested between 1979 to 1995. Elk harvests have shown a general increasing trend from 1979 to the present. The average annual harvest for the period 1979 to 1995 was 1,915 animals.

For the Wyoming Elk Hunt Areas which encompass the Forest (Figure III-4), elk populations have sustained annual elk harvests which have ranged between 66 to 205 animals harvested for the years 1979 to 1995. Elk harvests have shown a general increasing trend from 1979 to the present. The average annual harvest for the period 1979 to 1995 was 134 animals.

Age and sex composition data reported for elk populations on or adjacent to the Forest range from 29 to 53 calves per 100 cows, and the mid to low teens to 22 bulls per 100 cows (USDI Fish and Wildlife Service 1994). Using an average age and sex composition of 40 calves per 100 cows and 20 bulls per 100 cows, the pre-harvest elk population to sustain the average elk harvests from 1979 to 1995 is calculated to be 10,250 animals (the post harvest elk population would be 8,201). This is considered a minimum population.

estimate because it does not include the need to account for animals dying from natural causes and unreported wounding losses

Elk Vulnerability - Scale Principal Watershed

EV is defined as a measure of elk susceptibility to being killed during the hunting season (Lyon and Christensen 1992, IDFG letter May 12, 1995) EV is an important component of the State Fish and Game Departments' management goals and objectives The following describes the Idaho and Wyoming goals as related to EV

Idaho Department of Fish and Game

Game Management Units 60, 61, 62, 62A, 64, 65, 66, 69 (Figure III-4) These game management units are known as "Ready Access Units " For these units, the IDFG goal for the post hunting season population is > 15 bulls per 100 cows (this equates to a maximum of 60 percent bull elk mortality), with 40 percent of bulls branch-antlered, and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 50 percent and the percentage of mature bulls (having six points on one antler) at or above 10 percent (IDFG letters May 12, 1995 and Nov 15, 1995)

Game Management Units 58, 59, 59A, 67 (Figure III-4) These game management units are known as "Front Range Units " For these units, the IDFG goal for the post hunting season population is > 20 bulls per 100 cows (this equates to maximum of 50 percent bull elk mortality), with 50 percent of bulls branch-antlered, and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 35 percent and the percentage of mature bulls (having six points on one antler) at or above 20 percent (IDFG letters May 12, 1995 and Nov 15, 1995)

IDFG stated that these goals were not being met in all Game Management Units when the spike only general hunts were started in 1991 IDFG provided the following information for each Game Management Unit (Elk Task Group Workshop, Sept 15 and 21, 1992)

- Units 58, 62, 64, 65 no data or not enough data to know if goals are being met
- Units 59, 59A, 60, 62A not meeting goals
- Units 61, 66, 67 meeting goals

Wyoming Game and Fish Department (WGF)

Elk Hunt Areas 73 and 85 (Figure III-4) The WGF goal for the post hunting season population is > 20 bulls per 100 cows This equates to a maximum of 50 percent bull elk mortality These goals are being met in these elk hunt areas

EV models (Unsworth et al 1993) have been proposed as a predictive tool that managers can use to predict mortality rates and monitor elk vulnerability (IDFG letter May 12, 1995) Research conducted by the IDFG and the University of Idaho provides the basis for this EV analysis (Unsworth et al 1993) For the Forest Plan Revision, two parameters were determined to be most important for EV analysis

- 1 Hunter-day densities (measured in total hunter-days per square mile on a watershed basis)
- 2 Motorized road and trail densities and cross-country motorized access (measured in miles per square mile on a watershed basis)

For the Idaho portion of the Forest, EV analysis is used to predict percent mortality of bull elk during the general antlered elk rifle hunting season, which usually occurs in the month of October For the Wyoming portion of the Forest, this EV analysis is used to predict percent mortality of bull elk during the general license any elk-rifle hunting season, which usually occurs during the months of September and October

1/ Letters used for distributions among subsections are as follows
Y = Species presence and/or suitable habitat has been documented on the Forest For the grizzly bear, Y = areas within the recovery line
N = Species presence has not been documented on the Forest, suitable habitat has not been documented
U = Unverified but reliable sightings exist on the Forest, suitable habitat probably exists
S = Suitable habitat probably exists, but there have been no documented or unverified sightings on the Forest

2/ Letters used for Status are as follows E = Endangered, T = Threatened, NE = Nonessential Experimental, S = Sensitive species,
- = no formal status

3/ It is generally assumed that since conifer and/or aspen and/or cottonwood habitats exist in every subsection of the Forest, then habitat for most of these cavity nesting species occurs in each subsection

Sources of information for this table include Targhee National Forest AMS, 1992, Personal communication with K Johnson, Feb 8, 1995, B Aber, M Oechsner, B Alford, D Welch, R Newton, USFWS-Federal Register 61(40) 7595-7613 (Feb 28, 1996)

Targhee National Forest Elk & Deer Winter Range

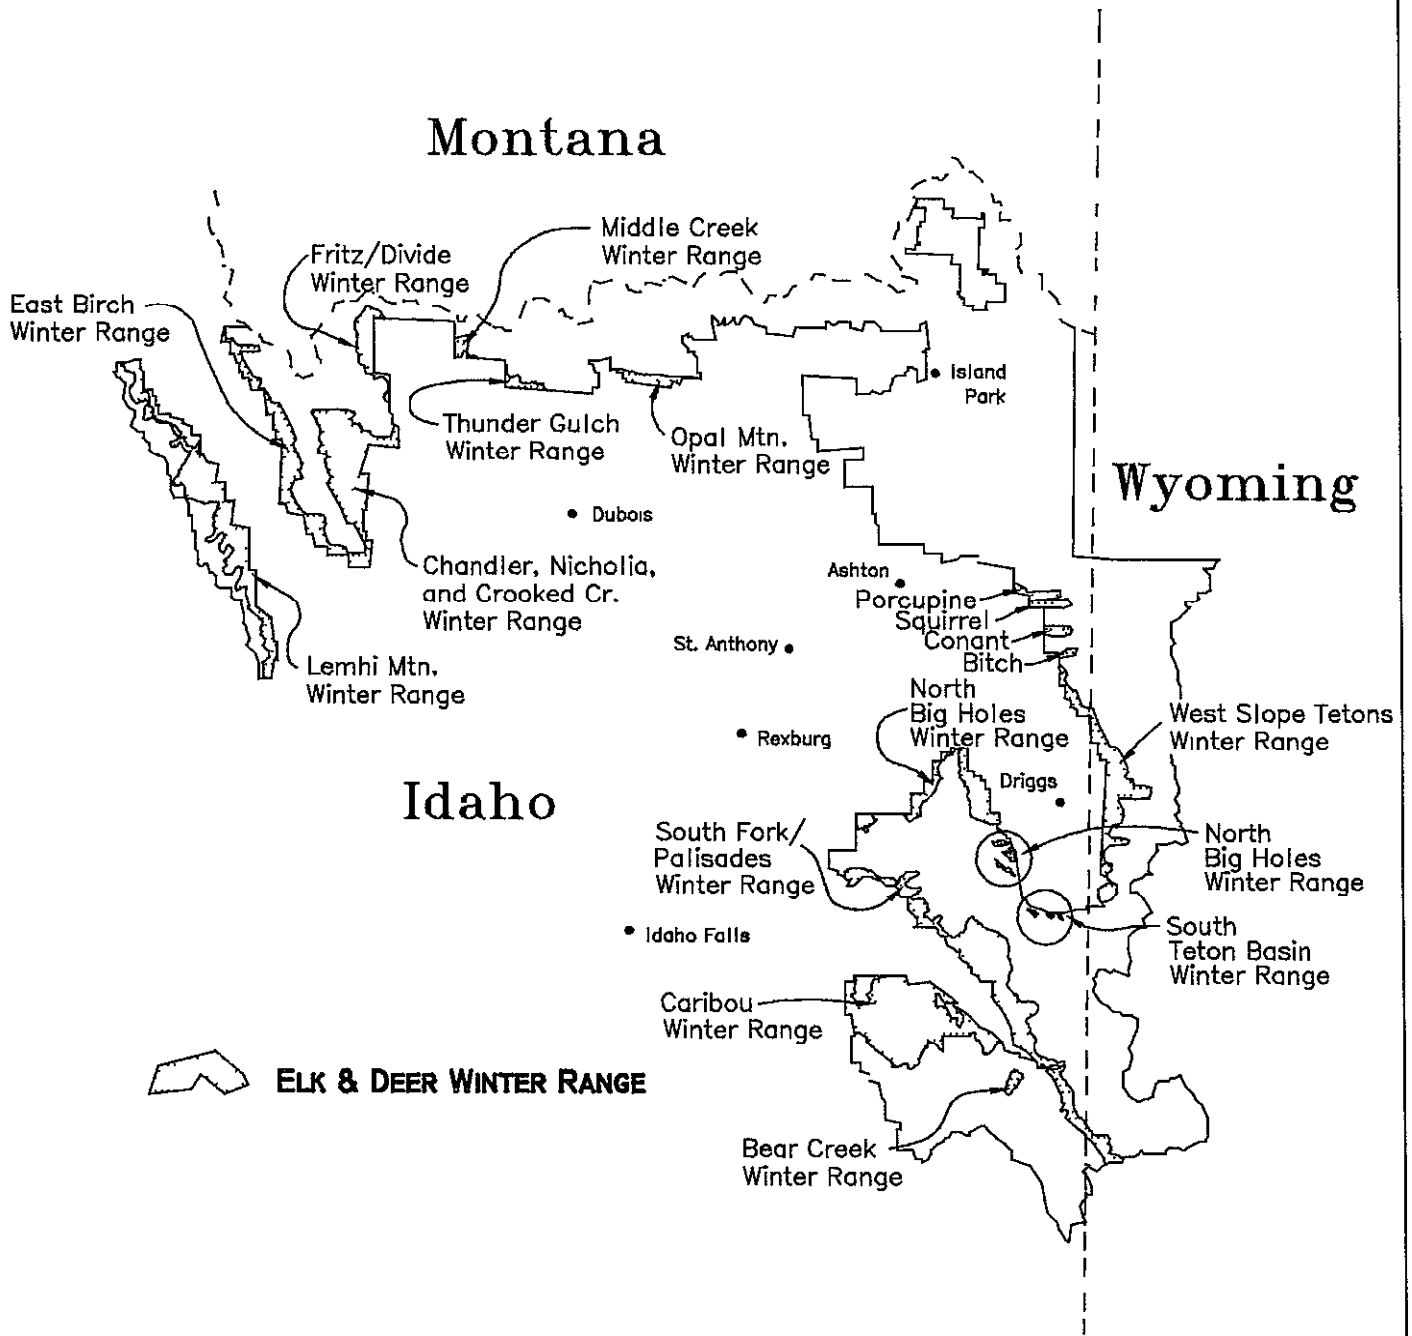

Figure III-5

Not To Scale

The bull elk mortality percentages indicate threshold levels, which if exceeded would likely require additional management actions to be initiated by the State Fish and Game Departments (IDFG letter, May 12, 1995). These management actions could include such items as shorter hunting seasons, restrictions on the type and number of animals to be harvested, restrictions on the number of hunters, more controlled hunts and less opportunity for general hunts, etc. The estimated current bull elk mortality, as calculated with the EV analysis, varies from a low of 21 percent mortality in Wyoming along the west slope of the Tetons to 97 percent mortality in the Buffalo River watershed. At the present time, 48 percent of the Forest meets State Fish and Game thresholds for EV.

Elk Habitat Effectiveness (EHE) - Scale Principal Watersheds

EHE is defined as the percentage of available habitat that is usable by elk outside the hunting season. EHE is not a measure of elk populations and it is not a measure of habitat carrying capacity (Lyon and Christensen 1992). For this EHE analysis, it is the spring, summer and early fall habitat that is usable by elk outside the general elk-rifle hunting seasons. The following two habitat parameters were determined to be most important for EHE analysis:

1. Motorized road and trail densities (measured in miles per square mile on a watershed basis). As motorized road and trail densities increase, EHE declines. This relationship is based on research by Dr. L. Jack Lyon (Lyon 1983).

2. Elk hiding cover, measured as a percentage of a watershed in hiding cover. Hiding cover is defined as vegetation capable of hiding 90 percent of a standing adult elk from the view of a human at a distance equal to or less than 200 feet (Lyon and Christensen 1992). Optimum habitat exists when 50 to 60 percent of a watershed is in hiding cover, this is based on the judgement of professional biologists involved in elk workshops on the Forest.

An EHE of 100 percent (usually displayed as 1.0) would require no motorized roads and trails within a watershed, and 50 to 60 percent of the watershed being in hiding cover. The existing values for EHE range from a low of 0.46 in a portion of the Centennial Mountains to a high of 0.74 in the Madison-Pitchstone Plateaus Subsection just south of the Park, an average forestwide EHE value is 0.57.

Elk & Deer Winter Range - Scale Forestwide

Generally, elk and deer winter range are those areas at lower elevations with lower snow accumulations, used by elk and deer during the winter months (Lyon and Christensen 1992). Map number 24 in the map packet and Figure III-5 display these winter ranges on the Forest.

The winter range areas on the Forest are the upper elevational limits of elk and deer winter ranges, more winter range acres exist at lower elevations on BLM, State, and private lands. Some elk and deer which summer on the Forest also winter on ranges in Montana and Wyoming. The distribution and number of wintering deer and elk on the Forest depends on winter severity. Generally a higher proportion of elk and deer winter at lower elevations on BLM, State and private lands. Development on private lands is a concern as it can adversely affect areas historically used by wintering elk and deer.

There are 313,825 acres of crucial mid-to-late elk and deer winter range on the Forest. These winter range areas have a wide range of vegetation types, with some of the areas mostly in mature forest and some predominantly in tall sagebrush/grass habitats. Some winter range shrub communities (such as mountain mahogany) are in overmature or decadent condition due primarily to historical fire suppression.

Currently, 12 percent of the winter range acres are closed to livestock grazing. On the acres open to livestock grazing, there are 6,352 AUMs of domestic sheep grazing and 26,423 AUMs of cattle grazing.

Currently, 78 percent of the winter range acres are meeting DVCs for condition, 13 percent of the winter range acres are improving and moving toward DVCs, and 9 percent of the winter range acres are not improving.

About 38 percent of the winter range acres are capable of being used for cross-country snowmachine use, i.e. slopes less than 50 percent and open vegetation conditions and types. Some winter range areas have historically been popular snowmachine use areas. In these areas the Forest has implemented restrictions on cross-country snowmachine use. Currently 28 percent of the winter range acres are closed to cross-country snowmachine use.

There is one feed ground for wintering elk and deer on the Forest, this is in Rainey Creek, within the South Fork/Palisades winter range area. The number of animals fed at this site varies each winter, primarily based on the severity of the winter. The Table III-17 displays data from the IDFG and illustrates what has occurred from 1978 to 1995.

Table III-17 Rainey Creek Feed Ground Data		
Winter Season	Number of Elk Fed	Number of Deer Fed

Grizzly Bear Population - Scale Yellowstone Grizzly Bear Ecosystem (YGBE) and BMU

Portions of the Forest are within the YGBE. The YGBE has been divided into BMUs. Portions of the Forest are within the following BMUs: Henry's Lake (Subunits 1 and 2), Plateau (Subunits 1 and 2), and Bechler/Teton (Figure III-6).

The following are recovery goals for the YGBE (U.S. Fish and Wildlife Service 1993):

"Fifteen females with cubs over a running 6-year average both inside the recovery zone and within a 10-mile area immediately surrounding the recovery zone, 16 of 18 BMUs occupied by females with young from a running 6-year sum of observations, no two adjacent BMUs shall be unoccupied, and known, human-caused mortality not to exceed 4 percent of the population estimate based on the most recent 3-year sum of females with cubs. Furthermore, no more than 30 percent of this 4 percent mortality limit shall be females. These mortality limits cannot be exceeded during any two consecutive years for recovery to be achieved."

Table III-18 presents grizzly bear population data for the YGBE for the years 1987-1996 (from personal communication with Dr. Chris Servheen, USDI Fish and Wildlife Service, 1996). As of 1996, the status of the grizzly bear population in relation to the recovery goals was as follows:

- The running 6-year average for unduplicated females with cubs was 22.8, compared to the recovery goal of 15.

- Average annual human-caused mortality was 7.1 bears, compared to the recovery goal mortality limit which is to be < 8.8 bears (< 4 percent mortality limit of the population estimate)
- Average annual human-caused female mortality was 2.8 bears, compared to the recovery goal mortality limit which is to be < 2.6 bears (< 30 percent of the total known mortalities)
- The distribution of females with young was 18 of 18 BMUs, compared to the recovery goal of 16 of 18 BMU's

Knight, et al (1995) report on appraising the status of the Yellowstone grizzly bear population. Using data collected from 1976 to 1993, they report the following estimated rates of annual increase in the population

- 3.9 percent annual increase using the annual totals of distinct family groups
- 4.6 percent annual increase using reproductive and survival data
- 2.2 percent annual increase using a common probability of sighting distinct family groups

Year	Annual Undup FWC's ^{2/}	Annual Adult Female Mortality	Annual All Female Mortality	Annual Total Mortality	4% Total Mortality Limit ^{1/}	30% All Female Mortality Limit	Annual Total Mortality 6yr avg	Annual Female Mortality 6yr avg
1987	13	2	2	3				
1988	19	0	3	5				
1989	16	0	0	1				
1990	24	4	6	9				
1991	24	0	0	0				
1992	23	0	1	4	9.4	2.8	3.7 (22/6)	2.0 (12/6)
1993	20	2	2	3	9.2	2.8	3.7 (22/6)	2.0 (12/6)
1994	20	3	3	10	8.2	2.5	4.5 (27/6)	2.0 (12/6)
1995	17	3	7	17	6.9	2.1	7.1	3.2
1996	33	3	4	9	8.8	2.6	7.1	2.8

Target	Target Number	1996 Number
Unduplicated females with cubs (6 year average)	15	22.8
Known mortality limit as 4% of total population estimate	8.8	7.1
Female mortality limit as 30% of total known mortalities	2.6	2.8
Distribution of female with young	16 of 18	18 of 18

1/ Calculated as 4% of the minimum population estimate for the most current year which is based on the minimum number of females with cubs seen over the past three years
2/ Annual Undup FWC's = Annual Unduplicated Females with Cubs
3/ Calculated with updated percentage of adult females in the population as 22.3%

Targhee National Forest Bear Management Units

Figure III-6

Not To Scale

Following is a brief overview of grizzly bear observations for the Forest portion of each BMU Subunit

Henry's Lake BMU - Subunit 1 - Compared to the other BMUs and Subunits on the Forest, this area had the fewest grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986)

From 1986 through 1995, we have records of one grizzly bear sighting in MS2 habitat, two grizzly bear sightings in MS3 habitat and two grizzly bear sightings on private lands. In addition to these sightings, radio collared bear #139 was trapped on MS3 and private lands in 1987 and 1988. Compared to the other BMUs and Subunits on the Forest, this area also had the fewest grizzly bear sightings from 1986 through 1995.

No female sows with cubs have been documented in the MS2 portion of this subunit (from available documentation dating back to 1959)

Henry's Lake BMU - Subunit 2 - Compared to the other BMUs and Subunits on the Forest, this area had the second highest number of grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986)

From 1986 through 1995, we have records of eight grizzly bear sightings, all on Forest land (three of these sightings are on the border between this subunit and the Plateau BMU). In addition, there are numerous recorded observations of radio-collared bear #258 (an adult female), which was relocated into this BMU subunit in the fall of 1995. Bear #258 left this BMU subunit in the spring of 1996 and returned to her previous home range.

Sows with cubs have previously been documented in this subunit. A female sow with cubs was documented in this BMU subunit (but not on the Forest) during 1996 (Interagency Grizzly Bear Committee News Release, Oct. 28, 1996).

Plateau BMU - Subunit 1 - Compared to the other BMUs and Subunits on the Forest, this area had one of the lowest number of grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986)

From 1986 through 1995, we have records of five grizzly bear sightings within subunit 1. In addition, there are many recorded observations of radio-collared bear #227 (a male) for portions of each summer from 1994 through 1996.

Searching through reports in our files, we can document that two sows with cubs were observed for the period 1965 to 1984 (one of the sows was shot and killed by hunters in the fall of 1984). From 1985 to the present, no sows with cubs have been reported in this subunit.

Plateau BMU - Subunit 2 - Compared to the other BMUs and Subunits on the Forest, this area had one of the lowest number of grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986)

From 1986 through 1995, we have records of six grizzly bear sightings within subunit 2.

From 1965 to 1984, there were four sightings of bear groups (two or more bears together) but our records do not confirm that these were sows with cubs. From 1985 to 1993, no sows with cubs were observed. In 1994, one sow with cubs was observed near the southern boundary of the subunit. No sows with cubs have been reported during 1995 and 1996.

Bechler/Teton BMU - Compared to the other BMUs and Subunits on the Forest, this area had the highest number of grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986)

From 1986 through 1995, we have records of 26 grizzly bear sightings, which is the highest number of sightings compared to the other BMUs and Subunits for this time period.

Four of the 26 grizzly bear sightings from 1986 through 1995 were sows with cubs. These four sightings are considered reliable, but none were verified. Therefore, these sightings have not been included in the official records for sows with cubs in each BMU. This BMU is currently occupied by a sow with cubs, based on verified sightings from the GTNP portion of the BMU.

Grizzly Bear Habitat - Scale Bear Management Unit and Subunit

Table III-19 outlines the existing habitat and conditions for the Forest portion of BMUs and subunits. Process Paper D presents an overview of food habitats, cover requirements, denning habitat, home ranges and motorized access effects. The following text represents some additional information for each BMU subunit.

Henry's Lake BMU, Subunit 1 -

- Most of the area is open to snowmachine use from December 1 to June 1.
- Even though there are nine sheep allotments and three cattle allotments in use, we have no record of grizzly bear/livestock conflicts on N F lands (1959-1997).
- Henry's Lake Flat and MS3 - About 42 percent (53,500 acres) of this subunit includes private lands on Henry's Lake Flat and highly developed Forest land classified as MS3 habitat. OROMTRD is 2.48 mi/sq mi on Henry's Lake Flat and 3.6 mi/sq mi on Forest lands. The average daily traffic for U.S. Highway 20 is about 2,400 vehicles per day. In 1995, there were 172,646 fishing hours of activity on Henry's Lake from May to October (IDFG Creel Survey Summary Sheet, Henry's Lake, 1995). Snowmachine use occurs whenever there is enough snow. Livestock grazing occurs on most of the private lands.

Henry's Lake BMU, Subunit 2 -

- In the Lionhead portion of this subunit, snowmachine use is allowed from December 1 to June 1. In the remainder of this subunit, snowmachine use can occur whenever there is enough snow.
- There have been no grizzly/livestock conflicts since sheep grazing was eliminated in this area in 1984.

Plateau BMU, Subunit 1 -

- Snowmachine use is allowed from December 1 to June 1 in the North Fork Fire area. In the remainder of the subunits, snowmachine use is allowed whenever there is enough snow.

Plateau BMU, Subunit 2 -

- Snowmachine use is allowed whenever there is enough snow.

Bechler/Teton -

- Outside of the designated wilderness areas, snowmachine use is allowed whenever there is enough snow.
- All sheep allotments in MS1 habitat have been closed. There are two sheep allotments in use in MS2 habitat and two grizzly/sheep conflicts have been documented. There are three cattle allotments in use with no documented conflicts.

Table III-19 Existing Habitat Conditions for the Forest Portion of Bear Management Units and Subunits					
Habitat Component	Henry's Lake BMU Subunit 1	Henry's Lake BMU Subunit 2	Plateau BMU Subunit 1	Plateau BMU Subunit 2	Bechler/Teton BMU

Notes: Information for the Henry's Lake BMU/Subunit 1, starting with motorized road and trail miles is for the MS 2 portion of the Subunit. Information for the MS 3 portion and Henry's Lake Flat are discussed in the text. Also, the last verified grizzly bear mortality on the Targhee occurred in 1984. There have been no verified grizzly bear mortalities on the Targhee from 1985 to present.					

Central Idaho Nonessential Experimental Population Area and Yellowstone Nonessential Experimental Population Area for Gray Wolf. (USDI Fish and Wildlife Service 1994 b)

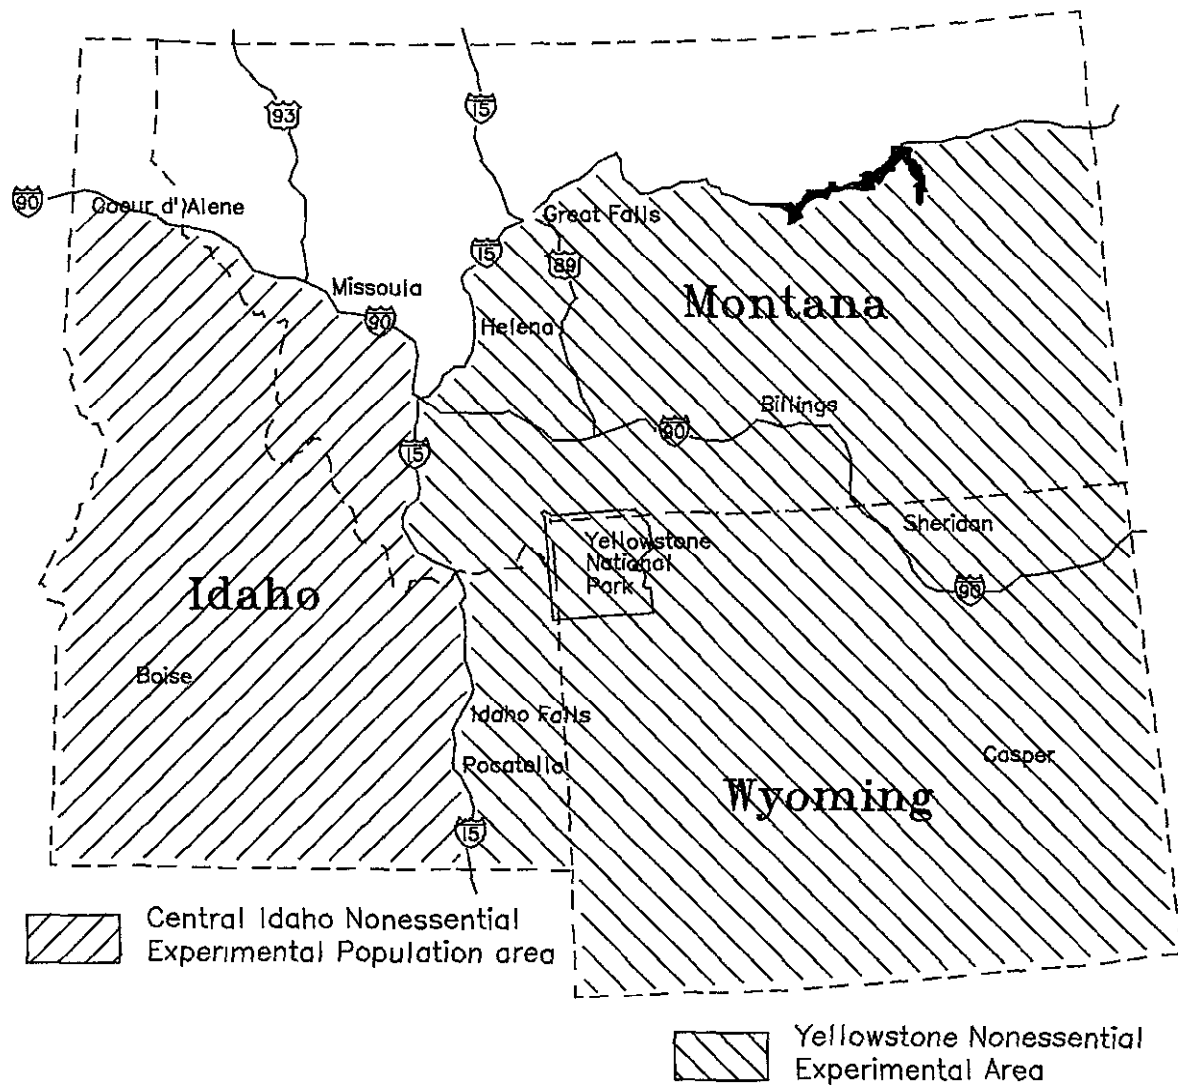

Figure III-7

Gray Wolf Populations and Habitat - Scale Forestwide

Possible sightings of gray wolves have occurred on the Forest and are summarized in the AMS and Process Paper D. There have been no reported sightings of packs or evidence of successful breeding. In April, 1994 the USDI Fish and Wildlife Service approved the Final EIS for The Reintroduction of Gray Wolves to the Park and Central Idaho (USDI Fish and Wildlife Service 1994a). In November of that year final rules were issued for the establishment of a nonessential experimental population of gray wolves in the Park, central Idaho, and southwestern Montana (USDI Fish and Wildlife Service 1994b). As a result of these actions, the following conditions exist:

The portion of the Forest west of Interstate 15 is within the Central Idaho Nonessential Experimental Population Area. The portion of the Forest east of Interstate 15 is within the Yellowstone Nonessential Experimental Area (Figure III-7). All wolves found in the wild within the boundaries of these management areas, after the first wolf releases, will be considered nonessential experimental animals (USDI Fish and Wildlife Service 1994a and b).

Status of Wolf Reintroductions - 1995 and 1996 - In the Yellowstone Nonessential Experimental Population Area

- 14 Canadian wolves were released in 1995,
- 17 Canadian wolves were released in 1996,
- 2 packs produced 9 pups in 1995,
- 3 packs produced 10 pups in 1996,
- as of September 10, 1996, there were 34 free ranging wolves and 15 wolves in captivity pens, 6 wolves have died. 3 were illegally shot, 1 was killed by a vehicle on a road, 1 was killed by agents from ADC after twice killing domestic sheep, 1 was killed in an accident (falling into a thermal pool). Note: Our records of wolves that died may not be complete,
- 1 male wolf (the mate of the wolf that died by falling into a thermal pool) was located on the Forest for a few days in 1996. This wolf has returned to the Park.

In the Central Idaho Nonessential Experimental Population Area

- 15 Canadian wolves were released in 1995,
- 20 Canadian wolves were released in 1996,
- no pups were born in 1995,
- 3 packs produced pups in 1996 we do not know how many pups,
- as of July 1996, there were 26 radio-collared wolves with known locations, there were 5 radio-collared wolves that have not been located for various periods of time,
- there have been 5 wolves that have died. 1 was killed by a mountain lion, 1 was shot, 1 died of starvation, 1 accidentally drowned during a control operation and 1 was euthanized during release.

This gray wolf reintroduction does not conflict with existing or anticipated Federal agency actions or traditional public uses of park lands, wilderness areas or surrounding lands (USDI Fish and Wildlife Service 1994b). Land use restrictions may be temporarily used by land or resource managers to control intrusive human disturbance, primarily around active den sites between April 1 and June 30, when there are five or fewer breeding pairs of wolves in a recovery area. After six or more breeding pairs become established in a recovery area, land-use restrictions would not be needed (USDI Fish and Wildlife Service 1994a).

The ability of individuals holding grazing permits on public land to harass adult wolves in an opportunistic, noninjurious manner will become part of their permit conditions so it is clearly understood exactly what can occur. There is a seven day reporting requirement for any such incident (USDI Fish and Wildlife Service 1994a).

The following conditions and criteria will apply in determining the problem status of wolves (USDI Fish and Wildlife Service 1994a). Livestock in this context refers to only cattle, sheep, horses or mules.

Wounded livestock or some remains of a livestock carcass must be present with clear evidence that wolves were responsible for the damage. Also there must be reason to believe that additional losses would occur if the problem wolf or wolves were not controlled. Such evidence is essential since wolves may simply feed on carrion they have found while not being responsible for the kill.

Artificial or intentional feeding of wolves must not have occurred. Livestock carcasses not properly disposed of in an area where depredations have occurred will be considered attractants. On federal lands, removal or resolution of such attractants must accompany any control action. Livestock carrion or carcasses on federal land, not being used as bait in an authorized control action (by agencies), must be removed, buried, burned, or otherwise disposed of such that the carcass(es) will not attract wolves.

On federal lands, animal husbandry practices identified in existing approved AMPs and AOPs for allotments must have been followed.

If additional livestock depredations were likely, proper animal husbandry practices were employed (proper disposal of livestock carcasses, etc.), artificial feeding did not take place, and federal grazing allotment plans were followed, agencies would harass, capture, move, or kill wolves that attacked livestock (defined as cattle, sheep, horses, or mules only) on public or private land. Prior to the establishment of six breeding pairs, depredating females and their pups will be captured and released at or near the site of capture, one time prior to October 1. If depredations continue, or if six packs are present, females and their pups will be removed.

Wolf recovery will not result in wolf travel corridors or linkage zones being established. The size and proximity of the areas where wolves will be managed for recovery are large enough, close enough and have enough public land between them that additional areas (travel corridors) are not required in the foreseeable future to maintain a viable wolf population after the three subpopulations become established (USDI Fish and Wildlife Service 1994a).

Primary Cavity Nester Populations - Scale Forestwide

Eight primary cavity nesting species potentially occur on the Forest. We do not know and are not able to provide population estimates for these species. Hejl et al., (1995) provided relative abundance ratings for these species for general mature to older forest habitats in the Rocky Mountains. These abundance ratings are shown in Table III-20.

Species	Relative Abundance by General Forest Habitat 1/			
	Mixed Conifer 2/	Lodgepole Pine	Spruce-Fir	Aspen
Lewis' Woodpecker	-	-	-	R
Red-naped Sapsucker	U	R	C	C
Williamson's Sapsucker	U	U	U	U
Downy Woodpecker	R	-	C	C
Hairy Woodpecker	C	U	C	C
Three-toed Woodpecker	R	U	U	U
Black-backed Woodpecker	R	R	R	R
Northern Flicker	C	C	C	C

1/ A=abundant, C=common, U=uncommon, R=rare, - = no information
 2/ Mixed conifer is primarily dominated by Douglas-fir

Three bird studies on the Forest (one completed and two in progress) have documented the presence of seven of the eight primary cavity nesting species, the Lewis' woodpecker that has not been documented in the studies (Douglas and Ratti 1984, Patla 1995 and Kliene 1996 progress reports, Hoffman and Rotella 1996 progress report) These studies indicate that red-naped sapsuckers and northern flickers are the most common primary cavity nesting species

Primary Cavity Nester Habitat - Scale Forestwide and Watersheds

Primary cavity nesting species excavate nest cavities in snags (dead standing trees) Live trees may also provide nest sites depending on the presence of infection or injury which would allow the birds to excavate a nesting cavity Table III-21 provides an overview of the habitat requirements for these species Because of the need to have large enough snags or live trees for excavating nest cavities, these species are most often associated with mature to old growth forests However, these species have been documented using areas following stand replacing fire and timber harvesting when snags are present

Species	Snag DBH (inches)	Snag Height (feet)	No of Cavities per year	Territory Size (acres) 1/	No Snags per acre for 100% Biological Potential 1/
Lewis's Woodpecker	12-27	5-170	1	0-15 (15)	48-1 01 (1 01)
Red-naped Sapsucker	9-47	15+	1	5 1-12 (10)	1 5 (1 5)
Williamson's Sapsucker	12-37	15+	1	10-12 (10)	33-1 5 (1 5)
Downy Woodpecker	6-14	6-50	2	5-50 (10)	16-5 (3)
Hairy Woodpecker	9-29	15+	3	6-25 (25)	6-1 92 (1 8)
Three-toed Woodpecker	7-19	15+	3	35-200 (75)	06- 6 (59)
Black-backer Woodpecker	8-17	6+	3	75-100 (75)	12- 6 (59)
Northern Flicker	10-51	6+	1	8-500 (40)	38- 48 (38)

1/ Numbers in parentheses indicate territory sizes and number of snags used for analysis purposes on the Forest

Four of these primary cavity nesting species (hairy woodpecker, northern flicker, yellow-bellied sapsucker, Williamson's sapsucker) require larger size snags and provide larger nesting cavities which are important for several other species of animals

We analyzed overall biological potential for the primary cavity nesting species as a group, and a biological potential analysis was done for the four species which require larger size snags These biological potential analyses are based on existing snag densities Currently, the biological potential for the primary cavity nesting species as a group is 0 61, and the biological potential for the larger cavity nesting species is 0 47 This biological potential is considered a minimum potential because it only considered snag densities Additional biological potential exists with live trees

Forest Owl Populations - Scale Forestwide and Subsections

Forest owls include the flammulated, boreal and great gray We do not know and are not able to provide population estimates for these species The following documents what we know about their relative abundance and distribution on the Forest, also refer to Table III-16 (USDA Forest Service 1994, AMS 1992)

Flammulated Owl We expect the flammulated owl to be present on the Forest only during the breeding season We consider this owl to be rare on the Forest, as we have only documented it in four locations

For lands adjacent to the Forest, flammulated owls have been documented on only three areas the Madison Ranger District of the Beaverhead N F , the Sand Creek Wildlife Management Area north of St Anthony, Idaho, and BLM land near Moose Creek (Keepout Draw) in Teton Valley

Boreal Owl The boreal owl is considered to be a year-round resident on the Forest When the AMS was completed in 1992, only three boreal owl observations had been recorded Sawtell Peak in 1987, Targhee Creek in 1988 and McGarry Canyon in 1990 All of these observations were in the Centennial Mountains Subsection Since completion of the AMS, more boreal owl surveys have been done on the Forest and boreal owls have been documented in five subsections Centennial Mountains, Island Park, Madison-Pitchstone Plateaus, Teton Range and Big Hole Mountains In relation to other owls on the Forest, we consider this owl to be uncommon in terms of abundance

For lands adjacent to the Forest, boreal owls have been documented in these areas the Leadore Ranger District on the Salmon/Challis N F , the Dillon and Madison Ranger Districts on the Beaverhead N F , the Hebgen Lake Ranger District on the Gallatin N F , Yellowstone and GTNP, the Greys River Ranger District on the Bridger-Teton N F

Great Gray Owl The great gray owl is a year-round resident on the Forest The great gray owl has been documented in every subsection on the Forest In relation to other owls on the Forest, we consider this owl to be common in terms of abundance

For lands adjacent to the Forest, great gray owls have been documented in these areas BLM lands and State of Idaho lands, the Madison Ranger District on the Beaverhead N F , Red Rocks Lake National Wildlife Refuge, the Hebgen Lake Ranger District on the Gallatin N F , Yellowstone and GTNP, the Greys River Ranger District on the Bridger-Teton N F

Forest Owl Habitat - Scale Subsection

Flammulated & Boreal Owls - The habitat components considered most important for the flammulated and boreal owls are a) the amount of mature and older Douglas-fir, mixed conifer and aspen; b) primary cavity nesting habitat for the larger woodpeckers (hairy woodpecker, northern flicker, yellow-bellied sapsucker and Williamson's sapsucker) Thirty acres encompasses the entire home range of a flammulated owl pair during the breeding/nesting period Thirty acres encompasses the largest size nest stands recorded in the literature for boreal owls Approximately 3,600 acres encompasses the winter home range of a boreal owl Summer home ranges are slightly smaller

Great Gray Owl - The habitat components considered most important for this species are a) mature or older forest habitat to provide suitable nesting sites, and b) suitable foraging habitat which includes nonstocked and seedling forests and nonforested habitats Great gray owl nest sites average 143 meters from nearest opening, a 143 meter radius circle is about 16 acres The largest home ranges recorded for great gray owls is 6.5 sq km , which is 1,622.4 acres (USDA Forest Service 1994a)

Furbearer Populations - Scale Forestwide and Subsection

We do not know and are not able to provide population estimates for wolverine, lynx, fischer and marten The following documents what we know about their relative abundance and distribution on the Forest

Wolverine - In 1985 a wolverine survey was done in Idaho to determine the location and status of populations (Groves 1987) Results of the survey indicated that three areas of the State had wolverine populations The Forest was not within one of these areas However, documented observations of wolverine on the Forest have occurred in the Centennial, Island Park, Madison-Pitchstone Plateaus, Teton Range and Caribou Range Mountains Subsections Respectively, there have been 18, one, three, seven and one observations between 1961 and 1995 Because of large home ranges, wolverine populations always exist at low densities

For lands adjacent to the Forest, wolverine have been documented in the following general areas: Leadore Ranger District on the Salmon/Challis N F, Dillon and Madison Ranger Districts on the Beaverhead N F s, Dillon District of the BLM, Hebgen Lake Ranger District on the Gallatin N F, and Yellowstone and GTNP

North American Lynx - Historically, lynx populations were minimal in the contiguous United States due to a lack of suitable habitat (U S Fish and Wildlife Service 1994c). Favorable habitat conditions for the lynx dissipate with decreasing latitude. Thus, the lynx is restricted to higher elevations the more southern the latitude (U S Fish and Wildlife Service 1994c).

The only documented reports of lynx on the Forest occur in the Wyoming portion of the Big Hole Mountains Subsection (USDA Forest Service 1994b). For lands adjacent to the Targhee N F, lynx have been documented in the Park, and the Greys River Ranger District. Based on current knowledge, it is unlikely that the Forest historically or currently provides habitat for a viable resident lynx population.

Fisher - Historically, fisher were never known to occur in the Idaho portion of the GYA (Clark et al 1989). However, one fisher was trapped in the Island Park Subsection at Warm River Butte in 1978. Also, fisher tracks were observed in the Teton Range Subsection near North and South Leigh Creeks during the winter of 1995 by a research team studying furbearers on the Forest. At this time, there is uncertainty about both the historical and current status of fisher populations on the Forest.

We are aware of one documented fisher sighting on lands adjacent to the Forest, this sighting was in 1990 near Drake Canyon (T3N, R45E, Sec 7) in Teton Basin. Also, during 1995, Yellowstone Ecosystem Studies (a private group from Bozeman, Montana) used a remote camera to photograph a fisher in Republic Creek on the Shoshone N F (K Barber, Shoshone N F, personal communication).

American Marten - Marten sightings have been documented within all subsections except Lemhi/Medicine Lodge. Marten are considered abundant on the Forest, and the state Fish and Game Departments provide a trapping season for marten.

We are not sure about the presence of American marten in the Lemhi/Medicine Lodge subsection. Suitable habitat exists for marten, however, conifer forests only make up 37 percent of this subsection, and the forests are not connected to other forested habitats with known marten populations. Therefore, there is uncertainty about marten populations and habitat in this part of the Forest.

Furbearer Habitat - Scale Forestwide and Subsections

The following documents what we know about these species on the Forest, also refer to Table III-16 (USDA Forest Service 1994b).

Wolverine - Home ranges of adult wolverine in North America range from less than 100 sq km to over 900 sq km (38.6 sq mi to 347.5 sq mi). Yearly home ranges for females with young range from 47 sq km to 105 sq km (18.2 sq mi to 40.5 sq mi). Wolverines occupy treeless alpine areas to dense forested areas. Wolverine food habits are generally described as opportunistic omnivores in summer and primarily scavengers in winter. Natal den sites have consisted of snow tunnels, talus and boulder fields, holes dug under fallen trees, within hollow trees, beaver lodges, old bear dens, under roots of trees, etc.

It has been suggested that wolverine habitat should consist of large refugia, representative of the vegetation zones that wolverine occupy. Details for these large refugia have not been established. It has been suggested that wolverine will benefit from conservation strategies for grizzly bears, wolves and cougars.

North American Lynx - Lynx habitat in the western mountains consists primarily of two structurally different forest types occurring at opposite ends of the stand age gradient. Lynx require early seral forests that contain high numbers of prey (especially snowshoe hares) for foraging and late-seral forests that contain

cover for kittens (especially deadfalls) and for denning. Intermediate seral stages may serve as travel cover for lynx but function primarily to provide connectivity within a forest landscape. Although such habitats are not required by lynx, they fill in the gaps between foraging and denning habitat within a landscape mosaic of forest seral stages.

Fisher In the western mountains, fishers prefer late-seral forests (especially for resting and denning) and occur most frequently where these forests include the fewest large nonforested openings. Avoidance of open areas may restrict the movements of fishers between patches of habitat and reduce colonization of unoccupied but suitable habitat. Large physical structures (live trees, snags and logs) are the most frequent fisher rest sites, and these structures occur most commonly in late-seral forests.

Until it is understood how these structures are used and can be managed outside their natural ecological context, the maintenance of late-seral forests will be important for the conservation of fishers.

American Marten Although American martens at times use other habitats, populations depend on coniferous forests. Martens associate closely with mesic, late-seral coniferous forests, but occur in other vegetation types. They use treeless areas less than predicted from their spatial availability, especially in winter. Clearcutting reduces marten densities for several decades. In some areas, under conditions that are not well understood, martens may use regenerating clearcuts after a decade or two if sufficient structures useful to martens persist from the clearcutting. The effect of other cutting regimes, including small patch cutting, seed tree cutting or salvage harvest of dead or damaged timber have not been widely studied.

Coarse woody debris, especially in the form of large diameter boles, is an important feature of marten habitat. Logs are most useful to martens for gaining access to subnivean areas and for resting. Removal of coarse woody debris from forests or interfering with processes that make it available in suitable sizes and stages of decay may reduce habitat quality for martens.

Knowledge of landscape-scale habitat use is almost completely lacking regarding behavioral or population responses of martens to such landscape attributes as stand size, stand shape, area of stand interiors, amount of edge, stand insularity, use of corridors and connectivity. Marten use of residual forest stands surrounded by clearcuts on Newfoundland Island was a function of stand size; stands < 15 ha (37 acres) in area had lower capture success rates than larger stands. However, the dearth of knowledge in this area makes managing forested landscapes for marten highly conjectural.

Northern Goshawk Populations - Scale Forestwide

We do not know and cannot provide a population estimate for northern goshawks on the Forest. Goshawk monitoring on the Forest has identified 50 goshawk territories, 13 of these territories are historic (meaning we have no record of activity since 1989) and 37 of these territories have been active one or more years from 1989 to the present (Process Paper D, Patla 1990, 1991, 1992, 1995 and personal communication). Not all of the Forest has been inventoried or monitored for goshawks, therefore we expect additional goshawk territories exist.

For lands adjacent to the Forest, goshawks have been documented in the following areas: Idaho National Engineering and Environmental Laboratory (INEEL), Dillon and Madison Ranger Districts on the Beaverhead N F, Red Rocks Lake National Wildlife Refuge, Yellowstone and GTNP, Sand Creek Wildlife Management Area, Greys River Ranger District on the Bridger-Teton N F, Grays Lake National Wildlife Refuge, and BLM lands.

Northern Goshawk Habitat - Scale Forestwide

The goshawk is a forest habitat generalist that uses a variety of forest types, forest ages, structural conditions and seral stages (Reynolds et al. 1992). It preys on small to medium sized birds and mammals.

(robins and chipmunks to grouse and hares), which it captures on the ground, in trees or in the air. Forests within goshawk nesting home ranges should be an interspersed mosaic of structural stages - young to old forests - to increase the diversity of habitat for goshawks and their many prey species. Northern goshawks have been documented in all seven subsections.

Nest Areas - Nest areas include one or more forest stands, several nests and several landform characteristics. Nest areas are occupied by breeding goshawks from early March until late September, and are the focus of all movements and activities associated with nesting. The size (20-25 acres) and shape of nest areas depend on topography and the availability of patches of dense, large trees.

Nest areas are often used more than one year, and some are used intermittently for decades. Many pairs of goshawks have two to four alternate nest areas within their home range. All previously occupied nest areas may be critical for maintaining nesting populations because they contain the habitat elements that attracted the goshawks originally. Additionally, replacement nest areas are required because goshawk nest stands are subject to loss from catastrophic events and natural decline.

Goshawk nest stands have a relatively high tree canopy cover and a high density of large trees. Studies suggest that the dense vegetation in these stands provide relatively mild and stable microenvironments, as well as protection from predators of goshawks. Nest areas are usually classified as mature and older forest stands.

Post-Fledging Family Area (PFA) - PFAs include the area used by the adults and young from the time the young leave the nest until they are no longer dependent on the adults for food. The PFA surrounds the nest area and, although it generally includes a variety of forest conditions, the vegetation structure resembles that found within nest stands. PFAs vary in size from 300 to 600 acres (mean = 415 acres). PFAs provide the young hawks with cover from predators, and sufficient prey to develop hunting skills and feed themselves in the weeks before juvenile dispersal. Forests in the PFA's should contain overstories and habitat attributes critical in the life-histories of goshawk prey species.

Foraging Area - Goshawks prey on birds and mammals in the larger body-size classes available to forest-dwelling hawks. Generally speaking, because larger species of vertebrates have less dense populations than smaller species, predators of large prey must hunt over large areas in order to meet their energy requirements. Goshawk foraging areas are about 5,000 to 6,000 acres.

Limited radiotelemetry evidence suggests that goshawks prefer mature forests for foraging. Additional information on the composition and structure of goshawk foraging habitat was gleaned from information on the habitat requirements of goshawk prey species. Raptor populations are often limited by prey populations, and choice of foraging habitat by goshawks is predicted, at least in part, on habitats where prey are abundant and accessible.

The foraging area comprises the largest portion of the goshawk nesting home range and therefore typically includes a greater diversity of landforms, forest cover types and vegetation structural stages. Important habitat components include snags, downed logs, woody debris, openings, large trees, herbaceous and shrubby understories and interspersed vegetation structural stages (forest seral stages).

Winter Habitat - Winter movements and winter habitat for goshawks are poorly understood. We know of only one published study in the Rocky Mountains (Squires and Ruggiero 1995). Documented migrations of four adult birds from nesting areas to winter areas ranged from 65 to 185 kilometers (40 to 115 miles). However, two of the adult birds could not be found for most of the winter period, so these distances may be minimums. Winter habitats included aspen with mixed conifer stands, spruce-fir and lodgepole pine stands, and small groves of cottonwood surrounded by open sagebrush-wheatgrass prairies (Squires and Ruggiero 1995).

One adult goshawk has been monitored during the winter period on the Forest. During the winter period, this bird made several migrations between its nesting territory in the Big Hole Mountains to the Henry's Fork of the Snake River near St. Anthony, Idaho (S. Patla, personal communication).

Red Squirrel Populations and Habitat - Scale Forestwide and Subsections

Red squirrels are so strongly associated with the conifer forests (Table III-16) that their population densities fluctuate with cone crops (Smith 1968, Gurnell 1983, Halvorson and Engeman 1983). Since red squirrels are so strongly dependent upon conifer seeds as a food supply, conifer forests must be of seed-producing age before red squirrels will make significant use of them. Habitat quality is also related to nesting cover and food-caching sites. Natural cavities are preferred by red squirrels as nest sites (Hamilton 1939, Layne 1954). However, underground nests and external tree nests are more commonly used where cavities are not available (Fancy 1980). Large diameter trees, large standing snags, and fallen trees are important sites for cone storage (Vahle and Patton 1983).

Suitable habitat for red squirrels exists in all subsections. At the present time, about 80 percent of the forested acres are of cone-bearing age (about 928,000 acres).

Red squirrels are known to defend territories of 0.5 to 7.5 acres in size (USDA Forest Service 1991). This would provide a range of 85 to 1,280 red squirrels per square mile of suitable habitat. There is about 1,450 square miles (928,000 acres) of suitable habitat on the Forest, so a population range for the Forest could be 123,000 to 1,856,000 squirrels. As stated above, red squirrel populations will fluctuate depending on fluctuations in cone crops. The red squirrel is considered abundant on the Forest.

Peregrine Falcon Populations - Scale Rocky Mountains and Forestwide

The Forest is within the American Peregrine Falcon Recovery Plan - Rocky Mountain/Southwest Population (USDI Fish and Wildlife Service 1977/revised 1984). The objectives for the Recovery Plan are a minimum of 183 breeding pairs with the following distribution: Arizona-46, Colorado-31, Idaho-17, Montana-20, Nebraska-1, New Mexico-23, North Dakota-1, South Dakota-1, Texas-8, Utah-21 and Wyoming-14.

In 1991, there were 363 known peregrine falcon pairs within the area covered by the Recovery Plan, in 1993, there were an estimated 450 pairs, and based on 1994 surveys, the current Rocky Mountain/Southwest population consists of 559 breeding pairs, surpassing the recovery objective by 376 pairs (USDI Fish and Wildlife Service 1994 and 1995).

In 1995, 13 pairs occupied territories within Idaho (six of these pairs were on the Forest), six pairs were successful in producing 16 young for an average of 1.2 young per pair and 2.7 young per successful pair (three of the successful pairs and eight of the young produced were on the Forest) (Levine et al. 1995). Peregrine falcon eyries are currently distributed within five subsections on the Forest.

The current reproductive level has been sufficient to support considerable population growth. At this time, the U.S. Fish and Wildlife Service has published an advanced notice of a proposal to remove the American peregrine falcon from the list of endangered and threatened wildlife (USDI Fish and Wildlife Service 1995).

For lands adjacent to the Forest, peregrine falcons have been documented in the following general areas: Big Butte and Medicine Lodge Resource Areas of the BLM, INEEL, Dillon Ranger District (Beaverhead N.F.), Dillon District (BLM, Montana), Hebgen Lake Ranger District (Gallatin N.F.), Yellowstone and GTNP, Market Lake and Mud Lake Wildlife Management Areas, Camas National Wildlife Refuge, Gray's Lake National Wildlife Refuge, and Gray's River Ranger District (Bridger-Teton N.F.).

Peregrine Falcon Habitat - Scale Forestwide

Peregrine falcons occupy a wide range of habitats (Table III-16), typically found in open country near rivers, marshes, lakes and coasts. They capture prey by striking from above with their talons after a high-speed dive. Foraging habitat includes wetlands and riparian habitats, meadows and parklands, croplands such as hayfields and orchards, gorges and mountain valleys and lakes which support good populations of small to medium terrestrial birds, shorebirds and waterfowl.

Cliffs are preferred nesting sites (also known as eyries), although reintroduced birds now regularly nest on man-made structures such as towers and high-rise buildings. Peregrines may travel more than 18 miles from the nest site to hunt for food, however a 10 mile radius around the nest is an average hunting area, with 80 percent of foraging occurring within a mile of the nest.

Peregrine falcons generally migrate south for the winter to the Gulf of Mexico, and into Mexico and Central America, or to large rivers and wildlife refuges in the United States (USDA Forest Service 1991).

Significance of environmental contaminants and other potential threats Peregrine falcons declined precipitously in North America following World War II. Research implicated organochlorine pesticides, particularly the pesticides DDT, DDE (a metabolite of DDT), and dieldrin, applied in the United States and Canada during this same period as causing the decline (USDI Fish and Wildlife Service 1994 and 1995). Use of these chemicals peaked in the 1950s and early 1960s and continued through the early 1970s (USDI Fish and Wildlife Service 1995).

The most significant event in the recovery of the peregrine falcon was the restriction placed on the use of organochlorine pesticides. Use of DDT was restricted in Canada in 1970 and in the United States in 1972. Restriction that controlled the use of aldrin and dieldrin were imposed in the United States in 1974. Since implementation of these restrictions, residues of the pesticides have significantly decreased in many regions where they were formerly used. Consequently, reproductive rates in most surviving peregrine falcon populations in North America improved and numbers began to increase (USDI Fish and Wildlife Service 1995).

There is no evidence, thus far, that any environmental contaminant other than DDT/DDE have been recently causing significant, widespread mortality or reproductive failure in the American peregrine falcon in the western United States (USDI Fish and Wildlife Service 1994).

Other known negative factors, such as illegal shooting and collisions with wires, fences, cars, and buildings, are much less significant to the western American peregrine falcon at the population level. On an individual nest-site basis, human-caused disturbance or habitat alterations close to an active peregrine falcon nest can be a problem. For example, in some areas, rock-climbing is a growing sport and has resulted in nest failure. Breeding-season closure of rock-climbing cliff areas in close proximity to nesting American peregrine falcons has recently prevented adverse effects. Power lines, especially distribution lines, cause peregrine falcon mortality, but the rate must be low, because many peregrine falcons nest successfully each year near power lines, especially in urban areas. Land-use practices adjacent to American peregrine falcon eyries that do not result in extensive habitat changes or excessive disturbance sometimes appear to have little adverse effect on nesting success. Generally, the recent apparent increase in the number of pairs of American peregrine falcons in the West provides evidence that significant adverse factors affecting the western subspecies at the population level are being alleviated or have been reduced (USDI Fish and Wildlife Service 1994).

Bighorn Sheep Populations and Habitat - Scale Forestwide and Subsections

Bighorn sheep are present in four areas of the Forest, with an estimated total population of 225 animals (AMS 1992)

Lemhi Mountains - These bighorn sheep are part of a population that includes the adjacent Challis N F. Forty-one bighorn sheep were transplanted on the Challis N F side in two transplants occurring in 1983 and 1984. A helicopter survey conducted in 1988 by IDFG found 31 bighorns (14 ewes, 8 lambs, 9 rams). No hunt has been authorized on these sheep.

South Beaverhead Range - (also referred to as the southern Bitterroot Mountains or the Medicine Lodge area). Forty-one bighorn sheep were introduced into the south Beaverhead Range in four transplants between 1976 and 1982.

This herd has not grown as expected. We do know that the transplanted bighorn sheep had lung worms at the time they were transplanted. A helicopter survey conducted in 1988 by IDFG found only 17 bighorns (13 ewes, 3 lambs, 1 ram).

The ear tags or remains of several of the released sheep have been found since the releases, but mortality causes are unknown. No hunt has been authorized on these sheep. Monitoring of bighorn sheep through recording of ground observations has been done by the Dubois Ranger District and IDFG. The highest number recorded from ground observations was 37 animals (5 rams and 32 ewes and lambs) in October 1995 (Process Paper D).

The Dubois Ranger District has implemented several habitat projects for bighorns in the south Beaverhead Range. Seven water developments, three of these in cooperation with the Foundation for North American Wild Sheep, have been installed for bighorns. Other water developments for upland game, deer, and elk on Forest Service and BLM lands are used by bighorns on transition range. Prescribed burns have been done to reduce sagebrush density and improve forage quality for bighorns.

All of the winter observations we know about have been on the Birch Creek side of the mountain range (we are not aware of observations in the Nicholia, Chandler, Kelly and Snakey drainages during the winter).

Lionhead Area - These bighorn sheep are part of a population that includes the Gallatin N F in Montana. During the summer and fall months, 12 to 15 sheep can frequently be seen in Idaho. Idaho has never authorized a hunt on this herd. Montana has authorized hunts on this population.

This sheep population winters on high elevation windswept ridges. There is historical low elevation winter range available, but the sheep do not use it. In the early 1990s, the Montana Department of Fish, Wildlife and Parks introduced bighorn sheep into the low elevation winter range, hoping they would associate with the bighorns at the higher elevations during the summer, and re-establish the migration to the low winter ranges. This has not happened, the introduced bighorns have remained at the low elevations year-around.

Westslope of the Tetons - These bighorn sheep are part of a population that includes GTNP. WGF authorizes a hunt for bighorns on the Forest, no bighorn sheep hunting is allowed in GTNP. A total of 11 rams were harvested from 1977 to 1986, no bighorns have been harvested during the hunt from 1987 to 1991. Table III-22 is a summary of herd composition counts which have been done by WGF.

Interviews with old timers who were familiar with the Teton Range suggest that the bighorn population may have declined to a low point in the 1930s and 1940s, with some recovery in numbers during subsequent years. Minimum counts of bighorn sheep (not necessarily based on full coverage of suitable habitat) have ranged from 39 to 97 since 1976. Whitfield (1983) believed that the total population approached 125 in

1981 and was static or declining Annual winter counts and high winter mortality during the last two years indicate that the population may have declined substantially

Date	Total	Rams	Ewes	Lambs	Unclass
November 1991	66	21	28	17	
February 1991	90	27	40	23	
November 1989	54	19	27	8	
December 1988	89	25	35	29	
March 1981	46	10	25	11	
January 1979	60	13	28	10	9
Dec/Jan 1977-78	39	12	18	9	
Jan/March 1976	53	17	23	13	(+18 tracks)
Nov/Dec 1975	26	9	11	6	
April 1974	42	14	15	7	6
March 1957	60	8	12	10	30

Winter range is one limiting factor for this bighorn sheep population All of the bighorns are wintering at elevations above 9,000 ft on windswept ridges For the past 8-9 years, no bighorn sheep have been documented wintering on the Forest, all have been found wintering in GTNP

Since 1994, GTNP has been doing a bighorn sheep study which involved radio-collaring and tracking Movements during the winter were minimal, commonly with sheep located only a few hundred meters away from the previous location Movements increased substantially in May when sheep commonly moved to lower elevations at the mouth of the canyons where snowmelt had occurred on south and east exposures. Summer ranges consisted of upper-elevation grassy benches and ledges near cliff areas for escape

Neotropical Migratory Bird Populations and Habitat - Scale Rocky Mountain and Forestwide

We do not know and cannot provide population estimates for neotropical migratory birds Hejl et al (1995) conducted an extensive review of literature on forest birds in the Rocky Mountains, and provided a relative abundance rating for species during the breeding season for general forest habitats, emphasizing mature or older stands Information from Hejl et al , (1995) for the four general forest types which encompass the Forest and bird species documented to occur on or adjacent to the Forest (AMS 1992) are listed in Process Paper D Of the 143 species listed there, 52 (36 percent) are long distance migrants, 48 (34 percent) are short distance migrants, and, 43 (30 percent) are permanent residents

Predator Control

Predator control activities have been conducted on the Forest since it was first established The 1996 APHIS-ADC Decision Notice and EA for Predator Damage Management in Southern Idaho provides direction for USDA Animal and Plant Health Inspection Service-Animal Damage Control (APHIS-ADC) in con-

ducting predator control activities on the Forest The APHIS-ADC Decision Notice selected the alternative, "Current Program plus Livestock Protection Collar " The Affected Environment, Chapter III, of the 1990 Targhee Forestwide Predator Control EA is incorporated by reference into this analysis The applicable sections of the Affected Environment, Chapter 2, of the 1996 ADC EA are also incorporated by reference into this analysis

Unique Ecosystems

Research Natural Areas (RNAs) - Scale Forestwide

RNAs are part of a national network of ecological areas designed in perpetuity for research and education and/or to maintain biological diversity on National Forest System lands (Table III-23) RNAs are for non-manipulative research, observation and study They also assist in implementing provisions of the NFMA

The forest currently has nine established RNAs, each having unique features representing some of the Forest's diversity In addition, there are three proposed RNAs No other areas are being evaluated for RNA status Site-specific information for existing and proposed RNAs on the Forest can be found in the 4063 files, which contain Environmental Analysis Reports, and/ or the Establishment Records and project files

Table III-23 Research Natural Area Descriptions				
Area Name	Year Established	Ranger District	Size in Acres	Area Features
Meadow Canyon *	1981	Dubois	3880	alpine tundra, rare plants
Copper Mountain	1987	Dubois	550	alpine grassland
Thurman Creek	1991	Island Park	330	spring fed streams
Moose Cr Plateau	1991	Island Park	440	obsidian sands, lodgepole pine

Targhee National Forest

Average Daily Traffic (ADT) at Selected Locations

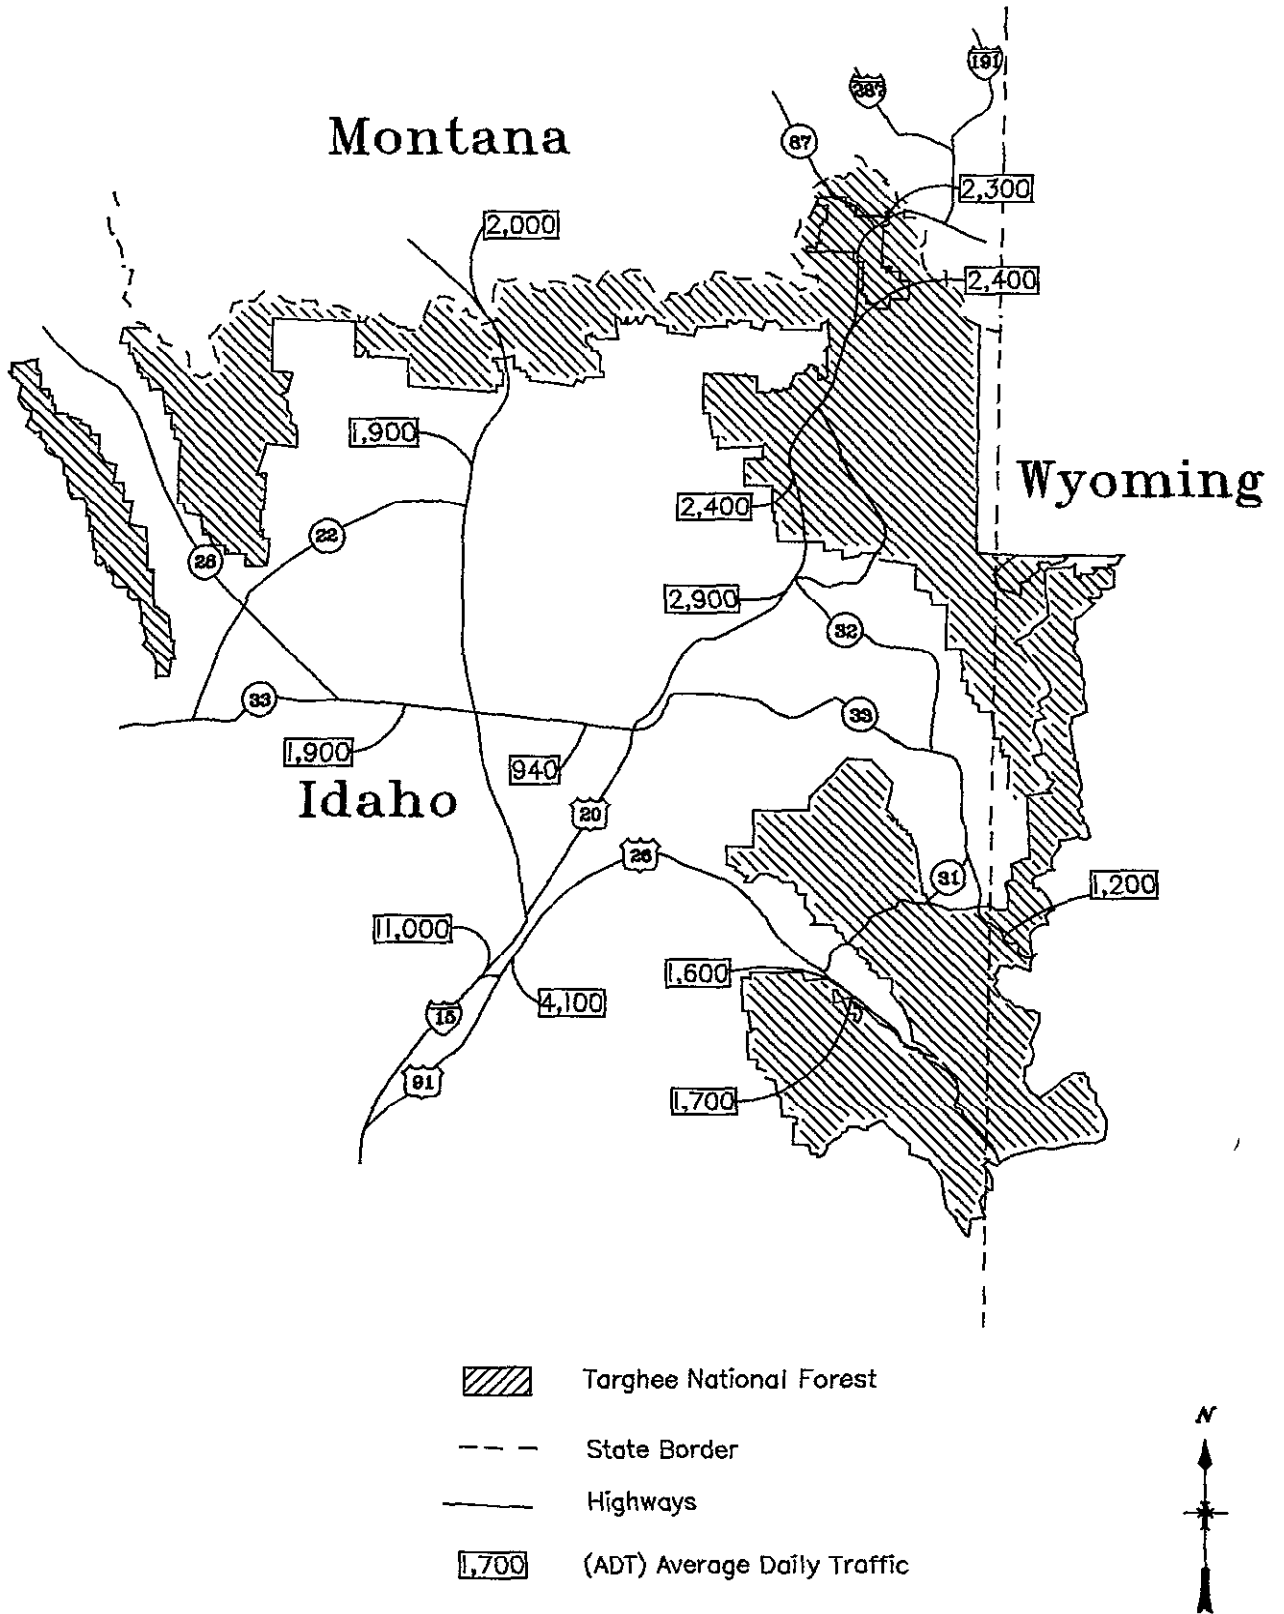

Figure III-8

FOREST USE AND OCCUPATION

ACCESS MANAGEMENT

Road System - Scale: Forestwide

The Forest road system provides access for recreation, industry and administration. Land transportation by motorized vehicles is the principle means of travel on the Forest. Seven major highways run through the Forest and all primary access begins from one of these highways. Average daily traffic counts collected by the Idaho State Highways Department (Gillespie 1994) suggest the heaviest traffic occurs on the highways between Idaho Falls and the northeast part of the Forest (Figure III-8). Many of the Forest's roads were constructed in the mid-1970's as part of the timber salvage program and provided access to recreationists, firewood gatherers and hunters. The roads have also proved useful for fire suppression activities. Forestwide there are 1,985 miles of open roads. In addition, motorized use is restricted on some roads as follows: 73 miles of roads have seasonal restrictions, 733 miles of roads have yearlong restrictions. Table III-24 displays the status of roads.

Functional Class	Open All Vehicles	Seasonal Restrictions (miles)	Yearlong Restrictions (miles)
Arterial	196	0	0
Collector	504	0	0
Local	1285	73	733
Total	1,985	73 *	733 *

* Open to snowmobile travel if designated

The Forest road system is essentially in good shape, with annual maintenance on arterial and collector roads and some local roads depending on resource needs. Further information on the Forest Development Road System can be found in the Transportation section of the AMS.

The current road system has created resource conflicts with wildlife, fish and watersheds. Road restrictions or reclamations have been requested by agencies and individuals to reduce resource conflicts. Law enforcement problems have also increased over the years due to the need to enforce restrictions.

The Forest has begun restricting and/or reclaiming roads to reduce resource conflicts. Many of the spur roads built during the salvage program are now restricted. Motorized use was restricted on 377 miles of road from 1981-1991 and on an additional 1,245 miles in 1992-1993.

There are approximately 2,791 miles of existing roads (Table III-25). Of these, 10 percent are classified as arterials. They are often two-lane and paved or have a good gravel surface and can handle unrestricted traffic at moderate speeds. Branching from the arterial roads are the collectors. Collector roads are medium standard roads that constitute about 25 percent of the mileage in the transportation system. Collector roads are stable enough for most traffic during normal season of use. Small single-lane roads, known as local roads, are found throughout the Forest and make up 65 percent of the road system. These minimum standard roads provide access for specific purposes, such as harvesting timber, maintaining electronic communication sites or reaching a trailhead. They allow limited passing, but the road conditions require that vehicles move slowly. Many of the local roads are currently restricted to vehicular traffic much of the time.

Two-track roads exist that are referred to as low standard roads (sometimes called "ghost roads"). These isolated roads were not designed or maintained for public use, they are created by repeated use by the

public Some vehicles cannot travel on these roads Road surfaces are generally rough and irregular with no drainage Some of these roads do not allow motorized use

Table III-25 Existing Road and Trail Access			
	Existing		Existing
Roads		Trails	
Miles - Open 1/	1,985	Miles - Open 1/	773
Miles - Seasonal Restrictions 2/	73	Miles - Restricted 4/	628
Miles - Yearlong Restrictions 3/	733	Miles - Nonfunctional	NA*
Miles - Reclaimed/Obliterated	NA*		
Total Miles	2,791	Total Miles	1,401
1/ Miles - Open means road and trail miles without restrictions on motorized use 2/ Miles - Seasonal Restriction means road miles on which motorized use is restricted for only a portion of the spring/summer/fall seasons 3/ Miles - Yearlong Restriction means road miles on which motorized use is restricted for the entire spring/summer/fall seasons 4/ Miles - Restricted means trail miles on which motorized use is restricted either for a portion of the spring/summer/fall seasons or yearlong (as in designated *wilderness areas) * This table refers to present time It does not take into account the 1,622 miles of road that were reclaimed or obliterated between 1981 and 1993			

The National Forest Scenic Byways Program was developed to increase public awareness and understanding of the National Forest and State activities and recreation opportunities Presently there are two Scenic Byways that pass through the Forest, the Mesa Falls and Teton Scenic Byways The Mesa Falls Scenic Byway follows old State Highway 47 from Ashton to where it ties back to US Highway 20 About 20 of the total 29 miles are located on the Forest The Teton Scenic Byway Route travels east from Idaho Falls to Swan Valley along Highway 26, then north to Victor on Highway 31, from Victor to Teton on Highway 33 to the intersection of Highway 32, and then to Ashton on Highway 32

The Forest has been working with the Federal Highway Administration on improving Forest Highways Funding provided by the Federal highways Administration allows the Forest to make improvements on roads which normally could not be made Roads that are identified for improvements are required to accommodate current conditions and impending future growth and road uses Without improvements, the highways cannot satisfy current and future traffic demands, safety requirements, Forest Service land and resource management objectives and maintenance capabilities of the various agencies

The roads that have been slated for improvement and the expected year for reconstruction are Forest Highway number 62, Mesa Falls (1997-1998), Forest Highway number 76, Fred's Mountain or Grand Targhee road (1999-2000), and part of the Kilgore-Yale road (est 2000)

There are 235 existing and 109 potential/needed material sources for gravel, rock riprap, and earth borrow sites This should serve the Forest's needs for the planning period The 1993 Compendium of Material Sources is available for further information

Summer Access for Off-Highway Vehicles (OHV) - Scale: Forestwide

Approximately 61 percent of the Forest (1,126,000 acres) is currently open for summer cross-country motorized and mechanized vehicle access There are 1,985 miles of open road and 773 miles of open trail (Table III-25) The Forest conducted an analysis of motorized access and road/trail density in the spring of 1995 to accurately inventory these opportunities The analysis is documented in Appendix C

There are very few trails designed specifically for motorized OHVs or mountain bikes, although some are *suitable in their present condition*. The Forest is currently reconstructing four to six miles of trail each year for motorized use. There is a significant increase in demand for such opportunities. Both types of use are increasing at a rate of five to ten percent per year on the Forest and adjacent lands. The highest concentration of these activities is in the Big Hole and Caribou Range Mountains Subsections, where there is significant use by motorcycles and mountain bikes. As noted in the Soil and Riparian section, there are areas of concern for OHV effects on soil and vegetation. There are no serious adverse consequences as a result of this use. However, it is possible that motorized use is affecting some big game wildlife habitat potential or vulnerability to hunting pressure.

Winter Access - Scale: Forestwide

There are approximately 450 miles of winter trails that are groomed on the Forest and 1,511,000 acres open to cross-country snowmobiling, see Table III-26. Groomed snowmachine and cross-country ski trails and their use are most numerous in the Island Park and Big Hole Mountains Subsections. The Centennial Mountains, Madison-Pitchstone Plateaus and Caribou Range Mountains Subsections surrounding these two hub areas also provide many winter opportunities. In contrast, the most undeveloped backcountry opportunities and the least used by both skiers and snowmachiners are found in the Lemhi/Medicine Lodge and Teton Range Subsections. Within the Teton Range Subsection, the Jedediah Smith Wilderness is closed to snowmobiling.

Snowmachine use and the associated commercial business has increased dramatically since 1985. Retail snowmachine sales, repair and related business growth in motel and restaurant services has increased noticeably in the Ashton, Island Park and West Yellowstone areas. Because of the intensity of snowmachine use in some areas, there is a need to develop guidelines for management of winter recreation on the Forest and in the GYA. An interagency assessment is currently underway to determine how to manage winter visitor use to avoid impacts to wildlife or user conflicts. Management guidelines are expected to be prepared through this assessment by late 1997.

Special use permits for outfitter-guide operations for snowmobiling, dog sledding and skiing are scattered across the Forest, but are most numerous in the Madison-Pitchstone Plateaus subsection where there are six commercial snowmachine operations. This is due to attractions such as the Two-Top National Snowmachine Trail near West Yellowstone, the Mesa Falls Scenic Area and an excellent grooming program by Fremont County, Idaho. Growth in snowmobiling has been increasing at five to ten percent per year annually across the Forest. As a result, the Forest constructed one new parking area and day lodge for winter users at Big Springs, in Island Park.

This winter activity has resulted in some concerns regarding conflicts with wintering wildlife, and several travel access closures have been implemented to reduce conflicts. A wildlife winter range and recreation analysis began several years ago for the Teton Basin Ranger District. The analysis from that study has been incorporated into the Revised Plan process as the goals, objectives, prescriptions and management direction were developed (Appendix C).

WILDERNESS AND RECREATION RESOURCES

Recreation, tourism and N F use are important to the area economy. The Idaho Department of Commerce estimates that tourism in Idaho is a two billion dollar industry, with 23 million visitors each year. The visitors to the Forest may account for over 10 percent of this industry. Table III-26 displays current recreation and wilderness information by ecological subsection.

Wilderness and Recommended Wilderness - Scale. Subsection

There are currently two designated wilderness areas on the Forest. These are the Jedediah Smith Wilderness (123,451 acres) and the Winegar Hole Wilderness (10,715 acres). The Jedediah Smith is mostly in the Teton Range Subsection with the balance in the Madison-Pitchstone Plateaus Subsection. Winegar Hole is totally within the Madison-Pitchstone Plateaus Subsection. Winegar Hole is largely primitive with very little recreational use. This is mostly due to access difficulty, since there are only four miles of trail in the area. Use of this area is mostly for hunting big game.

Activity	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison- Pitchstone* Plateau	Teton Range	Big Hole Mtns	Caribou Range Mtns	Forest Total 1/

* Includes Nonfunctional trails								

The Jedediah Smith is intensively used in the summer with approximately 60,000 visits for hiking, backpacking and horseback riding. This is a spectacular mountainous area on the west slope of the famous Teton Mountain Range. These wilderness areas are two of twelve designated in the GYA which total 3.8 million acres, and provide significant areas of biodiversity important to the GYE.

The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in 1984. The Study Area contains approximately 129,100 acres. Of these acres, over 79,800 are administered by the Bridger-Teton N.F. and 49,300 acres are administered by the Forest. In addition, there are 110,520 acres of this roadless area in Idaho which have had no action or recommendation taken on them. The studies on the Wyoming portion have not been conducted. Much of the Palisades Roadless area is under special use permit for heli-skiing operations which have been in existence for over 15 years. This heli-skiing operation is a recreational business operating out of Jackson, Wyoming. The Palisades area is also used by a large number of snowmobilers, except in the steep, avalanche prone areas.

Portions of Italian Peak, Lionhead, and Winegar Hole Roadless Areas (65,000 acres) were recommended wilderness in the 1985 Forest Plan, but no legislative action has been taken to-date.

Roadless Areas - Scale: Forestwide

There are 16 areas on the Forest which qualify as roadless or roadless adjacent to designated wilderness. These areas are described in the Process Paper Q and Forest Plan map number 25. These areas total about 841,000 acres. This acreage is approximately 30,000 acres less than the 1993 inventory. This is due to improved calculation from computer digitizing the area boundaries. The new roadless area acreages are shown in the Rating of Wilderness Characteristics Factors Table in Process Paper Q. Within these roadless areas, some 243,000 acres are closed to summer OHV use. The majority of the roadless acres are contained in the Lemhi/Medicine Lodge, Centennial Mountains, Big Hole Mountains and Caribou Range Mountains Subsections. The 1993 roadless inventory showed a net increase in qualifying acres over the inventory in the 1985 Forest Plan. This is because several of the roading and timber harvest projects proposed in that Plan were never completed. These areas were added to the previously inventoried areas. In contrast, the Signal Peak, Warm River South and East and Moody Creek areas incurred enough development to require them to be removed from the inventory. In 1990, the Centennial Mountains Wilderness Suitability Study EIS (Mt. Jefferson) was completed and none of the Forest portion was recommended wilderness. The Mt. Jefferson area was thereby released for management according to the 1985 Forest Plan direction.

There is an existing appeal settlement agreement with the Caribou N.F. concerning Bear Creek and Caribou City roadless areas on that Forest. The agreement states that no timber entry is scheduled before the year 2000 and that none will be made.

Wild, Scenic and Recreational Rivers - Scale: Forestwide

In November, 1994, an eligibility inventory was completed for the entire Forest, and approximately 245.5 miles of rivers and streams were determined eligible (Table III-26). These stream segments are described in detail in Process Paper R. The largest mileage of eligible stream segments is in the Island Park Subsection and the Big Hole Mountains Subsection has the second highest. The remaining subsections (excluding the Lemhi/Medicine Lodge) all have lesser mileages ranging from 17 to 31.5 miles.

The largest potential classification mileage is for Wild, followed by Recreational and Scenic which are almost equal. Suitability studies have not been completed for any of these streams.

Visual Resources - Scale: Subsection

The Forest has some very unique and outstanding scenery. It encompasses peaks over 10,000 feet, arid lands, timbered highlands, lakes and waterfalls. During the past decade, the greatest change in visual resources occurred among the vast expanses of mature lodgepole pine found in the Madison-Pitchstone Plateaus and Island Park Subsections. Large portions of this mature timber were clearcut. Some of this timber harvest occurred near major travel routes and use areas such as campgrounds, resorts, summer home areas and private lands. This changed many of the solid timbered areas to open meadow-like mosaics of scattered timber stands. Even though this was a drastic change from the past, it also provided variety in terms of scenic views and vistas. In some instances, this type of harvest enhanced areas from a visual standpoint.

The following displays the Forest acres currently in each visual quality objective.

<i>Visual Quality Objective</i>	<i>Acres</i>
Preservation	137,761
Retention	226,882
Partial Retention	804,784
Modification	519,184
Maximum Modification	148,189

Most of the Preservation acreage falls within the Jedediah Smith and Winegar Hole Wildernesses, which are in the Teton Range and Madison-Pitchstone Plateaus Subsections. Most of the Modification and Maximum Modification acres are in the Island Park and Madison-Pitchstone Plateaus Subsections. The other classifications are scattered throughout the subsections.

Developed Recreation Sites - Scale: Forestwide

Demand for new types of specialized facilities such as trailheads, mountain biking trails, boat ramps, fishing access and snowmachine facilities is increasing at five to ten percent annually. A strong increase in demand for group camping sites is an example of this type of specialized recreation facility need.

As shown in Table III-26, there are 61 developed recreation sites with facility investments over \$50,000 on the Forest. This figure includes both existing and planned sites. These sites, which include facilities such as campgrounds and boat ramps, have a total capacity of 8,890 persons at one time (PAOT). These sites receive approximately 608,000 visits and result in 703,000 12-hour recreation visitor days (RVDs) annually. Use is increasing approximately two percent per year. The Big Hole Mountains Subsection has the most sites (19), and the Island Park Subsection has the next largest number (18). The remaining subsections each have seven sites. Utilization rates for these sites range from low (<20 percent) to high (60 percent) across the Forest, the highest rates in the Warm River/Island Park and Palisades areas.

Developed recreation facilities are in fair to good condition across the Forest, but there is a significant backlog in heavy maintenance and reconstruction needs. The Forest has been able to reconstruct a few of the major sites. Approximately two-thirds of the developed campgrounds are operated and maintained by private concessions under special use permit from the Forest. Because many of our campgrounds and other developed facilities are adjacent to or along travel routes to Yellowstone and GTNP, use patterns on the Forest are affected by management actions and physical attractions of these parks.

Dispersed Recreation - Scale: Forestwide

The largest number of dispersed activity and camping sites are in the Caribou Range and western Centennial Mountains Subsections as shown in Table III-26. The next largest numbers of sites are in the Lemhi/Medicine Lodge and Big Hole Mountains Subsections. These sites receive approximately 1,147,000 visits.

and result in 992,000 RVDs annually. Dispersed sites have few or no structural facilities for recreation. They are used for general camping and to provide access to fishing, hunting, OHV areas and trails. Some of these sites have received increased use and number of camping spots, such as at Horseshoe Lake which has increased from three to seven sites in the last decade. Many dispersed activity uses are increasing at a rate of approximately four percent.

The capacity in PAOT of these sites is greater than the developed sites on the Forest. There are 106 heavy use dispersed sites on the Forest, and some of these dispersed campsites are showing damage to vegetation and soils. Field reviews during the summer of 1996 indicate a few of these sites are in need of management actions to stabilize or minimize such impacts.

There are approximately 773 miles of open and 628 miles of restricted trails for use on the Forest. Summer use trails are most abundant in Big Hole Mountains, Caribou Range Mountains, Teton Range and Centennial Mountains Subsections (Table III-25).

Outfitters and Guides - Scale: Forestwide

There are 83 permitted outfitter/guide operations on the Forest at the present time (Table III-26). Outfitted activities are most numerous in the Teton Range and Big Hole Mountains Subsections. The Centennial Mountains and Island Park Subsections also have a moderate number of permitted operations.

Forestwide, the largest number of these permits is for summer activities. These permits are for guided activities such as hunting, horseback riding, river trips, fishing, wagon rides, backpacking, horsepacking, etc. These activities represent a commercial industry with an annual income estimated at over 1.8 million dollars, and fees to the government of over \$53,000. There is continuing interest in new permits, however capacity determinations and commercial allocations have only been made for a few parts of the Forest. Therefore, a moratorium was recently initiated on the Forest to deny any new applications for permits, except in areas where capacity had been determined to be available through environmental analysis and documentation.

Special Uses - Scale: Forestwide

Excluding outfitter-guide permits, there are 267 other recreation special use permits on the Forest (Table III-26). These are issued for summer homes, organization camps, special events, ski areas, etc. The highest number of these are located in the Island Park and Caribou Range Mountains Subsections where there are large numbers of summer homes. There are moderate numbers of permitted activities in the Centennial Mountains and Big Hole Mountains Subsections. The Forest administers permits for 203 summer homes, 32 recreation special events, 14 organization camps and two regional-sized ski resorts. Development of the Grand Targhee Ski Resort is occurring, and all activities are guided by the 1995 Master Development Plan for the Resort. These permits are the major portion of the activity and result in returns to the treasury in the hundreds of thousands of dollars annually.

There are over 200 nonrecreation uses authorized by special use permit on the Forest. Uses authorized include roads, water transportation systems such as ditches, canals and pipelines, hydropower, communication sites, municipal watersheds, telephone, telegraph and power transmission lines, uses related to agriculture and industry, and uses related to research, training, cultural and historic resources.

ECONOMIC AND SOCIAL ENVIRONMENT

Figure III-1 shows how area population centers and county lines rest relative to the subsection boundaries outlined for the Forest. The area primarily affected by the Forest in terms of economic and social concerns comprises Bonneville, Clark, Fremont, Jefferson, Madison and Teton counties in Idaho. Together these counties make up the great majority of the Forest's total administrative area and account for the largest part of Forest-related employment, personal income and payments to local governments. These counties are recognized as being the Area of Primary Forest Economic Influence (APFEI) (Table III-27). Information for the Shoshone-Bannock reservation at Fort Hall is also provided.

County/CDP 1/	Population	% high school graduates	% college graduates	Unemployment % (yr)	Infant deaths per 1,000 live births (yr)	Occupied housing units wood heated	Social Security Recipients / % for 1993	Housing units owner-occupied %	Median household income \$ in 1989

8/ U S Bureau of the Census County and City Data Book 1994 Washington, DC U S Government Printing Office, 1994

Some observations can be readily made Bonneville county has the highest median household income and the highest incidence of college graduates Clark county has the highest incidence of Social Security recipients Fort Hall's median household income is somehow comparable to the counties listed and yet its unemployment rate seems inconsistently high This may be the result of having more wage-earners per household and/or some distortion in the estimate of unemployment Fremont county's high rate of unemployment was possibly associated with timber harvests which were declining from peak levels Jefferson county had the highest incidence of owner-occupied housing units and high school graduates Because most of these counties have very small populations, statistics must be thought through Teton county's infant death rate for instance, actually reflects the death of only a single infant Teton county has the highest rate of heating with wood and the lowest unemployment rate

The Forest is of lesser economic importance to other area counties including Teton and Lincoln counties in Wyoming and the Idaho counties of Bannock, Bingham, Butte and Lemhi Bannock and Bingham counties have no lands administered by the Forest The Forest does manage significant amounts of land in Butte, Lemhi, Lincoln, and Teton (Wyoming) counties However, management of the Forest as depicted in the various alternatives under consideration is not expected to have significant effects on these coun-

ties Even though these counties are not included in the APFEI they still have important links to the Forest The Grand Targhee Ski Resort, for instance, is located in Teton County, Wyoming It is an important source of income and employment Services and supplies for the facility must come through Teton County, Idaho, however

People from outside this area also have strong ties to the Forest Besides Idaho, Wyoming and Montana the Forest receives many visitors from Utah, California, and the rest of the nation The designation of an area of influence does not diminish the interests others have in the area or the attention paid to their input

Most of the area's population lives in cities like Idaho Falls, Blackfoot and Rexburg The area's population is relatively small and concentrated in Bonneville County which contains Idaho Falls, the area's largest city with a population in excess of 42,000 It regularly ranks as Idaho's second- or third-largest city

Perhaps the most striking characteristic of the area's population is the growth that has occurred in Bonneville and Madison counties during recent decades, and Teton county in recent years. Since 1950 the population within the APFEI has more than doubled, from 63,334 in 1950 to 137,991 in 1994 (REIS 1996) Bonneville and Madison counties have increased over 2.5 times during that same period Teton county's population has increased by more than six percent annually from 1990 to 1995 Available information indicates this population growth is traditional (based on employment growth), rather than being the cause of employment growth (Taylor and Fletcher 1995)

Table III-28 displays the relatively low population density of the six counties making up the APFEI, about 19 people per square mile Clark county is one of the least populated counties in the United States That characteristic poses many problems for its county commissioners who must address an abundance of needs with limited resources Based largely on their low populations, Clark, Fremont and Teton counties have all been identified as areas of low socioeconomic resiliency (USDA 1996)

As shown in Table III-28, dividends, interest and rent make up about 13 percent of APFEI personal income, transfer payments 14 percent Clark county has low figures in both of these categories (eight and ten percent respectively) Teton county has the high figure for dividends, interest and rent at 19 percent, while Fremont county has the high figure of 21 percent for transfer payments

Employment and Income

Although information is presented herein by county, economic sector or other grouping it is important that the associations among the various components not be overshadowed Area barley farmers support the Anheuser-Busch barley malting facility in Idaho Falls Idaho's largest potato farm is located in the area and potato growers support a wide-ranging potato industry including fertilizer, irrigation equipment, storage and packing facilities, equipment manufacture and repair and other agricultural support activities Some 9,000 workers at the INEEL live throughout the area and thus contribute to the well-being of a number of local communities

The entire area benefits from its proximity to Yellowstone and GTNPs Recreationists travelling through the area use the lodging and retail sectors of the economy Perhaps more importantly, many of those recreationists have bought summer homes in the area With improvements in roads and vehicles, more and more people are locating in areas which were previously considered inaccessible during the winter months

The presence of large numbers of recreationists drawn to the world-class attraction of the Park has made the area attractive for other types of spin-off recreation Examples are the grizzly bear theme park in West Yellowstone, Montana, just outside the APFEI and fishing on the Henry's Fork and South Fork of the Snake River

The Grand Targhee Ski Resort has emerged as a destination resort. Although it is located in Wyoming, all traffic into it flows through the APFEI. The resort has been successful in establishing itself as a year-round facility with attendant increases in the numbers of people employed and the seasons during which they are employed. Grand Targhee employs 166 people on a full-time equivalency basis on the site. Another 23 people are employed off-site. (USDA Forest Service, Grand Targhee DEIS 1992)

Unusual associations have developed as the area's economy has grown and evolved in different ways. The sand dunes in Fremont County draw large crowds of recreationists, but much of the economic activity associated with the dunes is associated with Madison County which offers a greater variety of retail services and the nearest hospital.

Major employment in the APFEI comes from the services, wholesale and retail trade, and government sectors (Table III-29). The Service sector includes a wide range of activities such as automobile repair, funeral services, lodging, health care, legal services, engineering services, amusement and miscellaneous repair shops.

The respective counties' economies differ greatly. Clark, Fremont, Jefferson and Teton Counties rely heavily on agriculture and related activities for their economic bases (Cook and Mirer 1989). Bonneville and Madison Counties both rely heavily on the services sector (most notably the INEEL and Ricks College) for their economic bases. The entire APFEI is within the 14 county Idaho Falls economic subregion as defined by the Bureau of Economic Analysis (BEA). The percentage of jobs in that subregion supported by recreation is estimated at 30 percent (Quigley et al. 1996).

The economy of Bonneville county is much larger than those of the other counties in the APFEI and thus tends to overwhelm the statistics. The primary economic driver of Bonneville county is the INEEL which accounts for the large showing of service sector employment.

Changes continue to occur in the local area's economy. Coors Brewing, long a purchaser of locally grown barley, pulled out of the local market. Canola is being grown on larger acreages of area farms. Idaho Forest Industries, long a major employer in Fremont County, closed its sawmill in St. Anthony in 1992. Louisiana-Pacific closed its Rexburg mill in 1995. The INEEL has eliminated thousands of jobs. Snowmachine activity has blossomed to the point that anticipated restrictions on their use in the Park seem likely to spur increased use on the Forest and other lands surrounding the Park. Jet ski use on area waterways is another recent development in area recreation.

Many people in the local area rely on Forest commodity production for their livelihoods to some extent. Loggers, mill workers, ranchers and truckers fall into this category. Area mills relying in part on timber from the Forest include numerous smaller mills producing posts, poles, house logs and dimension lumber. Before its closure in 1992, the large stud mill in St. Anthony (Fremont County) received about 80 percent of its raw material from the Forest. About half of the material processed at the Rexburg mill before its closure in 1995 likewise came from the Forest. The Forest is a significant supplier to the remaining facilities in the APFEI. Dead timber serves as an important fuel supply for home heating in the local area thereby providing a source of income for some and a source of heat for others.

Some area residents rely on Forest rangeland as a source of seasonal forage for their livestock. Normally this forage is an integral part of the ranch's overall operations. Alternative sources of supply suitable for the permittees' needs are difficult to come by.

Recreation is an important part of the local economy and one with significant growth potential. It includes readily-identifiable recreation resources like the Grand Targhee Ski Resort, Kelly Canyon Ski Resort, outfitters and guides, and snowmachine rental. Other related activities include sales at area restaurants, motels and retail establishments. Harriman State Park and private facilities located off-Forest also rely on the Forest for an expanded range of activities for their visitors.

Another recreation-related economic spin-off has been the proliferation of summer home residences in the area. This has increased the local tax base without increasing demands on area schools.

Some area residents have noticed an increasing level of recreation use which they attribute to overcrowding in the adjacent Yellowstone and GTNPs which are attracting record numbers of visitors.

The Forest Service employs some 140 workers to manage the Forest. The Forest Service is a major employer in the area and the great bulk of its annual budget (Table III-30) goes to salaries of Forest employees living in the local area. Additional background information on the local area is available in the Forest's AMS.

Payments to Local Governments - Scale: Regional

The Forest also plays a role in the area economy by generating revenues, a portion of which are returned to local governments. These funds result from the Payment In Lieu of Taxes (PILT) program administered by the U S Department of the Interior and from the 25% Fund (payments made under the National Forest Revenue Act of 1908 as amended).

1993	15.4
1994	15.7
1995	15.3
1996	13.8

Payments resulting from the 25% Fund are to be used as directed by the respective state legislatures for the benefit of roads and schools in the local government area where they were generated. Payments from the 25% Fund are calculated based on Forest receipts, both in cash and in kind, accruing from management activities in the local government area.

PILT payments are calculated for each local government (Table III-31) based on the amount of acreage administered by certain federal agencies, population, a schedule of payments, the Consumer Price Index, other federal payments (like the 25% Fund payment received in the prior year), and the level of funding. PILT payments may be spent by the local government for any governmental purpose.

Amenity Interests - Scale: Regional

Many people in the area, and outside the area, enjoy the Forest for the recreational opportunities it provides, for the scenic vistas it offers, for its aesthetic values, for its importance to wildlife and fish and for the contributions it makes to the greater ecosystem. Interests include those associated with the effects of clearcutting on the visual landscape and on area plants, fish, and wildlife, spiritual concerns, land ethics, and environmental concerns in general.

Many people value the Forest even though they have never been here. They recognize its place and importance in the larger ecosystem. The large clearcuts of lodgepole pine that began in the 1960s have been photographed extensively from the air and have been widely published. People have commented,

favorably and unfavorably, about this activity. The photographs have heightened the level of public consciousness of clearcutting on the Forest.

Understandably, most of the recreation that occurs on the Forest is associated with people who live in close proximity to it. Out-of-area recreationists, with the exception of hunters and anglers, are more likely to focus their recreational activities on the big-name attractions like Yellowstone and GTNPs. Local people have often grown up in the area, experiencing the Forest from the time of their youth, and enjoy the greater sense of freedom associated with the less-restrictive recreational experience available on the Forest compared to the Parks. Big game hunting, particularly elk hunting, is a fall experience of extreme importance to those who enjoy it.

Within the Forest boundaries are wildernesses, big-game herds, two ski resorts, waterfalls, a world-class fishery and the kind of scenery associated with the adjacent Park and GTNPs. These features give rise to a great deal of recreational use by those from outside the immediate area. Big-game hunting, camping, hiking, skiing, and recreational driving are major attractions for this group. Most of the big-game hunters are from other parts of Idaho. Residents of the adjoining states and California are the most common out-of-area users of the Forest.

2/ This information is based on the percentage of total PILT entitlement lands which the Targhee National Forest comprises It is meant to show how important the Targhee National Forest component is in terms of total PILT payments The parenthetic percentage is the Targhee's percentage of total PILT entitlement acres

Products such as timber, firewood, and grazing that the Forest provides are obviously important to the local communities. Less obvious are the plant products that individuals collect (commercially or for personal use) for food and medicinal purposes. Mushrooms, dried flowers and plants, trees and shrubs for landscaping, huckleberries and chokecherries (plus other berries) are yearly utilized by people both locally and from other areas. These products also have cultural significance to local American Indian tribes who utilize a wide variety of plants from the many habitat types on the Forest as shown in Table III-32.

Tribal Interests - Scale: Regional

The Forest lies within the aboriginal territory of the Shoshone-Bannock Tribes. The Tribes collectively comprise a single, federally recognized Indian tribe with a governing body, the Fort Hall Business Council, which is duly recognized by the Secretary of the Interior. Tribal members are successors-in-interest of Indian signatories to the Fort Bridger Treaty. In part, that treaty led to the creation of the Fort Hall Indian Reservation in the Idaho Territory as a permanent tribal homeland. The 544,000-acre reservation lies generally between Blackfoot and American Falls, Idaho.

Article 4 of said treaty secured for the Tribes in perpetuity the continuation of a wide variety of "use rights" to off-Reservation lands. More specifically, by virtue of Article 4 of the treaty, the Tribes expressly reserved the right to hunt "on the unoccupied lands of the United States so long as game may be found thereon" including such lands owned by the federal government outside the boundaries of the Reservation. The courts decided in the Tinno decision (*State v. Tinno* 1972) that the right to hunt also included a right to fish (*Shoshone-Bannock Tribes* 1992b). Hanes (1995) observed, "The court agreed that the Indian peoples expected rights to harvest food on the unsettled lands as a means of subsistence and an integral part of their way of life."

The Tribes have historically used the Forest for hunting, fishing and gathering. American Indians historically used at least 838 species of plants on the Forest, covering virtually every type of plant community. These activities are important economically as well as socially and culturally. Part of the economic importance to the Tribes lies in their use of hunted meat to provide food for the elderly and the disabled. "The philosophy and management direction from the Tribes has always been for subsistence hunting and this is reflected in the Tribes Big Game Regulations," (*Shoshone-Bannock Tribes* 1992a).

Rights to believe, express, and exercise traditional religions are protected by various federal laws, including the American Indian Religious Freedom Act of 1978. This includes, but is not limited to, access to sites, the use and possession of sacred objects and the freedom to worship through ceremonial and traditional rites. Additionally, rights reserved under treaty may possess an inherent measure of resource protection. (U.S. v. Washington (759 F.2d 1353, 1985) in Shoshone-Bannock Tribes 1992b.)

The Forest has worked with representatives of the Tribes to coordinate the Revision with them. Representatives of the Tribes have stressed the following points:

- Treaties are the supreme law of the land (U.S. Constitution, Article 6, Clause 2). Treaty rights cannot be negotiated at the Department level of the United States government. Consultations with the Tribes are on a government-to-government basis.
- The multiple jurisdictions they have to work with make any attempts at working with the Forest an extremely frustrating exercise. Their territory lies within the boundaries of many National Forests, on lands administered by the Bureau of Land Management, on state lands and on lands privately held. This complicates even relatively simple matters like interpretive signs.
- The processes the Forest uses to handle archaeological sites and cultural values do not fully address the Tribes' concerns. It is important to protect sites, to keep them unpublished and to recognize that providing access to sites invites vandalism. It is important for the Forest to consult with the Tribes on a case-by-case basis when providing protection to sites. It is important that vandalism of sites be vigorously prosecuted to serve as a deterrent.
- The Revision must recognize the sacredness of the land, need for protection, obligation to consult with the Tribes as outlined in the American Indian Religious Freedom Act, the NEPA and NFMA, and many aspects of reserved rights including, but not limited to, the priority nature of rights reserved under the treaty, as well as an inherent measure of resource protection to satisfy these rights.
- The Forest must be recognized for its religious and spiritual significance to the Tribes. That significance is not limited to vision quest sites or traditional camp sites. The Forest and even the lands beyond its borders are important in their entirety. As with many other religions, tribal members are not free to share all the dimensions of their faith.

The Tribes also have a significant economic interest in the Forest. These include subsistence activities like hunting, fishing and gathering. They also include important aspects of Tribal life like sharing the fruits of the land. Riverine ecosystems are important to the Tribes not only for their resources but also for the role they play in the Tribes' religion. The Forest will continue to work and coordinate with the Tribes.

Heritage Resources - Scale: Subsection

Lemhi/Medicine Lodge - This area contains over 200 heritage resources of predominately American Indian sites including habitation sites and rock art. The aboriginal settlement pattern for the area is related to scarce perennial water sources in generally high altitude settings. Archaeological excavations in the area indicate that high altitude hunting camps were used primarily for hunting mountain sheep.

European-American settlement in this area was focused on homesteading and lead mining in the late 19th century. The Birch Creek Charcoal Kilns is the most significant site relating to this period of settlement and is a major tourist attraction. The remains of ancillary sites associated with the lead mining industry are found in several canyons. The Working Cabins also have interpretive potential for late 19th century homesteading.

Impacts to heritage resources, such as prehistoric American Indian lithic scatters associated with hunting camps, are occurring from livestock grazing and antelope hunting blind construction. Construction of

hunting blinds involves digging a hole up to two feet deep, which can disturb cultural deposits. Since permanent water sources in this area are scarce, most springs have evidence of prehistoric American Indian occupations. Livestock tend to congregate at these springs, trampling surface cultural deposits. Soil erosion from lack of vegetation in these areas exposes buried cultural deposits.

Centennial Mountains - The Centennial Mountains contain the highest frequency of heritage resource sites on the Forest. Over 400 heritage resources of predominately American Indian sites have been identified. The aboriginal settlement pattern for the area is seasonal occupations for the extraction of obsidian and collecting camas plants for medicinal use. Site types include base camps, obsidian workshops, quarry sites and hunting camps. The most significant archaeological site in this area is the Big Table Mountain Obsidian Source. Monida Pass and Targhee Pass provided natural travel routes across the Continental Divide into the buffalo hunting grounds of Montana. The Nez Perce travelled through this area extensively. As a result, the Nez Perce National Historic trail has been designated through the area. These passes were also utilized extensively during the 19th century by fur trade companies and later as stagecoach routes.

European-American settlement of the area is in the form of late 19th and early 20th century homesteads along the Forest fringe bordering the upper Snake River Plain.

Some prehistoric American Indian sites, such as lithic scatters associated with hunting camps and lithic workshops, have been affected by logging. Monitoring following timber harvest in this subsection showed that all heritage resource sites located in cutting units were damaged by logging. Site avoidance recommendations discussed in Heritage Resource Survey Reports were not followed during timber sale administration. State authorities are aware of these, and the situation has been corrected.

Island Park - Heritage resources in the Island Park area are primarily related to the Tie Hack Period (cutting trees for railroad ties) and early Forest Service history. The 140 sites identified are composed primarily of tie hack camps associated with the Yellowstone Railroad, Forest Service administrative sites such as guard stations, ranger stations, fire lookouts and recreational cabins dating to the early 1900s. Social patterns in this area are closely related to the logging industry, Forest Service management and tourism. Few American Indian sites have been identified.

The most significant heritage resources in this area are Mesa Falls Lodge, Bishop Mountain Lookout, Squirrel Meadows Guard Station and Warm River Fish Hatchery. These sites receive high public visitation and have economic values associated with tourism.

Heritage resources in this area have been impacted by logging, road construction, historic building removals and the North Fork Fire.

Madison-Pitchstone Plateaus - The Madison-Pitchstone Plateaus contains one of the lowest frequencies of heritage resource sites on the Forest. Relatively extensive inventory has identified only 25 sites. The majority of these are tie hack sites associated with the Yellowstone Railroad. American Indian sites are few and seem to be related to transitory movements through the area. The only site identified as suitable for enhancement and interpretation is the Big Springs Fire Lookout.

Teton Range - The Teton Range has high frequencies of American Indian sites in the upper reaches of the drainages. Over 79 heritage resource sites have been identified. The vast majority are associated with high altitude adaptations by American Indians. This area may also contain spiritual sites important to local tribes. Historic Euro-American sites are generally related to early 1900s ranching.

This area has high economic values for heritage resource tourism with an emphasis on high altitude adaptations.

Big Hole Mountains - This area contains over 100 heritage resource sites with most sites located along the northwestern edge of the Big Hole Mountains. The majority of these sites are American Indian hunting camps and lithic workshops. Historic Euro-American sites are associated with early 20th century mining and ranching. The Palisades Mountains area is one of the least inventoried areas of the Forest. Site types and frequencies are relatively unknown.

There is potential to enhance and interpret early 20th century lime kiln and mining sites. Interpretation of a National Register-eligible American Indian site at Table Rock Campground also has potential.

Caribou Range Mountains - The Caribou Range is one of the least inventoried areas of the Forest, however, 50 heritage resources have been identified. All but two sites are American Indian hunting camps, lithic workshops and volcanic glass quarry sites. This area also contains the Currant Creek and Brockman Guard Stations, Forest Service administrative sites eligible for the National Register of Historic Sites. Potential exists for interpretation of the guard stations as early 20th century Forest Service sites.

Quality of Life - Scale: Regional

The Center for Business Research and Science (CBRS) and the Center for Rural Economic Development (CRED) of Idaho State University have conducted recent surveys of Quality of Life perceptions among area residents in Fremont County and the City of Idaho Falls. These two areas are vastly different in terms of population, income structure, employment opportunities and other demographic characteristics. In both surveys, many of the questions relate to concerns people have with regard to their everyday lives—things like shopping and local government services. The amount of information presented which relates to the Forest is limited. The surveys do provide some insight into how area residents perceive their living environments (CBRS, CRED a and b).

Fremont County

Air Quality and "Open Spaces and Green Spaces" were the quality of life attributes respondents were most satisfied with. Employment opportunities and the Availability of Retail Shopping were the attributes with the least amount of satisfaction. Among respondents, 43 percent felt that Tourism was the type of ideal business they would like to see locate in Fremont county. Some 34 percent felt the same way about General Manufacturing. Employment Opportunities, Level of Individual Well-Being and Public Education were identified as being the most important in determining quality of life (CBRS, CRED a and b).

City of Idaho Falls

Favorable characteristics of life in Idaho Falls included a Low Local Tax Rate, Medical Services and Salary and Wage Levels. In making choices among conflicting alternatives, respondents found these selections to be the most acceptable: Limit Economic and Population Growth (32 percent) and Increase Taxes and the Local Cost of Living (31 percent). The least acceptable choices were to Permit Degrading of the Environment (30 percent) and Increase Taxes and the Local Cost of Living (27 percent) (CBRS).

University of Idaho - Clark County

A separate survey was recently conducted of Clark county residents by the University of Idaho (McGuire and Harp). The strongest points of agreement in that study follow:

- 1 Livestock grazing is compatible with other natural resource uses. Agreement, 88.5 percent
- 2 We have enough area legally designated as wilderness in Idaho. Agreement, 83.9 percent
- 3 Large old trees that are cut and harvested will eventually be replaced by vigorous young trees that will be just as valuable. Agreement, 81.8 percent

It is noteworthy that while Clark county respondents feel they have enough legally designated Idaho

wilderness, that fewer than 20 percent agree with a "need to build roads and other accommodations that will provide greater access to undeveloped natural areas." Many people have advanced the view that they would like to enjoy these "undeveloped natural areas" without the extra restrictions associated with wilderness designation.

The three most serious concerns respondents identified for their community to deal with over the next five years are listed below:

- 1 Availability of good jobs for young people (32.7 percent)
- 2 Availability of money needed to develop economically (16.1 percent)
- 3 Individual and family income levels (11.3 percent)

University of Idaho - Interior Columbia River Basin

Still another survey of public views was conducted by the University of Idaho of Interior Columbia River Basin residents (Rudzitis et al. 1995). Some of its findings were highly predictable. For instance, respondents overwhelmingly identified Employment Opportunity and Access to Family and Friends as their most important reasons for moving to or staying in the area (58 percent). Most people have to make a living and word-of-mouth (from family and friends) is a traditional means for gaining employment. Family and friends normally comprise one's support system as well.

Respondents did not see "commodity-based strategies as the dominant management strategies to be pursued on public lands," but they did "in particular, feel some degree of timber harvesting and grazing on public lands should continue."

The most important public land uses were identified as:

- 1 Protect water and watersheds (20.2 percent)
- 2 Protect ecosystems (18.3 percent)
- 3 Recreational uses (16.9 percent)
- 4 Timber harvesting (16.3 percent)
- 5 Preserve wilderness values (9.6 percent)

Interestingly, "protect endangered species" polled less than two percent of respondents.

Utah State University and Washington State University Surveys in the Columbia River Basin (Brunson et al. 1994, Tennert et al. 1994).

Survey work conducted for the Interior Columbia Basin Ecosystem Management Project provided the following relevant attitude information (Trent 1995).

- Strong support exists for protection of fish and wildlife on public lands. The public generally supports a multiple benefits mode of management which emphasizes a long-term balance between human and ecological concerns.

- The public feels environmental and economic concerns can go hand in hand and should be given equal weight, if possible. If this is not possible, the environment is considered more important.

- The entities which the public trusts and feels should influence management decisions are local rural communities, western U.S. public opinion, university research scientists and the USDI Fish and Wildlife Service. Entities the public feels should have influence but in whom they do not have a great deal of trust include the Forest Service and the BLM. The public also feels it should play an active role in public land management.

Expect Conflicting Views

In any event, land managers need to know that the wide range of views they hear from the public are predictable. The case study conducted in the Teton county (Idaho) community of Driggs by the University of Idaho concluded that, "Driggs had yet to agree on what the future of the community should be," (Harris et al 1996). Likewise, tabular data presented in Trent, 1995, shows that in response to every survey question, Eastside Assessment public involvement participants were less neutral than those randomly polled. Perhaps it borders on tautology to observe that people who get involved are less likely to be dispassionate in their views.

Minorities and Women - Scale: Regional

Various programs have been implemented on the Forest to focus the resources of these group members on Forest activities to the benefit of both the Forest and the individuals. This effort is reflected in Forest Service hiring, supervising and contracting procedures. Under authority of a number of civil rights and equal employment opportunity acts and executive orders the Forest intends to continue:

- Eradication of all forms of illegal discrimination from facilities, programs, activities, contracting and hiring practices
- Positive action in helping to provide developmental opportunities for the disabled, minorities, women and all other employees
- Providing coordinators for the Equal Employment Opportunity, Federal Women's and Hispanic programs
- Civil Rights Action Team activities and civil rights training for all employees.

Coordination with Other Agencies - Scale: Regional

The importance of coordinating management within the GYE has been recognized by the public land management agencies. To that end, the Greater Yellowstone Coordinating Committee was established in the early 1960s. This group consists of National Park and National Forest managers who meet twice yearly to discuss issues and improve coordination between the two agencies.

There are many examples of how the various National Forests and Parks of the GYE have coordinated management across jurisdictional boundaries. The agencies have an ecosystem-wide Grizzly Bear Recovery Plan. Changes in these uniform guidelines for grizzly bear management are coordinated among the Forests and Parks. Uniform regulations for recreation use in the area were initiated for the 1995 summer season. Federal and state agencies in the GYE are implementing coordinated guidelines for management of noxious weeds and exotic plants. Fire management is another area where resources and policies are shared across Forest and Park boundaries. Currently the Forest is participating in the integrated winter sports planning taking place throughout the ecosystem. As the Revision for the Forest is implemented, coordination with fellow managers in the ecosystem will continue.

PRODUCTION OF COMMODITY RESOURCES

TIMBER

Timber - Scale: Forestwide and Subsection

The amount of forested land by species group, age class and subsection on the Forest was displayed earlier in Table III-3

Table III-33 displays the average mature volume of saw timber growing on the Forest by species and subsection

	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison- Pitchstone Plateaus	Teton Range	Big Hole Mtns	Caribou Range Mtns	Total

1/ MBF per acre (LP=6 1, DF=9 0, Mixed LP/DF=7 9, Other Mixed Conifer = 12 4, Spruce/Subalpine Fir=13 9, Aspen=3 2) x 57 (About 57% of the forested land is tentatively suitable) LPP = Lodgepole pine, DF = Douglas-fir, MX = Douglas-fir/Lodgepole pine, MX3 = three or more conifer species mixed, S/F = Englemann Spruce/Subalpine fir, AS = Aspen								

Tentatively Suitable Forest Land

While the volumes shown in Table III-33 exist on the Forest, not all acres are available for timber harvest. In order to determine which land can be managed for timber production, a Tentatively Suitable Forest Land Classification process was used.

Tentatively suitable forest land is defined as land that is producing or is capable of producing crops of industrial wood and meets the following criteria:

- Has not been withdrawn by Congress, the Secretary of Agriculture, or the Chief of the Forest Service
- Existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions
- Existing technology and knowledge provides reasonable assurance that it is possible to restock adequately within 5 years after final harvest
- Adequate information is available to project responses to timber management activities

Tentatively suitable acres for the Forest have been determined and the process is displayed in Process Paper C. This amounts to 703,100 acres or approximately 57 percent of the total forested land on the forest. Table III-34 displays Tentatively Suitable Acres by Ranger District and Ecological Subsection.

	Lemhi/ Medicine Lodge	Centennial Mountains	Island Park	Madison- Pitchstone Plateaus	Teton Range	Big Hole Mtns	Caribou Range Mtns	Total
Dubois	13,040	79,700	0	0	0	0	0	92,740
Island Park	0	91,100	64,000	47,640	0	0	0	202,740
Ashton	0	0	151,070	107,230	3,330	0	0	261,630
Palisades	0	0	0	0	0	33,580	30,730	64,310
Teton Basin	0	0	31,090	0	17,710	32,880	0	81,680
Total	13,040	171,800	246,160	154,870	21,040	66,460	30,730	703,100

The 703,100 acres shown above is 249,300 less than the 952,400 acres identified in the 1985 Plan. The primary difference between the two is associated with the amount of nonforest acres. The 1985 analysis identified 390,300 acres of nonforest lands and the current analysis identifies 681,079 acres, a difference of 290,779 acres.

The current analysis utilizes more up-to-date data than in 1985. The Forest has more stand exam information than previous and land-sat data was used in areas where stand exam data did not exist. A comparison of the two analyses is found in Process Paper C.

Similarly, Table III-35 displays tentatively suitable acres by species and age class.

Future Supply and Demand

The projected demand-supply situation in the United States implies rising prices for timber. In the U.S. economy, demand and supply market commodities are equated through price adjustments and other workings of the market. When demand increases faster than supply, price brings the two together by reducing demand and/or by inducing supply increase (USDA Forest Service, 1990 RPA Assessment).

In general, it is expected that the price of softwood roundwood will follow the historic trend and continue to increase faster than the rate of inflation for at least the next 50 years, an indicator that demand from an increasing population will rise faster than supply can respond.

Supply

The local demand-supply situation generally reflects the national and regional trend. The following is a brief analysis of supply and demand for our area.

Table III-38 displays sources of timber that have been available in the past. The volumes shown, (except for private land which is an estimate) are averages from fiscal years 1992-95 sell program from the agencies listed. While the actual amounts available in the future are unknown, all sources (except for the Forest) are assumed to be constant for at least the next three to five years. Of the total, 15.1 MMBF or 51 percent historically came from the Forest. This includes sawtimber, roundwood, commercial and personal use firewood.

Source	Total Annual Quantity (MMBF)	Sawtimber	Products
Targhee N F	15.1	8.8	6.3
Caribou N F	1.6	1.2	0.4
Bridger-Teton N F	0.2	0.0	0.2
Bureau of Land Mgmt	3.2	3.0	0.2
State of Idaho	4.3	4.1	0.2
Private Land	5.0	5.0	0.0
Total	29.4	22.1	7.3

Demand

Table III-39 below displays the expected demand for wood products in our area from all users. It does not include previous demand from Louisiana-Pacific as they have closed their Rexburg mill. It also assumes the present number and mix of large and small timber operators will remain fairly constant.

Present Level	Survival Level	Maximum Efficiency Level
35.7	31	36

The current demand for wood products in our area, all operators, large and small (including personal use firewood), is about 35.7 MMBF annually. The minimum level of timber demand, from all operators, necessary to meet the survival needs of timber industry and personal use is 31.0 MMBF. This level of harvest

will just barely provide for the existence of the current number of operators at their minimum operating level, plus meet the current demand for "walk-in-the door" products and personal use firewood. To provide for maximum efficiency of mill operation and meet all demands for wood products that small operators receive and meet the current demand for personal use firewood and walk-in traffic, the level of timber offer should be approximately 36 0 MMBF.

Reforestation/Timber Stand Improvement

Table III-40 indicates past levels of reforestation (artificial and natural) and timber stand improvement (thinning) Activities that have occurred on the Forest.

	Reforestation Acres	TSI Acres
1981-90	104,562	11,563
1991	3,152	1,210
1992	2,874	397
1993	3,163	759
1994	4,361	493
1995	2,753	111
1996	3,515	172
1997	766	850

LIVESTOCK GRAZING

Livestock Grazing - Scale: Forestwide and Subsection

Approximately 79 percent (1,466,475) of the 1.87 million acres under Forest grazing administration are identified as being in grazing allotments, which are open to grazing. These acres, about 782,005 (53 percent) acres are capable for livestock grazing. Approximately 400,640 acres (21 percent) are presently closed to grazing. There are 154 allotments (76 cattle and 78 sheep) on the Forest where livestock grazing occurs, of which 109 have AMPs. A portion of one of these allotments, Moose Creek S&G, is located on the Bridger-Teton N.F. All allotments on the Forest are managed under various strategies (Process Paper K). A summary of grazing activity by subsection is displayed on Table III-41.

Indicator	Subsection						
	LEMHI/MEDICINE LODGE	CENTENNIAL MOUNTAINS	ISLAND PARK	MADISON-PITCHSTONE PLATEAUS	TETON RANGE	BIG HOLE MTNS	CARIBOU RANGE MTNS
AUMS Sheep	3,111	16,464	2,016	2,830	3,162	14,899	13,267
AUMS Cattle	14,161	30,067	21,273	3,765	2,182	11,092	9,776
No of Sheep	8,930	17,770	2,072	0	3,700	18,500	21,013
No of Cattle	3,633	7,697	4,833	1,241	522	2,293	2,343
NO OF PERMITS	42	75	43	10	17	46	44

The current permitted livestock use reported on the Forest is 148,775 AUMs. Permitted livestock consists of 22,066 cattle and 71,985 sheep. Currently 182 permittees hold 277 grazing permits which authorize grazing on the Forest. Presently, based on 1993 data, the numbers of livestock actually using the forest are 20,362 cattle for 84,212 AUMs and 54,478 sheep for 44,006 AUMs.

As Table III-42 demonstrates, of these 154 allotments, 15 sheep allotments and one permit are vacant where little or no grazing presently occurs, unless authorized. There are no vacant cattle allotments or permits on the Forest.

District	Allotment Name, Number	Permitted AUMs	Status

1 = No grazing is authorized on these allotments
2 = Vacant allotment open to grazing
3 = Two permits (1 sheep and goat and 1 cattle and horse) occupy the same allotment. The sheep and goat permit is vacant, and the cattle and horse permit is not vacant.
4 = Management Situation 1 Grizzly Bear Habitat
5 = Management Situation 2 Grizzly Bear Habitat

A vacant allotment is an allotment where a livestock grazing permit has not been issued. The allotment may or may not be available for use by domestic livestock. District Rangers have the authority to authorize or deny grazing of vacant allotments. If grazing is authorized, it can be either permanent or temporary. On the Forest, when vacant allotments are temporarily grazed, they are referred to as swing allotments. A swing allotment is temporarily grazed by an existing permittee whose authorized allotment is not available.

swing allotment is temporarily grazed by an existing permittee whose authorized allotment is not available (whole or in part) The idea of using a vacant allotment on a temporary basis rather than a permanent basis is to provide flexibility for existing Forest permittees and their allotments At this time, cattle are not allowed to graze vacant sheep allotments Also, permittees who do not presently have an existing grazing permit on the Forest are not allowed to use swing allotments

The Forest coordinates grazing activities on six allotments with the Bridger-Teton N F Five are located on Forest lands (along the Snake River, above Alpine Junction, along highway 26/89) where the Bridger-Teton N F administers all resources, except grazing For these five allotments, the management direction (grazing utilization standards and guidelines, permit/allotment administration, AMP development, etc) in the Targhee Forest Plan applies The sixth allotment is that portion of the Moose Creek S&G allotment within the Bridger-Teton N F where the Forest also administers grazing activities and the Bridger-Teton N F administers everything else

To better manage livestock, many structural improvements have been constructed using equal (50 percent Forest Service and 50 percent permittee) contributions from the Forest Service and the grazing permittees These improvements include 563 miles of fence, 670 water developments, 72.5 miles of pipeline, 8 wells, 16 corrals, 7 stock bridges, 2 herder cabins, 74 cattleguards, and 25 miles of stock trail The Forest portion of these improvements is generated from grazing receipts (RBRB funds) and usually is in the form of materials and supplies Range improvement structures are maintained by the grazing permittees

A capability analysis has been completed for all allotments with range analysis surveys Areas capable and not capable of grazing livestock have been determined by field inspections using specific criteria (Process Papers H and I) identified in Forest Service Handbook FSH 2209.21 As shown on Map 29, of the 154 allotments (1,466,475 acres) where grazing is permitted, eight on the Island Park District, totalling 853 acres, do not have a range surveys and one on the Teton Basin District, totaling 1,446 acres, does not have a range survey

Not all areas on the Forest that are capable of grazing livestock are suitable for grazing For example, approximately 21 percent (400,640 acres) of the Forest is presently closed to grazing (Map 29) Even though these acres are now closed, at one time they were designated as being in allotments with about 53 percent of the lands capable of grazing domestic livestock Other areas on the Forest where grazing is not suitable are fenced developed recreation sites, some special use sites, administrative sites, RNAs, developed spring and seeps and some critical wildlife habitat such as bighorn sheep range in the Teton Range subsection A suitability analysis has not been conducted for all allotments on the Forest The suitability for livestock grazing is determined through a site-specific analysis, from which AMPs are developed As per direction found in the Rescission Act of 1995 (Section 504 of Public Law 104-19), the Forest has a schedule in place to complete this analysis for allotments that need it and intends to comply with this law as funding from Congress will allow

CHAPTER IV ENVIRONMENTAL CONSEQUENCES

READER'S GUIDE - In this chapter you will find:

A description of the consequences of implementing the alternatives with respect to the following components and key issues

- Ecological Processes and Patterns
 - Ecological Processes and Disturbances
 - Ecological Patterns
- Physical Elements of the Environment
- Biological Elements of the Environment
 - Aquatic and Riparian Ecosystems
 - Terrestrial Ecosystems
- Forest Use and Occupation
 - Access Management
 - Wilderness and Recreation Resource
 - Economic and Social Environment
- Production of Commodity Resources
 - Timber
 - Livestock Grazing
- Irreversible and Irrecoverable Commitment of Resources

The consequences are described in some or all of the following terms - Consequences Common to All Alternatives, Consequences Which Vary by Alternative and Cumulative Effects

ECOLOGICAL PROCESSES AND PATTERNS

This component describes the potential effects to forest structure, composition, disturbance regime and pattern. It is assumed that all future site-specific management activities will result from ecological assessments conducted in a manner similar to that described in the draft document entitled *Proper Functioning Condition* (Process Paper W).

Two issue indicators were developed for this component. The first issue indicator of "health of forest structure and composition" was derived by totaling the number of acres, under each alternative, where forest structure and composition may be maintained or improved through timber management activities. The second issue indicator is the "use of fire." It was derived by totaling the number of acres, under each alternative, where prescribed fire (both management-ignited and natural) may be used to maintain or improve ecological sustainability. Table IV-1 displays these indicators by alternative.

Table IV-1 Ecological Process and Pattern Indicators by Alternative							
Indicator	Alternatives						
	1	2	3	3-M	4	5	6
Prescribed Fire							
Prescribed Fire Allowed with Few Restrictions 1/ (MM Acres)	1 63	1 75	1 75	1 75	1 75	1 75	1 75

ECOLOGICAL PROCESSES AND DISTURBANCES

Old Growth, Late Seral and Mature Forests

In Chapter III, it was noted that about 79.6 percent of the forested acres were classified as mature, which included old growth and late seral forests. Additional analysis using permanent forest inventory plots indicated that 8.7 percent of the forested acres meet old growth characteristics for live trees and standing dead trees, 68.4 percent of the forested acres could be classified as late seral and 2.5 percent of the forested acres are younger and smaller mature trees.

Consequences Which Vary by Alternative - We modelled the effects of all standards and guidelines and management prescriptions to estimate the amount of timber harvesting that may occur. Table IV-2 displays how proposed timber harvesting (scheduled and unscheduled) in each alternative will change the amount of old growth, late seral and mature forest at the end of the first decade. On a forestwide basis, Alternative 2 has the highest proposed timber harvest, which reduces these acres about three percent at the end of the first decade. Alternative 6 has the lowest proposed timber harvest, which reduces these acres about one percent at the end of the first decade.

On a watershed basis, the following changes in mature, late seral and old growth forest acres are estimated:

- Four watersheds (010, 011, 012, 013) do not have any proposed timber harvesting that would create additional openings for the first decade in all alternatives. These are the watersheds where most of the lodgepole pine salvage timber harvesting occurred during the last two decades.
- 30 watersheds will have < five percent of the mature, late seral and old growth forest acres harvested.
- Six watersheds will have from 6 to 10 percent of the mature, late seral and old growth forest acres harvested.
- Four watersheds will have from 10 to 17 percent of the mature, late seral and old growth acres harvested.

At the end of the first decade, we estimate conditions for the principal watersheds for all alternatives:

- 23 watersheds will have > 90 percent of the forested acres in mature, late seral and old growth stages.
- 5 watersheds will have 80 to 89 percent of the forested acres in mature, late seral and old growth stages.
- 5 watersheds will have 70 to 79 percent of the forested acres in mature, late seral and old growth stages.
- 7 watersheds will have 60 to 69 percent of the forested acres in mature, late seral and old growth stages.
- 3 watersheds will have 50 to 59 percent of the forested acres in mature, late seral and old growth stages.
- 1 watershed will have 33 percent of the forested acres in mature, late seral and old growth stages.

Studies on the historical amount of old growth, late seral and mature forests have been completed for two watersheds, the Camas Creek watershed (025) and the upper Henry's Fork watershed (008). Both of these watersheds are in the Centennial Mountains Subsection. The following summarizes these studies:

Camas Creek Watershed (Report of the Camas Creek Landscape Team)

1850	54 percent in an early seral stage 39 percent in a mid seral stage 6 percent in a late seral
1900	27 percent in an early seral stage 64 percent in a mid seral stage 8 percent in a late seral
1950:	7 percent in an early seral stage 35 percent in a mid seral stage 57 percent in a late seral
1995	7 percent in an early seral stage 36 percent in a mid seral stage 56 percent in a late seral

Upper Henry's Fork watershed (Patten and Hansen, 1995)

1790-1870	< 20 percent open (nonforested) 80+ percent in mature forest
1870-1910	major natural disturbance about 1870 70-80 percent in open, seedling, sapling 20 percent in mature forest
1910-1950	< 20 percent open 50-60 percent in pole size forest 20-30 percent in mature forest
1950-1988	< 20 percent open 5-10 percent seedling, sapling (logging) 0-5 percent in pole size forest 60 percent in mature forest

Currently, the Camas Creek watershed (025) has 77 percent of the forested acres in old growth, late seral and mature seral stages. This is a higher percentage than existed from 50 to 150 years ago. The highest amount of timber harvesting (Alternative 2) still maintains 66 percent of the forested acres in old growth, late seral and mature seral stages.

Currently, the Upper Henry's Fork watershed (008) has 68 percent of the forested acres in old growth, late seral and mature seral stages. This is a higher percentage than existed from 50 to 150 years ago. All alternatives still maintain 68 percent of the forested acres in old growth, late seral and mature seral stages.

Cumulative Effects - It is not possible to identify and display how much timber harvesting will occur just in old growth or just in late seral forests because we do not have a completed, mapped inventory and the exact locations of future timber harvesting are not known. The inventory, mapping and locations of future timber harvesting will occur as site-specific analysis is done for specific projects.

Fire

The role of fire as an ecosystem disturbance agent has been greatly diminished by fire suppression since the early 1900s. To sustain healthy ecosystems on the Forest it is important to reestablish fire as a disturbance agent. This can be done by allowing lightning-caused fires to burn (prescribed natural fires) or by intentionally setting fires (prescribed management-ignited fires) to achieve specific management goals. Using prescribed fire in concert with silvicultural treatments to reestablish historic fire intervals should reduce the suppression costs and resource losses caused by severe wildfires. The following indicators measure how likely the Forest is to use prescribed fire as a tool in the next decade, given the risks and costs involved.

- 1 Acres where use of prescribed fire is allowed, with few restrictions
- 2 Acres where timber harvest is allowed with few restrictions. This tends to reduce the risks associated with using prescribed fire.
- 3 Miles of motorized road and trail access. Access can reduce the risks and costs associated with prescribed fire.

Consequences Common to All Alternatives - Fire management plans are required for portions of the Forest that will receive prescribed burning. To date, only one such plan has been written, the Jedediah Smith Wilderness Fire Plan (this fire plan has not yet been approved). This fire plan applies to all alternatives. This plan will result in increased natural fire ecology within the Wilderness, with the most potential for stand-replacing fires in the northern portion. Stand-replacing fires would only occur under drought conditions. In the southern part of the wilderness, fires would be expected to remain small and burn in isolated groups of trees.

Forestwide it is estimated that some 11,000 to 21,000 acres of the sagebrush/grass type will be burned in the first decade in all alternatives, which amounts to about 4 to 8 percent of this type on the Forest. The effect of this will be to move acres with dense sagebrush canopies to earlier seral stages where sagebrush is less dominant. This will create more of a mosaic of age classes than currently exists, thereby improving diversity by reestablishing grasses and forbs on these sites. However, the magnitude of this program is not sufficient to significantly alter the seral class distribution of sagebrush/grassland overall. Although the existing seral class distribution of this type is unknown, preliminary studies indicate the Forest supports a higher percentage of mid- and late-seral stages than existed historically. For example, on the Dubois Ranger District, there are approximately 42,310 acres in less than satisfactory condition because of a high density of mountain big sagebrush.

All alternatives allow the use of prescribed fire to some extent. Acreages of other vegetation communities to be treated with fire are unknown in any alternative, but the likelihood that management will use this tool varies by alternative.

Consequences Which Vary by Alternative - Table IV-1 shows, by alternative, the number of acres where prescribed fire is allowed without significant restrictions on its use. All alternatives except Alternative 2 allow 1,750,000 acres of prescribed fire with few restrictions. This equates to approximately 97 percent of the Forest. Alternative 2 allows 1,630,000 acres, which equates to approximately 90 percent of the Forest acres. Table IV-1 also displays that Alternative 2, followed by 1, 3, 3M, 4, 5 and 6 allow varied amounts of timber harvest.

Motorized road and trail access to prescribed burn areas can be important for reducing risks and costs associated with prescribed fire. Roads and trails can serve as containment lines and provide escape routes. Motorized access route mileage is summarized by alternative in Table IV-1. Motorized roads and trails generally decrease from Alternative 1 through 6.

Based on the three indicators, Alternatives 1 and 2 would allow for the highest use of prescribed fires, Alternatives 3 and 3M significantly lower amounts and Alternatives 4, 5 and 6 the least.

Cumulative Effects - Overall, the low number of acres scheduled for timber harvest and the restricted motorized access across the Forest will limit the use of prescribed fire for all alternatives, especially in the forested types. Alternative 2, with the highest number of acres scheduled for harvest, only harvests 2-3 percent of the existing mature-or-older forested acres over the next 10 years. Additional vegetation manipulation will occur via nonscheduled harvest (including unsuited lands) such as firewood removal, but this small amount of fuel manipulation is not enough to allow managers to restore fire over large acreages with acceptable risks. For community types where fire intervals are outside their historic range, all alternatives are expected to delay a return to more natural fire regimes for at least the next decade. A discussion of these effects by community type follows.

Sagebrush/Grass Ecosystem - With the removal of several fire cycles from these ecosystems, the preponderance of big sagebrush stands fall within the dense canopy coverage class (greater than 15 percent canopy coverage). Under all alternatives, only approximately 4 to 8 percent of the Forest sagebrush/grass acres are projected to be manipulated during the first decade. As a result, the majority of the big sagebrush acres will continue to decline in overall watershed conditions (loss of understory vegetation resulting in increased susceptibility to erosion, reduced water infiltration and decreased organic matter recruitment).

As these ecosystems simplify, becoming a homogeneous dense canopy of dense sagebrush, they become increasingly susceptible to fires of higher severity and intensity than what historically occurred. Implications of such fires include the following:

- 1 Potential for loss of species not adapted to these "altered" fire regimes (e.g., Idaho fescue),
- 2 Loss of nutrients and a lowering of site productivity potential (more nutrients being stored within the dense overstory versus within the soil profile as historically was the case, thus being more susceptible to loss through ignition),
- 3 Higher potential for having more acres severely burned with subsequent chances for altering the soil's physical and chemical properties,
- 4 Alteration of the natural resistance and resiliency of the soils.

Lack of management within the sagebrush/grass ecosystem will also result in more acres which historically supported sagebrush/grass being converted to conifers and subsequent decrease in overall inherent site productivity.

Aspen Ecosystem - Aspen is mainly found on soils that have a high inherent productivity due to the nutrient cycling (leaf fall) that occurs within healthy stands. Over time as conifers invade these sites the

soils begin to acidify and nutrients are leached out of the productive surface layers to lower depths within the soil profile. If left unchecked, these soils will mature and develop into soils more suitable for conifers and less likely to support healthy vibrant aspen communities. This will reduce future options or make future options more at risk for success.

Currently 93 percent of the aspen on the Forest is mature or at pathological rotation age. Inability to regenerate significant amounts of aspen by fire will maintain most of this type in the mature class and will result in aspen's being replaced by conifers in many cases. Where this occurs, the ability of the soils to support aspen may be lost due to changes in soil chemistry or due to loss of clone root vitality. Severe fires are more likely to occur where conifers have become mixed with aspen, which would tend to regenerate aspen as long as fires are not so hot that they destroy the aspen root systems (most root nodes for sprouting are 3-6 mm below the surface).

Dry and Moist Douglas-fir, and Mid and Lower Elevation Subalpine Forest Fire Groups - These fire groups occur within all subsections. Mean fire intervals within these fire groups indicate that one or more fire cycles may have been removed from these areas mainly through fire suppression. Results of altering the fire regimes in these fire groups include the following:

1. Thickening of the forest or potential loss of certain habitats (e.g., aspen stands, wet/dry meadows, riparian areas etc.) due to encroachment.
2. Accumulation of more large organic materials on the forest floor. As organic matter accumulates, decomposition rates decline and nutrient cycles stagnate. Nitrogen mineralization rates decline.
3. Decrease in stream flow and on-site water balance. Increase in interception, evaporation and transpiration. Available water is less.
4. Development of ladder fuels.

Implications if fires of higher intensity and severity were to occur are as follows:

1. The potential increases for the loss of species not adapted to these "altered" fire regimes (e.g., old, past fire-resistant Douglas-Fir).
2. Loss of nutrients and a lowering of site productivity potential. Storing more nutrients above ground in the denser (more stems per acre) forest canopy instead of the soil profile as was historically the case makes them more susceptible to loss through fire.
3. There is a higher potential for having more acres severely burned with subsequent chances for altering the soils' physical and chemical properties or of developing water-repellant layers with subsequent sensitivity to increased overland flows and erosion.
4. The natural resistance and resiliency potential for the soils would be altered, requiring longer recovery time and thus a longer risk period for resource damage.

Historic forest structures of large, widely spaced Douglas-fir trees would not be restored during the first decade. Susceptibility to Douglas-fir beetle and western spruce budworm are expected to remain high due to dense stocking and multiple-storied structure.

Due to the long fire intervals (50-350 years) in the subalpine fir type, the historic fire patterns most likely have not been significantly changed due to fire suppression. Failure to reintroduce fire in subalpine fir within the next decade is not expected to cause important impacts to this community type.

Lodgepole Pine - Historic fire regimes in the lodgepole pine community type have not been seriously

disrupted on the Forest. Significant lodgepole pine acreages have been returned to early age classes by past timber management and within the Greater Yellowstone Ecosystem a large proportion of this type was affected by the fires of 1988. Although the possibility of severe stand-replacing fires still exists within this type, such fires are in line with what historically occurred. The consequences of not reintroducing fire to this type are expected to be insignificant over the first decade.

High Elevation Whitebark Pine - Lack of fire reintroduction at high elevations where whitebark pine is found may contribute to the decline of this species. Newly burned areas which provide seedbeds will continue to be lacking. Since much of the whitebark pine is mixed with subalpine fir, fires would likely be of high intensity leading to loss of mature whitebark pine trees. Both these conditions would reduce opportunities in this species for improved genetic resistance to white pine blister rust via gene recombination.

Insects and Disease

The environmental consequences discussed here focus primarily on pest management through forest vegetation manipulation. Forest management on timberlands provides the best opportunity to prevent or reduce the amount and impact of pest-related damage, although direct actions against pests may be necessary in specific (small scale) situations, as it relates to forest vegetation. With greater opportunity to manage forest vegetation, less damage would be anticipated. Areas managed intensively for timber would present the greatest opportunity to reduce or prevent timber losses, while areas managed non-intensively for timber production would have anticipated higher timber losses. Another method in treating insects and disease is the use of baiting or trap trees. Prescribed fire may be an appropriate tool in managing insects and disease, under some conditions.

Reducing competing vegetation in plantations increases available soil moisture and available light and is essential for acceptable seedling survival and growth. Controlling tree densities in timber stands improves tree health and vigor and greatly increases their resistance to insect attack. Replacing existing stands which contain a component of overmature, decadent trees with young trees reduces mortality caused by insects and disease.

Indicators - Amount of treated acres of mature and older age classes

Consequences Common to All Alternatives - All alternatives allow some treatment of insects and disease, including vegetation manipulation. However, the intensity of application and opportunities for managing pests will vary according to the kinds and intensities of resource management planned for each alternative. Plantations of seedling, sapling and pole-size stands existing from previous vegetation manipulations will be treated during this planning period in order to enhance vigor and growth. The amount of treatment in these stands will be about the same for all alternatives.

All alternatives allow insects and disease to play their natural role in ecological succession in one or more management prescription areas. Endemic levels of insects and disease are natural and should be expected.

Vegetation management in developed recreation areas should result in improved health of the vegetation, decreased tree mortality and fewer hazardous trees. Vegetation management in developed recreation areas should remain about the same as the current situation assuming the same level of funding as in the past.

Consequences Which Vary by Alternative - The amount of forested vegetation manipulation varies in each alternative. The alternatives with the most acres in the 5-series prescriptions allow for the most vegetation management. Alternative 2 allows the most forest management and Alternative 6 the least (see Table II-1 and Table IV-1). While the level of insects and disease activities expected from each alternative is difficult to measure, the amount of vegetation manipulation in each alternative is not significantly different.

Cumulative Effects - All alternatives provide a low level of vegetation management and will not affect levels of insect and disease activity significantly from past forest plan activities. While the levels of vegetation management are lower than the previous planning period, treatment of mature stands at any level is beneficial in reducing insect and disease conditions.

Under all the alternatives pest-caused mortality would be expected to increase as mature timber stands continue to become overmature. This could result in both an increased level of annual losses and the increased possibility of large periodic losses from insect and disease epidemics. Pest-caused mortality would likely increase as vegetation management decreased, though the differences between alternatives are not likely to be significant.

ECOLOGICAL PATTERNS

Forest Structure, Composition and Natural Disturbance

Indicators - Health of forest structure and composition

Consequences Common to All Alternatives - The primary consequence common to all alternatives is that the existing conditions of the forest structure and composition will remain unchanged on at least 96 percent of the forested landscape over the coming decade. Areas with sustainable conditions of structure and composition will generally remain healthy. Areas such as the heavily harvested lodgepole pine forest within the Island Park Ecological Subsection are expected to improve in both structure and composition. Most areas that do not have healthy conditions of structure and composition due to fire exclusion are expected to remain unhealthy. There is an increased risk that some of these areas could be burned by wildfire or their condition could be further reduced by outbreaks of insects or pathogens.

Silvicultural activities such as timber harvest and fire (management-ignited and natural) directly affect forest structure and composition by changing plant species composition, ages, density and canopy characteristics. When properly designed and executed, silvicultural activities can maintain and improve forest structure and composition. However, silvicultural treatments are proposed on less than four percent of the forested landscape.

Consequences Which Vary by Alternative - The amount of forested landscape where timber harvest could take place varies by only about two percentage points between alternatives. Table IV-1 shows that between 20,700 and 58,600 acres could be treated. The proposed alternative could treat up to 45,200 acres. Management-ignited and natural fire could occur on 1.63 to 1.75 million acres per decade.

Cumulative Effects - Past management practices have inadvertently reduced the health of forests by altering their structure and composition. Past fire management practices reduced the spread of naturally ignited fires over much of the Forest. This allowed many stands to become overstocked and increased their susceptibility to damage by wildfire and to outbreaks of insects and pathogens. Past silvicultural practices did not always strive to achieve desirable conditions of forest structure and composition. Some timber harvest areas, although small in proportion to the entire forested area, left some landscapes out of balance in regard to structure and composition.

The present level of silvicultural treatments is very small as is the proposed level of treatment.

Cumulatively fire exclusion and to a much lesser extent timber harvest, has reduced the health of the forested landscape by altering the structure and composition. The proposed alternatives do little to change this trend.

Connectivity

Indicators

- 1 Acres where aquatic connectivity is improved or maintained
- 2 Open motorized road & trail miles, which decrease connectivity
- 3 Percent of forested acres in mature or older age classes
- 4 Patterns of mature forests

Consequences Which Vary by Alternative

Aquatic Influence Zone - Buffers intended to protect the entire AIZ and retain abundant riparian vegetation are utilized in Alternatives 4, 5 and 6. It is anticipated that these alternatives will restore near natural levels of connectivity at a relatively rapid rate (10-30 years). Alternative 3M which protects the entire AIZ but retains less riparian vegetation, will eventually restore near natural levels of connectivity. Alternatives 2 and 3 employ narrower buffers and less protective standards and guides. It is expected that these alternatives will not restore natural levels of connectivity. Alternative 1 provides the narrowest buffers and the least protective standards and guides. This alternative is expected to be the least effective in restoring natural levels of connectivity. Alternatives 1, 2 and 3 would not fully restore many stream reaches. Further information on aquatic ecosystems is shown in Table II-1 and under Aquatic and Riparian Resources in the Biological Elements section of this chapter.

Terrestrial Zone - Since open motorized roads and trails can interrupt wildlife movement and plant dispersal, the miles of such roads can be used as an inverse measure of connectivity. This is displayed for each alternative in Table IV-1. All alternatives show a gradually decreasing number of open motorized access miles. All alternatives are expected to reduce open road mileages from the existing conditions, thereby providing benefits to connectivity.

The amount and pattern of mature or older age classes across the Forest can also indicate levels of connectivity for species requiring this type of habitat. Higher amounts of mature age classes would likely provide greater connectivity. The percentage of forested acres in mature or older age classes is shown by alternative in Table IV-1. Across all alternatives the mature forested acres exhibit very little variation, ranging from 76 percent to 78 percent. Alternative 2, with the highest potential timber harvest acreage, would harvest 33,080 acres in the first decade, which translates to 2.7 percent of the forested land. This is not expected to create adverse effects on connectivity. Patterns of mature forest distribution do not vary by alternative. There is nothing in any alternative that would prevent managers from providing for connectivity by spatially arranging site-specific projects to approximate historic vegetation patterns.

Cumulative Effects - Clearcutting over the past decade in the Island Park and Madison Pitchstone Plateaus Subsections has altered vegetation patterns and connectivity from what existed historically in some watersheds. Since no created openings are planned in any of these watersheds in any alternative within the next decade, there is little likelihood that these areas will move further from their historic patterns, nor will they be restored to historic patterns. Connectivity based solely on vegetation patterns has not been significantly changed by past timber harvest in other subsections.

Current levels of motorized road and trail density have reduced connectivity from historic levels forest-wide. Reductions in motorized roads and trails proposed under all alternatives will eliminate some of these past effects. Road restrictions which occur near adjacent ownerships are expected to increase habitat connectivity over the current situation between Forest lands and those of its neighbors.

Along the western border of the Park, connectivity is significantly increased by road reclamation and restrictions in Alternatives 4, 5 and 6. More moderate gains are realized in Alternatives 1, 2, 3 and 3M.

Changes in connectivity from what existed historically may have already affected individual species or

ecosystem sustainability, however, the nature and magnitude of such effects on the Forest and whether they exist, are not known at this time

Adjacent Land Use Patterns

Land uses occurring adjacent to the Forest may or may not be consistent with management being proposed for the Forest. How the Forest fits within the context of its neighbors is an important factor in understanding the broad ecosystem patterns that result when the various alternatives are implemented. The Process Paper P contains information on current management of lands adjacent to the Forest.

Consequences Common to All Alternatives - For the most part, management of the Forest is expected to be compatible with adjacent land uses occurring on both public and private lands. However, there are some cases where conflicts may arise.

In all alternatives, the existence and effectiveness of winter ranges for elk, deer and antelope may be affected by activities on private land. Subdivision of agricultural lands for homes and businesses is expected to reduce winter range on private lands, thereby increasing pressure on the Forest's winter range. This is a concern especially in the Teton Range and Big Hole Mountains Subsections, where housing developments are increasing rapidly in key winter range in the Teton Basin and Swan Valley areas.

Other inconsistencies between Forest management and adjacent jurisdictions exist where there is a strong commodity emphasis next to designated or recommended wilderness. Intensive management activities can detract from the wilderness character and experience by creating noise or visual impacts that are not consistent with wilderness. The most obvious example of this lies along the western boundary of the Park where the Forest's past intensive timber management ends in a sharp, straight line against the wilderness emphasis of the Park. In all alternatives this will remain visible for several decades. Another situation that creates inconsistency is managing for nonmotorized recreation or wilderness adjacent to developed private lands. Private development and associated activities can detract from the intended nonmotorized experience by creating noise or visual impacts that do not appear natural.

In addition, keeping motorized vehicles off Forest lands is extremely difficult when individual homes have direct access to the Forest. This inconsistency exists in every alternative to some extent.

Consequences Which Vary by Alternative - Conflicts between grizzly bears and humans may become a problem where bear habitat exists next to private ranches or housing developments. Any conflicts that may arise would likely be tied to higher grizzly bear occupation of Forest habitat than currently exists. Although BMUs on the Forest do not change between alternatives, the likelihood of conflicts may be greater in alternatives which provide for better habitat effectiveness if there is a resultant increase in grizzly bear occupancy on Forest lands adjacent to other public and private lands (see the Biological Elements section of this chapter). Such problems would also be more prevalent in years when grizzly bear food sources are scarce. Adjacent lands most likely to experience conflicts between bears and ranching operations are in the Henry's Lake area, where grizzly bear habitat lies directly adjacent to active ranches. Private developments in Island Park, Henry's Lake Flat, Shotgun Valley and Robinson Creek/Fall River are those most likely to experience conflicts with grizzly bears.

There is an area of discontinuity between the Forest and the Gallatin N F in Alternative 2. The Lionhead area has been proposed as wilderness on both the Forest and Gallatin N F's in all alternatives except Alternative 2. The Forest portion in Alternative 2 would have a commodity emphasis which would not match well with the Gallatin N F proposal for wilderness. In addition, current management on the Gallatin is for intensive range management adjacent to a portion of Forest proposed for the Lionhead wilderness area. This creates a management inconsistency in Alternatives 1, 3, 3M, 4, 5 and 6.

Except for Alternative 2, all the alternatives recommend the Lionhead Roadless Area for wilderness. The

Lionhead recommended wilderness lies next to private lands which are rapidly being developed in Henry's Lake Flat

Private developments in the Swan Valley area abut small portions of the Forest proposed for nonmotorized recreation or wilderness in Alternatives 1, 2, 3, 3M and 4. Major portions of the Big Hole Mountains Subsection will have this problem in Alternative 6 where proposed wilderness adjoins developments in Swan Valley and southwest of Driggs. The Big Bend Ridge area near Ashton is proposed for nonmotorized management in Alternatives 5 and 6. This is inconsistent with development that is beginning to occur on private lands in this area.

Cumulative Effects - The distribution and number of wintering deer and elk on the Forest depends on winter severity. The elk and deer winter range areas on the Forest are the upper elevation limits for these ranges. Generally, more winter range acres exist at lower elevations on BLM, State and private lands and a higher proportion of deer and elk winter at these lower elevations during most winters.

As a result, subdivision and loss of agricultural lands adjacent to the Forest and increasing pressure on winter range may trigger reductions in herd size over the long term. National Forest winter ranges cannot compensate for the loss of winter range acres at lower elevations on adjacent lands. If big game populations outstrip winter range capacity, winter range on the Forest could become degraded. The greatest impacts to the Forest from adjacent land uses are expected to result from conversion of agricultural lands to housing and businesses. Agricultural lands provide some habitat for a variety of species and much of this habitat could be lost as development continues. Development may also create significant impacts on the Forest by increasing recreation pressures.

PHYSICAL ELEMENTS

Soils and Geology

Indicators

- 1 Scheduled Timber Harvest (ASQ) - acres disturbed
- 2 Roads and Trails - acres removed from productive land base
- 3 Miles of roads transecting soiltypes having mass stability concerns
- 4 Area of Forest open for cross-country motorized summer use
- 5 Acres placed back into productive land base
- 6 Soil Disturbance - range management
- 7 Soil Disturbance - dispersed recreation

Consequences Common to All Alternatives - Soil disturbances related to developed recreation sites, unmanaged dispersed (including OHV) recreation, concentrated developed areas (e.g. electronic sites, administrative sites, etc.), potential acres severely burned through prescribed fires within the sagebrush/grass and forested ecosystem and fuelwood harvest would be similar under all alternatives.

Soil disturbance would continue to occur across approximately 350 acres within developed recreation sites and special use recreation sites. Soil disturbance would mainly be the result of maintenance or reconstruction activities, vehicles and foot traffic in and between facilities. Such activities would have an effect on the soil hydrologic function (e.g. through compaction and/or puddling) and site productivity (e.g. erosion).

Soil disturbance from unmanaged dispersed recreation and OHV use will be one of the main challenges to soil quality management. Demand for these uses will continue to escalate with corresponding concerns. It is difficult to project which of the alternatives would present more concerns to soil quality.

Soil disturbance would continue to occur across approximately 110 acres of concentrated developed areas. Soil disturbance would be the result of construction/reconstruction/maintenance activities and vehicular/foot traffic. Areas of disturbance would be susceptible to being eroded, with a subsequent loss in site productivity.

Severely burned conditions have the potential of occurring across 560 acres (five percent of the area), where prescribed fire is used within the mountain big sagebrush/grass ecosystem. If areas of severely burned conditions occur in larger patches (acre or more), these areas would be more susceptible to erosion and would require a longer recovery period, thus presenting a longer risk period.

Nonscheduled timber harvest could occur on unsuitable lands. Under all alternatives, approximately 10,000 acres (approximately 20 MMBF) could be harvested in the first decade. Timber removal on non-ASQ lands would be in response to other resource needs, for instance, to remove hazard trees from developed recreation areas, to improve visibility along roadways, wildlife needs, EM or PFC objectives, etc. Concerns to the soil resource would be similar to those expressed later on ASQ lands with the added concerns of a large number of these acres occurring on steep slopes (greater than 40 percent) and/or not being readily accessible. Additional mitigation measures and management requirements will be required on these acres to assure adherence to Regional soil quality objectives (project level).

Approximately 38 million board feet of personal use fuelwood would be removed during the first decade. Areas designated for personal use and commercial fuelwood gathering would be susceptible to reductions in soil quality through such detrimental disturbances as displacement, compaction, puddling and removal of large woody debris necessary for maintenance of long term site productivity (harder to enforce down woody debris requirements). The development of random skidding and access roads is also a concern within fuelwood areas since there is a tendency to drive up to each log or snag harvested.

Consequences Which Vary by Alternative (Refer to Table II-1)

Scheduled Timber Harvest (ASQ Lands) - Land surface disturbed by a variety of logging systems (tractor/cable) and cutting prescriptions (primarily shelterwood harvests) was evaluated. Under Alternative 6 no scheduled timber harvest would occur, thus no surface disturbance. Of the remaining alternatives, Alternative 5 would result in the least acres disturbed (approximately 1339) over the coming decade. Using Alternative 5 as a base, the remaining alternatives (in ascending order) would expose twice as much (Alternatives 3M and 4), three times as much (Alternatives 1 and 3), and four times as much (Alternative 2) the amount of bare soil as Alternative 5. Areas of bare soil could be either compacted, displaced or puddled or a combination of these detrimental conditions. These areas would be susceptible to erosion and subsequent loss in site productivity. Disturbed areas would be the result of timber harvesting practices such as skidding, skid trail networks, landings, etc. Ground-based harvesting techniques may approach or exceed the 15 percent soil disturbance threshold, but should be held to acceptable levels by adhering to the Soil Quality Standards and Guidelines (Forest and Regional). Large woody debris for long-term site productivity should be maintained by following the forestwide large woody debris requirements, which are habitat type specific.

Roads and Trails- Land removed from the productive land base due to existing and proposed roads would be least under Alternative 6 (5,478 acres). Using Alternative 6 as a basis for comparing the remaining alternatives, Alternative 5 would remove 2 percent more acres from the productive land base, Alternative 4 would remove 14 percent more, Alternative 3 would remove 37 percent more, Alternative 3M would remove 31 percent more, Alternative 2 would remove 57 percent more and Alternative 1 would remove 79 percent more than Alternative 6. Presently, there are 10,049 acres removed from the productive land base from roads and trails, which is higher than any of the proposed alternatives. These lands would be effectively removed from the Forest's total productive land base for the life of the road and trail and would be susceptible to erosion and subsequent sedimentation. A high percentage of these acres occur within the AIZ, thus having a short delivery distance to a stream channel. One objective under the watershed activity schedule is to inventory roads, trails, culverts, fords and stream crossings within the AIZ by the

year 2007 This inventory will identify problem areas and suggest remedial actions

Miles of roads transecting soil types having mass instability concerns is least under Alternatives 6 (356 miles, of which 42 miles occur on slopes over 40 percent) The highest number of miles crossing sensitive soil types occurs within Alternative 2 (three times the miles within Alternative 6, 13 percent of which occur on slopes over 40 percent) The remaining alternatives (1, 3, 3M, 4 and 5) have twice the miles of Alternative 6 and 14 percent of their miles occur on slopes greater than 40 percent These road segments would be susceptible to mass erosion (especially those slopes greater than 40 percent) and to being major sediment producers—depending on their drainage systems

Although Alternatives 1 and 2 allow the most access (open roads) and acres available to cross-country motorized summer use (53 percent and 42 percent of the Forest available), it is difficult to predict if dispersal of increasing numbers of recreationists would result in more or less damage to the soil resource Similarly, Alternatives 5 and 6 allow the least access (open roads) and acres available to cross-country motorized summer use (3 percent and 2 percent of the Forest available) It is difficult to predict whether concentrating recreationists into less area would result in more or less damage to the soil resource Administration, monitoring and enforcement would be key in limiting damage to the soil resource Alternatives 3, 3M and 4 are intermediary (in descending order) to the above alternatives with respect to access and area open to summer cross-country travel

Acres placed back into productivity (stabilized and revegetated) through road reclamation/obliteration would be highest under Alternative 6 (4,571 acres) and least under Alternative 1 (861 acres) Alternatives 2, 3, 3M, 4 and 5 would be intermediary, in ascending order, as to the number of acres placed back into production Obliterated roads would have a lower inherent site productivity than adjacent undisturbed sites but overall benefits from obliteration is beneficial to soil and watershed conditions.

Range - Soil disturbance (areas with inadequate ground cover having exposed soil or areas where soil conditions are in a downward trend, e.g. eroding) would be least under Alternatives 4, 5 and 6 Alternatives 2, 3 and 3M would be intermediary Soil disturbance would be highest under Alternative 1 These areas would be susceptible to erosion and decreasing site productivity

Dispersed Recreation - Land surface disturbance within areas managed for dispersed recreation would be potentially greatest under Alternatives 1, 5 and 6 because they have the fewest acres on which dispersed recreation sites would be more strictly managed Alternatives 2, 3, 3M and 4 would place more dispersed sites under management and potentially result in less soil damage. Foot traffic and vehicles would be the main source of soil disturbance resulting in compaction, displacement or puddling These areas would be susceptible to erosion and have lower productivity potentials than adjacent undisturbed areas Game retrieval during the hunting seasons has been dropped from consideration, except from Alternative 2 This will help in reducing damage to the soil resources when soils may be moist/wet and susceptible to damage, except in Alternative 2

Cumulative Effects - Based on the level of activities being projected within the various ecosystems, some cumulative impacts will be similar across all the alternatives The ecological cumulative impacts to soils are described in the Ecological Processes and Patterns section

Because all of the alternatives call for management that may not return certain ecosystems into their PFC, it is very important to mitigate, protect or intensively manage these ecosystems to achieve and maintain the DFC These ecosystems are susceptible to fires of higher intensity/severity

It is anticipated that some ground disturbing dispersed recreation activities may increase over the current situation by 40 percent over the next decade thus having the greatest potential increase in relation to other Forest uses Demands and potential conflicts by this group of users (e.g. motorized versus nonmotorized users) will continue to escalate in the future Potential cumulative impacts from this use could be very similar under all alternatives (e.g., compaction/displacement, loss of vegetation ground cover, increased erosion potential, rutting, rill/gully formation, etc.)

Management-Induced - Open roads and trails also have the potential to produce continued cumulative impacts on soil quality (erosion and sedimentation) and overall watershed values. As mentioned previously, of particular concern is the potential for mass erosion occurring along roads that pass through soils having mass instability concerns (especially on those where side slopes are greater than 40 percent). Greatest potential for cumulative impacts (negative) from roads and trails is under Alternative 1, continuing in descending order of impacts—2, 3, 3M, 4, 5 and 6.

During the next decade, Camas Creek (Watershed 025) is the only watershed scheduled to have timber harvesting (ASQ and non-ASQ) in all alternatives, except Alternative 6, that has 20 percent or more of the area in a hydrologically disturbed condition. Note non-ASQ timber harvesting could occur in Alternative 6 within watershed 025 (Camas Creek).

Overall, soil quality on the Forest should improve over the existing situation under all alternatives. Soil quality standards and guidelines have been established to help direct soil quality improvement, maintenance and/or enhancement within managed portions of the Forest. These standards and guidelines have been incorporated in the Revision.

Management-induced cumulative impacts (acres disturbed compared to total acres/alternative open for multiple use management) to the soil resource would be greatest under Alternatives 1 and 3M (6 percent), Alternatives 2, 3, 6 (5 percent) and Alternatives 4 and 5 (4 percent).

Scheduled activities within the Camas Creek watershed (watershed 025) will need to be well planned, administered and monitored to assure that channel stability is maintained.

Ecological cumulative impacts to the soil resource are very similar under all alternatives, especially within the sagebrush/grass and aspen ecosystems and within the Dry and Moist Douglas-fir, and Mid and Lower Elevation Subalpine Forest Fire Groups.

There is a risk to soil quality within unmanaged portions of the Forest as mentioned under the previous section entitled "Ecological Processes." Because all the alternatives manage these ecosystems outside of their historic mean fire intervals, plans need to be formulated to mitigate, protect or intensively manage these ecosystems/fire groups to maintain the DFCs. Because this has not yet been done, there is a risk within these ecosystems/fire groups of having adverse effects take place to the soil resource through the occurrence of fires of higher severity and intensity than what historically happened.

Air Quality

Indicator - Potential to exceed Idaho or Wyoming Ambient Air Quality Standards

Consequences Common to All Alternatives - Forest lands in all alternatives are Class II areas.

Consequences Which Vary by Alternative - Alternative 1 allows the most activities on forest lands, this would subject air quality to more degradation from management activities than the other alternatives. Alternative 6 allows the least activities on forest lands, thus would be less likely to cause air quality degradation from management activities. An exception to these consequences would be the effects on air quality caused by catastrophic wildfire.

Cumulative Effects - Severe wildfire would be the primary event that would cause air quality degradation. Although there is risk of severe wildfire with all the alternatives, the risks would be higher with alternatives which limit the use of management activities the most. Activities such as prescribed fire (natural and management-ignited), timber harvest, or other vegetation manipulation methods used to reduce fuel loadings and modify stand structure, could decrease the risks of deteriorating air quality caused by wildfires on the Forest. Short-duration smoke events that meets state smoke management guidelines during early or late seasons could reduce the visual and health impacts caused by high severity wildfire during high visitor use season.

Caves

Consequences Common to All Alternatives - Impacts on cave resources would be the same for all alternatives. These would result from normal recreational use of the caves. Obtaining management funding for cave inventories, nominations, etc. may be more limited under Alternatives 4-6 than in higher activity alternatives (1, 2, 3 and 3M).

Lands

Cumulative Effects - There would be no impacts on lands from any alternative. The following plans are incorporated in the Revision by reference. They are located in the lands section office on the Forest and are subject to yearly updating by the lands section:

- Land Adjustment Plan
- Right-of-Way Acquisition Plan

Minerals

Indicators

1 Area Open to Locatable and Mineral Material Entry

Consequences Common to All Alternatives - Under all alternatives mineral resources will be available for extraction. The Forest Oil and Gas Leasing EIS will make the availability decision (acres available for oil and gas leasing) and will be coordinated with the Revision.

Consequences Which Vary by Alternative - Access and availability of lands for exploration and development will vary by alternative as indicated by Table IV-3. Alternatives reflecting more developed recreation sites and facilities, more roadless areas which are to remain undeveloped and more acres recommended for wilderness designation than in Alternative 1 will reduce the availability of lands for mineral exploration and development. Alternatives 1 and 2, in which no additional lands are recommended for wilderness classification than currently exist, provides the most land available for mineral exploration and development. Alternative 6, which has the most acres recommended for wilderness, provides the least amount of land available for mineral exploration and development.

Cumulative Effects - Alternatives which limit development activities on the Forest will have a tendency to also limit the utilization of mineral resources by restricting access and availability of lands for mineral extraction. Conversely, alternatives which provide opportunities for development activities will also provide opportunities for the utilization of mineral resources. Thus, cumulative effects of development activities in the long-run is beneficial to the utilization of mineral resources.

	Alternative						
	1	2	3	3-M	4	5	6
Acres Open to Locatable and Mineral Material Entry	1,384	1,415	1,326	1,295	1,348	1,200	965

Historically, discovery of valuable minerals in economic quantities to warrant development and production have been relatively infrequent on the Forest when compared to other forests in the Intermountain Region.

The probability of mineral resource development is marginal given the current geologic knowledge of the Forest. The only current mineral activity of consequence is the extraction of travertine on the Palisades Ranger District. Before that, in the mid-to-late 1800s, the mining of lead in the western portion of the Forest was significant.

BIOLOGICAL ELEMENTS

Two parts make up the description of the Biological Component. They are Aquatic and Riparian, and Terrestrial Ecosystems (upland forested and upland nonforested). Key indicators are discussed first, with other indicators described subsequently.

AQUATIC AND RIPARIAN ECOSYSTEMS

Riparian

Key Indicator - Riparian acres not meeting DVC

Plant communities comprise individual species that reach maturity at different times during the growing season. Season of grazing use and timing of defoliation can both have an effect on favoring the growth and maintenance of certain species over others.

Consequences Common to All Alternatives - The utilization standards for herbaceous and woody vegetation, for all alternatives, represent maximum allowable use levels, regardless of what animal species uses the vegetation.

Consequences Which Vary by Alternative - Riparian utilization in Alternative 1 (no action) is expressed as a percentage of forage utilized and ranges between 30 and 65 percent for herbaceous vegetation (including nonriparian species) and 20 to 40 percent for browse, depending on the type of grazing system and range condition. Alternatives 2-6 express riparian forage utilization in terms of stubble height of herbaceous key riparian species on and away from the hydric greenline (HGL), express upland herbaceous forage utilization in terms of percent utilization of key plants and implement browse utilization standards in terms of percent utilization of current year's growth, of key species.

Alternatives 2, 3 and 3M implement a 4-inch stubble height for key herbaceous riparian plant species at the HGL and in the riparian area away from the HGL, either at the end of the grazing period or for all pastures grazed after September 1. Alternatives 2 and 3 have buffer widths ranging from 100 to 200 feet on each side of all fish-bearing streams, depending on the subsection. Alternative 3M has wider buffer widths which range from 150 to 300 feet on each side of all fish-bearing streams, depending on the subsection. For Alternatives 2, 3 and 3M, riparian browse utilization ranges from 25 to 35 percent for season-long grazing systems (depending on range condition) and 35 percent for rotation grazing systems (regardless of condition). Literature supports the prediction that Alternatives 2, 3 and 3M will provide for a moderate rate of recovery of degraded riparian and aquatic systems together with a moderately high level of fisheries habitat quality (Clary and Webster 1989). Alternatives 2 through 6 express upland herbaceous forage utilization in terms of percent utilization of key plants, and implement browse utilization standards in terms of percent utilization of current years growth of key species. Alternative 3M also implements additional guidelines for occupied native cutthroat trout streams. Briefly those guidelines improve a variety of habitat features (pool frequency, large woody debris, bank stability, width/depth ratio, etc.), based on the best available information, including INFISH.

Alternatives 4, 5 and 6 implement a 6-inch stubble height for key herbaceous riparian plant species at the HGL and in the riparian area away from the HGL, either at the end of the grazing period or for all pastures grazed after September 1 and have buffer widths ranging from 150 to 300 feet on each side of all fish

bearing streams, depending on the subsection. Also, for Alternatives 4, 5 and 6, riparian browse utilization ranges from 25 to 35 percent for season-long grazing systems (depending on range condition) and is 35 percent for rotation grazing systems (regardless of condition). The additional guidelines identified in Alternative 3M designed to improve cutthroat trout habitat only apply to that alternative and not to Alternatives 4, 5 or 6.

Riparian utilization and/or stubble height is measured for key species, which are defined as "forage species of sufficient abundance and palatability to justify its use as an indicator to the degree of use of associated species." The basic assumption is that when the key species are properly grazed, associated plant species will also be utilized properly. Utilization standards are designed based on proper use of plant species. Proper use is defined as "a degree of utilization of current year's growth which, if continued, will achieve management objectives (DVC, PFC, wildlife and fish objectives, etc.) and maintain or improve the long-term productivity of the site. Information by Blaisdell (Blaisdell, Murry, McArthur and Durant, 1982) indicates that stocking rates, season of use, range condition, kind of livestock and grazing intensity are important factors in determining proper utilization levels and that applying utilization or stubble height standards across the board may not achieve desired management objectives. Information from Rasmussen (1996) indicates that the "plants ability to recover from grazing will depend on the availability of meristematic tissue. If the grazing does not remove current meristematic tissue the plant will recover from the herbivory event and the long term productivity and competitiveness of the plant will not be affected." Regarding Rasmussen's approach, the degree of utilization and/or stubble height is not as important as perhaps the season of use on meristematic tissue and water availability after the grazing event. For example, 25 percent utilization on a key herbaceous plant can be detrimental if that use is continual and occurs at the wrong time (stem elongation, etc.), but 55 percent use on the same plant is not detrimental if the use occurs at a different time of the year (prior to stem elongation or after seed set, etc.) or if adequate water is available.

Under Alternative 1, riparian vegetation trends will show slow improvements in species composition from fine-rooted species like Kentucky bluegrass, to coarse-rooted species like beaked sedge, on allotments with rotation grazing systems. Approximately 18,810 acres (68 percent) of the riparian vegetation will meet DVC, while 4,945 acres (18 percent) are predicted to move slowly toward DVC. Allotments with season-long grazing will tend to remain in their current condition (static), or as stream systems and water tables are lowered, the riparian communities will change to dryer upland species, lower seral riparian species or introduced and weedy species. Loss of habitat for riparian sensitive plant species is greatest in this alternative. Acres moving toward DVC will decrease from 5,338 acres (19 percent) to 4,945 acres (18 percent), while acres not meeting DVC will increase from 3,650 acres (13 percent) to 3,963 acres (14 percent) during the first decade (Table II-1, Process Paper J). Fish habitat conditions and bank stability would improve slowly to a moderate level, due to improved riparian vegetation conditions (definitions and measurement protocol from Quigley et al., 1989).

Alternatives 2, 3 and 3M increase the riparian acres meeting DVC from 68 to 72 percent, while 19 percent will move toward DVC with the 4-inch HGL stubble height grazing requirement. Streamside *Carex* species will increase along streambanks to better retain yearly sediments, increasing the habitat diversity, water-holding capabilities and hydrological conditions of the system. Sensitive plant habitats and biodiversity will increase moderately with these alternatives. Riparian acres not meeting DVC will decrease from 3,650 to 2,476 acres (9 percent) during the first decade (Table II-1). This would result in a moderate rate of recovery and moderately high level of fisheries habitat quality due to improved riparian vegetation and streambank conditions (Process Paper J).

Alternatives 4, 5 and 6 increase the riparian acres meeting DVC from 68 to 76 percent, while 18 percent will move toward DVC, with the 6-inch HGL stubble height grazing requirements. Increased vegetation cover will hold greater amounts of sediment, accelerating changes over those in Alternatives 2, 3 and 3M. These alternatives also have the greatest potential to improve riparian sensitive plant habitats and improve biodiversity by increasing habitat diversity. Riparian acres not meeting DVC will decrease from 3,650 to 1,744 acres (6 percent) during the first decade (Table II-1). This would result in a rapid rate of

recovery of degraded habitats and a high level of fisheries habitat quality due to improved riparian vegetation and streambank conditions (Process Paper J)

Alternative 1 will have 3,963 acres (14 percent), Alternatives 2, 3 and 3M will have 2,476 acres (9 percent) and Alternatives 4, 5 and 6 will have 1,744 acres (6 percent) of the riparian vegetation in undesirable, shallow rooted species. Plant communities with a high percentage of shallow rooted species increase the risk of flood events lowering stream channels, increasing bank-cutting, changing stream gradients and changing riparian communities to upland communities with lowering of water tables

Alternatives 2, 3, 3M, 4, 5 and 6 will all show an increase in *Carex* complexes along stream edges that have a greater chance of trapping and improving the vegetation diversity of the riparian areas

Water

Indicators

- 1 Acres impacted by developed recreational sites in the AIZ as defined by the buffers described in prescription 2 8 3
- 2 Number of stream crossings
- 3 Acres roaded in the AIZ
- 4 Acres of timber harvest in headwaters
- 5 Miles of native cutthroat trout stream with at least 6-inch HGL (Hydric Greenline) stubble height remaining at the end of the grazing period (Table II-1)
- 6 Miles of fish-bearing stream habitat with at least 4-inch HGL stubble height remaining at the end of the grazing period (Table II-1)

Consequences Common to All Alternatives - Land disturbance and impacts to riparian areas will take place under all alternatives, the magnitude of these effects will vary by alternative. Closure of roads and trails within the AIZ would create new sediment sources due to ground disturbance under all alternatives. This would be a short-term impact to riparian areas and water bodies, lasting approximately three years (until the disturbed sites were stabilized). These closures would, however, provide a long-term benefit to aquatic and riparian resources once they became effective (i.e., when the vegetation was established). If road prisms are not removed where they exist in floodplains, even with road closure, floodplain and stream functions could be adversely affected by the confinement presented by these features.

There is no difference between alternatives in the amount of water diverted from streams on Forest lands by private parties, for use under special use permits. There will also be no difference in the amount of water (consumptive uses) claimed for Forest purposes through the Snake River Basin Adjudication - no new uses after 1987 are claimed. There may be a difference between alternatives in the amount of water under application and license for consumptive use (e.g., for livestock watering), but the differences should be small. Compliance with legal requirements, such as meeting State water quality standards, will not differ between alternatives.

Acres affected by developed recreational sites and special use permit recreation sites within the AIZ would vary little by alternative. All alternatives would have approximately 1,100 acres of disturbance associated with these sites within the AIZ. Impacts from dispersed recreation are discussed in the recreation section.

Consequences Which Vary by Alternative

Direct Impact - See Table II-1. Direct impacts to streams and riparian areas on Forest lands are of three general types:

- 1 Change in riparian soil, vegetation and streambank characteristics,
- 2 Direct in-channel alteration,

3 Change in the amount of sediment delivered to streams and therefore the load that the stream must transport

Change in Riparian Soils, Vegetation and Streambanks - Damage of riparian soils by compaction, displacement, rutting or puddling can reduce riparian soil productivity through changes in infiltration characteristics and a reduction in the ability of soils to support desirable riparian vegetation. Changes in the composition of riparian vegetation communities and loss of plant vigor result from such adverse impacts to soils, as well as from direct impacts from overuse by wildlife, livestock or people. Refer to the key indicator discussion under Aquatic and Riparian Ecosystems.

Direct In-Channel Alteration - These actions include putting a structure into a stream and changing channel hydraulics or changing some aspect of the stream's geometry (e.g., increasing its gradient) by mechanical alteration.

Potential for direct impacts associated with road crossings would vary by alternative. The greatest potential would exist under Alternative 1, followed by 2, 3M, 3, 4, 5 and 6 in decreasing order. Alternative 6 has approximately 1,000 fewer crossings than Alternative 3M. This could be a tangible difference forestwide, even between consecutive alternatives (e.g., Alternative 2 has about 300 fewer crossings than Alternative 1).

Change in Sediment Delivery and Load - Natural events, such as high spring runoff, may lead to both increased sediment delivery to streams and increased erosive energy to move the sediment. Roads are major sources of sediment, especially when they are near streams or cross them. Since forest roads contribute an estimated 85-90 percent of the sediment reaching streams in disturbed forest land (Burroughs 1990), the amount of roads within the AIZ and number of stream crossings are used as indicators of sediment delivered to streams.

Many roads and trails located within the AIZ would be closed in all alternatives. Acres of roads within the AIZ steadily decreases from a high of 954 acres under Alternative 1 to a low of 474 acres under Alternative 6. Alternative 3M has 787 acres. Such a decrease in roads within the AIZ means a proportional decrease in the potential for sediment delivery to streams, for delivery of other pollutants and for detrimental impacts to riparian areas (note that AIZ widths vary between some alternatives). The influence of road prisms would still exist if they were not removed. Differences in impacts from road crossings would be the same as discussed under section 2, above (direct in-channel alteration). An inventory of roads will determine where there are problems and provide recommendations to reduce impacts to acceptable levels.

Cumulative Effects

Hydrologic Effects - Manipulation of vegetation has the potential to alter streamflow regimes. Researchers have shown that creation of large openings, especially in small (i.e., headwater) watersheds allows for increased snow accumulation and more exposure to the sun. This results in higher peak flows that occur earlier than under preexisting conditions, having the potential to deliver more sediment to streams and destabilize channels (Cheng 1989, Alexander and Watkins 1977). The increase in sediment delivery due to changes in peak flows cannot be calculated nor estimated.

The highest potential for cumulative impacts from vegetation manipulation in headwater areas would exist under Alternative 2. Alternatives 1 and 3 have the next highest potential. 3M, 4 and 5 have the lowest, for alternatives having vegetation manipulation. There would be no significant impact under Alternative 6. From a watershed perspective, watersheds 10 (Buffalo River) and 12 (Warm River) appear to have potential for adverse cumulative impacts under all alternatives due to past activities. No created openings are planned in these watersheds. These watersheds have approximately 30 percent of their headwaters in a hydrologically disturbed state for the decade, having stands that have already been manipulated and which would still be unrecovered by the end of the planning decade.

- 2 specific watersheds -

Although it is unlikely that any of the proposed alternatives would threaten the population viability of native cutthroat trout over the planning period, differences in rate of recovery of degraded habitats and overall habitat quality would result from implementation of various alternatives. Alternatives 1, 2 and 3 would protect the fewest acres within AIZs and would allow the greatest amount of potentially harmful activities associated with livestock grazing, timber harvest, riparian recreational use and roads and trails as displayed in Table II-1. Fisheries habitat quality, including that for native cutthroat trout, would be the lowest under Alternative 1. Alternatives 1, 2 and 3 would result in a slow rate of recovery of degraded habitats, reduced water quality and less habitat quality. Refer to Table II-1 for a quantitative view of riparian habitat change. Since Alternatives 4, 5 and 6 would emphasize more protection of AIZs, they would result in a rapid rate of recovery of degraded habitats and the highest levels of water quality and fish habitat quality. Alternative 3M would result in a moderate rate of recovery of degraded habitats and intermediate levels of water quality and fish habitat quality. All alternatives would meet State water quality standards.

Nearly all of the environmental consequences described for each alternative are cumulative in the sense that they reflect the environmental and management impacts of an accumulation of management actions that would occur under each alternative and that have occurred in the past. Many of these impacts have occurred over the last 100 years, some would cease with implementation of certain alternatives while others would continue over the planning period (10 to 15 years).

Wildlife Associated with Aquatic and Riparian Ecosystems

The effects of implementing the alternatives are displayed in terms of consequences for bald eagle, trumpeter swan nesting, spotted frog, common loon, and harlequin duck habitats.

Bald Eagle Nesting Habitat

Consequences Common to All Alternatives - At this time, we do not have much information about wintering habitat and migration habitat. This lack of information has not been detrimental to the growth of the bald eagle population as previously explained in Chapter III. However, the Revised Forest Plan establishes an objective to identify bald eagle wintering and migration habitat and to identify appropriate management needs for this habitat when it is identified. Table IV-4 displays an overview of the consequences of each alternative for this management indicator species.

Management Indicator	Existing	1	2	3	3M	4	5	6
Bald Eagle Habitat 1/ # of Nest Sites on Forest # of Territories on Forest	17 26	17 26	17 26	17 26	17 26	17 26	17 26	17 26
Trumpeter Swan Habitat	Forestwide Goals, Standards and Guidelines protect all nesting areas in all alternatives							
Spotted Frog Habitat (disturbance)	Most	Most	Mod	Mod	Mod	Least	Least	Least
Common Loon Habitat	Monitoring and Habitat Evaluation to be done in all alternatives							
Harlequin Duck Habitat	Forestwide Goals, Standards and Guidelines protect all nesting areas in all alternatives							
1/ Forestwide Goals, Standards and Guidelines protect all territories in all alternatives								

Cumulative Effects - Bald eagle nest zones and primary use areas occur on adjacent National Forest, BLM, state and private lands. Along the South Fork of the Snake River, the "Snake River Activities/

Operations Plan" was approved by BLM and the Forest Service in 1991. Bald eagle habitat management was a key component of that Plan.

Management actions of other agencies, such as management of fishing and fish populations by State agencies, management of river flows by the Bureau of Reclamation and southeast Idaho irrigators, may have positive or negative effects on the bald eagle population.

As previously presented in Chapter III, the bald eagle population on the Forest, as well as throughout the GYA, has increased to levels above the objectives in the Pacific States Bald Eagle Recovery Plan (USDI Fish and Wildlife Service 1986).

Human presence and activities have occurred and will continue to occur within and adjacent to bald eagle territories on the Forest. As long as humans are present, there will be probable occurrences of short-term displacement. However, every bald eagle territory which has become established on the Forest since the first recorded bald eagle nest in 1975 has been maintained. Proposed management direction will maintain suitable habitat on Forest lands for all existing bald eagle nesting territories and any new territories which may become established. In areas without territories, management prescriptions will maintain suitable habitat conditions for perching, foraging and potential future nest sites.

Trumpeter Swan Nesting Habitat

Consequences Common to All Alternatives - Refer to Table IV-4

Cumulative Effects - Many of the lakes and ponds historically used by trumpeter swans are naturally filling in with sediment and are becoming too shallow for swan use. Active management will be needed to help maintain suitable water depths for swans or the lakes and ponds will not be usable.

Spotted Frog Habitat

Consequences Which Vary by Alternative - Five AIZ management prescriptions have been developed for the seven alternatives. We evaluated how each alternative may affect spotted frog habitat as follows. Also, Table IV-4 displays an overview of the consequences of each alternative for this and the other four management indicator species.

Influence of Buffer Widths - Bartelt and Peterson (1993) noted that spotted frogs were always within 2 meters of water, none left riparian habitats, almost all were associated with ponds until September when they left the ponds for nearby streams, and ponds within 50 meters of permanent streams were an important combination of habitat characteristics. Based on this, the different buffer widths in each of the management prescriptions all appear to be adequate.

Some literature indicates that spotted frogs may move considerable distances after breeding, in these cases, the movements would be farther than any of the buffer widths in the management prescriptions. In these cases, we doubt there is much of a measurable difference in effect due to different buffer widths.

Timber Harvesting/Management - There is no data in the literature to suggest that spotted frogs are dependent upon a particular forested vegetation condition. Therefore, there is no difference between the alternatives in terms of effects from changes in forest vegetation due to timber harvesting. Concern has been expressed about timber harvesting changing humidity and temperature conditions. However, spotted frogs are found in nonforested riparian and wetland habitats, which have different humidity and temperature conditions than forested habitats. Therefore, we are not able to state that changes in humidity and temperature caused by timber harvesting would be detrimental. However, there may be a disturbance effect from the presence of human activity associated with timber harvesting. Therefore, Alternatives 1 and 2 which allow scheduled timber harvesting in the AIZs may have site-specific, short-term impacts on spotted frog populations and habitat.

Livestock Grazing - A recent conservation assessment for spotted frogs (Gomez 1994) listed concerns about possible threats to spotted frogs and habitat from livestock or grazing (Concerns included such things as reduced vegetation in riparian areas, potential increases in water temperature, trampling, etc) However, no documented studies were cited in support for these concerns

In studies done on the Forest, Clark et al (1993 and 1994 plus errata page) reported there appeared to be no significant relationship between spotted frog occurrence and evidence of grazing They stressed however, that no controlled study was performed investigating the effects of grazing on spotted frogs and therefore appropriate caution should be exercised when evaluating the importance of the results

Using an assumption that less grazing activity may result in potentially less effect on spotted frog habitat, Alternatives 4, 5 and 6 will have the least amount of potential disturbance, Alternatives 2, 3 and 3M will have moderate amounts of potential disturbance, and Alternative 1 the most amount of potential disturbance

Recreation and Other Activities - Using an assumption that less recreation activity and other human activities in spotted frog habitat may result in less potential effects on their habitat, Alternatives 4, 5 and 6 will have the least amount of potential disturbance, Alternatives 2, 3 and 3M will have moderate amounts of potential disturbance, and Alternative 1 the most amount of potential disturbance

Riparian Habitat Condition and Trend - In Alternative 1, 86 percent of the riparian acres are meeting DVC or will be improving toward DVC In Alternatives 2, 3 and 3M, 90 percent of the riparian acres are meeting DVC or will be improving toward DVC In Alternatives 4, 5 and 6, 93 percent of the riparian acres are meeting DVC or will be improving toward DVC

Cumulative Effects - All alternatives are expected to maintain the current spotted frog distribution on the Forest General habitat conditions are expected to improve with all alternatives, with the most improvement occurring in Alternatives 4, 5 and 6

Common Loon Habitat

Consequences Common to All Alternatives - The Forest has an objective to evaluate the potential to provide and maintain suitable breeding habitat for common loons at the sites mentioned in Chapter III If this evaluation proves that these sites are suitable breeding habitat for common loons, the Forest is to develop common loon management plans for these sites Current habitat conditions will be perpetuated at these sites in all alternatives.

Consequences Which Vary by Alternative - Table IV-4 displays an overview of the consequences of each alternative for this and the other four management indicator species

Harlequin Duck Habitat

Consequences Common to All Alternatives - There is a forestwide guideline to avoid establishing new trails, new roads or new recreation facilities within 300 feet of any stream reach with documented harlequin duck breeding activity There is no scheduled timber harvesting adjacent to any of the streams with documented breeding activity Livestock grazing, existing recreation activity (existing trails, recreation facilities, dispersed use, etc) and other human activities are not measurably different among the alternatives for the sites with documented reproduction Existing habitat conditions will be maintained in all alternatives Table IV-4 displays an overview of the consequences of each alternative for this specie

TERRESTRIAL ECOSYSTEMS

Upland Forested Ecosystems

Indicators - Acres and percent change in age classes of forested community types

Consequences Which Vary by Alternative - Table IV-5 shows the percent change mature forest with timber harvest for each subsection, by alternative. Changes in the mature forest acres do not necessarily reflect a change to a lower age class. The range of management methods, from clearcutting to thinning,

% Harvest 1/ % Mature	0 90	0 79	0 62	0 97	0 95	0 99	0 79.6
1/ The percent change from a mature age class, undisturbed forest, to an early age class or mature forest with previous harvest							

use of prescribed fire, will create a variety of changes in the vegetation composition in the mature forest. Changes will range from conversion to grass/forb communities with seedlings, to open stands of mature trees with different understory species, resulting from different light and moisture conditions.

Alternatives 1 through 5 have various harvest rates in each of the subsections. Changes in the mature stands range from 0 percent to a maximum of 6.6 percent in these alternatives, which is not a significant change of mature forests in any of the subsections. Forests in the mature age class will continue to dominate the landscapes in all alternatives.

Management for white bark pine is possible in all alternatives, but timber harvest is limited in BMUs, Alternatives 5 and 6, and in wilderness. Fire as a tool is available in all alternatives. Aspen volume was removed from the ASQ, therefore, management levels for all alternatives are insignificant in changing the age classes in aspen. Stands will continue to change to coniferous forest types, as

Douglas-fir and subalpine fir trees increase and dominate the aspen stands. Disease and insects common within mature age classes of aspen will accelerate the change to coniferous forest types.

Forestwide mature forest community types will continue to dominate the landscapes. Aspen stands for all alternatives will continue to be converted to coniferous forests as Douglas-fir and subalpine fir increase within the aspen stands. Aspen across the forest will decrease as a component of the landscape, which decreases the total biodiversity of the landscape. Aspen stands provide natural wildfire buffers that change the fire rates and intensities across the landscape. Loss of aspen stands to conifers creates larger continuous stands that can have high fire intensities that increase the severity of wildfire on the landscape.

Coniferous forests will continue to mature, increasing biomass, canopy cover, and fuel loading within the stands. The understory will change to shade-tolerant species and also decrease in the number of species as the forest habitat becomes more uniform. As mature conifer forests continue along current trends, insects and disease will increase, creating areas of dead trees and greater fuel loads, increasing the risk of large and intense wildfire. Open areas created by dead trees will provide sites for early seral species to establish and will increase the habitat and species diversity within large stands. Absence of periodic low impact fires will put most of the mature forest in jeopardy of stand-replacing fires over large areas due to fuel loading.

Coniferous forest species, especially Douglas-fir, will continue to encroach into sagebrush/grass, mahogany, grass/forb meadows, riparian, and mountain brush communities throughout the forest. Conversion of herbaceous and shrub communities decreases the biodiversity and habitat diversity of the mid-elevation and high elevation areas of the Forest. As forests mature, water requirements also increase, which decrease water availability to wet meadows and riparian areas.

Whitebark pine stands will continue to decline across the Forest. Regeneration in most stands is low due to encroachment of other coniferous species and lack of fire.

TES and Biodiversity

Indicator - Plant species

Consequences Common to All Alternatives - Potential for loss of individuals or populations and suitable habitat for Ute ladies'-tresses *Spiranthes diluvialis* (threatened species) and Payson's milkvetch *Astragalus paysonii* (sensitive species) are the same for all Alternatives. Fire is thought to be an important part of Payson's milkvetch life cycle, as it inhabits lodgepole pine and lodgepole pine/Douglas-fir mixed forests in the seedling to pole age classes, and in disturbed areas and openings in mature age classes (Fertig et al. 1993).

Potential for loss of individual TES plants, populations or habitat is dependent on site-specific projects and land uses, and is equal for all alternatives. As per direction and policy, no loss of TES populations will be allowed.

Upland Nonforested Ecosystems

Indicators - Acres (and percent) meeting DVC

Consequences Common to All Alternatives - From 11,000 to 21,000 acres of sagebrush/grass community type are planned to be burned, sprayed (500 acres) or rotobeat (1,300 acres) to meet management objectives over the coming decade. Management objectives will be tied to meeting DVC, documented in site specific analysis. As a result of treating these sites, sagebrush canopy cover will be reduced and desirable herbaceous vegetation will be increased resulting in a change in ecological status from high mid/late seral stages to early/mid seral stages. To achieve the 11,000 acre burning goal, an additional 10,000 acres (21,000 acres total) may be partially burned. The 11,000 acres scheduled for burning would be predominately in late-seral stage sagebrush with canopy cover greater than 30 percent. Some acres of mid-seral stage sagebrush, within the 11,000 acres, with canopy cover of 15-30 percent could be burned depending on project design. The 10,000 acres of partially burned areas are assumed to be converted from mid/late-seral to early/mid seral stage. Partially burned areas are those areas that are, 1) outside the main portion of the project where the fire is of low intensity or 2) outside the main portion of the project where the fire pattern creates a mosaic resulting in unburned areas. Treatment of the 11,000 to 21,000 acres of sagebrush/grass community type represents 4 to 8 percent of the acres that will move towards meeting DVCs over the next decade.

Consequences Which Vary by Alternative - For Alternatives 2, 3 and 3M upland forage utilization ranges from 35 percent for ranges in unsatisfactory condition, to 45 percent for ranges in satisfactory condition in season-long grazing. For rotation grazing systems, the utilization ranges from 45 percent for ranges in unsatisfactory condition to 55 percent for ranges in satisfactory condition. Browse utilization for Alternatives 2, 3 and 3M ranges from 25 to 35 percent for season-long grazing systems, depending on range condition, and is 35 percent for rotation grazing systems regardless of condition.

For Alternatives 4, 5 and 6 upland forage utilization ranges from 35 percent for ranges in unsatisfactory condition, to 45 percent for ranges in satisfactory condition in season-long grazing. For rotation grazing systems the utilization ranges from 45 percent for ranges in unsatisfactory condition to 55 percent for ranges in satisfactory condition. Browse utilization for Alternatives 4, 5 and 6 ranges from 25 to 35 percent for season long grazing systems depending on range condition, and is 35 percent for rotation grazing systems regardless of condition.

Compared to the existing situation, all alternatives close an additional 95,409 acres to grazing. Alternatives 3M and 4 phase-out grazing on another 125,853 acres and Alternatives 5 and 6 immediately close the same acres identified in Alternatives 3M and 4 (Process Paper L). These acres that will be closed will show improvements in vegetation composition in the upland communities faster than those with grazing.

Under Alternative 1, upland vegetation trends will show slow improvements in species composition from species of lower seral status to species of higher seral status. Approximately 1,065,748 (78 percent) acres will meet DVC, 162,193 (12 percent) acres will move toward DVC, and 129,531 (10 percent) acres will not meet DVC by the end of the first decade.

Compared to the existing situation, Alternatives 2, 3 and 3M increase the upland acres meeting DVC from 76 to 80 percent. Approximately 1,083,263 acres (80 percent) will meet DVC, 160,615 acres (12 percent) will move toward DVC, and 113,594 acres (8 percent) will not meet DVC by the end of the first decade.

Compared to the existing situation, Alternatives 4, 5 and 6 increase the upland acres meeting DVC from 76 to 82 percent. Approximately 1,105,894 acres (82 percent) will meet DVC, 156,105 acres (11 percent) will move toward DVC, and 95,473 acres (7 percent) will not meet DVC by the end of the first decade.

Cumulative Effects - A predominance of acres in high-seral and mid-seral stages will continue to dominate the landscapes under all alternatives. As shrub cover increases, productivity and biodiversity will decrease and potential for wildfires will increase. Lack of fire has decreased habitat potential for plant species that prefer early seral stage habitats such as *Penstemon lemhiensis* a sensitive species.

Canopy cover over 15 percent in sagebrush significantly impacts herbaceous species productivity and ability to reestablish over time. About 65 percent of the Forest's range land is currently in late-seral stage due primarily to lack of fire in these communities. Resting or eliminating grazing will not show significant improvements over time in understory herbaceous species when high canopies of sagebrush occur (Winward 1991). These communities increase the risk of large wildfires that are of higher intensity and severity than was historically present under 12-40 year fire cycles. These unnaturally hot fires could alter subsequent plant diversity by destroying existing soil seed banks, burning deeper into crowns of bunchgrasses and perennial forbs (and subsequently killing these plants) and changing the physiology of the soils by changing soil conditions and productivity.

Upland and riparian communities will continue to decrease with encroachment of coniferous forest species. Mahogany stands are all in the high-seral stage and are becoming decadent due to lack of fire and an increase in Douglas-fir establishment. Increases of spruce and subalpine fir along mid- and high-elevation riparian areas has decreased willow and other shade-intolerant riparian species within the riparian zone and increased the susceptibility of these sites to erosion.

Noxious Weeds

Consequences Common to All Alternatives - The effects of noxious weed control are disclosed in the 1987 Targhee National Forest Noxious Weed EA and Decision Notice. The effects of Alternative 2 - Integrated Pest Management (Selected Alternative) disclosed in Chapter IV, Environmental Consequences, of the 1987 EA, are also incorporated by reference into this analysis. Regardless of which alternative is selected for the Revised Plan, the amount of noxious weed infested acres treated yearly does not change. The Forest has an active annual program to control the spread of noxious weeds.

Wildlife Associated with Terrestrial Ecosystems

Indicator - Elk Vulnerability (EV)

Consequences Which Vary by Alternative - Table IV-7 displays the percent of the Forest which meets the EV threshold levels of the State Fish and Game Departments.

The primary effect over which the Forest Service has control in this EV analysis is the density of open motorized roads (OMR) and trails and the amount of area open to cross-country OHV travel. Since Alternative 1 has the highest density of OMR and the most area open to cross-country OHV travel, this alternative has the highest EV and the potential for a higher proportion of the bulls to be harvested, thus the lowest percentage of the Forest meeting State EV thresholds. Since Alternatives 5 and 6 have the lowest density of OMR and trails and the least area open to cross-country OHV travel, these alternatives have the lowest EV and the potential for the lowest proportion of the bulls to be harvested, thus the highest percentage of the Forest meeting State EV thresholds.

In Alternative 2, within certain management prescriptions which comprise 58.5 percent of the Forest, use of all-terrain vehicles (ATVs) is permitted cross-country and on restricted roads and trails during the big game hunting season for retrieval of legally harvested big game animals. Before hunters can use ATVs to

Table IV-7 Consequences of Alternatives for Terrestrial Ecosystems-Wildlife Management Indicators Species and Habitats

<p>1/ Elk habitat effectiveness is based on open motorized road and trail densities during the spring, summer and fall season, and hiding cover. A perfect rating would be 1.0, which would require no motorized access and 50 to 60 percent hiding cover. The numbers in the table are a weighted average for the entire Forest based on watershed analysis.</p> <p>2/ Elk vulnerability is based on motorized access density during the general elk hunting season and hunter-day densities. The numbers in the table are the percent of the Forest meeting elk vulnerability threshold levels set by the State Fish and Game Departments.</p> <p>3/ The numbers in the table are an index of biological potential for primary cavity nesting species. An index of 1.0 would mean that enough snags of the right sizes exist on every forested acre of the Forest to meet 100 percent of the habitat requirements for all primary cavity nesting species. The four large species are Williamson's sapsucker, northern flicker, hairy woodpecker, and rednapped sapsucker.</p> <p>4/ These are acres of mature and older forested habitat.</p> <p>5/ These are conifer acres with trees old enough to bear cones. Cone-bearing ages were defined as pole, mature and older size classes and age classes.</p>								

do this, certain conditions must be complied with, such as obtaining a permit from a Ranger District office. There has been no research or monitoring on how this provision might effect EV. There is concern from some agencies and individuals that this provision might result in higher EV.

Cumulative Effects - All roads and trails receiving motorized use and cross-country motorized use, are incorporated into the EV analysis. Hunter-day densities were provided by the State Fish and Game Departments. If hunter-day densities change in the future, due to changes in hunting seasons, motorized access restrictions or human populations, then this analysis will need to be updated.

Elk Habitat Effectiveness (EHE)

Consequences Which Vary by Alternative - Table IV-7 displays how EHE changes on a forestwide basis for each of the alternatives

The primary factor in EHE analysis is the density of OMR and trails. Since Alternative 1 has the highest density of OMR and trails, it has the lowest EHE value. Since Alternative 6 has the lowest density of OMR and trails, it has the highest EHE value.

A lesser factor in EHE analysis is the amount of hiding cover. In all alternatives, the amount of hiding cover improves slightly as new seedlings grow into sapling stands in previously logged areas of the Forest. The amount of timber harvesting proposed in all alternatives is less than the number of acres growing into better hiding cover.

The overall effect from improving EHE (which ranges from .60 in Alternative 1 to .70 in Alternative 6) is a probable wider distribution of elk into areas previously underutilized because these areas had high motorized access densities and densities are now reduced. Improving EHE does not mean elk populations will increase.

Cumulative Effects - All roads and trails receiving motorized use are incorporated into EHE analysis. All previous timber harvesting, plus all future proposed timber harvesting are incorporated in EHE analysis.

Effects of Motorized Use on Trails

In the analysis of EV and EHE, we treated the effects of motorized use on trails as being equal to the effects of motorized use on roads. In public comments to the DEIS and while working on the FEIS, some questioned the scientific basis for treating motorized use on trails as equal to motorized use on roads. The following provides a brief overview documenting the work done to obtain information about the effects of motorized use on trails.

The Forest had a series of elk workshops with the state Fish and Game agencies to work on analysis steps for EHE and EV for the final Revised Plan. According to Dr. L. Jack Lyon from the Intermountain Forest and Range Experiment Station, there is no research on the effects of motorized use on trails, but intuitively elk should respond to motorized use on trails the same as motorized use on roads. Based on that statement, motorized use on trails has been equated to motorized use on roads for the elk habitat effectiveness and elk vulnerability analysis.

At the public access meeting of January 5, 1994, Dr. Lyon provided a written response to questions from the public about motorized access. He stated that there has been no reported research on the effects of trails. At this public access meeting, alternative views were presented from the public. Marty Morache presented the most extensive alternative view that motorized trails do not have as much effect on elk as roads.

Idaho Department of Parks and Recreation cited the 1987-1988 Idaho Rifle Elk Hunting Study which documented that only one percent of hunters use trail bikes to hunt (during 1987-88). The implied question is, should we equate motorized trails which provide access for one percent of the hunters equal to motorized trails which provide access for 99 percent of the hunters in EV analysis? We do not know of any study conducted since 1987-88 which documents if a higher percentage of hunters are using trail bikes to hunt in 1996.

At the request of the Interagency Grizzly Bear Committee, a task force was created to establish standardized definitions for roads and trails and standardized methods to measure densities for roads and trails. In the final report (titled the "Interagency Grizzly Bear Committee Task Force Report - July 1994"), trails and roads are treated equally in determining motorized access density.

Recent work is in progress on the development of "Draft Interagency Guidelines for Managing Elk Habitats and Populations on USFS Lands in Central Idaho " In these guidelines, trails are given one-tenth the effect of roads Personnel on the Nez Perce N F have stated several qualifiers the guidelines are still draft, there is no research supporting that trails be given one-tenth the effect of roads, and, that biologists working on the draft guidelines agreed on the one-tenth criteria based on fewer number of vehicles on trails and lower sound levels (Steve Blair, personal communication, July 9, 1996)

At this time, there is no scientifically controlled research study on the effects of motorized use on trails To obtain an understanding of how much EV and EHE analysis would change if trails were not treated equally with roads, we analyzed EV and EHE for the existing condition and alternative 3M by giving motorized use on trails one-tenth the effect of motorized use on roads The results of this analysis are as follows

EV - existing condition, 55 percent of the Forest meets State Fish and Game thresholds
EV - alternative 3M, 91 percent of the Forest meets State Fish and Game thresholds
EHE - existing condition, 0 62
EHE - alternative 3M, 0 67

Comparing these results with those in Table IV-7 show that EV changes seven percent for the existing condition and two percentage points for Alternative 3M EHE changes five percentage points for the existing condition and three percentage points for Alternative 3M

These changes are small because

- 1) Motorized trails only account for 23 percent of the total motorized road and trail miles on the Forest When cross-country motorized use is also figured in for the EV analysis, then motorized trail miles only account for about ten percent of the total motorized access
- 2) The trail system is not equally distributed across the Forest and in those drainages where most of the motorized trails occur, the trail densities are generally low, which means they have less effect in the EV and EHE analysis
- 3) Motorized access on trails is only one factor in the EV and EHE analysis, the other factors such as hunter densities for EV and cover for EHE also contribute to the analysis

Elk and Deer Winter Range

Consequences Common to All Alternatives - The feed ground in Rainey Creek will remain in all alternatives

All elk and deer winter range areas mapped on Map 24 will be closed to cross-country snowmachine use in all alternatives (Table IV-7)

Consequences Which Vary by Alternative - The amount of winter range acres meeting DVC increases from existing levels as follows three percentage points in Alternative 1, four percentage points in Alternatives 2, 3 and 3M, six percentage points in Alternatives 4, 5 and 6 (Table IV-7)

The majority of the deer and elk that summer on the Forest do not winter on the Forest The number of deer and elk wintering on Forest winter ranges depends on the severity of the winter As far as we know, no alternative would decrease the suitability of winter ranges on the Forest for deer and elk from existing habitat conditions Improvements in the number of acres meeting DVCs and increased restrictions on cross-country snowmachine use will result in improved winter range conditions for deer and elk, but populations may not increase over existing levels

Cumulative Effects - Development on private lands is a concern as it can adversely affect areas historically used by wintering deer and elk

Grizzly Bear Habitat

Consequences Common to All Alternatives (within the BMUs) -

- 1 Acres within designated wilderness remains the same in all alternatives
- 2 The number of cattle allotments remains the same in all alternatives

Consequences Which Vary by Alternative (within BMUs) -

Key Indicator - Open Road and Open Motorized Trail Route Density (OROMTRD)

Tables IV-8 - IV-12 present an overview of future OROMTRD and other habitat conditions for the Forest portion of each of the BMUs for each of the alternatives. Other indicators shown in Tables IV-8 - IV-12 include

- 1 Winter Cross-Country Snowmachine Use
- 2 Total Motorized Access Route Density (TMARD)
- 3 Cross-country OHV
- 4 Forest Acres in Core Areas
- 5 Livestock Grazing
- 6 Timber Harvest

Winter Cross-Country Snowmachine Use - Snowmachine use is primarily a concern because of the potential to displace bears before they hibernate or after they emerge from their dens in the spring. We are not aware of specific problems or incidents occurring on the Forest, but the alternatives do prescribe different cross-country snowmachine use dates as follows in an effort to be sensitive to potential future effects.

Henry's Lake BMU, Subunit 1 - There are no cross-country snowmachine use restrictions in Alternatives 1, 2 and 3. In Alternative 3M, cross-country snowmachine use is permitted beginning on the Thanksgiving Day holiday and will be allowed until June 1, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc.) will be imposed to resolve human-grizzly bear conflicts. About 85 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1 in Alternatives 4, 5 and 6.

Henry's Lake BMU, Subunit 2 - About 46 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1 in Alternative 1. There are no cross-country snowmachine use restrictions in Alternative 2. In Alternative 3M, cross-country snowmachine use is permitted beginning on the Thanksgiving Day holiday and will be allowed until June 1, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc.) will be imposed to resolve human-grizzly bear conflicts. In Alternatives 3, 4, 5 and 6, an additional 50 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1.

Plateau BMU, Subunits 1 and 2 - About 8 percent of the BMU has cross-country snowmachine use dates of December 1 to June 1 in Alternative 1. There are no cross-country snowmachine restrictions in Alternative 2. About 20 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1 in Alternative 3. In Alternative 3M, cross-country snowmachine use is permitted beginning on the Thanksgiving Day holiday and will be allowed until June 1, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc.) will be imposed to resolve human-grizzly bear conflicts. In Alternatives 4, 5 and 6, all of the BMU has cross-country snowmachine use dates of December 15 to April 1.

Bechler/Teton BMU - About 34 percent of the BMU is closed to all snowmachine use in all alternatives in the Winegar Hole and Jediah Smith Wilderness Areas. Outside of the wilderness, the alternatives vary as follows. In Alternatives 1 and 2, there are no cross-country snowmachine use restrictions. In Alterna-

tive 3 an additional three percent of the BMU has cross-country snowmachine use dates of December 15 to April 1. In Alternative 3M, cross-country snowmachine use is permitted beginning on the Thanksgiving Day holiday and will be allowed until June 1, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc.) will be imposed to resolve human-grizzly bear conflicts. In Alternatives 4, 5 and 6, an additional 56 percent of the BMU has cross-country snowmachine use dates of December 15 to April 1.

Cumulative Effects - The only available tool that evaluates the cumulative effects of changing levels of human activities and changing habitat conditions is the grizzly bear cumulative effects model (CEM). The CEM was used to provide insight on the relative changes in habitat quality between the alternatives. Table IV-8 through IV-12 show CEM outputs for the alternatives. The CEM is still being validated and at this time, no conclusions can be made concerning grizzly bear populations or distributions based on CEM outputs.

At this time, no definitive statement can be made for a "threshold" number for TMARD, OROMTRD, amount of core area, timber harvesting, livestock grazing, snowmachine use or CEM outputs, in order to achieve a certain number of grizzly bears using a specific area. Analysis on female home ranges is currently being done by the Interagency Grizzly Bear Study Team, which may help define threshold levels in the future. Generally, the lower the TMARD and OROMTRD, the higher amount of core area, the lower the recreation use and the higher HE/HV CEM output, the better the habitat conditions are for grizzly bears.

Predicting future grizzly bear distribution and abundance by alternative is difficult. Based on data we have compiled from 1959 to the present, we offer the following general assessment for each BMU, subunit:

Henry's Lake BMU, Subunit 1 - This area has had the lowest documented grizzly bear sightings of any subunit on the Forest but it has the highest habitat value of any subunit. There has not been a verified sighting of a sow with cubs from 1959 to present. Even with nine active domestic sheep allotments, there have not been grizzly bear/livestock incidents. This subunit is positioned farther west than any other subunit in the GYA and contains the highest recreation use associated with Henry's Lake Flat. Even though there is a general trend of improving habitat conditions on the Forest from Alternative 1 to Alternative 6, we expect grizzly bear use to remain at low levels, similar to what has occurred in the past, in all alternatives.

Henry's Lake BMU, Subunit 2 - Compared to other subunits on the Forest, this subunit has had the second highest number of grizzly bear sightings and it has the second highest habitat value of any subunit. This subunit has been and currently is, occupied by a sow with cubs. This subunit is immediately adjacent to other occupied BMUs in the GYA. Even though there is a general trend of improving habitat conditions on the Forest from Alternative 1 through Alternative 6, we expect grizzly bear use to be similar to what has occurred in the past in all alternatives. We do not expect a measurable difference in grizzly bear use among the alternatives.

Plateau BMU, Subunit 1 - Compared to other subunits on the Forest, this subunit has had the second lowest number of grizzly bear sightings and it has the lowest habitat value of any subunit. Two sows with cubs have been documented from 1959 to the present. In the last two decades, the Forest portion has had what is considered high open road densities and high human activity, especially timber management activity. But the Yellowstone National Park portion has had very little human activity and still grizzly bear use has been low in that portion of the subunit. Generally, there is a trend of improving habitat condition on the Forest from Alternative 1 to Alternative 6. Because this subunit is adjacent to other occupied BMUs in the GYA, we expect that as habitat conditions improve, there is potential for increased grizzly bear use. We use the term potential because of historic low use of this subunit, even in the Yellowstone National Park portion where little human activity has occurred.

Plateau BMU, Subunit 2 - Compared to other subunits on the Forest, this subunit has had the third lowest number of grizzly bear sightings and it has the second lowest habitat value of any subunit. Until 1994, we had no records that confirm sightings of sows with cubs in this subunit. In 1994, one sow with cubs was observed one time near the southern boundary of the subunit, since 1994, no sows with cubs have been documented. In the last two decades, the Forest portion has had what is considered high open road densities and high human activity, especially timber management activity. But the Yellowstone National Park portion has had very little human activity and still grizzly bear use has been low in that portion of the subunit. Generally, there is a trend of improving habitat condition on the Forest from Alternative 1 to Alternative 6. Because this subunit is adjacent to other occupied BMUs in the GYA, we expect that as habitat conditions improve, there is potential for increased grizzly bear use. We use the term potential because of historic low use of this subunit, even in the Yellowstone National Park portion where little human activity has occurred.

Bechler/Teton BMU - Compared to other subunits on the Forest, this subunit has had the highest number of grizzly bear sightings and it has the third highest habitat value of any subunit. This subunit has been and currently is occupied by a sow with cubs. This subunit is immediately adjacent to other occupied BMUs in the GYA. There is a general trend of improving habitat condition on the Forest from Alternative 1 to Alternative 6. Because this subunit is adjacent to other occupied BMUs in the GYA, we expect that as habitat conditions improve, there is potential for increased grizzly bear use. We use the term potential because of historic high use of this subunit and we may not be able to measure more use when compared to the historic high use.

Since 1984, there have been no grizzly bear mortalities on the Forest. We do not expect any inherent differences among the alternatives in relation to grizzly bear mortalities. If grizzly bear use increases in the future due to improved habitat conditions, there may be potential for increased human/grizzly bear conflicts.

Linkage Zone Assessments - The Grizzly Bear Recovery Plan identified the need to assess the potential for linkage zones between the various grizzly bear ecosystems. The Yellowstone Grizzly Bear Ecosystem is about 240 air miles from the Selway-Bitterroot Grizzly Bear Ecosystem (USDI Fish and Wildlife Service 1993). Currently, very little is known about the potential for linkage zones. In order to adequately assess the capacity for linkage, the USFWS initiated a five year process to assess the linkage potential between the various ecosystems. This process will be led by the USFWS in cooperation with the States, provinces and various land management agencies. At the completion of the five year evaluation effort, a report will be available to the IGBC on the potential for linkage between existing ecosystems. This report will be the basis for future actions regarding the linkage zone question. Linkage zones are desirable for recovery, but are not essential for delisting at this time. The studies are in progress and no results are available.

The Grizzly Bear Recovery Plan states that future land management activities within potential linkage zones may be critical to maintaining their utility as linkage zones. It is essential that existing options for carnivore movement between existing ecosystems be maintained while the evaluation of linkage zones is underway. Management strategies that limit human-induced mortality and address the access management will facilitate the maintenance of the potential of these zones during the evaluation period. On public lands, management prescriptions similar to big game summer range prescriptions that address access management would likely conserve any existing potential of these areas for linkage until completion of the evaluation process (USDI Fish and Wildlife Service 1993). Access management was a key issue addressed in all alternatives considered in the Forest Plan Revision.

For the Yellowstone Grizzly Bear Ecosystem, the Recovery Plan states the following:

The Yellowstone grizzly bear population is the only one of five grizzly bear populations that is completely isolated from populations in other U.S. ecosystems and Canada. The population has approximately 300 bears. The population's small size and isolation make it vulnerable to the

detrimental effects of the loss of genetic diversity and to environmental and demographic stochasticity. Connectivity between the Yellowstone Grizzly Bear Ecosystem and other grizzly ecosystems is not likely to be realized in the near future because of the distance to other ecosystems and the intervening human development and alteration of landscape. Therefore, the recovery plan recommends that one grizzly be placed into the ecosystem from an outside population every ten years as an effort to maintain the genetic health of the population (USDI Fish and Wildlife Service 1993).

Gray Wolf

Consequences Common to All Alternatives - Application of the forestwide standards and guidelines is expected to allow wolf pairs to establish dens on the Forest if they choose to do so and to receive the protection of the nonessential experimental population rule (USDI Fish and Wildlife Service 1994b).

Primary Cavity Nesting Habitat

An overall biological potential for the primary cavity nesting species as a group was analyzed for each alternative. In addition, a biological potential analysis was done for four of the species which require larger size snags (red-naped sapsucker, Williamson's sapsucker, hairy woodpecker and northern flicker). These biological potential analyses are based on existing snag densities and projected changes in snag densities due to management activities as specified in the management prescriptions.

Consequences Common to All Alternatives - All of the management prescriptions which allow scheduled timber and fuelwood harvesting (with the exception of management prescription 5.2.2) require the retention of snags and green replacement trees. The snag and green replacement tree requirements vary in these management prescriptions, ranging from > 40 percent of biological potential to 100 percent of biological potential for primary cavity nesters.

In addition to the management prescriptions which allow scheduled timber harvesting, snag and green replacement trees requirements are also contained in other motorized management prescriptions where fuelwood harvesting could be permitted based on the presence of roads for access and management prescription direction which allows fuelwood harvesting. The snag and green replacement tree requirements vary in these management prescriptions, ranging from > 40 percent of biological potential to 100 percent of biological potential.

There are no snag and green replacement tree requirements in the management prescriptions which are nonmotorized, wilderness, wilderness study areas, proposed wilderness, research natural areas, wild/scenic/recreational rivers or special management areas. In these management prescriptions, timber harvesting is not scheduled and primary cavity nesting habitat will evolve with natural processes.

There are no snag and green replacement tree requirements in the recreation and concentrated development management prescriptions. In these management prescriptions, public safety and protection of facilities is the paramount importance, therefore snags and other hazard trees are generally removed from these sites. The total acres in these sites is less than one-half of one percent of the total acres on the Forest.

Table IV-7 displays the biological potential for the primary cavity nesting species for each alternative on a Forestwide basis. (Process Paper D displays the biological potential on a watershed basis for each alternative.) In all alternatives, the biological potential for all primary cavity nesting species is 0.61 and the biological potential for the larger cavity nesting species is 0.47. As a result of the snag and green replacement tree requirements in the management prescriptions, there is no measurable difference in biological potential for primary cavity nesting species between the alternatives due to scheduled timber harvest activities.

Cumulative Effects - The analysis for future biological potential does not include possible future effects of natural disturbances. Future natural disturbances may have a greater effect on the biological potential for primary cavity nesting species habitat than vegetation management activities proposed for each alternative. Generally, natural disturbances such as fire, insects and disease create additional snags in the short term.

Forest Owl Habitat

Consequences Common to All Alternatives - Proposed management activities are not expected to change habitat conditions for these species regardless of the alternative.

Flammulated Owl - All known nest sites and any new nest sites found in the future, whether or not they are active, will be protected in all alternatives.

Boreal Owl and Great Gray Owl - All known nest sites and any new nest sites found in the future, whether or not they are active, will be protected in all alternatives. Within home ranges around all nest sites, > 40 percent of the forested acres will be maintained in late seral stages.

Furbearer Habitat

Furbearers include the American marten, fisher, lynx and wolverine. These species require mature, late seral and old growth forest habitats for some or all of their habitat requirements. Snags and down woody debris are also important components of their habitat.

Consequences Common to All Alternatives - There is a Forestwide objective to identify potential wolverine natal den sites and to survey these potential sites to document wolverine presence.

Consequences Which Vary by Alternative - Table IV-7 displays how the quantity of late seral forest habitat is expected to change due to scheduled timber management activities in each alternative. The amount of late seral forest habitat changes by alternative according to the amount of timber harvesting proposed in that alternative. Alternative 1, 2 and 3 have the largest potential change in habitat (-3 percent) and Alternatives 5 and 6 the least potential change (-1 percent). The previous section on old growth and late seral forest provides additional information which is not repeated here. If furbearer populations are currently at habitat carrying capacity, then Alternatives 1, 2 and 3 would result in a three percentage point population decline, Alternatives 3M and 4 a two percentage point population decline, and Alternatives 5 and 6 a one percentage point population decline. All alternatives will contain suitable habitat in all principal watersheds on the Forest, thus maintaining well distributed populations.

Goshawk Habitat

Consequences Common to All Alternatives -

Nest Areas - A nest area of at least 200 acres in size is to be provided for all goshawk territories. These suitable nest areas are to be mature and older stands of trees, with numerous snags (80 to 100 percent biological potential for cavity nesting species). Any vegetation management within nest areas is to occur during the months of October to February. There are to be no new system roads.

Post-Fledging Family Area - This area is > 400 acres in size. A variety of forest seral stages can be present, but > 40 percent of the forested acres must be in mature and older size/age classes. Any created opening must be < 40 acres in size. Numerous snags are to be present (80 to 100 percent biological potential for cavity nesting species). Any vegetation management within this area is to occur during the months of October to February. There are to be no new system roads.

Foraging Area - This area is > 5,400 acres in size. A variety of forest seral stages can be present, but > 40 percent of the forested acres must be in mature and older size/age classes. Any created opening must

be < 40 acres in size. Numerous snags are to be present (> 60 percent biological potential for cavity nesting species). Vegetation management within this area can occur anytime during the year. Road densities are to be < the density required by the management prescription.

This management direction applies to all known territories and any new territories found in the future, whether or not they are active. The proposed management direction would maintain effective habitat and viable populations are expected to be sustained.

Red Squirrel Habitat

Consequences Which Vary by Alternative - Table IV-7 displays the acres of conifer cone-bearing habitat in each alternative. Alternatives 1, 2 and 3 result in a one percentage point decline of conifer cone bearing habitat, Alternatives 3M and 4 result in a less than one percentage point change, Alternatives 5 and 6 result in a one to two percentage point increase. The small changes in cone bearing habitat among the alternatives occurs as the result of some previously harvested acres approaching cone-bearing age during the decade. The number of acres coming of cone-bearing age is almost as large as the number of acres proposed for timber harvesting in any of the alternatives.

Peregrine Falcon Habitat

Consequences Common to All Alternatives - Forestwide Standards and Guidelines for peregrine falcon habitat apply in all alternatives. Suitable habitat will be maintained for all existing nesting pairs plus any new nesting pairs which may become established.

Bighorn Sheep

Consequences Common to All Alternatives - The following discussion is divided into four topics: 1) low elevational winter range, 2) disease, 3) genetic isolation, and 4) recreation.

Low Elevation Winter Ranges - Former low elevation winter ranges are not being used for a variety of factors, including permanent developments (highways, farms, towns, etc.), introductions of mountain goats and vegetation succession.

There has been no analysis about the feasibility of restoring use to these former low elevation winter ranges. Some of the winter ranges may be permanently lost due to permanent developments. It is our understanding that mountain goats use the same habitats, are more aggressive and will compete with bighorn sheep.

Many of the factors associated with this issue are not within the authority of the Forest Service to directly deal with (such as permanent developments on private lands and mountain goat populations). For these factors, the Revised Plan contains management direction to coordinate with other agencies in the management of bighorn sheep.

The Revised Plan contains management direction to develop a fire management plan for the entire westslope of the Tetons and to incorporate into the plan opportunities to improve bighorn sheep habitat.

Disease - In both fenced studies and free ranging herds, most contact between bighorn sheep and domestic sheep has resulted in pneumonia in bighorns and the deaths of all or most bighorns while domestic sheep remained healthy. Published research has shown that *Pasteurella haemolytica* (usually biotype A, serotype 2) is the major pathogen responsible for the death of bighorn sheep after contact with domestic sheep. DNA fingerprinting has proven the transfer of *Pasteurella* spp. between bighorn and domestic sheep under both controlled "experimental" and range conditions. The *Pasteurella* must be a "virulent" strain. Sometimes there have been contact between bighorns and domestic sheep without die-offs, reason - the domestic sheep did not have a virulent strain. No vaccine currently exists that will prevent

bighorn sheep from developing pneumonia after contact with virulent strains of *Pasteurella*. There is no way to test for virulent strains at the present time.

There are two times of year when contact between bighorns and domestic sheep are more likely to occur:

- 1) During the fall breeding season (November and December) when the younger rams are displaced by the older rams. The younger rams will often get involved with domestic ewes while looking for a mate.
- 2) During the spring when bighorn sheep and domestic sheep are using spring green up areas.

On the Westslope of the Tetons, 45,700 acres have previously been closed to domestic sheep grazing through annual plans of use and allotment management planning. These are the areas currently occupied by bighorn sheep. A bighorn sheep study is currently being conducted by GTNP. Several dead bighorn sheep have been sent to Dr. Beth Williams for necropsy. No *Pasteurella* from domestic sheep was found. Dr. Williams said the bighorns were very healthy. (Discussions with Dr. Beth Williams, Sept. 1996)

Domestic sheep are not grazed on the Westslope during the seasons when 'nose-to-nose' contact with bighorns is most likely to occur (the fall breeding season or the early spring).

Because of the acres currently closed to domestic sheep grazing and the fact that domestic sheep are not grazed during the seasons when contact is most likely to occur, we believe the probability for disease transfer is very low. To eventually reduce the probability for disease transfer to zero, the Revised Plan directs that all sheep grazing on the Westslope of the Tetons will be phased out on an opportunity basis. While the phase out is in progress, additional opportunities will be studied to adjust domestic sheep allotments to further reduce the probability of disease transfer.

In the South Beaverhead (Medicine Lodge) area, there are two vacant domestic sheep allotments adjacent to the currently occupied bighorn sheep areas. These two allotments will remain vacant until the necessary authorizations have been completed to convert them to cattle allotments.

There are three winter domestic sheep allotments adjacent to the currently occupied bighorn sheep areas. The Revised Plan directs that these winter allotments will be phased out on an opportunity basis.

Genetic Isolation - The Teton Range bighorn sheep population is among a small number of bighorn sheep populations that are endemic and have not been augmented with animals from other bighorn sheep populations (Teton Bighorn Sheep Working Group Report 1996). It has been suggested that these bighorn sheep have increased scientific value because of this fact (Teton Bighorn Sheep Working Group Report 1996).

Management of animal populations is the primary responsibility of State Fish and Game Agencies. The Revised Plan provides direction to coordinate with the State Fish and Game Agencies and the National Park Service on the management of bighorn sheep.

Recreation - Some publics have suggested that bighorn sheep may be avoiding some portions of suitable habitat because of recreation use. Also, Wyoming has maintained a small hunt on the Forest (no hunting of bighorns occurs in GTNP).

The Revised Plan directs the Forest to work with the Intermountain Forest and Range Experiment Station to develop and conduct a research study to assess the effects of recreational activity on bighorn sheep on the Westslope of the Tetons.

Recreational activities must be evaluated and coordinated between all of the agencies. This includes the permitting of hunting by the Wyoming Game and Fish Department. The Revised Plan directs the Forest to coordinate with other agencies on the management of bighorn sheep habitat and populations.

Neotropical Migratory Species

Consequences Common to All Alternatives - Hejl et al (1995) reviewed studies documenting differences in birds among natural stands of different ages. No common results for any one species nor obvious trends for any particular migrant group were found in the studies comparing natural stands of different ages.

Differences in Birds between Cut and Uncut Aspen Forests - In a review of aspen studies, the combined results are equivocal, therefore, no assessments can be made as to the effects of cutting aspen on any particular migrant group (Hejl et al 1995). Based on this information, natural disturbances and aspen treatments are not expected to result in measurable changes in bird species abundance among the alternatives.

Consequences Which Vary by Alternative - Hejl et al (1995) reviewed studies documenting the effects of silvicultural treatments (timber harvesting) on birds in conifer forests and old second growth forests and presented the following summaries:

Effects of Silvicultural Treatments on Birds in Conifer Forests - From community-wide studies, 26 species were less abundant in treated areas as compared to unlogged areas in general. In contrast, 15 species were generally more abundant in treated areas than in unlogged ones.

Old-growth and Old Second-growth - In a review of four studies which compared old-growth with old second-growth, 15 species were more abundant in old growth in at least one study, however, no species was consistently more abundant in old growth in all four studies that compared old-growth with old second-growth stands.

Since the forested acres proposed for silvicultural treatments during the first decade range between three percent in Alternatives 1, 2 and 3, two percent in Alternatives 3M and 4, and one percent in Alternative 5 and 6, the change in bird species abundance is expected to be very small among the alternatives. There is potential for 26 species to be less abundant on the one to three percent of the forested acres proposed for silvicultural treatments, and 15 species to be more abundant. Late seral forests will be distributed in all principal watersheds in all alternatives as displayed previously in Table IV-1.

We cannot offer managers as complete a synthesis as we would like. Too few studies have been conducted on the effects of silvicultural practices on birds in forests in the Rocky Mountains to make robust conclusions (Hejl et al 1995). Our results are limited in that they focus on short-term distributional changes as the result of two broad categories of timber harvesting (clearcutting and partial logging) lumped across conifer forests. The data indicate that many forest birds were less abundant in clearcuts than in uncut forests and species that frequent open forests or open habitats were more abundant in clearcuts than in uncut forests. Most permanent residents were less abundant after either kind of harvesting treatment, whereas about half of the migrant species were less abundant and half more abundant in harvested areas. The effects of partial cutting were less dramatic than those of clearcutting, these results may be partly due to the fact that partial cutting included many different kinds of harvesting treatments (Hejl et al 1995).

Additional information and discussion on neotropical migratory bird species is presented in Process Paper D.

Predator Control

Consequences Common to All Alternatives - The effects of predator control are disclosed in the 1996 APHIS-ADC Environmental Assessment for Predator Control in Southern Idaho, which incorporated the analysis of effects from the 1990 Targhee N.F. Predator Control EA and Decision Notice. The effects of Alternative 5 (selected alternative) disclosed in Chapter IV, Environmental Consequences, of the 1990 EA are also incorporated by reference into this analysis.

Unique Ecosystems

Research Natural Areas

Consequences Common to All Alternatives - Forestwide standards and guidelines apply in all alternatives plus site-specific direction identified in the Establishment Records for existing RNAs apply. To become established as an RNA, site-specific analysis at a later date will be conducted for proposed RNAs. Regardless of which alternative is selected, the number of proposed and existing RNAs does not change by alternative (Table III-21)

FOREST USE AND OCCUPATION

This component is described in four parts: Access Management, Wilderness, Recreation and Social and Economic. Under the first two parts, key indicators are discussed first, with subsequent discussion of other indicators. No key indicators are associated with the third and fourth parts.

ACCESS MANAGEMENT

Road and Trail System and Motorized Access

Consequences are presented in the winter and summer access sections which follow. In summary, winter motorized access will be maintained in most alternatives and summer motorized transportation system and access will be reduced in all alternatives.

Summer Access

Key Indicators

- 1 Miles of road open to summer motorized
- 2 Miles of trail open to summer motorized
- 3 Acres open to summer cross-country OHV

Consequences Common to All Alternatives - There will be some reduction from current levels in miles of road and trail open to motorized use in all alternatives. This would result in increased needs and costs for law enforcement and signing to manage the system of restricted roads and trails. Another consequence common to all alternatives is the routine reconstruction of roads and structures.

The forestwide guidelines concerning trail design, condition surveys and restricting OHV use on slopes 25-40 percent and greater should help meet the Revision goals of sustaining OHV opportunities and sustaining trails in good condition while minimizing effects to other resources.

Consequences Which Vary by Alternative - Table IV-13 shows a comparison of roads and trails by alternative that will be open to motorized use, restricted or reclaimed. Compared to existing conditions, changes in open roads and trails in the alternatives are as follows:

- open roads range from a decrease of 103 miles (5 percent) in Alternative 1 to a reduction of 757 miles (38 percent) in Alternative 6
- open trails range from a decrease of 201 miles (26 percent) in Alternative 1 to a reduction of 692 miles (90 percent) in Alternative 6

In the Selected Alternative (3M), most of the system roads proposed for reclaiming/obliteration, are located within the BMUs.

In most all cases, the system roads that have been identified to be reclaimed/obliterated are roads that are currently restricted and were originally constructed in conjunction with timber sales

Roads closed for resource management purposes limit opportunities for dispersed camping, berry-picking, sight-seeing and other activities that conventionally depend on road access. The amount of opportunities available with the various alternatives is varied, according to the programmed amount of new or existing road development and resource management activities, particularly timber harvesting

	Existing	1	2	3	3-M	4	5	6

1/ Road and trail miles without restrictions on motorized use 2/ Road miles on which motorized use is restricted for only a portion of the spring/summer/fall seasons 3/ Road miles on which motorized use is restricted for the entire spring/summer/fall seasons 4/ Trail miles on which motorized use is restricted either for a portion of the spring/summer/fall seasons or yearlong (as in designated wilderness areas) * This table refers to present time. It does not take into account the 1,622 miles of roads that were reclaimed/obliterated between 1981 and 1993								

Acres open to cross-country OHV travel decrease significantly from present levels in all alternatives (Table II-1). The decrease from present levels ranges from approximately 166,000 acres (15 percent) in Alternative 1 to over 1 million acres (97 percent) in Alternative 6. However, it should be recognized that many of these acres are in terrain and vegetative cover which do not actually permit cross-country travel. So, the decrease in acreage may not be as significant as it appears.

Costs for signing designated routes, rehabilitation of old alignments, and providing law enforcement will increase significantly, especially for Alternatives 3 - 6. Alternative 3M would cost \$150-200 thousand each year to reconstruct 10-20 miles of existing motorized use trails. Trail reconstruction and maintenance costs will also be much higher to meet soil and water standards and guides and to accommodate the higher use levels with motorized and mechanized equipment.

Most foot and horse trails would not be affected by any of the alternatives. However, under the alternatives with more motorized restrictions there would be some benefit to the nonmotorized user in terms of relief from interaction with motorized users. Some of the impacts to trails, such as rutting or displacement of soils, being caused by OHV use would also be reduced.

Cumulative Effects - As acres and roads/trails open to motorized access decrease from Alternatives 1 through 6, the density of OHV users on designated routes will generally increase on the remaining open routes. In addition, some loop trails will be eliminated, along with current access to some of the more spectacular scenic vistas. The increased interaction may result in increased user or resource conflicts and additional resource impacts. This could have an overall effect of loss of enjoyment of the recreation activity for some people in some of the areas. In other areas, it may be possible to develop "play areas" that become favorites of those who like a "social experience" or who enjoy the spectator opportunity.

A secondary effect of decreasing motorized access areas would be reduction of hunting and fishing opportunities for those requiring motorized access. This might not be too significant except in Alternatives 5 and 6.

An additional effect of decreasing motorized access would be decreased trail maintenance. A good portion of our trail maintenance work is performed by motorized users and the state of Idaho's Trail Ranger program which uses trail bikes for its maintenance crew. Motorized users and trail maintenance funding from the State would naturally decline as restrictions on motorized access increase, unless some type of reconstruction program can be initiated to improve trails for motorized use.

Overall, it is questionable whether there will be enough designated routes and cross-country areas open to travel to meet the needs of increasing motorized access demand in any alternative, but especially in Alternatives 5 and 6. Much of the cross-country use that is presently occurring would be eliminated by Alternatives 3-6. Therefore, the actual and apparent loss of OHV access and recreation opportunities may be of concern to some OHV users.

Winter Access

Indicators

- 1 Acres open to winter cross-country snowmachines
- 2 Miles of groomed trails for snowmachines

Consequences Common to All Alternatives - Management direction such as establishing linear capacities for snowmachine trails, providing networks of groomed trails, providing winter users with educational information and signing about wildlife needs, and prohibiting snowmachines and other equipment from groomed cross-country ski trails, should minimize adverse consequences on users and wildlife.

Consequences Which Vary by Alternative - Acreage open to cross-country snowmachine use (Table II-1) is maintained or increased for Alternatives 1-3, decreases (119,000 acres) in Alternative 5 and significantly decreases (404,000 acres) in Alternative 6. These decreases are due to increases in winter range and recommended wilderness prescription allocations. In Alternative 3M, a large portion of the decrease is due to the new forestwide standard which closes all inventoried winter range to cross-country snowmachine travel.

Miles of planned, groomed or marked snowmachine trails could increase approximately 93 miles over current levels in Alternative 3M. This planned increase is based on analysis contained in the Greater Yellowstone Winter Visitor Use Management (GYWVUM) Assessment as summarized in the Winter Access Analysis (Appendix C). Alternative 3M would also provide direction to establish a few nonmotorized winter recreation activity areas with easy access for uses such as telemark skiers, snowshoers or snowboarders by the year 2000 in conformation with results anticipated from the GYWVUM Assessment. This would result in reduced user conflicts as such activities increase. Alternative 5 maintains existing levels of trails. Alternative 6 would result in a significant decrease in designated snowmachine routes from current levels. This decrease is due to increased wildlife winter range and recommended wilderness allocations.

Cumulative Effects - Winter recreation use opportunities would in large part be maintained in all alternatives. However, Alternatives 5 and 6 would have more restrictions on winter motorized use and therefore, some reduction in those opportunities and use would be possible. Potential effects on wintering wildlife would be minimal in all alternatives. The selected alternative 3M would increase the potential for snowmachining on marked and groomed trails if the counties could afford to provide the marking and grooming.

WILDERNESS AND RECREATION RESOURCES

The following topics present the effects and consequences of the alternatives on the various wilderness and recreation resources. Key alternative comparison indicators for these resources are displayed in Table II-1. Overall, total recreation use would not change much between alternatives, but the types of use probably would. The trend from Alternative 1 to 6 would be away from semi-primitive motorized (SPM) and roaded natural appearing (RNA) recreation opportunities to an increase in primitive (P) and semi-primitive nonmotorized (SPNM), although some semi-primitive motorized (SPM) opportunities would remain. This overall trend would be due to the reduction in motorized access and increase in recommended wilderness from Alternatives 4 - 6. Such a trend would also support a shift from currently evolving tourism/rural development to a slower developing, eco-tourism pattern.

Wilderness and Recommended Wilderness

Indicator - Acres of recommended wilderness

Other Indicator - Acres of management opportunity classes for the Jedediah Smith Wilderness

Consequences Common to All Alternatives - Designated wilderness and wilderness study acres remain the same in all alternatives. Quality and character of designated wilderness would not be degraded by any alternative. All action alternatives include a monitoring plan based on the Limits of Acceptable Change (LAC) process for the Jedediah Smith Wilderness. The Winegar Hole Wilderness will be managed according to the prescription direction. The Revision prescriptions and monitoring plan will become the wilderness management plan for each wilderness. These plans provide direction for management and monitoring of resource and social conditions to address any changes which may result. These plans would maintain wilderness resources and recreation opportunities at approximately current levels and conditions.

Consequences Which Vary by Alternative - Recommended Wilderness - The 1985 Forest Plan analysis of recommended wilderness and roadless areas was re-evaluated in response to public comments and documented in an update to the Roadless Areas Process Paper (Appendix B). The rationale for or against selection of areas for recommended wilderness in Alternative 3M has been added to this Process Paper update, along with the Rating of Wilderness Characteristics (Table IV-14). As this re-evaluation of recommended wilderness was completed, a decision was made to include a large part of the Diamond Peak Roadless area as recommended wilderness. This was done because the area rated second highest of all roadless areas on the Forest. The 33,000 acres in Diamond Peak and 13,000 acres of digitizing updates to Italian Peaks raised the total recommended wilderness acres for Alternative 3M from the 125,000 acres in the DEIS up to 171,000.

Table IV-14 Rating of Wilderness Characteristic Factors for Remaining Roadless Areas (based on Section 2 of individual narratives from the 1985 Supplement to the DEIS for the 1985 Forest Plan)						
Area Name	Area Number	Manageability & Boundaries	Influence on Natural Integrity	Opportunity for Solitude	Opportunity for Challenging Experience	Rating Score
Diamond Peak (88,689 ac)	15-601	moderate	low	high	high	11
Italian Peak (141,792 ac)	15-945	moderate	low	high	moderate	10
Garfield Mtn (43,439 ac)	15-961	high	moderate	moderate	low-mod	9
Mt. Jefferson (63,969 ac)	15-962	1/				0
Raynolds Pass (7,709 ac)	15-603	moderate	low	low	low	7
Lionhead (16,892 ac)	15-963	moderate	low	high	moderate	10
Two-top (6,983 ac)	15-604	moderate	high	moderate	low	6
Winegar addition (4,032 ac)	15-347	low	moderate	moderate	low	6
West Slope Tetons	15-610	2/				0
Garns Mtn (95,632 ac)	15-611	moderate	low	high	moderate	10
Palisades (174,862 ac)	15-613	moderate	low	high	high	12
Bald Mtn (17,037 ac)	15-614	low	moderate	low	low	5
Bear Creek (97,775 ac)	15-615	moderate	low	moderate	low	8
Poker Peak (19,577 ac)	15-616	high	low	low	low	8
Caribou City (11,769 ac)	15-161	low	low	moderate	moderate	8
Pole Creek (2,683 ac)	15-160	low	moderate	low	low	5

Rating Score note: Manageability and Opportunity columns are scored - low=1, mod =2, high=3. Influence on Natural Integrity column is scored - low=3, mod =2, high=1. A rating of 10 or better is considered sufficient for wilderness recommendation, except in Garn's Mtn where a decision was made to manage for motorized use in Alternative 3-M, rather than roadless. The score of 10 was selected as the "break-point" because it represents the quality level of the areas previously recommended in the current Forest Plan, with the exception of the Winegar Hole addition, which had broad public support.

1/ This area was released for multiple use mgmt by decision of 1990 FEIS by BLM

2/ This area was released for multiple use mgmt by the 1984 Wyo Wilderness Act

With the exception of Alternative 2 which has no recommended wilderness, the acreage of recommended wilderness increases from Alternative 1 to Alternative 6, with the largest increases in Alternatives 5 and 6 (Table II-1). Motorized OHV travel would be impacted by Alternatives 3-6 and significant forestwide reductions in summer, cross-country OHV travel would result from Alternatives 5 and 6 to be consistent with the 1-3 prescription access table. In addition, the High Mountain Heliski operation which is dependent almost entirely on the Palisades Roadless Area could be eliminated by Alternatives 3 - 6 if wilderness designation resulted from recommendations of the Plan Revision. This heliski operation was seriously impacted in 1984 when the Wyoming Wilderness Act shut the skiing operation out of their main permit area. There would be little or no area left open to support this operation if designation occurred in the Palisades with no exception to allow continuance. This could eliminate a unique recreational opportunity for over 450 skiers annually. Considerable snowmachine activity and groomed snowmobile trails and play areas in Alternatives 5 and 6 could also be eliminated in the Garns Mountain and Caribou areas if wilderness designation occurred in these areas as recommended.

Existing Designated Wilderness - The main difference in designated wilderness would be in the Opportunity Class I-III allocations (Table IV-15) Opportunity Class I, II and III (see Plan Glossary and Jedediah Smith Wilderness Process Paper) areas are represented by prescriptions 1 1 6, 1 1 7 and 1 1 8 respectively. Alternative 1 contains prescriptions to match the current management situation. Alternatives 2-6 contain a variety of applications of the new prescriptions based on the LAC opportunity classes developed by the Jedediah Smith Project Team as documented in a process paper on file in the Supervisor's Office. These Opportunity Classes involve levels of recreation, research and maintenance and potential resulting changes in resource or social impacts. Generally, Alternatives 2 and 3 would have the highest social interaction effects among recreationists and the greatest chance for disturbance of wildlife. Alternatives 3M and 4 would have less chance of social interaction or wildlife disturbance impacts. Alternatives 5 and 6 would have the least chance of user conflicts or impacts to the wilderness resources or values, since these two alternatives do not contain any Class III (highest recreation level) areas.

Cumulative Effects - Alternative 1 has the highest probability of potential adverse impacts to wilderness character over time. This is because it lacks a management and monitoring process to measure change in wilderness values. All other alternatives should have little cumulative impact or secondary effects, since the LAC monitoring process should allow adverse interactions or impacts to be noted and a management response applied to appropriately deal with problems if they arise. Likewise, designation of wilderness in any alternative would have little effect on timber harvest. However, potential for effects on harvest would be greatest in Alternatives 5 and 6 which have the largest amount of recommended wilderness.

Mgmt Rx	Opportunity Class	Alternative (Thousand Acres)						
		1	2	3	3-M	4	5	6
1 1 1	NA 2/	40	0	0	0	0	0	0
1 1 2	NA 2/	11	0	0	0	0	0	0
1 1 3	NA 2/	32	0	0	0	0	0	0
1 1 4	NA 2/	25	0	0	0	0	0	0
1 1 5	NA 2/	27	0	0	0	0	0	0
1 1 6	I	0	83	83	102	102	115	115
1 1 7	II	0	39	39	20	20	19	19
1 1 8	III	0	13	13	13	13	0	0

1/ Opportunity Class - Class I is lowest recreation use level, and Class III is the highest
 2/ Prescriptions 1 1 1 - 1 1 5 are for the Current Forest Plan, which does not use LAC/Opportunity Class

Roadless Areas

Indicators - Acres of roadless

Consequences Which Vary by Alternative - The acres of roadless in Table II-1 have not changed from the DEIS. However, approximately 1,500 acres of roadless area in the Moody Creek area has been changed to non-roadless protecting prescription in the Final Plan as compared to the DEIS and Draft Plan. This change represents less than two-tenths of one percent of the inventoried roadless acres. The acres shown in Table II-1 reflect those protected by prescriptions which would prevent adverse impacts to wilderness potential. The reason that Alternative 3M is approximately 70 M acres less than existing condition, is that the prescriptions in Alternative 3M would not provide complete protection of roadless character. As shown

in Table II-1, the acres of roadless area protected by prescriptions would decrease slightly from Alternative 1 to Alternative 2 and then increase again through Alternative 6. Alternative 6 would have the highest amount, which approximates the existing inventory. Roadless areas receive the highest level of management protection in Alternative 6 because of the recommended wilderness (1.3 prescription) allocation, which increases significantly between Alternatives 1 and 6 and because of lower motorized road and trail density standards. Alternative 2 is an exception, in that it has no recommended wilderness acres in it. As a result, cross-country summer OHV travel opportunities become significantly reduced between Alternatives 2 and 6. Table II-1 shows another example of the increasing restriction to OHV activity within the indicator entitled "acres roadless closed to summer OHV." This acreage increases from 243,000 acres in Alternative 1 to 378,000 acres in Alternative 5 and takes a sharp rise to 614,000 acres in Alternative 6. This pattern is similar to and verifies the recommended wilderness indicator discussed previously.

Alternative 3M allows scheduled timber harvest within or near the Caribou City and Bear Creek Roadless areas adjacent to portions of those roadless areas on the Caribou N.F. Therefore, project-specific planning for any harvest in these areas of the Forest will likely have to address the existing settlement agreement issues on the Caribou N.F. if harvest is proposed prior to the year 2000.

Cumulative Effects - It should be noted that the Summer Transportation maps show some roads in roadless areas. This is considered acceptable since these are service level D roads that are not maintained for travel by standard passenger vehicles. Potential effects from timber harvest and roading would be highest under Alternative 2, with approximately 6,360 acres of roadless area possibly impacted during the next decade, compared to 71,600 projected in the 1985 Forest Plan. However, this represents potential impact of only one percent or less to the inventoried roadless acres. This potential impact declines to 4,970 acres in Alternative 3, 3,030 acres in Alternative 1, 2,990 acres in Alternative 4, to 2,910 acres in Alternative 3M, to 1,530 acres in Alternative 5 and no acres in Alternative 6.

Wild, Scenic and Recreational Rivers

Consequences Common to All Alternatives - The eligibility of these rivers is not affected by the alternatives and all of the outstanding resource values will be protected by management prescriptions until such time as suitability studies are completed. Suitability studies need to be completed for all of these segments. This would need to be done on a priority basis for approximately one-third of the streams at a time, starting with those in the South Fork-Snake River Basin because of a current cooperative agreement with the State of Idaho. These studies would be done in coordination with the State of Idaho's studies and legislative recommendations. The remaining streams would probably be done in two additional studies - one for those in the Henry's Fork basin and a second for those in the Teton River basin and probably in that order of priority. The values represented by State of Idaho Water Resources designations for the Henry's and South Forks will be protected by the proposed Wild, Scenic and Recreation classification prescriptions and the forestwide direction to protect native cutthroat trout watersheds.

Consequences Which Vary by Alternative - Alternative 3M has deleted from eligibility the 3.5 miles for McCoy Creek which were shown as tentatively eligible pending a joint study with the Caribou N.F. That study was done in July 1996 and the findings were documented in a study report which has been added to the Wild, Scenic and Recreational Rivers Eligibility Determination Process Paper R. Other changes in the Final Plan include changing one-half of a mile of the Henry's Fork at Upper Mesa Falls from a proposed classification of Wild to Scenic. This was done because of the large amount of developments and public use within this section.

Visual Resources

Indicator - Visual Quality Objectives (VQO)—Acres by VQO Class and associated ranges of VQO

Consequences Which Vary by Alternative - With the exception of Alternative 2, the alternatives generally trend toward larger allocations of VQO's for Preservation, Retention and Partial Retention going from

Alternative 1 to Alternative 6 (Table II-1)

It should be noted that the VQO data in Table II-1 is mostly displayed as a range of VQO, such as retention to partial retention. This was necessary because the alternative prescriptions are described as a range, rather than with a single VQO. Therefore, the analysis could not be done in a comparative manner to the existing VQOs shown in Chapter III.

Alternatives 1-3 could result in some reduction in visual quality in areas of additional intensive timber harvest activity where VQOs of Modification and Maximum Modification are higher than in Alternatives 3M - 6. Alternatives 5 and 6 would tend to maintain and could improve existing visual quality except in areas of management needs. For example, there are areas along major travel routes and use areas where greater restrictions on timber harvesting might prevent maintaining existing natural or created openings for scenic vistas over extended time periods. Such restrictions could preclude enhancement of some landscapes in thick monotonous timber stands.

Developed Recreation

Consequences Common to All Alternatives - Consequences will basically be the same for all alternatives because developed recreation facility construction and reconstruction will be about the same in all alternatives. This will include heavy maintenance and some reconstruction of recreation facilities, but little new site development. However, there may be some tendency for higher demand for developed recreation facilities in Alternatives 1-2, with decreasing demand in Alternatives 3-6. Demand for facilities in all alternatives will eventually become greater than supply. Therefore, development opportunities on private or other lands will increase.

Consequences Which Vary by Alternative - Generally, the higher the overall development and management activity levels, the higher the recreation use potential and associated development. This is due to user response to higher amounts of available opportunities and road and trail access. In Alternatives 1-2, there would be continuing diversity of opportunities with considerable motorized access. As the alternatives (3-6) increase in motorized restrictions for wildlife protection the need for developed facilities may decline somewhat. However, it is possible that the need for development of facilities such as trailheads to access wilderness, rivers, etc. may increase over time even in these lower-scale development alternatives. This increase might offset the projected decline in amount of developed facilities.

Cumulative Effects - As the alternatives become more restrictive in terms of motorized access and opportunity (i.e., Alternatives 3-6), there would likely be some displacement of recreationists from areas now being used. This could place a heavier burden on existing developed facilities and create a need for new ones in a more concentrated geographic area. Furthermore, as recreation demand continues to increase, displacement and crowding could have a negative effect on recreation and social experiences. Additional displacement from adjacent heavy use areas such as Yellowstone National Park could further increase these effects.

Dispersed Recreation

Indicators - Acres allocated to dispersed camping prescription

Consequences Common to All Alternatives - Approximately the same number of road-accessed, dispersed campsites (293) would continue to be used in all alternatives. The number of sites would probably stay the same, because existing sites that would become unavailable due to new management allocations would simply be relocated to sites in other adjacent areas. Approximately one-third of these are heavy-use sites used by large groups (35+) during most days of the summer.

Consequences Which Vary by Alternative - In the mapping of alternatives, a varying number of heavy-use dispersed campsites was allocated to the 4/3 dispersed campsite management prescription. Alternative

1 was given the least allocation for heavy-use dispersed sites (Table II-1) because very little management of dispersed sites is being done at present. Alternatives 2-4 have the most acres allocated (approximately 2,800 each) and Alternatives 5-6 were designed with 1,500 acres each of dispersed site prescription (Prescription 4.3) because the latter two are intended as less management intensive alternatives. The intent of this prescription allocation was to recognize the heavy public interest in these sites for camping and to place a management emphasis on maintaining them while also maintaining soil resources and aquatic and riparian habitat. Provided funding for monitoring and management of these sites is available, alternatives with the highest acreage allocation should provide a better chance of maintaining recreation settings and opportunities, reducing or minimizing impacts to soils and vegetation, and maintaining or improving aquatic habitat. This is because restrictions on use of open fires, tents and hardening of sites, etc. could be put into effect to reduce impacts to vegetation and soils in or near aquatic zones.

Summer-use trail mileage of nonmotorized system trails would increase across all alternatives. This is due to restrictions for wildlife, watershed and recommended wilderness.

Cumulative Effects - It is possible in Alternatives 1-3 that some existing, dispersed camping sites and trails would need to be moved or closed to resolve conflicts with wildlife or aquatic management standards and guidelines. In Alternatives 3M through 6, displacement or closure of such areas would be more likely to occur because there is less access and because aquatic buffer restrictions are greater. This could have an adverse impact on recreation experiences, due to having to add more facilities elsewhere or due to crowding/congestion in smaller geographic areas. This could result in a need for increased monitoring, law enforcement and management costs to prevent unacceptable impacts to soil, vegetation, aquatic or wildlife resources.

Outfitters and Guides

Consequences Which Vary by Alternative - The number of new outfitter and guide permits issued would probably be less in Alternatives 3M - 6 than in 1-3. Overall activity and amount of outfitted use would also be less in Alternatives 3M - 6. The type of activities outfitted in Alternatives 3M - 6 would be more related to backcountry, nonmotorized uses, due to increased restrictions on motorized and mechanized equipment in roadless, recommended wilderness and designated wilderness areas.

Cumulative Effects - Cumulative impacts would be higher in Alternatives 1-3 than in 3M - 6 due to the higher demand for and access to recreation opportunities.

Special Uses (Recreation)

Consequences Common to All Alternatives - Requests for special use permits for activities such as special events (e.g., races, group activities, etc.) and outfitting and guiding will likely increase gradually for all alternatives. At some point of saturation, the permitted activities would reach a plateau and level off.

Consequences Which Vary by Alternative - The trend for special uses in response to alternatives would be similar to that for developed sites. In Alternatives 1-3, there would be more increase in demand for special events and motorized access permits such as guided snowmachine or OHV trips. However, in Alternatives 4-6, the trend would be more towards undeveloped, backcountry experiences such as mountain biking, backpacking, horsepacking, hunting and similar opportunities. The number of new special use permits would probably be less in Alternatives 3M - 6 than in 1-3 and overall recreation use under permitted activities would also be less.

Cumulative Effects - Cumulative impacts of actual recreational use would likely be higher in Alternatives 1-3 than in Alternatives 3M - 6, but those impacts would tend to be in the more easily accessed areas and closer to existing developed areas or special interest roads, trails or attractions. In Alternative 3M - 6, the additional cumulative impacts of recreation use would tend to be in more undeveloped, backcountry areas.

with a more primitive experience level. These, too, could have a measurable effect on wildlife, etc

SOCIAL AND ECONOMIC EFFECTS

Indicators - The indicators used are jobs, personal income, employee compensation, payments to local governments (from both the 25 % Fund and the Payments in Lieu of Taxes program), the Forest budget, population characteristics, land use patterns, effects on American Indians and civil rights concerns. The factors are all discussed under the larger categories of lifestyles, attitudes-beliefs-values and social organization. Background information on these indicators is contained in Chapter III and in the AMS

Consequences Common to All Alternatives

Population Characteristics - As discussed in Chapter III, the area is experiencing significant population increases. This rate of increase is not expected to be significantly affected by any of the alternatives.

The proportion of the area's population which is interested in the Forest for its recreational uses is expected to increase as recreational use continues to grow. The proportion of the area's population which is interested in the Forest for timber and livestock production is expected to decline.

Increasing development of private property located within the Forest or along its boundaries speaks to the desirability many people identify in having the Forest as a neighbor. That increased development and its associated contributions to the local tax bases are expected to continue regardless of which alternative is selected. Contractions in the local economy associated with a reduced level of timber harvest have already largely occurred. The mills in St. Anthony and Rexburg closed in 1992 and 1995 respectively. Most of the equipment has long since been disposed of. Reductions in the tax base associated with these closures occurred prior to the actions associated with the Forest Plan Revision.

Increasing development may jeopardize traditional uses of private land like livestock grazing. It may simply not make good sense economically for an individual to run livestock on land ripe for real estate development.

The permanence of the Forest does in itself provide a certain attraction for those considering relocating a family or business. Private property can be managed many different ways while the Forest will "always" be managed as a National Forest.

Land Use Patterns - Lands adjacent to and within the Forest are increasingly passing from traditional uses like ranching to new uses like subdivisions. Forest management has to consider these new neighbors when deciding how best to manage Forest resources with particular attention being devoted to fire protection, visual quality and recreation opportunity. This challenge can be expected to continue to increase under all alternatives as the human population of the area increases.

Some newcomers to the area have deviated from long-held local custom by closing off access through their property to Forest lands. Their focus on having a Forest in a more natural condition has also been at odds with those who see the Forest as being a resource to be used. These sorts of conflicts can be expected to continue, if not worsen, under all the alternatives due to continuing in-migration.

American Indians - Input from the Shoshone-Bannock tribes indicates their strong concern for continuing the viability and abundance of plants, fish and wildlife on the Forest for the use of their members consistent with their treaty rights (Shoshone-Bannock 1992 a-b). Some of that input has focused on project-specific needs like providing designated routes for motorized access during the tribes' hunting season. The tribes have also commented on their need to have the public and the Forest Service respect their rights to practice their native religion. All the alternatives are structured so as to afford tribal members the

rights guaranteed them by treaty

Heritage Resources - No significant differences in alternatives would likely exist. However, there would be more risk of disturbance of sites in Alternatives 1-3M than in 4-6. This risk is proportional to the incidence of ground-disturbing activities, as is the likelihood of discovering new heritage resource sites during project-specific site surveys.

Lifestyles - The overall level of recreational use is expected to continue to increase along with its associated income and employment opportunities. Increased recreation use means more people from outside the immediate local area visiting, spending money and in some cases investing in local property. The overall increase in recreation is expected to occur regardless of which alternative is selected. A certain percentage of the people visiting Yellowstone National Park can be expected to visit Forest attractions like Mesa Falls, for instance.

As Yellowstone and GTNPs become more crowded the Forest can also expect to accommodate more of the resulting spillover traffic. For instance, because snowmachining in Yellowstone National Park is reaching saturation levels, the Forest is expected to receive more of that traffic—regardless of which alternative is selected.

The area also provides opportunities for further development of recreational activities. The recently opened Grizzly Bear Theme Park just outside Yellowstone's boundaries is an example of the kind of development which might occur regardless of which alternative is selected for the Revision.

All the alternatives provide for a ceiling of 20 MMBF per decade for material harvested outside the ASQ and fuelwood categories. This material may be logged, if appropriate, to meet ecosystem objectives. Any employment associated with this activity would be the same for all the alternatives.

Civil Rights - No civil rights effects associated with the alternatives have been identified. The contraction in the local timber industry (which has largely already occurred) is not expected to have disproportionate effects on women or minority groups. No civil rights effects have been identified as varying across the alternatives.

It is possible that with reduced budgets it will be more difficult for the Forest to achieve its affirmative action objectives. Some have speculated that reductions in the Forest budget might disproportionately affect women and minorities. The recent downsizing which occurred on the Forest did not have that effect. Future downsizing efforts are not expected to have disproportionately negative effects on women or minorities.

Consequences Which Vary by Alternatives

American Indians - Tribal members use the Forest in many different ways. Some of these uses are identical to those of the general population and are described elsewhere herein. Other interests may be unique to tribal members. For instance, gathering Forest products is an important part of the culture of some tribal members. Those who rely on open roads or motorized trails to access favorite spots may have to find alternative sites if motorized access is restricted. It is also possible that closing motorized access to some areas may effectively deny access to the physically challenged.

Discussions with the tribes to-date have not revealed a preference for more or less roading per se. Concerns have been voiced about closing roads during the tribes hunting season—something that needs to be addressed on a continuing, site-specific basis. In general though, as the alternatives reduce the amount of roads and trails available for motorized use, the time and effort involved in hunting is expected to increase. That also applies to other tribal activities which require access to the land. Reducing motorized use may improve the suitability of the land for vision quest and various other cultural activities.

Each alternative maintains large areas of the Forest in both motorized and nonmotorized use but it is unclear whether one alternative meets overall Tribal needs better than another

The Forest recognizes the rights afforded the tribes by treaty and by law as outlined in Chapter III of this document. All the alternatives comply with these requirements

Lifestyles - Under Alternative 1 the reduced timber harvests of the recent past (1992-1995) would increase slightly. This would mean that more of those people whose livelihoods depend on timber harvesting would retain those jobs and the associated income. Because access to fuelwood is frequently aided by timber harvests, people might find it a little easier to get fuelwood for home use

Those whose livelihoods are affected by the availability of Forest forage for domestic livestock would not expect to see their use of that resource significantly change in terms of overall use. Area livestock producers would however, have to invest more resources into the improvement of range allotments without necessarily seeing any increased use of available forage

In terms of the way the Forest looks, people are likely to be generally pleased as young trees continue to reestablish in the large clearcuts of the Caldera and Plateau areas near Yellowstone National Park

People's reliance on the Forest as a recreation resource rather than as a provider of timber or livestock forage will continue. Area schools and roads will be receiving less money from Forest activities that generate receipts through the 25 percent Fund. However, PILT are expected to rise sharply as shown in Table IV-16, for all alternatives because of recent legislative changes. The budget for the Forest (and its associated local expenditures for payroll and supplies) is shown in Table IV-17

What Table IV-16 and IV-17 show in their entirety is that the Forest's primary effect on the local economy derives from the recreational activity it provides. No alternative is expected to significantly change the overall level of use — though usage is expected to shift over the landscape and by type. Clark county stands apart in many respects because of its very small population. It is the most rural of the counties in the APFEI. It struggles to provide the services people normally expect to see a county government provide. It has been hit hard recently by reductions in Forest 25 percent Fund payments which have not been made up by increased PILT. Projections are however, that scheduled increases in PILT will more than make up for past reductions in 25% Fund payments

Attitudes, Beliefs, Values - Many people believe the Forest should be used to produce timber products in conjunction with other Forest uses. Alternative 1 allocates a similar amount of land to intensive timber production as the existing Forest Plan. It increases timber harvests from the levels of the recent (1992-1995) past

The Forest will be stepping up its enforcement efforts to ensure that roads and trails closed to motorized traffic are not used by motorized vehicles. Even though in Alternative 1 these efforts are focused on enforcing existing motorized use restrictions, many people will see them as increased efforts to restrict motorized access. Others who see the Forest as being currently over-loaded are not likely to accept Alternative 1's substantial reductions in motorized use through increased enforcement, more effective closures or an improved public involvement program

There is great skepticism as to whether the road closures can be effectively implemented without the support of the local citizenry. The likelihood exists that there will be an increased level of conflicts between Forest Service personnel working to effectively close roads and trails and those who have grown accustomed to using them

The motorized access situation is particularly troublesome in that for a number of years, roaded access on the Forest was continually increasing—largely as a consequence of logging activity. People had come to expect more and more motorized access. In recent years, that access has been decreasing in order to

provide better habitat for wildlife. Restricting motorized access can adversely or beneficially affect how people pursue their customs and traditions. Closing a route to motorized access may deny one family access to a traditional wood-gathering site, for instance—while at the same time, another family may gain a mountain bike trail.

Alternative 1 would likely not be acceptable to those whose belief systems are more tuned to nonconsumptive use of the Forest. That is due in large part to the fact that in the past, Alternative 1 called for scheduling timber harvests at such high levels that they could not be continued into the future. Thus, the frame of reference people have for logging on the Forest is that areas entered for logging are logged very heavily — not harvested at rates that are sustainable. As formulated, Alternative 1 discontinues the practice of logging at levels that cannot be continued into the future. It is unlikely though, that those whose value systems were offended by Alternative 1's high harvest rates of the past could come to accept this alternative even without the high harvest levels.

Columns may not total due to rounding

* PILT are a function of a given county's population, the area within it which is administered by the Forest Service, Bureau of Land Management, National Park Service, Bureau of Reclamation, Army, Fish and Wildlife Service, and Army Corps of Engineers, a schedule of payments, the last of whose changes occurs in 1999, payments received from other federal programs, the rate of inflation, and the level of funding. PILT figures shown in this table use the schedule of payments for 1999-on, the 25 % Fund payments shown, and funding at 72.852% (the average of the 77.373% funded in 1995 and the 68.330% funded in 1996). The figures shown do not reflect any increase for inflation, which is a factor in the calculations.

Big game hunting and in particular elk hunting, is a major event on the Forest. Participants eagerly await the season's arrival. The success they have enjoyed in recent years would be expected to continue with the selection of Alternative 1, although with continuing growth in the previously clearcut areas and more effective road closures, hunter success may be more difficult to achieve.

Sense of Control, Sense of Self-Sufficiency - The recent (1992-1995) reduced timber harvest rates would be increased only slightly in Alternative 1. During the recent reduced harvest period, businesses that could not get raw material from other timber sources either closed down or continued operations at reduced levels. Employees of those affected businesses had to find other jobs or relocate. These recent harvest reductions occurred because the Forest could not generate the timber harvests projected in the existing Forest Plan and comply with the full body of existing laws, regulations and Forest Plan direction itself. Projected decreases in fuelwood offerings are primarily associated with a recognition that the many restrictions on Forest fuelwood gathering have combined to make it less attractive for consumers.

People whose primary interest in the Forest is on nonconsumptive use would likely have a mixed response to the Forest's management under Alternative 1. Many of the Forest's watersheds that were previously heavily logged would be left largely undisturbed in Alternative 1 — including much of the area in the highly visible US Highway 20 corridor used by so many people heading into Yellowstone National Park. The timber harvest would, however, be moved into other areas to which a different set of recreationists might object.

Local governments receive payments associated with the Forest from the 25 percent Fund, which remits to local governments 25 percent of Forest gross receipts, and from the PILT program, which bases payments to local counties on their population, their area in certain federal ownerships, their receipts from other federal sources, a schedule of payments, the Consumer Price Index and the level of funding. Area counties receive substantially more from the latter program than from the former. It is expected to increase sharply in the coming decade, as shown in Table IV-16. Payments from the 25 percent Fund are expected to change as shown in Table IV-16. Money from these funds help compensate the local governments for expenses they incur relative to the federally-owned lands within their jurisdiction.

Social Organization, Community Cohesion - Selecting the Continue the Forest Plan Alternative (Alternative 1) would likely have no perceptible effect on community cohesion.

Social Organization, Community Stability - People involved in the timber industry and its related industries would likely see only minimal increases in jobs. More jobs will become available in the sectors serving recreationists. The livestock industry would see little change other than the need to invest more money into permitted use areas. For some who are operating on the margin, that could be the difference between maintaining an operation and getting out of the business, but overall use of the Forest forage resource by livestock is expected to change very little. Those trends have been in place in the local area for some time. They will continue under Alternative 1.

Economic Efficiency - The primary measure of economic efficiency used in the analysis is Present Net Value (PNV), i.e., "The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area (36 CFR 219.3)."

Dollar values were identified for recreation, timber, livestock grazing and water. Included in the analysis are all costs of managing the Forest, including firefighting, law enforcement and monitoring.

As shown in Table IV-17, the range of the PNVs is quite small. The predominant reason for this small range is that recreation and water benefits, which comprise the great bulk of dollar-valued benefits, are not expected to vary by alternative. Changes in recreation use may occur, such as concentration of use in smaller areas or movement of recreationists from one type of recreation to another. The overall level of recreation is expected to be the same for all alternatives. Likewise, no changes in water flows from the

Forest are anticipated by alternative Changes in benefits thus derive from changes in the range and timber programs

Variations in costs do occur across the alternatives and over time These are associated with different levels of timber harvest, increasing road restrictions and law enforcement and increasing costs of firefighting

Lifestyles - The numbering scheme of these alternatives stretches from 2 to 6 As the numbers assigned to the alternatives increase the alternatives move generally toward

- Fewer opportunities to make a living off the Forest by producing timber products or raising livestock
- Restricting those management activities which leave lasting visual reminders
- Increasing the possibility of lasting visual reminders due to unmanaged occurrences like wildfires
- Reduced incidence of livestock grazing
- Fewer roads and trails
- Fewer roads and trails open to motorized use
- Less cross-country motorized use
- More nonmotorized recreation opportunities
- Greater protection of wildlife habitat
- More recommended wilderness
- Less need for reforestation
- Faster watershed improvement

Timber-related employment would be expected to vary directly and proportionally to the projected ASQ

Reductions in domestic livestock grazing are significant in Alternatives 4, 5 and 6 The economic viability of grazing operations is likely to diminish as restrictions are placed on the allotments to improve resource conditions

Aesthetically, those desiring a more natural appearing landscape will see the heavily logged areas of the Forest coming back in new growth in all the alternatives The alternatives with higher levels of ASQ will harvest larger amounts of timber in other less-logged or nonlogged watersheds around the Forest Those areas will show the effects of humans working on the land, building roads, removing timber and establishing new timber stands in direct proportion to the amount of ASQ

Those alternatives with fewer miles of road and trail open for motorized use (as shown in Chapter II) would likely see increased concentrations of motorized trail use on the miles remaining open, lower increases in recreation dependent on motorized use, increases in nonmotorized recreation, or some combination thereof The way people recreate on the Forest will definitely change People will not have the same type of hunting experience in every alternative Opportunities for solitary experiences on the Forest will change as well

Attitudes, Beliefs, Values - The numbering scheme of these alternatives stretches from 2 to 6 Alternative 3M was substantially modified based on public input between the Draft and this Final document It provides many exceptions to the following generalization As the numbers assigned to the alternatives increase, the alternatives move generally toward

- Greater accommodation of those who feel the Forest's resources should be left to change without human intervention
- Less accommodation of those who feel the Forest's resources should be used for the benefit of humans
- Greater trust that developments which occur without human intervention will benefit the ecosystem

Table IV-17 Summary of Forest Economic Effects on the Area of Primary Economic Influence (APFEI)

Columns may not sum to totals due to rounding

1/ Recent levels for livestock are 1991-1993, recreation 1994-1996, and timber 1992-1995. Transfer payments are 1994. Payments to local governments are 1992-1996. Forest budget is 1992-1996. Dollar figures are not adjusted for inflation.

2/ Source: IMPLAN model. Full and part-time employment, seasonal and yearlong.

3/ Source: IMPLAN model. 1992 dollar terms. Employee Compensation comprises wages and salaries plus the value of benefits and any contributions to social security and pension funds by the employer and the employees. Property Income comprises Proprietary Income (the income of sole proprietorships), Indirect Business Taxes (sales excise and value-added taxes, and customs duties), and Other Property Income (dividend interest and rental income). USDA Forest Service, 1993. Micro IMPLAN User's Guide. Carol Tyler, Susan Winter, Greg Alvard, Eric Siverts. Land Management Planning Systems Group, Fort Collins, CO.

4/ Income payments to persons for which no current services are performed. These are payments by government and business to individuals and nonprofit institutions. Generally, they are paid in monetary form; major exceptions are food stamps and medical vendor payments. Government transfer payments to nonprofit institutions exclude payments for work under research and development contracts. Source: Regional Economic Information System (REIS) 1989-1994, Bureau of Economics Analysis, as maintained by the University of Virginia website: <http://www.lib.virginia.edu/socsci/reis/reis1.html>. Decade 1 estimates were developed by regressing a year 2002 figure from the REIS data for years 1984, 1989, 1993, and 1994.

5/ 150 year period of analysis, 4 percent discount rate, 1996 dollar terms.

6/ Nominal dollars. Average of 1994-1996 for recent levels. Payment-in-kind are purchaser road credits. Figures shown for the alternatives are in 1996 dollar terms.

Social Organization (Community Cohesion and Stability) - Any of the alternatives would create stress on the local social organization. The most stressful would likely be those alternatives near the extremes of the spectrum—1 and 2, 5 and 6—because they respond more clearly to the needs of one group rather than those of another. For instance, Alternatives 5 and 6 recognize the needs of those favoring increases in nonmotorized recreation and protection of wildlife habitat as being more important than the needs of those who favor motorized recreation use and timber harvest on the Forest.

In order for the local communities to come together in a positive manner, some sense of a new social order must emerge on the local scene that integrates the diverse views held on how the Forest should be managed. Otherwise the tensions and stresses associated with an un-networked leadership are likely to continue. The Forest can also work constructively in this area by maintaining its efforts in public involvement.

To the extent that new social order is not achieved, there will likely be progressively more vandalism and trespass associated with the alternatives as they decrease motorized access on the Forest.

Facilities

Consequences Common to All Alternatives - The individual facilities are not anticipated to have any major effects on environmental components beyond those existing today. The Forest may alter and repair such facilities as administrative sites and other structures on the land owned by the federal government, as necessary to carry out its mission. Any proposed facilities will be subject to environmental analysis to verify the need for the proposal, to review alternatives and to determine site-specific effects and mitigation measures as needed. Decisions on proposals will be based on separate environmental assessments or impact statements.

Non-Recreational Special Uses

Consequences Common to All Alternatives - There are approximately 204 existing special use permits, in addition to recreation special use permits on the Forest. Ditches, canals, fences, power plants, power-lines, telephone lines, fences, roads, electronic sites, communication sites and dams are all examples of these uses.

Any new proposed special use permits will be subject to environmental analysis to verify the need for the proposal, to review alternatives and to determine site-specific effects and mitigation measures as needed. Decisions on proposals will be based on separate environmental assessments or impact statements.

Consequences Which Vary by Alternative - Alternative 2 identifies two potential communication sites. One site is on the Island Park Ranger District, located on Two Top Mountain. The other is located on Palisades Ranger District on Big Elk Mountain. The other alternatives are unchanged.

PRODUCTION OF COMMODITY RESOURCES

Timber

Indicator - Volume Harvested, Allowable Sale Quantity (ASQ)

Other Indicators

- 1 Unscheduled Timber Harvested
- 2 Firewood/Product Volume
- 5 Harvest System
- 6 Timber Stand Improvement (TSI)
- 8 Suitable Timber Acres
- 6 Acres Harvested
- 7 Noninterchangeable Component (NIC)
- 8 Harvest Volume as a Percent of Long Term Sustained Yield
- 9 Supply and Demand for Wood Products
- 10 Reforestation

Consequences Common to All Alternatives

Unscheduled Timber Harvest - This is volume harvested from forested lands other than ASQ lands. All alternatives allow unscheduled timber harvesting for the following purposes

- Public safety,
- Visual quality,
- Long term maintenance of vegetation conditions,
- Commercial, personal use and camp firewood,
- Commercial and administrative post and pole cutting,
- Administrative use,
- Achieve mature growth standards,
- Meet specific recreation objectives,
- Attain desired vegetation characteristics,
- Improve wildlife habitat, and,
- Where needed to meet management prescription goals

The harvest volume allowed with unscheduled timber harvest for all alternatives is 20.0 MMBF for the decade. Treatments will occur to implement EM, meet various prescription direction, goals and objectives and follow forestwide standards and guidelines. Accomplishment of unscheduled timber harvest is not mandatory and requires site-specific NEPA analysis.

Firewood/Product Volume - All alternatives allow harvest of wood products other than ASQ volume. A goal of the Revision is to conduct an inventory for determining a sustainable level of firewood and then offer that level. A current estimate of volume (firewood and products) that would be available from the forest annually during this planning period (the first decade of revision implementation) is 3.8 MMBF. This compares to approximately 4.6 MMBF that was sold during Fiscal Year 95 and 6.3 MMBF which is a four-year average for the years of 1992-95.

All alternatives harvest less firewood and product volume compared to the levels associated with the past planning period. Demand for firewood is down, due to a decreased supply and the quality of offered material, over the past 4-5 years. The anticipated supply level is below the expected demand. This will result in more competition for sales and therefore, increased cost to purchasers. Demand for product volume (post and poles) is increasing within the planning area. There will be a decrease in availability of

personal use post and poles for farm and ranch use and a move toward competitive bids as demand will exceed supply. The supply of poles may be augmented by pre-commercial thinning material as thinning opportunities will increase during this planning period.

Harvest System - The ASQ acres for all alternatives will be harvested using even-aged silvicultural systems (clearcut, commercial thinning, seed tree, shelterwood and overstory removal) and uneven-aged systems (group selection, individual tree selection and commercial thinning). Specific direction regarding appropriate harvest systems for each species will be developed through silviculture prescriptions by certified silviculturists on a site-specific basis.

Timber Stand Improvement - All of the alternatives allow 19,500 acres of TSI to be accomplished during the decade.

Consequences Which Vary by Alternative - Table IV-18 displays the land classifications for the Forest

	ALT 1	ALT 2	ALT 3	ALT 3M	ALT 4	ALT 5	ALT 6
Non-Forest land (includes water)	681,079	681,079	681,079	681,079	681,079	681,079	681,079
Forest land	1,213,198	1,213,198	1,213,198	1,213,198	1,213,198	1,213,198	1,213,198
Forest land withdrawn from timber production	115,695	115,695	115,695	115,695	115,695	115,695	115,695
Forest land not capable of producing crops of industrial wood	84,458	84,458	84,458	84,458	84,458	84,458	84,458
Forest land physically unsuitable	309,945	309,945	309,945	309,945	309,945	309,945	309,945
Tentatively suitable Forest land	703,100	703,100	703,100	703,100	703,100	703,100	703,100
Forest land not appropriate for timber production	114,518	106,142	177,982	237,532	303,481	503,362	703,100
Unsuitable Forest land	624,616	616,240	688,080	747,630	813,579	1,013,460	1,213,198
Total suitable Forest land	588,582	596,958	525,118	465,568	399,619	199,738	0

Timber Prescription Areas - Table IV-19 displays the total number of acres within each alternative which are allocated to timber management activities. The display represents total acres within timber management prescription boundaries (includes forested and nonforested).

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Timber Prescription Ac	773,821	848,224	665,042	601,167	523,375	271,510	0

Suitable Timber Acres - All seven alternatives have different amounts of acres suited for timber management. Table IV-20 displays the numbers of acres of suitable timber available by alternative. Total tentatively suitable acres for the Forest are 703,100. The process used to determine total suitable acres is found in Process Paper C.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Suitable Acres	588,582	596,958	525,118	465,568	399,619	199,738	0

Total suitable acres shown reflect tentatively suitable forest acres within the timber management prescription acres shown in Table IV-19. The difference between tentatively suitable acres (703,100) and those shown in Table IV-20, reflect specific constraints within the prescription mix in each alternative. The alternatives with the largest acreages of suitable forest land will have the most effect on forested vegetation.

Table IV-21 displays the current and projected future age class distribution on suitable lands if ASQ projections are met. Alternative 6 is not shown in the table. Alternative 6 has no suitable acres and proposes no scheduled harvest (ASQ), therefore, no change is anticipated during the decade from vegetation treatments.

Alternative 1			Alternative 3-M

160 +	11,977	16,462	160 +	6,666	8,403

1/ Displays the current and future age class distribution of suitable acres for each alternative during the planning period. Changes between current and future are based on projected vegetation treatments (ASQ).

Acres Harvested - Table IV-22 displays harvest acres for each alternative. Harvest acres are determined by the number of suitable acres within management prescriptions that allow timber harvest activities. The differences between the acres shown below and the suitable acres shown above is due to specific con-

straints within each prescription area, past timber activities and that sustainability is based on a 150 year period of analysis rather than the first decade. Process Paper B provides information on the constraints used for this analysis.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6

Alternative 2 harvests the most acres during the decade followed by 1, 3, 3M, 4 and 5. There are no ASQ harvest acres associated with Alternative 6. All alternatives harvest 2.7 percent or less of the total forested acres and 5.6 percent or less of total suitable acres over the next decade.

Harvest Volume - Harvest volume data is shown in Table IV-23. ASQ is the amount of timber volume that each alternative schedules to be harvested based on the number of suitable acres, average volume per acre and management direction within each prescription area.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Annual (ASQ)	11,068	12,900	10,834	8,000	6,033	3,510	0
Decade (ASQ)	110,680	129,000	108,340	80,000	60,330	35,100	0
Average Vol/Ac	3,900	3,900	3,900	3,900	3,900	3,900	0
Doug Fir Volume	5,136	5,986	5,027	3,711	2,800	1,630	0
MX3 Volume	2,157	2,515	2,114	1,559	1,174	683	0
LPP Volume	1,903	2,219	1,864	1,376	1,037	605	0
MX Volume	1,829	2,129	1,790	1,322	998	581	0
SF Volume	43	51	39	32	22	11	0

Alternative 2 provides the most volume harvested during the decade, followed by Alternatives 1, 3, 3M, 4 and 5. Alternative 6 does not provide any ASQ harvest.

Volumes per acre are shown above in Table IV-23. The average volume per acre across the alternatives is about 3.9 MBF. During the previous planning period (1981 - 1990) the planned volume per acre averaged around 5.0 MBF and the actual sawtimber volume per acre was 6.2 MBF. The planned volume per acre is less than the previous planning period due to two wildlife constraints. One requires 20 logs per acre in each decomposition class be left on-site. These logs should be a minimum of 7-inch in diameter (average 9.5-inch in diameter) and be 20 feet long. This would equate to about 0.75-1.0 MBF per acre left on the ground if adequate down and woody material is not available. The second constraint requires leaving snags and snag recruitment trees. For a 100 percent biological potential at the high end, 10 snags per acre and 25 snag recruitment trees per acre (half in the 7.0-inch-9.9-inch diameter class) would have to be left. This would also equate to 0.65-1.25 MBF per acre being left standing.

Noninterchangeable Component (NIC) - Table IV-24 displays the number and percent of suitable acres by alternative that fall into a NIC. NIC acres are ASQ acres associated with forested slopes between 40-60 percent, specific prescriptions (5.3.2 - 5.3.5, 5.7, 5.8 and 5.9.2) and areas designated as roadless. This component indicates a portion of the ASQ which need not be substituted for from other areas or species types. Volume programmed from a NIC need not be replaced by volume from other NICs. Alternative 1 has the largest amount of NIC acres followed by Alternatives 3, 2, 3M, 4 and 5. Alternative 5 also has the least amount of suitable acres of any alternative with a scheduled timber harvest.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
NIC Acres (Total)	321,612	231,514	250,443	227,229	183,236	22,800	0

Long Term Sustained Yield Capacity (LTSYC) - LTSYC is the highest uniform wood yield from lands being managed for timber production that may be sustained, under a specified management intensity, consistent with multiple use objectives. Table IV-27 displays the LTSYC on an annual basis for each alternative. LTSYC generally shown in MCF (thousand cubic feet) is also displayed in MBF (thousand board feet) (estimate) terms for ease in comparing the alternatives.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
LTSYC (MCF/Yr)	6,181	6,269	5,513	4,889	4,196	2,097	NA
LTSYC (MBF/Yr)	25,997	25,632	22,868	20,275	17,403	8,693	NA
Proposed ASQ Harvest Volume as % of LTSYC	43	50	47	39	35	40	NA

LTSYC indicates the amount of volume that is produced annually from the suited acres shown for each alternative in the long term. This includes growth from all trees and does not necessarily mean total merchantable volume that is available for harvest. By law, harvest levels cannot exceed LTSYC. Alternative 2 comes the closest to meeting its LTSYC but only utilizes 50 percent in decade 1, about one half the annual growth predicted in the long term. Alternative 2 is followed by Alternatives 3, 1, 5, 3M and 4 respectively.

Supply and Demand - Chapter III displays information on the current supply for sawtimber and wood products and the predicted demand from operators in our area. Table IV-28 displays how the volume available from each alternative meets the demand.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
% Present Demand	42	47	41	33	28	20	11
% Survival Level	48	54	47	38	33	24	12

Present demand is for 35.7 MMBF of wood products. Alternative 1 provides 11.07 MMBF sawtimber and 3.8 MMBF of firewood products for a total of 14.87 MMBF or 42 percent of demand. Alternative 2 provides the most volume in terms of past supply and present demand but falls well short of historical levels provided by the Forest. Even during recent years (1991 - 1994) the Forest provided 54.4 percent of the volume available to the local demand area. Under Alternative 2, the Forest will supply about 47 percent of the volume available to the local market. Following Alternative 2, Alternatives 1, 3, 3M, 4, 5 and 6 provide decreasing amounts. Survival level is the minimum level of timber demand, from all operations, necessary to meet the needs of timber industry and personal use.

Future Harvest Levels - Table IV-29 displays future levels of harvest. It is assumed that management direction will remain the same for 150 years.

Decade	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
2	10,076	17,472	8,989	7,970	6,841	3,419	0
3	10,136	17,723	9,043	8,018	6,882	3,440	0
4	10,121	18,677	9,029	8,005	6,871	3,434	0
5	10,205	18,960	9,105	8,072	6,929	3,463	0
10	25,290	25,634	22,563	20,004	17,403	8,582	0
15	25,632	25,868	22,868	20,275	17,403	8,698	0

Reforestation - Table IV-30 displays the level of reforestation activities expected during the planning period and will be a mixture of artificial and natural regeneration. The amount of each will depend on the species harvested, harvest system used and suitability for natural regeneration during the planning period. This will be determined through site-specific analysis.

	Alt 1	Alt 2	Alt 3	Alt 3-M	Alt 4	Alt 5	Alt 6
Acres of Reforestation	4,650	5,000	4,650	4,150	3,800	340	230

Cumulative Effects

Silvicultural Systems - Even-aged management systems will continue to be used resulting in even-aged stands. Uneven-aged systems will also be used, but will have very little cumulative effect on forest succession as the seral stage generally does not change when these systems are used.

The type of silvicultural system applied has a bearing on the environmental effects. The systems are selected to achieve the objectives for an area, consistent with site-specific conditions.

Even-aged systems - The even-aged system of clearcutting, shelterwood and seed tree cutting affect the vegetation by creating earlier seral stages. This favors seral tree species (generally lodgepole pine, aspen and Douglas-fir) for the habitat type in which the cutting occurred.

Clearcutting removes all the merchantable vegetation at one time and requires the starting of a new stand by either natural regeneration or by planting seedlings. The new stand is generally established within 3 years of harvesting.

The shelterwood harvesting system also moves the vegetation to earlier seral stages. This system removes 60-70 percent of the vegetation at the first harvest, but leaves mature trees for shelter. Shelter trees moderate the environmental effects in comparison to clearcutting. Shelter trees provide shade that reduces soil temperature 10 to 30 degrees Fahrenheit and soil moisture is retained longer. Both conditions increase survival rates of the seedlings produced from the seed of shelter trees or of planted trees. When the new seedlings are two to eight feet tall, the overwood harvest is made, that is the shelter trees are removed leaving a new stand in the brush/seedling stage of succession.

Uneven-aged systems - The uneven-aged systems (group and individual tree selection, including salvage) do not generally change the seral stage over a large area. The individual tree selection system will not change the seral stage but may more quickly cause the stand to reach climax conditions, by favoring climax tree species and reducing the amount of the seral species. The group selection (openings of one-fourth to two acres) will create sufficient light and growing space to obtain regeneration of the seral species. Uneven aged systems have the least effect on the composition of the forested vegetation.

Even-aged management appears to include the most efficient and silviculturally correct cutting system for the lodgepole pine type. Uneven-aged systems appear to be the most efficient and silviculturally correct cutting system for spruce-fir types. However, during project analysis, the different silvicultural cutting systems will be reviewed to determine which systems best meet the silvicultural requirements of the tree species and site conditions of individual stands.

The harvesting of fuelwood will not substantially affect the forested vegetation. Fuelwood activities generally remove only the dead material (standing or down), thinning materials from beneath the crown canopy and slash from commercial timber harvests. This type of activity does not move stands forward or backwards in succession.

Intermediate cutting methods - Intermediate cutting methods such as thinning from above or below will be used throughout all timber types, intermediate cuts will be used to manage stand densities.

Fuelwood - The recent levels of fuelwood availability will continue to decrease due to the low number of acres treated under any alternative. Requirements for more down and woody vegetation and maintaining snags within harvest units will also reduce available fuelwood material offered in slash piles. Use of aspen for firewood material could increase due to the increased aspen acreage that is available for treatment.

Fire - The hazard from wildfire on the suited lands should remain about the same as in the past as the acres available to harvest, once harvested, will not reduce the composition of the mature component significantly. The hazard on the unsuitable lands should remain constant or slightly increase as the stands continue to mature and no activities are initiated to reduce fuel loading.

Insects and Disease - Insects and disease will continue to be present in both the suited and unsuitable lands. Vegetation management activities planned during this period will decrease in amount on the suited acres, but even a 2 percent or less reduction in mature stands provides some benefit in reducing insects and disease problems. On the unsuitable lands, insect and disease could build up to epidemic proportions.

Growth on the managed stands would increase with management intensity. As more lands are developed, total growth would increase. Growth on the unsuitable lands would remain constant or decrease as the stands increase in age and are past culmination in the later seral stages.

Livestock Grazing

Indicators -

- 1 Amount of permitted AUMs and livestock
- 2 Number of grazing permittees and permits
- 3 Amount of acres open to grazing
- 4 Number of allotments open to grazing
- 5 Acres of Range Management Prescription 6 1 (a-b)

Consequences Common to All Alternatives - For Alternatives 1 through 6, three vacant sheep allotments (1,483 AUMs) on the Island Park Ranger District and four vacant sheep allotments (2,830 AUMs) on the Ashton Ranger District will be closed to sheep and cattle grazing to better manage grizzly bear habitat, one vacant sheep allotment (585 AUMs) and one vacant sheep permit (540 AUMs) on the Dubois Ranger District and another vacant sheep allotment (750 AUMs) on the Palisades Ranger District will be closed to sheep and cattle grazing to improve watershed and soils conditions (Process Paper L). This reduction of 6,188 sheep AUMs reduces the number of open sheep allotments from 78 to 69 and closes 95,409 acres to grazing of domestic livestock. Since these allotments/permit are currently vacant, this reduction in a real sense has already occurred. Presently, based on 1993 data, the numbers of livestock actually using the forest are 20,362 cattle for 84,212 AUMs and 54,478 sheep for 44,006 AUMs. The reasons for the

difference between actual and permitted use are 1) the grazing capacities (livestock numbers and AUMs) for the vacant sheep allotments are counted as permitted because they are open allotments that are available for grazing, but because of resource concerns have not been grazed the last eight to ten years, and 2) livestock numbers and AUMs annually fluctuate because of market trends, changes in ranching operations, annual forage availability based on climate and weather conditions and implementation of changes in an AOP and/or AMP

For Alternatives 1 through 6 and the existing situation, all reconstruction of existing range improvements and all proposed new improvements will be needed equally. These improvements are needed to 1) arrest deteriorated range conditions and improve rangeland health, 2) maintain or implement improved grazing systems and AMPs and 3) mitigate site-specific situations identified in previously completed NEPA documents. All proposed new nonstructural improvements (burns, spray, rotobeat, seedings, etc.) and noxious weed control will be implemented to improve ecological conditions by meeting management objectives such as DVC and PFC. No increase in AUMs or livestock carrying capacity is anticipated from nonstructural range improvements.

There are 15 vacant sheep (S&G) allotments and no vacant cattle (C&H) allotments on the forest. As previously mentioned, nine vacant sheep allotments and one vacant sheep permit, for a total of 6,188 AUMs, will be immediately closed to cattle and sheep grazing when the Record Of Decision is signed. The remaining six vacant sheep allotments (4,206 AUMs) will remain open to grazing to be used by either permanent or swing sheep permittees (Table III-40). Two of these sheep allotments are on the Island Park Ranger District (Blue Creek and Hotel Creek) and are phase-out allotments (see Alternative 3M discussion and Process Papers L and N).

Depending on specific management prescription application, which varies by alternative, all permittees will be required to comply with the OROMTRD standards on their allotments (Process Paper N). Most grazing allotments are in more than one management prescription area.

Consequences Which Vary by Alternative - Unless otherwise specified, all environmental consequences are calculated to occur by the end of the first decade. The effects of implementation on indicators for all alternatives are shown in Table IV-30.

With the existing Forest Plan (Alternative 1), livestock management (grazing) systems are utilized to maintain or improve forage outputs for livestock and wildlife and to protect and improve watershed conditions. Direction is not given to sustain livestock use at any specified level. The direction is to "Obtain optimum use of all suitable grazing lands on the Forest consistent with other resource needs." Information about this direction and how well the existing Forest Plan met objectives can be found in the Range Section of the AMS.

Riparian utilization in Alternative 1 is expressed as a percentage of forage utilized and ranges between 30 and 65 percent for herbaceous vegetation and 20 to 40 percent for browse, depending on the type of grazing system and range condition. There is a 100 foot buffer zone on each side of all perennial streams.

Range Management Prescription 6.1 (a-b) provides two options. Category (a) allows motorized cross country travel with no open road density while Category (b) allows no motorized cross country travel and has an open road density of less than or equal to 2.0 miles/square mile. Presently, with the existing situation, unless otherwise shown as closed, all areas/roads/trails on the forest are open for motorized cross country travel with no road density restrictions.

Compared to the existing situation, Alternative 1 implements Range Management Prescription 6.1 (a-b) on 204,197 acres (202,701 acres in Category (a) and 1,496 acres in Category (b)) and maintains the existing number of grazing permits, permittees, sheep numbers and cattle allotments open to grazing. Compared to the existing situation, Alternative 1 projects a slight increase (one percent) in cattle numbers and cattle AUMs (1,201 AUMs) and reduces the number of sheep AUMs by 612. As previously mentioned, a 6,188 AUM reduction in sheep grazing has already occurred.

Alternatives 2-6 express riparian forage utilization in terms of stubble height of key species on and away from the HGL and have wider buffer zones than Alternative 1 or the existing situation. With Alternatives 2-6, livestock management (grazing) systems are utilized to maintain or improve forage outputs for livestock and wildlife and to protect and improve watershed conditions. The amount of protection varies among alternatives. Direction is not given to sustain livestock use at any specified level.

Alternative 2 implements an AIZ Prescription which provides for a 4-inch stubble height of key plant species at the HGL for all riparian areas either at the end of the grazing period or for all pastures grazed after September 1. Alternative 2 has buffer widths ranging from 100 feet to 200 feet on each side of all fish bearing streams, depending on the subsection. Compared to the existing situation, Alternative 2 implements Range Management Prescription 6.1 (a-b) on 193,403 acres (96,969 acres in (a) and 96,434 acres in (b)) and maintains the existing number of grazing permits, permittees and cattle allotments open to grazing.

Indicator	Existing	1	2	3	3-M	4	5	6
AUMs 5/ Sheep Cattle	55,295 93,480	48,495 94,681	48,195 90,341	48,195 90,156	1/ 48,195 90,156	1/ 47,596 82,217	4/ 39,140 82,217	4/ 39,096 82,217

Allotments 2/ Sheep Cattle	78 76	69 76	69 76	69 76	69 76	69 76	53 76	53 76
Acres Rx 6.1 "a" 3/ "b" 3/	0 0	202.7 1.5	97.0 96.4	97.0 95.6	0 157.4	0 171.2	0 32.2	0 17.5
1/ Phase out of sheep allotments/AUMs in bighorn sheep and grizzly bear habitat is expected to be completed within 30 years. No reductions associated with the phase-out are anticipated over the coming decade. 2/ Allotments open to grazing. 3/ Millions of acres. 4/ These figures reflect the immediate closure of sheep allotments/AUMs in bighorn sheep and grizzly bear habitat. 5/ Based on 1993 Forest Service Range Management Information System (FRAMIS) data.								

The grazing period is defined as the period of time livestock are using a specified pasture or unit within a grazing allotment, as identified in the yearly AOP or the AMP. The end of the grazing period will not coincide with the end of the permitted season, unless that pasture or unit is grazed last. The grazing period for a pasture or unit is shorter and not equal to the grazing season because there is usually more than one unit or pasture per allotment. The permitted season for the allotment is shown on the permit, the

grazing period for pastures or units is shown in the AOP

Compared to the existing situation, Alternative 2 projects additional reductions of sheep and cattle numbers and AUMs (Table IV-30). Alternative 2 will also require grazing permittees to comply with OROMTRD restrictions on an additional 96,434 acres (Category (b) portion of the 193,403 acres). As a result of providing improved riparian management, reductions in livestock AUMs are projected. Forestwide, a three percent reduction in cattle AUMs can be expected with implementation of Alternative 2. Most of the livestock reductions will occur on the Dubois Ranger District with reductions of 300 sheep AUMs and 4,224 (11 percent) cattle AUMs.

Alternative 3 is the same as Alternative 2, except for two items: 1) a slight reduction in cattle AUMs (185 AUM difference) and 2) the number of acres in Range Management Prescription 6.1.b (850 less acres in Alternative 3).

Alternative 3M, like Alternatives 2 and 3, implements the AIZ Prescription which provides for a 4-inch HGL stubble height for all riparian areas either at the end of the grazing period or for all pastures grazed after September 1. However, Alternative 3M has wider buffer widths than Alternatives 2 or 3, which range from 150 feet to 300 feet on each side of all fish-bearing streams, depending on the subsection.

For cattle numbers, AUMs, permittees, permits and allotments, Alternative 3M has the same effects as Alternative 3.

Compared to the existing situation, Alternative 3M implements a phase-out of sheep grazing on an opportunity basis to better manage grizzly bear and big horn sheep habitat on 16 open sheep allotments and one grazing permit on the Dubois, Island Park and Teton Basin Ranger Districts (Process Papers L and N). This phase-out will reduce sheep grazing by an additional 8,456 active AUMs. The reduction sustained as a result of grizzly bear habitat amounts to 3,964 AUMs on nine allotments, the reduction associated with bighorn sheep habitat amounts to 2,660 AUMs on five allotments and one permit and the reduction associated with both bighorn and grizzly bear habitat is 1,832 AUMs on two allotments. The phase-out not only reduces the sheep grazing on the allotments, but closes them to grazing as well, including cattle. As a result, an additional 125,853 acres would be closed on an opportunity basis (Process Papers L and N). As explained in Process Paper N, the allotments would be closed after all sheep are gone from the subsection.

Because of additional resource concerns, another 599 AUM reduction in sheep AUMs is anticipated with Alternative 3M. This reduction is not associated with the phase-out of sheep grazing.

Compared to the existing situation, Alternative 3M implements Range Management Prescription 6.1(a-b) on 157,385 acres. All of which is in category b which allows no motorized cross country travel and has an open road density of less than or equal to 2.0 miles/square mile. It also has the same effects on cattle grazing activities as Alternative 3.

Compared to the existing situation, Alternatives 4, 5 and 6 will achieve the best riparian and upland vegetation conditions in the shortest amount of time while still maintaining livestock production (Process Paper J), but will result in additional reductions of cattle AUMs. It is estimated that implementation of Alternatives 4, 5, or 6 will reduce cattle AUMs 12 percent (11,263 AUMs) forestwide. Alternative 4 implements the AIZ Prescription which provides for a 6-inch stubble height for riparian forage utilization at the end of the grazing period or for all pastures grazed after September 1 and has buffer widths ranging from 150 feet to 300 feet on each side of all fish-bearing streams, depending on the subsection. The most significant reductions in cattle AUMs will occur on the Dubois, Palisades, Teton Basin and Ashton Ranger Districts with projected reductions of 7,986 AUMs (22 percent), 1,770 AUMs (10 percent), 486 AUMs (8 percent) and 925 AUMs (6 percent) respectively.

Alternative 4 also implements the same phase-out of sheep grazing on the same allotments/acres for the same reasons as Alternative 3M and has the same consequences for the Dubois, Island Park and Teton Basin Ranger districts

Compared to the existing situation, Alternative 4 implements Range Management Prescription 6 1 b on 171,222 acres, all of which is in Category (b) which allows no motorized cross country travel and has an open road density of less than or equal to 2 0 miles/square mile

Alternative 5 is somewhat similar to Alternative 4, except for two items Alternative 5 does not allow sheep grazing in critical Grizzly Bear or bighorn sheep habitat As a result, all sheep grazing (nine allotments) on the Island Park Ranger District and four to five sheep allotments on the Teton Basin Ranger District and two winter allotments and one winter permit on the Dubois Ranger District will be immediately closed to sheep grazing rather than phased-out Alternative 5 implements Range Management Prescription 6 1 (b) on 32,186 acres

Except for a 44 AUM reduction in sheep AUMs on the Dubois Ranger District and the acres of Range Management Prescription 6 1, Alternative 6 is identical to Alternative 5 Alternative 6 implements Prescription 6 1 (b) on 17,484 acres

Cumulative Effects - Because ranching operations and allotment conditions vary across the forest, it is difficult to determine how each individual allotment or permittee will respond to implementation of the standards, guidelines and prescriptions associated with each alternative For example, a change in AUMs can be the result of changes in the number of livestock, permitted season or a combination of both As demonstrated by past situations the loss of AUMs can sometimes be mitigated while improvement in other resources such as fish and wildlife habitat and other noncommodity indicators occur

Forestwide, Alternative 1 will increase cattle AUMs and maintain the sheep AUMs presently in use on the Forest However, on a Forestwide scale, Alternative 1 will not meet the objectives

Compared to the existing situation Forestwide, the implementation of Alternatives 2, 3 or 3M are not likely to significantly or adversely affect the majority of livestock grazing permittees with grazing privileges on the Forest, except for cattle permittees on the Dubois Ranger District Improved riparian conditions as a result of implementation of a 4-inch stubble height along the HGL in the AIZ, is the main reason for the expected reduction in cattle AUMs across the Forest

Compared to the existing conditions, implementation of Alternatives 4, 5 or 6 will significantly affect livestock permittees on all Ranger Districts Because of improved riparian conditions resulting from implementation of the 6-inch stubble height standard along the HGL, Alternatives 4, 5 and 6 will have the most impact to cattle permittees, especially those on the Dubois and Palisades Ranger Districts Improved grizzly bear and bighorn sheep habitat resulting from the immediate closure of some sheep allotments in Alternatives 5 and 6 will have the most impact to sheep permittees, especially those on the Island Park, Teton Basin and to a lesser extent, Dubois Ranger District

IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

Irreversible commitment of resources refers to a decision that disturbs or reduces a nonrenewable resource or a renewable resource to the point that renewal can only occur over a long period of time and/or at a great expense Examples are minerals extraction, loss of cultural resources and construction of major roads or hydroelectric projects

Irretrievable commitment of resources refers to lost production or use of renewable resources due to land use decisions This represents the opportunities foregone for the period of time that the resource is unavailable

Mineral extraction activities will require site-specific environmental analysis that explores the extent and consequences of irreversible commitments. To lessen the irreversible commitment of resources, it is the Forest manager's job to provide mitigation that will minimize adverse environmental impacts.

The Forest has about 2,791 miles of open or restricted roads. Table IV-12 shows what will happen to that figure over the coming decade. Open and restricted road miles may be regarded as being effectively withdrawn from vegetation production. Roads reclaimed or obliterated may be regarded as beginning to regain their capability to produce vegetation.

There would be some irreversible losses to soil hydrologic function and site productivity in areas where management activities are directed. Adherence to soil quality standards and guidelines, which are designed to reduce adverse impacts to an acceptable level, should allow soils to recover their natural properties for resiliency (e.g., soil organic matter in both surface and subsoil layers, available water holding capacity, etc.).

Road construction, timber harvest, grazing, dispersed recreation and motorized recreation OHV use have the highest likelihood of producing irreversible damage to the soil resource. Wildfires within the cool, dry Douglas-fir forests, moist Douglas-fir forest and mid and lower elevation subalpine forests, where one or more fire cycles has elapsed due to fire suppression, might result in fires having a higher severity and intensity, resulting in irreversible losses (e.g., changes in the soils' chemical and physical properties or in the development of hydrophobic layers with subsequent increased overland flows and accelerated erosion) to the soil resource.

The portions of the inventoried roadless areas that are developed by roading and timber harvest will be lost for future wilderness consideration. Estimated acres that would be developed at some point during the next 150 years range from 0 acres in Alternative 6 to 63,600 acres in Alternative 2. Activities that are not scheduled by the Revision or are unforeseen, such as those external to the Forest Service (mining, power transmission lines), may also be regarded as an irreversible or irretrievable commitment of resources. See Table II-1 for a summary of wilderness and undeveloped acreage by alternative.

Adverse Environmental Effects that Cannot be Avoided - Adverse effects on some components of the environment cannot be avoided by actions proposed under the alternatives. Actions to benefit one component may have at least temporary adverse effects on another. A broad range of alternatives have been formulated, each with its own resource or environmental emphasis. Alternatives include management standards and guidelines, along with mitigation measures, to avoid or reduce adverse environmental effects. Monitoring will be used to measure how effective the standards and mitigation measures are in reducing adverse effects.

Some of the adverse effects that cannot be avoided in all alternatives include the following:

- Forest management activities frequently result in impacts upon the visual resource. These changes in the landscape, although usually temporary, are often objectionable to some observers.
- A short-term increase in fire hazard will occur due to waste material, limbs and tops left on the ground during and following timber harvest operations.
- A long-term increase in fire hazard will occur because actions are not being taken to reduce fuel loadings which are judged to be in excess of those which existed in the past.
- Intermittent and localized decrease in air quality may result due to dust from road construction, road maintenance and use, and due to smoke from wildfires, prescribed burns and campfires.

- Short-term localized increases in soil erosion, vegetation degradation and stream sedimentation may occur due to land-disturbing activities
- Elimination of small areas from vegetation production will occur due to construction of permanent physical developments
- Potential for additional conflicts between recreation use and other land use activities will increase in some alternatives
- Temporary disturbance of wildlife and their habitat conditions in localized areas may result from increased human activity and changed vegetation conditions
- Energy will be used to manage and provide goods and services
- Increased soil compaction may occur on activity sites such as timber harvest areas and recreation areas

Many of these adverse effects are temporary, occurring during the site-specific activity, or transitional as forest vegetation progresses through seral stages

Short-term Uses of the Human Environment and the Maintenance of Long-term Productivity - Short-term uses are those that generally occur on a yearly basis, such as livestock grazing or recreation site irrigation as a use of water. Long-term productivity refers to the capability of the land to provide for future generations. The quality of life for future generations is determined by the capability of the land to maintain its productivity.

Alternatives that have the greatest amount of timber harvest activity will result in the most short-term and continuing activity that may have an effect on the long-term productivity. Alternative 2 has the most potential for long-term effects, while Alternative 6 has the least. Other alternatives present middle range effects.

The loss of N F grazing privileges can cumulatively affect the stability of traditional values and income opportunities of the local rural areas. For example, if a local permittee loses a grazing privilege that accounts for 35 percent of the time needed to sustain livestock production for the overall ranching operation, then loss of the permit needs to be made up elsewhere. The purchase of additional hay or feed, reducing the base livestock herd or acquiring pasture elsewhere are ways this loss can be mitigated. If the 35 percent cannot be made up and the base herd is reduced to a level where it is no longer profitable or the costs for additional hay or pasture are too expensive or not available, then the ranch or portions of the ranch could be sold. Ranches and farms sold in this region have typically been sold for housing units or subdivisions. The loss of open space (ranch and farm land) that often also provides quality wildlife habitat, is an irreversible and irretrievable commitment of resources, resulting in direct adverse effects to such things as wildlife and fish habitat, aesthetics and the economic and social environment.
