1997 Revised Forest Plan

This Appendix A to the FEIS is a separate document because of its large size

APPENDIX B

UPDATE TO THE ROADLESS AREAS PROCESS PAPER FOR WILDERNESS RECOMMENDATION RATIONALE

The following text is provided as an update of the Roadless Process Paper. This narrative rationale for/against proposing each of the 16 remaining roadless areas as recommended wilderness in the Revised Forest Plan (Alternative 3M) is based on the ratings shown in Table IV-14 as shown in Chapter IV of the FEIS.

Italian Peak—This area was recommended for wilderness consideration for the following reasons:

The area has moderate manageability potential, low impacts to natural integrity, and high opportunity for solitude. It also has a high degree of opportunity for challenging experiences. Topography, vegetation, rock formations, and size of the area enhance the opportunity for primitive recreation. This area is recommended in the current Forest Plan and is adjacent to a recommended area on the Beaverhead National Forest. The total area recommended on both forests would be approximately 62,000 acres, which would be a fairly good wilderness package, although on the small end of the scale. The southern boundary for this area has been adjusted slightly from that displayed in the DEIS in an effort to match the boundary in our current Travel Plan Map. This line was selected for ease in boundary management and to select the area with the least impact potential from roads and motorized activity. There has been widespread public support for this area.

Diamond Peak—A portion (33,000 acres) of this area shown in the DEIS in Rx's 2.2, 3.1.1a, and 3.2c north of Pass Cr is recommended and has been changed in the FEIS to Rx 1.3 accordingly, for the following reasons:

The area is contiguous with 06-601 on the Salmon-Challis National Forest, and the Challis Forest Plan and EIS contains an analysis and recommendation that the entire area NOT be recommended as wilderness. However, because of the area's large size (166,639 acres), natural integrity, high opportunities for solitude and challenging experience, and considerable public comments, it should be considered for proposed wilderness contingent on additional analysis by the original lead forest (Salmon-Challis). We have contacted the Salmon-Challis Forest and requested they conduct additional analysis on this area as their Plan is revised. The final decision on recommendation for consideration as wilderness will be made based on that Forest's plan.

Garfield Mountain—This area was not recommended for wilderness consideration for the following reasons:

This area has moderate impacts to natural integrity by physical developments for mining and grazing. The area is also very linear and narrow in shape, and is almost divided by two roads in the middle of its configuration. *Opportunity for a challenging, remote, backcountry experience is low to moderate.* Public interest in previous years as well as in public comments on the DEIS is very low. There are no significant biodiversity features within this area that would warrant special consideration.

Mt Jefferson—This area was not recommended for wilderness consideration for the following reasons

This area was studied and released for multiple use management in 1990 by an Environmental Impact Statement prepared by the BLM. Boundaries of the area would be difficult to manage, and administration would have to be by three different federal agencies due to landownership. Influence on natural integrity is high due to mining and roads. Opportunity for solitude is low and opportunity for challenging experience would only be moderate. This area does not score at a level equal to other previously recommended wilderness on the Forest, and there is more public comment against recommendation than for it in response to the DEIS. Most of the public comment on this area is in support of designation as a wildlife migration corridor. Therefore, we are not recommending it again for wilderness consideration in this Plan Revision.

Raynolds Pass—This area was not recommended for wilderness consideration for the following reasons

This area is very small and adjacent to the moderately developed area surrounding Henrys Lake. Although boundary management would be fairly easy, the amount of disturbance to natural integrity is very high due to primitive roads. Opportunity for solitude and a challenging experience are low. This area rates very low on the rating table, and there was no public comment supporting recommendation. Biodiversity is relatively minor in this area.

Lionhead—This area was recommended for wilderness consideration for the following reasons

Boundaries are fairly well defined and management would be compatible with adjacent lands. Influence on natural integrity is low. Opportunity for solitude and a challenging experience are high and moderate respectively. This area was recommended in the current Forest Plan. It is contiguous to an area on the Gallatin National Forest to the north and its wilderness potential is thus increased. This area also contains significant biodiversity features. The area receives significant snowmachine and ATV use, and to accommodate this use, we have excluded a small roaded area along the eastern boundary from the recommended wilderness.

Two-Top—This area was not recommended for wilderness consideration for the following reasons

Boundaries are fairly well defined. The area is very small, and a primitive road through the middle of the area, vegetation manipulation, and mining activities interrupt the natural integrity. Opportunity for solitude is moderate, but opportunity for challenging experience is low. There were no public comments in response to the Plan Revision DEIS that indicated support for recommendation. This area rated relatively low in the wilderness characteristics table and has received little support from the public for recommendation.

Winegar Addition—This area was recommended for wilderness consideration for the following reasons

Although this area is less than 5,000 acres, it is adjacent to the existing Winegar Hole Wilderness. This area was recommended for consideration in the existing Forest Plan, but since it is in Idaho, it was not included in the Wyoming Wilderness Bill which designated Winegar Hole. Quality of wilderness characteristics is only low to moderate, but the addition of this area has had considerable public support, because it would "round out" the existing designated wilderness.

West Slope Tetons—This area was not recommended for wilderness consideration for the following reasons

Much of this area was included in the original recommendation for wilderness designation, and was not selected by the Congress. Therefore, we do not propose to revisit that decision (Wyoming Wilderness Act of 1984) which released the area for multiple use management. Very few public comments were received in favor of recommending this area as wilderness in our Revised Plan.

Garns Mountain—This area was not recommended for wilderness considerations for the following reason

Garns Mountain Roadless Area has little development of any type that would impact the natural integrity of the area for wilderness considerations. This area is a fairly large block of land with moderately easy defined boundaries. Opportunity for challenge is moderate with some steep and remote terrain, but also considerable amounts of much easier terrain. This area is currently used for motorized and non-motorized travel and is considered important by all user groups for recreational access. Opportunity for solitude is high if motorized use is removed. However, our Plan Revision proposes to designate this area for motorized use on trails, and to improve the trails in this area to provide a significant system of high quality that will meet public demand. Support and opposition are often very vocal concerning this area's recommendation for wilderness. There are no significant biodiversity features within this area that warrant special consideration, although there are areas within the roadless area which have high value resources.

Palisades—A portion of this area was recommended for wilderness considerations for the following reason

Palisades Roadless area has no development of any type that would impact the natural integrity of the area for wilderness considerations. This area is a fairly large block of land with moderately easy defined boundaries. Opportunity for solitude and challenge is high in most of the area with steep and remote terrain. Most of this area is currently closed to motorized travel. Where motorized travel is allowed, terrain restricts travel to designated routes. Public interest has been fairly strong for this area to be included into wilderness although some opposition has also been voiced. There are significant biodiversity features within this area that warrant special considerations. Furthermore, all oil and gas leases (which were the reason for not recommending this area in our current Forest Plan) have been terminated and there are no current leases or applications on file.

Only approximately 2/3 of the Idaho portion of this roadless area was recommended. This was due in part to the decision to continue to allow the motorcycle and snowmachine use in the area from Rainey Creek North. In addition, the difficulty in boundary identification and management would be reduced by using the Rainey/Palisades Cr. Ridge.

Bald Mountain—This area was not recommended for wilderness considerations for the following reason

Bald Mountain Roadless area is moderately developed with fence and adjacent road development that may impact the natural integrity of the area for wilderness considerations. This area is moderately small in size with boundary identification being difficult to define.

Opportunity for solitude and challenge is low to moderate for most of the area. This area is currently used for multiple use travel and is considered important by all user groups for recreational access. Public interest has been low for this area to be recommended as wilderness. There are no significant biodiversity features within this area that warrant special considerations.

Bear Creek—This area was not recommended for wilderness considerations for the following reason

Bear Creek Roadless area, although undeveloped, does have evidence of human influence through fence, trail and adjacent road development that may impact the natural integrity of the area for wilderness considerations. This area is moderately large tract of land but has many roads which have been “cherry stemmed” into the center of the roadless area. Boundaries will be moderately difficult to define although distinct boundaries could be established. Opportunity for challenge is low for most of the area. Opportunity for solitude is moderate. This area is currently used for multiple use travel and is considered important by all user groups for recreational access. Public interest has been low for this area to be included into wilderness. There are no significant biodiversity features within this area that warrant special considerations.

Poker Peak—This area was not recommended for wilderness considerations for the following reason

Poker Peak Roadless area is developed with fence and adjacent road development that may slightly impact the natural integrity of the area for wilderness considerations. This area is moderately small in size with boundary identification being fairly easy to determine. Opportunity for solitude and challenge is low for most of the area. Much of this area is currently closed to motorized travel. The remaining portion is used by OHVs during the hunting season. Public interest has been low for this area to be included into wilderness. There are no significant biodiversity features within this area that warrant special considerations.

Caribou City—This area was not recommended for wilderness considerations for the following reason:

Caribou City Roadless area has no development that should impact the natural integrity of the area for wilderness considerations. This area on the Targhee NF is moderately small in size with boundary identification being difficult to define, however, added to the portion on the Caribou NF, the area is a fairly large tract of land. Opportunity for solitude and challenge is moderate for most of the area. This area is currently used for multiple use travel and is considered important by all user groups for recreational access. Public interest has been low for this area to be included into wilderness. There are no significant biodiversity features within this area that warrant special considerations.

Pole Creek—This area was not recommended for wilderness considerations for the following reason

Pole Creek Roadless area is moderately developed with fence and adjacent road development that may impact the natural integrity of the area for wilderness considerations. This area is moderately small in size with boundary identification being difficult to define. Part of this roadless area is located on the Caribou NF. Combining both areas still shows this area to be very small in size and very linear in shape. Opportunity for solitude and challenge is low for this area. This area is currently used for multiple use travel, but not considered important to the public need. Public interest has been low for this area to be included into wilderness. There are no significant biodiversity features within this area that warrant special considerations.

APPENDIX C

SUMMER AND WINTER ACCESS

SUMMER ACCESS ANALYSIS PROCESS

The Forest Service is authorized and required by law to plan, develop, manage and maintain a system of roads and trails to serve National Forest resources and uses. The legal basis and specific authorities for regulation of motorized vehicle use on the National Forest are found in the Code of Regulations at 36CFR Part 295. After World War II, four-wheel drive vehicles became available to the public. More recently, other varieties of off-highway vehicles have become popular, such as the motorized trail bike, three, and four-wheel drive All Terrain Vehicles (ATV) and trucks. The development and popularity of these vehicles, and their effects on public lands, has had a significant role in the establishment of motorized use regulations.

One objective of national forest management is to be no more restrictive on road or trail vehicle use than is necessary to sustain and protect the natural resources. Since wildlife habitat and effects of motorized use on other resources (water quality, soils, riparian, etc.) are extremely variable across the Forest, the restrictions on vehicles vary from place to place. In some locations, yearlong closure or even obliteration of roads occurs, while in others, seasonal restrictions are effective in protecting resources. Topography, vegetation, soils, public support, and other factors also influence the extent and duration of road and trail restrictions.

As part of the plan revision process, a number of issues about roads and access were raised by the public, the Forest Service and other Federal, State, and local agencies. Following is a summary of these issues:

- What roads and trails are required for management of the Targhee National Forest?
- Should roads be built, where, and to what standard?
- What roads will be kept open and what roads will be closed?
- What parts of the forest will be open to off highway vehicles?
- What road densities are appropriate?
- What areas should have restricted motorized access in order to reduce impacts to forest resources?
- How should closed roads be maintained?
- What are the appropriate ways to close a road (gates, barriers, signs, what is the best time frame, etc.)
- How can the forest guarantee right-of-way to the forest where private lands block access?
- How should access to private lands within the forest be provided for landowners?
- What is the funding situation for enforcement, monitoring, and administration of forest roads?

A major objective of forest plan revision efforts is to resolve conflict by finding integrated, compatible management methods and prescriptions that allow public use of roads and trails to occur in a way that can best meet the needs of the resources and the recreating public. This report documents the process forest resource professionals used in analyzing current conditions and developing a travel management plan.

that would be compatible with other resource objectives, such as protecting soils, water quality, riparian habitat, wildlife habitat, or other forest resources

A forest team was established in 1991 to analyze motorized access on the Forest. District Travel Plan maps that show the official transportation system of roads and trails, the kind of authorized use permitted on each road or trail (motorized, nonmotorized), and open and closed areas for cross-country motorized use were used in the analysis. After an initial review the Forest was asked to complete additional analysis, since some members of the public felt the District Travel Plan maps did not accurately represent the transportation system that currently exists on the Forest.

The team considered two methods to address these additional concerns. The first method involved a survey during the 1992 fall hunting season in cooperation with Wyoming and Idaho Fish and Game departments. A District person and a Fish and Game Conservation Officer were assigned to monitor Forest system roads in designated areas to determine if motorized use was occurring on roads that were gated and closed. After some initial monitoring, the survey was dropped, because the agencies felt survey data collected was not adequate to quantify motorized use in a way that would be meaningful for Elk Habitat or Elk Vulnerability Models.

The second method was developed in an effort to match the analysis scale the Forest used to determine Elk Habitat Effectiveness modeling. Elk Habitat Effectiveness (EHE) modeling was designed using the 38 principal watersheds on the Forest. Forest personnel, Idaho Department of Fish and Game (IDFG) and Wyoming Game and Fish Department (WGF) agreed to separately analyze those portions of watersheds that were split by the State line. New criteria were identified for analyzing motorized roads and trail density.

The objective of this analysis was to accurately capture the total miles of roads and trails being used by motorized vehicles. Ranger District personnel and local state Fish and Game officers inventoried each watershed using the following criteria:

1. Accurately describe and quantify the existing situation for motorized use on roads, trails, open ridges, etc. during the spring-summer-fall season.
2. Principal watersheds will be used as the basis for the analysis and will include all roads and trails within each of the watersheds and within the outer boundary of the Forest. This includes all system roads and trails, all "ghost" (nonsystem) roads and trails, ridges and open terrain (estimate miles for these cases) that are used by motorized vehicles during the spring-summer-fall season.
3. Open miles of roads and trails means miles of roads and trails (including system, ghost, open ridges, etc.) that are used by motorized vehicles on an average of one to two vehicles per week during the spring-summer-fall seasons. Reliance on Forest/District travel plan maps is not appropriate, because some closures have not been effective and the Forest needs to account for ineffective closures.

Closed miles of roads and trails means miles of roads and trails that are not used by motorized vehicles, or the average use is less than one to two vehicles per week, during the spring-summer-fall season.

Roads and trails that experience motorized use for short periods, such as a one- or two-week period for tree planting, should not be counted in open road and trail miles.
4. For roads and trails that fall on a watershed boundary, include total miles for both watersheds and indicate the number of miles that are being counted in the adjacent watershed. Although some double counting may occur, this process should track how much double counting is actually occurring.

Results of these inventories were tabulated and used to establish the current existing condition of roads and trails being used by motorized vehicles on the Forest

During 1994, Idaho Fish and Game raised the issue that the Forest still lacked accurate information on *motorized access on the forest and expressed concerns that some areas on the Forest had vegetation and terrain which allowed for unrestricted, cross-country, off-highway vehicle (OHV) use*. Additional analysis was completed, using vegetation and slope, to identify areas which might be more accessible to OHV use (see Attachment F of Process Paper D for the criteria used in this analysis). The analysis, called the "infinitely open analysis," used the 38 principal watersheds as the basis for the analysis. Results showed that these watersheds currently range from less than one percent "infinitely open" to 95 percent "infinitely open" under the present travel plan.

Because the Elk Vulnerability (EV) model requires a number for motorized road and trail density, the "infinitely open" areas were converted to a road and trail density figure. The conversion used a formula that added an additional six miles of motorized road for each square mile of "infinitely open" area in each watershed. This conversion resulted in the addition of 4,669 miles of motorized road to the previously inventoried road and trail miles. This total number from the conversion and the inventoried road and trail miles was used in the Elk Vulnerability model (See Table 5.7 in Process Paper D). This table presents the current total motorized access density for each principal watershed, incorporating both the road and trail inventory and the "infinitely open" analysis. The total access densities presented in Table 5.7 were used in the Elk Vulnerability analysis to display the existing condition.

Open Road and Open Motorized Trail Route Density (OROMTRD) was established for individual management prescriptions using the most current research studies on motorized access in grizzly bear areas, elk vulnerability and elk habitat effectiveness models.

Each of the proposed alternatives in the Forest Plan revision was analyzed. Each Ranger District mapped the roads and trails that would remain open under each of the alternatives. These maps were then digitized in the Forest's Geographic Information System (GIS) database. Using GIS technology, the miles of roads and trails that would remain open in each watershed under each alternative were calculated. Additionally, each alternative varied in the amount of land open for cross-country OHV use. An "infinitely open" analysis was completed for each alternative to account for this motorized use. (See Process Paper D for more detailed information on Motorized Road and Trail Analysis and the effects on Elk Habitat Effectiveness and Elk Vulnerability.)

During the revision process several refinements were made. Using GIS capabilities, roads and trails were calculated for each prescription. Maps were created that displayed current road and trail densities by prescription, and future road and trail densities under the proposed Forest Plan Revision. Interdisciplinary teams, made up of Forest resource specialists and line officers, reviewed and analyzed the results. Factors of resource damage to soil, water, wildlife habitat, fisheries, riparian area, as well as recreation opportunities for trail systems, accessible scenic areas, and current volume and type of use on a road or a trail were considered.

The following chart, completed in 1997, displays by District and by alternative the miles of roads and trails that will remain open or have restricted use. Each Alternative also lists the miles of roads and trails that have been identified as "not necessary for administrative use" by the Forest.

Table C-1 Motorized Acces by District by Alternative							
Dubois	Alt 1	Alt 2	Alt 3	Alt 3M	Alt 4	Alt 5	Alt 6
Miles of open road	399	385	325	359	225	188	131

Teton	Alt 1	Alt 2	Alt 3	Alt 3M	Alt 4	Alt 5	Alt 6
Miles of open road	149	180	155	152	137	143	148
Miles of restricted road	134	72	46	65	40	37	31
Miles of open trail	124	108	102	142	101	31	17
Miles of restricted trail	5	11	1	204	1	0	2
Miles eliminated	22	50	118	85	130	121	126
Palisades	Alt 1	Alt 2	Alt 3	Alt 3M	Alt 4	Alt 5	Alt 6
Miles of open road	370	292	286	287	281	270	249
Miles of restricted road	33	15	23	37	25	13	12
Miles of open trail	320	241	233	258	213	168	27
Miles of restricted trail	1	1	1	271	1	0	0
Miles eliminated	0	76	74	57	77	99	191
Forest Total	Alt 1	Alt 2	Alt 3	Alt 3M	Alt 4	Alt 5	Alt 6
Miles of open road	1,882	1,863	1,589	1,577	1,372	1,237	1,228
Miles of restricted road	209	131	115	25	108	63	80
Miles of open trail	522	470	435	540	421	232	81
Miles of restricted trail	752	854	889	817	903	1,092	1,242
Miles eliminated	246	555	767	853	1,113	1,290	1,306

Determinations for leaving a road open were made using a priority system. First priority was given to Federal Highway system roads, State and county roads, existing roads needed to access private property, Yellowstone National Park, State Parks and State lands, and existing roads that access administrative sites, electronic sites, communication sites (under permit) or high use recreation sites such as ski areas, boat ramps, campgrounds, etc. In some areas the application of management prescriptions and the road density standard resulted in these "first priority" roads being the only roads designated "open" for the area. The Forest incorporated guidelines from the Eastside Ecosystem Management Project (EEMP) to establish a rule set to insure consistency as each District prepared their access maps. (See Road Analysis Process, in Appendix A) District personnel and Forest planning specialists met over several months to fine-tune and coordinate motorized access between Districts. Roads and trails were selected for restriction or closure depending on the need to maintain wildlife habitat, prevent resource damage, and to balance the level of use or recreation opportunity. Cost of maintaining the road or trail was also a factor. A set of Road Decision Criteria Tables have been developed, showing the decision in keeping roads and trails open in each Alternative. The tables are displayed in the 50 pages following page C-7, by Ranger District.

In some cases non-system trails and non-system roads were identified as needed for access, in managing the Forest. These roads and trails may not have Forest numbers assigned to them but if they remain on the Forest Transportation Inventory System, they will be given a name and a Forest number, for identification on Forest Maps and on the ground. The identification name and number will be given after the ROD has been signed.

All districts, with the exception of Island Park, used the method described above to determine District road and trail densities. Island Park Ranger District worked with the Intermountain Region using aerial photography to determine District road and trail densities. The results of this study show a total of 4,192 miles of existing roads and trails on the Forest, including both "system" and "non-system" roads and trails. Of these, 2,831 miles are being used by motorized vehicles and include roads and trails that have ineffective restrictions on them, such as gates, berms, etc. The remaining 1,361 miles of roads and trails are designated non-motorized. A total of 1,126,757 acres were identified as open for cross-country travel, but only 440,422 acres were identified as suitable for cross-country travel due to steep slopes or type of vegetation cover.

Comments received during public scoping on the Forest Plan revision in the spring of 1996 were considered and some suggestions were used in determining how the forest will implement access management in the future. A site-specific analysis will be used to determine which roads and trails will be closed, restricted, or obliterated. An interdisciplinary team will be prepared a separate analysis to address the 853 miles of roads and trails have been identified as "not necessary for administrative use" by the Forest. The analysis will include a cost estimate for this project.

Public acceptance and compliance with access management strategies will directly affect full implementation of other resource program objectives.

WINTER VISITOR ACCESS ANALYSIS PROCESS

In 1994, Yellowstone and Grand Teton National Parks in coordination with adjacent Forests, began a review of the 1990 Winter Use Plan. Winter visitors in and around the Park's boundaries were contacted and surveyed concerning possible issues and concerns with winter management or resource conditions. Yellowstone National Park was concerned that use levels had already reached levels forecast to be reached in future years. The purpose of the resulting Greater Yellowstone Winter Visitor Use Management (GYWVUM) assessment was to evaluate existing conditions and future opportunities for winter use management. During this time, the Targhee National Forest was completing an EIS for the Grand Targhee Ski Resort Master Development Plan. A significant issue during this analysis was concern for winter recreation use and wildlife conflict potential on the Teton Basin District. A commitment was made during this analysis to carry the findings of recent studies (e.g., Teton Basin District Winter Wildlife/Winter Recreation Management Plan—Draft) into the Forest Plan Analysis that was also underway. The purpose of incorporating this analysis into the Forest Plan revision was to get a broader picture of the concerns and proposed management actions so that a better planning job could be done and consultation with the US Fish and Wildlife Service could be done on a level of planning acceptable to that agency.

Since the Forest Plan Revision and GYWVUM planning processes were being conducted almost simultaneously, the winter use and wildlife analysis for the GYWVUM process were considered and incorporated into the Forest Plan. Analyses from the GYWVUM assessment which were used in the Forest Plan Revision include the following:

- Issues and concerns assessment based on surveys, public meetings, and public comments and letters
- Coordinated Goal Statements and Management Opportunities, based on an evaluation of the issues and the mapping of the following resource data:
 - a) actual recreation use areas
 - b) known winter range areas for wildlife
 - c) snow cover adequacy for winter activities
 - d) conflict areas between types of use or within uses
 - e) conflict areas between recreation and wildlife
 - f) closure areas
 - g) steep slopes or otherwise unusable areas
 - h) road and trail systems and access parking and facilities
 - i) avalanche and other hazard areas
 - j) trespass areas into the Parks, wilderness, or other closure

As this data and mapping was done for the GYWVUM assessment, much of the mapping was incorporated into the Winter Transportation Plan for the Forest Plan—Alternative 3M. Alternative Winter Transportation Plans and opportunities were also considered during the Forest Plan Revision analysis and EIS in other alternatives to the proposed Plan. As a result of this analysis, 93 miles of planned snowmachine routes were identified and added to the Alternative 3M Winter Transportation Plan. These routes were planned in areas away from winter range conflict areas in an attempt to provide users with additional opportunities and to reduce wildlife impacts. These routes would be marked and/or groomed in coordination with the counties in the future as additional capacity was determined to be needed, and as county funding and workload allows. These routes would be added to the Forest Travel Plan as they were developed.

This Winter Transportation Plan concept was reviewed with the public through numerous GYWVUM assessment meetings and through public review and comment on the Forest Plan Revision DEIS maps. Due to comments and administrative review of the draft Winter Transportation Plan, the following adjustments were made for the Final Forest Plan and FEIS:

• The following planned routes shown on the draft Winter Transportation Plan Map have been deleted from the final map

- a) Snow Creek Butte—deleted due to potential trespass concerns for Yellowstone National Park
- b) Cottonwood Creek and Camas Creek—deleted due to desire to manage these areas as undeveloped backcountry area
- c) Rainey Creek—deleted due to concerns with wintering wildlife and feed ground operations

The Forest Plan includes winter recreation Goals, Objectives, Standards, Guidelines, Prescriptions, and a Winter Transportation Plan which have been prepared in concert with the GYVVUM assessment analysis as much as possible. Not all of the pending guidelines of that assessment have been incorporated into the Forest Plan, but an objective was included in the Plan to address the remainder of the pending guidelines to provide for other winter opportunities. The objective states "By 2000, establish by prescriptions, Travel Plan designation or other method a few nonmotorized winter recreation activity areas with easy access for users such as telemark skiers, snowshoers, and snowboarders. Conform to results anticipated from the GYVVUM Assessment currently underway". The GYVVUM assessment is not scheduled to be completed until the end of 1997.

References to this process have been included in Chapters III and IV of the FEIS.

OPEN ROAD AND OPEN MOTORIZED TRAIL ROUTE (OROMTRD) DECISION CRITERIA TABLES

DEFINITIONS

Following are the definitions of the criteria used on the OROMTR Decision Criteria Tables:

- A. Core Access: Needed to access private property, adjoining State and Federal Parks or State Lands, and roads that access administrative sites, campgrounds and picnic areas, electronic sites, permitted communications sites, ski areas, boat ramps and special recreation sites such as Mesa Falls and Big Springs.
- B. First Priority: In some areas the application of management prescriptions and density standards resulted in this type of road/trail being the only facility designated "open" in the area.
- C. Eastside Ecosystem Management Project (EEMP) Guidelines: EEMP guidelines used to establish a rule set to insure consistency as each District prepared their access maps.
- D. Coordinated Access: Roads/trails that provide inter-District access.
- E. Maintenance of Wildlife Habitat: Road/trail selected causes less impact.
- F. Resource Damage: Road/trail selected caused less impact.
- G. Cost: Lower cost to maintain road/trail.
- H. District-specific criteria (if any).
- I. District-specific criteria (if any).

O	Implementing Ecosystem Management in Forest Plan Revisions (Sept 23, 1994)
P	Adjacent Land Use Patterns Analysis
Q	Roadless Areas
R	Wild, Scenic and Recreational Rivers Eligibility Determination
S	Recreational Use Projection Process for Targhee National Forest Plan Revision
T	Jedediah Smith Wilderness Environmental Assessment for Forest Plan Amendment
U	Supply, Demand and Production Potential
V	Key Indicators for Issue 1, Sustainability, Fire and Natural Disturbances
W	Draft Properly Functioning Condition (Sept 17, 1996)
X	Dispersed Camping Protocol for Monitoring Soil Quality
Y	Targhee National Forest Rangeland Monitoring Protocol
Z	Existing and Potential Rangeland Improvements

LIST OF PREPARERS

The following is a list of the current Forest Leadership Team (FLT) and Forest Interdisciplinary Team (IDT) members and others who developed the Targhee National Forest Plan, Final Environmental Impact Statement, and supporting documents

A Current Forest Leadership Team

Patricia Bates
District Ranger, Teton Basin Ranger District

Carol Cushing
Branch Chief for Land Management Planning

Ron Dickemore
District Ranger, Palisades Ranger District

Larry Gorringer
Branch Chief for Engineering, Lands, and Minerals

Adrienne Keller
District Ranger, Ashton and Island Park Ranger Districts

Ann Matejko
Public Affairs Officer

Mac Murdock
District Ranger, Dubois Ranger District

Jerry Reese
Forest Supervisor

Ric Rine
Branch Chief for Ecosystems

Chuck Sorenson
Administrative Officer, Branch Chief for Fire Management, Acting Forest Supervisor

B Forest Interdisciplinary Team (Present Members)

B Lynn Ballard

Natural Resource Specialist

Education B S , Forest Resource Management
Experience U S Forest Service
Timber Management - 14 years
Winter Sports Planning - 6 years
Function Core Team Member, Timber, and Insect & Disease

Leon Bleggi

Transportation Planner

Education Associate Degree, Engineering, Utah Valley Community College
Wildlife Management, University of Southern Utah
Experience. Bureau of Reclamation
Engineering Design and Inspection
Underwater Inspector (SCUBA Diver) - 8 Years
U S Forest Service
Engineering Design and Inspection - 11 years
Forest Transportation Planner - 12 years
Function Core Team Member, Engineering, Access Management, Facilities

Carol Cushing

Planning Branch Chief

Education B S , Forest Management
Experience U S Forest Service - 16 years
Function Planning Staff

Katina Harrison*

Function Document Preparation

Mark Orme

Wildlife Biologist

Education B S , Forestry, University of Idaho
M S , Wildlife Management, University of Idaho
Experience U S Forest Service - 14 5 years
University of Idaho - 2 years
Idaho Department of Fish and Game - 2 years
Function Wildlife Section

Dale Pekar

Team Leader, Forest Plan Revision

Education B A , Economics and Sociology
M S , Economics
Experience U S Army Corps of Engineers
U S Forest Service
Land Management Planning, Economic & Social Analysis -
19 years
Function Economic and Social Analysis

Alan R. Silker

Recreation Staff Officer

Education B S , Forest Management
M S , Forest Recreation Management
Experience U S Forest Service
Recreation Management - 25 years
Winter Sports Planning - 20 years
Function Developed and Dispersed Recreation, Roadless, Wilderness,
and Wild, Scenic, and Recreational Rivers analysis

Fred Straus

GIS Coordinator, Analyst

Education B A , Forest Management
Experience Peace Corps
U S Forest Service
Timber Management - 17 years
Function GIS, FORPLAN, Data Management, and Analysis

C Others Providing Substantial Contributions

Kendall Adams

Forest Land Surveyor

Education Cert Civil Technology
Experience Bureau of Reclamation
Surveyor - 5 years
U S Forest Service
Engineering - 9 years
Lands - 9 years
Function Lands

Bart Andreasen

Landscape Architect

Education B S , Landscape Architecture and Environmental Planning
Experience Bureau of Land Management
Visual Resources, Recreation Management - 1 year
U S Forest Service
Visual Resources, Recreation Management - 16 year
Function Visual Resources, Off-Highway Vehicles, and ROS

David Betz
Data Base Manager
Function GIS Analysis

Keith Birch
Forest Aviation and Fire Management Officer
Education B S , Forest/Range Management, Idaho State University
Experience U S Forest Service
Forest Engineering - 8 years
Range Management - 8 years
Recreation Management - 8 years
Fire Management - 7 years
Function Air Quality, and Fire

Brannon Bleggi*
Function Visual Resources

Bob Boyles
GIS/CEM Specialist
Education B S , Information Systems/Accounting, University of Nevada
Experience U S Army, Dept of Veteran Affairs
U S Forest Service
Function GIS and CEM Analysis

Dan Delany
Forest Fisheries Biologist
Education B S , Wildlife Management
Experience Bureau of Land Management
Range Management - 2 years
Fisheries and Wildlife Management - 14 years
U S Forest Service
New Perspectives - 1 year
Fisheries and Wildlife Management - 5 years
Function Fisheries and Aquatic Ecology

Kris Drewes
Forestry Technician
Function GIS Analysis

Rod Dykehouse
Forest Fuels Specialist
Education A A S , Forest Technology, Michigan Technology University
Experience U S Forest Service
Fire Management - 17 years
Function Fire, Air Quality, Jedediah Smith Wilderness Fire Management Plan

Ed Fischer
 Assistant Forest Planner

Education	B S , Forest Management, Michigan State University Course work completed toward M S in Silviculture at Oregon State University and University of Washington
Experience	U S Forest Service Forestry - 12 years Planning - 5 years
Function	Chapter 1, Wild and Scenic Rivers

Jim Gerber *
 Function Timber

Kevin Greenwood
 Island Park Ranger District
 Function Range

Walt Grows
 Range Management Specialist

Education	B S , Forest Recreation (major) B S , Range Management (minor)
Experience	U S Forest Service Resource Management - 20 years Forest Planner, Range Sub-Staff, District Ranger, Resource Officer (Assistant District Ranger), and Range Conservationist
Function.	Range, Acting Forest Planner

Jack Haddox
 Natural Resource Specialist
 Island Park Ranger District

Education	B S , Range and Forest Management, Colorado State University
Experience	U S Forest Service Range Management - 10 years Recreation Management - 8 years
Function	Recreation and Lands

Lynn Hansen*
 Function Lands

Gene Hardin
 Forester
 Island Park Ranger District

Education	B S , Forest Management, Clemson University Region 6 Silviculture Institute Oregon State University of Washington Wilderness Management, Colorado State University
Experience	U S Forest Service - 19 years
Function	Roadless Areas

James F Hayes*
 Operations Research Analyst
 Prospect Ranger District, Rogue River National Forest

Education	B A , Mathematics Graduate work in Systems Science and English Literature
Experience	Southern Oregon Regional Services Institute Urban Planning - 3 years U S Forest Service Land Management Planning - 11 years Project Planning - 3 years
Function	FORPLAN Modelling, Writer/Editor (Process Paper B)

Sue Heald*
 Forest Silviculturist

Education	B S , Forestry
Experience	U S Forest Service - 12 years
Function	Ecosystem Management Analysis, and Writer/Editor

Dusty Hincks
 Palisades Ranger District

Function	Range
----------	-------

Robin Jenkins
 Island Park Ranger District

Function	Wild, Scenic, and Recreational Rivers
----------	---------------------------------------

Bill Kirchhoff *

Function	GIS Analysis
----------	--------------

Bob Kirkpatrick *

Function	Facilities
----------	------------

Julie Lehmann*

Function	GIS Analysis
----------	--------------

Bill LeVere*

Lilly Mayer *

Function	Threatened, Endangered and Sensitive Species
----------	--

Maureen McBrien*, Past Forest Planner

Martha Merrill*

Function District Representative, Wilderness Specialist

Kaylene Monson

Rangeland Management Specialist

Palisades Ranger District

Education B S , Range Science
Experience U S Forest Service - 5 years
Function Range Management

Duane Monte

Soil Scientist

Education B S , Natural Resource Management/Biology - UWSP
Post Graduate Work - Soil Science - UWSP
University of Wisconsin - Stevens Point
Experience U S Soil Conservation Service - 4 Years
U S Forest Service -16 Years
Function Riparian, Wetlands, Aquatic Infln, and Soils section

Ronna Simon Monte

Hydrologist

Education B S , Geology
M S , Geography
M S , Watershed Management
Experience U S Forest Service
Watershed Management - 6 years
U S Geological Survey
Water Resource Monitoring, Quality Assurance - 1 year
Function Water section and assistance on Wetlands section

Craig Morris *

Function FORPLAN

Brent Porter

Recreation Forester

Palisades Ranger District

Education B S , Utah State University, 1972
Experience U S Forest Service since 1972
Recreation, Lands, and Trails - 20 years
Timber - 16 years
Minerals - 20 years
Function Recreation, Recreation Special Uses

Cheryl Probert Dubois Ranger District Function	Range
John Pruess Minerals Specialist Education Experience Function	B A , Liberal Arts, Gettysburg College M F , Timber Management, Duke University U S Forest Service - Timber - 16 years Minerals - 16 years Lands - 5 years Minerals and Lands sections
Betsy Rickards * Function	NFMA and NEPA Compliance
Robert Riley Supervisory Forester Function	Timber Public Involvement
Dee Sessions Forest Silviculturist Function	Public Involvement
Bill Shands * Function	Public Involvement
Greg Sorensen Teton Basin Ranger District Function	Range
Bob Specht Forest Botanist Education Experience Function	B S , Botany Bureau of Land Management Botanist - 1 year Range Technician - 2 years Range Conservationist - 1 year Soil Conservation Service Soil Conservationist - 1 1/2 years Range Conservationist - 6 years District Conservationist - 4 years U S Forest Service Botanist - 3 years Vegetation

Gretchen Straus *
Function Adjacency Analysis

Keith Tweedie
Dubois Ranger District
Function Range

Skip Willingham
Forest Archaeologist
Education B A , Anthropology and Philosophy, University of Alabama
Experience U S Forest Service
Heritage Resource Management - 13 years
Office of Archaeological Research, University of Alabama - 4 years
Function Heritage Resources

* - Not affiliated with the Targhee National Forest

**Recipi-
ents of
the FEIS**

Recipients of the FEIS

Copies of the FEIS and Forest Plan were distributed to the following government, state and local agencies, tribal governments, elected officials, organizations and businesses, and individuals. Copies of the FEIS and Forest Plan are available for review at all Forest offices.

THE PURPOSE OF APPENDIX A

Appendix A is a paraphrased summary and the Forest's responses to the substantive comments received during the public comment period of February 29 to June 27, 1996, about the Draft Revised Plan and the Draft Environmental Impact Statement. Letters received before the comment period or after the deadline were reviewed but were not formally acknowledged or analyzed.

New management direction and decisions were made after some of the responses to public comments were written. Although we tried to correct these as decisions changed, we may have missed correcting a few of them. If conflicts and discrepancies are noted, the Record of Decision, the FEIS, and the Final Revised Plan remain the official decision documents, not this Appendix.

BACKGROUND ON THE PUBLIC COMMENT PERIOD

A variety of methods were used to inform people about the draft and to seek input. These included mailings, news releases, newsletters, media interviews, open houses, executive summaries, copies in all local libraries, response forms for ease of response to key issues, meetings, an executive summary of the differences between the current plan and the proposed plan, and contacts with cooperators and other local, state and national agencies and organizations.

The Targhee emphasized the opportunity for extensive public involvement and one-on-one contact during the draft review -- a chance to ask questions, learn more about the issues, and provide input. To accomplish this, the Forest planning team and ranger district staffs held meetings about the draft plan between the dates of March to June throughout the local and extended communities served by the Targhee in Idaho in Ashton, Island Park, Dubois, Idaho Falls, Driggs, Blackfoot and Pocatello; in Wyoming in Jackson; and in Montana in West Yellowstone. The planning team also had meetings about the draft with all adjacent national forests, Bureau of Land Management offices, State Fish and Game agencies, and the U.S. Sheep Experiment Station; the two national parks; county commissioners; U.S. Fish and Wildlife Service; and the Shoshone-Bannock Tribal Council. The team presented information at additional meetings sponsored by other groups and organizations, at their request. Two meetings were held with all Targhee Forest Service employees.

COMMENTS AND ANALYSIS

The Targhee received 454 form Letters, 493 clip-out "coupons" sponsored by the Citizens for a User Friendly Forest (CUFF), 558 postcards sponsored by the Greater Yellowstone Coalition (GYC) and 663 individual letters for a total of 2,168. Another 200 form letters were received with illegible or missing names and addresses. All of these are available for public review at the Forest Supervisor's Office in St. Anthony. Appendix A is twice as large as the Plan and EIS and contains all substantive comments that were considered and addressed. Although Targhee employees and mailings emphasized that analysis of comments does not use vote counting, some groups persisted in sending in mass mailings of form letters, petitions, ballots, coupons and postcards. In the analysis, the same comment is listed once and is responded to once; these have an F (for Form letter) after them. Some Forest Service employees responded as Forest Service employees and their comments have a FS before their number. Copies of all letters signed by representatives of State or Federal Agencies or elected officials are reproduced at the back of the Appendix, as required by the National Environmental Policy Act. Responses

to these letters are treated the same as other comments and can be found throughout the appendix in the appropriate issue areas.

A 5-person team hired from the public-at-large and the public affairs officer analyzed the letters in their entirety, placing substantive comments under appropriate issue areas. Comments were reviewed by resource specialists, planners, and the leadership team to determine needs for further analysis and before making final decisions. Many decisions were changed or improved based on public comment. Most of these changes are explained in the responses of Appendix A and the Record of Decision.

The specialists or planners who coordinated the responses in Appendix A are indicated by their initial. The following Forest Service people coordinated responses: Lynn Ballard (LB); Leon Bleggi (LAB); John Councilman (JC); Walt Grows (WG); Mark Orme (MO); Megan Bogle (MLB); John Pruess (JP); Jerry Reese (JBR); Ed Fischer (EF); Dale Pekar (DP); Alan Silker (AS); Ann Matejko (AM); Ric Rine (RR); Carol Cushing (CC); Ronna Simon Monte (RSM); Duane Monte (DM); Dan Delany (DD); Fred Straus (FS); Jeff Larrieu (JL); Larry Gorringer (LG); Liz Davy (LD); Bud Alford (BA); Marynell Oechsner (MO5); Kendall Adams (KA); Dee Sessions (DS); Ron Dickemore (RD); Cheryl Probert (CP); Keith Tweedy (KT); Adrienne Keller (AK); Brent Porter (BP); and Mac Murdock (CMM).

COMMONLY USED ABBREVIATIONS

To shorten responses, the Forest abbreviated the following:

EIS = Environmental Impact Statement, the document that analyzes all the alternatives and shows the preferred one. DEIS is the draft. FEIS is the final.

Revised Plan = The Targhee National Forest Land Management Plan Revision, the preferred alternative 3-M, which will determine the direction of the Forest for the next 10 years. Sometimes the abbreviation is the "Final Revised Plan" to distinguish it from the Draft Revised Plan.

Targhee and the Forest = Targhee National Forest.

Respondents are from all geographical areas of the United States. Most respondents are from Idaho, followed by Utah, Wyoming, Montana. Attached is a list of every respondent next to his/her letter number.

DID ANYONE LISTEN TO ME? HOW TO FIND YOUR COMMENTS.

All substantive comments were read, considered and responded to. Some people think that if they don't get what they asked for, nobody listened. Although they may or may not get what they asked for, review of this document will show that they were heard. You can find your individual comments by checking your mail label or your letter number in the attached alphabetical list of individuals and organizations. Letters are usually filed under the name of the person who signed the letter, rather than the organization. Look up the subject of your comment, such as snowmobiling or grizzly bear, in the table of contents. Check the subheadings under the subject such as "snowmachines - dates." Look for your letter number under the issue areas.

ACCESS - 40% SLOPE

(CROSS REFERENCE: Soils; Riparian, Hydrologic Disturbance)

COMMENTS: Design effective road closures to "discourage" OHV use on slopes greater than 40 percent and list actions taken if violations occur.

1361

RESPONSE: The Revised Plan allows summer cross country motorized (OHV) use on only 7 percent of the Forest. The Revised Plan also provides OROMTRD standards for each management prescription. The collective effort of these is to reduce the miles of roads and trails open to motorized use. Those not open will be closed with effective closure devices. A new travel plan will implement the new restrictions. Law enforcement action can then be taken against violators. The Revised Plan also contains a guideline to discourage OHV use on slopes greater than 40 percent in the 7 percent of the Forest that is open. JR

COMMENTS: Create a standard which will prohibit OHV travel on steep slopes (e.g., greater than 25 degrees) and thus minimize risk for ATV use as well as erosion potential.

695, 697, 1273b, 1365

No hill climbing over 40-50% slope should be allowed.

FS-3

RESPONSE: Allowing travel on slopes up to 40 percent does not result in serious risk to OHV users. Recreation Standards and Guidelines for OHV use in Chapter III of the Revised Plan states that travel restrictions may be required in areas with 25-40 percent slopes if soil erosion factors warrant. Use is also restricted on identified areas of unstable soil. OHV use is permitted on designated routes and on roads and trails that may cross slopes that exceed 40 percent. The Revised Plan directly addresses the concern for OHV on steep slopes. The Revised Plan allows summer cross-country motorized use on only 7 percent of the Forest. The Revised Plan also has a guideline to discourage OHV use on slopes greater than 40 percent. LAB/TEM/JR

COMMENTS: Remove OHV restrictions on slopes of 25-40 percent.

693, 767

RESPONSE: In the Revised Plan, the Standards and Guidelines state that on slopes 25-40 percent the Forest may require travel restrictions, depending on soil erosion factors. The actual restrictions are provided in the Travel Plan which implements the Revised Plan. The Revised Plan allows OHV use on only 7 percent of the Forest to address a number of resource concerns. (Most areas closed to cross country also contain a good network of designated trails open to motorized use). LAB/TEM/JR

COMMENTS: In the case of 25-40 percent slope erosion concerns, clarify whether restrictions on use are imposed after erosion is identified, or if restrictions are imposed if soil erosion is suspected.

1361

RESPONSE: Most restrictions will appear in the Travel Plan which implements the Revised Plan. Only 7 percent of the Forest will be open to summer

ACCESS - 40% SLOPE

cross-country motorized use to address a variety of resource concerns (most areas also include a good network of designated trails which allow motorized use). In those areas remaining open, additional restrictions would occur only after monitoring and a site-specific analysis. JR

ACCESS - ANALYSIS PROCESS

More Comprehensive Analysis Needed

COMMENTS: The DEIS section of the cumulative impacts of roads on wildlife, soil and water of the forest should address whether those roads are under Targhee National Forest jurisdiction and management or not. The DEIS should also comprehensively address the issue of border roads as well.

1367b

Suggest a comprehensive road management and transportation plan evaluating the need for roads, how those needs are achieved and the impacts roads have on other forest resources. Restrictions should protect resources and public safety.

FS-11, FS-12, 389, 1345

The Plan should include a comprehensive review of the environmental and user impacts of the Recreational Management Plan on OHV use during the past ten years planning period due to the lack of a thorough monitoring/evaluation in original Revised Plan.

1365

RESPONSE: The FEIS addresses the impacts of roads on wildlife and other resources. The analysis for the Revised Plan is sufficient to address access management on National Forest System lands. For more detailed information, see the Access Appendix in the FEIS and Process Paper D, available in the Supervisor's Office. The analysis developed the standards for open road density for each management prescription. The mix of prescriptions and the amount of motorized access varies by alternative and the effects are compared in the FEIS.

The analysis does not include "border" roads outside the Forest boundary because doing so could be interpreted that the Forest Service has the authority to make management decisions for those roads. The road density standards only apply within the Forest boundary. For the same reason, the FEIS only addresses management direction for roads under Forest Service jurisdiction. The FEIS does provide a broader narrative view of the transportation system for Southeast Idaho to give a larger perspective.

The Analysis of the Management Situation provided the basic overview and update of the existing situation (the analysis of the past ten years). This defined the basis for need for change to mitigate environmental and user impacts. We disagree that there was a lack of thorough monitoring/evaluation in the original Plan. JBR/LRG

COMMENTS: Restrictions for off-road vehicles should be planned and implemented to protect resources and public safety.

1345

ACCESS - ANALYSIS PROCESS

RESPONSE: We agree. The Revised Plan restricts ORV use to protect resources and meet public safety needs. For example, 93 percent of the Forest is closed to summer cross-country motorized use in the Revised Plan. The Revised Plan also sets road and trail density standards to meet the needs of other resources. These standards resulted in fewer roads and trails being open for motorized use than is currently the case. JBR

COMMENTS: The DFPR and DEIS need to include: more analysis, stricter standard and guidelines, better methods and science, and adherence to environmental laws because of road closures and the monitoring program.

1361

RESPONSE: The road analysis in the FEIS and the Revised Plan is adequate to address the issues and provide a basis for decisionmaking (see previous response). Appropriate management prescriptions were developed and applied on the ground, along with Forestwide standards and guidelines to address resource concerns and public issues. Appropriate scientific information was used in this analysis. This is particularly true for development of road density standards to meet goals to reduce elk vulnerability, increase habitat effectiveness for elk, and to improve grizzly habitat. The monitoring of road closure effectiveness is a number one priority for the Revised Plan's monitoring. The travel management standards and guidelines are in compliance with applicable laws and regulations. JBR

Wildlife Analysis

COMMENTS: Harassment of wildlife by OHV's is not adequately considered in the Plan analysis, prescriptions or standards and guidelines.

1365

RESPONSE: We disagree. The needs of wildlife species, particularly elk and grizzly bears, were analyzed in depth and provide the basis for restrictions on cross-country motorized use by OHVs and reductions in the road density for motorized vehicles in the Revised Plan. Approximately 93 percent of the Forest is closed to summer cross-country motorized use in the Revised Plan and winter cross-country travel by snow machines is restricted to designated routes through big game winter ranges. These changes respond directly to concerns about harassment of wildlife from OHVs. JBR

COMMENTS: Proposed access program and analysis fails to recognize the beneficial effects on fish, wildlife, water quality, recreation or local economy.

1195

RESPONSE: The FEIS displays the positive and negative effects from implementing the Revised Plan and compares them to the other alternatives considered. The reductions in motorized access in the Revised Plan were developed with the objective of providing beneficial effects for wildlife and fish habitats and water quality. Changes anticipated in recreation opportunities are displayed in the FEIS and are both positive and negative. The effects on the local economy are difficult to quantify but are described in the economic analysis in the FEIS. JBR

ACCESS - ANALYSIS PROCESS

COMMENTS: Evaluate impacts the lack of road standards have on wildlife use and population in timber management areas.

1369

RESPONSE: The construction standards for particular roads will be decided in site-specific analysis when projects are proposed and will be based on project objectives and compliance with Standards and Guidelines in the Revised Plan. Timber access roads specified will be the lowest suitable standard that still facilitates removal of the harvested trees. Most new roads will be closed after removal of the timber to meet road density standards in the Revised Plan.

The impacts on wildlife are more related to the density of roads than the particular road construction standards. The impacts of roads are adequately addressed in the FEIS and the Revised Plan contains specific standards for road density that are designed to be compatible with wildlife habitat objectives. JBR

COMMENTS: Clarify the basis for such high OROMTRD standards of up to 2.0 miles per square mile and lower this standard to protect elk and deer. (CROSS REFERENCE: Access, Wildlife)

1273b

RESPONSE: Most management prescriptions have OROMTRD standards between 1.5 miles per square mile and 0.0 miles per square mile to address wildlife habitat objectives.

Only three prescriptions in the Revised Plan have OROMTRD standards higher than 1.5 miles per square mile. Prescription 5.1.3 (b) is an urban interface prescription and has a standard of 3 miles per square mile. The density relates to the developed nature of the lands, with summer homes, adjacent private land developments and similar human activities. Where this prescription overlaps winter range, the winter range area is restricted to designated routes for snowmachines in winter. Prescription 6.1 is a range management prescription with a density standard of 2 miles per square mile. No conflicts were identified with wildlife or other resources in areas where this management prescription applies that would dictate a lower density. Again where this prescription overlaps winter ranges, the winter motorized use is restricted to designated routes. Prescription 2.7 is the winter range prescription with a summer motorized density standard of 2 miles per square mile. Since wildlife are not concentrated on winter ranges during the summer, no need was identified to restrict motorized use beyond this level. Winter motorized access is limited to a few designated routes. JBR

COMMENTS: Add a provision to prohibit motorized activities if they conflict with the primary goal of providing and protecting big game habitat.

389, 640

RESPONSE: The Revised Plan includes specific management direction regarding motorized use. The road density standards for each prescription are specifically designed to meet wildlife habitat objectives (refer to Process Paper D in the Supervisor's Office for more detail). Cross-country motorized use is greatly reduced in the Revised Plan and roads and trails open to motorized use are reduced. JBR

ACCESS - ANALYSIS PROCESS

COMMENTS: The Plan should acknowledge that road density is significant in habitat management for the lynx and wolverines, both of which are in the Forest Service Region 4 Support List. (CROSS REFERENCE: Wildlife)

389

RESPONSE: The road densities provided in the Revised Plan are designed to meet the needs for wildlife habitat protection. The densities will meet the habitat requirements for viable populations of lynx and wolverine. JBR

COMMENTS: The Plan fails to recognize that the OROMTRD in BMUs does not address access of motorbikes in those areas. (CROSS REFERENCE: Road Density)

1361, 1367a

RESPONSE: The Revised Plan specifically addresses access of motorbikes in the BMUs. OROMTRD standards include all types of motorized use, whether cross country or on roads or trails, and include motorbikes. No motorized use of any kind is allowed in grizzly bear "core" areas and each BMU has an OROMTRD standard of less than or equal to 0.6 miles per square mile of motorized access routes, whether roads or trails. JBR

COMMENTS: The draft does not examine issues of fragmentation, edge effects, other impacts of roads on species other than elk and grizzly bear.

1365

RESPONSE: New information and analysis is in the FEIS concerning fragmentation. The effects on many other species besides elk and grizzly bears are presented in the FEIS and standards and guidelines are included in the Revised Plan to address habitat needs of those species. MO/JBR

COMMENTS: Recommend adding "Big Game Summer/Winter" to any list prioritizing or emphasizing implementation of motorized access.

766

RESPONSE: All acres on the Targhee National Forest were considered in the analysis of motorized access. Standards for each prescription address "Big Game Summer/Winter" issues (See Process Paper D in the Supervisor's Office and the Access Appendix in the FEIS for more details on the process used). MO/BBP

COMMENTS: Plan needs to include references and full citation to support the management direction and activities for big game security, winter and summer range.

389, 1365, 1369

RESPONSE: All references cited are located in the Access Appendix of the FEIS and in Process Paper D in the Supervisor's Office. BBP/MO

COMMENTS: Monitor BMUs when determining road closures.

58

RESPONSE: Monitoring road closure effectiveness is a priority #1 in the monitoring plan for the Revised Plan. Monitoring road closures in BMUs

ACCESS - ANALYSIS PROCESS

receives such high emphasis because successful road closures are necessary to achieve grizzly bear habitat objectives. BBP/JR

COMMENTS: Plan should integrate Key Issues 3-5 when addressing the impacts of roads on Threatened and Endangered Species.

1204

RESPONSE: All threatened and endangered (T&E) species were selected as Management Indicator Species for the Revised Plan and FEIS as documented in Process Paper D in the Supervisor's Office. The Revised Plan sets OROMTRD standards that address effects of roads and trails on T&E species. The effects are displayed in the FEIS and the Biological Assessment submitted for consultation with the U.S. Fish and Wildlife Service. BBP/MO

Single Track Trails

COMMENTS: The Plan equates single-track trails where motorized use occurs with a road and without any scientific basis and in face of significant opposition. Trails should not receive the same weight as roads. Consider using a Northern Idaho process which weighs motorized trails 1/10th the value of motorized roads with their impact on wildlife.

The analysis needs to compare the effects of single-track OHV trails to the forest roads maintained at various levels; recommend allowing wheel motorized access on trails unless otherwise designed; oppose converting single-track trails to be more accessible. (CROSS REFERENCE: Access, OHV; Wildlife)

629a, 1202, 1260

RESPONSE: To address these comments, a new analysis was completed between the Draft EIS and the FEIS to see what the differences might be using the two weighing systems. The results are presented in detail in the FEIS. Over the Forest, minor differences were noted between the two systems. The percent of the Forest meeting elk vulnerability objectives does not change. Elk vulnerability changes only 1 percent and elk habitat effectiveness changes 3 percent. Little difference in the amount of open motorized roads and trails is noted in the majority of watersheds.

Neither system has research which specifically supports one approach over the other. In fact, no research exists that objectively compares trail use to road use. Therefore, the Forest used the same process outlined in the DEIS and Process Paper D, which has been concurred with by the the Idaho Fish and Game Department and the Wyoming Game and Fish Department. The Northern Idaho process remains a draft and has not been adopted.

The reasons that the differences are minor in most watersheds are because: 1) Motorized trails account for 23 percent of the total motorized road and trail miles on the Forest. When cross-country motorized use is included (as described in Process Paper D) then only 10 percent of the motorized use is accounted for on trails. 2) The trail system is not equally distributed across the Forest, and in those drainages where most of the motorized trails occur, the trail densities are generally low (which means they have less effect in the EV and EHE analysis). 3) Motorized access on trails is only one factor in EV and EHE analysis; the factors such as hunter densities for EV and cover for EHE also contribute to the analysis. MO/JBR

ACCESS - ANALYSIS PROCESS

Non-System Roads

COMMENTS: Non-system road analysis is flawed. Analyze non-system roads per NFMA and Forest Manual direction.

1273b, 1361, 1365, 1367b

RESPONSE: Refer to Section II, Physical Elements, of the FEIS where nonsystem road closures are addressed. Each alternative includes differing mileages of open and closed roads. In any alternative, non-system ("ghost") roads are either added to the road inventory or closed. This complies with the intent of NFMA and Manual direction.

Correspondingly, the Revised Plan retains some non-system roads and trails, which will be made "system" roads and trails and added to the Forest travel maps. All roads not identified as part of the Forest Development Road System and not shown on the Forest Inventory will be closed after a site-specific analysis determines the method of closure, as funding permits. LRG

COMMENTS: Concerned how the Targhee National Forest proposes to address non-system road creation because of the negative impacts to resources if mileage from unauthorized roads are not contained for the duration of the Plan process. List all non-system roads and when they were created.

1273b, 1361

RESPONSE: This Revised Plan makes major changes in access management compared to the previous plan. The majority of the forest lands now will be managed as closed with access limited to designated routes. Indiscriminate cross-country travel is mostly prohibited (only 7 percent of the Forest is open to cross-country motorized travel in the summer). This type of use in the past facilitated the proliferation of non-system roads. With controls in place, unauthorized non-system road creation will be contained.

All non-system roads that we discovered were mapped and are included in the access analysis. However, many have never been named or numbered. The Forest does not know when most of these roads were created and that information is not needed to determine future management. The complete analysis of roads is summarized in the Access Appendix in the FEIS. LRG

COMMENTS: Designate uninventoried trails as a part of effective trail closure. Obliterate the 363 miles of non-system roads and 98 miles of non-system trails you are leaving open illegally.

1332, 1361

Justify why the Plan allows "created" routes to be "legal." Should not have included roads and trails illegally created/used by OHV users as legal routes.

1365

RESPONSE: The Revised Plan directly addresses this issue. During the planning process all roads and trails were inventoried, including "ghost" roads and motorized trails. Trails and roads which are to remain open will be added to the Forest Development System. Those not needed will be closed, with site-specific analysis determining the type of closure. The analysis is more fully described in Access Appendix in the FEIS. JBR

ACCESS - ANALYSIS PROCESS

COMMENTS: Define "historic recreation use" in road closure guideline. NFMA requires reclamation of non-system roads within ten years of their creation and therefore the definition of historic recreation use should not violate NFMA.

1361

RESPONSE: Historic recreation use relates to recreation use that has developed over time on either "system" or "nonsystem" roads and trails. The Revised Plan used historic use as one criterion for determining whether a particular road or trail should remain open or be closed. If designated as open, the road/trail will be added to the Forest Development System as described in previous responses. Other roads and trails will be closed.
JBR

COMMENTS: Consider more thoroughly the overall impacts of OHV use in the Plan. Disagree that there are no serious widespread adverse consequences as a result of rapidly increasing OHV use.

1365, 1367a

RESPONSE: The effects of OHV use are directly addressed in the Revised Plan and are described in the FEIS (see previous responses). The term "widespread" has a wide range of interpretations. The FEIS states that the problems exist in several places on the Targhee, but problems do not cover large areas. Sections along most trails are not currently suitable for motorized use because they were not originally designed for that use. However, most trails can accommodate the use and the bad sections can be relocated or reconstructed to eliminate the concern. In simple terms, the problems are mostly localized and can be corrected. JBR

COMMENTS: Because the Targhee's OHV data base is insufficient, need to perform floral/fauna inventory (regarding OHV/Recreation Impacts); and establish complete baseline ecological data for a thorough monitoring and evaluation plan.

1365

RESPONSE: The Revised Plan provides appropriate direction to guide our management of OHV use across the Forest. The Forest does not need a complete floral/faunal inventory to take appropriate actions. As site-specific analyses are completed to implement road and trail improvement projects, these surveys will be completed and used to guide location and design of specific roads and trails. Monitoring items are included in the Revised Plan to review the success of management and to identify new site-specific problems. Only 7 percent of the Forest will be open to summer cross-country motorized use in the Revised Plan and a significant reduction will occur in open motorized roads and trails. JBR

Include Roads Scholar Project in Analysis

COMMENTS: Need data on road closure effectiveness, suggest using Roads Scholar Program. Also, current data indicates ineffective monitoring, could use RSP to develop new measures.

643, 1361

ACCESS - ANALYSIS PROCESS

RESPONSE: The Forest has the information from the Roads Scholar program and will use it where appropriate. The definitions of "effective closure" and similar terms used in the Revised Plan conform to the Interagency Grizzly Bear Committee definitions and/or to the definitions agreed to with the Idaho Fish and Game and the Wyoming Game and Fish Departments. These are not the same definitions used in the Roads Scholar report (see Process Paper D in the Supervisor's Office for more detail). The Forest conducted an extensive inventory of all roads and trails, including "ghost" roads and considered them in the analysis (see the Access Appendix in the FEIS). Roads and trails which are retained are added to the Forest Development System. The others will be closed or obliterated. Only 7 percent of the Forest is open to summer cross-country motorized use in the Revised Plan. This will prohibit use on any routes not designated as open. Monitoring of road closure effectiveness is a number one priority for the Revised Plan. JBR

COMMENTS: Suggest using the Visitor Impact Management Access (Graefe, Kruss, Vashe).

1365

RESPONSE: The analysis, monitoring, goals and objectives, and other management direction adequately address the access issue and are based on studies cited in the References and Access Appendix in the FEIS. JBR/AS

Concerns about Road Analysis

COMMENTS: Designate all existing and proposed roads, trails, air fields, and other facilities as Forest Management transportation facilities.

1361

RESPONSE: These facilities are routinely included in the Forest transportation inventory system. All facilities not scheduled for permanent closure or obliteration will be added to the inventory, if not already included (see previous responses). JBR

COMMENTS: The open road analysis is egregiously flawed and uses simplistic assumptions: treats road closures as 100% effective; does not consider non-inventory roads or restricted road usage data; treats roads reclaimed/obliterated between 1981-1993 as absent; monitoring of road closures in priority level 2. (CROSS REFERENCE: Access, Roads)

375, 643, 697, 1277, 1361

RESPONSE: The assumptions in the open road analysis are consistent with the Interagency Grizzly Bear Committee Access Report and/or the agreements with Idaho Fish and Game and the Wyoming Game and Fish Departments. The analysis process considered all the items listed. See Process Paper D in the Supervisor's Office for details on Wildlife Analysis and the Access Appendix in the FEIS for the specific analysis of roads and trails. The Revised Plan directly addresses access concerns and the effects are displayed in the FEIS. Monitoring of road closure effectiveness was moved to priority one in the monitoring plan. JBR

ACCESS - ANALYSIS PROCESS

COMMENTS: Analysis should include an evaluation of the need for roads on forest and their impacts on other resources, such as: spread of disease and insects; hunting and fishing access; and, recreational opportunities.

325, 389, 697, 1195, 1276, 1368

RESPONSE: Development of a balanced transportation system, which meets the needs of users and managers, while protecting other resources, is a major focus of the Revised Plan. The effects of the changes in access are displayed in the FEIS. A primary concern was the effects on wildlife of a high density of roads and cross-country motorized access. Extensive analysis inventoried all roads and trails, including ghost roads, and identified areas of cross-country motorized use. The analysis is detailed in Process Paper D, in the Supervisor's Office and the Access Appendix in the FEIS. Only 7 percent of the Forest is open to summer cross-country motorized use in the Revised Plan and OROMTRD standards are established for each prescription which collectively reduce the miles of roads and trails open to motorized use. This reduces some recreational opportunities and increases others, as described in the FEIS. Standard procedures such as requiring certified weed free hay on the Forest and specific revegetation/treatment guidelines for activities causing soil disturbance address the spread of noxious weeds. Roads and trails do not have significant effect on spread of insects and diseases, and any such effects are reduced from the present. JBR.

COMMENTS: Recommends an additional EIS be done to evaluate impacts of road closure methods, which in turn will decide monitoring methods.

1206

RESPONSE: We disagree. Evaluation of impacts of road closure methods and corresponding decisions regarding monitoring methods are adequately covered in the Revised Plan. Additional site-specific analysis will be done to determine specifically "how" to close individual roads and trails scheduled for closure in the Revised Plan, such as obliteration versus gating. JBR

COMMENTS: Plan should require both access routes to recreation areas and traffic patterns to these areas be planned to avoid impact to sensitive species/area.

1365

RESPONSE: A site-specific NEPA document will assess the potential impacts on sensitive species and areas. Such analysis is standard Forest Service policy which is not repeated in the Revised Plan. All such projects will be surveyed by a qualified botanist and wildlife biologist to identify and address impacts to sensitive plant and animal species. JBR

COMMENTS: Plan needs to show how the forest evaluated the differing effect of forest levels 2 and 3 roads on forest natural resources.

1260

RESPONSE: In assessing the effects of roads on other resources at the Forest Plan level, road density is much more critical than the road maintenance level. While there may be some difference in the amount of traffic between the different maintenance levels, this is minor compared to the effects of

ACCESS - ANALYSIS PROCESS

road density. The standards for road density are established in the Revised Plan. Maintenance level is an operational decision based on site-specific use for the road. JBR

COMMENTS: When implementing the preferred Alternative, must consider gravel roads and trails as resources.

FS-12

RESPONSE: While the Plan does not directly state this, we agree that the infrastructure, which includes gravel roads and trails, is a resource needing proper management. LRG

COMMENTS: Change language to, "a road closure and reclamation project will ensure the signing of the Record of Decision of the Forest Plan." In addition, this section needs to specify inventoried and non-inventoried roads.

643

RESPONSE: The Revised Plan includes objectives to complete road closures and/or reclamation within three years of signing the Record of Decision in the Bear Management Units and by 2007 in the remainder of the Forest. This is a realistic schedule given funding constraints. We signed a site-specific Travel Plan decision implementing the road density standards in the Revised Plan at the same time the ROD was signed for the Revised Plan. Open routes will be designated on the ground and on maps immediately and enforcement of the Travel Plan will begin. Actual gates and other restrictive devices will be installed within three years in the BMUs and by 2007 on the remainder of the Forest. As stated in previous responses, all open roads are added to the Forest Development System and the others will be closed or obliterated. JBR

COMMENTS: Explain how Targhee National Forest will effectively manage these lands without a thorough inventory of existing roads and trails; state when the last on-the-ground road inventory occurred.

1273b, 1361

RESPONSE: A thorough inventory of existing roads and trails exists to manage Targhee National Forest lands. A specific effort was made to inventory all roads and trails, including "ghost" roads as part of the Revised Plan effort. See the Access Appendix in the FEIS for details. The most recent inventory was in 1996. The inventory is routinely updated each year. JBR

National/State Highways

COMMENTS: Corridors for maintaining connectivity along I-15/Highway 20 should be identified in the Plan so mitigation can be pursued with Highway Management.

1206

State highways passing through the Targhee National Forest should be in road analysis figures.

1367b

RESPONSE: State highways were included in road density calculations where they cross the Forest and they are included in the analysis. We disagree that the Plan needs to address connectivity corridors along I-15 and Highway 20. These can be addressed at the site-specific level within the Standards and Guidelines in the Revised Plan as problems are identified. If the intent is to reroute these major highways for this purpose it is outside the scope of the Revised Plan. JBR

COMMENTS: Spend more time explaining what is needed (e.g. I-15/Highway 20) than only speaking to road closures.

FS-12

RESPONSE: Road and trail access and the effects of roads and trails on other resources are key issues addressed by the Revised Plan. The Revised Plan explains key goals and objectives to be achieved in arriving at a Desired Future Condition. A standard is established in each Prescription for road density, which includes the major highways. Where current road density exceeds the standard, roads are scheduled for closure and obliteration. In no case does the Revised Plan suggest that a major highway be closed (see the Access Appendix in the FEIS). The Revised Plan and FEIS address road closures because in most cases the existing transportation system is larger than the desired future transportation system. JBR.

COMMENTS: Address the impact that highways have on rare carnivores and other wildlife species.

1206

RESPONSE: The existing highways are included in road density calculations that assess compliance with the OROMTRD standards in the Revised Plan. To a great extent, these density standards were determined by wildlife habitat needs (see the Process Paper D in the Supervisor's Office). The effects on wildlife are also displayed in the FEIS.

Consideration of future highway construction is outside the scope of the Forest Planning Process. The development of major highways on the Forest falls under the authority of the Federal Highway Administration (FHWA), not the Forest Service. When warranted, FHWA will from time to time propose to construct or reconstruct segments of these routes, initiate the NEPA process and seek public input. During this process, impacts on rare carnivores and other wildlife species are addressed. LRG

More Definition Needed

COMMENTS: Define the Forest Plan goals for the following problems: dirt bikes/four wheelers create new routed trails in Island Park and Centennials; riparian /wet meadows are deeply rutted along Henry's Fork; ghost roads are traveled regularly; roads previously closed are traveled in spite of gates/berms.

697

RESPONSE: The Revised Plan establishes OROMTRD standards for each prescription and the collective effect of these is to reduce the roads and

ACCESS - ANALYSIS PROCESS

trails open for motorized use. Only 7 percent of the Forest will be open to summer cross-country motorized use under the Revised Plan. These changes will directly address the concerns listed. For specifics, review the access tables for the prescriptions in Island Park and the Centennials and the new Forest Travel Plan. The analysis is detailed in the Access Appendix in the FEIS. The Forest intends to enforce these restrictions effectively. Monitoring the effectiveness of road closures is a number one priority in the monitoring plan for the Revised Plan. JBR

COMMENTS: The DFPR states net forest development road mileage will not increase. Clarify whether this is for open roads or all forest development roads. Plan should also clarify that the construction of temporary roads is new road construction.

667, 1273b, 1361, 1446

RESPONSE: The goal which includes this reference was removed in the Final Revised Plan because the Revised Plan provides specific OROMORTD standards for each prescription. We agree that the goal is confusing.

Construction of temporary roads must also conform to the density standards for the prescriptions. For example, if a temporary road is constructed that would exceed the road density standard for a particular prescription, another road of comparable mileage must be closed to achieve the density standard for the time that the temporary road is in use. JBR

COMMENTS: Does not support "designated routes" because it would be difficult to modify in the future.

1202

RESPONSE: The Revised Plan retains designated routes. This is the only feasible way to enforce road restrictions where areas are closed to summer cross-country motorized use. Only 7 percent of the Forest is open to cross-country motorized use in the Revised Plan. Modification of these routes can be done with a site-specific NEPA document documenting the rationale for the change with appropriate public involvement. JBR

COMMENTS: The Plan needs to consider OHV impacts on: loss of vegetation which is food and cover for wildlife; loss of structural variability/reduction in small mammal population; reduction of reptile number, diversity, bio mass and species richness; loss of migrating bird habitat, populations, and nesting areas; increase in mortality through harassment and shooting; feeding and spatial-use pattern that leads to decreased reproductivity; noise impacts wildlife by increasing nest and juvenile predation on birds and other wildlife which is exuberated after nightfall.

1365

RESPONSE: The Revised Plan and FEIS appropriately consider the impacts of OHV on wildlife habitat. The road and trail density standards in the Revised Plan in conjunction with other Standards and Guidelines provide for the habitat needs of the listed species. Cross-country motorized use by OHV is allowed on only 7 percent of the Forest. Collectively, a significant reduction in open motorized road and trails is provided in the Revised Plan. Not every wildlife species is evaluated separately in the FEIS; instead Management Indicator

ACCESS - ANALYSIS PROCESS

Species are used. Also, the direction for achieving Properly Functioning Condition provides for functioning ecosystems across the Forest with appropriate structure, species composition, and so forth for species dependent on these ecosystems. JBR.

COMMENTS: Disagree that (DEIS III-58) there are no serious widespread adverse consequences as a result of "rapidly increasing" OHV use.

1365

RESPONSE: DEIS III-58 describes the current situation regarding OHV use as not causing widespread adverse consequences. This section goes on to say that concern for OHV effects on soil and vegetation do exist in areas of highest concentrations such as the Big Hole Mountains/Palisades and Caribou Subsections and it is possible that motorized use is affecting some big game wildlife habitat potential or vulnerability to hunting pressure. These areas will be evaluated and measures established to correct the problems. The effects of OHV use are displayed in the FEIS and specific standards and guidelines are provided in the Revised Plan to address problems (see previous responses). JBR

COMMENTS: The Plan should close more than the 764 miles of existing roads and trails.

1367b

RESPONSE: The Revised Plan provides specific OROMRTD standards for each prescription area. Where existing open motorized road and trail route density exceeds these standards, specific roads and trails are identified for closure. The effects are displayed in the FEIS. A site-specific travel plan to implement the Revised Plan is also provided. The analysis is described in detail in Process Paper D in the Supervisor's Office and the Access Appendix in the FEIS. JBR

COMMENTS: The Plan should truly effect road/trail closures that will in fact regulate access and help restore wildlife security.

690

RESPONSE: We agree. The Revised Plan specifically provides for this. Thank you for your comment. JBR

COMMENTS: The final plan should change policy of allowing motorized bikes into non-motorized areas.

1273b

RESPONSE: The Revised Plan specifically establishes by prescription whether motorized bikes are allowed, either cross-country or on designated routes. Summer cross-country travel is allowed on only 7 percent of the Forest. Several prescriptions do not allow motorized use. Overall, a balance of motorized and non-motorized recreation opportunities is provided. JBR.

COMMENTS: Road closures that are being violated and have not been remedied should be in TMARD and OMTARD statistics.

1361

ACCESS - ANALYSIS PROCESS

RESPONSE: Road closures that are being violated highlight the need for more rigorous law enforcement action and/or the need to provide better physical restrictive devices. Monitoring of closure effectiveness is a number one priority in the monitoring plan for the Revised Plan because of the importance of maintaining effective closures. The OROMTR density standards set the upper limit and define the access density needed by prescription. Forest efforts will be focused on achieving those standards. JBR

COMMENTS: Justification of further restrictions on motorized recreation has not been proved.

300

RESPONSE: Considerable research documents the effects of motorized travel on roads to wildlife species like elk and grizzly bears. The Forest has monitoring information on erosion from road and trail systems on the Forest as well as considerable watershed and sedimentation research documenting the effects of roads and trails on water quality and fish habitat. This information was used to develop standards and guidelines for the Revised Plan. For specific references, refer to Process Paper D available in the Supervisor's Office and the Access Appendix and the references cited in the FEIS. JBR

COMMENTS: Plan should include research on trails as much as was done on roads.

1202

RESPONSE: Little specific research is available on the effects of trails, particularly the effects of motorized trails on wildlife populations. However, the information available along with professional judgments by resource specialists provide sufficient information to address trails in the Revised Plan. Monitoring will determine the effectiveness of the direction in the Revised Plan and changes can be made if necessary. JBR.

COMMENTS: Analysis is not specific enough on how road closures will be re-evaluated or changed.

697

RESPONSE: Site-specific analysis with public involvement will be the vehicle for re-evaluating road closures and making changes as necessary. Monitoring information will be used to determine the need to initiate a change. JBR

COMMENTS: Add to the DEIS any roads not in your inventory to be monitored.

1367

RESPONSE: Roads to be retained in the Revised Forest Plan will be added to the Forest Transportation System and will be monitored. Those scheduled for closure will be closed or obliterated and removed from the inventory. Monitoring will be done to assure the closures are effective as a number one priority in the monitoring plan for the Revised Plan. JBR

COMMENTS: Plan should receive more explicit attention to road closures.

489

ACCESS - ANALYSIS PROCESS

RESPONSE: The Revised Plan explicitly addresses road and trail access as a key issue, including closures where necessary. See previous responses. JBR

COMMENTS: The analysis is misguided/reckless in determining the difference between motorized access and human access.

496

RESPONSE: The studies that assess the environmental and social impacts associated with motorized and human access are sufficiently detailed and comprehensive to allow enlightened decisions in the Revised Plan. See previous responses. JBR

ACCESS - CROSS-COUNTRY

Cross-Country Summer - Non Support Restrictions

COMMENTS: Oppose proposed restrictions on summer cross-country access; support more access or at least keep at current management levels.

6, 21, 24, 26, 27, 28, 29, 30, 35, 36, 39, 40, 41, 43, 44, 45, 46, 47, 49, 50, 52, 53, 54, 55, 258, 285, 292, 316, 319, 337, 338, 347, 370, 413, 447, 481, 645, 645b, 646, 687, 1311, 1316, 1317, 1390, 1449

Disagrees with the Plan's duplication of road closures and summer OHV cross-country restrictions.

694

RESPONSE: Impacts to resources is occurring in many areas on the Forest due to the large increase in off-highway vehicles. Because of this, the Revised Plan redirects the future use of OHVs by restricting cross-country access. Each area on the Forest is covered by a management prescription which has road densities that determine how many roads are allowed in a particular area. The road densities are beneficial to wildlife and other resources. CMM

Support Restrictions

COMMENTS: Support restrictions on cross-country motorized travel to protect Forest resources and habitat. Eliminate cross-country motorized travel.

F-K(4), 1, 5, 27, 41, 42, 45, 62, 143, 156, 158, 161, 173, 176, 200, 212, 219, 227, 258, 266, 293, 305, 311, 312, 325, 351, 354, 356, 357, 373, 389, 391, 392, 406, 489, 610, 611, 625a, 631, 632, 643, 644, 645, 650, 655, 659, 662, 665, 667, 669, 687, 695, 697, 1247, 1257, 1258, 1273b, 1276, 1311, 1312, 1330, 1331, 1339, 1365, 1367b, 1371, 1378, 1387, 1388, 1395, 1399

RESPONSE: The Revised Plan eliminates summer cross-country motorized travel in all but seven percent of the Forest. CMM

Suggestions

COMMENTS: Partition the forest for various uses; close some areas to OHVs (summer) to protect wildlife/watershed values, reduce conflict with foot/stock

ACCESS - CROSS-COUNTRY

uses and give OHVs (summer) other places to go. (CROSS REFERENCE: Social Concerns)

5, 161, 173

RESPONSE: The Forest examined areas that can provide additional OHV (summer) use. Additional access will balance with the resource objectives in the Revised Plan. Education in trail etiquette for users is encouraged to reduce conflicts with foot stock and OHV. CMM

COMMENTS: The demand for cross-country opportunities should be equated to other recreational use, then enforced.

12

RESPONSE: Cross-country opportunities are considered in the road density for each prescription in a watershed. If a new opportunity is recognized it will be evaluated in relationship to the road density for that area. In most areas of the Forest there is adequate access and cross-country travel is unnecessary. Enforcement of the new travel plan receives high priority in the Revised Plan. LAB/CMM

Cross-Country Summer

COMMENTS: Change April 1 date for opening up winter range due to stress and mortality caused to ungulates by OHV travel.

643

RESPONSE: In winter range, OHVs are restricted to designated routes. After April 1, OHVs are still restricted to designated routes. OHV summer cross-country travel is restricted year-around. Changing the April 1st date will not change the use season for OHVs. The April 1st date pertains to people on foot, horseback, or mountain bike. CMM

COMMENTS: Use weather conditions and consultation with State game biologists to determine opening dates for summer cross-country travel.

643

RESPONSE: Only a few areas on the Forest are open to cross-country travel and the ground and weather conditions will determine when the summer travel plan will begin. Winter Range Prescription 2.7 (a) and (b) have special dates and conditions. Reference the 2.7 Prescription access table in Chapter III of the Revised Plan for the winter range conditions. There is no cross-country motorized travel allowed in winter range yearlong. CMM

COMMENTS: Allow cross-country use from June 15 to approximately October 10.

767

RESPONSE: Seven percent of the Forest is open to cross-country travel from early summer to Thanksgiving. The opening date to implement the summer travel plan will depend upon ground and weather conditions of the Forest. Some years the conditions could be ready before June 15th and some years later. Thanksgiving is the usual date most areas are closed by snow and it is also the end of many hunting seasons. LAB/CMM

ACCESS - DISABILITIES

COMMENTS: Concern that the disabled and elderly will be negatively impacted by the proposed access restrictions/road closures. Do not support motorized access restriction for persons with disabilities.

1, 46, 52, 240, 318, 319, 467, 511, 528, 607, 695, 713, 766, 1240

RESPONSE: Forest users will have access to most of the Forest as they do now, and major access roads will remain open. Occasionally a road that was open will be closed so that a road that was closed may be opened. There is a road density assigned by prescription to each area which determines how many miles of motorized roads or trails can remain open.

During the big game hunting seasons, persons with disabilities may be permitted to use motorized vehicles, if needed for mobility, on designated restricted roads and trails which are authorized for such use. A hunting license for disabled persons is issued by the State to qualified applicants. A special permit is issued by the Forest to allow access on designated roads for those with the State permit. This program has been going on for several years and is used by a small number of people. LAB/CMM

COMMENTS: The game retrieval system when used by the disabled needs to be monitored for disturbances and road densities.

1369

Need to show what roads are authorized for persons with disabilities or game retrieval, whether or not the roads are "open" at this time, and whether or not the OROMTRD will be recalculated and "made up for" with additional road closures elsewhere.

1273b, 1361

RESPONSE: Less than five Disabled Access permits are issued in any given year, and some years as little as one or none. The roads are not identified on the Travel Plan Map because the areas may differ from year to year on each district. Given the few people that participate in the Disabled Access permit, there will not be an impact on OROMTRD because use has been less than 1-2 vehicles per week on any road. If participation increases over the years, the Forest will reanalyze the road densities for the affected areas. LAB -

ACCESS - HUNTING

COMMENTS: Support limited access mainly to enhance hunting opportunities or experience; restricting hunters to a limited area will result in more hunting fatalities.

F-B(4), 157, 228, 270, 280, 413, 511, 1202

RESPONSE: Designated areas for hunting are determined by Idaho/Wyoming State Fish and Game agencies. The Forest Service manages access. If hunters feel an area has too much access, they may choose to hunt other areas. By reviewing the travel maps of the Forest it is possible to select areas that have the least or limited access. LAB/CMM

COMMENTS: No exceptions to motorized closures during hunting seasons should be allowed (including for hunters with disabilities).

157, 351, 694, 695

ACCESS - HUNTING

RESPONSE: The Revised Plan allows administrative access and the continuation of special access for hunters with disabilities through the Forestwide Access Standards and Guidelines in chapter III.

At this time, few hunters with disabilities use this special access. Administrative access is needed and may occur at any time of the year depending on emergencies or other special work projects. LAB/CMM

COMMENTS: Close some roads during elk season only.
1267, 1389

RESPONSE: The Targhee is doing this now and will continue to do so under Prescription 5.1.4 (a-c) in chapter III of the Revised Plan. The gates in 5.14(a) on these roads will be closed on October 1st, and 5.14(c) restricts use prior to and after fall hunts. LAB/CMM

COMMENTS: Confine motorized hunting opportunities to areas where road densities are excessive.
645

RESPONSE: Hunting areas and numbers of permits/hunters are determined by Idaho/Wyoming State Fish and Game agencies. Most people drive to their hunting areas or to a trailhead. The Revised Plan provides a road network that meets elk security and road density goals. LAB

COMMENTS: The Plan should include scientifically-based standards for managing OHV use in areas where this activity is permitted because inadequately managed OHV use on The Targhee has a major long-term negative impact on wildlife. These standards should include the following: impose additional seasonal or bag limits if justified by OHV-facilitated hunting mortality; and prohibit the transport of weapons on OHVs if justified by OHV-facilitated hunting mortality.
1365

RESPONSE: Seasonal or bag limits and prohibition of transport of weapons are determined by the Idaho/Wyoming State Fish and Game agencies. Information is provided to those agencies about motorized use after the Forest's monitoring is completed. These agencies can consider annual motorized information in determining limits. LAB/AM

ACCESS - LAW ENFORCEMENT

Access Enforcement Will Be Difficult

COMMENTS: Access enforcement will be difficult or impossible; the Forest Revised Plan will make enforcement worse because of increased closures and wilderness designation; better enforcement would reduce the need for more closures or restrictions. Problems with snowmachines on private land are a result of the Forest Service promoting this use without backing it up with appropriate level of law enforcement, particularly in the Centennials. Problems of habitual trespass by snowmobiles into wilderness on the Montana side of the Centennials is facilitated by illegal use on the Targhee. Lack of

ACCESS - LAW ENFORCEMENT

law enforcement of winter recreational activities is negatively affecting land owners. (CROSS REFERENCE: Centennials)

1, 36, 137, 175, 212, 277, 737, 1176b, 1322

Access enforcement has not occurred in the past. Current law enforcement is a joke or embarrassment: when someone shot a bear from a snowmobile, out of season, and reported it to the Game Warden and Forest Service, nothing was done. Failure to enforce rules breeds disrespect and because of problems, other agencies trying to enforce Targhee National Forest regulations. Some people enjoy breaking the law or ignoring restrictions.

1, 26, 161, 179, 296, 643, 737, 1277, 1322, 1337

RESPONSE: The Forest agrees that additional road closures and wilderness restrictions require an increase in enforcement efforts. Changes will increase the workload for the present law enforcement officers with no additional personnel expected. One additional source of assistance are permanent and seasonal Forest Protection Officers (FPO's) to supplement the Law Enforcement Officers (LEO's) with law enforcement duties, especially during peak use periods, such as the hunting and snowmobile seasons.

The Targhee continues to coordinate off-highway vehicles (OHV) and snowmobile restrictions with the surrounding forests: Gallatin, Beaverhead, Caribou, and the Bridger-Teton National Forests, so that restrictions and closures along borders are similar. For example, if a road or an area is closed on one forest, the bordering forest has a compatible closure so that enforcement is consistent.

The Forest Service does not promote OHV or snowmobile use on private lands surrounding the National Forest. Violations of trespass on private lands, due to a closure on public lands is a problem that must be coordinated with local and State law enforcement agencies so that trespass violators can be prosecuted. JL

Enforcement Funding and Personnel

COMMENTS: Access enforcement needs adequate funding and personnel. Cut backs in funding and personnel will make additional enforcement difficult or impossible. Do not approve of restrictions that will lead to additional enforcement costs for taxpayers.

161, 167, 169, 170, 191, 204, 212, 377, 392, 625a, 645a, 1276, 1330

RESPONSE: The Targhee recognizes the need for adequate funding and personnel for law enforcement. During these days of downsizing, funding for law enforcement is a challenge with all Federal, State, and local agencies. The Targhee has more of a funding problem than many forests. Two full-time funded LEO's are available to cover the entire Forest year-round, with an additional officer to help in the winter. The Forest is also proposing to fund law enforcement operations, using seasonal and permanent FPO's to assist the two LEO's in the enforcement of closures as well as other regulations. There are forest employees in other disciplines who also do part-time law enforcement. The two LEO's concentrate on areas of high-use or high-violation probability; therefore, providing adequate attention to these more heavily used areas.

To manage the National Forest under current concepts additional rules or restrictions become necessary. When additional restrictions occur of course additional monitoring or law enforcement must follow. The cost of

ACCESS - LAW ENFORCEMENT

monitoring or law enforcement is part of the new management. Budget allocations may be behind the need but the Forest tries to keep the programs in balance. The balance of funding and law enforcement are considered in the Revised Plan. JL/LAB/CMM

Enforcement Suggestions

COMMENTS: Suggestions for enforcement: Shift personnel from administration, office duties, or timber positions to enforcement; coordinate with other Forests or agencies on law enforcement; impose and advertise fines, which would help with funding for monitoring; use consistent and strict regulations; provide better signage for closed areas; better educate public to reduce need for regulations; and apprehend and punish persistent abusers. Support the CUFF Alternative because it would allow those who define recreation differently to legally engage in their definition without degrading forest.

1, 139, 161, 219, 296, 625a, 713, 737, 1330, 1337, 1357

RESPONSE: Presently the Targhee works with the Beaverhead, Gallatin, Caribou and Bridger-Teton National Forests, the U.S. Park Service and the State Fish and Game on periodic, joint enforcement operations involving illegal outfitter/guides, wilderness intrusions, and wood theft.

The Forest plans to train more people in other jobs to support the regular Law Enforcement Officers.

Often, newspapers print a list of violators and fines paid. Fines are paid to the United States Treasury and are not returned to the agency writing the citation.

Many closures are presently signed, but others are in need of signing. Notice of closures are published in newspapers before high-use seasons. Forest officers have met with, and will continue to meet with, user-groups to explain the closures and other regulations as well as solicit volunteers from these groups to assist in watching for violations, put in signs, and maintain trails, roads, and other sites. JL/LAB/CMM

Site Specific

COMMENTS: Problems with trespass in wilderness on the Montana side of the Centennials is facilitated by illegal use on the Targhee. There is little legal OHV use in Italian Peaks, but a lot of illegal use. There is concern about increased trespass into restricted areas, such as the Jediah Smith Wilderness. (CROSS REFERENCE: Access, Site-Specifics)

161, 643, 1322

RESPONSE: The Italian Peaks area has had a designated motorized trails system. This provides for legal motorized travel on the Targhee National Forest or Idaho side of the Centennials. Some users in the Italian Peaks will leave the designated trail and travel into the Beaverhead National Forest or Montana where the trails are signed closed. Patrolling this area by both Forests will help to control illegal use.

Motor vehicle use in wilderness areas (such as the Jediah Smith Wilderness) is mainly from snowmobile use rather than OHV's. Most of the trails and trailheads are signed so visitors know when motorized access is

ACCESS - LAW ENFORCEMENT

allowed. However law enforcement officers are hampered by vandalism of signs and by those who are eager to gain access to the area. JL/LAB/CMM/AM

ACCESS - MAPS

COMMENTS: Use maps and signs to educate the public about access issues on the Targhee National Forest. Need more maps and signs; control access through strong, visual displays and a travel map with all non-system and system roads; provide more education for the public on road closures; fund strategies for these requests.

1, 139, 161, 219, 296, 389, 625a, 629, 643, 690, 737, 1202, 1244, 1330, 1337, 1357, 1365, 1393, 1400

RESPONSE: The Forest will educate the public about access issues through the use of road signs and Forest and District travel maps. The Forest will also allocate funds for signing and access education when sufficient funds are available. LAB/TEM

Site Specific

COMMENTS: Post signs in Palisades Wetland area educating people about the negative impacts of human and motorized access to waterfowl.

389

RESPONSE: In the Revised Plan, the Palisades Wetland area, also called the "Alpine Wetland Area", is closed to all cross-country motorized travel year-long to protect the plant and wildlife resources using this area. This designation is currently on all of the Forest Travel Plan maps, and will be on the new Travel Plan map issued with the Revised Plan. Signing and education are always dependent on funding and priorities. MO

ACCESS - MONITORING

Support

COMMENTS: Support for monitoring access items in the Draft Plan, such as: effectiveness of road and trail closures; all accessible roads and trails; and, general access to the Targhee National Forest emphasized the need to educate the public of any monitoring implemented, and to make all monitoring direction explicit in the Revised Plan.

7, 62, 277, 334, 350, 489, 667, 687, 697, 1202, 1361, 1365

RESPONSE: Monitoring is an effective tool to assess compliance with the Revised Plan direction and after review of public comments it was changed from a Priority 2 to a Priority 1. The Targhee monitoring effort explicitly assesses closure effectiveness. The results of monitoring will be shared with the public. Education of the public regarding the monitoring activities is necessary and an ongoing process. LAB

ACCESS - MONITORING

Change Monitoring Methods

COMMENTS: Precision and reliability of monitoring will significantly decrease if just one user group is designated to do the monitoring.

629

RESPONSE: It is our intent to use a variety of methods and groups to assist with monitoring activities. LAB

COMMENTS: Frequency of monitoring is inadequate; Forest Service personnel could monitor 100% if they used trail bikes.

629

RESPONSE: We will monitor with the number of personnel and funding available each year. Monitoring of roads is a Priority One in the Revised Plan. Forest Service employees use trail bikes and other modes of transportation during monitoring. AM

COMMENTS: Institute citizen monitoring programs for education and enforcement, to develop Standards and Guides and regulations.

1365

RESPONSE: Greater reliance on user monitoring and input during the development of management direction through volunteer programs will assist Targhee. LAB

COMMENTS: Adequate monitoring and evaluation program must have the following four (4) components:

1. Scientifically sound method for assessing habitats and populations of the indicator species or groups of indicator species.
2. A reasonable frequency of measurement.
3. Pre-determined degree of change that will trigger a re-analysis of management activities.
4. Include an interrelated set of impact indicators.

1365

RESPONSE: The Monitoring and Evaluation Plan is in Chapter V of the Revised Plan. In the section titled "How will Monitoring information be used" frequency, degree of change, and indicators are some of the elements that are covered. The Revised Plan's Monitoring Plan will be followed as long as the reality of budget and workforce constraints meet the level and intensity of implementing these components. LAB

COMMENTS: Monitoring Plan and research of OHV impacts should be site-specific; examine short and long-term; consider multiple and cumulative effects; evaluate reinvasion, recovery rates, effects of disturbances be funded.

1365

RESPONSE: In the Monitoring and Evaluation Plan (Chapter V, Revised Plan), there is a monitoring item under Recreation that will assess impacts to

ACCESS - MONITORING

on-trail and off-trail soils and vegetation from impacts from various sources, including OHV'S. Annually we hope to monitoring 5-10% of the areas, initially focusing on the Big Hole Mountains and Palisades areas. LAB/CC

COMMENTS: Using one and two motorized vehicle trips per week is difficult to monitor, imprecise and not of concern. To be accurate, you should require counters with cameras.

629

RESPONSE: In areas of great concern and where resource protection needs warrant, the Forest agrees that counters and cameras should be used. Cost precludes uniform use throughout the Forest. LAB

Need More Monitoring Roads/Closures

COMMENTS: Need to effectively monitor road closures and roads and trails. Protect sensitive habitats and soils; enforce road restrictions to prevent abuses; and, protect wildlife. Monitoring and its funding should receive high priority and strict standards, guidelines and timetables. Monitor road closure as Priority I.

204, 489, 643, 690, 695, 1273b, 1365, 1361, 1446, 1367b

RESPONSE: Monitoring road closures is now a Priority One. The Targhee plans to implement strict standards, guidelines, and timetables as it implements road closure monitoring. LAB

COMMENTS: Road closure monitoring must include public input as required by 36 CFR 295.5.

1361

RESPONSE: The Targhee will comply with all laws, regulations, and policy relating to including public input in road closure monitoring. LAB

COMMENTS: Add, "road closure locations and designs" to effectively control use in the annual Monitoring Report.

1361

RESPONSE: Roads and trails that will be left open with the implementation of the Revised Plan are illustrated on the Summer Motorized Access map and a list of these roads is contained in the Access Appendix of the FEIS. The closure method (gate, obliteration, etc.) will be determined in a separate site specific NEPA analysis that will assess the tradeoffs of different closure methods and the potential effects on the resources. The annual Monitoring Report will display effectiveness of the actual closures. LAB/CC

Funding

COMMENTS: The program for obliterating, closing and monitoring roads should have its own budget and not be tied to other projects, e.g., timber sales. If funding is unavailable, the environmental consequences should be displayed in

ACCESS - MONITORING

the Final Environmental Impact Statement (FEIS). Also, the program should receive high priority and adequate funding.

356, 634, 643, 695, 766, 1195, 1247, 1273b, 1320, 1367, 1381

RESPONSE: The Forest is committed to the program of closing and monitoring the effectiveness of these closures, and funding will be allocated to accomplish these activities. Road closure effectiveness was elevated to priority one, after reviewing public comments. We plan to issue a yearly monitoring report that will illustrate accomplishments, clarify direction, and determine whether further evaluation is necessary. Road closure and monitoring does not have to be tied to other projects and has its own budget. LAB/CC

COMMENTS: Current funding is inadequate for trail program and more funding is needed for accurate road inventories.

734, 643, 695

RESPONSE: Funding for the trail program is not always adequate to accommodate the planned work. The Targhee has implemented an effective volunteer program, matching grants, and state assisted programs in an attempt to stretch the available funding as far as possible. The Revised Plan places a higher emphasis on the trail program and funding to provide accurate road inventories, along with implementation of the much stricter travel management direction. LAB

ACCESS - OHV/ATV

Specifically ATV Use

COMMENTS: Allow ATV use because use does not destroy vegetation or habitat, cause the spread of noxious weeds, or cause soil erosion.

319, 638

RESPONSE: Seven percent of the Forest is open to summer cross-country travel by ATVs. ATVs can cause resource damage if not properly managed. The Revised Plan provides direction to avoid resource damage and minimize impacts. The new travel plan will be in affect through the summer and early fall months to provide the necessary direction for access. CMM

COMMENTS: Restrict ATV use and access because restrictions can protect habitat. Support prohibiting ATV cross-country use.

F-K(4), 440, 610, 611, 621, 629, 1202, 1387, 1457

RESPONSE: Except for seven percent of the Forest, ATVs are restricted to designated routes. This was done in cooperation with the State Fish and Game Departments to address needs for elk habitat effectiveness and elk vulnerability. LAB/CMM

COMMENTS: Develop positive incentives to reduce or mitigate impacts by offering reduced user-fees for OHV users, and operating machines that meet noise and emission standards.

1365

RESPONSE: Incentive programs are effective in many situations, however, the Forest Service is not charging a user-fee for OHV users and the State enforces the noise and emission standards. LAB/CMM

COMMENTS: Before obliteration, consider opportunities to develop OHV/ATV roads if there are no conflicts with other resource objectives.

629

RESPONSE: The Revised Plan incorporates some of the old roads into motorized trail loops where terrain and road densities can accommodate them. The type of closure for roads no longer open to motorized travel will be determined in site-specific NEPA analysis and will include additional public involvement.

MLB

COMMENTS: Off-highway vehicle access should not be restricted in the Revised Plan. Respondents to this issue express opposition to Alternative 3M because of unreasonable closures and restrictions on OHV access.

215, 284, 288, 291, 367, 388, 486

RESPONSE: In the Revised Plan (Alternative 3M) seven percent of the forest is open to summer cross-country travel while OHV use on the rest of the forest is limited to designed routes. These access restrictions were made to aid in grizzly bear recovery; to reduce elk vulnerability; and to improve elk habitat effectiveness; and to protect other resources. LAB/CMM

COMMENTS: Disagree with the Standard. ORV use is one of the activities having the highest likelihood of producing irreversible damage.

1202

RESPONSE: The DEIS stated in Chapter IV, "Road construction, timber harvest, grazing, dispersed recreation and motorized recreation (OHV's) have the highest likelihood of producing irreversible damage to the soil resource." This statement is still true in that it speaks to "highest likelihood" and addresses cumulative effects across the forest without ranking them individually. Chapter IV of the FEIS under "Consequences Common To All Alternatives" emphasizes that unmanaged dispersed recreation and OHV use will be one of the main challenges in the future based on increases in demand for these uses. LAB/DM

Supports Restrictions On OHV Access

COMMENTS: Off-highway vehicle use should be restricted on the Targhee National Forest because of wildlife protection needs, equal access for non-motorized use, erosion concerns, emission concerns, safety concerns and the concern for general forest health. Limit OHV use to current roads and trails and provide proper enforcement of restrictions. (CROSS REFERENCE: Access, Law Enforcement)

27, 143, 157, 161, 165, 170, 176, 204, 271, 278, 280, 293, 296, 330, 359, 401, 489, 621, 625, 662, 695, 735, 766, 1202, 1273b, 1365, 1367b, 1387, 1457

ACCESS - OHV/ATV

RESPONSE: On all but seven percent of the Targhee, off-highway vehicles are restricted to designated routes. Each area on the Forest is covered by a prescription and each prescription has a road density that determines the amount of roads and trails that can be allowed in an area. The road density is based on wildlife values, such as elk vulnerability and grizzly bear security. Erosion and safety concerns are considered in the travel plan. Enforcement and education are an important part of implementing the access portion of the Revised Plan. LAB/CMM

COMMENTS: Prohibit access to the Targhee National Forest by OHV use because of abuse of historic logging roads; habitat sensitivity, threatened and endangered species (TES); riparian and wetland health; natural vegetation survival; forest health; degraded rangeland protection; noise impacts, impacts to Wilderness Study Areas (WSA), roadless, wilderness, and proposed wilderness areas; and, contamination of resources by vehicle refueling.

157, 179, 244, 376, 650, 719, 1365

RESPONSE: The Revised Plan designates 7% of the Forest open to summer cross-country travel. The remainder of the Forest is restricted to designated routes for many of the reasons cited above. The road density for each prescription will provide the direction for the amount of roads or trails that may remain open in each area. Contamination of resources by vehicle refueling has not been a problem on the Forest and with cross-country travel restrictions the potential for refueling contamination becomes smaller. LAB/CMM

COMMENTS: Does not support OHV use because of negative impacts on wildlife, vegetation, soils, water, air, trails/roads, aesthetics, user conflicts, and the spread of noxious weeds. (CROSS REFERENCE: Access, Noxious Weeds; Range, Noxious Weeds)

231, 291, 625, 1365

RESPONSE: The Revised Plan designates seven percent of the Forest open to summer cross-country travel. The remainder of the Forest is restricted to designated routes. All open routes meet road density which considers impacts on wildlife and other resources. The Revised Plan provides a balance of opportunities for a variety of users while reducing OHV impacts from the current situation. Noxious weeds are a growing problem on lands throughout the west. The Revised Plan has an aggressive program to control noxious weeds in all Targhee Forest activities. LAB/CMM

ACCESS - RANGE

COMMENTS: Support the language in the Preferred Alternative which allowed livestock permittees the use of "historic" roads for range facility maintenance.

432

RESPONSE: Forestwide standards and guidelines found in Chapter III of the Revised Plan allows permittee access to maintain range facilities. This permitted access is limited to less than 2 trips per week (average). The term "historic" roads is not retained in this direction. MLB

ACCESS - RANGE

COMMENTS: It is not acceptable to restrict permittees access to livestock once or twice per week.

1391

RESPONSE: A standard in the Revised Plan, under Production of Commodity Resources, states that if a road is used by a permittee consistently more than twice a week, for weeks at a time; or during the spring, summer, and fall period; then the road or trail is included in the calculation for Open Road and Open Motorized Trail Route Density (OROMTRD) in that prescription area. But, if a permittee needs to use a road or trail for less than this amount, the road or trail is not counted in the OROMTRD. LAB

ACCESS - RECREATION

Access For Dispersed Recreation

COMMENTS: Motorized access to dispersed campsites or picnic areas should only be allowed within 300 feet of existing open roads or trails (CROSS REFERENCE: Recreation)

643, 766, 1194, 1393, 1401

RESPONSE: We agree. The Revised Plan, Forest Use and Occupation, Dispersed Recreation Use, has a standard that allows motorized access (unless otherwise posted), for parking and dispersed camping within 300 feet of open motorized roads and trails. CC/JR

COMMENTS: Provide equal access opportunities for dispersed motorized recreation. (CROSS REFERENCE: Recreation)

300

RESPONSE: In the Revised Plan, approximately 7 percent of the Forest is open for summer cross-country motorized use. Parking and dispersed camping is allowed within 300 feet of a open road or trail, unless otherwise posted.

Access For Non-motorized Recreation

COMMENTS: Recreational opportunities will increase if we reduce motorized access. (CROSS REFERENCE: Recreation)

No Letter #

RESPONSE: This depends on how a person defines a recreational opportunity. Some consider motorized use a recreational opportunity. The Forest received requests to leave motorized access as it is, increase it or reduce it. It is true some types of nonmotorized recreational opportunities may increase if we reduce motorized access. The Revised Plan represents a balance. LAB/JR

Too Much Access For Recreation

COMMENTS: The large amount of roads and trails used for recreation need to be lower to ensure protection for wildlife and threatened and endangered species. (CROSS REFERENCE: Wildlife)

325, 1322

ACCESS - RECREATION

RESPONSE: The Revised plan directly addresses this issue by excluding motorized roads and trails from the core areas of the Grizzly Bear Management Units and allowing fewer open roads and trails in other portions of the Forest to provide protection for a variety of resources, including wildlife, fish and water (see Process Paper D available in the Supervisor's Office). The Revised Plan is made up of Management Prescriptions. Each prescription has an open motorized road and trail density attached to it, and allows a certain number of roads and trails per square mile. LAB/MB

Supports Access For Recreation

COMMENTS: Access should not decrease because there is an increase in recreation; and in fact, support more recreational access. Do not support any restrictions on recreational vehicles.

219, 291, 375, 1260, 1308, 1332, 1447a

RESPONSE: The increase in recreational use of all types necessitates some restrictions on use to address other resource concerns and to balance motorized and non-motorized use opportunities. The Revised Plan addresses this need for balance by establishing OROMTRD standards for each management prescription to achieve the goals and objectives for that prescription. Overall this has significantly reduced cross-country motorized travel on the Forest and will reduce that type of recreational opportunity. Most areas closed to cross-country have a reasonable network of designated trails for motorized use. In popular areas this may concentrate use and change the quality of the motorized recreation experience. If sufficient concern is developed, localized management actions may be necessary to alleviate conflicts and improve the experience. These will be implemented with a site-specific analysis and public comment. This is unfortunate, but increasing population and use make reasonable restrictions necessary. JR

ACCESS - RIPARIAN

COMMENTS: Prohibit motorized access to streams, wetlands, riparian areas, and restrict motorized access to these areas to existing system roads and trails as a way to better regulate access. Prohibit all cross-country travel, parking, etc. from 25 feet of any stream, pond or lake. Need to develop standards for roads in riparian areas. (CROSS REFERENCE: Riparian, General)

F-B(4), FS-10, 24, 136, 143, 157, 159, 180, 181, 185, 190, 209, 226, 227, 273, 359, 407, 643, 644, 659, 690, 697, 766, 1194, 1197, 1220, 1270, 1331, 1365, 1367, 1369, 1371, 1401

RESPONSE: In the Revised Plan, summer cross-country access is permitted on 7 percent of the Forest. The remainder of the Forest provides access during the summer on designated roads and trails. Forestwide standards and guidelines allow motorized access (unless otherwise posted) for parking and dispersed camping within 300 feet of open roads and trails. The Management Prescription 2.8.3, which covers water types such as streams and wetlands, contains guidelines for new road and trail construction, and improvement. CC

ACCESS - RIPARIAN

COMMENTS: Allow limited cross-country motorized access to riparian areas. Allow cross-country motorized access in areas already open for cross-country travel.

FS-10, 392

RESPONSE: In the Revised Plan, motorized access is allowed for parking and dispersed camping within 300 feet of roads and trails which are open for motorized use. CC

ACCESS - ROAD AND TRAIL

Road and Trail Closures

COMMENTS: Oppose any new or additional road/trail closures because the public needs access for safety and fire suppression efforts; impacts to livestock management on grazing allotments; negative impacts to recreation use and general enjoyment of Targhee National Forest; more congestion equates to higher impacts; in conflict with multiple-use philosophy; hunting opportunities are potentially lower; social concerns including historic use; view that the ecosystem is already healthy; access to firewood too limited; less access equals negative economic impacts; mineral entry restricted; too much public access locked up by proposals; and, human needs should take precedence over any other needs. Create new roads for viewing enjoyment.

(CROSS REFERENCE: Social Concerns)

F-C(13), F-F(6), F-G-2(2), F-O(4), 1, 3, 7, 11, 16, 20, 24, 32, 34, 38, 41, 42, 53, 56, 60, 61, 64, 69, 73, 75, 151, 174, 175, 178, 182, 242, 250, 251, 265, 267, 270, 271, 272, 277, 284, 285, 286, 287, 288, 293, 298, 300, 307, 309, 311, 314, 315, 316, 319, 323, 327, 342, 344, 348, 367, 369, 371, 374, 379, 380, 381, 388, 391, 397, 412, 429, 431, 439, 445, 451, 473, 474, 476, 479, 480, 481, 484, 495, 501, 505, 506, 511, 512, 524, 525, 528, 529, 607, 608, 610, 624, 625, 633, 634, 637, 645b, 646, 660, 665, 669, 687, 688, 691, 692, 694, 704, 715, 728, 1179, 1187, 1189, 1191, 1193, 1200, 1239, 1240, 1248, 1252, 1256, 1264, 1265, 1267, 1268, 1271, 1315, 1319, 1320, 1321, 1330, 1332, 1338, 1339, 1341, 1354, 1359, 1363, 1367, 1371, 1375, 1376, 1378, 1380, 1386, 1390, 1446, 1447, 1448b

Open currently closed roads to public access; implement 1965 Targhee National Forest Travel Plan.

2, 219, 412, 476, 607

Against any new or proposed trail closures because want more access; will negatively impact environment; recreation access will decrease; congested use will be a problem; and social concerns.

F-D(51), F-O(4), 11, 34, 35, 36, 46, 98, 156, 197, 203, 262, 270, 334, 367, 371, 374, 381, 397, 488, 520, 645, 645b, 648, 649, 702, 703, 1179, 1191, 1256, 1332, 1334, 1339, 1376, 1385

RESPONSE: The Forest received extensive public comment on both sides of the access issue. Some road and trail closures were made in the Revised Plan based on resources including erosion, soil, wildlife, water quality and existing access. The major change was the closing of 93 percent of the Forest to summer cross-country travel because unmanaged cross-country travel was causing resource damage. Each watershed on the Forest has a management

ACCESS - ROAD AND TRAIL

prescription which directs the activities in an area. Road density in the prescription determines the amount of roads and trails that can be open for motorized travel, and helps balance wildlife security and users' activities. The Revised Plan provides adequate access and allows motorized use on designated routes.

The Forest considered all specific comments about access. Changes were made conforming with the general thrust of the preferred alternative and the desired future condition. The Final Revised Plan represents a balance and accommodates those on both sides of the issue. See the Access Appendix in the FEIS and Process Paper D in the Supervisor's Office for more information about the access analysis for the Revised Plan. LAB/LG/CMM

COMMENTS: Do not abandon any trails without contacting Idaho Department of Parks and Recreation.

629

RESPONSE: The Targhee will continue to involve all interested parties in decisions that could affect forest users. This is especially true regarding trails that are of mutual interest to the Idaho Department of Parks and Recreation and the Forest. LRG

COMMENTS: Delete historic recreation use as a closure consideration because it is too arbitrary. Close roads only to protect wildlife, soil or for other ecosystem health reasons.

695

RESPONSE: Closing roads only to protect wildlife, soil or other ecosystem health reasons too narrowly defines the closure criteria. Humans are also part of the ecosystem; sometimes decisions regarding use of the Forest favors use by humans with less protection for wildlife, soil or other ecosystem health reasons. LRG

COMMENTS: Road restrictions and closures alone will not solve problems; Idaho Department of Fish and Game should do their part, too.

688, 689, 1336, 1448

RESPONSE: The Targhee National Forest will continue its current partnership with the Idaho Department of Fish and Game in an effort to find a common ground regarding the amount and kind of road restrictions and closures needed to meet their game populations and management needs. LRG

COMMENTS: Support proposed road/trail closures because closures protect the ecosystem, environment, wildlife, forest health, and grizzly bear; closures help maintain migration corridors; closures solve social and economic concerns; closures prevent erosion; and closures could possibly lengthen hunting seasons. Motorized travel should, as a whole, be limited to very few roads.

F-B(4), F-K(4), 5, 32, 37, 42, 62, 136, 143, 150, 155, 156, 162, 165, 167, 170, 171, 173, 174, 175, 181, 189, 190, 209, 212, 215, 227, 252, 266, 270, 278, 280, 292, 293, 311, 356, 357, 359, 361, 376, 389, 392, 396, 398, 441, 443, 467, 489, 490, 516, 527, 608, 611, 625a, 629, 631, 633, 643, 645, 650, 652, 655, 659, 665, 667, 668, 690, 694, 695, 719,

ACCESS - ROAD AND TRAIL

725, 731, 733, 1197, 1240, 1241, 1258, 1269, 1271, 1276, 1277, 1314, 1330, 1331, 1333, 1337, 1348, 1361, 1365, 1367, 1381, 1387, 1388

RESPONSE: Thank you for your support. The changes for access in the Revised Plan are based on the resources for reasons you stated. The Forest received extensive public comments on both sides of the access issue. The Final Revised Plan represents the best accommodation and balance of access for those on both sides of the issue. Summer motorized travel will be limited to designated routes throughout all but 7 percent of the Forest. See also the Access Appendix in the FEIS and Process Paper D in the Supervisor's Office.
LAB/LG/CMM

Road Obliteration

COMMENTS: Road obliteration and revegetation is the only way to achieve effective road closures; and as such, obliteration should be the emphasis of the Targhee National Forest road closure program. Obliteration is a waste of taxpayer dollars. Close or obliterate all unofficial roads and trails, built in conjunction with timber harvest.

4, 389, 621, 643, 690, 719, 1197, 1276, 1365, 1367b

Recommend that the road closure program emphasize obliteration over other forms of closure, and only obliterated roads be counted fully closed.

276, 370, 489, 643, 1194, 1365, 1367b, 1401

RESPONSE: A NEPA site-specific analysis is made for each road scheduled for closure. The decision on how the closure is accomplished is based on this analysis. Where warranted, obliteration and revegetation are utilized. In other instances, scarification, water, barring or gating might be the preferred solution. One closure action does not fit all situations. LAB/LRG

COMMENTS: Address effects of obliteration versus road closures, monitoring two days per week for administrative use of closed roads. (CROSS REFERENCE: Access, Monitoring)

1361

RESPONSE: This is considered in the site-specific analysis for each road scheduled for closure. Cost efficiency, closure effectiveness, and administrative impacts are addressed in the analysis. Road density standards in each management prescription will be achieved as soon as practical: three years in the Bear Management Units and ten years for all other areas.

Administrative use on restricted roads and trails are normally two types: emergency use such as fire suppression and search and rescue or planned project work. In planned project work, permission will be given by the Forest Supervisor or District Ranger and the entry is recorded. A sign is posted on the restricted road during the project. LAB/LG/CMM

ACCESS - ROAD AND TRAIL

Ghost Roads

COMMENTS: Close, obliterate, revegetate or otherwise remove "ghost roads." Use the best available ghost road data in OROMTRD. Remove the term from analysis use. (CROSS REFERENCE: Access, Process)
FS-11, 127, 136, 725, 1361, 1367

RESPONSE: There will no longer be ghost roads. The final disposition of ghost roads will either be closure, obliteration, revegetation, (such as removal from the Forest) or adding the road to the Forest Development Road System for management as a system road. LAB/LRG

Closing Roads

COMMENTS: Implement greater resource protection measures including road closures. Close all non-vital secondary roads; revegetate upon closure of all temporary roads; close short, spur roads; close those roads requiring extensive maintenance; close all nonsystem roads; close all roads built since 1965; close all old logging roads; and close all roads.
2, 61, 170, 178, 180, 204, 226, 396, 405, 445, 627, 643, 664, 690, 694, 695, 697, 698, 1202, 1204, 1314, 1361, 1367

RESPONSE: Access in an area is determined by road density standards described in each management prescription. The road density standard will be achieved as soon as practical: three years for Bear Management Units and ten years for all other areas.

A site-specific analysis is made for each road scheduled for closure. The decision on how the closure is accomplished is based on this analysis. Where warranted, obliteration and revegetation are utilized. In others instances, scarification, water barring or gating might be the preferred solution. One closure action does not fit all situations.
LAB/LRG/CMM

New Roads

COMMENTS: Oppose building any new roads on Targhee National Forest so wildlife habitat will continue to be protected.
174, 179, 181, 204, 209, 325, 389, 507, 690, 697, 1328, 1331, 1364, 1365, 1367

RESPONSE: Road density standards are part of every management prescription for each area on the Forest. Some management prescriptions do not allow new roads, such as Prescription 2.6.5 Grizzly Bear Security Area. Road density standards were developed considering elk vulnerability and grizzly bear security, providing emphasis for wildlife.

Road density provides the standard for the amount of roads or trails left open in an area. If an additional road is needed for a management activity, the road density determines whether another road would have to be closed before an additional road could be constructed or if a closed existing road could be opened. The Targhee National Forest will continue to be managed under the multiple-use, sustained-yield concept as currently reflected in ecosystem management. LAB/LRG/CMM

ACCESS - ROAD AND TRAIL

Road/Trail Management

COMMENTS: Provide non-motorized buffer zones around important areas; strengthen and enforce Bear Management Plans (BMPs); provide long distance travel corridors; designate trails/roads as strictly motorized or non-motorized; provide restrictions on pack animals and horse use; and, maintain existing roads and trails.

51, 175, 330, 632, 1249, 1276, 1365

RESPONSE: There are many areas on the Forest where non-motorized vehicles are restricted. Only seven percent of the Forest allows summer cross-country travel and motorized travel is restricted to designated routes on the rest of the Forest. Roads/trails are designated motorized or non-motorized. Horses and pack animal travel is not restricted except on some winter ranges. Long distance travel corridors will continue to exist.

The Bear Management Prescriptions in the Revised Plan strengthen and enforce the Bear Management Plans. They are Grizzly Bear Habitat, Grizzly Bear Core Area, and Grizzly Bear Security Area.

The Revised Plan provides for maintenance of existing roads and trails. LAB/LRG/CMM

ACCESS - ROAD DENSITY

General

COMMENTS: The current road density on the Targhee National Forest is too high. Road density should be decreased for riparian and ecosystem protection.

FS-10, F-K(4), 174, 625, 697, 1365, 1367b

RESPONSE: The Revised Plan decreases open road and trail densities throughout the Forest to enhance the wildlife habitat, riparian resource, and other components of the ecosystem. AM

COMMENTS: Need an accurate inventory of roads or road density standards are useless.

1365

RESPONSE: The Forest has made an intensive effort to inventory both "system" and "non-system" roads and trails during the Revision process (see Access Appendix in the FEIS). The Forest is continually updating this inventory. The Revised Plan will be implemented by a Travel Plan that identifies all roads and trails open for motorized use. Those not open will be closed or obliterated. LAB/JR

COMMENTS: The OROMTRD policy has been "crafted in darkness" with the GYC and does not follow NEPA.

393

RESPONSE: The Forest used the criteria established in the Interagency Grizzly Bear Committee's Task Force Report on Grizzly Bear/Motorized Access Management for establishing OROMTRD in the Grizzly Recovery Zone. Elsewhere, the need to reduce elk vulnerability was the key determinant of road density (see Process

ACCESS - ROAD DENSITY

Paper D in the Supervisor's Office). All alternatives in the EIS have different access travel management plans and the effects of various open road and trail densities are addressed in this analysis. Therefore, the policy follows NEPA. A very open public process has been used to craft the Revised Plan. CC/JR/AM

COMMENTS: Road densities used by recreationists adversely affect the suitability of the Forest for wolf habitat.

1365

RESPONSE: The Revised Plan adopted the direction in the EIS for reintroduction of gray wolves to Yellowstone National Park and Central Idaho. In general, road density is not a critical factor for wolf reintroduction as long as the habitat needs of prey species are met. The density standards in the Revised Plan directly address wildlife habitat needs. LAB/AM/JR

COMMENTS: If road restrictions are needed to protect biological diversity, restrict access only in areas of high road density.

629

RESPONSE: We agree. Each management prescription in the Revised Plan has a density standard tailored to the multiple-use direction in that prescription. JR

Road Density and Bear Management Units

COMMENTS: No new roads should be allowed in Bechler-Teton BMU and administrative use of restricted roads/trails needs to be added as a standard to the OROMTRD. Roads need to be closed elsewhere to keep the area within standards.

1273b

RESPONSE: In the Revised Plan, Prescriptions 2.6.2 (Plateau Core Area) and 2.6.5 (Bechler-Teton Security) have a open road and trail density of zero. In Prescription 5.3.5 (Grizzly Habitat Outside of Core) new roads are allowed if they are within the specified open road and trail density. In the forestwide standards and guidelines there are standards that must be followed when administrative use occurs. Many roads and trails throughout the Forest are being closed to protect a variety of resources, including grizzly bears, water quality, and elk. That is true in the Bechler-Teton BMU. CC/JR

COMMENTS: Reduce road densities more in areas surrounding BMUs.

1276

RESPONSE: In general, road densities are reduced adjacent to BMU's in the Revised Plan where the Targhee National Forest has management jurisdiction. The Plateau and Bechler-Teton BMU's are adjacent to National Parks on the East side where the road density remains near zero. Other areas of the BMU's are adjacent to private land or areas with highly concentrated recreation developments where grizzly bear occupancy is not desirable. Overall, the Revised Plan contains a grizzly habitat management strategy which provides for

ACCESS - ROAD DENSITY

recovery of the grizzly bear (see Fish and Wildlife Service Biological Opinion). JR

COMMENTS: Include all roads (Forest Service, private, County, State, two-track) when determining road densities within BMU.
1194, 1401

RESPONSE: All roads are included in the BMU when determining road densities.
LAB

COMMENTS: The Plan fails to address how total motorized density will be altered in BMU areas.
1376b

RESPONSE: Total motorized densities are listed for each BMU in the Revised Plan, Forest Use and Occupation section. In the FEIS, Chapter IV displays how total motorized density is altered in the BMU's by alternative. LAB

COMMENTS: Close the 0.2% of the Bechler/Teton BMU that is currently open to OHV use. If this is not done, a clear rationale and its beneficial or negative impacts to grizzly bear recovery must be stated.
1273b

RESPONSE: The two-tenths of 1 percent (0.2%) of open motorized use in the Bechler/Teton BMU allows access to dispersed camping areas. This will not cause negative impacts to grizzly bear recovery. LAB/JR

Issues/Concerns of Enforcement

COMMENTS: If areas around wild and scenic rivers are to have an OROMTRD of 0.0mi./Sq.mi., motor bikes must be prohibited, and the Final Plan should ensure that cross-country motorized use is prohibited.
1273b

RESPONSE: We agree. Lands within the Prescription for Eligible Wild Rivers (2.3) have an OROMTRD of 0.0 mi/sq. mi, where motor bikes and cross-country travel are not allowed. CC/JR

COMMENTS: There should be no exceptions to the 1.0 mi/Sq.mi. OROMTRD for semi-primitive. Exceptions belie the reasoning that set the standard. CROSS REFERENCE: Access, Standards & Guidelines)
1273b

RESPONSE: Not all of the semi-primitive motorized areas in the Revised Plan (3.2 Prescriptions) have the same density because different areas on the Forest have different motorized use objectives. If necessary, exceptions can be made to all density standards in the future provided a site-specific NEPA analysis is done, public involvement is conducted, and a Forest Plan Amendment accompanies the decision. CC/JR

ACCESS - ROAD DENSITY

COMMENTS: The EIS must identify priority watersheds where limits on additional road construction should be imposed and where road densities already exceed optimal levels.

1368

RESPONSE: In the Revised Plan, open road and trail density standards are established by prescription area. Where the current road density exceeds the standard, roads and trails are identified for closure to achieve the standard. Some prescription areas are at the maximum standard now. If new roads or trails would exceed the standard, then either existing roads must be closed to compensate or an amendment to the Forest Plan is required to change the density standard. CC/JR

COMMENTS: Do not allow OHV use to exceed road density levels.

1369

RESPONSE: Open road and trail densities are calculated on a prescription basis. Road and trail densities are standards, not guidelines, so if plans are surfaced to exceed use, a site-specific analysis with public involvement will have to be done to determine if density levels will be exceeded. To exceed the standard would require a Forest Plan Amendment. CC/JR

COMMENTS: Road density standards should be met and calculated on an activity area basis.

1446

RESPONSE: All the road densities are calculated on a prescription area, except for Bear Management Units where they are calculated by the BMU or the subunit of the BMU. This conforms to agreements with the Idaho Fish and Game Department, Wyoming Game and Fish Department and the Interagency Grizzly Bear Committee Access Report. (See Process Paper D in the Supervisor's Office). CC/JR

COMMENTS: Define actual expected road densities and do not just control to a certain level.

1369

RESPONSE: The Revised Plan provides road density standards for each prescription. The Travel Plan which implements the Revised Plan shows the actual roads and trails open for motorized use. JR

Recommend Specific Density

COMMENTS: Road and trail densities on the Targhee National Forest should be at two mile per square mile, with more restrictive standards by prescription area as needed.

389, 1247, 1273b

RESPONSE: The Revised Plan meets this direction as density standards are set by prescription. Only two prescriptions have a density of 2 miles per square mile and one prescription has a density of 3 miles per square mile. All others have a density of 1.5 miles per square mile or less. JR

ACCESS - ROAD DENSITY

Question Value of Analysis

COMMENTS: Suggest the Targhee National Forest research and adopt OROMTRD standards for the entire forest.

1367b

RESPONSE: The Revised Plan adopts OROMTRD standards across the entire forest. The same OROMTRD definition is used on the entire Forest; but the actual OROMTRD standard varies by prescription. LAB/KR

COMMENTS: Non-system roads need to be analyzed as per NFMA and Forest Service Manual direction. (CROSS REFERENCE: Access, Process)

1273b

RESPONSE: All roads on the Forest are analyzed, whether nonsystem or system, and dealt with as directed by the National Forest Management Act. (See Access appendix in the FEIS.)

LAB/JR

COMMENTS: No road density limits or road reclamation/obliteration requirements are proposed relative to watershed conditions and aquatic systems.

1368

RESPONSE: In the Revised Plan, any road that needs to be reclaimed/obliterated or effectively closed is identified (whether because of watershed conditions or some other reasons). LAB/JR

COMMENTS: The figures given for miles of open system roads do not include all applicable roads.

1367b

RESPONSE: The roads that show up as open system roads are accurate. The figures are applicable to all roads on the Forest. LAB

COMMENTS: Questions need for road density access standards deviation allowance for emergencies.

695

RESPONSE: Road densities are figured on less than 2 vehicles use per week or they are classified as "open roads". If there was an emergency and a road had to be used (like for fire or in a rescue) this use would not have an impact on long-term road density, because it is an intense short-term use. In such situations there is not time to complete a site-specific NEPA document to change the standard. LAB/AM/JR

COMMENTS: Open road densities need to be evaluated to determine the impacts on wildlife species other than the grizzly bear.

1369

RESPONSE: The effects of differing open road densities are evaluated and displayed in the FEIS, and do consider other wildlife species besides the

ACCESS - ROAD DENSITY

grizzly bear, including all the management indicator species for the forest. The analysis is described in detail in Process Paper D in the Supervisor's Office. LB

COMMENTS: Recommend replacing "road density" with "motorized access".

766

RESPONSE: The meanings of these phrases are not the same, and to change the phrases could change the direction of the Revised Plan. LAB

Methods of Determining Density

COMMENTS: Gated roads, or roads open to "administrative use," should not be considered a closed road when determining road densities for elk habitat guidelines.

204

RESPONSE: Traffic on gated roads is negligible and administrative traffic can be controlled. If administrative use exceeded an average of two trips per week, then it would be considered open. LAB/JR

COMMENTS: Existing road densities do not accurately depict actual road densities because they do not take into account private roads, county and non-inventoried roads.

643

RESPONSE: Inventoried roads include all roads of every description and jurisdiction. They are all included in the road density calculations. LAB/JR

COMMENTS: All potential off-highway vehicle use should be incorporated in the analysis of road density to determine impacts on habitat security and effectiveness (including the proposed use in the Wyoming part of Island Park, Madison Plateau, and Teton Range Subsections).

389

RESPONSE: The Forest incorporated your suggestion. LAB

COMMENTS: Road densities should be calculated for all un-roaded areas, and not disregarded for small prescription areas.

1247

RESPONSE: The vast majority of the Forest is included in the calculating of road density. The exceptions are minor. JR

COMMENTS: Adjust road densities based on the effectiveness of different seasons of closures (similar to Nez Perce Forest).

643

RESPONSE: Road densities are different from season to season. For example, the Forest closes more roads in the fall during the big game hunting season than in the summer months. LAB

ACCESS - ROAD DENSITY

COMMENTS: Consider best available data on ghost roads, ineffective closures, and authorized use of closed roads as components of OROMTRD.

1273b

RESPONSE: We used the best available data we had on ghost roads, and it is figured into the OROMTRD calculations. The analysis is described in detail in the Access Appendix to the FEIS. LAB

COMMENTS: Open road density analysis must include an allowance for closure violations, more effective closures and monitoring.

643, 690

RESPONSE: Violations and effectiveness of closures is part of the monitoring process, not of the planning process. Monitoring effectiveness of road closures is a number one priority in the Monitoring Plan for the Revised Plan. LAB/JR

COMMENTS: Do not compare road and trail densities the same because roads usually get used more. (CROSS REFERENCE: Access, Analysis Process)

363

RESPONSE: Several comments were received about the process used to address effects of motorized trails and motorized roads on wildlife. Specifically, several people commented that trails should not receive the same weight as roads. Several people suggested using a process being considered in Northern Idaho which weights motorized trails as only 1/10 the value of motorized roads. The Northern Idaho process remains a draft and has not been adopted. To address these comments, a new analysis was completed between the Draft EIS and the FEIS to see the differences between the two weighing systems. The results are presented in detail in the FEIS. Forestwide, minor differences were noted between the two systems. The percent of the Forest meeting elk vulnerability objectives does not change. Elk vulnerability changes 1 percent and elk habitat effectiveness changes 3 percent. Little difference in the amount of open motorized roads and trails is noted in the majority of watersheds.

Neither system has research which specifically supports one approach over the other. In fact, no research exists that objectively compares trail use to road use. Therefore, the Forest used the same process as outlined in the DEIS and Process Paper D, which has been concurred with by the Idaho Fish and Game and Wyoming Game and Fish Departments.

Differences are minor in most watersheds because:

1) Motorized trails account for only 23 percent of the total motorized road and trail miles on the Forest. When cross-country motorized use is included (as described in Process Paper D in the Supervisor's Office) then only 10 percent of the motorized use is accounted for on trails.

2) The trail system is not equally distributed across the Forest, and in those drainages where most of the motorized trails occur, the trail densities are generally low, which means they have less effect in the EV and EHE analysis.

3) Motorized access on trails is only one factor in EV and EHE analysis; factors such as hunter densities for EV and cover for EHE also contribute to the analysis. MO/JR

ACCESS - ROAD DENSITY

COMMENTS: When establishing road density standards exclude bear management units, roadless, wilderness acreages from road density calculations.
1367b

RESPONSE: For the most part, road densities are calculated by prescription, not by total Forest acres. Thus wilderness is not included in calculations of road density for prescriptions outside wilderness. In the bear management units, road densities are calculated for the BMU or subunit of the bear management units to conform with the Interagency Grizzly Bear Committee Access Report (see Process Paper D in the Supervisor's Office). LAB/JR

COMMENTS: Add "open" roads information when discussing road density.
FS-11

RESPONSE: Access density standards include open roads and motorized trails. Standards are by prescription areas, except in the BMU's. The accompanying travel plan displays the open roads and motorized trails across the Forest.
LAB/JR

COMMENTS: Count livestock operators against the scientific number used for OROMTRD.
FS-1.

OROMTRD (Section III Page 22, Part F): Review statement "For a short period (2 weeks?), a permittee may access area for maintenance purposes for as many as ten times per week." Consider if this fits with OROMTRD, and conflict and adverse effects would also occur if permittee is in an area where/when breeding/calving activities are occurring.
FS-5

RESPONSE: Livestock operators are counted toward the OROMTRD if they exceed the two trips per week for an extended period of time. Because this is of short-term duration, it would not have a negative effect on wildlife. LAB

COMMENTS: Temporary roads should be a part of the OROMTRD and TMARD.
766, 1446

RESPONSE: All open roads and trails are part of OROMTRD & TMARD, whether temporary or permanent. LAB/JR

COMMENTS: Modify Page III-16 (Road Densities) to emphasize TES and candidate species.
1446

RESPONSE: The Forest modified this to read, "Road density standards are emphasized in grizzly bear habitat, big game management prescriptions, and habitat for other species." LAB/MO

COMMENTS: An open road should be defined as any road that can be traveled on by motorized vehicles, even if the road is designated as closed.
389

ACCESS - ROAD DENSITY

RESPONSE: A closed road is closed and may not be traveled by motor vehicles. However, road usage occurring more than two times per week would be classified as an open road. LAB

COMMENTS: Refigure all applicable roads to be included in the open road system pertaining to the DEIS.

1367b

RESPONSE: Based on public comments, the existing road and trail data was re-examined. This analysis determined there are fewer roads and trails currently open than was displayed in the DEIS. The corrected information is displayed in the FEIS. JR

ACCESS - RS 2477

COMMENTS: Do not violate RS-2477 when closing roads, and keep all historic Right-of-Ways (per RS-2477) open.

413, 689, 1202, 1448b

RESPONSE: Roads which qualify as RS-2477 roads will pass to the jurisdiction of the County where located. The Revised Plan will need to be amended if it does not conform to the new jurisdiction. The RS 2477 determination has not been made for any Counties encompassed by the Targhee National Forest (as of 3/97), so this question will be addressed as these determinations are made. JR

ACCESS - STANDARDS AND GUIDELINES

Road Closure

COMMENTS: "Road closures will be located and designed to effectively control use. (S)" Will this be formalized as part of the annual monitoring report? Please qualify what effective means.

1273b

RESPONSE: Yes, monitoring of road closures is a number one priority in the Monitoring Plan for the Revised Plan. "Effectively control use" means a road will be effectively barricaded to prevent motorized vehicles from unlawfully accessing a restricted road. LAB/LG/JR

COMMENTS: Standards and Guideline Item 1-A should be changed to: "Road closures will be located and designated to effectively control human use."

1446

RESPONSE: Good point but instead of using "human" we changed it to "motorized" use. Thank you for your comment. LAB

COMMENTS: Forest should be closed unless designated as open in Prescriptions (adopt White Arrow Road Plan as done on Shoshone National Forest).

1247

ACCESS - STANDARDS AND GUIDELINES

RESPONSE: The Revised Plan is written like the White Arrow Road Plan; the Forest is closed except for routes designated open. On-the-ground, the open designated routes will be identified, similar to the White Arrow Program. LAB/LG/JR

Historic Use

COMMENTS: "Restrict or reclaim roads not needed for future management as determined in site-specific analysis, at the end of project use. Consider historic recreation use before closure. (G)" What does "historic recreation use" mean? Nonsystem roads must be reclaimed within ten years since their creation. What would consideration of "historic use" entail and would it violate the NFMA direction to reclaim nonsystem roads? Either reclaim or bring up to Standards as a system road. The Standards and Guidelines must make this explicit (CROSS REFERENCE: Access, Process)

1273b

RESPONSE: "Historic Recreation Use" relates to recreation use that developed over time on either "system" or "non-system" roads and trails. The Revised Plan uses this as one criterion for determining whether a particular road or trail should remain open or be closed. If designated as an open road or trail, the road/trail will be added to the Forest Road Development system. If not added, it will be closed or obliterated. You are correct in your description of the options for non-system roads. JR

Road Density

COMMENTS: "Other administrative uses (such as planned project work) on restricted roads, trails or areas will only be allowed with the following standards (S)":

Official use, permission of District Ranger or Forest Supervisor; A sign will be posted; and allowed by permit if project work is a) greater than 1 mile or 30 minutes walk b) equipment is unreasonable to carry c) contract inspectors with equipment. Request that a "Maximum Administrative use" be included in standards and guides on closed roads. If the maximum is surpassed due to high administrative use, then include direction that the closure of other roads maintain the OROMTRD.

1273b

RESPONSE: This is already considered in the Revised Plan (see Access Appendix in the FEIS). If a road is used more than the determined amount of traffic, (which is 2 days per week) whether for administrative or other uses, it will be reclassified and included as an open road, and must meet the OROMTRD Standard. LAB/LG/JR

COMMENTS: Develop a criteria for site-specific closures.

1365

RESPONSE: The Access Appendix in the FEIS describes the criteria used to determine which roads are open in the Travel Plan which implements the Revised Forest Plan. The Travel Plan can only be modified by a site-specific NEPA analysis with public involvement and the criteria would be developed in that

ACCESS - STANDARDS AND GUIDELINES

site-specific analysis. Some items that are considered in the analysis are erosion, water quality, soils, slope, wildlife, vegetation, use and the other resources in the site-specific area. LAB/LRG/CMM/JR

COMMENTS: The third objective - DFPR III-16, the net Forest development mileage will increase. This implies that the Forest Service will build new roads as fast as they are closed. Will road closures be re-evaluated and changed?

697

RESPONSE: This goal was deleted from the Revised Plan because it is confusing. Each management prescription has a road density standard in the Revised Plan that cannot be exceeded. The road density standard indicates the amount of road to be open. If a new road is proposed for a project and would exceed the standard, then another road would need to be closed to meet the road density standard. Changing the density standard would require a Forest Plan Amendment. The Forest will determine how each road will be closed by a site-specific analysis. A road could be closed by a gate, obliterated, or reclaimed. LAB/LG/CMM/JR

COMMENTS: There should be no exceptions allowed to the semi-primitive motorized road density standard ≤ 1.0 mile per square mile. (CROSS REFERENCE: Access, Road Density)

1361

RESPONSE: The Recreation Opportunity Spectrum classification for the Spring Mountain Canyon area (Lemhi Mountains, Dubois Ranger District), is a Semi-Primitive Motorized Prescription in the Revised Plan. This area allows 1.3 miles/per square mile, because the roads in this area access old mining claims and a route from the Challis National Forest, which both Forests will leave open. There are a few other semi-primitive motorized areas that are narrow and have roads or trails that pass through and cause them to exceed the ≤ 1.0 mile per square mile density mostly because of the long, narrow configuration. These are areas where management saw a need to keep a motorized trail or road open.

The 3.2 semi-primitive prescription area of the Big Hole Mountains will also exceed the 1.0 road density in the Final Revised Plan. In order to reach a compromise between motorized and non-motorized users, the road density standard in the Palisades portion is reduced to 0.5 (from 1.0) in the Final Revised Plan and increased in the Big Holes to 1.2 (from 1.0).

The decision to increase the density standard in the Big Holes is based partly on public demand. The character of the area will still fall well within the definition of "semi-primitive" (see glossary, "Recreation Opportunity Spectrum).\" LAB/LRG/CMM/JR/MLB

COMMENTS: Standard B., DFPR III-7, should preclude administrative use on restricted roads, trails or areas.

697

RESPONSE: Administrative use is necessary in many cases to meet management goals. An example is grooming cross-country ski trails with motorized equipment, which is otherwise excluded from motorized use. If approved by the

ACCESS - STANDARDS AND GUIDELINES

Forest Supervisor or District Ranger, administrative use will occur on a short-term basis when necessary. LAB/LG/JR

COMMENTS: Information is needed to demonstrate management guidelines on specific road densities.

1369

RESPONSE: The process used to develop road density standards and the research citations are included in Process Paper D available from the Supervisor's Office. JR

Timing of Implementation

COMMENTS: Include a standard to implement travel plan immediately.

1195

RESPONSE: The Travel Plan is implemented when the Record of Decision is signed. The ROD for the Travel Plan will be signed about the same time the ROD for the Revised Plan is signed. It will take some time to sign the open designated roads and trails. The Forest will proceed with signing as rapidly as possible. However, the Travel Plan will take effect immediately.

LAB/LRG/CMM/JR

COMMENTS: Implement motorized access, access to be a standard in the Plan immediately upon signing of the Record of Decision.

766

RESPONSE: OROMTRD Standards are included for each prescription in the Revised Plan. These standards will be implemented upon the signing of the Record of Decision. LAB/LG/JR

Temporary Roads Need Standards and Guidelines

COMMENTS: In the standard and guidelines address the designated temporary roads.

1446

RESPONSE: The Revised Plan OROMTRD Standards address this concern. A temporary road is a road other than a specified road which is constructed by a timber purchaser for the purpose of harvesting timber. Temporary roads are usually closed after completion of the contact. Any temporary roads constructed will need to meet the OROMTRD Standard in the Revised Plan. If the standard would be exceeded, another road would need to be closed while the temporary road is in use. For more information on temporary roads, see Glossary, Roads. LAB/LG/JR

Non-Motorized

COMMENTS: This Non-Motorized Management Prescription should be changed to the New Management Prescription in 2.2.1. Use strict, clear standards to implement this prescription area.

643, 1365

ACCESS - STANDARDS AND GUIDELINES

RESPONSE: This prescription was not adopted in the Revised Plan. The prescriptions adopted in the Revised Plan meet wildlife needs in balance with other resource objectives. Making the Centennial Mountains non-motorized is not necessary to manage the area for wildlife habitat needs. The road density standard in each prescription provides the necessary security for grizzly bears and meets elk vulnerability objectives. JR

COMMENTS: Recommend/Proposed Wilderness Prescription 1.3: Prescription 1.3 should be managed in a manner identical to that of wilderness; the Standard should be modified to read "they already exist as official and legal motorized travel ways."

1365

RESPONSE: This suggestion was not adopted in the Revised Plan. Forest Service responsibility is to maintain the wilderness character until Congress makes a decision as to whether the area will be wilderness.

The description says they will be "managed in their present condition" which means the Forest can allow motorized access on designated roads or trails in the prescription as long as wilderness character is maintained. The access table provides the specific standards for each area. LAB/LG/JR

Trails Need Standards

COMMENTS: Goals for trails are not adequate. Standards are needed to define requirements for trails.

697

RESPONSE: (Manual policy is not repeated in the Revised Plan), See Forest Service Manual, Policy, Appendix A, Pages 6, 27 and 28, for requirements of trails. LAB/LG

OHV

COMMENTS: Standards and guidelines should be made for physical damage related to logging and off-road vehicle use, implement protection standards for resources because of these impacts.

678, 697

RESPONSE: There are standards and guidelines for physical damage, related to logging and off-road vehicles, and many other uses on the Forest. Any time there is evidence of resource damage, the Forest can restrict the operation. The Revised Plan provides for summer cross-country motorized use on seven percent of the forest. The rest of the Revised Plan restricts summer motorized use to designated routes. LAB/LG/CMM/AM

COMMENTS: Forest should adopt a forestwide standard prohibiting all cross-country use except for snowmobiles.

695

RESPONSE: The Revised Plan prohibits summer cross-country motorized use on all but seven percent of the forest. Snowmobiles are allowed cross-country

ACCESS - STANDARDS AND GUIDELINES

without restrictions in all non-wilderness areas except in big game winter ranges where they are restricted to designated routes. AM/JR

COMMENTS: OHV Guideline three should be a standard not a guideline (Restrict OHV use on identified areas of unstable soil).

695

RESPONSE: The guideline provides more flexibility to deal with site-specific conditions. The Revised Plan only allows summer cross-country OHV use on seven percent of the Forest. JR

COMMENTS: OHV Standard and Guideline four: no motorized vehicles > 50" inches wide are allowed on trails unless the trails are specifically designed for such vehicles.

695

RESPONSE: This is correct. This standard prevents regular vehicles (pickups and jeeps) from traveling on motorized trails designated for OHVs. LAB/LG

COMMENTS: Evaluate in terms of the damage done by each use group (ORVs snowmobiles, etc.), then control access accordingly. (CROSS REFERENCE: Access, Trails)

351

RESPONSE: Resource damage is an important factor used in determining which roads and trail were to remain open. See Access Appendix in the FEIS for more details. This type of information is also collected in the monitoring reports and will provide information for needed changes in the future. LAB/LG
CMM/JR

COMMENTS: Proposed ORV corridor is objectionable, change to what was in Prescription 1.3.

No letter number

RESPONSE: Prescription 1.3 is appropriate for the areas for which it was set. LAB/LG/CMM/AM

Change Recreation Standards and Guidelines

COMMENTS: Recreation Standard and Guidelines for OHV's: Guidelines 1, 2, 3 should be standards; in Guideline 1 the word "discourage" should instead read "prohibit; Guideline 3 should include provisions for restricting and prohibiting snowmobile use on unstable soils when there is any significant risk of negative soil impacts; The ROS Standard should be changed to suit the non-motorized designation.

1365

RESPONSE: The guidelines provide the needed flexibility to manage the variety of conditions that exist on the Forest. The guideline provides the site specific direction needed in managing OHV's.

The word discourage is used because some slopes greater than 40% are stable enough to allow OHV use. Site-specific conditions will determine

ACCESS - STANDARDS AND GUIDELINES

the use that can be accommodated. Only seven percent of the Forest is open to summer motorized cross-country travel and within the seven percent there may be areas where use on slope greater than 40% is acceptable.

Guideline 3 is not intended to restrict snowmobiles. Soils usually become unstable when they are saturated with moisture rather than when they are frozen or overlaid with snow. The usual snowmobile activity on the Forest during the winter has not had an effect on unstable soils that have snow cover. Most of the snowmobile areas on the Forest receive an average of 3-12 feet of snow a year.

The Revised Plan uses a composite of specific multiple-use directions including goals, objectives, standards and guidelines with probable management practices. The Recreation Opportunity Spectrum was part of the management selection and was coordinated with other resources in the area. In recreation a motorized ROS standard is appropriate in some prescriptions just as non-motorized is suitable for other prescriptions. LAB/LG/CMM/JR

COMMENTS: It seems incongruent to set some guidelines for some uses, and then not deal with the damage caused by off-road vehicles.

697

RESPONSE: The Forest deals with damage caused by off-road vehicles by citing violators for resource damage, closing areas to off-road travel and rehabilitating some areas. Specific OROMTRD standards are established for each Management Prescription to address this concern. Only 7 percent of the Forest is open to summer cross-country motorized vehicles in the Revised Plan. LAB/LG/JR

COMMENTS: Forest use and occupation: all the guidelines should be standards.

1365

RESPONSE: Standards describe a condition of land, normally a maximum or minimum condition, that is measurable. Deviation from compliance with a standard requires a Forest Plan amendment. A guideline represents a preferred or advisable course of action that is generally expected to be carried out: Deviation from compliance with a guideline does not require a Forest Plan amendment, but requires a site-specific analysis with documented rationale. The Revised Plan provides the proper mix of standards and guidelines. Guidelines are applicable in site-specific projects when conditions are not uniform and flexible options may be the best to meet resource objectives. The guidelines allow for this flexibility. LAB/LG/CMM/JR

Wildlife - Recreation

COMMENTS: In DFPR, Forest use/occupation/access: modify access goal to emphasize threatened endangered candidate and sensitive species and big game habitat.

1446

RESPONSE: The access goals in the Revised Plan address these concerns. Each management prescription provides a OROMTRD standard which was determined to a great degree by wildlife concerns (see Process Paper D in the Supervisor's Office). LAB/LG/CMM/JR

ACCESS - STANDARDS AND GUIDELINES

COMMENTS: In DFPR, Recreation/OHV/Objective: expand objective to minimize effects of OHV on Riparian Aquatic, and critical/crucial wildlife; Develop motorized recreation management Standard and Guidelines to exclude use within crucial seasonal wildlife habitat.

1446

RESPONSE: The objective was not expanded to minimize effects of OHVs on riparian aquatic and critical wildlife. Neither were the recreation management standards and guidelines developed to exclude use within crucial seasonal wildlife habitat. However both situations are covered in the individual Management Prescriptions 2.7 (a-b) Elk and Deer Winter Range and 2.8.3 Aquatic Influence Zone. In both management prescriptions OHVs are restricted to travel only on designated roads or trails. Winter motorized use is also restricted to designated routes in winter range areas outside of the 2.7 prescription in the Final Revised Plan. The road density standards further emphasize wildlife by controlling the amount of road or trail open for motorized travel. Elk vulnerability and grizzly bear security are both considered in developing the road density standards for a prescription.
LAB/LR/CMM

COMMENTS: Need a Standard with mandatory environmental review process for all site-specific projects; impose/enforce speed limits in a standard; impose restrictions on party size and length of stay; prohibit use during slush conditions; base season of use on conditions.

1365

RESPONSE: The standard mandatory environmental review process used for site-specific projects is the NEPA process. This will be used for each site-specific project proposed on the Forest. The Revised Plan does not duplicate existing legal requirements or policy direction. Most of the suggestions are not appropriate to be included in the Revised Plan because they are site-specific decisions.

The Forest recommends speed limits but does not have authority to enforce them on National Forest Road Systems. The local County Sheriff enforces speed limits.

The Targhee, under "Special Orders," limits length of stay and party size. The travel map for the Forest will also establish road closing dates to meet traditional weather conditions. Opening and closing some roads can also be done in accordance with weather conditions.

LAB/LG/CMM/JR

ACCESS - SEASONAL RESTRICTIONS

COMMENTS: Oppose seasonal restrictions. Use seasonal restrictions through the use of gates. Support access restrictions for elk protection.

4, 181, 350, 646

RESPONSE: There need to be some seasonal restrictions on access in the spring to protect resource damage and big game calving areas, and in the fall for protection of resources and big game security. In most cases, restrictions are done by gating, unless these prove ineffective; then more restrictive measures are taken. LB

ACCESS - SEASONAL RESTRICTIONS

COMMENTS: Adjust road mileages for seasonally restricted roads according to the proportions of each season they remain closed (similar to the Nez Perce Forest).

643

RESPONSE: Roads which receive two vehicle trips per week are considered open for the purposes of analysis; they are included in the open road density analysis. This is in agreement with other agencies. LB

ACCESS - SITE-SPECIFIC

Site Specific Dubois Ranger District

Support Closures - Italian Peaks

COMMENTS: Close the following trails in Italian Peaks "Wilderness Area": Webber Creek-Divide (111); Myers Creek (113); Crooked Creek-Willow Creek (081).

395, 695

Close Italian Peaks to OHV and all motorized use.

161, 200, 643, 725

RESPONSE: When the area was proposed as wilderness, the Forest agreed to allow motorbike access on designated trails including the ones listed above as long as the wilderness character was maintained. These trails make up the only bike loop system in the high country on the Dubois Ranger District.
LMM/KT

Non Support Closures - Italian Peaks

COMMENTS: Off-road travel into Italian Peaks does not cause lasting damage, therefore do not close Italian Peaks.

270, 1202

RESPONSE: The Italian Peaks area has steep slopes, shallow soils, and little vegetation to protect the resources from off-road travel. OHV's on the slopes can destroy vegetation; without the vegetation, runoff and rainstorms can rapidly cut gullies in the shallow soils. Much of the area is a fragile alpine environment where even walking can cause damage. The trail system was left open to certain motorized and non-motorized use in order to provide continued access. LMM/KT

COMMENTS: Open Scott Canyon road to Italian Peaks.

1202

RESPONSE: Scott Canyon road is not currently used and is closed as part of the compromise to allow some motorized use in the Italian Peaks proposed wilderness area. The closure allows some nonmotorized use of trails by visitors wanting a more primitive experience. LMM/KT

ACCESS - SITE-SPECIFIC

Support Closures - Centennials

COMMENTS: Keep roads for the Sheep Station in the Centennials open for determining long term ecological trends.

1398

RESPONSE: East Dry Creek Road is open in the Revised Plan. LMM

COMMENTS: The use of snowmachines in the Centennial Mountains stresses and impacts: wildlife (birds); private land owners; and the forest.

1322

RESPONSE: The Revised Plan provides continued public access to the National Forest and Centennials in the winter. Some areas in the Centennials are designated winter range and snowmachines are restricted to designated routes through the winter range. Most of the birds remaining on the Forest during winter seek tree cover for shelter and security. Tree cover is often heavy enough that snowmachines go around them or they are on steep slopes that snowmachines cannot traverse. Private landowners can post their lands to remind snowmobilers to avoid their private property. LMM

COMMENTS: Restrictions should remain for cross-country motorized travel in the Centennial Mountain Subsection.

432, 1333

RESPONSE: Thank you for your support. The Revised Plan retains cross-country motorized travel restrictions in the Subsection.

LMM

Non Support Closures - Centennial Mountains

COMMENTS: Do not maintain the Centennial Mountains as a crucial roadless corridor.

368

RESPONSE: The major access routes in the Centennial Mountains are still open to motorized uses. LMM

COMMENTS: Oppose closing the areas around Centennials.

342

RESPONSE: In the Centennial Mountains the main access roads are still open to travel. There are some trails that remain open for motorized use. On all but 7 percent of the Forest, summer motorized travel is restricted to designated routes. Closing some areas in the Centennials helps the Forest meet elk security requirements and to reduce potential damage to fragile soils. LMM/AM

Support Closures - Sheep Creek

COMMENTS: Access restrictions should be applied to Sheep Creek - Road 325.

1185

ACCESS - SITE-SPECIFIC

RESPONSE: Sheep Creek is a dead-end road that provides access to Sheep Creek. The only access allowed is on the main road. The Revised Plan does not allow cross-country motorized access in the area. LMM

Support Closures - East Dry Creek

COMMENTS: Supports closures in the East Dry Creek area.
432

RESPONSE: East Dry Creek is open to access the Sheep Station. LMM

Non Support Closures - Eight Mile/Pass Creek

COMMENTS: Designated routes in Eight Mile/Pass Creek area have had little off-trail impacts and should be left open.
1202

RESPONSE: These routes have received a lot of impact. They are steep trails used for hill climbing that have received significant amounts of erosion and these are now closed. LMM

Support Closures - Other - Dubois

COMMENTS: System roads #185, #022, and #204 should be closed from their junction in S22, T13N, R43E.
643

RESPONSE: Roads #185 and #022 are closed in the Revised Plan because they are not passable and have not been maintained. However, 204 was left open for permittee access. LMM

COMMENTS: System roads #010, #019, #674, & #675 should be closed.
643

RESPONSE: The Forest carefully considered each road during the Forest Plan revision process. After road densities were determined for each prescription area, management decided which roads to leave open or closed. Road #010, a dead end road providing the main access to Pete Creek, remains open. Road #019, a dead end road providing access to the Bear Gulch canyon and access for livestock and timber management, remains open. Roads #674 and #675, both old timber roads, are closed because they are no longer needed. LMM/KT

COMMENTS: Motorized use of Trail #110 (and associated trails) should be eliminated.
643

RESPONSE: Because this trail provides access to Corral Canyon and ties in with other roads, the Revised Plan leaves it open to motorized use. LMM

COMMENTS: Supports closures on roads #530, #531, #534, #539, #540, #173, and #240 as well as roads to Bald Mountain and Pass Creek.
643

ACCESS - SITE-SPECIFIC

RESPONSE: All these roads remain open because there is no resource damage. The Revised Plan provides road density compatible with wildlife, while still allowing some motorized access. LMM

COMMENTS: Trails that need to be closed are #045, #046, and #047.
643

RESPONSE: #047 Rocky Canyon will be closed. Trail #45 and #46 connect with access on the Challis National Forest and will remain open. LMM

COMMENTS: Supports closures #020 and #021.
459

RESPONSE: #020 Long Creek provides access to electronic sites on the mountain and a cattle allotment; #021 Threemile a main system road, provides access to Threemile Canyon, the head of Rattlesnake Canyons, livestock, timber, and Signal Peak. LMM

COMMENTS: Leave Modoc, Medicine Lodge, and Crooked Creek areas open for ORV's.
348

RESPONSE: Parts of Medicine Lodge and Crooked Creek area are in proposed wilderness. These areas are closed to cross-country motorized travel because of steep slopes and to maintain wilderness characteristics, but they are open on designated trails. The Modoc area is closed from September 1 to July 1 except for designated roads. Snowmobiles are allowed in the area from Thanksgiving until June 1, except in designated winter range where travel is restricted to designated routes. LMM

COMMENTS: Wants to have trail access in the following areas: #2, #4 thru #9, #26, #45, #47, #81, #110, #111, #113, #175, #177, and #179.
262

RESPONSE: All trails are open except for two: Rocky Canyon #47 is closed because of resource damage and because it provides important wildlife habitat. The main portions of the canyon are closed to livestock use also. The trail #9 of East Camas-Table Mountain was closed to meet elk vulnerability standards and to provide security for elk. LMM

Mapped "Comments"

COMMENTS: The following responds to requests for road and trail changes submitted on maps without dialogue.

RESPONSE: Pleasant Valley, Road 323 remains open it access the area as well as State lands; there is low resource impact; and is a designated route.

Spur off of 020 - Remains open because it provides access to an electronic site.

Spur off of Sheep Creek #325 - Remains open because it provides access to private land.

ACCESS - SITE-SPECIFIC

Dairy Creek Road #017 is a major system road, accesses State land and the National Forest, and has no major resource damage. Therefore it remains open.

Road 534 - The Forest will not close this road as it provides the only viable access into Deer Canyon.

Road 539 - Because it provides access into Surette Canyon, the Forest will not close this road.

Road (unnumbered) Little Sawmill - The Forest will leave it all open. It is within density standards and provides access to National Forest lands.

Road (unnumbered) fork of Road 296 - The Forest will leave it open because it provides access to private lands.

Pasture Creek Road #023 - Goes to trailhead. Major access. Timber/sheep access. Already closed.

Mandingo #175 - Already closed. Only used administratively to plant trees.

Ching Creek Road - #027 - Remains open because it is the major access to Aldous Lake Trailhead. LMM

Site Specific Island Park

Support Closures - Lionhead

COMMENTS: Supports closures for Lionhead Roadless area.
362, 695, 727

RESPONSE: Lionhead Roadless area is closed to motorized vehicles except snowmobiles. It is open to snowmobiles from Thanksgiving to June 1.

COMMENTS: Prohibit motorized access in Lionhead because it will diminish the prospect for wilderness designation.
727

RESPONSE: There is one motorized trail that goes through approximately 1/8 of the roadless area in T16N, R44E section 19. This is a Gallatin National Forest motorized trail. Cross-country is not allowed because the area has steep terrain and a pristine character; cross-country would cause irreparable damage to its wilderness character.

Non Support Closures - Lionhead

COMMENTS: Open all of Lionhead for the summer and winter activities.
F-I(4), 342

RESPONSE: Lionhead is proposed for wilderness designation and the lake basin and surrounding area was designated a Research Natural Area. It is open for snowmobiling from Thanksgiving Day to June 1. The area is closed to summer motorized use to protect and preserve its pristine character and to prevent user conflicts.

ACCESS - SITE-SPECIFIC

Support Closures - Targhee Creek

COMMENTS: Supports closure for Targhee Creek.
695, 362

RESPONSE: We agree. It is closed in the Revised Plan. AK

Support Closures - Red Rock Pass Road

COMMENTS: Maintain habitat security on Red Rock Pass Road.
1185

RESPONSE: Red Rock Pass Road (053) remains open in the the Revised Plan since it is a Forest development road and provides access to Lakeview, Montana. Habitat security is maintained for the area by meeting road density standards. JH/MLB

Support Closures - Buffalo River Headwaters

COMMENTS: Eliminate vehicle access directly to the spring by designating a parking area 1/4 mile from the spring and adding pit toilets to the parking area near Buffalo Headwater.

1276

Do not close roads 291 and 292 to the 1219 because wants access to put canoe in headwaters of Buffalo River.

511

RESPONSE: Roads 291, 292 and 1219 provide access to the Buffalo Headwaters and remain open in the Revised Plan. The roads are needed to access an area of heavy recreation use to both developed and undeveloped sites. The Forest will continue to monitor the area for resource damage. AK/AO/MLB

Non Support Closures - Wood Road #461

COMMENTS: Close Woodroad #461.
1371

RESPONSE: Road 461 is closed in the Revised Plan. AK

Non Support Closures - Black Canyon Road

COMMENTS: Open Black Canyon.
F-I(4), 227, 323, 380, 412, 466, 473, 474, 476, 524, 648, 1202
Roads that are now closed should be open, especially the Black Canyon Road.
F-C(13)

RESPONSE: Part of the Black Canyon road is open to 068. A portion of the road, which was originally closed for rehabilitation following the North Fork fire, remains closed in the Revised Plan in order to meet the road density standards needed for bear security in the Bear Management Unit. Other roads remain closed in the Revised Plan in order to meet road density standards per

ACCESS - SITE-SPECIFIC

individual prescription. Refer to the Access Appendix in the FEIS and Process Paper D, available in the Supervisor's Office, for more information concerning road densities. AO/JH/MLB

Non Support Closures - Keg Springs

COMMENTS: Keep Keg Springs Road open.

F-C(13), F-I(4), 19, 323, 380, 412, 473, 474, 476, 524, 643, 648, 1202, 1308, 1310, 1350, 1455

Keg Springs system roads should be open approximately one mile north of Forest Service southern boundary.

F-I(4)

Leave Blair Lake Road open.

19

RESPONSE: The Keg Springs Road north of the Forest Service southern boundary (near Blair Lake) is in the U.S. Sheep Experiment Station and outside Forest Service jurisdiction. This road remains closed to the public due to the Station's research work. Forest Road 042 is open to Keg Springs in the Revised Plan. AK/JH/MLB

Non Support Closures - Blue Creek and West Blue

COMMENTS: Blue Creek and West Blue needs to have hunting access for disabled/handicapped.

713

RESPONSE: Blue Creek remains open to the bridge, but the bridge is unsafe to cross. Both roads are closed in part or whole to meet BMU density standards. The Forest has areas accessible to hunters with disabilities. AK

Non Support Closures - Willow Creek

COMMENTS: Willow Creek system roads should be open approximately one (1) mile north of Forest Service southern boundary.

643

RESPONSE: This area is open to the culvert and closed beyond the culvert for resource protection and to meet road density standards. AK

Non Support Closures - East Dry Road

COMMENTS: Open East Dry (327) system road south of S32, T15N, R40E.

643, F-I(4)

RESPONSE: This road is open to motorized travel to within 1/4 mile of the Continental Divide (CD). The CD trail portion is not built for motorized vehicles. The Sheep Experiment Station land is closed to motorized vehicles. AK

ACCESS - SITE-SPECIFIC

Non Support Closures - Two Top

COMMENTS: Open Two Top for recreational use.
342, 1308, 1310, 1333, 1350

RESPONSE: This area is in Situation 1 grizzly bear habitat. The Revised Plan designates one route for OHVs greater than 50 inches open to motorized use. Additional open areas would exceed road density and cause further resource damage (soils) and conflict with the bear. The road to Two Top remains open. The road from Meadow Creek to Tygee Creek Basin remains open. It is the only road in the area (#061). AK

Non Support Closures - Other - Island Park

COMMENTS: Preserve road/trails in the Island Park areas.
298
Closing Island Park area is not acceptable.
4

RESPONSE: The Revised Plan does not close Island Park. Roads and trails will be preserved to the extent that roads meet the road density standards, and there are no adverse environmental effects. AK

COMMENTS: Open more trails in Island Park area.
262

RESPONSE: The Revised Plan closes more roads due to adverse environmental effects and to meet road density standards. The Forest also considered intermingled ownerships. AK

COMMENTS: Designate trails for ATV use.
1202

RESPONSE: The Revised Plan adds a system of loop trails that connect to West Yellowstone and the railroad right-of-way North of Ashton to West Yellowstone. As the Forest implements the plan, other loop trail opportunities will be examined within the road density standards. AK

COMMENTS: Create a motorized trail from Warm River to West Yellowstone.
640

RESPONSE: This area is closed to motorized use to protect fisheries beyond Warm River; however, it is open beyond Mesa Falls in the Revised Plan. AK

COMMENTS: Leave roads as they are for winter and summer activities.
529

RESPONSE: The Forest must meet road density standards and close roads that show adverse environmental effects. Please refer to the Access Appendix to the FEIS and Process Paper D, available in the Supervisor's Office, for a more detailed explanation. AK

ACCESS - SITE-SPECIFIC

Support Closures - Other - Island Park

COMMENTS: Supports the closure of road #024.
459

RESPONSE: If this is referring to the Sawtell Road, it will remain open because the road serves the FAA and high recreation use in summer. AK

Support Closures - Subsections - Island Park

COMMENTS: Island Park Subsection: close significant amount of roads.
Madison Plateau Subsection: close as many roads as possible.
489

RESPONSE: Roads are closed to meet road density standards, protect grizzly bears in BMU's, and prevent resource damage or effects on water quality and fisheries. AK

Site Specific Ashton Ranger District

Non Support Closures - Antelope Flats

COMMENTS: Open Antelope Flats.
1455

RESPONSE: Antelope Flats is open in the Revised Plan. AK

Support Closures - Aspen Ridge

COMMENTS: Preserve roads and trails in Aspen Ridge area.
298

RESPONSE: Forest Service system roads are partially open and limited in the Bootjack area behind the Aspen Ridge Estates. Most trails in the area were not built by the Forest Service and do not meet trail standards; they were created by "dispersed use". The Forest will continue to preserve roads in the area consistent with road density standards and resource concerns. AK

Non Support Closures - Fish Creek

COMMENTS: Open Fish Creek for recreational vehicles.
6, 1308, 1310, 1350

RESPONSE: Fish Creek Road #082 is open in the Revised Plan. The surrounding area is closed to summer cross-country motorized travel in order to meet BMU standards. AK

Non Support Closures - Fish Creek Road/Baker Draw Road

COMMENTS: Open Fish Creek Road from Baker Draw Road for outdoor activities (hunting, snowmobiling).
F-P(2)

ACCESS - SITE-SPECIFIC

RESPONSE: The Fish Creek Road is open to hunting and snowmobiling in the Revised Plan. The areas on either side of the Fish Creek Road are closed to summer cross-country motorized travel during the snow free seasons. The area closure is necessary to provide security for wildlife. During the snow season, the road and adjacent areas are open to snowmachine travel. AK

Non Support Closures - Fall River Ridge

COMMENTS: Keep Fall River Ridge open to snowmachines and for elk hunting.
F-P(2)

RESPONSE: The Revised Plan allows motorized travel on designated routes in the Fall River Ridge area. Cross-country travel in the area is not permitted during snow free seasons to provide security for wildlife. The area is also Situation 1 grizzly bear habitat. During snow seasons cross-country snowmachine travel is permitted. AK

Support Closures - Porcupine

COMMENTS: Oppose the easement that provides access by Porcupine Station.
153

RESPONSE: If this is referring to the request for access across National Forest System lands from the Fall River Ridge road to private land on the north side of Fall River, the issue is outside the scope of the Forest Plan and is being addressed in a separate environmental analysis. AK

Non Support Closures - Pole Bridge Campground

COMMENTS: Provide handicapped/disabled access to clearcuts behind Pole Bridge Campground.
713

RESPONSE: Road #153 is open. Other roads are closed to meet BMU standards.
AK

Non Support Closures - Other - Ashton District

COMMENTS: Designate ATV trail in the Ashton area.
1202

RESPONSE: The railroad grade from Road 154 north to West Yellowstone is designated as an ATV trail. AK

COMMENTS: Supports motorized trail from Warm River to West Yellowstone.
640

RESPONSE: This area is closed beyond Warm River to protect the fisheries; however, it is open beyond Mesa Falls in the Revised Plan.

COMMENTS: Provide access across Fall River Ridge from Porcupine Lake Road.
199

ACCESS - SITE-SPECIFIC

RESPONSE: Road #243 is designated open in the Revised Plan. AK

Support Closures - Other - Ashton District

COMMENT: Supports two miles or less of roads per square mile with more restrictive Standards dependent on specific Prescriptions on portions of the Ashton Ranger District, especially the portions of that District located in Wyoming.

389

RESPONSE: The road density standards in each prescription in the Revised Plan are designed to compliment the management intent of the prescription. A large portion of the Ashton Ranger District in Wyoming is designated Wilderness which has no roads. The other prescription in this area is 5.3.5 (Grizzly Bear Habitat). The road density for this prescription is calculated on a Bear Management Unit basis which would be the Targhee Portion of the Bechler-Teton BMU. The Total Motorized Access Route Density (TMARD) standard for the BMU is 1 mile/square mile and the Open Road and Open Motorized Trail Route Density (OROMTRD) is 0.6 miles/square mile. AK

COMMENTS: Close Reclamation Road near Ashton to Flagg Ranch because it: fragments wildlife habitat; endangers grizzly bear; is most damaging and unnecessary road in Yellowstone Ecosystem; as use grows, road becomes more difficult to close and more damaging.

171

RESPONSE: The Reclamation Road will remain open in the Revised Plan. This road serves as a designated route that links the community of Ashton, ID, with recreation opportunities at Flagg Ranch, WY, the John D. Rockefeller Jr. Memorial Parkway, and Yellowstone and Teton National Parks. This road provides access to an established youth organization camp and developed trailhead facilities for people accessing the Winegar Hole and Jedediah Smith Wildernesses. AK

Prescriptions - Big Bend Ridge

COMMENTS: It is crucial that the Big Bend Ridge be managed with a non-motorized prescription to ensure its protection in the face of growing development pressures.

1365

RESPONSE: This area is closed to cross-country snowmachine travel except from January 1 to April 30, and open to cross-country travel for motorized vehicles <50" wide from June 15 to September 30. AK

Mapped "Comments"

COMMENTS: The following responds to requests for road and trail changes submitted on maps without dialogue.

ACCESS - SITE-SPECIFIC

RESPONSE: Snow Creek (094), Road 702, and Road 572 (Big Grassy) will remain restricted year-long for a portion of the road to meet road density in the BMU.

Trail Canyon goes through CORE of Plateau BMU. Density standard is 0.0.

The Forest decided not to build new connector from 749, Fish Creek Spur #3, because it would go through Core in BMU.

Although Fish Creek Spur #3 is not in Core, but in security area, the Forest will not open it due to road density standards.

The Forest can not open #037 (Moose Creek Trail) to motorized use because part of it is in Core where Standard is "0", and part is in security area for BMU.

The Forest can not open #554 year-long (Snow Creek Spur #1), because of required road densities in BMU Security area. AK

Site Specific Palisades Ranger District

Analysis Process

COMMENTS: Table on Page III-101 is incorrect. For 10-15 years roads have been closed to snowmobiles from Heise Canyon to Blacks Canyon to protect critical winter range. Prohibit vehicles, including snowmobiles, on designated trails.

FS-3

RESPONSE: This area was incorrectly shown as open to snowmachines on the draft's map. This was corrected in the Final and is closed. The River Road from the Forest Boundary to Blacks Canyon is closed to snowmachines to protect critical winter range. BBP

Support Closures - Garns Mountains

COMMENTS: Close the following trails to ORV use in the Garns Mountains Roadless Area: Big Burns Creek #068; Hell Hole #070; Jensen Creek Coal Mine #064; Beartrap Canyon; Little Burns Creek #071; Slide Rock #072; Little Burns - Slide Rock #073.

695

RESPONSE: Burns Creek Drainage: (068 Big Burns Creek Trail) is a main OHV loop trail. Resource damage along this trail is minimal with little damage at stream crossings or along trailheads. This trail remains open to OHV travel except from the junction of Bear Trap Trail to junction of Slide Rock Trail 072, where it will be closed and not maintained. This portion will be allowed to return to natural conditions. The Forest made this decision because the trail goes through a designated RNA and does not provide a connection since Slide Rock trail will also be closed.

Hells Hole (070) was proposed to be closed in the DEIS, because of exceeding road density standards. After further review the prescription road density standard was not exceeded and the trail was left open.

Jensen Creek Coalmine (064), Little Burns Creek (071) and Bear Trap trails provide important access loops to OHV users. The Forest determined them suitable for designated routes. Slide Rock (072) is closed to OHV travel

ACCESS - SITE-SPECIFIC

and all other uses due to resource damage. This trail will not be maintained and will be allowed to return to natural conditions from junction of Trail 073 to junction of Bear Trap Trail. From junction of Trail 073 to Liars Peak Trail, 072 will remain open to OHV Travel.

Little Burns/Slide Rock (073) trail will remain open for OHV use and has the same attributes as Trails 046, 071, and the Bear Trap Trail. BP

Support Closures - Fall Creek

COMMENTS: Support a new winter time route through June Creek Winter Range to connect to Skyline Drive.

1202

RESPONSE: June Creek is outside the critical winter range and therefore, a designated route is not needed for this area. Snowmachine trail grooming will be allowed on the June Creek Road as part of the county grooming program. BP

COMMENTS: Designate Fall Creek area for ORV use.

206, 204

Unfair closures to OHVs in Fall Creek.

1190

RESPONSE: Fall Creek is open for OHV use; summer cross-country travel is restricted in all of the Palisades District. BP

COMMENTS: All system trails should be opened to motorized use.

1202

RESPONSE: While not all system trails should be closed to motorized use, it is equally true that some areas should not be opened. This decision was evaluated for each area in the Revised Plan.

During the Plan Revision, the Forest looked at motorized use and its compatibility to other resource values (such as wildlife, watershed, water quality, recreation uses and needs). Current restrictions and closures were reviewed to see if they were still needed or if additional closures were warranted due to increased use. If the situation showed changes were needed, then changes were recommended in the Revised Plan. The biggest change for all the Districts was the recommendation for cross-country travel restrictions. Most of the Palisades Ranger District is steep and has terrain that limits cross-country travel. This type of activity was occurring in the form of hill climbing where evidence of resource damage was readily visible. Where terrain was less restrictive, damage occurred simply because of the increased number of OHV's that have been introduced since the last planning period. New and better machines caused trails/roads to appear. In many cases, visual resources were a major reason for recommending closure of cross-country travel. MB

COMMENTS: Palisades (Antelope, and Fall Creeks) are excessive motorized travelways in important big game range; highest road densities and highest elk vulnerability. Limit use seasonally or all year. Idaho Fish and Game says there are too many vehicles in here.

FS-4

ACCESS ~ SITE-SPECIFIC

RESPONSE: This area was evaluated in the open road density calculation. Those roads and trails proposed open to motorized use are within the standard for this prescription. Some resource areas, when considered alone, may appear to have too many roads. The standard in the prescription is a mix of all resource considerations. BBP

COMMENTS: Close Burns Creek and 1000 Springs to cross-country because of destruction to riparian areas and decrease in wildlife security.

632

RESPONSE: These areas are closed to cross-country travel in the Revised Plan. Travel is restricted to designated routes, which are existing trails in the area. BBP

Support Closures - Poker Peak

COMMENTS: Support the proposal of Poker Peak non-motorized Prescription 3.1.1 (a).

695

RESPONSE: This area is closed to motorized travel under the Revised Plan. Boundaries were selected which could easily be followed and understood by the public and administrators. BBP

Non Support Closures - Pine Creek

COMMENTS: Establish a motorized corridor between Pine Creek and Indian Creek.

1202

RESPONSE: A corridor would require a trail system through the Palisades Creek OHV closure. The Forest decided to leave this area closed. BBP

Support Closures - Indian Creek

COMMENTS: Close Indian Creek to ORV's.

161, 200

Motorized access to Indian Creek is unfair.

304

RESPONSE: Indian Creek is within the Wyoming Wilderness Study Area. This WSA allows motorized use on designated trails (Indian Creek) until a wilderness decision is made by Congress for this area. BBP

COMMENTS: Concerned about unsafe horseback/ORV use of trails.

304

RESPONSE: The Forest does not agree that horseback and OHV uses are unsafe on trails. It is true that some users create unsafe situations on forest trails. This is best handled through education rather than closures. BBP

Non Support Closures - Indian Creek

COMMENTS: Establish a motorized corridor between Pine Creek and Indian Creek.
1202

RESPONSE: This would require a trail-system through the Palisades Creek OHV closure. After review of this area, the Targhee decided not to provide a loop in the Revised Plan. BBP

Non Support Closures - Red Ridge

COMMENTS: Closing OHV use in Red Ridge area is unfair.
1190

RESPONSE: Red Ridge is closed to cross-country travel as is the entire district. Trails in Red Ridge area are left open. With the exception of cross-country travel, which is difficult due to steep terrain, access in this area changes very little in the Revised Plan. BBP

COMMENTS: Apply OROMTRD in Table Rock.
1273b

RESPONSE: Table Rock was included in the road density calculations. Prescription standards are developed and will be implemented. BBP

Support Closures - Bear Creek

COMMENTS: Close entire roadless area in Bear Creek to motorized use.
204, 1202

Close to OHV use to retain big game security, reduce erosion, and provide solitude in Bear Creek drainage.
204

RESPONSE: Bear Creek is a major motorized use area and remains open. The Fall Creek/Bear Creek area was reviewed for the amount of OHV use and its compatibility with other resources and uses. OHV use was determined to be compatible with uses and resources needs with some trail work and relocation. Road density was within the Plan standard, and so no adjustment was needed. One trail (less than one mile) was closed to all uses and allowed to return to natural conditions in the four corners area because it paralleled another system trail serving the same area. Other than this one trail, all other system trails in the Caribou subsection remain open in the Revised Plan. BBP

Non Support Closures - Bear Creek

COMMENTS: Open all system and non-system trails Big Holes, Fall Creek, Bear Creek, Palisades to motorized use.

OHV closures in Bear Creek are unfair.
1190, 1202

ACCESS - SITE-SPECIFIC

RESPONSE: All but one short trail are open to motorized use in Bear Creek. Cross-country travel is restricted (hill climbing and random travel). RD

Support Closures - McCoy Creek

COMMENTS: Prohibit winter motorized travel north of McCoy Creek road with date restriction November 1 - August 31 to protect nesting areas.

389

RESPONSE: There are no nesting areas north of McCoy Creek Road. There are identified eagle nesting sites between McCoy Creek Road and Palisades Reservoir. McCoy Creek Road has long been a major groomed trail. There is no evidence to suggest this has been a problem. In fact, new nesting sites have been recorded during the snowmachine use period. JR

COMMENTS: Do not make a trail head at Long Springs because of contamination.

459

RESPONSE: The District is not currently planning to develop a trailhead at this area. However, there will be a road end and trail beginning location. This would be an undeveloped trailhead. BBP

Non Support Closures - McCoy Creek

COMMENTS: Establish ORV use in McCoy Creek.

204, 206

RESPONSE: OHV use is allowed in McCoy Creek except for cross-country travel.

BBP

Non Support Closures - Palisades Creek/Big Elk

COMMENTS: Change Prescription 1.3 (Plan III-69) to leave drainages of Big Elk and Palisades Creek open to snowmachine use.

395

RESPONSE: The lower part of these drainages are within identified Big Game Critical Winter Range, and are closed to snowmachine use. No designated route is planned for these areas. Big Elk Creek Road is a county road and use of the road is allowed or disallowed by the county from US Highway 26 to the trailhead. From the trailhead up stream to the boundary of the winter range closure, the trail is closed to snowmachines and is not a designated route.

BBP

Closures - General - Palisades

COMMENTS: Keep all Palisades off limits to ORVs.

F-M(5), 200

RESPONSE: The Revised Plan continues summer time OHV restrictions. OHV travel is prohibited in the Palisades backcountry area and is limited to designated routes in other areas of the Snake River Range. BBP

ACCESS - SITE-SPECIFIC

COMMENTS: Close trails: #065, #089, #051, #090, #045, #055, #046, #099, #057, and #058.

RESPONSE: These trails were evaluated for what type use would be allowed. None were determined as not needed, however, some were closed to motorized use to meet road density standard or some other resource need. The following closures refer to motorized closures only. Trails will be maintained for other uses.

#065 - Mike Spencer - Trail used by OHV, designated route for OHV.
#089 - North Fork Rainey Creek - Trail used by OHV as loop trail.
#051 - Sheep Driveway - Closed.
#090 - South Fork Rainey Creek - Used by OHV as loop trail.
#045 - Poker Peak - Closed.
#055 - Box Canyon - Trail does not currently exist and will not be reopened for any uses.
#046 - Big Elk Mountain - OHV trail open along ridge-top.
#099 - Waterfall Canyon - Closed.
#057 - Burnt Timber - Open OHV designated route trail.
#058 - Deadhorse - Open OHV designated route trail. RD

COMMENTS: Locate corridors for winterized travel in the Palisades Wetland area on or south of McCoy Creek (regarding trumpeter swan and waterfowl).

389

RESPONSE: The snowmachine designated route for this area is on the south side or along the existing McCoy Creek Road as recommended. BPP

COMMENTS: Prohibit motorized access from November 1 - August 31 to protect mating and brood rearing periods in the Palisades wetland areas.

389

Provide access in the following areas: Palisades Ranger District, (including Caribou Forest administered by Targhee Forest) trails #4, #26, #27, #28, #30 thru #50, #55, #60, #63, thru #68, #70, thru #74, #78, #79, #80, #82, #83, #86 #89 thru #92, #94, #107, #120, #138, #140, #142, #144, #145, #148; #155, #157, #158, and #159.

262

OHV closures in Palisades are unfair.

F-M(5), 1190

Open all system trails in the Palisades to motorized use.

F-M(5), 1202

RESPONSE: The proposed designated route system for winter time travel and the summer time seasonal restriction should adequately protect the wetland and wildlife.

Most areas that are currently open for motorized use are still open. Palisades and Big Elk Creek areas are currently closed to motorized travel during the summer time and will remain closed because of amount of use, type of use, terrain features and future desired conditions of the area.

During the plan revision, the Forest looked at motorized use and its compatibility to other resource values (e.g., wildlife, watershed, water quality, recreation uses and needs). Current restrictions and closures were reviewed to see if they were still needed or if additional closures were

ACCESS - SITE-SPECIFIC

warranted due to the increased use. If the situation showed changes were needed, they were recommended in the Revised Plan. The biggest change for all the Districts was the recommendation for summer cross-country travel restrictions. Most of the Palisades Ranger District is steep and has terrain that limits summer cross-country travel. Where this type activity was occurring, it was in the form of hill climbing where evidence of resource damage was readily visible. Where terrain was less restrictive, damage occurred simply because of the number of OHVs that have been introduced since the last planning period. New and better machines caused trails/roads to appear. In many cases, visual resources were a reason for recommending closure of cross-country travel.

The following is a brief summary of the recommendation for the Revised Plan by subsections:

Big Holes - Most system trails were compatible with existing use and resources. However, it was recognized that many trails were not properly located and would require trail work.

Road density review was made for the Big Holes for elk vulnerability and security and motorized road/trail density was slightly above the established standards. It became necessary to reduce the road/trail density in order to meet the standard. Trails were closed that were used the least and would be the most difficult to bring up to standard. Loop ride trails were considered important and received high consideration.

Only a small number of trails were closed to motorized travel for either of the reasons stated above. Most trails remain open in the Big Holes and access to the Big Holes remains basically the same as before.

Palisades - Existing closures were reviewed in this area, particularly the Palisades Lakes area. Considering the amount and type of use which occurs in this part of the Forest, a closure was decided in the Revised Plan. Motorized use in this area is not compatible with existing uses.

Other parts of the Palisades Mountain Range were also evaluated for motorized use and were compatible with designated route selections. Routes in the Indian Creek area were left much as they existed. Selection of the closed routes were the same as in the Big Holes.

Fall Creek/Bear Creek - This subsection was reviewed for the amount of OHV use and its compatibility with other resources and uses. OHV use is compatible with uses and resources needs with some trail work and relocation. Road density was within the Plan standard, and so no adjustment was needed. One trail (less than one mile) was closed in the four corners area because it closely paralleled another system trail serving the same area. Other than this one trail, all other system trails in the Caribou subsection remain open in the Revised Plan. BBP

Site-Specific Teton Ranger District

Support Closures - Big Holes

COMMENTS: Restrict off-highway vehicle (OHV) travel in Big Holes to prevent resource damage.

215

RESPONSE: All summer motorized travel is limited to designated roads and trails and closed to cross-country in the Revised Plan. By having a defined

ACCESS - SITE-SPECIFIC

system of motorized roads and trails, resource protection is more easily obtained through trail maintenance, reconstruction, and/or relocation. MB

Support Closures - Spring Creek

COMMENTS: Motorized use in the Spring Creek area (Prescription 3.2) should be limited to designated routes.

1312

RESPONSE: Spring Creek is located above the Rapid Creek Guard Station. When reviewing this area for access and potential problems, the Forest determined that terrain limits cross-country travel so a closure to cross-country travel was not needed. The winter range portions of the area are closed to both motorized and non-motorized use from Thanksgiving Day until June 1. BP/LD/MLB

COMMENTS: Do not create more needless access to the Big Hole Mountains to maintain Elk Security.

325

RESPONSE: The Revised Plan reduces motorized access from the current situation. By eliminating cross-country motorized travel and designating roads and trails open to motorized use, the problem with access in the Big Holes should be reduced significantly. Any changes to access as presented in the Revised Plan will be subject to project-specific analysis. Some trails may be relocated as part of reconstruction but there are no plans at this time for construction of additional motorized access in the Big Holes.

Some roads and trails were closed to motorized use in order to comply with density standards of the Revised Plan.

The Targhee has always considered public access to the National Forest and elk security as important elements of forest management. Elk security is a major consideration when determining road standards and was evaluated in the plan revision. No needless access is allowed to occur in the Big Holes. MLB/BP

COMMENTS: Need more restrictions on the cross-country off-road vehicles in the Big Holes area.

387

RESPONSE: All summer motorized travel will be limited to designated open roads and trails and closed to cross-country in this area. This is more restrictive than current management. MB

COMMENTS: Wants more road/trail closures in the Palisades Big Holes Units.

387

RESPONSE: Motorized access has been a polarized issue, particularly in the Palisades Big Holes Subsection. After reviewing public comments and revisiting access as proposed in the Draft Revision, the Forest changed the open road and trail densities in Prescription 3.2(g) which represents the majority of the subsection. The Revised Plan divides the 3.2(g) areas to allow a lower road density (from 1.0 to 0.5) in the Palisades portion of the subsection next to recommended wilderness and a higher road density (from 1.0

ACCESS - SITE-SPECIFIC

to 1.2) in the Big Holes Subsection. The result will be less motorized access than is allowed under current management and more than was proposed in the Draft Revision. MB/BP

Non Support Closures - Big Holes

COMMENTS: All system roads in Big Holes should be open to motorized use.
F-G-2(2), 1202

RESPONSE: All roads were evaluated in the Revised Plan. Those identified as needed and within the road density standard will remain open and become system roads. Those identified as not needed or outside the standard will be closed. More system roads will be open in the Big Holes in the Final Revised Plan than was proposed in the draft. In the north end of the Big Holes (Prescription 5.1.4(b)), it is impossible to leave all the system roads open and stay within road density standard of 1.5 miles per square miles. In the south end of the Big Holes, all system roads will be open in the Final Revised Plan with the exception of Power Line Road. The Power Line Road will be open to off-highway vehicles and motorcycles from Mike Harris Campground to Murphy Creek and closed to all motorized vehicles from Murphy Creek west to Rainey Creek. The reason the western section is closed is because the powerline access is not contiguous, traverses steep terrain and does not currently receive a lot of use. The entire powerline corridor is open to Bonneville Power Authority for service. MB

COMMENTS: Disagree with statement RE: unacceptable resource damage in Big Hole/Palisades as stated in DEIS.
1202

RESPONSE: The summer access reference in Chapter III of the EIS states, "The highest concentration of these activities are in the Big Hole/Palisades and Caribou Subsections, where there is significant use by motorcycles and mountain bikes. As noted in the Soil and Riparian section, there are areas of concern for OHV effects on soil and vegetation. There is not serious widespread adverse consequences as a result of this use." The soils and riparian sections for the Big Hole/Palisades Subsection identifies OHV use as one of many activities affecting soil and riparian quality. The Forest will continue to repair resource damage caused by all forms of access in the Subsection. MB/DM

COMMENTS: Discriminating to include Big Holes as wilderness.
311

RESPONSE: The roadless area of the Big Hole Mountains are not currently managed as wilderness nor proposed by the Forest Service to be wilderness. The motorized access provided for in the Revised Plan would not be allowed if the area was designated wilderness. MB

COMMENTS: OHV use must be regulated and monitored in the Big Hole Mountains.
215

ACCESS - SITE-SPECIFIC

RESPONSE: The Forest concurs that the Final Revised Plan provides a network of designated motorized roads and trails that will be better regulated than the current situation (which allows extensive cross-country motorized travel). Chapter V of the Revised Plan provides for monitoring and regulation of OHV use, as funding and personnel allow. MB

COMMENTS: Does not want trails closed in the Big Holes area.
54, 97, 1282, 1449

RESPONSE: The Revised Plan provides a workable network of trails together for the Big Holes area. The revised trail system provides general access to most areas in the subsection and provides several loop opportunities of various lengths and degrees of difficulty which are feasible to maintain and manage. Because the resulting network exceeded the road and trail density standard in the Draft 3.2(g) Prescription, the Revised Plan increases the density in the prescription to provide motorized access on most of the site-specific trails requested to be open by the public. Closure of some of the trails in the Big Holes was necessary to meet road density standards and address resource concerns. Trails closed to motorized use will remain open to other uses when possible and maintained accordingly. MLB

COMMENTS: Provided access into the Big Hole Mountains should continue.
311

RESPONSE: Most of the existing trail system remains open to motorized use in the Revised Plan. The major change in access is the closure of the area to summer cross-country motorized travel. Cross-country motorized travel in the Big Holes has resulted in numerous unplanned roads and trails which often access areas already provided by existing trails. Undesigned roads and trails can cause negative impacts to soil, water quality and wildlife. These "trails" can result in confusion for recreation users since they are not on maps. Maintaining or rehabilitating these "trails" are not the best use of limited trail maintenance funds nor to other Forest resources. The District attempted to keep all specifically requested trails open in the Final Revised Plan. See also site-specific responses in this section. MB

COMMENTS: Big Hole/Palisades. Correct misstatement: "there are no serious widespread adverse consequences as a result of this use." Not true. This area has a serious problem and most trails need to be rerouted to be suitable. Most of the problems are in MA17 and MA21.

FS-2

RESPONSE: The statement in the Revised Plan remains as written. The Forest recognizes that there are some serious local problems on trails which must be corrected by relocation or closure of the trail, (e.g., Castle Lake to Blacktail Pass, and Slide Rock Trail). Action will be taken as funding and opportunity become available. This is not a widespread problem - it is not occurring everywhere, nor are the trails in serious condition. BP

ACCESS - SITE-SPECIFIC

Support Closures - South Leigh Lakes

COMMENTS: No trail construction to accommodate use at South Leigh Lakes.
1312

RESPONSE: There is no constructed, maintained trail into the South Leigh Lakes Basin. The Revised Plan does not propose one, nor are any projects planned to provide such access. Use of the unmaintained route area is expected to continue. The Forest will monitor the South Leigh Lakes basin and has no intentions of encouraging additional use of the area. MB

Non Support Closures - Fox Creek

COMMENTS: Maintain a public right-of-way to Fox Creek Quarry.
1312

RESPONSE: The Forest Service has legal public access through the Fox Creek quarry. The quarry was inactive for years and recreation access through the quarry was not a problem. Now that the quarry is active, heavy equipment and mining activity pose a potential safety hazard to the public. A more indepth site-specific analysis will occur to involve the public in the decision making process. Any proposal to change public access in the area would be conducted in compliance with the National Environmental Policy Act. MB

Support Closures - Canyon Creek

COMMENTS: Support closures to motorized recreation from Canyon Creek to Garns Mountain.
1312

RESPONSE: After considering public comments, the Revised Plan provides motorized access (#063, 064 and 066) into this area. This increase in motorized access meets open road and trail density standards and responds to the demand for more motorized access in the Big Holes. MB

COMMENTS: Leave Canyon Creek open.
342

RESPONSE: Trail #064 North Fork of Canyon Creek and Trail #063 South Fork of Canyon Creek remain open in the Revised Plan. MB

Non Support Closures - Castle Lake

COMMENTS: Thousand Springs to Castle Lake should be opened.
397

RESPONSE: Thousand Springs/Castle Lake Trail remains open under the Revised Plan. This trail was identified as a shared use trail including motorized use. In the field season of 1996 the trail was rerouted around Castle Lake to

ACCESS - SITE-SPECIFIC

Blacktail Pass in order to correct resource damage on the old trail. The new trail was relocated on a good grade with good water drainage. BP

Non Support Closures - Pine Creek/Piney Pass

COMMENTS: Open Pine Creek to Piney Pass.
397

RESPONSE: Trail #050 is open in the Final Revised Plan.

Non Support Closures - Ryan's Creek/Elk Flat

COMMENTS: Open Ryan's Creek across Elk Flats.
397

RESPONSE: This area was not located on maps. BP

Non Support Closures - Pony Creek

COMMENTS: Oppose closing the area around Pony Creek.
342

RESPONSE: All motorized travel in the Big Holes subsection is limited to designated routes. Pony Creek Road #666 is restricted year-long in the Revised Plan because existing road densities exceed the standard established by the management prescription. The District intentionally left the north end of the Big Holes slightly below the allowable road density so that closed system roads such as Pony Creek could be opened occasionally for wood cutting, hunting or other purposes.

Support Closures - Other - Teton

COMMENTS: Supports closure to trails: #039 and #052 and to Missionary Ridge.
643

RESPONSE: Commissary Ridge is on the Caribou subsection. Trail #039, the Indian Creek Trail, is in the same subsection but 10 to 15 miles from Commissary Ridge; however trail #052, North Fork Palisades, is in a different subsection. All trails in this subsection were evaluated in the Revised Plan. If a trail was needed and met open road and trail density standards, it was declared a designated route. BP

COMMENTS: Support management of Teton District (Prescription 3.2) to offer semi-primitive motorized and non-motorized recreation for hiking, horseback riding, mountain bikes.
389

RESPONSE: Thank you for your support. The Final Revised Plan refines this need by applying three slightly different versions of the 3.2 Prescription in order to provide an array of recreational opportunities and respond to polarized comments on the recreation access issue. MB

ACCESS - SITE-SPECIFIC

COMMENTS: Supports two miles or less of roads per square mile with more restrictive standards dependent on specific prescriptions on Teton Basin Ranger District, the northern portion of District specifically.

389

RESPONSE: Thank you for your support. All prescriptions in this area provide road densities of two miles per square mile or less.

COMMENTS: Wants access to the following areas: Teton Ranger District Trails #43, #44, #49, #50, #51, #53, #54, #56, #62, #63, #64, #66, #75, #76, and #77.

262

RESPONSE: Trails #43 and #44: Burbank and Mail Cabin are closed to maintain the wilderness and roadless character of the Palisades Wilderness Study Area.

Trail #49: Mikesell-Mail Cabin trail dead ends in the wilderness. Since no loop opportunities are available, the Forest closed them to prevent an enforcement problem of motorized use in the wilderness.

Trail #50: Sheep Driveway trail is open for summer access.

Trail #51: Pole Canyon is open for summer access.

Trail #53: A motorized trail along the Big Hole crest is open for summer access.

Trail #54: The Patterson Creek trail is open for summer access.

Trail #56: Big Hole Crest trail is open for summer access.

Trail #62: Elk Flat - Relay Ridge trail is open for summer access.

Trail #63: Canyon Creek - South Fork trail is open for summer access.

Trail #64: North Fork Canyon Creek is open for summer access.

Trail #66: Garns Mountain trail is open for summer access.

Trail #75: The Liar's Peak trail is closed to motorized travel for summer access. This closure was needed to allow the route along the Big Hole crest to stay within the road density standard in the prescription. The Final Revised Plan increases the density standard in that area from 1.0 to 1.2. Comments were polarized about motorized access in the Big Holes. The Liar's Peak trail is an expert level trail. The Forest responded to the Idaho Trail Machine Association's request that they would rather have the Crest Trail open than Liar's Peak.

Trails #76 and #77: The Red Creek and Corral Creek trails have not been maintained for years, receive minimum use by skilled riders (Corral Creek gets more use than Red Creek), are poorly located in creek bottoms, have steep slopes, are difficult to ride and are difficult to maintain for motorized use. Both trails are connectors that could provide additional loop opportunities but are not necessary to provide general access. The trails were closed to motorized use to meet density standards and to open other trails with better potential as motorized trails. MB

COMMENTS: The same prescription as at Henry's Lake should apply to the west slope of the Tetons in the Sorenson Creek development area.

1360

RESPONSE: There are five prescriptions which border the Henry's Lake private inholding. The Sorensen Creek "development area" is adjacent to the Winter Range Prescription 2.7 (a). All 2.7 (a) are critical winter range for big

ACCESS - SITE-SPECIFIC

game animals and need the standards and guidelines included in that prescription. Site-specific decisions for projects which may affect adjacent landowners are subject to the requirements of the National Environmental Policy Act (NEPA). MB

COMMENTS: Pole Canyon Road (one map shows it as #060 another shows it as #051) should be closed because it leads to non-motorized areas where people use trails illegally.

725

RESPONSE: Pole Canyon Road (051) is an open motorized trail in the Final Revised Plan. The Pole Canyon route is half of a motorized loop trail that leads to a large network of non-motorized trails. The prescription is well below road density and meets the demand for some motorized trail routes in this area. The loop of the road makes the management of the trail system more feasible. MB

COMMENTS: Concerned about developing site specifics for area 7.1 (b) due to proximity to the Henderson Canyon Road. Concerned about fire burning (supports burning), logging, exploration, access, recreational use, visual appearance, wildlife. Wants opportunity to be informed and comment prior to site specifics being approved.

708

RESPONSE: The Revised Plan changed the block of 7.1 (b) to 5.1.3 (b) because Prescription 7.1 (b) was unclear in several respects. Prescription 5.1.3 (b) is similar to 7.1 (b). Site-specific projects are subject to NEPA and will include public involvement. Public involvement opportunities are sent out in a NEPA quarterly report to any requestors. MB

Mapped "Comments"

The following responds to requests for road and trail changes submitted on maps without dialogue.

COMMENTS: Road 922 Wright Creek - Bleggi Gooseneck Road should remain closed. Missing Letter #

RESPONSE: This is a two-track road accessed across private lands or from the Grandview Main Road, the primary road into the north Big Holes. Road 922 does not connect. If it was open, it would encourage users to create a new, nonsystem connecting road. MB

COMMENTS: "Road 657" is not a road but is the Carlton cut-off Trail.

RESPONSE: Road 665 is the new road which provides vehicle access to the same area. This trail will remain open as a trail, since it is not passable with a jeep.

COMMENTS: Open the Spur road off Pine Creek Road on D-4.

ACCESS - SITE-SPECIFIC

RESPONSE: Most roads off Pine Creek Highway are open and will remain open under the Revised Plan. BP

ACCESS - SOCIAL CONCERNS

General

COMMENTS: Oppose any or all road restrictions for reasons regarding quality of life, such as: access supports local economics; future trends and growth indicate need for more access; and, concerned that the Targhee National Forest is locking the public out. Access to the Forest should increase, or at least remain at current management levels.

24, 25, 26, 35, 46, 63, 124, 182, 229, 250, 259, 262, 300, 309, 316, 318, 319, 330, 391, 413, 439, 447, 512, 607, 1321, 1332, 1390

Restrict access for reasons regarding quality of life such as: access regulates human contact with ecosystem; protects the environment; and, reflects social access needs.

12, 23, 318, 333, 407, 640, 694, 1197, 1370

RESPONSE: Access was one of the most polarized issues during the planning period. Each watershed on the Forest is delineated by management prescriptions. Each prescription has a road density standard. The road density standard provides a cost effective road system that integrates human needs, wildlife needs (specifically elk and grizzly bear), and other resource values. A few existing roads will be closed to meet the road density standard. Most of the main roads and trails on the Forest will remain open on designated routes and only seven percent of the Forest will remain open to summer cross-country travel. In most prescriptions the road density standard is about 1.5 miles per square mile.

Social concerns were considered in arriving at the final decisions on motorized and nonmotorized access on the Forest. The Revised Plan is a balance between competing interests, protects resource values and still provides sufficient access for users. The Access Appendix in the FEIS details the access analysis used in the Revised Plan. LAB/CMM/MLB

ACCESS - SOIL

COMMENTS: Discuss what soil erosion factors restrict OHV use.

413

RESPONSE: The soil erodibility factor (K-factor) is a measure of the susceptibility of soil particles to detachment and transport by rainfall and runoff. Soil properties considered in developing the soil erodibility factor include: soil texture (especially percent of silt plus very fine sands), percent sand greater than .1mm, organic matter content, soils structure, soil permeability, clay mineralogy and coarse fragments in soil layer being evaluated.

Rainfall intensity, distribution, amount, length and steepness of slope, vegetative cover (or lack of cover) and erosion control practices all influence soil erodibility. Chapter III of the Revised Plan includes Forestwide guidelines for slope steepness and stability to identify situations where the soil erodibility factor would be accelerated on a trail system. DM

ACCESS - SOIL

COMMENTS: Disagree that rutting or displacement of soils is caused by ORV use. It is caused by design and maintenance of the trail, not the type of use.

629

RESPONSE: Rutting and displacement of soils occurs on numerous non-designated OHV trails that traverse steep slopes. On designated routes, the above comment is basically correct. A portion of the designated OHV trails are not designed or adequately maintained to reduce resource damage. DM/TEM

ACCESS - TIMBER MANAGEMENT

COMMENTS: The OROMTRD in Timber Management Areas of ≤ 3.0 miles per square mile allows a high open road/trail density which exhibits no attention to wildlife needs and should be drastically reduced.

1273b, 1361

RESPONSE: The Timber Management Prescription that has the OROMTRD of ≤ 3.0 miles per square miles is 5.1 (b). There were some changes from the Draft Plan to the Final Revised Plan and Prescription 5.1 (b) was not used. The concern of a high open road/trail density in timber management areas was taken into account. CMM

ACCESS - TIME FRAME

Road Closure Implementation in BMUs

COMMENTS: Provide a time-specific plan which describes the prioritization scheme for implementing road closure programs within BMUs. Specify implementation of road closures within one year of ROD, and completion in three years. Complete it sooner than the proposed three years.

(CROSS REFERENCE: Wildlife, Grizzly Bear)

127, 643, 695, 766, 1273b, 1361

Provide a time-specific plan which describes the prioritization scheme for implementing road closures. Recommended time frames for completion include five, three and sooner than the proposed ten years.

127, 643, 690, 695, 766, 1194, 1361, 1401, 1407, 1446

RESPONSE: The Forest will implement road closures after the Record of Decision (ROD) is signed. The BMU road closures are the first priority and will be completed within the first three years of the release of the Revised Plan. How the roads are to be closed will require site-specific NEPA documentation and public involvement. LB/CMM

Nonsystem Roads

COMMENTS: Revegetate all nonsystem roads, in accordance with NFMA, within ten years. (CROSS REFERENCE: Access, Process)

1361

RESPONSE: Many of the nonsystem roads are designed for re-establishment of vegetative cover and will conform with NFMA requirements within ten years.

ACCESS - TIME FRAME

Some of the nonsystem roads will require special treatment which will be directed by the site-specific NEPA document. Not all roads need to be revegetated. If access is removed from roads, many will revegetate naturally. The Revised Plan provides for restricting or reclaiming roads not needed for future management as determined in site-specific analysis, at the end of project use. LB/CMM

COMMENTS: Nonsystem roads must be closed within ten years of their creation, or they must be added to the road inventory. Publicize a list of nonsystem roads and what decisions the Targhee has regarding them. (CROSS REFERENCE: Access, Analysis Process)
1273b

RESPONSE: NFMA requires all roads to be planned and designed to re-establish vegetative cover on the disturbed area within a reasonable period of time, not to exceed ten years after the termination of a contract, lease or permit, unless the road is determined necessary as a permanent addition to the National Forest Transportation System. The Revised Plan designates the open roads. How the other roads will be closed will be determined in a site-specific analysis. The public will be notified of the road closure through the analysis process. LB/CMM

COMMENTS: Revegetate all logging roads within a ten year time frame.
1347

RESPONSE: All logging contracts require that logging roads are revegetated at the completion of the timber sale if they are no longer needed and are removed from system roads. LB

ACCESS - TRAILS

COMMENTS: Oppose the proposed trail restrictions or closures in Alternative 3M and support more non-motorized and motorized trail access to the Forest. Concerned about having less trail access to enjoy the outdoor experience. Increase trail numbers for the public, particularly to please mountain bike users. (CROSS REFERENCE: Access, Road & Trail; Access, Site Specifics)
17, 25, 35, 36, 49, 53, 54, 63, 156, 182, 211, 262, 265, 285, 286,
288, 290, 306, 310, 313, 315, 324, 330, 367, 375, 413, 477, 488, 514,
629, 640, 659, 669, 697, 728, 1202, 1240, 1241, 1259, 1314, 1332,
1339, 1376

RESPONSE: The Revised Plan has many opportunities for both motorized trail use and non-motorized. Trail closures are necessary to protect various resources including wildlife habitat, water quality and fisheries. During implementation trails may be reconstructed to accommodate various uses. Most trails are open to mountain bikes. CC/AM/JR

COMMENTS: A better trail design would prevent erosion and maximize protective cover between wildlife and OHVs.
629, 1365

ACCESS - TRAILS

RESPONSE: During implementation of the Revised Plan, it is likely numerous trails, particularly in the area of the Big Hole Mountains, could be reconstructed to a better design. The Revised Plan has an objective to assess 5-10% of open trails on a yearly basis to determine rehabilitation needs. CC

COMMENTS: Define what "resource" means on Page III-60 of the DFPR in the sentence, "Trails are maintained to protect the resource."

1277

RESPONSE: Resource refers to wilderness values, since that is the prescription area involved. LAB

COMMENTS: Better address the Continental Divide National Scenic Trail. The motorized vehicle restrictions to that trail system applies to mechanized bikes as well. However, the Plan as written fails to provide the outdoor experience sought by hikers and horseman and recognized as a goal in the Trail Act. At a minimum, the Plan should identify an acceptable level of use and then provide monitoring and evaluation.

345

RESPONSE: Direction is not duplicated for management of the Continental Divide Trail as that was included in a separate environmental assessment completed in cooperation with the Northern Region of the Forest Service. Our intent is to complete construction of the few remaining segments of the trail on the Targhee National Forest as soon as funds permit. For example, a segment in Targhee Creek was completed in cooperation with the Gallatin National Forest in 1996. Directions for management of the experience along the Trail is provided in the specific management descriptions.

The Revised Plan does not address acceptable level of use. However, it does distinguish between which trails are open for non-motorized or motorized uses. Five to ten percent of the trails will be assessed to determine if any rehabilitation needs are necessary and trail use will be monitored during implementation of the Revised Plan. LAB/JR

COMMENTS: Develop a trail system which designates specific trails for specific trail users (bikes, OHV, 4-wheelers, hikers, horseback).

5, 12, 345, 1457

RESPONSE: In general, our policy is to encourage multiple use of trails. That way, as many people as possible can enjoy the trail experience. In practice funds do not permit construction of separate trails for everyone. However, such management prescriptions in the Revised Plan provides access tables which lists whether trails are open to motorized use. In some areas motorized use is allowed and in others it is not. This may help some people to select a particular trail for their recreation needs. In particularly high use or conflict areas, trail users are separated. For example, the Palisades Creek Trail is one trail that only allows hikers, non-motorized bikes and horseback use. Such designations will be done on a project-specific basis when the need exists. LAB/JR

ACCESS - TRAILS

COMMENTS: Restrictions on access should be based on an evaluation of impacts or damage to resources by each user group.

351

RESPONSE: We agree. For details of the analysis for the Revised Plan, refer to Process Paper D in the Supervisor's Office and the Access Appendix in the FEIS. JR

COMMENTS: Prefer dispersed OHV trail use; support better trail maintenance; adopt some trail rules like other National Forests have; trail numbers are adequate; share trails with various user groups; and, support closing trails to add in prevention of non-motorized illegal use.

F-G-1(475), 7, 24, 262, 306, 313, 371, 525, 725

RESPONSE: We agree. Thank you for your comments. The Forest improved the trails management guidelines in the Forestwide goals, objectives, and standards and guidelines. We hope to devote increased attention to trails as we implement the Revised Plan. LAB/JR

COMMENTS: Restrict motorized access to the maximum extent.

631

RESPONSE: The Forest restricted motorized access to the extent needed to protect resources and provide a variety of recreational experiences and other uses as required by the Multiple Use Act. The net effect was to reduce motorized access. Fewer roads and trails are open to motorized use in the Revised Plan than currently. Only 7 percent of the Forest is open to summer cross-country motorized use in the Revised Plan. LAB/AM/JR

ACCESS - USER CONFLICTS

COMMENTS: Off-highway motorized recreational activity and non-motorized recreational activity occurring in the same areas pose safety hazards. Also, the noise and air pollution of those vehicles displaces non-motorized users.

1365

RESPONSE: This is acknowledged in the EIS analysis documentation. OHV use is limited in the Revised Plan to designated trails except for seven percent of the Forest where summer cross-country travel is permitted. Safety is important in recreational activities. Education of users is also important in developing courtesies and safety along the trail. There are many prescriptions where non-motorized travel can take place, just as there are many prescriptions where motorized travel is acceptable on designated routes. LAB/CMM

ACCESS - WILDERNESS, ROADLESS, RESEARCH NATURAL AREA, & WILDERNESS STUDY AREA

Access In RNAs

COMMENTS: Do not allow motorized use, including mountain bikes, within Research Natural Areas; however, non-vehicular recreation should be allowed except when the activity threatens RNAs.

ACCESS - WILDERNESS, ROADLESS, RESEARCH NATURAL AREA, & WILDERNESS STUDY AREA

For recreation, utilize access restrictions or closures under CFR Subpart B. (CROSS REFERENCE: RNA)

612

RESPONSE: Motorized use is not prohibited by law in Research Natural Areas. Motorized use is allowed in the Revised Plan on designated routes in some RNAs. This use is allowed to continue where it does not compromise RNA objectives. Similarly, other human recreation use is allowed where it does not compromise RNA objectives. JR

Access In Wilderness Study Areas (Palisades)

COMMENTS: There should be no motorized vehicle use in WSAs; support winter access only. (CROSS REFERENCE: Wilderness)
150, 161, 171, 189, 206, 280, 396, 443, 491, 611, 643, 666, 692, 739, 1245, 1270, 1273b, 1365, 1381, 1401

By allowing any motorized use in Wilderness Study Areas, future designation to wilderness will be difficult. (CROSS REFERENCE: Wilderness)
157, 174, 209, 242, 252, 273, 278, 280, 392, 632, 643, 727, 1206, 1270, 1276, 1388

RESPONSE: The Wyoming Wilderness Act of 1984 states that motorized access is allowed on designated routes only in this Wilderness Study Area. These routes are located in the Indian Creek Area. The Revised Plan follows the direction of the Wilderness Study Area (WSA) for this area and prohibits motorized vehicles over 50" in width while allowing OHVs under 50" wide on designated routes only. The Act also states snowmobiling shall continue to be allowed in the same manner and degree as was occurring prior to the date of the enactment of the Act in the Palisades WSA. Therefore, snowmachine use is allowed in the Wilderness Study Area. This will not preclude designation as wilderness if the Congress so chooses. BBP/LAB/JR

COMMENTS: Clarify and define the statement for WSAs: "Roads are allowed only to the extent they already exist." Explain specifically: if roads are closed or open; if roads are sources of sediment; if roads then open loop roads; is obliteration scheduled for closed roads; and, if "already exist," are they on final road inventory. (CROSS REFERENCE: Wilderness)
1273b, 1361

RESPONSE: The Wyoming Wilderness Act limits roads to those that currently exist. No plans exist or are proposed in the Revised Plan which allow new road construction in the WSA. Road closures are shown in the travel plan; those identified to be open are shown on the Revised Plan inventory; those not identified to remain open will be closed. All roads differ as to the extent they cause sediment. This is evaluated in the Revised Plan and the results are shown in the travel plan. BBP/LAB

Access In Wilderness

COMMENTS: Support motorized use in wilderness or recommended wilderness.
F-G-2(2), 22, 28, 30, 42, 55, 63, 270, 280, 311, 344, 358, 366, 367, 381, 385, 386, 413, 476, 638, 645, 664, 702, 737, 738, 1183, 1332, 1375

ACCESS - WILDERNESS, ROADLESS, RESEARCH NATURAL AREA, & WILDERNESS STUDY AREA

Oppose motorized use in these areas. (CROSS REFERENCE: Wilderness)
F-B(4), F-G-1(475), F-H(8), F-J(3), 34, 73, 150, 157, 161, 162, 165,
168, 170, 171, 174, 175, 179, 180, 185, 189, 201, 206, 209, 212, 213,
226, 242, 273, 278, 280, 331, 351, 376, 377, 382, 392, 396, 398, 400,
405, 424, 439, 441, 444, 491, 516, 607, 609, 611, 613, 620, 622, 632,
636, 640, 643, 644, 650, 653, 656, 662, 666, 690, 695, 725, 727, 731,
739, 1194, 1202, 1205, 1206, 1243, 1270, 1273b, 1275, 1276, 1313,
1327, 1330, 1360, 1361, 1365, 1382, 1388, 1395, 1443, 1458

RESPONSE: The areas already designated as wilderness by the Congress are closed to motorized and mechanical access by law. In recommended wilderness, Forest Service responsibility is to retain the wilderness character until the Congress makes a decision about whether to add them to the National Wilderness System. Motorized access is provided in some recommended areas in the Revised Plan. JR

Access In Roadless Areas

COMMENTS: Roadless areas should exclude all motorized vehicles, and be managed for trails not roads. (CROSS REFERENCE: Wilderness)
382, 396, 400, 408, 430, 491, 492, 611, 622, 643, 695, 1202, 1365

RESPONSE: No specific legal requirement prohibits motorized use in roadless areas. In the Revised Plan the vast majority of the roadless country will remain roadless throughout the life of this Plan. The Revised Plan provides motorized access on trails in several roadless areas to provide quality recreation opportunities for motorized users. JR

COMMENTS: Motorized use in roadless areas recommended for wilderness is incompatible and contrary to the intent of management prescriptions. Existing roads should be scheduled for closure and eventual obliteration. (CROSS REFERENCE: Wilderness)
643, 1273b

RESPONSE: Forest Service responsibility in roadless areas recommended for wilderness in the Revised Plan is to protect the wilderness character of the area until Congress makes a decision whether to designate the area as part of the National Wilderness System. Motorized use on trails or snowmobile use is not prohibited unless the Congress makes that determination. Management direction in the Revised Plan protects the wilderness character of these areas pending a decision by the Congress. JR

Access In Special Management Areas

COMMENTS: Objects to new road construction in any special management areas because fragmentation is a problem that needs to be reduced.
1369

RESPONSE: Fragmentation is addressed in the Revised Plan. The open road and open motorized trail density standard is a result of this analysis. (See Process Paper D available in the Supervisor's Office and the Access Appendix

ACCESS - WILDERNESS, ROADLESS, RESEARCH NATURAL AREA, & WILDERNESS STUDY AREA

in the FEIS for more details). The net result is that fragmentation is reduced in the Revised Plan. Collectively, the OROMTRD Standards result in a reduction of roads and trails to motorized use. Only 7 percent of the Forest remains open to summer cross-country motorized travel. Any new construction is included in the open road density figure for the particular prescription area and will conform to the OROMTRD standard. Site-specific analysis may also address fragmentation prior to project implementation for any new road construction project. BBP/JR

ACCESS - NOXIOUS WEEDS

COMMENTS: Deal with weed control through road access. Limiting access will help reduce distribution of new weed infestations; however, completely closing roads will make it difficult to control existing weed infestation problems. (CROSS REFERENCE: Range, Noxious Weeds)

432

RESPONSE: Motorized activity can aid in the spread of noxious weeds, but this is dependent on many factors such as season-of-use, species of plants, suitable opportunities for establishment, or duration of use. It is impossible to calculate how much road use causes the spread of noxious weeds. The Forest will use some roads for administrative access to handle some noxious weed problems. LAB/WG

ACCESS - WILDLIFE

For issues about elk and access; grizzly bear and access; wildlife general and access, see wildlife, elk; wildlife, grizzly bear; and wildlife, access.

Big Game Winter Range and Access

COMMENTS: Protect big game winter range through the use of road closure and restrictions on motorized access, both cross-country and road/trail. Support access restrictions to minimize impacts of winter recreation; to decrease development of adjacent private lands; and to protect crucial big game winter range. Manage cross-country skiing in these areas. Use Wyoming Game and Fish Department's "crucial" designations. Keep winter access at current levels.

7, 9, 150, 185, 189, 195, 201, 206, 213, 227, 265, 339, 359, 389, 645, 669, 1183, 1202, 1247, 1311, 1316, 1345, 1456

RESPONSE: The winter range boundaries in the FEIS were cooperatively determined by the Targhee and State fish and game agencies. Motorized access is limited in big game winter range to designated routes year-round. CC

COMMENTS: Prescription 2.7 should be changed to big game winter range, to include moose and bighorn sheep.

1247

RESPONSE: This management prescription is developed primarily for elk security while also allowing for other multiple uses. The habitat conditions provided by this prescription are suitable for a variety of other wildlife species, including big game animals like moose and deer. Bighorn sheep are

ACCESS - WILDLIFE

also protected through other prescriptions for roadless and wilderness areas where they are generally found. MO/AM

Access Disturbance to Wildlife

COMMENTS: Bird populations and their habitats are negatively impacted by cars on roads because of noise, vibration, visual stimuli and exhaust.

1367b

RESPONSE: We agree that bird populations and their habitats can be negatively impacted by cars on roads. Road density standards for elk and grizzly will reduce the number of roads open for motorized use thus indirectly benefitting other wildlife such as bird populations. AM

COMMENTS: Change DEIS language: "Where possible, open road density should be zero," to "in goshawk nesting and post-fledging areas it will be zero."

1273b

RESPONSE: On a forestwide basis, the average open road and open motorized trail density is less than two miles per square mile. This change was not made in the Revised Plan because in some cases open roads will be needed in goshawk nesting and post-fledging areas. CC

General

COMMENTS: Oppose restrictions on access because there is no evidence to support the belief that motorized traffic effects wildlife any more than non-motorized. Closing the forest to public use is not the answer for protecting game animals.

28, 226, 313, 488, 1320, 1332

RESPONSE: There is research which shows that higher road density results in less elk security and higher elk vulnerability. Process Paper D contains numerous citations. Most of the Forest remains open and accessible through motorized use on designated routes. CC

COMMENTS: Close big game areas to OHVs during hunting seasons.

157, 174, 181, 204, 278, 357, 511, 1270

RESPONSE: Only 7% of the Forest is open to summer cross-country OHV use. The game retrieval provision was dropped from the Final Revised Plan due to concerns regarding enforcement, administration and monitoring and potential impacts to other resources. CC

COMMENTS: Support closing roads, trails and off-road traffic to protect wildlife. Prohibit motorized access if it conflicts with a goal of providing and protecting big game habitat.

136, 162, 168, 226, 242, 271, 389, 390, 437, 448, 634, 652, 655, 658, 735, 1313, 1361, 1367b, 1466

ACCESS - WILDLIFE

RESPONSE: Only 7% of the Forest is open to summer cross-country OHV use. The Forest is closing some roads and trails to protect wildlife and maintain habitat. CC

COMMENTS: Recommend allowable summer motorized route densities \leq mile per square mile for areas providing crucial winter and summer big game habitat.
766

RESPONSE: Open motorized road and trail density is two miles per square mile in winter range and densities are 1.25 miles per square mile or less in summer range. CC

ALTERNATIVES

Alternative 1 - Support

COMMENTS: Prefer the previous management plan (Alt. 1); prefer Alternative 1 for the level of access or the amount of wilderness proposed. Alternative 1 has an acceptable Bear Management plan; Alt. 1 is better for elk.

F-G2 (2), 6, 24, 25, 30, 31, 33, 39, 40, 41, 43, 44, 46, 47, 48, 49, 50, 52, 53, 54, 265, 293, 316, 319, 1252, 1357

RESPONSE: Your comments were noted and considered. AS

Alternative 1 - Non-Support

COMMENTS: Do not support Alternative 1 because the access is too high; not adequate for elk security; unsustainable ASQ; negative impacts to wildlife from access; Ecosystem Management is impossible under this alternative; and lack of information on ASQ in the alternative.

38, 41, 61, 166, 457, 658, 664, 690, 731, 1333

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the record of decision. AM

Alternative 2 - Support

COMMENTS: Supports Alternative 2 because of access concerns: does not want area, slope, or date restrictions on access and other alternatives restrict favorite areas for recreation access, such as the Island Park area. Alternative 2 keeps the Forest open to the public; it permits access for firewood gathering. Alternative 2 might help open roads closed in the past five years.

7, 18, 21, 22, 28, 29, 31, 33, 35, 36, 47, 50, 51, 53, 56, 63, 67, 297, 300, 306, 316, 330, 346, 363, 413, 488, 529, 607, 635, 646, 717, 1205, 1259

Alternative 2 provides a better balance between commodity use and resource protection; provides better for the economy of local communities; does not detract from income and way of life; and it will not harm the livestock industry.

F-A(344), 369, 378, 454, 464, 478, 1240, 1248, 1341, 1386

Alternative 2 meets resource and wildlife protection goals while maintaining an acceptable level of harvest; it is logger friendly; it would clear out areas of extreme deadfall and density; and it is sustainable. Supports Alternative 2 because it doesn't bow to environmentalists or misuse NEPA and ESA; it addresses concerns of the local people; it considers people as well as wildlife, or doesn't favor wildlife over people; it supports the needs of the innocent; favors the human factor; and is the most fair for the most people. It offers some protection to grizzly bears but with a larger degree of use; or grizzly bears are not important.

Supports Alternative 2 because it is a better compromise; a better choice for the ecosystem; better for forest health, especially fire danger. Alternative 2 is better for range improvements and AUMs should not be reduced. Alternative 2 is less restrictive and meets resource objectives;

ALTERNATIVES

supports recreation, local communities, productive use of resources, and protection of resources; is less disagreeable; is the needed direction; allows enjoyment of Idaho resources; reflects the needs of the Forest; creates no more wilderness areas; favors sportsmen; is better for elk herds because elk populations are high. Agree with the proposals in Alternative 2 for wilderness, logging, wildlife, grizzly bear, elk, grazing, and riparian areas. Alternative 2 is the better alternative for multiple-use. It is also the alternative supported by local communities according to a referendum held in six local counties.

Alternative 2 is a better option; things will get worse at a slower rate with Alternative 2; too much change is bad therefore choose Alternative 2.

Letter numbers that Support Alternative 2:

F-A(344), F-C(13), F-F(6), F-I(4), F-M(5), F-N(6), F-O(4), F-P(2), F-Q(447), 1, 2, 4, 7, 8, 9, 13, 14, 15, 17, 18, 20, 21, 22, 25, 27, 28, 29, 30, 31, 32, 33, 35, 36, 37, 39, 44, 46, 47, 50, 51, 52, 53, 54, 55, 56, 57, 59, 60, 63, 67, 69, 70, 71, 72, 75, 89, 90, 97, 98, 135, 160, 188, 198, 216, 220, 221, 222, 234, 235, 256, 272, 277, 284, 287, 288, 289, 290, 291, 292, 296, 297, 298, 300, 303, 306, 309, 315, 316, 323, 324, 330, 344, 346, 347, 348, 355, 358, 363, 367, 369, 371, 374, 375, 378, 380, 385, 386, 387, 388, 397, 403, 406, 413, 423, 425, 426, 429, 431, 432, 435, 436, 439, 446, 454, 462, 464, 465, 466, 469, 472, 473, 474, 475, 476, 478, 480, 485, 488, 495, 497, 498, 499, 500, 509, 513, 514, 515, 517, 522, 523, 524, 528, 614, 626a, 628a, 629a, 633, 635, 641, 646, 648, 660, 665, 687, 688, 689, 693, 700, 702, 703, 709, 714, 716, 717, 718, 720, 724, 729, 733, 734, 737, 767, 1176b, 1179, 1182, 1189, 1190, 1191, 1193, 1198, 1200, 1202, 1205, 1239, 1240, 1248, 1253, 1255, 1259, 1260, 1265, 1306, 1308, 1309, 1310, 1315, 1317, 1320, 1321, 1323, 1329, 1332, 1334, 1335, 1239, 1341, 1346, 1350, 1353, 1363, 1372, 1375, 1376, 1377, 1378, 1386, 1389, 1390, 1448b, 1449

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-to-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the record of decision. AM

Citizens for a User Friendly Forest (CUFF) adopted Alternative 2, but recommend the following changes in an "Alternative 2M"

COMMENTS: Change Alternative 2 and create an Alternative 2M per the recommendation of the Citizens for a User Friendly Forest (CUFF) that would: amend summer OHV map for alternative per the enclosed map; remove the date restriction on snowmobile use; increase ASQ to 20 MMBF with >12 MMBF live and 30-50% lodgepole pine; change 20% nonstocked standard to 45%; change the mature percent stand from 40 to 30 percent; define Hydrologic Disturbance at less than 20 years; allow sustained harvest in roadless areas and no Non Interchangeable Component; allow harvest in all Bear Management Units with a Non Interchangeable Component in Situation 1; if 20 MMBF is not possible, look at departure; add 2 areas in Caribou to suitable timber base (on enclosed map); change large 6.2 (b) in Caribou to 6.1 (a); delete forestwide Guideline

ALTERNATIVES

restricting Off Highway Vehicle use on slopes 25-40%; drop Targhee and Robinson Creeks from Wild and Scenic River eligibility; reduce the number of live trees per acre from 25 to 10; and change 5.2.4 (a) to allow cross-country travel from 6/15 to just prior to big game rifle season.

767

RESPONSE: The Forest considered but dismissed this proposal from detailed study for the reasons documented in Chapter II of the FEIS. A few of the key components of this proposed alternative are already depicted by Alternative 2 with a recalculated ASQ at 20 MMBF. Alternative 2M is therefore not substantially different from the maximum commodity production and motorized access alternative presented in the DEIS under the Alternatives that were considered but dismissed from detailed study. In addition, most of the constraint changes recommended by CUFF (see the following comments) are not advisable because they are outside the Desired Future Conditions (DFC) and Purpose and Need outlined in the EIS. Below are responses to each specific change requested by CUFF. AS

COMMENTS: Amend summer OHV map for Alt 2 per enclosed map.

767

RESPONSE: The Forest decided not to adopt the additional open motorized roads and trails proposed for alternative 2M because it would increase road densities to a level above the highest density sideboards. Levels of open motorized use above Alternative 2 are contrary to Desired Future Condition (DFC) for "habitat conditions contributing toward recovery of Threatened and Endangered (T&E) Sensitive wildlife." Also the Need for Change identifies the "need to meet goals for improving elk habitat and reduce human activities in grizzly bear habitat". Therefore, the Forest decided that increasing motorized access to levels identified for Alternative 2M would not meet the Purpose and Need as described in the DEIS. AS

COMMENT: Remove date restrictions on snowmobile use prescription 2.4, 2.5, 3.2c, 3.2d, 3.2g, and 5.4c in grizzly Bear Management Units.

767

RESPONSE: The Forest changed the December 15 date restriction to Thanksgiving weekend on all Districts except Palisades for cross-country snowmachine travel, and changed the April 1 date to June 1 in the Plan and FEIS. The April 1 date is not needed to protect denning bears. However, the Forest added a management direction guideline to the Forestwide Standard & Guidelines to allow site-specific closures if necessary to protect bears. The Thanksgiving date is intended as grizzly protection. Before Thanksgiving, most cross-country snowmachine use is limited due to minimal snow cover. This date also assists Fish and Game from having big game chased by snowmobiles during some of the late hunts. AS

COMMENT: Increase ASQ to 20MMBF with >12MMBF live & 30-50% lodgepole pine.

767

ALTERNATIVES

RESPONSE: ASQ was recalculated in the alternatives. New Forplan runs indicate it is theoretically possible to achieve 20MMBF with alternative 2. Therefore, the Forest does not believe another alternative (proposed 2M) is needed to evaluate this option. This recalculation meets constraint needs to the fullest extent possible from non-ASQ lands. Doing this frees up more ASQ land for timber harvest scheduling. The prior formulation met constraints proportionally from both ASQ and non-ASQ lands. AS

COMMENT: Change 20% nonstocked standard to 45%.

767

RESPONSE: The Forest did not adopt this change because 45% nonstocked would violate the standards and guidelines established to meet the Desired Future Conditions outlined for sustainability, biodiversity, and ecosystem health as described in the Purpose and Need section of the FEIS. AS

COMMENT: Change % mature stand from 40% to 30%.

767

RESPONSE: The Forest has not made this change because 40% mature is needed to maintain habitat conditions for goshawk and other species and to meet the overall Desired Future Conditions of sustainability, biodiversity, and ecosystem health as described in the Purpose and Need section of the FEIS. A change in percent mature is not needed to reach a 20MMBF ASQ. AS

COMMENT: Define hydrologic disturbance in timber stands less than 20 years of age.

767

RESPONSE: The Forest updated the DEIS to include the following definition which is in the Glossary under the term "hydrologically recovered condition": "Vegetative life form where natural canopy coverage is achieved and subsequent streamflow quantities and character (timing and amount) reflect more natural conditions. Within the forested ecosystem this equates roughly with the sapling/early pole life form. This life form is achieved at approximately 20 to 30 years of age, depending upon cover type and inherent site productivity potentials."

COMMENT: Allow sustained harvest in roadless areas and no non-interchangeable component (NIC).

767

RESPONSE: A Forplan analysis was done on this basis with a NIC constraint and the Forest decided to change the sustainable harvest for alternatives 1-5. Not every roadless area contains prescriptions with ASQ. AS

COMMENT: Allow harvest in all bear management units (BMU) with NIC in Situation 1 only.

767

RESPONSE: In Alternative 2, the Forest did allow harvest in all BMU's with the exception of the Henry's Lake subunit #2 Two-Top. Harvest in less than 100%

ALTERNATIVES

of the BMU's was considered essential to meet the stated Desired Future Condition for grizzly bear. The Forest did consider an alternative 2 that prescribed a significant part of the BMU situation 2 as non-NIC. AS

COMMENT: If 20MMBF isn't possible, look at departure.

767

RESPONSE: The Forest has not given any further consideration to this proposal, as it would represent the same situation (departure) that it has been in for the last 10 years. This situation resulted in the Need for Change and Desired Future Conditions listed in the Purpose and Need for FEIS. One of the key Desired Future Conditions listed is: "commodity production, such as timber, firewood, mining, and others are conducted at sustainable levels". Therefore, this proposal would not meet the Purpose and Need of the FEIS.

COMMENT: Add two areas, Black Mountain and Fall Creek in Caribou, to the suitable timber base in maps.

767

RESPONSE: The Forest did show the Black Mountain area in the 5.4 (c) prescription in alternative 3M which is a timber base prescription. However, in alternative 2, this area is in prescription 3.2 (f) non-timber base. This appears to be the reverse of the Forest's intent for the alternative design trend. The Black Mountain area appears suitable for harvest, so the Forest corrected this in Alternatives 1 through 3, but not in Alternative 3M through 6. However, the Fall Creek area does not have enough contiguous stands of timber to justify placing it in an ASQ prescription.

There would be significant adverse effects on wildlife winter range and unstable soils from development of roads and harvest units. These consequences are contrary to the Desired Future Conditions and Need For Change outlined in the Purpose and Need section of the DEIS i.e., "need to balance timber harvest with wildlife needs"; "need to meet goals for improving elk habitat"; and "a system of trails and support facilities exist which are compatible with resource capabilities". AS

COMMENT: Change large 6.1 (b) in Caribou to 6.1 (a).

767

RESPONSE: District and Forest staff reanalyzed this area and determined that such a change would be detrimental to unstable soils, wildlife spring/fall/winter range, and would not meet the Desired Future Conditions or the Purpose and Need. The 6.1 (a) prescription would allow cross-country travel to access the area. AS

COMMENT: Delete forestwide guideline restricting OHV use on slopes 25-40%.

767

RESPONSE: The guideline simply allows us to implement travel restrictions if soil erosion factors warrant them. It is not a blanket restriction. Therefore the Forest determines there is no need for a change. AS

ALTERNATIVES

COMMENT: Drop Targhee and Robinson Creeks from Wild & Scenic River eligibility.

767

RESPONSE: The Forest did not adopt these changes. Forest policy direction is clear that all eligible streams must be protected in all alternatives until such time as suitability studies are completed. Since these streams were determined to be eligible in our final inventory, and since suitability studies are not being done as part of the plan revision analysis, there is no option to delete any of the eligible streams. AS

COMMENT: Reduce the number of live trees/ac from 25 to 10.

767

RESPONSE: No change is needed on our analysis. In areas where harvesting is allowed, the Forest is requiring 10 to 15 trees/acre be left for habitat. This is clarified in the prescriptions Standards and Guidelines. The Table in forestwide Standards and Guidelines shows varying percent of habitat capability. None of the prescriptions used actually require more than 10-15 trees/acre except for goshawk territories. Some goshawk areas require 80% (20 trees/ac) to 100% (25 trees/ac). AS

COMMENT: Change 5.1.4 (a) to allow cross-country travel from 6/15 to just prior to big game rifle season.

767

RESPONSE: The Forest changed the footnote to the applicable access tables to indicate that summer cross-country travel is allowed up to October 1. This was done to simplify administration and travel map preparation and improve public understanding and compliance. AS

Alternative 2 - Non Support

COMMENTS: Oppose Alternative 2 or the CUFF version of Alternative 2 because: it is a bad, or "unspeakably wrong" approach; it will contribute to resource damage from over-use; it is excessive resource extraction; it allows too much access; it will have negative impacts on wildlife; it does not consider grazing impacts, or elk and grizzly bear security; it is inconsistent with wilderness proposals on other Forests; it makes the forest fail in its obligation to fully protect the land; the ASQ in Alternative 2 is unsustainable; ecosystem management would not be possible; it is not balanced; the CUFF group has been misleading the public; the vote CUFF presented to local communities was inaccurate and misinformed.

46, 47, 61, 259, 357, 391, 413, 444, 496, 654, 658, 664, 667, 690, 1183, 1331, 1333, 1365, 1381

Change Alternative 2M; acknowledge that helicopter skiing is a past and current use on the Forest; open more trails to summer ORV use; and add more roadless areas; and recommend Winegar Hole and Italian Peaks as wilderness; manage some other areas as back country.

Clarify or change the DEIS regarding Alternative 2, such as: make the grazing write-up consistent with the tables; clarify the meaning of the NIC component of 237,137 acres listed in the DEIS for Alternative 2; change

ALTERNATIVES

the large area on 6.1(B) in Caribou to 6.1(A), as was pointed out in a Cuff meeting and map.

53, 228, 292, 347, 413, 687, 693, 1373

RESPONSE: The Forest acknowledges your comments. Responses to specific recommendations for changes can be found in the subject area in Appendix A. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Alternative 3 Comment

COMMENTS: Need to show that Alternative 3 would eliminate much cross-country travel, not just 3M-6.

629a

RESPONSE: Page IV-39 of the DEIS clearly indicates that cross-country access would decrease from present levels in all alternatives and states: "Much of the cross-country use that is presently occurring would be eliminated by Alternatives 3-6." AS

Support 3M

General

COMMENTS: Supports Alternative 3M because it is the best choice, a significant improvement over the previous management plan, and superior to other alternatives. Approve of the shift in management from resource extraction to one that recognizes recreational and wildlife values. 3M is balanced or a good compromise between resource use and resource protection. 3M changes the course of forest management to fit current ecological, social, and economic needs; it is reasonable politically; it balances many perspectives; it doesn't change things too much; it is fair; it meets the interests of the local public; it supports multiple use; it at least takes some action. It protects the ecosystem; is a good start for ecosystem management; it proposes an adequate buffer zone; and it is the only alternative that may lead the forest to biological health.

7, 22, 23, 25, 27, 29, 30, 31, 37, 39, 40, 53, 62, 143, 156, 161, 173, 200, 211, 212, 215, 227, 242, 263, 266, 293, 305, 317, 339, 340, 341, 354, 357, 361, 370, 373, 413, 437, 453, 459, 479, 496, 502, 527, 610, 634, 636, 654, 659, 662, 664, 667, 669, 690, 708, 727, 730, 731, 1185, 1196, 1239, 1242, 1258, 1269, 1273b, 1277, 1311, 1312, 1314, 1322, 1333, 1348, 1360, 1367, 1381, 1392, 1399, 1400

Change 3M to include revisions of language or prescriptions in the Draft Forest Plan Revision; correct editorial or factual errors. Recommend more wilderness in 3M. Recommend less wilderness in 3M. Clarify how much timber will be cut in 3M. Restrict grazing allotments in 3M. (Note: Many comments which refer to "the plan," are addressed in the comments and responses section of the Revised Forest Plan.)

The preferred plan (3M) is acceptable but: requires better scientific foundation or more references/citations; the forest should be managed to be healthy, viable, and diverse; the needs and desires of the

ALTERNATIVES

public must be fully addressed; 3M needs more restrictions. Prioritize goals and objectives in 3M so it will be clear how funding will effect implementation; clarify whether timber, wildlife, or recreation in 3M has priority. Combine the best attributes of Alternative 2 and 3; and adopt provisions for cutthroat trout outlined in Alternative 4.

Show how the preferred plan 3M will be implemented with inadequate funding and personpower. Give more attention to restoring degraded habitat. Explain how alternative 3M meets the goal of sustainability and why resource protection appears incompatible with timber harvest and providing jobs. Disclose publicly what quality of timber is to be logged in 3M. Explicitly address protection of riparian areas in 3M; address roadless areas in 3M; and describe management direction for Grand Targhee Ski area in Alternative 3M.

21, 159, 164, 200, 265, 282, 308, 340, 354, 362, 393, 444, 491, 625, 632, 637, 643, 658, 690, 695, 1206, 1249, 1276, 1307, 1324, 1360, 1364, 1365, 1368

Supports the limits 3M proposes on access, such as a good balance between human wants and resource protection; allow 1988 miles of open roads; 3M's closures are reasonable. 3M allows good amounts of cross-country, summer, and winter snowmobile access; and provides a generous amount of groomed trails. 3M does a good job of keeping access limited to designated roads and trails; doesn't restrict traditional horse use and access; and provides adequate trail access for backpackers. 3M is good because motorized access is not in the same management niche; approve of the amount of access in 3M on Sheep Creek and Red Rock Pass Roads.

22, 31, 37, 39, 40, 42, 44, 45, 49, 50, 52, 55, 143, 161, 193, 227, 325, 354, 359, 373, 526, 610, 645, 645a, 659, 662, 668, 690, 734, 735, 1185, 1245, 1250, 1257, 1269, 1360, 1392, 1399, 1402

Other reasons provided for support of 3M are: it provides adequate consideration of grazing, timber, riparian areas, wilderness, and wildlife; it strikes a good grazing level; it reduces grazing; it phases sheep out of grizzly bear habitat; permittees may use historic roads to maintain range; It protects rivers, streams, riparian areas, and aquatic influence zones (AIZ); it restricts riparian grazing. 3M is a good plan from the perspective of the USDA Sheep Experimental Station.

3M's ASQ level is acceptable or sustainable; 3M should provide priority on smaller cuts for local operators, which would improve watershed; the Forest Service should enforce restrictions and not give in to timber interests in 3M.

3M has good wilderness and wild & scenic river recommendations; other alternatives have inadequate recommendations.

3M does a good job of protecting wildlife and habitat; 3M protects elk, grizzly bears, and wolverines; 3M doesn't increase grizzly bear protection; 3M allows elk herds to build up.

3M restores fishing and hunting opportunities; 3M provides adequately for recreation.

Letter numbers supporting 3M:

11, 21, 22, 24, 26, 31, 32, 35, 36, 37, 45, 49, 51, 53, 54, 143, 181, 182, 193, 211, 228, 258, 325, 339, 351, 354, 359, 362, 370, 432, 479, 526, 610, 615, 632, 645, 645a, 658, 662, 690, 719, 731, 1180, 1185, 1226, 1245, 1250, 1269, 1276, 1311, 1324, 1348, 1360, 1368, 1374, 1392, 1398

ALTERNATIVES

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Oppose 3M

COMMENTS: Alternative 3M is too restrictive, excessive or discriminate against off-road users. It discriminates against the elderly, very young, and those physically unable to hike, cross-country ski, or ride horses. 3M is unfair; contrary to historic use; favors wealthy, out-of-area visitors; is unwise in the face of increasing population and demands; will lead to more concentrated use, more accidents, and negative impacts in unrestricted areas; is unnecessary for protecting resources or grizzly bears and other wildlife; will lead to illegal uses; or is unenforceable because of low budget. The statement in DEIS, Page IV-45, Lifestyles, on increase in recreation and associated income/employment is inconsistent with access restrictions in 3M. 3M restricts snowmobile use in specific areas; and extrapolates conclusions about road and trail use and impacts on wildlife with no evidence.

F-A(344), F-C(13), F-M(5), F-N(7), F-O(4), F-Q(447), 1, 20, 21, 26, 27, 28, 29, 30, 33, 34, 35, 39, 40, 44, 46, 50, 51, 53, 54, 55, 63, 98, 198, 202, 234, 258, 272, 288, 291, 292, 297, 303, 306, 309, 315, 319, 323, 342, 348, 352, 355, 367, 378, 380, 403, 406, 413, 425, 426, 431, 498, 499, 500, 505, 513, 517, 528, 629a, 633, 635, 645b, 646, 648, 661, 702, 713, 728, 1176b, 1182, 1185, 1187, 1190, 1198, 1239, 1240, 1252, 1253, 1255, 1256, 1262, 1264, 1316, 1317, 1320, 1321, 1330, 1335, 1341, 1348, 1355, 1359, 1363, 1365, 1367, 1375, 1390, 1447a

Oppose Alternative 3M because it allows too much access; has too high a road density for wildlife protection; lacks proper restrictions, does not apply appropriate OROMTRD standards; permits too much winter access; or allows game retrieval with ORVs. Concerned about the lack of enforcement and lack of funding for enforcement. (CROSS REFERENCE: Access-General, Access-Game Retrieval).

31, 143, 215, 340, 356, 615, 668, 713, 735, 1313, 1317, 1367, 1378

Oppose Alternative 3M because: of economics, especially to local communities; effects upon jobs, heliskiing, grazing and renewable resources which have not been adequately considered; and tax monies. Alternative 3M prohibits people from using forest products so they are left to rot or burn, then taxes people to control the catastrophic fires. Alternative 3M impacts multiple use industries through restrictions on motorized access and recreation (CROSS REFERENCE: Economics, Recreation.)

3, 152, 292, 296, 307, 311, 341, 393, 413, 472, 482, 499, 505, 642, 647, 689, 718, 1176b, 1189, 1248, 1325, 1341, 1377, 1378, 1448b

Alternative 3M limits timber sales and because the Forest can support a much greater harvest; less logging means an accumulation of older trees which are subject to catastrophic fires and insect infestations. Alternative 3M is a total abortion of scientific knowledge on how to manage lodgepole. Sustained yield would allow 3.5% of the forest to burn each year, which will add to air pollution and the constrained logging and let-burn policy violate the Clean Air Act, the Weeks Act of 1911, and the Clarke-McNary Act of 1924. 3M should allow comparisons of the social and economic effects

ALTERNATIVES

due to the constraint on road development and timber harvest. (CROSS REFERENCE: Timber; EM).

F-A(344), 29, 34, 46, 55, 98, 176, 202, 275, 312, 341, 393, 406, 413, 432, 499, 688, 1198, 1256, 1335, 1341, 1390

Oppose 3M because it allows too much timber harvest; proposed levels are too great because of past excessive logging; doesn't limit logging enough; ASQ should be lowered to the level in Alternative 4, or to a sustainable level. 3M presents a biased assessment that less logging means greater fire risk since meteorology and weather are greater factors than fuels; 3M allows too much timber harvest in the Centennials; 3M's timber harvest is not tailored to address watershed needs; and there is too much room for unscheduled timber harvest under the guise of ecosystem management.

179, 325, 356, 668, 690, 1273b, 1313, 1330, 1364, 1370

Oppose 3M because of its recommendations for wilderness designation; too much wilderness is proposed. Since roadless areas are already being accessed and have historic uses, they cannot be designated as wilderness in 3M. A compromise between the wilderness proposals in Alternatives 3M and 2M would be superior. (CROSS REFERENCE: Wilderness)

F-C(13), F-O(4), 1, 20, 21, 28, 29, 34, 35, 36, 37, 39, 40, 52, 53, 54, 55, 314, 388, 413, 482, 513, 528, 648, 1182, 1187, 1190, 1198, 1265, 1335, 1363

Oppose 3M because it proposes too little wilderness, does not do enough to protect roadless areas, intends to log in roadless areas, and it should stipulate that roadless areas be off limits to development so they may qualify for wilderness.

31, 143, 165, 174, 242, 305, 317, 356, 610, 622, 652, 659, 664, 689, 1197, 1243, 1273b, 1337, 1367

Oppose Alternative 3M because it is not a sustainable plan; it fails to protect the ecosystem and resources for future generations; it doesn't go far enough to preserve currently pristine areas or restore damaged areas; it uses ecosystem management improperly and allows unsustainable timber harvest; it has patch size limits that are flawed or too large; or that 3M prefers timber harvest over sustainable activities; livestock grazing impacts have not been sufficiently considered; or that grazing must be controlled, reduced, or eliminated.

Other concerns are that stubble height, protection of riparian areas, water quality, cutthroat trout streams, aquatic resources, and wetland areas have not been thoroughly researched, discussed, and provided for. Nature can better manage itself better than humans can; 3M is a concession to extractive and recreation industries and is a compromise of scientific fact.

Alternative 3M fails to address the legacy of damage done by decades of excessive logging and roading, and doesn't protect resources, scenic values, or biodiversity. 3M has insufficient scientific basis or research in all components; it is too conservative and focuses on unnecessary goals; it is a weak compromise; and it is designed to pacify Fish & Game and user groups. Public interest is contrary to the Forest Service's mission to protect biodiversity. Multiple use in 3M leaves too much room for overuse and abuse.

3M causes concern for the spotted frog; 3M should separate bighorn and domestic sheep; fisheries, wildlife, migration corridors, winter range,

ALTERNATIVES

and habitat need more protection than 3M offers. Research must detail existing conditions better and address habitat needs through standards and guidelines.

F-B(4), F-K(4), FS-7, 61, 136, 143, 161, 174, 184, 189, 242, 259, 266, 267, 275, 290, 292, 293, 308, 310, 325, 337, 351, 357, 496, 519, 622, 643, 652, 656, 659, 668, 690, 719, 735, 766, 1177, 1185, 1188, 1206, 1241, 1243, 1277, 1331, 1364, 1365, 1367

Alternative 3M does not apply the multiple use principle; it is in violation of sustained multiple use; it gives too much weight to a single use; it assumes one use group must preclude others. It eliminates multiple use; it will close the little remaining multiple use land in the Jackson Hole area; it is focused on lands favored for timber harvest; and it does not represent multiple use as outlined by a 1994 J.W. Thomas letter. (CROSS REFERENCE: Multiple Use, Ecosystem Management)

F-B(4), 12, 90, 135, 614, 642, 1189, 1332, 1369

Oppose Alternative 3M because of its wildlife prescriptions. Too much land is set aside for grizzly bears which eliminates use for summer and winter recreation; Alternative 3M makes grizzly bears more important than people; wolf and grizzly bear protections in 3M negatively impacts the ranching industry. There is too much emphasis on grizzly bear protection; because grizzly and endangered species habitat is favored, grazing and timber harvest are reduced; and elk security and vulnerability are given too much emphasis in Alternative 3M.

F-F(6), 1, 7, 28, 29, 30, 46, 47, 48, 50, 52, 55, 202, 267, 290, 293, 296, 298, 310, 413, 432, 1187, 1198, 1239, 1246, 1254, 1262, 1332, 1341, 1390

3M reduces resource development to unnecessarily low levels; limits recreation; reduces trails too much; and doesn't address mountain bikers.

Opposed to the plan and philosophically opposed to the ideas behind it; 3M is perpetuating a United Nations goal of an 80 mile zone of no use around Yellowstone; it sets precedent for more closures in the future; has negative impacts on logging, recreation, access, grazing, and local economies; restricts the public too much; is bad, a joke, seeks to eliminate families, or is a flawed concept; it does not adhere to various laws; it limits future management options; it is too harsh; and it does not represent the direction in which the forest should be moving. 3M favors special interests, environmentalists, preservationists, or groups who will litigate decisions. 3M lacks sufficient research or scientific basis, and the Forest Service will be sued if alternative 3M is selected.

The sentiments, rights, or opinions of the public or of local groups are ignored in 3M; 3M places too many limits on people; children should have same access as adults have had; personal freedoms are being denied; 3M was voted against in a referendum vote, and the Forest Service should listen to the majority. Oppose 3M without any specific reason given.

F-A(344), F-F(6), 1, 20, 21, 24, 30, 33, 90, 202, 222, 227, 262, 266, 267, 285, 290, 292, 296, 298, 304, 310, 316, 324, 355, 358, 397, 406, 413, 432, 435, 447, 488, 497, 513, 517, 607, 608, 614, 623, 628a, 629a, 633, 646, 661, 687, 688, 689, 714, 718, 724, 733, 1187, 1188, 1202, 1239, 1246, 1254, 1256, 1262, 1264, 1316, 1317, 1319, 1321, 1334, 1335, 1339, 1343, 1357, 1363, 1378, 1384, 1389, 1391, 1448, 1448b, 1456

ALTERNATIVES

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Alternatives 1, 2, 3, Non Support

COMMENTS: Does not support alternatives 1, 2, or 3.
690

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Support Alternative 4

COMMENTS: Alternative 4 is superior to the others because of its emphasis on riparian, wildlife, and wilderness protection. Support the 6" stubble height in Alternative 4. Support the amount of motorized access and favor no restrictions on people entering the wilderness in Alternative 4.
42, 169, 171, 308, 643, 690, 719, 1276, 1277, 1311

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

COMMENTS: Change Alternative 4 to close more roads. Add additional 14,000 acres in wilderness designation to Alternative 4.
171, 690

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Support Alternative 5

COMMENTS: Supports Alternative 5 because it protects wildlife and recreation; is superior for forest health; sustains multiple use; and is better for elk vulnerability, riparian condition, water quality, fisheries, DFC, and grizzly bears.
174, 175, 181, 331, 356, 1370

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

ALTERNATIVES

COMMENTS: Alternative 5 would be better with an additional 100,000 acres of wilderness.

690

RESPONSE: Your comment was noted and considered. AS

Support Alternatives 4/5

COMMENTS: Supports Alternatives 4 & 5 because they have better access for the Centennials, there are fewer "patches," and because they have a lower ASQ.

173, 176, 325, 1185, 1348

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Support Alternative 6

COMMENTS: Supports Alternative 6 because of its preservation of roadless characteristics or recommendations for wilderness, especially of specific areas such as the Medicine Lodge/Italian Peaks area; summer travel is best in Alternative 6. The proposals for wildlife, critical winter or key low elevation habitat, aquatic or riparian areas, water quality, and specific species such as elk or grizzly bear are best in Alternative 6. Support the low amount/lack of timber sales, fewer stream crossings, and reduced livestock grazing in Alternative 6. Alternative 6 is the best management strategy; would best heal the scars of prior overuse; has the lowest impact; and helps the economy of local communities.

F-K(4), 61, 156, 181, 207, 293, 304, 356, 382, 387, 609, 611, 625a, 631, 650, 652, 657, 659, 666, 668, 690, 727, 1185, 1270, 1325, 1330, 1331, 1348, 1367, 1387

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Non Support Alternative 6

COMMENTS: Do not support Alternative 6 because it restricts people and access too much; has too many restrictions going into wilderness; has too many snowmobile restrictions; and has too many summer OHV access restrictions.

41, 42, 215, 1333, 1367

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

ALTERNATIVES

Proposed Changes to Alternative 6

COMMENTS: Change Alternative 6 such as add 340,000 acres to wilderness designations; reduce cross-country travel on 90% of the Forest and ASQ to 7.5 MBF; recommend larger wilderness for Big Hole and Palisades Mountains; recommend more winter range; and add more ASQ.

659, 690, 695, 1270, 1348, 1365

RESPONSE: Comments noted and considered. As

Alternatives 5/6 Support

COMMENTS: Supports Alternatives 5 and 6 because they are better for the ecosystem, riparian areas, wildlife, and DFC; they are better for particular species, such as grizzly bears and deer/elk winter range; they have better restrictions on access and logging; they have more wilderness areas or better protect roadless areas; and they contribute to the long-term welfare of the area.

61, 176, 181, 212, 341, 359, 610, 631, 664, 695, 731, 1196, 1201, 1393

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Alternatives 4-6 Non Support

COMMENTS: Alternatives 4-6 are not in the best interest of the general public, because they favor special interest groups.

215

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road, Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record of Decision. AM

Alternatives 4-6 Support

COMMENTS: Support Alternatives 4-6 because they appear environmentally sound; have better provisions for wildlife, especially elk, and winter range; and have better wilderness designations of Lionhead/Targhee Pass area.

658, 1185, 1239, 1348

RESPONSE: The Forest acknowledges your comments. After examining all alternatives and public comments, the leadership team chose to remain with the revised, middle-of-the-road Alternative 3M. For a thorough explanation of the rationale for selecting Alternative 3M, see the Record Of Decision. AM

Alternatives - General Comments

COMMENTS: Disappointed that specific management prescriptions are presented only for Alternative 3M; Alternatives 1-6 should represent a full range of

ALTERNATIVES

alternatives for winter OHV use; public meetings and participants reflect only local concerns, which are usually proprietary views and narrow-minded. The county election on the alternatives in May 1996 was confusing and seemingly inaccurate, an "election fraud," and the Forest Service should do something.

282, 399, 1347, 1367b

The Forest Service has not fulfilled its legal obligation to consider and analyze an adequate range of alternatives or the range of impacts of various management activities.

1365,

RESPONSE: Specific prescriptions are identified for all alternatives in Chapter II of the DEIS. The Forest provided a full range of alternatives. Some alternatives were considered early on, but were dropped, as explained in Chapter II of the DEIS. Meetings discussing the range of alternatives had attendees from several states representing local, state, and national organizations and agencies. All public have a voice in the management of the Targhee and all views are considered during deliberations. Elections are outside the range and scope of a Forest Plan other than to indicate local preferences related to some issues.

The range of alternatives was sent out for review several times. The range was expanded twice to include two more alternatives in the DEIS and two others were considered but dismissed in the FEIS. The alternatives analyzed consider a wide range of possible management prescriptions and opportunities. A winter use travel plan was included for each alternative in the DEIS and represent a wide range of winter travel opportunities. AS

COMMENTS: The Forest filled out the range of alternatives based on proposals from participants in the public involvement process, rather than based on rigorous analysis of data on forest resource conditions. The Forest has violated the NEPA guidance on alternative development.

643

RESPONSE: The Forest developed alternatives in conformance with the Purpose and Need, all applicable laws and regulations, and within the context of an extensive review of existing resource conditions, to address the issues raised by the public during an exhaustive public involvement process.

After issues were received from the public and analyzed, a concentrated list of issues was developed to guide the development of the Forest Plan Revision. Concurrently with this effort, an extensive review of existing resource conditions was taking place. The effort culminated in the issuance of the Analysis of the Management Situation (AMS), which has since been updated periodically. This effort also contributed significantly toward the information base in the Forest Geographic Information System (GIS).

The first phase of the alternative development process incorporated work done on the Forest Service National Hierarchical Framework of Ecological Units. This geographic mapping effort provided a stratification of ecological units based on physiographic characteristics. The Forest filled out the descriptions of the seven ecological subsections overlaying lands managed by the Forest. Using this mapping system, and the extensive information in the AMS and GIS, the Forest built a proposed action, the so-called Ecological Unit Approach, which is now labelled Alternative 4. Several other alternatives

ALTERNATIVES

were then molded around the proposed action. These addressed the issues in different ways using the information base.

It is true that the Forest entertained proposals from at least one Forest user group in developing an alternative that responded to their concerns. However, this proposed alternative was dismissed from detailed analysis. AS

COMMENTS: The Change By Advantage (CBA) decision making process used to select the preferred alternative is flawed. The value weighing system is wrong, placing Ecosystem Management (EM) at the top with a value of 100, with other factors rated 70-80 and wilderness lower. Use a different system, with support for local economy equal to EM, followed by elk security and access; motorized use, timber and riparian; grizzly bear and firewood; and wilderness. The CBA process is skewed in favor of environmental factors with little or no consideration for the local economy and social impacts of access and recreation.

317, 413, 767

RESPONSE: The CBA process is dropped from the FEIS, and the rationale for the final decision is contained in the Record of Decision (ROD). The value ranking in the original CBA process was the Management Team's best effort at matching factors with the Desired Future Condition identified with the public. The factors could be ranked and rated differently if different conditions or values are identified as more important. AS

COMMENTS: The Range of Alternatives presented at the top of page 8 of the Executive Summary presents the erroneous impression that reductions in timber harvest and livestock grazing is a result of increased wilderness designation. This creates a bias against higher numbered alternatives.

643

RESPONSE: The recommendation of wilderness in several alternatives results in some reduction in ASQ although there is not a direct, inverse relationship. The EIS does not intend to suggest such a relationship and the Alternative Continuum in Chapter II of the EIS is updated to clarify this. AS

COMMENTS: A section in the DEIS, page IV-10 last paragraph, uses Alternative 5 as a basis for comparing soil disturbance to other alternatives, which is at odds with NEPA.

413

RESPONSE: NEPA direction suggests using the no-action alternative as the comparison base, as it generally has the least impacts. In the analysis, alternative 5 has the least impacts to soils, and thus was used as the comparison base for ease of narrative presentation. AS

Greater Yellowstone Coalition recommended components for an alternative that was most like a mix of alternatives 5 and 6 which the Forest analyzed as "Alternative 5M":

COMMENTS: Consider an alternative with a mix of the attributes of alternatives 3M, 5 and 6 that would maintain the AUMs of 3M; maintain as much

ALTERNATIVES

of the ASQ of 3M as possible on sustainable basis; recommend substantially more wilderness than even 5 or 6; modify 3M grizzly prescription in the Bechler area to provide harvest mitigation; and create a wildlife linkage corridor in the Centennials with no ASQ.

643, 695

RESPONSE: We considered but dismissed this alternative proposal from detailed study. (See Chapter II of the FEIS for additional information.) These proposals would potentially be within the Purpose and Need and Desired Future Condition (DFC) with the exception of the amount of recommended wilderness. The DFC did not call for recommending the majority of inventoried roadless as wilderness. Furthermore a "Maximum Wilderness" alternative was previously considered in Chapter II of this EIS and dismissed because it does not respond to the DFC and because not all of the roadless areas rated high enough in the analysis. Below are responses to each specific change requested by commentors. AS

COMMENTS: Maintain the AUMs of alternative 3M.

643, 695

RESPONSE: This proposal is workable as suggested and has already been analyzed. AS

COMMENTS: Maintain as much of the ASQ of 3M as possible on sustainable basis.

643, 695

RESPONSE: The loss of the 5.x prescription acres in 3M (to create the Centennials wildlife linkage corridor) would eliminate the potential to harvest a major portion (over 75%) of the available ASQ in that alternative. This is due to the fact that the majority of the remaining ASQ lands are in Management Area 5 of the current Plan, which would not be available for harvest because they are over the hydrologic disturbance limit. This would produce a result that would be contradictory to the objective of maintaining the ASQ level. AS

COMMENTS: Recommend substantially more wilderness than even 5 or 6.

643, 695

RESPONSE: As stated above, there is no Purpose and Need or DFC indicating this is a desirable thing to do. Furthermore, there has been no legislative action on the three areas recommended in the last Plan. Also, in the FEIS we have added documentation of the roadless analysis to show a wilderness characteristics rating. This rating indicates that some of Diamond Peak should be recommended for wilderness. Therefore, we added a large portion of Diamond Peak to Alternative 3M in the Final Revised Plan. Finally, recommending the areas suggested as wilderness would further reduce the ASQ potential which would be contrary to the overall objective of this alternative proposal. AS

COMMENTS: Modify the grizzly bear prescription in the Bechler area to allow ASQ as in 3M, but with tighter mitigation requirements on harvesting.

643, 695

ALTERNATIVES

RESPONSE: We believe the standards and guidelines in grizzly bear prescription 5.3.5 provide the necessary habitat conditions to protect the grizzly bear. MO

COMMENTS: Place the Centennial Mountain in a set of prescriptions that would create a wildlife migration corridor through the area.
643, 695

RESPONSE: Placing this area in such prescriptions would significantly reduce the potential for obtaining ASQ as indicated above. As indicated in the EIS comment responses, the prescriptions identified for this area in 3M adequately address habitat connectivity concerns. AS

CENTENNIALS

Protect

COMMENTS: Support protection of the Centennials; preserve the roadless character; designate the Centennial Range as a wilderness area. Identify the Centennials as a migration corridor which provides genetic diversity for the grizzly bear, gray wolf, elk, and other wildlife species between the Greater Yellowstone Ecosystem, Central Idaho and Northern Montana.

Protect the Centennial Range from fragmentation occurring from too much ORV use, logging and road building.

F-B(4), F-G(475), 19, 60, 73, 136, 157, 158, 162, 165, 167, 168, 174, 175, 176, 178, 180, 181, 184, 185, 193, 194, 200, 203, 204, 206, 210, 212, 213, 244, 252, 274, 278, 280, 293, 325, 341, 362, 390, 396, 400, 410, 438, 444, 496, 615, 621, 622, 627b, 640, 643, 644, 652, 653, 664, 670, 690, 695, 697, 725, 739, 795, 1185, 1197, 1204, 1206, 1270, 1273b, 1275, 1277, 1314, 1327, 1331, 1348, 1369, 1381, 1387, 1392, 1395, 1443, 1448a, 1458

RESPONSE: The management prescriptions in the Revised Plan will maintain the potential for the Centennials to function as a migration corridor for wildlife. The Fish and Wildlife Service has asked Federal agencies to maintain this as a potential corridor, pending a study to determine whether such a corridor is feasible for grizzly bears. They recommend a timber/wildlife summer range type prescription with low road densities. The management prescriptions in the Centennials provide this direction at a minimum, and, in addition, provide extensive area in roadless, undeveloped prescriptions. Regarding wilderness designation, the Mt. Jefferson Roadless Area was studied in an earlier EIS and not recommended for designation. JBR

Range

COMMENTS: Use sheep as a tool to enhance the range resource in the Centennials.

432

RESPONSE: Within the limits specified by the respective prescriptions, this can be done. JBR

COMMENTS: Incorporate the U.S. Sheep Experiment Station Lands into managing the corridor.

643

RESPONSE: We considered the presence of the U.S. Sheep Experiment Station lands in developing the management plan for the Centennials. We conducted an adjacency study to coordinate our management with all adjoining Federal and State land agencies. DP/JBR

Mining

COMMENTS: Screen mining carefully. Withdraw the Centennials from mineral entry because it is an important corridor. (CROSS REFERENCE: Mining/Geology)

643, 1275

CENTENNIALS

RESPONSE: Any mining within the Centennials will be conducted pursuant to all applicable laws and regulations. Restrictions on mineral activities varies in the Centennials depending on prescription area. Mineral potential is limited except in localized areas and is not expected to significantly impact the area during the planning period. DP/JBR

Access

(CROSS REFERENCE: Access)

COMMENTS: Oppose new road construction; ATV/OHV use especially in spring; and suggest the Targhee National Forest limit recreation projects in the Centennials to protect corridor.

Expand summer motorized access in the Centennials.
136, 300, 345, 643, 652, 697, 1185, 1204, 1277, 1348

RESPONSE: The Forest Plan limits new road construction on the Forest to conform with the road density standards in the management prescriptions. ATV/OHV use will be restricted to designated routes. The Centennials have two designated routes: Keg Springs and East Dry Creek. All other routes have travel restrictions on them. Most recreation projects in the Centennials will be development of trailhead facilities or trail construction/maintenance or reconstruction of existing developed facilities. LAB/JBR

COMMENTS: Manage road access in Camas Creek watershed area.
1185

RESPONSE: Road access in the Camas Creek Watershed area will be managed by prescriptions. Motorized access will be allowed only on designated roads and trails within the road density standards in the management prescriptions. A net reduction of roads will occur in Camas Creek. LAB/JBR

COMMENTS: Give the Centennials the same OROMTRD of 0.0 - 0.5 mi./sq.mi., similar to that used for big game summer range.
1273b

RESPONSE: The OROMTRD varies in the Centennials depending on management prescription. In the higher portions of the Centennials, Prescriptions 3.1.2 and 3.1.1(a) have an OROMTRD of 0.0 mi/sq. mi. Other prescriptions for this area allow access only on designated routes, and they generally have an OROMTRD between 0.5 miles/sq. mile and 1.5 miles/sq. mile. LAB/DP/JBR

Timber

COMMENTS: Maintain the natural process of late seral coniferous/aspen stands in the Centennials. (CROSS REFERENCE: Timber, Aspen)
1185, 1348

RESPONSE: Natural processes will be used where appropriate to maintain vegetation composition and structure in the Centennials. Silvicultural treatments and prescribed burning, along with other treatments, will also be used. The particular treatments will be decided upon on a site-specific basis as projects are developed. JBR

CENTENNIALS

COMMENTS: Silvicultural prescriptions should be designed to help small, locally-owned logging companies.

1185

RESPONSE: Silvicultural treatments address the correct methods to maintain forest structure and regenerate timber stands. The layout of sales and their size often determines whether large or small operators bid on them. Large timber companies generally will not travel long distance to purchase small volume timber sales, therefore the small logging companies have an advantage for these sales. We typically provide a mix of small and large sales so all operators can compete. Also, the Small Business Administration, in conjunction with the Forest Service, has a "Small Business Set-Aside Program" where small businesses are guaranteed the right to purchase a pre-calculated percentage of all timber sales offered on each National Forest. This percentage is computed based on historical timber purchases on each specific National Forest for 5 year intervals. It is updated every 5 year period. If small business does not purchase its allotted share the first 6 month period of the year, then the share for the second 6 months plus the deficit for the first 6 months is "Set Aside." Large business is not allowed to bid unless small business fails to bid. JBR

COMMENTS: Prohibit unscheduled "EM" timber harvest in Centennials. Do not include the Centennials in the suitable timber base.

643, 1273b

RESPONSE: This was not adopted in the Revised Plan. The scheduled and nonscheduled timber harvest in the Centennials is provided in an appropriate balance with other resources uses. A ceiling of 20 MMBF/decade is placed on Forestwide ecosystem management timber harvest to address public concerns about extensive harvest on unsuitable lands. DP/JBR

COMMENTS: Change the current management prescription from 5.1 Timber - Management to 3.1 Non-motorized.

739

RESPONSE: This recommendation was not adopted in the Revised Plan. No significant resource concerns exist that require such a change and would limit the ability to manage stand structure over time. Eliminating scheduled timber harvest in the Centennials would also markedly reduce the Forest's first-decade timber production. The production levels specified in the Revised Plan are an important contribution to the livelihood of some area residents; and harvests will be sustainable over time. DP/JBR

COMMENTS: Oppose logging activities in the Centennials because they should be protected as a roadless, wildlife corridor. Timber harvest should be secondary to protection of wildlife and old growth harvest should be prohibited. Object to acreage proposed for harvest in Centennials as proposed in Alternative 3M. (CROSS REFERENCE: Wildlife)

F-G-1(475), F-H(8), F-J(3), F-K(4), 40, 167, 200, 212, 280, 325, 330, 376, 377, 379, 396, 398, 400, 405, 409, 411, 424, 438, 441, 4899, 491, 492, 519, 620, 621, 622, 640, 643, 650, 652, 655, 665, 670, 695, 697,

CENTENNIALS

1185, 1197, 1204, 1243, 1275, 1277, 1314, 1324, 1330, 1348, 1360, 1381, 1382, 1387, 1393

RESPONSE: Protection of the resource, including soil, water, air, wildlife, and vegetation, is a primary concern of Forest management. As a result of doing this well, various outputs and activities can occur. The management direction specified in the Revised Plan responds to the needs of the Forest and will also provide a wide range of uses and enjoyment for the people. Old growth standard and guidelines were added to the Revised Plan which will maintain this resource over time. Wildlife habitat is provided in the prescription and is a major focus of management in the Centennials. DP/JBR

COMMENTS: Provide data that explains, if past timber management activities have not produced a range of variation, that more timber activity will produce better results. (CROSS REFERENCE: Timber; Ecosystem Management)

1388

RESPONSE: The Range of Natural Variation merely shows the range of conditions that ecosystems evolved with and adapted to over time. The suppression of fire has altered the natural disturbance pattern in some parts of the Forest. Silvicultural treatment can be designed to move ecosystems out of balance back to a more sustainable condition. Any timber harvesting activities need to be conducted in a manner sensitive to the needs of the resource, using the best available information. The Forest has considerable work underway with Montana State University to help provide that information base which can be used to design treatments that sustain ecosystem functions. We will treat areas, monitor the results, and adapt to those techniques that prove most successful. DP/JBR

Wildlife

COMMENTS: Protect the Centennials for the benefit of goshawk nesting and forage; wolverine who rely on old growth in the Centennials and for the grizzly bear. Remove the fences in the Centennial Range to reduce the fragmentation that affects carnivores.

643, 1185, 1348

RESPONSE: The Forestwide standards and guidelines and the management prescription respond directly to habitat needs for the goshawk, grizzly bear and wolverine. JBR

COMMENTS: Manage the Centennials to avoid conflicts between the grizzly bear and humans.

1185, 1193

RESPONSE: In the Grizzly Recovery Area, the objective is to provide habitat to sustain a recovered population of grizzly bears. Part of that direction is to minimize conflicts between people and bears. Numerous standards and guidelines in the Revised Plan address this concern. JBR

CENTENNIALS

COMMENTS: The DFPR and DEIS should address the significance of the Centennials and Madison Mountain Ranges as biological corridors as well as other portions of the forest.

410

Establish the Centennials as a corridor for the grizzly bear.
643, 1273b

RESPONSE: The Madison Mountain Range is not on the Targhee National Forest, although it is in the general vicinity of the Forest. The Forest does not anticipate that the management nearest the Madison Range could adversely affect any interchange of species between these areas.

Habitat connectivity in the Centennials is important. Relevant information from the Grizzly Bear Recovery Plan (9-10-93) states:

"One factor that may affect the sustainability of grizzly bear populations in the future is the ability of individual animals to move between ecosystems." They identify the distance between the Bitterroots and Yellowstone as 240 air miles.

"In order to adequately assess the capacity for linkage, the Service initiated a 5-year process to assess the linkage potential between the various ecosystems. This process will be led by the U.S. Fish and Wildlife Service in cooperation with the States, provinces, and the various land management agencies. This evaluation also will address linkage potential between existing areas in Canada. At this time, very little is known about the potential for linkage zones. At the completion of the 5-year evaluation effort, a report will be available to the Interagency Grizzly Bear Committee (IGBC) on the potential for linkage between existing ecosystems. This report will be the basis for future actions regarding the linkage zone question. Linkage zones are desirable for recovery, but are not essential for delisting at this time.

"Future land management activities within these areas may be critical to maintaining their utility as linkage zones. It is essential that existing options for carnivore movement between existing ecosystems be maintained while the evaluation of linkage zones is underway. Management strategies that limit human-induced mortality and address access management will facilitate the maintenance of the potential of these zones during the 5-year evaluation period. On public lands, management prescriptions similar to big game summer range prescriptions that address access management would likely conserve any existing potential of these areas for linkage until completion of the 5-year evaluation process.

"The Yellowstone grizzly bear population is the only one of five grizzly populations that is completely isolated from populations in other U.S. ecosystems and Canada. The population has approximately 300 bears. The population's small size and isolation make it vulnerable to the detrimental effects of the loss of genetic diversity, and to environmental and demographic stochasticity. Connectivity between Yellowstone Grizzly Bear Ecosystem and other grizzly ecosystems is not likely to be realized in the near future because of the distance to other ecosystems and the intervening human development and alteration of landscape. Therefore, the recovery plan recommends that one grizzly be placed into the ecosystem from an outside population every ten years as an effort to maintain the genetic health of the population."

CENTENNIALS

When the grizzly bear corridor studies are completed we will review them. We will continue to work with the U.S. Fish and Wildlife Service to recover the grizzly bear and otherwise meet wildlife needs. We have no indication from USFWS that our proposed management of this area would interfere with the land's use as a corridor for wildlife--including the grizzly. We believe the management prescriptions for the Centennial subsection maintain future options should the USFWS study recommend a linkage corridor.

Chapter I of the Wolf Reintroduction FEIS states: "Wolf recovery will not result in wolf travel corridors or linkage zones being established. The Yellowstone and central Idaho areas are separated from northwestern Montana by enough human settlement (a social rather than physical obstacle that results in some level of increased wolf mortality) that it could take decades for population recovery to begin. However, once established in each of the recovery areas, enough wolves from each area would disperse that some would successfully travel through or live in areas other than those in Yellowstone National Park and central Idaho. The size and proximity of 3 areas where wolves will be managed for recovery are large enough, close enough, and have enough public land between them that additional areas (travel corridors) are not required in the foreseeable future to maintain a viable wolf population after the 3 subpopulations become established."

Based on this information, the blend of prescriptions the Forest identified for this area better meets the needs of both the resource and the public. DP

Wilderness

COMMENTS: Recommended Mount Jefferson in the Centennials as wilderness area. (CROSS REFERENCE: Wilderness)

F-B(4), F-G-1(475), F-G-P(1), F-G-P(5), F-H(8), F-J(3), 19, 136, 143, 157, 163, 165, 174, 179, 180, 1811, 185, 192, 203, 209, 226, 252, 273, 278, 356, 359, 362, 368, 377, 379, 396, 405, 424, 430, 441, 443, 444, 491, 492, 516, 519, 613, 621, 622, 640, 651, 652, 653, 664, 690, 695, 739, 1194, 1197, 1206, 1241, 1243, 1257, 1270, 1275, 1328, 1330, 1368, 1381, 1382, 1395, 1401

RESPONSE: The Mount Jefferson Roadless Area was studied in an earlier EIS and was not recommended as wilderness. For more details, refer to the process Paper on roadless areas. JBR

Monitoring

COMMENTS: Recommend the DEIS/DFPR provide evidence and monitoring data that supports the management proposal to harvest Douglas-fir in the Centennials; show how harvesting will not impact wildlife survival. Address how wildlife viability will not be significantly impacted in previously harvested areas.

1369

RESPONSE: We are familiar with the existing conditions in the Centennials and with what we expect those conditions to be under the various alternatives. We are familiar with the existing literature relative to wildlife needs and survival. We see our proposed management as being a good fit to the needs of

CENTENNIALS

wildlife. Effects on wildlife from any harvest proposals will be identified in a separate NEPA analysis with public involvement. DP

COMMENTS: Develop, fund, and implement a monitoring plan that addresses the Greater Yellowstone Coalition's goals for the Centennials as a corridor.
643

Create specific standards addressing the Centennials.
643, 1273b

RESPONSE: After carefully reviewing Greater Yellowstone Coalition's proposal for managing the Centennials as a corridor, the decision was that the fully Revised Plan addresses habitat connectivity concerns without additional changes. The standards and guidelines in the Centennial prescriptions are sufficient to meet ecological and multiple-use objectives. The monitoring plan addresses monitoring needs for the Centennials along with the rest of the Forest. DP

New Prescription

COMMENTS: Proposes a new management prescription for the Centennial Mountain Range as a critical wildlife corridor as follows: Goal: To protect and perpetuate the qualities and importance of the linkage corridor.

Objectives: 1) Insects, fire and disease are allowed to play their natural role in ecological succession without restriction. 2) Actively seek to incorporate the US Sheep Experimental Station lands into the overall management of the corridor 3) Develop, fund and implement a monitoring plan that addresses the goal of the corridor.

Standards and Guidelines: Forestwide Standards and Guidelines apply.

Ecological Processes

Fire/Fuels

Use only minimum impact suppression tactics. (S)

Prescribed fire, utilizing both management-ignited and natural ignitions, may be used to maintain fire dependent ecological processes and to provide for a natural range of fuels, understory vegetation, and successional stages. (S)

Physical Elements

Soils and Water

Watershed restoration will be done where deteriorated soil or hydrologic conditions are caused by humans and their domestic livestock. (S)

Promote natural healing where natural vegetation would return within two years. (S)

Use native plant species to reestablish vegetation where there is no reasonable expectation of natural healing. (S)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of resources. (G)

Lands

Activities which may adversely affect the quality of viability of the corridor will not be allowed. (S)

No Special Use Permits or operating plans are allowed. (S)

Minerals/Geology

CENTENNIALS

Locatable-Withdraw from mineral entry, or remove from mineral entry through the notation rule. Valid, existing rights will be purchased by the federal government at fair market value. (S)

Mineral Material - This area is not available for mineral entry.

(S)

Heritage Resource

Remove structures that do not qualify for the National Register of Historic Places, or allow them to deteriorate naturally. (G)

Biological Elements

Wildlife: No wildlife habitat improvement projects are allowed. (S)

Forest Use and Occupation

Access (S) - 2.2.1(a) Same as 1.1.7.

2.2.1(b) Same as above except system roads 042 and 046 would be open for approximately 1 mile north of the Forest Service's southern boundary; system road 327 would be open south of section 32, T15N, R40E; FS system road 193 would be closed. System roads 185, 022, and 204 are to be closed from their junction in Section 22, T13N, R34E, Motorized use of trail 110 and its associated trails would be eliminated; cross-country snowmachining travel is allowed between December 15 and April 1.

2.2.1: Same as MP 2.2 except that there will be no Cross-country snowmachine travel before December 15 or after April 1. Roads and trails noted as open on Map 11 within the boundaries of this area, except Forest Service system roads 010, 019, 674 and 675 which would be closed.

Recreation

Trails - No new trails (S)

ROS - Primitive to semi-primitive non-motorized. (S)

VQO - Retention (S)

Production of Natural Resources

Timber:

Lands are not included in the suitable timber base. They do not contribute toward the ASQ.

There will be no unscheduled, ecosystem management timber harvest.

(S)

No vegetative management of any kind will occur. (S)

643

RESPONSE: This prescription by the Greater Yellowstone Coalition for the Centennial Mountains was not adopted because the Revised Plan addresses habitat connectivity concerns without making most of these changes. The standards, guidelines and management prescriptions in the Revised Plan are sufficient to meet the ecological and multiple-use objectives. See other detailed responses that address the Centennial corridor concern. JBR

DESIRED FUTURE CONDITION

Desired Future Condition General

COMMENTS: Support the direction in which the Targhee National Forest is headed as reflected in the section on Desired Future Condition (DFC); pleased that it de-emphasized resource extraction and livestock grazing and stresses biological health. In most cases, the DFCs provide a reasonable vision and philosophical position for the next decade, although in many cases the Forest has not made a strong commitment to DFCs. Supports the need for change section; the summary rationale is excellent, and the DFC section in the summary is comprehensive and unbiased.

489, 727, 1367b

RESPONSE: The goals, objectives, standards and guidelines in other parts of the Revised Plan flow from the larger-scope Desired Future Conditions (DFC's). The intent is to manage the Forest such that conditions show a trend toward or actually achieve the DFC's. The pace at which progress is made toward these conditions will depend on a number of factors including appropriations to the Forest. EF

Analysis Process

COMMENTS: The DFCs in the Executive Summary are too broad, lofty and unrealistic. Set realistic and specific goals that cover ecosystems, habitats, resources, and the social and economic values. The DFCs reflect two polar opposites with the Plan recommending a middle ground. The design is weak. The DFC is process driven, not people driven; driven by need for change, regardless of what percentage of people want the change. The DFCs have voids which will leave people guessing about the effects and impacts of forest management. The description of DFC in the DEIS consists of vague paragraphs where almost any activity could be construed to meet the goals; it could be argued that the Targhee National Forest already meets the DFC. DFC is so vague as to provide little useful management direction or goals to which the Forest can be held accountable. A failure to correct, coupled with increase in recreational use could permanently damage this critical component of the Greater Yellowstone Ecosystem.

393, 413, 618, 697, 1365, 1393

RESPONSE: DFC's are not intended to be an exhaustive statement of detailed conditions to be achieved. They are designed to provide a broad but clear picture of where we intend to be upon achievement of the stated goals and objectives of the Revised Plan. There are many ways to define and display DFC, all of which could be equally useful in communicating the vision for management on the Targhee. The current set of DFC statements are adequate and provide sufficient description of where we hope to be in the future. RR

Goals and Objectives

COMMENTS: The Plan demonstrates an overriding concern for preventing catastrophic fire and insect outbreaks despite the DFC acknowledgement that such things are within the Range of Natural Variation. There are no goals for soil conditions, erosion, air quality, caves, land management, or how

DESIRED FUTURE CONDITIONS

vegetation, wildlife, or riparian zones will be in ten years. The forest has shifted to a goal of DFC for riparian areas instead of standards and guidelines for watersheds. The standards and associated monitoring plan will not result in meeting the stated DFC for riparian areas, and the riparian DFC will not meet with essentially unregulated cross-country motorized access. Clarify what level of sagebrush is required for the DFC for vegetation. The DFC arbitrarily assumes a reduction in mature forest. A mosaic of age classes and types sustained through time, one objective of DFC, has never existed on the Targhee and will not without proactive management.

393, 489, 697, 766, 1368

RESPONSE: Forestwide, Subsection, and Management Prescription goals and objectives augment the DFC descriptions with more specifics on where and how the Forest will move forward in the different resource areas. These provide more detail than the DFC's alone and represent a composite of the total array of conditions the Forest aims for. RR

Structure and Design

COMMENTS: The DFCs are organized under three headings in the DFPR and four in the DEIS, even though the DFCs seem about the same. Suggests they be consistent, and that the stronger statements be used. Subsection descriptions are a very confusing place to include DFCs. DFCs violate ecological principles following watersheds. The statement for DFC's, "timber harvest, prescribed fire, and grazing are used as tools to achieve ..." is out of place in the DEIS and DFPR because these are tools, not conditions.

489, 695, 697

RESPONSE: The content and wording of the DFC's were changed to be consistent in wording and intent in the Final Revised Plan and EIS.

Desired Future Conditions are entirely appropriate at different ecological scales as long as they are consistent with those at other scales.

It is true that timber harvest, prescribed fire and livestock grazing are tools which can be used to achieve desired landscape and vegetation conditions. In the Draft Plan and EIS, timber harvest and grazing were included under the Economic Component and Production of Natural Resources component, respectively, to paint a broad picture of the experience which can be expected on Forest lands. In the same way we included statements about growing and diverse recreation needs and increased recreational opportunities. Further, the statement that these commodity uses of the Forest are used to achieve desirable vegetation conditions indicates a shift in the emphasis in these programs to more clearly line up with objectives for achieving sustainable resource conditions. EF

Wilderness

COMMENTS: Provide specific provisions for achieving 3rd DFC, and suggest wilderness designation is the appropriate method.

489, 643,

DESIRED FUTURE CONDITION

RESPONSE: The Final Revised Plan recommended a large portion of Diamond Peak as wilderness. Not all roadless areas score high in wilderness criteria. Therefore, it is inappropriate to recommend all roadless areas as wilderness. Other prescriptions, standards and guidelines can assist in achieving this DFC.

Timber

COMMENTS: Be more specific about how logging and grazing will be used to achieve DFC; discuss harvest methods and grazing systems employed to reach DFC.

489

RESPONSE: The method used to achieve the DFC presented in the Final Revised Plan is the subject of Plan implementation and project-level analysis. From a comparison of existing landscape conditions with desired conditions, opportunities for treatment are identified. Possible management practices on the ground are then listed, and individual project proposals are formed from these. Public review will be invited on these project proposals, which must either be consistent with Forest Plan standards and guidelines or be an amendment to them. EF

Recreation

COMMENTS: Develop a DFC for Forest Development Road System, and one for recreation.

FS-11

Include a DFC for developed downhill skiing. DFC has many voids and should use a finer scale of analysis.

618

Recommend user targets and DFC for both summer and winter recreation.

1342

RESPONSE: Desired Future Conditions (DFC's) are appropriate at broad scales for land conditions, user experiences, and so forth. They are intended to serve as targets to orient management and may be attained at some point in the future. Such targets when applied at finer scales or within defined time frames are termed goals or objectives. These can be refined and the Revised Plan amended based on subsequent watershed analyses, capacity studies, and so forth. EF

Time Frame

COMMENTS: Develop a clear and definite time frame for each geographic subsection to attain its DFC.

1446

RESPONSE: The job of the Final Revised Plan is to present the Desired Future Conditions and base management direction upon them. DFC's by their nature are designed to be attained at some undefined point in the future. It is difficult to assign a clear time frame to the achievement of such

DESIRED FUTURE CONDITION

large-scale target conditions since this is subject to limitations of budget and unforeseen circumstances. The DFC's present a solid foundation on which management is built, and thus serve the purpose for which they are intended. EF

Economics

COMMENTS: Traditional logging and grazing account for less than 1% of local jobs and income, and DFC should state that in 10 years economy will be growing based on various tourism and recreational opportunities.

697

RESPONSE: It is not the job of the Forest Service to set goals for areas outside of agency jurisdiction. The Final Revised Plan and EIS note the trend toward recreation and tourism in the area. Employment and income in the area of Forest influence is described in detail in the EIS in Chapter III. EF

Site-Specific

COMMENTS: The DFC for Caribou subsection (DFPR III-53 & 55) states that the area is being managed to provide high quality nonmotorized and dispersed camping recreation, which is in contradiction to an item in the recreation section about improving the quality of summer OHV use in this subsection. The DFC for Caribou subsection (III-53) leaves out motorized use which the area currently provides and will continue to provide.

The DFC for Lemhi/Medicine Lodge subsection needs to be expanded to create more ATV opportunities.

Page III-20, Table III-4: clarify how the Teton Range Subsection was determined considering the Aquatic Habitat Condition and Trend, and Vegetation Seral Stage and Trend are unknown. Modify document to explain source of numbers or change to status unknown.

389, 489, 629, 643

RESPONSE: The DFC for the Caribou subsection was rewritten to show the intent to manage for both motorized and non-motorized recreation uses.

The DFC for the Lemhi-Medicine Lodge subsection allows motorized use opportunities. Refer to the goals and objectives for the subsection. EF

Wildlife

COMMENTS: Suggest replacing words "sustained populations of all native and desirable species thrive" (Pages S-4, I-12) with "viable populations of all native and desirable species are sustained. "The meaning of the second DFC (native over non-native species) should clarify what undesirable is.

Include on Page III-45 the DFC objective of maintaining a population of at least 150-200 bighorn sheep; coordinate management with other agencies.

489, 643, 699

RESPONSE: We changed the wording to reflect the suggestion. The new wording provides a better link to direction in the NFMA implementing regulations.

DESIRED FUTURE CONDITION

The meaning of the word "undesirable" in the Biological/Physical DFC can be inferred from various sources including State lists of noxious plants. The purpose of the Desired Future Condition statement is to frame a large picture of the condition we would like to have on the Forest at some future point in time. The statement as written adequately does this and can be interpreted during Plan implementation. EF

DRAFT FOREST PLAN REVISION

(CROSS REFERENCE: Alternatives)

Support

COMMENTS: Supports DEIS and DFPR because they depart from past management practices, adopt sustainable ASQs, decrease road densities, limit x-country, protect riparian areas and watersheds, and provide greater wildlife security and increase wilderness area.

697

RESPONSE: Thank you for your comments. EF

Lack of Science

COMMENTS: Use current, sound science, and cite references used in developing goals, objectives, and standards and guidelines. Adequate consideration of recent, valid, peer-reviewed scientific studies should be applied to Plan development. Do not base management on cultural biases or politics. Lacking adequate science, the Targhee National Forest is unable to fulfill basic legal, ethical, or responsible mandates of National Forest and National Grassland management. Conclusions in DFPR contradict available research and indicate an effort to steer management in predetermined direction.

293, 393, 643, 697, 1364, 1365, 1369

RESPONSE: The Forest used the best science available to us through literature searches, results of research and studies conducted on the Forest and other sources. The Forest recognizes there are other sources with conflicting conclusions, but feel confident in our use of good science.

The Forest made good use of current peer-reviewed research in development of the Revised LMP. Examples include: Southwestern goshawk guidelines and research on the Forest; research by Idaho Fish and Game Department and U.S. Forest Service researchers regarding elk vulnerability and road access; Interagency Grizzly Bear Study Team studies concerning habitat needs and road density; and the hydrologic disturbance threshold study.

Use of the OROMTRD indicator is appropriate in the BMU's and represents application of the best available science.

The Forest acknowledges that contradictory opinions will always exist in the scientific community. EF

COMMENTS: Conclusions are unsubstantiated and often refuted by conclusions of on-going study by the Targhee and Montana State University as part of the Henry's Fork Watershed efforts.

643

RESPONSE: This study was conducted over a small area of the Forest, and was designed to test methodology, not to define conditions. The study is still in draft form, and any attempt to extrapolate its results at this point to larger areas of the Forest is premature and beyond the scope of the study or the Revised Plan. EF

DRAFT FOREST PLAN REVISION

COMMENTS: Although there may be a dearth of recent, complete, accurate, or ecologically significant scientific data, a great deal is known about impacts of various management activities. Apply knowledge gained on other forests. The Forest Service is obligated to undertake research needed to fill in gaps in knowledge about impacts on species, habitat, and ecosystem; and until such research is completed the Forest Service must restrict any potentially harmful activities. A failure to do so is arbitrary and capricious, and a heinous violation of the public trust.

1276, 1365

RESPONSE: The Forest consulted current and applicable literature and research where available and needed, and adopted relevant conclusions on which to base proposed future management. The call to consult and integrate all of the best available research is neither feasible nor based in applicable planning regulations, which call for the use of high-quality scientific information and insuring scientific integrity in the analysis (40 CFR 1500.1(b), 1502.24; 16 U.S.C. 1536).

The Forest acknowledges there are research gaps in the information needed to fully support proposed management direction and to disclose the effects of this management. Further, there always will be gaps of this kind. The Forest has identified research needs in some of these cases, and has committed to taking an adaptive management approach which includes continuing current partnerships with the research and academic communities. The call to eliminate all existing information gaps prior to outlining and proceeding with management direction for the Forest is neither feasible nor based in applicable planning regulations, which call for identifying knowledge gaps where they exist and proceeding with the best available science (40 CFR 1502.22; 16 U.S.C. 1536).

COMMENTS: Specific areas cited as needing more scientific basis or research include, among others: issues of seismic potential; ground water concerns (Madison Limestone is a significant aquifer); watershed analysis; mineralization such as copper, silver, zinc, lead, granite, limestone, and phosphate; cultural resources; abundance, distributions, and ecology of species; and management impacts on wildlife and habitat, especially for threatened or endangered, sensitive, and globally imperiled G1, G2, & G3 species (Heritage Foundation ranking for extinction risk, 1 being highest).

389, 643, 1365

RESPONSE: Proposed management activities will not endanger or jeopardize any of these features. While more research and scientific investigation will probably always be needed to exactly describe management needs for these and other resources, the standards and guidelines are sufficient to protect them, and the goals and objectives provide restoration opportunities.

The issues of seismic potential and groundwater concerns are so large as to be beyond the scope of the Revised Plan. Objectives in the Draft Revised Plan for watershed needs analysis were supplemented with additional goals and objectives in the Final (see Chapter III, Ecological Processes and Patterns and Biological Elements). These provide opportunities to identify any program restoration needs.

DRAFT FOREST PLAN REVISION

The protective measures currently in place for cultural resources are sufficient. Standards and guidelines for wildlife habitat needs more than adequately address the needs of species inhabiting the Forest. EF

COMMENTS: The AMS indicates the Forest has yet to undertake a rigorous spatial or temporal analysis of existing conditions. The Forest presents tables of data or conditions with little information as to how derived.

643

RESPONSE: The Analysis of the Management Situation (AMS) was developed over the last five years and represents a compendium of data concerning the current state of resources on the Forest. Reasonable inferences were derived from this data.

Legal Compliance

COMMENTS: In development and implementation of the DFPR, the Forest Service must adhere to the legal and policy requirements of: NEPA, NFMA, APA, RPA, the Organic Act of June 4, 1897 (30 stat. 35), the Transfer Act of 1905 (33 stat. 628, 16 USC 472), the Multiple-Use Sustained-Yield Act of 1960 (16 USC 528-531), Executive Orders 11644 and 11989 (on OHV use), FSM sect. 2670 (on Biological Diversity and Threatened and Endangered Species), 36 CFR 219.19, the Endangered Species Act (sect. 7(a)(1) and (2), 16 USC 1604 (g) (3) (b), 36 CFR 219.27 (a) & (g), 16 USC 1604 (e), 16 USCA 1604 (C) (1), 36CFR 219 concerning wilderness and roadless values, 36CFR 219.17, 60 Fed. Reg. 18931 S219.14 (b), or State water quality guidelines. The Plan either fails or only nominally adheres to these laws and policies because of lack of adequate referencing; inadequate direction or analysis for wildlife; air quality; wetlands; fire management; threatened, endangered, sensitive and indicator species; Archaeological and Historical Preservation; biological corridors; roadless areas to be proposed as wilderness; range of alternatives; or that the policy was not developed with open public participation but was crafted in the dark with the help of Greater Yellowstone Coalition et. al.

275, 341, 389, 393, 607, 689, 697, 766, 1273b, 1364, 1365, 1367b, 1369, 1446

RESPONSE: The Forest is aware of responsibilities under these and other statutes. The Forest has complied with all applicable laws, regulations and policies in the development of this Final Revised Plan.

Extensive public involvement was conducted for this effort, which stretched over five years. The mailing list of those requesting to be kept informed of the project includes the names of over 2,000 individuals and organizations. Numerous public meetings were held which generated many comments and information which was used in the development of the Final Revised Plan. The Forest fully met the letter and intent of all requirements for public involvement.

Executive Order 11644 authorizes the administrative designation of use and non-use OHV areas and provides for public participation and monitoring. E.O. 11989 amends it to authorize closures of areas for real or imminent damage caused by OHVs. The Final Revised Plan regulates OHV use extensively through prescriptions and Forestwide standards and guidelines.

DRAFT FOREST PLAN REVISION

The monitoring plan includes an item monitoring seasonal trail use impacts including OHVs. The Revised Plan complies with the letter and intent of these Executive Orders.

The Final Revised Plan complies with the current NFMA viability requirement, NEPA, the Administrative Procedures Act, the Organic Act (June 4, 1897), the Multiple Use-Sustained Yield Act (MUSYA) of 1960, and other applicable direction.

The Organic Act deals with the reasons for establishing a National Forest, but does not require scheduled timber harvesting. The MUSYA is part of a broader spectrum of laws directing the management of the National Forests which includes the National Forest Management Act, the National Environmental Policy Act, and the Endangered Species Act. The timber output in the Final Revised Plan is at a level which can be generated consistent with the requirements of other direction Congress has provided. The Final Revised Plan represents a balance between often-conflicting wants and direction for resource management. EF

COMMENTS: Additionally, FSH 2409.13 requires the plan appendix to include items that were not included in the draft: Land Classification, Section 42.1; The average annual acreage to which the vegetation management practices shall apply for suitable lands during the first decade, Section 42.2; The Allowable Sale Quantity and Timber Sale Program Quantity of sawtimber and other products, Section 42.4; Allowable Sale Quantity and Long-Term Sustained Yield Capacity, Section 42.4; Present and Future Condition, including Growth and Mortality, Section 42.6; The 10-year Timber Sale Schedule, Section 42.7; and Timber Management on Unsuitable Lands, Section 42.8.

413

RESPONSE: All required items are included in the Final Revised Plan. EF

Analysis Process

COMMENTS: Analysis is incomplete or inconsistent; "flawed;" requires more analysis of past impacts; needs improvement in presentation; the process of analysis for developing or implementing the plan is inadequate; changes in the land may not occur in a narrow time frame but in 50-300 year cycles; many objectives are not measurable or followed by Standards and Guidelines to assure they will be met; the TNF's role in the Greater Yellowstone Ecosystem is not explicitly addressed in the DFPR goals and objectives, or in the DEIS.

309, 389, 413, 489, 643, 689, 697, 699, 766, 1369, 1395, 1446

RESPONSE: Between the Draft and Final Revised Plan, many of the objectives were changed to goals or time frames were added to many more objectives. Some of the time frames were changed to reflect realistic budgets and priority one monitoring items. A brief discussion is included on the Targhee's role within the Greater Yellowstone ecosystem however, much of this is already included in the Framework document for the GYE (Greater Yellowstone Coordinating Committee's Framework document, USFS, USNPS, September 1991) and does not need to be repeated. CC

DRAFT FOREST PLAN REVISION

COMMENTS: Time frames for undertaking important analyses are so long as to make them totally disjunct from management decision-making (i.e. RNV analysis by 2007, watershed improvement needs inventory by 2007).

643

RESPONSE: The time frames given for analyses are reasonable and necessary. They take into account personnel and funds available for conducting analyses, as well as the time needed to produce meaningful results. RSM

COMMENTS: Plan requires more analysis on: fragmentation caused by roads and timber harvest; old growth upon which many species depend and which might be eliminated under the Plan; firewood harvest and loss of biological potential; sensitive species, of which the Plan mentions only Goshawk and two owl species; and forest songbirds in lower elevation habitat, which has been seriously impacted by past management practices. Analyze potential environmental consequences of alternatives and of what could be an extensive logging program under the guise of ecosystem management. Place more emphasis on value levels and less on utilization levels. Clarify existing conditions; identify factors causing conditions, ensure standards, guidelines, and prescriptions will accommodate resources into the future.

643, 697, 699, 766, 1367b, 1369

RESPONSE: The Final EIS evaluates a range of alternative ways to address these and other issues. The selected alternative and the Final Revised Plan provide for restoration of past impacts and define future direction for the management of healthy ecosystems. The consequences of specific proposals to implement the Revised Plan will be evaluated in separate site-specific environmental analyses.

The cycle of planning-implementing-revising will always be with us because conditions and knowledge will always change. In developing the Final Revised Plan the Forest made use of the best available knowledge for current conditions; and it can be changed as conditions and knowledge evolve. EF

COMMENTS: Explain need for new plan and how adequate revisions will be in view of the extent 1985 plan has or has not been accomplished; explain how management emphasis delineations are made; include forest-wide direction for infrastructure management. The Forest Service should stick with the plans it makes rather than make new ones.

FS-11, 309, 699, 1395, 1369

RESPONSE: The need to embark on the Forest Plan Revision process is explained in the EIS (Chapter I) and the Revised Plan (Chapter I). The Final Revised Plan for the Targhee National Forest is supported by information in the Analysis of the Management Situation (AMS). Plan revisions are required periodically by current regulations governing National Forest management, and are appropriate when conditions in the planning area have changed or new information is available on which to base management decisions.

Many objectives of the original Forest Plan were implemented in whole or in part. The Forest intends to implement the Final Revised Plan to the best of our abilities consistent with appropriated funding. EF

DRAFT FOREST PLAN REVISION

COMMENTS: Explain why Targhee National Forest has substituted goals and objectives for standards and guidelines, by what analysis they were developed, what legal context used for interpreting them, how they relate to policy for implementing NFMA and/or NEPA, how much consideration they are given, and how funded and applied.

643

RESPONSE: The role of standards and guidelines in the forest planning process is outlined in 36 Code of Federal Regulations Part 219; policy is articulated at Forest Service Manual Chapter 1920 and Forest Service Handbook Chapter 1909.12. The application of standards and guidelines in the Final Revised Plan is explained in Chapter III. Standards are constraints on management activities or practices; deviation from compliance with a standard requires a Forest Plan amendment with its accompanying public involvement. Guidelines represent a preferred or advisable course of action which shall be the general rule; deviation from compliance with a guideline does not require a Plan amendment but shall be explained with written rationale.

In developing the Final Revised Plan the Forest tried to be consistent in designating a measure as a goal, objective, standard or guideline. This was not always possible in individual cases, and some changes were made to provide Forest managers with flexibility to address changing conditions, knowledge and opportunities and to deal with unforeseen circumstances. Without this flexibility Forest personnel might spend more of their time in planning exercises and less in gathering field information monitoring, and implementing projects. The Final Revised Plan is unambiguous in its intent to give adequate protection and direction for restoration where needed. EF

Specific Sections

COMMENTS: In the introduction, last paragraph relating to emergency events, include a list of all potential events to give reader a better idea of what constitutes an emergency; appears to include only law enforcement, search and rescue, and fire.

1446

RESPONSE: It is impossible to foresee all of the emergency events that might occur over the next ten to fifteen years, and it is unwise to attempt to provide an all-inclusive list. The phrase in Chapter III of the Final Revised Plan indicates that emergency events "include such things as law enforcement, search and rescue, and fire." This adequately shows our intent as to what events might be considered emergency in nature and allows for unforeseen circumstances to be addressed. EF

COMMENTS: Page II-1, I. Introduction--Describes Chapter II as a summary of the Analysis of the Management Situation (AMS). A more comprehensive analysis of the management situation, particularly in relation to the extent that

DRAFT FOREST PLAN REVISION

management direction in the 1985 Plan (see Appendix A) has or has not been accomplished, should be included in the Final Plan Revision or FEIS. This is needed to properly justify the need for revising the 1985 Plan and to evaluate the adequacy of proposed revisions.

699

RESPONSE: The Analysis of the Management Situation is a large compendium of information assembled over the last five years showing the status of many resources on the Forest. After each description, information is included showing the difference between the current situation and Forest Plan direction or projections; and changed conditions or the need for change in management. This information was important in confirming the need to revise the Forest Plan, and to focus on the areas where most change was needed.

It is true that this information can also serve as a check on how well we did our job in revising the Forest Plan. An honest accounting will show we emphasized the correct elements, provided adequate protection for Forest resources and provided opportunities for restoration where needed. EF

COMMENTS: Since only a summary of the Analysis of Management Situation (AMS) is given in Chapter II, a citation to the full AMS should have been included in the Introduction; i.e., (USDA Forest Service, Targhee National Forest 1992), as the AMS is listed in the References Cited section of the Draft Plan Revision.

699

RESPONSE: This was done. Thank you for your comment. EF

COMMENTS: Pg 1-6. Key issues missing: 1) jobs; 2) support local economy in wages/salaries; 3) summer x-country OHV use; 4) areas without snowmobile date restrictions; 5) firewood production.

413

RESPONSE: These concerns are shown in the Issues chapter of the AMS, in the Consequences section of the Final EIS, and in the larger-scope issues shown in Chapter I of the EIS.

COMMENTS: Goal statements Pg 111-20 imply wildlife is not a basic resource. Wyoming Game and Fish disagrees, and forage production should be considered before other consumptive uses.

389

RESPONSE: The Forest agrees that wildlife is a basic resource. Utilization standards apply to use by livestock and wildlife. EF

COMMENTS: Pg 1-4, last paragraph seems prejudicial because the Forest is not meeting 1985 Plan goals for timber harvest, summer OHV x-country use, grazing, and snowmobiles, but these are not discussed.

413

DRAFT FOREST PLAN REVISION

RESPONSE: The Forest substantially met major goals for timber harvest and regeneration. Therefore the conditions under which the original Forest Plan was developed have changed. Increasing demand for summer and winter OHV use represents a changed condition and were recognized in the decision to revise the current Forest Plan. EF

COMMENTS: Concerned with prescription 7.1 because of wildfire potential.
325

RESPONSE: Prescription 7.1 was deleted from the prescription menu for the Final Revised Plan. EF

COMMENTS: Pg IV-50, 2nd Para.: Comparison between reductions in logging and livestock grazing implies that, although effects on livestock are bad, ranchers should feel good because at least effects aren't as bad as on logging industry.
413

RESPONSE: Thank you for your comment. The effects displayed in the EIS are best estimates of potential impacts for both the timber and livestock industries on a forestwide scale. An actual change in livestock AUMs can only occur with a site-specific analysis of each grazing allotment. Whether it is logging or grazing, on a site-specific basis, it is likely a rancher whose grazing permit is reduced could be affected as much as a logger whose wood supply is reduced. WG

Implementation, Monitoring, Enforcement

COMMENTS: Explain whether implementation and enforcement will be applied in broad prescription areas or individual polygons; the Plan allows few future management options; proposed changes are too radical or too sudden; and repercussions are not known, such as the impacts of wolf reintroduction on coyotes and foxes. Need information on what basis, besides legal requirements, certain management emphasis delineations are made; Monitoring and Evaluation chapter doesn't address those topics well. Develop specific, strict, enforceable standards to ensure DFPR goals are realized; develop a standard that any activity causing negative environmental impact be terminated until such time as it does not cause such impact. Change guidelines to standards to help Targhee National Forest meet goals. No plan will succeed because of human population explosion. A determination that Plan revisions have no significant environmental impact requires that ecosystem enhancement projects will be conducted, and authorized actions that have potential to harm resources will be monitored. Require commitment to adaptive management, a method that uses scientific experimentation to develop and modify management decisions, and is crucial to ecosystem management. Develop action protocols for when noncompliance is unavoidable.

6, 90, 166, 282, 305, 389, 643, 766, 1369, 1446

DRAFT FOREST PLAN REVISION

RESPONSE: The Final Revised Plan contains management direction in the form of standards, guidelines, goals and objectives for the Forest as a whole; for ecological subsections; and for individual prescription areas. The Plan will be implemented and enforced based on the level at which these measures apply. The standards and guidelines are adequate to meet the goals and objectives to protect and enhance Forest resources, and the Forest intends to abide by these standards and guidelines with provision made for unforeseen circumstances.

The Final Revised Plan represents a change from the original Forest Plan in that it implements lesser amounts of intensive management over fewer widespread areas of the Forest. This approach presents opportunities for restoration where needed, as well as for adaptive management trials of new techniques in concert with the academic and research communities to identify ways of carrying out the mission of ecosystem management. In this sense the Monitoring and Evaluation Plan is one part of a larger effort.

No project decisions are made in the decision to implement the Final Revised Plan. Instead, resources will be committed in individual project decisions. EF

COMMENTS: There is lack of provision and funding, and indication of low priority for monitoring and enforcement. The plan doesn't identify how goals and objectives will be prioritized, and therefore how funding will effect implementation. The specific activities in the Plan to specific budgets, including reforestation, logging and riparian area restoration, enforcement of road and trail closures. Disclose what percentage allocated for each program, and whether funding is "constrained" or "nonconstrained."

766, 643, 1206, 1249

RESPONSE: The Forest Service operates on monies appropriated by Congress and the Administration. The mix of funding and priorities is subject to change from year to year. The Forest can not predict what the funding priorities will be. The Forest will endeavor to carry out the direction in the Final Revised Plan within the funding constraints enacted by Congress and approved by the Administration. Final budgets are a matter of public record and can be reviewed by any interested party. EF

COMMENTS: Develop specific, strict, enforceable standards sufficient to ensure that the DFPR goals and intents are realized. The Plan should articulate a standard that requires that any activity causing negative environmental impact be terminated until such time as it does not result in negative impacts.

1365

RESPONSE: This suggestion is not conducive to multiple use or in the best interest of the public owners of the National Forest. The standards and guidelines in the Final Revised Plan are adequate to protect Forest resources and promote restoration where needed. The extent to which goals and objectives are realized will depend to some degree on the will of Congress and the Administration as expressed in yearly appropriations. EF

DRAFT FOREST PLAN REVISION

COMMENTS: Show that the "Forest User's Survey" is a valid approach to evaluate the effects of the Plan because it isn't designed to answer specific questions.

697

RESPONSE: The Forest Users Survey monitoring item provides Forest managers with an indication of the degree of satisfaction of Forest users with the direction of management under the Revised Plan and how that direction is being administered. It is written broadly and can be implemented using a variety of methods. Specific questions are asked of Forest users to identify areas of satisfaction or concerns. The survey is one possible tool that can gauge the satisfaction of the public with the management of their public lands. We are open to suggestions on other tools that might be more effective. EF

Change Priorities

COMMENTS: Priority 3 status for the Biological Diversity monitoring item (page V-13) indicates lack of commitment; should be assigned Priority Group I and a time line included in Implementation Schedule Chapter IV, plus must provide additional description for components.

643

RESPONSE: There is a difference between Forest Plan monitoring, which the Monitoring and Evaluation Plan is designed to do, and research on complex subjects such as biodiversity, which Forest Plan monitoring is not designed to do. Ongoing and future cooperative efforts will continue to gather information on elements of biodiversity, and Forest Plan standards and guidelines will be modified as needed based on this forthcoming information. EF

COMMENTS: Change Forest Priority Group ratings as follows: Detrimental Soil Disturbance to Group 1; Fine Organic Matter Retention to Group 2, Application and BMPs to Group 2, Biological Diversity Study to Group 2, Standing Dead Tree Habitat to Group 2, User Satisfaction to Group 3, Seasonal Trail Use Impacts to Soil & Veg to Group 1, Recreation/Wildlife Conflicts to Group 1, Jedediah Smith Wilderness LAC to Group 2, Authorized Use/Game Retrieval Use Level to Group 1, Road Closure Effectiveness to Group 1, Achievement of Road Density Standards to Group 1, Riparian Plant Use/Trampling to Group 1, AMP Planning Admin. Site Use to Group 2, Upland Forage Utilization to Group 2; Sage/Grasslands Canopy Coverage to Group 2, Maximum Created Opening Size to Group 2, Security Cover Retention to Group 2; and Large Forested Block Retention to Group 1.

1365

RESPONSE: The Forest reassessed the priorities of the various monitoring items based on comments from the public internally and externally. Several of the changes requested here were made, including the shifting to Priority 1 of the Road Closure Effectiveness, Achievement of Road Density Standards, and Riparian Plant Use/Trampling. EF

DRAFT FOREST PLAN REVISION

Design & Structure

COMMENTS: Meanings are unclear or definitions inaccurate; references and citations are lacking; the DFPR and DEIS are inconsistent with each other; the text and maps are inconsistent with each other; and prescriptions, charts, maps, and columns are often not appropriately named or described. Add a code at the bottom of each page to identify DFPR or DEIS; expand readers guide at beginning of each chapter. DFPR and DEIS are inconsistent due to conflict between old production of goods emphasis and new ecosystem management focus. The DFPR is overly complicated, confusing, and time consuming to grasp; a waste of tax dollars; and marred by verbatim repetition.

282, 489, 643, 695, 766, 1200, 1276, 1446

RESPONSE: Based on public comments and internal review, the Forest brought more consistency to the Final EIS and Revised Plan, and used clearer language and graphics to describe proposed management and its consequences. Nonetheless, the subject matter is often complex; documents are written for a broad audience including lay persons and scientists; and there are limits to how much simplification can be achieved.

The Forest added more terms to the glossary and attempted to define these terms in non-technical terminology. We removed direction that is redundant in law, regulation or policy and cited this in the appendix. We included citations and references to technical documents and listed these in full in the back of the Plan and EIS. We reviewed the Plan and EIS for consistency of terms both within and between them. And we responded to a tremendous amount of public comment on the draft documents, much of which dealt with readability and consistency. The final documents are improved over the drafts, and we are open to suggestions on subsequent improvements or explanatory materials that might aid users in understanding them more fully.

Some commenters noted a conflict in the documents between ecosystem management and proposed management. Ecosystem management is an evolving concept. The Forest Service still has responsibilities to adjacent public and private landowners to minimize damage proceeding from National Forest System lands. Stewardship responsibilities on the Forest can present dilemmas in the form of conflicting species needs or other questions. These and other competing demands on Forest resources and lands may appear to limit the application of "pure" ecosystem management. The Revised Plan will preserve the pieces and provide for restoration where needed. EF

COMMENTS: Request changes or corrections, additions or deletions, explanation or clarification: provide clarification of prescriptions and maps in subsections of Chapter III as these are too complex; eliminate numerous inconsistencies in Section III pages 26-55 - the Figures list prescriptions and the attendant acres for prescriptions in a Table, but many of the prescriptions are not listed on the map or are listed on the map but not in the Table. The Desired Future Conditions do not list similar statements in the Standards and Guidelines section for Goals and Objectives. These two sections should support each other. There are no "core" or "security" areas shown for Henry's Lake BMU or "security" area for Bechler-Teton BMU. Page III-42 lists a prescription 1.1.1 for 10,664 acres, but there is no prescription 1.1.1 shown. Where do these acres belong? The entire section

DRAFT FOREST PLAN REVISION

must be reviewed and the information adjusted to reflect consistency with maps, tables and narrative.

282, 1446

RESPONSE: Chapter III of the Final Revised Plan shows management direction at the Forestwide, subsection and prescription area levels. We acknowledge that the interaction between layers of direction is not easily grasped and will require some time working with it to become comfortable. We explained this system in more detail in the Introduction section in Chapter III, and cleaned up errors and inconsistencies in the places mentioned. Thank you for your comments.

The Desired Future Condition (DFC) statements in the subsection descriptions are based on conditions in, and are unique to, each individual subsection. The goals and objectives listed in the Forestwide Standards and Guidelines are broader in scope and pertain to the Forest as a whole. The DFC's for the individual subsections fall within the scope of, and are supported by, Forestwide goals and objectives.

There are no core or security area prescriptions for Henry's Lake BMU. Prescription 2.6.5 provides a security area in the Bechler-Teton BMU in addition to the extensive areas in designated wilderness. There are several other prescriptions applied to these areas that contain the needed attributes to serve as core areas, according to the Interagency Grizzly Bear Committee definition. These include designated and proposed wilderness, nonmotorized, research natural area and wild and scenic river prescriptions. A "core area" analyses is displayed for each BMU in the Final EIS that shows how much of each BMU meets "core" criteria. The grizzly bear habitat is adequately protected using this range of prescriptions. EF

COMMENTS: Define NIC.

697

RESPONSE: See Glossary in the Final Revised Plan. EF

COMMENTS: Pages III 66 & 97 use heading "Ecological Process," yet page III 75 uses "Ecological Events." Explain difference if any.

1446

RESPONSE: The correct term is "Ecological Processes". We made the change to be consistent. EF

COMMENTS: Subsection descriptions do not contribute any more information than could have been included under Standards, Guidelines, and Prescriptions. It is a confusing array of database and DFC's in the middle of strategies and methods for achieving plan goals. Describe what ecological analysis was used to form the basis of subsection descriptions.

643, 697

DRAFT FOREST PLAN REVISION

RESPONSE: The Forest applied information from the National Hierarchical Framework of Ecological Units with particular attention to the subsection level. Viewing the ecosystem from different levels is a concept consistent with ecosystem management principles. By looking at the Forest from the Forestwide, subsection and prescription area levels, we gained some perspective on management that we otherwise would not have had.

Some of the information and analysis tools used to describe the subsections include the Integrated Resource Inventory, a professional agency effort which has mapped and described vegetation and soils on the entire Forest; the Geographic Information System (GIS) data storage and retrieval whose base was derived from commercial satellite data and Forest timber stand exam; and Forest specialist's knowledge of on-Forest conditions coupled with professional understanding of soils, vegetation succession patterns, visitor use patterns, and so forth. EF

COMMENTS: The boundary between the Teton Range subsection and the Madison Plateau and Island Park subsections is unclear (written and map). This could potentially lead to a miscalculation of potential/future timber outputs.

1311

RESPONSE: Harvest is not scheduled on a subsection basis. Individual timber harvest proposals are made on the basis of prescription direction and evaluated against standards and guidelines. The Forest does not foresee a problem with calculation of potential timber outputs based on subsection boundaries. EF

COMMENTS: On Map #10, Alt 3M Prescriptions, designation 7.1 (Intermingled Public/Private Lands) explain to people that the intention was to construct a fire break. The same situation should apply to the west side of the Tetons. Suggest using the same prescription as for Henry's Lake instead of #7.1 a&b.

1360

RESPONSE: Prescription 7.1 was deleted from the menu of prescriptions used in the Final Revised Plan. EF

Ecosystem Management

COMMENTS: Lack of ecosystem view is evident in the artificial separation of plant community dynamics and those of aquatic/riparian communities. Principles of ecosystem management are not readily discernable. DFPR is inconsistent or misleading in definitions of forested, created opening, late seral, and ages of tree stands; it is incorrect in its analysis of successional and climax communities; it uses too narrow a time frame to evaluate landscape and ecosystem changes; it assumes that logging and related silviculture activities are effective methods to restore ecosystem health, and fire and insects are undesirable; and time frames for analysis are so long as to be ineffective. Although the DFPR includes some excellent steps toward a sustainable future, it is seriously flawed, especially in the understanding of ecosystem management; and in allowing unscheduled or "ghost" harvests. Unlimited vegetative manipulation under the guise of ecosystem management may lead to extensive logging with no analysis of environmental consequences.

DRAFT FOREST PLAN REVISION

Clarify if the Ecosystem Management process was subjected to the NEPA process. Others support the Draft Forest Plan Revision (DFPR) in the way it departs from previous management practices; or favor the section of Needs for Change (pages II 3-4) as commendable and needed.

607, 643, 695, 697, 766

RESPONSE: Ecosystem management was officially announced as policy for the management of the National Forests and Grasslands on June 4, 1992 by then Chief F. Dale Robertson. In his letter, Chief Robertson stated,

"...the Forest Service is committed to using an ecological approach in the future management of the National Forests and Grasslands. By ecosystem management, we mean an ecological approach will be used to achieve the multiple-use management of the National Forests and Grasslands. It means that we must blend the needs of people and environmental values in such a way that the National Forests and Grasslands represent diverse, healthy, productive, and sustainable ecosystems."

The Chief went on to direct that, as forest plans are amended or revised, they should reflect the new policy on ecosystem management. The policy is not to question under NEPA whether or not to implement it, except as it pertains to the No Action alternative. As such we comply with this national direction.

Management of ecosystems is a tremendously large and complex subject which necessarily must be broken into parts to facilitate description. This disaggregation can be termed an artificial separation of related components regardless of how it is done. We added direction for properly functioning condition (Forestwide Standards and Guidelines, Ecological Processes and Patterns) which applies to all ecosystems including aquatic/riparian areas. Such a large subject can be described only in its components. The direction in the Final Revised Plan is integrated and singular in intent despite being described in several parts.

The Final Revised Plan is built on a number of ecosystem management concepts, such as disturbance regimes, vegetation seral stage, properly functioning condition, and the allowance for vegetation manipulation in forested and sagebrush/grassland habitats to meet related objectives.

Ideally we will be able to reference a larger-scale analysis of the Greater Yellowstone Ecosystem in the future which would provide the basis for meaningful standards and guidelines defining the role of the Forest within it.

We used current accepted science to design standards and guidelines for hydrologic disturbance and grizzly bear and aquatic/riparian habitat which will protect and preserve the essential pieces and restore habitat where needed. In the Final Revised Plan we refined certain definitions and analyses related to successional and climax communities (Forestwide Standards and Guidelines for Vegetation), based on recent work by the agency to define old-growth characteristics (USDA Forest Service, 1993). We committed ourselves to gain further information through appropriate research and studies, and management will be refined as we learn more.

DRAFT FOREST PLAN REVISION

Permitting the unfettered play of potentially catastrophic disturbance agents such as insects, disease and fire would be poor stewardship of increasingly scarce and valuable resources, and would recklessly threaten adjacent property. Ecosystem management can be carried out in a prudent manner which reduces risks to resource values and neighbors. Vegetation management tools including prescribed fire and timber harvest, used judiciously, can in many instances restore balance and healthy conditions where these are now lacking. Monitoring and adaptive management trials will confirm successful practices and help to develop new ones.

We added a standard (Forestwide Standards and Guidelines for Vegetation) capping timber harvest on lands not included in calculation of the allowable sale quantity (ASQ) at 20 million board feet (MMBF) per decade. This will give enough flexibility to manage vegetation where it is most needed to be consistent with ecosystem management principles, yet address the concerns about unlimited treatments. EF

COMMENTS: Explain why a major need for change for revising the Plan has disappeared. Timber harvest objectives and management were identified as major reasons for revising the Plan in early scoping, since bug and fire disturbances have passed. Development of plan appears to be top-down driven instead of locally developed.

1202

RESPONSE: This need for change is described in the Analysis of the Management Situation section of the Revised Plan, Chapter II. An intensive public involvement effort, primarily consisting of local participants has been ongoing since the revision began 6 years ago. RR

COMMENTS: In your discussion of need for change, explain why you feel the revised Forest Plan will be more sustainable than the 1985 Plan.

228

RESPONSE: The original 1985 Plan was never sustainable by intent, with respect to timber harvest levels. The driving purpose for the plan was to provide for aggressive, efficient harvest of dead and dying lodgepole pine stands as quickly as possible and begin renewing the forest with an aggressive reforestation program. These levels of harvest were unsustainable and were primarily salvage of a resource which would be lost if action was not taken. In contrast, the Revised Plan recognizes that the salvage era is over, and the new focus is to manage the lodgepole community type, which is virtually a "new" forest, at a sustainable level for the future. The ASQ level of proposed harvest is sustainable at low levels in this coming decade until the lodgepole becomes commercial size in the future. At this time harvest levels could increase to reflect the ingrowth of stands attaining harvestable size. RR

Desired Future Condition

COMMENTS: Clarify DFC goals, objectives, standards and guidelines because they are a hodge-podge of statements that are inadequate to set a clear

DRAFT FOREST PLAN REVISION

direction for the future; are often confusing because standards and guidelines may appear in isolation rather than clearly tied to an objective; and are not in parallel form. The Plan is inconsistent in definitions of Desired Future Conditions. Methods are driving outcome in the plan; if the Forest Service defined "desired ecological conditions" first, an entirely different plan would have been developed. Develop methods for determining differences between current and desired conditions. The Plan needs better provisions for restoration. Move away from harvest and allow ecological recovery; adequate improvements be made to keep the area as an ecological system, not a maze of stumps and washed-out roads.

183, 489, 643, 695, 697, 1367b

RESPONSE: The Forest changed the organization of direction in the Final Revised Plan to better facilitate understanding. There are three levels of direction in the Plan--Forestwide, subsection, and prescription area. Each has goals, objectives, standards and guidelines. Since this layering was confusing, we explained the concept further in the Final (Chapter III).

Goals and objectives, and standards and guidelines at all three levels of direction were developed subsequent to establishment of Desired Future Conditions and flow logically from the DFC's. Standards and guidelines represent constraints on management actions. They may respond to goals and objectives in the Final Plan which are specific to conditions on the Targhee; or they may respond to standing direction for the management of all national forests, which is referenced in Appendix A. If the latter is the case, a standard may not appear to be directly related to goals and objectives in the Plan other than by subject matter.

The goals and objectives in the Final Revised Plan are well-stated and definable. The Desired Future Conditions and corresponding goals and objectives are consistent in their intent within the Final Revised Plan and FEIS. A major step in implementing the Final Revised Plan will be to determine differences between current conditions and desired conditions represented by goals and objectives. These differences can be characterized as opportunities for management and will form the basis for management actions over the next ten to fifteen years.

An objective look at the glass as half full rather than half empty will reveal that most harvested areas are regenerating adequately if not vigorously, thus achieving a major goal of the original Forest Plan. The programmed harvest over the next decade is one-tenth that conducted under the original Forest Plan. Occasional localized erosion problems on roads and trails are addressed in the Final Revised Plan through closure or rehabilitation.

The standards and guidelines in the Final Revised Plan adequately protect fish and wildlife habitat and plant species and meet the mandate of the NFMA. Direction for aquatic habitat and riparian areas is greatly improved over the original Forest Plan by using new information. The pieces of the ecosystem are preserved and restoration programmed where needed. The Final Revised Plan is unambiguous in featuring ecological restoration. EF

DRAFT FOREST PLAN REVISION

More Protections

COMMENTS: Impacts from logging and intense recreational and motorized use must be better analyzed, and better standards and guidelines or more restrictive measures taken, to protect the ecosystem, wildlife, wetlands, riparian areas, indicator species, archaeological and historical artifacts, biological corridors, air and visual quality. Have fewer and smaller roads for wildlife security and visual impacts. The standards and guidelines should contain fewer exceptions or caveats because these indicate lack of commitment, and lack of confidence that compliance is feasible. Some guidelines be made standards; standards be more precise and better enforced.

643, 697, 766, 1365, 1367b, 1369, 1446

RESPONSE: Analysis shows that the standards and guidelines in the Final Revised Plan will be effective in meeting the goals and objectives and provide adequate protection for Forest resources. The road closures to be implemented under the Final Revised Plan represent a balance of needs for protection with other uses of the Forest.

A major factor in deliberations between standards or guidelines was to include a certain amount of flexibility to address changing conditions, knowledge and opportunities, and to address unforeseen circumstances. The intent of direction stated in Chapter III of the Final Revised Plan is clear with respect to standards and guidelines, as are the definitions in the Glossary. Adherence to standards is not optional and guidelines normally will be followed or a written rationale explanation given as to why they were not. Management direction is clearly stated and the intent is unequivocal. EF

COMMENTS: Page III-3-5, Caves: Guidelines 1, 2, and 3 should be standards.

Page III-6, Minerals: Standard and Guideline 2 should read, "The Forest is not open to exploration and development and production of locatable, leasable, and mineral material resources unless otherwise specified in the management prescriptions." The prescriptions should be altered accordingly. The default management provision should generally be the most conservative guideline or standard of those available.

Page III-8: This section should include standards and guidelines that will ensure the protection of special forest products and the habitats and species which their use may negatively impact.

Page III-56, Timber Management: Eliminate prescriptions 5.1.3a and 5.1.3b

Page III-70, Soils and Water; Lands: All four guidelines should be standards.

Page III-71: No motorized activity should be permitted, and especially cross-country motorized activity should be prohibited.

Page III-71, Roads: No new roads should be permitted.

Page III-71, Recreation: The ROS guideline should be a standard requiring primitive to semi-primitive nonmotorized.

Page III-71, Timber: The guideline should be a standard.

Page III-72, Range: The guideline should be a standard prohibiting grazing and associated developments unless it can be shown that negative environmental impacts will not and are not occurring.

Page III-73, Fire/Fuels: The MIST guidelines should be standards.

DRAFT FOREST PLAN REVISION

Page III-73, Physical Elements: All the guidelines should be standards.

1365

RESPONSE: The Forest Leadership Team considered these proposed changes but decided not to adopt them.

With respect to protection of special forest products, habitats and species, the Forest has not experienced much demand for these products. If demand increases we will assess the pressure on resources at that time and can amend the Plan if needed.

The goal of these prescriptions, 5.1.3(a) and 5.1.3(b), is to manage vegetation and fuels to minimize fire risk for urban facilities within the interface zone on the Forest. Development has increased within and adjacent to Forest lands in Island Park, the Bighole Mountains and the Pallsades Reservoir area where this prescription is applied. It is unwise to hamper abilities to mitigate dangerous forest fuel conditions by removing this prescription from the Final Revised Plan.

The comments on pages III-70 through III-72 pertain to prescription 2.1.1, Special Management Areas. In the Final Revised Plan, summer motorized cross-country travel is prohibited on all but 7% of the Forest. This adequately protects the character of the areas where this prescription is applied. We believe the remaining proposed changes to this prescription are unwarranted and restricts the ability to manage these areas in the public interest. EF

Public Involvement Process

COMMENTS: The DFPR is biased against people; does not adequately address public opinion; proposes too much wilderness; and does not consider the needs of the local communities. The Plan implies that lawsuits reflect changing social needs and desires when they really only represent certain groups who take the time and effort to obstruct management. The Plan is biased against people toward wildlife; favors certain groups or special interests. The Plan must consider impacts to local communities and economy. No evidence on how public concerns are reflected. Even after making great efforts to attend public meetings and participate in the process, public opinion is not considered so it seems a wasted effort. My input was not considered. 90, 166, 229, 296, 413, 435, 689, 1368, 1369, 1389

RESPONSE: All comments from participants in the process were considered. It is incorrect to assume that, because a participant did not see the results they hoped for, their input was not considered. There has been a tremendous amount of deliberation regarding the competing uses of the Forest. Likewise, Forest specialists considered the implications of much recent scientific knowledge having a bearing on a number of these issues. Through it all, the Forest sought a reasonable balance between use and protection of National Forest System lands.

The FEIS describes demands on Forest resources, presents stewardship needs, and shows the consequences of implementing a range of alternatives. Effects to the economy of local counties are included in this

DRAFT FOREST PLAN REVISION

assessment. The Final Revised Plan provides direction to meet a variety of demands as well as our stewardship responsibilities.

Appeals and litigation were but one measure of changing social conditions which called for a Forest Plan Revision. The myriad of public concerns considered in this effort are shown in several places. The Analysis of the Management Situation (AMS) contains a chapter detailing the issues raised during the initial scoping period at the beginning of the process. Records of public involvement meetings and expressions are included in the planning files. The Final EIS includes a synopsis of public comments on the Draft EIS and Revised Plan and Forest's responses to them, giving an indication of how public comment is reflected in the final documents. EF

COMMENTS: In using Change by Advantage (CBA) as a decision tool, decision factors seem skewed toward environmental factors and not enough consideration of jobs, Cross-country, OHV-use, snowmobile use without date restrictions, and firewood. These factors must be added as key issues to CBA.

413

RESPONSE: The Choosing By Advantages (CBA) process is an effective decision making tool. It was used by the Forest Leadership Team to pick a preferred alternative for the Draft EIS and Revised Plan. It was not used to select the final alternative. There is inherent subjectivity in the process, which can be both a strength and a drawback. The Leadership Team rated those advantages of each alternative the highest which were seen as most important. Rather than being purely a mechanical process, Forest managers could emphasize the importance of advantages as they saw them both from a resource and social standpoint. In this way the Forest harnessed the strength of the subjectivity of the process. EF

ECONOMICS

Draft Environmental Impact Statement

COMMENTS: DEIS, Page III-66: Discuss how the Targhee National Forest can make dramatic changes in use and not have an economic effect.

602

Commodity production is overstated in the DEIS, 66 and 69, and is in direct contrast to the facts.

1368

Table III-19 and Table IV-13 put too much emphasis on forest grazing and timber to local communities.

1368

Include a reasonable range of Alternatives for Table IV-13, Summary of Forest Effects on Local Economy and reevaluate the analysis for this table because the same constraints are placed on all Alternatives producing a leveling effect.

413, 1202

Address how management decisions will not have the benefit of NEPA analysis and an alternative that reflects economic impacts of decisions since 1985.

393

Address the Targhee's role in attracting and retaining people and businesses to the area; how the economy of the area has changed over time; the benefits of non-consumptive uses to local economies; and how to provide for sustainable communities.

3, 228, 248, 314, 393, 413, 602, 640, 643, 697, 766, 1198, 1202, 1264, 1267, 1364, 1368, 1384

RESPONSE: Two changes the Forest made could probably be labelled "dramatic." The first is the sharp reduction in scheduled timber harvest from what was established in the original Forest Plan. The Forest could not generate that much timber and meet all the legal requirements under which it operates. The local industry has already downsized in response to that reduction in timber availability.

The second "dramatic" change is the sharp reduction in motorized access. Some of the reductions in motorized access simply reflect effectively closing roads that are already closed. In other words, the roads are currently closed but people have still been using them. The Revised Plan shows these roads as being closed--even though they were already legally closed.

Other roads targeted for closure were never part of the official system of roads on the Forest. Called "ghost roads", they were formed when people simply drove cross-country over the same route several times. Other closures are part of the official road system. Even after these closures, there will be adequate motorized access to the various parts of the forest. There will still be surplus capacity over the coming decade for increased usage on the remaining motorized routes. In later decades capacities will be reached on motorized trails.

The Forest finds no overstatement of commodity production. Those tables present information on forest grazing and timber in order to show differences among the Alternatives.

The alternatives constitute a reasonable range. The constraints used in the alternatives are those necessary to address resource needs like

ECONOMICS

those associated with water and wildlife. Removing those constraints would be an interesting exercise, but it would effectively remove the alternatives from the decision space.

The FEIS estimates future environmental consequences with the selection of various alternatives. There is no attempt to present an analysis of the various decisions which have taken place from 1985 to the present. However, the Forest could not produce the outputs specified in the original Forest Plan and comply with all the national, regional and Forest Plan direction. DP

COMMENTS: DEIS, Page II-17, Number of Jobs: Comparisons are not accurate because contributions to total tax base of community was not considered.

432

RESPONSE: In response to this comment, the Forest added a discussion of the local tax base to the Final Revised Plan. The relationship of the job figures to the tax base is indirect. Tax bases are normally expressed in terms of property value--which can change based on locally prevailing market conditions, new industry or commercial developments, residential construction and the like. The tax base question is best addressed separately.

Property values may increase when a local economy grows. However, the electorate may decide to tax property at a lower rate--resulting in the same amount of taxes to local government. It's not a certainty (although a likelihood perhaps) that an increase in the value of a tax base will necessarily translate into more local government services and more local government employment.

Managing the Forest under the different alternatives would not significantly affect local property values and tax bases. The timber mills located in St. Anthony and Rexburg have already closed and much of their equipment has already been removed from their premises. That reduction in the local property tax base has already occurred.

Property values associated with recreational developments are expected to increase under every alternative. Much of this development would likely occur on vacant land or land used for farming or ranching. These developments will be taxed at higher rates than agricultural land. DP

COMMENTS: The Plan does not adequately address the huge social and economic growth of a worldwide ecotourism based economy. Recommend the Area Primary Forest Economic Influence (APFEI) in the DFCs address this growth for the next ten years.

697, 1327

RESPONSE: The FEIS shows that the Forest's primary contribution to the local economy is, and will continue to be, recreation-related. It shows that importance continuing to increase in every alternative considered. The FEIS focuses on items that vary by alternative. DP

COMMENTS: Address and evaluate the economic costs and benefits that could be gained by employing people in local communities in reclamation work including reforestation, watershed, and road restoration. The Targhee could implement a

ECONOMICS

program to restore the ecosystem and use it as an opportunity to provide a stable economy.

1364

RESPONSE: Forest Service reforestation, watershed work and road restoration contracts are open to potential contractors within and outside the local area. Local contractors are free to bid on jobs outside the local area as well. Local contractors win some of the local contracts but there is no set-aside program to reserve contracts to them.

Scheduled activities for much of this kind of work (like road restoration) is the same for all alternatives. The Forest focuses on information expected to vary by alternative. DP

Site Specific

COMMENTS: Consider heritage resources in the Island Park area and added costs which do not go back to the forest.

697

RESPONSE: The Forest complies with all federal direction pertaining to heritage resources, as efficiently as possible. DP

Data

COMMENTS: The quality of experimental design and statistical procedures for reevaluating data should be stated.

384

The economic analysis should be subject to outside review when the resulting information may impact important decisions.

384

Analysis should include the regional Economic Information System of the Bureau of Economic Analysis-U.S. Department of Commerce.

1368

Data used for DFPR needs to be more recent.

444, 1368

Cost benefit analysis of economic damages is inadequate because areas considered needs to include more Idaho counties and some in Nevada and Utah.

275, 691, 1202

Use the DEIS, Table III-19, when assembling economic data along with Wyoming Department of Employment Data and self-employed information on non-laboring sources of income.

740, 1368

RESPONSE: In response to comments, the Forest expanded, updated, and corrected the treatment of social and economic effects in the FEIS. Information from the Regional Economic Information System is included. The FEIS is a summary of various analyses which were conducted. More detailed information on particular analyses is available on request, but is not included in the FEIS.

The Forest did not include estimates of "economic damages" on Nevada, Utah, and counties in Idaho other than those previously selected. The

ECONOMICS

Forest did not identify just what those "economic damages" might be. Purchasers of local timber products who reside in those areas can buy timber products manufactured in the Area of Primary Forest Economic Influence (APFEI) or from other sources. The more removed a county is from the local area, the more substitutes are likely for any given commodity or activity. Enlarging the APFEI to the suggested proportions would reduce the significance of any change in Forest management, because as the size of the APFEI increases, the economic significance of the Forest in that APFEI decreases. DP

Tourism/ Recreation

(CROSS REFERENCE: Recreation)

COMMENTS: Support recreational opportunities such as; hunting, fishing, hiking, camping, snowmachining, and berry picking because they will provide more economic benefit to the economy than extractive commodity industries. Support recreation because it accounts for a large portion of the Forest Service contribution to the gross domestic products and provides jobs and supports local economies.

Jobs and economics related to forest commodities have decreased while economic growth from other factors has increased. Manage for the growing tourism market which contributes positive economic benefits to state and local economies, including Fremont County. Do not let forest restrictions affect tourism.

Oppose recreation because it will not compensate for the loss of revenue from timber and ranching.

F-G-P(1), F-H(8), 93, 98, 159, 204, 215, 248, 293, 413, 444, 506, 527, 621, 692, 697, 702, 718

RESPONSE: The Revised Plan concurs with the observations that the Forest's contribution to recreation is more important to the local economy than its contribution to timber processing.

The overwhelming bulk of timber harvest reductions occurred before the Revised Plan was put into effect.

The Forest estimates increased recreational use of the forest will counterbalance the losses suffered in the timber and livestock industries. Total jobs and total employee compensation are expected to increase--regardless of which alternative is selected. That does not mean that loggers and mill workers will necessarily desire, seek, or find new work in those sectors. They may be displaced from the area; they may have to take other jobs; or they may have to work multiple jobs.

The Forest expects per capita earnings to decrease in every alternative because we estimated that the replacement jobs associated with recreation will not pay as well as the jobs lost in the timber processing sector. DP

COMMENTS: Clark County should be an exception to the Inplan Economic Model because of low population and lack of tourism/recreation.

691

RESPONSE: The Revised Plan includes more economics information on Clark and all the other individual counties in the APFEI. It shows the real differences which exist from county-to-county. DP

ECONOMICS

COMMENTS: Maintaining biodiversity for tourism should be given top priority.
F-H(8), 185

RESPONSE: The Forest must maintain biodiversity in order to respond to ecosystem needs and, as a result, remain attractive for tourism. DP

Recreation - Fees

COMMENTS: Fees generated from hunting, fishing, campers, boats, snowmachines, ATV's/OHV support the forest economically. Establish a more systematic or comprehensive system of recreational user fees when determining the economic value of the forest. User fees should go directly toward the forest to cover impacts.

735, 1194, 1239, 1365

RESPONSE: Most of the fees collected for these activities accrue to the state or county. Permitted outfitters and guides pay fees to the federal government for their business pursuits on the Forest. Establishing a systematic or comprehensive system of recreational user fees is beyond the scope of the Revised Plan. A user fee system would most likely result from a legislative initiative. DP

Range

(CROSS REFERENCE: Range)

COMMENTS: Oppose reducing or phasing out grazing allotments on the Targhee because of the negative economic impacts to the sheep and cattle industry, cultural traditions/heritage and local livelihoods.

Manage grazing allotments for the least amount of damage to the resource.

272, 481, 625, 663, 691, 718, 1187, 1354, 1364, 1381

RESPONSE: A substantial livestock grazing program remains in effect under the Revised Plan. It is consistent with our ecosystem management objectives. Livestock grazing is an outcome of proper management of the range resource. The projected levels of livestock grazing will allow us to improve the range resource. The gradual phase out of some sheep allotments is designed to minimize impact to individual operators as it is to be conducted on an opportunity basis. DP

Timber

(CROSS REFERENCE: Timber)

COMMENTS: Oppose logging limits because timber provides resources for the furniture industry; business opportunities; supports construction industry; raw materials; personal wages; balances the local economies; provides taxes and treasury receipts to counties. Restricting timber activities will have a negative affect on economy. Timber sales should be designed and offered to local operators rather than out-of-state mills. The Targhee should offer at least 5 mmbf to local operators. Private industry would be limited to implement sound management practices without a timber supply. Those who

ECONOMICS

appeal timber sales should put up as much money as those who bid on timber sales.

Oppose below cost timber sales because they are not economically beneficial to taxpayers. Prescribed burns would be a better management tool because reforestation costs and erosion would be less.

F-G-P(1), F-H(8), 29, 64, 168, 204, 268, 269, 272, 394, 505, 525, 663, 693, 697, 718, 1202, 1242, 1259, 1339, 1365, 1368, 1386, 1389

RESPONSE: Timber harvesting is an important part of ecosystem management. In caring for the resource we provide a continuing supply of raw material for the various uses described above. All the alternatives provide a continuing supply of raw materials.

Changing the procedures for handling logging appeals is outside the scope of a Forest Plan Revision. The Forest has no authority to exclude nonlocal operators from bidding on, or purchasing Forest timber. Such a proposal would require a legislative initiative. Local operators are free to bid on and purchase timber from other National Forests.

The Forest is concerned about below-cost timber sales and is working to improve efficiency in operations, to reduce the costs of reforestation and road work. Prescribed burns are recognized as a legitimate management tool and will be employed where appropriate. DP

COMMENTS: Once sustainable harvest levels are achieved the economic benefits will occur.

1242

RESPONSE: None of the alternatives harvest timber at nonsustainable levels. DP

COMMENTS: Conduct a true economic evaluation with 20 MMBF ASQ.

1267

RESPONSE: Forest Service personnel conducted numerous reviews of the proposed timber harvest schedules. Harvests at 20 MMBF ASQ would put the Forest in violation of established Standards and Guidelines which are designed to protect the soil, water, and wildlife resources. DP

Wildlife

(CROSS REFERENCE: Wildlife)

COMMENTS: Oppose management efforts to protect wildlife and wildlife habitat because of the economic benefits they provide (i.e. hunting, fishing) for the future. The loss of some local commercial revenues is a nominal price to pay for wildlife protection.

185, 318, 328, 527, 1365

Do not support management efforts to protect wildlife and wildlife habitat, (i.e. grizzly bears, wolves, bighorn sheep) because people's values, interest and livelihoods are more important.

1, 59, 447, 525, 663, 1187, 1354, 1381

RESPONSE: The Forest can simultaneously protect the resource and provide valuable recreational opportunities in the form of hunting and fishing. The

ECONOMICS

two are not mutually exclusive. All the alternatives provide for a continuation of abundant habitat for various wildlife species. DP

COMMENTS: Develop an alternative to show the social/economic costs of meeting elk security and measures used to mitigate the issue.

393

RESPONSE: The alternatives displayed in the FEIS show a wide range of management and corresponding changes in elk vulnerability, budgets, Present Net Value, jobs, employee compensation, and social information. DP

COMMENTS: Address the amount of money the forest would save if we protect species by preserving habitat and attempt to pre-empt their listing under Endangered Species Act.

1364

RESPONSE: The broad thrust of Forest wildlife management is to provide adequate habitat for all species. The Region maintains a listing of sensitive species we hope to keep off the threatened or endangered lists.

Any estimates as to the amount of money saved by such actions are highly speculative. Indeed, there is no assurance that such actions save money at all. Conducting such a study is outside the scope of a Forest Plan Revision. DP

General

COMMENTS: Recognize and manage for local economic opportunities; consider industry as a source of local economic/social well being; differentiate between publics who are more impacted by Plan decisions; consider local taxpayers needs; don't limit local economy because of past corporation abuse.

F-A(344), F-C(13), 61, 168, 663

Recognize and manage to the highest possible standard of natural resource health and do not be influenced by other economic interests; balance the commercial use of the forest with protection of wildlife and people for all Americans and their heirs.

271, 393, 625, 1365

RESPONSE: In order to better respond to these concerns, the Forest expanded the amount of information in the FEIS. All the alternatives are designed to adequately address ecosystem concerns such as those described above. Differences in the alternatives vary in their respective emphases but adequately respond to ecosystem concerns. DP

COMMENTS: Ecosystem management provides local economic benefits as well as a unique ecosystem. It should receive high priority funding and implementation.

61, 159, 196, 393, 1380

RESPONSE: Ecosystem management provides for the needs of the ecosystem and provides local economic benefits. The Revised Forest Plan reflects our commitment to fund and implement its provisions. DP

ECONOMICS

Alternatives

(CROSS REFERENCE: Alternatives)

COMMENTS: Oppose Alternative 3M because of the potential negative effect to local economies, specifically logging and recreation.

292, 402, 413, 429, 464, 465, 477, 628, 689, 702, 1189, 1271, 1335, 1339, 1389, 1448, 1448b

RESPONSE: The Forest estimates local businesses associated with recreation will generally continue to grow under all the alternatives because the Forest enjoys a general surplus of recreational opportunities (supply) in excess of existing and anticipated demand over the coming decade.

The closure of hundreds of miles of roads and motorized trails to motorized use and the closure of a great deal of forest to cross-country summer motorized use may drive motorized recreation users from the Forest. It is also possible that they will simply use the remaining open roads, trails, and cross-country areas more intensively. If they cease using the Forest for motorized recreation, it is possible others will take their place. It is also possible that those who enjoy nonmotorized recreation will increase their use of the Forest.

Motorized trail use is one of the very few categories of recreation in which we expect to see demand outstripping supply after the first decade of Plan implementation.

The negative effects from reduced logging levels have already been experienced in the local area. Mills in Rexburg and St. Anthony were closed and their lumber processing equipment removed. There is a small reduction in timber harvest associated with the Forest Plan Revision. Its effects are included in the FEIS along with those for the other alternatives considered.
DP

Access

(CROSS REFERENCE: Access)

COMMENTS: Support more motorized access because it provides economic gain in farming, logging, grazing, local business and recreational (profit) opportunities. Support access because resources should be made available to taxpayers; taxpayer dollars should not be used to close roads; taxpayers should be allowed access for economic gain.

F-C(13), 29, 392, 447, 455, 467, 468, 505, 524, 700, 704, 728, 1259

RESPONSE: Motorized access facilitates farming, logging, livestock grazing, and business uses associated with motorized recreation. Access for these uses is a valid concern. Motorized access provided in the Final Revised Plan is adequate for these needs. DP

COMMENTS: Use money from the Idaho Department of Parks and Recreation-ORV program which would allow better management of the forest and give users, "excellent return for fees".

348, 629

RESPONSE: The Forest works cooperatively with state agencies to improve the resource and recreational experiences. We have completed partnership-funded

ECONOMICS

projects for trail reconstruction, construction of snow parks and boat ramps, and reconstruction of campground facilities throughout the Forest. We will continue to initiate cooperative projects of this nature, using state funding from the RV and ORMV funds. AS/DP

COMMENTS: Oppose ORV access into roadless areas because of the negative economic impact on my business. (CROSS REFERENCE: Wilderness)

392

RESPONSE: Motorized use can threaten other forms of recreation and recreation-related employment. The Revised Plan strikes a good balance between these competing needs. DP

PILT and 25% Fund

COMMENTS: Explain how PILT payments remain the same in all Alternatives, if the 25% Funds vary and if PILT payments are dependent on 25% Fund. Explain how PILT payments change with the decrease/increase in populations of affected counties.

If ASQ is dropped as proposed (25% Fund) the amount of monies returned to counties will drop significantly and have a negative impact on the forest and surrounding communities.

228, 413, 432, 689, 1384

Explain how reduced ASQ or grazing will lead to lower payments to counties. All the counties that receive payments from activities on the Targhee receive 25% Fund payments for below the minimum amount guaranteed to them by PILT. In 1994 25% Fund payments ranged from \$1.01 per acre to \$0.191 per acre, while the remainder was supplemented by PILT to \$0.75 per acre. Even if the 25% Fund were to drop to zero, counties would still receive \$0.75 per acre.

1365

RESPONSE: In response to these and other comments, the discussion on payments to local governments in the documents has been updated and greatly expanded. There is not a direct trade-off between PILT payments and the 25% Fund payments. That is, a \$1 reduction in 25% Fund Payments does not translate into a \$1 increase in PILT in every case. Depending on a county's population, area and other considerations, there may be no effect at all.

It is incorrect to say that counties would still receive \$0.75 per acre from the PILT program. Clark County for instance, has a PILT ceiling based on its population. For the foreseeable future, its PILT payments will only change as a result of recently-implemented changes in the PILT formula, funding, changes in the consumer price index, and the county's population. DP

COMMENTS: PILT payments made to Clark Country are low because population numbers are small. Dividends currently being distributed should remain the same.

691

RESPONSE: Clark County's PILT payments are low because of its small population. Future PILT payments for Clark County will only be affected by changes in its population, implementation of the legislative changes to the

ECONOMICS

PILT formula, changes in the consumer price index, and congressional funding of PILT payments. Under the recent legislative changes to the PILT formula, PILT payments to Clark County will increase substantially if they are funded at the same proportions as in the past. DP

ECOSYSTEM MANAGEMENT - THE CONCEPT

Definitions and Goals

COMMENTS: Want the definition of EM to be clearer, changed, modified, or with additional information:

- Define EM as "managing multiple uses of Forest so that management does not disturb the intricate interrelationships" of Forest components; include EM as managing for all Forest values.
 - Clarify the term "EM" without using words like ecocentric, ecoregion, etc.
 - Provide a clear working definition of EM; define activities that can occur in EM.
 - Add adaptive management flexibility, human/social, and global factors to the definition.
 - Add Aquatic Influence Zones, riparian areas, fisheries to the definition.
 - Clarify difference between EM and silviculture (tree farming).
- 190, 252, 275, 280, 282, 384, 413, 489, 643, 665, 697, 734, 1257, 1264, 1276, 1364, 1341

RESPONSE: While there are many definitions proposed for EM in scientific literature, all of them incorporate similar core principles with differing emphases. The definition provided in the glossary states the fundamental concepts in applying EM as the framework for the revised Plan on the Targhee. It is taken from General Technical Report RM-246, An Ecological Basis for Ecosystem Management, May 1994. The definition is not intended to be comprehensive or exhaustive.

Some specific attributes of EM are discussed in the Plan and DEIS. We briefly define EM and show how we are implementing the core concepts of EM in plan direction for the next decade, while disclosing expected effects of permitted activities. We do not offer a treatise or literature search of EM concepts and definitions.

The Revised Plan provides an integrated, holistic approach to managing Forest resources in an ecological context. Because analyzing all ecosystem components is enormously cost prohibitive, selected critical components of ecosystems are evaluated as indicators of overall ecosystem health and sustainability. In some cases, this evaluation of effects occurs in a larger context, such as in an ecoregion. The Revised Plan is a significant departure from the traditional, narrow, single resource emphasis. Silvicultural and range management techniques which are valid scientifically will continue to be used where they meet ecological health and multiple use objectives.

Forest health is broadly implied in the definition of EM as "healthy ecosystems." We have added a section in Forestwide Standards and Guidelines on Properly Functioning Condition (PFC) which describes direction for maintaining or promoting forest health. PFC is a more specific application under the broader EM umbrella.

While not explicitly incorporated into the glossary definition of EM, adaptive management and flexibility are critical elements of effective EM implementation, especially in monitoring and evaluation and refining and modifying practices.

The EM definition includes language about "social, physical, economic, and biological needs and values", thereby including human and global

ECOSYSTEM MANAGEMENT - THE CONCEPT

factors in the equation. Public input and scientific review continues to be a routine, ongoing practice for EM and the Plan.

A definition of silviculture is included in the Glossary section of the Plan. It focuses on using principles of tree and forest biology to meet specific land management objectives, including furthering the health of non-timber resources.

The "productive, healthy ecosystems" language implicitly includes Aquatic Influence Zones, riparian areas, and fisheries in the definition of EM. RR

COMMENTS: Clarify, change, add to the goals of ecosystem management:

- Add to EM goals "the conservation of a unique and irreplaceable part of the Greater Yellowstone Ecosystem as a priority above all other considerations."
 - Make goal of EM to protect or improve the integrity biodiversity; "native biodiversity", entire ecosystem; "ecosystem function"; not simply to minimize negative impacts.
 - Base goal of EM on what citizens of US want from their lands: balanced use; meeting equal interests for people, companies, wildlife and other resources.
 - Add goals for restoring habitat; and/or health of the Forest by reestablishing missing wildlife populations; managing watersheds; providing long-term health; sustainability; protection of all species and their habitat.
 - Maintain Ecosystem for tourism as a top priority goal.
- 12, 23, 27, 73, 167, 173, 179, 215, 242, 266, 325, 370, 384, 399, 489, 643, 659, 695, 697, 1193, 1275, 1276, 1365, 1369, 1392, 1399

RESPONSE: The Targhee recognizes the uniqueness of the Greater Yellowstone Ecosystem (GYE). The Plan reflects that emphasis through specific treatment for grizzly bears, watershed, fisheries, etc. The Plan provides guidance to ensure that activities which produce commodity outputs, such as timber or grazing, do so in a fashion that maintains ecological integrity and function.

Management direction includes pro-active efforts in providing the ecological conditions and diversity which promotes healthy forests, not just mitigative actions to minimize adverse effects. The preferred alternative reflects a balance of competing interests and conflicting objectives in an even-handed manner.

Protection is a minimum threshold for permitted management actions. The Plan goes beyond protection to address desired conditions and to provide the means to move the Forest forward to healthy ecosystems.

The National Forests are principally concerned with providing habitat conditions conducive to sustaining endemic wildlife populations. Responsibility for re-establishing species extinct from their historic range belongs to the states or the U.S. Fish and Wildlife Service (FWS) where the species is listed as threatened or endangered. The Targhee cooperates with the FWS in establishing habitat conditions for recovery of the grizzly bear, bald eagle, and peregrine falcon. Region 4's sensitive species, such as the northern goshawk, receive specific attention to maintain favorable habitat conditions to sustain viable populations. Watershed boundaries are explicitly used as domains for management directions and guidance.

ECOSYSTEM MANAGEMENT - THE CONCEPT

Tourism is but one of many aspects of sustainability that EM considers. The Plan allows for a balanced approach towards resource sustainability that includes tourism. RR

COMMENTS: Establish a board of scientific advisors to help implement EM goals.

1276, 384, 643

RESPONSE: The Targhee employs highly qualified, resource experts who are active in the daily implementation of EM on the Forest. We will continue to participate in a number of partnership agreements with the scientific community to assist the Forest in implementing EM. We expect members of the scientific and research community to continue to provide input to project proposals. RR

COMMENTS: Integrate EM goals between subsections, the Forest and Greater Yellowstone Area.

643

RESPONSE: The Revised Plan does this through its ecological subsection descriptions, and its forestwide programmatic direction. RR

COMMENTS: Base EM on wildlife science and a full spectrum of regulations, not on logging dictates or practices.

179, 293, 643, 669

RESPONSE: The Revised Plan provides for a balance of considerations, including wildlife and wood production. RR

COMMENTS: Base EM on good science, not local cultural preferences or politics.

293

RESPONSE: By definition, EM includes "social, physical, economic, and biological" considerations, meaning that EM is based on good science, local cultural preferences, politics, and many other factors. RR

COMMENTS: Develop EM hypothesis through objectives and policies, test EM hypothesis, monitor EM effectiveness.

1249

RESPONSE: The Plan adopts the applicable concepts, objectives and policies available for implementing EM. Built into the Plan and EM process are "adaptive management" principles including a practical monitoring plan which provides feedback on project implementation and effectiveness. This yields important information on our overall success in implementing EM. RR

Support/Non-Support of EM Concept

COMMENTS: Support Concept of EM because it will restore health of Forest, prevents further damage and is "the right thing to do."

430, 643, 1242, 1276, 1312, 1365

RESPONSE: We agree that EM is the best approach to forest management. RR

COMMENTS: Do not support EM concept because:

- Not approved by Congress; not legal.
- Does not follow NEPA process for EM and FS uses faulty assumptions conditions and restrictions in its implementation of EM.
- Forest doesn't have a "solid understanding" of EM and needs to consult with more scientists; needs more citations, studies, measurements, "solid evidence", peer reviews, and scientific studies to justify EM.
- EM is not understood and is a "vague concept;" too philosophical; not enough known yet.
- EM provides "too much management."
- Ecosystem does not need improvements; current management approach "has been done well."
- EM is biocentric in design and application, based on value systems. F-G-2(2), 5, 6, 28, 38, 62, 161, 182, 211, 258, 265, 311, 319, 382, 388, 393, 438, 607, 689, 727, 734, 1202, 1276, 1317, 1448b

RESPONSE: An important foundation of legislation governing Forest Service management is the premise that "best science" will be used. Scientific advancement in natural resource management has led to the widely accepted conclusion that natural resources exist in ecosystems, not as independent entities apart from the processes that act on them nor out of context with other components that coexist with them in their native setting. Ecosystem management is the result of best available science and is fully consistent in meeting existing law and regulation.

EM is not a Federal "proposed action" which triggers NEPA, but a conceptual framework for natural resource management. Activities which implement EM, such as the Forest Plan Revision, are subject to NEPA and are analyzed and disclosed according to established NEPA procedures.

Because we use the EM process throughout the Plan revision, we included provisions for adaptive management which requires a checkup of our actions, an evaluation of the results, and a prescriptive action to correct, modify or affirm the original action. We use the developing and established scientific basis for EM in our proposed activities.

We have and will continue to consult with experts within and outside the agency.

A bibliography is provided in Appendix R-1 of the Plan. We have added some EM literature that is commonly used by land management agencies and universities. The Forest Service began a transition to EM about 1989 through its "New Perspectives" program, then adopted EM as the approach for the agency in 1992.

As a concept, EM is broad but not undefined. It becomes more specific when individual projects are proposed which implement the general EM principles. This revision adds substantial detail to how the Targhee will implement EM at the forestwide scale. See "Forestwide Standards and Guidelines, Ecological Processes and Patterns" section for more specifics. The Targhee made efforts to ensure continued local and national access and public participation in the management of public lands while protecting and maintaining resource values.

ECOSYSTEM MANAGEMENT - THE CONCEPT

An abundance of scientific evidence exists to support using EM at the level proposed in the Plan. (See references added to the bibliography in Appendix R-1, which includes peer review publications.) Granted, philosophy and politics can become involved in discussions about EM, but the Revised Plan attempts to prescribe land stewardship direction to meet a complex array of conflicting uses and demands in a balanced fashion.

Management activities are proposed in some areas of the Forest where a healthy ecosystem are not being sustained. Actions and decisions are made according to project level objectives, consistent with the Forest Plan. The ability to implement EM-based projects are subject to available funds and staff.

By definition, EM includes consideration of social and economic values in management proposals. Arguably, everything is based on value systems. The Forest addresses many differing values and interests while still realizing that EM is deeply rooted in scientific evidence. RR

Sustainability

COMMENTS: The Forest needs to ensure sustainability -- for the Forest; for the entire ecosystem (not just a few threatened and endangered, sensitive species); for wildlife, fish, recreation & forest products; for communities; and for economic benefits.

22, 33, 37, 48, 61, 174, 190, 227, 432, 659, 687, 1258, 1328

RESPONSE: The Revised Plan provides for sustainability; the Plan meets the requirements of the law and regulations to ensure sustainability of forest resources; and the Plan takes a broader look than a single species, a single resource, or a single socio-economic factor. RR

COMMENTS: Recommended ways to ensure sustainability - through road closures; revising trends of favoring timber industry; revising trends of soil damage and reduction of biodiversity; reducing roading, ORV use, grazing in riparian areas, snowmobiling in winter range, clearcutting, excessive predator management in wilderness and fire suppression; and defining "capability of the ecosystem, then eliminating activities that threaten that capacity."

37, 174, 244, 293, 444, 507, 697

RESPONSE: The Forestwide Standards and Guidelines section describes conditions that allow for a sustainable level of use consistent with resource and ecological maintenance, protection, and enhancement. The Plan considers issues of capability and sustainability and proposes protective or mitigative measures. RR

COMMENTS: Improve Sustainability Analysis by explaining how harvesting less than 1/5 the forest meets EM principles for the long-term; analyzing new alternatives that reflect proactive management; explaining how to sustain vegetation conditions; describing mitigation protection, and intensive management processes to achieve Desired Future Condition; showing how to avoid catastrophic fire w/current plan; and showing timber harvest as a sustainable goods and service.

393, 413, 697, 1369

ECOSYSTEM MANAGEMENT - THE CONCEPT

RESPONSE: The Forest completed additional sustainability analysis, especially as it related to timber, goshawk, and vegetation. Changes are explained in the Forestwide Standards and Guidelines, Ecological Processes and Patterns section (Revised Plan, Chapter I) and in various resource sections.

Wood fiber production is one aspect of managing complex forest ecosystems. Other resource management objectives may place higher priority on prescriptions which are incompatible with timber harvest. Much of the fastest growth occurring in the lodgepole community type is non-commercial sized, reforested plantations and will not be available as wood products for several decades.

NEPA requires analyzing a reasonable range of alternatives which respond to public issues raised during scoping and the Purpose and Need for the proposed action. The Targhee believes the alternatives reflect proactive management.

Using the Glossary, "sustainable vegetation conditions" would be those in which floral ecosystems maintain ecological processes and functions, biological diversity and productivity over time.

The revised plan provides comprehensive direction for mitigation, protection and management of ecosystems. Plan direction governs actions for the next decade, but establishes trends for achieving desired conditions for the longer term. Assuming no change in current law, the Plan will be revised at 10-15 year intervals and is expected to address successional conditions and management actions which could lead to catastrophic fire.

See the section in the Revised Plan which allows for sustainable timber production: "Production of Commodity Resources -- Timber Management", Chapter III. RR

COMMENTS: Supports Sustainability. Just do it. Sustainability is the direction the Forest Service must go to ensure future economic benefits for local economies.

22, 33, 48, 61, 227

RESPONSE: Your comments are noted. AM

Change the Assessment/Scale

COMMENTS: Enlarge scale of analysis. Enlarge scale of analysis to consider multiple ecological scales when evaluating temporal and spatial patterns and to more adequately consider fragmentation patterns (connections and dispersal pathways) both within and between subsections. Include ground truthed corridors.

643, 1365, 282, 690

RESPONSE: The selected scales for analysis were the most appropriate for a disclosure of expected outcomes and impacts, for each subject being considered. There is no one-size-fits-all geographic scale at which analysis is most appropriate. The issue at hand determines the most appropriate scale (Salwasser, 1994). The Forest Plan provides programmatic direction at the forestwide scale.

As part of the revision effort and ongoing business, the Forest coordinates with communities, agencies, and private organizations and individuals within the larger Greater Yellowstone Area (GYA), and will

ECOSYSTEM MANAGEMENT - THE CONCEPT

continue to do so. The public participation phase of the revision includes substantial public involvement and cross-boundary coordination in the GYA. RR

COMMENTS: Address forest stand age composition and diversity at a larger scale so that fragmentation patterns and cumulative effects of extensive clearcutting on patch size are given adequate attention.

643

Evaluate needs for proposed actions on a forestwide scale or in relation to the Greater Yellowstone Area.

489, 1368

RESPONSE: The scale selected is adequate to disclose the impacts and expected outcomes of the Revised Plan. (See previous response.) RR

COMMENTS: Use entire drainage or watershed, set DFC for area and decide what traditionally occurring activities are useful for meeting DFC, then eliminate those activities that do not help meet DFC.

1249

Consider ecosystem boundaries that do not follow forest, park, BLM, county, state or private property lines.

392, 719, 1395, 643

Integrate ecological function across boundary lines that address downstream conditions and ecological effects of management activities.

643

RESPONSE: These comments basically summarize the approach taken in the Revised Plan. Goals and objectives for the Plan establish desired outcomes, though at the Forest scale. Prescriptions and management direction describe the means to achieve these goals and objectives. Standards and guidelines define limits on activities to maintain a course for advancing the DFC accomplishment. The Subsection descriptions illustrate how the Forest did this where it made analytical sense. The drainage or watershed scale is used where appropriate to describe environmental consequences. At the site-specific project level, drainage or watershed scales are more critical as a context for project planning and implementation. RR

COMMENTS: Incorporate data/studies/science/findings from adjacent National Forests; Parks; Yellowstone; the Upper Columbia River Basin Study, "Henry's Fork Watershed, Idaho, A Comparison of Management Alternatives for the Targhee National Forest", (eg elk cover needs in the Centennials as compared to Gallatin, Beaverhead, Yellowstone NP).

643, 695, 719, 1343

RESPONSE: The proposed activities in the Revised Plan are based on the Purpose and Need at the forestwide scale. See Chapter I, FEIS. The effects analysis discloses anticipated environmental effects at the Forestwide scale. See Chapter IV, FEIS. The purpose of the Revised Plan is to develop management direction for the next ten years at the forestwide scale. Because direction only applies to Federal lands administered by the Targhee National Forest, lands beyond the Targhee administrative unit are not addressed for management action in the Plan. However, the effects analysis of the FEIS does consider environmental effects beyond the Targhee's borders, where they can be

identified, and when predictions can be extrapolated as a result of implementation of the Revised Plan. RR

Research findings from adjacent lands such as Yellowstone National Park are used in the development of this approach. The Upper Columbia River Basin (UCRB) ecosystem management project data and reports were used in the revision process and analysis, where available and relevant. Many studies were still in draft at the time the revision analysis was completed. The UCRB findings, when available, are useful for the larger regional scale of the Basin watershed but are not essential to disclosing effects or making a reasoned choice among the revision alternatives. See Literature Cited. DM/RR

COMMENTS: Enlarge scale of analysis to incorporate larger temporal and spatial patterns.

392, 413, 643, 690, 719, 1365, 1395

Analyze the larger temporal and spatial patterns of the region before concluding that the observed pattern in one or several subsections is in need of remedial attention. Put EM where large geographical areas are analyzed so that they will not be ecologically disjunct from the landscape in which they occur. 643

Enlarge scale beyond seven subsections because context and content considerations within the larger ecosystem may have been overlooked. The idea that a subsection is a complete system is not in proper context with the rest of the Forest or the Greater Yellowstone area.

643, 690

Use larger scale than watershed or subsection to analyze vegetation patterns and consequences to biodiversity, threatened and endangered, timber and so on.

413

RESPONSE: The Forest considers the scale of analysis for the seven subsections as adequate for the purpose of the analysis which was to disclose expected impacts from the different alternatives. Chapters III and IV of the FEIS address "Adjacent Land Use Patterns" and consider larger temporal and spatial patterns. The subject area determined the appropriate scale. RR

COMMENTS: Diversity treatment is needed at a regional scale. Improve the treatment of diversity issues by requiring a full landscape level analysis and address the size, structure, dynamics, spatial arrangement, function, integrity and connectivity of habitat patches up to a regional scale.

1365

RESPONSE: The scale used is adequate for the scope and resolution of this analysis. Landscape analysis is more appropriately used at the site-specific project level to provide an ecological context during project implementation. RR

Improve the Cumulative Effects Analysis

COMMENTS: Expand the Analysis of cumulative effects because they are based on unfounded assertions; incorrect information; unrealistic; unscientifically

ECOSYSTEM MANAGEMENT - THE CONCEPT

sound; and inadequate to evaluate the consequences of management alternatives.
1368

RESPONSE: The cumulative effects analysis adequately describes the interactive effects of the Revised Plan with past, present and foreseeable management actions. RR

COMMENTS: Take into account cumulative impacts to the entire ecosystem for all management activities and include future effects of natural disturbances since they may have an effect on the biological potential for primary cavity nesting habitat more than vegetation management.
1365

RESPONSE: Evaluating the effects of unspecified natural disturbances is highly speculative, given the uncertainty about location, timing, and nature of the disturbance. The cumulative effects analysis in Chapter IV, FEIS considers the effects of past, present and foreseeable management actions. Natural disturbances are not a foreseeable phenomena. RR

Range of Natural Variability

Improve Discussion and Application of Range of Natural Variability (RNV)

COMMENTS: Describe how you will establish the Range of Natural Variability by describing what characteristics (including aquatic) will be measured, how and at what frequencies these characteristics will be measured, and how many of each type of characteristic will be measured. There is no evidence this will be seriously addressed.
282

RESPONSE: These are implementation issues that are addressed upon completion of the Revised Plan. Techniques for establishing RNV vary depending on whether you are dealing with vegetation, aquatic systems, fire regimes, or other resource areas. RR

COMMENTS: Define historic conditions and time period used, and explain why historical conditions are ideal.
1369

RESPONSE: Historic conditions are not considered "ideal". They are simply one ecological record of landscape change and development. They represent a benchmark against which current conditions can be compared and inferences made about successional processes, ecological patterns through time, and predictions of future outcomes under alternative courses of action. Some argue that historic or presettlement conditions are desirable and should be a goal of future management. The Targhee does not use historic conditions as a goal but as a reference point. RR

COMMENTS: Explain how you are using RNV to ensure viability of all native species.
1369

ECOSYSTEM MANAGEMENT — THE CONCEPT

RESPONSE: RNV can be viewed as sideboards within which habitat conditions evolve through time. If plant and animal communities have historically occupied a region and the variation in habitat conditions can be determined, predictions can be made about how species may respond to artificial disturbances or alterations introduced by management actions.

Departures from the historic range of habitat conditions may introduce changes exceeding the adaptive ability of some specialized species. Conversely, if management activities alter ecosystems consistent with how they have fluctuated historically, the expectation is that the species will persist, because the changes are not substantially different from those for which they are genetically and behaviorally adapted. RNV provides a means to assess risk to sensitive species under different management scenarios. RR

COMMENTS: Consider fossil pollen records that indicate the relationship of climate on vegetational change as part of the establishment of RNV. This may explain the cause of Doug-fir encroachment as a consequence of human activities versus climatic change.

489

RESPONSE: This is an implementation issue that can be considered as the Forest develops specific approaches to identifying RNV. Pollen records are one of the many tools that establish historic conditions. They are not essential to this analysis nor the development of the revised Plan. RR

COMMENTS: Discuss the previous state you think the forest will return to in 50, 100, and 5000 years, and how the forest will reverse carbon dioxide buildup from global warming.

1360, 1314

RESPONSE: This is outside the scope of the Revised Plan process which focuses on development of management direction for the next decade. The goal is not to "return to" a particular state but to identify desired conditions in the future and progress towards them by implementing direction in the forestwide and management area prescriptions. As plant communities persist and change through ecological succession and artificial or natural disturbance, carbon sequestration and recycling will occur. Influence on global atmospheric carbon is unknown; it is not essential to this analysis, determination of environmental consequences, or a reasoned choice among alternatives. RR

COMMENTS: Discuss how you will manipulate RNV and over what time frame. Include estimations of soil changes.

1360, 1314

RESPONSE: The Forest does not manipulate RNV. RNV is identified through analysis of historical evidence and/or modeling. The time context for RNV is unknown. This process will be implemented after adoption of the Revised Plan. RR

COMMENTS: Include fungi, moss, insects, nematodes and other micro biota in the definition of Range of Natural Variability.

1360, 1314

ECOSYSTEM MANAGEMENT - THE CONCEPT

RESPONSE: If appropriate, insects, invertebrates or lesser plants are used to determine RNV on a small scale. It is impossible to measure or analyze every component of the ecosystem, nor is it necessary. Usually, a limited set of representative species can be used as indicators for other species. RR

COMMENTS: Use Yellowstone National Park studies to establish a scientifically defensible RNV.

1273b

RESPONSE: Refer to the "Properly Functioning Condition" section of the Forest Plan (Chapter III). Through an ongoing partnership agreement with Montana State University, the Forest is continuing to develop a scientifically defensible approach for landscape level analysis. Research findings from adjacent lands such as Yellowstone National Park are used in the development of this approach. Because this process is on-going, it is incorporated through reference. Once finalized, the process will be incorporated through the Forest's adaptive management approach to ecosystem management. DM

COMMENTS: Shorten timeline for completing the RNV determination and the inventory on native cutthroat trout populations. Long timelines do not enhance an adaptive management philosophy.

643, 695, 1369

RESPONSE: The Forest included additional direction on inventory of the cutthroat trout with expanded objectives. The timeframe was adopted, because it represented a realistic date for completion. The timeline for completing RNV was replaced by the Properly Functioning Condition section which includes RNV where appropriate. PFC is more complete in the criteria for analysis. RR

COMMENTS: Refrain from harvest until RNV is determined. Change the timeline for completion of the RNV for all subsections or include direction that states no large vegetation management decisions will be made until RNV is established.

690, 1273b

Refrain from harvest until landscape of RNV is completed and reviewed by scientific community and has gone through adequate public review.

766, 690

RESPONSE: Ceasing all vegetation management or timber harvest activities until RNV is established is not necessary nor desirable. The Forest has enough expertise and information to proceed with sound vegetation management activities while determining RNV. Internal and external scientific communities and research literature are consulted in the determination of RNV. RR

COMMENTS: Clarify the RNV of vegetation management on winter range and what outcomes can be expected, since excessive livestock grazing is often the single most detrimental cause of impacts to big game winter range. (CROSS REFERENCE: Range, RNV; Range, Vegetation; Wildlife, Winter Range)

643

ECOSYSTEM MANAGEMENT - THE CONCEPT

RESPONSE: Knowledge of the RNV for winter range vegetation is not necessary to provide best management practices, because the Forest has other information available such as condition and trend data, utilization studies, and actual use information for domestic livestock grazing. Proposed utilization standards are expected to meet the physiological needs for vegetation and provide for the protection and maintenance/improvement of uplands and riparian areas. The Revised Plan has been modified to better reflect the needs of wintering wildlife and the potential for conflict with domestic livestock on a forestwide basis.

The grazing utilization standard applies to all utilization on plants, regardless of animal species, and addresses maximum allowable use. Regardless of what animal species utilized the plants as forage, livestock will be removed once the desired utilization level is achieved. Issues such as AUM's needed for wintering wildlife and domestic livestock grazing are best handled within the framework of a site-specific project level or landscape level analysis. The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the Forest or Ranger District levels and is not intended to analyze specific "how to's" of project implementation. WG

COMMENTS: Provide mandatory direction for site-specific projects that all activities will be planned to approximate historic vegetation patterns.

1365

RESPONSE: This is a site-specific analysis issue and not necessary for this level of programmatic analysis. The Plan establishes broad direction within which individual project proposals can occur. There is no need for preemptively requiring all vegetation manipulation activities to mimic a redefined set of patterns. Historical vegetation patterns are highly variable, and site-specific analyses consider this in the context of a number of desirable objectives and may depend on other considerations than historic vegetation patterns. RR

COMMENTS: Explain the reasoning of treating sagebrush when Forest has not established a RNV for sagebrush and why similar treatment are not proposed for the forested component. (CROSS REFERENCE: Range, Sagebrush)

766

RESPONSE: The Forest recognizes that there is an overabundance of mature component in the sagebrush community. The amount of manipulation through prescribed fire is fairly modest and is not expected to fall outside the RNV. Treatments proposed for forested ecosystems are consistent with the differences between these two communities -- forests can produce commercial wood products, sagebrush can not. RR

COMMENTS: Discuss how the forest will determine the RNV for AIZs. Use longer timeline instead of a snapshot which may not present a fair representation of conditions over time. (CROSS REFERENCE: Riparian, AIZ)

643

RESPONSE: Goals and objectives relating to the RNV for aquatic influence zone characteristics were deleted from the AIZ prescription. Direction on

ECOSYSTEM MANAGEMENT - THE CONCEPT

evaluation of ecosystem characteristics, including those within AIZ's, is now described in the Revised Plan, Forestwide Standards and Guidelines, under the subtitle "Properly Functioning Condition". DD/RSM

Improve Discussion of Fire's Role in RNV

COMMENTS: Include additional analysis of two historically proven fire cycles - massive cycle every 250-300 years and shorter cycle every 22-50 years. 1911 photos depict the forest after it closed canopy after previous short cycle fires in the mid 1800s. Need to capture larger role of fire.

275

Reexamine your conclusion that beetle infestation was not outside the RNV. It is a prime example of an ecosystem outside its RNV because of 60 years of fire suppression.

413

RESPONSE: Longer cycle fire regimes up to 300-350 years were addressed in the FEIS, Chapter III, "Fire - Scale: Vegetative Community and Subsection", specifically in the subalpine fir and whitebark pine fire regimes discussion. Additional analysis is not necessary, because these community types, while important, do not comprise a large component of the Forest's vegetation communities. This level of analysis is commensurate to the degree in which these types factor into the overall management direction of the Plan. A more complete discussion of fire regimes can be found in Bradley et al., 1992.

The importance of fire is incorporated in the expanded section in Forestwide Standards and Guidelines, Ecological Processes and Patterns, Fire, in which the role of fire management and suppression is clarified and described (Chapter III, Revised Plan).

Fire suppression policies of the last 80 years exacerbated the risk to bark beetle suppression and altered the natural successional process for maturing lodgepole forests in the West. The natural factors influencing successional development are similar to an extended period of fire exclusion or absence; this probably did not occur historically in Targhee lodgepole communities. However, the end of the successional pathway -- a large-scale bark beetle epidemic causing massive die-off of the mature component in a relatively short period of time -- is most likely within the RNV. Lodgepole is well adapted to large-scale disturbances and very effectively re-occupies sites after an epidemic or fire. RR

COMMENTS: Reconsider fire frequency intervals in the Range of NV. Several studies suggest longer intervals for Doug-fir and lodgepole pine. Assumption that the forest is more susceptible to catastrophic and low intensity fire may not be as severe as presented.

1273b

RESPONSE: Fire frequency is an important variable for identifying historic range of variability, because it provides indications of past disturbance and ecological response. See Revised Plan, Chapter III, Ecological Processes and Patterns. The Forest has conducted fire scar analysis and will continue to do so. RR

COMMENTS: Discuss effects of Yellowstone National Park fires on regional landscape patterns, especially in the proposal to treat aspen stands to reduce conifer. (CROSS REFERENCE: Timber, Aspen).

643

RESPONSE: The 1988 Yellowstone fires are outside the scope of this forestwide analysis and not essential to adequate disclosure of expected effects or a reasoned choice among revision alternatives. The Camas Creek Aspen Regeneration Project is a site-specific analysis being conducted in compliance with the existing Forest Plan and is also outside the scope of this analysis.

COMMENTS: Increase historic fire cycle to 200-300 years. This will change RNV from the current range that describes a much younger forest than was presettlement norm.

643

RESPONSE: Documented cycles of 200-300 years occurred in certain community types, while shorter cycles occurred in other types. These are described in the FEIS, Chapter III, "Fire - Scale: Vegetative Community and Subsection".
RR

RNV Will Require More Burning, Polluting of the Air

COMMENTS: Managing within the RNV you have established will require annual burning of 3.5% of the Forest. This is wasteful and will not offset our fossil fuel burning. Forest will use as much oxygen as it produces, and fires will produce as much carbon dioxide as the forest consumes.

275

RESPONSE: RNV is not a goal for management. It is a reference point for assessing ecological change and response. The Forest is not proposing to burn 3.5% of the Forest, which would be over 60,000 acres annually. RR

COMMENTS: RNV will require seven times the amount of burning than is currently occurring. This will reduce air quality and pollute the Class I airshed for Yellowstone National Park. (CROSS REFERENCE: Wilderness)

275

RESPONSE: RNV is a reference point for assessing ecological change and response and will not require any particular amount of burning. Air quality effects would be an important consideration for any proposal to burn near the Yellowstone National Park or Grand Teton Park airsheds. RR

Use a Different Time Window for Determining RNV

COMMENTS: Expand temporal scale to evaluate historical patterns. Snapshots from any single period are not likely to capture a full range of spatial patterns.

643, 690

Expand scale of analysis and time window for Range of Natural

ECOSYSTEM MANAGEMENT - THE CONCEPT

Variation. Appears the forest will use a preliminary understanding of RNV to create mega openings that have negative impacts on sensitive wildlife species.

643, 690

Use longer time window to establish the Range of NV to better represent a more accurate historical picture and better display the role of natural fire disturbance on vegetation patterns.

643, 695

Adopt broader time horizons of 50-300 years for RNV in order to meet realistic EM outcomes.

643, 690

RESPONSE: These are all very good suggestions and will be considered as the Forest develops the process for identification of RNV. RR

COMMENTS: Use 1860 to current day as the time frame for RNV to coincide with timeframe being used by USF&WS.

314

RESPONSE: This time frame is a reasonable option and will be considered along with others suggested in the research. RR

Eliminate Range of Natural Variability

COMMENTS: Prefer a more productive approach to understand change processes which are going on in the forest today, and use this information to predict different management scenarios for the future, rather than trying to return the forest to a previous state we know little about.

1360

RESPONSE: RNV is not the only approach to understanding ecological change. Successional pathways, disturbance frequency and magnitude, and historic records and photos are other types of sources for clues to ecological change. RNV is not an attempt to take the Forest back to a previous time period, although the Forest may want to reproduce natural processes or conditions artificially if that is an appropriate management objective. RR

COMMENTS: Eliminate the Range of Natural Variability. It has not been reviewed by the scientific community or the public.

1446

RESPONSE: The Final Revised Plan describes the principles and objectives of Properly Functioning Condition (PFC) which incorporates RNV but uses other criteria for identifying ecological systems at risk or in PFC. The concept of RNV originates in the scientific record and, although a relatively new concept, shows merit as one tool for implementing ecosystem based management. The specifics of identifying and applying RNV will be determined after adoption of the Revised Plan. RR

COMMENTS: Have Range of Natural Variability reviewed by scientific community for accuracy and application in resource management prior to plan

implementation. Cannot determine wildlife impacts or impacts to TES based on the present definition.

389

RESPONSE: RNV is a product of scientific research and has had considerable review within the scientific community. The Forest will continue to cooperate actively with the research community during Plan implementation. RNV is not intended to be an indicator of impacts to wildlife or Threatened and Endangered Species. Those effects are disclosed in Chapter IV, Environmental Consequences. RR

COMMENTS: Selecting a point in time to define the Range of Natural Variability is controversial and achieving a workable RNV by 2007 unrealistic.

7

RESPONSE: The Forest agrees that RNV is controversial. We have removed the objective to determine RNV by 2007 and replaced it with a set of goals and objectives for implementing PFC which we believe is a more useful and effective approach. See Revised Plan, Chapter III, Forestwide Standards and Guidelines. RR

Change Objective for RNV

COMMENTS: Change objective to read "Historical" Range of Natural Variability. Little if any vegetation landscape remains unaltered.

7

RESPONSE: There are several variations in the scientific literature. The concept of RNV as a benchmark or reference condition, rather than a desired 'past condition', remains the same. RR

Discuss How you Will Meet RNV Objectives

COMMENTS: Discuss how you plan to meet RNV objectives by the year 2007, a year after the ten-year plan is completed and three years before the DFC.

697

RESPONSE: RNV is replaced as an objective by the PFC section in Chapter III of the Plan. It is a reference condition the Forest will identify for selected ecosystems. The PFC process is undeveloped but will be after the Revised Plan is final. RR

COMMENTS: Consider Dr. Kay's presentation and slide program on historical vegetation patterns on the Targhee and discuss why Alternative 3M will lead us to that RNV.

1346

RESPONSE: Dr. Kay's presentation only spoke to portions of the Centennial Subsection. Refer to the Properly Functioning Condition (PFC) section of the Revised Plan, Chapter III. The Forest is adopting the regional concept of PFC and evaluating ecosystems against this criteria rather than solely utilizing RNV. Other issues raised within the Centennial Subsection (e.g. grizzly bear

ECOSYSTEM MANAGEMENT - THE CONCEPT

recovery area, goshawk) may limit the ability of the Forest to manage for PFC in portions of the Centennials. DM

RNV - Timber

COMMENTS: Clarify RNV for Aspen. Reevaluate succession conclusions regarding lodgepole pine, Doug-fir, and aspen that led the forest to conclude that aspen is outside RNV and thus is a reason for management intervention. Aspen is more abundant now than historically. (CROSS REFERENCE: Timber, Aspen)
643, 489

RESPONSE: The Forest's findings do not support a conclusion that aspen is more abundant now than in the past. The basis for the assertion that aspen is outside RNV is that fire suppression has virtually eliminated the primary disturbance regime responsible for perpetuating aspen communities in their historic range. In the absence of periodic fires, aspen is being replaced by other shade-tolerant community types such as Douglas-fir. RR

COMMENTS: Include livestock grazing impacts and fire suppression in your analysis that aspen is outside the RNV.
695

RESPONSE: Fire and fire suppression are discussed in the FEIS in Chapters II and IV. Research shows that grazing is not as significant an effect (refer to Camas Creek Aspen Rejuvenation Project NFMA/NEPA documents) in causing the loss of aspen as is conifer encroachment. The conifer encroachment is the result of removing the natural fire disturbance regime and continued fire suppression. Grazing is acknowledged as a factor in reducing or altering fire patterns. DM

COMMENTS: Explain the basis for the aspen guidelines and why you picked the target successional stage distribution as ideal.
1369

RESPONSE: The section on forested successional stages is expanded to include old growth guidelines (Chapter III, Revised Plan). These guidelines are consistent with research and professional experience (USDA Forest Service, 1993). The ages displayed in the table are not a 'target' nor considered 'ideal' but are representative ages of dominant individuals in a community type at which a block of forest vegetation would be considered late successional. This age is used to identify and maintain late successional or old growth patches to the specified guideline. The absolute number can be debated, but the ages displayed represent reasonable values based on science for purposes of this Plan and analysis. RR

COMMENTS: Evaluate proposed aspen management guidelines and objectives on wildlife and include impacts of a structured rotation age.
1369

RESPONSE: The forestwide effects on wildlife of vegetation management activities proposed in the Plan, including those associated with specific rotation ages, are disclosed in Chapter IV of the FEIS. The guideline for

ECOSYSTEM MANAGEMENT - THE CONCEPT

Forested successional stages is expanded to include old growth guidelines (Chapter III, Revised Plan). The effects of any specific proposal which harvests aspen is a site specific activity which is outside the scope of this analysis and would be conducted in a separate NEPA analysis with disclosure of effects. RR

COMMENTS: Apply RNV at a coarse level to capture the decline of old growth regionally.

643

RESPONSE: This is outside the scope of the proposed action. The level of analysis displayed in the FEIS is sufficient to disclose the effects of the alternatives and desired outcomes. RR

Improve Existing Condition Descriptions

COMMENTS: Include maps of the existing condition so comparisons can be made easily to the proposed actions.

1362

RESPONSE: Alternative 1, includes maps which describe the current condition. These are sufficient for comparison. Chapter II of the FEIS provides a matrix for comparing differences between alternatives. The project record for the Revised Plan includes additional maps. RR

COMMENTS: Illustrate general spatial patterns. Tabular presentations, especially of riparian areas, AIZs, and vegetation cover, do not present essential information.

1362

RESPONSE: The Forest acknowledges that graphic presentations might be more illustrative. Graphics were not used to display the requested information because: they are redundant to information presented in the documents; respondents generally have called for more detail in the documents, rather than more summary presentations; and the limitation of patch size has been dropped as an indicator of sustainability, fire, and natural disturbances. DP

COMMENTS: Describe how mature category relates to late successional ages given on Page III-3 in describing the existing condition of forest resources.

643

RESPONSE: The Forest expanded the discussion and direction on "Forest Successional Stages" to include standards and guidelines for old growth and late successional stages. RR

COMMENTS: Characterize the forest as a crown fire ecosystem with relatively few, infrequent fires and manage for a larger proportion in a mature age class.

489

ECOSYSTEM MANAGEMENT - THE CONCEPT

RESPONSE: Chapter III of the FEIS, Ecological Processes and Patterns, describes the fire regimes associated with the Forest and the Greater Yellowstone Area. RR

COMMENTS: Improve existing condition description by including specific categories which define elevation, canopy closure of stands, age of stands, etc. Overall implication that the Forest is dominated by relatively pristine conditions is inaccurate.

1369

RESPONSE: This level of detail is not essential to describing the Forestwide existing condition or the effects of the alternatives. The project record contains these types of detail. RR

COMMENTS: Identify extensive harvest at low elevations as part of the existing condition.

1369

RESPONSE: The Affected Environment chapter of the FEIS discusses extensive harvest in individual subsections. This adequately describes the existing condition, whether at high or low elevations. RR

COMMENTS: Correct description of existing condition to one that depicts a forest that is recovering from past disturbance (fire) rather than one predominantly exhibiting the effects of overzealous fire suppression. Past disturbance cycles created the now homogeneous age class over large areas. Aspen abundance is within past levels and is more plentiful now than in the past. Old growth and mature forest formerly dominated the landscape in greater degrees than currently. *

643

RESPONSE: Historic fire frequency and behavior have shaped the forest observed today. More recent fires, the Gallagher Peak 1979 and North Fork 1988, are discussed in the Affected Environment section. The Forest did not portray this as an either/or choice between disturbance scenarios. The most dominant influence on development of forested landscapes in the last 80 years has been the aggressive suppression of fire. The effects of fire suppression in altering successional development, vegetation patterns, structure, and diversity, and subsequent fire behavior is well established in scientific literature. The Forest does not agree that aspen abundance is greater now than in the past. RR

COMMENTS: Site data source for the statement that the Forest has more area in mature age classes now than the historical record indicates. This is not a reasonable conclusion on a forestwide scale given the sizeable area subjected to clearcutting over the last two decades.

643

RESPONSE: Data sources include: Camas Creek Landscape Analysis; Caldera Project (MSU); Old Henry's Lake Reserve (1912-1916) Vegetation Maps; and the Targhee National Forest GIS Data Base. All of these sources show more acreage in early age classes than what is currently present on the Targhee. LB

COMMENTS: Provide scientific foundations for conclusions regarding ecological structure and function, role of fire and fire suppression in creating existing vegetation and range conditions and trends.

690

RESPONSE: Scientific publications are listed in Appendix R-1 "References Cited" in the Revised Plan and FEIS documents. RR

COMMENTS: Provide existing condition of watersheds on the forest. Without defined existing conditions one cannot effectively compare alternatives.

1369

RESPONSE: The Forest used watershed components important to analyzing the effects of the alternatives, such as water quality and channel stability. Watershed conditions are described in Chapter III, Affected Environment in the FEIS. RR

COMMENTS: Include a discussion of the appropriate role of disturbances and succession to existing condition and those that existed historically.

643

RESPONSE: This discussion can be found in Chapter III Affected Environment in the FEIS, Ecological Processes and Disturbances. RR

Age/Class Delineation Portrays Inaccurate Existing Condition

COMMENTS: Age classifications used in the Plan obfuscate the stand age analysis and mislead the reader as to the actual existing condition.

643

RESPONSE: The age class distribution is sufficient for this scale of analysis. It portrays an accurate picture of the vegetation condition at the subsection or forestwide scale. A finer resolution of the data is always useful to have but is not necessary to assess effects of possible management actions and evaluate the differences between the alternatives. RR

COMMENTS: The supposed lack of age class diversity in subsections like the Centennials and Big Hole Mountains is due to bias sampling and data analysis more than an actual lack of diversity on the ground.

643

RESPONSE: The data standards and sampling methods are sufficient for this level of analysis, because they portray a reasonably accurate distribution of age classes at the forestwide scale. RR

COMMENTS: Reconsider the lumping of forest age classes for tabulation of existing forest conditions. Current presentation creates erroneous impression that much of the Forest is in an advanced stage and distracts attention from those areas that actually provide functional old growth. The Plan's

ECOSYSTEM MANAGEMENT - THE CONCEPT

definition of age classes biases the plan in favor of more harvest. The percent of trees in "mature" age class (78% mature) seems to be high in regards to wanting age class diversity.

643, 695, 432

RESPONSE: The Forest reconsidered the age class distribution and determined that it was adequate for this analysis and represented an accurate portrayal of the distribution of age classes Forestwide. The Forest expanded the guidance for old growth and late successional stages in Forestwide Standards and Guidelines, Chapter III. RR

COMMENTS: Classification ignores important structural distinctions among classes of "mature" timber, including stem exclusion, understory reinitiation and old growth structural classes. It is impossible to tell from Table how structural classes greater than seven-eight inches dbh are distributed on the Forest. Table should be redone to show size and age class distributions of stands larger than "pole."

1368

RESPONSE: The Forest added an expanded section on old growth, including forestwide goals, objectives, standards, and guidelines. The indicators necessary to describe existing conditions, assess effects of alternatives, and make comparisons were used in this analysis. Other indicators, such as those described in this comment, are more useful when evaluating projects at the site specific level and are not essential to a programmatic analysis. RR

COMMENTS: Descriptions of the Forest as mostly "mature" in the plan bear little resemblance to the reality of high grade stands and massive clearcutting over many parts of the Forest.

1277, 1369

RESPONSE: Subsection descriptions provide a clearer picture of forested community types, including differentiating between those with higher levels of past harvest and those unharvested. Those that had little harvest show the highest proportion of mature component. RR

Need Standard for Restoration

COMMENTS: Incorporate language that stipulates compulsory management action to repair, upgrade or enhance watersheds and ecosystems.

389

RESPONSE: The Revised Plan provides for action to restore aquatic and ecological systems not meeting properly functioning condition. See Forestwide Standards and Guidelines section, Chapter III, Properly Functioning Condition of the revised Plan. See also Management Prescription 2.8.3, Aquatic Influence Zone, Chapter III. DM/RR

COMMENTS: Initiate and fund an educational campaign and include this requirement in each alternative. Address public misconceptions regarding the biological role of fire and the implications of returning natural fire to the

ECOSYSTEM MANAGEMENT - THE CONCEPT

ecosystem, the biological role of insects and disease, the biological impacts of continued road building, recreation, logging, grazing and mining.

1364, 389

RESPONSE: Education and information about ecological processes remains an ongoing part of Forest Service activities, especially during public participation opportunities related to site-specific NEPA documents. Some of the agency's activities include maintaining a library of literature and videos; conducting field trips; working with the local media; visiting schools; leading scouting and youth projects; and developing and distributing literature about management of natural resources, including fire and ecosystem management, as money, time and personnel availability allows. It is inappropriate to place an ongoing education program in the allocation alternatives of a land management plan. AM

Commit More Resources and Funding to Research and Monitoring EM

COMMENTS: Commit more resources and funding to broad research and associated monitoring needed for adaptive management.

643, 690

RESPONSE: The Forest will commit as much funding as possible, given workload, budget, staff availability and the broad array of management commitments that must be met. The Forest will continue to pursue partnerships and cost/share programs that mutually benefit universities and scientific organizations and Revised Plan objectives and goals for ecosystem management. AM

ECOSYSTEM MANAGEMENT - BIODIVERSITY

General Comments on Biodiversity

COMMENTS: Maintain biodiversity, for without it, the human race is lost. Implement methods to restore and recreate diversity, because past habitat destruction/past management activities and status quo continue to reduce biodiversity.

F-H(8), 293, 1275, 1365

The best plan to conserve biodiversity is to recognize the role of natural disturbance without human intervention.

1368

RESPONSE: The Forest agrees that maintaining biodiversity is key to maintaining healthy ecosystems and that healthy ecosystems are needed to support a high quality of life. The Revised Plan recognizes the ecological roles that natural disturbances play in ecosystems and sets direction for promoting the proper functioning condition of ecosystems. Whether to allow natural processes to regulate ecosystems or to initiate active management will be based on the management prescription of the area, as well as the site specific ecological, social and economic considerations. DD

ECOSYSTEM MANAGEMENT - BIODIVERSITY

Explain Management Strategy/Discussions About Biodiversity

COMMENTS: Explain how preferred management strategy will meet long term biodiversity since the current proposals reduce the creation of young seral stages and retain older age classes.

413

RESPONSE: The Revised Plan provides for the maintenance of biodiversity through improved goals, objectives, standards and guidelines using the best available knowledge. The Revised Plan provides direction to manage forested ecosystems for age classes within limits representative of similar ecosystems in properly functioning condition. DD

COMMENTS: Discuss strategies and methods for maintaining genetic and species diversity. Don't lose native plant and animal species and manage watersheds instead of political boundaries.

697

RESPONSE: The Revised Plan contains goals, objectives, and guidelines to maintain genetic and species diversity. This provides a framework for the protection and recovery of many threatened, endangered, sensitive, and rare plants, animals, habitats, and ecosystems. DD

COMMENTS: Ensure biodiversity by creating a variety of habitats and a mosaic of age classes because different species will use different age classes and vegetation types; providing adequate early seral stages; reducing clearcut patch size because this reduces the number of species that need early seral stages for survival and other species that prey upon them.

413

Providing for and maintaining connectivity between and within landscape fragments.

1365

Reducing roading, clearcutting, ORV use, snowmobiling on winter range, grazing in riparian areas, excessive predator management in the wilderness, and fire suppression because of sustainability.

293

RESPONSE: The Forest considered all these items in the development of the various Revised Plan alternatives. The selected alternative incorporates all these items, where appropriate. DD

Recommend Changes to Biodiversity Objectives

COMMENTS: Make conservation of biodiversity an objective for each subsection. Tier conservation objectives to community level and correlate to subsection.

1368

RESPONSE: The Revised Plan emphasizes the conservation of biodiversity for a variety of plant and animal species and communities at a variety of geographic scales. The Revised Plan contains goals, objectives, standards, and guidelines to conserve biodiversity for native cutthroat trout (at the

ECOSYSTEM MANAGEMENT - BIODIVERSITY

watershed and forestwide scales); eight species of primary cavity excavators (at the prescription area and forestwide scales); late successional/old growth related species (at the watershed scale); and a variety of plant communities (at landscape and forestwide scales). DD

COMMENTS: Consider preserving some areas as gene banks, model ecosystems, and examples of pristine watersheds.

1443

RESPONSE: The Revised Plan includes direction to coordinate with the States of Idaho and Wyoming to: identify population strongholds of native cutthroat trout; protect their habitats; and to assist in protecting the genetic integrity of these populations. The Revised Plan identifies 17 of the 39 primary watersheds on the Forest as Native Trout Watersheds, which are areas of high aquatic integrity where research and recovery efforts are focused. DD

COMMENTS: Add to biodiversity objectives, objectives for aquatic biodiversity in AIZ and ecosystem function and process. Currently objectives only address terrestrial components as they relate to vegetation. Include specific direction for maintaining biodiversity, riparian function, and standards of rare and management indicator aquatic species. (CROSS REFERENCE: Riparian, AIZ; Fisheries)

643, 1273b

RESPONSE: The Revised Plan includes new goals, objectives, and guidelines adapted from the Inland Native Fish Strategy (INFISH). These address the conservation of aquatic biodiversity, riparian structure and function, and the recovery of native cutthroat trout populations and habitats. DD

Better Define/Improve Biodiversity Discussion

COMMENTS: Define and link the relationships of forest habitats to biodiversity. Include present age, basal area, average dbh, and canopy cover.

1369

RESPONSE: The Revised Plan provides direction to manage ecosystems, hydrologic regimes, animals, and soils in proper functioning condition (PFC). The process used to assess PFC evaluates the structure, composition, disturbance regime, and patterns and considers the factors in the comment above. DD

COMMENTS: Explain the role of patch size and connectivity in biodiversity and how these are incorporated into biodiversity objectives.

1369

RESPONSE: Patch size and connectivity are addressed in the section Ecological Patterns and Process, Properly Functioning Condition. Patch size and connectivity are not used as measures of biodiversity, but as measures of "patterns", one of four criteria used to assess PFC. DD

ECOSYSTEM MANAGEMENT - BIODIVERSITY

COMMENTS: Include the role of natural disturbances and their relationship in creating biodiversity.

695

RESPONSE: The role of natural disturbances is addressed in the Revised Plan in sections about Properly Functioning Condition; Insects and Disease; Fire; Fisheries, Water and Riparian Resources; Wildlife; and in a variety of management prescriptions including wilderness, aquatic influence zones, and special management areas. DD

COMMENTS: Discuss the aquatic environment in biodiversity, including whether beneficial uses for aquatic life are fully supported in Idaho water bodies.

1362

RESPONSE: The aquatic environment is discussed within the Revised Plan under the section Biological Elements, Fisheries, Water and Riparian Resources. The EIS states that the selected alternative meets State water quality standards which means that beneficial uses for aquatic life are fully supported. DD/RSM

COMMENTS: Acknowledge the role of fungi in the ecosystem; provide for the inventory of fungal flora in various regions using various tree and plant species of various age classes; monitor fungi with a mycologist rather than a plant pathologist. Some fungi help trees and are needed to provide food sources for small mammals, and indirectly, they are important for raptors.

731

RESPONSE: The Forest acknowledges the role of fungi in the ecosystem. The Revised Plan contains language to: retain higher levels of snags, green replacement trees, and down woody materials; increase protection of aquatic influence zones; and emphasize conservation of biodiversity. DD

COMMENTS: Demonstrate to the public how biodiversity is going to be measured.

1369

RESPONSE: The method of monitoring biodiversity is described in Chapter V (Monitoring Item - Biological Diversity) of the Revised Plan. DD

ECOSYSTEM MANAGEMENT - FIRE

Fire Management Direction Planning, Goals and Standards

COMMENTS: Include a fire management plan that gives forestwide direction for how the forest is to manage fire from both human-caused ignitions and natural causes.

1273b, 1368

Discuss the fire management plan that was in effect prior to the 1988 Yellowstone National Park fires and your current fire management approach.

1204

ECOSYSTEM MANAGEMENT - FIRE

Change the goal of fire management to provide well-planned and executed fire management programs that mimic natural fire regimes, are efficient and are responsive to Forest goals and objectives.

389

RESPONSE: Refer to Objective #1 under fire, which addresses the development of fire management plans within the Revised Plan. Previous to 1988 the Targhee had three fire management plans in effect: the High Country Plan (areas above 8,000 feet); the Big Hole Plan; and the West Slope Tetons Plan. After 1988 these plans were reviewed, and it was determined that they needed to be updated. Work began and is almost complete on the fire management plan for the Jedediah Smith Wilderness. DM

COMMENTS: Replace the guideline on III-129 (5.2.1) with a standard requiring that such practices related to fire suppression must be of the minimum impact possible.

1365

RESPONSE: Refer to the glossary for the definition of a guideline ("preferred or advisable course of action that is generally expected to be carried out"... "Deviation requires documented rationale"). Suppression methods will be determined on a case-by-case basis, depending upon the resources at risk and potential dangers. DM

COMMENTS: Provide some examples of before and after treatments in various community types (mini-Camas Creek). Simplistic table values and percentages on connectivity, patch size etc. are not helpful.

1311

RESPONSE: The Camas Creek and East Beaver Creek landscape analysis will serve as future demonstration areas for the Targhee's approach to ecosystem management. These landscape efforts have not been fully implemented at this time and do not provide information that can be incorporated into the Revised plan other than theory. DM

COMMENTS: Clarify contradictions regarding fire as an important force in shaping the forest versus fire as something that needs to be suppressed.

695

RESPONSE: Refer to Goals 1-3 and Objective #1 under fire within the Revised Plan. These goals provide guidance as to how fire will be managed and/or suppressed. Further guidance would appear within individual site-specific fire management plans which will determine how fires will be managed, based on a number of site-specific variables. DM

COMMENTS: Discuss the schedule and expected funding for completing fire plans.

695

Discuss forestwide direction for how you propose to manage fire from both human-caused ignition and natural causes.

1273b

ECOSYSTEM MANAGEMENT - FIRE

RESPONSE: The schedule for completing fire plans will be developed once the Revised Plan is in place. Funding expectations, for the next ten years, would be speculative. RR

COMMENTS: Want more use of prescribed fire:

432, 1364, 1365, 1393

- to remove fire ladders, reduce fuel loads, reduce fire risks

432, 1364

- to treat a sufficient amount of acres.

1393

- to manage range resources where vegetation diversity is suffering from decadent stands of brush

432

- because fire is the most important secondary factor for the maintenance of the Forest

1365

- as a management tool for timber resources

432

- to reduce too many mature tree stands

432

- to increase in-stream flows.

432

- to reduce amount of waste of wood products.

432

RESPONSE: Use of prescribed fire to achieve a variety of objectives is addressed at the project level where specific fuel types, conditions and associated risks are considered. Also, refer to Objective #1, under fire, in the Revised Plan which addresses the development of fire management plans. DM

More Explanation Needed about Too Small Amount of Use of Prescribed Fire.

COMMENTS: Although prescribed fire is allowed on 1.2 million acres, explain why 2,000 acres a year will be sufficient. At that rate it will take 600 years to treat 1.2 million acres.

1393

RESPONSE: The Forest realizes this may not be sufficient but is constrained by past activities or other resource needs. Managed natural fires may provide an opportunity to treat more acreage. Note that the 2000-acre figure is a minimum. Refer to Objective #1, under fire, in the Revised Plan which addresses the development of fire management plans. DM

COMMENTS: Explain how harvesting only 1.7% of the mature component over 10 years will achieve historic fire intervals that will reduce suppression costs and resource losses from severe wildfires. Suggest you harvest 8-10% of the mature component over ten year period. (CROSS REFERENCE: Timber, Old Growth)

413

RESPONSE: This percentage (1.7%) is a result of meeting other resource concerns/objectives. We may need to continue aggressive fire suppression efforts in areas at risk. DM

ECOSYSTEM MANAGEMENT - FIRE

COMMENTS: Prefer prescribed fire in place of timber harvest because prescribed fire provides better health/habitat for amphibians, elk and other wildlife; reduces fuels; costs less than below-cost timber sales; causes less erosion.

20, 212, 643, 1360, 1364, 1387, 1393

Use fire as a management tool for timber resources. Lack of fire has resulted in more mature tree stands, higher fire risks, and decreased in-stream flows as well as a waste of wood products.

432

Against prescribed fire because burning is wasteful; reduces air quality; and negatively affects wildlife, watershed, and riparian areas.

275, 300, 1176

Refrain from using radical new programs like prescribed fire to improve forest health until some method is developed to assess the relative contribution of these management strategies and the prolonged drought to the current forest health "crisis".

1365

Wise removal of forest products is no more harmful than uncontrollable burning. To prohibit use of forest products so they can rot or burn and then tax me to fight fires is ludicrous.

296

Reexamine your assumption that the only approach to fire control is to reduce fuels and increase fuel diversity.

212, 643, 1257, 1273b, 1368

Consider other complex factors such as insect boom/bust population dynamics linked to fire dynamics, pathogens, and insectivores, birds, and mammals.

643, 1368

Vegetation management can control wildfire. Wildfires often occur at the landscape scale. Treating vegetation at the stand or individual site-level is ineffective.

1273b

The opening of forest canopies through fire proofing operations can dry forest understories earlier in the fire season; the disruption of soil by heavy equipment can reduce soil moisture retention creating drier conditions. Fine fuels left by slash contribute more to fire spread than large fires that are difficult to ignite.

643

Other factors such as climate, drought, weather are more important than vegetation in controlling fire. Logging only removes woody debris which often does not burn anyway.

1273b

Logging and salvage are no substitute for natural fire in an ecosystem.

212

Logging does not mimic the natural disturbance/regeneration regime.

1365

Large scale timber harvests cannot be justified and silvicultural systems must be evaluated in this context.

1365

ECOSYSTEM MANAGEMENT - FIRE

Remove any correlation between mature forests and elevated disturbance risks. This is a flawed contention and there is no evidence that intensive logging of mature stands will reduce disturbance hazards.

1368

RESPONSE: It is true that timber harvest by itself does not mimic the effects of fire. The heat-killing and nutrient-converting attributes of fire cannot be duplicated by timber harvest. Likewise, large and fine woody debris retention and distribution may be quite different between a fire and a timber harvest operation. Secondary effects from timber harvest such as, scarification, roads, skid trails, or compaction are not usually associated with a fire.

Depending upon the fire group, the use of silvicultural techniques and prescribed fire might be the best solution to developing sites that are both resilient and resistant to perturbations. Research silviculturists and fire ecologists are finding that a carefully selected combination of silvicultural techniques combined with prescribed fire is effective for restoring and maintaining forest cover that is resistant to severe insect, disease, and wildfire damage. The combination of silvicultural treatments and prescribed fire facilitate long-term stand maintenance because favorable burning periods (burning windows) are often limited. Weather, availability of personnel, and timing of funding make it impractical to implement safe burns in heavy complex fuel types. Combining silviculture and prescribed burning also has the advantage, at least initially, to reduce adverse burns, which can last for long periods of time and cause human health risks; timing or avoidance of sensitive amphibian breeding sites; timing or avoidance of elk calving areas; avoidance of highly erodible soils; and so forth. Proper application of fire, used with other management techniques, is often the best option for meeting specific objectives while creating the least amount of adverse environmental damage. After implementing prescribed fire and silvicultural techniques, it may be possible to maintain resilient and resistant stand structures with periodic prescribed burning alone. Within other fire groups, the use of prescribed or managed natural fires might be used. Refer to Goals 1-4 and Objective #1 under fire in the Revised Plan. Wildfires are not always favorable for various resource values depending on their intensity/severity and their aerial extent. DM

COMMENTS: Prefer prescribed fire over use of chemicals to reduce shrub invasion of grasslands.

1364

RESPONSE: This is best addressed at the project level scale and depends upon issues raised, goals and objectives of the project, and other resource concerns and site factors. Chemicals (such as Spike 20P) have not been extensively used on the Forest. DM

COMMENTS: Use timber harvest in place of fire as a management tool. It provides greater control of shape, size, location, timing, and level of tree removal.

386, 687

Consider harvest rather than prescribed fire because understory in mature stands is too thick and different in composition and could result in

ECOSYSTEM MANAGEMENT - FIRE

more intense fire. Too many people reside adjacent to the forest and homes and property would be put at risk.

1202

RESPONSE: Prescribed fire and timber harvest will be permitted by the Revised Plan. Project-specific objectives will determine which is more appropriate.
RR

Ecological Processes - Fire

COMMENTS: Include fire under ecological processes and patterns.

695

RESPONSE: Your comment is acknowledged. Fire is added to this section. See goals, objectives and standards/guidelines for fire under Chapter III of the Revised Plan. DM

COMMENTS: Let wildfire take its natural course; let wildfire burn; human control is futile; use minimum impact suppression in responding to wildfire; include beneficial factors of natural fire in the ecosystem; don't introduce fire into systems with long fire intervals; use suppression only to protect lives or structures.

24, 695, 1273b, 1312, 1330, 1364

RESPONSE: Refer to the Goals, Objectives and Standards/Guidelines for Fire in the Chapter III, Forest Plan. Fire management plans will determine how fires will be treated within a given area. Treatment is site-specific and depends on numerous variables such as resource values at risk or life and property risks. DM

COMMENTS: Fires do not require a rapid human response and in some cases, acting too quickly can create new problems. Federal fire policy has resulted in decreased fire starts and an increase in fuel accumulation. Suppression costs too much and no reduction in fire risk has occurred.

1364

RESPONSE: These factors are considered in developing responses to wildfire suppressing and fire management planning. The Forest intends to move from suppressing fires to reducing fuels by prescribed fire and vegetation manipulations. RR

COMMENTS: Establish forestwide standards and guidelines for fire that will allow natural fire to burn without intervention.

695

RESPONSE: Fire management plans will be developed for various areas of the Forest (refer to the Goals and Objectives for Fire in Chapter III, Forest Plan). How a fire might be handled depends on a number of site-specific variables and is best analyzed at a finer scale. DM

ECOSYSTEM MANAGEMENT - FIRE

Control Wildfire

COMMENTS: Prefer control of wildfire. Large areas of the Park burned and lie devastated and useless.

7

Prefer control of wildfire, but let insect and disease run their course.

35

Consider proactive management of wildfire to reduce runoff erosion. Yellowstone National Park experienced increased erosion after fires because of water repellent soils.

393

Let some fires burn if the disturbance of putting it out is greater than letting the fire go.

32

RESPONSE: All of these concerns are best handled through fire management plans that will be developed for various areas of the Forest (refer to the Goals and Objectives for Fire in the Forest Plan - Chapter III). How a fire might be handled depends on a number of site-specific variables and is best analyzed at a finer scale. DM

Discuss More about Fire

COMMENTS: Consider an alternative to recover natural wildfire regime without extensive mechanical thinning and salvage.

1364

RESPONSE: Mechanical manipulation of forest vegetation is permitted by the Revised Plan. Individual fire management plans will help determine appropriate actions within a particular area on the Forest. RR/DM

COMMENTS: Discuss the effects that wildfire may have on age class distribution.

228

RESPONSE: This type of discussion better applies to site specific landscape or project-level analysis versus forestwide analysis. Effects of wildfires are variable, even within the same fire group, depending on site-specific factors. Site-specific analysis and fire management plans will determine the best course of action and the effects that course of action will have on age class distribution. DM

Relate Fuel Types to Fire Behavior

COMMENTS: Discuss the types of fuels that exist on the Forest and their relationship to fire behavior. Fine fuels are an important source of fire spread while heavy fuels are an important source of fire intensity.

1273b

Consider that slash and fine fuels left behind by intensive logging can increase fire risks. Forest fragmentation and removal of older green trees, snags and down wood, which are habitat for natural pest enemies, reduce

capacity of biological control, creating more intense insect outbreaks and fire intensities.

1368

Fuel loads do not determine burn severity. Severity of a burn is a function of fire size, and fire size is a function of weather. Reduced fire severity in untreated stands is a result of the absence of logging slash, the lack of opening in forest canopy which reduces insulation, wind, movement near the surface and the associated drying of fuels.

643

Consider that fire suppression has had little effect on many areas of the forest, especially in ecosystems with infrequent fire like subalpine areas.

643

RESPONSE: General fuel types found on the Targhee are discussed in Chapter III & IV in the DEIS. Fire behavior depends on numerous variables (such as climatic variables such as wind speed/direction, temperature, relative humidity; and site variables such as slope, elevation, aspect) that would be difficult to discuss on a forestwide basis. These and other considerations are evaluated when developing burn plans or fire management plans on a more site-specific level. DM

COMMENTS: Include note that clearcutting and fire in aspen fire regimes and conifer encroachment have different ecological effects. Clearcutting removes organic matter and lowers pH while burning adds organic carbon and increases pH that allows aspen to compete with other vegetation. (CROSS REFERENCE: Timber, Aspen)

643

RESPONSE: Generally, the effects you describe exist. The degree of the PH effect depends on site-specific management. How aspen communities and conifer encroachment are treated within a particular landscape is best addressed at the project level. DM

Management Actions to Control Fire May Produce Unintended Effects

COMMENTS: Management techniques intended to control fire can exacerbate insect populations by removing natural predators and their habitat, i.e., predators like insects, wasps, ants and birds. Prescribed fire increases insect pest densities by eliminating nesting substrate for ants and destroying dead wood for nesting or foraging substrate for insect-eating birds and predatory parasitic insect species. Management actions (salvage, thinning, and logging which remove dead wood) reduce or eliminate the checks and balances to control insect pest populations.

643

RESPONSE: Refer to the woody residue requirements table under soils, and the goals under fire in the Revised Plan. These factors are best evaluated at the landscape or project level scale. RR/DM

COMMENTS: Use more Timber and Range Management to mimic the role of fire; to mimic and sustain natural ecologic processes to reduce fuel loads and prevent

ECOSYSTEM MANAGEMENT - FIRE

catastrophic fires; to achieve historic fire intervals; to provide a diversity of vegetation age classes; to provide for economic stability; to use forest products before they rot or burn.

296, 413, 432, 1364, 1378

RESPONSE: Vegetation management by timber harvest, mechanical methods, and grazing are permitted by the Revised Plan. RR

Timber Management Methods Do Not Mimic Fire

COMMENTS: Reduce or eliminate clearcutting/logging. It does not mimic natural fire because...

150, 212, 242, 643, 644, 695, 697, 1257, 1273b, 1331, 1364, 1368, 1446

- it causes erosion and weakens the ecosystem so it becomes more prone to disease

150, 242, 643, 644, 1331, 1364

- clearcutting removes organic carbon, while fire retains it

1273b

- clearcutting is not the same in terms of energy and nutrient movement in the ecosystem

1446

- logging does not restore landscape vegetation patterns to those that existed presettlement; logging fragments and cannot reproduce a cycle that occurs under a natural regime.

643

- it is the root of many Forest problems in riparian areas

697

- the Forest recovers quicker from natural disturbance than logging

1257

- it causes further fragmentation

1273b

- studies show that other factors (climate, drought, weather) are more important than vegetation in controlling fire; logging only removes large woody debris which seldom burns.

1273b

- not the only solution to fuels buildup and fuels diversity.

643, 1368

- no evidence that intensive logging of mature stands will reduce disturbance hazards.

1368

RESPONSE: It is true that timber harvest by itself does not mimic the effects of fire. The heat-killing and nutrient-converting attributes of fire cannot be duplicated by timber harvest. Likewise, large and fine woody debris retention and distribution may be quite different between a fire and a timber harvest operation. Secondary effects from timber harvest such as, scarification, roads, skid trails, or compaction are not usually associated with a fire.

Depending upon the fire group, the use of silvicultural techniques and prescribed fire might be the best solution to developing sites that are both resilient and resistant to perturbations. Research silviculturists and fire ecologists are finding that a carefully selected combination of

silvicultural techniques combined with prescribed fire is effective for restoring and maintaining forest cover that is resistant to severe insect, disease, and wildfire damage. The combination of silvicultural treatments and prescribed fire facilitate long-term stand maintenance because favorable burning periods (burning windows) are often limited. Weather, availability of personnel, and timing of funding make it impractical to implement safe burns in heavy complex fuel types. Combining silviculture and prescribed burning also has the advantage, at least initially, (to allow the use of measure to) reduce adverse burns, which can last for long periods of time and cause human health risks; timing or avoidance of sensitive amphibian breeding sites; timing or avoidance of elk calving areas; avoidance of highly erodible soils, and so forth). Proper application of fire, used with other management techniques, is often the best option for meeting specific objectives while creating the least amount of adverse environmental damage. After implementing prescribed fire and silvicultural techniques it may be possible to maintain resilient and resistant stand structures with periodic prescribed burning alone. Within other fire groups, the use of prescribed or managed natural fires might be used. Refer to Goals 1-4 and Objective #1 under fire in the Revised Plan. Wildfires are not always favorable for various resource values depending on their intensity/severity and their aerial extent. DM

Include Conditions for Fire in Grizzly Bear/Elk/Wildlife Areas.

COMMENTS: Be explicit about the use of prescribed fire and the conditions when human-ignited fires are permitted. State under what conditions a human-ignited fire is permitted. Include more meaningful standards such as the size or acreage of grizzly bear/elk security area allowed to be impacted by fire. Include a standard that once a certain percentage of acres of bear security areas has burned, then fire suppression would occur.

1273b

RESPONSE: This is an implementation issue to be addressed during the development of site-specific fire management plans. RR

COMMENTS: Use MIST whenever possible regarding wildfires and pre- and post-fire strategy. Replace the first guidelines with a standard requiring the use of MIST whenever possible.

1365

RESPONSE: MIST techniques apply to grizzly bear core areas (See Prescription 2.6.2). MIST techniques can be used in other areas, depending upon the nature of the fire and the values that are at risk. DM

Consider Grazing as Important in Controlling Fires and Sustaining Ecosystems

COMMENTS: Use fire to manage range resources. Vegetation diversity is suffering from decadent stands of brush, restricted ground water flows which cause livestock to seek riparian areas rather than the uplands. Fire can be used to gain proper use levels.

432

ECOSYSTEM MANAGEMENT - FIRE

RESPONSE: We agree. Many rangeland ecosystems have altered fire intervals (for instance, mountain big sagebrush ecosystems have a 10-25 year fire interval due to past suppression efforts). Fire is needed within these ecosystems to maintain their resiliency and resistance to future perturbations. Fire intervals may need to be restored at intensity/severity levels greater than historical. Refer to the Fire and Vegetation Goals, Objectives and Standards/Guideline section of the Revised Plan. DM

COMMENTS: Promote managed use of rangelands and use grazing as a tool to sustain resources. Allow appropriate tools to be used, like grazing, prescribed fire and timber harvest to sustain ecosystem.

432

RESPONSE: Refer to the Goals, Objectives and Standards/Guidelines for Vegetation within the Revised Plan. DM

COMMENTS: Review bias toward mature forest and strategies that convert old vegetation to young vegetation through prescribed fire, i.e. prescribed fire needs to be managed, a lack of roads and timber management options discourage the use of prescribed fire; therefore, more harvest is needed to encourage prescribed fire.

Missing Letter #

RESPONSE: Prescribed fire (natural and management ignited) is a management tool that can be used to achieve desired results such as returning vegetation in late successional stages to early- or mid-successional stages of vegetation. The lack of roads and timber management do not discourage the use of prescribed fire. There is no relationship between the amount of harvest and the use of prescribed fire. These two methods may be used in conjunction with each other to meet resource goals but are not dependent on each other. In some situations prescribed fire may be the only tool used to meet desired objectives. RD/DM

COMMENTS: Grazing does not mimic natural disturbances such as fire.

697, 1204

Discuss the benefits of grazing in the control of fires.

251

Consider fire as the most important secondary factor for the maintenance of forest conditions. Livestock grazing is the key factor in the widespread conversion of savannah to forest.

1365

Address grazing impacts on Doug-fir having small stems in forests that are dominated by non-lethal underburning. This consideration may influence management prescription for restoration of Doug-fir where fire suppression has disrupted fire cycles.

1273b

RESPONSE: Grazing can effectively reduce fine fuels and thereby aid in controlling wildfires. In the sage/grass ecosystem, contiguous dense stands of sagebrush are a concern and would not be modified through grazing.

The Targhee acknowledges that grazing does not mimic natural disturbances. Numerous factors play a role in the expansion or encroachment

ECOSYSTEM MANAGEMENT - FIRE

of conifers within a given area such as site conditions, fire suppression, or management emphasis. DM

COMMENTS: Review cumulative effects section for upland forested and upland nonforested ecosystems in that it seems to predict forest changes if fire is suppressed rather than being allowed to function in a natural role.

695

RESPONSE: Within ecosystems where there is a likelihood of having altered fire regimes, risks exist for experiencing fires of a higher intensity/severity than what historically occurred. Under these conditions, it is advisable to continue to suppress fires until various techniques (such as prescribed fire, combination of silvicultural techniques and prescribed fire, and so forth) can be used to restore a better balance. Then it could be possible to allow fire to function more naturally, depending upon the resources at risk. DM

Fire and Soils

COMMENTS: Risk to soils is not a justification for fuels management since studies in Yellowstone National Park show soils were heated only lightly or moderately and that soil and site productivity was not decreased.

1273b

Consider broadcast burning following a sale as well as increase the minimum amount of debris left on the ground to benefit soil objectives. Slash pile burning serves no ecological purpose.

625

Opening forest canopies through fire proofing operations will disrupt soil by use of heavy equipment, reducing soil moisture retention.

Missing Letter #

RESPONSE: Risk to soils is considered at the site-specific project level. Soil risks are evaluated, in the case of a natural fire, to determine appropriate burned area emergency rehabilitation measures. Within certain fire groups, where fire suppression has caused one or more mean fire intervals to lapse, there may be a realistic risk to the soil resource from fires burning at a higher intensity/severity than what occurred historically which may result in higher potentials for resource damage.

Broadcast burning is best addressed at the project level. Refer to the Table in Chapter III of the Revised Plan for minimum woody residue requirements needed to maintain long-term site productivity.

Secondary effects from timber harvesting (opening forest canopies) through scarification, roads, skid trails, or compaction are not usually associated with fire but they can adversely affect the soil resource. Soil quality standards and guidelines are identified within the Revised Plan to address this concern. Also, review the soils sections within Appendix A of the Revised Plan. DM/DD

ECOSYSTEM MANAGEMENT - FIRE

Seeding, Especially for Restoration after Burns

COMMENTS: Use native seeding for restoration, erosion control, and revegetation projects whenever possible. Change first guideline on Page III-8 to a standard.

695, 697, 766, 1276

Prohibit the seeding of exotic non-native species in burned areas. Exotic species do little to reduce erosion potential and inhibit the post fire development of populations of native species. Non-native species like Timothy and smooth brome do little to reduce erosion and prohibit the re-establishment of native species. Include sagebrush, forbs and native grasses in fire rehabilitation seeding mixtures.

489, 731, 766

Consider species variety in replanting. One or two commercially valuable species does not a forest make.

1396

RESPONSE: Refer to Objectives and Standard/Guidelines for Vegetation in Chapter III of the Revised Plan. Refer to the glossary for the definition of a guideline and its requirements. For burned area rehabilitation, native species are desirable if they have been proven effective in controlling erosion. Species recommended for seeding that are not mandatory for erosion control can be used within the seed mix provided they are paid for with program dollars. Emergency funds are not available to purchase species that are mainly beneficial for other purposes but are not needed for the immediate emergency such as loss of soil and onsite productivity, and/or loss of water control and deterioration of water quality. DM

Structures

COMMENTS: Discourage new or reduce the number of structures in fire prone areas by developing policies.

1364

RESPONSE: Refer to Goals, Objectives and Standards and Guidelines for Fire in the Revised Plan. Development on adjacent and/or private lands is beyond the control of the Forest Service. Refer to Prescription 5.1.3 within the Revised Plan which addresses Urban Interface Fuels Management. DM

Miscellaneous

COMMENTS: Consider the use of spot burning instead of burning one large area. Don't try to change everything at once.

219

RESPONSE: This is best considered at the project level.

COMMENTS: Use fire management to maintain a supply of post and poles.

293

RESPONSE: This is a project level decision. Refer to Goals for Fire in the Revised Plan.

ECOSYSTEM MANAGEMENT - FIRE

COMMENTS: Eliminate fire fuel standard.

1365

RESPONSE: The Forest retains a fire fuel standard because it is important.
RR

COMMENTS: Add a monitoring element to track the number of fire ignitions managed as prescribed burn and how noticeable fire suppression efforts are one year after the fire.

1312

RESPONSE: The monitoring program in Chapter V focuses on the most critical activities and is cost-effective and reasonably achievable, given anticipated staff and budgets. This item was considered for inclusion in the monitoring program, but was dropped, because it received a lower priority than other, more critical, activities. RR

COMMENTS: Allow prescribed burning in Research Natural Areas in accordance with the RNA's Establishment Record in that prescribed fire may be used to maintain fire dependent ecological processes and to provide a natural range of fuels, understory vegetation, and successional stages where specific direction is not provided, or modification is needed. Prescribed fire in these areas should be developed and approved by the Research Station Director.

1181

Add a guideline to prescribed fire section that prescribed fire plans for RNA's will be developed in conjunction with the Intermountain Research Station and approved by the Station Director.

612

RESPONSE: Prescription 2.2 (Research Natural Areas), allows the use of prescribed fire (guidelines under Fire/Fuels in Chapter III). Prescribed fires planned within Research Natural Areas follow proper protocol during the NEPA process. DM

ECOSYSTEM MANAGEMENT - FOREST HEALTH

Change Analysis, Definitions of Forest Health

COMMENTS: Reassess the Forest's health. Language is inflammatory and there is no scientifically proven answer to what constitutes a healthy forest. Provide basis for ecological analysis or vegetation data and analysis that form the basis for forest health descriptions found in the subsection write-ups. Reconsider subsection descriptions which identify forest health issues as crowding, insect and disease, and catastrophic fire as a basis for action or treatment.

643, 695, 1364

Define how forest health will be measured in quantitative terms.

Include wildlife in the definition of forest health.

1369

RESPONSE: See the "Forest Health" definition in Revised Plan Glossary. The aspects of forest health noted are not exhaustive or comprehensive. Opinions

ECOSYSTEM MANAGEMENT - FOREST HEALTH

about what constitutes a healthy forest vary, but substantial evidence supports the indicators of forest health identified in the Plan such as insect and disease risk, aspen decline, risk of catastrophic fire, lack of species diversity, water quality limited segments (WQLS), measures of hydrologic disturbance, and elk vulnerability. Most standards and guidelines include measures which will (likely) maintain or improve forest health.

Documentation of analysis and data used is included in the "References Cited" section of the Revised Plan and FEIS and in the analysis file at the Supervisor's Office. Some documentation can also be found in Appendix A-1, National Goals Relevant to Land and Resource Management.

The subsection descriptions present a representative portrayal of the ecological condition. The goals and objectives, and standards and guidelines provide management direction responsive to these conditions and that foster forest health in the aggregate. The Forest does not expect unilateral agreement with proposals in the Revised Plan, but adequate scientific basis exists for proceeding adaptively with implementation.

Forest health will not be measured quantitatively as a single item. An array of indicators described in Monitoring and Evaluation, Chapter V, will determine the overall health of the Forest and the extent to which desired conditions have been achieved. Other assessment tools such as Properly Functioning Condition will be used to determine ecosystem components that may be "at risk." Properly Functioning Condition assessments incorporates wildlife habitat. RR

Additional Causes of Poor Forest Health

COMMENTS: Consider that roads and management activity increase the risk of tree diseases such as the spread of fungal disease. Forest practices in Pacific NW have increased the incidence of soil-borne tree diseases caused by altering stand structure and composition and altering soil drainage patterns by the creation of logging roads. Roads used for harvest and fire suppression allow increased human access; 90% of all wildfires are human-caused.

643

RESPONSE: Damage from mechanical disturbances to individual trees or stands can increase risk of spread of pathogens. The degree to which this may have affected forest stands on the Targhee is unknown. This information is not essential to making a reasoned choice among alternatives for this analysis. Roads, by design, are intended to improve human access. The Revised Plan provides detailed direction for managing access in a balanced manner to provide for recreation opportunity, transportation, and services while protecting critical wildlife habitat, soil, and aquatic resources. There is a significant reduction of open roads in the Revised Plan. RR

COMMENTS: Discuss the proliferation of human-related disturbance as the principal cause for forest health problems. Undisturbed areas are surrounded by a sea of disturbance which have profound repercussions for forest ecosystems to sustain themselves.

643

RESPONSE: Human demands on ecosystems introduce a complex set of effects. The notion of human influence as a "principle" cause of forest health problems

ECOSYSTEM MANAGEMENT - FOREST HEALTH

probably enjoys no more consensus than many contentions in matters related to ecosystem management. However, these demands on public lands are a fact and condition of contemporary National Forest management. Provision for goods and services remains a mandate of public law and policy, under Multiple Use Sustained Yield (MUSY) Act, Resource Protection Act (RPA), NFMA, and other laws or regulations. The issue is, "how do we conduct public land management to meet human needs while maintaining the health, diversity, and productivity of ecosystems?" (Thomas and Huke 1996). Human induced disturbance does not perfectly replicate natural disturbance processes, and we do not contend that it does. However, artificially designed disturbance can achieve desired social, ecological, and economic effects while ecologically approximating natural disturbance, with mitigation for risk to undesirable adverse effects. Humans will continue to affect ecosystems. The Revised Plan provides for this in a manner consistent with maintaining sustainable ecosystems. RR

ECOSYSTEM MANAGEMENT - INSECT/DISEASE

Broaden Scale of Analysis for Insects and Disease

COMMENTS: Examine major past population fluctuations at a larger geographical scale. Population fluctuations of defoliators are driven by dynamic processes that sometimes operate at a regional scale.

643

RESPONSE: New language is included in the Revised Plan which recognizes the role insects and disease play in forest ecosystems. The Regional Office (Forest Health Protection) provides the Forest with annual reports on the status of insect and disease surveys and findings. Forest Health Protection also completes surveys periodically on the Targhee. This information is taken into consideration when planning and implementing project level work. Due to the temporal and spatial variances with insect and disease outbreaks, it is difficult to properly examine this within the context of a Forest Plan. DD/DM

EM Goals and Standards for Insects and Disease Treatments

COMMENTS: Expand Insects and Disease section and link goals of EM to ensure aquatic habitat protection is maintained throughout the Plan.

643, 1446

RESPONSE: New language is included in the final Revised Plan which recognizes the role insects and disease play in forest ecosystems. Refer to the Goals, Objectives and Standards/Guidelines for Properly Functioning Condition (PRC) in the Revised Plan, "Ecological Processes and Patterns", Chapter III, and to the Prescription 2.8.3 in the Revised Plan. DD/DM

COMMENTS: Consider an environmental assessment or watershed analyses for fire and insect and disease infestations.

1365

RESPONSE: The Forest will assess the properly functioning condition of various ecosystems using guidelines found in the report entitled Properly Functioning Condition Process-1996 (draft). Ecosystems strongly controlled by

ECOSYSTEM MANAGEMENT - INSECT/DISEASE

fire or insect and disease infestations, or have the potential to be affected, will receive priority for assessment. Plans are already underway to assess the condition of the lodgepole pine ecosystem in the Island Park Ecological subsection. DD

COMMENTS: Establish a standard that no damaged or diseased trees will be removed, and specifically state exceptions to this standard. Let natural disturbance play its role in ecosystem dynamics.

695, 697

RESPONSE: The Final Revised Plan includes direction for the management of snags and green replacement trees; dead and down woody material; and natural disturbances supported in scientific literature. Each situation will be evaluated on a case-by-case basis by an Interdisciplinary Team. Potential resource values at risk, endemic versus epidemic insect and disease evaluations, spatial and temporal considerations will be evaluated to arrive at a recommended course of action, including no action. DD/DM

COMMENTS: Disclose who will decide insects and disease goal compatibility, and the factors/measures that will be used; explain how conflicts will be addressed when insects and disease have benefits for wildlife but negative effects to vegetation.

1369

Include a discussion of how the Forest intends to prevent a recurrent of the insect infestations that have occurred in the past.

166

RESPONSE: The Forest will determine whether various ecosystems are in properly functioning condition (PFC) by using the procedures outlined in the report entitled Properly Functioning Condition Process-1996 (draft). This process evaluates ecosystems at the watershed and other geographic scales and considers the role that fire, insects and disease play in maintaining ecological integrity. Ecosystems not in properly functioning condition, or near their threshold, will be further evaluated as to the associated risks. If risks are significant, then alternatives will be developed and evaluated through an environmental assessment process to determine a preferred course of action, if any. Plans are already underway to conduct a PFC assessment of the lodgepole pine ecosystem in the Island Park Ecological subsection. DD

COMMENTS: Provide scientific references or analysis that support the implication that cutting mature trees should be favored to increase forest diversity and reduce the risk of insect and disease outbreaks. Provide clear proof that mature forest are more susceptible to insect and disease.

1368

RESPONSE: Bark beetles present the most serious insect threat to lodgepole pine (Amman 1975). The mountain pine beetle is by far the most significant insect pest of lodgepole pine (Amman 1978). The significance of the problem was thoroughly discussed in a symposium held in 1978 in Pullman, Washington (Berryman and others 1978).

Amman (1978) listed the following stand characteristics associated with epidemics: 1) trees more than 80 years old, 2) mean tree diameters over

ECOSYSTEM MANAGEMENT - INSECT/DISEASE

eight inches, 3) a substantial proportions of trees over 12 inches d.b.h. with phloem thickness of 0.1 inches or more, and 4) elevations where temperatures are optimum for brood development. DS

ECOSYSTEM MANAGEMENT - LANDSCAPE MOSAIC

Define/Clarify Mosaic You are Attempting to Achieve

COMMENTS: Define the mosaic you want to achieve for age and structural criteria such as age classes, dbh, canopy closure requirements, desired combination of age classes based on wildlife needs and current science.
643, 1369

RESPONSE: The scale used is adequate for the scope and resolution of this analysis. Landscape analysis is more appropriately used at the site-specific project level to provide an ecological context during project implementation.
DD

COMMENTS: Cite scientific references you used to define a desired mosaic of habitats that create adequate biodiversity and demonstrate how you will measure biodiversity based on that mosaic of patterns.
1369

RESPONSE: As we implement the Revised Plan, The Targhee will use relevant scientific literature and information from on-going cooperative research studies with several universities. Some assessments will use processes outlined in the following documents: Properly Functioning Condition Process - Version May 24, 1996; Riparian Area Management - Process for Assessing Properly Functioning Condition for Lentic Riparian-Wetland Areas. TR 1737-11, 1994; Riparian Area Management - Process for Assessing Properly Functioning Condition. TR 1737-9, 1993. DD

Discuss How You Will Maintain Mosaic

COMMENTS: Explain how you will maintain a mosaic of age classes and patterns if the forest only plans to harvest 1/5 of the growth of the Forest and how this approach protects forest health.
413

RESPONSE: A mosaic of age classes and patterns can be achieved by natural and prescribed fire, insect and disease activity, windthrow, timber harvest, and so forth, or a combination of these disturbances. The exact level of timber harvested will be determined through site-specific analysis aimed at producing timber and restoring ecosystem sustainability. DD

ECOSYSTEM MANAGEMENT - NATURAL DISTURBANCES

Address Ecological Consequences for Unmanaged vs. Managed Land Perspective

COMMENTS: Include studies like UCRB that indicate unmanaged lands are more

ECOSYSTEM MANAGEMENT - NATURAL DISTURBANCES

resilient and healthy and have more natural disturbances patterns and fire regimes than managed lands.

643, 695

RESPONSE: The Forest considered an array of scientific literature in completing the Final EIS and Revised Plan, including some of the available literature used for the UCRB. The Targhee will continue to use these and other science to plan and implement management activities. DD

COMMENTS: Discuss the broader ecological consequences of natural disturbance and suppression for long-term maintenance of biodiversity and sustainability.

643, 695

RESPONSE: The Forest considered the consequences of natural disturbance and fire suppression in more detail relative to sustainability and biodiversity during preparation of the Final EIS and Revised Plan. The Final Revised Plan includes more specific direction on this subject than did the Draft. DD

Modify Goal of Ecological Processes and Patterns

COMMENTS: Change goal for ecological processes and patterns from maintaining a mosaic of age classes and types of vegetation to one that focuses on preserving the full complement of native flora and fauna with maintenance of genetic species community and landscape diversity.

697

RESPONSE: The Final Revised Plan includes direction on maintenance of properly functioning condition of ecosystems at various geographic scales. It also includes new goals to maintain and restore biodiversity. DD

COMMENTS: Add to the ecological goal that you want to prevent new listings of Threatened and Endangered Species.

389

RESPONSE: This is implied within other goals and policies (such as sensitive species listing to prevent threatened and endangered status) involving properly functioning condition of ecosystems, biodiversity, fisheries, and wildlife. DD

COMMENTS: Change goal to, "provide well-planned and executed fire management programs that mimic natural fire regimes, are efficient and are responsive to resources and meet goals and objectives."

389

RESPONSE: The Forest included such a goal in the Final Revised Plan. DD

Include Beneficial Role of Natural Disturbances

COMMENTS: Review your approach to ecological processes. Provide more comprehensive discussion of the beneficial good that natural disturbances play in the ecosystem. Your emphasis is not to preserve and work with natural

ECOSYSTEM MANAGEMENT - NATURAL DISTURBANCES

ecosystem processes such as fire, insects and disease, but rather to suppress them. Document is full of these kinds of contradictions.

282, 489, 643, 1446

RESPONSE: The Final Revised Plan acknowledges the beneficial roles natural disturbances play in sustaining ecosystems and emphasizes restoration of these natural processes where feasible. DD

COMMENTS: Correct misconceptions about the role of natural disturbances and processes of succession which have led to erroneous conclusions regarding existing conditions and historical conditions.

643

RESPONSE: The Final EIS more clearly describes the role of natural disturbances, plant succession, existing vegetative condition, and historical vegetative conditions. DD

COMMENTS: Include possible future effects of natural disturbances. They may have an effect on the biological potential for primary cavity nesting habitat more so than vegetation management.

1365

RESPONSE: The Forest considered the possible future effects of natural disturbances on biological potential for primary cavity nesting habitat in development of the Final Forest Plan. This is reflected in the management direction relative to restoring ecosystems to properly functioning condition; the use of natural and prescribed fire; and retention levels of snags, green replacement trees, and down woody material. DD

Provide Direction to Allow Natural Disturbances to Function

COMMENTS: Let nature take its course.

42, 174, 175, 643, 1387, 1392

Let natural processes function in their unmanaged role and reap the outputs as they are available without seriously compromising natural processes.

695

Prevent the active suppression of fire or other natural disturbances. This is not good management for the long-term maintenance of diversity and sustainability.

174, 175, 181, 282, 643

Reassess goals, objectives, standards and guides for ecological processes and patterns. The way it is written, you will use silviculture and grazing techniques to manage forest ecology. Allow natural disturbances to play their unique role.

697

Include specific direction to require preservation of natural ecosystem processes such as fire, insects and disease and provide specific direction on how to maintain positive outcomes of these processes, especially in AIZs. Make intent of the forest clear so ground management conforms with EM philosophy.

643, 1194, 1401

ECOSYSTEM MANAGEMENT - NATURAL DISTURBANCES

RESPONSE: The Forest Service is mandated to use ecosystem management to maintain and restore ecosystem sustainability while producing a variety of goods and services. Simply letting nature take its course does not accomplish this mandate. Instead, the Forest will implement management activities which improve and restore ecosystems to properly functioning condition. Processes are outlined in the following documents: Properly Functioning Condition Process - Version May 24, 1996 Draft (Page 31); Riparian Area Management, Process for Assessing Properly Functioning Condition, TR 1737-9 1993 (Page 51); and Riparian Area Management, Process for Assessing Properly Functioning Condition for Lentic Riparian - Wetland Areas, TR 1737-11 1994 (Page 37). DD

COMMENTS: Include specific direction and standards and guides to maintain the positive outcomes of natural disturbances. Instead, emphasis is on limiting their influence.

643

Establish objectives, standards and guides that allow for natural processes such as fire, avalanches, floods and episodic outbreaks that provide for large and small scale disturbances as a means of providing ecosystem diversity.

1273b

RESPONSE: The Revised Plan acknowledges the roles that natural disturbances play in sustaining ecosystems and emphasizes restoration of these natural processes where feasible. DD

COMMENTS: Emphasize managing natural disturbances to protect structures and human safety, while allowing more of forest restoration to occur through natural fire.

1273b

Control fires and insect and disease outbreaks. We are opposed to letting these disturbances run rampant.

1261, 1457

RESPONSE: The Final Revised Plan acknowledges the roles that natural disturbances play in sustaining ecosystems and emphasizes restoration of these natural processes where feasible (in compliance to pertinent laws, regulation, and Forest Plan). At the same time, the Forest is mandated to use ecosystem management to maintain and restore ecosystem sustainability while producing a variety of goods and services. Always letting nature take its course does not accomplish this mandate. The Forest will use a combination of natural disturbances and prescribed management activities to improve and restore ecosystems to properly functioning condition. The processes the Forest will use are outlined in the following documents: Properly Functioning Condition Process - Version May 24, 1996 Draft (Page 31); Riparian Area Management, Process for Assessing Properly Functioning Condition, TR 1737-9 1993 (Page 51); and Riparian Area Management, Process for Assessing Properly Functioning Condition for Lentic Riparian - Wetland Areas, TR 1737-11 1994 (Page 37). DD

ECOSYSTEM MANAGEMENT - NATURAL DISTURBANCES

Incorporate Studies that Address Ecology of Greater Yellowstone Area

COMMENTS: Incorporate various peer reviewed studies that address the ecology of the Greater Yellowstone Area. None are cited and few assertions are supported with appropriate citations.

489

RESPONSE: In development of the Final EIS, the Forest used an array of scientific literature, including those that address the ecology of the Greater Yellowstone Area. Additional scientific literature will be used as the Revised Plan is implemented. DD

Clarify/Integrate Ecological Process and Elements

COMMENTS: Explain the difference between ecological processes and ecological elements. This is confusing unless they are the same. Be consistent in your use of terms.

1446

RESPONSE: Ecological process refers to a series of natural biological, physical, and social actions or events that link the growth and development of organisms (including humans) within their environments. In the field of landscape ecology, landscapes are characterized as to pattern. Patterns are often described in terms of ecological elements which are the discrete units or patches, including vegetative types, roads, buildings, fields, and so forth. DD

COMMENTS: Improve ecological view by linking biological components from ecological processes, e.g., fire, insects or other natural disturbances.

697

Integrate ecological function across boundary lines that address downstream conditions and ecological effects of management activities.

643

RESPONSE: The Forest improved the discussion of ecological processes in the effects analysis in the Final EIS. DD

ECOSYSTEM MANAGEMENT - OLD GROWTH

Old Growth and Disturbance Hazards are Inaccurate

(CROSS REFERENCE: Timber, Old Growth)

COMMENTS: There is no evidence that intensive logging of "mature" stands will reduce disturbance hazards.

1368

RESPONSE: Logging mature stands reduces disturbance hazards through the removal of species that provide ladder fuels or by reducing the density of trees. DM

ECOSYSTEM MANAGEMENT - OLD GROWTH

COMMENTS: No scientific evidence or analysis is offered in support of statements that the replacement of existing stands with younger trees reduces mortality caused by insect and disease.

1368

RESPONSE: Amman 1978, listed the following stand characteristics associated with epidemics: 1) trees more than 80 years old; 2) mean tree diameters over 8 inches; 3) a substantial proportion of trees over 12 inches dbh with phloem thickness of 0.1 inches or more; and 4) elevations where temperatures are optimum for brood development. DM

COMMENTS: Correct the DEIS's flawed assumption that "mature" forests are usually less susceptible to stand replacing fire than younger stands. Forest fragmentation and removal of older green trees, snag and down wood, can reduce the capacity for biological pest control.

1368

Provide evidence to support EIS contention that overstory removal and regeneration in mature stands will reduce fire, insect and disease hazards since intensive logging in mature stands would more likely exacerbate fire, insect and pathogen outbreak intensities and durations.

1368

DEIS (Page III-6) portrays an overriding concern that mature age classes are more susceptible to stand-replacing fires. If the Targhee National Forest is to move toward Ecosystem Management that more closely emulates natural processes, managing for a larger portion of mature forests would be appropriate.

489

Discuss your claim that the lack of old growth is due to ecological conditions which do not favor very old trees. Various studies dispute this conclusion.

643

RESPONSE: A write-up on old growth is incorporated into the Final Environmental Impact Statement (FEIS). Additionally, standards and guidelines pertaining to old growth are added to the Revised Plan under Biodiversity, Chapter III. Past information on old growth is derived from analyzing the permanent Forest inventory plots. Data from the plots was compared to the region's old growth definitions to better determine the amount of old growth that might be present on the Targhee. This information was extrapolated across the Forest, using the inventory plots as a representative sample.

Biological pest control will be evaluated on a case-by-case basis at the landscape or project level of analysis.

Through the removal of species that provide ladder fuels or by reducing the density of trees, the Forest may achieve levels of older trees higher than what historically occupied the site. DM

COMMENTS: In subsection descriptions, the plan's definition of old growth concludes these types of mature stands are more susceptible to large fires and insects and disease. Silvicultural systems that promote mature and old growth stands increase the risk of insect and disease epidemics. Characteristics of large diameter, low vigor attract insects and disease. To reduce

ECOSYSTEM MANAGEMENT - OLD GROWTH

susceptibility to insects and disease is to convert to a younger age class, thereby allowing for more harvest of old growth.

695

RESPONSE: Your comments are acknowledged. Refer to the additional standards and guidelines concerning old growth added to the Biodiversity section of the Revised Plan, Chapter III. The old growth component provides critical habitat for forest interior dependent species, many of which are on the Forest's sensitive species list. It is important to maintain and perpetuate old growth conditions on both spatial and temporal scales to meet the needs of these species. DM

ECOSYSTEM MANAGEMENT - PATCH SIZE

Human Management Not the Same as Natural Disturbances

COMMENTS: Consider that restoring patterns to the landscape does not necessarily have the same effect as restoring the processes that formerly caused the pattern, e.g., clearcuts to mimic fires versus fire in a natural role.

1273b

RESPONSE: The Forest acknowledges that the natural processes of fire, windthrow, insect and disease activity create the patterns seen on the landscape. These processes cannot be exactly duplicated through artificial means such as timber harvest. However, the Forest considers it as beneficial to attempt to restore patterns when accomplishing timber management and prescribed burning. DD

COMMENTS: A mosaic of age classes and types of vegetation sustained through time has not existed with proactive management. Natural disturbances have resulted in a pure, even-aged lodgepole pine stand.

393

RESPONSE: Within the Targhee as a whole, a mosaic of age classes and types of vegetation existed through time, even within the lodgepole pine type. While natural disturbances within lodgepole pine stands tend to perpetuate stands which are relatively large, simple and even-aged, measurable variation in patch size, plant diversity and age class exists and is reflected within the potential plant community for a particular site. Factors affecting site potential include topography, soil type, elevation, aspect, and annual precipitation. DD

COMMENTS: Consider that natural patches have rich internal patch structure where fragmented landscape has simplified patches; natural landscape has less contrast between adjacent patches and less intense edge effects; roads and various human activities pose specific problems to wildlife population viability.

1367

RESPONSE: The Forest acknowledges that natural patches tend to have richer internal patch structure and traditional timber harvest practices tend to

ECOSYSTEM MANAGEMENT - PATCH SIZE

simplify internal patch structure. The Forest will incorporate this information into future silviculture prescriptions. The Revised Plan provides goals to improve the management of biodiversity, snag and down wood retention, patch size and shape, age class diversity, and natural and prescribed fire. The Forest acknowledges that roads and associated human activities pose problems to some wildlife species. To reduce conflicts with wildlife, and to achieve other resource objectives, the Revised Plan greatly reduces open road and trail densities. DD

COMMENTS: Consider that species and habitats intended to be beneficiaries of habitat manipulation (patches) may not respond as predicted, while other non-focal species may be negatively impacted.

643

RESPONSE: Your comments are acknowledged. The Forest will use the best science available when forested habitats (created patches) are manipulated. The Forest will adjust future actions based on the results of monitoring. DD

Clarify Your Use of Patch Size

COMMENTS: Clarify confusion between forest patch size and opening size. They are not the same thing. Forest patches can be larger or smaller than catastrophic disturbances.

1368

Evaluate the distribution of patch size within the context of the entire forest and adjacent land. Any further fragmentation or reductions in patch size as a result of timber management must be carefully evaluated.

489

Fully explain the use of patch size as an indicator of sustainability. The idea is confusing. Explain how much and what kind of information you have that supports using this indicator.

325, 643

RESPONSE: Various plant communities are sustained over time through natural processes such as fire, insect and disease activity, grazing, flooding, and windthrow. These processes recycle nutrients, control plant succession, and provide habitats for wildlife species, many of which contribute to sustaining the very conditions that are necessary for the natural processes to operate. For example, insects and diseases often create patches and, in some ecosystems, provide the fuels necessary for fire to start and spread. These natural processes are reflected on the landscape in a characteristic pattern of patches of various sizes, shapes and structure. They are the "signature" of the landscape and give insight as to how individual landscapes have been sustained over time. For example, on a given landscape, if patch size caused by fire is generally 100-300 acres and fires begin to exceed 1000-2000 acres, it indicates that the system is not sustainable and is at risk of catastrophic damage from fire. This situation commonly occurs as a result of fuel loading in excess of natural levels. Excessive fuel loading is commonly caused by fire exclusion. When fire is excluded, patches appear to "grow together" into larger connected patches. Fuels build up in the form of dead trees through the processes of plant succession and insect and disease outbreaks. The result is larger, more intense fires.

ECOSYSTEM MANAGEMENT - PATCH SIZE

By regulation (36 CFR 219.27), a "created opening" is an opening in the forest canopy created by the application of even-aged silvicultural practices such as clearcuts and group selection harvest. A patch is an area of vegetation that is internally homogeneous, differing from the surrounding vegetation. Patches are recognizable at various geographic scales.

A complete discussion of how the Forest will use patch size as an indicator of sustainability is found in the draft document entitled Properly Functioning Condition Process - Draft 1996. In brief, vegetation "patterns" is one of four criteria used to evaluate properly functioning condition of ecosystems. Indicators of patterns include connectivity, patch shape, patch size, and patch distribution. Each of these criteria can be assessed at three geographic scales: regional, subregional, and landscape. The landscape scale is hundreds to thousands of acres. DD/LB

COMMENTS: Clarify how the forest will use patch size to manage within the range of natural variation (RNV). Forest acknowledges the nature and magnitude of the RNV but little is known at this time.

1273b

Consider the patch size is a narrow view of EM sustainability; however, past history of salvage logging may make this a pertinent parameter.

317

Tie historic patch size to planned management and state objectives in regard to patch size.

1369

Account for the relative representation of seral plant communities on the landscape with patch size indicator. Include relative abundance and distributions of differing patch compositions in patch size indicator. Exclusive reliance on patch size and vague biodiversity objectives will not ensure biodiversity is conserved.

1368

Patch size indicator alone may not be sufficient to ensure all habitat types are represented on the landscape in appropriate age and distribution patterns that approximate the RNV.

643

RESPONSE: The Forest will manage ecosystems in properly functioning condition. This entails an evaluation of four criteria: structure, composition, disturbance regimes, and patterns. Within properly functioning (sustainable) ecosystems, these criteria function within a range of natural variability. Patch size, patch shape, patch distribution, and connectivity can be used to evaluate the "patterns" criteria. The range in variation of patch size, shape and distribution can be evaluated against historic (100-400 years) ranges.

Percent seral stage and age class distribution can be used to evaluate the "structure" criteria.

The process used to assess ecosystem sustainability is described in a draft document entitled Properly Functioning Condition Process - Draft 1996. DD

ECOSYSTEM MANAGEMENT - PATCH SIZE

Consider Other Patch Size Related Indicators of Forest Health

COMMENTS: Integrate the difference between timber management induced patch sizes and naturally caused patches and the effects of the 30% hydrologic disturbance factor on patch size. (CROSS REFERENCE: Riparian, HD 30%)
1367a

RESPONSE: The 30% hydrologic disturbance factor does not have a direct effect on patch size. Calculating hydrologic disturbance involves measuring the amount of a watershed that has changed in natural streamflow quantities and character. The cause of the change may be either management induced or natural. DD/DM

COMMENTS: Include principles of island biogeography that include direct relations between species numbers, richness and refuge size, and a direct relationship between the relaxation rate and the distance from the continent or source populations. (CROSS REFERENCE: Centennials)
410

RESPONSE: The theory of island biogeography is relatively new and is largely untested for ecosystems such as the Centennial Mountains. The Forest protected the structure and function of the Centennials within the Preferred Alternative through the application of management prescriptions, standards, and guidelines. The concept of protecting the structure and function of the Centennial Mountains was addressed in NFMA and NEPA analysis entitled "Re-establishment of Aspen Plant Communities in the Camas Creek Watershed", 1996. In the future, the Forest intends to use information gained from a corridor analysis by the US Fish and Wildlife Service to help plan and evaluate other Forest projects in the Centennial Mountains. DD/DM

COMMENTS: Include forest patch sizes. Your indicator only describes the amount of land subject to clearcut limitations. Restrictions on clearcut size will cause a loss of large patches only if those patches become riddled with holes from over zealous cutting. (CROSS REFERENCE: Timber, Silvicultural Harvest Methods).
1368

RESPONSE: The indicator selected in the Draft EIS to measure "sustainability, fire, and natural disturbances" was titled "percent of the Forest with limitations on the size of created openings or patches" (Chapter II). This indicator is not used in the Final EIS. The Final Revised Plan describes a process for determining Properly Functioning Conditions which uses a variety of ecological indicators including patch size. DD

COMMENTS: Consider that landscape structure and patch size may be adequate for those species where patch size distribution is a primary determinant of population, but fails to address the complex mechanistic relationships that may cause declines in other species. No "fine filter" was used. (CROSS REFERENCE: Wildlife, EM)
643, 1368

ECOSYSTEM MANAGEMENT - PATCH SIZE

RESPONSE: The Forest used the habitat requirements of a host of "management indicator species", research study areas and unique areas identified by the State of Idaho as a "fine filter". The "management indicator species" include all of the threatened, endangered, and sensitive species. When management activities are proposed, planned, and implemented at the project level, the Forest evaluates the potential impacts to these special habitats and species as well as threatened, endangered, and sensitive species. DD/MO

COMMENTS: Discuss the impact of existing fragmentation and how this will change with selected alternative. (CROSS REFERENCE: Timber)

1369

RESPONSE: The existing condition of the landscape, including the level of fragmentation, is considered during effects analysis of the various alternatives. The level of fragmentation is also a consideration when setting road density standards, ASQ, and other resource objectives affected by forest fragmentation. DD/MO

COMMENTS: Not enough is known about historical landscape patterns and patch dynamics to attempt to depict landscape level patterns or justify various habitat manipulations.

Missing Letter #

RESPONSE: In the field of natural resource management, it is difficult to accurately predict outcomes; however, this is not an excuse to do nothing. The Forest will use the best science available to manage resources. Outcomes of management activities will be monitored and adjustments made based on monitoring results. DD

Change/Reanalyze Patch Size

COMMENTS: Supports 40 acre patch size.

1242

Reduce patch size because there is no evidence patch size is sustainable; because 20 acres is better; because clearcutting in small 5 to 40 acres irregularly shaped clearcuts provides 46.5 times as much nutrition per acre for elk than do forested acres; and because 16 hectares with good cover nearby, an absence of slash and high vegetation height provides the necessary forage for big game.

61, 175, 212, 275, 1367

Increase patch size to 3,000 to 10,000 acre over 20 to 30 years because this is more representative of historical patches and increases biodiversity. Increase patch size to reduce cookie cutter effect and fragmentation on the forest.

413

Increase 40-acre patch size and apply to all of the forest, not just 14%. Limiting this requirement will not remotely approximate disturbance regimes suggested in the Forest proposal. Make this a standard.

1365

Mandated harvest unit size or single species consideration should not be allowed to dictate ecological management that is outside the RNV.

432

ECOSYSTEM MANAGEMENT - PATCH SIZE

Standardize the maximum clearcut patch size and dimensions to adequately protect fish and wildlife.

1449

Stay within patch size limit set by NFMA and Regional Guide. Tier timber even-aged management patch size to regional direction which state created openings larger than 40 acres requires Regional Forester approval.

1273b

Determination of appropriate patch size should be peer-reviewed by scientific community.

731

Cite scientific data for established clearcut size and consider that light, wind, moisture regime, and vertical stratification of vegetation in an area may be such that the area is no longer a created opening.

1446

A 40-acre opening makes no sense and contradicts research that indicates canopy cover should range from 50 - 90% in the PFA. The PFA should remain unmanaged and undisturbed.

643, 1369

RESPONSE: The 40 acre "created opening" size limitation is a federal regulation (36 Code of Federal Regulations 219.27) based on the National Forest Management Act (NFMA). Forest Service policy allows for exceptions to this limitation as described in the Regional Guide. Many management prescriptions limit "created openings" to areas much smaller than 40 acres. This is prescribed only when necessary to achieve specific resource objectives such as for grizzly bear and goshawk habitat. DD/LB

COMMENTS: Evaluate the distribution of patch size within the context of the entire forest and adjacent land. Any further fragmentation or reductions in patch size as a result of timber management must be carefully evaluated.

489

Include natural or man-made gaps in any analyses for mean patch size. Forest must look at smaller openings as well as openings that remove the forest canopy over a large number of acres. Allow prescribed burning in highly fragmented areas. Logging has increased the mean number of patches and total perimeter. It has caused a decrease in mean patch perimeter, mean patch shape, mean patch size and factual dimension.

1273b

Complete a thorough landscape analysis on the effects of forest fragmentation including determinations of the amount of forest interior habitat, mean and median patch size, patch area/perimeter ratios, demographics, genetics, and connectivity between forest stands to evaluate the effects on biodiversity and on Threatened and Endangered Species. Only alternatives that do not contribute to further fragmentation should be considered.

1365

RESPONSE: The Forest will use all of the tools available to characterize present and historic landscapes. The Forest collaborates with universities and researchers to gain the necessary information needed to improve management of forested, shrub/grass, and riparian/aquatic ecosystems. The knowledge learned thus far is incorporated into the Revised Plan. The Forest

will continue to collaborate with the scientific community as it implements the Revised Plan. DD

COMMENTS: Use expanded fire cycles to determine the percent of average openness. If you use Yellowstone National Park fires, the average openness would be about 60%. Limit of 14% is abnormally low. If you used Yellowstone National Park average of 60% plus 14% you proposed from 1911 cover, the average openness would be about 37%.

275

RESPONSE: The Forest acknowledges that the 14% value estimated for the Preferred Alternative is much lower than what occurred historically. The lower value is the result of many factors including: 1) requirements to meet habitat needs for grizzly bear and goshawk; 2) requirements to protect scenic values; 3) requirements to protect our existing facilities and private property; and 4) the need to mitigate the effects of past timber management. DD/LB

Distance Between Patches

COMMENTS: Provide 40-acre patch size and distance between patches for the whole forest, not just for a small percentage of the Forest. Provide an assurance that when a 40-acre opening is cut, another 40-acre opening cannot be created immediately adjacent to the first.

58, 305

RESPONSE: The Forest will manage patch size based on the ecological character of the area, the management prescription within which the area lies, public input, and regulations. DD/DP

Change/Add to Analysis and Effect of Patch Size/Fragmentation/Connectivity

COMMENTS: Discuss cumulative effects of clearcutting on patch size and fragmentation. Include these in calculating the portion of the forest in mature stage or when evaluating treatments to reduce conifer encroachment in aspen. (CROSS REFERENCE: Timber, Aspen)

643, 489

RESPONSE: The Forest added discussion on fragmentation in Chapter IV of the Final EIS. The Final Revised Plan contains management direction to evaluate patch size, fragmentation, and other ecological indicators when analyzing potential timber harvest activities. Comparisons of natural patterns to those created by past clearcutting would be part of any assessment where it is determined to be a relevant issue. DD/DP

COMMENTS: Discuss the effects of patch size in environmentally stressed areas; especially regarding microclimatic and hydrologic changes as a consequence of harvest. Harvest leads to increased ground temperature, desiccation, soil erosion, etc.

1314, 1360

ECOSYSTEM MANAGEMENT - PATCH SIZE

RESPONSE: The Forest acknowledges that changes in microclimate and hydrologic function tend to increase as the size of a created opening increases. This will be taken into account when we prescribe silvicultural treatments. DD

COMMENTS: Consider that unscheduled harvests designed to bring patch size and stand characteristics into accordance with historical range of variation may have exactly the opposite effect than what was originally intended. (CROSS REFERENCE: Timber, Unscheduled Timber Harvest)

643

RESPONSE: Unscheduled harvest will occur on Forested lands that are not included in the timber base (ASQ). Volume harvested would be a secondary benefit of any proposed activity on unscheduled lands. Timber harvest is used where necessary to meet specific ecological needs, not to produce timber as a commodity. Unscheduled timber harvest is not mandatory and is subject to site specific NEPA analysis where effects are analyzed. DD/LB

Goshawk Constraints

COMMENTS: Reconsider conclusions that limitation on opening size, established in goshawk guidelines to maintain large forest patches, will move the forest away from its RNV and will create a threat to forest health. (CROSS REFERENCE: Wildlife, Goshawk)

228, 413, 1368

RESPONSE: The 40 acre "created opening" size limitation is a federal regulation (36 Code of Federal Regulations 219.27) based on the National Forest Management Act (NFMA) and applies to all areas of the forest, not just portions of goshawk habitat. A "created opening" is an opening in the forest canopy created by the application of even-aged silvicultural practices such as clearcuts and group selection harvest. Forest Service policy allows for exceptions to this limitation as described in the Regional Guide. The guideline to not create openings within the "nest area" is intended to protect specific habitat requirements for nesting. In many cases, uneven-aged timber management, which is permitted within goshawk habitat, can be used to restore large forest patches. DD/MO

Wildlife

COMMENTS: Discuss effects of openings on species other than those who appear to thrive in patches. Increases in edge species can dramatically alter natural community assemblages. (CROSS REFERENCE: Wildlife, EM)

1367

RESPONSE: The Forest uses a host of "management indicator species" in the broad-scale analysis of effects. The "management indicator species" include all of the Forest's threatened, endangered, and sensitive species. The effects of forest fragmentation on western coniferous forests is not well-defined and needs more research. Consequently, the discussion of effects of fragmentation in the Final EIS is quite brief. The Forest is currently involved in two research projects aimed at learning more about the effects of forest fragmentation on neotropical migratory birds and forest carnivores.

Also, the Final Revised Plan provides direction to manage forest ecosystems in properly functioning condition and outlines a process for doing so. DD/MO

Aquatic Zones:

COMMENTS: Use aquatic connectivity as an indicator of ecosystem patterns. Discuss how aquatic connectivity is measured; how critical values are determined; and why maintaining connectivity in 448,000 acres of aquatic zone is preferred choice.

1362

RESPONSE: As described in Process Paper-Key Indicators for Fisheries and Aquatic Ecosystems, aquatic connectivity was measured as "acres of aquatic influence zone managed to maintain connectivity." The rationale was: Habitat fragmentation/connectivity occurs both longitudinally and laterally and takes place within the aquatic influence zone. Connectivity is the inverse to fragmentation. The assumptions used were: 1) traditional roading, timber management, and livestock grazing tend to reduce aquatic connectivity; 2) the aquatic management prescription (e.g., buffer widths), standards and guidelines defined in Alternatives 3-M, 4, 5, and 6 will adequately maintain aquatic connectivity in the future; 3) narrower buffers provide less connectivity; and 4) other Management Prescriptions compatible with the aquatic prescription (such as wilderness or roadless) also maintain connectivity.

The Revised Plan proposes maintaining connectivity on 512,000 acres. This acre value resulted from adoption of the "full" buffer widths combined with those management prescriptions with compatible objectives (such as wilderness or roadless) found within the Preferred Alternative. DD

Use Fragmentation Patterns and Connectivity as the Indicator for EM Health
Along with a Patch Size

COMMENTS: State how patch size and connectivity will be managed in conjunction with other habitat factors. Use distribution, patch size and connectivity of habitats. You have devised an evaluation system which prevents meaningful analysis of habitat impacts or viability from your proposed management actions and further reducing forest-wide patch size will result in greater fragmentation than already exists. Include an analysis of fragmentation patterns and connectivity with patch size as a more comprehensive indicator for EM.

643, 1369

RESPONSE: The Final Revised Plan contains direction to manage ecosystems in properly functioning condition. This entails an evaluation of four criteria: structure, composition, disturbance regimes, and patterns. Within properly functioning (sustainable) ecosystems, these criteria function within a range of natural variability. Patch size, patch shape, patch distribution and connectivity are measures of "patterns". The process the Forest will use to assess ecosystem sustainability is described in a draft document entitled Properly Functioning Condition Process - Draft 1996. DD

ECOSYSTEM MANAGEMENT - SITE-SPECIFIC

Centennials

COMMENTS: Rewrite the Centennial Subsection because severe fires, insects and disease are a natural component of this area; there is too much logging and roading already, with major impacts to wildlife; you are using RNV to reduce the risk of catastrophic events as an excuse to log the Centennials; and you don't know the real RNV.

695

RESPONSE: Refer to the Goals/Objectives and Standards/Guidelines for Properly Functioning Condition (PFC) and Fire in the Revised Plan. PFC is emphasized over RNV in the Revised Plan. The "setting" section provides a general overview for the subsection. Site-specific landscape analysis assessments or projects determine the feasibility and scale (spatial and temporal) of opportunities that exist within this subsection, and consider ecological, social and economic implications. These assessments identify associated risks and mitigation/management requirements (such as aggressive fire suppression) if no action is the most desirable option. DM

Lemhi/Medicine Lodge

COMMENTS: Rewrite Lemhi - Medicine Lodge Subsection, because there is a large amount of biodiversity with a large number of plants, animals and fungi species in spite of the fact that there is a lack of the species diversity; it is not undesirable that these forests are more susceptible to insects, disease and larger fires since that is within its normal process and function; plant associations should be managed for a longer Range of Natural Variability; natural processes should be allowed to function to create diversity; and the recreation objective to increase motorized use will cause more problems, especially on trails.

695

RESPONSE: Refer to the Goals/Objectives and Standards/Guidelines for Properly Functioning Condition (PFC) and Fire in the Revised Plan. PFC is emphasized over RNV in the Revised Plan. The "setting" section provides a general overview for the subsection. Site-specific landscape analysis assessments or projects determine the feasibility and scale (spatial and temporal) for opportunities that might exist within this subsection, and consider ecological, social and economic implications. These assessments identify the associated risks and mitigation/management requirements (such as aggressive fire suppression) if no action is the most desirable option. The Lemhi-Medicine Lodge Subsection contains no suitable timber lands within the 3M Alternative. Management activities rely on achieving other resource values or are responsive to natural events. Refer to the Objective for Recreation in this subsection which states, "Provide increased designated motorized road and trail access in a managed low impact method." DM

Teton Range

COMMENTS: Rewrite the Harvest Plans for the Teton Range Subsection because

ECOSYSTEM MANAGEMENT - SITE-SPECIFIC

this area has already had too much silvicultural treatment and does not need any more.

695

RESPONSE: The Teton Range Subsection contains no timber management emphasis prescriptions. Areas of suitable lands exist within this subsection but any timber management that might occur will be done in a manner that is sensitive to the resource objective(s) for the prescription area (such as visuals). Approximately 95% of the public lands in the subsection is not part of the suitable timber base and the remaining 5% has other management emphasis. DM

COMMENTS: Explain the term "over-mature vegetation" in an ecosystem context.

695

RESPONSE: Refer to the glossary section of the Revised Plan for the definition of this term. From an ecosystem context, the concern about vast acreages of overmature trees is that they might be more susceptible to insect and disease or fire, may lose diversity, or may be simplifying. DM

COMMENTS: Add a goal of fire management to restore bighorn sheep habitat, particularly winter habitat, that has been degraded by the natural fire regime.

699

RESPONSE: Refer to the first Fire Objectives in the Revised Plan which addresses development of fire management plans. DM

Caribou Subsection

COMMENTS: Rewrite the Caribou Subsection to explain why there is a risk of large fires and insect and disease outbreaks, but the area is outside the timber base in 3M.

695

RESPONSE: Portions of the Caribou Subsection are within the suitable timber base. These areas contribute toward ASQ. Risk to fire and insect and disease outbreaks is based on the fire groups that make up the Caribou Subsection and the amount of mature/over mature age classes. DM

Improve the Subsection Descriptions

COMMENTS: Discuss ecological analysis that is specific to the Targhee National Forest that form the basis for the descriptions of the subsections. Forest numbers are grossly inaccurate and misrepresent vegetation conditions.

643

RESPONSE: The setting sections provide a general overview of conditions within the various subsections. Numbers were derived from the Geographical Information System data base and reviewed several times by the Ranger Districts for accuracy. These figures and general observations are further evaluated and refined at the landscape or project level of analysis. DM

ECOSYSTEM MANAGEMENT - SITE-SPECIFIC

Jackpine Loop and Leigh Creek

COMMENTS: DEIS, III-2: While it may be true at higher elevations that the Teton Range and Centennials exhibit greater connectivity, it is unlikely to be true at lower elevations. Intensive timber harvests occurred in the Jackpine Loop and Leigh Creek Areas, creating unnatural openings that span hundreds of acres. Shrub slopes at lower elevations (critical ungulate range) are no longer bordered by good hiding and thermal cover due to timber harvest. Shrub slopes are in proximity to new houses, roads and activities on adjacent private lands. Roads and trails are present in almost all of the drainages in the Tetons. Teton Pass Road and the Ashton-Flagg Ranch Road may have a major effect on landscape connectivity for large and small animals.

643

RESPONSE: The subsection description (DEIS III-1 III, and IV) are general and are intended to provide basic information. Past activities are analyzed when future activities are proposed in these areas (such as cumulative effects analysis) in site-specific projects. DM

Big Holes

COMMENTS: Do not log the west slope of the Big Holes as a means of fire prevention.

Missing Letter #

RESPONSE: Virtually all of what might be described as the west slope of the Big Holes falls into Prescription 5.1.4 (b), 3.2 (i), and 2.7 (a). Timber harvests are scheduled in the 5.1.4 (b) Prescription for insect and disease treatment, but not in the others. No specific need is identified at this time to log this area as a means of fire prevention. DM

ECOSYSTEM MANAGEMENT - SUCCESSION

General

(Note: Discussions about Succession and Old Growth in lodgepole, Douglas-fir and aspen are cross-referenced in Timber; Discussions about Succession and Late Seral in sagebrush are cross-referenced in Range, Sagebrush.)

COMMENTS: Expand and include current thinking and knowledge of community ecology and dynamics. Current theories on the state and transition model of community change have not been incorporated. Show that vegetation composition does not follow a predictable unidirectional advancement from early post disturbance communities until it reaches a preconceived vegetation climax.

643, 1446

Attributing all of the changes in forest and shrub communities to fire suppression oversimplifies the complex processes that interact to cause changes in forest communities such as the effects of grazing that have shifted species composition of the riparian areas and have contributed to Doug-fir encroachment in aspen stands.

643

ECOSYSTEM MANAGEMENT - SUCCESSION

Consider that vegetation composition does not follow a predictable unidirectional advancement from early post disturbance communities until it reaches a preconceived vegetation climax. Most studies have shown this is not the case, but more dependent on species present prior to disturbance and a mix of slope, soils, aspect, elevation and other topo-edaphic factors that characterize the site.

643

RESPONSE: Grazing effects are included in the discussion on succession. Within a forestwide document, introducing some of the major influences such as fire suppression that have an effect on plant succession is appropriate. At the landscape or project level, the Forest looks at things in more detail. The Targhee is working with Montana State University to develop modeling procedures. Much of this work is still conceptual or in the testing stage and is unavailable for incorporation into the revision process. As the Forest's landscape efforts proceed, these concepts may lead to amendments to the Revised Plan as more knowledge/insight is gained about the various ecosystems that make up the Targhee. DM

COMMENTS: Define why a variety of successional stages is a management objective. Describe why this is needed to maintain wildlife and how patch size and connectivity will be managed with other habitat factors.

1369

RESPONSE: The objective of managing for an array of successional stages is to improve the overall biodiversity in sections of the Targhee. Mixes of successional stages and the maintenance of key species (e.g., aspen) makes the ecosystem more resistant to perturbations and more resilient when perturbations occur (keeps the systems from becoming simplified). Refer to the Properly Functioning Condition section of the Revised Plan under "Ecological Processes and Patterns", Chapter III. An array of ecological indices (e.g., patch size, patch shape, connectivity, diversity) are being considered at the Forest's landscape level analysis and are being evaluated when considering management options. The intent of the Revised Plan is to introduce some of these key concepts and to lay the foundation for finer levels of analysis that are or will be occurring on the Forest. DM

COMMENTS: Include stand structure characteristics in your criteria for late successional. Include minimal basal area, snag density and average dbh requirement so public can understand the value of late successional to wildlife.

1369

RESPONSE: Please refer to the Old Growth and Late Successional Forest section within the Final Environmental Impact Statement. In particular, refer to the Table AA. DM

COMMENTS: Correct contradictions that upland non-forested areas are trending toward a predominant mid to late seral stage and then contradicting statements that mid-seral stage is a satisfactory ecological condition. This illustrates how classic succession theory can get you into trouble.

489

ECOSYSTEM MANAGEMENT - SUCCESSION

RESPONSE: Chapter III of the Revised Plan states: "Satisfactory ecological condition is defined as being in mid-seral stage or higher ecological status and having a stable or upward trend in soil and vegetation condition". Several factors are evaluated in arriving at ecological condition. Refer to the glossary section of the Revised Plan for the definition of "Desired Vegetation Condition". DM

Ecological Processes - Climate Factors

COMMENTS: Include a discussion of climatic factors that have stimulated forest changes. Regional climatic trends have trended toward warmer and wetter growing seasons since the end of the Little Ice Age.

643

Consider large-scale meteorological mechanisms, like El Nino-Southern Oscillation, and relationship to local processes such as vegetation development of fuels accumulation that affect fire frequencies or intensity. These local events may be swamped by larger spatial and temporal events.

1273b

RESPONSE: These comments are outside the scope of this document. DM

ELK - ANALYSIS PROCESS

General

COMMENTS: The key issues that drive the Plan should address the health of the resource not elk security because elk security allows Fish and Game to force the Forest into unhealthy management of both timber and range.

432

RESPONSE: Elk security was only one of the key issues considered in the Revised Plan. Other key issues were sustainability, fire and natural disturbances, riparian, grizzly bear management, access, roadless area management, and timber harvest. These and numerous other issues were all considered in the analysis for the Revised Plan. The Forest works cooperatively with the State Fish and Game agencies to help them meet their objectives while also meeting the other multiple uses mandate of the Forest Service. A healthy ecosystem includes healthy elk, range and timber. MO

COMMENTS: Explain why Alternative 2 (in DEIS chapter 2) "slightly improves" elk security when alternative 3M (in DEIS chapter 2) "greatly improves" elk security with only a 1/2 increase. Define terms, explain standards.

629a

RESPONSE: We agree that the terms "slightly improves" and "greatly improves" are relative and subjective. That is why the actual percent change in acres of the Forest meeting elk vulnerability thresholds was displayed in the DEIS and is displayed in the FEIS. MO

COMMENTS: The Forest fails to accurately state the agreed upon State of Idaho elk hunting objectives.

766

RESPONSE: In the DEIS, the Forest accurately stated a portion of the State of Idaho elk hunting objectives. For the FEIS, the Forest accurately states the entire State of Idaho elk hunting objectives. Elk hunting objectives are set by the State Fish and Game agencies. The Forest works with the State Fish and Game agencies to analyze how the Final Revised Plan contributes towards achieving their objectives. The Forest incorporated the State Fish and Game agency's most recent research on elk vulnerability into the Final Revised Plan and used an elk vulnerability model developed by the Idaho Department of Fish and Game. This model predicts overall bull elk vulnerability during the general elk rifle hunting season, based on motorized access and hunter densities. The model does not predict the number of branch antlered bulls which will remain in the population, nor the percentage of yearling bulls to be harvested, nor the percentage of mature bulls which will remain in the population. The Forest emphasized the portion of the State elk hunting objectives that fit the results of the analysis. Many factors affect elk vulnerability which are outside the control of the Forest Service, such as numbers of hunters, distribution of hunters, length of seasons, different types of seasons, and weather conditions. The Forest will continue to emphasize management of its contribution to elk vulnerability, but cannot plan for or control other factors and conditions. MO

ELK - ANALYSIS PROCESS

COMMENTS: Restate the first ecological component in the DFPR Chapter II: "manage to improve elk security."

766

RESPONSE: In the Draft, the Forest used the statement: "Manage to reduce elk vulnerability." Reduced elk vulnerability is the modeling tool that shows improvements in elk security. The wording is better clarified in the Final Revised Plan. MO

COMMENTS: Address elk vulnerability/effectiveness. Revise the following: decrease elk vulnerability, increase elk habitat effectiveness and cross-country motorized closures, and increase elk security through effective roads & trails.

766

RESPONSE: The Revised Plan decreases elk vulnerability by closing more roads and trails to motorized travel and by reducing the amount of the Forest open to summer cross-country motorized travel from 62% to 7%; increases elk habitat effectiveness by closing more roads and trails to motorized travel and increases cover as previously harvested areas grow back into tree cover; emphasizes making road and trail closures effective, and makes road closure effectiveness monitoring a number one priority monitoring item. MO

COMMENTS: Road closures to protect big game require: more analysis, better methods and science, stricter standards and guidelines, and better adherence to environmental laws.

1361

RESPONSE: The analysis of roads and trails for the Final Revised Plan includes a complete Forestwide inventory. Other agencies, such as the Idaho Department of Fish and Game, assisted with the inventory. Every existing road and trail closure is evaluated for its effectiveness. Cross-country OHV travel incorporated GIS technology showing slope and vegetation characteristics that identify areas of the Forest where OHV travel can occur.

The Revised Plan establishes open road and open motorized trail route densities using standards for every area of the Forest.

The Forest used the most recent research on elk vulnerability and the most recent guidelines for motorized access in grizzly bear habitat. The Forest is adhering to all environmental laws. MO

Criticism of Elk Vulnerability Figures Used by the Forest

COMMENTS: The Plan indicates 91% of the Forest meets Idaho Fish and Game's elk vulnerability thresholds, which is not true.

58

RESPONSE: Using the most recent research on elk vulnerability, which includes an elk vulnerability model developed by the Idaho Department of Fish and Game, the Forest predicts that in the preferred alternative, 89% of the Forest would meet the elk vulnerability thresholds established by the Idaho Fish and Game Department and the Wyoming Game and Fish Department. It will take several years to implement all of the changes in motorized access to achieve these

ELK - ANALYSIS PROCESS

predictions. Many factors are outside the control of the Forest Service which influence elk vulnerability, such as changes in the number of elk hunters, changes in elk seasons, weather patterns, and so forth. It will take monitoring and cooperative work with the State Fish and Game agencies to achieve the predicted results. MO

COMMENTS: To be realistic the Elk Vulnerability chart should be based on a percentage of the maximum attainable.

375

RESPONSE: The elk vulnerability chart accurately displays the percentage of the Forest which meets the elk vulnerability thresholds established by the State Fish and Game Departments. MO

Elk Vulnerability - Examine Other Studies

COMMENTS: Include a radio-telemetry study on elk.

766

RESPONSE: Information from the elk studies which were cooperatively funded by the State Fish and Game agencies and the Forest Service during the 1980s and early 1990s were used as the Forest worked with the State Fish and Game agencies to identify issues, and the actions needed to resolve the issues. Techniques for monitoring included radio-telemetry, depending on the researcher's preference and study objectives. MO

Elk Vulnerability - Winter and Summer Populations

COMMENTS: Elk sub-populations summering on the Targhee National Forest are not the same population that is visible on winter range; collect data on both populations because it is misleading to only collect data on winter populations.

766

RESPONSE: Data on elk populations is collected by the State Fish and Game agencies and shared with the Targhee. They have both summer and winter data about distributions of elk. MO

COMMENTS: A credible evaluation of big game population requires habitat quality and population size, spatial and temporal distribution of animals, herd composition, vulnerability to harvest, productivity, calf/fawn survival, quality of hunting experience, and the amount of hunting opportunity.

766

RESPONSE: The Forest Service is primarily responsible for managing the habitat for big game on National Forest lands. State Fish and Game agencies are primarily responsible for managing the big game populations. Big game population data is collected by the State Fish and Game agencies. Therefore, in the Final Revised Plan and Environmental Impact Statement, the Forest emphasizes the Forest Service responsibility for managing habitat conditions, and does not display detailed population data. MO

ELK - ANALYSIS PROCESS

COMMENTS: Correct errors and use the Idaho Fish & Game elk population numbers and methods.

690

RESPONSE: The Forest used the Idaho Fish and Game elk population numbers and methods. Information from the elk studies (which were cooperatively funded by the State Fish and Game agencies and the Forest Service during the 1980s and early 1990s) were used as the Forest worked with the State Fish and Game agencies to identify issues and the actions needed to resolve the issues. The Forest used the most recent research on elk vulnerability, which included an elk vulnerability model developed by the Idaho Department of Fish and Game and an elk habitat effectiveness model developed cooperatively with the State Fish and Game agencies. MO

Elk Hunting Objectives - Bull:Cow Ratio

COMMENTS: Incorporate more than just one indicator of elk vulnerability (bull:cow ratio on winter range) in order to adequately monitor elk security.

766, 1365

RESPONSE: The bull:cow ratio on winter ranges will not be the only indicator of elk vulnerability for monitoring. The State Fish and Game agencies collect a variety of information about big game populations, and the Forest will continue to work cooperatively with them to monitor both habitat conditions and big game populations on the Forest using other indicators. MO

COMMENTS: In the analysis of hunting qualities, include the number of elk available in the hunting season and the portion of total bulls comprised of branch antlered bulls.

766

RESPONSE: The Forest Service is primarily responsible for managing the habitat for big game populations on National Forests. State Fish and Game agencies are primarily responsible for managing the big game populations. Big game population data is collected by the State Fish and Game agencies. In the Final Revised Plan and Environmental Impact Statement, the Forest emphasizes its responsibility for managing habitat conditions. The Forest does not display detailed population data. MO

COMMENTS: Complete the elk hunting objectives in the DEIS (Chapter III) by adding the following after the respective bull:cow ratio: for Ready Access units: "with 40% of bulls branch-antlered; and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 50% and the percentage of mature bulls (having at least 6 points on one antler) at or above 10%." For Front Range units: "with 50% of bulls branch-antlered; and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 35% and the percentage of mature bulls (having at least 6 points on one antler) at or above 20%."

643, 766

Include in the DEIS one of the four State of Idaho objectives for elk vulnerability.

766

ELK - ANALYSIS PROCESS

RESPONSE: Elk hunting objectives are set by the State Fish and Game agencies. The Forest works with the State Fish and Game agencies to analyze how the Final Revised Plan contributes towards achieving their objectives. The Forest incorporated the State Fish and Game agencies' most recent research on elk vulnerability into the Final Revised Plan and used an elk vulnerability model developed by the Idaho Department of Fish and Game. This model predicts overall bull elk vulnerability during the general elk rifle hunting season, based on motorized access and hunter densities. The model does not predict the number of branch antlered bulls which will remain in the population, nor the percentage of yearling bulls to be harvested, nor the percentage of mature bulls which will remain in the population. The Forest emphasized the portion of the State elk hunting objectives that fit the results of the analysis. Many factors affect elk vulnerability which are outside the control of the Forest Service, such as numbers of hunters, distribution of hunters, length of seasons, different types of seasons, and weather conditions. The Forest will continue to emphasize management of its contribution to elk vulnerability, but cannot plan for or control other factors and conditions. MO

COMMENTS: The Forest expresses Elk Vulnerability goals using an indicator (winter range herd composition) which does not relate directly to elk management. The Forest should revise Elk Vulnerability goals in the DEIS (Chapter III) to reflect Idaho Fish & Game's position (use numbers and bull ratios on the Forest during hunting season); use this information in the analysis.

643

RESPONSE: We agree that the bull:cow ratio on winter ranges may not be the best indicator of elk vulnerability. The State Fish and Game agencies collect a variety of information about big game populations, and the Forest will continue to work cooperatively with them to monitor both habitat conditions and big game populations on the Forest. MO

Elk Habitat Effectiveness

COMMENTS: Do not rely on Elk Habitat Effectiveness in order to determine how many trails to close because it is based on two studies conducted by one individual (Lyon) which does not provide enough statistically defensible scientific data to justify its use.

270

RESPONSE: Elk habitat effectiveness is only one of many considerations used in determining how many trails to close or keep open to motorized use. The Forest used a variety of studies by several researchers. Scientific research, such as that by Lyons, is peer-reviewed and is part of the overall deliberations. MO

ELK - HABITAT

General

COMMENTS: Protect and restore elk habitat to ensure the security and success of elk.

34, 62, 136, 180, 252, 325, 697

RESPONSE: Elk habitat is an important consideration in the Revised Plan. The Final Revised Plan improves elk habitat conditions by reducing the density of open motorized roads and trails, reducing the amount of the Forest open to cross-country motorized travel, and reducing the amount of proposed timber harvesting which allows hiding cover to increase in the future as trees in previously harvested areas grow back into hiding cover. MO

COMMENTS: Oppose issues of elk habitat because it is misleading to the public.

311

RESPONSE: The elk habitat analysis in the Revised Plan incorporates the most recent research and best information available for elk vulnerability and elk habitat effectiveness. The Forest encourages anyone with questions about elk habitat to visit the Targhee offices or the Fish and Game Departments. MO

Range Health

COMMENTS: Address the health of the grazing, range resource when analyzing factors that affect elk security.

432

RESPONSE: The Forest analyzed factors which are identified as the most important for elk security (such as open road and trail densities, cross-country OHV access, hunter densities, and hiding cover). At this time, the grazing-range resource is not identified as a factor affecting elk security. MO

Amount of Range

COMMENTS: Address 250 forested acres needed to complete security for big game; define whether the entire 250 acres must qualify as security.

1273b, 1369

RESPONSE: The wording in the Draft Forest Plan Revision was difficult to understand. The Forest clarified this direction for the Final Revised Plan. For management prescriptions 5.1.4 and 5.4, the Forest will manage for blocks of the Forest that are greater than 250 acres in size. These blocks can be a combination of sapling, pole, mature and old growth trees.

Also, in management prescriptions 5.1.4 and 5.4, "security areas" will be maintained adjacent to areas where timber sales are in progress. Security areas do not need to be all cover. They will normally be large areas incorporating both cover and openings, with low road densities, and no disturbance activity is allowed until the timber sale activity is completed. MO

ELK - HABITAT

Enforce Range Protection

COMMENTS: Enforce protection of big game range because even with three agencies managing big game (Bureau of Land Management, U.S. Forest Service, and Idaho Fish & Game) there is still a need for enforcement & protection.
314

RESPONSE: The Forest cooperates with other agencies for law enforcement and notifies the appropriate agency and law enforcement personnel when aware of a violation. Cooperative law enforcement efforts will continue into the future. MO

Cover

COMMENTS: Define thermal cover as 45% canopy closures by using scientific references.
1369

RESPONSE: During the first five years of drafting the Revised Plan, the Forest held a series of elk workshops with State Fish and Game agencies and reviewed a lot of literature. Although some literature discusses and defines thermal cover, absolute thermal cover requirements are not justified on the Targhee. Elk can be found year around in desert habitats without thermal cover, and they occur in a wide variety of mountain habitats with a wide range of cover and noncover attributes. Also, elk continue to use lodgepole pine forests in areas where the mountain pine beetle killed high percentages of the trees, and where reduced canopy closure is far below 45%. For the Final Revised Plan, elk security was determined the most important concern. The most important habitat features dealing with elk security are motorized access density, hunter density, and hiding cover. MO

COMMENTS: Leave enough cover when harvesting timber for elk security.
625

RESPONSE: Management prescriptions 5.1.4 and 5.4 require that only 20% of the forested acres can be in a created opening at any point in time. Therefore, 80% of the forested acres in these management prescriptions will provide cover for elk at any point in time. Also, these management prescriptions require management for large blocks of cover (greater than 250 acres in size). MO

COMMENTS: The Elk Habitat Effectiveness model is dependent upon elk hiding cover. Professional biologists suggest increasing optimum elk hiding cover levels from 40% to 50-60% of a watershed.
No letter #, 413

RESPONSE: The Elk Habitat Effectiveness model recognizes that optimum habitat conditions exist with 50 to 60 percent hiding cover in a watershed. However, research indicates that hiding cover is not the most important factor in predicting potential elk use in a watershed. Other factors, such as motorized access density, are more important than cover in predicting potential elk use in a watershed. Detailed hiding cover analysis for the watersheds on the Forest show that no watershed currently has optimum hiding cover conditions,

ELK - HABITAT

including those watersheds in wilderness which have never had timber harvesting activity. Some watersheds have as little as 6 to 12 percent hiding cover (such as the watersheds in the Birch Creek and Medicine Lodge), yet have an increasing elk population during the last decade. MO

Corridors

COMMENTS: Manage for elk migration corridors.
189, 356, 625

RESPONSE: Elk migration between summer and winter ranges occurs almost everywhere on the Forest. A general overview of elk migration is as follows:

In the Lemhi Mountains and Medicine Lodge Subsections, elk generally migrate to lower elevations to reach winter ranges. Some of these winter ranges occur on BLM lands, the Salmon/Challis National Forest, private lands, and in Montana.

Elk which summer in the Centennial Mountains migrate either north into Montana or south to the desert west of St. Anthony to reach winter ranges.

Elk which summer in the Island Park area and in Yellowstone National Park migrate south and west to winter on the desert west of St. Anthony.

Elk which summer on the west slope of the Tetons migrate east to Jackson Hole, or west to lower elevation winter ranges along the Forest boundary.

Elk which summer in the Big Hole/Palisades Subsection migrate to lower elevation winter ranges along the Forest boundary, and to Wyoming State feed grounds near Alpine.

Elk which summer in the Caribou portion of the Forest migrate west to the Fall Creek and Tex Creek winter areas.

Elk will migrate through a variety of vegetation types, including forests, deserts, and grasslands. Elk will migrate to seasonal ranges across open roads. A notable example are the elk which summer in the Island Park area and in Yellowstone National Park, and winter on the desert west of St. Anthony. These elk migrate across many open roads, including State Highway 47 and U.S. Highway 20. The Targhee is unaware of any migration being stopped because of forest management activities, including the lodgepole pine salvage program which occurred during the last decade.

However, the following concerns have been expressed about elk migration to winter ranges: 1) if winter range areas are closed to hunting, then elk are not available to be hunted if they migrate too quickly through the huntable areas; and 2) elk which arrive on winter ranges too early use forage which may be needed later in the winter. The Forest Plan Revision addresses these concerns. It closes 94% of the Forest to summer cross-country motorized vehicle travel; reduces the number of miles of open road by about 1,000 miles; and allows 20 percent of the forested acres to be in a created opening at any one time, thereby providing more cover in areas where timber harvesting can occur.

Hunting pressure during the fall big game hunt may influence how quickly elk migrate between summer and winter ranges in some areas of the Forest. Hunting pressure is primarily influenced by the hunting regulations of the State Fish and Game agencies, but can be influenced partially by the

ELK - HABITAT

amount of motorized access and the amount of cover. By closing 94% of the Forest to summer cross-country travel, reducing the number of open roads, and limiting the amount of created openings where timber harvesting occurs, hunting pressure may be changed which may allow elk to move more slowly to winter range areas. MO

ELK - HUNTING

Elk Security Negatively Impacts Hunting

COMMENTS: Object to closed roads because closures reduce hunting areas and crowding hunters onto small areas will cause more fatalities.

3, 48, 511

Road closures will cause more "winter kill" in winter range, more "slob hunts" and more "Indian kill".

277, 388

Object to the Forest's desire to eliminate motorized trail bikes in order to reduce elk vulnerability to hunting pressure because: Idaho Fish and Game shows only 1% of hunters use trail bikes to hunt; Hunting Unit #39 has some of heaviest OHV recreation and motorized trail densities and had increase from 100 elk harvest in 1980 to 600 in 1989; and increased harvest in Unit #39 was result of increased herd size, which occurred while OHV use was also increasing.

629a

Open gates in elk habitat areas to two weeks to allow for more consistent hunter success.

250

Elk Security Positively Impacts Hunting

Support hunting and ensure quality hunting.

20, 278

Protect and improve the hunting experience by prohibiting OHV travel because motorized access is the reason for the loss of the amount of elk hunting on the Targhee National Forest.

190, 215

Restrict access to critical winter range to improve hunting.

212

Establish a uniform opening date to eliminate preference to special interest/farmers groups.

250

Recognize and add two key elements to elk/hunting management: 1) The fact that Forest management affects hunter density and distribution, and the quality of the hunting experience; 2) The importance of managing forests efficiently, with high levels of elk habitat effectiveness, so that big game remain on forest lands and are therefore available to the hunting public of Idaho rather than being driven into refuge areas or across state borders to secure habitat.

766

Close roads and trails because elk are the foundation of a multi-million dollar hunting business in Idaho.

185

ELK - HUNTING

Limit motorized use in conjunction with over-harvested areas because it would result in longer hunting season and increase habitat for other species.

270

Protect Elk from Hunters

Recommend to Idaho Fish and Game to cut back on permits.

50

Prohibit any vehicle from closed areas.

170

Close big game areas to ORVs during hunting season.

157, 165, 168, 174, 180, 181, 187, 190, 203, 226, 278, 280, 360, 650, 690, 1247, 1313, 1388

Close roads only during hunting season, not year-round.

51, 375, 393, 413, 687, 693, 1202, 1267, 1317, 1389

Address elk security year-round, not just during the hunting season.

305

Close selected roads and trails to reduce elk vulnerability.

2, 24, 32, 331, 731

Idaho Fish and Game

Leave management of the elk security issue entirely to Idaho Fish and Game. Support Idaho Fish and Game's proposals and 5-year elk plan.

182, 357, 625, 766

Use Idaho Fish and Game elk population counts.

690

Allow Idaho Fish and Game to implement wildlife management to manage elk population.

393

Look at Idaho Fish and Game thresholds for elk vulnerability and how they fit each planned unit.

1341

Because 90% of bull elk mortality is caused by hunters, the Forest Service should recommend that Idaho Fish and Game shorten or eliminate the general season, implement a permit system, and implement road closures; use these guidelines, don't just close roads.

629a

Oppose the use of the issue 3 indicator of elk security (the extent to which elk are protected from hunting pressure) because the U.S. Forest Service is allowing Idaho Fish and Game to direct management practices.

432

Do not use Fish and Game regulations when determining elk vulnerability thresholds because the agency is not trustworthy.

270

The Forest has met Idaho Fish and Game goals at the expense of other users evidenced by a dramatic reduction of ASQ and access even though there has been an increase in elk numbers over the last 10 years.

692

Idaho Fish and Game regulations for elk security do not consider elk populations, hunter success, numbers of licenses sold, numbers of hunters and economic return to Idaho.

228

ELK - HUNTING

Closing 2/3 of the roads is Idaho Fish and Game's way of keeping an open bull season (not restricting the number of hunting permits) at the expense of other users such as ORV users.

393, 413

Opposed to closures, seasonal restrictions, and elimination of cross-country and OHV travel to reduce elk vulnerability because Idaho Fish & Game has another agenda and elk vulnerability is "over-kill."

646

RESPONSE: (TO ALL) Before responding to the above comments, note that State Fish and Game agencies manage hunting regulations and animals populations. Therefore the Fish and Game agencies determine hunting dates, number of permits, sex and age, licensing and fees, length of season, and economic returns to the state. The Forest Service is charged with managing habitat, including motorized recreational use.

Elk were selected as a management indicator species for the Final Revised Plan because: 1) they are a species commonly hunted; and 2) population changes (number of animals and/or distribution of animals) indicate the effects of Forest management activities on habitat conditions that are important to elk and other wildlife. Since elk are hunted, population changes also indicate the effects of hunting regulations. Most often, it is combinations of habitat conditions, access and hunting regulations that affect elk populations.

One of the goals for the Revised Plan is: "Provide habitat to support the wildlife and hunting goals of the States of Idaho and Wyoming."

The elk population goals for the Idaho Department of Fish and Game (IDFG) are:

Game Management Units 60, 61, 62, 62A, 64, 65, 66, 69: Known as "Ready Access Units", the IDFG goal for the post hunting season population is ≥ 15 bulls per 100 cows (this equates to a maximum of 60 percent bull elk mortality), with 40% of bulls branch-antlered; and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 50% and the percentage of mature bulls (having 6 points on one antler) at or above 10%. (IDFG letters: May 12, 1995 and Nov. 15, 1995)

Game Management Units 58, 59, 59A, 67: Known as "Front Range Units", the IDFG goal for the post hunting season population is ≥ 20 bulls per 100 cows (this equates to maximum of 50 percent bull elk mortality), with 50% of bulls branch-antlered; and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 35% and the percentage of mature bulls (having 6 points on one antler) at or above 20%. (IDFG letters: May 12, 1995 and Nov. 15, 1995)

IDFG stated that these goals were not being met in Game Management Units 59, 59A, 60, and 62A (Elk Workshop, September 1992).

The elk population goals for the Wyoming Game and Fish Department (WGF) are:

For all of the Wyoming units on the Forest, the WGF goal for the post hunting season population is ≥ 20 bulls per 100 cows. This equates to a maximum of 50 percent bull elk mortality.

For all of the Wyoming units on the Forest, these goals are being met.

For elk habitat effectiveness, IDFG requested maintaining elk habitat effectiveness values of at least 0.6 in each subwatershed (IDFG letter

ELK - HUNTING

dated June 25, 1996). Currently, elk habitat effectiveness values are below 0.6 in many watersheds of the Forest.

For elk winter ranges, the goal is to provide quality winter range conditions, including managing motorized access to provide security for wintering animals.

For the Final Revised Plan, the Targhee identified the habitat components most important to support the above stated goals for populations, elk habitat effectiveness, and winter range. These components include motorized access density, and hiding cover. The Revised Plan provides for the following changes in motorized access density and hiding cover to support the above stated goals:

1) Cross-country snowmachine travel is prohibited on all elk winter ranges to provide security for wintering animals. Only a few designated routes are allowed for motorized access through elk winter ranges during the winter time.

2) Cross-country motorized travel is prohibited on 94% of the Forest during the spring, summer and fall periods to provide for improved elk habitat effectiveness and lower elk vulnerability.

3) An open road and open motorized trail route density is established for every area of the Forest. The result of these specified densities is that about 600 miles of currently open motorized roads and about 130 miles of currently open motorized trails are closed to motorized use, improving elk habitat effectiveness and lowering elk vulnerability. These road and trail closures include system and nonsystem roads and trails.

4) The number of forested acres proposed for timber harvesting during the next decade is greatly reduced from what occurred during the previous decades. About 30,500 forested acres are proposed for some kind of timber harvest or other type of vegetative treatment (such as prescribed fire) during the first decade. This amounts to only 2.5% of the total forested acres on the Forest. This will allow for a net increase in cover as the previously harvested areas continue to grow and provide cover for elk and other wildlife. MO

ELK - OPEN ROADS

COMMENTS: Road density standards must be adopted as a key indicator for elk.

1367b

Big game winter and summer ranges should be included in any implementation of motorized access targets.

766

Reduce motorized road densities by closing roads, enforcing closures, reducing motorized activity and reclaiming and replanting roaded areas.

F-K(4), 204, 370, 656, 1330, 1331

Expand the discussion of how habitat effectiveness is reduced through increased road densities.

1446

Question the Forest's emphasis on reducing road and trail densities because we disagree that the Targhee is over-roaded from past logging activities. Elk security is only threatened if elk are adjacent to the road - not 200 yards away.

12, 26, 1202

ELK - OPEN ROADS

RESPONSE: The Forest held several elk workshops with scientists from within and outside the Forest Service to identify the habitat factors which are most important for elk. The scientists and their research clearly indicated that motorized access is one of the most important factors affecting elk habitat and populations. The Forest subsequently conducted a detailed inventory and analysis of motorized access in watersheds on the Forest. The results showed that open road and open motorized trail densities in watersheds varied greatly across the Forest, ranging from .01 miles/square mile to 2.25 miles/square mile. Therefore, the need to reduce motorized access on roads and trails varied across the Forest. In the Revised Plan, motorized access density on roads and trails increases by varying amounts in 6 watersheds, remains unchanged in 2 watersheds, and declines by varying amounts in 37 watersheds. Overall, the Revised Plan provides improved elk habitat effectiveness and lower elk vulnerability. More information about motorized access on roads and trails and the effects on elk habitat and populations is presented in the FEIS and Process Paper D. MO

OROMTD Formula

COMMENTS: Dislike the number of open roads and motorized trails per square mile the Forest recommends.

Allow summer motorized route densities of ≤ 1 mile per square mile in areas providing elk and deer summer habitat and crucial winter range;
766

Lower to ≤ 2 miles per square mile for snowmobiles in elk & deer winter ranges;
1273b, 1361

Establish ≤ 2 miles per square mile except in wildlife security areas adjacent to timber sale areas when it should be increased 3-4 times.
389

The road density calculation should not be limited by the size of the prescription area (Prescription 5.4).
1247

RESPONSE: The Revised Plan establishes an open road and open motorized trail route density (OROMTRD) for almost every prescription area of the Forest. The elk analysis for the Revised Plan was done on a watershed basis. All watersheds provide summer habitat for elk. Eight watersheds have an OROMTRD of 1.0 to 1.5 miles/square mile, and 37 watersheds have an OROMTRD of less than 1.0 miles/square mile. On elk and deer winter ranges, no cross-country snowmachine use is allowed at any time, and OROMTRD must be less than or equal to 2 miles per square mile. MO

Open Road Definition

COMMENTS: Define an open road as any road that can be traveled on by a motorized vehicle (even if it is designated as closed or gated); count only those roads that are obliterated as fully closed.
389, 643

Redefine "open road/trail" because the measurement of more than 1-2 motorized vehicle trips per week is so low as to be of no concern; it underestimates elk habitat effectiveness and vulnerability which is unfair to

motorized users; there is no scientific proof for this figure; and without cameras on every road, there is no way this monitoring item will work. (CROSS REFERENCE: Access - Road Density)

629a

RESPONSE: The Revised Plan contains a Glossary with three pages of definitions about roads and road density. The definition of an open road for elk habitat is based on research by Dr. L. Jack Lyon, Forestry Sciences Lab, Missoula, Montana. Elk research shows that effective road closures provide good habitat for elk. Therefore, road obliteration is not a necessity to improve elk habitat. Monitoring road and trail motorized access is a number 1 priority item for the Forest. MO

Motorized Trail Densities Versus Road Densities

COMMENTS: Object to the Forest lumping open motorized trails together with open roads. Explain how trail densities harm elk and what scientific data was used to determine effects. There is no scientific proof that as motorized trail densities increase, elk security declines. (Lyon's studies do not extend to trails.)

26, 288, 291, 344, 367, 528, 629a, 1191, 1202, 1332, 1376

There is no data to support that motorized trail densities have the same/similar effect on elk as open road densities, the DEIS and DFPR should not treat them the same and they should not be a part of the Elk Habitat Effectiveness formula. Proof that elk security is not affected by increased trail densities: Draft Interagency Guidelines for Managing Elk Habitats and Populations on USFS Lands in Central Idaho does not equate motorized trails as having the same effects as motorized roads; study shows in Hunting Unit #39 that elk vulnerability due to OHV hunting pressure does not significantly decrease with the elimination of trail bikes from the area; the Idaho Fish & Game 1988 Deer/Elk Rifle Hunting Study shows only 1% of hunters use trail bikes to hunt. That leaves 99% of hunters in the area; "Elk Calf Response to Simulated Noise Disturbance in Southeast Idaho," Journal of Wildlife Management 49(4): 926-930 showed there is no significant impact to elk numbers/calf survival.

Close roads and trails for wildlife protection only when scientific facts support the reasoning for closures. (CROSS REFERENCE: Access - Single Track)

629a

RESPONSE: Because of much discussion and debate about the effects of motorized use on trails, the following provides a brief overview documenting the work done to obtain information about the effects of motorized use on trails.

The Forest held a series of elk workshops with the State Fish and Game agencies to work on analysis steps for elk habitat effectiveness and elk vulnerability for the Final Revised Plan. According to Dr. L. Jack Lyon, Intermountain Forest and Range Experiment Station, there is no research on the effects of motorized use on trails, but intuitively elk should respond to motorized use on trails the same as motorized use on roads. Based on that statement, motorized use on trails has been equal to motorized use on roads for the elk habitat effectiveness and elk vulnerability analysis.

ELK - OPEN ROADS

At the public access meeting of January 5, 1994, Dr. L. Jack Lyon provide a written response to questions from the public about motorized access. He stated again that there has been no reported research on the effects of trails. At the public access meeting, alternative views were presented from the public about the effects of trails. Mr. Marty Morache presented the most extensive alternative view that motorized trails do not have as much effect as roads.

Idaho Department of Parks and Recreation cited the 1987-1988 Idaho Rifle Elk Hunting Study which documented that only 1% of hunters use trail bikes to hunt (in 1987-88). The implied question is, should the Targhee equate motorized trails, which provide access for 1% of the hunters, equal to motorized roads, which provide access for 99% of the hunters, in elk vulnerability analysis? The Forest did not find any study conducted since 1987-1988 which documents if a higher percentage of hunters are using trail bikes to hunt in 1996.

At the request of the Interagency Grizzly Bear Committee, a taskforce established standardized definitions for roads and trails and standardized methods to measure densities for roads and trails. In the final report (titled the "Interagency Grizzly Bear Committee Taskforce Report - July 1994") trails and roads are treated equally in determining motorized access density.

Recent work is in progress on the development of "Draft Interagency Guidelines for Managing Elk Habitats and Populations on USFS Lands in Central Idaho." In these guidelines, trails are given 1/10th the effect of roads. Personnel on the Nez Perce National Forest said that the guidelines are still draft, there is no research supporting that trails be given 1/10th of the effect of roads, and that the biologists working on the draft guidelines agreed on the 1/10th criteria based on 1) fewer number of vehicles on trails and 2) lower sound levels. (Steve Blair, personal communication, July 9, 1996.)

At this time, there is no scientifically controlled research study on the effects of motorized use on trails. In Process Paper D for the Final Revised Plan, the Forest provides new elk habitat effectiveness and elk vulnerability analysis wherein motorized use on trails is given 1/10th the effect of motorized use on roads. This new analysis is then compared with the previous analysis wherein motorized use on trails is equal to the effect of motorized use on roads. In the Final EIS, we discuss the uncertainty associated with the analysis of motorized use on trails.

Other Studies

COMMENTS: Do not overlook studies that show that nonmotorized users affect elk security.

Look into studies that prove that single-track trails, hiking and, mountain biking are disruptive to elk habitat.

346

Information in the Draft Interagency Guidelines for Managing Elk Habitats and Populations on USFS Lands in Central Idaho shows that roads and trails restricted from motorized users actually increased elk vulnerability by making elk habitat more accessible to non-motorized users.

629a

ELK - OPEN ROADS

Refer to the Elk Telemetered Heart Rates Study by the Rocky Mountain Forest and Range Experiment Station which found that close-range gunshots and humans on foot (from as far away as 400-800 meters) consistently produced more elk reaction (either altered behavior or running) than did automobiles, motor bikes & aircraft. This study suggests protection would be provided by placing roads in areas hidden by trees & away from elk feeding sites.

313, 270, 1449

RESPONSE: The Forest acknowledges that any time humans approach elk (especially elk which are hunted), there is a response by elk. However, motorized access is identified as one of the most important factors affecting elk habitat effectiveness and elk vulnerability on the Forest. Most people use motorized vehicles to gain access into the Forest. That is why it received special emphasis in the Final Revised Plan. No major issues or concerns were identified for nonmotorized summer use on trails or roads. There is concern about nonmotorized uses on elk and deer winter ranges. Winter Range Prescription 2.7a prohibits nonmotorized cross-country use during the winter period in winter range. MO

COMMENTS: Address habitat fragmentation, not just road density limits;
1368

Limit the number and size of patches (and the accompanying roads) because according to Lyon 1980 and Van Dyke 1995, the single most important function in elk utilizing an area is the proximity of an active road.

1367

RESPONSE: Management Prescriptions 5.1.4 and 5.4 require management for large blocks of forest cover greater than 250 acres in size. Large blocks reduce fragmentation and provide more security for elk. The Forest agrees that motorized access is the most important variable predicting potential elk use in an area. In the analysis of potential elk use, motorized access accounted for 70 to 80 percent of the effects. MO

ELK - ROAD CLOSURE

This subcategory addresses access issues from an elk security perspective. Cross reference to the Access category for additional information.

Supports

COMMENTS: Favor closures due to concerns about elk security and elk habitat. Motorized use has a negative impact on wildlife.

136, 143, 173, 174, 201, 226, 265, 270, 280, 337, 356, 357, 370, 459,
631, 643, 656, 668, 697

Support current level of elk security but want some closures when snow depth is an issue.

1240

Limit some access for elk security, but leave some open.

35

Cut out backcountry access.

26

ELK - ROAD CLOSURE

Close non-system roads to help elk.
227

Close access to elk sensitive areas.
F-K(4), 650

Close all roads where elk migrate.
1331

Close motorized access to important elk habitat seasonally or year-round.

F-B(4), 157, 167, 174, 179, 181, 212, 252, 278, 305, 339, 360, 490, 659, 669, 690

Do not build new roads because they create needless access to areas that jeopardize elk security.

325, 1331

Restrict OHV, ORV, and ATV travel from elk security areas.
37, 176, 226, 370, 619, 652, 667, 1331

Restrict OHV use during the summer.
305

Monitor effectiveness of road closures for elk security.
175, 643

Enforce road closures in elk habitat.
174, 204, 1331

Non Support

COMMENTS: Oppose road and trail closures for elk security.

34, 39, 43, 47, 49, 53, 319, 445, 687, 1240, 1264

It is inconsistent management to close trails to OHV users but then allow hikers and then release wolves which feed on elk.

397

Roads never bothered elk security. No evidence to support that elk will not cross roads or be otherwise adversely affected by roads not used by armed humans.

36, 53, 393, 1240

Oppose closures because elk thrived during the last 10 years when timber harvesting brought high road useage; if elk were bothered by roads they would have stayed in more remote areas.

12, 272, 275, 1202

There are enough areas for elk, including feeding areas, already.
687, 1264

Opposed to closing roads in both elk summer and winter range because elk populations are not a problem. The population is usually so high that many elk have to be harvested each year to keep the population in balance; there are more elk than ever before. There are so many that Idaho Fish & Game is selling 4,000 controlled hunt permits this year.

270, 272, 646, 693

OHVs/ATVs do not harm elk populations; (some cite Idaho Fish & Game).

319, 397

Motorized users just go around gates anyway.

1

ELK - ROAD CLOSURE

There is no scientific evidence that equates single track trails or roads with wildlife impacts.

F-O(4), 393, 1202

Road closures are a political move to protect the elk which resulted in reduced ASQ.

228

Road management will have little effect on elk mortality when 86% of mortality is caused by hunting and 14% by natural causes.

1202

Road closures will not have the desired effect because roadless hunting units are not abundant in elk.

687

RESPONSE: (TO BOTH SUPPORT AND NON-SUPPORT) At the beginning of work on the Revised Plan, the Forest held several elk workshops, inviting scientists from within and without the Forest Service, to identify the habitat factors which are most important for elk. The scientists and their research clearly indicated that motorized access was one of the most important factors affecting elk habitat and populations. Elk will migrate across roads and many do so to get to winter and summer ranges. Human activity on roads can effect migration, causing elk to either migrate more quickly or even delay migration. Subsequently the Forest conducted a detailed inventory and analysis of motorized access by watersheds on the Forest (watersheds are one way to define a geographical area for scientific study). The results of this inventory and analysis showed that open road and open motorized trail densities in watersheds varied greatly across the Forest (ranging from .01 miles/square mile to 2.25 miles/square mile). Therefore, the need to reduce motorized access on roads and trails varies across the Forest. In the Revised Plan, motorized access density on roads and trails increases by varying amounts in 6 watersheds, remains unchanged in 2 watersheds, and declines by other amounts in 37 watersheds. As a result, 8 watersheds have an open road and open motorized trail route density (OROMTRD) of 1.0 to 1.5 miles/square mile, and 37 watersheds have an OROMTRD of less than 1.0 miles/square mile. Overall, the Revised Plan provides for improved elk habitat effectiveness and lower elk vulnerability. More information about motorized access on roads and trails and the effects on elk habitat and populations is presented in the FEIS and Process Paper D. MO

ELK - STANDARDS AND GUIDELINES

Elk Habitat Effectiveness

COMMENTS: Add a wildlife standard to maintain an elk habitat effectiveness value of at least 0.6 in each sub-watershed (approximately 2000-6000 acres).

766

RESPONSE: The Forest evaluated this suggestion in detail, but could not adopt it for the following reasons: 1) In some areas of the Forest, Districts could not close enough roads to achieve an elk habitat effectiveness (EHE) value of at least 0.6 because established developments in the areas require access; there are private, state, and other Federal lands which require access; and most public does not want some historic access roads closed. 2) Cover values

ELK - STANDARDS AND GUIDELINES

are naturally low in some watersheds, especially those with a low percentage of forested acres. The low amount of cover reduces elk habitat effectiveness, and makes it impossible to achieve an elk habitat effectiveness value of 0.6 in each sub-watershed.

On a Forestwide basis, the Revised Plan improves EHE from a Forestwide average of 0.58 for the existing condition to a Forestwide average of 0.64. In the Revised Plan, 68 percent of the Forest has an EHE of greater than or equal to 0.6. MO

COMMENTS: Create standards for deer and elk hiding and thermal cover.

1365

Develop guidelines for elk cover/forage relationships (i.e. sight distance, logging impacts, and elk vulnerability) and incorporate as standards in prescription areas contributing to timber ASQ's.

389

RESPONSE: While working on the Final Revised Plan, the Forest held a series of elk workshops with State Fish and Game agencies and reviewed a lot of literature. Although some literature discusses and defines thermal cover, absolute thermal cover requirements are not justified. Elk can be found year around in desert habitats without any thermal cover, and they occur in a wide variety of mountain habitats with a wide range of cover and noncover attributes. Elk continue to use lodgepole pine forests in areas where the mountain pine beetle killed high percentages of the trees, and where reduced canopy closure is far below 45%. For the Final Revised Plan, the Forest determined that elk security is the most important issue. The most important habitat features dealing with elk security are motorized access density, hunter density, and hiding cover.

Management prescriptions 5.1.4 and 5.4 require that only 20% of the forested acres can be in a created opening at any point in time. Therefore, 80% of the forested acres in these management prescriptions will provide cover for elk at any point in time. Also, these management prescriptions require management for large blocks of cover (greater than 250 acres in size). MO

COMMENTS: Drop the statement on Page III-2: "human access routes may have reduced the ability of species to move between habitat blocks" because there is no evidence; oppose year-round closures because there is no scientific data to prove elk will not cross roads.

393, 413

RESPONSE: The statement on Page III-2 is a general comment agreeing with a considerable amount of literature which document the effects of roads on wildlife. The statement is accurate in that it uses the words "may" and "reduced". More detailed analysis on the effects of roads is presented further in Chapters III and IV of the EIS. MO

COMMENTS: Increase a forest-wide direction to limit cross-country motorized travel in order to protect big game habitat.

389

ELK - STANDARDS AND GUIDELINES

RESPONSE: The Revised Plan proposes to prohibit summer cross-country motorized travel on 93% of the Forest. Prior to the Revised Plan, cross-country motorized travel was prohibited on 38% of the Forest. MO

Elk Vulnerability

COMMENTS: Clarify what the State Vulnerability Standards are for elk; how the habitat measure is derived; and what and where estimated vulnerability levels are. Define in guidelines the scientific basis for defining unsuitable areas as security by simply increasing the acreage of lower quality areas.

1369

RESPONSE: The State goals for elk vulnerability; a map showing where these goals are applied; a brief discussion explaining elk vulnerability; and scientific literature cited are shown in the FEIS.

The Revised Plan does not define unsuitable areas as security by increasing the acreage of lower quality areas. MO

COMMENTS: Make a Standard that the elk vulnerability model only be applied as a temporary measure during the hunting season.

1389

RESPONSE: The FEIS clearly defines elk vulnerability as applying to the hunting season. The elk vulnerability model is an analysis tool not a standard. MO

COMMENTS: Correct error on elk security and graphing on the CBA chart in Alternative 2.

413

RESPONSE: The Counting By Advantages (CBA) process helped select the preferred alternative in the DEIS. It was not used in formulating the final preferred alternative. The CBA chart is not contained in the FEIS. MO

Elk and Deer Winter Range (Management Prescription 2.7(a-b))

COMMENTS: Incorporate crucial elk winter range prescriptions into the Plan.

389

Create standards and guidelines for big game winter range areas not already under Management Prescription 2.7 Elk and Deer Winter Range.

FS-9

Big game winter range is sometimes in conflict with another prescription. If another prescription is chosen, the winter range prescription cannot be used. Prepare a new winter range map and write a standard and guide to go along with the map.

FS-3

RESPONSE: The Revised Plan updates the mapping of elk and deer winter range in cooperation with the Idaho and Wyoming Fish and Game agencies. Some of the elk and deer winter ranges are not mapped with the winter range prescription.

ELK - STANDARDS AND GUIDELINES

For example, some of the winter ranges are mapped with a grizzly bear prescription or a proposed wilderness prescription. The other prescriptions will still maintain the habitat conditions important for wintering deer and elk. The Forest added a forestwide standard to the Revised Plan to close all elk and deer winter range areas to cross-country snowmachine use, regardless of the management prescription they receive. MO

COMMENTS: Write a standard to separate out livestock forage from game forage on critical ranges.

FS-3

RESPONSE: The Forest clarified the wording in the Forestwide standards and guidelines to show when forage utilization on elk and deer winter ranges will be measured. It is important to look at the combined forage utilization by both livestock and wildlife, so that these areas can be maintained in a productive state. MO

COMMENTS: Develop objectives, standards, and guidelines for elk and deer winter range that have substance. Develop a standard to calibrate the success of vegetation improvement; describe forage conditions in a quantifiable manner.

no letter #

RESPONSE: Management Prescription 2.7(a-b) was developed to fit a wide range of vegetative conditions for elk and deer winter ranges across the forest. These winter range areas vary from being mostly sagebrush/grass to mostly aspen or conifer. More specific direction on forage may be good for one area, but not applicable to another. Each winter range area will be managed according to the potential for that particular area. One item the Forest strengthened in the final Revised Plan pertains to cross-country snowmachine use. All elk and deer winter range areas are closed to cross-country snowmachine use. MO

Timber Management (Big Game Security Emphasis) (Management Prescription 5.1.4(b))

COMMENTS: Oppose efforts to manage for elk security in Management Prescription 5.1.4(b) and support elk hunting here because lack of access imposed by prohibiting ORV travel, establishing buffer zones and preventing logging in many timbered areas provides security enough.

432

RESPONSE: Management prescription 5.1.4(b) is designed to allow timber harvesting while maintaining suitable elk habitat conditions, so that elk use would be maintained in these areas. The Forest did not deem it desirable to reduce elk use in these areas. MO

Elk & Deer Summer Range (Management Prescription 5.4 (a-c))

COMMENTS: The management prescription for elk and deer summer range allows for timber harvest and roading in response to insect and disease epidemics

which fails to fully protect security areas.

643

RESPONSE: The objective, as stated in the management prescription, is to use silvicultural techniques which prevent or lessen insect and disease epidemics to maintain cover values for elk. This objective provides direction for keeping forest stands healthy, which will provide better cover for wildlife over time. All of the other standards and guidelines in the management prescription must also be followed. MO

COMMENTS: Make the following changes to Prescription 5.4 (a-c): Elk & Deer Summer Range:

Third Paragraph: "Timber management emphasizes security for big game species."

Objective: "Fire, insects and disease are allowed to play their natural role in ecological succession to create and maintain a variety of forested age classes which in turn provide the requisite cover and forage for big game species."

Roads: "No new roads will be allowed."

Timber: "No clearcutting, no shelterwood cuts in lodgepole, no seed tree cuts. Only individual and group selection harvest will be allowed.

"No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated a security area. Security area designations will be at least 10 years in duration. New security areas will be designated and protected at least 18 months prior to entry into currently designated security areas."

643

RESPONSE: The Revised Plan does not makes these changes to timber harvest in Management Prescription 5.4 for the following reasons: From 1980 to 1992, the Forest conducted an elk monitoring project associated with some timber sales on the Dubois Ranger District. Results of this monitoring illustrated that elk use declined (but was not eliminated) in the timber sale areas during the years of road building and harvesting, but increased again after this activity was completed. Elk and deer use clearcuts, shelterwood cuts, and seed tree cuts. At the beginning of work on the Revised Plan, the Forest held a series of elk workshops with State Fish and Game agencies, and reviewed a lot of literature. From this work, elk security was determined to be the most important issue. The most important habitat features dealing with elk security were motorized access density, hunter density, and hiding cover. Hunter density is regulated by the State Fish and Game Departments. Motorized access and hiding cover are regulated by the Forest Service. Management prescription 5.4 establishes direction for low motorized access and for maintaining high levels of hiding cover over time. This prescription also provides for maintaining security areas adjacent to areas with timber harvesting activity, but it is not necessary to have these areas designated for at least 10 years.

The goal statement and the standards and guidelines in this prescription emphasize the need to provide security for big game while allowing some timber harvesting to occur. Most big game species are habitat generalists, and can accommodate a wide range of habitat conditions and changes. Historically, big game species accommodate a wide range of fire,

ELK - STANDARDS AND GUIDELINES

insects and disease events. The objective, as stated in the management prescription, is to use silvicultural techniques which prevent or lessen insect and disease epidemics to maintain cover values for elk. This objective provides direction for keeping forest stands healthy, which will provide better cover for wildlife over time. Maintaining high amounts of cover over time is considered important for supporting the goals of the Idaho and Wyoming Fish and Game agencies. The use of fire is allowed to maintain important habitat components. New roads are allowed, but open road and open motorized trail route density must be maintained less than or equal to 0.5 miles per square mile. MO

ELK - SECURITY

Support Measures for Elk Security

COMMENTS: Support elk security because elk are part of the ecosystem and because it is enjoyable to see elk.

20, 21, 23, 43, 46, 49, 51, 53, 156, 265, 285, 340, 445, 1176, 1204

Support Idaho Fish and Game's elk vulnerability standards and proposals to protect elk.

61, 331, 690

Establish secure areas for no less than 10 years and do not distribute these areas across the forest so they can function as a network rather than isolated islands.

1194

Use science acquired from the Targhee or similar forests when making decisions on elk.

1267

Non Support Measures for Elk Security

Oppose measures for elk security in general.

27, 29, 30, 33, 39, 50

Leave elk security the way it is.

55, 1319, 1321

Elk security closes off/limits access to the forest including hunting access; DEIS does not prove that elk populations need security.

46, 52, 393, 607

Idaho Fish and Game plan shows elk population has never been in better condition.

393, 431, 1239

There is sufficient cover.

1316, 1392

Nature should be allowed to take its course.

38

Motorbikes do not disturb elk.

1449

Security measures are bad for economics.

293

Elk security is not the Forest's problem.

251

ELK - SECURITY

Using elk security as a key indicator violates the multiple use mandate.

393

Elk security forces the US Forest Service into unhealthy management of both the timber and range resource.

432

Consider an alternative that clearly shows the social & economic cost of meeting the key issue of security for elk and measures that could mitigate this issue.

393

RESPONSE: (TO BOTH SUPPORT AND NON SUPPORT) As evident from the many public responses on elk security, there is no agreement about elk security. Some public want the Forest Service to be more supportive of State Fish and Game agency goals, while others want the Forest Service to be less supportive. The following explains the Forest's final decisions after reviewing these comments:

Elk were selected as a management indicator species for the Forest Plan Revision because: 1) they are a species commonly hunted; and 2) population changes (number of animals and/or distribution of animals) indicate the effects of Forest management activities which alter or change habitat conditions. Since elk are hunted, population changes also indicate the effects of hunting regulations. Most often, it is a combination of both habitat conditions and hunting regulations that affect elk populations.

One of the goals for the Revised Plan is: "Provide habitat to support the wildlife and hunting goals of the States of Idaho and Wyoming."

The elk population goals for the Idaho Department of Fish and Game are:

Game Management Units 60, 61, 62, 62A, 64, 65, 66, 69: These game management units are known as "Ready Access Units." For these units, the IDFG goal for the post hunting season population is ≥ 15 bulls per 100 cows (this equates to a maximum of 60 percent bull elk mortality), with 40% of bulls branch-antlered; and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 50% and the percentage of mature bulls (having 6 points on one antler) at or above 10%. (IDFG letters: May 12, 1995 and Nov. 15, 1995)

Game Management Units 58, 59, 59A, 67: These game management units are known as "Front Range Units." For these units, the IDFG goal for the post hunting season population is ≥ 20 bulls per 100 cows (this equates to maximum of 50 percent bull elk mortality), with 50% of bulls branch-antlered; and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 35% and the percentage of mature bulls (having 6 points on one antler) at or above 20%. (IDFG letters: May 12, 1995 and Nov. 15, 1995)

Idaho Department of Fish and Game stated that these goals were not being met in Game Management Units 59, 59A, 60, and 62A (Elk Workshop, September 1992).

The elk population goals for the Wyoming Game and Fish Department are as follows:

For all of the Wyoming units on the Forest, the WGF goal for the post hunting season population is ≥ 20 bulls per 100 cows. This equates to a maximum of 50 percent bull elk mortality.

ELK - SECURITY

For all of the Wyoming units on the Forest, these goals are being met.

For elk habitat effectiveness, the Idaho Department of Fish and Game requested maintaining elk habitat effectiveness values of at least 0.6 in each subwatershed (IDFG letter dated June 25, 1996). Currently, elk habitat effectiveness values are below 0.6 in many watersheds of the Forest.

For elk winter ranges, the goal is to provide quality winter range conditions, including managing motorized access to provide security for wintering animals. Currently, not all winter ranges have motorized access restrictions, and this situation is analyzed in the Forest Plan Revision.

The Revised Plan identifies the habitat components most important to support the above stated goals for elk populations, elk habitat effectiveness, and elk winter range. Habitat components include motorized access density and hiding cover. The Revised Plan provides the following changes in motorized access density and hiding cover to support the above stated goals:

Cross-country snowmachine travel is prohibited on all elk winter ranges to provide security for wintering animals. Only a few designated routes are allowed for motorized access through elk winter ranges during the winter time.

Cross-country motorized travel is prohibited on 93% of the Forest during the spring, summer and fall periods, to provide for improved elk habitat effectiveness and lower elk vulnerability.

The Forest Plan Revision establishes an open road and open motorized trail route density for every area of the Forest. The result of specified densities is that about 600 miles of currently open motorized roads and about 130 miles of currently open motorized trails are closed to motorized use in the Revised Plan, improving elk habitat effectiveness and lowering elk vulnerability. Closures include both system and nonsystem roads and trails.

The number of forested acres proposed for timber harvesting during the next decade is greatly reduced from what occurred during the previous decades. In the Revised Plan, about 30,500 forested acres are proposed for some kind of timber harvest or other type of vegetative treatment (such as prescribed fire) during the first decade. This amounts to 2.5% of the total forested acres on the Forest and allows a net increase in cover while the previously harvested areas continue to grow and provide cover for elk and other wildlife. MO

COMMENTS: Page III-126 to III-128, Use the best science (Lyon and Canfield 1991, Hillis et al 1991) to provide big game security. Provide blocks of hiding cover greater than 250 acres and greater than 1/2 mile from open roads.

1273b

RESPONSE: Management prescriptions 5.1.4 and 5.4 require blocks of cover greater than 250 acres in size. The distribution of these blocks, and whether they are always greater than 1/2 mile from an open road will depend on site-specific analysis. See Process Paper D and the list of citations for science used. MO/AM

School Section Creek and Modoc Creek

COMMENTS: Obliterate any roads associated with silvicultural techniques upon completion to protect elk and deer summer range at School Section Creek and Modoc Creek.

1185, 1348

RESPONSE: These areas of the Forest are within Management Prescription 5.4(c), which has an open road and open motorized trail density standard of less than or equal to 1.25 miles per square mile. This means there can be a maximum of 1.25 miles of road for every square mile. Timber harvest roads will either be opened or closed based on this figure and other site-specific conditions identified during project work. MO

Lemhi Ranger District

COMMENTS: The Elk Habitat/Vulnerability Analysis assumes that if a road or trail was open to motorized use, then it was used more than twice per week by motorized users. Explain why, then, some of these routes disappear because of lack of use (Example: lower trail of Pass Creek on Lemhi Ranger District and the North Fork of Pine Creek Trail in the Big Holes).

629a

RESPONSE: If the average motorized use on roads and trails is less than 1 to 2 vehicles per week, the Forest does not count those roads and trails in the analysis of elk habitat effectiveness. Each Ranger District reviewed all of the road and trail data for the Final Revised Plan, and their review is incorporated in the analysis. MO

Lionhead

COMMENTS: In Lionhead do not close roads to protect elk if closures will impede winter access in Lionhead.

7

RESPONSE: In the Revised Plan, the Lionhead area is open for snowmachine use. MO

Fall River Ridge

COMMENTS: I use Fall River Ridge for elk hunting in the fall. Do not close.
461, 463

RESPONSE: Fall River Ridge is within the Bechler/Teton Grizzly Bear Management Unit. This area has restrictions on motorized access to achieve habitat conditions necessary for recovery of the grizzly bear population. During the spring, summer and fall, motorized travel is permitted on a few open roads, but cross-country motorized travel will not be permitted. MO

ELK - SITE-SPECIFIC

Table Rock

COMMENTS: In Table Rock apply the OROMTRD in the 2.7(a) Prescription (Elk) for this area to be consistent.

1361

RESPONSE: The lower portion of Table Rock Creek has Management Prescription 2.7(a). MO

Big Holes

COMMENTS: Opposed to snowmobile and trail bike restrictions because there is scant evidence deer are bothered in the Big Holes area. (CROSS REFERENCE: Access - Snowmobiles)

67

RESPONSE: Snowmachine restrictions apply to the areas of elk and deer winter range; these restrictions are necessary to protect wintering deer and elk. Reductions in motorized access are being implemented to reduce elk vulnerability on the bull segment of the elk population, to help support the goals of the Idaho Department of Fish and Game. (See response to elk-road closure). MO

COMMENTS: Road closures defeat Fish and Game's purpose of allowing elk harvest in the Big Holes to keep elk from eating farmer's hay and to keep from having to pay for the damage.

F-G(2)

RESPONSE: Reductions in motorized access are being implemented to reduce elk vulnerability to the bull segment of the elk population and to help support the goals of the Idaho Department of Fish and Game. The Idaho Department of Fish and Game has not suggested a need to increase motorized access in order to resolve elk depredation problems on private lands. MO

Fox and Moose Creeks

COMMENTS: Protect elk in Fox and Moose Creeks.

1331

RESPONSE: The Revised Plan meets the goals for elk vulnerability established by the Wyoming Game and Fish Department. Elk habitat effectiveness ratings for Fox and Moose Creeks range from .67 to .76. These are among the highest ratings for elk habitat effectiveness on the Forest. MO

Horseshoe-Packsaddle

COMMENTS: Prohibit mountain bike use in Horseshoe Packsaddle critical winter range to protect the elk.

329

RESPONSE: Cross-country travel by mountain bikes is prohibited during the winter period, to protect wintering elk and deer. MO

Timber Harvest and Elk

COMMENTS: Timber harvest, specifically clearcuts, has negative impacts on elk security.

47, 293, 317, 640, 668

Forbid logging/new roads in elk habitat year-round.

211, 212, 280, 357

Oppose logging to improve elk habitat; logging is not needed for elk habitat "health";

51, 252, 396, 622, 1194

Prove with documentable evidence that timber harvest does not harm elk habitat.

625

Revise management prescription for elk & deer summer range to not allow timber harvest as a response to insect & disease.

643

Rather than using the elk habitat effectiveness model, an unbiased scientific study would show that mature stands of timber devoid of an understory make poor security for elk as compared to timber stands in the advanced seedling/sapling stage.

393

Supports logging because elk thrive in clearcut and abandoned forests.

275

Do not change the way elk are managed, except for reducing ASQ's in the lodgepole pine forests.

687

RESPONSE: (TO ALL OF THE ABOVE COMMENTS) Elk use areas of the Forest where timber harvesting has occurred. The Forest conducted a long term monitoring study on elk use in a timber sale area on the Dubois Ranger District. Monitoring showed that elk use declined, but was not eliminated, during the active years of the logging, and returned to pre-logging levels after the logging activity was done. Elk use occurs in all stages of forest succession, from the grass/forb and seedling stage to the old growth stages.

The Revised Plan allows for future timber harvesting, but takes into account the most important habitat considerations for elk, which are motorized access density and hiding cover. The Revised Plan reduces motorized access density from existing levels. The Revised Plan allows hiding cover to increase as trees in past logged areas grow to provide cover. Management prescriptions 5.1.4 and 5.4 allow timber harvesting, but require that 20% of the forested acres can be in a created opening at any point in time. Therefore, 80% of the forested acres in these management prescriptions will provide cover for elk at any point in time. These management prescriptions require management for large blocks of cover (greater than 250 acres in size). MO

COMMENTS: Address how the agreement with Idaho Fish and Game on elk security has greatly reduced the ASQ.

393

ELK - TIMBER

RESPONSE: The ASQ is the result of the cumulative effects of many goals, objectives, standards and guidelines, and management prescriptions which have been incorporated into the Revised Plan. An analysis of how each goal, objective, standard and guideline, and management prescription affects the ASQ has not been done, and is not necessary to effectively disclose environmental effects or provide a reasoned choice between alternatives. MO

ELK - WINTER/SUMMER

Protection - Winter Range

COMMENTS: Protect elk winter range and "critical or crucial" elk winter range.

136, 161, 174, 180, 189, 331, 340, 356, 357, 659, 662, 664, 697, 766

Discuss and incorporate the Teton Front Winter Recreation Plan regarding big game winter habitat objectives and ORV restrictions. (CROSS REFERENCE: Recreation)

1446

RESPONSE: The Forest worked with Idaho and Wyoming Fish and Game Departments to identify the critical elk and deer winter range areas on the Forest. In the Revised Plan, all elk and deer winter range areas are closed to cross-country snowmachine use. In some places, the elk and deer winter range areas fall within other management prescriptions, such as wilderness, proposed wilderness, wild and scenic and recreational rivers, and grizzly bear habitat. Even though they are within other management prescriptions, the habitat components that make them winter range areas are protected. MO

COMMENTS: Winter elk herd population is already as large as private property can withstand; as large as winter range can stand.

687, 1378, 1389

RESPONSE: Many elk winter on lands off the National Forest. Many factors affect where elk will winter, including migration, winter severity, quality of the winter range, and size of the elk population. The Forest Service will maintain good quality winter range on the National Forest. The responsibility for managing the size of elk populations and resolving problems on private property resides with the State Fish and Game Departments. MO

COMMENTS: Object to restrictions of cross-country travel in winter range because there are already enough laws in effect.

319

RESPONSE: In the Revised Plan, all elk and deer winter ranges are closed to cross-country travel to protect wintering big game animals during a time of the year when they need to conserve as much energy as possible. By protecting elk winter range, the Forest is responding to all the laws, including those requiring management for wildlife and cooperation with State Idaho Fish and Game agencies. MO

Quantity of Elk Winter Range

COMMENTS: Wants more elk winter range; clarify why the amount of elk winter range proposed is less than currently present.

389, 1267

RESPONSE: Working with the Idaho and Wyoming Fish and Game agencies, the Forest identified the crucial mid-to-late natural elk and deer winter ranges on the Forest. Crucial winter ranges are those areas which determine a population's ability to maintain itself at a certain level over the long term. Identifying crucial winter range is a challenging task, because the distribution and number of wintering deer and elk on the Forest depends on winter severity. The winter range areas on the Forest are the upper elevational limits of elk and deer winter ranges. Generally, a higher proportion of deer and elk winter at lower elevations on BLM, State, and private lands during most winters. Some elk and deer, which summer on the Targhee, winter on ranges in Montana and Wyoming. MO

Protection - Summer Range

COMMENTS: Protect elk breeding/calving areas from adverse effects by prohibiting logging, roading & motorized vehicles.

F-B(4), F-G-1(475), FS-5, 136, 150, 157, 162, 167, 174, 175, 180, 181, 185, 189, 190, 203, 206, 209, 212, 219, 226, 252, 266, 275, 278, 280, 340, 357, 360, 490, 622, 659, 662, 667, 690, 1270, 1348, 1388

RESPONSE: Elk use areas of the Forest for breeding and calving where timber harvesting occurred. The Forest conducted a long term monitoring study on elk use in a timber sale area on the Duboise Ranger District which showed that elk use declined, but was not eliminated, during the active years of the logging, and returned to pre-logging levels after the logging activity was done. Elk use, including breeding and calving, occurs in all stages of forest succession, from the grass/forb and seedling stage to the old growth stages.

The Revised Plan allows for future timber harvesting, but takes into account the most important habitat considerations for elk, which are motorized access density and hiding cover. The Revised Plan reduces motorized access density from existing levels. The Revised Plan allows hiding cover to increase as trees in past logged areas grow to provide cover. Management prescriptions 5.1.4 and 5.4 allow timber harvesting, but require that 20% of the forested acres will be in a created opening at any point in time. Therefore, 80% of the forested acres in these management prescriptions will provide cover for elk at any point in time. Also, these management prescriptions require management for large blocks of cover (greater than 250 acres in size).

Numerous other management prescriptions, such as wilderness, proposed wilderness, nonmotorized, semi-primitive motorized, grizzly bear, and so forth, maintain or improve elk habitat by reducing motorized access and maintaining or improving hiding cover.

The Revised Plan reduces elk vulnerability in support of State Fish and Game goals, and improves elk habitat effectiveness. MO

ELK - WINTER/SUMMER

COMMENTS: Monitor reduction of ORVs in summer elk habitat.
161

RESPONSE: Monitoring motorized access, including areas of summer habitat, is a number 1 priority monitoring item in the Revised Plan. MO

Quality of Summer Range

COMMENTS: Good summer habitat prevents starvation/winter kill.
275

RESPONSE: We agree that good summer and fall habitat brings animals into the winter period in good condition, which improves winter survival. MO

COMMENTS: Include goals and objectives in the Allotment Management Planning for the number of animal unit months needed to sustain elk on their summer and winter range.
1206

RESPONSE: The forage utilization standards in the Revised Plan include the needs of wildlife. If forage utilization standards are exceeded, domestic livestock grazing is adjusted to meet the needs of wildlife. MO

Amount of Summer Range

COMMENTS: Explain why such a small portion of the Forest defines summer habitat for management.
1369

RESPONSE: Nearly all of the Forest receives summer use by elk. Elk habitat needs are taken care of by numerous management prescriptions, including wilderness, proposed wilderness, aquatic influence zones, research natural areas, grizzly bear habitat, nonmotorized, semi-primitive motorized, range management, and so forth. The Revised Plan improves elk habitat effectiveness, and reduces elk vulnerability in support of State Fish and Game Department goals. MO

FIREWOOD

Access to Personal Firewood Areas - Support

COMMENTS: Keep the access to firewood.

39, 43, 51, 213, 251, 277, 406, 440, 524, 1265, 1335

RESPONSE: Access to firewood is generally retained or re-opened for commercial firewood in timber sale areas. Ranger Districts will schedule firewood/products sales to meet road density objectives. BR/LB

COMMENTS: Allow firewood only on public lands.

156

RESPONSE: Public land is the only place where the Forest Service has jurisdiction. LB

COMMENTS: Allowing firewood collecting is good for the forest and public relations.

62

RESPONSE: Your comment is acknowledged. Firewood gathering can be beneficial in reducing fuel loading while providing economic benefits. BR/LB

COMMENTS: Require that slash piles be stacked by commercial loggers so that individuals can access it for firewood.

697

RESPONSE: Site-specific analysis will determine if slash piles should be stacked or dispersed in the project area based on the site-specific needs of the resources affected by management activities. RB/LB

COMMENTS: Increase harvest of firewood because there is more dead lodgepole than you have acknowledged or identified.

11

RESPONSE: After additional analysis, the Targhee has retained 3.8 MMBF for firewood/forest products in the Final Revised Plan.

COMMENTS: Allow access to firewood because it is an historic use, and collection does little damage to forest.

214

Provide more access to firewood than is currently allowed.

293

RESPONSE: Access issues are resolved by each Ranger District as the firewood program is implemented. The Revised Plan proposes a firewood/product harvest program of 3.8 MMBF/year. As post harvest or firewood areas become available, access, though generally temporary in nature, will be made available. LB

COMMENTS: Allow firewood harvesting of snags within 100 feet along a road because birds can use other trees.

309

FIREWOOD

RESPONSE: Harvesting within 100 feet of a road could be allowed if direction in the Revised Plan is met and site-specific analysis determines firewood harvesting is appropriate, based on site-specific resource needs. LB

COMMENTS: Allow firewood harvesting but do not build new roads.

325

RESPONSE: Access for any project is determined on site-specific analysis. If firewood harvesting requires new access, access would be analyzed in a site-specific NEPA document and would comply with direction in the Revised Plan. LB

COMMENTS: Reconsider your position that firewood is not a key issue because 70% of the homes in the Upper Snake River Valley burn firewood to heat their homes.

55, 413

RESPONSE: As the quality and accessibility of firewood decreases, demand decreases. The Ranger Districts will keep track of demand during the firewood season. If demand exceeds supply or if the resource is available it is possible to review it and take the steps to balance the program. 3.8 MMBF/year is an average volume. Total annual volume could be more or less but should average this level. LB

Access to Personal Firewood Areas - Non Support

COMMENTS: Reduce the limit for personal firewood availability because of impacts of "random skidding and access roads" and impacts to natural habitats.

1365

RESPONSE: 3.8 MMBF is the proposed harvest level for the Forest during this decade. Skidding methods and access opportunities are determined during site-specific analysis. These concerns will be mitigated in order to harvest this material. LB

COMMENTS: Enforce the fuelwood limits.

1365

RESPONSE: This is done to the best of our ability. The Forest uses monitoring to determine if firewood harvests are correct. Usually this involves going out in the field and checking permits and amounts being removed. LB/BR

COMMENTS: Clarify the impacts of firewood harvest in security areas and decide whether it will be allowed.

1369

RESPONSE: Impacts of firewood harvest on security areas are better analyzed at a site-specific level. Management direction for maintaining security areas is included in the Revised Plan. The FEIS discusses the effects and consequences of firewood harvest in these areas. BR/LB

FIREWOOD

COMMENTS: Oppose the firewood harvests when they occur in Aquatic Influence Zones.

282

RESPONSE: The Aquatic Influence Zone Prescription (2.8.3) allows salvage and commercial firewood cutting when catastrophic events result in degraded riparian conditions. LB

COMMENTS: Opposed to firewood harvests in order to meet Objective 3: "to maintain or restore ecological health and function."

282

RESPONSE: This objective allows treatment of wood residue only, if needed to restore ecological health and functions. Situations may exist where natural occurrences have altered ecological health and function. These objectives are designed to allow treatments that restore these processes and functions. LB

Salvage Timber

COMMENTS: Allow blown down trees to be salvaged for firewood. Allow dead and dying trees to be harvested with up to five cords per family to help clean up downed timber.

214, 243, 285, 472, 1239

RESPONSE: The Targhee has allowed harvest of these materials in the past. Depending on the amount of material and location, blown down trees can be harvested as firewood or as commercial timber. The amount available per family each year varies, based on changing supply and demand. BR/LB

COMMENTS: Harvest dead lodgepole pine for firewood to reduce flammable material that ignites spontaneously.

285

RESPONSE: Past firewood harvest came from this type of material. The majority of the 3.8 MMBF will come from the lodgepole pine component. LB

ASQ

COMMENTS: Enforce ASQ limits. Reduce the ASQ limit substantially (to an ASQ of zero as recommended in Alternative 6 if possible).

1365

RESPONSE: The ASQ is a ceiling; it is not a projected future sale level or target and does not reflect all of the factors that influence future sale levels. ASQ is based on the amount of suitable acres in each Alternative. In Alternative 6 there are no suitable lands. ASQ volume in all alternatives is lower than past harvest levels. LB

COMMENTS: Supports ASQ amount in Alternative 2 for increased firewood harvest.

47, 1335

FIREWOOD

Support ASQ in Alternative 3M as long as it does not affect firewood cutting.

44, 49, 53

RESPONSE: All alternatives include a firewood harvest volume projection of 3.8 MMBF. LB

COMMENTS: Include the harvest of firewood in the ASQ because it can constitute a substantial portion of the harvest of forest trees; to show it separately is misleading.

282, 625

RESPONSE: The ASQ of 8.0 MMBF/year does not include firewood or products of less than sawtimber size. Dead material is not included in the yield calculations. BR/LB

COMMENTS: Opposed to reductions from 11 million board feet to 3.8 million board feet of firewood available because the reduction means that: 70% of people dependent on firewood for warming their homes will freeze, a total of \$6,152,000.00 per year will be spent by the state of Idaho to subsidize heating bills for poor Idahoans, and taxpayers will subsidize fossil fuels.

275

RESPONSE: According to "Atlas of Social Indicators for the Upper Columbia River Basin" (1995) about 17% of the housing units in Bonneville, Clark, Fremont, Jefferson, Madison and Teton Counties are heated by wood. Teton County has the highest incidence of wood use for home heating at 50%. As wood has become progressively more difficult and costly to access and retrieve, people have switched to other fuels. The Targhee recognizes that wood is an important fuel for home heating. A volume of 3.8 MMBF of fuelwood/product is an estimate of the volume expected to be sold, on average, over the next decade. Recent fuel sales are below the 11.0 MMBF level mentioned. DP

COMMENTS: Recalculate the projected harvest figure of 3.8 MMBF to a figure of 14 MMBF because: 14 MMBF figure is based on mathematical calculations determined after attending a public meeting with Forest Service officials in May 1996. More accurate estimated dead volumes can be determined from the vegetation attribute tables that exist for each mature stand. Estimates of the demise of availability of dead lodgepole are grossly exaggerated (based on authors detailed calculations). There remains about 400 MMBF of dead timber and 30% of this is usable as house logs or firewood.

413

Explain how the 3.8 million board feet of firewood figure was established as the amount available.

228

RESPONSE: The 3.8 MMBF figure was determined by professionals familiar with the resource, the ground, and forestwide goals, objectives, standards, and guides. 3.8 MMBF is the firewood/forest product volume the Targhee can reasonably provide on an annual basis, while complying with the constraints in management prescriptions. LB

FIREWOOD

COMMENTS: Determine sale of firewood by deadstand, beetle kill, and the economic sustainability of the area harvesting the wood.

265

RESPONSE: The Ranger Districts determine where firewood harvest will occur. Firewood opportunities must comply with the restrictions, constraints, and/or objectives detailed in the Revised Plan. LB.

Economics

COMMENTS: Provide quality firewood for local community.

62, 293, 1265, 1313

RESPONSE: All alternatives will provide 3.8 MMBF/year of firewood. LB

Wildlife

COMMENTS: Evaluate the effects of firewood gathering on wildlife habitat and describe past impacts of significance and future management plans. Explain impact of firewood gathering in wildlife security areas.

1369

Need second guideline for cavity nesters: "Consider cavity nest species and protection measures for retained wildlife trees in cutting units when designating fuelwood areas and sales, both commercial and personal use charge areas." (CROSS REFERENCE: Wildlife, Snag/Cavity Nesters)

FS-9, FS-10

RESPONSE: The past effects of firewood harvests is included in the analysis for management indicator species. For example, all nonstocked and seedling areas, whether created by timber harvesting or firewood gathering, are included in the analysis of cover for elk habitat effectiveness. The snag analysis for existing condition includes the effects of past firewood harvesting that removed dead standing trees.

Future firewood harvesting will meet the forestwide standards and guidelines and the direction outlined in each management prescription. Some examples are: 1) If a management prescription only allows 20% of the forested acres to be in a nonstocked or seedling stage at any point in time, firewood gathering must meet this direction; 2) Firewood harvesting must meet the direction for dead and down material in the forestwide standards and guides; 3) Firewood harvesting must meet the snag habitat biological potential of each management prescription.

The future effects of firewood harvests are included, where appropriate, in the analysis for management indicator species. The details of the analysis are documented in Process Paper D. The DEIS and FEIS provide the results of the analysis. MO

GRIZZLY BEAR - ACCESS

Support Closures

COMMENTS: Address road/trail access as it pertains to grizzly bears, grizzly bear habitat, and Bear Management Units (BMU). Give road closures as high a priority as habitat improvement. Limit or restrict access by: placing a moratorium on new roads in management Situation I and II grizzly habitat; close existing roads; and close trails including restricting and/or limiting ORV/ATV use in grizzly bear habitat; ensure effective road closures.

32, 62, 151, 156, 162, 165, 168, 170, 173, 175, 206, 265, 297, 317,
357, 359, 389, 610, 620, 625, 652, 667, 695, 697, 1273b, 1331, 1361,
1365, 1446, 1667

RESPONSE: The Revised Plan reduces OROMTRD in the BMU's, reduces TMARD in the BMU's, and nearly eliminates cross-country motorized OHV use. For the Targhee portion of each BMU, OROMTRD is less than or equal to 0.6 miles per square mile, and TMARD is less than or equal to 1.0 miles per square mile. MO

COMMENTS: To allow motorized bikes into BMUs does not support bear protection efforts.

1273b

RESPONSE: The Revised Plan allows motorized bikes on roads and trails designated open for motorized use in the BMU's where bear recovery will not be jeopardized and trail/road densities are met. Motorized bikes are not allowed on any road or trail closed to motorized use. MO

Non Support Closures

COMMENTS: Oppose road and trail closures; closing access will not help grizzly bear recovery efforts.

27, 35, 36, 45, 46, 47, 52, 240, 446, 501, 546, 633, 693, 709,

Warning signs would be preferred to road closures in Grizzly Bear Country.

25

RESPONSE: Historical records show that grizzly bear populations survive where frequencies of contact with humans are low. Populations of grizzly bears and other large carnivores persist in those areas where large expanses of relatively secure habitat are retained and where human induced mortality is low. In the lower 48 conterminous states, this is primarily associated with National Parks, Wilderness areas and large blocks of public lands.

By managing motorized access on the landscape, the following grizzly bear management objectives are met: minimize human interaction and potential grizzly bear mortality; minimize displacement from important habitats; minimize habituation to humans; and provide relatively secure habitat where energetic requirements can be met.

The management of human use levels through access route management is one of the most powerful tools available to balance the needs of grizzly bears with the needs of humans. It is documented in several research projects, both completed and ongoing, that unregulated human access and development within grizzly bear habitat can contribute to increased bear mortality and affect bear use of existing habitat. MO

GRIZZLY BEAR - ACCESS

COMMENTS: Do not close access because of grizzly bear or wolves because they are not Threatened or Endangered. (CROSS REFERENCE: Wildlife, Specific Species - Wolves)

715

RESPONSE: In the lower 48 States, the grizzly bear is classified as a threatened species, and the gray wolf is classified as a nonessential experimental population, under authority of the Endangered Species Act. The Revised Plan reduces access within the grizzly bear BMU's to improve habitat conditions to support grizzly bear recovery goals. Access restrictions for the gray wolf will occur within one mile around active den sites and rendezvous sites between April 1 and June 30, when there are five or fewer breeding pairs of wolves in the Yellowstone or Central Idaho Nonessential Experimental Population Areas. MO

General

COMMENTS: Need more research on trail access to grizzly bear habitat and the impacts they have.

1202

RESPONSE: Additional research on the effects of trail access helps the Forest understand how to better manage trail use. Research on grizzly bears is done by the Interagency Grizzly Bear Study Team, and such research would be helpful to our management efforts. MO/JR

Open Road Densities

COMMENTS: Reconsider open road/open motorized trail route density as an indicator for grizzly and develop a new indicator based on social/economic effects of constraint on road development and timber harvest.

393

RESPONSE: The management of human use levels through access route management is one of the most powerful tools available to balance the needs of grizzly bears with the needs of humans. It is documented in several research projects, both completed and ongoing, that unregulated human access and development within grizzly bear habitat can contribute to increased bear mortality and affect bear use of existing habitat. By managing motorized access on the landscape, the following grizzly bear management objectives can be met: Minimize human interaction and potential grizzly bear mortality; minimize displacement from important habitats; minimize habituation to humans; provide relatively secure habitat where energetic requirements can be met. The social/economic effects are discussed and displayed in the FEIS. MO

COMMENTS: The two vehicles per week maximum allowance is flawed, because the policy indicates that grizzly bears will still be displaced by very little traffic.

1273b, 1361

GRIZZLY BEAR - ACCESS

RESPONSE: The two vehicles per week criteria is used for elk habitat effectiveness analysis, not grizzly bear analysis. For grizzly bear analysis, the Forest uses the criteria established in the Interagency Grizzly Bear Committee's Task Force Report on Grizzly Bear/Motorized Access Management and the Grizzly Bear Cumulative Effects Model. MO

COMMENTS: Provide best available data on "ghost roads," roads, authorized use of closed roads, and ineffective road closures as components of the OROMTRD for grizzly bears.

1273b, 1361

RESPONSE: The Ranger Districts conducted a complete inventory of all roads and trails on the Forest, which included identifying and mapping all "ghost" roads and trails. They used knowledge and information from other agencies, such as the State Fish and Game agencies. The Ranger Districts also evaluated motorized use on all roads and trails. In analyzing effects on grizzly bears, the Forest used the criteria established in the Interagency Grizzly Bear Committee's Task Force Report on Grizzly Bear/Motorized Access Management and the Grizzly Bear Cumulative Effects Model. MO

COMMENTS: Unclear that road/trail densities of .29 - .56 miles/square mile will correlate with grizzly management practices.

690

RESPONSE: The road and trail densities in the Revised Plan meet, and in most cases are lower than, the recommendations in the 1993 Grizzly Bear Recovery Plan. At this time, additional research and analysis is being done on road and trail densities in the Yellowstone Grizzly Bear Recovery Zone. When this research and analysis is done, the Forest will know more about how the road and trail densities in the Revised Plan will affect grizzly bear management. MO

COMMENTS: Use information provided by Roads Scholar Project to accurately depict road densities within BMUs.

643, 1361

RESPONSE: Our road inventory information is more current than that in the Roads Scholar Report. The roads which will remain open after the Plan is implemented are used to determine road density. All other roads will be closed or obliterated and cross-country motorized is not allowed. Therefore, the road density depicted is accurate.

We will use the Roads Scholar information as appropriate as we work through the task of closing and obliterating roads.

The analysis of road density as it relates to grizzly bear was done from the Interagency Grizzly Bear Committee. JR

COMMENTS: Include specifics on exactly when road density standards will be achieved. Needs to be achieved sooner than three years.

643, 1361

GRIZZLY BEAR - ACCESS

RESPONSE: The subject roads will be closed by a Forest Supervisor's order when the Record of Decision is signed. However, adding physical restriction devices or obliteration of the roads will require three years to complete.

Therefore, the objective in the Revised Plan is to implement the access standards in the BMU's within 3 years of the implementation of the Record of Decision. This is an ambitious, yet achievable, objective which takes into account the realities of accomplishing this huge task. MO/JBR

COMMENTS: Support Forest's intent to reduce road densities in BMUs. Support using OROMTRD.

393, 625, 1273b, 1276, 1367b

RESPONSE: Thank you for your support. The Forest used the criteria established in the Interagency Grizzly Bear Committee's Task Force Report on Grizzly Bear/Motorized Access Management and the Grizzly Bear Cumulative Effects Model. MO

COMMENTS: Add to the OROMTRD that roads must be closed elsewhere to keep the area within standards.

1273b

RESPONSE: The OROMTRD standard includes all open roads and open motorized trails within the Targhee portion of each BMU subunit. This is consistent with the criteria established in the Interagency Grizzly Bear Committee's Task Force Report on Grizzly Bear/Motorized Access Management. MO

COMMENTS: Do not allow comparison numbers for road density calculations to include two tracks, motorized trail and motorized cross-country use.

658

RESPONSE: For road and trail density calculations, the Forest used the criteria established in the Interagency Grizzly Bear Committee's Task Force Report on Grizzly Bear/Motorized Access Management and the Grizzly Bear Cumulative Effects Model which includes two-tracks, motorized trails, and motorized cross-country use. MO

COMMENTS: Expand the FEIS to consider more than the grizzly bear when increasing road densities and reduction of cover.

1446

RESPONSE: The DEIS and the FEIS incorporated road and cover analysis for other management indicator species, where it was appropriate to do so. MO

GRIZZLY BEAR - ADMINISTRATION

Goals/Objectives

COMMENTS: DFPR III-11, Goals - Grizzly Bear Habitat: Rewrite Goal #1 as follows: "Habitat conditions will conserve and sustain a recovered population of Grizzly Bear in Greater Yellowstone Ecosystem and Targhee Forest."

1446

GRIZZLY BEAR - ADMINISTRATION

RESPONSE: This change was not incorporated into the Final Revised Plan. The existing goal provides the same direction which is to provide habitat for a recovered population of grizzly bears. JR

COMMENTS: DFP, Designated Wilderness Page III-57 to 65: Include a goal to maintain grizzly bear habitat for a viable population of bears.

389

RESPONSE: Designated Wilderness contributes towards grizzly bear habitat, and the analysis for the Revised Plan takes this into account. However, a recovered bear population will use more areas than just designated wilderness. Therefore, it is not appropriate to include this recommendation. MO

COMMENTS: Rewrite objective I to read: "Meet or exceed recovery criteria in the Grizzly Bear Recovery Plan"; rewrite Objective III to read: "Provide Safe, secure release sites for relocation of nuisance bears;" rewrite Objective IV to read: "Implement road density standards in the BMU's within one year of the signing of the ROD in coordination with Federal and State Wildlife Agencies."

1446

RESPONSE: These changes were not incorporated in the Final Revised Plan. Objectives 1 and 3, as written, meet the same purpose as the suggested wording. Objective 4 provides 3 years to completely implement the road density standards in grizzly bear areas, because of the magnitude of this job. The closure will be implemented immediately upon signing the ROD by signing. However, road obliteration and/or gates or other effective closure devices will not be completed within one year because of cost. JR

COMMENTS: Objective VII: Include wording which provides for CEM Thresholds model used to access cumulative impacts.

643

RESPONSE: The CEM is an analysis tool, which is still being validated and tested. It is not appropriate to include it in an objective but the Forest used the CEM in the analysis of the alternatives for the EIS. MO

COMMENTS: Include a more thorough discussion of grizzly bear recovery challenges in Goals and Objectives.

727

RESPONSE: After consideration, the Forest decided the appropriate place to discuss recovery challenges is in the Grizzly Bear Recovery Plan. MO

Core Areas

COMMENTS: Support "Grizzly Bear Core Areas"; protect and identify them by using Management Prescription 5.3.5 or the Plateau Prescription; do not allow motorized disturbance.

643, 658, 690, 719, 1381

GRIZZLY BEAR - ADMINISTRATION

Identify core areas using BMUs stating the areas it will connect with or lie adjacent to.

1273b

Change Management Prescription 5.3.5 to designate core areas as true refuges for Grizzly Bears.

644, 690

RESPONSE: In the Revised Plan, the following management prescriptions meet core area criteria: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2. Management prescription 5.3.5 is not a core area for grizzly bears. The FEIS and the Biological Assessment for grizzly bears document the amount of core area within each BMU for each alternative. MO

COMMENTS: Change the third paragraph in Forest Acres within Core Areas. This section should reflect the goal to meet all of the core area standards due to the lack of past management.

1446

Expand core areas for protection of Grizzly Bears.

631, 643, 1387

RESPONSE: In the Revised Plan, the following management prescriptions meet core area criteria: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2. The FEIS and the Biological Assessment for grizzly bears document the amount of core area within each BMU for each alternative. At this time, there is no completed research or analysis which answers the question of how much core area is needed. When they are completed, the Targhee will evaluate conditions to see if more or fewer core areas are needed. MO

COMMENTS: Core areas should have "actual" road densities, not just Forest Service roads.

731, 1194, 1387, 1401

If research indicates core areas are to leave OROMTRD of 0.0 mi/sq.mi, then they must be restricted or prohibited.

1273b, 1361

RESPONSE: Core areas prohibit motorized access on any roads and trails during the non-denning period. MO

COMMENTS: Support management plans in core areas that remain inviolate for eleven years, with additional core areas secure in no less than two years.

643

RESPONSE: In the Revised Plan, the following management prescriptions meet core area criteria: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2. These management prescriptions are in place for the 10 to 15 year duration of the Revised Plan. Where needed, additional security areas will be identified adjacent to areas where management activities are taking place. These security areas must be in place as long as the management activities are occurring. MO

GRIZZLY BEAR - ALTERNATIVES

(CROSS REFERENCE: Alternatives)

Alternative 2

COMMENTS: Support Alternative 2, because it places access as a higher priority than grizzly bears.

F-F(6), 98, 267, 717

RESPONSE: The Revised Plan provides a network of roads and trails open for public and use that provides good access to the Forest. However, reductions in road density were included to meet habitat requirements for a recovered population of grizzly bears. We have a legal responsibility to provide sufficient habitat to remove grizzly bears from threatened status.

Historical records show that grizzly bear populations survive where frequencies of contact with humans are low. Populations of grizzly bears and other large carnivores persist in those areas where large expanses of relatively secure habitat are retained and where human induced mortality is low. In the lower 48 conterminous states, this is primarily associated with National Parks, Wilderness areas and large blocks of public lands.

By managing motorized access on the landscape, the following grizzly bear management objectives can be met: minimize human interaction and potential grizzly bear mortality; minimize displacement from important habitats; minimize habituation to humans; provide relatively secure habitat where energetic requirements can be met.

The management of human use levels through access route management is one of the most powerful tools available to balance the needs of grizzly bears with the needs of humans. It is documented in several research projects, both completed and ongoing, that unregulated human access and development within grizzly bear habitat can contribute to increased bear mortality and affect bear use of existing habitat. MO/JR

Alternative 3M

COMMENTS: Support Alternative 3M because of its grizzly bear recovery measures including phasing out grazing and sheep allotments over a period of time and reflecting the needs of the 4 Endangered Species Act species on the Targhee.

11, 37, 40, 143, 181, 182, 193, 211, 314, 325, 340, 359, 370, 442, 625, 643, 658, 664, 695, 1273b, 1276, 1351, 1392

RESPONSE: Thank you. This is indeed one of the reasons why the Forest selected Alternative 3M. MO

COMMENTS: Oppose Alternative 3M because it either provides too much protection for grizzly bear or not enough.

6, 30, 47, 52, 53, 98, 170, 290, 311, 337, 343, 445, 481, 640, 690, 1176, 1389

RESPONSE: At this time, research is unable to define absolute levels of protection necessary for the grizzly bear. The range of alternatives in the Revised Plan provides a range of protection measures and is based on the best information and the best professional judgements available at this time.

GRIZZLY BEAR - ALTERNATIVES

The Revised Plan will meet grizzly recovery objectives and maintain habitat for a recovered population of bears. MO/JR

GRIZZLY BEAR - ANALYSIS PROCESS

DEIS

COMMENTS: DEIS indicates measuring viability of grizzly bear is inadequate and needs to reflect the court's refutation of this methodology; DEIS claims the Yellowstone grizzly population is increasing. Needs a reference for this.
1361, 1369

RESPONSE: The Revised Plan uses the criteria for grizzly bear recovery established in the 1993 Grizzly Bear Recovery Plan. Recovery plans are developed by the U.S. Fish and Wildlife Service. This recovery plan has been challenged in court, and if a court ruling results in changes to the recovery plan, the Forest will evaluate how the changes may affect the Targhee National Forest. The reference for the population data in the DEIS and FEIS is Dr. Chris Servheen, Grizzly Bear Recovery Coordinator, USDI Fish and Wildlife Service, 1995 and 1996. MO

COMMENTS: In Table IV-7 of the DEIS, total forested acres are broken down into categories. When was this data gathered? Why didn't this table follow the model of Table III-14 for comparison?
1273b

RESPONSE: The data in Table III-14 showed the existing condition for each of the BMUs. The data in Tables IV-7 through IV-10 compared how each BMU would change by alternative, compared to existing conditions. The existing conditions in Tables IV-7 through IV-10 are the same as the existing conditions for each BMU displayed in Table III-14. MO

EIS

COMMENTS: Expand the FEIS to consider more than the grizzly bear when increasing road densities and reduction of cover.
1446

RESPONSE: The Revised Plan includes analysis for 26 management indicator species. Where appropriate, road densities and cover analysis are done for more species than just the grizzly bear. MO

COMMENTS: Clarify the bar graph comparisons on grizzly bear management.
375

RESPONSE: The bar graph displays how open road and open motorized trail route densities change in each BMU for each alternative. Generally, open road and open motorized trail route densities are higher in Alternatives 1 and 2, and decline in each subsequent alternative, with Alternatives 5 and 6 having the lowest densities. MO

GRIZZLY BEAR - ANALYSIS PROCESS

COMMENTS: The DEIS needs more analysis, stricter Standards and Guidelines, better methods of science. It should abide by environmental laws. The EIS's measuring viability of grizzly bears is inadequate. Change this to reflect the courts' refutation of this methodology.

1361

RESPONSE: For the Revised Plan, the Forest used the newest version of the grizzly bear cumulative effects model. The Forest follows the Interagency Grizzly Bear Committee direction on motorized access management. All of the data for the cumulative effects model and motorized access includes all of the past timber harvesting, a complete inventory of all roads and trails (including system and nonsystem roads and trails), and an accounting of all human activities which could be identified.

The Revised Plan uses the criteria for grizzly bear recovery established in the 1993 Grizzly Bear Recovery Plan (recovery plans are developed by the U.S. Fish and Wildlife Service). This recovery plan has been challenged in court, and if a court ruling results in changes to the recovery plan, the Forest will evaluate how the changes may affect the Targhee. MO

COMMENTS: The DEIS needs to be concerned about ESA and domestic grazing and how phasing out sheep will polarize people against protecting grizzly bears.

1446

RESPONSE: The Forest is phasing out domestic sheep grazing within the grizzly bear BMUs on an opportunity basis. This action is specifically designed to help prevent polarizing the issue. A phase out can occur while achieving a recovered grizzly bear population. MO

COMMENTS: The DEIS/FEIS should include core and security areas to prevent timber harvesting in designated BMUs.

1446

RESPONSE: The following management prescriptions meet the criteria for core areas: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2. No timber harvesting is allowed in these management prescriptions. Some timber harvesting may occur in management prescription 5.3.5, but must follow all of the standards and guidelines required in this management prescription. MO

Data

COMMENTS: Use the latest data on grizzly bear recovery in GYE; lack of baseline data would reduce effectiveness of grizzly bear management because relocating security areas would cause more damage; need scientific data to validate on an ecosystem scale whether or not insects and disease will have any significant negative impacts on the maintenance of grizzly habitat; redesign Management Situation Areas I, II, III to reflect the past ten (10) years of data on grizzly bear use.

176, 643, 1273b, 1381

GRIZZLY BEAR - ANALYSIS PROCESS

RESPONSE: For the Revised Plan, the Forest uses the newest version of the grizzly bear cumulative effects model. The Forest follows the Interagency Grizzly Bear Committee direction on motorized access management. All the data for the cumulative effects model and motorized access includes all the past timber harvesting, a complete inventory of all roads and trails (including system and nonsystem roads and trails), and an accounting of all human activities which could be identified.

The Revised Plan uses the criteria for grizzly bear recovery established in the 1993 Grizzly Bear Recovery Plan (recovery plans are developed by the U.S. Fish and Wildlife Service). This recovery plan has been challenged in court, and if a court ruling results in changes to the recovery plan, the Forest will evaluate how the changes may affect the Targhee National Forest.

The Forest is unaware of scientific data which validates, on an ecosystem scale, whether or not insects and disease will have any significant negative impacts on the maintenance of grizzly habitat.

In the Revised Plan, MS 1 areas remain as they are because these areas have the highest grizzly bear use; MS 2 areas become more like MS 1 areas to encourage increased grizzly bear use; and MS 3 areas remain as they are because of high human use and numerous developments. MO

COMMENTS: There is not enough data on whether or not there are any grizzly bear dens in the Plateau BMU.

1202

RESPONSE: Documented grizzly bear use in the Plateau BMU shows that such use is low, compared to other BMUs. Within the past few years, a few radio-collared grizzly bears were documented using the Plateau BMU. At this time, the Forest does not know how many bears may be denning in the Plateau BMU. MO

COMMENTS: Use best science available; use more research on trail access in grizzly habitat for impacts; need more baseline data to reduce the need for relocating security areas; use science gathered from Targhee or other similar forest when making grizzly bear decisions.

393, 667, 692, 1202, 1267

RESPONSE: For the Revised Plan, the Forest uses the newest version of the grizzly bear cumulative effects model. The Forest follows the Interagency Grizzly Bear Committee direction on motorized access management. All of the data for the cumulative effects model and motorized access include all the past timber harvesting, a complete inventory of all roads and trails (including system and nonsystem roads and trails), and an accounting of all human activities which could be identified.

The Revised Plan uses the criteria for grizzly bear recovery established in the 1993 Grizzly Bear Recovery Plan (recovery plans are developed by the U.S. Fish and Wildlife Service). This recovery plan has been challenged in court, and if a court ruling results in changes to the recovery plan, the Forest will evaluate how the changes may affect the Targhee National Forest. MO

GRIZZLY BEAR - ANALYSIS PROCESS

DFPR

COMMENTS: The Grizzly Bear Management issue is ill-conceived, misrepresented, and public input process is inadequate.

182

RESPONSE: The grizzly bear is listed as threatened under the authority of the Endangered Species Act. The Endangered Species Act was passed by Congress after much public input and debate. The Grizzly Bear Recovery Plan was developed by the U.S. Fish and Wildlife Service, after review and comment by the public. The Revised Plan for the Targhee National Forest is developed with full public input as required by the National Environmental Policy Act and the National Forest Management Act. MO

COMMENTS: Clarify the meaning of 7,000 acres of undisturbed habitat next to timber sales; clearcut size of 40 acres or less does not benefit grizzly bear telemetry work.

625, 1364, 1369

RESPONSE: The conditions of the 7,000 acre security areas are defined in Management Prescription 5.3.5. There is no requirement for clearcut sizes of 40 acres or less. MO

COMMENTS: The DFPR needs to clarify the following statement: "Activities will not occur when grizzly bears are active."

643, 1273b

RESPONSE: This wording appears in Management Prescriptions 2.6.2 and 2.6.5. The standards and guidelines in these management prescriptions identify what activities are permitted and under what conditions. MO

COMMENTS: The DFPR needs to include sufficient standards to ensure protection of grizzly bears.

1365

RESPONSE: The Revised Plan contains all of the goals, objectives, standards, and guidelines which are necessary to meet recovery goals which have been established for the grizzly bear population in the Yellowstone Grizzly Bear Recovery Zone. MO

COMMENTS: Include 1995 data on high grizzly mortality rates in the DFPR.

690, 1381

Amend the statement under Grizzly Bear Management, "All demographic recovery targets are currently being met" to reflect new data on recovery in Greater Yellowstone Ecosystem.

643, 690, 1381

RESPONSE: The Revised Plan and FEIS contain the 1996 data, the most current data available (published or officially approved and released for use). MO

GRIZZLY BEAR - ANALYSIS PROCESS

COMMENTS: The DFPR did not include requirements for food storage methods, monitoring bear activity and domestic grazing.

1277

The DFPR needs to include garbage storage requirements, including a definition of: "A minimum of 10' off the ground and 4 feet from any vertical supporting structure."

389, 643

RESPONSE: Food and garbage storage requirements are covered in a special order which has been in existence for several years. There is no need to repeat this special order in the Revised Plan.

The Revised Plan contains several monitoring items relating to grizzly bear habitat, including monitoring road closure effectiveness, achievement of road density standards, and grizzly bear habitat improvement. The Forest will continue to cooperate in the reporting of grizzly bear observations, especially for female grizzly bears with cubs.

The Revised Plan contains direction to phase out domestic sheep grazing in all BMUs. Existing cattle grazing allotments are allowed to remain, but specific standards and guidelines must be followed. MO

COMMENTS: Prescription 2.6 Map 10 lists 2.6.3 as Grizzly Bear - Plateau BMU - Security Area. The Plan should include 2.6.2 or 2.6.3 in this map. Include the reason for designating 2.6.5 as Grizzly Bear Security Area.

1277

RESPONSE: The Revised Plan includes Management Prescription 2.6.2 in the Plateau BMU. Management Prescription 2.6.5 was developed to meet the unique management conditions which exist in the Bechler/Teton BMU. Management Prescription 2.6.3 is not used in the Revised Plan. Analysis indicates that the combination of management prescriptions used in the grizzly bear BMU's improves habitat conditions sufficient to meet recovery plan goals for the grizzly bear in the Yellowstone Grizzly Bear Recovery Zone. MO

DFPR - Security

COMMENTS: Access management and security concerns for grizzly bear are directly related. The Targhee National Forest needs to provide greater security for Grizzly Bears.

667, 697

RESPONSE: The Forest agrees that access management and security concerns are directly related. In the Revised Plan, TMARD and OROMTRD are reduced in all of the BMUs to provide better security for the grizzly bear. Cross-country motorized travel is nearly eliminated in all BMUs. Every BMU has core areas which do not allow any motorized access at all. Adequate security will be provided for the grizzly bear when the Revised Plan is fully implemented. MO

COMMENTS: The DFPR fails to consider the large amount of management activities in security areas.

1273b

GRIZZLY BEAR - ANALYSIS PROCESS

RESPONSE: All linear features (roads and trails), all point activities (developed sites, concentrated use areas, and so forth), all dispersed activities (grazing, general recreation use, and so forth) are mapped for all BMUs. All this data is part of the cumulative effects model, which is used to analyze the effects of the existing condition and all alternatives. MO

COMMENTS: Define security areas and whether these areas receive high levels of logging/road building under the current Forest Plan.

1273b

RESPONSE: The Revised Plan identifies the following management prescriptions as meeting core area criteria: 1.1.6, 1.1.7, 1.3, 2.6.2, 2.6.5, 2.3, and 3.1.2. These management prescriptions constitute security areas for the grizzly bear. No logging or road building are allowed in these management prescriptions. Security areas are defined in prescription 5.3.5. MO

COMMENTS: The DFPR III-136 (5.3.5. Grizzly Bear Habitat) needs to consider changing the maximum opening size to accurately reflect security needs of the grizzly bear.

643

RESPONSE: The Final Revised Plan adequately addresses grizzly security. No research shows a particular opening size is needed. The relative importance of cover to grizzly bears is documented by Blanchard (1978) in a 4-year study in the Yellowstone ecosystem. Ninety percent of 2,261 aerial radio relocations of 46 instrumented grizzly bears were in forest cover too dense for observation. Whether grizzly bears use forest cover because of an innate preference or to avoid humans is unknown (Blanchard 1978). The importance of an interspersed open parks as feeding sites associated with cover is also recorded in Blanchard's study: "Only 1 percent of the relocations were in dense forest more than a kilometer from an opening."

Forest cover is important to grizzly bears for use as beds. Most beds are found less than a yard or two from a tree (Servheen and Lee 1979, Blanchard 1978). Blanchard further records only 16 of 233 beds observed (6.7 percent) were without immediate cover. Schallenberger and Jonkel (1980) found grizzly bears preferred forest in over 80 percent of their radio relocations.

There is no research documenting requirements for the distribution, quantity or quality of cover on a "landscape" scale or within grizzly bear home range. Changes in the distribution and quantity and quality of cover are not necessarily detrimental to grizzly bears. At the September 19-21, 1993, symposium on "The Ecological Implications of Fire in Greater Yellowstone - Second Biennial Conference on the Greater Yellowstone Ecosystem," the Interagency Grizzly Bear Study Team presented a paper titled "Effects of Wildfire on Grizzly Bear Movements and Habitat Use" where they state:

"On the average, grizzly bears used burned habitats in proportion to their availability within individual annual ranges during 1989-1992. Seasonal indices of movement and annual range sizes of cohorts are not statistically different from the 1975-1987 averages."

The grizzly bear cumulative effects model was recently used to assess and compare the habitat quality in some female home ranges prior to and following the 1988 wildfires in Yellowstone National Park. This information was presented at a meeting held on the Forest on September 14, 1995, and is:

GRIZZLY BEAR - ANALYSIS PROCESS

	<u>Female 125</u>		<u>Female 126</u>	
	<u>Pre- fire</u>	<u>Post- fire</u>	<u>Pre- fire</u>	<u>Post- fire</u>
Vegetation Value	.28	.39	.24	.27
Habitat Value	.31	.40	.26	.30
Habitat Effectiveness	.23	.33	.21	.25

CC/JR

COMMENTS: DFPR needs to define what habitat improvements will be allowed and what specific activities are considered improvements.

1369

RESPONSE: The Revised Plan establishes the goals, objectives, standards and guidelines which provide direction for future site specific projects. It is not the place of forest plans to define or describe specific improvements or activities. This would be done in a site-specific NEPA analysis. MO

COMMENTS: DFPR III-89: Security area should encompass a minimum 7,000 acres and must be effective.

643

RESPONSE: This Management Prescription 2.6.5 is 19,975 acres in size and the only motorized access allowed is on two roads. This security area is very effective. MO

COMMENTS: Protection of grizzly bears leaving dens could be accomplished with site specific and time specific measures rather than disallowing any activities.

1389

RESPONSE: The Forest is in agreement. In the Revised Plan, the Forest removes the cross-country snowmachine closure date of April 1 in the BMU's, and adds the following standard: "Within grizzly bear BMUs, site specific restrictions on winter recreation activity (such as area closures, timing restrictions, and so forth) will be imposed to resolve human-grizzly bear conflicts."

COMMENTS: Recommend vegetative manipulation not be permitted regardless of pine-nut crop yield. It is a weak assumption that if there is a bad pine-nut crop, bears will not be there and contact with people will be minimized.

643, 1273b

RESPONSE: The Revised Plan has a guideline stating there will be no vegetation manipulation in whitebark pine areas in the fall, except in years of poor cone crops, in order to help avoid conflicts with bears in whitebark pine areas. MO

COMMENTS: Lack of baseline data reduces the effectiveness of grizzly bear management because relocating security areas causes more damage.

176

GRIZZLY BEAR - ANALYSIS PROCESS

RESPONSE: There are two kinds of security areas in the Revised Plan: permanent security areas and short term security areas associated with timber sale activities.

The permanent security areas are established by management prescription, and meet "core area" criteria as identified in the Interagency Grizzly Bear Committee Task Force Report on Grizzly Bear/Motorized Access Management. These management prescriptions are in place for the 10 to 15 year planning period of the Revised Plan. These management prescriptions include the following: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2.

Short term security areas are established adjacent to active timber sale areas, and are in place for the duration of the timber sale activity. MO

GRIZZLY BEAR - BEAR MANAGEMENT UNITS

Support

COMMENTS: Protect grizzly BMUs by locating them in wilderness areas; prohibiting firearms, and prohibiting off-highway travel.

F-K(6), 393, 659, 692, 1239, 1273b, 1316, 1322, 1330, 1365, 1390

RESPONSE: The grizzly bear recovery zone includes more areas than just wilderness areas. Wilderness areas, by themselves, will not support a recovered grizzly bear population.

Prohibiting firearms is a drastic measure that would end all hunting within the BMUs. Data on the bear population indicates that it is increasing, so it is not necessary to prohibit firearms.

The Revised Plan closes nearly all of the BMUs to cross-country motorized travel. MO

COMMENTS: Do not convert from a cattle allotment to sheep allotments in BMU.
1446

RESPONSE: The Revised Plan contains such a standard to prohibit this from occurring. MO

COMMENTS: Incorporate into the grizzly bear management prescriptions: Recommend habitat effectiveness goals and provide a solid time line which will achieve grizzly bear habitat effectiveness.

643

RESPONSE: At this time, the cumulative effects model is not validated, and therefore there is no specific habitat effectiveness goal which can be established. MO

Non Support

COMMENTS: Do not support BMUs for grizzly bears because bears do not winter in them and they are just a backdoor to expand Yellowstone National Park. If you want to expand the park, you should put it to a vote.

285, 607, 728

GRIZZLY BEAR - BEAR MANAGEMENT UNITS

RESPONSE: Grizzly bears den within the BMUs. Grizzly bear BMUs are not a backdoor to expand Yellowstone National Park. They are based on year round habitat needed to sustain a subpopulation of bears. MO/JR

GRIZZLY BEAR - COMMITTEE GUIDELINES

Support Committee Guidelines

COMMENTS: Supports the use of the Interagency Grizzly Bear Committee Guidelines including the use of Situation I, II, and III. Implement Situation I under the Biological Elements Sections. Put the IGBC Guidelines under Grizzly Habitat Standards and Guidelines.

F-D(51), F-F(6), 135, 267, 293, 323, 346, 367, 374, 381, 385, 386, 389, 393, 404, 413, 473, 474, 476, 481, 495, 524, 628, 643, 1187, 1202, 1273b

RESPONSE: The Revised Plan incorporates the Interagency Grizzly Bear Guidelines in the management prescriptions which are within the grizzly bear recovery zone. This direction is not repeated in the Revised Plan. MO

Address Changing Habitat Needs

COMMENTS: On Pages II-3, 4, and 5 Needs for Change of the IGBC Guidelines: Delete the last paragraph and replace with the following: "The provisions of the ESA have not yet changed since the Plan was put into effect in 1985. However, the understanding of the habitat needs of the listed species, in particular the grizzly bear, changed management on a large portion of the Forest. New information, accumulated over the last ten (10) years, provides new insight and direction regarding effective management access, vegetation manipulation, and human activities in grizzly bear habitat."

This change will alleviate the need for discussion of why Alternative 1 does not fully comply with the 1985 FP or Guidelines direction for timber management in Situation 1-2 grizzly bear habitat.

1446

RESPONSE: The wording in Section VII was changed as you suggested. JR

COMMENTS: Specify an adaptive approach to the response to habitat change in the IGBC Team Guide; add monitoring.

297, 697

RESPONSE: The Forest concurs that adaptive management and monitoring are important parts of the Revised Plan. Refer to the Monitoring and Evaluation section for grizzly bears for more information. MO

COMMENTS: Explain when/why the IGBC discarded the habitat system on page II-17 and why this approach is not accepted by today's scientific community.

228

RESPONSE: The Interagency Grizzly Bear Guidelines have not been officially discarded. Areas within the recovery zone are managed in accordance with Management Situation 1 Guidelines, thereby doing away with designations of

GRIZZLY BEAR - COMMITTEE GUIDELINES

Management Situation 2. Within the grizzly bear recovery zone, grizzly/human conflict minimization and grizzly bear habitat management receives the highest management priorities. Management decisions favor the needs of the grizzly bear population when grizzly habitat and other land uses cannot be made compatible. Occasionally individual grizzly bears might be removed or relocated when conflicts occur. This is only done according to the nuisance bear guidelines and when the action will not threaten the population.

Developed areas are managed in accordance with Management Situation 3 Guidelines. In developed areas where human presence results in conditions which make grizzly presence untenable for humans and/or grizzlies, grizzly bear presence and factors contributing to their presence are actively discouraged. Grizzlies frequenting such developments are managed according to nuisance bear guidelines. MO

Oppose Committee Guidelines

COMMENTS: Oppose the use of the Interagency Grizzly Bear Committee Guidelines because of the restrictions and closed door approach and because people should be considered, not just threatened and endangered species.

608, 648, 702, 1202

The decision to move bears to zoos should be transferred to a committee of citizens at risk by the bears rather than IGBC.

275

RESPONSE: The Forest must follow laws and regulations contained in the Endangered Species Act, The National Forest Management Act, and other acts, manuals and handbooks pertaining to the management of National Forests. The only human related activity that will be completely eliminated within the grizzly bear recovery zone is domestic sheep grazing (the domestic sheep grazing will be phased out over time). Other human activities are allowed to occur within the grizzly bear recovery zone, but they must follow specific standards and guidelines as outlined in the Revised Plan. Removal of the bears to zoos or any other location is under the direction of the Fish and Wildlife Service. MO

GRIZZLY BEAR - GENERAL

Non Support

COMMENTS: Oppose grizzly bear management efforts because it should not have priority over any other issue including human needs, grazing, rights, and economic needs of small communities; oppose expansion of grizzly population; too many bears, too many conflicts.

12, 24, 34, 42, 219, 285, 298, 311, 341, 344, 346, 388, 393, 431, 432, 450, 525, 607, 608, 665, 720, 1202, 1242, 1259, 1354, 1358, 1390, 1395

Public lands should be managed for public needs, not primarily for grizzly bears, therefore management guidelines should be followed without "politics."

F-F(6), 242, 292

Handicapped people do not want to encounter a grizzly in the forest.

446

GRIZZLY BEAR - GENERAL

RESPONSE: The Forest must obey laws and regulations contained in the Endangered Species Act and National Forest Management Act pertaining to threatened and endangered species, which includes the grizzly bear. The only human activity that will be completely eliminated within the grizzly bear recovery zone is domestic sheep grazing which will be phased out over time. Other human activities are allowed to occur within the grizzly bear recovery zone, but they must follow specific standards and guidelines as outlined in the Revised Plan. Information is available at Forest Service offices about how to safely coexist with the grizzly bear, with a minimum of conflict.
MO/AM

Support

COMMENTS: Expand management plans and management situation lines to accommodate growing bear populations and their use of the Forest; ensure grizzly bears remain a part of our ecosystem and heritage; management of grizzly should have priority over other human activities including logging, recreation and grazing; management of grizzly bears is necessary for viable populations; protect grizzlies even in conflict with humans because they deserve a chance to live.

49, 179, 226, 293, 464, 468, 519, 615, 662, 694, 1194, 1273b

RESPONSE: The Revised Plan does not expand the grizzly bear recovery zone. The Revised Plan gives grizzly bears and grizzly bear habitat management emphasis within the recovery zone. All human activities within the recovery zone must follow standards and guidelines developed to protect the grizzly bear population and maintain or improve grizzly bear habitat. MO

COMMENTS: The Forest Service should consult with the U.S. Fish and Wildlife Service on all of the allotments within Grizzly Bear Recovery Zone.

1269, 1446

RESPONSE: The Forest formally and informally consults with the U.S. Fish and Wildlife Service on all of the provisions of the Revised Plan, including the livestock grazing standards and guidelines within and without Grizzly Bear Recovery Zones. MO

Miscellaneous

COMMENTS: The Forest Service should maintain existing carnivore movement between existing ecosystem until completion of the five year evaluation process.

1273b

RESPONSE: The 1993 Grizzly Bear Recovery Plan identified the need to assess the potential of linkage zones between the different grizzly bear recovery areas. At this time, little is known about the potential for linkage zones. The linkage zone assessment for the Centennial Mountains is not done. While the assessments are being done, the Recovery Plan suggests the following management considerations:

"Future land management activities within these areas may be critical to maintaining their utility as linkage zones. It is essential that

GRIZZLY BEAR - GENERAL

existing options for carnivore movement between existing ecosystems be maintained while the evaluation of linkage zones is underway. Management strategies that limit human-induced mortality and address access management will facilitate the maintenance of the potential of these zones during the 5-year evaluation period. On public lands, management prescriptions similar to big game summer range prescriptions that address access management would likely conserve any existing potential of these areas for linkage until completion of the 5-year evaluation process."

"Connectivity between the Yellowstone Grizzly Bear Ecosystem and other grizzly ecosystems is not likely to be realized in the near future because of the distance to other ecosystems and the intervening human development and alteration of landscape. Therefore, the recovery plan recommends that one grizzly be placed into the ecosystem from an outside population every ten years as an effort to maintain the genetic health of the population."

The Revised Plan incorporates these management considerations by reducing motorized access throughout the Centennial Mountains and in other possible linkage zones, and by using management prescriptions which improve or maintain big game habitat. MO

COMMENTS: Need to carry firearms in grizzly bear country, especially when leading young people, to scare grizzlies away. Need alternatives to cover head and protect vital organs.

FS-6

RESPONSE: Firearms are allowed on National Forest lands. It is lawful to protect yourself from a grizzly bear attack. Within the grizzly bear recovery zone, there are regulations which require people to store their food so as not to attract grizzly bears. MO

COMMENTS: Base grizzly bear management on the best science available.
393, 692, 1267

RESPONSE: For the Revised Plan, the Forest used the research conducted on grizzly bears in the Yellowstone ecosystem and the grizzly bear cumulative effects model to analyze habitat conditions. This is considered as some of the best science available. MO

COMMENTS: Removal of carcass or complete incineration is only alternative to prevent a bear from using the carcass.
389

RESPONSE: The Forest allows the use of explosives to "remove" the carcass of a dead animal so it does not attract a grizzly bear. MO

COMMENTS: Recommend restricting toxicants because they may violate the "Endangered Species Act" for such as the grizzly bear.
389

RESPONSE: All chemicals used on the Forest must be approved prior to their use through site-specific project analysis. This analysis ensures that the Endangered Species Act is not violated. MO

GRIZZLY BEAR - GENERAL

COMMENTS: Grizzly bear populations have increased and are now found in range that has not been occupied for many decades.

1188, 1363

RESPONSE: Research on the Yellowstone grizzly bear population indicates that the population is increasing between two to five percent per year. MO

COMMENTS: Concerned about recreational and environmental impacts that "buffer areas" have.

694

RESPONSE: We are not clear what "buffer" areas are being referred to. The grizzly habitat management strategy implemented in the Final Revised Plan addresses grizzly habitat needs within the Recovery Area that has been in place for many years. JR

COMMENTS: The Fish and Wildlife Service must administer the Endangered Species Act as well as work with numerous other Federal environmental laws. The lawsuit regarding grizzly bears will be resolved pending the outcome of the Targhee Plan. The Forest Service is writing the biological assessment and then the USFWS will respond.

314

RESPONSE: The Forest agrees. MO

GRIZZLY BEAR - MONITORING

COMMENTS: The Forest should monitor people driving through fences/gates on closed roads; install and monitor proper closure devices for effective security for grizzly bears.

175, 667

RESPONSE: The Revised Plan establishes motorized access as a number one monitoring priority. The Plan provides direction to make road closures and restrictions effective, so that people do not drive around them. MO

Maps/Signs/Education

COMMENTS: Provide brochures, posters and educational efforts at trailheads, campsites and areas open for travel in grizzly bear country; establish a timeline for grizzly bear education program. (CROSS REFERENCE: Recreation)

643

RESPONSE: The Revised Plan contains a guideline on grizzly bear education, focusing efforts on residents in residential and summer home areas, developed recreation site users, wilderness users, hunters, outfitters and guides, and permittees. The grizzly bear education program is continuous, therefore, no timeline is established. MO

GRIZZLY BEAR - MONITORING

Time Lines

COMMENTS: Recommend a time specific plan that describes the prioritization scheme for implementing the road closure program for grizzly bears; plan a schedule for closing sheep allotments; identify the sheep allotments that have the most potential for livestock/grizzly interactions within one year and address in Objective 9 to discontinue livestock grazing in grizzly bear habitat.

643, 1273b, 1277

RESPONSE: The Revised Plan has an objective to implement the TMARD and OROMTRD within three years in the grizzly bear BMU's. The Revised Plan directs the phasing out of domestic sheep allotments in the grizzly bear BMU's, but no time line to accomplish this is established because the phase out is on an opportunity basis. MO

Implementation

COMMENTS: Support management activities in core areas to remain inviolate for 11 years; secure additional core areas for no less than two years.

643

RESPONSE: The following management prescriptions meet core area criteria, and are designed to be in place for the entire 10 to 15 year period of the Revised Plan: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2. MO

GRIZZLY BEAR - POLITICS

COMMENTS: The government should not manage for the grizzly bear; oppose reintroduction efforts to Central Idaho and Island Park areas; Congressional legislation was not intended to favor grizzly bear over people.

5, 12, 467, 469, 688

RESPONSE: The Forest is obeying laws and regulations pertaining to the Endangered Species Act and the National Forest Management Act. MO

GRIZZLY BEAR - PRESCRIPTIONS

COMMENTS: Include a contingency standard management prescription that addresses grizzly bears using areas outside of BMU's and to allow Forest Service personnel to verify bear sightings.

643

RESPONSE: Grizzly bears outside the BMU's are protected under authority of the Endangered Species Act. Management currently follows the Interagency Grizzly Bear Guidelines. The Interagency Grizzly Bear Committee is working on a conservation strategy which will further address the management of grizzly bears outside of the recovery zone.

Current policy provides for Forest Service personnel to provide information on grizzly sightings. MO/JR

GRIZZLY BEAR - PRESCRIPTIONS

Management Prescription 5.3.5

COMMENTS: Change Prescription 5.3.5 to designate core areas as a true refuge for grizzly bears.

644, 690

RESPONSE: Management prescription 5.3.5 is not a core area. Other management prescriptions (1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, 3.1.2) meet core area criteria for the grizzly bear. MO

COMMENTS: Prescription 5.3.5 is not listed on Map; 1.1.1 prescription with 10,000 acres - where are they? There is also inconsistency which needs fixing where the same item is identified as a standard in one place and a guideline in another.

314

RESPONSE: Management prescription 5.3.5 only occurred on Map 10 (Alternative 3M) in the Draft Plan. Your reference to prescription 1.1.1 is listed in the prescription table for the Madison subsection. This is an error. Prescription 1.1.1 is not used in alternative 3M. Thank you for pointing this out. We have searched out inconsistencies to correct them in the Final Revised Plan. MO

COMMENTS: Explain in Management Prescription 5.3.5 Grizzly Bear Habitat if map 29 indicates where cattle grazing is allowed.

695

RESPONSE: It is not necessary to explain in Management Prescription 5.3.5 that map 29 indicates where cattle grazing is allowed. MO

Management Prescription 2.6.X Series

COMMENTS: DFPR III-86: The area covered by Management Prescription 2.6.1(a) serves as a critical corridor for grizzly bears. While lands are not in the suitable timber base and will not contribute toward the ASQ, there is potential for timber harvest under ecosystem management. This must be clearly addressed in the management prescription. Timber Sale Contract for DFPR III-122 management prescriptions include mitigations such as those described in Forest Service Regulations CT6.25.

643

RESPONSE: In the Final Revised Plan, a limit of twenty million board feet per decade has been placed on harvest opportunities that occur on unsuited lands. All unscheduled timber harvest must follow forestwide standards and guidelines, and management prescription direction and standards and guidelines. There will also be site-specific NEPA analysis, and informal or formal consultation with the U.S. Fish and Wildlife Service. MO

COMMENTS: Regarding Prescription 2.6.5: Mountain biking and other mechanized travel should be discouraged in core areas; create a standard that there will be no construction of temporary roads; begin the reclamation of all roads within one year of signing of the ROD and make this a standard; allow

GRIZZLY BEAR - PRESCRIPTIONS

outfitter and guide permits only if the activities are compatible with core areas.

1446

RESPONSE: There is no data to suggest that mountain biking or other nonmotorized mechanized travel causes any more impact than walking, hunting, or horse travel.

The standard for the roads prescription says: "Construct no new roads." This means any type of road, including permanent or temporary. The Revised Plan objective for closing and obliterating roads in the BMU's is to accomplish this work within three years of implementation of the ROD. The three-year time period recognizes the large amount of work and cost that will be involved and budget limitations.

Existing outfitter and guide permits are allowed, but no new outfitter and guide permits are allowed. There have been no grizzly bear conflicts with the existing permittees. MO

COMMENTS: Favor Prescription 2.6.X series for grizzly habitat rather than 5.3.5.

695

RESPONSE: The Forest analysis indicates that the combination of management prescriptions in the grizzly bear BMU's will provide the necessary habitat conditions for bear occupancy and use. MO

COMMENTS: Revise the Management Prescription for BMU's south of Robinson Creek 5.3.6. In order to emphasize "a high degree of security and resource conditions which contribute toward the conservation and recovery of the grizzly bear, and benefits to other wildlife." Emphasize a high degree of security and resource conditions which contribute toward the conservation and recovery of the grizzly bear, and benefits to other wildlife, while providing some timber harvest opportunities for local businesses and individuals. (The second paragraph is the same as the second paragraph in MP 5.3.5). The third paragraph should be modified to read as follows:

The abundance and distribution of natural food sources (such as huckleberry habitats, whitebark pine, etc.) are maintained or improved by natural events such as fire and insect disturbances. A variety of forest successional stages are present due to restraint from human interference with natural events and disturbances. Habitat conditions which contribute to the movement of bears to adjacent bear management units are maintained. Human activities are managed so that human conflicts with grizzlies are unlikely; this includes increased public education on grizzly bear, elk and other wildlife species dependent on similar habitat needs. Motorized access is reduced to protect other resource needs. Objectives: Same as 5.3.5. Standards and Guidelines: Same as in 5.3.5, but with the changes noted below.

Under the subsection that discusses "Insects & Disease," there is no scientific validity to the assumption that, on an ecosystem scale, insects and disease will have any significant negative impacts on the maintenance of grizzly habitat. The negative tone and word selection only contributes to the unsubstantiated claims that a forest that has insects and disease is "unhealthy". This unfounded bias will ultimately lead to inappropriate timber harvest such as we have seen on the Targhee in the past. Timber harvest and

GRIZZLY BEAR - PRESCRIPTIONS

its accompanying roading are the causes of grizzly bear impacts on the Forest, not insects and disease. The last phrase of this Guideline which reads "...unless this conflicts with the maintenance of grizzly bear habitat" needs to be deleted.

Wildlife: Maintain snag habitat at >60 percent of the biological potential for woodpeckers. (Convert this stipulation from a Guideline to a Standard).

Number, Size and Location - Change to the following: Security areas will encompass a minimum of 7,000 acres, contain no roads, be devoid of major human activities, and contain seasonal habitat components important to grizzly bears. They will be distributed across a landscape so as to function as a network, rather than merely isolated "islands". (S)

The Standard for "Number, size and location" of activity areas with its requirement that areas shall not exceed 7,000 acres in size seems to be in conflict with the Guideline that addresses EA analysis areas. That guideline requires that analysis areas are suppose to be "at least 7,000 acres in size."

Paragraph 1 on Page III-134, change "should" to "will" and make this a Standard. Paragraph 2, Page III-134, add the following sentence and make this a Standard. "No more than one entry into an area per decade, not to exceed three years in duration."

Forest Use and Occupation: Access(S). Same as MP 5.3.5 except System roads 804, 383, 254 from its junction with road 656 to where it ends, and 267 would be closed. Roads

No new roads for any management activity will be constructed unless an equal or greater number of miles of existing roads are identified for obliteration, and obliterated at least two years prior to new road construction. New road construction will comply with the following requirements: (S)

The four road requirements will remain the same as noted on Page III-134 and III-135.

Recreation. Trails - New or relocated trails will meet the following: 1. Avoid high quality grizzly bear habitat. (S)

Sanitation - Human activity sites will be kept clean of all potential grizzly bear attractants. This includes human food, garbage, horse pellets, dog food and waste. Reasonable standards for front country and backcountry sanitation will be applied throughout the BMU's (S).

Production of Natural Resources. Timber.

The minimum cover standard is 50%, including a minimum 20% hiding cover, 20% thermal cover, and an additional 10% hiding or thermal cover. Hiding cover is defined as the ability to hide 90% of a grizzly bear at 200 feet. Thermal cover is defined as trees at least 40 feet tall, with a closed canopy of at least 70%. The documents include more detailed definitions. Furthermore, cover will not be considered effective unless they are at least 4 to 8 sight distances across (4 to 8 times the maximum distance one can spot a bear or other animal). In areas in or adjacent to riparian areas, the minimum standard is 6 to 8 sight distances. (S)

Maximum distances to security cover will be at least 150 feet, based on the FWS Biological Opinion. (S). New, created openings shall not exceed 1.6 acres in size, and no existing openings greater than 1.6 acres in size shall be enlarged. No new created openings are allowed adjacent to existing openings (including meadows and created openings). Size restriction

GRIZZLY BEAR - PRESCRIPTIONS

of new openings ensures there will be no further loss of habitat available to grizzlies for foraging. (S)

Group selection or individual tree selection harvest methods will be the preferred silvicultural technique. No sale shall exceed 50 MBF. Sales will only be offered to qualified small businesses with fewer than 20 employees. (S)

Security cover is defined as forested acres (all tree species) which have not been managed or burned in the last 40 years. (S)

No activity is permitted for the purposes of maintaining natural openings. (S)

There will be no vegetation management in riparian areas or in whitebark pine areas. (S)

Dead and Down Component - all tops and limbs resulting from timber harvest will be scattered in the immediate vicinity of harvested trees. (S)

Security areas must provide the following conditions:(S) 1. No change. 2. No change. 3. No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated as a security area. The minimum length of time that an area will be designated as a security area will be ten years.

643

RESPONSE: The Forest considered all of the above recommendations, but decided that the combination of management prescriptions applied in the Revised Plan for the lands south of Robinson Creek provide for grizzly bear occupancy and use to achieve the objectives of the grizzly bear recovery plan.

The Fish and Wildlife Service covered this in their Biological Opinion on the Revised Forest Plan. MO/JR

GRIZZLY BEAR - RANGE/HABITAT

COMMENTS: Support phasing out sheep allotments to improve grizzly habitat; prohibit grazing in high quality food production areas.

1185, 1273b, 1331

Oppose phasing out sheep allotments and grazing to improve grizzly habitat.

404, 1188, 1354, 1363,

RESPONSE: The Targhee has a well documented history of grizzly bear and domestic sheep incidents. All of the domestic sheep allotments in Management Situation 1 habitat are already closed. The remaining domestic sheep allotments, which are in Management Situation 2 habitat, are to be phased out on an opportunity basis in the Revised Plan. The Forest chose the phase out because these allotments have not had grizzly bear/sheep incidents, or the number of incidents have been few, and no grizzly bears have been harmed or killed. MO

COMMENTS: Grazing permits should include specific language that assures guidelines for minimizing grizzly bear/livestock conflicts.

389

GRIZZLY BEAR - RANGE/HABITAT

RESPONSE: All grazing permits within the grizzly bear recovery zone have specific direction for minimizing and responding to grizzly bear/livestock conflicts. MO

COMMENTS: Reduce the maximum distance to security cover for grizzly bear from 300 feet to 150 feet. Stated amount is twice the recommended amount.
643

RESPONSE: There is no data available which establishes the amount of distribution, or the size of cover for grizzly bears on a landscape basis. The guideline in the Revised Plan follows what limited research is available, but allows for site-specific considerations, such as for natural patch sizes and other ecosystem management needs. MO

COMMENTS: Riparian, wetland, and stream areas (on Targhee National Forest) should be preserved and dedicated as grizzly bear sanctuary.
276, 1383

RESPONSE: These areas are managed according to direction contained in management prescription 2.8.3. This management direction will maintain or improve these areas for the grizzly bear as well as many other species which use these areas. MO

COMMENTS: Address habitat fragmentation not just road density limits in grizzly bear areas.
1368

RESPONSE: Based on this information the Revised Plan will not result in habitat fragmentation detrimental to grizzly recovery. In fact, the reduction in road density, combined with the standards and guidelines for vegetation management, will reduce any fragmentations which may exist presently.

There is no research which defines habitat fragmentation for grizzly bears. The following summary on food habits and cover illustrate that bears use a wide variety of habitats and have been able to respond to large changes in habitat conditions, such as the 1988 Yellowstone fires:

FOOD HABITS - GENERAL OVERVIEW (U.S. Fish & Wildlife Service 1993)-
The broad historic distribution of grizzly bears suggests adaptive flexibility in food habits of different populations. Although the digestive system of bears is essentially that of a carnivore, bears are successful omnivores, and in some areas may be almost entirely herbivorous. Although grizzly bears in many areas are almost entirely herbivorous, they are lacking in multiple stomachs and a caecum and are therefore unable to digest cellulose. Bears feed on animal or vegetable matter that is highly digestible and high in starch, sugars, protein, and stored fat.

Grizzly bears must avail themselves of foods rich in protein or carbohydrates in excess of maintenance requirements in order to survive denning and post-denning periods. Herbaceous plants are eaten as they emerge, when crude protein levels are highest. These levels decline rapidly in many plant species as the plants mature.

Grizzly bears are opportunistic feeders and will prey or scavenge on almost any available food including ground squirrels, ungulates, carrion, and garbage. In areas where animal matter is less available, roots, bulbs,

GRIZZLY BEAR - RANGE/HABITAT

tubers, fungi, and tree cambium may be important in meeting protein requirements. High quality foods such as berries, nuts, and fish are important in some areas.

The search for food has a prime influence on grizzly bear movements. Upon emergence from the den they seek the lower elevations, drainage bottoms, avalanche chutes, and ungulate winter ranges where their food requirements can be met. Throughout late spring and early summer they follow plant phenology back to higher elevations. In late summer and fall, there is a transition to fruit and nut sources, as well as herbaceous materials. This is a generalized pattern, however: bears are individuals trying to survive and will go where they can best meet their food requirements.

COVER - GENERAL OVERVIEW (U.S. Fish and Wildlife Service 1993) "The relative importance of cover to grizzly bears is documented by Blanchard (1978) in a 4-year study in the Yellowstone ecosystem. Ninety percent of 2,261 aerial radio relocations of 46 instrumented grizzly bears were in forest cover too dense to observe the bear. Whether grizzly bears use forest cover because of an innate preference or to avoid humans is unknown (Blanchard 1978). The importance of an interspersed open parks as feeding sites associated with cover is also recorded in Blanchard's study: 'Only 1 percent of the relocations were in dense forest more than a kilometer from an opening.'"

"Forest cover was found to be very important to grizzly bears for use as beds. Most beds were found less than a yard or two from a tree (Servheen and Lee 1979, Blanchard 1978). Blanchard further records only 16 of 233 beds observed (6.7 percent) were without immediate cover. Schallenberger and Jonkel (1980) found grizzly bears preferring forest in over 80 percent of their radio relocations."

There is no research documenting requirements for the distribution, quantity or quality of cover on a "landscape" scale or within grizzly bear home range. Changes in the distribution and quantity and quality of cover are not necessarily detrimental to grizzly bears. At the September 19-21, 1993, symposium on "The Ecological Implications of Fire in Greater Yellowstone - Second Biennial Conference on the Greater Yellowstone Ecosystem," the Interagency Grizzly Bear Study Team presented a paper titled "Effects of Wildfire on Grizzly Bear Movements and Habitat Use." The following is quoted from the abstract of the paper:

"On the average, grizzly bears used burned habitats in proportion to their availability within individual annual ranges during 1989-1992. Seasonal indices of movement and annual range sizes of cohorts are not statistically different from the 1975-1987 averages."

The grizzly bear cumulative effects model was recently used to assess and compare the habitat quality in some female home ranges prior to and following the 1988 wildfires in Yellowstone National Park. This information was presented at a meeting held on the Forest on September 14, 1995, and is presented below:

	<u>Female 125</u>		<u>Female 126</u>	
	<u>Pre-</u>	<u>Post-</u>	<u>Pre-</u>	<u>Post-</u>
	<u>fire</u>	<u>fire</u>	<u>fire</u>	<u>fire</u>
Vegetation Value	.28	.39	.24	.27
Habitat Value	.31	.40	.26	.30
Habitat Effectiveness	.23	.33	.21	.25

GRIZZLY BEAR - RANGE/HABITAT

Positive aspects of timber management include an increase in bear foods (such as forbs, berries, and grasses) in certain regions through vegetative manipulation (such as tree removal, riparian management, or prescribed burning). Timber management programs may negatively affect grizzly bears by removal of cover, displacement from habitat during the logging period, and increases in human/grizzly bear confrontation potential or disturbance factors as a result of road building and management. (U.S. Fish and Wildlife Service 1993) MO

GRIZZLY BEAR - SITE-SPECIFIC

Dubois District

COMMENTS: Support the proposal for Italian Peaks area to wilderness status to enhance grizzly habitat. (CROSS REFERENCE: Wilderness)
643, 1314

RESPONSE: Thank you for the support, however, Italian Peaks is outside the grizzly bear recovery zone, and is proposed as wilderness because of other factors, not the grizzly bear. MO

COMMENTS: Place a strong grizzly conservation emphasis at McGarrey Canyon, West Three Mile Creek, West Camas Creek, and Telephone Creek.
1348

RESPONSE: These areas are outside the grizzly bear recovery zone, and do not receive special emphasis for grizzly bear management in the Revised Plan. MO

Island Park District

Support

COMMENTS: Support proposal 2.6.1(a) in Two Top Roadless Area; support Grizzly Bear Management at Sawtell Peak, Carrot Canyon, Taylor Creek, Sheridan Creek and Table Mountain; upgrade Henry's Lake Mountains to non-motorized grizzly bear habitat; keep Lionhead free from encroachment by motorized vehicles.
362, 643, 695, 1185, 1348

RESPONSE: The Revised Plan incorporates these management recommendations. MO

COMMENTS: Address the need for bear-proof dumpsters in Island Park.
1276

RESPONSE: Bear-proof dumpsters in Island Park require the continued cooperation and involvement of state, county, and municipal governments, and the numerous private businesses and land owners. The Targhee National Forest will help and cooperate as much as possible. MO

Non Support

COMMENTS: Oppose closing any sheep allotments, both active and vacant to manage for grizzly bears; oppose grizzly bear management in Island Park

GRIZZLY BEAR - SITE-SPECIFIC

because grizzly bears will not go in designated areas of Cave Falls up to Old Faithful; strongly oppose expansion of grizzly bear populations in Area 61.

F-F(6), 267, 298, 413, 433, 466, 694

RESPONSE: The Revised Plan phases out all domestic sheep allotments within the grizzly bear recovery zone because of the well documented history of conflicts between grizzly bears and domestic sheep.

The area referred to from Cave Falls to Old Faithful applies to the Plateau BMU. This BMU has lower habitat values and documented use for grizzly bears than most other BMU's and lower documented grizzly bear use than most other BMU's. However, management will emphasize the grizzly bear for the next 10 years to evaluate grizzly bear occupancy and use of this area.

Area 61 refers to Idaho Department of Fish and Game, Game Management Unit 61. A portion of this game management unit is within the grizzly bear recovery zone, and grizzly bear management is emphasized in this portion. MO

COMMENTS: Oppose closing nine vacant sheep allotments on this district because these allotments are located on Situation 2 grizzly habitat which is poor grizzly habitat.

413

RESPONSE: The nine sheep allotments referred to are within the grizzly bear recovery zone of the Island Park Ranger District. There are also two sheep allotments on the Teton Basin Ranger District within the grizzly bear recovery zone. These 11 allotments are to be phased out on an opportunity basis in the Revised Plan. The reason they are being phased out is because of the well documented history of conflicts between grizzly bears and domestic sheep in Situation 1 habitat. As the grizzly bear population continues to expand, the Forest expects the same kinds of conflicts in Situation 2 habitat in the future. MO

Garns Mountain

COMMENTS: Make Garns Mountain a wilderness to ensure adequate grizzly habitat.

181

RESPONSE: Garns Mountain is outside the grizzly bear recovery zone, and management emphasis is not placed on the grizzly bear in this area of the Forest. MO

Jackpine Creek

COMMENTS: Supports retaining roadless character of the Jackpine Creek area for grizzly bear security.

1312

RESPONSE: The Jackpine Creek area is maintained as a roadless area in the Revised Plan. This area meets core area criteria as defined in the Interagency Grizzly Bear Committee Taskforce Report on Grizzly Bear/Motorized Access Management. MO

GRIZZLY BEAR-- SITE-SPECIFIC

Centennials

(CROSS REFERENCE: Centennials)

Support

COMMENTS: Support the Centennial Mountains as grizzly bear habitat.
136, 174, 175, 176, 180, 212, 278, 436, 1185, 1381

RESPONSE: The eastern portion of the Centennial Mountains is within the grizzly bear recovery zone for the Yellowstone Recovery Area, and in this portion, the grizzly bear receives management emphasis.

The western portion of the Centennial Mountains is identified for a study by the Interagency Grizzly Bear Team to assess the potential for a linkage zone or corridor to connect the Yellowstone area with central Idaho and northwestern Montana. As of this date, the study has not been done. MO

COMMENTS: Proposed timber sales should be reduced or eliminated in favor of less sensitive areas because timber activities including roads will not improve grizzly bear habitat and will cause fragmentation.
438, 690, 1360

RESPONSE: All timber harvesting in the portion of the Centennial Mountains within the Recovery Zone must follow the standards and guidelines in management prescription 5.3.5. These standards and guidelines are developed to maintain or improve grizzly bear habitat while allowing for some timber harvesting. The Revised Plan also reduces and establishes standards which cannot be exceeded for TMARD and OROMTRD in the Centennial Mountains. MO

COMMENTS: Eliminate grazing on the east end of the Centennials; grazing, in general, is a problem in the Centennials.
695, 1387

RESPONSE: The Revised Plan calls for phasing out all domestic sheep allotments within the grizzly bear recovery zone in the Centennial Mountains. Grazing, in general, is not a problem in the Centennials. MO

COMMENTS: The entire Centennial Mountain Range should be designated a "core" Grizzly Bear Management Area.
1387

RESPONSE: The Revised Plan establishes core areas within the grizzly bear recovery zone. However, it is not possible or necessary to make the entire Centennial Mountain Range a core area for grizzly bear management. MO

COMMENTS: The Centennials will need careful management to avoid conflicts between grizzly bears and people.
1348

RESPONSE: Within the grizzly bear recovery zone, grizzly bear management is emphasized to avoid conflicts between grizzly bears and people. MO

GRIZZLY BEAR - SITE-SPECIFIC

Non Support

COMMENTS: Do not consider the Centennials as grizzly bear habitat.
1314

RESPONSE: The eastern portion of the Centennials is within the Yellowstone grizzly bear recovery zone as established in the Grizzly Bear Recovery Plan.
MO

Corridors

COMMENTS: Preserve the Centennial Mountains as an important linkage and do not fragment by logging activities.

652, 690, 1387

Protect the Centennial Mountain Range and manage it in cooperation with adjoining public land managers with a long-term conservation strategy because it will encourage genetic diversity within grizzly bear populations.

690

The Centennial Range is a link to the Yellowstone Ecosystem as well as other large ecosystems in Idaho and Montana.

3, 51, 136, 157, 174, 175, 180, 181, 203, 209, 252, 270, 276, 280, 293, 356, 411, 496, 516, 643, 659, 690, 1185, 1273b, 1348, 1381, 1385, 1387, 1393

Use OROMTRD in the Centennial Corridor.

1273b

Treat the Centennial Range as a single landscape unit.

1185

RESPONSE: The 1993 Grizzly Bear Recovery Plan identified the need to assess the potential of linkage zones between the different grizzly bear recovery areas. At this time, little is known about the potential for linkage zones. The linkage zone assessment for the Centennial Mountains has not been done. While the assessments are being done, the Recovery Plan suggests the following management considerations:

"Future land management activities within these areas may be critical to maintaining their utility as linkage zones. It is essential that existing options for carnivore movement between existing ecosystems be maintained while the evaluation of linkage zones is underway. Management strategies that limit human-induced mortality and address access management will facilitate the maintenance of the potential of these zones during the 5-year evaluation period. On public lands, management prescriptions similar to big game summer range prescriptions that address access management would likely conserve any existing potential of these areas for linkage until completion of the 5-year evaluation process."

Connectivity between the Yellowstone Grizzly Bear Ecosystem and other grizzly ecosystems is not likely to be realized in the near future because of the distance to other ecosystems and the intervening human development and alteration of landscape. Therefore, the recovery plan recommends that one grizzly be placed into the ecosystem from an outside population every ten years as an effort to maintain the genetic health of the population."

GRIZZLY BEAR - SITE-SPECIFIC

The Revised Plan incorporates these management considerations by reducing motorized access throughout the Centennial Mountains, and using management prescriptions which improve or maintain big game habitat. MO

Ashton Ranger District

Support Grizzly Bear

COMMENTS: Support grizzly bear management efforts; close "Reclamation Road"; create new management prescriptions designed to protect land within the grizzly bear BMUs south of Robinson Creek; support Winegar Hole as wilderness for grizzly bear habitat.

171, 643, 690

RESPONSE: The Revised Plan does not close the "Reclamation Road" because it does not need to be closed to meet grizzly bear recovery goals.

All of the management prescriptions south of Robinson Creek in the Bechler/Teton BMU are designed to provide the habitat conditions necessary to meet grizzly bear recovery goals.

The Revised Plan recommends the Idaho portion of Winegar Hole as wilderness. MO

Non Support Grizzly Bear

COMMENTS: Oppose grizzly bear management efforts because it would close four sheep allotments on the Ashton Ranger District. Strongly opposes expansion of grizzly bears in areas 60 and 61.

F-F(6), 267, 298,

RESPONSE: The Revised Plan officially closes all domestic sheep allotments within the grizzly bear BMUs on the Ashton Ranger District. They are currently vacant. This was done because of the well documented history of conflicts between grizzly bears and the grazing of domestic sheep within the BMU's.

Areas 60 and 61 refer to Game Management Units of the Idaho Department of Fish and Game. Part of 61 is within the grizzly bear recovery line and receives emphasis in management for grizzly bears. All of area 60 is outside the grizzly bear recovery line, and does not receive emphasis in management for grizzly bears. As the grizzly bear population grows, there is a possibility that grizzly bears will be present outside the recovery line. MO

Bechler/Teton BMU

COMMENTS: Follow the rule set standards set forth in the draft Grizzly Bear Management direction.

1446

RESPONSE: We assume you are referring to the rule set in the Biological Opinion for the Plateau Bear Management Unit. That rule set is replaced with the standards and guidelines in the Revised Plan, and a new Biological Opinion has been issued. The grizzly bear habitat management guidelines in the Final

GRIZZLY BEAR - SITE-SPECIFIC

Revised Plan were developed to implement the direction in the Greater Yellowstone Grizzly Conservation Strategy as best we can interpret it at this time (it is a draft). JR

COMMENTS: Include a "security" area in the Bechler/Teton BMU; develop a management prescription and designated core areas in this BMU because protection is needed for the grizzly bear.

1273b, 1446

RESPONSE: The following management prescriptions meet core area criteria and provide security for the grizzly bear in the Bechler/Teton BMU: 1.1.6, 1.1.7, 1.3, 2.3, and 2.6.5. MO

COMMENTS: The Final Plan should close the 0.2% that is currently open to OHV use. Otherwise, show a clear rationale for how it is benign or beneficial to grizzly bear recovery.

1273b

RESPONSE: The 2% of the OHV use in this area is to the existing recreation sites. This recreation use will not have a negative impact on the bear. LB

COMMENTS: Phase out grazing in the southern end of this BMU.

695

RESPONSE: The Revised Plan phases out domestic sheep grazing in the southern end of this BMU. MO

Henry's Lake BMU

COMMENTS: Include a management prescription and core and security areas for Henry's Lake BMU. Appropriate conservation measures in this area will result in greater number of bears seeking habitat farther west (Centennials).

1273b, 1348, 1446

RESPONSE: The Revised Plan includes Management Prescriptions 3.1.2, 1.3, and 2.3 in the Henry's Lake BMU, all which meet core area criteria. It is unknown if a greater number of bears will use this area or areas further west. It will take several years of monitoring to assess changes in grizzly bear use in this area. MO

COMMENTS: Phase out grazing in grizzly bear habitat in most of the Henry's Lake BMU and in Madison BMU near the Two Top area.

695

RESPONSE: There has been no sheep grazing in the Two Top area for nearly ten (10) years. The Revised Plan has direction to phase out the remaining sheep allotments in the Henry's Lake BMU. MO

COMMENTS: Allow timber harvest in Henry's Lake BMU using Situation 1.

413

GRIZZLY BEAR - SITE-SPECIFIC

RESPONSE: The Revised Plan allows timber harvesting in Henry's Lake BMU, Subunit 1. There are specific standards and guidelines which must be followed when timber harvesting is done. MO

Plateau BMU

General

COMMENTS: Designate security areas for no less than ten years across the BMU rather than "island-like" areas; phase out grazing not including areas already closed; manage BMU for recreation, access and commodity because it is not Situation I; allow timber harvest using Situation 1.

413, 643, 695, 1202

RESPONSE: The Revised Plan establishes 30,000 acres of core area on the Targhee, to provide security for the grizzly bear. Core areas will exist for the 10 to 15 year life of the Plan. In addition to core areas, the Revised Plan establishes additional security areas to be established when there are major disturbance activities occurring, such as timber sales. These security areas will exist as long as the major disturbance activity occurs.

In addition, there are 275,000 acres in Yellowstone National Park which provide security.

There is no livestock grazing in the Plateau BMU.

In the previous Plan, a portion of this BMU on the Targhee was designated Management Situation 2 habitat. For the Revised Plan, increased emphasis is placed on all habitat within the grizzly bear recovery zone. Therefore, the Plateau BMU will be managed like Management Situation 1 habitat. Recreation, motorized access, and timber harvesting will be allowed in the BMU, but these activities must follow standards and guidelines in the Revised Plan. MO

COMMENTS: Change the Prescription language for this BMU to read, "In newly harvested units, soil disturbance shall not exceed 20% of the unit;" change canopy cover to 70% not 45% to represent standards previously set in DFPR III-136 and address this in Prescription; follow rule set standards for Plateau BMU.

643, 1446

RESPONSE: In the Revised Plan, scarification is limited to \leq 15 percent of an area where soil disturbance impedes the reestablishment of grizzly bear foods. Greater than 70 percent of the forested acres must provide security cover for the grizzly bear. Thermal cover is defined as 45% canopy closure, because natural stands of trees on the Targhee rarely provide more canopy closure, especially as high as 70 percent. MO

COMMENTS: Continue to use the weighted method to measure road densities in the Plateau; close 300 miles of roads in core areas for security purposes and leave 125 miles of open roads.

643, 695

RESPONSE: The Revised Plan uses the definitions and methods for measuring road densities that are established in the Interagency Grizzly Bear Committee

GRIZZLY BEAR - SITE-SPECIFIC

Taskforce Report on Grizzly Bear/Motorized Access Management. This Report does not use the weighted method to measure road densities. In the Revised Plan, there is no motorized access allowed within core areas. The Revised Plan establishes an OROMTRD of ≤ 0.6 miles per square mile in the Plateau BMU, which means that about 280 miles of motorized roads and trails are restricted to motorized access or obliterated. About 94 miles of roads and trails are open for motorized use in the Plateau BMU. MO

Non Support

COMMENTS: Oppose Plateau BMU: No evidence of survival rates; Plateau BMU does not fit grizzly bear habitat requirements, i.e. hot, dry, south/west slopes dominated by lodgepole pine; insufficient huckleberry patches; several studies indicate grizzly bears have not entered this BMU; local people who lived in Island Park have never verified grizzlies on Plateau. Close Plateau Bear Management Unit.

413

Use of the Plateau by grizzly bear is questionable even under the settlement terms and the Plateau BMU strategy; provide proof. None of the proposals in this BMU should be enacted in the Final Plan.

314, 393, 413, 688, 692, 1202, 1389

RESPONSE: The Plateau BMU is within the grizzly bear recovery zone. In 1993 and 1994, a study was conducted to evaluate habitat and grizzly bear presence in the Plateau BMU. The conclusion and recommendation of that study is (Puchlerz 1994):

"Caldera Subunit has existing habitat values that would be considered moderate. However, the yearlong occupancy of this BMU by an adult female grizzly bear with young should not be expected. The primary reason for this conclusion is that existing habitat effectiveness is low with a 51% reduction of the habitat value that currently exists. Mortality risk to grizzly bears would be considered high due to high road densities and the human use related to the existing road network."

"It is the committee's recommendation that the Targhee National Forest improve habitat effectiveness levels by implementing access management measures approved by the IGBC in July of 1994. With improved habitat effectiveness, occupancy should be expected. Continued monitoring for evidence of reproducing females is recommended."

"The Moose Creek/Pitchstone Subunit has existing habitat values that are considered low. They are currently the lowest we have recorded in the Yellowstone Recovery Zone. There are areas of moderate value habitat on the periphery of the subunit where bear use would be expected. Little reduction in habitat value has occurred as the majority of the subunit is without significant levels of human activity. The exception to this is the Targhee National Forest portion of the unit where high road density reduces habitat value significantly. The yearlong occupancy of this subunit by an adult female grizzly bear with young should not be expected."

"It is the committee's recommendation that the Targhee National Forest improve habitat effectiveness levels by implementing access management measures approved by the IGBC in July of 1994. Continued monitoring for evidence of reproducing females is recommended."

GRIZZLY BEAR - SITE-SPECIFIC

"In both the Caldera and the Moose Creek/Pitchstone subunits there exists an access management strategy, jointly developed by the Targhee National Forest and the U.S. Fish and Wildlife Service for the Targhee portion of the Plateau BMU. If this strategy were implemented it would greatly improve habitat effectiveness and security within the subunits." MO

COMMENTS: Clarify the status of whitebark pine in the Plateau because of its food source for grizzly bears.

413

RESPONSE: Most of the forested acres in the Plateau BMU are classified as lodgepole pine cover type. Only 20 percent of forest inventory plots contain whitebark or limber pine, and for these plots, 99.1 percent of the whitebark or limber pine trees are less than 2 inches in diameter, therefore not cone producing trees. MO

COMMENTS: Allow timber harvest in Plateau. Use of the Plateau by grizzly bears is questionable.

393, 692

RESPONSE: Management Prescription 5.3.5 applies to 107,500 acres of the Plateau BMU. This management prescription allows timber harvesting activity as long as specific standards and guidelines are followed. The following documents grizzly bear use in the Plateau BMU:

Plateau BMU, Subunit 1: Compared to the other BMU's and Subunits on the Forest, this area had one of the lowest number of grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986). From 1986 through 1995, five grizzly bear sightings were recorded within subunit 1 in addition to many recorded observations of radio collared bear #227 (a male) for portions of each summer from 1994 through 1996. Two sows with cubs were observed for the period 1965 to 1984 (one of the sows was shot and killed by hunters in the fall of 1984). From 1985 to the present, no sows with cubs have been reported in this subunit.

Plateau BMU, Subunit 2: Compared to the other BMU's and subunits on the Forest, this area had one of the lowest number of grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986). From 1986 through 1995, records show six grizzly bear sightings within Subunit 2. From 1965 to 1984, there were four sightings of bear groups (two or more bears together) but records do not confirm that these were sows with cubs. From 1985 to 1993, no sows with cubs were observed. In 1994, one sow with cubs was observed one time near the southern boundary of the subunit. No sows with cubs have been reported during 1995 and 1996. MO

Palisades Ranger District

COMMENTS: Add all of Palisades and Diamond Peak to wilderness to ensure grizzly bear habitat. (CROSS REFERENCE: Wilderness)

181, 643, 1314, 1360

RESPONSE: Palisades (located on the Palisades Ranger District) and Diamond Peak (located on the Dubois Ranger District) are both outside the grizzly bear recovery zone. They are not needed to achieve grizzly bear recovery.

GRIZZLY BEAR - SITE-SPECIFIC

However, large portions of both areas are recommended as wilderness for other reasons. MO/AM

Teton Basin Ranger District

Big Holes

COMMENTS: Oppose managing for grizzlies in the Big Holes because the population is doing well and there may be a few too many. It would be alright if there were no population.

F-G-2(2), 50, 311

RESPONSE: The Big Holes are outside of the grizzly bear recovery zone, and are not managed for grizzly bears in the Revised Plan. MO

Jedediah Smith Wilderness

COMMENTS: Oppose allowing human activity areas of 30 day periods during the active bear season because it contradicts bear security efforts.

1277

RESPONSE: Grizzly bear security was an important consideration in the development of the Revised Plan. The Revised Plan directs that Forest Service management activities within the grizzly bear BMU's are to be concentrated in time and space, and must follow specific standards and guidelines.

Human activities are restricted in the grizzly habitat prescriptions that meet "core" criteria in the Revised Plan. These "core" areas are undisturbed refugia for security of bears. In other areas, human activities are restricted in time and space to minimize disruption to grizzly activities and adjacent security zones are established to provide areas for escape while the activity occurs. This will meet grizzly security needs during periods of human activity. MO/JR

GRIZZLY BEAR - STANDARDS AND GUIDELINES

COMMENTS: Change the following guidelines to standards: Page III-11, Grizzly Bear Habitat, the four Objectives and one Guideline should be standards; Page III-133, Wildlife (5.3.5) - The Snag Guideline should be a Standard; The Guideline describing the shape and size of the activity area should be a Standard; Page III-134, both Guidelines should be Standards. The second one (characterizing management activities) should be amended to read "...on habitat quality and quantity and the potential for disturbing hibernation sites." On the same Page in Paragraph 1 change "should" to "will" and make this a Standard. On the same Page in Paragraph 2 add the following sentence and make this a standard, "No more than one entry into an area per decade, not to exceed three years in duration; Page III-136, Timber - The Dead and Down Component should be a Standard; Page III-137, Range - The first Guideline should be a Standard.

643, 1365

RESPONSE: The Forest considered these recommendations in detail, most of which would change objectives and guidelines to standards. The analysis of

GRIZZLY BEAR - STANDARDS AND GUIDELINES

grizzly bear habitat shows that there are broad ranges in habitat conditions, resulting from natural conditions and past management activities. Making everything standards does not recognize this broad range of conditions. To be responsive to the variety of conditions that currently exist, and will exist into the future, the Forest did not make these recommended changes. MO

COMMENTS: Include Standards for education of employees working in grizzly habitats, including information about food storage and direction to suspend activity if and when a bear is sighted. Develop standards for human food storage, garbage, horse pellets, dog food and waste for BMU's in front and backcountry areas.

643

RESPONSE: A special order on sanitation and food storage in grizzly bear habitat has been in place for many years. It is not necessary to repeat this special order in the Revised Plan. All people, including Forest Service employees, must follow the rules of this special order when using grizzly bear habitat. Information is available at all Targhee offices. MO

COMMENTS: Grazing permits should include specific language to assure guidelines for minimizing grizzly bears/livestock conflicts.

389

RESPONSE: All grazing permits within the grizzly bear recovery zone contain specific language requiring the permittee's full compliance in meeting grizzly bear management goals and objectives. MO

COMMENTS: Page III-134, Roads (5.3.5) Item 1 under Guideline should be a Standard. An additional standard should be included prohibiting the construction of new roads and requiring the obliteration of any roads with potential to adversely affect the habitat or ecosystem qualities of the area.

1365

RESPONSE: Item #1 is a guideline that allows for site specific considerations and analysis. Each BMU has an OROMTRD and TMARD established for it. New roads can only be built if the OROMTRD and TMARD remain below the standards for the BMU, or if an existing road or trail is restricted or obliterated so that the standards are not exceeded. MO

COMMENTS: Page III-135, Roads (5.3.5) Item 3 should be a Standard and should be rewritten as follows: "Fully revegetate temporary roads with native species immediately following use."

1365

RESPONSE: Item #3 is a guideline that allows for site-specific considerations and analysis. MO

COMMENTS: Develop standards to correct the impact done to grizzly habitat by clearcutting and road building and prevent future impacts.

1365

GRIZZLY BEAR - STANDARDS AND GUIDELINES

RESPONSE: The Revised Plan takes into account the effects of past management activities and reduces TMARD and OROMTRD for future timber harvesting. MO

COMMENTS: Include specific language to ensure Guidelines for minimizing grizzly bear - livestock conflicts.
389

RESPONSE: The Revised Plan phases out all domestic sheep grazing on an opportunity basis within the grizzly bear recovery zone. All grazing permits within the grizzly bear recovery zone contain specific language requiring the permittee's full compliance in meeting grizzly bear management goals and objectives. MO

COMMENTS: The following should be included as standards for grizzly bear habitat: 1) Sanitation standards will be set for human habitation and use on portions of the forest within the recovery zones; 2) Core area maps for each BMU are enclosed in the appendix; 3) Pursuant to the Grizzly Bear Recovery Plan, no timber cutting activities will be allowed within Situation I and II Habitat.
1446

RESPONSE: A special order on sanitation and food storage in grizzly bear habitat has been in place for many years. It is not necessary to repeat this special order in the Revised Plan.

The following management prescriptions meet core area criteria as defined in the Interagency Grizzly Bear Committee Task Force Report on Grizzly Bear/Motorized Access Management: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2.

The Grizzly Bear Recovery Plan allows timber harvesting within Situation I and II habitat as long as necessary considerations for the grizzly bear are implemented. MO

Core areas are displayed on the prescription map. MO

COMMENTS: Change Standard and Guidelines on Page III-87 to 89 to reflect the new scientific data on grizzly bears which contradicts the use of Management Situation 1 as a Biological Standard for grizzly bear.
1446

RESPONSE: The Revised Plan references the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat because these guidelines are still valid. Additional standards and guidelines are also listed in the management prescriptions which incorporate new scientific data. MO

COMMENTS: Page III-18, Dispersed Camping Management: Show information, education and sanitation standards for grizzly bear recovery zones in this section under Description or a section titled "Wildlife" under Standards and Guidelines. (CROSS REFERENCE: Recreation - Camping)
1446

RESPONSE: A special order on sanitation and food storage in grizzly bear habitat has been in place for many years. It is not necessary to repeat this special order in the Revised Plan. A guideline on grizzly bear education

GRIZZLY BEAR - STANDARDS AND GUIDELINES

exists in the Wildlife Section of the Revised Plan. This education guideline focuses on a broad range of people who use grizzly bear habitat, including dispersed camping users. MO

COMMENTS: Page III-91, Recreation (5.3.5): The trails standard should also mandate the obliteration of any trails causing or likely to cause significant negative impacts to primitive or semi-primitive non-motorized uses. (CROSS REFERENCE: Recreation)

1365

RESPONSE: The OROMTRD and TMARD for the BMU's focus on the needs of the grizzly bear, and not primitive to semi-primitive non-motorized recreation. MO

COMMENTS: Page III-87, Physical and Biological Elements, Land: The Rule Set developed for grizzly bear management, in the Grizzly Bear Management Strategy for the Plateau BMU, should be incorporated as a table in this section.

1446

RESPONSE: The Grizzly Bear Management Strategy for the Plateau BMU is not fully incorporated in the Revised Plan because there are some items that can not be implemented, new boundaries for Plateau BMU subunits require changes, and some items are inconsistent with new direction from the Interagency Grizzly Bear Committee (such as the Task Force Report on Grizzly Bear/Motorized Access Management). MO

COMMENTS: Page III-88, Forest Use and Occupation: For the most part, mountain biking and other mechanized travel should be discouraged from core areas. Beginning the reclamation of all roads within one year of the signing of the ROD should be considered a Standard to be consistent with Objective 4, Page III-11, Forestwide Standards and Guidelines. A Standard should state no construction of temporary roads in core areas.

1446

RESPONSE: There are no data to suggest that mountain biking is any more detrimental to grizzly bears than walking, and at this time the Forest does not propose closing core areas to all human entry.

The Forest selected three years as the objective to achieve the TMARD and OROMTRD in the BMU's, taking into account the large amount of work and cost involved to accomplish this. It is not feasible to do it in one year.

The standard for Management Prescriptions 2.6.2 and 2.6.5 states, "construct no new roads." This standard applies to all roads, permanent and temporary. MO

GRIZZLY BEAR - TIMBER

Support Harvest in Grizzly Habitat

COMMENTS: Timber harvesting activities, with proper management, do not impact grizzly bear habitat. To prohibit timber harvest would not help the grizzly

GRIZZLY BEAR - TIMBER

bear recovery effort. Allow commercial harvesting in the Greater Yellowstone Ecosystem.

275, 393, 692, 693

RESPONSE: Management Prescription 5.3.5 allows timber harvesting within the grizzly bear BMU's under standards and guidelines which maintain grizzly bear habitat. MO/JR

COMMENTS: Allow timber harvest in all grizzly habitat, and include good access and vulnerability constraints, i.e., no firearms, open and closed gates, etc.

693

RESPONSE: Management Prescription 5.3.5 allows timber harvesting within the grizzly bear BMU's. All of the BMU's have standards for OROMTRD and TMARD to regulate motorized access. The Revised Plan does not prohibit firearms in the BMU's. Hunting is a major activity which is allowed in all of the BMU's on National Forest lands. Fish and Game determines if firearms are prohibited. MO

COMMENTS: Correct DEIS, Alternative 2. This alternative allows timber harvest in both the Henry's Lake and Plateau BMUs. To the extent that Situation I habitat is involved, it is a NIC component, but only if it is a Situation I. Allow harvest in all BMUs, subject to an NIC component in Situation I habitat.

413, 767

RESPONSE: Alternative 2 allows timber harvest in all BMU's, including the Henry's Lake and Plateau BMU's. Alternative 2 allows timber harvest in Situation 1 habitat as a NIC component to the ASQ. MO

COMMENTS: Allow timber harvest in Situation I habitat and in roadless areas. Use lower quality of roads with immediate closure after use.

693

RESPONSE: Management Prescription 5.3.5 allows timber harvesting in grizzly bear habitat, which includes both Management Situation 1 and 2. Standards for OROMTRD and TMARD results in many road restrictions and obliteration. MO

COMMENTS: Commercial timber harvest will not by itself reduce food and cover habitat to the extent full recovery goals could not be met. Commercial timber harvest can enhance tree growth and speed development of cover for grizzly habitat. Consider an alternative based on the best science for grizzly management.

393, 692, 1267

RESPONSE: The Forest generally agrees. The Revised Plan allows for timber harvest within the grizzly bear BMU's and incorporates the latest science. MO

COMMENTS: Oppose Targhee National Forest severely restricting timber harvest and using the BMU's OROMTRD as constraint. Use of the constraint developed

under Settlement Agreement with Greater Yellowstone Coalition, et al, was crafted without going through NEPA. This severely restricts harvest within areas defined as habitat for grizzly bear. Evaluate the social and economic impact of constraining road development and timber harvest.

393

RESPONSE: OROMTRD was not used as a constraint in modeling the timber harvest and selecting an ASQ for the Revised Plan. The settlement agreement is temporary, and the provisions of the settlement agreement will be replaced with the provisions and management direction in the Revised Plan. There are numerous standards and guidelines which affect the amount of timber harvesting proposed in the Revised Plan. The social and economic impacts of the Revised Plan are displayed in the DEIS and the FEIS. MO

COMMENTS: Clearly state the limits on clearcut size to "40 acres or less on approximately 14% of the Forest" are not arbitrary to benefit grizzly bear telemetry work.

625

RESPONSE: The Revised Plan does not have a clearcut size limit of 40 acres in grizzly bear habitat since 40 acres is the required limit already determined by NFMA. The Plan does not repeat existing laws and regulations. There is a guideline which states: "For created openings, maximum distance to security cover should be 300 feet." The guideline is not used to benefit grizzly bear telemetry work. MO/CC/JR

Address Effects on Unscheduled EM Harvests on Grizzly Bear

COMMENTS: Clearly address EM timber harvests and road building, specifically in Prescription 2.6.1 (a). Even though these lands are not in the suitable base, they serve as a critical corridor for grizzly bear.

643

RESPONSE: The Revised Plan establishes a limit on EM, NIC related timber harvests and displays how much total timber harvesting is expected to occur within each BMU Subunit. Lands within prescription 2.6.1(a) are not included in the suitable timber base but, harvest could occur on the unsuited lands, following a site specific environmental assessment. Included in this assessment, should one occur during the life of this plan would be the no action alternative and environmental effects of this alternative and all action alternatives. The Revised Plan maintains suitable habitat for grizzly bear movements while studies are being done on the feasibility of corridors for grizzly bears.

The Revised Final Plan places a limit on EM harvest that can occur in the decade. Road building is controlled by the road density standard within Bear Management Units (0.6 miles/sq. mile OROMTRD and 1.0 TMARD). MO/JR

GRIZZLY BEAR - TIMBER

Include Appropriate Mitigation Measures in Timber Sale Contracts

COMMENTS: Include mitigation measures like those found in Forest Service Regulations CT 6.5 in all timber sale contracts.

643

RESPONSE: Forest Plans contain goals, objectives, standards and guidelines which provide management direction for future projects. Specific mitigation measures are developed during the analysis which is done for each site specific project. Appropriate contract clauses will be included. MO/JR

Non Support Harvest in Grizzly Habitat

COMMENTS: Prohibit timber harvest in BMU's and sensitive bear habitat areas because historic logging, fragmentation and roading contribute to diminishing grizzly bear habitat. Oppose Prescriptions 2.6 - 2.6.5 Grizzly Bear Habitat and 5.3.5 Timber because they allow too much timber harvest; explain why harvest is going to occur in grizzly bear habitat.

51, 136, 252, 293, 356, 389, 396, 611, 622, 640, 692, 695, 1194, 1273b, 1361, 1365, 1367, 1369

RESPONSE: Management Prescriptions 2.6.2 and 2.6.5 do not allow any timber harvesting. They are designed to be grizzly security areas. Timber harvesting is allowed in Management Prescription 5.3.5 according to specific standards and guidelines. The maximum amount of possible timber harvested during the next decade amounts to one to two percent of the forested acres in the BMU's. TMARD and OROMTRD are reduced in all of the BMU's. Grizzly bear habitat will improve from the existing conditions with the management direction in the Revised Plan. Timber harvest is allowed when compatible with grizzly habitat needs to maintain long-term the minimum of vegetation types in the BMUs. MO/JR

COMMENTS: Prohibit logging in grizzly bear areas to reduce habitat fragmentation and improve migration corridors.

179, 211

RESPONSE: Timber harvesting is allowed in Management Prescription 5.3.5 according to specific standards and guidelines. The amount of timber harvesting that may occur during the next decade amounts to one to two percent of the forested acres in the BMU's. TMARD and OROMTRD is reduced in all BMU's. Grizzly bear habitat will improve from the existing conditions with the management direction in the Revised Plan. Migration corridors are currently being studied, as outlined in the Grizzly Bear Recovery Plan. At this time, the Forest does not know the feasibility of migration corridors for the grizzly bear. The management direction contained in the Revised Plan will maintain future options for migration corridors if the studies prove their feasibility. MO

COMMENTS: Define what habitat improvements and activities for grizzly bear will be allowed in Prescription 2.6.5. Cite scientific references for these choices. Define what disturbances will be allowed in grizzly bear security

GRIZZLY BEAR - TIMBER

areas and how you will balance these disturbances with increased mortality risk and displacement.

1273b, 1369

RESPONSE: The objectives, standards and guidelines of Management Prescription 2.6.5 describe the kinds of improvements and activities that are allowed. For example, since the prescription has an OROMTRD standard of 0.0 miles per square mile, there will be road restrictions and road obliterations. Scientific references can be found in the FEIS, the Biological Assessment for Grizzly Bears, and Process Paper D. All documents are available to the public.

The combination of management prescriptions applied to the grizzly bear BMU's provides for improved grizzly bear habitat conditions. There are decreases in OROMTRD and TMARD in all BMU's. There are increases in the amount of area meeting core area criteria. These changes increase grizzly bear security. MO

COMMENTS: Further define how you will apply the 7000 acre standard of undisturbed habitat for grizzly bear protection. Define what percentage of the area needs to be maintained as undisturbed. One 7000 acre undisturbed area could conceivably be surrounded by timber sale areas.

1369

RESPONSE: The combinations of standards and guidelines requiring security areas of at least 7,000 acres in size, maintaining 70 percent security cover and 20 percent thermal cover, the OROMTRD and TMARD standards, plus numerous other standards and guidelines which must be followed, will make it impossible for one 7,000 acre undisturbed area to be surrounded by timber sale areas. MO

COMMENTS: The Plan and FEIS should include "core" and "security" areas to prevent timber harvesting in these designated BMU's.

1446

RESPONSE: The following Management Prescriptions meet core area criteria: 1.1.6, 1.1.7, 1.3, 2.3, 2.6.2, 2.6.5, and 3.1.2. It is not necessary to completely eliminate all timber harvesting in the BMU's to achieve the recovery goals for grizzly bears. MO

MAPS/REFERENCES

ATTACHMENTS TO LETTERS (Maps, References, Bibliographies, Articles)

RESPONSE: These materials were shared with appropriate managers, planners and resource specialists. More detailed responses can be found in specific resource areas in this appendix. AM

- SUMMARY:** 1. Map of roadless areas on the Targhee to replace Map 25. Includes a portion of their comments stating why a new map is needed: DEIS has an inadequate analysis of roadless areas on the Forest; issue a supplemental DEIS for public comment; and clearly identify roadless areas by name.
2. Map of specific areas using 5.3.6 Grizzly Bear Habitat (NIC for ASQ - small sales only, no cross-country, phase out sheep), near Jedediah Smith and Winegar Hole Wildernesses.
3. Prescription/Map of the Centennial Mountains showing an Ecosystem Linkage Corridor (2.2.1 a,b,c).
4. Bibliography citing 78 sources, mostly circa 1990s
5. Map of Idaho Wildlands Defense Coalition's wilderness recommendations with an outline of roadless areas in black, showing wilderness substantially increased throughout most of the Forest.
6. Satellite photographs of the Island Park area of the Targhee National Forest. Four photographs taken between 1974-1992 show the progression of extensive clearcutting on the Island Park and Ashton Ranger Districts claiming that the Forest's analysis of 60+ percent mature forest is flawed.
7. Copy of April 26 letter to Forest Supervisor Reese regarding inadequate analysis on roadless areas and wilderness recommendations in the DEIS.

643

- SUMMARY:** 1. An 85-page thesis discussing erosional impacts of hikers, horses, off-road bicycles, and motorcycles on mountain trails, with various charts, graphs, diagrams, and references.
2. Report about the denning of grizzly bears in the Yellowstone National Park Area.
3. Report about the effects of access on human-caused mortality of Yellowstone grizzly bears.
4. A letter discussing elk habitat effectiveness and elk vulnerability analysis with an attached map showing all districts and some specific areas.
5. A copy of a 21 question-and-answer brainstorm handout about roads, wildlife, trails, and so forth from the speakers at a Citizens Involvement Group access meeting.
6. Report about elk habitat effectiveness as influenced by roads and cover.
7. Sections from various documents discussing management of elk habitats and populations, and elk and road issues.
8. A Journal of Forestry September 1983 article describing elk habitat effectiveness using charts and graphs.

MAPS/REFERENCES

9. Map designating specific trails for ATV use in the Ashton and Island Park area. The routes require little construction and ATV users would welcome recreational opportunity available there.

1202

10. Two maps showing roads and trails in specific areas that should be open. Maps are very specific.

1202

SUMMARY: 1. Appendix A recommends the Targhee adopt an alternative from the Beaverhead Forest Plan's amendment using alternative approaches to grazing management and changing some riparian and range goals, objectives and standards.

2. Appendix B is a five-step planning approach for streams and other resource management issues, providing some grazing management guidelines, strategies, monitoring and evaluation.

432

SUMMARY: 1. Appendix A about the effects of access upon human-caused mortality of Yellowstone grizzly bears.

2. Appendix B about the denning of grizzly bears in the Yellowstone National Park area. Shows a study that indicates the exclusionary date for cross-country snowmobile use could be moved back to at least November 1 and not affect the bears plus there are no den sites on the Targhee save the den in the Plateau BMU.

3. Copy of a two-page letter to Senator Craig from United States Department of Commerce discussing aquatic conservation measures, land allocations, and roadless areas.

4. Appendix D showing the relationships of Rocky Mountain elk and Rocky Mountain mule deer habitat to timber management in the Blue Mountains of Oregon and Washington.

5. Appendix E summary of findings about cover, clearcuts, foraging, and so forth in "Elk-Roads-Logging Relationships".

6. Appendix F showing an application of existing knowledge for protection of big game habitat in timber sale design, layout and administration, giving specific guidelines about two kinds of cover.

7. Appendix G showing elk habitat relationships for Central Idaho and discussing reconciling land management activities with requirements of elk habitat.

8. Appendix H showing elk management by the Northern Region related to considerations in Forest Plan updates or revisions.

9. Appendix I discusses species management and habitat effectiveness, and recommendations for forest plans.

10. Appendix J shows the Timber Sale Program Annual Report Fiscal Year 1993 for the Targhee and contains grazing, water yield and economic account tables.

413

SUMMARY: Article dated January 1995 titled, "Resiliency", discusses forest landscapes, wildlife, timber, and other topics dealing with EM Sustainability.

275

MAPS/REFERENCES

SUMMARY: 1. Forest Health/Grazing Bibliography and References: 178 sources dated from 1923-1994. Mostly circa 1970s-1980s.

2. The effects of Ski Area Development on the Environment Bibliography: 43 sources dated 1970-1981.

3. Recreational and Other Impacts Bibliography: approximately 2000 sources dated predominantly circa 1970s and 1980s.

4. Report and Formal Comments on the Current and Potential Adverse Impacts of Winter Recreational Use in Yellowstone National Park and the Winter Visitor Use Management Planning Process by the U.S. Park Service (Biodiversity Legal Foundation: Boulder, CO) 1996. Forty-nine page report with an 83 page bibliography on Recreational and Snowmobile Use in Yellowstone National Park. The study addresses the environmental impacts of snowmobiling on wildlife, vegetation, and soils and analyzes the winter visitor planning process.

1365

SUMMARY: 1. Two identical maps for Alternative 2 summer motorized access and management changes that reflect a reduced number of road closures. Specific changes from the large areas 6.1 (b) in the Caribou to 6.1 (a).

2. Specific changes to 5.1.3 (a) Prescription areas, adding two areas in the Caribou to the suitable timber base.

767

SUMMARY: Map proposes additional road closures, indicating that the West Yellowstone roaded area is too dense for the summer motorized access in Alternative 3M, and highlighting short spur or parallel roads that should be reconsidered for closures.

690

SUMMARY: Provides eight references he co-authored about riparian habitat, grazing, and amphibian sampling related to spotted toads.

1343

SUMMARY: GIS Map of the grizzly bear areas and Centennials. Comments and references dealing with cumulative effects on grizzly bear management, especially in this area.

1348

SUMMARY: 1. References about spotted frogs, threatened and endangered species, ecological mystery, wildlife, and amphibians/reptiles.

2. Newspaper article from Juneau Empire 13 June 1996 titled "Logging Dead Trees May Actually Boost Fire Risk." Article details a situation in Alaska where slash burns and chip piles left from logging were ignited.

1277

SUMMARY: Three references about grizzly bears.

363

SUMMARY: Article titled "Telemetered Heart Rate of Three Elk as Affected by Activity and Human Disturbance," commenting about biological elk behavior; range; heart rate and activity biotelemetry system; ecological energetics;

MAPS/REFERENCES

white-tailed deer; bighorn sheep; mule deer, the movement and activities of cow elk; and the grazing of transplanted elk.

313

SUMMARY: Four references from 1982-1995 containing information on EM, fisheries, successional forests, and watersheds.

690

SUMMARY: Movements, Distribution, Mortality and Genetic Status of Bighorn Sheep in the Teton Range: Progress Report, citing preliminary findings on the status of the Teton Range bighorn sheep herd. Includes charts, graphs, and literature on mortality rates and seasonal movements.

699

SUMMARY: Article from Beef Today May 1996: 22, "A Settlement on Sediment" describing new research by the University of Wyoming on managing streambank vegetation.

267

SUMMARY: Thirty-six page graduate thesis and report on analysis of goshawk habitat at five spatial scales on the Targhee and how timber harvesting has affected goshawk nesting habitat over time. Report is entitled: Analysis of Goshawk Nesting Habitat at Five Spatial Scales in Undisturbed and Timber Harvest Territories on the Targhee National Forest.

1370

SUMMARY: Two newspaper articles from The Fall River Review, 18 April 1996, "The Forest Plan and Local Interest" and "The Pitfalls of Public Process."

1258

SUMMARY: Copy of a list of proposed wilderness areas for the Targhee from the Idaho Wildlands Coalition.

210

SUMMARY: "A Serious Newsletter for Serious Recreationists" article from the newsletter Idaho Outside in which Governor Batt states that this newsletter is a way to inform recreationists where their tax dollars are spent.

1390

SUMMARY: Eleven literature cited from 1971-1989 dealing with grazing, wildlife, bats, bighorn sheep and riparian areas.

389

SUMMARY: 1. Map showing Bigholes/Palisades Subsection with proposed Prescription 5.1.4 (d) highlighted.

2. Map showing a 6-plus square mile enlargement of the Kelly Canyon-Hawley Gulch area and recommending closing the area to snowmobile use.

701

MAPS/REFERENCES

SUMMARY: Bibliography of eight sources from 1968-1996 concerning wolverines, grazing, riparian areas, elk/deer hunting, breeding dens for bears and Henry's Fork Wetlands.

766

SUMMARY: An attached copy of a pamphlet with rewards for Eco-Terrorists involved in cattle killing, eco-sabotage, or pipe bombs in wilderness.

300

SUMMARY: Attached the Targhee National Forest 1985 Land Management Plan, 711 pages long.

1395

SUMMARY: Newspaper article from the Idaho Falls Post-Register, 16 May 1996, "Budget Lags While Forest Use Soars" about the less-than-expected revenue generated from recreation on the Targhee National Forest.

348

SUMMARY: One page copy of part of a resolution from the Idaho Republican Party stating opposition to Alternative 3M and the Draft Forest Plan and indicating support for the preferences of the Citizens for a User Friendly Forest.

1448

SUMMARY: Letter from David Hunte, Wildlife Veterinarian, Idaho Fish and Game to Stan Boyd, Director, Idaho Wool Growers Association, stating that the outbreak of pneumonia in bighorn sheep in Hells Canyon was not caused by domestic sheep but by their own strain of pasteurilla.

1188

SUMMARY: 1. Untitled article from Discover (November 1995) about species in tropical rain forests and the vital importance of species such as fungi, dead wood and old growth to the ecosystem. 2. Article from Casper Star-Tribune, 20 June 1996, "Bringing Back the Fire" on the benefits of burning to help wildlife, cattle and aspen. 3. Article from High Country News, 11 December 1995, "Outfitters Take Aim at Four-wheelers", about people using ATVs to hunt and retrieve game and the conflicts between this user group and outfitters. 4. Article from Jackson Hole News, 12 June 1996, "Man barred from Park for Snowmobile Trespass" about frequent snowmobile trespass into Grand Teton National Park and Jedediah Smith Wilderness.

1393

SUMMARY: Narrative and map of proposed changes for access for the Swan Valley - Teton Transmission Line along with a set of 37 standard BPA transmission line maintenance photo maps showing right-of-way, mile number, tower location, and access roads.

1279

SUMMARY: Furniture catalog entitled Grand Teton Furniture Collection from the Grand Teton Furniture Company, Inc.

268

MAPS/REFERENCES

SUMMARY: Letter-to-the-editor from Kent Briggs criticizing the motorized game retrieval proposal in Alternative 3M and support for Alternative 2.

278

SUMMARY: A water map showing existing wilderness areas and a copy of the Idaho Wildland Coalition's proposed wilderness areas for the entire state of Idaho.

1206

SUMMARY: Information and a map on ski trails and Forest Service roads showing specific areas for skiing.

628b

SUMMARY: 1. Five Ashton and Island Park Ranger Districts' Landsat MSS maps showing old/new clearcuts.

2. Article from the July/August issue of Inner Voice containing information on "Cattle and Sheep - The Forgotten Pathogens."

3. Cites 26 references from 1973-1994 with information on wildfires, biodiversity, vegetation, goshawk, fire, grizzly bears, and so forth.

1273b

SUMMARY: Cites 23 references from 1968-1994 (one he authored) containing information about fires and lodgepole pine.

489

SUMMARY: Lists three bibliographies upon which conclusions in their letter are based. Forest bibliography is untitled and lists 26 sources ranging from 1972-1996. The second is untitled and lists 71 sources mostly circa 1980s. The third is "Roads in Riparian Areas" and lists seventy-one sources circa 1970s-1980s.

1367b

SUMMARY: Authors of the 33-page article Draft Management Recommendations for Aquatic Conservation on Federal Lands in the Rocky Mountain West (Pacific Rivers Council: Bozeman, MT October 1995) argue that riparian areas and aquatic refugia must be identified and preserved, and they outline principles for management of these areas.

1367a

SUMMARY: Letter-to-the-Editor from Dick Marler dated 6/21/96 regarding restoring day-use at Warm River Campground.

1251

SUMMARY: A copy of a page from a West Yellowstone Chamber of Commerce bulk mailing sent to all chamber members. The form letter is from the Blue Ribbon Coalition urging chamber members to write the Targhee regarding road and trail closures.

395

SUMMARY: 1. A graph of The Bureau of the Census, Decennial Census of Population and Housing 1995: online fire STF1A population estimates; 1994:

MAPS/REFERENCES

CD-ROM STF1A; 1980: General Population Characteristics U.S. Department of Commerce, Washington D.C.

2. A graph from Forest acreage obtained from Payments to States from National Forest Receipts, fiscal year 1985, 1990, 1994, USDA Forest Service, Washington D.C. showing the 25% Fund/Acre was obtained by dividing 25% Fund payment as reported in Table III-21 of the Draft EIS by the amount of county acres inside Forest boundaries.

1368

SUMMARY: Two-hundred page State of Idaho Water Plan for Henry's Fork Basin containing maps, appendix, and several charts with detailed information on Henry's Fork Basin.

1207

MINING, MINERALS, GEOLOGY

General

COMMENTS: Restrict or limit mineral exploration and mining; do not issue permits or renew oil and gas leases until an EIS is completed; support more control of mining industries, but doubt the Forest Service can do so legally with outdated mining laws. Implement standards and/or guidelines stating that the Forest is not open to exploration and development/production of mineral resources unless otherwise specified in prescriptions; if protective standards, including standards for denial, are not included, it will be business as usual. Provide restrictions on soils, silt, gravel, solid wastes, slash, debris or chemicals deposited in areas where they may aggregate or become concentrated in surface waters. Define more clearly Forest requirements for mineral activities.

305, 389, 695, 697, 1365

RESPONSE: As a parallel process to the revision, the Targhee is preparing a FEIS covering oil and gas leasing which identifies forest land for leasing and conditions under which the lands will be offered for lease. The oil and gas FEIS will reflect revised management prescriptions so that both documents are compatible in resource management direction. In addition, the Forest is legally compelled by the Energy Security Act of 1980 and the Leasing Reform Act of 1987 to conduct a separate NEPA oil and gas leasing analysis. Close coordination is required between both documents.

Restrictions on mineral activities vary on the Forest by prescription areas. The majority of the Forest is open to mineral activity, but some of it is restricted, subject to valid existing rights.

All mining involving hardrock minerals, mineral materials, and leasable minerals are conducted pursuant to applicable laws, acts, and regulations. Those specific to hardrock minerals (gold, silver, lead, opal) are the General Mining Law of 1872, Multiple-Use Mining Act of 1955, Mining and Minerals Policy Act of 1970, Federal Land Policy and Management Act of 1976, and Forest Service Minerals Regulations (36 CFR 228, Subpart A).

Specific laws, acts, and regulations pertaining to mineral materials (common varieties of sand, stone, gravel, pumice, pumicite, and cinders) are the Materials Act of 1920, Multiple-Use Mining Act of 1955, Mining and Minerals Policy Act of 1970, Federal Land Policy and Management Act of 1976, and Forest Service Minerals Regulations (36 CFR 228, Subpart C).

Leasable minerals (oil and gas, phosphate, geothermal) are subject to exploration and development under leases, permits, or licenses under the Mineral Leasing Act of 1920, as amended; the Mineral Leasing Act for Acquired Lands of 1947; the National Environmental Policy Act of 1969; the Geothermal Steam Act of 1970; the Federal Land Policy Management Act of 1976; the Coal Leasing Amendments Act of 1976; the Surface Mining Control and Reclamation Act of 1977; the Multiple Minerals Development Act of 1977; the Federal Onshore Oil and Gas Leasing Reform Act of 1987; the Geothermal Steam Leasing Amendments Act of 1988; Forest Service Minerals Regulations (36 CFR 228, Subpart B; and specifically Bureau of Land Management Minerals Regulations (43 CFR 3201.1-6(f) which implement Public Law 98-473, the Geothermal Steam Leasing Amendments Act of 1988. JP

COMMENTS: Request a more thorough analysis and referencing of known and potential phosphate reserves on the Targhee, especially in Big Hole/Palisades,

MINING, MINERALS, GEOLOGY

Caribou Mountains, Centennials, and Teton range. Need to adequately consider these before exclusion for wilderness designation, and they deserve more than casual reference. Request acknowledgement in Index (Section III) of geothermal production and protection, and a citation of regulations pertaining to geothermal resources.

493, 691, 1351

RESPONSE: Interest in exploration and development of phosphate reserves are not anticipated until the Soda Springs Area Reserves in southwest Idaho are near depletion. Conservative estimates expect this event will not happen for the next 40-50 years.

The best potential for discovery of geothermal resources lies in the Island Park area of the forest. However, due to its proximity and uncertain geologic relationship to thermal features of Yellowstone National Park; language in the Geothermal Steam Act of 1988 that prohibits leasing in the Island Park Caldera; and conclusions denying leasing in the "Island Park Geothermal Area", USDA/USDI, 1-15-80; it is unlikely that this resource will ever be explored or developed. JP

MISCELLANEOUS

Air Quality

COMMENTS: A non-particulate indicator directly related to fossil fuel combustion should be included in air quality program monitoring.

1365

RESPONSE: Chapter V of the Revised Plan discusses air quality monitoring. Specific details regarding how monitoring will take place will be determined when the standards are quantified. LB

COMMENTS: By limiting logging and fire, excess CO² is not absorbed because stands of old trees do not absorb as much CO² as healthy, young trees growing. Targhee should consider its contribution to reducing global warming: the absorption of CO² by growing trees, the concurrent production of O², and the sequestering of CO² in wood products used in building. Calculations demonstrate that a 100-year harvest rotation would greatly offset CO² produced from burning of fossil fuels.

275

RESPONSE: Addressing global warming is outside the scope of the Forest Plan Revision. We acknowledge that CO² production and CO² consumption vary by various stand characteristics which are influenced by management activities. However, the range of these values would be quite small across the alternatives.

Converting large portions of the Targhee into some form of CO² absorption management regime would likely constitute a violation of the habitat needs for various species protected under the Endangered Species Act. It would also beg the larger question in global warming: if the CO² effectively entrapped in the tree is not effectively preserved, it will simply end up being released back into the atmosphere. The Targhee has literally no control over whether wood products fashioned from Forest timber will be effectively preserved. DP

COMMENTS: The Targhee is in the Yellowstone National Park class I air pollution zone and violates the Clean Air Act and Clarke-McNary Act if you go back to natural ecosystem management where seven times as much fire occurred.

275

RESPONSE: Forest Service air quality objectives are to "Protect air quality and related values, including visibility, on wilderness land designated class I by the Clean Air Act as amended in 1977" and to "protect air quality in wilderness areas not qualifying as class I under the same objectives as those for other National Forest System lands" (FSM 2120).

Prescribed burning activities are challenged by air quality restrictions but the Forest is not precluded from using this as a tool in meeting ecosystem management goals. LB

Cooperative Planning

COMMENTS: Cooperative planning include: coordinate planning with other federal agencies, such as the Beaverhead and Gallatin National Forests, Red Rock Lakes National Wildlife Refuge, Bureau of Land Management, and the Sheep

MISCELLANEOUS

Experimental Station; participate on the Henry's Fork Watershed Council; make explicit the necessity of cooperative planning among state and federal agencies and administrative units in the Greater Yellowstone area; and make specific, accountable provisions in the Plan for this cooperative management.

1276, 1333, 1365, 1387

RESPONSE: The Forest worked hard during the planning process to involve neighboring agencies, other organizations and the public as a whole in the development of the Revised Plan. The Forest conducted an Adjacency Study to better consider how management of the Targhee would fit adjoining land uses. We also conducted a number of information-sharing meetings with our neighbors. In keeping with the principles of ecosystem management, the Forest expects that coordination to continue. The Forest does not see the need to set up some kind of structure to ensure that this gets done, since it has been and will continue to be our standard method of operation.

The Forest actively participates and is involved with federal, state, and local agencies and organizations, such as those listed above. See the public mailing list in this appendix to see the breadth of contact through mailings alone. DP

COMMENTS: Incorporate information found in Upper Colorado River Basin (UCRB) study into the Plan; conduct ecosystem management conducted on a forest-by-forest basis. Consider the impact of not-yet-completed NFMA Forest Planning Rules change and the UCRB Management EIS in the Plan; inform the public of possible impacts of these documents; and use the best science from the UCRB EIS.

643, 1273b, 1343

RESPONSE: To the extent possible, the Targhee used UCRB information in preparing the Revision. Some of it was not completed or finalized in time for use in preparing the Revision. UCRB direction does not apply directly to the Targhee.

The Revision effort for the Targhee began in 1990--before the Forest Service formally adopted ecosystem management--and therefore practical implementation of EM on a forestwide basis remained an issue.

The Targhee considered the "not-yet-completed NFMA Planning Rules" in developing this Revision. Because they are not completed, it is impossible to speculate on their impact. DP

COMMENTS: Use this report as background information about the Targhee: the United Nations Food and Agriculture Organization World Resources: A Guide to the Global Environment 1996-1997, which states that the US lost 1.1% of its total forest cover in the decade 1982-1992, and that temperate forests suffered from intensive logging, air pollution, and fire suppression.

410

RESPONSE: The principles of ecosystem management require that the Forest look beyond the immediate boundaries of the Targhee in proposing its future management. In looking at ecosystem conditions, and beyond its boundaries, the Forest recognized the need to better address resource concerns on the Forest. To that end, the Forest reduced the scheduled timber harvest to sustainable levels; reduced cross-country motorized access; and provided

MISCELLANEOUS

improved riparian conditions. These efforts allow the Forest to continue to produce a wide range of goods and services for people while protecting ecosystems. DP

COMMENTS: The Forest Plan is part of a United Nations scheme to create a buffer zone around Yellowstone. Preserve our lands for Americans.

1264

RESPONSE: Employees continue to protect essential resource values on the Targhee, while providing a wide array of goods and services. The Forest has received no communications from the United Nations. DP

Cultural Resources

COMMENTS: Preserve and develop various cultural resources including the old dam on the Buffalo River, Yellowstone Railroad Tunnel and Trestles, Yellowstone Railroad sidings at Island Park and Thirsty Creek, Big Table Mountain Complex, and Camas Creek Arch. Work with the Island Park Historical Society and State Historical Society to review and prioritize "900" cultural resources on the Targhee.

696, 697

RESPONSE: Heritage resource preservation and interpretation opportunities are identified during heritage resource inventories and evaluations in compliance with the National Historic Preservation Act. We are currently focusing on the enhancement and interpretation of the Birch Creek Charcoal Kilns, and Mesa Falls Lodge. Other heritage resources will be prioritized in terms of funding, site significance, and cooperation with special interest groups such as the Island Park Historical Society. SW

COMMENTS: Homesteaders should receive the same respect for ancestors as do Native Americans.

1256

RESPONSE: Under the Archaeological Resources Protection Act of 1979 as amended in 1988, all historic properties 50 years or older receive the same consideration. AS

COMMENTS: Remain sensitive toward Native American cultural traditions when implementing management prescriptions.

1185, 1348

RESPONSE: Sensitivity to Native American cultural traditions is mandated by the American Indian Religious Freedom Act and the National Historic Preservation Act. The Final Revised Plan is in compliance with these documents. AS

COMMENTS: Follow procedures established in the National Historic Preservation Act Section 106 and Advisory Council regulations 36 CFR Part 800. Provide surveys, evaluations, and protection of significant historic and archaeological sites prior to disturbance.

389

MISCELLANEOUS

RESPONSE: This statute is routinely followed on the Forest. The direction is not repeated in the Forest Plan. AS

Visual Quality Objective in Bigholes

COMMENTS: No justification of VQO of maximum modification in the area of East Slope of the Bigholes (Prescription 7.1).

1277

RESPONSE: The prescription in this area was changed to 5.1.3 (b) in the Revised Plan. This prescription does not allow clearcutting and the VQO was reduced to a more conservative range of partial retention to modification. AS

Education

COMMENTS: For an up-to-date administration and informed public, make education an integral part of Forest management. Do a better job of educating about: degradation to the forest; and ecological, social, and economic implications of each alternative. Allocate funds to mount an education campaign on the biological roles of fire, insects and disease, road building, logging, grazing, and mining. Implement scientific standards accompanied by an active public education program. Educate farmers and loggers about forest devastation, such as that in Thailand where over 60% of forests were logged or cleared resulting in drought, erosion, unproductive lands, and dire social consequences.

399, 507, 1364, 1365

RESPONSE: Education is an integral part of the forest management program. The Forest recognizes the need to educate others and ourselves. The Forest provides educational opportunities at fairs, schools, field trips, outdoor events, with the media; in brochures and signing; in environmental documents and many other outlets within personnel, time and financial constraints.
DP/AM

Fungi

COMMENTS: Acknowledge role of fungi in the forest. Inventory fungal flora in various regions with various age classes. Use the data in developing plans to manage the ecosystem, and have a professional mycologist monitor and evaluate the fungi present in the Forest. Develop standards to limit the harvest of fungi species and other natural resources that could be negatively impacted by commercial or personal exploitation. (CROSS REFERENCE: Monitoring; Ecosystem Management)

731, 1273b

RESPONSE: Fungi are important to effective ecosystem function in a varied, complex way. Inventories have not been conducted on the Forest. This data is not essential to understanding Forest ecological processes or evaluating effects on fungi or other resources from proposed management direction in the Revised Plan. Commercial mushroom gathering is not significant on the Forest and no significant increase is expected to occur in the next decade. Personal gathering is minor and extremely limited in scale and largely associated with

MISCELLANEOUS

access availability by the public. The effects of incidental gathering that occur are equally limited and not significant. The access restrictions in the Revised Plan will likely limit mushroom gathering more than the current situation. Inventory, monitoring and evaluation by a professional mycologist are not believed to be necessary. Implementation of the Ecological Processes and Patterns direction for Properly Functioning Condition (Revised Plan, Chapter 2) will provide for sustainable conditions for fungi. No additional direction is needed to protect or allocate fungal resources. Should a concern develop which requires more specific action, the Revised Plan provides the necessary direction to respond. RR

Land Exchange

COMMENTS: Recommend land exchanges between the Forest Service and private land owners or public land agencies. Go ahead with such proposals because they would benefit local economies, protect critical areas, and reduce "strip" development along highways. Study and incorporate the proposals contained in the Fremont County Comprehensive Plan, Policy 5 (Page 11). Clarify why land exchanges are discussed in the old plan but not in the new plan. Include these in the Right-of-Way Plan, Endorsement Plan, and Acquisition Plan. Resolve conflicts between commercial leasing of state lands and Forest Service objectives.

65, 314, 697, 723, 1276, 1342, 1351

The Forest Service should not swap land with Targhee Ski Resort.

F-G-P(1)

RESPONSE: The Forest carefully considers all proposed land exchanges. The lands section in the Supervisor's Office is charged with monitoring a Lands Acquisition Plan and a Right-of-Way Plan, for instance. Because those plans are subject to annual update, they are not physically included in the Forest Plan Revision. DP

Planning Process

COMMENTS: Forest Supervisor and staff did an excellent job revising the Plan and EIS and they did a good job summarizing and presenting information to the public. Appreciate the hard work that went into revising the Plan; appreciate the Forest Service creating alternatives and inviting public comment because significant time and resources went into developing each alternative.

181, 331, 432, 725, 1177, 1269, 1398

RESPONSE: Thank you for expressions of support. DP

COMMENTS: Don't just keep and publish comments that agree with your plan; explain the reason for public input since the plan did not change to reflect public's desire to retain motorized use of trails; public comments indicate that people feel the government is excluding them from public lands and reforms are not in their best interests; and wouldn't have known about plan if "motorized" people hadn't advertised in the Post-Register. Plan revision process did not have true public involvement, led to polarization rather than consensus and acceded to demands of environmental groups. The planning process

MISCELLANEOUS

forces us to choose between the good, the bad, and the ugly and ended up with the ugly (3M), which is not acceptable.

219, 262, 453, 1202, 1365, 1448b

RESPONSE: The Revision process received extensive media coverage. Thousands are on the Revision mailing list. Public meetings occurred on Saturdays, weekdays and evenings in Idaho, Montana and Wyoming. The Forest used every avenue available to notify people about meetings.

All comments were reviewed and addressed. Many people disagree with the draft plan. Because a segment of public does not get its way does not mean they were ignored or excluded. In selecting the preferred alternative the Forest considered public and other agencies input; the entire body of established laws, regulations and other direction; science; other plans; the needs of the resource; economics; and social considerations. DP/AM

COMMENTS: The planning process established an adversative atmosphere, did not adequately disclose scientific information or legal constraints, and told state and federal agencies that they had same status as individuals and they must get consensus from citizens to implement their mandated goals. For future planning, use a complete scientific analysis in cooperation with other agencies, Indian tribes, and groups; conduct public scoping to determine needs and recommendations; use scientific analysis to determine methods of achieving goals; and present scientifically based alternatives to the public.

766

RESPONSE: The Forest worked to get the various members of the public and the various government agencies talking together and there were some successes. Some interpreted this as creating an adversarial atmosphere. The intent of the meetings was to allow people to work out their problems as they discussed them.

The special status of the Tribes and agencies working on the Revision was not abridged. It is guaranteed by law and regulation.

Since all power flows from the people, they can change results through the legislative process if agency meetings are unsatisfactory.

The Forest used and will continue to use the best available science. Scientists have different views as to what constitutes a complete scientific analysis. Scientific information was shared at meetings--such as one on Saturday dealing with wildlife and motorized access, and another that explained the FORPLAN model. The Forest will continue its efforts to improve cooperation, coordination, and scientific knowledge with the Tribes, agencies and interested groups. DP

Public Lands

COMMENTS: Oppose public lands being sold to private individuals, as happened in Texas where there now are no more public lands because setting aside public land is one of the smartest things America ever did. Public lands belong to all of us, are priceless and not for sale to highest bidder, and are irreplaceable. The key word is public, not private as some environmental groups and individuals think.

6, 348, 408, 1449

MISCELLANEOUS

The federal government takes land away from the public, and proposing more wilderness is extremist; take public lands back from the federal government.

1447a

RESPONSE: Your comments for and against public lands are acknowledged. The Revised Plan allows for land exchanges where high environmental values would be realized and where high environmental values could be irretrievably lost. Land exchanges are also targeted for inholdings that would make the Forest easier to manage. Site-specific NEPA documents are prepared for all land exchange proposals, allowing public concerns and comments. The Forest Service has no authorization to sell National Forest System lands. KA

Sensitive Plants

COMMENTS: Ensure compliance with procedure and biological requirements for sensitive plants.

1273b

RESPONSE: Compliance is required by Forest Service direction. DP

Island Park

COMMENTS: We plan to live in Island Park (IP) and practice low-impact living; everyone else should do the same. IP is our playground where we fish, hunt, and use RVs. Don't make it another Yellowstone where people are herded through on crowded highways. Force the snowmobile industry to clean up emissions because IP smells like oil in winter.

266, 407, 511

RESPONSE: The Forest will try to retain the natural setting and recreation opportunities that you enjoy in Island Park. The area is experiencing a great deal of growth and building on private land over which the Forest has no jurisdiction. Cleaning up snowmachine emissions is outside the scope of the Revised Plan. DP/AM

Two-Top, D-2

COMMENTS: Continue to deny the once-proposed Two Top Communication Site and recognize your responsibility to maintain aesthetic value of the area.

1276

RESPONSE: The Final Revised Plan does not establish Two Top as a communication site. The Forest recognizes the aesthetic value of the area. DP

D-2, D-3

COMMENTS: Close the Island Park, Ashton, and St. Anthony Ranger Stations and use the money for something else.

1321

MISCELLANEOUS

RESPONSE: We have been downsizing our organizations to meet budget limits and are currently managing the Ashton and Island Park Districts under one Ranger. In addition we are sharing many forest staff functions with the adjoining Caribou National Forest. The idea is to reduce overhead and put more of our resources on the ground. However, we also need to provide for service to visitors, so the offices will remain open. JR

Jedediah Smith Wilderness, D-3

COMMENTS: The Jedediah Smith Wilderness was better, had fewer people, less litter, less competition, before it was designated a wilderness.

645

RESPONSE: The act of designating a wilderness can increase its use and it can be "loved to death". However, the standards and guidelines adopted for the Jedediah Smith should help to address these concerns. JR

South Fork Snake River

COMMENTS: Manage South Fork in compliance with 1991 Snake River Activity/Operations Plan.

766

RESPONSE: The two management prescriptions identified for this area stipulate that the management direction contained in the Snake River Activity/Operations Plan applies. DP

Big Holes

COMMENTS: Do not log the west slope of the Big Holes as a means of fire prevention.

212

RESPONSE: Virtually all of what might be described as the west slope of the Big Holes falls into prescriptions 5.1.4(b), 3.2(g) and 2.7(a). Timber harvests are scheduled in the 5.1.4(b) prescription, but not in the others. No specific need is identified at this time to log this area for fire protection. DP

COMMENTS: Closing the Big Hole Mountains discriminates against those who do not have the money to pay the government for violating Wilderness designation. Allowances are made only for those with the money to pay, like Jackson Hole airport.

311

RESPONSE: The Revised Forest Plan does not recommend the Big Hole Mountains for wilderness. DP

MISCELLANEOUS

Clark and Teton County, D-5

COMMENTS: Work with the University of Idaho Department of Economics and Rural Sociology regarding management impacts on Clark and Teton Counties.

1384

RESPONSE: The Forest consulted the latest publications from the University of Idaho for use in our analyses. DP

Want Management Changes

COMMENTS: Recognize your duty to protect the natural heritage and not concede to logging contractors or consumptive uses because local biases and politics have led to mismanagement. Insure sustainability and protection of wildlife and resources. Keep Idaho wild and protect Targhee National Forest resources against those who want to use them up. Protect natural diversity and prevent extirpation of species because Forest Service has not taken an ecological approach in the past. Strengthen the DFPR because it is disheartening to fly over the forest and see all the clearcuts and provide tourists with a positive first impression. Protect watersheds, prohibit clearcutting, restore degraded areas, protect wilderness, secure migration corridors, and keep ORVs out of wilderness study areas, for our children's sake. Keep the Targhee as a place that is sacred, inspiring, and reminiscent of Handel's "Verdant Meadows, Stately Forests."

157, 189, 226, 293, 320, 613, 620, 654, 658, 766, 1273b, 1312, 1365, 1380, 1396, 1401

RESPONSE: The Forest is managing for a sustainable ecosystem; providing for natural diversity; and promoting the recovery of threatened, endangered or sensitive species. In doing this, people will still have the opportunity to use its goods and services.

The visual effects of the past mountain pine beetle epidemic and subsequent harvest of lodgepole pine are fading. The use of clearcutting is limited, watershed protection has increased, and efforts are underway to improve various resource conditions. The prescriptions identified in the preferred alternative provide important habitat connectivity. The Palisades Wilderness Study Area is being managed as directed by law.

The Forest acknowledges your impression that the Targhee is a place that is sacred, inspiring, and reminiscent of Handel's "Verdant Meadows, Stately Forests." We do not expect anything in the preferred alternative will change that impression. The preferred alternative is not Bradamante to your Ruggiero. DP

COMMENTS: There should be no change because cattlemen and loggers have always cared for the forest; leave things alone, there is too much wilderness now; the Targhee has been mismanaged and should consider the plan of the Teton County Commissioners; likes past management.

229, 293, 525, 738

RESPONSE: Alternative 1 would continue existing Forest management (with some changes) into the future. The Forest selected alternative 3M (Final Revised Plan) instead because it provides a better response to the various issues. We

MISCELLANEOUS

did not identify a conflict between the Revised Plan and Teton County's Comprehensive Plan as amended on March 11, 1996. DP

Consumptive Uses

COMMENTS: Oppose all logging, grazing, mining on the Targhee because of impacts on soil, water, wildlife, fish, vegetation, visual qualities, roadless and wilderness resources.

276

RESPONSE: Logging, grazing, mining, recreation and other human uses have impacts on resources. Human use is part of the ecosystem. The multiple-use mandate requires us to care for the land and serve the people. DP/AM

COMMENTS: Support removal of forest products because removal is no more harmful than fire and nature can recover from anything.

296

RESPONSE: Nature's recuperative powers are remarkable--though not unlimited. The Revised Plan provides a sustainable ecosystem that in turn, provides people with a variety of goods and services. DP

Population

COMMENTS: National Parks, National Forests and wilderness areas are exploding in use due to population explosion. Change the way we use land because people must realize that the more children they have, the more things will change. As population increases there will be a greater need to use our forests. If people are crowded into a smaller space, these areas will become overused.

250, 527

RESPONSE: The Forest anticipates increased use and the Revised Plan responds to it. DP

User Fees

COMMENTS: Establish a systematic-comprehensive system of user fees within the confines of law. Use funds to support mitigation of user impacts, ecosystem monitoring, acquisition of new lands, environmental education, and administrative costs. Integrate a permit system into the user fee system to control impacts in a high-intensity use area. Maximize public access while preserving biological diversity, and be available to a reasonable proportion of commercial and non-commercial users.

1365

RESPONSE: Establishing such a system is outside the scope of the Forest Plan. Direction for establishing fees comes from legislative action. Congress recently authorized (by the 1996 Omnibus Consolidated Recissions and Appropriations Act) a system for evaluation of fee collection potential for a variety of major types of recreation use. The Forest Service is currently evaluating new fee proposals known as "Fee Demonstration" projects to demonstrate the feasibility of a comprehensive system of user fees. This

MISCELLANEOUS

authorization allows 80% of fees to stay at collecting site for administration and maintenance. Permit systems are determined by area management plans and are also not part of the Forest Plan. AS

COMMENTS: Improve management of utility corridors. Designate road closures where there would be no effect on access to corridors for maintenance and emergency activities. Refer to the 1993 Western Regional Corridor Study when considering land use that may affect existing or proposed corridors. Provide access to and maintenance of Right-of-Way in accordance with special use permits, land use grants and easements. Encourage ROW vegetation management which reduces impacts while enhancing ecosystem values. Require utility companies to verify the condition of some access roads and the usefulness of several roads that cross streams.

Show the proposed line from Swan Valley Substation to Teton Substation and associated access roads; add the Targhee to Drummond line and the section of Drummond to Madison line from Macks Inn to Madison to the Forest Geographic Information System and maps. The management prescriptions for the Targhee to Drummond line in Table 1 were determined using Map #10, Alternative 3M, in the Forest Plan DEIS and may be misidentified in Table 1. Create a new management prescription with standards and guidelines for transmission corridors that applies to all current and potential corridors identified by the Western Utility Group. Reclassify all existing and potential transmission line corridors under Management Prescription 8.1 concentrated development area. Clarify in Forest Plan and EIS how transmission line corridors will be managed given the current management prescriptions in the DEIS. Allow utilities to adequately construct, operate and maintain lines and corridors.

1279

RESPONSE: The Forest basically agrees with your proposals and used the Western Utility Group's maps. The Revised Plan shows larger power lines with their designated corridors and applies the 8.1 prescription to them. The Plan shows existing lines and not potential, unless an approved location was identified. New proposals need an analysis. All other lines or corridors that run through prescription areas and forestwide standard and guidelines (FWSG) will apply. Most utility corridors will require a completed EIS, EA or MOU and an operations and maintenance plan for work activities within the corridors. LAB

COMMENTS: Because clearcuts destroy the aesthetics and possibly devalue property of an area, reconsider Objective 1, 5.2.2 - Silviculture practices cannot maintain visual quality, much less emphasize it; the Forest Service cannot compete with nature. Add as Objective 7, 5.2.2: "Maintain or enhance inherent values associated with fish, wildlife, and vegetation of the area."

325, 697, 1446

RESPONSE: The purpose of prescription 5.2.2 is to maintain visual quality through the use of "natural vistas." Therefore, clearcutting would not likely be used. The description states, "signs of commercial harvesting will generally not be evident." The objective (#1) is correct as written in the context of the prescription description. With the limited resource activity

likely to occur on this prescription, the additional objective (#7) as suggested is not warranted. DP

Intermingled Public/Private Lands

COMMENTS: The east slope of the Big Hole mountains is of high value for a variety of wildlife. This habitat is threatened because of human population growth in the Teton Basin area. Reconsider the 7.1(b) designation because it will lead to degradation of habitat and wildlife under the guise of fuel management.

643, 1277

This prescription allows timber harvest outside the ASQ and thus in areas not designated as suitable for timber harvest. "Fuels management" is too broad and vague to provide a basis for management in this ecologically diverse area fuels management should not be conducted to protect isolated homes and the Targhee National Forest should communicate this policy clearly to the public.

643, 1277

Prohibit Forest Service land exchanges that result in additional private development in areas along the existing Forest boundary.

643

At a minimum, predesignate the area currently outlined as 7.1(b) to match the adjacent prescription 3.2(g). Limited areas of concern for fuels management within this area could be identified and a supplemental NEPA document involving the public should be undertaken to evaluate actual fire risk, potential management options and their chances of success and impacts to other resources.

643

Concerned about the intermingling of public/private lands in this area because I am a home owner. However, it is ultimately the homeowners responsibility for fire breaks.

325

Explain to the public that the intention of this prescription was to construct a fire break to reduce the chance of fire for dwellings, and should apply to the west side of the Tetons. Recommend same prescription as Henry's Lake area rather than 7.1 (a&b).

1360

RESPONSE: The Forest considered a wide range of management intensities for this area. They included Recommended Wilderness (1.3), Elk and Deer Winter Range (2.7(a)), Semi-Primitive Motorized (3.2(g and h)), and Timber Management (5.1.3(b)).

Based on the prevailing and anticipated future use of adjoining private lands, legal requirements to address safety and property rights, the many issues facing the Forest, and the assessment of potential environmental effects, the Forest selected management prescription 5.1.3(b) in the Final Revised Plan. DP

MONITORING AND ENFORCEMENT

General Monitoring

COMMENTS: Management actions on the Targhee National Forest need to be monitored to ensure no negative environmental impacts occur; clarify how monitoring objectives will be met when objectives in 1985 Plan were not; monitoring activities to date reveal need for rigorous, ongoing monitoring of forest management; all monitoring and enforcement plans should include work load analysis; monitoring programs are needed to identify current status of forest plan relative to goals, identify accomplishments and future management direction; Chapter V, Monitoring and Evaluation does not really address those two topics well in relation to forest operations, especially as they relate to 3M, lacks ecosystem view and appropriate spatial and long term temporal perspective.

282, 389, 643, 690, 699, 766, 1446

RESPONSE: Forest Plan monitoring is required by regulations at 36 CFR 219 which implement the National Forest Management Act (NFMA). It is designed to measure whether or not the agency is complying with standards and guidelines in the Forest Plan, and whether or not that direction is bringing about the desired results.

Forest Plan monitoring is part of a larger program of monitoring which includes scientifically rigorous experiments and trials usually conducted by the research arm of the Forest Service; work program monitoring such as the administration of special use permits (such as for grazing) and contracts (such as for timber sales); and work required to show compliance with certain laws or regulations (such as regeneration surveys). In addition, individual projects may have monitoring associated with them as mitigation or other such commitment. This is explained in the first part of Chapter V of the Final Revised Plan.

Under one or more of the above, management actions will be monitored to show whether project outcomes and environmental impacts are within limits predicted or specified in the Forest Plan and project-level analysis and decision documents. We anticipate issuing a yearly report to the public on our findings.

The Monitoring and Evaluation Plan (Chapter V) in the Final Revised Plan complies with NFMA direction and will adequately monitor the application of management direction, and whether that direction is contributing toward achievement of desired conditions. This monitoring plan is more realistic and achievable than was the original Forest Plan monitoring plan. For example, the items monitoring Management Indicator Species in the original Plan called for monitoring populations of certain species that proved to be difficult or impossible to accurately count. The methods planned in the Final Revised Plan comply with NFMA requirements, are more practical to implement and will provide the information needed to determine if a course adjustment is warranted.

Funding of monitoring activities has been a concern for many years. Although we have tried to streamline the monitoring program we acknowledge that all items may not be funded. We have prioritized the items in the monitoring plan to indicate the information that is most crucial to operating the Forest under the revised guidance. On the basis of comments on the Draft we raised the priorities of several items including riparian forage

MONITORING AND ENFORCEMENT

utilization, achievement of road density standards and effectiveness of road closures. EF

Funding

COMMENTS: Monitoring is essential so commit enough funding to ensure it is carried out; effectiveness monitoring is important, and though it costs more, funding must be dedicated; clarify what decision process will be used to determine priority in allocating funds; clarify how the Targhee will monitor and enforce priority items with shrinking budget and staff; prioritization scheme must ensure that monitoring will be completed, monitoring must not be dependent on budget but be tied to each project, which also allows flexibility; funding must be provided to enforce restrictions on access or motorized use; to maintain a watchdog program, commit more funding to research and monitoring for adaptive management.

356, 432, 444, 643, 690, 695, 1273b, 1446

RESPONSE: We agree that monitoring is important to indicate the health of Forest resources and whether revised management is warranted. The full monitoring program outlined in the Final Revised Plan, though streamlined to an extent, is still expensive, and we anticipate it will not be fully funded in most years. We will do the best job we can to implement the plan by combining items with similar indicators, seeking out partnerships where appropriate, and other means.

Monitoring can be tied to individual projects when, for example, it is included in the mitigation of environmental effects. In these cases it is an integral part of the project decision, and project implementation may then be contingent upon funding of the monitoring. These monitoring items are usually specific to an individual project rather than forestwide. Adaptive management can be implemented in this way if a project includes new technology or scientific basis and should be rigorously studied. EF

Funding/Monitoring Recommendations

COMMENTS: Use citizen monitoring program to educate users on Forest regulations; take an adaptive approach to management and actively involve citizens in monitoring and project implementation; use personnel who previously administered timber activities to monitor and enforce Plan; establish a systematic-comprehensive program of user fees with the funds used to support ecosystem monitoring projects; incorporate monitoring into project development as planning, inventory, and monitoring are on same budget item; Monitoring and Evaluation Chapter should include how well management is meeting goals, and early warning system to permit timely adjustment if it is not.

282, 389, 1273b, 1312, 1337, 1365

COMMENTS: We agree that the public can play an important part in the overall Forest monitoring program. We look forward to the participation of individuals and user groups in monitoring activities as appropriate. Other avenues for public participation include partnerships and cooperative study agreements with academic institutions.

MONITORING AND ENFORCEMENT

Several surveys in recent years show a willingness on the part of the public to pay reasonable fees for the use of public lands to offset management expenses if services meet their expectations. We will look into opportunities to assess fees as appropriate and to use a portion of these monies for conducting monitoring.

Monitoring can be tied to individual projects when, for example, it is included in the mitigation of environmental effects. In these cases it is an integral part of the project decision, and project implementation may then be contingent upon funding of the monitoring. These monitoring items are usually specific to an individual project rather than forestwide. Adaptive management can be implemented in this way if a project includes new technology or scientific basis and should be rigorously studied.

We agree that forest plan monitoring should indicate how well management is meeting goals and objectives, and show when a change of management is warranted. The monitoring and evaluation plan in the Final Revised Plan complies with direction in the regulations implementing the NFMA and accomplishes these aims. EF

COMMENTS: Effectiveness monitoring will provide more useful information than implementation or validation monitoring; consider using photo plots as a monitoring tool.

432

RESPONSE: Photo points or plots have been used successfully in the past in many places as a monitoring tool. Trends in the condition of trails and riparian, upland and forest vegetation are but a few of the uses that can be made of this method. Video cameras and the advent of computerized image storage may provide opportunities for future use. We will consider any reasonably available tools in the Forest monitoring program where appropriate. EF

MULTIPLE-USE

Multiple-Use Comments

COMMENTS: Maximize multiple-use of the forest as the best way to get maximum income to citizens with minimum impact to the forest.

12, 271, 393

RESPONSE: The Forest recognizes the multiple-use mandate by the American people for managing their National Forests. DP

COMMENTS: Need to adequately acknowledge the principles of multiple-use. Obey the Multiple-Use Sustained Yield Act. Consider multiple-use in developing your Plan. Don't let excessive bureaucracy cripple multiple-use. Multiple-use has failed, not because it was a flawed concept, but because the federal government lacked the integrity to carry it out. Provide multiple-use in the revision -- it only directs what lands will be used for timber unless there is a legal restriction but, without wildlife standards for most of the forest, multiple-use management is violated.

309, 629, 714, 1340, 1369

RESPONSE: The Forest practices the principle of multiple-use management. Multiple-use does not mean that every use has to occur on every acre of forest. Forest management under the Revised Plan is a mix of management activities designed to address multiple-use management. For instance, much of the Forest will be managed as wilderness areas; as eligible wild, scenic, or recreational rivers; as grizzly bear habitat; for nonmotorized recreation use; for developed recreation; for timber management; and for range management. In addition, the Forest will protect important resources like air, water and visual qualities, and heritage resources.

Legislation and implementing regulations require the Forest to identify those lands which will be scheduled for timber harvest. Most of the Forest is not scheduled for timber harvest even though a great part of that land could legally be harvested. It is not scheduled for timber harvest for a variety of multiple-use reasons including wildlife needs, aesthetics, recreational uses, concerns relating to cost-efficiency, and resource protection needs.

The entire Forest is protected by all applicable laws and regulations, manuals, and handbooks whether the land is scheduled for timber harvest or not. Wildlife standards and guidelines exist on a forestwide basis. Individual prescriptions recognize that forestwide standards and guidelines (FWS&G) apply, but in some cases they specify a higher degree of resource protection than that afforded by the FWS&Gs.

Forest management under the Revised Plan is in compliance with the Multiple-Use Sustained Yield Act. All the alternatives presented in the EIS provide for sustainable harvest levels. DP

COMMENTS: Special interests or groups have more influence over determining uses than others; multiple-use is a right; animals' needs shouldn't outweigh the public's; and if loggers and grazers were going to hurt the land they would have done it years ago. Emphasize more uses such as logging, grazing, and recreation; emphasize less wilderness, animals, and environmentalists. Excessive bureaucracy is crippling effective multiple-uses. Local interests,

MULTIPLE-USE

hunters, fishermen, and wildlife must have more influence on determining multiple-use.

98, 268, 271, 285, 309, 439, 460, 461, 467, 468

RESPONSE: The Forest carefully considered all input, regardless of source, before arriving at a Final Revised Plan. Multiple-use management is the law. The American people, acting through their elected officials, set up a body of law and regulations under which Forest management is conducted.

This process can result in people unhappy with management of the forests since the laws are not passed by unanimous vote. The acrimony that ensues when the legislation was considered is revisited when the law is put into effect.

The Final Revised Plan has a multiple-use mix of management activities like logging, grazing, and recreation that are compatible with resource protection. The Revised Plan strikes a balance in which the needs of the resource are addressed and a wide range of goods and services are provided for the public. The Forest recognizes that our Revised Plan does not, and cannot, fully meet conflicting users' expectations. DP

COMMENTS: Past management over-emphasized timber or extractive uses; multiple-use must include fishing, hiking, wilderness, and/or environmental considerations. Valuing lands for timber to the exclusion of other uses is narrow-minded and antiquated. Choose an alternative with a balance of multiple-use and wilderness.

F-B(4), 185, 271, 625

RESPONSE: Thank you for your support of the Final Revised Plan. DP

COMMENTS: Disclose information on specifics of multiple-use and fisheries prior to their adoption.

1261

RESPONSE: The FEIS discloses information appropriate for a programmatic document. It includes consideration of other fishery studies like INFISH and the Draft UCRB publications. Additional analysis at a site-specific location will be conducted before actual projects are implemented. DP

COMMENTS: Oppose all logging, grazing, and mining because of impacts on all other resources especially in wilderness.

276

RESPONSE: These uses are consistent with the Forest Service's multiple-use mandate from the American people. Wilderness areas are managed pursuant to enabling legislation which normally eliminates logging and restricts mining and grazing. DP

COMMENTS: Ensure sustainable levels of wildlife, fish, recreation, and forest products.

174

MULTIPLE-USE

RESPONSE: The Forest provides for sustainable levels of ecosystem needs--including wildlife, fish, recreation and forest products. The Final Revised Plan is formulated with these ideas in mind. DP

NOXIOUS WEEDS

COMMENTS: In reference to Table III-1.1, "Noxious Weed Inventory" on Page III-38 of the DEIS: Please clarify if group of plants is listed by APHIS. Consider all plant species as part of a fully functioning ecosystem unless they are non-native.

1446

RESPONSE: Noxious weeds are not listed by APHIS; they are listed by the state. The species listed in the table are plants not native to the United States and have been designated by the States of Idaho and Wyoming as "noxious." When, in abundance, these plants are not part of a properly functioning ecosystem. WG

COMMENTS: DEIS needs to identify OHV and snowmobile use as a major source of noxious weed spread and address the implications of increased motorized use.

1365

RESPONSE: It is not the intent of the DEIS to identify all sources of noxious weed spread or the primary causes of infestation. Motorized recreation activity does aid in the spread of noxious weeds but is dependent on many factors. The Targhee has an approved forestwide EA for the control of noxious weeds. WG

COMMENTS: The DEIS does nothing to address the impacts of managing noxious weeds in the alternatives discussion, nor does it propose control strategy.

1368

RESPONSE: Noxious weeds and management are more clearly addressed in the FEIS in Chapters III and IV. WG

COMMENTS: The Targhee has too many noxious weeds and does little to limit weed spread. Could use grazing as a tool to control noxious weeds and add a standard requiring the use of weed free feed.

6, 333, 1312, 1351

RESPONSE: The Targhee has approximately 19,000 acres of noxious weed infestations. The number of acres treated yearly is dependent on budget and work force constraints. The Targhee has an approved NEPA document for the control of noxious weeds, which uses grazing as one of several approved control methods. All National Forest System lands require, through state law, the use of weed seed free forage of straw, hay, and mulch. WG

COMMENTS: Weeds are the biggest threat to viable ecosystem. Refrain from closing roads where old noxious weed infestation exist because this limits the ability to control the weeds.

432

RESPONSE: If needed for administrative purposes, "closed" (restricted) roads that are not permanently closed and obliterated will remain open for activities such as fire control, tree planting, or noxious weed control. For areas without road access, pack and saddle stock, biological control, mechanical control and backpack sprayers are available for use to transport people and supplies to weed infested areas. WG

RANGE

Social and Economic Concerns

COMMENTS: Grazing domestic livestock on the Targhee is supported. Respondents feel grazing should at least remain at current levels. Reasons supporting this use of the Targhee include: grazing can help sustain forest health; sustain rural economies; buffer Targhee from development pressure; enhance vegetation for wildlife; and, provide for multiple use.

153, 272, 285, 288, 300, 432, 473, 474, 514, 525, 661, 692, 709, 715, 720, 1202, 1259, 1335, 1391

Plan does not adequately recognize grazing as a part of the heritage and economic importance to Clark County. The value added to Clark County is very significant, with over 100,000 AUMs and a value of \$1040 per AUM per year, according to the IRS.

691

RESPONSE: A substantial livestock grazing program remains in effect under the Revised Plan which is consistent with management objectives for ecosystem management, wildlife, fisheries, and so forth. The projected levels of livestock grazing will maintain cultural heritages and most local livelihoods, while at the same time improve the land resource and value.

Although the Forest is not sure how the \$1,040 per AUM was generated, we recognize the economic importance of grazing to the area's economy. WG

COMMENTS: Grazing domestic livestock on the Targhee is not supported. Respondents feel grazing levels should be reduced and have more restrictions on implementation. Reasons for not supporting this use of the Targhee include: protection of habitat; protection of grizzly bear; protection of entire Greater Yellowstone Ecosystem; drastic increase in world population; and changes in the nature of beef production.

F-H(8), 7, 11, 77, 207, 266, 317, 328, 331, 650, 695, 733, 1185, 1203, 1299, 1335, 1348, 1392, 1393

RESPONSE: The Targhee is managed under the multiple use concept where potentially conflicting uses and values coexist. The consequences identified in Chapter IV of the FEIS project reductions in livestock use, commensurate with the management of other uses and consistent with numerous management objectives (ecosystem, wildlife, and riparian). Livestock grazing is an outcome of proper management of range and related resources. An actual adjustment (up or down) in AUMs will only occur with a site-specific analysis for each active allotment. WG

COMMENTS: Explain how the goals and objectives on page III-20 can be achieved while still maintaining grazing opportunities.

1446

RESPONSE: Livestock grazing is not the sole contributor to declining rangeland conditions. Fire, invasion of noxious weeds from a variety of sources, past inappropriate livestock grazing practices, road construction and recreation use are a few examples of causes contributing to the decline of riparian and rangeland health. As described in Process Paper J - Logic Used to Estimate Effects of Livestock Grazing on Riparian and Upland Vegetation,

RANGE

rangeland and riparian health can be improved with livestock grazing by implementing the Standards and Guidelines in the Final Revised Plan. WG

COMMENTS: All alternatives close an additional 98,214 acres to grazing. Do not think the analysis adequately provides the public an assessment of the economic impacts of closing this acreage.

228

RESPONSE: The 98,214 acres was an error in the DEIS; there are actually 95,408 acres. As explained in Chapter IV of the FEIS, the 95,409 acres are not presently grazed by livestock; in fact, some of these areas have not been grazed for nearly 10 years. There is no economic impact because no practical reduction in AUMs will occur. An economic analysis was conducted for the AUMs that would be lost when the sheep allotments would be immediately closed to improve grizzly bear and bighorn sheep habitat. These AUMs are authorized to graze on 125,853 acres. WG

Range Improvement Issues

COMMENTS: Supports the preferred alternatives' emphasis on riparian protection from cattle. Agree with the salting requirements and feels all new water developments should also be constructed outside riparian areas. (CROSS REFERENCE: Riparian, General)

204, 265, 697

RESPONSE: Thank you for your support. The Forestwide standards and guidelines and the Aquatic Influence Zone Prescription implement these concerns. WG

COMMENTS: Access behind locked gates on grazing allotments is crucial for permittees to effectively maintain fences and improvement structures. (CROSS REFERENCE: Access, Range)

432, 1378

RESPONSE: Permittees are allowed access behind locked gates to maintain range improvements as documented in the forestwide standard: "Permittees are allowed motorized access to maintain facilities. AMPs and annual operating plans will include direction that motorized access must be less than 1 to 2 vehicles per week. (This permitted access is not included in the OROMTRD) (S)" WG

COMMENTS: Cattle should be required to be quarantined for three days before they are turned on to National Forest land, to help prevent noxious weed spread.

204

RESPONSE: This is outside the control of the Forest Service. Only the States of Idaho or Wyoming could impose a quarantine on livestock. WG

RANGE

Site-Specific

COMMENTS: Range management guidelines for School Section Creek-Modoc Creek should be amended to include measures for minimizing conflict with grizzly bears and other predators.

1348

RESPONSE: Livestock grazing that occurs in grizzly bear management units (BMUs) have specific conditions that apply. School Section Creek and Modoc Creek are not within grizzly BMUs and so will not be managed with those special conditions. Future conflict could warrant site specific analysis.

Other predator conflict will meet the direction specified in the 1996 APHIS-ADC Environmental Assessment for Predator Damage in Southern Idaho which incorporates the existing Targhee National Forest direction. WG

COMMENTS: The following areas have prescriptions emphasizing range management; however, these areas contain or are near roadless areas and should be in prescriptions with wildlife habitat emphasis: Diamond Peak (lower elevations), Italian Peak (most of area), and Garfield Mountain (central portion).

695

RESPONSE: The Forest decided on the management for this portion of the forest and chose it as the preferred management. WG

Timber

COMMENTS: There should be no grazing in aspen and/or conifer regeneration areas.

697

RESPONSE: The Revised Plan provides for protection of regenerating conifer/aspen on a forestwide scale. This issue/concern is best handled within the framework of a site-specific project level or landscape level analysis where aspen and conifer regeneration are identified as key issues. WG

COMMENTS: Page III-21 (AMP) should read: "salting will also be placed at least 500 feet away from aspen and conifer regeneration (plantation and natural) that are less than two feet tall." A linear measurement would be better than a time measurement.

283

RESPONSE: Your suggested change was not adopted because there is a forestwide guideline in the Revised Plan that provides for the management of conifer regeneration and the placement of salt. WG

RANGE

Riparian

COMMENTS: Grazing is a major problem on some streams, but there is nothing mentioned about standards and guides for aquatic resources. Streams must be protected. (CROSS REFERENCE: Riparian, General)

359, 695

RESPONSE: Prescription 2.8.3, Standards and Guidelines for range and riparian and the Rangeland Monitoring Protocol will protect riparian areas and riparian-dependent species. The measures prescribed are based on research and on work conducted elsewhere and are the measures accepted by the Forest. RM

Questions Analysis

COMMENTS: Primary deficiency with the range program in the Plan and DEIS are: 1) inadequate utilization levels in riparian areas; 2) use of unreliable and/or outdated and unscientific data to estimate range condition and make predictions; and, 3) lack of a well conceived monitoring program. (CROSS REFERENCE: Riparian, Stubble Height)

432, 643, 690, 1194, 1206, 1401

RESPONSE: The riparian and upland utilization levels, the utilization standards, and other standards and guidelines will achieve the desired results. The standards and guidelines provide a moderate rate of recovery of degraded riparian and aquatic systems together with a moderately high level of quality fisheries habitat. Scientific literature supports this.

The data used to analyze the consequences in the FEIS was generated from the District range data files, which are updated annually. The foundation information in the range files are range analysis surveys conducted on the forest, for all but nine allotments (1,813 acres). This information is 25 to 30 years old. Those data were converted to Ecological Status in 1986 and were used in the 1991/1992 AMS. Based on professional judgement (sound principles conducted by well trained individuals), range trend is reflected in the FSRAMIS data base as riparian or upland acres estimated or verified as meeting, moving toward, or not meeting forest plan management objectives.

Each district provided estimates of how the capacity for each allotment would be affected by each of the alternatives. A 500 page document contains information about every Targhee allotment open to grazing. The consequences for each allotment, by alternative, is documented in terms of both AUMs and/or livestock numbers.

A rangeland monitoring protocol will assist in Forest Plan implementation. This will also outline the monitoring procedures for utilization and trampling criteria. Permittees will be trained by Forest personnel in implementing this protocol and will be held responsible for meeting the Standards and Guidelines of the Revised Plan. WG

COMMENTS: Page V-20, DFPR, Streambank trampling: to have a plan where an EIS approves something that has yet to be developed is not acceptable.

432, 643

RANGE

RESPONSE: The intent of this monitoring item is to help in the development and validation of this parameter. Some monitoring techniques are already available, but the Targhee wants to develop a site-specific monitoring protocol using methods that are proven reliable. WG

Wildlife

COMMENTS: Establish a standard and a monitoring plan for total use by both wildlife and livestock to determine if standards for livestock use are achieving the desired objectives for wildlife.

389, 643

RESPONSE: The grazing utilization standard applies to maximum allowable use of plants regardless of animal species (wildlife, livestock, or a combination of both). No matter which animal species utilized the plants as forage, livestock will be removed once the desired utilization level is achieved. Monitoring items for riparian and upland forage are outlined in Chapter V and a Rangeland Monitoring Protocol (in development). WG

COMMENTS: Too much utilization of upland shrubs and grasses on winter range degrades capacity and sustainability.

FS-9

Reserve as much forage as possible for wildlife, especially in winter ranges by reducing grazing.

389, 1203

RESPONSE: The standards and guidelines were modified in the Revised Plan to better address the winter range issue on a forestwide basis. This issue is best handled within the framework of a site-specific project level or landscape level analysis such as an Allotment Management Plan where big game winter range and livestock grazing are identified as key issues. WG

COMMENTS: The Targhee should consult with USFWS on all allotments within the grizzly bear Recovery Zone.

1446

RESPONSE: During the development of the Revised Plan, the Targhee formally consulted with the USFWS. Additional consultation will also occur during the NEPA process for site-specific range management proposals. MO

COMMENTS: Livestock have not impacted the wildlife other than to help them by creating more water holes.

661

RESPONSE: Impacts of livestock grazing on wildlife are complex. Some species are benefited by livestock grazing and some species are adversely affected by livestock grazing. The Revised Plan addresses numerous livestock/wildlife issues relating to grizzly bear, bighorn sheep, riparian areas, and winter ranges. MO

COMMENTS: Use the following habitat treatment standards for sage grouse: Vegetation manipulation (fire, herbicide, and mechanical treatments). Grazing

RANGE

management: To improve spring breeding habitat, manage for a healthy understory of perennial grasses and forbs and fall stubble height of ≥ 7 inches. To improve brood rearing habitat, manage to produce a fall stubble height of ≥ 4 inches.

766

RESPONSE: Forestwide standards and guidelines for big sagebrush/grassland habitats will provide for all species which use this habitat, including sage grouse. Future project level activities will consider sage grouse habitat needs on a site-specific basis. MO

COMMENTS: Wildlife will have to be accountable for use of forage (Page III-21, S&G 1). If it exceeds acceptable limits, agency responsible for wildlife management will have to remedy situation.

432

RESPONSE: Your comment is acknowledged. Management of wildlife populations is the responsibility of the state, although the Forest Service coordinates with the appropriate agency in wildlife management activities. WG

COMMENTS: Water developments should be prohibited in areas that will dramatically affect the quality and quantity of forage for wildlife & big game distribution.

389

RESPONSE: This concern is best handled within the framework of a site-specific project level or landscape level analysis such as an Allotment Management Plan where big game winter range and livestock grazing are identified as key issues. Also, the standards and guidelines were modified in the Revised Plan to better address the winter range issue on a forestwide basis. WG

COMMENTS: Removal of livestock carcasses or complete incineration is the only alternative that will prevent a bear from using the carcass. Grazing permits should assure such.

389

RESPONSE: This direction is presently incorporated into livestock grazing permits within Grizzly Bear Management Units. WG

COMMENTS: Add the following to Allotment Management Plans: management should maintain or improve edge, edge contrast, food & cover for wildlife; maintain key forage species in grass, forb & shrub communities on seasonal range; and develop an integrated range/wildlife condition class objective.

389

RESPONSE: The Revised Plan addresses these concerns in a variety of ways, such as: new upland forage utilization standards and guidelines; new riparian forage utilization standards and guidelines; aquatic influence zone management prescription; and management prescriptions 5.1.4, 5.3.5, and 5.4 which require maintaining large blocks of cover. MO

RANGE

COMMENTS: There is no analysis of existing or planned habitat conditions of small mammals, either those associated with range or with old growth.

1369

RESPONSE: The Revised Plan addresses these concerns in a variety of ways such as: Forestwide standards and guidelines for downed woody debris, old growth habitat, late successional forests, big sagebrush/grassland habitat, forage utilization, or snags. No small mammal populations were identified as threatened, endangered, proposed, or sensitive species, nor are they used as Management Indicator Species. MO

COMMENTS: There are no wildlife standards in range areas. This implies there are no wildlife values in these areas that can be impacted by domestic livestock. There are no standards for birds and small mammal habitat on grazing allotments. They are strongly influenced by amounts of litter thus profoundly impacted by grazing.

1369

RESPONSE: The forestwide standards and guidelines for wildlife apply to the grazing allotments, unless there is specific direction that overrides the wildlife standards and guidelines. The range utilization standards and guidelines apply to all species of animals which use the range forage. The aquatic influence zone management prescription benefits wildlife. Cross-country OHV travel is not allowed, which benefits wildlife. The forestwide standards and guidelines for big sagebrush/grassland habitats provide habitat for all species of wildlife which use this type of habitat. The consequences identified in Chapter IV of the FEIS project reductions in livestock use, commensurate with the management of other uses consistent with numerous management objectives (ecosystem, wildlife, riparian, and so forth). Livestock grazing is an outcome of proper management of the range and related resources. MO

COMMENTS: Nesting swan habitat cannot be managed without considering grazing; there are no grazing standards.

1369

RESPONSE: The aquatic influence zone management prescription applies to all trumpeter swan habitat. Also, forestwide standards and guidelines for trumpeter swans specifically addresses livestock grazing. MO

COMMENTS: There are no standards for wolf populations that may recover on the Targhee. There will be an unavoidable conflict between wolves and domestic livestock, the Plan indicates livestock will automatically take priority.

1369

RESPONSE: Forestwide standards and guidelines implement the requirements for the reintroduction of gray wolves as per the direction documented in the 1994 FEIS for the Reintroduction of Gray Wolves to Yellowstone National Park and Central Idaho, as described in Chapter III of the FEIS. WG

RANGE

COMMENTS: There should be no grazing in high quality grizzly bear food production areas.

1273b

RESPONSE: The Revised Plan will phase out domestic sheep grazing on an opportunity basis in all grizzly bear management units. Cattle grazing will be allowed, but must be done in accordance with specific forestwide standards and guidelines for grizzly bear habitat. MO

COMMENTS: To provide for big game security it also is necessary to direct livestock use away from big game security areas.

1273b

RESPONSE: We held several elk workshops with State Fish and Game agencies. Livestock use was not identified as an important consideration related to elk security for the Revised Plan. MO

COMMENTS: The Forest Service has only a preliminary understanding of what RNV is and so winter range for wildlife could not be adequately managed, i.e. grizzly controlled.

643

RESPONSE: This issue/concern is best handled within the framework of a site-specific project level or landscape level analysis where winter range and Properly Functioning Conditions (PFC) of winter range ecosystems are identified as key issues. The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the Forest or Ranger District levels. The Revised Plan is not intended to provide or analyze specific "how to's" of project implementation. WG

COMMENTS: AMPs should be required to include number of AUMs needed to sustain deer and elk on their summer and winter ranges, as well as total AUMs of forage available on each allotment.

1206

RESPONSE: Forestwide standards and guidelines for forage utilization include the forage used by wildlife. Additional analysis and management direction will be handled within the framework of a site-specific project level or landscape level analysis where big game forage, habitat conditions, livestock grazing are identified as key issues. MO

COMMENTS: Should not close vacant allotments in Situation 2 habitat on D2 and D5.

413, 693, 767

RESPONSE: The sheep allotments in Situation 2 habitat on the Island Park and Teton Basin Ranger Districts will have grazing phased out on an opportunity basis as described in the Revised Plan. This is being done to support the recovery goals for grizzly bear. MO

RANGE

COMMENTS: Disclose the role of the Animal Damage Control (ADC) and include analysis of the impacts ongoing ADC activities will have on native wildlife species.

1364

RESPONSE: As per the direction specified in the 1996 APHIS-ADC EA for Predator Damage Management in Southern Idaho; the USDA Animal and Plant Health Inspection Service-Animal Damage Control (APHIS-ADC) carries out predator control activities on the Forest. The APHIS-ADC EA incorporates the existing Targhee direction, which analyzed the impacts to wildlife. WG

COMMENTS: On page III-20, wildlife should be considered a basic natural resource and forage production should be considered before other consumptive uses.

389

RESPONSE: The Revised Plan provides suitable habitat for all species of wildlife as far as we can discern. Forage production and forage utilization standards and guidelines apply to wildlife and domestic livestock. MO

Monitoring/Implementation

COMMENTS: Estimate what portion of the grazing allotments will actually receive monitoring of upland forage utilization.

643, 1206

RESPONSE: Utilization monitoring will be conducted in key areas on grazing allotments using key species. Key areas are representative of the suitable rangeland and are areas that are sensitive to changes in livestock management. Data extracted from these areas will be indicative of the management of the areas represented. The number of key areas on any specific allotment depends on the complexity of the allotment. This issue/concern is best handled within the framework of a site-specific project level or landscape level analysis where monitoring of livestock grazing is identified as a key issue. WG

COMMENTS: Explain whether overall use in an allotment will be averaged or will any use exceeding the standard be subject to management intervention.

643

RESPONSE: Briefly, livestock grazing capacity is based on proper use of key species in key areas. Each pasture or unit within a grazing allotment is evaluated. Allotments usually have one or more units/pastures, but in some cases the entire allotment is the unit/pasture. This is usually the case on allotments with small acreages or where having more than one unit is not practical. Accurate actual use records for each unit/pasture on the allotment are essential. The number of use days a unit/pasture receives when proper use is reached on key areas under a specific stocking rate and management scheme is the figure verified as the carrying capacity. Capacity is calculated by a ratio of utilization achieved per use days by livestock per grazing unit or pasture.

RANGE

If utilization standards in an allotment are exceeded, the Forest Rangeland Management Specialist has several management options, including removal of livestock from the unit or pasture. WG

COMMENTS: Show a point in time when maximums will be measured or achieved.
FS-9

RESPONSE: Utilization monitoring can occur more than once a year, depending on the resource issues and values associated with the allotment. This issue/concern is best handled within the framework of a site-specific project level or landscape level analysis where monitoring of livestock grazing is identified as a key issue. WG

COMMENTS: Clearly ensure that the South Fork is managed in compliance with 1991 Snake River Activity/Operations Plan. Make provisions to that plan to reduce grazing/riparian habitat conflicts on FS - BLM land.

643, 766, 1194

RESPONSE: The Revised Plan adopts all direction identified in the Snake River Operations Plan, which was jointly developed between the BLM and the Forest Service. Within this Plan is specific direction for livestock management activities and forage utilization criteria. The Revised Plan will amend the utilization standards in the Snake River Operations Plan, as needed. WG

COMMENTS: The success or failure of the Targhee to achieve range goals & objectives will depend on monitoring. Therefore state honestly what level of funding & priority status will be and own up to the fact that it probably won't get done. Livestock operators must be made to take more responsibility for monitoring through Targhee educating and holding them, through permits, accountable.

644, 1206

RESPONSE: The Forest has a process in place to take action, as necessary, to achieve better management practices in uplands and riparian areas. Presently, there are numerous methods that determine utilization levels and compliance with the terms and conditions of grazing permits. Monitoring items for riparian and upland forage in Chapter V show that, where concerns (wildlife or watershed) are present more monitoring will be done. This monitoring item was elevated to Priority Group 1. Funding levels on the Forest are appropriated by Congress, and, depending on the allocation, may effect the level of intensity of monitoring in any given year.

A monitoring protocol will assist in outlining the monitoring procedures for both utilization and trampling criteria. Permittees will be trained by Forest personnel in implementing this protocol and are responsible for meeting the Standards and Guidelines of the Final Revised Plan. WG

COMMENTS: BMPs for grazing were developed by the SCS. These are only supposed to be used as planning guidelines, not monitoring.

432

RANGE

RESPONSE: The Targhee does not use grazing Better Management Practices developed by the Soil Conservation Service (now known as the Natural Resource Conservation Service). The Forest decided on the components of the standards and guidelines for livestock management and the components of the forestwide monitoring program. WG

COMMENTS: Supports that plans will be flexible enough to incorporate any new scientific information concerning sensitive species.

1446

RESPONSE: Your comment is acknowledged. The Revised Plan is adaptable to changing conditions. WG

DFPR/DEIS

COMMENTS: Clarify whether utilization levels are averaged forestwide or if any use exceeding the standard is subject to intervention. Place more emphasis on maintaining/improving resource value ratings and less on utilization levels to be consistent with ecological approach. Only 10% of allotments have allotment management plans and these must have higher priority. Increase in timber sold or livestock grazing is possible without plan amendment, so therefore an increase in old growth habitat should also be possible without amendment. Clarify meaning of double starred note on page V-10, it appears to be an excuse for Forest to not meet legal and ethical responsibilities.

282, 389, 413, 643

RESPONSE: Livestock grazing capacity is based on proper use of key species in key areas. Each pasture or unit within a grazing allotment is evaluated. Allotments have one or more units/pastures. In some cases the entire allotment is the unit/pasture. This is usually the case on allotments with small acreages or where having more than one unit is not practical. Accurate actual use records for each unit/pasture on the allotment are essential. The number of days a unit/pasture receives when proper use is reached on key areas under a specific stocking rate and management scheme is the figure verified as the carrying capacity. Capacity is calculated by a ratio of utilization achieved per use days by livestock per grazing unit or pasture. WG

In-place direction for the administration of grazing on allotments is designed to protect resources and ensure compliance with established standards and guidelines. Utilization studies and exclosures (used as "baseline" comparisons) are monitored across the Forest to determine if use levels are appropriate. As the Forest's work force decreases, the Forest will depend more on the permittees to help with monitoring, to move their livestock when needed and to maintain improvements and fences. The Revised Plan, allows for a cooperative monitoring strategy (including water quality monitoring) that will result in good quality Forest resources. RM

Resource Value Rating (RVR) is defined as the value of vegetation present on an ecological site for particular use or benefit. RVRs may be established for each plant community capable of being produced in an ecological site, including exotic or cultivated species. The Targhee does not have site-specific RVRs established for any rangeland vegetative community. This issue is best handled at the site-specific project level. Utilization

RANGE

studies are part of the short term monitoring programs. Implementing the utilization levels described in the LMP will achieve desired DVCs (ecological status) of its rangeland resources. WG

A analysis shows that currently 8.7% of the forested acres on the Targhee National Forest meet the definition of old growth as described in "Characteristics of Old Growth Forests in the Intermountain Region" (USDA Forest Service 1993). Forestwide standards and guides provide that a minimum of 10% of forested acres in each principle watershed should meet old growth characteristics, where such vegetation exists. The existence of more or less than this amount would not necessitate a Forest Plan amendment. However, a change in the guideline based on new information would require that the Plan be amended. EF

Regarding the Monitoring and Evaluation Plan on page V-10 of the Draft Revised Plan, the double-starred note at the end of the item for monitoring of Water Quality Limited Streams (WQLS): This note is not intended to provide an avenue of relief from this monitoring item. The note stresses the importance of conducting the monitoring shown in the item, which is to verify the water quality in listed streams. The Forest boosted the item to a #1 priority between the draft and final Revised Plan. EF

COMMENTS: Wording on pages III-20 thru III-22 should be changed to read that data will be collected, not should be collected.

389

RESPONSE: The word should is usually used in the context of a Guideline (G) and the word will is most often used with a Standard (S). Your comment was used to check the appropriate wording for standards and guidelines. WG

COMMENTS: Utilization rates in Table 1 page III-21 are consistently 5-10% higher than levels recommended in the scientific literature and should be modified.

389

RESPONSE: The utilization standards for upland vegetation in this table were modified. They were reduced 5% between draft and final. The revised utilization levels are considered to be maximum levels unless a written rationale is provided by an interdisciplinary team to deviate from these by increasing the maximum utilization standard. Utilization levels are dependent on site-specific circumstances such as kind of livestock, season of use, ecological status of the vegetation, management objectives for the area, stocking rate and intensity, and key plant species. Utilization monitoring can occur more than once a year, depending on the resource issues and values associated with the allotment.

This concern is best handled within the framework of a site-specific project or landscape level analysis where monitoring of livestock grazing and utilization levels are identified as key issues. Some references used in the development of these utilization criteria include: Desk Guide October 1993 Intermountain Region Ogden Utah, USDA Forest Service. Forage Utilization Standards and Guidelines for Pacific Northwest Region, USDA Forest Service, (A Process Paper by Dr. Leonard A. Volland, April 18, 1990);

RANGE

Managing Intermountain Rangelands-Sagebrush Grass Ranges, Intermountain Forest and Range Experiment Station, USDA Forest Service (Blaisdell, Murray, and McArthur), October, 1982; livestock Grazing Impacts on Rangeland Ecosystems, Holechek, July/August, 1980; application of New Theories on Plant Responses to Grazing, Rasmussen, Utah State University, 1995; Effects of Livestock Grazing at Proper Use on the Dixie National Forest, October 1995; and Winward, A.H., personal communication on September 24, 1996. WG

COMMENTS: Establish standards and guides for forage utilization standards, for upland and riparian areas.

FS-9

RESPONSE: The utilization Standards and Guidelines are located in Chapter III of the Revised Plan under Range. WG

COMMENTS: Section on grazing in an RNA should be reworded to say: "Prohibit livestock grazing, except when it is used to approximate a natural grazing regime for maintaining the native vegetation. No salting, water developments or other range improvements are allowed in RNAs." (s) (CROSS REFERENCE: RNA)

612

Standards & Guides for range are grossly inadequate.

643

RESPONSE: Both the FEIS and the Revised Plan were significantly modified to address these concerns. As changed, the grazing standards and guidelines in Management Prescription 2.2 in the Revised Plan are now consistent with policy identified in FSM 4063 and the Establishment Records for existing RNAs. WG

COMMENTS: Page III-49 last paragraph. The last sentence should read "Prior to the establishment of six breeding pairs, depreddating females and their pups will be captured and released at or near the site of capture, one time prior to October 1. If depreddations continue, or if six packs are present, females and their pups will be removed."

1446

RESPONSE: The last sentence was corrected to read as you have stated it in the Revised Plan. MO

COMMENTS: On page 84, the word "consider" should be changed to "use" to be consistent with the other areas.

1446

RESPONSE: Your comment was considered. The Forest decided that "consider" was still appropriate for management of this portion of the forest. WG

COMMENTS: Page III-122, Range, last paragraph. This item should be replaced with the statement shown under 3.A, on page III-21 to be consistent.

1446

RANGE

RESPONSE: This is not inconsistent because these are two separate issues. One page deals with dispersed recreation and the other deals with conifer regeneration. WG

COMMENTS: Page III-20, Objectives - Under objective 3, change the Roman numerals to ordinal numbers for consistent format.

1446

RESPONSE: Thank you for your observation. WG

COMMENTS: Reword the following guideline so that it does not suggest that projects can only be done if the FS provides 50% of the necessary funding... Range Standards and Guidelines 3.E on page III-22.

1446

RESPONSE: The Forest decided not to add your suggested changes. WG

COMMENTS: Summarize and/or elaborate on the outlined process in the National Programmatic Agreement, option 2 referenced on page III-22, Range Standards and guidelines 3.G.

1446

RESPONSE: Briefly, this agreement guides the Forest compliance with the National Historic Preservation Act (NHPA) for rangeland management activities. Option 2 provides criteria and standards for determining inventory areas and methods, the circumstances that prompt heritage resource evaluation, and standard protective management measures. This lengthy agreement (20 + pages) is located in the Forest files. The Revised Plan does not include specific direction found in manuals, handbooks and Memorandum of Understanding. WG

COMMENTS: Rewrite Range goal #2 as: "Domestic livestock grazing is permitted where it does not conflict with the maintenance of plant and litter cover, nutrient recycling, forage for wildlife species, seed production, or the restoration and maintenance of riparian communities.

1194

RESPONSE: Your comment was considered. The Forest decided on the components that made up the Range Goal #2 as the preferred goal statement. WG

COMMENTS: Statement on livestock conversions on page III-21 in 3C should only allow conversions if "they will serve" resource needs. (wildlife, soils, recreation).

341, 389

RESPONSE: Your comment was considered. The Forest decided to remain with the same components that made up the Standards and Guidelines. WG

COMMENTS: List criteria on page III-20 that will be used to determine desired vegetative conditions for site specific areas.

1446

RANGE

RESPONSE: This concern is best handled within the framework of a site-specific project level or landscape level analysis. Desired Vegetation Condition is a reliable indicator that can be measured with various monitoring criteria. DVC is modified in the glossary of the Revised Plan to read as follows: Desired Vegetation Condition (DVC): For both riparian areas and nonforested uplands is defined as: The specific future condition of rangeland resources, aquatic habitat, and water quality that meet management objectives identified in the Forest Plan, Allotment Management Plans, or other documents. Additional clarification can be found in the nonforested vegetation section of Chapter III of the EIS. WG

COMMENTS: The guideline for vegetation (DFPR III-8) should be a standard, and should require only native species for vegetation.

697

RESPONSE: Your comment was considered. The Forest decided this should remain a guideline. WG

COMMENTS: Prescription 5.3.5 on page III-137 says "Cattle grazing is allowed"; clarify whether it would be allowed only where map 29 does not indicate that grazing is to be phased out.

695

RESPONSE: The "Phase Out" only applies to sheep allotments in the grizzly bear BMUs and in critical bighorn sheep habitat. Cattle grazing will continue and is not scheduled to be "Phased Out" in grizzly bear BMUs or bighorn sheep habitat. WG

COMMENTS: The level of precision implied by last statement on (DFPR, Page V-29) is completely unrealistic.

489

RESPONSE: We agree that this level of precision (within 1%) is not realistic. This monitoring item in the Revised Plan is modified to read as follows: When the forestwide standards and guidelines for biodiversity (sagebrush/grassland habitats) are not within the specified ranges, an evaluation by a qualified cadre of individuals (Interdisciplinary Team) will evaluate the site(s) on a project level or landscape level basis to determine a course of action. WG

COMMENTS: Very much opposed to the forestwide standard (DFPR, Page III-22) that livestock conversion must be evaluated and approved by a cadre of IDT specialists. Missing from this group is someone concerned about the rancher. Specialists may be consulted, but approval must remain with the District Ranger & permittees.

267, 290, 310, 404

RANGE

RESPONSE: Your comment was considered. We intend to continue to use the Interdisciplinary Team specialists. Section 8 of Public Law 95-514 the Public Rangelands Improvement Act of 1978 allows for permittee involvement with their grazing allotments. WG

COMMENTS: Modify the 2nd paragraph at top of Page III-22 by: inserting after "conversion" something like, " and restoration of range deteriorated by previous use" and; adding to the second sentence, "and must be completed to the satisfaction of the District Ranger before permission to convert goes into effect."

341

RESPONSE: Your suggestion was considered but not adopted. WG

COMMENTS: Page II-5, Alternative 2, first paragraph: says grazing will continue at current levels but Tables on pages S-11 and IV-60 both show reductions.

413

RESPONSE: Page II-5 was not correct. The information on S-11 and IV-60 were correct. WG

COMMENTS: The standard as stated for this issue (DFPR III-100, watering facilities) is weakened to a guideline by words "appropriate mitigation measures."

697

RESPONSE: Your comment was considered but not adopted. WG

COMMENTS: The monitoring indicator (page V-29) of number of allotments with or without rotation grazing seems to tie the hands of local manager by demanding rest or rotational grazing systems.

432

RESPONSE: Between draft and final this monitoring item was dropped. WG

COMMENTS: Monitor cultural resource sites on grazing allotments consistent with the national programmatic agreement. These sites must be identified and a monitoring schedule provided to be able to assess selected alternative.

1455

RESPONSE: Under this agreement, the Targhee has a monitoring plan in place. This monitoring plan was added to the Revised Plan as a standard. CGW

COMMENTS: Standard restricting conversion of cattle to sheep should also apply to grizzly bear habitat.

643

RESPONSE: Your comment was considered but not adopted. WG

RANGE

COMMENTS: Issue of grazing, as presented in the plan, is vague and arbitrary. There seems to be no agreement on range as an issue. Try cooperating more with other agencies like the USDA Sheep Experiment Station.

612d, 630, 1333, 1398

RESPONSE: Grazing is not one of the seven key issues that drove the selection of the preferred alternative. The Forest reached agreement on many issues that either affected grazing or were affected by grazing. The Targhee cooperates with the US Sheep Experiment Station; they hold an active grazing permit on the Forest. WG

COMMENTS: Vegetation (Page III-8): The Forest Plan failed to give direction for sensitive or threatened plant species on the forest. The Forest Service Manual Section 2670.45 (see section on forest carnivores for language).

The DFP failed to comply with the direction given to Forest Supervisor by the FSM. The DFPR needs to implement this by explicitly stating this direction in the S&Gs for vegetation the protection of sensitive plant species and develop a monitoring plan for known populations of species with limited distribution.

In another related vegetation issue, there should be standards in the Forest Plan for special forest products. At this time there are only two objectives. The plan should include limits of harvest to protect fungi species and other natural resources that could potentially be negatively impacted by commercial or personal exploitation. This could be included in the first objective by stating that standards and guidelines will be developed that amend that Forest Plan after each special forest product's needs are evaluated.

1273b

RESPONSE: Your comments were considered, but not adopted because there is adequate direction in existing Forest Service Manuals. It is not appropriate to restate manual direction or policy in the Revised Plan. However, the Forest did develop additional goal statements and standards for the management of Threatened, Endangered and Sensitive plants. WG

COMMENTS: DFPR fails to determine livestock grazing suitability as required by NFMA.

1206

RESPONSE: Chapter III in the FEIS is modified to include a section on grazing suitability. Except for nine allotments covering 1,813 acres, livestock capability is determined for all allotments open to grazing. WG

COMMENTS: Range goals refer to DVC but have no identification of those conditions.

1206

RESPONSE: This concern is best handled within the framework of a site-specific project level or landscape level analysis. Desired Vegetation Condition is a reliable indicator that can be measured with various monitoring criteria. DVC is redefined in the glossary of the Revised Plan as follows:

RANGE

Desired Vegetation Condition (DVC): For both riparian areas and nonforested uplands is defined as--The specific future condition of rangeland resources, aquatic habitat, and water quality that meet management objectives as identified in the Forest Plan, Allotment Management Plans, or other documents. Additional clarification can be found in the nonforested vegetation section of Chapter III of the EIS. WG

COMMENTS: Range Objective 1 does not define mid and late seral stages for riparian areas.

1206

RESPONSE: This concern is best handled within the framework of a site-specific project or landscape level analysis where identifying ecological status of sites are identified as key issues. The ecological status of a site is measured against the Potential Natural Community (PNC) for a specific area. PNC is the biotic community that becomes established on an ecological site if all successional sequences were completed without interference by humans under present environmental conditions. Natural disturbances such as drought, flood, wildfire, grazing by native fauna, insects, and disease, are inherent in its development. The PNC may include acclimatized or naturalized non-native species. Early seral ecological status is 0-39% of PNC; mid seral ranges from 40%-59% of PNC, late seral ranges from 60%-85% of PNC and PNC is considered to be greater than 86% of PNC. WG

COMMENTS: AMP standards and guidelines contain no direction to complete range inventory which AMS said was necessary to develop adequate management plans.

1206

RESPONSE: Times have significantly changed since the development of the Analysis of Management Situation. Budgets do not facilitate gathering this type of data, nor are updated range analysis needed to develop adequate Allotment Management Plans (AMP). Using other available information such as utilization and trend studies, adequate AMPs can be implemented to achieve the goals and objectives of site-specific landscape or allotment analysis.

Two important tasks are needed to implement a successful AMP. The first is administration by the Forest Service of the grazing permit and the second is monitoring. This monitoring item was elevated to a Forest Priority Group 1. Funding levels on the Forest are appropriated by Congress and, depending on the allocation, may effect the level of intensity for monitoring each year. WG

COMMENTS: The Targhee is repeating a pattern of denial with regard to livestock grazing. It is essential that environmental impacts of grazing have a central place in planning/decision process. DFPR and DEIS seriously deficient in this area.

1365

RESPONSE: Grazing is not one of the seven key issues that drove the selection of the preferred alternative. The Forest reached agreement on many issues that either affected grazing or was affected by grazing. The FEIS and Revised Plan accurately reflect the grazing situation on the forest. An actual

RANGE

adjustment (up or down) in AUMs will only occur with a site-specific analysis for each active allotment open to grazing. WG

COMMENTS: Page III-21 AMP; guidelines 1-3 should be standards.
1365

RESPONSE: Your comment was considered, but not adopted. WG

COMMENTS: AMP monitoring (Page V-29) should be FP Group 2.
1365

RESPONSE: Your comment was considered, but not adopted. WG

COMMENTS: The Forest Service has designated as a standard that all administrative sites will comply with forest wide standards and guidelines for livestock pastures. However, no other livestock pastures are required to meet this compliance. Forest Service should clarify this discrepancy, and justify management of select livestock pastures by guidelines rather than standards.
389

RESPONSE: Your comment was considered, but not adopted. WG

COMMENTS: Range goal #2 states that domestic livestock grazing will be managed "to promote the desired conditions of various resources..." The plan should be more specific as to how this will be accomplished i.e. in a measurable way. Stating that "grazing systems will be implemented on all grazing allotments by 2007" does not provide sufficient detail to evaluate this proposal.
643

RESPONSE: This goal will be met by identifying specific issues/concerns within the framework of a site-specific project or landscape level analysis. The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the Forest or Ranger District levels. The Revised Plan is not intended to provide or analyze specific "how to's" of project implementation. WG

COMMENTS: Recommend range goal #2 be changed to the following: Domestic livestock grazing is permitted where it does not conflict with the maintenance of plant and litter cover, nutrient recycling, forage for wildlife species, seed production, and the restoration and maintenance of riparian communities. The accompanying objectives should also be changes to read as follows: By 2007, improve all upland acres currently reported as being in unsatisfactory ecological condition to satisfactory condition; By 2007, grazing systems will be implemented on all grazing allotments to meet the range goal for uplands noted above; and by 2007, improve the ecological status of all riparian habitat presently in unsatisfactory ecological condition to satisfactory ecological condition.
643

RESPONSE: Your comments were considered, but not adopted. WG

RANGE

COMMENTS: A standard should be added to prohibit season-long grazing unless the land in question meets the goals of the plan and site-specific studies show that season-long grazing will not be detrimental to the health of the land.

1206

RESPONSE: Your comment was considered, but not adopted. WG

COMMENTS: There is a contradiction on EIS, pages III-35, 36: at the bottom of page III-35, concern is expressed whereby upland non-forested areas are trending toward a predominance of mid and late seral stage. But in the 2nd paragraph on page 36, "satisfactory ecological condition is defined as being in mid-seral stage or higher."

489

RESPONSE: The FEIS was modified to correct these contradictions. WG

Vegetation

COMMENTS: Does not believe that forest-wide utilization standards and guidelines are adequate and will meet the DFCs. Recommend either changing proposed utilization to levels supported by scientific literature, or providing site-specific evidence that the proposed levels will meet water quality, watershed, fisheries and sagebrush-grassland ecosystem objectives.

389, 643, 766

RESPONSE: The Forest changed the upland Forage utilization standards between draft and final. The proposed standards were reduced 5%. Utilization standards and other standards and guidelines (wildlife, watershed, standards and guidelines for example) will achieve desired results. The utilization standards and guidelines provide for a moderate rate of recovery of degraded riparian and aquatic systems together with a moderately high level of fisheries habitat quality. As a result of this, the uplands are likely to respond as well. Scientific literature supports this prediction. WG

COMMENTS: Application of generic utilization levels to all shrubs is inappropriate.

389

RESPONSE: This concern is best handled within the framework of a site-specific project or landscape level analysis where shrub utilization is identified as a key issue. Until there is site-specific analysis, the Forestwide utilization standards and guidelines will apply and will achieve desired results. WG

COMMENTS: Recommend more emphasis on resource value ratings for rangelands and less on utilization levels. RVRs are more of an ecological approach. Establish goals for RVRs greater than 50 (i.e., good to excellent).

389

RANGE

RESPONSE: Resource Value Rating (RVR) is defined as the value of vegetation present on an ecological site for particular use or benefit. RVRs may be established for each plant community capable of being produced in an ecological site, including exotic or cultivated species. The Targhee does not have site-specific RVRs established for any rangeland vegetative community. The ecological status of a site is measured against the Potential Natural Community (PNC) for a specific site.

PNC is the biotic community that would become established on an ecological site if all successional sequences were completed without interference PNC humans under present environmental conditions. Natural disturbances such as drought, flood, wildfire, grazing by native fauna, insects, and disease, are inherent in its development. The PNC may include acclimatized or naturalized non-native species. Early seral ecological status is 0-39% of PNC; mid seral ranges from 40%-59% of PNC; late seral ranges from 60%-85% of PNC and PNC is considered to be greater than 86% of PNC. Determining ecological status of sites is part of the long-term trend monitoring program. Utilization studies are part of the short-term monitoring programs. Implementing the utilization levels described in the Revised Plan will achieve desired DVC's for rangeland resources.

Establishing goals/objectives for RVR's greater than 50 was considered, but not adopted because if RVR's greater than 50 were established for all vegetation communities across the forest, then Desired Vegetative Conditions might not be met. DVC is redefined in the glossary of the Revised Plan as follows: Desired Vegetation Condition (DVC): For both riparian areas and nonforested uplands is defined as -- The specific future condition of rangeland resources, aquatic habitat, and water quality that meet management objectives as identified in the Forest Plan, Allotment Management Plans, or other documents. Additional clarification can be found in the nonforested section of Chapter III of the EIS. WG

COMMENTS: Further reductions in grazing does not produce a long term forest health and development. "No use" does not automatically translate to "wise use."

1448b

RESPONSE: Your comment is acknowledged. A substantial livestock grazing program remains in effect under the Revised Plan. It is consistent with numerous management objectives (ecosystem, wildlife, riparian, and so forth). Livestock grazing is an outcome of proper management of the range and related resources. The projected levels of livestock grazing allow us to improve a variety of resources and values. An actual adjustment (up or down) in AUMs will only occur with a site-specific analysis for each active allotment open to grazing. WG

COMMENTS: Livestock grazing causes changes in vegetative composition. This is demonstrated on page III-19 where it is noted that grazing has shifted species composition on 32% of riparian areas.

643

RESPONSE: Your comment is acknowledged. WG

RANGE

COMMENTS: FRES level D should not be considered as part of the management goal because it is not consistent with the desired future conditions.

1446

RESPONSE: As defined, FRES level D is consistent with multiple use objectives. This concern is best handled within the framework of a site specific project or landscape level analysis. WG

COMMENTS: Reduce the standard for retaining 50% of the fine organic matter in activity areas. 65% ground cover is high for some natural rangelands. Tall forb plant communities in the Centennials does not meet this requirement. Most sedimentation problems do not come from the uplands.

432

RESPONSE: The "indicator" section (page V-9) also states "an equivalent percentage if the site cannot naturally attain the minimum percentage mentioned above." In other words, if a site cannot attain the 65% ground cover naturally, than a different percentage requirement would be identified based on what it can naturally attain. DM

COMMENTS: Conflicts between livestock grazing and habitat conservation need to be identified for all riparian, aquatic and wetland habitat. Method for conflict resolution should be developed.

389

RESPONSE: These concerns are best handled within the framework of a site-specific project or landscape level analysis where conflict with livestock grazing is identified as a key issue. WG

COMMENTS: Define "forestwide" forage utilization standards in the Plan. List prescription standards for high value wildlife habitats and/or areas susceptible to domestic livestock grazing.

389

RESPONSE: The forestwide Utilization Standards and Guidelines apply to most areas of the forest and are used in conjunction with additional standards and guidelines included within each management prescription. The forestwide range standards and guidelines, in Chapter III of the Revised Plan, were modified to include more direction for other resources such as wildlife and fisheries. Site-specific utilization standards are best handled within the framework of a site-specific project or landscape level analysis where utilization is identified as a key issue. WG

COMMENTS: Research and relevant scientific literature has shown cattle and sheep are a significant cause of increased tree distribution and density in many western forests, and can reduce fire frequencies thus changing savannah to forest.

1365

RESPONSE: Your comment is acknowledged. WG

RANGE

COMMENTS: The EIS must also address grazing as a cumulative effect in timber sales and must specifically define how grazing is to be considered in the context of ecosystem management.

1365

RESPONSE: This concern is best handled within the framework of a site-specific project or landscape level analysis. The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the Forest or Ranger District levels. The Revised Plan is not intended to provide or analyze specific "how to's" of project implementation. WG

COMMENTS: The emphasis being placed on the needs of indicator species and patch size in the new Plan and not on the health of the range resource will eventually decrease the rangeland available to the point that the rancher will not be able to afford to use the land.

432

RESPONSE: A substantial livestock grazing program remains in effect under the Revised Plan. It is consistent with numerous management objectives (ecosystem, wildlife, riparian, and so forth). Livestock grazing is an outcome of proper management of the range and related resources. The projected levels of livestock grazing will allow us to maintain cultural heritage and most local livelihoods while at the same time improve a variety of resources and values. WG

COMMENTS: Review cumulative effects section for upland forested and upland nonforested ecosystems in that it seems to predict forest changes if fire is suppressed rather than being allowed to function in a natural role.

695

RESPONSE: This is best handled within the framework of individual fire management plans that will be developed for various areas of the forest (refer to the Goals and Objectives for Fire in the Revised Plan - Chapter III). How a fire might be handled is dependent on a number of site-specific variables and is best analyzed at a finer scale versus forestwide. This concern is best handled within the framework of a site-specific level or landscape level analysis where fire management and cumulative effects, are identified as key issues. WG

COMMENTS: Planning documents only hint at how the forest would use livestock grazing as a means of insuring sustainable conditions through vegetation manipulation. There should be more detail.

489

RESPONSE: This concern is best handled within the framework of a site-specific project level or landscape level analysis. The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the Forest or Ranger District levels. The Revised Plan is not intended to provide or analyze specific "how to's" of project implementation. WG

RANGE

COMMENTS: There are no goals identified for what vegetation will be like in 10 years.

697

RESPONSE: Forestwide Goals and Objectives for vegetation are identified in the Revised Plan. The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the Forest or Ranger District levels. DVC is a reliable indicator that can be measured with various monitoring criteria. DVC is redefined in the glossary of the Revised Plan as follows: Desired Vegetation Condition (DVC): For both riparian areas and nonforested uplands is defined as--The specific future condition of rangeland resources, aquatic habitat, and water quality that meet management objectives as identified in the Forest Plan, Allotment Management Plans, or other documents. Additional clarification can be found in the nonforested vegetation section of Chapter III of the EIS. WG

COMMENTS: Use the grazing resource or it will deteriorate and be replaced by shrub and timber encroachment. Grazing sheep and cattle offer time control necessary to sustain range resources, can be useful tool in fire suppression and can increase/enhance wildlife forage.

333, 432, 691, 1239

RESPONSE: Your comments are acknowledged. WG

COMMENTS: Unclear why drafts do not say why only 26,400 acres of upland range will be improved in 10 years. Disclose what percentage of total degraded range this represents.

1369

RESPONSE: Presently; 89,221 acres of "uplands" do not meet Desired Vegetation Conditions (DVC). The 26,400 acres represents 29.6% of the total upland acres not meeting DVC. Livestock grazing is not the sole contributor to declining rangeland conditions. Fire, invasion of noxious weeds from a variety of sources, past livestock grazing practices, road construction, and recreation use are a few examples of causes contributing to the decline of riparian and rangeland health. As described in Process Paper J - Logic Used to Estimate Effects of Livestock Grazing on Riparian and Upland Vegetation, rangeland and riparian health can be improved by livestock grazing by implementing the Standards and Guidelines in the Final Revised Plan. WG

COMMENTS: The increase shown in nonriparian and riparian acres meeting DVC comes from the allotments with sheep removed or where cattle reductions are made.

432

RESPONSE: You are not correct in your assumption. As described in Process Paper J - Logic Used to Estimate Effects of Livestock Grazing on Riparian and Upland Vegetation, rangeland and riparian health can be improved by implementing the Standards and Guidelines in the Final Revised Plan. WG

- - -
RANGE

COMMENTS: Trampling is a poor measurement: it will not work except to move the grazing tool off the resource and additional monitoring costs.

432

RESPONSE: The trampling monitoring criteria are not intended to remove grazing from the Targhee. The intent of this monitoring item in Chapter V is to help in the development of this parameter so that it is reliable and specific to the Targhee. The Forest changed both the Streambank Trampling and Riparian Forage Utilization monitoring items to a Forest Priority 1. A monitoring protocol will assist in outlining the monitoring procedures for both utilization and trampling criteria. Permittees will be trained by Forest personnel in implementing this protocol and will be held responsible for meeting the Revised Plan Standards and Guidelines. WG

COMMENTS: Clarify what a "naturalized" species is.

1446

RESPONSE: A naturalized species is any species of flora or fauna that occurs in an area that is not originally native to the area. It is an introduced or alien species that is now permanently established and reproducing spontaneously (without human fostering). WG

COMMENTS: Please quantify the "reasonable time" for the specific project or activity as so stated on the section on pages III-73, 76, 80, 84, 103, and 105.

1446

RESPONSE: A "reasonable length of time" is tied to a specific project. A "one size fits all" approach is not appropriate for quantifying "reasonable time". With this Revised Plan a reasonable length of time could range from one to ten years after the Record of Decision is signed depending on each circumstance. WG

Sheep Management Issue

COMMENTS: Phase out sheep allotments as proposed. The FEIS needs a schedule for closure.

643, 1273b, 1277, 1393

RESPONSE: Sheep allotments located within the grizzly bear recovery area are identified in Appendix III of the Revised Plan for Process Paper L - Sheep Allotments affected by grizzly bear, bighorn sheep and watershed conditions). The Process Paper, and Chapter IV of the FEIS show some sheep allotments will be immediately closed and others will be phased out on an opportunity basis. WG

COMMENTS: Sheep can be a very ecologically sound way to combat noxious weeds.

432

RANGE

RESPONSE: Sheep grazing is a useful tool for controlling some patches of noxious weeds. The Targhee practices integrated pest management to control noxious weeds including biological control methods such as livestock grazing. WG

COMMENTS: It is unimaginable that forest management supports the removal of sheep from the Centennial Mountains.

432

RESPONSE: Sheep allotments that are located within the grizzly bear recovery area are identified for removal (see Appendix III of the Revised Plan for Process Paper L - Sheep Allotments affected by grizzly bear, bighorn sheep and watershed conditions). The sheep allotments in the Centennial Mountains will be phased-out on an "opportunity basis," not immediately closed. Opportunity basis is defined in the glossary of the Revised Plan. WG

COMMENTS: Economic loss to local economies from phasing out sheep grazing is too great. Object to phasing out sheep grazing to protect the grizzly bear.

F-F(6), 413, 1180, 1354, 1363, 1398

RESPONSE: A substantial livestock grazing program remains in effect in the Revised Plan and it is consistent with numerous management objectives (ecosystem, wildlife, riparian, and so forth). Livestock grazing is an outcome of proper management of range and related resources. The projected levels of livestock grazing allow the Forest to maintain cultural/heritage values and local livelihoods, while improving a variety of resources and values at the same time. WG

COMMENTS: Does not agree that livestock conversions must be evaluated and approved by an Interdisciplinary Team (IDT).

F-F(6)

RESPONSE: Using an Interdisciplinary Team to evaluate livestock conversions, in conjunction with range permittees, provides the most thorough and complete evaluation of the pros and cons on a case-by-case basis. Conversions are not approved by the ID Team but by the appropriate line officer with ID Team input. WG

Sheep General

COMMENTS: Sheep entry/exit in Moose Creek conflicts with big game winter range.

293

RESPONSE: This concern is best handled within the framework of a site-specific project (AMP for example), or landscape level analysis where big game winter range and livestock grazing are of paramount concern. WG

COMMENTS: Page III-22 should read, "Do not convert from a cattle allotment to a sheep allotment within bighorn sheep habitat or in a grizzly bear BMU."

1446

RANGE

RESPONSE: All sheep allotments in grizzly bear BMUs and bighorn sheep habitat are scheduled to be phased out on an opportunity basis in the Teton Range subsection and the Island Park portion of the Centennial Mountain subsections.
WG

COMMENTS: Sheep grazing can have a considerable impact on mountain goat summer range; impacts were not in drafts. (CROSS REFERENCE: Wildlife, Mountain Goats)
389, 766

RESPONSE: The Forest considered your comment and after summary analysis, determined there is no conflict between domestic sheep and mountain goats on summer range on the Targhee; therefore, no additional analysis in the DFPR or DEIS was needed. Impacts can occur on winter range and those changes are included in the Revised Plan. WG

Bighorn Sheep

(CROSS REFERENCE: Wildlife, Bighorn Sheep)

COMMENTS: Keep domestic sheep out of big horn sheep habitat, or have a buffer zone of at least three miles. (CROSS REFERENCE: Wildlife, bighorn sheep)
181, 212, 274, 293, 389, 1247, 1277

RESPONSE: The Forest has already implemented protection measures to reduce the transmission of disease between domestic sheep and bighorn sheep. In addition, the Revised Plan provides some new management direction. What the Forest has already done: on the west slope of the Tetons, 45,700 acres of bighorn sheep habitat do not have domestic sheep grazing at this time. These 45,700 acres include all areas currently used by bighorn sheep. Domestic sheep are not grazed on the west slopes during the seasons when "nose-to-nose" contact with bighorn sheep is likely to occur. Therefore, the potential for disease transfer is low, there is no forage competition, and there is no displacement. In the Lionhead area, there is no domestic sheep grazing. Therefore, the potential for disease transfer is zero, there is no forage competition, and there is no displacement.

New management direction contained in the Revised Plan will phase out domestic sheep grazing on the west slope of the Tetons on an opportunity basis; phase out winter domestic sheep grazing in the Medicine Lodge Subsection; evaluate additional opportunities for adjusting domestic sheep grazing while the phase-out program is in progress; and allow no conversions from cattle allotments to domestic sheep allotments within bighorn sheep habitat. MO

COMMENTS: Recent research indicates that a pneumonia problem experienced by bighorns can not be passed on by domestic sheep. Therefore, cannot have standard (Page III-21).
432, 1188

RESPONSE: Pneumonia can be transferred, therefore, your comment was considered, but not adopted. WG/MO

RANGE

COMMENTS: Implement Teton Range Bighorn Sheep Working Group's Strategic Plan.
690, 1395

RESPONSE: Portions of the working group's Plan were adopted. The Forest added new management direction in the Revised Plan and a new section on bighorn sheep in the FEIS. Process Paper D also contains new bighorn sheep information. MO

RECREATION

Environmental Impacts Associated with Camping

COMMENTS: Protect vegetation in and around campgrounds, especially dispersed campsites, by developing dispersed camping standards and goals; signing; developing guidelines for edging, maintenance and graveling of vehicle use areas; closing campgrounds; and enforcing these conditions even on Sunday. Measure soil loss at campsites by a permanent calibrated stake because Frissell Condition Class method is inadequate.

697, 1312, 1365

RESPONSE: Site surveys conducted during the summer of 1996 indicate that the dispersed campsite conditions are not as poor as suggested in the DEIS. The 4.3 Dispersed Camping Management Prescription and Standards and Guidelines established in the Revised Plan along with the monitoring requirements will adequately prevent significant adverse affects. These guidelines include a new Dispersed Camping Protocol (Process Paper X) for monitoring dispersed campsites. The Frissell method will be used only in wilderness and roadless areas. The 15% detrimentally disturbed soil standard will be used at all other dispersed campsites. AS

COMMENTS: Define a standard of no more than x number of campsites per trail mile or lake basin and define acceptable location (e.g. 50-100 ft. from streams, 100-200 ft. from lakeshores). (CROSS REFERENCE: Riparian)

1312

RESPONSE: These standards were developed for campsite and trail user density in the Jedediah Smith Wilderness and are described in the Process Paper. The Limits of Acceptable Change (LAC) process will be used to monitor resource changes. The dispersed campsite prescription (4.3) also contains direction for improved management of these sites. AS

COMMENTS: Restrict motorized access to dispersed campsites and to picnic sites to within 300 feet of an existing road or trail; add language to Dispersed Recreation Use standards & guidelines so that would-be OHV violators do not exploit this access. (CROSS REFERENCE: Riparian)

643

RESPONSE: The Forest changed the wording for the dispersed camping standard regarding access within 300 feet of a road, to clarify that the intent is not for any activity but for parking and dispersed camping. The new wording is "Unless otherwise posted, motorized access is allowed for parking, and dispersed camping, within 300 feet of roads and trails which are open for motorized use." This wording would not allow general OHV use of the 300 foot area. AS

Economic Impact of Recreation to the Economy

COMMENTS: Recognize the importance of recreation to the local and state economy in general tourism. Road and trail closures and additional wilderness will adversely impact tourism. Explain how reducing motorized OHV recreation will continue to attract visitors for the same number of days and for the same job compensation. Support the shift from a timber-based to a recreation-based

RECREATION

economy. Object to the reduced employee compensation from recreation-based jobs. Refigure the compensation table concerning jobs in the timber sector because it is inaccurate to show employee compensation from recreation remaining at existing levels.

98, 168, 215, 226, 228, 292, 358, 392, 413, 621, 643, 702, 1242, 1322, 1335, 1345, 1364

Analyze the economic impact of decisions since 1985 and the future economic impact of each alternative in order to adequately address the issue of the local economy.

393

RESPONSE: The FEIS analysis indicates that the total recreation use would not change much between alternatives and that a shift towards more non-motorized opportunities in some areas may have only a slight effect of slowing tourism and road development. This analysis supports the economic conclusion of little change in the economy based on recreation opportunities.

Fortunately the Forest enjoys a surplus of recreational opportunities relative to existing and predicted use levels. The most noteworthy exception to this is motorized use of trails. The Forest expects trail usage to reach capacity under the preferred alternative due to increases in use and reductions in the trails open to motorized use. When that happens, any one of a number of different combinations may occur: usage could level off; people may tolerate increased crowding and usage would continue to rise; or usage could reduce to a new level. As population pressures continue to grow, people may become accustomed to higher degrees of crowding; find ways to recreate on less-crowded dates; find other opportunities for motorized use off-forest; or take up a different form of recreation.

Although rapidly rising and well represented, motorized trail use is a small part of the total Forest recreation picture. Even substantial changes in this category of recreation is insignificant at the Forestwide level of consideration. It is possible that nonmotorized forms of recreation may increase enough to compensate for possible reductions in motorized use.

The Forest agrees that recreation-related employee compensation is lower paying than timber-related employee compensation. The table shows employee compensation associated with recreation increasing from existing levels, not staying the same. DP/AS

COMMENTS: Manage the Targhee to provide tourists with a positive image as they make their way to Yellowstone.

226

RESPONSE: This is the intent of the Visual Management Prescription 5.2.1 along Highway 20 north of Ashton. AS

COMMENTS: Oppose limiting recreation because if people are limited to fewer areas in which to recreate they will over populate those areas still available, get frustrated and leave, taking tourist dollars with them.

413

RESPONSE: Recreation is like any other resource use; there are physical, biological, and social limits as to how much use can occur in an area without conflicts or adverse consequences to other resources or activities. The EIS

RECREATION

indicates the potential for displacement of some users and the possibility of loss of some recreation opportunities. AS

COMMENTS: Recognize the importance of the tourism-recreation industry in Idaho and the importance of national Forest land to the state's economy.
1345

RESPONSE: We added information to Chapter III of the EIS under the heading "Wilderness and Recreation Resources" to indicate the significant effect of the Targhee resources on tourism in Idaho. AS

COMMENTS: Oppose motorized game retrieval because ORVs will spoil the roadless areas that I wrote about in my commercially-successful hiking book and I will no longer be able to make a living from my book.
392

RESPONSE: The Forest dropped game retrieval from the Revised Plan so there will be no effect as suggested here. AS

Provide Recreational Opportunities

COMMENTS: The Forest fulfills our need for recreation. Prefer Alternatives 2 and 3M because of the recreational opportunities provided in each. Oppose Alternative 3M because unlimited recreation is restricted; Alternative 3M gives no consideration to handicapped access to recreation.
F-M, 97, 98, 135, 216, 272, 288, 289, 291, 306, 313, 324, 328, 528,
529, 608, 614, 623, 631, 634, 638, 642, 713, 737, 1371, 1376, 1449

RESPONSE: Recreation is one of the multiple uses provided by national forests and will remain an important resource on the Targhee. No alternatives have unlimited recreation. Direction for accessible facilities is provided in Appendix A of the Revised Plan. AM/AS

COMMENTS: Quantify planned increases in Persons-At-One-Time (PAOT) with site development.
FS-11

RESPONSE: Increases will be done at the project level of planning. As indicated in the FEIS, increases in PAOTs will be minor and will occur from "little, new site development." AS

Restrict Recreational Opportunities

COMMENTS: Want recreation growth controlled and natural resources prioritized because Forest managers are obligated to protect the resource and because studies show human disturbances are primarily responsible for unhealthy forests.
643, 1365

RESPONSE: Humans are part of ecosystems. The Revised Plan meets the multiple use mandate by balancing natural resource needs with human needs, particularly in the area of recreation. Recreation use results in small areas of

RECREATION

disturbance to soils and vegetation but generally there are no large-scale effects. The standards, guidelines, and monitoring plans are adequate to meet recreation growth and protect the resources. AM/AS

Hunting

COMMENTS: Consumptive recreation such as hunting causes negative impacts on wildlife populations by altering feeding patterns, population structure, and behavior and by causing mortality.

1365

RESPONSE: While it is true that hunting does disturb wildlife, hunting seasons and methods are controlled by State agencies. The prescriptions, standards and guidelines in the Revised Plan will minimize the negative impacts. AS

Fishing

COMMENTS: Address and preserve public fishing access.

1276

Fishing and other consumptive forms of recreation can have a negative impact on eagles, waterfowl and other birds.

1365

RESPONSE: Public fishing access will be maintained. While it is true that fishing and other recreation does disturb wildlife, the prescriptions and standards and guidelines in the Revised Plan will minimize the negative impacts. AS

Caving

COMMENTS: Do not mark caves or encourage this type of recreation because it causes a decline in the number of sensitive wildlife populations.

1365

RESPONSE: Cave management direction is under the forestwide standards and guidelines section entitled Physical Elements/Caves. AS

Climbing

COMMENTS: Rock climbing negatively impacts critical nesting times for birds.

1365

RESPONSE: The Forest created a forestwide Standard "Restrict climbing and other human disturbances when necessary to avoid adverse impacts at known falcon nest sites." AS

RECREATION

Boating Environmental Impacts

COMMENTS: Restrict motorized boating access to protect resources. Boating causes harmful impacts to birds, chemical pollutions and plant mortality. Monitor and enforce boat launching regulations to prevent bank disturbances.
209, 650, 697, 1365

RESPONSE: The Aquatic Influence Zone prescription direction regarding 15% soil displacement provides a control for when restrictions on boat launching are needed to prevent disturbance. Motorized restrictions are determined in individual river management plans done at the project level of planning. Levels of boating use are determined through monitoring and individual river planning. AS

Mountain Biking

COMMENTS: Do not take away the enjoyable activity of mountain biking on trails and roads in the backcountry because mountain bikers act responsibly and do not harm wildlife or the environment.
1385, 1449

RESPONSE: The Revised Plan does not take away most mountain biking opportunities. It provides direction to improve trails for such uses. AS

COMMENTS: Consider impacts of mountain bike use on the environment; explain how the growth rate of 5-10% was determined.
1365

RESPONSE: Impacts of mountain bike use are considered in the summer access analysis. The growth rate is determined from observations, local bike sales and national use trends. AS

COMMENTS: Discourage mountain biking and other mechanized travel from core wildlife areas.
1446

RESPONSE: Restrictions are placed on mechanized travel in areas such as winter range during the fall, winter, and spring impact periods for wildlife. They are not restricted from grizzly bear core areas as bike use is considered equivalent to hiking in terms of potential impacts. AS

Incompatible Use ~ Summer

COMMENTS: Separate users in order to enhance recreation experience and prevent user conflicts. Focus on separating motorized from non-motorized activities: ORVs from hikers, horseback riding concessionaires from cabin sites, and ORVs and logging from fishing and hunting areas. Place campgrounds and ORV trails in already developed areas; create more trails; enforce access restrictions and separate recreationists. Redesign areas that are designated for use by both motorized and non-motorized recreational users because of safety hazards, conflicts, noise, and crowding.
618, 632, 651, 1345, 1365, 1371, 1457

RECREATION

RESPONSE: The Revised Plan initiates actions to separate motorized and non-motorized uses in more areas than the current plan. Motorized use is restricted to fewer miles of roads and trails and cross-country OHV use is restricted to 7% of the Forest. The Revised Plan provides a goal to redesign trails for motorized and non-motorized uses so that they will be able to withstand use with relatively minor maintenance. AS

COMMENTS: Place all campgrounds and ORV raceways near already developed areas.

1371

RESPONSE: We are not planning any new campgrounds or development of any ORV "raceways". AS

Environmental Impacts from Recreation

COMMENTS: Monitor and allocate funds for recreation impacts on the Forest ecosystem. Step up monitoring of dispersed campsites, trails, shore banks, wildlife, habitat, wilderness, and user group conflicts. Enforce regulations. Use the best possible science from all disciplines when calculating recreational impacts on the ecosystem.

697, 1365, 1371

RESPONSE: Several monitoring and evaluation systems are established in the Revised Plan to determine impacts of OHV use; dispersed camping; trail impacts; and wilderness use. These should be adequate to determine if goals, objectives, standards and guidelines are being met. AS

COMMENTS: Consider zoning (core reserves, inner buffers, central buffers, outer buffers, matrix, and corridors) as a way to manage environmental impacts of recreational activities.

1365

RESPONSE: This was considered and in several cases (developed recreation or dispersed recreation) separate distinctions were made. Future designations are likely for water recreation to separate users, as indicated in the EIS, under winter access analysis. AS

COMMENTS: Establish a comprehensive fee system (within the confines of existing law) that is used to mitigate recreational impacts, monitor projects, buy new land, subsidize environmental education programs and for administration costs.

1365

RESPONSE: This is up to Congress. The Targhee will implement all existing, authorized fee systems. AS

Monitoring Methods

COMMENTS: Monitor 20% rather than 10% of dispersed campsites and wildlife winter range; provide staff with trail bikes; eliminate user groups from the monitoring process; create comment cards to monitor conflicts.

RECREATION

Monitor trail design and how useable trails are in order to prevent erosion; monitor the number of campsites per trail mile or lake basin.
629, 1312, 1365

RESPONSE: Based on initial field analysis during the summer of 1996, the level and frequency of monitoring described in the Revised Plan is adequate. For example, dispersed campsite impacts were less than originally estimated, therefore, a more intense monitoring level was not warranted. These sites were also reviewed for wildlife winter range monitoring and trail conditions and were found adequate.

Comments from user groups are always accepted as input for analysis and as an indication of possible monitoring needs or deficiencies. AS

Recreation vs Protection Priority

COMMENTS: Change Forest Priority Group Column: change user satisfaction to Group 3; change seasonal trail use impacts to soil and vegetation, and recreation/wildlife conflicts to Group 1.

1365

RESPONSE: Your comments were noted and considered. The requested changes were not made. AS

Mitigate Recreation Impacts

COMMENTS: Clarify how recreational impacts will be mitigated; establish a fee and permit system to mitigate impacts.

1365

RESPONSE: Recreational impacts are mitigated by the Standards and Guidelines in the forestwide and prescription direction. Monitoring and evaluation processes determine when mitigative action (management direction implementation) is needed. Fee permit systems are in place in most developed sites to help control use and mitigate impacts. AS

COMMENTS: Monitor the condition of trails not by trail width but by how useable the trail is (if parallel trails are being created, or if trail is too eroded or boggy to use).

1312

RESPONSE: The monitoring direction in Chapter V of the Revised Forest Plan does not refer to trail width. Soil and vegetation conditions on and adjacent to the trails will be monitored. AS

COMMENTS: Monitor and enforce boat launching regulations to prevent increasing areas of bank disturbance.

697

RESPONSE: The Aquatic Influence Zone Prescription direction regarding 15% soil displacement would generally control when such use restrictions are necessary. AS

RECREATION

COMMENTS: Monitor the number of campsites per trail mile or per lake basin because this is a better indicator of impacts than measuring the condition of campsites.

1312

RESPONSE: The number of campsites that users may see from their site (Indicator #1) is one of the factors measured in the wilderness monitoring plan for the Jedediah Smith Wilderness. AS

COMMENTS: Recognize that improper trail design, not the type of use, is the main cause of erosion (p. V-17).

629

RESPONSE: The goals and objectives in Chapter III address the problem of poor or insufficient designs/construction standards for trails in an effort to avoid erosion of the trail head or adjacent areas. AS

Allow Recreation in the Spirit of Multiple Use

COMMENTS: Manage the Forest for multiple use; balance the needs of natural resources with what will be politically viable. Don't lock out people from recreation, particularly motorized recreation, because the opportunity to perform all types of recreation in the Forest has been historically established, is good for the economy, and is what sets our region, including Jackson Hole, apart from others in the country and makes it special.

12, 135, 278, 342, 490, 608, 614, 625, 631a

RESPONSE: As indicated in the Consequences Section, Chapter IV of the FEIS, the Forest is still managed for multiple uses, including recreation. Most recreation uses and opportunities are not significantly reduced from existing levels. There will be somewhat fewer motorized opportunities and a slight increase in non-motorized opportunities. AS

COMMENTS: Recognize that a poll commissioned by the USFS found that most Americans want National Forests used for recreation and wildlife protection rather than lumber production.

1364

RESPONSE: Your comment was noted and considered. AS

Motorized Use from a Recreational Standpoint

COMMENTS: Want more motorized recreation because of the sense of freedom associated with it and the convenience it provides people who have limited time to enjoy the Forest. Make a motorized corridor along the entire Yellowstone ecosystem. Treat motorized users equally.

285, 300, 645, 1193, 1346, 1365

Want more motorized restrictions to protect natural resources, vegetation (especially in alpine areas above timberlines), waterways and wetlands. Study past, current and future impacts from motorized recreation on the environment; conduct a flora and fauna inventory and assessment of OHV impacts on habitat; and use an adaptive management approach incorporating the

RECREATION

best science. Develop education programs to communicate OHV restrictions to the public. Replant damaged areas using funds from state ORV stickers and fines.

212, 219, 650, 1365,

Partner with the Idaho Department of Parks and Recreation ORMV Program to provide the motorized recreation user an excellent return on his/her fees that were used to develop ORMV facilities in the Targhee National Forest.

629

RESPONSE: The Revised Plan limits OHV use in cross-country areas and some wildlife habitat and monitors actual use impacts to determine if restrictions are appropriate and effective. A proactive approach is being taken to improve trails for motorized use in a concentrated area of the Big Hole Mountains. Education programs about OHV restrictions remain ongoing. Restoration work comes from federal, state and private funds on a grant, cost-share or other cooperative agreement basis. The State determines the use of the funds they collect. Fines collected by federal law enforcement officers return to the national treasury.

The Forest will continue the partnership currently underway with the Idaho Department of Parks and Recreation to reconstruct motorized trails to improve the quality of recreation opportunity for ORMV (Off-Road-Motor Vehicles) owners and natural resources. AS/AM

COMMENTS: Prove that with fewer miles of roads and trails open for motorized use there would be a decrease in motorized recreation and an increase in non-motorized recreation.

629

RESPONSE: The analysis does not indicate there would be a decrease in motorized recreational use. The summer access cumulative effects analysis states that opportunities (miles of designated roads and trails and open acres) decrease, but that continued increasing use levels will create congestion and decrease recreational experiences. AS

Research Natural Areas

COMMENTS: Close off recreation entirely or severely limit it from Research Natural Areas in order to prevent negative environmental and scientific impacts. (CROSS REFERENCE: Special Areas: Research Natural Areas)

612, 1181

RESPONSE: All management activities, including recreation, within Research Natural Areas are managed at levels that do not degrade the characteristics of the Natural Area. There is no need to close these areas entirely. AS

Outfitter And Guides - Economics

COMMENTS: Issue permits for non-obtrusive guided and outfitted services such as backpacking and mountain biking - not just for private ranches - because there is great economic potential for these businesses.

1183

RECREATION

RESPONSE: Decisions on outfitter-guide proposals are made as specific project applications are submitted. Applications are reviewed against public need, competition, interest and the capacity determination objective in Chapter III of the FEIS. AS

COMMENTS: Do not jeopardize outfitters and guides because of unreasonable changes to emphasize wildlife in the new plan.

387

RESPONSE: Existing outfitter-guide operations will probably not be jeopardized by any of the decisions in the Revised Plan. As indicated in the EIS, additional opportunities for outfitting may be less, especially for motorized activities. AS

COMMENTS: Use smaller timber sales designed for local business and for rehabilitation work to restore degraded fish and wildlife habitats so that there is more wildlife which in turn benefits local outfitters & guides.

204

RESPONSE: The size of timber sales has not adversely affected outfitter opportunities. During the time of intensive timber harvest, outfitting continued to increase with the increase in numbers of visitors. AS

Monitor Outfitters and Guides

COMMENTS: Add monitoring element to track the quality of public services offered by outfitters; work with professional outfitters guides.

1183, 1312

RESPONSE: It is unnecessary to include such an element in a Forest Plan. Quality of service is covered by the administration of the special use permit which provides for an annual performance rating of each outfitter's operations. AS

COMMENTS: Address the increase of commercial outfitters and guide use from 4,500 to 21,000 in the DEIS.

643

RESPONSE: The Forest is unaware of any such increase being mentioned in the Plan Revision or DEIS. This comment may be in reference to some project specific proposals recently being considered by the Island Park District which is not a Forest Plan consideration. AS

COMMENTS: Define "low level of use" when regarding outfitter and guide use in objective 8.

1249

RESPONSE: This term is defined in the Jedediah Smith Wilderness Environmental Assessment Process Paper which states, "a limited number of day use permits may be used...in areas where the standards will not be exceeded." AS

RECREATION

Outfitter and Guide Permits

COMMENTS: Control outfitter and guide use through a permit process. Ensure that the permits are compatible with the objectives for the security area. Include the same standard for range permittees on Page III-91, in the Recreation, Outfitter and Guides section.

1276, 1446

RESPONSE: Outfitters are managed through a special use permit process. The operation plans for these uses are reviewed for compatibility with objectives for areas where operations occur, prior to approval. These grazing standards are not applicable to outfitters and guides, therefore this change was not made. AS

COMMENTS: Develop outfitters and guide standards and guidelines including a standard to limit outfitter and guide special use permits from December 1 - April 30, especially in prescription 2.7 to protect big game crucial winter range. (CROSS REFERENCE: Wildlife - Elk, Winter Range)

389, 1247

RESPONSE: Outfitters are subject to the same winter range restrictions as the general public. There are currently few outfitter operations within winter range areas. Future proposals are subject to environmental analysis and compliance with the management direction of the Plan. AS

COMMENTS: The overuse of resources by outfitters and guides diminishes the availability of resources for those unable or unwilling to use their services. For example, they put a tremendous pressure on fishing resources. Use a permit system to have guides teach techniques, biology, and ethics rather than catching fish.

697

RESPONSE: Outfitted recreation is a relatively small portion of the total hunting and fishing use on the Forest. Most outfitters teach their clients about the environment and the history of the area during trips. Such activities are described in the Operations Plan which is part of their special use permit. AS

Outfitter and Guide Access

COMMENTS: Do not allow outfitters to cut new trails or to use non-system trails.

329

RESPONSE: New trails can not be developed without the required environmental analysis. The Forest is unaware of any new trails being approved or developed. Outfitters are free to use any areas of the Forest including non-system trails, following the same rules and regulations as the general public. AS

RECREATION

Outfitter and Guide Standards and Guidelines

COMMENTS: Change the following guidelines to standards: Page III-86: The Outfitter/Guide should be a standard; the Timber guidelines should be a standard; Page III-99: the first G should be a S; Page III-121: the last Road and Trails guidelines should be a standard; the fire Recreation and Outfitter/Guide guideline should be a standard. The fire circles guideline should be a standard. The first sentence of the boat launching guideline should be a standard.

1365

RESPONSE: These comments were noted and considered. The requested changes were not made. AS

Jedediah Smith Wilderness

COMMENTS: Designating this area as Wilderness ruined the recreational experience because it brought more people and guided outfitters to the area.

645b

RESPONSE: Designation occurred prior to and outside the Plan Revision process. The analysis and planning approach for the Jedediah Smith indicates that the areas has not been ruined by recreationists and outfitters. Monitoring is designed to prevent wilderness values from being degraded in the future. AS

Wilderness

COMMENTS: Requests information on how commercial/recreational use (hut skiing operation) fits into future plans for proposed wilderness.

191

RESPONSE: Guided skiing operations would be allowed to continue. Facilities such as huts would not be allowed in the wilderness. AS

Rivers

COMMENTS: Provide more rivers to fish, float and enjoy because of population growth.

382

RESPONSE: The Goals, Objectives, Standards, Guidelines and Prescriptions of the Revised Plan significantly improve or maintain the quality of streams for these areas. The analysis indicates there will be no adverse effects as a result of the Plan. AS

COMMENTS: Ban motorized use on recreational rivers during desirable recreational seasons and in desirable recreation areas.

F-K(3)

RECREATION

RESPONSE: Motorized use is often considered appropriate on rivers designated by Congress as "Recreational Rivers." Decisions on possible restrictions are made on individual river management plans in the future. AS

COMMENTS: Withdraw the management area described on pp. III-82 to III-84 from suitable timber base as harvest is inappropriate for an Eligible Recreational River.

1273b

RESPONSE: It is not part of ASQ. See the Timber in section Chapter III which says, "not included in suitable timber base." AS

Roads and Trails

COMMENTS: Support road closure and reduced trail maintenance in order to control the amount of recreation people can do in the Forest. Open roads and trails for recreation and more Forest personnel maintaining trails. (CROSS REFERENCE: Access)

46, 48, 51, 643, 1365

RESPONSE: The Revised Plan provides opportunities for continued motorized use of trails while protecting the natural resources. There is no proposal to reduce trail maintenance, and the FEIS indicates that more trail maintenance will be needed and will occur. AS

COMMENTS: Write standards to define the requirements for trails; goals are inadequate.

697

RESPONSE: Trail standards are determined at the regional and national levels. The Revised Plan has adequate goals, standards, guidelines, and prescriptions, as well as monitoring and funding direction to meet trail requirements. AS

COMMENTS: Indicate the practices intended to provide for the recreational potential associated with the Continental Divide National Scenic Trail; consider and plan for the visual resource as seen from the trail, the location of the travel way, the status of its development, and provisions for monitoring and evaluation.

345

RESPONSE: The management for this trail is analyzed in the environmental analysis for the trail designation. Detailed management practices are considered in project specific analysis rather than in a forest plan. The management direction in the Revised Plan is adequate for monitoring the valuable assets of the Continental Divide Trail. AS

COMMENTS: Define what historic recreational use means.

1361

RESPONSE: This generally refers to the types and amounts of recreational use in a given area. AS

RECREATION

Recreation Standards & Guidelines Need Revisions

COMMENTS: Recreation impacts on the environment and the analysis is flawed. The analysis needs more data/studies; better science; stronger language; standards rewritten; objectives eliminated; statements amended; and guidelines changed to standards - for the purpose of reducing negative environmental impacts and recognizing that limits to recreational growth and development may be necessary.

489, 695, 1365, 1395

Include a future management direction for outdoor recreation in the Management Prescription section - follow NFMA section 219.21.

1345

RESPONSE: The Revised Plan contains management direction for recreation as required by NFMA. These are in the Forestwide Standards, Guidelines, Goals, Objectives within each management prescription. The Analysis of the Management Situation fully analyzes the recreation opportunities and resource characteristics required by NFMA. Analysis of current conditions and potential consequences is based on scientific data and knowledge of an interdisciplinary team of biological and social scientists. AS

COMMENTS: Develop standards and guidelines to help achieve the goal to minimize winter recreation impacts on wintering wildlife (p. III-17).

389

RESPONSE: A new standard was added to the Revised Plan to restrict cross-country snowmachine use from all inventoried winter range. AS

COMMENTS: Revise goal to read: "Provide a high quality winter recreation experience to accommodate current and future use. On big game winter ranges, minimize impacts of winter recreation use."

1202

RESPONSE: The Goal was revised to read: "Provide a quality winter recreation experience while minimizing conflicts between motorized and nonmotorized use and wintering big game." AS

COMMENTS: Write standards to define the requirements for trails; goals are not adequate.

697

RESPONSE: The standards are covered by manual and handbook policies for trail design and maintenance. AS

COMMENTS: Define what we want the Forest to be like (regarding camping) in 10 years.

697

RESPONSE: The Revised Plan's goals, objectives, standards and guidelines provide that definition. AS

RECREATION

D-4

Big Holes/Palisades/South Fork of Snake

COMMENTS: Revise the statement on p. III-49, under Desired Future Condition, to recognize that this subsection provides quality non-motorized recreation too. Include the word "non-motorized" in the statement.

629

RESPONSE: The Desired Future Condition for the subsection is rewritten in the Revised Plan to include a reference to non-motorized experiences. AS

COMMENTS: Keep Palisades/South Fork of Snake River closed to winter, cross-country motorized use to protect crucial big game winter range.

629, 766

RESPONSE: Most of the winter range in this area is placed in the winter range prescription and is thereby closed to all cross-country travel. Also, the area not in the winter range prescription is closed to cross-country snowmachine travel. AS

Kelly Canyon

COMMENTS: Recognize the importance of Kelly Canyon-Hawley areas as cross-country skiing areas because most of the acreage is for snowmobilers and cross-country skiers need a place to ski; keep the area open after the ski hill closes; close the area to winter motorized cross-country use to protect crucial winter range.

F-L(3), 658, 766

RESPONSE: The Forest recognizes the importance of this area for cross-country skiing. An objective and standard within the Big Holes Subsection in chapter III provides specific management direction to maintain these opportunities. The Forest revised the Alternative 3M map to show a prescription 5.1.4(d) which closes the area described to cross-country motorized travel. The ski hill is open to the general public use for cross-country skiing once the resort is closed for the season. AS

Caribou Subsection

COMMENTS: Clarify which type of use will be allowed here (motorized or non-motorized) and specify such in the Desired Future Condition statement; correct the inconsistencies between the DFC statement on p. III-53 and Objective 1 under "recreation"; include a statement that allows motorized use, since the area currently provides it and will in the future.

489, 629, 643

RESPONSE: The text is rewritten to indicate a DFC for both motorized and non-motorized to match existing conditions. The objective is now consistent. AS

RECREATION

D-5

Grand Targhee Ski Resort

COMMENTS: Do not allow impediments to potential expansion of the Grand Targhee Ski Resort. Plan ahead (including working with the Idaho Department of Commerce and the Governor's Office) to remove impediments and to meet present and future demands for ski resorts; indicate under Goals and Objectives that Grand Targhee Ski Resort will continue to grow and expand in the Recreation Resource Section (219.21).

248, 389, 618, 697, 1342, 1345

RESPONSE: The Revised Plan provides no impediments to expansion of the Grand Targhee Ski Resort. A Master Plan was approved in 1995 for resort development. The Forest added direction to the Teton Range Subsection narrative that the Forest will follow the intent of the Master Plan and FEIS mitigation. AS

COMMENTS: Develop standards and guidelines identifying how much land is available for ski area expansion and where and under what conditions future land exchanges would be considered; stop legal delays due to lack of management direction; protect areas adjacent to Grand Targhee Ski Resort as areas of potential expansion.

248, 618, 1277, 1342, 1345

RESPONSE: Land available for ski area expansion is contained within the 4.2 prescription for Kelly Canyon and Grand Targhee Resorts. They will be developed within approved Master Plans. Any land exchanges are handled as project specific proposals outside the Forest Plan. AS

COMMENTS: Correct map in Alternative 3 Prescriptions to show Grand Targhee Ski Resort as a 4.1 Developed Recreation Site, or as a 4.2 Special Use Permit Recreation Site.

248

RESPONSE: It is shown as a gray, 4.2 prescription area on Alt. 3M map. AS

Jedediah Smith Wilderness Area

Climbing

COMMENTS: Allow bolts for climbing only at rappell points and other key anchor points to emphasize self-reliance and discovery - not a ladder of bolts.

1312

RESPONSE: This is addressed by ongoing management and monitoring of the wilderness and within current policies. Direction is not needed in a forest plan. AS

RECREATION

Fishing

COMMENTS: Include a statement that fish stocking for recreational purposes is not permitted (as stated in Opportunity Class I, EA).

1277

RESPONSE: If such a statement was made in the draft Jedediah Smith Environmental Assessment, it was in error. Such stocking is appropriate in waters, such as Fish Lake, noted in the legislation for designation. AS

Teton Range Subsection

COMMENTS: Revise statement under Recreation - Monitoring Item - Conflicts between all forms of recreation and wildlife to say, "It is expected that monitoring partnerships can be developed with state wildlife agencies, state recreation agencies, possibly recreation user groups, and for bighorn sheep in the Teton Range, with Grand Teton National Park."

699

RESPONSE: It is standard practice to coordinate and cooperate with other agencies and user groups in monitoring wildlife and/or recreation and the Forest will continue to do so for the next 15 years. Such direction is inappropriate for inclusion in a Forest Plan. AS

Teton Canyon

COMMENTS: Develop a management plan to protect and manage recreational use in Teton Canyon because the Mail Cabin - Stateline areas and the Teton Pass back-country area are already getting a lot of skiing use and there is not enough parking now.

329

RESPONSE: This may be done later as a project-level plan; however, it is not appropriate in a Forest Plan analysis. AS

Teton County

COMMENTS: Serve the increasing recreational needs in Teton County because the population has made the largest gains between 1990-1995.

314

RESPONSE: The Goals, Objectives, Standards and Guidelines of the Revised Plan address this need. AS

Big Hole Mountain (Prescription 3.2(g))

COMMENTS: Favor both non-motorized and semi-primitive motorized recreation in this area as long as the motorized recreation is restricted to a well-designed and well-marked loop trail system; such a trail system would minimize resource damage and take pressure off the Jedediah Smith Wilderness.

1312

RECREATION

RESPONSE: Your comments are noted. The management direction in the Plan will create a well-designed and maintained motorized trail system in this area. AS

COMMENTS: Offer both semi-primitive motorized and nonmotorized recreation.
1312

RESPONSE: The 3.2 Prescription text was revised under the Recreation Opportunity Spectrum heading to indicate a range of opportunity from semi-primitive non-motorized (SPNM) to roaded natural appearing (RNA). We discovered that the ROS inventory shows non-motorized areas in the Big Holes. AS

Manage for Recreation, Not Timber

COMMENTS: Manage for recreation rather than timber harvests. Fairly compare environmental impacts caused by recreationists versus impacts caused by timber harvests. Do not allow logging and grazing impacts to go inadequately monitored, reported and regulated. Rewrite chapter II-2 so that it does not reflect a predisposition against recreation. Manage for sustainable levels of all resources including both timber and recreation.

174, 208, 280, 293, 308, 341, 621, 1203

RESPONSE: The Plan and FEIS address all resources with no predisposition against recreation. Each resource area has Goals and Objectives based on the Desired Future Condition (DFC) expressed by the public during the issues analysis. DFC direction states that "Commodity production such as timber, firewood, mining, livestock forage, or outfitter and guide services are conducted at sustainable levels." The DFC also states, "Growing and diverse recreational, cultural, visual....needs are accommodated based on the capability of the ecosystem to sustain these uses." All resources will be monitored to determine if Standards, Guidelines, Goals and Objectives are being met. AS

COMMENTS: Change the wording in Chapter II, p. II-2 so that it reflects an attitude that both logging and recreation should be managed to minimize user conflicts, and not a predisposition against recreation as is currently written.

341

RESPONSE: Logging is covered under the Economic Component on the next page. Recreation is simply addressed as one activity under the first Social Component DFC. There is no predisposition against recreation. AS

Allow Recreation in Wilderness

COMMENTS: Manage the wilderness as a "recreation area" because this would allow managers better choices for all concerned.

665

RESPONSE: We are managing the wilderness for its nonmotorized recreational and biodiversity values as required and allowed by the Wilderness Act. AS

RECREATION

COMMENTS: Oppose wilderness designations because wilderness imposes limits on recreationists and Forest managers. Manage wilderness as "recreation areas" because more land is needed to accommodate recreation pressure in the back country and roadless areas are vital to recreation.

291, 643, 665, 704, 1377

RESPONSE: It is true that wilderness designation results in the need for careful management of recreation use to prevent adverse effects on wilderness. However, these areas are sensitive to use impacts and must be managed regardless of the wilderness designation. Therefore there is little loss of nonmotorized recreation opportunity. AS

Prohibit Recreation in Wilderness

COMMENTS: Eliminate/prohibit trailhead facilities from Opportunity Class I areas.

1312

RESPONSE: Trailhead facilities are not included within the Class I areas, since facilities are not allowed within the wilderness. Developed trailheads are in Prescription 4.1. AS

Effects of Recreation in Wilderness

COMMENTS: Explain the Limits or Acceptable Change (LAC) system and whether it will allow additional recreational use and increase degradation in wilderness areas; include statistical data on the magnitude and trends of recreational activities on wilderness and nonwilderness; address recreational impacts on wilderness and non wilderness; clarify how impacts will be mitigated.

325, 699, 1365

RESPONSE: The LAC system is described in the Jedediah Smith Wilderness process paper referred to in the EIS and is part of the Revised Plan. Acceptable change is determined by degree of change in the resource or social factor to be monitored as shown in the monitoring plan. As indicated in the wilderness consequences section of the EIS, additional use expected to occur within the wilderness should result in, "Little cumulative impact or secondary effects." This is a result of the monitoring process that detects unwanted changes in biological, social or other factors. Mitigation occurs as a result of implementing corrective actions listed in the monitoring Plan in the EIS. AS

Effects of Recreation on Wildlife

COMMENTS: Concern about the negative effects of recreation on wildlife. Minimize these effects - create a recreation use management program using correct scientific data and manage conservatively until this data becomes available; discourage recreational use in wildlife zones (a.k.a. cores or corridors); protect amphibians by not placing roads and trails near marshes and seasonally wet meadows; create a standard that controls the location of campsites and trails in peregrine falcon habitat; establish minimum approach

RECREATION

distances to wildlife; and conduct a forest-wide flora and fauna inventory and study the recreational impacts on these species. (CROSS REFERENCE: Wildlife) 643, 1365, 1446

RESPONSE: The Revised Plan contains management direction for recreation as required by NFMA. These are in the Forestwide Standards, Guidelines, Goals, Objectives and management prescriptions. The Analysis of the Management Situation fully analyzes the recreation opportunities and resource characteristics required by NFMA. Analysis of current conditions and potential consequences is based on scientific data and knowledge of an interdisciplinary team of biological and social scientists. AS

COMMENTS: Any and all human activity, in this case recreation, negatively impacts wildlife as numerous studies prove. Harmful recreational pursuits are nature viewing, hiking, backpacking, horseback riding, camping, skiing, hunting, fishing, boating, rock climbing, caving, mountain biking, snowmobiling, and small aircraft. Conduct scientific studies to analyze past, current, and future impacts on the ecosystem, and adapt management based on the findings; with an emphasis on limiting/prohibiting all human activities on the Targhee National Forest if any past, current, or potential impacts are discovered.

1365

RESPONSE: The effects of recreation activity on winter and summer habitat are well documented in scientific studies. These were noted in the AMS and considered in the analysis process. The Revised Plan adopts considerable direction to respond to this concern and minimize potential effects. AS

COMMENTS: Clarify how campsite facilities will facilitate recovery of Threatened and Endangered species.

1446

RESPONSE: Developed campsite facilities can concentrate use away from threatened and endangered species habitat; or facilities such as bear-proof food boxes can prevent conflicts. AS

COMMENTS: Coordinate with Idaho Fish and Game to develop watchable wildlife programs.

1446

RESPONSE: Such coordination is an ongoing administrative effort. AS

Effects of Recreation on Bighorn Sheep

COMMENTS: Protect bighorn sheep habitat from negative recreational impacts by regulating recreation: close campgrounds, prohibit new trails and campsites, and prohibit domestic sheep in key bighorn sheep areas; include a standard that prohibits all human activity on crucial bighorn sheep range from Dec. 1 - April 30; add an objective to the Designated Wilderness - Opportunity Class I,

RECREATION

II, and III objectives that eliminate recreational use in bighorn sheep winter range in the Jedediah Smith Wilderness Area between Dec. 1 - April 30. (CROSS REFERENCE: Wildlife, Bighorn Sheep).

389, 699

RESPONSE: Bighorn sheep habitat on the Forest is within designated wilderness, proposed wilderness, and semi-primitive backcountry areas. These areas already have limited access. Concerns about possible or potential adverse effects of recreation activity have not provided substantive documentation to support the claim that recreation activity is adversely affecting bighorn sheep populations. For the Revised Plan, an objective was added to work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons. Standards or guidelines such as the proposed date restriction will be determined based on results from the research. MO

Protect Riparian Areas from Recreation

COMMENTS: Give special protection to riparian areas because they are important wildlife habitat. Address impacts recreationists (horses, ATVs, campers and picnickers) have on riparian areas; explain why there are no access density guidelines for riparian corridors; and develop management objectives that are compatible with other resource protection objectives. Want management approaches in riparian and aquatic diversity areas to include: modifying recreational facilities, changing maintenance practices, limiting use, or closing areas; and educating people about these measures. Specific approaches include: restricting motorized recreation and mountain bike travel altogether in riparian areas and Aquatic Influence Zones; restrict motorized crossings of streams and wetlands to roads and trails; prohibiting new roads, including temporary roads in riparian and aquatic habitat; prohibit dispersed camping entirely in riparian areas and Aquatic Influence Zones; prohibit recreation within 50-100 feet of a watershed, increase 300 foot corridors along designated roads; do not allow motor vehicles within 25 feet of stream banks, springs, or wet meadows except on designated routes and stream crossings; enforce restrictions (CROSS REFERENCE: Riparian)

FS-3, FS-5, FS-8, FS-9, FS-10, 212, 643, 1367, 1369, 1446

RESPONSE: All these concerns are addressed in the dispersed camping prescription; the riparian prescription; and the OHV Standards, Guidelines, Monitoring and Evaluation requirements. AS

COMMENTS: Address the impacts recreationalist (horses, ATVs, picnic, campers) have on riparian areas because they are harder on an area than livestock and firewood gathers.

FS-3

RESPONSE: There is no data or evidence to this effect. In fact, research shows that hooved animals have more impact than hikers and bikers. Depending on the location, intensity and duration of any type of activity, adverse consequences can occur. AS

RECREATION

Recreation in Grizzly Bear Areas

COMMENTS: Prioritize grizzly bear management over recreation; install educational posters at trailheads; develop goals, objectives and standards for proper sanitation and how to travel and camp in Special Use Permit Recreation Sites in grizzly bear recovery zones. (CROSS REFERENCE: Wildlife, Grizzly Bear)

179, 643, 1446,

RESPONSE: This has basically been accomplished through development and use of the grizzly bear guidelines. Information and a law enforcement restriction order regarding recreational activities in grizzly bear habitat are posted at trailheads. When area occupation and conflict are known or likely, additional emphasis is placed on notifying the public entering the area. AS

Increased Winter Recreation

COMMENTS: Commit funds to provide adequate increased winter recreation use. Unease about winter use increasing and growth referred to in the findings of negative environmental impact from winter use in Yellowstone National Park. Analyze current winter use, including safety, wilderness trespass, and demand for developed areas and develop policies to prevent future negative impacts to the environment and recreationists. Develop acceptable use levels and a policy for determining when levels will be reconsidered to avoid unacceptable conditions.

643, 1342, 1367(b)

RESPONSE: The forestwide goals, objectives, standards, and guidelines should resolve these concerns. We added a goal to the Final Revised Plan to use the guidelines anticipated from the pending Greater Yellowstone Winter Visitor Use Management Assessment by the year 2000. These guidelines help us plan for capacities and avoid conflicts and adverse conditions. AS

COMMENTS: Clarify the statement: "promote opportunities for backcountry winter recreation" and whether this means motorized. Clarify whether the Plan has any method of receiving funds to manage this use and the expense of backcountry accidents.

643

RESPONSE: This is intended to mean non-motorized. The Forest can develop cooperative agreements for groups to collect funds to manage these areas. AS

COMMENTS: Discuss how the increase in the number and miles of marked and groomed snowmobile routes will affect winter recreation users.

1351

RESPONSE: This was done in the FEIS, Chapter IV under the heading "Winter Access - Cumulative Effects." The Forest added some additional analysis of potential effects on snowmobile opportunities. AS

COMMENTS: Provide more information on the existing condition and growth of winter use activities and analyze the impacts of providing increased winter

RECREATION

recreation opportunities in order to develop levels and a policy for when levels will be reconsidered to avoid unacceptable conditions.

643

RESPONSE: The Forest added text to the winter access section of the FEIS to indicate the growth in this activity. We also added a goal to the Final Revised Plan to incorporate guidance from the Greater Yellowstone Winter Visitor Use Management Assessment in future winter recreation planning. AS

Effects of Winter Recreation on Wildlife

COMMENTS: Concerned about the negative effect of winter recreation on wildlife including snowmobile use on crucial elk and deer winter range. Explain the rationale for permitting cross-country snowmobile use on 66% of crucial elk and deer winter range. Minimize negative impacts by including: establishing minimum approach distances; revising goals and developing standards and guidelines; reducing noise impacts by requiring ski area developers to use noise-limiting devices and low noise equipment, reducing speeds, and limiting duration; and incorporating the Teton Front Winter Recreation Plan and its ORV restrictions and crucial big game winter habitat objectives. (CROSS REFERENCE: Wildlife)

389, 766, 1202, 1365, 1446

RESPONSE: The new standard of the Revised Plan prohibits cross-country snowmachine use in winter range areas. Designated routes through winter range were selected to minimize potential effects on wintering wildlife. The winter management direction, prescription, Winter Travel Plan, and winter recreation/wildlife monitoring requirements address the concerns of the Teton Front Winter Recreation Plan. AS

COMMENTS: Minimize winter recreation use in habitats for all Threatened, Endangered & Sensitive Species and big game. (CROSS REFERENCE: Wildlife)

1446

RESPONSE: This is accomplished by Goals, Objectives, Standards and Guidelines for Threatened, Endangered, and Sensitive Species as stated in Chapter III of the Revised Plan. AS

Effects of Winter Recreation on Wolverine

COMMENTS: Protect wolverine denning habitat by creating a 8 km buffer in wolverine denning habitat from Jan. 1 - May 31 and restrict recreational activity (e.g. skier/snowmobiler) for the remaining winter season; plan for non-motorized and motorized recreation in high elevation areas to protect wolverine dens. (CROSS REFERENCE: Wildlife, Wolverine)

766, 1185, 1348

RESPONSE: Surveys are currently underway and an objective was added to the Final Revised Plan to identify denning areas and determine actual use. An assessment will be completed following data gathering and will include recreational management direction. AS

RECREATION

Economic Importance of Winter Recreation

COMMENTS: Concern about winter recreation's importance to the economy because more wilderness designations will destroy Idaho and Wyoming communities that rely on heliskiing and snowmobile businesses. Recognize the importance of ski area development by working with the Idaho Department of Commerce and the Governor's Office to ensure present and future demand for downhill skiing will be met; downhill skiers represent a substantial commitment of money.

358, 618, 1342, 1345

RESPONSE: Although the Revised Plan recommends some areas for wilderness designation, it takes an Act of Congress to make it happen. In the interim, existing motorized uses which do not degrade the roadless areas' wilderness character are allowed to continue. That was and continues to be the case with the Italian Peaks, Lionhead and the Idaho portion of Winegar Hole areas, recommended for wilderness designation ten years ago. When Congress designates an area as Wilderness, they have the option to continue motorized uses, but that is highly unlikely. Usually a newly designated wilderness bill will prohibit heliskiing, snowmobiles and all motorized uses. The Forest is always willing to work with the Idaho Department of Commerce and the Governor's Office to address the needs of downhill skiers. DP

Winter Incompatible Use - Conflicts

COMMENTS: Separate winter users in order to enhance the recreation experience and prevent user conflicts, especially between cross-country skiers and snowmobilers. Need more cross-country ski areas because the speed, noise, and pollution from snowmobiles impacts their enjoyment of the forest. Alleviate user conflicts by developing an overall winter recreation management plan (similar to ski area Master Plans) that includes specific (by type of use) and clear allocations of users among cross-country skiing, snowmobiling, downhill skiing, and general snowplay. Submit this plan for public input as required by NEPA; fund this plan by developing a statewide licensing organization.

618, 643, 697, 1263, 1342, 1345

RESPONSE: We added a goal to the Final Revised Plan to use the guidelines from the pending Greater Yellowstone Winter Visitor Use Assessment by the year 2000 to establish a few non-motorized winter activity areas. This should help reduce conflicts and adverse conditions. AS

HeliSkiing

COMMENTS: Do not support more wilderness because heliskiing will be prohibited from wilderness areas which will force heliskiing tour companies out of business and devastate local economies. Prove that there is evidence of lasting damage from helicopter skiing over the previous decades. Heliskiing recreation is important to lives and peace of mind. (CROSS REFERENCE: Wilderness)

F-E(2), F-K(2), 172, 281, 358, 366, 405, 521, 642, 647, 712, 1123, 1183, 1189, 1342, 1373, 1385, 1454

RECREATION

Allow heliskiing in areas that are already disturbed/developed to protect the Wilderness.

1393

More adequately address heliskiing in the DFPR; heliskiing industry could rally in support of a fair plan that balances multiple-use with wilderness.

358, 402, 625

RESPONSE: Although the Revised Plan recommends some areas for Wilderness designation, it takes an Act of Congress to designate an area. In the interim, existing motorized uses, including heliskiing, which do not degrade the area's Wilderness character, are allowed to continue. DP

COMMENTS: Small aircraft, glider planes, and wing aircraft cause stress response in wildlife.

1365

RESPONSE: Your comment was noted and considered. We are unaware of any adverse effects on wildlife. We are aware of some possible effect on nesting peregrine falcon. Potential aircraft effects on planning considerations is noted in the forestwide guideline for peregrine. AS

Cross-Country Skiing

COMMENTS: Increase/preserve cross-country ski areas.

711

RESPONSE: The Plan direction will increase or preserve cross-country skiing opportunities. A new goal was added to the Final Revised Plan which directs the establishment of a few additional areas of non-motorized winter activity by the year 2000. AS

Dog Sledding

COMMENTS: Designate dog sled trails.

697

RESPONSE: We did not designate separate trails at this time. Dog sleds are free to use groomed snowmachine trails. In the future, dog sled trails may be designated according to guidelines from the pending Greater Yellowstone Winter Visitor Use Assessment. AS

Downhill Skiing/Developed Recreational Facilities/Ski Resorts

COMMENTS: Emphasize in the Recreation Resource section (219.21): Appraise developed recreational facilities and their ability to meet present and future demand; consider established facilities, regulation of use, and recreational opportunities when planning for future demands; plan and implement off-road vehicle use to protect land, promote safety and minimize user conflicts.

389, 618, 697, 1345

RECREATION

RESPONSE: The Revised Plan contains management direction for recreation as required by NFMA. These are in the Forestwide Standards, Guidelines, Goals, Objectives and management prescriptions. The Analysis of the Management Situation fully analyzes the recreation opportunities and resource characteristics required by NFMA. Analysis of current conditions and potential consequences is based on scientific data and knowledge of an interdisciplinary team of biological and social scientists. AS

COMMENTS: Take a cautious approach and consider the impacts developed recreational facilities and ski resorts have on wildlife and the environment including the air, soil, vegetation and water. Develop an objective that adjusts the use level of developed facilities consistent with other resource management objectives (e.g. aquatic and riparian health). Make no decisions until they are funded and after fully considering a comprehensive scientific study that examines and monitors cumulative past, current and future environmental impacts caused by developed recreational facilities and ski resorts. Incorporate limits on the numbers and affect of recreationists: create visual buffer zones, channel traffic, establish a permit and fee system; educate the public; and develop ski areas in areas of low sensitivity (matrix areas).

643, 1365

RESPONSE: The Revised Plan takes a conservative approach to potential effects of recreation on the environment and provides numerous mitigations to avoid adverse effects. The winter range prescription is an example of these conservative efforts. AS

COMMENTS: Include under Goals, Objectives and Standards/Guidelines a management direction for developed ski areas because lack of direction might cause legal problems/delays in future ski area expansion projects.

248, 618, 1342, 1345

Include in the Management Prescriptions, standards and guidelines identifying how much land is available for ski area expansion and where and under what conditions any future land would be considered.

248, 618, 1342, 1345

RESPONSE: We added management direction to the Final Revised Plan for the Teton Range Subsection to require the intent of the 1994 Master Plan FEIS and 1995 Master Plan for Grand Targhee Resort to be followed. Both Grand Targhee and Kelly Canyon are mapped in the 4.2 Special Use Permit Recreation Site prescription which provides additional management direction. AS

COMMENTS: Develop programs to use ski areas (developed recreational sites) year-round to meet growing demands of recreationists.

1342, 1345

RESPONSE: This development is the responsibility of each resort owner within the scope of their approved Master Plan. AS

COMMENTS: Make the permit approval process, including NEPA requirements, the same for all ski areas in Idaho.

1342, 1345

RECREATION

RESPONSE: This is a policy matter that is outside the scope of a forest plan document and decisions. AS

COMMENTS: Consider seismicity when designing, building, and siting facilities.

389

RESPONSE: This is a routine consideration for all publicly occupied buildings which require plan review by Forest Service regional engineering staff. AS

COMMENTS: Develop an objective that determines what allowable levels of use are consistent with other resource management objectives (e.g., aquatic and riparian health) and then adjust the level of developed facilities accordingly.

643

RESPONSE: An objective is not needed. We indicate in the Final Revised Plan and EIS (Chapter IV - Developed Recreation) that only minor additional facilities are proposed as shown in the implementation schedule. This was determined after analysis of demand, adjacent public and private facilities and the condition of existing facilities. AS

COMMENTS: Fund a monitoring and evaluating program for the impacts caused by ski resorts. Fully consider and utilize substantive scientific data on the impacts of ski resorts. Develop ski resorts in areas of low sensitivity to developmental impacts (matrix areas) in order to minimize negative impacts; if not possible then do not develop in the area in question.

1365

RESPONSE: Master Plans with supporting environmental analysis were approved for both existing ski resorts. The approval for these resorts requires certain levels of monitoring for wildlife, wilderness and community development concerns. A detailed review process for all future development projects at Grand Targhee is in place and has been functioning successfully for two years. There are no other inventoried potential ski area sites on the Forest other than Kelly Canyon and Grand Targhee. AS

RESEARCH NATURAL AREA

Research Natural Areas - General Recommendations

COMMENTS: Recommend more Research Natural Areas (RNAs). Improve and revise current and proposed network of RNAs so that they represent all habitat types and are of sufficient size to derive meaningful and useful data.

163, 1365

RESPONSE: At this time, there are three proposed and nine existing RNAs on the Targhee. This list of proposed RNAs is identical to that of the Forest Service Regional Office in Odgen, Utah and the Intermountain Research Station in Missoula, Montana. There are no other proposals for RNAs.

The existing and proposed RNAs on the Targhee meet the standards required for establishment and management. It is not the intent of the RNAs program to have all habitat types on a specific forest represented in RNAs located on that same forest. WG

COMMENTS: Use goal and objective statements to reference the process for recognizing RNAs needs; identifying new candidate areas; and delineating the purpose of these areas to preserve a wide spectrum of pristine representative areas that typify important ecosystem types.

1181

RESPONSE: The direction for the management of existing RNAs and the establishment of proposed RNAs is located in Forest Service Manual 4063. The Targhee does not restate manual direction or policy in the Revised Plan. WG

COMMENTS: Identify proposed and existing RNAs by name and objective, with a brief description of their values. The status of proposed RNAs is not adequately addressed in the Draft; the fate of proposed RNAs should be determined by including them in the alternatives, in the management area prescriptions, and elsewhere in the documents. RNAs should be placed in a single Forest Plan Management Area. Reasons for dropping certain areas from consideration must be disclosed.

612, 1181

RESPONSE: The RNA sections in both the FEIS and Revised Plan are modified in response to public comments. Identification of proposed and existing RNAs, with a brief description of their values in Chapter III and effects by each alternative in Chapter IV of the FEIS were added and changes to Management Prescription 2.2 in the Revised Plan. WG

RNAs - General Recommendations (continued)

COMMENTS: Do not put RNAs under title "Unique Ecosystems" because they are intended to feature representative as well as unique systems, title "Research Natural Areas." Do not place RNAs under the terrestrial ecosystem since they also have aquatic and riparian elements. Place RNAs in the section on Ecological Processes and Patterns since they are reference areas for monitoring, research, conservation and education within context of understanding Range of Variability and because they help in the understanding of ecosystem management.

612

RESEARCH NATURAL AREA

RESPONSE: Your comment was considered and discussed. Because the Forest believed that to adopt the change would create confusion both internally and externally, we chose not to adopt this proposal. Keeping RNAs under Unique Ecosystems does not effect on-the-ground management. WG

COMMENTS: Need to agree on which proposed areas were dropped from further consideration and document those decisions with written concurrence from the R4 INT/RNAs Committee. List specific names of established and proposed RNAs in DFPR and DEIS; include maps. Provide more information on individual areas in the DEIS, such as RNAs acreage and vegetation types represented. Link the revised goal and objective statements to a presentation of various plant communities and an assessment of the conservation status of these elements of biological diversity. Disclose the effects of managing for maintenance of biological diversity through RNAs management prescription in the EIS.

1181

RESPONSE: Presently, the Targhee, the Regional Office (R4), and the Intermountain Research Station all agree on the proposed RNAs. The FEIS and Revised Plan were modified to include the names and locations of proposed RNAs, as well as acres and vegetation types. More detailed information on proposed RNAs is located in Targhee resource files. WG

COMMENTS: Rewrite portions of the management area prescription that do not meet the intent of RNAs management policy. Describe the relationship between the Forest Plan and Establishment Record in the management area description. Modify the standards and guidelines section to be consistent with the FSM policy guidelines; reference Establishment Record as source of specific prescriptions; and indicate that management activities that fall outside the Establishment Record and must be approved by Station Director, Intermountain Research Station. Show that all restoration and rehabilitation management activities must be approved by the Station Director.

Reword description area to include more precise and thorough description of RNAs; the variety of purposes they serve; on what basis they are selected; and how they should best be managed. Include proposed restrictions on recreational, extractive, or consumptive uses. Reword goal statement: "Maintain natural conditions by allowing ecological processes to prevail with minimal human intervention.

612, 1181

RESPONSE: The FEIS and the Final Revised Plan are significantly modified to address these concerns. As changed, Management Prescription 2.2 in the Revised Plan is now consistent with policy identified in FSM 4063 and the Establishment Records for existing RNAs. WG

Specific Revisions/Corrections

COMMENTS: DEIS incorrectly mentions 3 proposed RNAs when there are 4 areas.
612

RESPONSE: This error is corrected in the FEIS. There are only three proposed RNA's on the Forest (see Table III-21 FEIS). WG/CC

RESEARCH NATURAL AREA

COMMENTS: Recommend the following corrections to DFPR, pages III 72-75, Description: Replace "steering committee" with R4/INT Station RNAs Committee; Add monitoring to list of RNAs uses; Replace "... are good examples of physical or biological units"; with "provide excellent examples of common and unique ecosystems..."; Add "direct" before "human intervention"; Omit statement on interpretation of special features; Omit current sentence on road or trail; State that timber harvest is not allowed; and omit sentence on livestock grazing - it is not correct. Suggest replacement language: "Generally RNAs are closed to grazing unless grazing is necessary to approximate natural grazing regime.

612

RESPONSE: "Steering committee" was replaced in the text with "R4/INT Station RNAs Committee" as suggested. The entire Management Prescription 2.2 in the Revised Plan was modified to incorporate all policy and direction identified in FSM 4063. Recommendations 2 through 8 were not adopted because they either: restate FMS direction; are presently incorporated into the Establishment Records for existing RNAs; or, because historical use, at the same levels, are not deemed threatening to the values of the RNAs. WG.

Management Prescriptions

COMMENTS: Maintain consistent direction across the national network of RNAs. The Forest Plan should state that RNAs are closed to motorized use and indicate where there are exceptions due to special situations. Mountain bike use is also not permitted within RNAs - this needs to be indicated in the Plan. In general, discourage horse/packstock use in RNAs, and where this use occurs it should be restricted to trails. Not a good idea to allow horse/packstock travel, especially as it may influence distribution of weeds. Perhaps impose a weed-free hay requirement for stock use in RNAs.

Address integrated pest management, noxious weeds, special forest products. Make the following changes: Allow natural outbreaks of native insects and diseases to proceed without intervention unless they are a substantial threat to important resources inside or outside RNAs boundary. (S) Use control methods which minimize disturbance to natural values of the RNAs. (S). Control populations of exotic (non-native) plant and animal species where feasible. Use control methods which minimize threats to native species. (G). Harvest of special forest products will not be allowed within RNAs.

Add general standard: Protect the natural condition of the ecosystem and its processes and any species or values for which the RNAs was proposed. (S)

(Soil & Water): Soil and water standards and guidelines are not consistent with the intent of RNAs. Minimize human impacts; this includes some traditional watershed restoration practices. Not really justified in post-fire rehab seeding - the value of an RNAs is to let nature take its course. Watershed rehab structures are not allowed in RNAs. Seeding, especially of non-indigenous species is not desirable. Eliminate this section There is no such section for designated wilderness management area prescription.

(Fish & Other Aquatic Resources): In addition to present wording, make statement indicating stocking of non native fish is not permitted.

RESEARCH NATURAL AREA

(Recreation): Allow non-vehicular recreation, except when it is a threat to the values for which the RNAs was proposed. (S) Utilize restrictions or closures under 36 CFR subpart B when necessary to protect the area from actual or potential damage due to public use. (S) Delete Item "ROS - Primitive to semi-primitive motorized." Motorized use is not allowed in RNAs.

(Trails): Keep present language on trails.

(Timber): Replace second standard (Timber) "No timber harvesting..." with "Prohibit logging and wood gathering activities."

(Range): Omit current language in Draft Forest Plan. Livestock grazing is not allowed in RNAs unless it is deemed necessary as a tool to manage vegetation to mimic natural grazing regimes. Cannot think of any situation on Targhee where livestock grazing is justified. Reword: "Prohibit livestock grazing except when used to approximate a natural grazing regime for maintaining the native vegetation. No salting, water developments or other range improvements allowed.

(Ecological Processes - Fire/Fuels): Add: "Prescribed fire plans for RNAs will be developed in conjunction with the Intermountain Station, and approved by Station Director" -- at the end of prescribed fire guideline.

612

RESPONSE: The entire Management Prescription 2.2 in the Revised Plan is modified to incorporate all policy and direction identified in FSM 4063. All recommendations proposed were not adopted because they: restate FMS direction; are presently incorporated into the Establishment Records for existing RNAs; or, historical use, at the same levels, are not deemed threatening to the values of RNAs. WG.

COMMENTS: Prescribed fire may be needed to maintain ecological processes and the current statement regarding fire use (pg III-73) should reflect this.

Change language in "Physical Elements, Soil and Water" pertaining to burned area rehab and the other three guidelines to show that restoration and rehabilitation will be incident specific and must be approved by the Director.

To effectively attain the prescription goal of maintaining natural processes, no "semi-primitive motorized" use, ROS classification must be "primitive." More exacting restriction on recreational use should be defined (i.e., horse and packstock limited to roads and trails; no motorized use, summer or winter). Recreation use of RNAs raises paradoxical issues of balancing public use with pristine, representative, natural conditions; and use threatens the perpetuity of such conditions. Management strategy similar to LAC may be appropriate.

1181

RESPONSE: The entire Management Prescription 2.2 in the Revised Plan is modified to incorporate all policy and direction identified in FSM 4063. All recommendations proposed were not adopted because they either: restate FMS direction; are presently incorporated into the Establishment Records for existing RNAs; or, historical use, at the same levels, are not deemed threatening to the values of RNAs. WG.

RESEARCH NATURAL AREA

COMMENTS: Allow prescribed burning in RNAs in accordance with the RNAs Established Record in that prescribed fire (management and natural ignition) may be used to maintain fire dependent ecological processes and to provide a natural range of fuels, understory vegetation, and successional stages where specific direction is not provided, or modification is needed. Prescribed fire plans in these areas should be developed and approved by the Research Station Director.

612, 1181

RESPONSE: The entire Management Prescription 2.2 in the Revised Plan was modified to incorporate all policy and direction identified in FSM 4063 relevant to prescribed fire. All recommendations proposed were not adopted because they either: restate FMS direction; or are presently incorporated into the Establishment Records. WG

RIPARIAN - FISHERIES

Habitat Protection

COMMENTS: Protect fish (mostly cutthroat trout) and fish habitat and restore some past damage to these areas from logging and grazing. The Preferred Alternative does not do enough to effect needed change; support stronger management.

13, 62, 136, 150, 157, 158, 162, 168, 174, 178, 181, 194, 208, 226,
271, 278, 282, 308, 318, 323, 400, 519, 610, 621, 627b, 629, 631, 640,
643, 651, 652, 659, 662, 666, 697, 739, 1177, 1243, 1327, 1328, 1364,
1365, 1367a, 1369, 1446, 1448a, 1458

RESPONSE: The Revised Plan places more emphasis on fisheries. It contains new goals for fisheries and special objectives and guidelines to identify and better protect all native cutthroat trout habitats. DD

Specific Habitat Protection

COMMENTS: City of Irwin supports cutthroat trout habitat protection because it is valuable in the Palisades region for aesthetic and economic reasons.

1244

Burns Creek, a tributary of South Fork of the Snake, is one of the few spawning streams left and should be protected.

632

Garns Mountain roadless area supports the most important tributaries of the South Fork of the Snake including Burns Creek and Pine Creek.

1337

RESPONSE: The Revised Plan recognizes the aesthetic, economic, and scientific values of maintaining viable populations of native cutthroat trout and new goals, objectives, and guidelines were developed to identify and better protect all native cutthroat trout habitats. DD

COMMENTS: Extend boundary widths in Island Park and Madison Plateau subsections to 300 feet unless site-specific scientific data indicates otherwise.

1446

RESPONSE: The boundary width used within these subsections was based on an evaluation of the geology, landform, and slope. During project planning, they can be increased or decreased based on site-specific analysis. DD

Analysis Flaws

COMMENTS: Recommends using Prescription 2.8.1 to expedite recovery rates and to achieve a higher level of quality cutthroat trout habitat. (CROSS

REFERENCE: Riparian, Stubble Height)

FS-7

RESPONSE: Although Prescription 2.8.1 would expedite recovery and achieve a higher level of quality cutthroat trout habitat than the selected prescription, the Revised Plan strengthens the selected 2.8.3 Prescription by

RIPARIAN - FISHERIES

adding new goals, objectives, and guidelines to identify and better protect all native cutthroat trout habitats. DD

COMMENTS: Cutthroat are declining in upper Snake, and less than one percent of observed fish in Warm River are cutthroat. In the Greater Yellowstone Ecosystem, Yellowstone cutthroat exist in only ten percent of historical stream habitats due to habitat degradation, yet planning documents fail to address this issue in any substantial manner.

643

RESPONSE: The population status of native cutthroat trout on the Forest and throughout their entire home range is described in the FEIS and in the Biological Evaluation for native cutthroat trout. The Revised Plan contains new goals, objectives, and guidelines to identify and better protect all native cutthroat trout habitats. DD

COMMENTS: Table III-7 portrays a bleak picture of cutthroat trout status, and though Alternative 3M included improvements over past management, it is not pro-active enough in managing timber harvest and livestock to maintain and restore Yellowstone cutthroat.

643

RESPONSE: The Revised Plan strengthens the 2.8.3 Prescription by adding new goals, objectives, and guidelines to identify and better protect all native cutthroat trout habitats. DD

COMMENTS: For all streams found to contain native trout, the Plan needs a standard requiring the immediate adoption of a minimum 300 foot buffer zone and minimum 6" stubble height, with road closures effectively implemented and grazing management plans adjusted to protect streams.

1276

RESPONSE: The buffer widths and stubble-height requirements adequately protect native trout habitat. In addition, the Revised Plan contains new goals, objectives, and guidelines to identify and better protect all native cutthroat trout habitats. DD

COMMENTS: Stream classifications systems and/or riparian area sensitivity levels should be established to evaluate importance of each stream.

697

RESPONSE: This recommendation was considered but later dropped. The Revised Plan allows for additional analysis to be used, as needed, to address site-specific situations. The Revised Plan also contains new goals, objectives, and guidelines to identify and better protect all native cutthroat trout habitats. DD

COMMENTS: Management actions to date by federal land managers have not adequately protected or improved the condition of federally managed watersheds and riverine ecosystems in the Region. Existing national forest management

RIPARIAN - FISHERIES

plans do not reflect current science because a comprehensive, landscape level conservation strategy is lacking.

1367a

RESPONSE: The Forest Service is involved in many on-going, broad scale conservation efforts. The Intermountain Region is participating in the Interior Columbia Basin Ecosystem Management Project, the implementation of the Inland Native Fish Strategy, and several species-level conservation strategies. The Revised Plan incorporates many of the conservation measures discussed in these broad scale conservation efforts. DD

COMMENTS: The most effective strategy to ensure the long-term health of the Region's watersheds and fish habitat in the region is to a) protect biologically key watersheds and riparian areas from potentially destructive management activities, and b) take all necessary steps to prevent irreversible damage to these areas from landslides, mass erosion, sedimentation, wind drying and wind erosion.

1367a

RESPONSE: The Revised Plan designates 17 of the 39 Forest watersheds as Native Trout Watersheds which receive special management emphasis, including protection. All Research Natural Areas and Special Management Areas (areas with unique cultural, botanical, geological, or zoological values) are identified and receive special management emphasis, including protection. DD

Specific Alternative Support

COMMENTS: Supports Alternatives 4, 5, and 6 because cutthroat trout are a "sensitive" species and a maximum number of miles should be protected for fish and fishing.

1206

Support Alternative 6 because it provides for a reduction in the number of stream crossings from the present number of 5,680 to 1,204. Would end all timber harvest in head water areas, and reduce the detrimental effects of roads and OHV use the most.

1367b

RESPONSE: Alternative 6 was not selected, because it did not provide the overall advantages to all the resources that Alternative 3M does. The Revised Plan places a higher emphasis on fisheries. It contains new fisheries goals and new objectives and guidelines to identify and better protect native cutthroat trout habitats. DD

Fishing and Fisheries

COMMENTS: Does not support fish habitat improvements that emphasize recreational fishing opportunities.

1273

RESPONSE: The Revised Plan provides direction to plan and implement a variety of fish habitat improvements. Whether these improvements benefit fish habitat, recreational fishing, or both, is determined through site-specific

RIPARIAN - FISHERIES

analysis which evaluates ecological capabilities, social needs, and economic needs. DD

COMMENTS: Trout could be one of the Targhee's most sustainable harvests but lack of trout is caused by the inability of the streams to support fish food chains and to supply sufficient sensitive breeding areas.

1392

RESPONSE: The ability of a particular stream to support trout is determined by its biological potential and the amount of fish mortality (fishing pressure). The majority of fish-bearing streams on the Targhee are in a "good" condition class. Those that are below a "good" condition receive greater emphasis under the Revised Plan. The Revised Plan also contains new goals, objectives, and guidelines to identify and better protect native cutthroat trout habitats. DD

COMMENTS: Public fishing access points need to be addressed more thoroughly.

1276

RESPONSE: Public fishing access sites were analyzed early in the planning process (refer to Analysis of Management Situation document). No new sites are planned for development, although maintenance and minor improvements to existing access sites is expected. DD/AS

COMMENTS: Fishing can potentially impact population and behavior of fish species.

1365

RESPONSE: The Targhee coordinates with Idaho Fish and Game and Wyoming Game and Fish when planning and implementing activities which could impact the level or type of fishing. DD

Alternative 3M

COMMENTS: Does not support Alternative 3M Riparian Management because on-going surveys will show cutthroat trout populations are in poorer condition (DEIS Table II-I) and that subspecies will be nominated for consideration as threatened and endangered under Endangered Species Act.

308, 1367a

TNF should be using the criteria prescribed by INFISH. It does not appear the Plan has adequately considered the study.

FS-7, 1367a

RESPONSE: The Revised Plan includes the eight riparian goals from INFISH; new objectives to survey native trout populations and habitats, to define recovery needs and opportunities; and new guidelines to improve management of livestock grazing. It designates 17 of the Forest's 39 primary watersheds as Native Trout Watersheds and places more emphasis on protection and restoration of native trout habitats and populations. DD

RIPARIAN - FISHERIES

COMMENTS: 3M standards and guides unfairly single out timber and grazing as contributing to declining fisheries.

432

RESPONSE: The effects of timber harvest (including road construction and use) and livestock grazing on fisheries resources is evaluated in the FEIS. Effects vary by alternative based on the amount of timber harvest and livestock grazing permitted. Alternative 3M is selected as the "preferred" alternative, because it provides the best balance for all resources within an acceptable level of environmental effects. The standards and guidelines found in the 3M Alternative meet the desired future conditions of the Revised Plan.
DD

COMMENTS: Could not find any discussion why the key indicators in 3M were the preferable conditions (e.g., estimated thresholds of minimum stream miles with adequate habitat to support cutthroat trout.) Should be presented in an analysis.

1177

RESPONSE: The indicators in the FEIS display the effects between alternatives for specific aspects of each alternative. The indicators do not represent good or bad conditions or outcomes. The rationale for selecting the Preferred Alternative 3M is specifically described in the Record of Decision. DD

COMMENTS: Recommends the NFMA and FSM should be included as central reasons for revising the Plan, and the ESA should be used as a planning tool to accomplish the purposes of the NFMA and FSM.

1446

RESPONSE: The National Forest Management Act and related FS Manuals have not changed substantially from the time the original Forest Plan was prepared. The original Forest Plan and the Revised Plan are in compliance with NFMA. The Endangered Species Act was a primary consideration in preparing the Revision and its provisions are addressed. In many ways, ESA serves as part of the foundation for the Revision. DP

COMMENTS: The DFPR should include existing populations of cutthroat requirements and population trends to each species.

1364

RESPONSE: Management of fish populations is the responsibility of the States. The Revised Plan contains several major objectives including the need to coordinate with the States of Idaho and Wyoming to reassess the health of native cutthroat trout populations throughout the Forest, define species recovery needs, and determine which habitats are vital to recovery. DD

COMMENTS: Page III-58, Designated Wilderness - Opportunity Class I, Objective I: Suggest the Targhee National Forest adapt the State of Wyoming's Fishery Management Plan for wilderness fisheries because this is a state jurisdictional responsibility.

389

RIPARIAN - FISHERIES

RESPONSE: The Targhee coordinates with the States of Idaho and Wyoming in the management of wilderness resources, including fisheries. The Forest Service has the responsibility to coordinate with State fish managers to ensure that fish stocking does not compromise Federal interests (e.g., compliance with the Endangered Species Act, and Wilderness Act). This direction is in accordance with Forest Service Manuals 2640 and 2323.3 and the agreement between Forest Service, Bureau of Land Management, and the International Association of Fish and Wildlife Agencies entitled "Policies and Guidelines for Fish and Wildlife Management in National Forests and Bureau of Land Management Wilderness".
DD/MO

COMMENTS: It would be beneficial that direction be given for the protection and expansion of any genetically pure native fish species in wilderness regardless of opportunity class.
1273b

RESPONSE: Direction in the Revised Plan for wilderness management allows for this. In addition, the Revised Plan contains new goals, objectives, and guidelines to identify and better protect all native cutthroat trout habitats, regardless of whether fish are found within wilderness designated areas.
DD/MO

COMMENTS: Page III-20 Table III-4, Fish Bearing Streams: Change the text and table by adding a footnote to the table for clarification, because neither indicate the type of fish considered for this classification.
389

RESPONSE: The term "fish" refers to all fish, regardless of species. Not all streams are fish bearing. DD

COMMENTS: The DEIS Page IV-18, Wildlife Associated with Aquatic Ecosystems: The Forest suggest this resource element be included in this part of the document by including cutthroat trout habitat. This section makes no mention of impacts to any fish species, which seems inappropriate, given the ability of fish community structure and abundance to reflect watershed and riparian conditions. Include this as part of the document.
389

RESPONSE: The environmental consequences to fisheries habitat are analyzed under the preceding headings entitled Riparian and Water. DD

COMMENTS: Page III-6, 7 Aquatic Riparian Resources and Watershed: Listed goals are incomplete, recommends defining as general goal of maintaining natural conditions for aquatic life, or to fully support attainable beneficial uses for the non-cutthroat trout streams.
1362

RESPONSE: The Revised Plan contains eight new fisheries goals adopted from the Inland Native Fish Strategy. DD

RIPARIAN - FISHERIES

Fisheries and Stubble Height

(CROSS REFERENCE: Riparian, Stubble Height)

COMMENTS: Recommends a minimum of six inches stubble height for existing and potential cutthroat trout habitat and of streams that affect cutthroat trout habitat in a watershed.

766

RESPONSE: The stubble height requirements apply at the end of the grazing period. In most cases, a 6" stubble will remain at the end of the growing season, which is usually adequate to maintain and restore stream and riparian habitats and meet water quality standards. If site-specific analysis shows that the Plan standards will not maintain and restore stream and riparian habitats or will not meet water quality standards, then more restrictive grazing standards will be implemented. DD

COMMENTS: Problems with using stubble height as a monitoring tool are determining which plant species are being measured for stubble height and if these criterion allow for perpetuation of undesirable plant species (i.e. Kentucky blue grass).

1446

RESPONSE: The criteria for selection of key species used in monitoring of stubble height addresses this question in detail. Refer to the current version of the Targhee Rangeland Monitoring Protocol (1997). DD

COMMENTS: The DFPR should adopt the Beaverhead Riparian Guidelines rather than the Riparian Forage Utilization, DFPR III-21.

697

RESPONSE: The Targhee reviewed the Beaverhead Guidelines while preparing the Final Revised Plan and incorporated those aspects of the guidelines that are applicable to the Targhee's situation. Additional standards, such as streambank stability, will be developed within five years. DD

Stocking Issues

COMMENTS: Does not support the DFPR Designated Wilderness - Opportunity Class III, Page III-63 to III-65, that gives direction to stock non-native fish in Wilderness Areas.

1273b

RESPONSE: Permitting the stocking of native and non-native fish into only those waters previously stocked by State Fish and Game Departments is in keeping with Forest Service policy direction. The Forest Service has the responsibility to coordinate with State fish managers to ensure that fish stocking does not compromise Federal interests (e.g. compliance with the Endangered Species Act, and Wilderness Act). This direction is in accordance with Forest Service Manuals 2640 and 2323.3 and the agreement between FS, BLM, and the International Association of Fish and Wildlife Agencies entitled "Policies and Guidelines for Fish and Wildlife Management in National Forests and Bureau of Land Management Wilderness". DD/MO

RIPARIAN - FISHERIES

COMMENTS: Page III-59, Designated Wilderness - Opportunity Class I, Biological Elements, Fish and other Aquatic Resources: Recommends modifying this verbiage to accurately reflect states' rights to stock fish in waters contained in this jurisdiction.

389

RESPONSE: The Forest Service has the responsibility to coordinate with State fish managers to ensure that fish stocking does not compromise Federal interests (such as compliance with the Endangered Species Act and Wilderness Act). This direction is in accordance with Forest Service Manuals 2640 and 2323.3 and the agreement between Forest Service, Bureau of Land Management, and the International Association of Fish and Wildlife Agencies entitled "Policies and Guidelines for Fish and Wildlife Management in National Forests and Bureau of Land Management Wilderness". DD/AS/MO

COMMENTS: The standard for fish stocking should read "non-native" rather than non-exotic.

1273b

RESPONSE: Your comment is acknowledged. The guideline was changed to read "native and non-native..." DD/MO

COMMENTS: Recommends management direction that ensures no stocking of non-native fish that would threaten viability and genetic integrity of any native species.

136, 389, 643, 1273b

RESPONSE: Idaho Department of Fish and Game and Wyoming Game and Fish Department have authority to regulate fish stocking. The Forest Service has the responsibility to coordinate with State fish managers to ensure that fish stocking does not compromise Federal interests (such as compliance with the Endangered Species Act and Wilderness Act). This direction is in accordance with Forest Service Manuals 2640 and 2323.3 and the agreement between Forest Service, Bureau of Land Management, and the International Association of Fish and Wildlife Agencies entitled "Policies and Guidelines for Fish and Wildlife Management in National Forests and Bureau of Land Management Wilderness". DD/AS

RIPARIAN - HYDROLOGIC DISTURBANCE 30%

COMMENTS: What is the basis of 30% constraint? Cite references.

643, 695, 1273b, 1362, 1365

RESPONSE: Research by Cheng (1989) and King (1989) also found that when a watershed approached 25 percent to 30 percent clearcut, changes in peak flows were documented. This change in peak flows has the potential to alter stream channel stability and the amount of sediment being transported.

Cheng, J.D. 1989. "Streamflow Changes after Clearcut Logging of a Pine-Infested Watershed in Southern British Columbia, Canada"; Water Resource Research, V. 25, No. 3, pp. 449-456.

King, J.G. 1989. "Streamflow Response to Road Building and Harvesting: A Comparison with Equivalent Clearcut Area Procedure"; Research

RIPARIAN - HYDROLOGIC DISTURBANCE 30%

Paper INT-401. Ogden, Utah, Utah: USDA-FS, Intermountain Research Station, 13 pp. DM

COMMENTS: Discuss the relationship between water yield and timber harvest (clearcut equivalency) for each watershed. Some watersheds such as Pack Saddle Creek have nearly all of their headwaters subject to clearcutting. (CROSS REFERENCE: Timber, Site Specific)

643

RESPONSE: Total water yield on the Targhee is about 1.4 million acre-feet. Management activities such as timber harvests and methods have the potential to change the timing and amount of water delivered to stream channels which is discussed by subsection in the Final Environmental Impact Statement (FEIS), Chapter III. A discussion on cumulative effects and which watersheds would be effected by alternative is discussed in Chapter IV, FEIS. DS

Constraint Needs to be Better Defined - Recovery

COMMENTS: Define when a logged area is reclassified as no longer disturbed, i.e., how long after canopy is removed does it return to natural canopy? Include a definition of natural canopy.

Reduce water yield recovery to 10-15 years and re-define hydrologic disturbance to canopy with Camas Creek Aspen Project where recovery occurred in approximately 20 years or when sapling stage has been established.

413, 643, 697, 767, 1276, 1362, 1389

RESPONSE: The glossary section of the Revised Plan defines "Hydrologically Recovered Condition" as a vegetative life form where natural canopy coverage is achieved and subsequent streamflow quantities and character (timing and amount) reflect more natural conditions. Within a forested ecosystem this equates to the sapling/early pole life form. This life form is achieved at approximately 20 to 30 years of age, depending upon cover type and inherent site productivity potentials." DM

Constraint Needs to be Better Defined - Wildfire and Timber Harvest

COMMENTS: Is there a difference in the hydrologic effects between openings created by wildfire or timber harvest; does constraint apply only to timber harvest? Watershed cover should be changed to something like 45-50% or non-stock requirements should be changed.

228, 643, 693, 1389

RESPONSE: The Glossary section of the Revised Plan defines "Hydrologically Disturbed Condition" as a "change in natural canopy cover (vegetation removal) or a change in surface soil characteristics such as compaction that may alter natural streamflow quantities and character. Acres of vegetation within a watershed that are in a non-stocked, seedling, sapling or first entry category; acres in roads, acres from other types of mechanical treatments such as roto-beat acres within the sagebrush ecosystem; and burned acres are included in the calculation of hydrologically disturbed." Other types of disturbances (man- and nature-caused) are included in the constraint. Timber recovering time from burns depends on the type of vegetation burned, the

intensity of the burn and the inherent productivity of the site that was burned.

Research by Cheng (1989) and King (1989) also found that when a watershed approached 25 percent to 30 percent clearcut, changes in peak flows were documented. The 30% constraint is a guideline and can be modified based on site-specific conditions. Any change will be documented in a site-specific NEPA analysis. DM

Site-Specific

COMMENTS: Buffalo River and Warm River have approximately 30% of their headwaters in a hydrologically disturbed state and are likely to suffer adverse impacts under any of the alternatives and exhibit impacts which will be "unrecovered" by the end of the coming planning period. The continuation of widespread logging under the guise of "intensive management" or "restorative treatment" will exacerbate forest health problems.

643

RESPONSE: The Buffalo (#10) and Warm River (#12) Watersheds presently exceed the 30% hydrologically disturbed guideline. Any proposed activities that create additional disturbed acres will be analyzed on a site-specific basis, subject to the 30% limit. These watersheds have limited opportunity for activities that would create additional openings until recovery from past disturbances occurs.

Management activities that do not create openings could be conducted. Scheduled and unscheduled timber harvest could occur within these watersheds during this planning period but, would be analyzed on a site-specific basis. DM

Socio/Economic Effects of Constraint

COMMENTS: Display an alternative that illustrates the effects of this constraint on social and economic values.

393

RESPONSE: Consequences, including the 30% constraint, for all alternatives are discussed in Chapter IV of the Final Environmental Impact Statement. A separate alternative is unnecessary. DM

Supports Constraint as Defined in Plan

COMMENTS: Supports concept of 30% disturbance for better protection of watershed.

1276

RESPONSE: Your comment is acknowledged. DM

Constraint Needs to Better Defined - Roads

COMMENTS: Does 30% of the watershed have to be actual area of road, or is there some density of roads that measures 30%? The standard should include,

RIPARIAN - HYDROLOGIC DISTURBANCE 30%

"any road density greater than one mile per square mile should be considered disturbed."

697

RESPONSE: A number of factors are considered when determining the percent hydrologically disturbed (see glossary). The intent of this calculation is to determine how much of a watershed is disturbed using equivalent clearcut acres. The factors used to measure 30% disturbance are converted to acres and compared to the acres in the watershed. Road density is not an appropriate measurement because of the number of factors that are used to calculate the constraint. The measurement should be consistent or at the same scale (i.e., acres). DM

Constraint Needs to be Better Defined - Soils

COMMENTS: Since roads are compacted and are known to alter hydrology, how are they included in surface soils characteristics; what other kinds of soil disturbance are included?

No letter #

RESPONSE: The Glossary section of the Revised Plan defines "Hydrologically Disturbed Condition" as "Changes in natural canopy cover (vegetation removal) or a change in surface soil characteristics (e.g., compaction) that may alter natural streamflow quantities and character. Acres of vegetation within a watershed that are in a non-stocked, seedling, sapling or first entry category; acres in roads, acres from other types of mechanical treatments (e.g., roto-beat acres within the sagebrush ecosystem); and burned acres are included in the calculation of hydrologically disturbed." DM

Constraint Adversely Affects Lodgepole Component

COMMENTS: Add flexibility for vegetation management and timber harvest particularly in lodgepole types.

Constraint ignores lodgepole ecosystem which consists of very deep volcanic soils. Constraint places most of lodgepole component "off limits" to timber management, including salvage, for up to four decades.

If you have sustained yield removal of wood by logging, you will remove 1% of your 100-year old forest each year. The entire forest will be at 30% disturbance. This is not a reason to close the Forest. 30% constraint limits the ability to manage and ignores the responsibility to improve forest health, both inside and outside suitable base.

Constraint has been improperly interpreted as being 30% of the forested area in a drainage. If half of a drainage consists of non-forested land, then up to 60% of the forest in that drainage could be logged before entire drainage would reach 30% limit. This should allow more logging than the present plan permits.

FORPLAN model used "previously logged areas in a non-stocked, seedling or sapling condition" to determine watersheds where management activities are not allowed until over 30% of watershed reaches "mature" stage." It appears constraint is based on "worst-case analysis."

90, 275, 393, 1389

RESPONSE: The 30% hydrologically disturbed condition is a forestwide guideline. A guideline "represents a preferred or advisable course of action that is generally expected to be carried out. Deviation from compliance with a guideline does not require a Forest Plan amendment, but the rationale for such a deviation shall be documented in the project decision document." In Chapter V of the Revised Plan, implementation and validation monitoring of the 30% hydrologically disturbed condition is placed in Forest Priority Group 1. Watershed 10, 11, 12, and 13 (predominantly lodgepole pine) and Watershed 25 are targeted for implementation and validation monitoring. Monitoring will determine if bank instability is occurring within these watersheds and which ones are approaching, or over the 30% constraint, thereby determining the sufficiency of the 30% guideline.

The constraint is determined by looking at all acres within the analysis area (e.g., a watershed) and was incorporated into the re-analysis of the forestwide ASQ analysis.

This analysis is not considered a "worse-case scenario" but based on research conducted by Cheng (1989), and King (1989). Their studies found changes in peak flows were documented when a watershed approached 25 percent to 30 percent clearcut. Changes in peak flows have the potential to alter stream channel stability and the amount of sediment transported.

The Glossary section of the Revised Plan defines "Hydrologically Recovered Condition" as vegetative life form where natural canopy coverage is achieved and subsequent streamflow quantities and character (timing and amount) reflect more natural conditions. Within a forested ecosystem, this equates to the sapling/early pole life form. This life form is achieved at approximately 20 to 30 years of age, depending upon cover type and inherent site productivity potentials." Recovery is not dependent on reaching the "mature" stage. DM

Constraint is Too Restrictive

COMMENTS: Constraint is arbitrary and a flawed human guess without ecosystem or scientific basis or merit; Targhee's concern over more damaging flood peaks is not based on scientific fact and is contradicted by scientific studies (See literature cited). Protecting intermittent and ephemeral drainages should occur only in the muddy season. The rest of the year they should be open for use.

275

RESPONSE: The hydrologic disturbance limitation is a guideline. Research by Cheng (1989) and King (1989) found changes in peak flows when a watershed approached 25 percent to 30 percent clearcut. Change in peak flows have potential to alter stream channel stability and the amount of sediment transported.

In order to improve, maintain or restore the health and proper functioning conditions of Aquatic Influence Zones, ephemeral and intermittent streams are considered in the proper management of perennial streams (Refer to Prescription 2.8.3 Final Revised Plan). DM

RIPARIAN - HYDROLOGIC DISTURBANCE 30%

Constraint is Too Lenient

COMMENTS: Allowing 30% disturbance is inconsistent with goals regarding biodiversity, soils, aquatic, riparian, watershed, municipal watershed, vegetation, wildlife and Threatened and Endangered Species. Allowing 30% disturbance would adversely affect Bureau of Land Management efforts to improve and enhance natural resources on the land. 30% seems too high, given the size of the analysis unit (principal watershed and its subwatersheds).
643, 697, 1401, 1446

RESPONSE: The Glossary section of the Revised Plan defines "Hydrologically Disturbed Condition". An understanding of this definition is needed in order to place it in its proper context. This guideline is consistent with the goals expressed under other resources. As a guideline, the Forest may deviate provided the "deviation shall be documented in the project decision document" and is done to meet other resource objectives. The guidelines would be used at the subwatershed scale for project level analysis. A 30% disturbance will not adversely affect Bureau of Land Management efforts, nor the Targhee's efforts, to improve and enhance natural resources. DM

Constraint Should be a Standard, Not a Guideline

COMMENTS: Standard should be no more than 5% of any subwatershed that is disturbed. The overall percentage should be 20% rather than 30% to stay below the 25-35% canopy removal that has been shown to result in hydrological disturbance. Twenty percent should apply to subwatersheds so that one subwatershed cannot be severely disturbed when others are left undisturbed.

Should be a standard to incorporate greater certainty of protection. "Not more than 30% of any of the 39 principal watersheds..." there needs to be more explicit direction for this goal and it needs to be a standard, not a goal. This guideline should be rewritten as a standard which limits disturbance on the subwatershed level with a more precise definition of "disturbed" provided.

643, 697, 1273b, 1276, 1401

RESPONSE: The hydrologic disturbance limitation is a guideline. Research by Cheng (1989) and King (1989) also found that when a watershed approached 25 percent to 30 percent clearcut, changes in peak flows were documented. The 30% constraint is a guideline and can be modified based on site-specific analysis. Any deviation from this guideline will be documented in the site-specific NEPA analysis.

A guideline "represents a preferred or advisable course of action that is generally expected to be carried out. Deviation from compliance with a guideline does not require a Forest Plan amendment, but the rationale for such a deviation shall be documented in the project decision document." Future monitoring should help determine if this guideline is effective. Based on monitoring data, the Targhee may determine this guideline should be a standard. The Forest Plan would be amended at that time to reflect the change. DM

Implementation

COMMENTS: It should not take two decades to implement grazing standards which address riparian problems.

489

RESPONSE: The standards and guidelines take effect as soon as the Revised Plan is signed. RSM

COMMENTS: Past Plan standards for livestock grazing in riparian areas did not work (i.e., Teton Canyon) so the new Plan proposals won't work either.

444

The Forest Service is well known for optimistic estimates of their ability to protect and restore habitat. The plan should consider that there is already inadequate levels of riparian protection may not be met.

1365

Put into place accountable monitoring of riparian areas and budget so resource protection is achieved.

625a

RESPONSE: New standards and guidelines in the Revised Plan will better maintain the condition of riparian areas. It is unclear if old standards were inadequate or if grazing permit administration was too lax. New standards and guidelines and new rangeland monitoring protocol will maintain good conditions where they exist and improve less than desirable conditions. Standards and guidelines address impacts from recreational use, roads, and mining, as well as grazing. Monitoring items in the riparian and upland section of Chapter V include additional monitoring where concerns for wildlife, watershed or other resources are present. Monitoring for riparian area condition was changed to a Forest Priority Group 1 in the Revised Plan. Available Forest funding may affect the amount of monitoring that occurs in a given year. RSM/WG

COMMENTS: Grazing by livestock should have specific areas designated as a "control" so effects to riparian habitat and species can be interpreted.

438

RESPONSE: The Targhee incorporates the concept of grazing exclosures in the Revised Forest Plan to provide ungrazed areas for comparison with the rest of the pasture in which they are located. Under the Revised Plan, permanently marked monitoring sites are used to monitor trends in stream channels and riparian areas. Interpretation of the effects of grazing and other uses on riparian areas will determine where more stringent management is needed. RSM

COMMENTS: Identify rigorous and ongoing monitoring and implementation plans to prevent overgrazing and enforce compliance with established Standards and Guidelines.

643

RESPONSE: Existing direction for grazing administration on livestock allotments is designed to protect resources and ensure compliance with established standards and guidelines. Utilization studies and exclosures, used as "baseline" comparisons, are monitored to determine if use levels are

RIPARIAN - GENERAL

appropriate. Permittees move livestock when stubble height requirements dictate the need. The Revised Plan includes a cooperative monitoring strategy, including water quality monitoring, between the Targhee and livestock permittees. RSM

COMMENTS: Prove that studies and monitoring data that indicate a 30% utilization on willow will allow full restoration of natural habitat potential.

1369

RESPONSE: This information is from the Region 4 Desk Guide, Page III-33 and is documented in the Revised Plan. RM/WG

General

COMMENTS: Page III-18, Recreation/Objective OHV: Expand this objective to minimize the effects of OHV use on riparian, aquatic, critical and crucial seasonal wildlife habitat. Develop motorized recreation management standards and guidelines to exclude use within crucial seasonal wildlife habitat.

1446

RESPONSE: These concerns are addressed in the Standards and Guidelines for the Aquatic Influence Zone (2.8.3), the Dispersed Camping Management (4.3) and Winter Range (2.7) Prescriptions. Expanding the objectives is not necessary to achieve protection of these resources. AS

COMMENTS: The most visible damage in riparian areas is done by cattle, but since the most restrictive alternative (6) cuts livestock grazing by less than 25%, I would conclude that nobody considers it much of a problem.

1317

RESPONSE: Although grazing livestock can cause damage in riparian areas when cattle are allowed to congregate over long periods of time, other activities, such as roads or dispersed recreation, cause resource damage as well. More stringent standards and guidelines were included in the Revised Plan to better protect these important resource areas. Better monitoring protocol and permittee cooperation should reduce impacts without severe reductions in permitted numbers of livestock.

In Alternatives 4, 5, and 6, cattle grazing is reduced by 12% forestwide. Some sheep allotments, approximately 19%, will be eliminated in the Revised Plan. A Table in Chapter IV of the FEIS shows more specific information. WG

COMMENTS: Agree with the need to protect riparian areas.

1, 22, 24, 26, 30, 31, 43, 50, 53, 60, 73, 156, 157, 158, 162, 168, 174, 175, 176, 194, 195, 201, 219, 227, 244, 252, 271, 356, 357, 359, 360, 382, 610, 611, 631, 665, 690, 695, 697, 1204, 1392, 1459

RESPONSE: Your comments are acknowledged. The Revised Plan includes new standards and guidelines designed to protect these important resource areas. RSM/WG

RIPARIAN - GENERAL

COMMENTS: Offer the highest degree of protection to headwater areas because they affect the entire ecosystem.

631

RESPONSE: Headwater areas are critical to the health of watersheds and ecosystems. Specific protection measures are determined through site-specific analysis. Standards and Guidelines for soil, water, vegetation and other resources are designed to ensure watershed stability. RSM

COMMENTS: The management of AIZ's, riparian areas and fish habitat should be a major objective of Targhee National Forest, but the Plan does not indicate that it is. Support GYC and AWL comments.

1364

RESPONSE: AIZs receive added emphasis in the Revised Plan. Standards and Guidelines are consistent with the Inland Native Fish Strategy (INFISH) and meet or exceed water quality standards set by the states of Idaho and Wyoming. RSM/DD

COMMENTS: Strengthen riparian protection measures by: prohibiting unregulated motorized access to streams, wetlands, riparian areas; regulate/control motorized access to these areas; and Pages III-98, 99, and 120, Roads and Trails: The first line should start, "No new roads, including temporary roads..." To be consistent with protection for the riparian and aquatic habitat, all of the guidelines in this section should be made standards.

F-B(2), F-G-2(2), 34, 41, 42, 45, 136, 157, 173, 179, 180, 181, 185, 187, 190, 203, 209, 212, 226, 252, 271, 273, 356, 357, 359, 360, 392, 490, 496, 632, 643, 650, 659, 687, 690, 766, 1245, 1270, 1314, 1319, 1325, 1331, 1369, 1392

RESPONSE: Prescription 2.8.3 includes guidelines that restrict motorized use in riparian areas. Cross-country motorized travel is not permitted except for recreational purposes, such as dispersed camping, picnicking, or fishing. Monitoring of dispersed recreation sites is scheduled to determine if soil quality standards are being met. All water bodies and wetlands are covered by Prescription 2.8.3. Refer to the definition of a "guideline" that clarifies the difference between a standard and guideline. RSM

COMMENTS: Protect intermittent and ephemeral drainages from impacts only in the muddy season.

275

RESPONSE: The Targhee protects these drainages year-round for a variety of reasons. Sediment entering these drainages during the dry season is flushed downstream during wet cycles. Soil compaction and reduction or loss of vegetation at any time of the year can affect the way these drainage systems work. RSM

Erosion

COMMENTS: Reconstruct the streambanks to increase trout populations.

1242

RIPARIAN - GENERAL

RESPONSE: Streambanks will be rested from overuse to allow bank restoration. Tree revetments will be used to slow water velocities and hold sediment. Reconstruction of streambanks should improve the quality of trout habitat.
RSM

Stream Buffer Zone and/or AIZ

COMMENTS: The 100 foot buffer zone may not be necessary with selective logging and managed grazing.

F-K(4), 51

Buffer zone is good management; continue with that practice and be sure to enforce.

5, 11, 407, 1257

Increase the size of the buffer zone identified in 3M.

156, 1258

Use a buffer zone to prevent erosion.

627

Use buffer zones to exclude logging within 300 feet of water.

664

A buffer zone would protect toads as well as frogs.

1204

Provide the public with a simple, easily identified measure of riparian habitat, such as 100 feet. The current system is difficult to interpret.

1369

Definition in the plan is too ambiguous. A minimum of at least 200 feet should be stated. No mention of buffers for lakes and ponds. These should be identified. The plan indicates there was no timber harvest planned in riparian areas, however it does not include "salvage logging". This should be clarified to include salvage logging also.

58

3M buffers are minimally adequate for areas in Island Park but my need to shift them upward in site specific areas across the Forest.

643

Make boundary widths (Table III-96) wider and a standard. Site-specific analysis takes too long and would require an EIS or FP amendment.

697

Factors such as slope, stream channel stability and fish habitat should be considered when determining appropriate buffer zone width.

389

Vegetation buffer strip for selective harvest (wider buffer for steep slope or erosive soils) within 100 feet of any lotic (moving water, e.g., streams) or lentic (still water, e.g., lakes, ponds) shoreline.

389

Support 150-300 foot buffer zone if that width is sufficient to protect the entire AIZ, otherwise it must be larger.

1276

Watersheds in the Island Park and Madison Plateau subsections have been impacted by resource extraction. Suggest the boundary widths be extended to 300 feet unless site-specific scientific data indicates otherwise.

1446

Page IV-15, First Paragraph: Timber harvest is another impact to riparian areas that should be included as a reason for riparian acres not meeting the DVC.

1446

RESPONSE: Aquatic Influence Zone (AIZ) widths in the Revised Plan exceed the minimum stream protection zones in the Idaho Forest Practices Act. They were developed using PACFISH and INFISH guidelines and on-the-ground knowledge of each ecological subsection. Although the Targhee considered establishing a single width boundary forestwide, ecological and physical differences between subsections could not be addressed using this approach. In some subsections larger AIZs may be necessary, depending on site-specific factors such as soil, existing vegetation, fish habitat protection, condition of drainage systems and so on. Other AIZs may be in better condition and require smaller widths. Overall, AIZs are used to protect streambank and channel stability, water quality and fish habitat. RSM/DD

COMMENTS: Clarify why the AIZ minimum boundary widths for Subsections 3 and 4 are half of those for other subsections.

643

RESPONSE: The Island Park (#3) and Madison Plateau (#4) subsections have narrower boundary widths, because slopes are generally less steep than in other subsections and other geologic factors make the risks for slope erosion and sediment transport lower than other subsections. RSM

COMMENTS: Unfortunately, the Revised Plan promises little in improvement over the existing situation. The lack of an appropriate ecosystem view and application of ecosystem principles is nowhere more evident than in the artificial separation of forest (and other plant community types) dynamics from those of the aquatic/riparian systems. For example, larger trees and snags in the aquatic influence zone (AIZ) are viewed largely as something to be eliminated from the system rather than as a source of continual renewal of large woody debris for habitat for fish and other aquatic biota. Also, the effects of the various prescriptions on the AIZ are not given adequate consideration either separately (e.g., building culverts to accomplish a timber harvest) or collectively (for example, the effects of all the culverts and roads in a watershed or subsection). Finally, the utilization standards for the AIZ are not sufficient to protect fish habitat or other riparian values.

643

Address in-stream quality issues (e.g., instream flow, instream woody debris and other structures, rates, and distribution of sedimentation).

1204

RESPONSE: Aquatic and riparian system dynamics are separated from upland dynamics for ease of discussion. The Targhee recognizes the interconnection between different parts of the landscape, and that animals, nutrients, water, and other components of the environment cross boundaries.

Refer to Wildlife Standards and Guidelines, Description of the Aquatic Influence Zone, for information regarding large trees and snags in AIZs, Objective in Insect and Disease section where salvage is only permitted

RIPARIAN - GENERAL

where needed to attain the goals of the management prescription providing other goals of this Management Prescription [2.8.3] are not adversely affected; Wildlife Guideline; and other changes in the Revised Plan such as maintaining and restoring riparian vegetation to provide an amount and distribution of large woody debris characteristic of natural aquatic and riparian ecosystems.

AIZs are adequately protected by standards and guidelines.

Utilization standards were strengthened for AIZs and will protect fish habitat and other riparian values. RSM

COMMENTS: All perennial streams should have the same protective buffer requirements.

389

RESPONSE: In the Revised Plan buffer widths vary by subsection to account for differences in slopes, erosivity of soils, and other physiographic differences. RSM

COMMENTS: Include specific direction to maintain positive outcome of natural ecosystem processes like fire and insect and disease in the AIZ so intent is clear and ground management conforms to ecosystem management philosophy.

282, 643

RESPONSE: The Goal and the Guideline in Prescription 2.8.3 and the new "Ecological Processes and Patterns" section in the forestwide standards and guidelines provide this information. RSM

COMMENTS: Include additional direction for management indicators and specific direction for maintaining biodiversity in the AIZ.

1194

RESPONSE: New language is added in the Revised Plan in Chapter III that provides additional direction for native cutthroat trout and for maintaining biodiversity in the AIZ. DD

COMMENTS: Expand boundary widths to accomplish goals of minimizing adverse effects, promoting health and function and allowing endemic levels of insects and disease in AIZ. Use INFISH or PACFISH guidelines as models for all subsections of the Targhee National Forest. Use language that would limit new stream crossings and remove old ones within those areas.

1361

RESPONSE: The boundary widths described in the Revised Plan were developed using PACFISH and INFISH guidelines and site-specific knowledge of each ecological subsection. New language from the INFISH strategy is added to the Revised Plan to emphasize AIZ protection. DD

COMMENTS: Forest must take greater initiative to guarantee that AIZ's are fully protected.

643

RIPARIAN - GENERAL

RESPONSE: The Revised Plan strengthens protection of these vital resources through standards and guidelines. Better monitoring protocol should provide data to determine if standards and guidelines are effective. As new protection methods are developed, the Targhee will analyze and adapt management if necessary. RSM

COMMENTS: The standard that no burning of mechanized treated wood residue occur within the bankfull channel should be expanded to apply to the entire AIZ.

643

RESPONSE: The guideline for minimal mechanized treatment of wood residue in AIZs should adequately protect streams. RSM

COMMENTS: The standard is too weak for allowing livestock watering facilities. Should read "none" will be allowed in AIZ.

643

DFPR III-99 and III-100 should read that proposed livestock improvements should not be permitted within riparian vegetation.

1276

RESPONSE: The standards in the Revised Plan adequately protect AIZs. RSM

COMMENTS: DFPR IV-1, woefully inadequate section, especially since two of the objectives in Chapter III are missing. Section should include specific tasks, rather than objectives, and should contain many more than those given here. Tasks should be provided for each subsection with level of detail matching that given for Designated Wilderness Prescriptions (Page IV-2). Lacking this detail, it is hard to believe Targhee National Forest is serious about protecting the AIZ.

282, 643

RESPONSE: The two objectives referred to had no timeframe for execution and were changed to goals in the Revised Plan. The objective that was included without a timeframe was deleted. This is discussed in the new section entitled "Ecological Processes and Patterns." The Targhee is unable to provide more detail in a programmatic Plan. Site-specific analysis will provide detailed information at a finer resolution. RSM

COMMENTS: Add a guideline to Prescription 2.8.3 encouraging the adoption of a cooperative livestock management strategy between Forest Service and Bureau of Land Management (BLM) where feasible when a stream crosses both ownerships of adjacent Forest Service and Bureau of Land Management land.

1446

RESPONSE: Where possible, the Targhee uses the Coordinated Resource Management (CRM) program to manage adjacent grazing allotments that are administered by the BLM and the Forest Service. The CRM approach helps resolve site-specific conflicts. A guideline is not necessary, since the process is in place as described in FSH 2209.21. The Revised Plan does not restate handbook policy or direction. The Forest currently uses the CRM

RIPARIAN - GENERAL

approach, as demonstrated by the existing CRM effort in the Medicine Lodge portion of the BLM Resource Area and the Dubois Ranger District. WG

COMMENTS: Provide more information on how the Forest will restore/maintain AIZs in ways that produce desired resource values, products, protection, restoration, enhancement, interpretation and appreciation of these areas. The only standard given is stubble height which is not consistent with best science.

282, 643

RESPONSE: All the standards and guidelines in the Revised Plan that specifically relate to AIZs are designed to restore or maintain desired resource conditions. The monitoring section addresses the ways goal accomplishments are verified. Monitoring protocols for recreation and rangeland use are included to determine if goals and objectives are being met. WG

Specific Recommendations

COMMENTS: Page III-7 under Aquatic Resources: delete "where feasible". This shows bias toward forest uses and not conservation.

341

RESPONSE: The Targhee included "where feasible," because this particular guideline deals with existing uses. For example, in some cases it would not be feasible to attempt to restore vegetation if the site is not capable or does not have the potential to support a preferred vegetation type. Any new proposed uses would have to meet all Standards and Guidelines. RSM

COMMENTS: Do not delete the paragraphs on Pages III-35 and III-47. These provided clear direction on management prescriptions.

489

RESPONSE: The Revised Plan retains this material. RSM

COMMENTS: Clarify Objective 3 and discuss what will be done to meet this objective. It is unclear the way it stands now.

282

RESPONSE: The objective reads, "Manage wood residue (natural and human-made), including fuelwood, to maintain or restore ecological health and function." Standards and guidelines throughout the Revised Plan describe, in detail, amounts and sizes of wood that should be left after management activities to benefit soil productivity, wildlife, and fisheries, without compromising fire hazard limits. The objective reiterates, or summarizes, the importance of this wood for ecological health and function. RSM

COMMENTS: More details must be provided as to exactly what set of circumstances would lead the Forest to propose commercial salvage, fuelwood cutting, etc. in the AIZ.

643, 766

RIPARIAN - GENERAL

RESPONSE: Site-specific analysis will provide detailed information about on-site conditions that would allow commercial salvage or fuelwood cutting in an AIZ. Potential impacts to other resources would be considered, and standards and guidelines that require protection of riparian-dependent resource values in AIZs would be met. RSM

COMMENTS: Objective #1 should be replaced with a firm commitment to remedy offending stream crossings.

643

RESPONSE: Refer to the Standards and Guidelines for Roads and Trails in Prescription 2.8.3. The Targhee considered changing the wording on this particular objective but decided to retain the original language. The objective commits the Targhee to identify where problems exist, setting priorities for resolving problem stream crossings, and scheduling them for restoration. RSM

COMMENTS: Range Objective #4 states a streambank stability standard will be established in 5 years. Targhee National Forest should do it sooner.

489, 643, 697, 766

RESPONSE: The objective states, "Within five years after the signing of the Record of Decision, establish a stream bank stability (trampling disturbance) standard correlated to stubble height at the hydric greenline (HGL)." The Targhee set a flexible timeframe, since realistically, it may take that long to gather necessary data and correlate it to stubble height at the hydric greenline. RSM

COMMENTS: Map and present to the public a detailed description of all seriously degraded riparian areas and watersheds.

1365

RESPONSE: Summary information on watershed and stream conditions, based on available inventory information, is provided in the FEIS. This is sufficient for the purposes of forest planning. RSM

COMMENTS: Reinstate discussion about riparian habitats into the preferred alternative.

389

RESPONSE: The FEIS adequately describes conditions of the resources by alternative on the Forest. RSM

DFPR/DEIS Comments

COMMENTS: Class I, II, III aquatic/riparian goals from the EA are not in DFPR. (The EA in question is the draft wilderness EA.)

1277

RESPONSE: The Targhee must meet Wyoming water quality standards for wilderness, so there is no need to reiterate those standards for class I waters. The goals are implicit in the Revised Plan. RSM

RIPARIAN - GENERAL

COMMENTS: Aquatic/Riparian: Riparian and aquatic monitoring should receive as high a priority as hydrologic disturbances in Watersheds. Recommend a monitoring program to emulate a pulsed monitoring format for watershed and stream restoration.

1446

RESPONSE: Monitoring of Water Quality Limited streams is a Priority 1 item. Hydrologic disturbance is a Priority 2 Item. RSM

COMMENTS: Page II-19, Table II-1 Biological/Other Riparian and Water Indicators: The category "M1 cutthroat stream with a minimum of 6" stubble height at HG-L," shows the worse mileage. We can assume there is a mistake here. The preferred alternative likely cannot reach all of the stated riparian and water quality goals if it results in fewer stream miles with 6" stubble than the existing level of management.

1446

RESPONSE: There is no mistake. In order to fully understand the effects of implementing a particular alternative, specialists consider all of the effects shown for each alternative. Neither the existing level of management nor Alternative 3M (the Revised Plan) requires a 6" stubble height; the respective values of 97 and 83 simply represent the miles of cutthroat trout stream not grazed by livestock. On the other hand, the Revised Plan provides for a 4" stubble on all (2,863 miles) fish-bearing streams. The existing level of management provides for a 4" stubble on only 323 miles of fish-bearing stream. DD

COMMENTS: Page III-6, Last paragraph: Other "natural causes" such as high water runoff and floods would be more likely to cause changes in stream channel stability than avalanches in this area. This point should be expanded in the FEIS.

1446

RESPONSE: Your comment is acknowledged. High water runoff and floods are more likely to cause changes in stream channel stability. Streams in the Teton Range subsection (Teton Creek) are subjected to avalanches which frequently deposit large quantities of rock and trees in channels, causing them to readjust. Avalanches are an example of a naturally caused change to channel stability. No change is needed in the FEIS. RSM

COMMENTS: Page III-7, Standards and Guidelines - Municipal Watershed: Add standards and guidelines having livestock grazing, timber harvest, camping and all terrain vehicle restrictions to ensure adequate protection of municipal watersheds.

1446

RESPONSE: We dropped the standards and guidelines for municipal watersheds. The Targhee does not have municipal watersheds; instead the Forest has public water systems. Draft management direction for public water systems was issued recently by the Washington Office and the final direction will be in national or regional manuals or handbooks. The Revised Plan does not repeat manual and handbook direction. RSM

RIPARIAN - GENERAL

COMMENTS: Page III-7: Goals/Objectives and forestwide standards and guidelines for wetland types are available but have not been fully developed in the Plan. These need to be included in the FEIS because of the Executive Orders that pertain to wetland protection.

1446

RESPONSE: Refer to Prescription 2.8.3 for more direction on wetlands. The Revised Plan complies with Executive Order 11990, which states, "Each agency shall provide leadership and shall take action to minimize the destruction, loss or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands in carrying out the agency's responsibilities..." (Section 1). The EO is also cited in Appendix A of the Revised Plan. RSM

COMMENTS: Page III-21, Water: In both the DEIS and the Plan Revision, water is included as a biological element, when it is really a physical element. Correct or explain the reasons for the characterization.

1446

RESPONSE: Listing water as a biological element was a formatting, organizational decision to combine soil, fisheries, vegetation, and water where interconnectedness occurs. All water-related resources were "lumped" together in the biological section to accommodate fisheries and riparian vegetation issues. Technically, you are correct. RSM

COMMENTS: Page III-23, Lemhi/Medicine Lodge: The third paragraph indicates no standards for nutrients or any direction as to what forms of nitrogen and phosphorus are to be monitored. Suggest specific studies be referenced in the document to allow understanding why these criteria were used.

1446

RESPONSE: The literature cited below were used to determine which forms of nitrogen and phosphorus would be analyzed:

Bauer, S.B. and T.A. Burton, 1993. Monitoring protocols to evaluate water quality effects of grazing management on western rangeland streams. USEPA/910/R-93-017, Region 10, Seattle. 179 pp.

MacDonald, L.H., A.W. Smart, and R.C. Wissmar, 1991. Monitoring guidelines to evaluate effects of forestry activities on streams in the Pacific Northwest and Alaska. USEPA/910/9/9-91-001, Region 10, Seattle. 166 pp.

The U.S. Geological Survey in Boise, responsible for conducting much surface water quality monitoring, was consulted. The State has standards for ammonia, but available literature state that this form is best considered where a concentrated source of livestock waste exists (such as in feedlots). This is not the situation on the Targhee. There are no State standards for phosphorus. RSM

COMMENTS: Page III-26, Second paragraph from the bottom: Expand the discussion about influence zones to include; topography, geology, location, and season. The second sentence should be rewritten to read "The entire watershed and climate influence..." The third sentence should read "Lakes,

RIPARIAN - GENERAL

reservoirs, ponds, perennial, and intermittent streams and wetlands provide unique..."

1446

RESPONSE: The direct effects of aquatic influence zones on aquatic systems are addressed in discussions about resources at the subsection scale. RSM

COMMENTS: Page III-29, Goals/Objectives/Aquatic/Riparian Ecosystems: Add the following streams to this objective: Pass Creek, Warm Springs Creek, Divide Creek, and West Fork Irving Creek. Unless riparian conditions are improved, the Targhee National Forest will not be able to meet any of its goals related to biodiversity, T&E species, wildlife, soils, aquatic, and riparian protection.

Page III-35, Goals/Objectives/Aquatic and Riparian Ecosystems: Add the following streams to this objective: East Fork Irving Creek, Dry Creek, Middle Creek, West Fork Indian Creek, Middle and East Fork of Dry Creek. Unless riparian conditions are improved, the Targhee National Forest will not be able to meet any of its goals related to biodiversity, threatened and endangered species, wildlife, soils, aquatic, and riparian protection.

Page III-51, Goals/Objectives/Aquatic and Riparian Ecosystems: Add Wolverine Creek to the list.

1446

RESPONSE: The streams listed above are those for which stream channel stability data exist and that indicate conditions are less than desirable.

The Targhee will continue to gather information on other Forest streams and address concerns as they become apparent. The lack of a list in the Revised Plan does not mean the Targhee will ignore the stream. Divide Creek is already listed. RSM

COMMENTS: Page III-95: Second paragraph, change "ecolody" to "ecology". Recommends certain geomorphic types be included in the boundary width that include but are not all inclusive: 100 year floodplain, areas with unstable soils, landslides, and landslide prone areas. Under goals #1 delete the last two words so the sentence ends after word "variation".

1446

RESPONSE: The typing error was corrected. The boundary width includes the 100-year floodplain, areas with unstable soils, landslides and landslide prone areas. Unstable areas are discussed in the forestwide soils standards and guidelines. The 100-year floodplain is typically of concern in areas, such as for campground design or placement, that might encroach on the floodplain. In any event, site-specific analysis addresses appropriate boundary widths based on site-specific factors. The Targhee included "where feasible," because in some cases it would not be feasible to attempt to restore vegetation if the site is not capable or does not have the potential to support a preferred vegetation type. RSM

COMMENTS: Page III-96, Boundary Widths of Water Types by Subsections: Fish

RIPARIAN - GENERAL

bearing streams and non-fish bearing streams should have the same standards because of their importance for watershed cumulative effects analysis.

1446

RESPONSE: The Forest used scientific findings and recommendations from the PACFISH and INFISH Strategies and on-the-ground knowledge of each ecological subsection to design boundary widths. The Revised Plan applies larger boundary widths to fish-bearing stream reaches, because they warrant greater protection than perennial nonfish-bearing stream reaches. During cumulative watershed analysis, boundary widths would be determined by hydrologic characteristics rather than by the presence of fish. DD/RSM

COMMENTS: Page III-99, Paragraph 4: Additional standards on in-stream sediment generated by temporary stream crossings should be developed for the section.

1446

RESPONSE: No additional standards were added. The standards and guidelines will adequately protect streams for permanent and temporary stream crossings. RSM

Miscellaneous - General

COMMENTS: Riparian areas are covered with cabins so cannot assess what condition they are in. Public access to "banks" is gone.

1316

RESPONSE: Cabins in riparian areas occur in only a few areas and are not the norm on the Targhee. Currently, 203 permits for summer homes exist on the Targhee (Chapter III, FEIS). Where summer homes are near streams, most are not located streamside, but are set back from streambanks. Streambank access is available in these areas. This comment probably refers to summer home areas in Island Park, where some development has occurred along streams. Although the Palisades Ranger District has a number of summer homes, most are located around Palisades Reservoir. RSM

COMMENTS: The Draft and the EIS failed to define how channel stability ratings will be measured, who will do it and how ratings will be tracked forestwide.

1369

RESPONSE: Channel stability ratings and a description of their use are included in the new Rangeland Monitoring Protocol. The Targhee uses the Pfankuch method described in the Integrated Riparian Evaluation Guide to assess channel stability. This well-established method provides a good evaluation of channel conditions. Assessments will be completed by Forest hydrology and rangeland management specialists. The information will be compiled and stored in the Supervisor's Office. RSM

COMMENTS: An investment in the health of the riparian area would pay off in improved future productivity (for grazing).

1206

RIPARIAN - GENERAL

RESPONSE: Healthy riparian areas benefit many uses, specifically riparian-dependent plant and wildlife species. Riparian areas help buffer flood flows by absorbing water and slowing water velocities, and they hold water for later use in the riparian area and adjacent stream channel. Other benefits are not yet apparent. There is no question that healthy riparian areas are important. RSM

COMMENTS: The riparian portion of the Plan is well-focused, i.e., it manages the "big picture"; be sure to carry this focus through all other issues related to the needs of fish and wildlife species.

1446

RESPONSE: Your comment is acknowledged. RSM

COMMENTS: The Targhee planning documents present evidence of substantial decline in riparian and aquatic ecosystems. Yet, the planning documents fail to address these issues in any substantial manner.

643

RESPONSE: Planning documents present several discussions on riparian decline, such as the invasion of upland plant species into riparian areas, areas of overuse by livestock and people; and evidence of stable or improving conditions. Henry's Fork and most of the Buffalo River are in good to excellent condition; Moose Creek shows some negative effects from the North Fork Burn and management activities but is also showing good recovery. A Table in Chapter III shows aquatic habitat trends to be mostly stable or moving upward, with conditions mostly "moderate" or "pristine". Preliminary information from fish habitat surveys on more than 200 miles of streams conducted by the Henry's Fork Foundation in 1996 point to generally good to excellent conditions on the Targhee with degraded conditions on non-forest lands. Final results are pending and surveys are continuing.

The standards and guidelines, monitoring plans, and other direction found in the Rangeland Monitoring Protocol address riparian conditions on the Targhee. Adaptive management allows the Targhee to amend the Plan if monitoring shows existing direction is not effective. RSM/WG

COMMENTS: The Plan fails to sufficiently protect riparian areas and species dependent on those areas.

1365

RESPONSE: The Targhee designed Prescription 2.8.3, Standards and Guidelines, and the Rangeland Monitoring Protocol to protect riparian areas and riparian-dependent species. The measures prescribed are based on research findings and work conducted elsewhere. RSM

COMMENTS: The Forest Service is out of compliance with legal mandates. (36 CFR 219.27 (a) (10) (a) (11) and (e).

1367

RESPONSE: Existing laws, regulations, manual and handbook direction, and direction contained in the Revised Plan meet all legal mandates including the above Code of Federal Regulations. DP

COMMENTS: Clarify why the Targhee National Forest did not establish access density guidelines or standards for riparian corridors.

1369

RESPONSE: Riparian areas tend to be long, narrow features, generally too narrow to be properly defined at a forestwide scale. For that reason, road density guidance was not established for these areas. Instead, enhanced standards and guidelines were designed to protect these areas. Road location and management are more critical than road densities. RSM

COMMENTS: Explain why riparian areas have Desired Future Conditions (DFC) goals instead of standard and guides for watersheds, as other resource areas have.

1369

RESPONSE: Refer to the Aquatic section for Forestwide Standards and Guidelines and Prescription 2.8.3 for Standards and Guidelines for the Aquatic Influence Zone. All resources have goals, standards and guidelines, including watersheds. RSM

COMMENTS: The section on S&P: Biological Elements is "appalling"; it does not begin to address the biological elements of AIZ.

282

RESPONSE: Many of the biological elements referred to are addressed in the forestwide standards and guidelines, subpart Biological Elements. Language in Chapter III was changed to make this format clearer to the reader. DD

COMMENTS: Address how management concerns revised under the Aquatic and Riparian Ecosystems section will be handled over the next 10-15 years.

282

RESPONSE: New standards and guidelines will be implemented. Monitoring and inventory methods will be used to determine needs for change in management. RSM

COMMENTS: Unclear how the management of riparian zones has been affected by the Eastside Ecosystem Project (the Inland Fish Strategy).

228

RESPONSE: The Revised Plan contains new direction on management of riparian zones and fish habitat as discussed and described in the Inland Native Fish Strategy. DD

Range of Natural Variability

COMMENTS: It is not correct to assume each stream reach must adhere to the broader pattern (RNV) as is suggested in one of the goals of AIZ prescription.

282, 643

RIPARIAN - GENERAL

RESPONSE: Goal #1 states, "...aquatic ecosystems are managed to promote their health and function within the range of variability, where feasible." In this context, aquatic ecosystems are much larger in scale than individual stream reaches. Goals and objectives for riparian areas that relate to Range of Natural Variability are incorporated into a new section called "Ecological Processes and Patterns, Properly Functioning Condition". DD/RSM

COMMENTS: Objective #2 seeks to establish the RNV for AIZs. Unclear how exactly this could be done and how information could be applied to management.

282, 643

RESPONSE: New language is added to the Revised Plan that describes the process the Targhee will use. Objective 2 was deleted from the Revised Plan. DD

Access

COMMENTS: Obliterate all roads in riparian, wetland and streams. Area should be a grizzly bear sanctuary.

276

RESPONSE: Aquatic Influence Zone Management Prescription maintains and improves grizzly bear habitat. The Revised Plan reduces open roads and open motorized trail densities in grizzly bear habitat. "Core areas" for grizzly bear, with no motorized access, were established in the Revised Plan. MO

COMMENTS: Snowmachines should be excluded from established riparian area buffer zones along the Henry's Fork and Buffalo Rivers to reduce impacts on wintering wildlife.

1276

RESPONSE: The Forest has limited information regarding wintering wildlife populations along the Henry's Fork and Buffalo Rivers. An objective was added to the Revised Plan to gather data about wintering bald eagle populations and winter habitat. Additionally, a guideline was added to minimize conflicts between recreation activities, developments and bald eagle winter habitat. As the Targhee learns more about wintering wildlife along the Henry's Fork and Buffalo Rivers, additional direction may be included and the Plan amended to address these concerns. MO

Vegetation

COMMENTS: All acres on the forest should meet DVC: The 2476 acres not meeting DVC in AIZ in Alternative 3M is too many.

61, 362, 690, 1269, 1365

RESPONSE: The acres and timeframe given for meeting Desired Vegetation Condition are reasonable, especially for the 10-15 year lifespan of the Revised Plan. Attaining DVC on the 2,476 acres may take longer if the Targhee lacks resources and budget to accomplish. The existing condition on some of

RIPARIAN - GENERAL

those acres may require more intensive and expensive restoration, and therefore, recovery is anticipated to take more time. RSM

COMMENTS: See no rationale for allowing new roads in riparian areas, since this is prime wildlife habitat.

1369

RESPONSE: Any new roads proposed are evaluated on a site-specific basis, and, based on the Revised Plan's Standards and Guidelines, riparian values cannot be adversely affected. Any new roads would result if no feasible alternative route exists. Few, if any, new roads are predicted for these areas in the Revised Plan. RSM

COMMENTS: The DVC appears to be a good indicator of the riparian area health.

731

RESPONSE: Your comment is acknowledged. RSM

COMMENTS: Use of DVC alone as an indicator of riparian health is inadequate. Things like sediment load, turbidity and water temperature should also be used/monitored.

1365, 1367

RESPONSE: Refer to the definition of riparian areas in the Glossary of the FEIS. Riparian areas are adjacent to water, not in water bodies. Instream parameters, such as the ones referenced, are monitored and described in the Water Quality section. RSM

COMMENTS: Couple the green-line monitoring with the bank instability monitoring at little additional cost and do both as Priority 1.

489

RESPONSE: The Revised Plan was changed to incorporate this suggestion, and this item was given a Priority 1 monitoring rating. RSM

COMMENTS: Damage to or reductions in riparian vegetation, which can be caused by snowmobile use, leads to problems with the food chain through increased sediment load to streams. (CROSS REFERENCE: Snowmobiles)

697, 1276, 1365

RESPONSE: On-the-ground observation and monitoring indicate snowmobile use does not significantly impact vegetation. Snow acts as a cushion for underlying vegetation, and the damage referenced is not apparent on the Targhee. Snow typically acts as a buffer and no evidence of sedimentation problems have appeared as a result of this use. Most snowmobile impacts relate to conflicts with wildlife, other recreation uses and personal safety. The new practice of "skipping" a snowmobile across a stream may result in additional water quality concerns, but generally, this activity is addressed in county ordinances. RSM

.

RIPARIAN - GENERAL

COMMENTS: Riparian vegetation needs to be kept healthy to be used for grazing livestock, but 3M does not allow enough flexibility in the standards and guidelines to design good, ecologically sound grazing schemes. (CROSS REFERENCE: Range)

432

RESPONSE: Healthy riparian areas benefit many uses. The Standards and Guidelines provide minimum stubble heights and maximum browse utilization needed to maintain healthy riparian vegetation. Monitoring protocols are used to determine if Standards and Guidelines are achieving desired conditions on the ground. If monitoring data indicates a "need for change" in management, the Plan will be amended to address the change.

Livestock grazing under the Revised Plan allows AUM adjustments after a site-specific analysis is completed on active allotments. In some cases, based on site-specific conditions, more stringent guidelines may be applied to achieve a desired condition. On other allotments, where existing conditions are at or exceed the desired condition, less stringent management may be applied. RSM/WG

COMMENTS: Clarify why there are not indicator species for willow habitat in riparian areas for both birds and mammals.

1369

Need to have standards for willow habitat in riparian areas because this is a major public issue; also please address the future management of willow habitat which should promote viability of bird species associated with it.

1365, 1369

RESPONSE: The Targhee did not develop management indicator species (birds, mammals, and so forth) for willow habitat. The Targhee will use the Aquatic Influence Zone Management Prescription as a "coarse filter" approach for maintaining all riparian habitats, including willow, in properly functioning conditions. The Targhee is currently cooperating in a research project on neotropical migratory birds in riparian areas in the Big Hole Mountains. The findings of this study will help the Targhee better manage riparian habitats, including willow habitat. Management activities that are proposed, planned, and implemented at the project level are subject to site-specific NEPA analysis. Special habitat and species needs are considered and addressed in the site-specific analysis of the project area. The Targhee intends to manage Forest ecosystems at properly functioning condition. Four criteria are evaluated in a Properly Functioning condition assessment: structure, composition, disturbance regimes, and patterns. Each of these criteria function within a range of natural variability. Refer to draft document entitled Properly Functioning Condition Process - Draft 1996. WG/MO

COMMENTS: DVC as an indicator for the riparian issue is far too nebulous to provide meaningful direction for forest management, i.e. it has no uniform method to measure anything.

643, 1277

RESPONSE: Desired Vegetation Condition can be measured through monitoring criteria. The Revised Plan glossary includes a modified definition of DVC

RIPARIAN - GENERAL

that reads: "For both riparian areas and nonforested uplands is defined as the specific future condition of rangeland resources, aquatic habitat, and water quality that meet management objectives as identified in the Forest Plan, Allotment Management Plans, or other documents. Additional clarification can be found in the nonforested vegetation section of Chapter III of the FEIS." DVC is established in site-specific or landscape level analysis, based on site-specific factors. WG

COMMENTS: DEIS III-20: Table III-4 gives data for aquatic and riparian conditions by subsection. How is vegetative seral stage defined in this table? That is, on what species is it based? The definition of DVC is non-exact. What criteria were used to classify riparian condition relative to DVC? Were classification methods standardized? How much effort was invested in this classification and when were the data collected? Was any attempt made to verify, validate or calibrate field work to minimize or remove observer bias? We have been informed that these data were collected up to 20 years ago and hence their reliability are highly questionable. Describe the methodologies used to generate these statistics and any limitations in the data so that the reader can weigh the numbers.

389, 643

RESPONSE: District range data files were used to analyze environmental consequences in the FEIS. Range data files are updated annually to capture changed conditions. Range analysis surveys conducted 25 to 30 years ago serve as the baseline for determining change. Although this information is dated, data reliability is high and based on sound principles. All but nine allotments (1,813 acres) have completed range analysis surveys. In 1986, the Targhee converted condition class to ecological status and identified trends. This information was used in the 1991-1992 Analysis of the Management Situation (AMS) Report. Additionally, in 1992, new reporting direction from the Intermountain Region was implemented. "New Measures" used 1986 ecological status data and stratified the information into components used on the Targhee today.

Approximately 66% of the Targhee's grazing allotments have had grazing systems in place for many years (prior to 1980). The Targhee's present LMP grazing utilization standards have been in place since 1980 for all grazing allotments, and livestock use (AUMs) for both sheep and cattle have been reduced over time, where needed. Overall, rangeland resources for both uplands and riparian areas have improved over the last 25-30 years.

The ecological status of a site is measured against the Potential Natural Community (PNC) for the site. PNC is the biotic community that would become established on an ecological site if all successional sequences were completed without interference by humans under present environmental conditions. Natural disturbances such as drought, flood, wildfire, insects, and disease are inherent in its development. The PNC may include acclimatized or naturalized non-native species. Early seral ecological status is 0-39% of PNC; mid seral is 40%-59% of PNC; late seral is 60%-85% of PNC; and PNC is greater than 86%. Change in ecological status is tracked in the range data base and used on a site-specific basis to determine if riparian and upland acres are meeting, moving toward, or not meeting forest plan management objectives.

RIPARIAN - GENERAL

Refer to Process Paper J - Logic Used to Estimate Effects of Livestock Grazing on Riparian and Upland Vegetation for information on how the environmental consequences were analyzed. WG

COMMENTS: The ecological status of riparian habitat may be more beneficial to the ecosystem by remaining in an early seral stage rather than moving to a mid/late-seral stage.

1446

RESPONSE: The Revised Plan provides direction for assessing and managing riparian areas in a properly functioning condition which includes evaluating the amount and distribution of seral stages, along with other criteria, appropriate for the various types of riparian ecosystems. DD

COMMENTS: DEIS III-19: Here we find another example wherein the Forest does not seem to recognize the full scope of the ecosystem management concept. Trees and other upland vegetation in the riparian zone (or the lack of willows) do not necessarily constitute an "ecological concern." Rather than assuming that these changes are negative, they should be viewed in the context of the causative agent(s) at a broader landscape-level. Have these changes resulted from livestock grazing, from natural succession, or other causes?

643

RESPONSE: The Targhee intends to manage Forest ecosystems at properly functioning condition. Four criteria are evaluated in a Properly Functioning condition assessment: structure, composition, disturbance regimes, and patterns. Each of these criteria function within a range of natural variability. Refer to draft document entitled Properly Functioning Condition Process - Draft 1996. DD/DM

COMMENTS: Be more specific when suggesting "you will maintain riparian vegetation in DVC." Wording is ambiguous, could apply Habitat Conservation Assessments and Management Recommendations developed by the USFWS for Idaho Species.

1249

RESPONSE: Desired Vegetation Condition is a reliable indicator that can be measured with various monitoring criteria. The DVC definition was modified in the glossary of the Revised Plan to read: "The specific future condition of rangeland resources, aquatic habitat, and water quality that meet management objectives as identified in the Forest Plan, Allotment Management Plans, or other documents. Additional clarification can be found in the nonforested vegetation section of Chapter III of the FEIS." WG/MO

Grazing

COMMENTS: Grazing in riparian areas must be greatly restricted and has already caused damage.

26, 204, 293, 325, 339, 340, 354, 356, 357, 359, 496, 650

RESPONSE: The Targhee is managed under the multiple-use, sustained-yield concept. Grazing has long been recognized as a legitimate use of National

RIPARIAN - GENERAL

Forest System lands and is balanced with other multiple uses such as recreation, wildlife, timber, mining, and water, among others. The FEIS and Revised Plan predict a reduction in livestock use to meet numerous management objectives (ecosystem, wildlife or riparian). Actual adjustments (up or down) in AUMs will occur after site-specific analysis is completed on each active allotment. The Revised Plan incorporates more stringent riparian guidance that should result in improved riparian areas. The standards and guidelines for livestock management and riparian areas are found in the forestwide range standards and guidelines in Chapter III of the Revised Plan. WG

COMMENTS: Fence off riparian zones from cattle and install access ladders for fisherMen.

204

Cattle should be excluded from riparian areas.

F-K(4), 175, 212, 438, 609, 697, 1203, 1204, 1330, 1331, 1392

RESPONSE: The Revised Plan provides adequate direction for allowing grazing in an environmentally sound manner. Where fencing is used to protect riparian areas, public access can be provided. WG/DD

COMMENTS: Locate more stock tanks away from streams to help distribute animals away from water.

173, 265, 697, 1240

RESPONSE: The Targhee uses this approach when water developments are installed to distribute and disperse cattle and reduce the opportunity for cattle to congregate in small areas. Generally, water development and placement are discussed in a site-specific NEPA document or Allotment Management Plan rather than in the Forest Plan. WG

COMMENTS: Set up a dispersed salting regime to keep cattle out of riparian areas.

204

RESPONSE: The Revised Plan includes forestwide direction for livestock salting. Specific salting requirements are included in the individual annual operating plans for each allotment on the Forest. WG

COMMENTS: Use innovative methods to reduce intensity of animals in riparian areas and monitor. 3% reduction of AUMs (in 3M) may not be good enough.

625a

RESPONSE: The AIZ prescription provides standards and guidelines to maintain and improve riparian areas. Range specialists work with permittees in designing effective grazing patterns, water developments, and herding methods to reduce livestock impacts on riparian areas. The FEIS and Revised Plan predict a reduction in livestock use to meet numerous management objectives (ecosystem, wildlife or riparian). Actual adjustments (up or down) in AUMs will occur after site-specific analysis is completed on each active allotment. The Revised Plan incorporates more stringent riparian guidance that should result in improved riparian areas. The standards and guidelines

RIPARIAN - GENERAL

for livestock management and riparian areas are found in the forestwide range standards and guidelines in Chapter III of the Revised Plan. WG

COMMENTS: Identify conflicts between livestock grazing and habitat conservation for all riparian, aquatic, and wetland habitats. Methods for resolution should be developed.

389

RESPONSE: The Aquatic Influence Zone Management Prescription is a "coarse filter" for maintaining all riparian, aquatic, and wetland habitats in properly functioning condition. The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the site-specific level. The Revised Plan is not intended to provide or analyze specific "how to's" of project implementation. WG/MO

COMMENTS: Should implement trampling standard now based on available information from other forests already implementing.

643

RESPONSE: Forests share their different approaches for range and wildlife management. However, information from other forests is generally not indicative of conditions that exist on the Targhee. If correlations are determined to be reliable, additional management direction can be adopted at any time through a Forest Plan amendment. Monitoring for trampling was elevated to a Priority 1 in the Revised Plan. WG

COMMENTS: The frequency of monitoring description for riparian forage utilization should be amended to read "...wildlife, vegetation or other ecological concerns. Each..."

1365

RESPONSE: Your comment is acknowledged and was considered. The components of this monitoring standard remain unchanged. WG

COMMENTS: A guideline should be added to discourage hot season grazing of riparian areas.

1206

RESPONSE: AIZ standards and guidelines provide the necessary framework within which to address problems within individual riparian areas. The season of livestock use is one consideration in managing individual riparian areas. WG

COMMENTS: Develop more specific criteria to characterize what constitutes wildlife overutilization.

389

RESPONSE: Grazing utilization standards apply to plant utilization regardless of animal species (wildlife, livestock, or a combination). The standards and guidelines in Chapter III provide the maximum allowable use regardless of species. Livestock will be removed once the desired utilization level is achieved.

RIPARIAN - GENERAL

Monitoring items for riparian and upland forage in Chapter V reference wildlife concerns and where more monitoring will be done. WG

COMMENTS: DFPR III-20 Make the following a goal: restoration of riparian vegetation back to mesic forbs and grasses. It is unclear if this is the intent of Objective 1 on Page III-20.

1249

RESPONSE: Your comment was considered. The components of the forestwide standards and guidelines and the goals and objectives are adequate and remain unchanged. WG

COMMENTS: DFPR III-15 There are no forestwide standards or guidelines pertaining to amphibians. There is however one forestwide objective for spotted frog habitat. DVC is not defined and therefore this objective does not provide clear direction for maintaining habitat for spotted frogs or other amphibians. Suggest the following objectives be added: avoid use of pesticides/herbicides that may affect breeding sites and occupied aquatic habitat; discourage use of recreational and livestock use in seasonal meadows; prohibit livestock trailing through known amphibian breeding areas, particularly those few areas where the Western Toad exists; protect unknown amphibian breeding sites by prohibiting harvest activities, road construction or livestock concentrated use that will separate ponds, vernal pools or marshes from permanent streams. (CROSS REFERENCE: Wildlife, Amphibians)

643

RESPONSE: DVC is defined in the glossary of the Revised Plan and is analyzed in Chapters III and IV of the FEIS.

Your suggested objectives were not added because the Revised Plan provides adequate analysis and direction to protect amphibians, including the spotted frog. WG/MO

COMMENTS: Under Objective #1 it may be difficult to manage for mid to late seral riparian communities since they are continually undergoing change. The ecological status of riparian habitat may be more beneficial to the ecosystem by remaining in an early seral stage rather than moving to a mid or late seral stage. Add an objective to recruit and re-establish riparian-wetland communities back into these riparian zones.

1446

RESPONSE: The Revised Plan provides direction for assessing and managing riparian areas in properly functioning condition (PFC) and includes an evaluation of the distribution of seral stages, along with other criteria, appropriate for the various types of riparian ecosystems. DD

COMMENTS: Page III-21, Riparian Forage Utilization - B Riparian Vegetation Stubble Height: If the 4" stubble height is applied only to native and desirable non-native species without standards, you may perpetuate unhealthy unstable riparian zones. Recommends the 4" stubble height be used throughout the entire riparian zone.

1446

RIPARIAN - GENERAL

RESPONSE: The standards for riparian vegetation will improve riparian zones.

A 4-inch stubble height requirement at the hydric greenline and a separate 3-inch stubble height away from the hydric greenline will provide a greater level of protection to the hydric greenline. These areas are generally more sensitive to damage by livestock and often receive disproportionately more use than adjacent riparian areas. If the same stubble height requirement were applied to the entire riparian zone, then the stubble height could be exceeded at hydric greenline prior to being met on the adjacent area. This could lead to damage of streambanks prior to reaching an average 4-inch stubble height across the entire riparian area. DD

COMMENTS: Page IV-16, Water Indicators: In addition to stubble height as a monitoring method Forest Service should incorporate two other key factors in fisheries habitat and they are: percent of bank covered with a deep, binding root mass and percent of tree and shrub regeneration along the stream bank end.

1446

RESPONSE: Percent bank covered with deep binding root mass and percent of tree/shrub regeneration along the stream are two studies the Forest uses to monitor long term trend. These studies are called: Greenline Vegetation Composition - designed to identify the species and amounts of plants with or without deep binding root mass; and Woody Species Regeneration - designed to measure woody species regeneration along the greenline transect.

Monitoring items for riparian and upland forage in Chapter V reference where concerns (wildlife or watershed, for example) are present and where more monitoring will be done. This monitoring item is elevated to a Forest Priority Group 1. The techniques for these two studies are discussed in the Integrated Riparian Evaluation Guide, Intermountain Region, March 1992. WG

Timber

COMMENTS: There should be NO vegetation manipulation in riparian or whitebark pine areas at any time. These lands should also be taken out of the suitable timber base.

1273b

Targhee National Forest says in several of the revision documents that unscheduled timber harvest may be necessary within the AIZ; this is most disturbing.

Not aware of any credible scientific research indicated that timber removal has improved riparian values associated with riparian health.

766

Page 19 Clarify the stream buffer paragraph. Unclear what type of riparian or aquatic objectives will require timber harvest and how extensive it would be.

625a

RESPONSE: In Chapter III-99 Timber, the AIZ is removed from the suitable timber base. They are not part of the ASQ. Much of the whitebark areas are also removed from the suitable timber base through the various screens that

RIPARIAN - GENERAL

are used to determine the suitable base, such as steep slopes or low productivity potentials.

Silvicultural prescriptions are only used in the AIZ where they meet AIZ Management Prescription Goals (Chapter III) and are addressed through site-specific analysis. Silvicultural methods may be appropriately used in stands where overstories (such as conifers) might be inhibiting understory species that are important in providing channel stability (such as willows). At a minimum, the Revised Plan meets the guidelines in the Rules pertaining to Idaho Forest Practices Act (specifically those dealing with stream protection). DM

COMMENTS: Recommend the Targhee National Forest review The Conservation Strategy for Henry's Fork Basin Wetlands (Jankovsky-Jones 1996) and use to address wetland plant community management.

766

RESPONSE: The "Conservation Strategy" was reviewed. Category I and II wetlands not protected by other designations (such as RNA, Wilderness, Wild and Scenic River) were added to the 2.1.1 Management Prescription (Special Management Areas). This document identifies baseline or benchmark areas for comparisons with adjacent wetland health conditions. DM

COMMENTS: Clarify how overall forest health and the danger of intense wildfire was considered in management of riparian zones.

228

RESPONSE: The Revised Plan contains new direction on managing riparian and Forest ecosystems in a Properly Functioning Condition and on managing both natural and human-ignited fires. Refer to Ecological Processes and Patterns and Biological Elements in Chapter III - Part 1. DD

COMMENTS: Concerned that the Forest does not currently have sufficient data to characterize the RNV with any degree of confidence. Therefore, could also not understand how the RNV varied on smaller scales. (DFPR III-95, AIZ).

282, 643

RESPONSE: Refer to the Goals/Objectives and Standard/Guidelines pertaining to Properly Functioning Condition (PFC) in the Revised Plan. The Forest is adopting a Regional approach of using PFC assessments. DM

Wildlife

COMMENTS: The basis for determining proposed use levels, on willow and that level's ability to restore willow areas to optimum and historical conditions for wildlife is questionable.

1369

RESPONSE: After refining riparian and upland utilization levels, the Targhee determined that the standards and guidelines will achieve desired results. The standards and guidelines provide for a moderate rate of recovery of degraded riparian and aquatic ecosystems and a moderately high level of fisheries habitat quality. Reference the USDA Forest Service, October 1995,

RIPARIAN - GENERAL

Dixie National Forest, "Effects of livestock grazing at proper use on the Dixie National Forest." WG

COMMENTS: The co-occurrence of frogs and cattle does not constitute evidence that grazing has no effect on frogs or their ability to reproduce and persist in an area.

1277

RESPONSE: The relationship between cattle grazing and frogs is not definitively established. The discussion in the EIS and Revised Plan concerning spotted frogs and livestock grazing is accurate to the extent that available research exists. MO

COMMENTS: Need a timeline for beaver re-introduction in the implementation schedule for AIZ's.

282, 643

RESPONSE: The Revised Plan does not propose any beaver re-introductions. State Fish and Game agencies are responsible for the management of beaver populations. MO

COMMENTS: Re-analyze timber harvest on spotted frog habitat in Alternatives.

643

RESPONSE: No data in literature suggests spotted frogs are dependent upon a particular forested vegetation condition. Timber harvesting may change temperature and humidity conditions, but no specific temperature and humidity conditions required by spotted frogs are given. Spotted frogs are also found in desert areas where adequate water and riparian habitat conditions exist. MO

COMMENTS: Use some mammals (beaver, mink, otter) as good indicators in addition to the birds and amphibians currently proposed.

282, 643

RESPONSE: The Aquatic Influence Zone Management Prescription is a "coarse filter" to maintain aquatic and riparian habitats in properly functioning conditions. All threatened, endangered, and sensitive species are used as management indicator species. This provides adequate management direction for riparian habitats and wildlife. MO

COMMENTS: Several proposals already incorporated should benefit amphibians.

643

RESPONSE: Your comment is acknowledged. The AIZ Management Prescription is used as a coarse filter to maintain aquatic and riparian habitats in properly functioning conditions. This prescription will benefit amphibians. MO

COMMENTS: Include not only spotted frogs but also western toads (*Bufo boreas*).

1204

RIPARIAN - GENERAL

RESPONSE: The western toad, plus numerous other species, were suggested by the public for inclusion as management indicator species. The Targhee's management indicator species include all the threatened, endangered, and sensitive species on the Forest. These are species considered most sensitive to human activities. Habitat available for these species generally provides habitat for less sensitive species. As more information becomes available on western toads, management direction may need to be amended to address this concern. MO

COMMENTS: Page III-19, Riparian: Recommends a review of the document to ensure that management is applied to other issues related to the needs of fish and wildlife.

1446

RESPONSE: No additional draft review documents are scheduled for release. Changes between Draft and Final are based on public comments and new information and do not require another draft. MO

COMMENTS: The biological elements/wildlife standards and guidelines in the AIZ should have specific direction for maintaining biodiversity, riparian functions which maintain habitat, standards for specific species known to be rare or affected by past management practices and additional direction for management indicators.

643, 1401

RESPONSE: The Revised Plan contains specific standards and guidelines for all threatened and endangered species on the Targhee. The purpose of the AIZ is to provide protection and maintenance of Properly Functioning Conditions for the species dependent on the AIZ. More specific standards and guidelines other than those already incorporated in the Revised Plan are unnecessary. MO

COMMENTS: Consider that local changes in hydrology, ground cover, surface moisture, humidity, and temperature resulting from timber harvest may negatively affect spotted frogs and other amphibians.

643

RESPONSE: Rules in the State's Forest Practices Act state, "During and after forest practice operations, stream beds and streamside vegetation shall be protected to leave them in the most natural condition as possible to maintain water quality and aquatic habitat" (Rule 030.07). Also, 75 percent of the current shade must be left over Class I streams (those streams used by fish or for domestic water supplies) per Rule 030.07(e)11. No scheduled timber harvest may take place in Aquatic Influence Zones, and any timber removal must benefit riparian-dependent species, including amphibians. The potential effects are analyzed at the project level, and the activity is designed to avoid negative impacts to the local microclimate. RSM

COMMENTS: Riparian areas do not warrant more protection.

29, 38, 55, 258, 1239, 1240

RESPONSE: See the Aquatic and Riparian Ecosystems section of the FEIS (Chapter III) for a description of the importance of riparian areas (and

RIPARIAN - GENERAL

riparian vegetation), and areas where recreational use (such as OHV or dispersed camping) has caused resource concerns. Also see the description for Prescription 2.8.3 in the Final Revised Plan. RSM

RIPARIAN - STUBBLE HEIGHT

Does Not Support 4-inch Stubble Height - Grazing

COMMENT: Object to this or any standard because wildlife impacts are not accounted for and therefore could unfairly affect livestock grazing.

F-F(6), 267

RESPONSE: Both wild and domestic ungulates are taken into account during monitoring. The Forest Service has no control over wildlife numbers. In areas where wildlife use is excessive, domestic livestock grazing could be affected. DM

COMMENT: The stubble height should not be measured at the end of the grazing period, but at the end of the growing season. This would allow us to continue using various grazing schemes as management tools without being penalized.

432

RESPONSE: Riparian stubble height standards at both the hydric green line (HGL) and away from the HGL are measured at the end of the grazing period. These standards allow for deviations through site-specific analysis. Flexibility is allowed and depends upon the success of various grazing schemes (for example, at the Allotment Management Plan level). DM

Watershed Integrity

COMMENT: Four-inch hydric green line stubble height will not adequately protect integrity of the riparian zones.

308, 634, 643, 644

RESPONSE: Forestwide Standards (Chapter III) ensure that stubble heights, both on and away from the hydric green line, are maintained at the end of the grazing period. Re-growth of riparian vegetation, except possibly the last pasture grazed, should exceed the 4-inch requirement on the hydric green line and the 3-inch requirement away from the hydric green line. Flexibility is allowed and depends upon the success of various grazing schemes. DM

Supports a 4-Inch Stubble Height

COMMENT: Support 4-inch stubble height.

20, 35, 36, 51, 611, 1244, 1391

RESPONSE: Your comment is acknowledged. DM

Monitoring

RIPARIAN - STUBBLE HEIGHT

COMMENT: Concerned there is not anyone accountable if stubble height standards are exceeded.

624a, 1206

RESPONSE: Under the terms and conditions of the grazing permit, the permittee is accountable. The Forest is responsible for allotment administration and accountable for enforcing permit provisions. DM

COMMENT: The monitoring plan fails to ensure that riparian monitoring will either be adequately funded or dictate when livestock are moved.

432, 625a, 766, 1204

RESPONSE: Streambank Trampling and Riparian Forage Utilization monitoring items were changed to a Forest Priority 1 in the Revised Plan. Permittees will assist in monitoring range utilization and soil conditions on their allotments following an established protocol. Funding levels vary and may have an effect on the level or intensity of monitoring in any given year.

Monitoring Item "Riparian Forage Utilization," section "Tolerance, or Variability Indicating Action" (Chapter V) states, "when standard/guideline is more than 5% outside the range." This means that when the standard/guideline is attained or not exceeded by more than 5% of allowable, it is time to move livestock. Stubble height, browse utilization and streambank trampling are used to determine if livestock are being properly managed. DM

COMMENT: Even though the standard is proposed to be monitored at the end of the grazing season, that does not ensure that re-growth between end of grazing and end of growing season, thus concerned how the 4-inch stubble height will be monitored effectively.

317, 444, 766

RESPONSE: Although this statement may be true during periods of extreme drought, in normal years all but the last pasture in a grazing scheme would have ample time for re-growth. The last pasture grazed would leave a 4-inch stubble height which is adequate to allow for properly functioning conditions. (Clary/Webster, Kauffman, Platts etc.). DM

COMMENT: Monitoring of the hydric green line requires a waters edge; therefore no monitoring would occur in seeps, bogs, wet meadows, etc. These types of areas provide habitat values and contribute to biodiversity, for greater than their relative occurrence.

766

RESPONSE: Riparian forage utilization standards pertain to riparian areas away from the hydric greenline such as the type of areas described in this comment. DM

Stubble Height In Theory

COMMENT: Stubble height does not measure the rate of recovery of a riparian

RIPARIAN - STUBBLE HEIGHT

area after a disturbance and is therefore too objective (sic) to allow flexibility needed to manage different/changing range conditions.

432

RESPONSE: Stubble height does not measure the rate of recovery after a disturbance. Stubble height requirements are intended to retain sufficient quantity and quality of riparian vegetation biomass to maintain and restore riparian plant vigor, protect streambanks, trap sediments, maintain and restore habitat for aquatic insects and other wildlife, and restore a source of organic debris to the aquatic system. The Revised Plan (Chapter III) allows for flexibility in the stubble height standard at the hydric greenline to manage different/changing range conditions. Deviations from the stubble height standard are allowed through site-specific analysis. DD

COMMENT: Definition in the Plan too loose; 4-inch stubble height, while good, seems like it should apply to the whole riparian zone, not just the hydric greenline.

314

RESPONSE: A 4-inch stubble height requirement at the hydric green line and a separate 3-inch stubble height away from the hydric greenline provides a greater level of protection at the hydric greenline. The hydric greenline is more sensitive to damage by livestock than the adjacent area and often receives disproportionately more use than adjacent riparian areas. If the same stubble height requirement was applied to the entire riparian zone, then stubble height could be exceeded at the hydric greenline prior to being met on the adjacent area. This could allow damage to streambanks to occur before an average 4-inch stubble height was attained across the entire riparian area. DD

COMMENT: Scientific accountability for stubble height is necessary if grazing is to continue on public lands.

636

RESPONSE: The use of riparian stubble height criteria in managing livestock grazing within riparian areas is well documented in scientific literature. In combination with riparian stubble height requirements, the Revised Plan incorporates a livestock utilization limit on woody riparian plants, a high priority for monitoring of results, and a provision to adjust the standards as necessary to meet objectives for riparian areas. Some references used in development of these stubble height criteria include:

Clary, Warren P.; Webster, Bert F. 1989. Managing grazing of riparian areas in the Intermountain Region. Gen. Tech. Rep. INT-263. Ogden, UT: U.S. Department of Agriculture, Forest Service, Intermountain Research Station. 11 p.

Clary, Warren P.; Kinney, John W. 1994. A photographic utilization guide for Key Riparian Graminoids. Gen. Tech. Rep. INT-308. Ogden, UT: U.S. Department of Agriculture, Forest Service, Intermountain Research Station. 13 p.

Platts, William S.; Raleigh, Robert F. 1984. Impacts of grazing on wetlands and riparian habitat. In: *Developing Strategies for Rangeland Management*. Boulder, CO: Westview Press: 1105-1117.

Platts, William S.; Nelson, Roger Loren. 1985. Streamside and upland vegetation use by cattle. In: *Rangelands* 7 (1): 5-7.

Clary, W.P., Christopher I. Thornton, and Steven R. Abt. 1996 Riparian stubble height and recovery of degraded streambanks. In: *Rangelands* 18(4): 137-140. DD

COMMENT: Stubble height and utilization in riparian areas are excessive according to scientific literature.

389

RESPONSE: The appropriate stubble height and utilization standard used is determined by the objectives set for the Forest. The Targhee evaluates three sets of objectives: 1) provide for a slow rate of recovery of degraded riparian and aquatic systems together with a moderate level of fisheries habitat quality as described in Alternative 1; 2) provide for a moderate rate of recovery of degraded riparian and aquatic systems together with a moderately high level of fisheries habitat quality as designed in Alternatives 2, 3, and 3M; and 3) provide for a rapid rate of recovery of degraded riparian and aquatic systems together with a high level of fisheries habitat quality as designed in Alternatives 4, 5, and 6.

Scientific literature supports the prediction that the Revised Plan achieves the set of objectives described above. The scientific literature used to design the alternatives includes those listed in the response immediately preceding this. DD

COMMENT: Studies show sediment entrapment and retention (of overland flow) is better where vegetation is shorter than the 6" stubble height proposed in the standards and guidelines, unless ground cover is <50%.

432

Ongoing research findings by the University of Wyoming indicates a possible counterpoint to the scientific support of higher stubble heights. Results of the cited study (Grant. "A settlement of sediment" in *Beef Today*, May 1996), show streambank vegetation clipped continuously to 1-inch stubble height had similar impacts as taller heights on: sediment deposition (traps just as much sediment when streams overflow); plant productivity (production just as good as 6" stubble height); and, plant health (biomass height did not change with stubble heights).

F-F(6)

RESPONSE: First, research conducted by Abt, Clary and Thornton (1994) entitled "Sediment Deposition and Entrapment in Vegetated Streambeds" shows that the shorter stubble heights were as efficient in producing sediment deposition as taller stubble heights. The difference was that the taller stubble heights

RIPARIAN - STUBBLE HEIGHT

(blade lengths) increased retention potentials (for example, bank building). Second, continuous clipping to a 1-inch stubble height ignores the effects large ungulates have on streambanks being grazed to that same 1-inch stubble height (for example, compaction and its effect on riparian functioning). One of the reasons for using a 4-inch stubble height standard is to protect banks and woody browse, based on findings from Clary and Webster (1989), Kovalchik and Elmore (1992), and Platts (1981). DM

COMMENT: Measuring stubble height at the HGL is inadequate and should use Beaverhead Riparian Guidelines.

697

RESPONSE: According to the Beaverhead Riparian Guidelines for measuring stubble height and woody browse, "This is measured in two places: 1) along the water/soil interface known as the "green line" and 2) away from the stream channel in the "key area" where especially palatable species exist." The Targhee uses a similar process and similar parameters for monitoring purposes (for example, stubble height, percent utilization, browse utilization and bank trampling). DM

COMMENT: Research shows that both bank stability and regeneration of woody species are protected when stubble heights are enforced.

1206

RESPONSE: Your comment is acknowledged. The Revised Plan is specific on its stubble height recommendations and the time it is measured. Trampling and browse utilization are also collected to make sure that stubble height recommendations are achieving desirable objectives. DM

Supports a 6-inch Stubble Height

COMMENTS: Since riparian areas influence much of their watersheds, support a 6-inch hydric green line stubble height to return riparian areas to proper functioning condition most quickly and better protect habitat for native cutthroat trout.

314, 389, 643, 690, 695, 719, 766, 1204, 1206, 1276, 1401

Stubble heights should be 4-6 inches within streamside riparian areas, not just the green line; 3-4 inch stubble heights are not adequate.

FS-5, FS-7, FS-9

The proposed protection of cutthroat trout in Alt. 4, 379 miles protected with 6-inch HGL stubble height should be incorporated into 3M.

308, 643, 695, 1206,

A 6-inch stubble height should apply to entire AIZ.

FS-5, 643, 695, 766, 1194, 1401

Recommend that all stubble heights should be 5" and 6" for satisfactory and unsatisfactory condition (riparian vegetation) respectively, unless the FS can provide scientific documentation to support the levels.

389

An additional standard of 6", remaining at the end of the grazing period, should be added for areas determined to be non-functioning or functioning at risk.

1206

RIPARIAN -STUBBLE HEIGHT

Riparian stubble height standard should be more conservative because of the lack of reliable data used by the FS.

643

RESPONSE: Stubble height requirements at both the hydric greenline (HGL) and away from the HGL are measured at the end of the grazing period. Measurements at the end of the grazing period allow for re-growth to occur on all pastures (have stubble heights in excess of 4-inches), except for the last pasture where a 4-inch stubble height remains. These standards allow for flexibility based on site-specific analysis.

Recommendations

COMMENT: A stubble height of 2-3 inches is sufficient for this higher altitude area. There isn't scientific data stating streambanks hold any better or grass recovers any faster at 4-inches than 2-3 inches.

1378

The provision allowing the Forest to use a 6-inch stubble height is strongly opposed; should only be used in extreme situations, other measures for rate of recovery should be used first.

319, 1244, 1378

RESPONSE: Stubble height requirements were developed based on comprehensive scientific findings. Some references used in development of these stubble height criteria include:

Clary, Warren P.; Webster, Bert F. 1989. Managing grazing of riparian areas in the Intermountain Region. Gen. Tech. Rep. INT-263. Ogden, UT: U.S. Department of Agriculture, Forest Service, Intermountain Research Station. 11 p.

Clary, Warren P.; Kinney, John W. 1994. A photographic utilization guide for Key Riparian Graminoids. Gen. Tech. Rep. INT-308. Ogden, UT: U.S. Department of Agriculture, Forest Service, Intermountain Research Station. 13 p.

Kauffman, J. Boone; Kruger, W.C. 1984. Livestock impacts on riparian ecosystems and streamside management implications-a review. Journal of Range Management. 37(5): 430-438.

Platts, William S.; Raleigh, Robert F. 1984. Impacts of grazing on wetlands and riparian habitat. In: Developing Strategies for Rangeland Management. Boulder, CO: Westview Press: 1105-1117.

Platts, William S.; Nelson, Roger Loren. 1985. Streamside and upland vegetation use by cattle. In: Rangelands 7 (1): 5-7.

The parameters that the Targhee is proposing to utilize are similar to what other forests and land management agencies are using. DM

COMMENT: Degraded riparian areas may require complete rest to initiate recovery process.

389

RIPARIAN - STUBBLE HEIGHT

RESPONSE: Your comment is acknowledged. The Revised Plan allows for deviation, where needed, based on site-specific analysis. DM

COMMENT: Other indicators such as plant density, plant composition and litter should be used with standards assigned to each criterion, not just stubble height as the plan proposes.

643, 766

RESPONSE: Plant frequency, plant composition and litter are measured on benchmark sites, which are permanent indicator sites. The Targhee Rangeland Monitoring Protocol outlines the establishment of benchmark sites for long-term trend studies and the parameters that would be analyzed. DM

COMMENT: Essential to determine/develop a streambank stability standard correlated to stubble height at the hydric green line. Should include the Beaverhead standard or something instead of waiting five years to develop.

1206

RESPONSE: Baseline data is insufficient on the Targhee to develop a streambank stability standard. In the interim, stubble height standards will be used to protect streambanks. This monitoring item was elevated to a Forest Priority Group 1.

The Beaverhead standards are specific to various mountain ranges on the Beaverhead National Forest and their physical features (site-specific). DM

RIPARIAN - WATER QUALITY

Sediment

COMMENTS: DEIS and DREV have limited information on sediment and turbidity despite the fact that sediment is the biggest pollutant on the Targhee.

1367

RESPONSE: Currently, the Forest has limited information to assess the impact of sediment and turbidity on aquatic systems. The Targhee uses two types of water quality standards established by Idaho and Wyoming state laws: specific criteria (turbidity, water temperature) and general criteria for maintaining unimpaired beneficial uses.

With respect to specific sediment criteria, extensive data collection is required during storms and spring run-off, since turbidity varies with discharge and is not always related to suspended sediment quantities. Previous, dated Forest turbidity records indicate levels are below limits set by the States. The Targhee conducts surveys to determine if beneficial uses are adversely impacted by management activities. Fisheries surveys, including Wolman pebble counts and macro invertebrate data, have not shown sediment to be a significant problem on the Targhee. RSM

COMMENTS: The Plan identifies sediment as the biggest pollutant but efforts to obliterate roads that are the primary source of this sediment is insufficiently identified and committed to.

1365

RIPARIAN - WATER QUALITY

RESPONSE: Objective #1 in Prescription 2.8.3 includes direction to inventory, evaluate, and schedule for restoration those roads, trails, and stream crossings that do not meet prescription goals. Implementation and monitoring of Best Management Practices required by the States also address this concern as does objective #1 under Aquatic Standards and Guidelines for the watershed improvement needs inventory. RSM

Roads

COMMENTS: Road density limits or road obliteration requirements should be proposed relative to watershed conditions and aquatic systems; key watersheds where road densities might pose specific concerns to aquatic ecosystems and water quality should be identified.

1368

RESPONSE: Available information indicates road density is less critical than road location. No clear evidence is available that supports the assumption that a specific road density in a watershed leads to adverse water quality impacts. Substantial information validates that roads within a given distance of a stream, based on such factors as slope steepness, slope stability and existing vegetation, can lead to adverse water quality impacts. The Revised Plan focuses on roads within the Aquatic Influence Zone that have the greatest potential for delivering sediment to water bodies. AIZ widths vary by subsection and allow the Targhee to examine different geomorphic areas on the Forest during site-specific analysis.

Standards and Guidelines, Best Management Practices, Idaho Forest Practices Act, and site-specific recommendations provide adequate protection to watershed and aquatic systems without adding additional road obliteration requirements. RSM

COMMENTS: Prioritize watersheds for restoration and protection, limits for additional road construction.

1368

RESPONSE: Priorities for restoration are determined through the watershed improvement needs inventory. Those watersheds posing the greatest threat to resource values are restored first. Restoration work is monitored to insure effectiveness and to determine if on-going maintenance is required. Refer to Objective #1 in the Aquatic Standards and Guidelines.

Protection needs are determined on a case-by-case basis, depending on a project's objectives. As part of the site-specific NEPA process, watershed resources and alternatives are evaluated, and Best Management Practices and mitigation measures are developed to address site-specific needs. RSM

Recreation

COMMENTS: OHV use, which can damage or reduce riparian vegetation, will lead to soil erosion increase which can negatively impact aquatic communities.

1365

RESPONSE: OHV use may cause damage to riparian areas, mainly through soil compaction, puddling, and rutting. High silt/clay soils are especially

RIPARIAN - WATER QUALITY

sensitive during wet cycles. OHV impacts are prevalent in specific locations on the Targhee, rather than uniformly distributed.

The Revised Plan improves management of OHV use, specifically on steep upland slopes and in riparian areas. In riparian areas, camping near streams is limited to designated dispersed sites (Prescription 4.3). The Targhee will monitor camping and OHV impacts to riparian soils and vegetation. Based on monitoring data, the Targhee will periodically validate whether objectives in Prescription 2.8.3 are being met and adapt management accordingly. RSM

COMMENTS: OHV use can cause soil erosion and sedimentation which leads to increases in turbidity; and refueling/spills can lead to chemical contamination of water.

1365

RESPONSE: Most OHV impacts in riparian areas result in soil compaction, puddling, and rutting which can lead to erosion. The primary concern is the loss of stabilizing vegetation in areas where OHV use has impaired soil quality. Vegetation helps the soil absorb water and acts as a buffer against surface run-off. Lack of adequate stream-side vegetation is a primary cause of erosion. Utilization and minimum ground cover standards are included in the revised Plan.

A new guideline was added in Prescription 2.8.3 that addresses possible risks to water quality from fuel storage and vehicle refueling. RSM

COMMENTS: The Plan needs to fully address the issues of water quality degradation resulting from recreational and other uses on the Targhee. Specifically, include thorough, strict, clear provisions to insure impacts to water quality do not occur.

1365

RESPONSE: The Revised Plan's goals and objectives, standards and guidelines serve as an umbrella for site-specific project work. Standards and guidelines provide the direction and limitations for all project-related activities. Water quality is best analyzed at the site-specific level based on site-specific factors. In some projects, stricter standards than those found in the Revised Plan may be used, if site-specific conditions warrant. Regardless of the nature of the project, State water quality standards must be met. This is generally achieved through site-specific mitigation. RSM

General

COMMENTS: No discussion of ground water concerns, specifically to the Madison limestone as a significant aquifer.

389

RESPONSE: No evidence exists that management activities proposed under any alternative would impact aquifers. Water quantity depends on natural precipitation patterns and the amount of water being withdrawn from an aquifer for consumptive uses. Impacts to aquifer water quality are expected to be insignificant, in that burying or injecting hazardous waste on National Forest land is prohibited. Where petroleum products or other hazardous materials are

RIPARIAN - WATER QUALITY

stored, safe storage facilities are required to prevent contamination of soil and water resources. RSM

COMMENTS: Base management decisions of sustainable activities on protecting watersheds and water quality.

376

RESPONSE: All planning activities on the Forest require site-specific assessment of impacts to resources, including water quality. All projects must satisfy a variety of rules and regulations contained in State water quality standards during and after project implementation. RSM

COMMENTS: Support reducing pressures of grazing bovines and motorized vehicles to restore waterways and keep them healthy.

406

RESPONSE: Standards and guidelines in the Revised Plan are designed to reduce impacts to streams. Also refer to specific standards and guidelines regarding grazing and motorized use. Implementation and monitoring will identify if Revised Plan direction is not meeting resource needs. Under adaptive management, remediation will be taken. RSM

COMMENTS: Targhee should continue to identify areas in need of restoration and use native species wherever possible. Continue to solicit help from Henry's Fork Foundation.

1276

RESPONSE: Watershed Improvement Need Inventories are currently being conducted across the Forest to identify and prioritize restoration needs. A decision to use native species would be made at the project level and would usually be preferred. Refer to Vegetation section of the Standards and Guidelines. The Forest will continue to work with the Henry's Fork Foundation. RSM/DM

COMMENTS: Major emphasis should be placed on restoration in order to heal past errors along streams and within whole watersheds.

620

RESPONSE: Watershed Improvement Need Inventories, as outlined in the Objective under Aquatic Resources, are currently being conducted across the Forest to identify and prioritize restoration needs. The Revised Plan emphasizes a preventive approach through appropriate Standards and Guidelines. RSM

COMMENTS: Designating lands as wilderness protects water quality.

136

RESPONSE: A variety of methods and tools are available to protect water quality other than designating lands as wilderness. All proposed management activities must adhere to Standards and Guidelines in the Forest Plan and meet State and Federal water quality regulations. RSM

RIPARIAN - WATER QUALITY

COMMENTS: Many activities can reduce stream flow and water clarity which threaten the riparian ecosystem. Activities include diversions for irrigation or channelization, gravel washing operations, grading of dirt roads that cross streams and upland grazing. Past activities on the Targhee may have impacted the western boreal toad, spotted frog, and predatory birds.

1365

Oppose logging, roading, mining, grazing due to impacts to soil and water resource.

276

RESPONSE: Although the activities noted have potential to reduce streamflow, water quality, or both, the Revised Plan contains many standards and guidelines that address these concerns. In addition, site-specific mitigation measures, on a project-by-project basis, are developed as needed through the NEPA process to insure stream channel and water quality protection along with State Best Management Practices. RSM

COMMENTS: Detailed watershed modeling should accompany the EIS.

1364

RESPONSE: The Revised Plan provides general management direction and sets minimum acceptable levels (Standards and Guidelines) to be used in project implementation. Detailed watershed modeling is more appropriate at the watershed or project level and is not necessary to assess the impacts of the various programmatic alternatives under consideration. Instead, "indicators" provide a valid indication of potential impacts under the various alternatives. RSM

COMMENTS: Revision appears to be consistent with United States Bureau of Reclamation in supplying water and maintaining water quality.

314

RESPONSE: Your comment is acknowledged. RSM

COMMENTS: Concern over effects on private land and water quality if Forest Service cuts back on range.

314

RESPONSE: The Targhee adjusts grazing permits from time to time to ensure resources are not degraded. Proposed reductions in permitted livestock use on the Targhee are not predicted to affect water quality or land condition on private land. Impacts to land and water on private lands, as a result of grazing on those lands, is outside the jurisdiction of the Forest Service. RSM

COMMENTS: Targhee could learn from Lemhi Model Watershed Project with FS and BLM, regarding riparian habitat gains.

314

RESPONSE: The Targhee relies on information or findings from a variety of other sources. The Revised Plan incorporates direction and monitoring protocols for riparian areas from projects like the Lemhi Model Watershed

RIPARIAN - WATER QUALITY

Project. Future monitoring will determine the success of these protocols, and management will be adjusted as necessary. RSM

COMMENTS: Disagree that there will be no change in water yield by alternative.

413

RESPONSE: The number of acres disturbed in a given watershed and the type of disturbance expected, predict no change in water yield by alternative. Similar and more refined analysis occurs at the site-specific level as part of a proposed project's NEPA analysis before a project is implemented. RSM

COMMENTS: Forest must address and disclose predicted impacts and discuss how activities will affect other related resources, i.e., Fish, Threatened and Endangered, sensitive species.

643, 766

RESPONSE: The FEIS discloses the direct, indirect, cumulative, and irreversible/irretrievable effects anticipated for each alternative under consideration. Effects on each resource are also disclosed in Chapter IV of the FEIS. Site-specific projects will receive site-specific analysis in the NEPA process. RSM

COMMENTS: Our mountain streams are not as polluted as you would have us believe.

316

RESPONSE: Although this may be the case in many areas, the Targhee lacks sufficient monitoring data to insure this is, in fact, true. For that reason, the Revised Plan increases monitoring activities. RSM

COMMENTS: Sediment and turbidity levels should also be indicators in addition to desired vegetation condition, especially where harvest and roads are present.

1367

RESPONSE: Monitoring sediment delivery to streams requires more time and resources (personnel and budget) to evaluate than vegetation condition. For that reason, sediment monitoring targets Water Quality Limited streams first, and then other areas where activities have taken place and Best Management Practices have been applied. In locations where sediment monitoring is not feasible, vegetation condition is used as a proxy indicator. This is the best method available to evaluate sediment delivery at this time. RSM

COMMENTS: Additional aquatic studies, including the relationship between roads and sediment, should be completed before the FEIS. (Reference made to Megahan and Kidd study)

1367

RESPONSE: The relationship between roads and sediment delivery to streams continues to be researched by Megahan and others. All research findings are similar in that roads are sources of sediment to streams, and various measures

RIPARIAN - WATER QUALITY

are needed to reduce the amount of sediment delivered. The Targhee used the Megahan studies, among others, to develop standards and guidelines for water quality and aquatic systems and in planning roads at the project level. As researchers publish new findings or offer new management suggestions based on their findings, the Targhee will incorporate them during project implementation activities. RSM

COMMENTS: Preparation and operation of ski slopes can lead to extensive sedimentation.

1365

RESPONSE: Regardless of the nature of a proposed project, whether a timber sale or ski hill operation, soil disturbance is mitigated through application of Best Management Practices or other appropriate measures to minimize soil erosion and reduce sediment delivery to water bodies. Refer to the FEIS - Grand Targhee Ski Area - as an example. RSM

COMMENTS: Snow making can consume considerable volumes of water and produce severe distortions in hydrologic cycles.

1365

RESPONSE: Snowmaking does use water; however the two ski areas on the Targhee do not have on-Forest permits for withdrawing water for snowmaking. Grand Targhee Ski Area does not make snow. While Kelly Canyon makes snow for parts of the lower slopes, they do not apply snow to slopes located on the Forest. Water for Kelly Canyon snowmaking comes from a private water source. It is unlikely that severe distortions in the hydrologic cycle result from this activity, since it occurs in a small area. RSM

Specific Citations in DREV

COMMENTS: Page III-7 section only addresses streams that are presently impacted and where water quality improvements are desired. Modify to indicate water quality would be maintained or improved to meet State standards.

389

RESPONSE: Goal #3 was changed to read: "Water quality is maintained or improved to meet water quality standards for the appropriate state (Idaho or Wyoming)." RSM

COMMENTS: Page III-7 DREV: Guidelines 1 and 2 should be standards, under Municipal Watersheds; Page III-7 Emergency in Guideline (G) 1 should have more specific provisions; and page III-7 Avoid in Guideline 2 should be replaced with Prohibit.

1365

RESPONSE: We dropped the standards and guidelines for municipal watersheds. The Targhee does not have municipal watersheds; instead the Forest has public water systems. Draft management direction for public water systems was issued recently by the Washington Office and the final direction will be in national or regional manuals or handbooks. The Revised Plan does not repeat manual and handbook direction. RSM

RIPARIAN - WATER QUALITY

COMMENTS: A few well placed rolling dips and light scarification will be effective in rehabilitation of disturbed areas. Targhee has done lots of this and don't support continued reference needing to fix old timber roads.

687

RESPONSE: Your comment is acknowledged. The Targhee will continue to employ these methods as determined by site-specific analysis. RSM/DM

COMMENTS: Strengthen BMP's for roads that are left open, and obliteration should be considered as primary option for road closures.

1276

RESPONSE: Idaho State Best Management Practices for roads, and standards and guidelines in the Revised Plan, specifically under prescription 2.8.3 for roads and trails, provide protection to other resources from the impacts of roads. If other needs are identified for specific roads, including obliteration, they are handled on a case-by-case basis. RSM

COMMENTS: Plan should develop standards for roads in riparian areas, management of the Targhee has neglected to protect riparian areas. Riparian road densities exceed 15 mi/sq. mile and Plan doesn't propose adequate remedy for this.

1367

RESPONSE: Refer to Prescription 2.8.3 for standards and guidelines for roads in the aquatic influence zone. Note that under the Objectives in this prescription, the Targhee will evaluate roads for resource concerns, identify where problems exist, and prescribe solutions.

Road density in riparian areas is difficult to calculate. Riparian areas are linear features and are limited in lateral extent. Quantitatively, it is difficult to define these areas in GIS on a forestwide scale. While road densities in riparian areas may be calculated from information in the FEIS, the numbers should be viewed cautiously. RSM

COMMENTS: With 5,680 stream crossings on the Targhee, risk of large scale erosion events is extremely likely. Plan fails to adequately address the serious threat to aquatic systems posed by the existing stream crossings.

1367

RESPONSE: Stream crossing data in the DEIS were incorrect. After additional analysis and recalculation, the Targhee has 4,530 stream crossings. Corrections also were made to the information about stream crossings in each of the alternatives in the FEIS. RSM

COMMENTS: Road decommissioning requirements are inadequate to protect aquatic ecosystems.

1368

RESPONSE: Goals and objectives in the section for aquatic, riparian resources, and watersheds establish priorities using the watershed improvement needs inventory. Watersheds that have 30% or more hydrologic disturbances were given the highest priority for assessment and restoration. See

RIPARIAN - WATER QUALITY

Prescription 2.8.3 for direction on the inventory of roads, trails, and stream crossings for rehabilitation needs. Future priorities will be based on monitoring results. For example, water quality limited streams that are not meeting water quality standards for sediment would be a high priority for watershed assessment and restoration. Road density limits for watershed protection are not well-documented. Roads having the greatest direct impacts on streams are targeted for assessment. DM/RSM

COMMENTS: Support effort to reduce summer cross-country OHV travel since it can be a major sediment contributor.

161, 1276

RESPONSE: Your comment is acknowledged. RSM

COMMENTS: Page III-7: Aquatic Guideline 2 should be a standard.

1365

RESPONSE: Required minimum flows, fish passage, and fish screens on new special use permits are standards in the Revised Plan. On existing permits, values are protected through guidelines, allowing the Targhee to evaluate needs on existing projects on a case-by-case basis. RSM

COMMENTS: Forestwide standards and guidelines - Ecological and Biodiversity left out discussion of the aquatic environment.

1177

RESPONSE: The aquatic environment is discussed under the standards and guidelines of Prescription 2.8.3. New information was added to this section describing how the Targhee will use "properly functioning condition" of plant communities, streams, and watersheds to more effectively manage for desired conditions. RSM/DD

COMMENTS: Modify statement to "State and/or Forest specified instream flows" on III-7 since Wyoming allows the State to acquire instream flows.

389

RESPONSE: The statement is modified in the the Final Revised Plan. RSM

COMMENTS: Page III-35 Goals: Disagree with efforts being placed on West Dry Creek because only unnatural condition exists below sheep station diversion. Water seldom flows below diversion after 7-15. Should put efforts elsewhere.

432

RESPONSE: This focuses on West Dry Creek at the western edge of the Island Park Ranger District near Antelope Valley. The Targhee is interested in the part of West Dry Creek upstream of this diversion. Approximately 10 miles of stream in this drainage is on the Forest and may provide habitat for fish and other aquatic organisms. RSM

COMMENTS: Time frame for completing watershed improvement needs inventory is too long.

643

RIPARIAN - WATER QUALITY

RESPONSE: The timeframe for completing watershed improvement needs is realistic, given budget and personnel constraints. RSM

COMMENTS: Page III-76: Add additional BMPs to the Minerals/Geology section of the Eligible Wild River prescription: "No pollutants, such as topsoil, silt, sand, gravel, solid wastes, slash, debris or chemicals, should be stored or deposited within the active floodplain, in areas immediately adjacent to riparian areas or in natural drainages, e.g., draws, land surface depressions or other areas where overland flow could concentrate materials and carry pollutants directly into surface waters."

389

RESPONSE: A standard was added to address this concern. RSM

COMMENTS: DREV III-95: Objective 1 should be a standard, and modified to read "will be scheduled for restoration or obliteration."

1365

RESPONSE: Although the Revised Plan retains this as an Objective, the wording was modified as suggested. RSM

COMMENTS: Goals III-95 unclear what "where feasible" means. Please define.

1177

RESPONSE: "Where feasible" assumes some systems are functioning outside the range of variation. For example, some streams in the Tetons that experience frequent disturbances from avalanches are considered unstable. Although they may be functioning hydrologically, they may not meet the general parameters established for streams on the Targhee. Another example is Irving Creek. The headwaters are in good condition. As a result of a rain-on-snow event in 1995, the channel downcut approximately five feet, and tributary drainages moved huge amounts of sediment. This stream will likely function outside the range of variation until it adjusts to the new conditions or until a similar event takes place. RSM

COMMENTS: DREV III-97: All three guidelines should be standards under Fire and Fuels. Replace avoid with prohibit.

1365

RESPONSE: Refer to the definition of a "guideline". Guidelines are actions that are expected to be carried out. Rationale for deviating from the guideline is documented in the site-specific NEPA project decision. Because fires may threaten human life, property, or Forest resources, flexibility is needed for suppression efforts while allowing for the protection of riparian resources. RSM

COMMENTS: Page III-97 Minerals: Final guideline should be a standard, and modified to "consistent to the fullest extent possible."

1365

RESPONSE: Refer to definition of a "guideline." Guidelines are actions that are expected to be carried out. Rationale for deviating from the guideline is

RIPARIAN - WATER QUALITY

documented in the site-specific NEPA project decision. Plans of operation are consistent with Standards and Guidelines. New wording in the guideline includes the language suggested in the comment. RSM

COMMENTS: Page III-98: All three guidelines should be standards. The second standard should be modified (see letter); Page III-99 Roads and Trails. First guideline should be a standard. First sentence of second guideline should be a standard. Last two guidelines should be standards; and, Page III-99 Recreation First guideline should be a standard.

1365

RESPONSE: Refer to the definition of a "guideline." Guidelines are actions that are expected to be carried out. Rationale for deviating from the guideline is documented in the site-specific NEPA project decision. The soil guideline is a Regional guideline for soil quality.

The second guideline is modified as suggested to read "Improve; seasonally close; close and relocate and stabilize; or obliterate roads and trails that have been identified as posing a high risk for causing unnaturally high levels of sediment input into fish spawning areas or are known to be doing so. Site-specific analysis on a project-by-project basis will determine the action(s) to be taken, based on travel management, terrain, the need for the road or trail, the potential environmental impacts, and resource priorities." RSM

COMMENTS: Make sure the state basin plan is incorporated. Targhee needs to work closely with Ellen Berggren, Idaho State Department of Water Resources, to integrate the Henry's Fork Basin Plan into the Revision.

314

RESPONSE: The Targhee coordinates with State agencies in water planning efforts, particularly in the development of the State basin plan for the South Fork Snake River Basin. Efforts have included sharing information resources and periodic meetings between agency personnel. The Targhee will also be a cooperator in updating the Henry's Fork Basin plan.

The South Fork Basin Plan addresses an area that crosses jurisdictional boundaries and is greater in scope than the Targhee's Revised Plan. The Targhee will consider recommendations from these efforts and adapt management if necessary. EF

COMMENTS: Targhee isn't in compliance with 36 CFR 219.27, and Forest needs a clear plan for meeting requirements (specifically mentions sec. (a) 1, 4, and 6).

Meet the Forest Service planning regulations concerning minimum specific management requirements in accomplishing the goals and objectives in Forest Plans.

Significant widespread damage to streambanks and riparian areas is occurring as a direct result of negligent management practices, especially roading. There are 15.3 miles per square mile of roads in riparian areas on the Forest. Dedicate more attention to riparian areas, show "a drastic reduction of road densities" in these areas.

1367

RIPARIAN - WATER QUALITY

RESPONSE: Management of riparian areas is governed primarily by the goals, objectives, standards and guidelines in Prescription 2.8.3, for the Aquatic Influence Zone (AIZ). This prescription recognizes the importance of these areas for biodiversity and provides direction for protection and restoration. One of the goals speaks to minimizing adverse effects to aquatic and riparian dependent species from past, existing and proposed management activities. One objective inventories and evaluates the condition of all existing roads, trails, culverts, fords and stream crossings within these lands, and schedules restoration activities in all areas that do not meet the goals of the prescription.

The Revised Plan complies with these and other regulation requirements and meets the protection and restoration needs of riparian areas on the Targhee. EF

COMMENTS: Need close monitoring of water quality to allow better control and conservation of the ecosystem.

11

RESPONSE: Your comment is acknowledged. Throughout the Revised Plan, these ideas are incorporated, specifically in the monitoring and evaluation program. EF

Water Quality Limited Streams (WQLs)

COMMENTS: Include a disclaimer that monitoring to determine compliance with state standards will change as science and standards change.

1177, 1362

RESPONSE: A statement was added that changes to water quality standards and assessment procedures are likely to occur during the life of the Revised Plan. EF

COMMENTS: For WQL streams to be delisted, they must be monitored to determine if beneficial uses are fully supported. DEQ is approaching these requirements by comparing macroinvertebrate and fish (and potentially algal) communities in streams to reference conditions as the primary measures. Secondly, if data for parameters which have numerical standards are available, the data would be compared against these standards to determine whether these standards are met. (i.e. chemical or physical integrity).

1177, 1362

RESPONSE: The indicators in the monitoring plan verify whether stream reaches on the Forest meet the definition of a Water Quality Limited Stream. Other parameters, as determined by Idaho DEQ and/or EPA, may also be monitored. Given the State's emphasis on biological communities, monitoring includes information on fisheries. The Targhee is an active cooperator with the Division of Environmental Quality (DEQ) in continuously refining monitoring protocols to provide accurate information to assess the water resource. EF

COMMENTS: Idaho's beneficial use reconnaissance program (BURP) protocols need to be included in the monitoring.

1177, 1362

RIPARIAN - WATER QUALITY

RESPONSE: BURP protocols were added to the Revised Plan. BURP protocols are a reconnaissance assessment method, and not monitoring in the normal sense of making repeated visits to a site to get trend and condition data over time. Instead, BURP is a "snapshot" of conditions at one site at one instant in time. BURP is a point from which to initiate further, in-depth monitoring.
RM

COMMENTS: WQL segments should be prioritized for monitoring.
1273b

RESPONSE: Priorities for monitoring WQL segments are set statewide by DEQ. On the Targhee, priorities are determined by resource specialists responsible for assessing WQL segments on the Targhee. Initial monitoring showed that no segments appear to have significantly greater concerns than any other. Monitoring of WQL streams segments was moved to a priority 1 in the Revised Plan. RSM

COMMENTS: The Forest is out of compliance with several laws and regulations concerning Water Quality Limited Streams (WQLS) if Alternative 3M were implemented. A provision from the NFMA regulation states:

"Forest planning shall provide for...Compliance with requirements of the Clean Water Act, the Safe Drinking Water Act, and all substantive and procedural requirements of Federal, State, and local governmental bodies with respect to the provision of public water systems and the disposal of waste water;...

Streams on the WQLS list are in violation on account of sediment, and the Forest cannot permit additional loadings of sediment into these waters. Disclose the impacts of future activities on WQLSs, in the EIS. For those WQLSs where water quality standards have not been attained, the Forest may not permit any further degradation through activities until total maximum daily loads (TMDLs) have been developed.

643, 644, 766, 1177, 1194, 1273b, 1362, 1364, 1401

RESPONSE: The Targhee is required to comply with all environmental regulations related to water quality. Best Management Practices implemented on the Forest generally exceed the minimum requirements set by state agencies. Management activities are adjusted or mitigated to avoid impacts to WQL streams. Pending court litigation and evolving interpretations of law may require the Targhee to amend the Forest Plan in the future.

The following streams on the Targhee were identified in 1994 as being WQL streams:

Stream name	Reach boundaries	Pollutant	Priority
Antelope Creek	Hdwater to S.Fk. Snake River	sediment	low
McCoy Creek	Palisades Res to Iowa Cr.	none listed	low
Tex Creek	Hdwater to Willow Creek	sediment	low
Brockman Creek	Hdwater to Grays Lk. Outlet	sediment, nutrients	low
Corral Creek	Hdwater to Brockman Creek	sediment, thermal	low
Sawmill Creek	Hdwater to Brockman Creek	sediment, thermal	low
Edie Creek	Hdwater to Med. Lodge	sed, nuts, hab alt	low
Irving Creek	Hdwater to Med. Lodge	sed, nuts, hab alt	low

RIPARIAN - WATER QUALITY

Warm Creek	Hdwater to Med. Lodge	nutrients, thermal	low
Warm Springs Cr.	Entire	sediment, nutrients	low
Fritz Creek	Hdwater to Med. Lodge	nutrients, thermal	low
Henry's Fork	Buffalo R. to Riverside	sediment	low
Teton River	Hdwater to Trail Creek	habitat alteration	low
Packsaddle Creek	Hdwater to Teton River	sediment, flow alt	low
Horseshoe Creek	Hdwater to Teton River	flow alteration	low

The South Fork Snake River, from Palisades to Heise, is also a listed WQL stream and flows adjacent to Forest lands.

While other streams in the vicinity of the Targhee have been listed, the designated reaches are downstream of the Forest boundary. These streams include Camas Creek, Beaver Creek, and Medicine Lodge Creek. Several listed streams that flow from the Teton Mountains have headwaters on the Forest and are located in Wyoming while on the Forest. These headwaters are in the Jedediah Smith Wilderness and include Teton Creek, Leigh Creek, Darby Creek, Fox Creek. The fact that these streams are listed for reaches downstream of National Forest System lands suggests that the problems identified for the streams originate on non-forest lands.

The Clean Water Act delegates authority for establishment of WQL priorities to the States. In the "Decision Document for Idaho sec. 303(d) List" dated October 7, 1994, The Environmental Protection Agency affirms that it is reasonable to allow the state to determine the relative importance of streams for establishment of TMDL's, because "implementation and enforcement of nonpoint source controls is exclusively within the province of the state," specifically nonpoint sources from activities such as Forest management.

Senate Bill 1284 requires that water quality must fully support existing beneficial uses where there is no numeric water quality standard, or must meet the standard where one is established. The requirement applies to all water bodies, listed and not listed. "Low" priority bodies (all streams on the Targhee are in this category) are those where limited data suggest that beneficial uses are not fully supported, but risks to humans and aquatic life are minimal. For streams in this category, corrective action is taken for "such changes in permitted discharges from point sources on the water body or to the best management practices for nonpoint sources within the watershed deemed necessary to prohibit further impairment of the designated or existing beneficial uses." In this regard, these streams are not subject to the development of TMDL's; they are subject to monitoring of best management practices to ensure their effectiveness and to monitoring designated beneficial uses to ensure they are supported. The bill does not imply all management activities must cease in these watersheds. The Targhee is required to meet water quality standards and insure that best management practices protect beneficial uses. If monitoring identifies water bodies that are not meeting water quality standards, the source for water quality impairment is found and corrected.

The Targhee is validating WQL streams to determine water quality concerns and cooperates with the Division of Environmental Quality to develop suitable monitoring and assessment methods, including the state-approved Beneficial Use Reconnaissance Program protocols. Monitoring efforts and information are shared with other state and federal agencies, including DEQ and EPA. Identified water bodies have limited data. Some speculation exists as to whether they even need to be listed. Warm Creek is a case in point. It is listed because of thermal concerns, but has a warm spring as its source that

RIPARIAN - WATER QUALITY

provides a higher than acceptable temperature. Changing management activities to correct this naturally occurring condition is not feasible.

The Targhee uses stringent management requirements in WQL watersheds. Baseline monitoring is occurring in at least one WQL watershed where new management activities are planned in an effort to assess existing fish populations and fish habitat conditions. Impacts to WQL streams are analyzed at on a site-specific level where best management practices can be designed to address site-specific concerns and issues. RSM/EF

DREV and Monitoring Chapter

COMMENTS: More monitoring is necessary in riparian areas due to the severely degraded condition they are in due to resource developments.

643

RESPONSE: The Revised Plan's prescriptions, goals, objectives, standards and guidelines, as well as the monitoring program, effectively address the health of riparian areas. Prescription 2.8.3 for the aquatic influence zone (AIZ) includes a goal for enhancing the health and function of these areas. Objectives include inventory and evaluation of all existing roads, trails, culverts, fords and stream crossings within three years of the Revised Plan's implementation date, with subsequent scheduling of rehabilitation activities in those areas not meeting prescription goals. Four monitoring items address riparian areas and are generally high priority monitoring. EF

COMMENTS: Need definition of Priority 3 in monitoring plan, and whether the ranking for 3 falls at the top or bottom of the range. Please clarify.

1177, 1362

RESPONSE: Monitoring of WQL streams is given a Priority 1 rating in the Revised Plan. As described on Page V-2, "Monitoring and the Budget," priorities for annual monitoring are based on annual budgets and program direction and on the priority of the item, in descending order from Forest Priority Group 1 to Forest Priority Group 3. Priority 3 items are funded last; however, normal operating procedures, such as implementing BMPs, are always required on site-specific projects. Monitoring of BMPs on a forestwide basis is somewhat restricted. If BMPs have not been applied in some cases or if they were ineffective, the Targhee would reevaluate the priority of the BMP monitoring item. RSM/EF

COMMENTS: V-10 DREV Unclear what * * means.

282

V-10 suggests Forest doesn't intend to meet its legal and ethical responsibilities with regards to water quality; compliance plan with Executive Order 12088 is lacking and note on V-10 indicates Forest wishes to be excused from this obligation.

643

RESPONSE: The statement was intended to show the seriousness of the WQL issue and the task of developing TMDL's for remaining listed streams if monitoring is neglected. The asterisk was used to draw the reader's attention to the

RIPARIAN - WATER QUALITY

Targhee's obligation to monitoring and the long-term costs of not meeting monitoring obligations.

The Forest is complying with the Executive Order 12088 in preventing, controlling and abating pollution as a result of management activities. The Targhee cooperates with other agencies and consults regularly concerning techniques to prevent water quality deterioration. RSM

General

COMMENTS: State of Idaho and Targhee need to reinvigorate their land exchange program, including addressing lands outside the National Forest System.

314

RESPONSE: The Targhee has an active land exchange program designed to consolidate National Forest System lands for more effective management. The Forest has no jurisdiction over private lands; these are outside the scope of the Revised Plan. The Targhee and the Department of State Lands continue to look for mutually beneficial and advantageous land exchanges that meet shared goals. RSM/AM/DD

COMMENTS: V9 and 10 DREV Citations. WQL streams and BMP's are not included as goals in AIZ Prescription.

282, 643

RESPONSE: A goal to delist WQL streams is found in forestwide standards and guidelines in the Aquatic section. Application and monitoring of Best Management Practices is required under state law for most activities. Appendix A in the Revised Plan displays a list of documents that contain BMPs. RSM

DREV and Monitoring Chapter

COMMENTS: Monitoring plan must be active to respond to Federal Clean Water Act.

643

RESPONSE: Targhee management activities must meet the requirements of the Clean Water Act, regardless of additional direction found in the Forest Plan. The Monitoring Plan, Chapter V, shows the minimum amount of monitoring required to meet legal obligations. The monitoring program is not all inclusive. Additional monitoring required by other state or federal agencies is not repeated in the monitoring program. RSM

COMMENTS: The Revised Plan fails to provide a comprehensive plan for watershed analysis, restoration, monitoring, and adaptive management; to inventory, monitor and develop site-specific plans for riparian management; and to tailor timber management to watershed needs as identified through these processes. Furthermore, the Revised Plan does not include details of the actions the Forest intends to take relative to Water Quality Limited Stream Segments.

643

RIPARIAN - WATER QUALITY

RESPONSE: The Revised Plan provides broad programmatic direction and Standards and Guidelines which must be met during project level implementation. Comprehensive watershed analysis direction is currently being developed by the Intermountain Region. As this information becomes available, the Revised Plan may be amended to incorporate new information or direction.

The Targhee is cooperating with the State of Idaho to detail actions to be taken on WQL streams. Monitoring in the Revised Plan was developed to delist WQL streams on the Targhee. Rangeland Monitoring Protocol, incorporated by reference into the monitoring plan, provides various measures of riparian health that are used to determine if standards and guidelines are effective.

Watershed restoration is accomplished through the Watershed Improvement Needs inventory. Refer to Chapter V in the Revised Plan for a discussion of the monitoring strategy. Riparian area inventory and monitoring is incorporated in the monitoring plan by reference to rangeland and recreation monitoring protocols. Site-specific analysis will be completed to determine appropriate riparian management. Timber management activities are determined on a site-specific basis and will be responsive to all Standards and Guidelines in the Revised Plan. RSM

DEIS Specific Citations

COMMENTS: DEIS says channel stability ranges from fair to good. This is so vague, it is meaningless. Suggest including if conditions are related to grazing; identify problem areas; will revision improve these; state how conclusions were developed; and cite references.

1177, 1362

RESPONSE: The Water section of the FEIS provides a discussion of this information. Channel stability ratings and types and locations of impacts are also summarized. Standards, Guidelines and monitoring are designed to improve resource conditions, particularly in problem areas. RSM

COMMENTS: Summary Page 5 "a healthy riparian area indicates..." is not valid. Raw sewage released into a stream is an example of the statement's lack of validity.

282, 643

RESPONSE: Your comment is acknowledged. The statement was corrected in the Revised Plan. The quality of instream components cannot always be judged from the quality of riparian areas. Monitoring activities and inventories will address instream characteristics of water quality and fish habitat as well as assessing the condition of riparian areas. RSM

COMMENTS: Page III-23: Appears to be a typo in temperatures.

1362

RESPONSE: Your comment is acknowledged. A correction was made. RSM

COMMENTS: Statement regarding "conclusions can't be drawn from Idaho DEQ sampling of streams in 1994" is unclear (Page III-26 - DEIS, Caribou Subsection).

1177, 1362

RIPARIAN - WATER QUALITY

RESPONSE: DEQ sampled listed streams in 1994 using the BURP process. At this time, DEQ has not analyzed the data, nor are they able to state whether beneficial uses are being supported in the streams at this time. RSM

COMMENTS: DEIS III-27: Inaccurate citation "48 miles from Medicine Lodge - Beaver/Camas hydrologic sinks to Thousand Springs area". Distance is much further.

1177

RESPONSE: Your comment is acknowledged. A correction now reads "approximately 150 miles..." RSM

COMMENTS: DEIS IV-17, fifth full paragraph, "Researchers have shown...". Cite source of data describing the effects of vegetation manipulation on stream flow.

1177

RESPONSE: Please refer to the following literature:

Cheng, J.D., 1989. Streamflow changes after clear-cut logging of a pine beetle-infested watershed in southern British Columbia, Canada, Water Resources Research, v.25, no. 3. Page 449-456.

King, J.G., 1989. Streamflow responses to road building and harvesting: a comparison with the Equivalent Clearcut Area procedure, Res. Pap. INT-401, Ogden, UT, U.S. Department of Agriculture, Forest Service, Intermountain Research Station. Page 13.

Gottfried, G.J., 1991. Moderate timber harvesting increases water yields from an Arizona mixed conifer watershed, Water Resources Bulletin, AWRA, v. 27, no. 3. Page 537-547.

Alexander, R.R. and R.K. Watkins, 1977. The Fraser Experimental Forest, Colorado, USDA Forest Service, General Technical Report RM-40. Page 32. RSM

COMMENTS: Unclear what time we are working towards for a DFC which is more stable and productive watersheds.

314

RESPONSE: The Targhee is using a range of historic variation to evaluate the degree of change that has occurred in the past. It is not our intention to replicate a Forest appearance as it may have existed at a given point in time. Rather, the range of historic variation is used to determine a range of vegetation conditions that promotes forest sustainability to insure that all components of the ecosystem remain intact. DM

COMMENTS: DEIS states mass wasting is a principal concern in four out of seven subsections but adequate measures aren't taken to prevent this.

1367

RESPONSE: Identified mass wasting are listed as ecological concerns, in that they are due to natural conditions, such as fine textured subsoils which have a moderate to high slumping potential. They are not a result of management activities. Inherent site conditions are considered during management

RIPARIAN - WATER QUALITY

activities. Although natural instability cannot be prevented, management activities should not make it worse. RSM

COMMENTS: Targhee National Forest may be in violation of Section 401 of the Clean Water Act (CWA) by granting grazing permits in various drainages suffering from moderate to severe water degradation problems. Our interpretation of the CWA requires Forest Service to receive certification from the states prior to issuing grazing permits.

401 of the CWA does apply to water pollution from activities such as grazing and the interpretation of discharge cannot be limited to point-source discharge alone. Consequently, we request that this issue and concern be addressed in the Final EIS.

1365

RESPONSE: Intermountain Region direction requires the Targhee to continue "to issue term grazing permits under existing Agency regulations and policies, until further notice." The ONDA vs. Thomas case in Oregon and the Idaho Conservation League vs. Caswell case in Idaho are currently pending. No final judgment has been issued in either case. Based on decisions in these cases, the Targhee may be required to address activities that result in non-point pollution discharges. RSM

SAGEBRUSH

Sagebrush as Biodiversity Indicator

COMMENTS: Cover of big sagebrush is not an adequate indicator of biodiversity on rangelands. Adopt a more direct and scientifically supported measurement of species diversity; perhaps use native herbaceous perennials coupled with information on presence/abundance of exotic species.

432, 489, 643

RESPONSE: Cover is one of several indicators that can be monitored. For trend comparisons in herbaceous plant communities, basal cover is generally considered the most stable. There are several monitoring techniques and vegetation attributes, including cover, that the Targhee uses to monitor rangelands. Refer to the following publication for additional details: Sampling Vegetation Attributes, Interagency Technical Reference, 1996. WG

COMMENTS: Cite references to justify your claim that biodiversity decreases as sagebrush increases and specifically state the nature of the problems you are trying to address.

1369

RESPONSE: Some of the problems being addressed include: 1) increased risk of fires of higher severity/intensity than historically occurred; 2) loss of species diversity; 3) loss of understory grasses due to sagebrush competition; 4) improve watershed conditions; and 5) alter patch sizes of same age sagebrush.

References include but are not limited to: Winward, A.H., 1991 Management in the Sagebrush Steppe. Special Report 880, June 1991, Agricultural Experiment Station and Winward, A.H., 1992. From presentation at: Prescribed Fire for Resource Management Workshop, February 18-19, 1992. WG

COMMENTS: Sagebrush habitat should have management indicator species.

1369

RESPONSE: The Targhee did not develop management indicator species for sagebrush habitat. Forestwide standards and guidelines were developed for big sagebrush/grassland habitats as a "coarse filter" approach for maintaining these habitats in properly functioning condition. Management activities that are proposed, planned, and implemented at the project level are subject to site-specific NEPA analysis. Special habitat and species needs are considered and addressed in the site-specific analysis of the project area. The Targhee intends to manage Forest ecosystems at properly functioning condition. Four criteria are evaluated in a Properly Functioning Condition assessment: structure, composition, disturbance regimes, and patterns. Each of these criteria function within a range of natural variability. Refer to draft document entitled Properly Functioning Condition Process - Draft 1996. Process Paper D provides an overview on specific species associated with sagebrush/grassland habitats. WG/MO

Improve Vegetation Analysis

COMMENTS: Identify the existing seral distribution of sage/grass before applying prescribed burns to 11,000 to 21,000 acres of mature sagebrush.
1368

RESPONSE: Using existing information from the districts, an estimated 11,000 to 21,000 acres of sagebrush could be burned. These acres range from mid to late seral condition. Site specific analysis includes seral distribution, canopy cover, understory species composition, estimated effects and response of burning and is completed prior to implementation of any project. WG

COMMENTS: Complete a more comprehensive analysis of the factors that have contributed to encroachment on grasslands by Douglas-fir to an increase in the relative cover of big sagebrush on rangelands in this area. Include the role of livestock grazing and its effect on competition from forbs and grasses that have contributed to encroachment.
489

RESPONSE: The Revised Plan serves as an "umbrella" document for the environmental analysis of proposed projects at the Forest level. The Revised Plan is not intended to provide or analyze specific "how to's" of project implementation. Because of this, a more comprehensive analysis of the factors contributing to encroachment of Douglas-fir onto rangelands is not needed at the Forest Plan Revision level. The role livestock grazing has played in the encroachment of Douglas-fir onto rangelands was somewhat expanded between Draft and Final in Chapter III of the FEIS. WG

COMMENTS: Discuss the relationship of mature age class forestation on shrubland/rangeland and its effect on declining populations of sage grouse.
695, 766, 1202, 1368

RESPONSE: Forestwide standards and guidelines for big sagebrush/grassland habitats provide for all species which use this habitat, including sage grouse. Process Paper D provides an overview on specific species associated with these habitats. Future project level activities will consider sage grouse habitat needs on a site-specific basis. Loss of the properly functioning sagebrush ecosystems because of forest encroachment onto rangelands was not identified as an issue on the Targhee. The publication from the Idaho Fish and Game--Idaho Sage Grouse Management 1996-2000, (Draft), June 1996, identifies numerous issues that contribute to the decline of sage grouse in Idaho. Forestation on shrubland/rangeland was not identified as an issue in this document. WG

COMMENTS: Consider a natural mix of sagebrush into a class of 75 percent from 5 to 20 percent canopy cover, rather than 5 to 30 percent. If sagebrush is allowed to get too heavy, excessive fuel loads increase the chance of damage to native grasses and natural seed banks in the soil.
432

RESPONSE: Concerns such as damage to native grasses on a project level would dictate the amount and timing of acreage that would be treated, if any. The

SAGEBRUSH

desired canopy coverage percentages are based on research done by Dr. Alma Winward and Region 4's ecosystem PFC research. WG

COMMENTS: State what level of sagebrush is required to meet the desired vegetative condition.

1369

RESPONSE: This is best addressed at the landscape or project scale of analysis because the desired vegetative conditions for the diverse landscapes across the forest will vary. WG

Sagebrush Control Using Fire

COMMENTS: Discuss how grasslands and shrub steppe ecosystems have been altered by fire suppression, grazing and introduction of non-native species. Alteration has been profound, and tied to domestic livestock grazing.

1364

RESPONSE: Chapter III of the FEIS contains a discussion of these issues. WG

Questions Sagebrush Control Needs

COMMENTS: There is not adequate evaluation of the proposed sagebrush control efforts on wildlife, therefore, eliminate all plans to exercise sagebrush control. Sagebrush removal does not improve habitat, and it harms more wildlife than it helps. It also removes soil building capacity and creates the potential for soil erosion (cites a J. Petersen reference).

384, 643, 1369

RESPONSE: There are no site-specific sagebrush "control" projects identified in the Revised Plan. Using existing information from the districts, an estimated 11,000 to 21,000 acres of sagebrush could be available for burning. Site specific analysis at either the landscape or project level, and including seral distribution, canopy cover, understory species composition, effects on wildlife and watershed conditions, would be completed prior to implementation of any project. WG

COMMENTS: No current research indicates burning sagebrush represents vegetative improvement; this is being used to disguise that the Targhee is burning sagebrush to increase livestock forage.

305, 1369

RESPONSE: As identified in Chapter IV of the FEIS, an increase in AUMs is not anticipated from burning sagebrush. References include but are not limited to: Winward, A.H., 1991 Management in the Sagebrush Steppe. Special Report 880, June 1991, Agricultural Experiment Station and Winward, A.H., 1992. From presentation at: Prescribed Fire for Resource Management Workshop, February 18-19, 1992. WG

COMMENTS: Clarify what research shows sagebrush burn cycles on the Targhee averaged 12-40 years.

1369

SAGEBRUSH

RESPONSE: References include but are not limited to: Winward, A.H., 1991 Management in the Sagebrush Steppe. Special Report 880, June 1991, Agricultural Experiment Station and Winward, A.H., 1992. From presentation at: Prescribed Fire for Resource Management Workshop, February 18-19, 1992. WG

SHOSHONE-BANNOCK TRIBE

The Shoshone-Bannock tribal members submitted the following comments regarding tribal concerns and the Revised Plan.

1455

Tribal Treaty Rights

COMMENTS: Consider alternatives which maintain established treaty rights for tribal members to harvest firewood, posts and poles for personal use.

Discuss and recognize Tribal Treaty rights to harvest firewood and wood products, or provide justification for not doing so. It is important to continue this right with minimal interference (i.e., fee permit harvesting).

Treaty rights cover more than just hunting and fishing. Show evidence that tribal rights for gathering personal use forest products have not been extinguished.

Consider tribal need to use wood gathering in support of other rights, activities, (e.g., corral poles used for promoting agrarian livelihood, firewood/poles utilized when hunting or conducting ceremonies).

RESPONSE: This Final Revised Plan does not infringe on the treaty rights of any tribal member. The ease with which tribal members can use the Forest for different purposes varies by alternatives that are discussed in the FEIS.

On occasion, the tribes have asserted treaty rights for harvesting various timber products from the Forest. According to our Office of General Counsel, no right to harvest timber on the Targhee has been recognized in any court. The Swim v. Bergland case, cited in the Tribal letter, concerns portions of the Caribou that were ceded lands, and on which a right to harvest timber was specifically reserved in the Agreement of 1898. That agreement does not reserve a right to harvest timber from the Targhee. The State v. Tinno case, cited in the Tribal letter, is related to fishing rights, and does not address other Forest products such as post and poles. The Tribe can submit legal briefs in support of their position to the Office of General Counsel (OGC) in Ogden, Utah. If OGC determines that providing free forest products is appropriate at a later date, then the Forest Supervisor will do so. Absent of any new legal information, the Forest cannot recognize this claim because there is no adequate basis for the claimed right in the treaties or case law. JBR

Access

COMMENTS: Assess the direct, indirect and cumulative effects of existing and proposed road closures on tribal rights activities; describe in detail the nature and extent of previous closures.

RESPONSE: The information presented in the FEIS is sufficient to gain a good understanding of road closures in each alternative. No limits are placed on tribal access beyond limits for the general public. Reasonable access is provided to the Forest for hunting and fishing activities as outlined in the Fort Bridger Treaty. JR/DP

COMMENTS: Revise the access management strategy to provide reasonable access to Antelope Flats Rd. #771 and Keg Springs Rd. #042 prior to and following general rifle season.

SHOSHONE-BANNOCK TRIBE

RESPONSE: Road #771 is a popular, short, cut-off road between North and South Antelope Roads (both of which remain open under the Revised Plan). Road #771 is closed to meet wildlife needs. The other open roads still provide adequate access to the area. Keg Springs Road is open under the Revised Plan. DP

COMMENTS: The Revised Plan's seasonal closure of roads beginning prior to archery season should address the tribal request to leave roads open from August 1st to the opening of the general rifle season, because this is a critical time for tribal resource use. Consider leaving roads open during this time to determine the effects on tribal rights activities from cumulative road closures.

RESPONSE: The Forest considered this request. Some prescriptions permit more open roads prior to big game hunts, others do not. The Targhee recognizes the need to improve wildlife conditions while providing adequate motorized access. Regarding roads seasonally restricted, the Targhee changed the restriction date to October 1, just prior to the big game rifle season. This directly responds to the tribe's concern regarding restrictions which would begin in August or September. Other roads are restricted year-round in the Final Revised Plan and will not be available for motorized access during the August/September period. JR/DP

Monitoring

COMMENTS: Monitor cultural resource sites on grazing allotments consistent with National Programmatic Agreement.

RESPONSE: A forestwide standard was added to address Tribal coordination and the procedure adopted addresses this concern. DP

COMMENTS: Include provisions to establish a consultation procedure and intergovernment agreement with the tribes to guide future cooperative efforts. Include this process as mitigation proposal for effects on tribal activities; include in the schedule of activity.

RESPONSE: A forestwide standard was added to address Tribal coordination, which, along with procedures established in Forest Service Manuals and Handbooks, addresses any mitigation needs. Because it is a standard and always in effect on the Forest, including it in a schedule of activities is unnecessary. DP

Management Cooperation

COMMENTS: Recognize tribes as co-managers along with other agencies including Idaho Department of Fish and Game as established by CFRs 1502.16(c); 40 CFRs 1506,2(d).

RESPONSE: All CFRs remain in effect. In the interest of brevity, the Forest does not duplicate their language. The Targhee will continue to cooperate on matters of mutual interest. JR/DP

SHOSHONE-BANNOCK TRIBE

COMMENTS: Conduct a socio-economic analysis which describes the reservation as a discreet economic unit. Refer to the Challis Resource Area BLM Analysis currently in process.

RESPONSE: The Targhee obtained a copy of this analysis and expanded the information to the extent it was appropriate and available. DP

Planning

COMMENTS: Commit to developing a minimum baseline level analysis to be incorporated into each NEPA document prepared under the plan in the future to address Tribal concerns at the site-specific project level; discuss this commitment in a mitigation proposal; propose a schedule to work toward developing this procedure.

RESPONSE: Existing direction for site-specific NEPA documents is sufficient to address Tribal concerns. The level of analysis for each project should be commensurate with the significance of the effects and the issues involved.

The Targhee agrees that tribal consultation is appropriate on proposed actions for site-specific projects. Site-specific analysis will address issues and concerns identified by the tribes. JR

COMMENTS: Recognize Tribal Rights are a protected interest and not a privilege afforded the tribe by the Forest Service.

RESPONSE: This is specifically addressed in Chapter III of the FEIS. DP

SNOWMOBILES

Plan Analysis and Development

COMMENTS: Address snowmobiling use more adequately in the EIS; all alternatives should address problems caused by snowmobiles in winter. Use considerable amount of available scientific data showing snowmobile impacts in developing standards and guidelines. Establish snowmobile season based on snowfall and temperature patterns to minimize negative impacts.

Amount of snowmobile access in all alternatives is acceptable; proposed snowmobile access is a good compromise; favor the increased snowmobile use as stated in 3M; support the increase in number of groomed trails. Allow additional trails to be constructed under a categorical exclusion.

18, 22, 28, 30, 31, 35, 37, 39, 40, 44, 49, 50, 52, 53, 55, 182, 212, 266, 293, 310, 325, 618, 643, 1202, 1205, 1244, 1263, 1276, 1351, 1360, 1365, 1367b

RESPONSE: Additional text is added to the FEIS describing snowmobile use and trends, consequences, and pending guidelines for management from the Greater Yellowstone Winter Visitor Use Management study which is underway. These guidelines separate some user activities to resolve conflicts. A restriction on cross-country snowmachine travel on additional areas of winter range prescription was added to the Revised Plan. These areas include all winter range inventoried with the Game and Fish Departments.

The EIS shows the planned groomed or marked trails shown in the Transportation Plan. Grooming is done by the counties and will depend upon their funding options. Planned trails were analyzed as part of the pending Greater Yellowstone Winter Visitor Use Management (GYWVUM) Assessment. AS

COMMENTS: Modify Alternative 6 for winter recreation management and snowmobile use. Only Alternative 6 calls for a reduction in groomed snowmobile trails. Needs more analysis, discussion.

643, 1367b

RESPONSE: Alternative 6 was not modified because more snowmachine use would not meet the goals and objectives or design of this alternative. AS

COMMENTS: Page I-4, last paragraph seems prejudicial because the Forest is not meeting 1985 Plan goals for snowmobiles, timber harvest, among other things, but these are not discussed.

413

RESPONSE: There were no goals for snowmobile activity in the 1985 Plan. In fact snowmobiles were hardly mentioned. The Revised Plan addresses snowmobile activity. AS

User Conflicts

COMMENTS: Address in the EIS the impacts of increased use on marked or groomed trails and impacts on users. Address conflicts between users (for instance, cross-country skiers and snowmobiles); use land allocations to reduce conflicts between different winter recreation users. Do not allow snowmobiles on existing trails that are used by cross-country skiers.

SNOWMOBILES

Restrictions and closures for snowmobile use will lead to improper behavior/use in smaller areas; do not force snowmobilers to ride in more confined areas as it will lead to more accidents. Designate snowmobile-free areas along plowed roads so skiers and snowshoers won't have to hear/smell snowmobiles. Reduce snowmobile use and improve winter recreation.

354, 608, 679, 697, 1202, 1263, 1276, 1335, 1342, 1351, 1367, 1387, 1395

RESPONSE: The Revised Plan contains a forestwide winter recreation standard that prohibits snowmachines and dogsleds from using designated cross-country ski areas. The Final Revised Plan also contains a new objective directing the establishment of a few non-motorized activity areas by the year 2000, in accordance with guidelines forthcoming from the pending Greater Yellowstone Winter Visitor Use Assessment. AS

Safety

COMMENTS: Establish and enforce speed limits; snowmachine guides should have safety training before using Forest trails. Coordinate with Idaho Department of Parks and Recreation to establish a linear capacity for two-way snowmobile trails. Coordinate with Idaho Parks and Recreation and local law enforcement to develop standards and guidelines for safety, speed limits, and private property protection. Require snowmobile users to have a permit and be a certain age. Prohibit use of snowmobiles after dark.

13, 65, 325, 629, 697, 1276, 1365

RESPONSE: Safety training is an operational requirement of the outfitter's special use permits. No requirement is needed in the Revised Plan. Speed limits are an administrative decision separate from the Revised Plan. Speed limits are being considered and may be established in the future. A minimum age requirement is a State or County legislative action. Coordination with other agencies is ongoing and is not necessary to add to a Forest Plan. The Forest does not have a nighttime restriction since snowmachines are designed for such use and such a decision is administrative and would not be included in a Forest Plan. AS

Monitoring, Enforcement, Funding

COMMENTS: Institute citizen monitoring programs to enforce and educate people about the regulations. Provide funding to conduct a Forestwide assessment on the impacts of snowmobiling on flora and fauna; commit funding and personnel for implementing snowmobile management strategies. Develop a comprehensive review of environmental and user impacts of snowmobile use over the past ten years, using best science; develop baseline data, and continue to refer to science in management decisions. Monitor the number of snowmobile trespasses; annually report monitoring of snowmobile use and make enforcement adjustments to correct abuses; monitor big game winter habitat, bear management units, and Jedediah Smith Wilderness for encroachment by snowmobiles. Fund enforcement in winter range to protect moose; monitor snowmobile use as it increases because most big game are dispersed in winter; explain where big game winter range snowmobile use will be permitted; protect/maintain all winter range snowmachine access. Do not assume areas not included in

SNOWMOBILES

restrictions are too difficult for today's high performance machines; prohibit snowmachines from hydroplaning on river. Enforce non-motorized wilderness restrictions to snowmobiles.

FS-10, 161, 167, 179, 191, 215, 293, 307, 311, 319, 625a, 644, 659, 697, 1245, 1277, 1312, 1313, 1314, 1330, 1360, 1365, 1393

RESPONSE: The Forest Plan includes considerable direction to protect and monitor impacts of snowmobile activity on wildlife. Monitoring and evaluation for the last 10-20 years indicates that snowmobiling results in minimal impacts to flora or fauna or other resources. The Targhee will continue enforcing restrictions such as the prohibition of snowmachine use in wilderness. Citizen-reported monitoring information is always welcome. No effort has been made to organize a specific citizen's monitoring group. A monitoring and evaluation action item is established to monitor BMUs and other restricted areas for snowmobile encroachment. AS

COMMENTS: Revise Jedediah Smith monitoring plan to include monitoring over winter survival of yearlings and to include the park.

699

RESPONSE: The Jedediah Smith Wilderness is closed to snowmobiles. Wyoming Fish and Game monitors winter survival of wildlife and includes the Park. AS

COMMENTS: Need additional funding sources if grooming of additional trails will happen.

629, 734

RESPONSE: The Targhee makes it clear in the EIS and Revised Plan that additional trail development is subject to County or other funding. AS

Cooperative Management

COMMENTS: Use information from the "Report on Formal Comments on Current and Potential Adverse Impacts of Winter Recreation Use in Yellowstone National Park." Develop an overall winter recreation management plan based on the Master Development Plan model used by alpine ski areas to minimize conflicts. Coordinate snowmobile use with surrounding public lands managers; include snowmobile users in planning process. (CROSS REFERENCE: Recreation)

413, 618, 1263, 1342, 1345, 1367b

RESPONSE: Additional text is added to the FEIS to describe snowmobile use and trends, consequences, and pending guidelines for management which may result from the pending Greater Yellowstone Winter Visitor Use Management study. The Targhee will continue to coordinate snowmobile use with surrounding public land managers. Through public meetings and mailings, users assist in determining the issues, desired future conditions, prescriptions and alternatives. AS

Impacts

COMMENTS: Impacts from snowmobiles that must be noted, evaluated, monitored, and mitigated, using best available science and citations, include:

SNOWMOBILES

contamination of soils from refueling, accidental spills, and on-trail maintenance; exhaust impacts on trout ability to swim upstream; water quality and hydrologic processes; sedimentation and turbidity; lead contamination; impacts to aufwuchs communities; impacts on below surface vegetation, browse plants, plant phenology, delay in snowmelt and vigor characteristics; spread of noxious weeds and exotics; changes in plant density and species composition, diminished yields of forage grass and other plants, and changes in wildlife foraging patterns; changes in duration and timing of moisture release to plants; concentration of run-off at road edge causing increased erosion; blockage of run-off causing muddy roads and trails; snow compaction leading to reduced soil temperature, retarded microbial activity, changes in soil micro-structure and seed germination; destruction of vegetative cover; impacts on sub-nivean species; wildlife stress responses; elk and big horn sheep home range carrying capacity reduction; noise impacts on wildlife such as nest abandonment and juvenile predation and mortality; loss of ptarmigan; grizzly bear den abandonment; and impacts on sensitive areas such as old growth, threatened and endangered species habitat, semi-natural meadows and grasslands, alpine areas, and degraded range land; and aesthetic impacts. (Numerous studies on snowmobile impacts cited.)

1365

RESPONSE: Many of these concerns are better addressed at project scale. Potential soil impacts, although generally negligible, are also dependent on site factors such as snow depth, coarse fragments, texture, structure, presence or absence of down woody material, habitat type, slope, and/or aspect. Impacts of soil contamination are difficult to analyze and probably of small area extent. Monitoring and evaluation for the last 10-20 years indicates that snowmachining results in minimal impacts to flora or fauna, with no need for noise or emissions restrictions at the present time. This is better analyzed at project level if it becomes a problem. AS

Mitigate Impacts

COMMENTS: Prohibit snowmobiles in areas where impacts are likely to be significant; use less ecologically sensitive areas for snowmobiles; create a buffer zone around important habitat and around all Class I (Clean Air Act) areas; develop a zoning scheme for motorized and non-motorized corridors, within ecological and biological constraints, to allow continuous travel in the Greater Yellowstone Ecosystem. Design trails so protective cover between snowmobiles and wildlife is maximized; do not allow snowmobiles to stop in areas that may exacerbate wildlife stress responses. Impose restrictions on party size and length of stay; prohibit travel on steep slopes ($>25^{\circ}$); greater than $>40^{\circ}$. Develop a policy dealing with exhaust emissions; establish emission and noise standards. Develop positive incentives to reduce snowmobile impacts, e.g., reduced fees to users whose snowmobiles meet emission and noise standards. Impose seasonal restrictions on bag limits and prohibit the transport of weapons on snowmobiles if snowmobile-facilitated hunting mortality warrants. Develop an interpretation/education program to explain restrictions. Evaluate in terms of damage each user group (snowmobiles, ORVs etc) does, then control access accordingly.

61, 175, 266, 351, 410, 618, 655, 1273b, 1365

SNOWMOBILES

RESPONSE: Many of these mitigations are addressed by the winter range prescriptions, standards and guidelines in the Revised Plan. The pending Greater Yellowstone Winter Visitor Use Management Guidelines will also address the zoning concept, emissions, and similar concerns. Using less ecologically sensitive areas for snowmachines is accomplished through the application of prescriptions, standards and guidelines, and monitoring direction. The Forest has no evidence to support a need to create buffer zones and has not created any. The Winegar Hole and Jedediah Smith Wilderness provide a buffer to the Grand Teton and Yellowstone National Park airsheds. Due to extremely low levels of concentration of users on the Forest, emission and noise restrictions appear unwarranted. An interpretation/education program will continue each year, with emphasis during the date when the Travel Plan is approved for implementation and when maps are ready for distribution. There is no indication of need for restrictions on party size and length of stay at this time. Site-specific decisions can be implemented in the future as needed. AS

Does Not Cause Erosion

COMMENTS: Snowmobiles do not cause erosion because of snowpack; the local farming community is helped by winter vehicles because the resulting snowpack reduces erosion and slows spring runoff.

307, 311

RESPONSE: Your comments were noted and considered. AS

Economic Impacts

COMMENTS: Snowmobiling provides economic support to local communities and prohibiting snowmobiles in certain places or at certain times will negatively affect local economies.

4, 72, 168, 220, 289, 395, 405, 413

RESPONSE: The restrictions contained in the Revised Plan have minor, limited potential for economic effects. The vast majority of snowmobile use potential is unrestricted, and many miles of additional trails are potentially available for marking and grooming. AS

Oppose Closures/Restrictions/Change Dates

COMMENTS: Oppose some or all snowmobile restrictions:

F-C(13), F-F(6), F-I(4), F-M(5), F-N(7), F-O(4), 4, 7, 8, 9, 10, 12, 13, 15, 17, 18, 26, 29, 32, 33, 34, 37, 38, 42, 46, 52, 53, 54, 55, 56, 59, 66, 67, 69, 70, 71, 72, 89, 97, 98, 156, 160, 169, 181, 182, 188, 198, 216, 220, 227, 234, 235, 258, 265, 267, 272, 277, 280, 285, 286, 287, 289, 290, 300, 303, 310, 319, 323, 342, 351, 363, 367, 380, 381, 385, 386, 388, 412, 413, 429, 430, 431, 437, 473, 470, 473, 474, 476, 481, 495, 506, 515, 524, 529, 608, 626, 627a, 629, 635, 645, 668, 669, 692, 695, 713, 715, 717, 718, 728, 729, 733, 734, 738, 767, 1176, 1182, 1202, 1239, 1248, 1256, 1259, 1267, 1268, 1314, 1316, 1319, 1320, 1333, 1355, 1358, 1359, 1366, 1378, 1389, 1392, 1456

SNOWMOBILES

Oppose closures in Bear Management Units because: not necessary because bears are hibernating; find better ways to protect bears leaving den; don't put grizzly bears in forest; insufficient science to support restrictions; in higher elevations because bears migrate to lower elevations; allow controlled use in BMUs; the OROMTRD used in BMUs not supported by scientific evidence.

F-M(5), F-N(7), 8, 9, 59, 66, 69, 70, 71, 89, 169, 188, 216, 220, 235, 277, 285, 289, 629, 692, 717, 1202, 1316, 1358, 1389

Wolves do more damage to wildlife than snowmobilers.

17

Insufficient evidence wildlife, deer, elk are bothered.

7, 67

Oppose restrictions to protect Bald Eagles because they nest near human activity, as at Kennedy Space Center.

734

Allow more access outside big game winter ranges.

645

Oppose snowmobile restrictions in big game winter range because snow has melted by this time and it is a useless restriction.

272, 767, 1202

Restrictions prevent using excellent snow conditions found off-trail.

413

Restrictions are unenforceable.

1316, 1320

Oppose date restrictions:

F-C(13), F-I(4), F-M(5), F-N(7), 7, 8, 9, 10, 12, 15, 18, 53, 56, 59, 66, 67, 69, 70, 71, 72, 89, 97, 160, 169, 188, 216, 220, 234, 235, 265, 267, 272, 277, 285, 287, 289, 290, 303, 323, 363, 367, 380, 388, 413, 437, 476, 481, 495, 506, 515, 524, 529, 608, 626, 629, 692, 695, 713, 717, 718, 729, 767, 1176, 1202, 1267, 1268, 1316, 1333, 1355, 1389, 1402

Oppose date restrictions because: unenforceable; unreasonable; dates are arbitrary, do not consider snow conditions; there is not enough snow before December 15 to go off trail anyway; if there is not enough snow, people don't ride anyway; April/May are great snowmobiling times; there is no record of snowmachine conflict with grizzly bears; only if bears begin using area; bears aren't around until May, and if they ever are they go to lower elevations; there is no research of effects on bears; snowmobiles don't chase bears; bears hibernate depending on temperature and snow depth, not dates; enjoy snowmobiling from November to May; far away from game wintering areas; bears are in hibernation; is past hunting season; no bears in upper elevations; no scientific basis for dates, most bears are dened by November 8.; select Alternative 2.

F-M(5), F-N(7), 7, 8, 9, 10, 12, 18, 53, 56, 59, 66, 67, 69, 70, 71, 89, 97, 160, 166, 169, 188, 216, 220, 234, 235, 258, 277, 289, 303, 342, 363, 380, 413, 515, 629, 635, 692, 713, 717, 718, 734, 767, 1202, 1267, 1268, 1316, 1333, 1355, 1389

RESPONSE: All of the elk and deer winter range areas on the Forest are closed to cross-country snowmachine use throughout the entire period. This is done to protect the wintering animals and help them conserve their energy.

SNOWMOBILES

For the Fall season, outside of elk and deer winter range, the Revised Plan allows cross-country snowmachine travel beginning Thanksgiving Day on all Districts except Palisades. On the Palisades District, cross-country snowmachine travel will be allowed beginning Dec. 15. Since the mean date for grizzly bear denning in the Greater Yellowstone Area is Nov. 9, these cross-country snowmachine dates allow grizzly bears adequate time to inhabit potential dens. These cross-country snowmachine dates also prohibit big game hunters from using snowmachines to pursue big game animals for most of the general and controlled hunting seasons. On the north end of the Forest, there are a few late season controlled hunts after Thanksgiving Day, therefore some hunters may pursue big game animals on snowmachines for these late season controlled hunts.

For the spring season, outside of elk and deer winter range areas, cross-country snowmachine travel is allowed until June 1. Within the grizzly bear recovery zone, site-specific area closures are allowed to resolve any conflicts between snowmachine use and grizzly bears which have come out of their dens. MO

COMMENTS: April 1 is far too early to open winter range because spring is time of greatest stress; date should depend on conditions and be established through consultation with state game biologists.

643

Restrict cross-country snowmobile use after April 15 to protect bears emerging from their dens.

1351

Restrict snowmobiles to early winter months (January - March) because of stress to grizzly bears.

61, 212, 305, 1322

Restrict snowmobiles in BMUs between December 15 and April 1.
731, 1276

Support snowmobile closures between December 15 and April 1.
610, 1276

Allow snowmobiles only on existing trails, outside proposed wilderness, between December 15 and April 1.

395, 437, 731

Restrict snowmobiles in grizzly habitat for full winter season, not just December 15 to April 1.

171

Restrict snowmobiles in areas already degraded by overcutting.

167

Shorten the season two weeks on either end of the date rather than the month proposed.

1402

Establish a snowmobile season based on snowfall and temperature patterns, both general and site-specific.

1365

If dates needed, open from November 15 to June 1.

53, 629

Extend snowmobiling season to end of April.

166

SNOWMOBILES

Set December 15 opening date for snowmobiling in grizzly habitat.

695

Do not restrict snowmobiles in early winter and late spring because bears will not be in areas of sufficient snow, and where not sufficient snow, snowmobiles will not be, so point is moot.

718

Unclear if snowmobile cross-country travel into BMUs from December 15 - April 1 will fit with recent reports of non-denning grizzly bears in other areas.

690

Oppose closures, select Alternative 2.

F-M(5), F-N(7), 56, 66, 67, 89, 97, 188, 216, 234, 235, 303, 342, 635

Oppose closures/restrictions in: Lionhead, Island Park, Big Holes, Palisades, Italian Peaks, Diamond Peaks, Centennials, Two Top, Fish Creek, Sheep Mountain, Chick Creek, Bechler Meadows, Pony and Canyon Creek area, Keg Springs, Snow Creek, Fall River Ridge, South Plateau, Black Bear Canyon, Centennial Valley, and/or corridor from Byrne's Siding to backcountry beyond Kelly Canyon.

F-C(13), F-I(4), F-L(3), F-M(5), F-N(7), F-O(4), F-P(2), 2, 8, 9, 13, 15, 66, 67, 72, 89, 97, 98, 160, 169, 188, 198, 216, 229, 234, 235, 300, 303, 323, 342, 380, 381, 385, 386, 412, 413, 429, 437, 461, 463, 466, 469, 473, 474, 476, 495, 515, 517, 524, 529, 608, 660, 728, 1202, 1253

Doubtful if snowmobiles that frequent area from the Centennials north to Cliff Lake-Wade Lake Bench area disturb bears in hibernation.

169

Remove date restrictions on snowmobile use in Prescriptions 2.4, 2.5, 3.2c, 3.2d, 3.2g, 5.4c.

767

Oppose restrictions on cross-country snowmobiling.

F-C(13), F-I(4), F-O(4), 181, 220, 267, 280, 290, 310, 323, 367, 381, 385, 386, 412, 430, 473, 474, 476, 481, 495, 506, 608, 626, 669, 715, 738, 1202, 1256, 1314, 1316, 1366, 1378, 1392

RESPONSE: The summer travel plan takes effect yearly in the spring as local conditions become suitable to support wheeled vehicle traffic on roads without damage. Snowmachines may use roads and trails shown on the summer travel plan as open to motorized use. Cross-country snowmachine travel is allowed only where the summer travel plan allows cross-country motorized travel after June 1.

The winter travel plan takes effect yearly on Thanksgiving Day. Snowmachine travel is allowed consistent with the winter travel plan map. Cross-country snowmachine travel is permitted from Thanksgiving Day through June 1 except on the Palisades Ranger District which permits usage from December 15 through June 1. Cross-country snowmachine travel is allowed in prescription area 5.1.4(c) (Big Bend Ridge) from January 1 until April 30.

Cross-country motorized use is not allowed on elk and deer winter areas at any time of the year. Nonmotorized cross-country use (walking, horses, etc.) is allowed from April 15 to Thanksgiving Day on all Districts except Palisades. On Palisades District, non-motorized cross-country use is allowed from April 15 to December 15. MO

SNOWMOBILES

COMMENTS: Clarify season to allow spring snowmobiling in Kelly Canyon after ski hill closes.

60, 1202

RESPONSE: The Forest added a new Prescription 5.1.4(d) which allows snowmobiling on the Kelly Canyon road only when the resort is closed for the season. No cross-country snowmachine use in the area is allowed. AS

Support Closures/Restrictions

COMMENTS: Support some or all restrictions on snowmobile use: they damage vegetation and soils; compact snow; damage sub-nivean environment; disturb wildlife; have offensive noise, sight, smell; they pollute; to protect wildlife; allow only in certain areas or at certain times; allow only on existing roads and trails; restrict from Bear Management Units; do not allow in wilderness study areas; restrict in areas degraded by overcutting.

F-B(4), F-G1(475), F-H(8), F-J(3), FS-10, 1, 3, 21, 31, 60, 61, 73, 120, 143, 150, 157, 158, 161, 162, 165, 167, 168, 170, 171, 173, 174, 175, 178, 179, 180, 185, 187, 189, 190, 192, 195, 201, 203, 206, 209, 212, 213, 226, 227, 244, 252, 263, 273, 274, 276, 278, 285, 293, 305, 317, 325, 328, 341, 351, 353, 354, 356, 359, 360, 373, 376, 389, 395, 396, 400, 438, 441, 442, 443, 444, 448, 490, 516, 519, 527, 610, 611, 615, 617, 622, 625a, 627b, 631, 632, 640, 643, 645, 651, 653, 655, 662, 664, 669, 690, 695, 697, 725, 731, 739, 766, 1183, 1245, 1247, 1270, 1273b, 1276, 1277, 1313, 1314, 1322, 1327, 1330, 1331, 1351, 1360, 1361, 1365, 1367b, 1381, 1387, 1388, 1393, 1395, 1399, 1458

RESPONSE: Refer to the Winter Recreation Standards and Guidelines in the Revised Forest Plan (Chapter III-Part I) and the Access tables for the various prescription areas (Revised Forest Plan Chapter III-Part 3). AS

COMMENTS: Prohibit snowmobile travel on steep slopes (more than 25 degrees) to minimize avalanche risk and erosion risk.

1365

RESPONSE: Avalanche hazard depends on snow and weather conditions. Exposure and risk are up to the operator. The Targhee is unaware of any erosion impacts occurring on steep slopes from snowmachine use. AS

To Benefit Wildlife

COMMENTS: Protect wildlife in areas used by snowmobiles; minimize snowmobile impacts during period of peak wildlife mortality. There is too much winter access; allow only in higher elevations to protect wildlife at lower elevations; restrict to low impact areas. Close more areas, especially in elk and deer winter range; restrict in all areas identified by Idaho Fish and Game as winter range. Explain rationale of allowing cross-country snowmobile use on 66% of crucial winter range when neither scientific literature or largest snowmobile advocacy group supports it. Allowing snowmachine travel in area allotted to other prescriptions in winter range may allow deer and elk to be harassed during period of greatest stress. Lower prescription on motorized use in elk and deer winter range because <2 mi./sq. mi. is too high. No

SNOWMOBILES

increase in snowmobile access because it interferes with wildlife winter survival and creates historic precept even if area proves to be important habitat; keep snowmobiles out of elk and moose habitat because the two don't mix; add a standard to prohibit human presence in critical big game winter range from Dec 1 to April 30; require seasonal or year-round closures for all motorized vehicles in important elk habitat, sensitive habitat, areas of "Concern", areas of Threatened and Endangered Species, areas of vegetation, old growth, alpine areas and on degraded range land. Make all deer and elk winter range off limits to snowmobiles. Prohibit game retrieval by using snowmobiles.

F-B(4), F-G-1(475), F-G-1-P, FS-10, 5, 31, 120, 143, 150, 161, 162, 168, 170, 171, 174, 175, 178, 179, 185, 189, 203, 206, 212, 213, 227, 274, 285, 293, 305, 319, 359, 376, 389, 610, 617, 625a, 643, 645, 669, 690, 695, 697, 731, 766, 1183, 1245, 1247, 1273b, 1277, 1322, 1361, 1365, 1381, 1458

RESPONSE: All of the elk and deer winter range areas on the Forest are closed to cross-country snowmachine use throughout the entire period. This is done to protect the wintering animals and help them conserve their energy.

For the Fall season, outside of elk and deer winter range, the Revised Plan allows cross-country snowmachine travel beginning Thanksgiving Day on all Districts except Palisades. On the Palisades District, cross-country snowmachine travel will be allowed beginning Dec. 15. Since the mean date for grizzly bear denning in the Greater Yellowstone Area is Nov. 9, these cross-country snowmachine dates allow grizzly bears adequate time to inhabit potential dens. These cross-country snowmachine dates also prohibit big game hunters from using snowmachines to pursue big game animals for most of the general and controlled hunting seasons. On the north end of the Forest, there are a few late season controlled hunts after Thanksgiving Day, therefore some hunters may pursue big game animals on snowmachines for these late season controlled hunts.

For the spring season, outside of elk and deer winter range areas, cross-country snowmachine travel is allowed until June 1. Within the grizzly bear recovery zone, site-specific area closures are allowed to resolve any conflicts between snowmachine use and grizzly bears which have come out of their dens. MO

COMMENTS: Of greatest concern is the allowance of cross-country snowmachines travel within winter ranges allocated to other prescriptions. This is the case for winter range that falls within Management Prescription 5.3.1(a-b) Timber management, MP 5.3.5 Grizzly Bear Habitat; MP 5.4(a, b, c) Deer and Elk summer range; MP 6.1(b) Range Management; MP 3.2(a-g) Semi-Primitive Motorized and MP 5.1.4(a-c) Timber Management, where both winter and summer cross-country motorized travel is allowed. Under these other Management Prescriptions there is every reason to believe that deer and elk will be harassed intentionally or not during the period of greatest stress.

643

If the Forest believes that the areas used as deer and elk winter range but not covered by MP 2.7(a-c) are not accessible to snowmachines, then there is no reason for not placing all of those areas into MP 2.7(a-c).

No letter #

SNOWMOBILES

RESPONSE: The Revised Plan has forestwide standard under winter recreation which restricts snowmachine use to designated routes in all inventoried winter range. AS

COMMENTS: Design trails so that protective cover between snowmobilers and wildlife is maximized.

1365

RESPONSE: The trail layout of existing and planned snowmachine trails and restriction of cross-country travel in winter range areas addresses this concern. AS

Bear Habitat

COMMENTS: Restrict snowmobiles in bear habitat: because it would be a mistake to cater to a limited number of users at the expense of bear habitat; support ban of snowmobiles in bear management units; Fremont County Commission agrees to no cross-country snowmobiling in BMUs. Restrict snowmobiles in Island Park and Fish Creek Areas because the important issue is the grizzly bear and its habitat; protect bears emerging from dens; restrict snowmobiling to early winter months because of stress to grizzly.

61, 167, 168, 173, 212, 263, 305, 314, 395, 610, 731, 1276, 1322, 1351

RESPONSE: The Targhee established a restriction of cross-country snowmachine travel prior to Thanksgiving day (except for the Palisades District which is Dec. 15) in order to benefit bear and elk management as well as other resources. AS

Cross-Country

COMMENTS: Support closures/restrictions on cross-country snowmobiling; permit snowmobiles only on existing roads and trails, make no new ones; use existing trails/roads planned with other agencies and private land owners; so cross-country skiers don't have to see, smell, or hear them. Restrict cross-country snowmobiling because of impacts on vegetation and wildlife; they are polluting; ensure they have enough trails so they don't have to access the entire forest; allow snowmobiles only on existing trails, outside proposed wilderness between December 15 and April 1.

1, 9, 61, 143, 158, 293, 305, 325, 354, 359, 373, 395, 437, 442, 610, 631, 655, 690, 731, 734, 1202, 1276, 1331, 1360, 1365, 1387, 1395

Oppose restrictions on cross-country snowmobiling.

F-C(13), F-I(4), F-O(4), 181, 220, 267, 280, 290, 310, 323, 367, 381, 385, 386, 412, 430, 473, 474, 476, 481, 495, 506, 608, 626, 669, 715, 738, 1202, 1256, 1314, 1316, 1366, 1378, 1392

Forest should adopt a forestwide standard prohibiting all cross-country use except for snowmobiles.

695

In Management Prescription 2.2.1(b) allow cross-country snowmachine travel between December 15 - April 1; in 2.2.1 do not allow cross-country snowmobile travel before December 15 or after April 1.

643

SNOWMOBILES

RESPONSE: All of the elk and deer winter range areas on the Forest are closed to cross-country snowmachine use throughout the entire period. This is done to protect the wintering animals and help them conserve their energy.

For the Fall season, outside of elk and deer winter range, the Revised Plan allows cross-country snowmachine travel beginning Thanksgiving Day on all Districts except Palisades. On the Palisades District, cross-country snowmachine travel will be allowed beginning Dec. 15. Since the mean date for grizzly bear denning in the Greater Yellowstone Area is Nov. 9, these cross-country snowmachine dates allow grizzly bears adequate time to inhabit potential dens. These cross-country snowmachine dates also prohibit big game hunters from using snowmachines to pursue big game animals for most of the general and controlled hunting seasons. On the north end of the Forest, there are a few late season controlled hunts after Thanksgiving Day, therefore some hunters may pursue big game animals on snowmachines for these late season controlled hunts.

For the spring season, outside of elk and deer winter range areas, cross-country snowmachine travel is allowed until June 1. Within the grizzly bear recovery zone, site-specific area closures are allowed to resolve any conflicts between snowmachine use and grizzly bears which have come out of their dens. MO

Wilderness, Wilderness Study Areas, Roadless Areas

COMMENTS: Do not allow snowmobiles in wilderness, wilderness study areas, and/or roadless areas: it detracts from wilderness quality and sets historic precedent; to protect wildlife; except in higher mountains; is incompatible with the wilderness ethic

F-B(4), F-G-1(475), F-J(3), 3, 60, 73, 150, 157, 162, 165, 168, 170, 174, 175, 179, 180, 185, 187, 189, 190, 192, 195, 201, 203, 206, 209, 212, 213, 226, 244, 273, 274, 278, 280, 289, 351, 360, 376, 396, 400, 438, 441, 444, 448, 490, 516, 615, 622, 627b, 632, 640, 651, 652, 653, 659, 664, 690, 692, 695, 725, 738, 739, 1183, 1245, 1270, 1276, 1277, 1314, 1327, 1330, 1360, 1365, 1388, 1393, 1458

Do not allow snowmobiles in wilderness study areas because: use sets historic precedent and makes wilderness designation difficult or impossible. Wilderness is incompatible with motorized use; because they disrupt wildlife and damage habitat. Limit to established routes with clear condition that such use will cease if area is added to wilderness preservation system. There is enough National Forest for them; must preserve some areas as smokeless and quiet, and allow solitude.

F-B(4), F-G1(475), F-H(8), F-J(3), 73, 157, 162, 165, 168, 170, 174, 175, 179, 180, 201, 209, 226, 252, 273, 278, 280, 351, 622, 632, 662, 1270, 1276, 1313, 1387, 1388, 1395

Abolish snowmobiles and severely restrict ORV use in order to protect the wilderness values of the roadless areas in the Centennials, Palisades Roadless Area, and Big Holes.

725

RESPONSE: Snowmachines are not allowed in wilderness. Snowmachines are generally allowed in roadless and recommended wilderness areas. The Wyoming Wilderness Act allows snowmobiles in Wilderness Study Areas. Snowmachine use does not degrade wilderness potential and historical use can be managed. AS

SNOWMOBILES

COMMENTS: Oppose closures/restrictions in wilderness, wilderness study areas, and roadless areas: because not a threat except where big game range is a concern; our company tests snowmobiles there; should not be banned but regulated; snowmobiling doesn't hurt vegetation under the snow; the real threat is logging and mining; because too restrictive.

26, 29, 272, 280, 286, 367, 476, 627a, 669, 738, 1202

RESPONSE: Snowmachines are not currently banned from the Palisades Wilderness Study Area. They are allowed by the Wyoming Wilderness Act. Other comments are noted and considered. Snowmobiling in designated wilderness areas is illegal as determined by Congress. AS

COMMENTS: Address how the 1,516,000 acres left open to snowmobiling compares in annual snowfall, terrain quality, and regional accessibility to the roadless area land because our company traditionally field tests its products in roadless area land.

627a

RESPONSE: About one-half this area is roadless. Roadless areas typically have better snow, because they are in the higher elevation terrain; however, roadless terrain is also steeper, thus limiting some access. All the area tends to be about equal in terms of snowmachine opportunity. AS

COMMENTS: Support unrestricted snowmobiling in Semi-Primitive Non-Motorized (Dark Green Rx).

1202

RESPONSE: Thank you for your support. AS

COMMENTS: Recommend a new prescription that manages areas as wilderness in summer and allows snowmachines access in areas where big game winter range is not a concern (Big Holes, Centennials).

669

RESPONSE: This would not be compatible with the Wilderness Act. AS

Riparian

COMMENTS: Exclude snowmobiles from all established riparian buffer zones along the Henry's Fork & Buffalo Rivers except where trails cross.

1276

RESPONSE: There is no need for restrictions here because they cross, and do not run along beside the riparian areas. AS

COMMENTS: Prohibit snowmobiling from 50-100 yards from Henry's Fork River from Big Springs to Forest boundary above Three Rivers, except at bridge crossings, to protect waterfowl and moose.

697

RESPONSE: Such a general restriction on so many miles of river is not workable and does not need to be addressed by this Plan. Site-specific

SNOWMOBILES

closure restrictions are implemented as needed to address areas of resource impact. AS

COMMENTS: Prohibit snowmobile access to streams, wetlands, and riparian areas.

273, 1365

RESPONSE: The Revised Plan prohibits cross-country motorized access in two wetland areas: the Alpine wetland area and the west end of Island Park Reservoir. These two wetland areas are important waterfowl use areas.

We have not identified the need to prohibit snowmachine access to all streams, all wetlands and all riparian areas. If there are specific areas which need protecting, like the two mentioned above, we will do the site-specific analysis necessary to provide the protection. MO

COMMENTS: Close corridor along Henry's Fork to snowmachines under Aquatic Influence Zones Prescription 2.8.3.

697

RESPONSE: Your comment was noted and considered but not implemented. Such a restriction is not necessary as little use occurs in these areas. AS

Dubois Ranger District D-1

Clark County - Non Support of Closures

COMMENTS: Oppose groomed trails in Clark County (Kilgore) because there need to be some areas left open to cross-country snowmobiling.

1366

RESPONSE: No groomed trails are proposed. The proposed routes in Camas and Cottonwood Creeks shown in the Draft Winter Transportation Map were deleted. Most of Clark County is open to cross-country snowmobiling. AS

Italian Peaks

COMMENTS: Supports unrestricted snowmobiling in Palisades and Italian Peaks.

300, 1202

RESPONSE: These areas are unrestricted except for a winter range corridor along the south. AS

COMMENTS: Does not support ORV use/roads to snowmachines in Italian Peaks.

161, 200, 396, 643, 695

RESPONSE: Your comments were noted and considered. AS

Diamond Peaks

COMMENTS: Supports unrestricted snowmachine use in Diamond Peaks.

300

SNOWMOBILES

RESPONSE: No restrictions exist except in winter range corridor on the lower eastern edge. AS

Island Park Ranger District D-2

Lionhead

COMMENTS: Supports restrictions to snowmobiling in Lionhead.
341

RESPONSE: Snowmachines are allowed in this recommended wilderness and potential wilderness values of area will be maintained. AS

COMMENTS: Opposed restrictions to snowmobiling in Lionhead and Sheep Mountain.
F-I(4), 529

RESPONSE: Your comments are noted and considered. AS

Chick Creek

COMMENTS: Against closures in Chick Creek.
469

RESPONSE: The December 1 date was changed to Thanksgiving Day to allow earlier cross-country use. JH

Bechler Meadows

COMMENTS: Against closures in Bechler Meadows.
469

RESPONSE: Part of Bechler Meadows is in Yellowstone National Park. The December 1 date was changed to Thanksgiving Day to allow earlier cross-country use. JH

Centennials

COMMENTS: Would like to see snowmobile use in the Centennials.
169, 437, 515, 660

RESPONSE: Snowmobiling will continue in the Centennials. AS

COMMENTS: Reduce snowmobile travel in the Centennials because of heavy impacts to area.
697

RESPONSE: The Forest is unaware of any heavy impacts to the area and has no plans to restrict the area. AS

SNOWMOBILES

Black Mountain

COMMENTS: Against closures in Island Park (Black Mountain).
2, 469, 517

RESPONSE: Comments noted and considered. AS

Two Top

COMMENTS: Against closures in Two Top.
469

RESPONSE: Visitors can cross-country snowmobile throughout this area after Thanksgiving Day and until June 1. These date changes were made to include the first heavy-use weekend, and the end of the snowmachine season in the high country. AS

Yellowstone/Targhee Boundary

COMMENTS: Delete the trails adjacent to Yellowstone National Park on Map 12, winter motorized access, Alternative 3M because a buffer is needed to reduce snowmobile trespass in the Park.
1351

RESPONSE: The Snow Creek Butte Loop shown in the DEIS as a future marked snowmachine route is deleted from the FEIS and Revised Plan. This change reduces the potential for impact to Yellowstone National Park. The 15.2 miles deleted is less than 5% of the proposed additional designated snowmachine trails and thus no change in the analysis is needed. AS

General

COMMENTS: The Plan unreasonably restricts snowmobiling in the Island Park, Two Top, Lionhead, Centennial and Keg Springs areas.

F-N(7), F-M (5), 8, 9, 13, 15, 66, 67, 89, 97, 160, 188, 216, 229,
234, 235, 300, 303, 342, 466, 515, 728

Because the area is far away from any game wintering area.

F-M (5)

RESPONSE: The Revised Plan has no restrictions for cross-country snowmobiling after Thanksgiving Day on all Districts except Palisades (which will be Dec. 15). A spring closure date of June 1 will be in effect forestwide. This allows cross-country travel during the first heavy-use weekend and the majority of the high-country season. JH

COMMENTS: Restrict snowmobiles in Island Park and Fish Creek areas because the important issue is the grizzly bear and its habitat.

395

RESPONSE: Cross-country snowmobiling is restricted until after Thanksgiving Day through June 1, to allow for bear hibernation and emergence from the den.
AS

SNOWMOBILES

Ashton Ranger District D-3

Fish Creek

COMMENTS: The Plan unreasonably restricts snowmobiling in the Fish Creek, and Snow Creek area.

F-M(5), F-N (7), 8, 9, 13, 15, 66, 67, 72, 89, 97, 160, 188, 216, 234, 235, 303, 728, 1253

RESPONSE: Cross-country snowmobiling is unrestricted after Thanksgiving Day and prior to June 1. JH

Fall River Ridge

COMMENTS: Open Fall River Ridge for snowmachining.

461, 463

RESPONSE: It is open after Thanksgiving Day and until June 1 to cross-country snowmachining, except within the cross-country ski trail area. JH

COMMENTS: Uses the Fall River Ridge and the area north of there to snowmobile in the winter and early spring.

F-P(2)

RESPONSE: Your comment was noted. AS

Palisades District D-4

Big Elk/Palisades Creek

COMMENTS: Oppose opening drainages in Big Elk and Palisades Creek to snowmachines as stated in 3M.

695, 766

RESPONSE: The lower part of these drainages are within identified big game winter range and as such will be closed to snowmachine use. No designated route is planned for these areas. BP

Fall Creek

COMMENTS: Implement the groomed trail route through the Fall Creek Winter Game prescription to connect to Skyline Drive.

1202

RESPONSE: An alternative route is identified in the Final Revised Plan which is outside the winter range. The route is along the June Creek Road and will be groomed for snowmachines. BP

General

COMMENTS: Make all elk and deer winter range off-limits to snow machines (regardless of whether you think it's accessible) - especially south end

SNOWMOBILES

Beaverhead range benches and slopes of south fork of Snake, east Kelly Canyon, and west of Burns Creek near north end of Grandview.

643

RESPONSE: Winter range areas are identified and mapped in conjunction with the Idaho and Wyoming Fish and Game Departments. These areas are restricted to cross-country travel. Designated routes allow access to areas behind the winter range. BP

COMMENTS: Restrict snowmachines use in Palisades area and the high Palisades. Make the Palisades a wilderness area because too many animals are already disturbed by the many snowmobiles.

68, 356, 695, 725

RESPONSE: During the review of this area, no reasons were identified to restrict snowmachine use. One exception is in the lower Palisades area where wintering goats could be affected. After review, this was mitigated by restricting access on the lower part of the trail. The terrain of the lower Palisades also limits or stops use in this area. The upper Palisades area was changed from current restrictions to match the Bridger-Teton side which allows snowmachining. Snowmachine use will continue until wilderness legislation is passed. The use would then be determined by Congress. Generally designated wilderness areas do not allow snowmachines or any type of mechanized/motorized uses. BP

COMMENTS: Support unrestricted snowmobiling in Palisades and Italian Peaks.
300, 1202

RESPONSE: These areas are unrestricted except for a winter range corridor along the south. AS

COMMENTS: Do not limit off-trail use in South Plateau, Black Bear Canyon, Centennial Valley and the southern part of the Targhee.

380

RESPONSE: Your comment was noted and considered. AS

Kelly Canyon/Hawley Gulch

COMMENTS: Close road #218 to junction of #217 (2 miles) to snowmachines.
F-L(3), 616, 617, 628b, 701, 736, 738, 1347

RESPONSE: Road #218 is opened as a designated route through the closure area from the Kelly Canyon Ski Hill to the open area following closure of the ski hill. This was not stated in the Draft Plan Revision and is added for clarification to the Revised Plan. BP

SNOWMOBILES

COMMENTS: Close snowmachine use in Area J as shown on 1994 Travel Plan Map.

F-L(3), 617, 701, 1347

Supports closure in Kelly Canyon - Hawley Gulch area.

F-D(51), F-L(3), F-M(5), 616, 617, 628b, 637, 670, 701, 732, 736, 738, 1245, 1293, 1347, 1451

RESPONSE: An error in mapping the 3M Alternative showed this area being open to snowmachines. Under the Revised Plan, the current restriction will continue. The designated route along Buckskin Morgan road will continue. Prescription 5.1.4 (d) is added to the Final Revised Plan to address this closure. AS

COMMENTS: Alternatives 2, 3, 3M, and 4 eliminate previous cross-country skier trails between Hawley Gulch and the divide by opening up to snowmachine use. Do not open to snowmachines.

F-L(3), F-M(5), 637, 738, 1245

RESPONSE: The Forest added a new Prescription 5.1.4 (d) which allows snowmobiling on the Kelly Canyon road only when the resort is closed for the season. The Buckskin-Morgan designated route will continue. The rest of the area is closed to cross-country snowmachine travel. AS

COMMENTS: Parking area at junction of #218 and #217 should be eliminated.

F-D(51), F-L(3), 616, 628b, 670, 701, 732

RESPONSE: The Forest added a new Prescription 5.1.4 (d) which allows snowmobiling on the Kelly Canyon road only when the resort is closed for the season. AS

COMMENTS: Leave the snowmobile corridor from Byrne's Siding to the backcountry beyond Kelly Canyon because this set up (established in 1993) has been satisfactory for both cross-country skiers and snowmobilers.

F-L(3)

RESPONSE: No change is made to this recently established corridor.

AS

COMMENTS: Prohibit snowmobiles from Kelly Canyon because they are too noisy, pollute, riders are inconsiderate of others, and they destroy the beauty of the winter scene.

1178, 1403, 1404, 1453

RESPONSE: The Forest added a new Prescription 5.1.4 (d) which allows snowmobiling on the Kelly Canyon road only when the resort is closed for the season. AS

SNOWMOBILES

COMMENTS: Establish the snowmobile destination rest area at the head of Hawley Gulch not at the proposed location at the intersection of Forest roads on the Table Rock divide above Kelly Canyon in order to keep snowmobiles out of the area heavily used by skiers and moose and elk.

1245

RESPONSE: The Forest left the proposed parking location as shown in the DEIS. Project specific analysis and NEPA documentation are necessary prior to construction of the facility. The Hawley Gulch location is considered an alternative at this time. AS

COMMENTS: Clarify season to allow spring snowmobile use in Kelly Canyon after ski hill closes.

60, 1202

RESPONSE: The Forest added a new Prescription 5.1.4 (d) which allows snowmobiling on the Kelly Canyon road only when the resort is closed for the season. AS

COMMENTS: Establish snowmobile traffic north and east of Hawley Gulch area heavily used by skiers.

1245

RESPONSE: The Revised Plan will continue to manage this area for skiing rather than snowmachines. The current travel management will be continued. AS

COMMENTS: Restrict snowmobilers from Kelly Canyon after the resort closes down in the late winter.

658

RESPONSE: The Revised Plan allows snowmachine use on the road after the ski season in the same way that the area has been managed historically. AS

COMMENTS: Close area between Kelly Mountain and Buckskin Morgan in the winter to snowmobiles to protect the big game.

637

RESPONSE: The Forest added a new Prescription 5.1.4 (d) which allows snowmobiling on the Kelly Canyon road only when the resort and the Buckskin Morgan route is closed for the season. The remainder of the area is closed to cross-country snowmachine travel. AS

Teton Ranger District D-5

General

COMMENTS: Support Closures of: Oliver Peak, Stateline & Miskell Canyons, SW facing slope of Mosquito Creek drainage to Mosquito Creek, and Plummer Canyon.

1395

SNOWMOBILES

RESPONSE: Oliver Peak, Stateline and Mikesell Canyons are located within prescription 3.2(g). There are no designated snowmobile trails in this area however cross-country snowmobiling is allowed. The area receives a variety of winter uses including skiing, helicopter skiing and snowmobiling. Prescription 3.2(g) allows for a variety of recreation opportunities including motorized and non-motorized uses. There are no plans for designated snowmobile routes in the area. Mosquito Creek is located on the Bridger-Teton National Forest.

Plummer Canyon is located on the Teton Basin Ranger District and is shown as a small isolated block of 3.2(g) in the Draft Forest Plan Revision and is nestled between the Wilderness and a Winter Range Prescription 2.7(a). Both motorized and nonmotorized cross-country winter use is allowed in the 3.2(g) area and closed in the 2.7(a) area. MB

COMMENTS: Limit snowmobile use in critical winter range in the Teton Basin to open roads.

171

RESPONSE: We concur: Prescription 2.7 accomplishes this. Some other, smaller areas of critical winter range located in other prescriptions were identified since the Draft. These areas will limit motorized and nonmotorized cross-country winter travel to designated routes but will not be classified in the winter range prescription. MB

COMMENTS: Close areas to snowmobiles on the northeast side of ID 33, east of the ID/WY State line, including the Plummer Canyon area because snowmobiling is incompatible with skiing.

1395

RESPONSE: See discussion on Plummer Canyon above. The 2.7(a) portion of the Plummer Canyon area will limit motorized and nonmotorized winter access to designated routes to reduce disturbance of wintering wildlife. The 3.2(g) portion is wide-open to all winter uses.

The Forest has not specifically closed areas to snowmachines because of conflicts with skiing. Separation of users is being considered in the ongoing interagency planning effort by the pending Greater Yellowstone Winter Visitor Use Management Committee. The Revised Plan also directs the Forest to plan for some non-motorized recreation use areas. MB

Big Holes

COMMENTS: Would like to see snowmobile use in the Big Holes (winter use only).

660

RESPONSE: The draft Forest Plan allows for this use. The only restrictions for winter use are the cross-country restrictions in the 2.7 Winter Range Prescription and several small areas identified as winter range outside of the 2.7 Prescription (refer to winter range map). MB

SNOWMOBILES

COMMENTS: The Plan unreasonably restricts snowmobiling in the Big Holes.
F-M(5), F-N(7), 8, 9, 13, 15, 66, 67, 72, 89, 97, 160, 188, 216, 234,
235, 303, 728

RESPONSE: The only restriction is for cross-country winter travel through the critical winter range areas. The Revised Plan has no additional restrictions for snowmachine use on the Palisades District. MB/BP

COMMENTS: Prohibit cross-country snowmachine use in big game hunt areas during open season (conflicts in Palisades and Big holes Subsection).
766, 1195, 1202

RESPONSE: The summer travel plan takes effect yearly in the spring as local conditions become suitable to support wheeled vehicle traffic on roads without damage. Snowmachines may use roads and trails shown on the summer travel plan as open to motorized use. Cross-country snowmachine travel is allowed only where the summer travel plan allows cross-country motorized travel after June 1.

The winter travel plan takes effect yearly on Thanksgiving Day. Snowmachine travel is allowed consistent with the winter travel plan map. Cross-country snowmachine travel is permitted from Thanksgiving Day through June 1 except on the Palisades Ranger District which permits usage from December 15 through June 1. Cross-country snowmachine travel is allowed in prescription area 5.1.4(c) (Big Bend Ridge) from January 1 until April 30.

Cross-country motorized use is not allowed on elk and deer winter areas at any time of the year. Nonmotorized cross-country use (walking, horses, etc.) is allowed from April 15 to Thanksgiving Day on all Districts except Palisades. On Palisades District, non-motorized cross-country use is allowed from April 15 to December 15. MO

Supports Closures - Jedediah Smith

COMMENTS: Protect Static Peak and Fox Creek divide (within the Jedediah Smith Wilderness area) from snowmobile use. Enforce snowmobile closures in the Jedediah Smith Wilderness. Prosecute trespassers.
191, 644, 659, 664, 1313, 1330, 1331

RESPONSE: The Forest concurs. Snowmobiles use is illegal and inappropriate in the Wilderness and Grand Teton National Park (GTNP) (Static Peak). This illegal activity is currently enforced and will continue to be enforced as funding and personnel allow. A formal cooperative agreement with GTNP allows us to enforce each other's regulations. MB

Pony and Canyon Creek

COMMENTS: Oppose closures in Pony and Canyon Creek areas.
342

RESPONSE: Your comment is noted and considered. AS

SOILS

Physical Elements

COMMENTS: Chapter IV does not provide discussion of the value of leaving dead and dying trees in place to replenish the nutrient cycling of soil. Soil nutrition is basically glossed over.

727

RESPONSE: Forestwide Standards and Guidelines for Soil Quality (Chapter III of the Revised Plan) speak to woody residue requirements. A Table lists the dominant forested habitat types and the woody residue requirements needed to sustain long-term site productivity. Requirements are based on research findings by Russ Graham, research silviculturist. A monitoring item for "dead and down material for meeting soil and wildlife requirements on Forest," (Chapter V of the Revised Plan) is a Forest Priority Group 1 and will provide information on long-term site productivity. Refer to Chapter III of the FEIS which identifies subsections where past management might have affected long-term site productivity through the removal of woody residue. DM

COMMENTS: Snow compaction leads to reductions in soil temperature (re: snowmachines). Snow-compacted, induced soil temperature decreases retard microbial activity which can lead to severe reductions in soil fauna. These temperatures also negatively affect the soil surface micro-structure that can greatly reduce the seed germination suitability of a site. (CROSS REFERENCE: Snowmobiles)

1365

RESPONSE: Your comment is acknowledged. The effects of snow compaction are more appropriately examined at the site-specific level, because they depend on site factors such as snow depth, coarse fragments, texture, structure, presence or absence of down woody material, habitat type, aspect, slope and so on. DM

Erosion Concern-Fire

COMMENTS: Erosion in the watersheds was caused by the Yellowstone fires in 1988. Watersheds were not heavily salvaged or clearcut due to steep slopes, watershed concerns, and low timber value. However, nature's salvage, an intense fire, resulted in water repellent soils and erosion. One could easily argue that fuel reduction through pro-active management in these watersheds would have minimized erosion from the Yellowstone fires.

393

Fuels management would decrease the risk of wildfire to soils.

1273b

RESPONSE: Fire and erosion hazards will be evaluated at the site-specific or landscape level. Refer to the FEIS, the Fire - Scale, Fire Risk and the Soils and Geology sections. DM

SOILS

General Comments

COMMENTS: Frissell Condition Class is not an adequate method to measure soil displacement on campsites. Would suggest a permanent calibrated stake method.

1312

RESPONSE: The use of the Frissell Condition Class system is used only for dispersed campsites within wilderness, proposed wilderness and roadless areas. For these areas, a correlation can be made between the Frissell Condition Class and Soil Quality Standards. On the remainder of the Forest the forestwide standard or guideline that "no more than a total of 15% of an activity area being in a detrimentally disturbed soil condition" (see glossary) will be used for monitoring purposes. Soil displacement occurs when either two inches or one-half of the humus enriched top soil (A horizon), or both, are lost from an area of one square meter or larger. DM

COMMENTS: The use of leaded gasoline in snowmobiles can lead to soil contamination. Refueling, accidental spills and on-trail maintenance of snowmobiles can lead to chemical contamination of soil.

1365

RESPONSE: Your comment is acknowledged. Effects of these impacts tend to be site-specific and affect relatively small areas making forestwide analysis difficult. DM

COMMENTS: Statement in DEIS IV-61 is wrong; it simply attempts to paint OHV use as excessively impacting to soil resource.

1202

RESPONSE: The FEIS states in Chapter IV, "Road construction, timber harvest, grazing, dispersed recreation and motorized recreation OHV's have the highest likelihood of producing irreversible damage to the soil resource." The FEIS emphasizes that unmanaged dispersed recreation and OHV use will be a major challenge based on increased demand. A increased number of existing OHV trails are not adequately designed and maintained for use and are contributing to resource damage. The Revised Plan includes an objective to, "Provide a network of OHV trails while minimizing the effects of OHV on soils." DM

COMMENTS: DEIS IV-10, last paragraph - This section uses Alternative 5 as basis for comparing soil disturbance to other alternatives. This is at odds with NEPA.

413

RESPONSE: NEPA requires that effects be analyzed and disclosed to the public. There is nothing within the NEPA regulations that directs comparisons specifically to the No-Action Alternative. NEPA regulations (1502.4 & 1502.16) states, "it should present the environmental impacts of the proposal and the alternatives in comparative form." DM

SOILS

COMMENTS: Soil scarification was a common practice associated with silviculture under 1985 Plan, a standard should be included prohibiting this in the new plan. (CROSS REFERENCE: Timber, Silviculture)

643

RESPONSE: The type and amount of post harvest treatments are best assessed and analyzed at a site-specific level. Some scarification may be appropriate to meet a project's objectives. DM

DFPR

COMMENTS: Page III-66 and III-70, all four soil and water guidelines should be standards.

1365

RESPONSE: Guidelines provide appropriate direction; however, since the soil and water guidelines are relatively new they will be evaluated for effectiveness. Refer to the definition of guideline in the glossary. DM

COMMENTS: Page III-66, last guideline should also include provisions requiring that any such work not cause negative environmental impacts, that the repaired or reconstructed structures not cause negative environmental impacts, and that any structure that does cause such impacts be removed.

1365

RESPONSE: The first guideline under Soil and Water, Chapter III addresses this concern. DM

COMMENTS: Page V-8, 30% may not be a real number and may have to be re-defined, because it is hard to tell if disturbance is natural or man caused. (CROSS REFERENCE: Riparian, Hydrologic Function)

432

RESPONSE: Refer to the definition of hydrologic disturbance in the glossary section of the Revised Plan. Both man-caused and natural disturbances, such as fire, are considered in this definition. DM

COMMENTS: Page V-8, many activities cause soil disturbance greater than 15 percent. That number is too restrictive and will limit the flexibility to manage the resource with different options or tools. (CROSS REFERENCE: Riparian, Hydrologic Function)

432

RESPONSE: The 15% threshold is a Regional Guideline to identify practices that consistently exceed the 15% threshold. Evaluation of these practices will be made to improve techniques or find alternate solutions. DM

COMMENTS: Page V-9, 65 percent ground cover is very high in some natural rangelands; most sedimentation problems do not come from uplands.

432

SOILS

RESPONSE: The "Indicator" section also states: "an equivalent percentage if the site cannot naturally attain the minimum percentage mentioned above." If a site cannot attain the 65% ground cover naturally, then a different percentage requirement would be identified based on what it can naturally attain. DM

COMMENTS: Page IV-11, the soil disturbance threshold and soil quality standards and guidelines must be enforced vigorously.

1365

RESPONSE: Agreed. This is the intent of various monitoring items on soil quality in Chapter V of the Revised Plan. Both implementation and effectiveness monitoring are proposed. DM

COMMENTS: Soil disturbance monitoring must also include an evaluation of the adequacy of the 15 percent standard itself. The fine organic material monitoring must include evaluation of the adequacy of 50 percent standard.

1365

RESPONSE: Annual implementation monitoring evaluates the adequacy of standards and guidelines applied on-the-ground and effectiveness monitoring evaluates whether standards and guidelines achieved expected results. Possible modifications may be recommended based on these findings. DM

COMMENTS: The soils section failed to address soil compaction as a loss of long term soil productivity and no direction is given for this. Also, there is no direction given for road development, oil and gas development, or exploration occupancy on mass instability slopes.

1273b

RESPONSE: Soil compaction is addressed in Regional Soil Quality Standards and Guidelines (FSH 2509.18). Regional direction is not repeated in the Revised Plan. Oil and gas development is being addressed through a separate Environmental Impact Statement. Slope stability for mineral activities is addressed in Chapter III of the Revised Plan. DM

COMMENTS: Guidelines or standards for physical damage to soil by OHV and logging are lacking.

697

RESPONSE: Forestwide standards and guidelines and Regional Soil Quality Standards and Guidelines (FSH 2509.18) apply to all management activities and are applied throughout activity areas (See definition for activity area in the glossary section of the Revised Plan). DM

COMMENTS: Motorized users need to know what soil erosion factors restrict OHV use on slopes of 25-40 percent; otherwise they can't decide if that is a reasonable constraint. Also, it would be difficult to implement without further information. (CROSS REFERENCE: Access, Soil; Access, Percent Slope)

413

SOILS

RESPONSE: Soil factors considered include such things as: soil texture, percent sand greater than .1mm, soil organic matter content, soil structure, soil permeability, clay mineralogy and coarse fragments in the surface soil layers. Trails that are properly designed for motorized use can be constructed on steeper slopes. Soil concerns focus on slopes where cross-country travel and trails were not designed for motorized use. DM

COMMENTS: The U.S. Fish and Wildlife Service Biological Opinion on Plateau BMU states: "In newly harvested units, soil disturbance shall not exceed 20 percent of unit," (p. 35). Adopt this language for prescription on page III-135.

643

RESPONSE: Regional direction for soil quality maintenance is more restrictive. No more than 15% of an activity area is allowed to be in a detrimentally disturbed condition (FSH 2509.18). DM

Erosion Concern-General

COMMENTS: Restrict human disturbances on steep slopes and easily erodable soils.

1367a

RESPONSE: Steep slopes and erodible soils were considered when designating ASQ lands and restricting cross-country OHV use (refer to the standards and guidelines under the Recreation section for OHV and under Timber for logging systems). Slopes and soils are analyzed in site-specific NEPA for all proposed projects. DM

COMMENTS: Opposed to all activities which might degrade soils; the local farming community is helped by winter vehicles because of the resulting packed snow which aids in reduction of erosion and prolonged spring run-off.

276, 307, 311

RESPONSE: Your comments are acknowledged. The purpose of regional and forestwide standards and guidelines for soil quality are to better protect the soil resource. DM

COMMENTS: Surface disturbing activities in areas with slopes greater than 40% are a special concern because of potential problems with soil stability. Special technical consideration should be given to the proposed activities in these areas, including coordination with Wyoming Game and Fish.

389

RESPONSE: Refer to the standards and guidelines under the Recreation section for OHV and under Timber for logging systems. Steep slopes and erodible soils were considered when designating ASQ lands and restricting cross country OHV use. Slope classes are also analyzed for all site-specific proposals. DM

SOILS

COMMENTS: Should designate potential erosion areas and to place them off limits before erosion occurs. This should be addressed in the standards and guidelines.

330

RESPONSE: Site-specific analysis is the appropriate avenue for identifying and protecting highly erosive areas. Steep slopes and erodible soils were considered when designating ASQ lands and restricting cross-country OHV use.

Refer to the standards and guidelines under Recreation section for OHV and under Timber for logging systems. DM

Recreational Vehicles

COMMENTS: Restrict horse use, pack animal use, mountain bikes, motorized vehicles such as snowmobiles, winter skiing, and bulldozers preparing for winter skiing because they increase soil erosion and disturbance.

175, 219, 307, 311, 1203, 1365

RESPONSE: Your comments are acknowledged. Refer to the standards and guidelines under the Recreation section for OHV. Effects of these uses are best evaluated at the site-specific level. DM

COMMENTS: ORV use should be restricted because it increases soil erosion.

293, 632

RESPONSE: Soil properties, such as slope, were used to restrict cross-country OHV use. Refer to Standards and Guidelines-OHV in Chapter III of Revised Plan. DM

COMMENTS: Big game retrieval by ATVs is a poor idea because of increased erosion.

293, 1365

RESPONSE: The big game retrieval concept was dropped. DM

COMMENTS: Snowmobiles do not cause erosion because of snowpack.

307, 311

RESPONSE: Erosion can result from snowmobile use in the early or late season when snow packs may be marginal or intermittent, but damage would be limited in extent. DM

COMMENTS: The standards and guides on III-17 don't go far enough in preventing soil erosion.

697

RESPONSE: Forestwide and regional soil quality standards and guidelines apply and are sufficient to reduce risks to soil erosion. DM

SOILS

Recreational Vehicles - OHV Impacts

COMMENTS: Soil disturbances caused by OHVs can favor the establishment of weedy vegetation (Bury 1980); OHV use can lead to a loss of surface organic horizons (Burden and Randerson 1972); OHV use can lead to mineral soil compaction, resulting in an increase in the mechanical resistance of soil to root penetration which can in turn reduce emergence of seedlings (Iverson et al. 1981); soil compaction can lead to soil invertebrate declines (Bayfield 1979; Chappell et al. 1971; Duffey 1975).

OHV use leads to reductions in soil microbe activity that impairs decomposition processes (Seastedt 1984); OHV use has negative effects on the germination, establishment, growth, and reduction of plants (Harper et al. 1965); OHV use causes soil compaction which reduces the heterogeneity of soil surfaces and the density of favorable germination sites (Harper et al. 1965); OHV use can lead to reductions in macro and total porosity that can in turn result in oxygen and water depletion (Monti and Mackintosh 1979); OHV use can lead to reductions in infiltration rates (James et al. 1979); OHV use can lead to increases in soil erosion (Wilshire et al. 1978).

OHV can lead to changes in soil moisture (Settergren and Cole 1970); OHV use can lead to increase in diurnal and possibly a seasonal range of soil temperatures; the use of leaded gasoline in OHVs can lead to soil contamination. Refueling, accidental spills and on-trail maintenance can all lead to chemical contamination of soil; OHV use can result in dramatic shifts in species composition of soil fauna and microfauna (Anderson 1978; Paul and Clark 1989; Wallwork 1970); as a consequence of these sorts of impacts, OHV use can result in reduced vegetation vigor and productivity.

1365

RESPONSE: Your comments are acknowledged. Currently, approximately 62 percent of the Targhee is open to cross-country travel. The Revised Plan limits summer cross-country to seven percent of the Targhee. Forestwide standards and guidelines provide mitigation for these effects. DM

Streams/Riparian

COMMENTS: In riparian areas with increasing erosion problems, use boardwalks and culverts to improve or maintain stability.

307, 311

RESPONSE: This is more appropriately addressed at the site-specific level.
DM

COMMENTS: Protect riparian areas from any activity which would decrease cover and soil stability and increase siltation in streams and rivers.

335

RESPONSE: Refer to Prescription 2.8.3 in Chapter III of the Revised Plan. The purpose of this prescription is to provide protection to riparian ecosystems. DM

SOILS

Roads and Trails

COMMENTS: Leave roads open not causing erosion problems.

219

RESPONSE: Roads not causing erosion were considered in the recommended travel network for various themes presented in each alternative. DM

COMMENTS: Take this opportunity to design a trail network that eliminates use of fine-textured, erodible soils in the Big Hole Mountains; build small bridges across some creeks.

219, 1312

RESPONSE: Design of trail networks in the Big Hole mountains is more appropriately evaluated at the landscape or site-specific level. Trail networks were designed to address themes in the various alternatives. DM

COMMENTS: Issue of soil erosion was presented poorly and is misleading to the public.

307, 311

RESPONSE: Your comment is acknowledged. Soils sections in the Revised Plan are rewritten to help clear up points of confusion. DM

COMMENTS: If the Forest Service would maintain their trails and roads, erosion would not be a problem.

307, 311

RESPONSE: Annual budget allocations for road and trail maintenance fluctuate. Reducing the number of roads may lead to better and more consistent maintenance than in the past. The Forest continues to build partnerships, such as "Adopt-a-Trail" and coop maintenance agreements with counties, to help maintain transportation networks. DM

COMMENTS: Road management is crucial to protect water quality and soil stability.

1249

RESPONSE: The 2.8.3 Aquatic Influence Zone Prescription is designed to protect water quality and soil stability. DM

COMMENTS: Permanent closures will actually increase erosion by concentrating use.

97

RESPONSE: This may be true in certain locations. Overall problems should not increase and closures will also help reduce impacts by having fewer miles of roads to evaluate and maintain. Road maintenance dollars will go farther in maintaining a smaller road network. DM

SOILS

COMMENTS: Rutting or displacement of soils on trails is caused by the design and maintenance of the trail, not the type of use on it.

629

RESPONSE: While this may be true, the level or season of use a trail receives compounds rutting and soil displacement. The Targhee considered these factors in designing trail networks to address themes in each of the alternatives. DM

Timber

(CROSS REFERENCE: Timber)

COMMENTS: Statement on Page III-13 of DEIS is unclear. Assume that concerns about soil quality in relation to conifer encroachment are related to the

hypothesis that soils will become more acidic. Cite data to support this hypothesis.

489

RESPONSE: Refer to Cryer, D.H., and J.E. Murray, 1992. "Aspen Regeneration and Soils." Rangelands 14(4). Page 223-226. Ecological Unit Inventory of the Targhee National Forest, Idaho. Interim Report #4. July, 1996. DM

COMMENTS: Until Forest Service has data to definitely demonstrate that Douglas-fir expansion is having detrimental impacts on soil quality, there should be no vegetation treatments based on those assumptions.

489

RESPONSE: Refer to Cryer, D.H., and J.E. Murray. 1992. "Aspen Regeneration and Soils." Rangelands 14(4). Page 223-226. Ecological Unit Inventory of the Targhee National Forest, Idaho. Interim Report #4. July, 1996. 1914-1922. Historical Vegetation Inventories. USDA Forest Service, Targhee National Forest, St. Anthony, Idaho.

The intent is not to wait until changes occur in the soil, but to maintain or return plant biodiversity being lost as ecosystems simplify as-a result of removal or disruption of disturbance regimes. DM

COMMENTS: Harvest constraints to avoid erosion are excessive. (Page III-25, DFPR), a requirement to stay on designated skid trails with skidding equipment during periods of wet weather would be better to prevent rutting or compacting.

90

RESPONSE: Soils are susceptible to compaction, erosion and displacement when dry. Designated skid trails, that are properly located and laid out, greatly reduce the area of disturbance created by harvest operations. Designated skid trails have been used effectively in all regions of the west to maintain soil quality. Timber sale contract provisions include this requirement. DM

COMMENTS: Aspen should only be skidded on dry or frozen soils.

90

SOILS

RESPONSE: Skidding requirements are addressed within the timber sale contract provisions. Skidding is usually conducted when soil conditions are favorable (that is, dry or frozen conditions) for this type of operation and its effect on soil quality. DM

COMMENTS: Logging is the removal of valuable nutrient, fiber, and organic matter from the forest and its soils, in conjunction with the serious impacts from roading.

150

RESPONSE: The intent of the table in Chapter III of the Revised Plan is to present required minimum levels of woody residue to be dispersed on the site during project implementation. Minimum woody residue levels are based on research findings on representative habitat types. DM

COMMENTS: Intent to increase amount of woody debris on ground after harvest will benefit soils.

625a

RESPONSE: Your comment is acknowledged. DM

COMMENTS: Prohibit timber logging in areas prone to landslides unless found by scientific studies that harvest activities will not degrade the soils or release sediment to streams.

1367a

Prohibit logging or mining on fragile sites pending conclusive demonstration through scientific study that soil can be protected and forest regeneration accomplished.

1367a

RESPONSE: In determining timberland suitability, unsuitable acres were identified, specifically where irreversible damage could occur or where low site productivity exists (regeneration is doubtful). Intensive management activities are not planned on these acres. DM

TIMBER - ASPEN

COMMENTS: Explain the basis for the footnote (Page III-23) in the lower table stating that aspen counts toward stocking levels in other forest types.
643

RESPONSE: Stocking guidelines in the past sometimes failed to count aspen in minimum stocking levels. In the current Forest Plan, minimum stocking is, in part, designed around the reestablishment of big game hiding cover. Aspen does not contribute as much year-round big game hiding cover as conifers and was not included in hiding cover calculations. The Targhee has since established a cover value for aspen. (Elk Habitat Effectiveness and Elk Vulnerability Process Papers, Revised Plan). Aspen was highlighted in a footnote as a reminder to record its presence. Aspen has cover value and is an important seral species in natural succession. JC/LB

COMMENTS: Explain the basis for the aspen guideline and why you picked the target successional stage distribution as ideal.
1369

RESPONSE: The rotation age of 60 years for Aspen is a guideline to help managers design entry cycles for areas where aspen is being managed as a commercial timber species. The National Forest Management Act requires that all even-aged commercial stands scheduled for harvest during the planning period will be at the culmination of mean annual increment of growth. Sixty years is only an estimate of aspen culmination. (See 60-year cycle study by Schiers, Jones and Winoker 1985 and Schier and Campbell 1980). JC

COMMENTS: Define the age class distribution you plan to manage for in aspen stands that are experiencing conifer encroachment.
1273b

RESPONSE: A 60-year rotation is a reasonable guideline for sustainable aspen stands, however site-specific analysis may conclude conifer encroachment is better for the health of the Forest in some areas. See previous response. AM

Supports Aspen Management Goals

COMMENTS: I support aspen component in Plan. Aspen has incredible regenerative abilities.
719

RESPONSE: Your comment is acknowledged. Aspen's ability to regenerate rapidly is the result of an aggressive root system. JC/LB

Improve Discussion of Age/Class Distribution for Aspen

COMMENTS: Discuss the basis you will use for determining the appropriate distribution of aspen age classes, and your strategy for maintaining a sustainable aspen resource.
1368

RESPONSE: Appropriate distributions of age classes on a large scale can be discussed as part of a mid-level analysis such as in a landscape analysis. A landscape analysis looks at large areas of the forest and establishes the historic distribution of aspen communities. This is accomplished through on-site examinations, historic records and techniques such as stand backdating. Then, many important site specific resource concerns are evaluated at the project level. This information influences the final recommended distribution of age classes. For example, the distribution of age classes could be a function of how often a disturbance would be allowed to occur, how large an area could be disturbed each time and what size classes are needed for other resources such as wildlife, watershed integrity, visuals, and so forth.

A project to reestablish aspen communities is then evaluated and disclosed as part of the NEPA process and a site-specific silvicultural prescription proposes how this is achieved over time.

The National Forest Management Act directs National Forests to grow commercial timber to a point called the "culmination of mean annual increment" which means the point at which the tree growth slows and begins to decline. The Guideline states that aspen should be grown to a minimum age of 60 years which is based on the estimated culmination of mean annual increment. After 60 years stands begin to decline and their ability to regenerate after a disturbance is reduced (Schier, Jones, and Winokur 1985 and Schier and Campbell 1980). Following this strategy, about every 60 years an aspen stand would have to be regenerated either by fire, girdling, felling, logging, root ripping or a combination of these practices. This is the basis for determining the appropriate distribution of aspen age classes and to maintain a sustainable aspen resource. A simplistic example is, if 90 acres of aspen needed to be maintained and you want three age classes, you enter a third of the stand every twenty years. The strategy for sustaining aspen must consider numerous variables on a site-specific basis. Most situations would be more complex and the 60 year time period is designed as a guideline. JC/LB

Aspen Management Need More Analysis

COMMENTS: Assess the effects of aspen regeneration in the Centennials and its affect on wildlife values and habitat. Conclusions are drawn from site-specific examination which does not consider the ecosystem.

161

Provide an evaluation of the proposed aspen management guidelines and objectives on wildlife. Include a discussion of the impacts of aspen harvest on wildlife and on the structured rotation age.

1369

RESPONSE: Effects on wildlife are discussed in Chapter IV of the FEIS, including impacts from planned activities, such as regeneration of aspen. Because the Revised Plan is programmatic rather than a site-specific document, the effects are summarized on a forestwide basis. The effects of these activities are evaluated in Chapter IV. For the purposes of the Targhee's Revised Forest Plan evaluation of effects in Chapter IV is sufficient for wildlife at the Forest scale. JC

TIMBER - ASPEN

COMMENTS: Reassess the logic that vegetation occurring on the Forest, particularly the decline of aspen due to conifer encroachment, is outside the Range of Natural Variation and is in need of treatment. Various studies disagree with this assumption.

643

RESPONSE: Studies, research, and historic documents indicate seral aspen is rapidly declining on many areas of the Targhee and are outside, or soon-to-be-outside, their range of natural variability due to replacement by conifers. This is also true in other areas of the Rocky Mountains. Researchers (Mueggler 1988) indicate that throughout the West "...stands once dominated by aspen are well along in the process of replacement by conifers." Aspen studies reviewed as part of the Revision process support these findings. Field observations the last two years by the Targhee in the Centennials, also substantiate these findings.

Not all forest types historically supported aspen. The higher elevations of the lodgepole pine type along the western boundary of Yellowstone Park, for example, had very few aspen. Historic vegetation analysis in these areas indicates few aspens occurring historically, and that the current level of aspen is likely within the historic range of natural variation. JC

Succession in Aspen

COMMENTS: Clarify RNV for aspen. Reevaluate succession conclusions regarding lodgepole pine, Doug-fir, and aspen that led the Forest to conclude that aspen is outside RNV and thus is a reason for management intervention. Aspen is more abundant now than historically.

489, 643

RESPONSE: The Forest's findings do not support a conclusion that aspen is more abundant now than in the past. Fire suppression has virtually eliminated the primary disturbance regime responsible for perpetuating aspen which allows other shade-tolerant community types such as Douglas-fir to replace aspen. RR

COMMENTS: Include livestock grazing impacts and fire suppression in your analysis that aspen is outside the RNV.

695

RESPONSE: Fire and fire suppression are discussed in the FEIS in Chapters II and IV. Research shows that grazing is not as significant an effect (refer to Camas Creek Aspen Rejuvenation Project NFMA/NEPA documents) in causing the loss of aspen as is conifer encroachment. Conifer encroachment is the result of removing or suppressing the natural fire disturbance regime. Grazing is a factor in reducing or altering fire patterns. DM

COMMENTS: Consider historical aspen regeneration is a result of low ungulate numbers, climatic conditions and extensive fires that favored aspen regeneration and that Doug-fir were commonly found in lower elevations over much of the last several thousand years.

643

TIMBER - ASPEN

RESPONSE: The distribution of vegetation, and the processes that maintained these distributions will be defined through Properly Functioning Condition assessments as they are completed for various areas of the Forest. The direction to establish PFC's in each subsection is included in the forestwide goals and objectives.

Ungulate use, climate, and fire are factors considered in aspen studies. Refer to the NFMA/NEPA documents for the Camas Creek Aspen Rejuvenation Project on the Targhee National Forest as an example of analysis at a landscape and site-specific level. These documents provide information about aspen management in aspen-dominated parts of the Forest. DM

Manage Aspen as a Wildlife Resource

COMMENTS: Aspen is not a merchantable product on the Targhee and therefore cannot be considered in the ASQ and should be managed as a wildlife resource.

693

RESPONSE: The Allowable Sale Quantity (ASQ) does not include fuelwood or other nonindustrial wood. The majority of aspen on the Targhee is nonindustrial and is not included in the ASQ for the Revised Plan. LB

Reconsider the Option to Log Douglas-Fir to Maintain Aspen

COMMENTS: Clarify why Douglas-fir are being cut to encourage Aspen. This is a natural and healthy progression.

Consider planting aspen (as well as fir) in clearcuts and let aspen be replaced by firs slowly and naturally.

Prohibit the cutting of mature Douglas-fir to make room for quaking aspen.

F-K(4), 58, 176, 656, 726

RESPONSE: The Revised Plan allows aspen regeneration projects in areas historically occupied by aspen to meet biodiversity objectives of maintaining a diverse distribution of plant communities. Aspen developed across the Forest over many centuries and was perpetuated by periodic lightning and human-caused fires. Without a cycle of disturbance, more shade-tolerant conifers may replace aspen in a single generation (Brinkman and Roe 1975, Mueggler 1985).

Logging conifers is proposed to create fuel loading that is more conducive to prescribed fire or prescribed natural fire treatments. Unpredictable fires, including wildfires, may result in the loss of habitat for threatened, endangered and sensitive species and critical hiding cover for economically important species such as elk.

Planting aspen in clearcuts may be an option in areas where aspen occurred historically. If the area has been clearcut and was historically occupied by aspen, aspen responded to the clearcutting and regenerated. This is typically the case across the Forest.

Currently the range of natural variation for forest types has not been established. Historical vegetation conditions have been developed for two watersheds: 76,000 acre Camas Creek in the Centennial Mountains and the upper Henry's Fork. Environmental assessments will be developed for

TIMBER - ASPEN

project-level activities not specifically described in the Final Revised Plan and will concentrate on issues unique to the project. DS/JC

Aspen Regeneration Impacted By Grazing

COMMENTS: Exclude livestock from regenerating aspen stands until saplings are well above the reach of those stock. Current guideline on Page III-21 is inadequate to protect regenerating aspen.

Restrict livestock grazing to protect young aspen shoots.
489, 634

RESPONSE: The need to protect aspen regeneration will be evaluated on a project-by-project, site-specific basis. The need for protection is a function of grazing levels, timing of grazing, distribution of livestock, anticipated number of aspen suckers, distribution and size of aspen regeneration sites, and so forth. More restrictive protection may be needed, in areas where livestock or wildlife concentrate. These concerns will be identified during site-specific analysis with appropriate mitigation. JC

Conifer Encroachment on Aspen Caused by Climatic Trends

COMMENTS: Consider other factors like regional climatic trends toward warmer and wetter growing seasons since the end of the Little Ice Age as a possible cause for conifer encroachment on some high mountain meadows.

489

RESPONSE: Climatic trends over hundreds of years and how they relate to local changes in vegetation are hard to establish, controversial, and are beyond the scope of the analysis for the Final Revised Plan and EIS. Forest observations indicate that conifer encroachment into high mountain meadows is a slow process and takes a long time to complete. The absence of fires igniting at lower elevations and burning up into higher meadows allows this process to continue.

Shrub and herbaceous vegetation is appearing in alpine areas where tree encroachment appears to be limited because of defoliation and harsh winds. Subalpine areas contain open meadows with tree islands (transition zones) between forested and alpine plant associations. These tree islands are generally 200 years old when considering initial whitebark pine establishment followed by subalpine fir growth. If these areas were established prior to the 1800's, warmer/wetter climate of the Little Ice Age did not influence their presence. Limited individual tree data in other high elevation forested areas show whitebark pine age from 165 to 395 years. It is doubtful that the Little Ice Age played a significant role in vegetation development. JC/JR

Reconsider Use Of Clearcutting To Treat Aspen Stands

COMMENTS: Reconsider the use of clearcuts in aspen stands to mimic fire disturbance. Burning adds organic carbon and increases soil pH allowing aspen to better compete with other vegetation. Clearcuts remove organic matter and lower pH.

643

RESPONSE: Unless Forest objectives dictate otherwise, harvesting either leaves the timber stand in an improved condition or provisions are made for regeneration. The Revised Forest Plan permits all harvest methods, including even-aged systems and burning. Clearcutting is a viable method of regenerating a stand of trees and not an expedient of logging. Clearcutting does not duplicate the role of fire (it does not increase pH or soil carbons to the degree fire does) but clearcutting can approximate the role of fire. (Daniel, Helms, and Baker 1979). DS

COMMENTS: Refrain from treating aspen stands until it is demonstrated through monitoring and research that such treatments like burning and clearcutting are effective.

489

RESPONSE: Studies show that clearcutting in aspen stands usually results in profuse and rapid aspen suckering (regrowth of young trees) (Crouch 1983; Crouch 1981; Bartos and Mueggler 1982; Baker 1925; Hittenrauch 1976; Jones 1975; Mueggler and Bartos 1977; Sampson 1919; Smith et. al. 1972).

In aspen stands seral to conifers, clearcutting is the method of choice. Any other method puts the objective of aspen regeneration at risk. (Examples of Aspen Treatment, Succession, and Management in Western Colorado 1985).

Numerous examples of successful aspen regeneration exist on the Targhee. Regeneration is evident in many clearcut areas specifically along Highway 20. The potential to regenerate aspen through logging and other techniques is evident in types other than lodgepole.

Clearcutting and extensive removal of logging slash can reduce the organic material available on the site. Nutrients contained in a tree are in the small limbs and foliage. Standards and guidelines for retention of downed woody material and logging slash to maintain site productivity over the long term are found in the Revised Forest Plan.

The Forest will evaluate appropriate methods to achieve regeneration. Clearcutting may not always be used to regenerate aspen. Many other techniques exist, such as prescribed fire, aspen felling, girdling aspen and conifers, partial removal of conifers, and removal of small groups of conifers, among others. JC/DS

COMMENTS: Test prior to implementing aspen treatments. The paper by Cryer and Murray, 1992 is only a hypothesis. No data is presented and no studies are cited to support it.

489

RESPONSE: Soil profiles, and their associated chemistry and nutrient cycling processes occurring within different types of aspen stands, have been studied extensively (Jones and Debyle 1985, Morgan 1969, Morgan and Tew 1968, Hoff 1957, Tew 1968, Lutz and Chandler 1946, Stoeckler 1961, Daubenmire 1953, Troth et. al. 1976, Young and Carpenter 1967, Bartos and Debyle 1981, Daubenmire and Prusso 1963, Hayward 1945, Potter and Krenetsky 1967, and others). Several studies are documented in the Cryer and Murray (1990) article that describe changes in soil characteristics and losses in organic matter when aspen stands are invaded by conifers (Birkeland 1974, Brady 1974, Tisdale and Nelson 1975, Boul, Hole and McCracken 1973). These changes can result in soil

TIMBER - ASPEN

characteristics that make it difficult for aspen to reestablish (Epstein 1972).

The high concentrations of litter created by forbs, grasses and aspen leaves and the rapid rate of litter decay associated with aspen stands contribute to the soil's characteristics (Bartos and Debyle 1981). In northern New Mexico, Potter and Krenetsky found that grasses underneath aspen stands contributed greatly to the organic matter in the soil beneath aspen improving soil water-holding capacity, percentage of base saturation, soil structure, and permeability.

Aspen soils differ from soils found in adjacent conifer stands (Hoff 1957) in that they are darker and contain considerably more organic matter. Aspen foliage has a higher nutrient content than conifer foliage (Jones 1985; Daubenmire 1953; Troth et. al. 1976; Young and Carpenter 1967). This, combined with the rapid decay in aspen stands, provides a quick return of nutrients to the soil (Bartos and Debyle 1981; Daubenmire and Prusso 1963; Hayward 1945).

Soil pH is generally higher on aspen soils than in those areas dominated by conifers (Jones and Debyle 1985, Morgan 1969). Jones (1985) documents that after several generations of aspen occupancy, a soil typical to aspen develops. Jones also notes that even after one generation of conifer occupancy, the result is a leached, light colored upper soil horizon which increases soil acidity making it hard for aspen to compete with spruce-fir forests (Epstein 1972).

In aspen stands are seral to conifers, clearcutting is the method of choice. If the stand objective is to improve or initiate aspen regeneration, clearcutting (including all the conifer stems) is the preferred method. Any other method, including fire, puts the objective of aspen regeneration at risk. (Examples of Aspen Treatment, Succession, and Management in Western Colorado 1985). Numerous examples of successful aspen regeneration exist on the Targhee as a result of management treatment. JC

Aspen Patch Cuts

COMMENTS: Eliminate the statement, "patch cuts are used to provide disturbance needed to regenerate aspen. " Patch cuts are used for many reasons.

283

RESPONSE: Your comment is acknowledged. The Forest made this change. LB

Use Aspen as Marketable Species

COMMENTS: Use aspen as marketable species at least in proportion to its availability. It is a quicker growing species with quicker regeneration.

625

RESPONSE: The majority of the aspen component on the Targhee does not produce crops of industrial wood. Aspen is not included in the 8.0 ASQ calculations. Aspen will be treated where appropriate or needed and counted as part of the 3.8 MMBF ASQ for product or firewood. LB

Monitor Aspen Treatments

COMMENTS: Include monitoring on the effectiveness of vegetation treatments related to aspen regeneration or upland rangelands as a high priority.

489

RESPONSE: Monitoring aspen regeneration is part of each District's annual program of work. Each time a Forest regeneration project is implemented, stocking surveys are scheduled. All areas required by the National Forest Management Act to be reforested within the five year standard are tracked annually in a data base.

The frequency of surveys depends on the type of regeneration project. Planted areas are examined during the first, third and fifth growing season after planting. Areas of natural regeneration are examined the third and fifth year after cutting. JC

Include Skidding Standards and Guidelines For Aspen

COMMENTS: Prohibit skidding or harvesting of aspen with ground based equipment in wet weather as this causes serious damage to root systems of the clones. Skid only on frozen or dry soil.

90

RESPONSE: Standards are developed for each timber sale on a site-specific basis and implemented through contract provisions. Many standards and specific contract provisions are included in every timber sale contract. Some of these include: CT6.3 Schedule of Operations, CT6.410 Felling and Bucking, CT6.411 Directional Felling, CT6.425 Tractor and Rubber Tired Skidder Yarding, and CT6.61# Wetland Protection. These provisions, among others, are designed to reduce soil disturbance and compaction, especially during wet weather.

JC/JR

COMMENTS: Include standards and guidelines and other pertinent information you will use to treat aspen plant communities. Currently, there is no way to analyze the scope of impacts based on information in the Draft Forest Plan Revision.

643, 766

RESPONSE: Refer to subsection descriptions and direction to establish Properly Functioning Condition. Properly Functioning Condition Assessments establish a range of conditions under which aspen can function as a viable part of the ecosystem. A landscape analysis will determine total areas, specific stands and successional stages needed to maintain the aspen component.

Standards and Guidelines in Chapter III of the Revised Plan address recommended silvicultural systems, rotation ages and minimum stocking for aspen. Planned acres and volumes of timber sale activity are identified by watershed in Chapter IV. The levels of harvest are included in the impacts evaluated in Chapter IV of the Final EIS.

Areas on non-ASQ lands have set maximum levels of harvest and are included in the evaluation of impacts. JC

TIMBER - ASPEN

Reflect Effects of Yellowstone Fires on Aspen Component

COMMENTS: Discuss the effects of Yellowstone fires on regional landscape patterns. The Targhee Forest has not considered fires in the proposal to treat aspen stands to reduce conifer encroachments.

643

RESPONSE: Historic patterns and processes at the regional scale are beyond the scope of the analysis needed to assess the impacts of the Revised Plan and EIS. Direction is included in the Revised Plan to identify Properly Functioning Conditions at various landscape scales in each subsection under forestwide goals and objectives. Identifying natural structure, composition, disturbance regimes and patterns across the landscape will be part of assessing Properly Functioning Condition. Patterns of fires in the Yellowstone area will be considered in this assessment.

Direction to use fire where appropriate is included in the Revised Plan. Fire may be used to regenerate aspen but will be evaluated on a site-specific, case-by-case basis. Fire may not always be safe or the most effective method to use. JC

Include Aspen Restoration Harvests In 3.7 MBF

COMMENTS: Conifers harvested to restore aspen should be part of the 3.7 MMBF/ASQ. To do otherwise offers unlimited cutting.

Aspen is not a merchantable product on the Targhee National Forest and therefore cannot be considered in the ASQ and should be managed as a wildlife resource.

658, 693, 1267

RESPONSE: Aspen will not be included in the 8.0 ASQ. Most of the aspen on the Targhee is unmerchantable. Harvested aspen volume will either fall under the firewood program if the acres are suitable or under the unscheduled program if acres are unsuitable. Where conifers are removed on suitable lands they will be counted against ASQ. LB

TIMBER - ALLOWABLE SALE QUANTITY

General Comments and Questions On Allowable Sale Quantity (ASQ)

COMMENTS: Display existing ASQ level.

166, 1367

RESPONSE: This is displayed in Table II-1 in the FEIS as potential yield. LB

COMMENTS: Display the 10-year average sale volume in the Table on Page 11.

166

RESPONSE: The 10-year average sale volume is not a component used to compare alternatives in the Table on page II. It is discussed in Chapter III (Affected Environment) of the FEIS. LB

TIMBER - ALLOWABLE SALE QUANTITY

COMMENTS: Be specific regarding when, where, and how much logging will be permitted so industry, recreationists, preservationists can predict impact on their area of interest, and display the harvest.

496, 625a, 669, 1269, 1330, 1392

RESPONSE: The DEIS and DREV were silent on potential location of unscheduled acres. Proposed harvest acres, both ASQ and unharvested, are provided by watershed for each alternative. Site-specific effects are determined through a project-level EA or EIS when a timber sale is proposed. LB

COMMENTS: Is there really 7.5 MMBF left on the forest without going into roadless areas, old growth and sensitive areas?

625a

RESPONSE: Roadless areas account for approximately 8% of the suitable acres in the Revised Plan. Suitable acres account for 40% of the total forested acres on the Forest. Most sensitive areas are not included in the suitable base. LB

COMMENTS: ASQ is very low. Can amendments on timber yield and access be made as needed over time?

314

RESPONSE: Changes to the Revised Plan can occur over time. Changes are generated through site-specific NEPA analysis which indicates the need for a plan amendment are part of a project decision. LB

COMMENTS: Green sales should be reduced commensurate with increase in salvage sales.

1365

RESPONSE: ASQ levels for all alternatives are revised. ASQ volume is generally considered green or "live" volume. The Revised Plan proposes to increase green sales as salvage sales decrease. Salvage efforts have largely been completed. LB/RR

COMMENTS: Incorporate studies by Henjum (Henjum et al, 1994) and by Patten and Hansen (1995) into the Revised Plan.

690

RESPONSE: Patten and Hansen (1995) are incorporated in the Biological Assessment for the Revised Plan and provide supportive information regarding old growth on the Forest. Henjum, et.al. was not used as a source in these documents. LB

Long-Term Sustained-Yield Capability

COMMENTS: Support an effective long-term sustained yield management approach that properly conserves a full spectrum of forest resources and reflects multiple-use responsibilities.

244, 408, 411, 490, 1203

TIMBER - ALLOWABLE SALE QUANTITY

RESPONSE: Long-Term Sustained-Yield (LTSY) is 22.0 MMBF. The ASQ is 8.0 MMBF. The difference between these amounts reflects the multiple-use responsibilities the Targhee is required to meet. LB

COMMENTS: Provide documentable evidence that ASQ is sustainable and that it will not reduce elk cover, increase road density, soil erosion or disturb watersheds above existing levels.

625a, 1365

RESPONSE: LTSY is approximately 22.0 MMBF. ASQ is 8.0 MMBF. Effects of implementing the proposed ASQ harvest level are discussed in Chapter IV of the FEIS. Whether the Targhee achieves this level depends upon site-specific analysis. Harvest activities could reduce elk cover, increase road density, soil erosion or disturb watersheds above existing levels. LB

COMMENTS: Move more of the 27 MMBF of sustained yield ahead to show some attempt at leveling out sales instead of boom-bust cycles.

334, 1339

RESPONSE: Long-Term Sustained-Yield is approximately 22.0 MMBF, not 27 MMBF. The Forest increased ASQ from 3.7 MMBF to 8.0 MMBF. Our analysis shows an ASQ of 8.0 MMBF is sustainable and provides a reasonable program level until regenerated lodgepole pine stands become commercially available. LB

COMMENTS: Targhee has been a non-sustainable tree farm for loggers far too long.

60

RESPONSE: The Targhee intends to manage the Forest for the sustainability of all ecological components. The proposed ASQ of 8.0 MMBF is significantly lower than the 22.0 MMBF for long-term sustained yield. LB

COMMENTS: Long Term Sustained Yield at 27 MMBF a year is constrained by goshawk habitat.

154

RESPONSE: The LTSY for the Revised Plan is approximately 22.0 MMBF. Proposed ASQ is 8.0 MMBF. The difference between these two figures reflects other multiple-use objectives, including goshawk needs. LB

COMMENTS: Disclose and discuss the method and process of field validation used to arrive at the LTSYs in Table IV-19.

Discuss process used to reduce LTSY in Alternative 3 by 14.9 mmbf. Such a large reduction calls formulation of the model into question.

Discuss how FORPLAN results for LTSY were field validated.

1389

RESPONSE: On-the-ground timber inventory data was used in FORPLAN. LTSY calculations are derived from FORPLAN outputs. LTSY calculations are a measure of average annual growth of the forest on all of the suitable acres and field validations are not useful. Two field validations were completed on the ASQ output generated by FORPLAN. Both indicated a reduction of

TIMBER - ALLOWABLE SALE QUANTITY

approximately 35% from the FORPLAN output. The reduction reflects management prescriptions, objectives, standards and guidelines which could not be modeled in FORPLAN and that affected the ASQ estimate. LB/RR

COMMENTS: Re-examine data and process for arriving at LTSY and proposed ASQ. Re-examine constraints that could result in pulling more harvest volume into the first decade of the Plan.

1389

RESPONSE: The FORPLAN model was rerun between the Draft Plan and Revised Plan. The Targhee overconstrained ASQ by only allowing 20% of the suitable base to be in a created opening at one time. The correct constraint is 20% of total forested acres. LTSY, which is a measure of the growth on suitable forested acres, was calculated at approximately 22.0 MMBF. The field-validated ASQ is 8.0 MMBF which is an increase over that shown in the DEIS. LB

Alternatives and ASQ

COMMENTS: Define how much of the ASQ in Alternative 2 and Alternative 3M are in a NIC component.

228

RESPONSE: The total NIC acres for roadless and steep slopes in these two alternatives are 92,845 and 45,074 respectively. It is not possible to determine an ASQ level in the NIC component until site-specific analysis is completed. A site-specific analysis will determine where harvest will occur. LB

COMMENTS: Don't blame motorized trails in roadless areas not even being considered for harvest as a reason for the decline in the ASQ.

228, 1202

RESPONSE: Motorized trails in roadless areas are not included in ASQ calculations. JR

Alternatives and Economic Concerns

COMMENTS: Any alternative that decreases ASQ will have a negative impact on fiscal health of surrounding communities.

432

RESPONSE: Any alternative that decreases ASQ may have a negative impact on the fiscal health of some surrounding communities. Because of the interplay between Payment in Lieu of Taxes and the 25% Fund and recent changes in the formula used in the Payments in Lieu of Taxes program, the negative impacts are minimal. The actual numbers are shown in the FEIS. DP

COMMENTS: High percentage of NIC in Alternatives 1-5 lowers practical ASQ to the point that all alternatives are nearly equal. 40 CFR 1502.41 requires the Forest Service to explore and evaluate reasonable Alternatives.

393

TIMBER - ALLOWABLE SALE QUANTITY

RESPONSE: The range of alternatives is reasonable. Based on public comments, ASQ in the alternatives is adjusted upward 0.0 - 12.9 MMBF compared to 0 - 5.9 MMBF in the DEIS. The percentage of NIC acres decreased as a result of removing aspen from the ASQ totals. NIC acres (slopes, roadless, and sensitive areas) are still included in suitable acres. LB

New Alternative Suggestions

COMMENTS: Consider an alternative that has a larger ASQ to prevent or reduce the amount and impact of insect and disease damage. Waiting until an epidemic starts is too late and increases the risk of wildfire.

413

RESPONSE: The number of acres proposed for harvest has doubled between Draft and Final. Assuming mature/at risk acres are prioritized for harvest, the opportunities for reducing risk to insect and disease damage have increased. More treatment could occur in future decades as stands grow back. RR/JR

COMMENTS: Consider an alternative of 12 MMBF of live, with at least 30-50% in lodgepole pine. A harvest weighted toward Douglas-fir will not help local timber industry. 413, 767, 1267

RESPONSE: ASQ levels for Alternatives 1-5 were adjusted upward. The Revised Plan proposes an ASQ of 8.0 MMBF. FORPLAN modeling indicates lodgepole pine would make up approximately 25% with the rest coming from other species, including mixed conifer types which includes some lodgepole pine. During the current planning period, lodgepole pine was extensively treated due to the mountain pine beetle epidemic. Since most areas of lodgepole pine have been treated, the majority of harvests will come from the mixed conifer and Douglas-fir components. Harvest location is a function of silvicultural need and multiple use objectives and is determined through site-specific analysis. LB

COMMENTS: Evaluate an alternative that maintains the existing Southeast Idaho timber industry - 20 MMBF without an NIC component.

393

RESPONSE: Alternative 2 proposes a potential ASQ of 12.0 MMBF, 3.8 MMBF of firewood/products and 2.0 MMBF of unscheduled harvest, for a total of 18.7 MMBF. A NIC designation is required in certain instances, such as for roadless areas, in all alternatives. LB/JR

COMMENTS: Analyze an alternative that reflects economic impact of decisions since 1985 and the closure of four lumber mills. Implementation of any of the existing alternatives will continue this impact. (CROSS REFERENCE: Economics, Timber)

393, 394

RESPONSE: Timber harvest at the 1985 level is not sustainable. Alternatives that did not meet long-term sustained yield requirements were dropped from further analysis. Information on decisions made from 1985-1995 are beyond the scope of this analysis. DP/JR

TIMBER - ALLOWABLE SALE QUANTITY

COMMENTS: Evaluate an alternative closer to the Long Term Sustained Yield capability.

228

RESPONSE: The LTSY of the Preferred Alternative is 22.0 MMBF. Alternative 2 proposes an ASQ of 12.9 MMBF, firewood/product of 3.8 MMBF, and 2.0 MMBF of unscheduled harvest potential for a potential harvest of 18.7 MMBF. LB/JR

COMMENTS: Include EM acres/volume expected over the next ten years and calculate how successful regeneration might contribute to Long-Term Sustained-Yield.

154

RESPONSE: The Forest provided an estimate of the maximum EM volume of 2.0 MMBF/year from unsuitable or non-ASQ acres. Growth in regeneration stands does contribute to Long-Term Sustained-Yield in the models the Targhee used. LB

COMMENTS: Increase the proposed 49% set aside to 100%. Even 100% does not take care of local community needs.

1349

RESPONSE: The proposed set aside is determined by regulation and computed by analyzing all sales sold over the prior 5 year period. (It has to be agreed on with Small Business Administration). It cannot be increased or decreased arbitrarily. BR

ASQ Is Too Low

COMMENTS: ASQ is too low.

20, 29, 267, 283, 285, 290, 309, 310, 394, 445, 473, 474, 476, 1198

RESPONSE: The Forest increased the ASQ from 3.7 MMBF in the Draft to 8.0 MMBF in the Final. ASQ is the amount of allowable timber that is sold from a plan area in a decade. Each Forest Plan proposes an allowable sale quantity. The allowable quantity is a ceiling, not a future sale level or target, and does not reflect all of the factors that may influence future sale levels. FORPLAN ASQ estimates are field-validated by resource professionals who are familiar with on-the-ground conditions and the constraints in management prescriptions. Actual ASQ may be more or less than those stated. If actual ASQ is higher than what was proposed, an amendment to the Plan is required with input and review by the public. LB/JR

COMMENTS: Too much of a drastic change from current direction. ASQ should be staged in small increments and over longer periods of time.

7

RESPONSE: ASQ was re-analyzed between the Draft and Final Forest Plan and increased from 3.7 MMBF to 8.0. The five year average sale volume for 1992-96 was 13.8 MMBF, including sawtimber, firewood, and product volume. The three year average sale volume 1994-96 was 9.6 MMBF. The Final Revised Plan allows an ASQ of 8.0 MMBF and firewood/product harvest of 3.8 MMBF. While this level

TIMBER - ALLOWABLE SALE QUANTITY

is less than the period 1985-94, it is in line with the past 3-5 year sale activity. Future decadal programs show an increase in ASQ over time. LB

COMMENTS: Need to harvest dead and dying trees so Forest will flourish; eliminate fire hazard.

12, 34, 272, 665, 709, 728, 1200, 1240, 1257, 1264, 1316, 1319, 1335

RESPONSE: The Revised Plan permits timber harvest and prescribed fire to regenerate stagnant stands. The Revised Plan also allows insects and disease to play a role in natural vegetation succession. LB/JR

COMMENTS: Should not cut back on timber sales - trees are falling over and going to waste or increasing fire danger.

Allow as much cutting as possible to avoid huge stands of bug, rust, and fire dead trees.

391, 661

RESPONSE: Timber harvest will continue to be a tool used to meet forest vegetation objectives. LB

COMMENTS: Alternative 3M will result in the accumulation of older age classes susceptible to mountain pine beetles in 40 to 50 years - even 20 mmbf will not be sufficient.

413

RESPONSE: All alternatives display predicted outcomes of age classes. The Revised Plan provides direction for the next decade and establishes goals for managing lodgepole pine density to reduce the risk of susceptible to bark beetles. The current decade ASQ is constrained by past harvest. Properly functioning condition assessments will be completed for lodgepole pine to address long-term management that will guide management activities. LB/RR/JR

COMMENTS: The needs of the timber resource should drive the ASQ. Elk, goshawk, grizzly bear, song birds, road densities, water quality should not determine ASQ.

432

RESPONSE: Management prescriptions were established to provide balance between competing resources. The ASQ is derived from management prescriptions. The National Forest Management Act requires that all resources be considered. JR

COMMENTS: The quickest way to destroy the sustainability of the environment is to take away the tools needed to allow it to work and remain healthy, diverse and full of vitality.

432

RESPONSE: The Revised Plan allows the use of a variety of tools and methods to sustain the forest environment. Monitoring, evaluation and adaptive management will determine if and when the Revised Plan needs to be amended.

LB

TIMBER - ALLOWABLE SALE QUANTITY

COMMENTS: Log at a sustainable rate. We need to be able to get firewood to burn. (CROSS REFERENCE: Firewood)

257, 649, 1315

RESPONSE: An ASQ of 8.0 MMBF is sustainable based on a LTSY of 22.0 MMBF. The Revised Plan allows for fuelwood harvest. Future decades should show an increase in harvest opportunities as regenerated lodgepole pine stands reach commercial size. LB/RR

COMMENTS: Makes no sense to harvest only 3.7 MMBF out of a sustainable 30 MMBF.

346, 380

RESPONSE: The Long-Term Sustained-Yield for the Revised Plan is 22.0 MMBF. Adjusted ASQ for the Revised Plan is 8.0 MMBF. The ASQ is less than LTSY because of the need to maintain and improve other resources. LB/JR

COMMENTS: Manage timber for better productivity. Cut mature timber, clear non-producing thickets, remove firewood, and plant when necessary.

439

RESPONSE: Your comment is acknowledged. Silvicultural prescriptions are developed on a site-specific basis. Harvest levels are balanced with other resource needs. LB

COMMENTS: Embarrassingly small volume of ASQ when you consider the extensive productive land base of 487,000 acres which are growing at a rate of 54 mmbf a year and only 7% of this net annual growth is being proposed for harvest.

1389

RESPONSE: The Long-Term Sustained-Yield for the Revised Plan is approximately 22.0 MMBF. The ASQ is 8.0 MMBF. Firewood/product volume is an additional 3.8 MMBF. A net annual growth of 36% is proposed for harvest. ASQ increased from 3.7 MMBF in the Draft to 8.0 MMBF in the Final. Harvest is reduced in this planning period, because of the intensity of past treatments. LB/JR

COMMENTS: Write in flexibility to the plan to increase the decade harvest above 37 MMBF if salvage, forest health or as ecosystem goals dictate.

90

RESPONSE: If monitoring and evaluation determine a higher ASQ is appropriate and desirable, the Plan will be amended. LB/JR

COMMENTS: Harvest more timber, but do it more profitably and efficiently without damaging new growth.

182

RESPONSE: ASQ was increased from 3.7 MMBF in the Draft EIS to a sustainable 8.0 MMBF in the Final EIS. Economic efficiency, consistent with meeting ecological and multiple use objectives, is required by NEPA. RR

TIMBER - ALLOWABLE SALE QUANTITY

COMMENTS: Increase timber production while protecting over logged watersheds.
285

RESPONSE: The Revised Plan directly addresses this concern. The ASQ in the FEIS was increased in Alternatives 1-5. Increases in ASQ do not include regeneration harvest in Watersheds 9-13. LB/JR

COMMENTS: Offer more post and pole sales as well as a few more timber sales.
F-G2(2), 311

RESPONSE: Site-specific analysis determines the mix of sawtimber and products offered on an annual basis. Stand needs, silvicultural analysis, supply and demand, and Desired Future Condition guide these decisions. LB

Miscellaneous

COMMENTS: Plan limits harvest activities to 11,430 acres for the decade. Land manager's options are constrained as new methods of providing ecologic diversity are developed.
90

RESPONSE: The new proposed ASQ of 8.0 MMBF/year allows harvest on approximately 20,520 acres over the decade. An additional 2.0 MMBF/year could come from unscheduled harvest to meet other resource objectives. LB/RR/JR

COMMENTS: Use a "mature trees" only logging policy with exceptions for disasters.
428, 608

RESPONSE: ASQ volume is mature trees. LB

ASQ Is Too High

COMMENTS: ASQ is too high.
42, 174, 266, 620, 668, 1365, 1368

RESPONSE: ASQ is the amount of allowable timber that can be sold from a plan area in a decade. Each Forest Plan establishes an allowable sale quantity. The allowable quantity is a ceiling, not a future sale projection or target, and does not reflect all of the factors that may influence future sale levels. FORPLAN ASQ is field-validated by resource professionals who are familiar with on-the-ground conditions and the constraints in management prescriptions. If ASQ is increased, an amendment to the Forest Plan is required. An ASQ of 8.0 MMBF/year is sustainable and is well below projected Long-Term Sustained Yield of 22.0 MMBF. LB/JR

COMMENTS: The ASQ should not exceed 37 million board feet over the decade and the ASQ will be from areas of the forest that do not violate other guidelines and standards.
697

TIMBER - ALLOWABLE SALE QUANTITY

RESPONSE: ASQ in the preferred alternative is 8.0 MMBF/year or 80 MMBF for the decade. The Revised Plan provides direction in the form of goals, objectives, standards, and guidelines that prevent harvest in unsuitable or sensitive areas. LB/RR

COMMENTS: The Revised Plan should focus on restoration in general or specifically fish and wildlife restoration.

F-H(8), 11, 136, 239, 266, 325, 620, 651, 652

RESPONSE: The Revised Plan addresses ecosystem needs. Improved guidance for fish and wildlife including restoration are incorporated. LB

Reduction Of Mountain Pine Beetle Requires Reduction In ASQ

COMMENTS: Recognition that pine bark beetle salvage is finished suggest a greatly reduced ASQ.

527, 634, 668

RESPONSE: All proposed ASQ levels are less than ASQ levels during the current planning period. The preferred alternative proposes an ASQ of 8.0 MMBF/year below projected LTSY of 22.0 MMBF. LB

COMMENTS: Green timber sales were not balanced with extensive salvage of pine beetle timber. Need change in management enthusiasm.

341

RESPONSE: ASQ levels in each alternative reflect green volume. Salvage will be limited during this decade. LB/JR

COMMENTS: Reduce harvest to improve scenery.

6, 215

RESPONSE: Visual objectives are incorporated in each alternative. Harvest is lower than in the previous decade. LB

ASQ Too High If Majority Of Harvest Occurs In Centennials & Beaverhead Ranges

COMMENTS: ASQ is too high if the Forest carries out its proposals to harvest, on average, half of the proposed volume from the Centennials Mountains and the Beaverhead Range. (CROSS REFERENCE: Centennials)

643

RESPONSE: Approximately 35% of the proposed annual ASQ harvest is scheduled in the Centennial Mountains and Beaverhead Range. Site-specific analysis with public input will be used to develop individual project proposals. Field verification indicates timber harvest is feasible in these areas and will meet standards and guidelines in the Revised Plan. LB/RR/JR

Prefer Current Harvest Levels No Action

COMMENTS: We are satisfied with the current harvest levels of the Forest.

23, 738

TIMBER - ALLOWABLE SALE QUANTITY

RESPONSE: ASQ has changed from 3.7 MMBF in the Draft to 8.0 MMBF in the Final. LB

Support For ASQ In Cuff Proposal

COMMENTS: Support ASQ as described in the CUFF proposal in general or for economic reasons, recreation, forest health.

288, 501, 1176, 1309

RESPONSE: ASQ was re-analyzed between the Draft and the Final Revised Plan. Alternative 2 approximates the CUFF proposal and is analyzed in the FEIS. LB

Support For ASQ In Alternative 1

COMMENTS: Support Alternative 1 because of economic benefits from recreation and timber.

292

RESPONSE: The Forest agrees Alternative 1 would be more responsive to local economy concerns, as shown in the FEIS, Chapter IV. The Targhee modified Alternative 3M, in part, to improve local economic conditions; however, Alternative 3M provides a more balanced response to the wide range of issues facing the Forest. DP

Support For ASQ Amount In Alternative 2

COMMENTS: Correct Alternative 2 to indicate timber harvest is allowed in the Plateau BMU (Page IV-34). (CROSS REFERENCE: Grizzly Bear - Plateau BMU)

413

RESPONSE: Alternative 2 was corrected in the FEIS. LB

COMMENTS: Support ASQ amounts in Alternative 2 for wildlife, forest health, and economic reasons.

30, 34, 36, 46, 47, 50, 54, 90, 98, 272, 296, 309, 334, 462, 687,
1335, 1378, 1390

RESPONSE: ASQ level for Alternative 2 increased from approximately 6.0 MMBF to 12.9 MMBF between Draft and Final. Firewood/post ASQ remains at 3.8 MMBF. LB

Support For ASQ Amount In Alternative 3M - With Exceptions

COMMENTS: Support ASQ in Alternative 3M as long as it does not affect firewood cutting. (CROSS REFERENCE: Firewood)

44, 49, 53

RESPONSE: All alternatives allow the harvest of 3.8 MMBF of firewood across the Forest. This volume is not included in ASQ projections. LB/JR

COMMENTS: Support harvest in Alternative 3M in general, for maximum sustainability forest recovery, science recommends this level, promotion of

TIMBER - ALLOWABLE SALE QUANTITY

forest health, improvement of environmental quality, reduction in wildlife impacts, multiple use oriented, economics.

F-B(4), F-J(3), 11, 27, 58, 143, 157, 159, 162, 165, 167, 173, 175, 180, 181, 183, 185, 190, 192, 193, 200, 203, 209, 212, 213, 226, 252, 278, 280, 335, 356, 357, 359, 360, 362, 368, 370, 377, 379, 390, 392, 398, 400, 405, 407, 410, 424, 430, 438, 441, 448, 490, 491, 496, 519, 622, 632, 640, 643, 644, 650, 652, 659, 662, 664, 666, 667, 690, 697, 719, 725, 731, 1197, 1243, 1257, 1270, 1273b, 1276, 1313, 1327, 1328, 1330, 1337, 1351, 1381, 1388, 1395, 1399, 1443

RESPONSE: ASQ output for Alternative 3M increased from 3.7 to 8.0 MMBF. Forestwide standards and guidelines for vegetation address most of these concerns. LB/RR

COMMENTS: Support ASQ in Alternative 3M except for 4,700 acres proposed for harvest in the Centennial Mountains. (CROSS REFERENCE: Centennials)
1204, 1314, 1387

RESPONSE: Approximately 35% of the proposed annual ASQ harvest is scheduled in the Centennial Mountains and Beaverhead Range. Site-specific analysis with public input will be used to develop individual projects proposals. All projects must meet standards and guidelines. LB/JR

Support For ASQ Amount In Alternative 4 - With Exceptions

COMMENTS Support for ASQ in Alternative 4 because of fish and wildlife, roadless set aside.
176, 308, 325

RESPONSE: ASQ level for Alternative 4 increased from approximately 2.5 MMBF to 6.0 MMBF. LB

COMMENTS: Support ASQ amount in Alternative 4 if timber is sold to local companies.
61

RESPONSE: Sales are sold by competitive bid. Local industry is invited to bid on sales. LB/JR

Support for Alternative 6

COMMENTS: Support for ASQ in Alternative 6 in general, for restoration, to protect headwaters, less impact to wildlife, protect riparian areas, wilderness.

F-G-1(475), F-K(4), 207, 279, 317, 328, 382, 609, 631, 655, 739, 1275, 1321, 1340, 1367, 1387

RESPONSE: The ASQ for Alternative 6 remains at zero and did not change between draft and final. LB

TIMBER - ALLOWABLE SALE QUANTITY

Support For 3MMBF ASQ

COMMENTS: Support 3 MMBF ASQ because it takes waste practices/waste margin into consideration and thereby reduces ASQ.

1324

RESPONSE: The timber sale appraisal process considers various defects that occur in the timber resource and in harvest operations, regardless of the selected alternative. LB

COMMENTS: The Final Plan should include a strict adherence to the specified ASQ of 3.7 MMBF per year and the specified 3.8 MMBF per year for other forest products.

690

RESPONSE: Re-analysis of ASQ between the Draft and Final Revised Plan increased from approximately 3.7 MMBF to 8.0 MMBF. Firewood/forest product levels remain at 3.8 MMBF/year. LB

Support 5MMBF ASQ - Economics Reasons

COMMENTS: Local timber interests need 5mmbf to remain viable.

154

RESPONSE: The Revised Plan provides 8.0 MMBF. LB

COMMENTS: Limit logging to 5 MMBF for sound management.

179

RESPONSE: The ASQ for each alternative was recalculated. The Preferred alternative proposes an ASQ of 8.0 MMBF, below the LTSY of 22.0 MMBF/year. LB

COMMENTS: Goshawk constraint was only applied to 487,000 suitable acres rather than total Forest lands (1,219,741 acres) or tentative total Forest lands (703,100 acres). The 20% constraint was intended to apply across the whole forest. A recalculation would increase ASQ to 5 MMBF.

Adjust proposed ASQ upwards to 5 MMBF by revising Goshawk constraint. (CROSS REFERENCE: Wildlife, Goshawk)

154, 1258

RESPONSE: Your comments are acknowledged. The Targhee re-analyzed ASQ predictions and applied the goshawk constraint against total forest acres. As a result ASQ increased from 3.7 MMBF to 8.0 MMBF in the Revised Plan. LB

Support for 10MMBF ASQ

COMMENTS: Ensure that the Forest retains expertise to put out quality timber sales; supports viable timber industry.

283

TIMBER - ALLOWABLE SALE QUANTITY

RESPONSE: The Final Revised Plan proposes an ASQ of 8.0 MMBF/year which should allow timber sale preparation and administration expertise to remain on the forest. LB

Support For 20MMBF ASQ

COMMENTS: None of the existing alternatives will support a viable timber industry which affects local communities.

692

RESPONSE: Chapter III of the EIS projects that a viable timber industry would need 31.0 MMBF for survival including firewood. Approximately 50% of this amount would come from the Targhee. The Revised Plan proposes 8.0 MMBF of sawtimber and 3.8 MMBF from firewood and a potential of 2.0 MMBF from unscheduled timber harvest for a total of approximately 13.7 MMBF. Alternatives 1-3 come close or exceed this level. LB/JR

COMMENTS: A reasonable NEPA/NFMA analysis to sustain timber industry in Southeast Idaho would provide 20 MMBF a year.

393

RESPONSE: The Long-Term Sustained-Yield for the Targhee is 22.0 MMBF. Based on the prescription mix and validation of ASQ, a 20.0 MMBF level can not be sustained in this decade and would not be supported by NEPA/NFMA analysis. LB

COMMENTS: Early in the planning process, the Forest was looking at 20 MMBF/year including post, poles, firewood, and sawtimber with half of the ASQ to be sold in small class lodgepole. Stick to your agreement.

1267

RESPONSE: Early ASQ estimates were based on the best information available but did not represent an "agreement". Based on our re-analysis, the Targhee is proposing a potential harvest program of 13.7 MMBF under Alternative 3M

(includes products). To propose a 20.0 MMBF program under 3M would not meet other important resource needs associated with this alternative. Alternative 2 proposes 18.7 MMBF. LB

Support For 25-30 MMBF ASQ

COMMENTS: Support for 25-30 MMBF for economics, scenery, reduce fire hazard, forest health.

Support for 26-28 MMBF ASQ for economics.
471, 476, 694, 1202, 1239

RESPONSE: An increased ASQ of 25-30 MMBF would exceed the Long-Term Sustained-Yield level of 22.0 MMBF and would benefit these areas of concern only in the short term. Until previous harvest areas reach harvestable growth, a 20.0 MMBF level would not meet objectives outlined in the FEIS for other resources. LB/JR

TIMBER - ALLOWABLE SALE QUANTITY

COMMENTS: Support for ≥ 30 MMBF for sustainability, economics, reduce fire frequency.

98, 275, 413, 495, 503, 564, 702, 1202

RESPONSE: LSTY is generally viewed as a cap. Changes in ASQ that exceed LSTY predictions require a Forest Plan amendment. This was the case in the current planning period when the Targhee departed from estimated ASQ levels to reduce impacts from insect and disease in lodgepole pine stands. The Long-Term Sustained-Yield for The Revised Plan is estimated at 22.0 MMBF. None of the proposed alternatives exceed the LSTY. LB/JR

COMMENTS: Prohibit Logging: 1) in the Centennials, 2) Big Holes, 3) Teton Basin, 4) Plateau Area, 5) Snake River Range, 6) All roadless areas, 7) All aquatic/riparian areas, 8) Old growth stands, 9) Grizzly bear, Sit 1, 10) Spotted frog habitat, 11) Winter range and calving areas, 12) Yellowstone ecosystem and surrounding corridors.

F-G-1(475), F-H(8), F-J(3), F-K(4), 23, 203, 212, 278, 335, 389, 489, 611, 625, 640, 643, 650, 655, 690, 695, 697, 739, 1194, 1239, 1243, 1276, 1328, 1330, 1395

RESPONSE: Management prescriptions that describe permitted activities in various areas on the Targhee are included in the Revised Plan. Although harvest may be permitted in some of these areas, site-specific analysis is required. Standards and guidelines were designed to provide adequate protection of resources. LB/CC/JR

Wildlife Habitat Needs Should Be Tied To Timber Harvests

COMMENTS: Associate wildlife habitat needs with proposed ASQ.
136, 1369

RESPONSE: The majority of the management prescriptions are designed for resources other than timber, but allow different levels of harvest to take place as long as the direction for the area is followed. Therefore, wildlife habitat needs are associated with ASQ. LB

COMMENTS: On wildlife and ecosystem projects that include removing conifer, let it be a wildlife project instead of including it in the ASQ.
1267

RESPONSE: To count as part of the proposed ASQ level of 8.0 MMBF, volume must come from suitable lands. If the project, regardless of its objectives, is located on suitable land, any harvest would count toward ASQ. If the project is located on unsuitable land, any harvest would be counted against the Non-Interchangeable component that limits volume to 2.0 MMBF/year. LB

COMMENTS: Don't stop logging, just make sure new roads get closed and that some cover is left for game.
336, 1333

RESPONSE: All alternatives in the Revised Plan allow logging. Roads and access will be managed according to the needs of the resource through

TIMBER - ALLOWABLE SALE QUANTITY

site-specific analysis. Many existing roads are scheduled for closure and road density standards have been established. Elk cover standards were established to ensure cover is provided for game. LB/JR

Restore Degraded Wildlife Habitat From Past Harvest Activities

COMMENTS: Restore any habitat that has been degraded as a result of logging and road-building.

396, 640, 651, 652, 665

RESPONSE: Laws, regulations, and the Revised Plan's standards, guidelines, goals, and objectives emphasize restoration of degraded habitat regardless of the activity that created the problem. LB

COMMENTS: Need to restore areas and get back to sustainable harvest of trees.
60

RESPONSE: All alternatives propose ASQ levels that are sustainable and lower than the Long-Term Sustained-Yield of 22.0 MMBF. LB

COMMENTS: Move toward protection of all plants and animals and the habitat that supports them. Too much harvest has occurred in the past.

620

RESPONSE: Management prescriptions and standards and guidelines in the Revised Plan are designed to provide adequate protection of all resources. Each alternative's proposed ASQ level is lower than the anticipated LTSY of 22.0 MMBF. Site-specific NEPA analysis may determine more restrictive protection measures are necessary than those outlined in the Revised Plan. LB

TIMBER - BIG GAME

(CROSS REFERENCE: Wildlife, Elk)

COMMENTS: Improve analysis of the effects of harvest on wildlife and include the following: How was it determined, how many acres could be harvested to maintain wildlife species; assess existing wildlife populations, source habitats and determine if the habitats are adequate; evaluate impacts on big game security in timber harvest areas; show the effect past logging roads has had on declining big game populations, and existing forest conditions.

244, 475, 643, 1369

RESPONSE: Management indicator species were selected for the Revised Plan. These species include all threatened, endangered, and sensitive species on the Forest, plus other species. Habitat requirements were identified, and appropriate standards and guidelines and management prescriptions were developed to maintain suitable habitat conditions. The Revised Plan's standards and guidelines and management prescriptions were incorporated into the Forplan Model used in calculating ASQ.

The AMS, DEIS, FEIS and Process Paper D assess the available population and habitat conditions for each of the management indicator species.

TIMBER - BIG GAME

The Forest evaluated effects on big game security with two models: elk habitat effectiveness (EHE) and elk vulnerability (EV). The Revised Plan reduces the amount of motorized access on the Forest, which improves both EHE and EV. The Forest also developed two Management Prescriptions (5.1.4 and 5.4) which address security issues associated with timber harvesting.

The EHE and EV analysis in the FEIS discusses existing condition, which incorporates all past timber harvests and all motorized access. MO

COMMENTS: Draft implies elk depend on logging to create forage habitat which conflicts with studies documenting a loss of forage caused by regeneration logging practices (stem exclusion phase).

RESPONSE: Nowhere in the Revised Plan is there an implication that elk depend on logging. MO

COMMENTS: Reduce harvest so 100% of the Forest meets Fish and Game goals for elk security.

625a

RESPONSE: One of the goals for the Revised Plan is: "Provide habitat to support the wildlife and hunting goals of the States of Idaho and Wyoming." The Revised Plan reduces the timber harvest volume, but timber harvest is only one of many factors considered in meeting Fish and Game goals for elk security. Other factors, such as travel management, road density, and hunter density are also considered.

Proposed changes in more restrictive snowmachine travel, cross-country motorized travel, and a reduction in open road and open trail route density should result in improved habitat effectiveness and lower elk vulnerability.

During the next decade, the number of forested acres proposed for timber harvesting is reduced from what occurred in the past decade. In the Revised Plan, about 30,500 forested acres are proposed for timber harvest or vegetative treatment (such as prescribed fire) during the first decade. Only

2.5% of the total forested acres on the forest will be affected by harvest activities. A net increase is predicted in cover as the previously harvested areas continue to grow and provide cover for elk and other wildlife.

Predicted improvements in habitat conditions are only part of the answer. Some areas of the Forest have high hunter density. State Fish and Game agencies must also manage hunter densities if goals are to be met. MO

Goals For Wildlife Do Not Provide For Other Multiple Uses

COMMENTS: Goals for elk security are unsubstantiated and do not consider other multiple uses and resulting economic effects. Elk populations have increased over the last ten years and as long as numbers remain high, the argument for limited access and setting aside 50-60% of the watershed for cover is a moot point.

692

RESPONSE: Goals for elk security are developed by State Fish and Game departments. The FEIS considers other multiple uses and economic effects.

TIMBER - BIG GAME

Elk populations have increased in many areas of the Forest, but declines in elk use have occurred on portions of the Forest which have experienced timber management or have high road densities. The Idaho Department of Fish and Game indicates that elk goals are not being met in Game Management Units 59, 59A, 60, and 62A. The Revised Plan reduces motorized access and allows cover to increase in previously harvested areas in support of State Fish and Game goals. MO

Reconsider Timber Harvest On Winter Range

COMMENTS: Specifically disclose habitat needs of wintering big game and proposals to improve winter habitat quality. Cite scientific evidence to demonstrate a wildlife need for timber harvest on winter range or delete from the Plan.

766

RESPONSE: The Targhee cooperated with State Fish and Game agencies to identify important elk and deer wintering areas on the Targhee. A winter range management prescription was developed to provide habitat conditions needed by wintering big game animals. In these areas harvesting will only be allowed when site-specific analysis indicates winter habitat conditions will be maintained or improved. Any timber harvest occurring in elk and deer winter range prescription is not counted in the proposed 8.0 MMBF/year. Timber harvesting can improve winter range, especially when trees have shaded out important forage plants and reduced the amount of winter forage. MO

Change Standards

COMMENTS: Change last item under standards and guidelines for the management prescription of Timber Management (Big Game Security Emphasis) to read as follows: "No timber harvest activities or similar type of activity can occur within a security area during the time it is designated a security area. Security area designations will be at least ten years in duration. New security areas will be designated and protected at least 19 months prior to entry into a currently designated security area."

643, 1401

RESPONSE: From 1980 to 1992, the Targhee conducted an elk monitoring project associated with several timber sales on the Dubois Ranger District. Results indicated elk use declined (but was not eliminated) in timber sale areas during years of road building and harvesting, but increased again after management activities were completed. Elk and deer will use clearcuts, shelterwood, and seed tree cuts. The Targhee determined elk security was an important issue. Habitat features that affect elk security are motorized access density, hunter density, and hiding cover. Hunter density is regulated by the State Fish and Game departments. Motorized access and hiding cover are regulated by the Forest Service. Management Prescription 5.4 establishes direction for low motorized access and maintenance of appropriate levels of hiding cover over time. The prescription provides direction for maintaining security areas adjacent to timber harvesting activity which eliminates the need to designate these areas for 10 years. MO

TIMBER - BIG GAME

Prohibit Harvest Activities In Elk Calving And Summer Habitat

COMMENTS: Prohibit logging in elk calving and big game summer habitat.

278

RESPONSE: Elk calving and summer use occurs where timber harvesting has and does occur. The Targhee conducted long-term monitoring on elk use in timber sale areas on the Dubois Ranger District.

Harvested areas are used by elk during calving periods and throughout the summer. Study results indicated elk use declined, but was not eliminated, during active management years of the logging, and returned to pre-logging levels after the harvest activities. Elk use occurs in all stages of forest succession, from grass/forb and seedling stage to old growth stages.

The Revised Plan allows for timber harvesting, but takes into account important habitat considerations for elk, including motorized access density and hiding cover. The Revised Plan reduces motorized access density from existing levels and allows hiding cover to increase as trees in previously logged areas to grow. Management Prescriptions 5.1.4 and 5.4 allow timber harvesting, but require that only 20% of the forested acres to be in a created opening at any point in time. Approximately 80% of forested acres in these management prescriptions will provide adequate cover for elk at any point in time. The management prescriptions require large blocks of cover (greater than 250 acres in size). MO/LB

Include Appropriate Mitigation Measures

COMMENTS: Consider appropriate mitigation measures to maintain elk habitat effectiveness and require Fish and Game to manage elk populations.

393

RESPONSE: The Revised Plan reduces motorized access (reduces open roads and trails and eliminates summer cross-country motorized travel) on about 94% of the Targhee and reduces timber harvesting. These actions should improve elk habitat effectiveness in most areas. State Fish and Game departments are responsible for managing elk populations. MO

TIMBER - DESIRED FUTURE CONDITION

Alternative 3M

COMMENTS: Ensure Alternative 3M meets recommendations on Page 3 (DEIS) and identify the most important priority...wildlife, recreation, timber harvest, etc. (CROSS REFERENCE: Alternatives)

625

Explain why road closures and other items cannot meet DFC while still cutting timber and providing jobs.

625

RESPONSE: All alternatives address the Purpose and Need and Desired Future Conditions including sustainability. The Revised Plan responds to a variety of issues and concerns. The expected outcome of plan implementation through site-specific projects, is to move forest resources toward a desired condition

TIMBER - DESIRED FUTURE CONDITION

described in the Revised Plan. In response to wildlife issues and concerns, the Targhee proposes to close more roads to motorized access and to close more areas to cross-country motorized use. All alternatives except Alternative 6 propose timber harvest.

Resource priorities were replaced by Desired Future Condition statements. Information on sustainability is presented in the EIS in each resource section and under the topic of Ecosystem Management. AS

Timber Harvest

COMMENTS: Be more specific about how logging will be used to achieve DFC, e.g., in overstocked Douglas-fir, smaller trees will be harvested to create open, park-like structure of widely spaced old trees thought to exist prior to settlement.

489

RESPONSE: The DFC for Ecosystem Processes and Patterns states: "A mosaic of age classes and types of vegetation are sustained through time and exist across the landscape." A Table in Chapter III of the Revised Plan displays tentatively suitable acres by species and age group. The table indicates that 94% of the Douglas-fir group is in the mature category. Specific silvicultural needs will be determined through site-specific analysis and will reflect direction provided by management prescription. DFC statements are broad and long-term in nature and may not be realized during a 10-15 year planning cycle. The Targhee will use properly functioning condition assessments to maintain healthy ecosystems. (Refer to new standards and guidelines for Properly Functioning Condition).

The "vegetation" section under biological elements was expanded to provide direction for using timber harvest to achieve desired conditions in forest ecosystems and to meet a broad range of ecological and multiple-use objectives. LB/RR

Roadless Areas

COMMENTS: Eliminate Timber Prescription 5.1.4 (b) and 5.3.5 from roadless areas. Timber harvest eliminates or reduces future wilderness preservation options.

695

RESPONSE: The decision to allow timber management activity in roadless areas is a specific element of the Revised Plan to meet multiple-use objectives. Less than 0.2 of one percent of total roadless acres would be impacted by the Revised Plan, and the DFC would be met. AS

TIMBER - ECONOMICS

Needs Additional Analysis/Changes

COMMENTS: Correlate the price of lumber and the proposed ASQ or lack of wood coming off the Forest.

602

TIMBER - ECONOMICS

RESPONSE: No correlation is made between the price of lumber bought and sold in a national marketplace with the ASQ of the Targhee. The volume of timber provided by the Targhee is insignificant relative to the price of lumber in a national market. DP

COMMENTS: Discuss more about new building innovations in relationship to supply and demand for wood products (for example, vinyl siding, steel studs, joists) where the source is to sustain lodgepole pine wood products (most can not be made from fir or aspen); and what the production of "services" has to do with the production of natural resources.

613, 697, 1339

RESPONSE: These factors, (among others) are considered by prospective bidders competing for Targhee timber. The marketplace constantly develops new markets, competing materials, and applications for traditional products like lumber. Expanded discussion of the marketplace are unwarranted in an EIS for an individual National Forest Plan. DP

COMMENTS: Reduce unnecessarily strict constraints on FORPLAN model.

413

RESPONSE: In response to this and other comments received on the question of timber harvest, the Targhee re-examined constraints on scheduled timber harvest. Initial Forplan calculations incorrectly constrained ASQ, for goshawk considerations. The constraint was calculated only on suitable acres and should have been calculated on total forested acres, regardless of suitability. As a result of correctly applying the goshawk constraint to total forested acres, the Revised Plan shows an increase in ASQ from 3.7 MMBF/year to 8.0 MMBF/year. DP/LW

COMMENTS: Table IV-13 skews the PNV analysis in Alternative 6 toward undeveloped recreation which you admit is hard to predict.

393

RESPONSE: Table IV-13 in the DEIS showed identical recreation figures for all alternatives. DP

COMMENTS: Ensure that timber pays its way; don't operate at a fiscal loss, requiring public subsidy. Address the issue of below-cost timber sales, especially as it relates to salvage logging, since Rocky Mountain salvage logging is clearly not beneficial to the U.S. taxpayer.

F-G-P(1), 219, 279, 320, 336, 340

RESPONSE: The Forest Service maintains a tracking system for reporting costs, benefits, receipts and other information pertinent to the timber sale program on this and other forests. The costs associated with the timber program have exceeded receipts and benefits. The Targhee does not expect any of the alternatives will move the timber program into the black. This is largely the result of the costs associated with building roads and reforestation, coupled with comparatively low stumpage values and volumes per acre. The Revised Plan emphasizes reliance on natural reforestation and

TIMBER - ECONOMICS

silvicultural systems that promote natural reforestation and greater attention to cost effective road design.

The costs and benefits associated with the timber program, and other Forest programs, were considered in developing the Revised Plan. They were, not however, the primary concern. Rather, the Forest seeks to achieve the best balance of goods and services for people while ensuring the protection and sustainability of the resources. DP

COMMENTS: Evaluate a new alternative that sustains current timber industry and personal use needs and shows the significant economic impacts that have occurred as a result of a reduced ASQ in the 1985 plan.

394

RESPONSE: The Targhee recalculated the timber harvest model so it met as many constraints as possible on lands which were not scheduled for timber harvest which caused substantial increases in the timber (ASQ) in every alternative with an ASQ. ASQ volumes displayed in some alternatives generally approximate harvest levels from 1992-1995.

During the time the 1985 Forest Plan has been in effect, the level of timber harvests has declined sharply. The reduction in ASQ was not a result of Plan Revision and is not included in this analysis. DP

COMMENTS: There is only a difference of 15 jobs, or 1%, projected between Alternative 2 and Alternative 3M. This difference is too small to be a significant factor in supporting a higher ASQ.

667

RESPONSE: Even though the difference is small, disclosure is required by law. DP

Include Non-consumptive Uses in Timber Economics Rewrite

COMMENTS: Re-write economic section and show benefits of non-consumptive uses to local economy.

643

RESPONSE: The sections of the EIS dealing with economics were rewritten. The benefits of nonconsumptive uses to the local economy are described there. DP

COMMENTS: Support or qualify the Page S-7 statement that "a greater harvest of timber aids the local economy . . ." since this applies to a consumptive industry and not to local recreational business, much less regional tourism incomes.

727

RESPONSE: Within the context of the Revised Plan, the statement is correct. Predicted timber harvests are not expected to adversely affect recreation or other local or regional businesses or personal income. DP

TIMBER - ECONOMICS

COMMENTS: Reconsider economic time frames since Dr. Tom Powers, University of Montana, maintains that long-term economic impact of resource exploritive industries is likely to be negative, even for timber dependent communities.

727

RESPONSE: The long-term economic impacts of resource extractive industries may be negative or positive even for timber-dependent communities. Timber harvests proposed in the Revised Plan are not estimated to have long-term negative economic impacts. Growth in recreational activities and recreational residences has occurred in the vicinity of past timber harvests. DP

COMMENTS: Manage forest resources better even at the economic expense of logging. If not, we lose more than economic opportunity.

168

RESPONSE: The Revised Plan emphasizes lower timber harvests and more protection for basic resources such as soil and water. JR

COMMENTS: Recreation will bring more prosperity to the area than will logging.

F-G-P(1), 187, 190, 208

RESPONSE: Recreation and logging are viewed as compatible uses in the Revised Plan. The Targhee does not exclude one to achieve the other. The Revised Plan predicts that the overall level of prosperity will be greater with both uses than if either one were excluded. DP

COMMENTS: More fully discuss PILT payments to counties and the economic consequences of a reduced harvest level, but an increase in non-consumptive uses. Write-up perpetuates common misconceptions and is biased against non-extractive uses.

643

RESPONSE: The Forest updated and expanded the discussion of Payments in Lieu of Taxes in the FEIS in response to this and similar comments. DP

Include Non-consumptive Uses in Timber Economics Rewrite

COMMENTS: Include economic facts about low paying recreation seasonal jobs that can not replace 187 timber jobs and the more predictable levels of employee compensation in timber and livestock industries.

228, 346

RESPONSE: The FEIS presents information on both job numbers and employee compensation to address this concern. Overall levels of recreation are expected to be about the same in each alternative. The Targhee contains sufficient recreation capacity to handle substantial increases in almost all forms of recreation proposed in each alternative. Timber and livestock employment is expected to vary by alternative, because the amounts of timber harvested and the level of livestock grazing varies by alternative. Employee compensation in timber and livestock is not necessarily more predictable than

TIMBER - ECONOMICS

that associated with recreation. There is uncertainty in every sector of the economy. DP

Discuss International Timber Company Impacts on Local/Regional Economy

COMMENTS: Discuss the role of multi-international corporations in modern timber economy and make distinctions between the needs/desires of rural communities and the goals of major corporations and associations. Elaborate on the difficulty of supporting communities by profit requirements of corporate logging enterprises with headquarters in other regions. Include an analysis of the percent of revenue generated from timber sales that remain within the local area versus the percent that leaves the region in the form of profits.

1364

RESPONSE: This is beyond the scope of a Forest Plan. Economic effects are displayed on a local economic level by alternative. JR

General Economic Issues

COMMENTS: Provide small timber sales, post and pole, and all types of salvage sales to keep qualified local loggers in the area, for small business and local use only.

64, 1240, 1313, 1330

RESPONSE: Small timber sales are provided under the Revised Plan. DP

TIMBER - GENERAL

Manage for More Than Timber Harvests

COMMENTS: Manage for the benefit of all forest values including wildlife, fisheries, and recreation because these are important values and because managers are obligated to protect the resources.

278, 1396

RESPONSE: The Revised Plan provides balanced management direction for the benefit of all forest values. The management prescriptions apply different management intensities to various resources based on suitability and capability. LB

COMMENTS: Educate loggers and farmers on the importance of sustaining diversity because indiscriminate logging driven by economic need is devastating our forests. Manage by science, not local cultural preferences.

179, 293, 507

RESPONSE: The science of adaptive management is a focal point of the Revised Plan. Through time, the Targhee will learn more about the resources and the science that results in good stewardship. Logging and ranching operations have changed over time based on needs of the land and consumers. The Revised Plan reflects changed attitudes and increased knowledge but should not be viewed as the ultimate answer. Science continues to provide information

TIMBER - GENERAL

critical to good decision-making. Fundamental EM principles incorporate "best science". LB/RR

COMMENTS: Oppose all logging, grazing and mining because of impacts on all other resources especially wilderness.

No letter #

RESPONSE: The Multiple-Use, Sustained-Yield Act requires the Targhee to manage National Forest System lands for a variety of uses within the capability and sustainability of the land. Timber harvests are prohibited in wilderness areas. Mining and grazing are usually permitted to some extent and are subject to specific laws and regulations regarding wilderness areas. LB

COMMENTS: Restore fish and wildlife habitat degraded by past logging and roading.

F-G-1(475)

RESPONSE: The Targhee addresses habitat restoration through Watershed Needs Inventory. The inventory identifies problems and prescribes remedial measures. The Revised Plan proposes to reduce miles of open roads forestwide. No new roads are proposed for any new created opening in decades 1-3 in watersheds that were affected by lodgepole salvage harvesting activities. RSM/MO

COMMENTS: Transition to alternative resources and recycling because the loss of trees is a loss of recyclable minerals and nutrients and a loss of microhabitat.

No Letter #, 1314

RESPONSE: The Targhee supports recycling, both locally and nationally. Standards and guidelines in the Revised Plan address the need to retain an adequate amount of down woody debris to ensure an ample and continuous supply of nutrients, minerals and microhabitat to maintain forest productivity. LB

COMMENTS: Calculate net cooling effect on northern hemisphere as a consequence of proposed plan. Timber harvest will increase global warming.

275

RESPONSE: A calculation of this magnitude is beyond the scope of this analysis. Little change in effect on global warming is anticipated as a result of implementing any of the seven alternatives. Timber harvest will only affect 1.56% of total Forest acres during the decade. LB

COMMENTS: Reconsider an aggressive management approach that promotes harvests, salvage harvest, thinning, prescribed fire without considering wildlife or the beneficial aspect of fire renewal. Reconsider the assumption that managed lands are more healthy than unmanaged.

695, 1365

RESPONSE: The Revised Plan presents a balanced program of management activities that should result in healthy ecosystems. None of the management prescriptions emphasize timber production over other resources. Although some

TIMBER - GENERAL

prescriptions permit timber harvest, generally this use is subordinate within the prescription. Some prescriptions limit timber harvest in support of wildlife needs. If managed properly, public lands can remain healthy and resilient to natural and human-caused disturbances. LB

COMMENTS: Explain on Page S-4 how the forest will manage conflicts between resources when forest health is not an issue. Consider something like, "Forest production within forest health limits is managed to minimize conflicts with non-consumptive uses and is curtailed (with due regard to economic considerations) if conflicts cannot otherwise be minimized."

341

RESPONSE: Management prescriptions are designed to resolve conflict between uses. Goals, objectives, standards and guidelines are developed for resources and reflect resource importance in achieving prescription goals. LB

Manage for Timber Harvests

COMMENTS: Manage logging. Further reduction of logging & grazing do not produce long-term forest health. "No use" does not translate to "wise use".

660, 1448b

RESPONSE: The Revised Plan permits timber harvests in areas that are suitable and capable of sustaining this type of management activity. Other direction provided in standards, guidelines and timber contract provisions ensure timber harvest is completed in a managed and environmentally sound manner. RR

COMMENTS: Explain why the Forest constrained timber harvest by timber compartment and watershed rather than ecological subsection.

228

RESPONSE: Harvest is constrained by watershed because of potential cumulative effects from harvest in a given watershed. Watersheds were the land unit used to assess cumulative effects on hydrology. RSM

COMMENTS: Clarify the amount of timber and wilderness on the Forest and how much is in ASQ.

314

RESPONSE: Chapter III of the FEIS describes the current acres designated as wilderness. A Table in Chapter III of the FEIS displays the total forested suitable acres. The ASQ is 8.0 MMBF/year. LB

TIMBER - GOALS AND OBJECTIVES

Goals

COMMENTS: Develop goals that are realistic and consider Greater Yellowstone ecosystem, social and economic values of local communities and the unique ecosystem of the Targhee National Forest.

393

TIMBER - GOALS AND OBJECTIVES

RESPONSE: The Forest goals are realistic, based on resource needs, and recognize the Greater Yellowstone ecosystem. Social and economic values of local communities were considered and disclosed in the FEIS, Chapter III. LB

COMMENTS: Consider big game security habitat in timber management goals. (CROSS REFERENCE: Wildlife, Elk; Timber)

389

RESPONSE: The management prescriptions are a composite of the specific multiple-use direction applicable to all or part of a management area. While there is one prescription where timber management is the primary purpose, past harvesting activities limit extensive management action. All of the prescriptions concentrate on resource objectives other than timber, although varying degrees of timber activities are allowed in each.

The Revised Plan allows for future timber harvesting, but takes into account important habitat considerations for elk including motorized access density and hiding cover. The Revised Plan reduces motorized access density from existing levels and allows hiding cover to increase as trees on past logged areas grow. Management Prescriptions 5.1.4 and 5.4 allow timber harvesting, but limits to 20% the forested acres that can be in a created opening at any point in time. Therefore, 80% of the forested acres in these management prescriptions will provide cover for big game at any point in time. These management prescriptions also require management for large blocks of cover (greater than 250 acres in size). LB/MO

Objectives

COMMENTS: Remove Item #2 in the Precommercial Thinning section. Future resource products, other than saw timber, should be produced naturally.

283

RESPONSE: Post, pole, firewood, ornamentals, and such are products that develop naturally and are not usually managed. This objective provides for specific areas with ecosystem, environmental, or silvicultural needs. As a result products that may not develop naturally could become available. LB

COMMENTS: Add the following as Objective 5 in Chapter III on Page 123 and Objective 7 on Page 131: "Maintain or enhance inherent habitat values associated with fish, wildlife and vegetation of the area." This will assist in obtaining goals and DFC.

1446

RESPONSE: Forestwide standards and guidelines, in the Revised Plan, Chapter III address this concern. LB

TIMBER - MISCELLANEOUS

Prohibit Timber Harvest In Special Management Areas

COMMENTS: Prohibit timber harvest in special management areas for the long-term maintenance of vegetation conditions. Maximum diversity will be

TIMBER - MISCELLANEOUS

achieved without timber harvest. (CROSS REFERENCE: EM, Diversity)
1369

RESPONSE: In general, timber harvest is excluded from special management areas except where needed to meet specific objectives. DP

COMMENTS: Prohibit timber harvest in eligible recreational river management areas. (CROSS REFERENCE: Wild and Scenic Rivers)
1273b

RESPONSE: According to the Wild, Scenic, Recreation Rivers Act, timber harvest is allowed in recreational river management areas as long as standard timber harvest practices are followed which protect the river environment and associated values (Forest Service Handbook). Resulting volume is not included in calculations of the ASQ. AS/JR

Define Harvest Criteria For Rangelands

COMMENTS: Define criteria for what timber harvests on rangeland constitute habitat or wildlife improvements and when optimum conditions occur that require timber harvest.
1369

RESPONSE: These areas are outside the suitable timber base and are limited to 2.0 MMBF, or less, per year, forestwide. Removal of timber products, for any reason, requires a site-specific analysis that identifies consequences and advantages of the project and conditions under which the project may proceed. Recent timber harvest projects demonstrate that timber can be harvested on the Targhee for the benefit of other resources. A recent example of conifer removal to improve resource conditions is the Environmental Assessment for Reestablishment of Aspen Plant Communities in the Camas Creek Watershed signed July 18, 1996. The Revised Plan provides direction for using timber harvest to achieve a wide variety of non-timber objectives, such as removing encroaching conifers from rangelands. WG/RR

COMMENTS: Address grazing impacts on Doug-fir having small stems in forests that are dominated by non-lethal underburning. This consideration may influence management prescription for restoration of Doug-fir where fire suppression has disrupted fire cycles.

Consider various studies by Rummell, Madany, West, Zimmerman, and Neuenaschwander that identified livestock grazing as the principle factor in causing forest overstocking, not the exclusion of fire. Other studies describe the complex interactions needed to provide increased tree density once grazing has been introduced. (CROSS REFERENCE: Range)
1273b, 1365

RESPONSE: Grazing does not mimic natural disturbances and may effect these disturbances, such as helping with the control of fire. Analysis of conifer expansion or encroachment is better evaluated at the landscape or project level. Numerous factors such as site conditions, fire suppression, or management emphasis may contribute to the expansion or encroachment of conifers within a given area. DM

TIMBER - MONITORING

Improve Monitoring for Timber

COMMENTS: Incorporate a two step monitoring process: Check suitability assessments and volume projections frequently for their accuracy through regular monitoring; and where monitoring shows that assessments and projections fail to reflect the true productivity and sustainability of the land base, adjust the ASQ promptly.

1365

RESPONSE: This process is already in place and described in 36CFR 219.10 (f) and 219.14 (a) and (c). LB

COMMENTS: More information is necessary for landscape level research and more comprehensive monitoring is needed for future forest planning.

1194

RESPONSE: Adaptive management is central to the Revised Plan. Management direction can be changed as new information from monitoring, evaluation, and research evolve through the amendment process under NFMA. LB

COMMENTS: Include monitoring of the effectiveness of vegetation treatment (unscheduled harvests) related to aspen regeneration or upland rangelands as a high priority. (CROSS REFERENCE: Timber, Aspen)

489, 643

RESPONSE: All vegetation treatments including unscheduled harvest are analyzed through site-specific NEPA analysis. Completed projects are routinely reviewed to determine if NEPA direction was followed as a standard operating procedure. These activities are monitored regardless of our monitoring plan. LB

COMMENTS: Reassign a higher priority of monitoring to the Biological Diversity Study and all timber items.

643

RESPONSE: The Forest reassessed priority ratings on a number of monitoring and evaluation items based on public input. Several items were assigned a higher priority in the Final Revised Plan. The suggestion to raise the priority of this (biodiversity) item was considered but not adopted. The Targhee in cooperation with academic and research communities, continues to search for appropriate monitoring to assess the impacts of management activities on biodiversity. EF

COMMENTS: Include monitoring to evaluate the effects of removing conifer from aspen and riparian areas and effects of creating more patches in late seral forests. If vegetation is removed, changes in plant species (type and number) used by wildlife and the effects of these altered vegetation types on other wildlife species should be monitored.

643, 690, 697

RESPONSE: These types of monitoring are more site-specific in nature. As projects are implemented, monitoring activities will be identified to assess

TIMBER - MONITORING

effectiveness. This type of monitoring is not displayed in the Forest-level monitoring program of the Revised Plan but will be included with site-specific project analysis. RR

TIMBER - OLD GROWTH

Note: The citation Characteristics of Old Growth Forests in the Intermountain Region, USDA Forest Service, 1993 is referred to as Characteristics of Old Growth Guide.

COMMENTS: Question breakdown of age classes; show ages for each class, e.g. pole, mature. Clarify whether the classification included structural classes and ages.

Clarify definition of late successional, display size and age class distribution of stands larger than pole; and to use the best available science when determining definitions, classes etc.

489, 643, 644, 690, 1276, 1368, 1369

RESPONSE: Refer to the Table in the Revised Plan for the revised definition of age classes. The Forest used the six successional stages found throughout silvicultural literature, most recently in Characteristics of Old Growth Guide. Late seral and climax species may be present in young stands. This can occur in any habitat type. DS

Age Class Delineation Portrays Inaccurate Existing Condition Data

COMMENTS: The portrayal of forest age classes in the DEIS creates the erroneous impression that much of the forest is in an advanced age class, and this bears little resemblance to the areas on the forest that have been harvested heavily in the past.

643, 695, 1277, 1368, 1369

RESPONSE: The Forest is classified 79.6% mature. Of the 1,237,281 forested acres approximately 120,000 acres have been harvested and regenerated. Corrections to old growth were made in the Revised Plan. The subsection descriptions discuss differences between various areas of the Forest. DS

COMMENTS: The forestwide percent of stands in the mature age class (78%) is too high for wanting age class diversity.

432

RESPONSE: Silviculture techniques and other practices such as prescribed fire will be used as tools to manage or manipulate vegetation for the purpose of achieving Forest Plan resource objectives. In some areas fire plans will be developed to facilitate ecological change. Even so, it will be a long-term effort to restore historical age class distribution in many areas. See Ecological Processes and Patterns, Chapter III, Revised Plan Revision. DS

Definition of Mature is Inadequate

COMMENTS: Define mature age class.

228

TIMBER - OLD GROWTH

RESPONSE: Plant communities evolve through a series of conditions, as they progress from seedlings to the final stage called climax. This gradual process is called succession. Mature stands have reached their height growth when their crowns start to widen, but other stand conditions do not meet all old growth characteristics. For example, climax (shade tolerant) tree species are evident in the understory, but large snags and down woody materials are uncommon. (Characteristics of Old Growth Guide). DS

COMMENTS: Clarify the relationship between mature age class and late successional (Page III-3 Plan).

643

RESPONSE: Mature stands have reached their height growth when their crowns start to widen, but other stand conditions do not meet all old growth characteristics. Climax (shade tolerant) trees species are evident in the understory, but large snags and down woody materials are uncommon. Vegetation classified as mature is found in the later successional stages of a plant community. As mature trees age or fall down in the late successional stage, the early phase of old growth begins. (Characteristics of Old Growth Guide). DS

COMMENTS: Consider using the following ages for your definition of mature: spruce/fir and mixed conifer at low elevations, 250-300; aspen on sites where aspen is a seral species, 100 years; lodgepole pine at lower elevations, 150; lodgepole pine at higher elevations, 250.

489

The Forest delineation of late successional is arbitrary and not supported by science.

489, 643, 766, 1249

Use the Despain study of Yellowstone National Park for historic age classes.

489, 643, 731, 1276

RESPONSE: The definition of old growth characteristics by forest type is found in Characteristics of Old Growth Guide. Refer to the Table in the Revised Plan for the definition of late successional stages by forest type. Clarifications were added to old growth in the Revised Plan. DS

COMMENTS: Old growth definition of 20 years for juniper and mountain mahogany seems too short. Sixty to 80 years would be reasonable.

489

RESPONSE: The Forest lacks adequate data about juniper and mountain mahogany. It was dropped from the Table that defines late successional stages. DS

COMMENTS: Develop an old growth analysis displaying acreages and distribution.

389, 643, 690, 1273b, 1365

RESPONSE: The Forest completed additional analysis between the Draft and Final Revised Plan. Changes were made to the Revised Plan. The Forest used the best data available from Forest Stand Inventory and Landsat data. A task

TIMBER - OLD GROWTH

group analyzed permanent forest inventory plots using the Regional definitions for old growth. DS

COMMENTS: Define old growth and relate its value to biodiversity.
1273b

RESPONSE: Refer to the Biodiversity Section of the forestwide standard and guidelines for a discussion and direction on biodiversity. Table AA summarizes the characteristics of old growth forests as described in Characteristics of Old Growth Guide. DS

COMMENTS: The Plan is lacking in its old growth management strategy because: no plan on how to replace old growth; no provision to increase old growth habitat; no areas are designated as potential old growth.
389, 643, 1194, 1401

RESPONSE: The Revised Plan was expanded and revised old growth information to address these concerns. Refer to "Ecological Processes and Patterns." DS

COMMENTS: Use R4 definition of old growth and conduct an analysis evaluating the effects of each alternative on old growth dependent species and values.
643, 1194, 1368, 1401

RESPONSE: Chapter III of the Revised Plan outlines the standards and guidelines for maintaining or enhancing a diverse array of habitats and relate to the natural occurrence and distribution of plant communities. Using permanent forest inventory plots and the Regional definitions for old growth, the Old Growth Task Group concluded the Forest contains approximately 8.7% of all acres in old growth acres. Specific standards and guidelines were added in the Revised Plan to ensure that old growth will be maintained. DS

COMMENTS: Clarify how the plan distinguishes between 6" lodgepole and old growth.
658

RESPONSE: Plant communities evolve through a series of conditions as they progress from bare ground to the final stage called climax. This gradual process is called succession. Stage 3 defines trees that are taller than 10 feet, but are usually less than 8 inches in diameter. Old growth, stages 6 and 7, is defined by the attributes outlined in Characteristics of Old Growth Guide. Refer to guidelines in the Biodiversity Section of the forestwide standards and guidelines in the Revised Plan. For lodgepole to be defined as old growth, according to the R4 Guidelines, a stand must have at least 25 trees/acre, be greater than 11 inches in diameter at breast height, and at least 140 years old. DS

COMMENTS: Studies dispute your claim that the lack of old growth is due to ecological conditions which do not favor very old trees.
643

RESPONSE: For the most part, lodgepole pine on the Targhee plays a dominant seral role, while in other areas of the Greater Yellowstone Ecosystem,

TIMBER - OLD GROWTH

lodgepole pine is in a persistent seral role and can even be a climax species. The dominant seral role of lodgepole pine shows it occupies a site for 100 to 200 years. In these stands, more shade tolerant species are present and will generally replace lodgepole pine in the absence of fire. In these circumstances, old growth characteristics are usually not found, because stand density is usually too high to allow large tree that meet the characteristics defined of old growth. (Characteristics of Old Growth Guide). DS

COMMENTS: Table on Page IV-1 for Alternative 2 appears incorrect as it implies 275,000 acres are scheduled, and if this is 1.7%, the total acres are much higher than the 1.8 million acres on the Forest.

1311

RESPONSE: Table IV-1 displays 275,000 acres of forested lands in Prescriptions 5.1 and 5.1.3 that have a potential to be harvested over time. However, not all stands are scheduled for harvest this decade. This portion of the table was misleading and was dropped from the Final EIS. LB

COMMENTS: Your current vegetation map should include a finer classification of age classes.

No Letter #

RESPONSE: The map displayed in the FEIS map package is a representation of the actual data. Because of scale limitations, it is impossible to display the data at a more refined resolution. The actual data was collected on areas as small as one acre and broken out by five age classes within eight species groups. LB

Old Growth Analysis

COMMENTS: Complete an old growth analysis that includes the following: Large snags used as an indicator of old growth; identify more thoroughly all old growth associated and dependent species; analyze connectivity of existing old growth stands; add standards and guidelines for forest carnivores; add a prescription for old growth; add standards and guidelines for maintenance of old growth; determine how many acres are necessary to maintain 100 acres of old growth; discuss impacts on TES Species when old growth is lost.

134, 389, 489, 643, 644, 1194, 1276, 1361, 1364, 1365, 1369, 1401

RESPONSE: The Forest completed additional analysis between the Draft and Final EISs. Changes were made to the Revised Plan to address these concerns. Table AA summarizes the characteristics of old growth, as described in Characteristics of Old Growth Guide. Refer to Final Environmental Impact Statement, Affected Environment, Chapter III, Fisheries - Scale: Hydrologic Unit, Wildlife Associated with Aquatic and Riparian Habitats, and Wildlife Associate with Terrestrial Habitats. DS

TIMBER - OLD GROWTH

Goshawk

(CROSS REFERENCE: Wildlife, Goshawk)

COMMENTS: Change the rotation ages in goshawk PFAs and foraging areas to: 240 for Douglas-fir, 140 for lodgepole.

643

RESPONSE: Goshawk Post Fledging Areas (PFAs) and foraging areas are large (\geq 400 acres for PFAs and \geq 5,400 acres for foraging areas) and most often contain a variety of forest types which may include aspen, lodgepole, Douglas-fir, mixed conifer, and spruce-fir. The rotation ages in the forestwide standards and guidelines are presented as ranges and cover all of the various forest types which may occur within PFAs and foraging areas. MO

COMMENTS: 40% mature is below what is needed to maintain goshawk breeding pairs. Change to 60-80%.

643, 1273b, 1370

RESPONSE: The Targhee analyzed 28 goshawk territories on the Forest. Monitoring records showed these territories successfully produced young. The range in mature to old growth forests in the PFAs was 28 to 100 percent. The range in mature to old growth forests in the foraging territories was 34 to 100 percent. Based on monitoring results, the forestwide guideline for maintaining \geq 40 percent mature to old growth forests in the PFAs and foraging areas is within the range.

The forestwide standards and guidelines limit the amount of acres in an area that can be in the nonstocked/seedling stage at any point in time. Standards and Guidelines limit how fast timber harvesting can occur. Reductions in mature and old growth harvest to maintain this \geq 40% level will take several decades to accomplish. MO

COMMENTS: Analyze the effect logging has on mature forests, foraging habitat and increases in fragmentation (Crocker Bedford).

1273b

RESPONSE: The DEIS and the FEIS display how mature forests will change over time as a result of proposed timber harvesting. On a forestwide basis, proposed timber harvesting during the first decade is proposed on 2.5 percent of the forested acres. The Revised Plan contains new standards and guidelines for old growth and late successional forests. The FEIS contains additional information about old growth and late successional forests on the Targhee. MO

Miscellaneous

COMMENTS: Songbirds, including those dependent on older forest should be addressed (CROSS REFERENCE: Wildlife, Specific Species).

1369

RESPONSE: No songbird species were selected as management indicator species for the Revised Plan. However, the Analysis of the Management Situation and

TIMBER - OLD GROWTH

Process Paper D provide the following: 1) a list of all bird species which may occur on or immediately adjacent to the Targhee; 2) a summary of the types of habitat these bird species may use; and 3) the effects that proposed timber harvesting may have on these species.

The Forest is currently cooperating in several studies to gather more information about songbirds on the Forest and how management activities may affect them. MO

Disturbance Inaccuracies

COMMENTS: No evidence to support EIS contention that overstory removal and regeneration in mature stands will reduce fire and insect and disease hazards. Rather, intensive logging in mature stands would more likely exacerbate fire and insect and pathogen outbreak intensities and durations.

The DEIS's flawed assumption belies the fact that "mature" forests are usually less susceptible to stand replacing fire than younger stands. Forest fragmentation and removal of older green trees, snags and down wood, can reduce the capacity for biological pest control.

1368

Explain why large fires, insects and disease are viewed as problem in "mature age class" when they are not going to be in the timber base.

695

RESPONSE: Fire has had a more profound effect on the character of the Forest than any other factor. As a result of fire, lodgepole pine often exists in extensive, pure stands. The effects of fire, fuel accumulation, stand development, and insects and diseases in lodgepole pine are all part of a set of complex biological and physical relationships. One example is the relationship between mountain pine beetle epidemics and fire. Mortality from beetle epidemics creates large jackstraw fuel loadings some decades after the epidemic (Ecology and Regeneration of Lodgepole Pine). These conditions are found in the late successions and old growth stages, not in younger stands.

Amman (1978) listed the following stand characteristics associated with epidemics: 1) trees more than 80 years old, 2) mean tree diameters over eight inches, 3) a substantial proportion of trees over 12 inches d.b.h. with phloem thickness of 0.1 inches or more, and 4) elevations where temperatures are optimum for brood development.

Bark beetles present the most serious insect threat to lodgepole pine (Amman 1975). The mountain pine beetle is by far the most significant insect pest of lodgepole pine (Amman 1978). The significance of the problem was thoroughly discussed in a symposium held in 1978 in Pullman, Washington (Berryman et al. 1978). The epidemics that periodically occur in many lodgepole stands seriously affect the sustained yield and regulation of managed stands (Wellner 1978). DS

COMMENTS: Would like to see the percent in mature/old growth reduced to 30% in lodgepole pine since mountain pine beetles generally prevent stands from reaching old growth. 40% in other types is okay.

413

RESPONSE: Your comment is acknowledged. Standards and guidelines in the Revised Plan provide that: "In each principal watershed (38 watersheds in

total), the combination of old growth and late forested successional stage acres will be $\geq 20\%$ of the forested acres." DS

COMMENTS: DEIS (Page III-6) portrays an overriding concern that mature age classes are more susceptible to stand-replacing fires. If the Targhee is to move toward ecosystem management that more closely emulates natural processes, managing for a larger portion of mature forests would be appropriate.

489

RESPONSE: Biodiversity is maintained or enhanced by a diverse array of habitats that relate to the natural occurrence and distribution of plant communities. Objectives outlined under Vegetation, Chapter III, Revised Plan state: By 2007, "identify Properly Functioning Condition (PFC) and systems at risk for forested landscapes." DS

COMMENTS: In subsection descriptions, the Plan's definition of old growth concludes these types of mature stands are more susceptible to large fires and insects and disease. Silvicultural systems that promote mature and old growth stands increase the risk of insect and disease epidemics. Characteristics of large diameter, low vigor attract insects and disease. To reduce susceptibility to insects and disease is to convert to a younger age class, which thereby allows for more harvest of old growth.

695

RESPONSE: Fire has had a more profound effect on the character of the Forest than any other factor. As a result of fire, lodgepole pine often exists in extensive, pure stands. The effects of fire, fuel accumulation, stand development, and insects and diseases in lodgepole pine are all part of a set of complex biological and physical relationships. An example of these relationships is the one between mountain pine beetle epidemics and fire. Mortality from beetle epidemics creates large jackstraw fuel loadings some decades after the epidemic (Ecology and Regeneration of Lodgepole Pine). The Revised Plan allows fire to play more of a natural role than in the past. Prescribed fire plans will include ecosystem management objectives. DS

Old Growth Should be Protected and Preserved

COMMENTS: Older forests are a rare ecosystem component. Conservation efforts should focus on retaining as much of it as possible.

643

RESPONSE: ~~Biodiversity~~ is maintained or enhanced by managing for a "diverse" array of habitats related to the natural occurrence and distribution of plant communities. The Forest will maintain $\geq 20\%$ of the forested acres in a late successional/old growth stage in each biological subsection. The Revised Plan was changed to reflect this direction. DS

COMMENTS: Preserve all old growth in a national Old Growth Preservation System.

276

TIMBER - OLD GROWTH

RESPONSE: This consideration is outside the scope of this analysis and is not within the purview of the Forest Service. LB

COMMENTS: Late successional old growth stands are critical to maintaining ecosystem health in the interior Columbia River Basin. Old growth for all forest types is, on a regional scale, far below historic levels.

643

Need to quit logging and roading the remaining old growth because they are less plentiful and are rich in biodiversity.

695

RESPONSE: The Final Revised Plan includes new standards and guidelines to maintain old growth and late successional stands. Based on the Targhee's analysis, the Forest has more late successional stands than historically. The Targhee Landscape I Team's detailed study on the 76,000 acre Camas Creek watershed in the Centennial Mountains and Montana State University's study of historic vegetation patterns on the upper Henry's Fork watershed show a large increase in mature acres from 1870 to present. DS

COMMENTS: Given the length of time for regeneration of Douglas-fir, it should be considered a non-renewable resource which should be managed for its old growth value.

1276

RESPONSE: Regenerating Douglas-fir naturally is usually more difficult than other species, such as lodgepole pine. By using proper "leave tree" spacing, shading, scarification and timing, regeneration can be successful. Artificial regeneration, such as bare root planting, has also been successful on the Forest. DS

COMMENTS: We support the halting of all logging in remaining old growth areas on the forest.

690

I am against the harvesting of old growth.

1371

RESPONSE: Permanent regional plots show that approximately 8.7 percent of the Forest meets the old growth definition. In each principal watershed, the combination of old growth and late successional acres will be $\geq 20\%$ of the forested acres. Where it exists, at least half of this (10% of the forested acres) should meet old growth characteristics. Biodiversity is maintained or enhanced by managing for a diverse array of habitat that relates to the natural occurrence and distribution of plant communities. Refer to goals under Vegetation in the Revised Plan (Chapter III-Part 1). DS

Old Growth Should Be Harvested

COMMENTS: Continue to convert mature age classes to younger classes on a planned, sustainable basis; concerned that 20 MMBF per year will not do that.

TIMBER - OLD GROWTH

A change in mature stands ranging from 0 to 3.4% for the decade indicates you are not harvesting enough for forest health reasons. The Forest should be closer to 8-10% for the decade.

413

I recommend 15-20% of forested acres remain as old growth.

719

Prevent old growth from just falling over and going to waste or becoming fire fodder.

661

RESPONSE: Permanent regional plots show that approximately 8.7 percent of the Forest meets the old growth definition. In each principal watershed, the combination of old growth and late successional acres will be $\geq 20\%$ of the forested acres. Where it exists, at least half of this (10% of the forested acres) should meet old growth characteristics. Biodiversity is maintained or enhanced by managing for "diverse" array of habitat related to the natural occurrence and distribution of plant communities. Direction in Chapter III, Revised Plan states, "Regenerate and maintain plant association within the range of natural variability for each ecological subsection and watershed." More harvest is predicted to occur in future decades as watersheds recover. DS

COMMENTS: Maintaining at least 78% of the Forest in a "mature" age class in all alternatives indicates you are perpetuating the factors that almost guarantee another major catastrophe that will provide a more balanced age class distribution.

166

RESPONSE: The ASQ was increased in the Revised Plan for the first decade. A Properly Functioning Condition (PFC) assessment will evaluate long-term management options for lodgepole pine types. More harvest is predicted to occur in future decades as watersheds recover. Standards and guidelines, restrictions and mitigations contained in the Plan, are designed to achieve balance between needs and uses of the Forest. DS

COMMENTS: Harvest in spruce-fir or Douglas-fir types should only occur when there is evidence the site will naturally regenerate within the designated 5-year period.

389

RESPONSE: National Forest Management Act requires all stands harvested using regeneration methods will be regenerated within five years. The Revised Plan complies with this Act. LB

COMMENTS: Remove mature trees to keep forest healthy. Young timber is great cover for wildlife and will also help the economy.

1390

RESPONSE: Harvesting mature stands for forest health reasons is permitted in the Revised Plan. Harvest is constrained to meet objectives for effective cover for wildlife. DS

TIMBER - OLD GROWTH

Site-Specific

COMMENTS: Some stands on the Targhee National Forest would conform to the Region's old growth definitions, but the Targhee failed to delineate these. They are: South of the Snake River in the Caribou subsection; Rainey Creek in the Palisades; in and throughout the Palisades drainage; in the Big Hole Mountains; in the unharvested areas of the Centennial Mountains.

643

RESPONSE: A task group analyzed permanent forest inventory plots using the Regional definitions for old growth. Results indicate that 8.7% of the plots met all old growth characteristics. See Old Growth and Late Successional Forests, Chapter III, Revised Plan. DS

COMMENTS: Forest's numbers are grossly inaccurate, specifically in the subsection descriptions for Island Park and the Madison Plateau that claim more than 61% and 63% respectively are in a "mature or older age class". Yet when that description, along with map 23 are compared to the landsat photos of the same areas, widespread clearcutting has occurred over the past 30 years in these same areas.

643

RESPONSE: The Targhee's analysis shows the existing percent of old growth, late successional, and mature timber are as follows: Island Park, 60.7%, and Madison Plateau, 63.3%. DS

COMMENTS: The DEIS states there is a lack of age classes in subsections such as the Centennial Mountains and Big Hole Mountains due to an overabundance of "mature" forest habitat. Apparently the inventory data used as a basis for this claim normally only counts "mature" size trees for most plots. This means that if all trees sizes were tallied, the Forest and public would see that these supposed "mature" stands contain a large age class diversity within them. The supposed lack of age class diversity is due to biased sampling and data analysis more than an actual lack of diversity on-the-ground. 643

RESPONSE: Stand Exam, Landsat, and Permanent Forest Inventory plots were used to determine age classes on the Targhee. All three methods take into account all age classes. Stand Exam and the Permanent Forest Inventory plots use both variable and fixed plots. DS

TIMBER - PRESCRIPTIONS

Change Timber Harvest Prescriptions

COMMENTS: Address EM timber harvest and road building in Prescription 2.6.1 (a). This area serves as a critical link for wildlife even though lands are not included in the suitable base.

643

RESPONSE: EM timber harvest and road building can occur in Prescription 2.6.1 (a) to maintain and improve grizzly habitat. The type and level of harvest is subject to NEPA analysis and must follow all standards, guidelines, and

TIMBER - PRESCRIPTIONS

management prescriptions. While harvest projects could occur in this prescription the Revised Plan does not require harvest to take place. The EM harvest volume of 2.0 MMBF/year is not included in the ASQ. LB

COMMENTS: Change the Big Game Security Emphasis Prescription: "No timber harvesting activity or similar type of activity can occur within the security area during the time it is designated as a security area. Security area designations will be at least ten years in duration. New security areas will be designated and protected at least 18 months prior to entry into a currently designated security area." (CROSS REFERENCE: Wildlife)
643, 1194

RESPONSE: From 1980 to 1992, the Targhee conducted an elk monitoring project associated with several timber sales on the Dubois Ranger District. Results of this monitoring illustrated that elk use declined (but was not eliminated) in timber sale areas during years of road building and harvesting, but increased again after management activity was completed. Elk and deer will use clearcuts, shelterwood, and seed tree cuts. The Targhee determined elk security was an important issue. Habitat features that affect security are motorized access density, hunter density, and hiding cover. Hunter density is regulated by the State Fish and Game departments. Motorized access and hiding cover are regulated by the Forest Service. Management Prescription 5.4 establishes direction for low motorized access and maintenance of appropriate levels of hiding cover over time. The prescription provides direction for maintaining security areas adjacent to timber harvesting activity, which eliminates the need to designate areas for at least 10 years. MO

COMMENTS: Consider land with 60% cover and over for possible harvest. 693

RESPONSE: The Revised Plan does not restrict harvest of forested vegetation based on percent cover within the stand. Harvest is based on silvicultural need and other management objectives. LB

COMMENTS: Revise Management Prescription 5.1.3 (a-b) Timber Management as submitted by the Greater Yellowstone Coalition.
643

RESPONSE: The Forest reviewed changes submitted by Greater Yellowstone Coalition and decided to retain Prescription 5.1.3 (a-b). The game retrieval provision was dropped. LB

COMMENTS: Add the two areas in the Caribou to the suitable base. One has 67% of its slopes under 40% and the other has 75% of its slopes under 40%.
693, 767

RESPONSE: The DEIS, Alternative 3M, showed the Black Mountain area in the 5.4 (c) Prescription - a timber based prescription. However, in Alternative 2, this area was in Prescription 3.2 (f) Non-Timber Base. The Black Mountain area appears suitable for harvest. The FEIS shows it suitable for harvest in Alternatives 1 through 3, but not in Alternatives 3M through 6. The Fall Creek area does not contain adequate contiguous stands of timber to justify placing it in an ASQ prescription.

TIMBER - PRESCRIPTIONS

Road development and timber harvest would cause significant adverse effects on wildlife winter range and unstable soils in these areas. The anticipated consequences of intensive management are contrary to the Desired Future Conditions and Need For Change outlined in the Purpose and Need section of the DEIS, i.e., "need to balance timber harvest with wildlife needs," "need to meet goals for improving elk habitat," and "a system of trails and support facilities exist which are compatible with resource capabilities." AS

TIMBER - REGENERATION

Change Regeneration Discussion

COMMENTS: Discuss past regeneration successes and failures and make regeneration the #1 priority because of past unsustainable harvest.

625

Disclose how many of the clearcuts in lodgepole pine have regenerated satisfactorily and how many have not.

228, 1365

RESPONSE: Of approximately 120,000 acres harvested under the clearcut method, less than 7,700 acres have not successfully regenerated as of September 1996. This backlog will be completed by 1999. About 80% of the harvested acres regenerated naturally while approximately 20% were planted.
DS

COMMENTS: What is a "naturalized" species? Quantify "reasonable time" for specific project activity.

1446

RESPONSE: "Naturalized" species are introduced or alien (not native) species that have permanently established and are reproducing spontaneously (without human fostering). "Reasonable time" varies by specific project and the objectives the project is designed to meet. BS/RR

COMMENTS: On Page 84, change the word "consider" to "use" to be consistent with other areas.

1446

RESPONSE: The Targhee decided to retain the word "consider" in the context of a Guideline (G). The word "use" would change the Guideline to a standard.
(S). WG

COMMENTS: Improve suitability assessments to increase the success of regeneration and adjust ASQ to prevent wholesale over cutting based solely on optimistic estimates of the Forest's potential productivity.

1446

RESPONSE: Of approximately 120,000 acres harvested under the clearcut method, less than 7,700 acres have not successfully regenerated as of September 1996. This backlog will be completed by 1999. About 80% of the harvested acres regenerated naturally while approximately 20% were planted.

TIMBER - REGENERATION

Appropriate techniques for natural regeneration and/or planting of Douglas-fir are included in the Revised Plan. DS

COMMENTS: Regeneration should be initiated in cut-over areas.

405

RESPONSE: The National Forest Management Act at 219.27C3 requires that adequate restocking of harvested areas be accomplished within five years after final harvest. LB

Reconsider your Definition of "Forested"

COMMENTS: Reconsider the definition that any area where regeneration has reached a certain density of trees seven feet or greater is considered "forested." This creates the erroneous impression that most of the acres harvested over the last two decades have already succeeded to mature timber.

643

RESPONSE: "Forested" land by regulation is defined as "land with at least ten percent occupied by forest trees of any size, or formerly having had such tree cover and not currently developed for nonforest use." Using this definition, land could be bare and still be called "forested" if it has at least 10% cover.

The reference to tree height of seven feet or greater relates to wildlife hiding cover. It is also used to establish when "created openings" move out of a "created opening" status. The trees seven feet and greater responds to hiding cover or when a "created opening" moves out of a "created opening" status. LB

TIMBER - RIPARIAN/AQUATIC INFLUENCE ZONE

Prohibit Harvest in Riparian/AIZ Areas

COMMENTS: Prohibit timber harvest, including salvage logging in riparian and aquatic influence zones, including headwaters, and within 1/2 mile of any stream or riparian area. Riparian areas should be out of the suitable timber base. (CROSS REFERENCE: Riparian)

F-K(4), 58, 175, 212, 335, 611, 650, 697, 1239, 1273b, 1276

RESPONSE: Chapter III, Final Revised Plan removes the AIZ from the suitable timber base. They are not part of the ASQ.

Silvicultural prescriptions are only used in the AIZ where needed to meet AIZ Management Prescription Goals. Any silvicultural treatment proposal is evaluated on a site-specific level by an interdisciplinary team. Further, as a minimum, the Forest must meet the guidelines and rules found in the Idaho Forest Practices Act and Wyoming Silviculture Best Management Practices (specifically those dealing with stream protection). DM

COMMENTS: Logging will not benefit riparian areas, conifer encroachment areas or an aging forest. It does not make sense to provide buffer zones and then allow harvest in riparian areas. This is a warped view of ecosystem management and should be dropped. Cite research that supports the notion that

TIMBER - RIPARIAN/AQUATIC INFLUENCE ZONE

logging improves riparian conditions. Clarify how Objective 3 (fuelwood cutting) will restore ecological health and function.

23, 282, 643, 690, 695, 766, 1276

RESPONSE: Silvicultural prescriptions are used only in the AIZ where needed to meet AIZ Management Prescription Goals. Silvicultural prescriptions are only one option to attain AIZ goals. All silvicultural treatment proposals are evaluated on a site-specific level by an interdisciplinary team. One appropriate example where silvicultural methods could be used is in stands where overstories (e.g. conifers) might be inhibiting understory species that are important in providing channel stability (e.g. willows) and where prescribed fire might be risky. Another example might be in seral aspen stands that are experiencing conifer encroachment, and a disturbance is needed (e.g. prescribed fire or silvicultural techniques or both) to perpetuate a diverse, productive aspen community. Further, at a minimum, the Forest must meet the guidelines and rules found in the Idaho Forest Practices Act and Wyoming Silviculture Best Management Practices (specifically those dealing with stream protection).

Fuelwood gathering is another option that could be used to meet AIZ goals. Site-specific analysis would determine the appropriateness of this activity. Refer to the Timber section in the Aquatic Influence Zone Prescription. Fuelwood cutting is restricted to commercial use only. DM

COMMENTS: Include a statement that timber harvest is another impact to riparian areas and contributes to riparian areas not meeting DVC. 1446

RESPONSE: It is not the intent of the FEIS to identify all causes contributing to deteriorated riparian conditions. The Targhee agrees that inappropriate timber harvesting activities may cause deterioration in sensitive areas.

When properly conducted to improve or maintain healthy riparian ecosystems, timber harvest can be beneficial. WG/RR

COMMENTS: Detail your proposals for unscheduled timber harvest in AIZs as to exactly what circumstances would lead you to propose salvage, fuelwood cutting, or other manipulations. No habitat manipulations should be allowed unless you can realistically predict ramifications of these activities; it will be interesting to see whether felled trees are left or whether heavy equipment damages the area dragging logs away.

643

RESPONSE: The Revised Plan does not identify the site-specific location of unscheduled harvest; rather it sets the maximum amount of volume (20 MMBF/decade) that can be harvested under this activity. Site-specific analysis will determine if an unscheduled harvest is needed to meet an area's management objectives. Riparian resources are protected from adverse impacts in the AIZ through the application of standards and guidelines. RSM

COMMENTS: Prohibit timber harvest including road building clearcuts in important amphibian and spotted frog habitat which include along intermittent stream courses, vernal pools, areas adjacent to this habitat, and areas that have not had time for shrubs and trees to grow to provide shade for boreal

TIMBER - RIPARIAN/AQUATIC INFLUENCE ZONE

(western) toads. Harvest activities that alter hydrologic characteristics, temperature, moisture and connectivity of occupied habitat may have a large effect and may result in long-term losses. (CROSS REFERENCE: Wildlife, Frogs, Toads, Amphibians)

643, 1277

RESPONSE: State regulations in the Forest Practices Act require, "During and after forest practice operations, stream beds and streamside vegetation shall be protected to leave them in the most natural condition as possible to maintain water quality and aquatic habitat" (Rule 030.07). In streams used by fish or for domestic water supplies, 75 percent of the current shade must be left (Rule 030.07 (e)ii). No scheduled timber harvest may take place in Aquatic Influence Zones, and any timber removal must benefit riparian-dependent species, including amphibians. The potential effects are analyzed at the project level, and the activity is designed to avoid negative impacts to the local microclimate. RSM

Reconsider the Role of Timber in Riparian Habitat

COMMENTS: Reconsider your ecosystem view in regards to the artificial separation of forest dynamics from those of the aquatic/riparian system. For example, larger trees and snags are viewed as something to be eliminated from the system rather than a source of continual renewal of large debris for fish habitat and aquatic biota.

643

RESPONSE: Refer to Wildlife Standards and Guidelines in the Revised Plan, Chapter III; Description of the Aquatic Influence Zone; Objective 3, Insect and Disease section (where salvage is only permitted, "where needed to attain the Goals of this Management Prescription providing other Goals of this Management Prescription [2.8.3] are not adversely affected"); Wildlife Guideline; and new additional statements that were added, such as, "Riparian vegetation is maintained or restored to . . . provide an amount and distribution of large woody debris characteristic of natural aquatic and riparian ecosystems." RSM

COMMENTS: View trees and other upland vegetation in the riparian zone (or lack of willows) in the context of causative agents at a broader landscape level than assuming these changes are negative or an ecological concern.

643

RESPONSE: This concern is best handled within the framework of a site specific, project level or landscape level analysis where identifying ecological status of riparian areas and other issues are specifically addressed. WG

COMMENTS: Reconsider that the lack of understory in spruce forest riparian areas may be affected by livestock grazing and recreation, not just shading.

643

RESPONSE: This issue was reconsidered and the FEIS is modified in Chapter III. WG

TIMBER - RIPARIAN/AQUATIC INFLUENCE ZONE

COMMENTS: Clarify why 6.7 MMBF will have an adverse effect on world class fisheries when past harvest of 85 MMBF has not hurt these fisheries.

1267

RESPONSE: The EIS stated that some adverse effects to fisheries would result from implementing the various alternatives, specifically from timber harvest, road construction and use, livestock grazing, off-road vehicle use, camping along streams, and so forth. "Best management practices" are used during timber management activities to reduce the risk of adverse effects. Although some adverse effects may still occur, they are generally at an acceptable level.

Data shows that past timber harvest activities, including road construction and use, have had an adverse effect on fisheries habitat. Past timber harvest along streambanks removed much of the large wood needed for floodplain maintenance and fish habitat. Road construction and use increased sediment to streams, thereby reducing fish habitat quality in some areas. The Final Revised Plan includes several measures which will reduce the cumulative effects of all management activities on fisheries habitat. DD

Monitor Effects of Timber Harvest in Riparian Area

COMMENTS: Collect data on and monitor the effects of forest practices on aquatic, riparian zones.

282, 643

RESPONSE: Please refer to monitoring items: 1) Compliance with Policy of 15% Detrimental Soil Disturbance in Activity Areas (Chapter V); and 2) Monitoring of Application of Best Management Practices related to Maintaining and Improving Water Quality (Chapter V) in the Revised Plan. Each site-specific NEPA document contains a monitoring section. DM

COMMENTS: Tailor timber management to watershed needs through a comprehensive plan for watershed analysis, restoration, monitoring and adaptive management to inventory and develop site-specific plans for riparian areas.

643

RESPONSE: The Revised Plan meets these objectives. Watershed elements are used on several of the screens to determine the suitable timber base such as low productivity sites, irretrievable and or irreversible damage, and so forth). Refer to: 1) Standards and Guidelines for Watershed - General; 2) Objective 1 and 2 - Aquatic, Riparian Resources, and Watersheds; 3) Aquatic and Riparian Ecosystems Goals and Objectives within the Subsection Descriptions; 4) Objective 1 Prescription 2.8.3 (Aquatic Influence Zone); and 5) Chapter V (Monitoring and Evaluation). DM

Add Standards or Guidelines for Harvest Activities

COMMENTS: In order to protect amphibian habitat, create a guideline to avoid road construction or other management activities that will separate ponds, vernal pools, or marshes from permanent streams; create a guideline to maintain adequate slash piles; create a standard to prohibit harvest along intermittent stream courses and around vernal pools; create a standard to

TIMBER - RIPARIAN/AQUATIC INFLUENCE ZONE

prohibit harvest or clearcuts beside an area that has not had time for shrubs and trees to regrow and provide shade for amphibians.

643

RESPONSE: The Revised Plan and State regulations in Forest Practices Act provide this protection. "During and after forest practice operations, stream beds and streamside vegetation shall be protected to leave them in the most natural condition as possible to maintain water quality and aquatic habitat" (Rule 030.07). In those streams used by fish or for domestic water supplies, 75 percent of the current shade must be left over Class I streams. (Rule 030.07 (e)11). No scheduled timber harvest may occur in Aquatic Influence Zones, and any timber removal must benefit riparian-dependent species, including amphibians. The potential effects are analyzed at the project level, and the activity is designed to avoid negative impacts to the local microclimate. RSM

COMMENTS: Impose stricter standards for riparian protection when an area is to be logged or grazed.

204

RESPONSE: Utilization standards and other standards and guidelines in the Revised Plan will achieve desired results. The standards and guidelines will provide for a moderate rate of recovery of degraded riparian and aquatic systems with a moderately high level of fisheries habitat quality. WG

COMMENTS: Include a standard for a 100 foot vegetation buffer strip, managed for individual tree removal only (selective harvest) for lakes, streams, wetlands, and impoundments. A wider buffer is necessary for areas with steep slopes and/or erosive soils.

F-K(4), 389

Add a Standard that logging is prohibited or excluded from any area within 300 feet of a water source.

664

RESPONSE: The boundary widths used for the AIZ are sufficient to protect aquatic and riparian resources, and yet allow for management of these areas, too. The widths exceed the "minimum stream protection zones" defined in the Idaho Forest Practices Act regulations, and were designed using PACFISH and INFISH guidelines and site-specific knowledge of each ecological subsection. The Forest considered using a single boundary width, but a single width does not address the ecological and physical differences that exist across the Targhee. Adjusting boundary widths for channel stability and fish habitat, specifically, is not possible at this time as data is not available everywhere. The widths used should address these issues.

Regarding lakes and ponds: See Chapter III, Revised Plan. Lakes and ponds are included. RSM

COMMENTS: Include a standard to prohibit clearcuts of up to 50% of a timbered shoreline (lentic or lotic).

389

TIMBER - RIPARIAN/AQUATIC INFLUENCE ZONE

RESPONSE: This is not allowed under the Idaho Forest Practices Act regulations. RSM

COMMENTS: Expand and apply to the entire AIZ the standard that no burning will occur within the bankfull channel.

643

RESPONSE: The guidelines that limit mechanized treatment of wood residue, including burning, within the AIZ, should provide adequate stream protection. RSM

TIMBER - ROADLESS

Prohibit Harvest

COMMENTS: Prohibit logging, mining and ORV use in remaining roadless areas. 179, 204, 280

RESPONSE: Roadless area designation does not preclude management activities. Some activities can possibly be allowed without changing roadless characteristics (if impacts are minor). For example, aerial yarding or helicopter logging can be done without road construction or changing roadless characteristics. Mining may also take place but may be subject to additional restrictions. ORV use may be allowed, as well, without jeopardizing the quality of the roadless area. LB

COMMENTS: Remove roadless areas from the suitable timber base (eliminate Timber Prescription 5.1.4 (b) and 5.3.5) and do not include any timber management prescription because timber harvest eliminates or reduces future wilderness options.

643, 690, 695

RESPONSE: There is no policy or law prohibiting timber harvest in roadless areas. The Revised Plan provides direction to manage suitable timber lands in roadless areas. A complete analysis through NEPA (EIS) must be completed at the site-specific level before harvest is allowed. LB/JR

Allow Timber Harvest

COMMENTS: Eliminate the constraint that all roadless areas be in a non-interchangeable component (NIC) and change prescription in Alternative 2 to allow harvest as part of the suitable timber base without NIC classification.

413

Allow sustainable harvest in roadless areas with no NIC component unless it falls in Situation 1 Bear Habitat.

767

RESPONSE: The 1995 Draft RPA Assessment directs the Targhee to quantify the contribution of Rare II areas to the maximum amount of timber that can be sold in a decade. This amount is identified as a non-interchangeable component (NIC) of the ASQ in the Revised Plan to prevent over-harvesting in roaded

TIMBER - ROADLESS

areas, in the event roadless areas cannot be harvested. Site-specific analysis is necessary for entry into roadless areas. In the first round of the Forest Plan, much of the volume in roadless areas could not be harvested.
LB/JR

Better Describe Impact Between Alternatives

COMMENTS: Reduce linkage between the amount of wilderness and timber ASQ in all alternatives, i.e., more wilderness recommendation does not mean less ASQ and state that recommending more wilderness will have a minor effect on ASQ under any of the alternatives because only a small portion of tentatively suited timberlands fall within the roadless areas.

643, 695

RESPONSE: By definition Allowable Sale Quantity (ASQ) is: "The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan for a time period specified by the Plan"(FSH 1900). If additional wilderness recommendation removes acres of timber suitability from the base, ASQ will decrease. If additional wilderness recommendation comes from an area that was not considered suitable, then no change in ASQ is expected. LB

TIMBER - ROADS

Discourage New Roadbuilding

COMMENTS: Discourage excessive logging and prohibit new road building because roads serve only a minor percent of users; reduce roading and clearcuts.

178, 179, 293, 325, 399, 411

RESPONSE: Any logging in the future will utilize existing roads where possible, and will minimize any new road building. LB

COMMENTS: Reduce and close roads immediately after harvest to prevent massive erosion and landslides. Studies in California show that regardless of improved design and construction, roads are still a major reason for erosion and landslides.

1367

RESPONSE: Roads are closed after timber harvest is completed unless there are other resource needs, such as planting new trees. Each prescription includes road density standards. Timber activities must adhere to the standards and guidelines of the prescription. Regardless of location, erosion and landslides are caused by many factors such as climatic and environmental factors such as intensity, duration, and flashiness of storms; occurrence of rain-on-snow events; freeze-thaw cycles; and snow accumulation in clearcuts and other clearings. Most road-caused erosional problems are attributed to improper road and skid trail design, location and layout. LAB

TIMBER - ROADS

Close Roads after Harvest

COMMENTS: Close timber access roads after harvest to allow for new crop of trees to establish.

336

RESPONSE: All single-purpose roads only used for timber harvest are closed at the completion of the timber sale. Some roads may remain open short-term to accomplish other resource work, such as tree planting. Road density standards set for each prescription area will be maintained. LB/LAB

COMMENTS: Close roads where applicable to allow past logging excesses to heal.

F-B(4), 162, 278, 400, 1313

RESPONSE: Roads are evaluated on a site-specific basis to determine if they are no longer needed for Forest administration or if they are causing resource damage. Through site-specific analysis, a decision will be made on whether to keep the road open or close it. LB/LAB

Other Timber Road Concerns

COMMENTS: Control historic logging roads from becoming open access and make timber companies pay for them.

650

RESPONSE: Some road closure methods, such as tank trapping and water barring, have not been effective on the Forest. These methods are usually successful for the first four or five years after management activities are completed. At that point, soils settle, and forest users are generally able to access these roads. Timber companies are responsible for closing timber roads once operations are completed. Enforcement of road closures is a Forest responsibility. LB/LAB

COMMENTS: Ensure access to State Land Sections.

314

RESPONSE: Forest roads that access state and private lands, State or National Parks, or special facilities or features will remain open. LAB

TIMBER - SILVICULTURAL/HARVEST

General

COMMENTS: Reduce inflammatory language designed to foster public hysteria regarding perceived forest health crisis. Consider recovery time frames presented and reconsider aggressive logging approach preferred in the Plan.

1364

RESPONSE: The Targhee presents the Forest health issue professionally. For example, the Plan under Insects and Disease states, "Insects and disease are allowed to play their natural role in ecosystem dynamics to the extent

TIMBER - SILVICULTURAL/HARVEST

compatible with other resource objectives." The Forest recognizes many damaging agents such as mountain pine beetle, dwarf mistletoe, and fire have been and are still a threat to forest health. Descriptions are rewritten to place the amount of mature forest in perspective.

During the last decade, due to the mountain pine beetle epidemic, the Forest employed an aggressive logging approach, harvesting up to 80 million board feet/year of dead and dying lodgepole pine. As stated under Timber Management, Chapter III, Revised Plan, "Silvicultural techniques will be used as a tool to manage or manipulate vegetation for the purpose of achieving Forest Plan resource objectives. Emphasis will be placed on restoration of ecological function, structure and composition," and elsewhere in the Chapter, "Design timber management projects to simulate natural patch sizes, patch shapes, connectivity, and species composition and age class diversity". DS/LB

COMMENTS: More timber harvesting, especially the dead stuff.

285

RESPONSE: The Revised Plan increases the ASQ to 8.0 MMBF/Yr compared to 3.7 MMBF/Yr in the Draft. Salvage will be less than in the past and focus is on long-term sustainability rather than salvage. JR

COMMENTS: Reconsider your management direction for logging when a section of the forest is designated "mature" or "unhealthy". Removal of trees eliminates advantages of leaving trees, such as recycling of natural materials in a healthy ecologic cycle, nurturing of succeeding generations of plants, no soil disturbance by logging activities, no destruction of moisture-holding and cooling created by canopy.

1337

RESPONSE: Not all of the stands on the Forest will be logged even though they may be designated "mature" or "unhealthy." The Targhee is a multiple-use Forest. The Revised Plan provides an increase in ASQ to 8.0 MMBF/Yr compared to 3.7 MMBF/Yr in the Draft. Salvage will be less than in the past and focus is on long term sustainability rather than salvage. DS

COMMENTS: Limit logging to five sustainable, low impact methods.

179

RESPONSE: Methods used will be those which meet the objectives of the specific project with the least impact. All methods must meet Forest Plan standards and guidelines for resource protection. The Revised Plan provides for significantly less clearcutting and more selection and shelterwood silvicultural methods. DS

COMMENTS: Allow certified silviculturist to determine appropriate silviculture treatment project-by-project on a site-specific basis. Don't limit silviculturist tools in the Plan because there is a big difference in a silviculture system and silviculture cutting methods.

283

TIMBER - SILVICULTURAL/HARVEST

RESPONSE: All silvicultural systems and harvest methods will be determined through a site-specific NEPA analysis by a certified silviculturist. The site-specific NEPA analysis will disclose which silviculture prescription and harvest method is appropriate. DS

COMMENTS: Log "mature trees" only.
608

RESPONSE: All silvicultural systems and/or methods will be determined through site-specific NEPA analysis by a certified silviculturist. To develop and manage uneven-aged stands, a desired number of trees of all age classes needs to be maintained. In regeneration cuts, such as shelterwood, all age classes need to be cut for desired stocking level. During thinning operations, small stems are removed. These are just a few of the examples of when seedling, saplings, poles, thrifty mature, and mature timber will need to be removed. DS

COMMENTS: Increase number of acres from 11,430 acres identified for timber management over the next decade. Land managers' options could be severely limited as new ways to provide ecological diversity are developed. Maintain suited land base to as many acres as possible to allow insect and disease treatment or fire and to allow maximum flexibility in implementing ecosystem management.
90

RESPONSE: Suited land base is a reflection of management prescriptions on the tentatively suitable base and is strictly fixed by the prescriptions. Flexibility exists within the Revised Plan to implement ecosystem management. After a reanalysis of the ASQ calculation, the ASQ increases from 3.7 to 8.0 MMBF per year. The acres treated are estimated to be about 2,052 per year or 20,520 during the decade. LB

Silvicultural Treatments Need Changes

COMMENTS: Clarify the definition of silviculture system. It is a process. There are only two silvicultural systems - even aged and uneven aged management.
283

RESPONSE: The revised definition of silvicultural system includes the addition: "... that results, even aged and uneven aged." DS

COMMENTS: Examine a full range of cutting methods by each alternative. This would remedy current legal deficiencies and help public understanding.
305, 1365

RESPONSE: All cutting methods are available for use in all alternatives. Silviculture prescriptions are site-specific or written for each treatment of a stand. The Final Revised Plan does not identify which stands will be treated or how. The Revised Plan gives general guidelines as to which silvicultural systems and methods may be used within a given area. DS/LB

TIMBER - SILVICULTURAL/HARVEST

COMMENTS: Maintain huckleberry and other berry-producing shrubs in timber harvest areas by limiting silvicultural practices such as soil scarification that destroys shrubs and shrub rhizomes.

643

RESPONSE: The Final Revised Plan, while still allowing clearcutting as a harvest method, favors liberation cuts in mature and over mature lodgepole pine stands with adequate regeneration. However, when the understory has been infected by mistletoe, gall rust or other pathogens, clearcutting with scarification for natural regeneration may be necessary. Areas of huckleberry and other shrubs that need protection will be identified in the individual project's NEPA document and silvicultural prescription on a case-by-case basis. DS

COMMENTS: Remove any reference to a supposed correlation between mature forest and elevated disturbance risks. There is no evidence that intensive logging of mature stands reduces disturbance hazards.

212, 1368

RESPONSE: Literature supports the characteristics associated with mountain pine beetle epidemics Amman (1978) listed the following stand characteristics associated with mountain pine beetle epidemics: 1) trees more than 80 years old, 2) mean diameters over 8 inches, 3) a substantial proportion of trees over 12 inches d.b.h. with phloem thickness of 0.1 inches or more, and 4) elevations where temperatures are optimum for brood development.

Ralph Thier, USDA Forest Service Entomologist, developed the Douglas-fir Beetle Hazard Rating. His studies show that increases in density, age, basal area, and diameter increase the potential outbreak rating. Other studies of insects and pathogens have shown the same results. DS

COMMENTS: Under "Ecological Processes, Insects and Disease" discard the guideline to control through silviculture practices. Remove references that silvicultural techniques can restore ecological function, structure and composition. The purpose of cutting trees is to provide lumber. Pure silviculture does not take into account wildlife, visual, aesthetics, fisheries, recreation values, etc.

697

RESPONSE: Silviculture is concerned with controlling the establishment, growth, composition, and quality of forest vegetation (Daniel, et al. 1978). Clearly defined management objectives that describe what is to be achieved in any given forest cover and locality is necessary. Each management objective, then, must be interpreted in terms of the kind of stand structure that is most suitable. Objectives vary between production of wood, water, wildlife, recreation, soils, and so on, and will obviously require forests of quite different structure; that is, the presence, absence, or relative abundance of litter, grass, brush, reproduction, saplings, poles, mature trees, and overmature trees should vary in managed stands depending on the particular management objective. Furthermore, each objective will influence the mixture of species and age classes present and the extent to which vegetation components are layered or grouped, both vertically and horizontally in relatively uniform aggregations or mosaics within a stand.

TIMBER - SILVICULTURAL/HARVEST

Complex objectives involving multiple-use commonly require a correspondingly complex and diverse structure with some loss in efficiency for any one particular use. Silvicultural strategy depends on the overall objective of stand management. As objectives change, so will the silvicultural prescription, since stands of different structure will probably be required. DS

COMMENTS: Design silvicultural prescriptions to specifically benefit smaller, locally owned logging companies. (CROSS REFERENCE: Timber, Economics)
204, 214, 1185, 1348

RESPONSE: Silvicultural prescriptions, in themselves cannot be altered, because they are used to achieve specific management objectives. Objectives may limit flexibility in altering cutting unit size or treatment methods. However, sale size, timing of when sales are sold, and the length of time a contractor has to complete a sale can often be modified to help smaller operators. The Forest has attempted to do this on many sales over the past several years. JC

COMMENTS Consider horse and mule logging; permit horse logging in the winter.
1314, 1316, 1392

RESPONSE: Horse and mule logging is allowed on all timber sales on the Forest. The size of the sale and/or environmental constraints determine the type of skidding equipment used. DS

COMMENTS: Use under thinning to remove fire ladders and reduce fuel loads.
1364

RESPONSE: The Revised Plan allows thinning from below when appropriate. Silviculture prescriptions are site-specific or written for each treatment of a stand. The Revised Plan identifies which silvicultural systems and methods may be used on stands within a given prescription. DS

COMMENTS: Logging may be an ineffective solution for the reduction of severe fires, because studies have shown (Williams and Rothermel 1992) large woody fuels are not usually consumed by fires, and weather and climate conditions are more important factors in fires than vegetation.
1273b

Re-evaluate your conclusions that silviculture treatment can minimize the effects of drought, fire, insects and disease and other pathogens. Various studies indicate scientific evidence does not support this hypothesis.

643, 695

RESPONSE: Silvicultural treatments such as harvesting, thinning, and prescribed fire can be used to create and restore forest conditions that are within their historic range of variability and that are less susceptible to insects, diseases, fire, drought, and other disturbance events. This is well established in scientific literature, though exceptions can be documented. DS

TIMBER - SILVICULTURAL/HARVEST

Consider Selective Harvest Methods Only

COMMENTS: Encourage selective harvesting, helicopter logging, or controlled burning and eliminate clearcutting to use renewable timber resource and maintain beauty of the area. Contention that clearcuts mimic the effects of fire has been refuted.

317, 321, 359, 489, 694, 1276, 1314, 1316, 1365

Adopt single tree selection method for less destruction and long-term forest health.

1243

RESPONSE: Unless objectives for nontimber commodities dictate otherwise, harvesting should either leave the stand in an improved condition or provisions must be made for regeneration. All harvest methods and systems are considered when writing a silvicultural prescription. Silviculturally, clearcutting is a viable method of regenerating a stand of trees and not an expedient of logging. The Revised Plan provides for significantly less clearcutting and more selection and shelterwood logging. Clearcut harvesting imperfectly mimics wildfire. Clearcuts with retention of ten to 20 percent standing and down lodgepole pine biomass more closely approximate wildfire effects (Koch 1996). Clearcutting under the standards and guidelines of the Revised Plan (requiring, snag retention, reserve trees, dead and down requirements, and so forth) differs from clearcutting in the past. DS

Opposed to Salvage Harvesting/Use on Experimental Basis

COMMENTS: Recommend an adaptive approach for salvage harvest as an experiment on a limited scale, monitored and evaluated to guide management in the future.

1365

RESPONSE: All silvicultural activities, whether salvage logging or logging of green trees are monitored and evaluated. This is and has been a standard practice of the Forest Service. Salvage logging during this revision period will be on a limited scale as compared to the previous decade. LB

COMMENTS: Salvage harvest is nothing more than an excuse to build more roads and cut more of the Forest under the pretense that a certain area of the forest is subject to fire, disease or past questionable maturity and facing death.

1314

Salvage harvest is a bogus excuse for past excesses.

664

RESPONSE: During the last decade, due to the mountain pine beetle epidemic, the Forest took an aggressive logging approach, harvesting up to 80 MMBF/Yr of dead and dying lodgepole pine. As stated under Timber Management, Chapter III Revised Plan, "Silvicultural techniques will be used as a tool to manage or manipulate vegetation for the purpose of achieving Forest Plan resource objectives. Emphasis will be placed on restoration of ecological function, structure and composition" and elsewhere in the same Chapter, "Design timber management projects to simulate the range of natural variation for patch sizes, patch shapes, connectivity, and species composition and age class

TIMBER - SILVICULTURAL/HARVEST

diversity." Salvage logging during this revision period will be on a limited basis as compared to the previous departure during the last decade. LB

COMMENTS: Use natural methods rather than logging.

1337

RESPONSE: Silvicultural systems and methods are essential to meet Forest Service objectives established by Congress. See "National Goals Relevant to Land and Resource Management," Appendix A, Revised Plan. LB

COMMENTS: Address the issue of below-cost timber sales, especially as it relates to salvage logging, since in the Rocky Mountains salvage logging is clearly not beneficial to the U.S. taxpayer. The Targhee is a "case study" of the economic effects of salvage logging. (CROSS REFERENCE: Timber, Economics)

1368

RESPONSE: Costs are related to meeting a variety of objectives. The Forest is managed to respond to the needs of a diverse constituency, subject to the body of existing laws and regulations. DP

COMMENTS: Restrict salvage until more information is available on the effects of current management techniques. No long-term plans should be made because we don't know.

1365

RESPONSE: Forest resource professionals are continually learning. All silvicultural activities are monitored and evaluated. The Targhee finished an extremely large salvage program and had tremendous success in regenerating thousands of acres of beetle killed lodgepole pine. Salvage will continue over the next decade, but to a lesser extent than in the past. DS

Clarify Salvage Logging

COMMENTS: Clarify salvage logging in terms of the number of trees and diameter to be left per acre after harvest and what will be logged or not logged.

317, 1324

RESPONSE: The Revised Plan does not give specific "how-to's" of project implementation. Implementation plans will be developed during the life of the Plan that will provide this operational direction. These plans will be adapted as new scientific principles and methods to improve resource management activities become available. Each salvage operation will be

proposed through site-specific NEPA analysis, and a silvicultural prescription will determine the number of trees, types of cutting methods used, and so forth. Refer to Chapter III, Ecological Processes and Patterns, Biodiversity, Dead and Down Materials. Also see Snag Requirements under Wildfire. DS

COMMENTS: Disclose on a forestwide level how many acres of dead timber remain with 2 mbf or more of dead per acre.

228

TIMBER - SILVICULTURAL/HARVEST

RESPONSE: Using fuel modeling, less than 2% of the forested acres on the Targhee, including mature, pole, sapling, seedling and non-stocked acres, have less than five tons of dead fuel remaining. Five tons equals approximately four cords or 2 MMBF. The Forest has 1,237,281 forested acres of which no less than 1,212,536 contain at least 2 MMBF of dead timber. This includes sound logs and logs in varying stages of decay. DS

COMMENTS: Discuss the impact of heavy timber harvest on native wildlife species in the lodgepole pine salvage areas.

1369

RESPONSE: Refer to Chapter III, Affected Environment, FEIS for a discussion on this topic. DS

COMMENTS: Disclose what is known and unknown about the health of the forest and how forestwide and project-level salvage decisions will be made in the future.

1365

RESPONSE: A comprehensive review of the existing Plan is included in the Analysis of the Management Situation (AMS). This analysis: 1) describes the present Forest condition; 2) defines progress made in implementing the Plan with respect to accomplishment of goals and objectives; and 3) shows how effective standards and guides are in achieving the desired future conditions described in the Plan.

The Revised Plan does not give specific "how-to's" of project implementation. Implementation plans will be developed during the life of the Plan that will provide this operational direction. These plans will be adapted as new scientific principles and methods to improve resource management activities become available. Each salvage operation will be proposed under a site-specific NEPA document, and a silvicultural prescription will determine the number of trees, types of cutting methods used, etc. DS

Clearcutting: Discuss and Clarify

COMMENTS: Include a full and open discussion of the pros and cons of clearcutting versus natural processes and events.

1365

RESPONSE: The Revised Plan provides for significantly less clearcutting than the existing Plan. However, clearcutting along with other silvicultural systems and methods are essential to meet Forest Service objective established by Congress. Refer to "National Goals Relevant to Land and Resource Management", Appendix A, Revised Plan.

The pros and cons of clearcutting can be compared to other silvicultural methods used to meet Forest Service objectives. Outcomes of these objectives can then be compared to natural processes and events. This comparison is evaluated in Chapter III, Final Environmental Impact Statement, Affected Environment. DS

COMMENTS: Find a balance between clearcutting and locking up the forest.

649

TIMBER - SILVICULTURAL/HARVEST

RESPONSE: During the revision process, alternatives were developed, analyzed, and compared, and a preferred alternative selected. The Revised Plan is based on a balanced approach between use and protection. DS

COMMENTS: Identify goals for this management method and clarify why clearcutting is the most appropriate technique for these goals.

389, 643

RESPONSE: Silvicultural techniques will be tools to manage or manipulate vegetation for the purpose of achieving Revised Plan resource objectives. The choice of reproduction method, such as clearcut, is frequently a compromise between what is biologically ideal and what is economically and socially acceptable. DS

COMMENTS: Discuss the relationship between water yield and timber harvest (clearcut equivalency) for each watershed. Some watersheds such as Packsaddle Creek have nearly all of their headwaters subjected to clearcutting.

643

RESPONSE: Total water yield on the Forest is about 1.4 million acre-feet. Management activities have the potential to change the timing and amount of water delivered to stream channels which is discussed by subsection in the Final Environmental Impact Statement (FEIS), Chapter III. A discussion on cumulative effects and which watersheds would be effected by alternative is discussed in Chapter IV, FEIS. An hydrologically disturbed constraint restricts the number of acres in each watershed that can be in a created opening status. LB/DS

COMMENTS: Define more clearly the cumulative impact of post-clearcut logging with its associated road network. Plan is deficient in the "reasonably foreseeable" choice of logging methods for individual projects.

1365

RESPONSE: Chapter III, Final Environmental Impact Statement, Affected Environment addresses current conditions regarding past logging and roads. Chapter IV describes the effect of alternatives. The Final Revised Plan serves as an "umbrella" for the environmental analysis for proposed projects at the Forest and Ranger District levels. Future environmental analyses, documented in EAs and EISs, will refer to the Plan, the accompanying EIS, and related documents wherever possible. Environmental assessments will be developed for project-level activities not specifically described in the Plan and will concentrate on issues unique to the project. DS

COMMENTS: Explain how you classified acres when a partial timber harvest eliminates cover, but still has more trees on it than a seed cut. Provide a classification for all habitat structures as per cover and forage rather than leaving a huge majority of acres in an undefined category. Extensive shelterwood cuts require clarity about what cover category these open stands fall in.

1369

TIMBER - SILVICULTURAL/HARVEST

RESPONSE: A stand is certified as stocked when there are 150 - 250+ trees/acre established, regardless of size, five years after a regeneration cut. Other objectives or guidelines, such as hiding cover (250 trees per acre, seven feet tall, capable of hiding 90% of an elk at 200 feet) are met for reasons other than stocking certification. DS

COMMENTS: Patch size is pertinent because of history of salvage logging on the Forest. (CROSS REFERENCE: EM, Patch Size)

317

RESPONSE: The Revised Plan provides extensive guidance for patch size to mimic historical patch sizes and shapes. Refer to Revised Plan, Chapter III: "Design timber management projects to simulate the range of natural variation for patch sizes, patch shapes, connectivity, and species composition and age class diversity." DS

Clarify Clearcut Patch Size

COMMENTS: Explain that clearcut size of 40 acres or less on 14% of the Forest does not mean clearcuts can be greater than 40% on the remaining 86% of the Forest and that the 40-acre clearcut unit size comes from research on elk distribution and movement and grizzly bear telemetry work.

625

Cite scientific data to support Size of Harvest Units and Leave Block/Strips Standard. Light, wind, moisture regime, and vertical stratification of vegetation may be such that the area is no longer a "created opening."

1446

RESPONSE: Created openings cannot exceed 20% of the forested acres within a watershed.

The 40-acre restriction comes from the National Forest Management Act. NFMA restricts openings on the Targhee to 40 acres except where larger units will produce a more desirable combination of net public benefits. Such exceptions shall be provided for in regional guides.

Size limits exceeding those established ...are permitted on an individual timber sale basis after a 60-day public notice and review by the Regional Forester. Identification of created openings will be made on a site-specific basis.

"The established limit shall not apply to the size of areas harvested as a result of natural catastrophic conditions such as fire, insect and disease attack, or windstorm." LB

COMMENTS: Include an analysis of fragmentation patterns and connectivity with patch size as more comprehensive indicators for Key Issue #1.

643

RESPONSE: Discussion on fragmentation is added in the FEIS. The Revised Plan provides several prescriptions, standards, and guidelines that limit the amount of early successional stage that can exist at one time. This direction should reduce cumulative impacts. MO

TIMBER - SILVICULTURAL/HARVEST

COMMENTS: Drop the statement: "Patch cuts are used to provide the disturbance needed to regenerate aspen." Patch cuts are used for many reasons. (CROSS REFERENCE: Timber, Aspen)

283

RESPONSE: We agree. This correction is made in the Revised Plan. LB

COMMENTS: Tier timber management to the NFMA and Intermountain Regional Guide which require Regional Forester and public approval of patch sizes of 40 acres or more.

1273b

RESPONSE: Regional Forester approval for openings > 40 acres is part of the normal procedures in project planning. LB

Reduce Patch Size

COMMENTS: Reduce patch size since you have no evidence to support stated size; reduce to a maximum of twenty acres.

61, 212

RESPONSE: The definition of patch size is adjusted to 1-20 acres in the glossary. LB

COMMENTS: The argument for aggregating small clearcuts into larger ones overlooks adverse impacts of larger clearcuts on recreation, visual quality, increased soil erosion, and ecosystem degradation.

1365

Pervasive use of many small clearcuts to reach timber targets can result in unacceptable habitat fragmentation.

325, 1365

RESPONSE: The Revised Plan contains direction to manage ecosystems in properly functioning condition. This entails an evaluation of four criteria: structure, composition, disturbance regimes, and patterns. Patch size, patch shape, patch distribution and connectivity are measures of "patterns". The size of clearcuts or patch sizes for timber harvesting are determined through the site-specific NEPA process. Impacts on recreation, visual quality, soils, and fragmentation as well as other resources are considered at this time. AM

Clearcutting - Standardize Clearcut Size

COMMENTS: Standardize the maximum clearcut size under the Preferred Alternative to adequately protect fish and wildlife resources.

1446

RESPONSE: The National Forest Management Act restricts the size of clearcuts to 40 acres unless site-specific analysis shows that larger openings would be environmentally sound. Some management prescriptions in the Revised Plan restrict clearcutting to less than 40 acres or not at all. LB

COMMENTS: Make patch size specific for the whole forest and include guidelines on how far apart patches should be.

305

RESPONSE: The Forest believes that standard patch size limits ability to maintain diversity. Using new tools in landscape analysis and design, and new direction to mimic historical patch size and shape is included in the Revised Plan. DS

Clearcut Patch Size Can Adversely Affect Wildlife

COMMENTS: Maintain adequate cover for wildlife and restrict large openings for timber harvest where you cut more trees than you can grow back.

1443

RESPONSE: The majority of management prescriptions that allow timber harvest are designed to benefit wildlife or other resources. Any harvest project will meet the objectives established in the prescription. LB

COMMENTS: Leave strips of a size large enough to provide cover for an adult elk and to withstand windthrow to protect migration corridors and habitat.

625

RESPONSE: We agree. The Revised Plan includes direction to provide adequate wildlife cover and protects habitat. See Elk and Summer Range Prescription in the Revised Plan (Chapter III-Part 3). LB

Clearcutting with Strict Guidelines is Necessary

COMMENTS: Include language that states clearcutting should be used only in settings and vegetative species where harm to natural environment will be insignificant and where other methods cannot achieve clearly defined multiple use objectives.

1365

RESPONSE: Harvest methods will meet the objectives of the specific project with the least impact. All methods must meet forestwide standards and guidelines for resource protection. The Plan provides for significantly less clearcutting and more selective and shelterwood logging. DS

COMMENTS: Monitor and evaluate the use of even aged management for any unexpected impacts and ensure management action is taken to mitigate those impacts in the future.

1365

RESPONSE: All harvest activities are monitored as outlined in the National Forest Management Act. The Revised Plan serves as an "umbrella" for the environmental analysis for proposed projects at the Forest and Ranger District Levels. DS

TIMBER - SILVICULTURAL/HARVEST

Prohibit or Consider Fewer Clearcuts

COMMENTS: Consider fewer clearcuts.

F-K(4)

Reduce clearcutting so there can be appropriate limits on both clearcuts and habitat fragmentation.

Develop plans that effectively implement the statutory presumption against the use of clearcutting.

1365

RESPONSE: Future environmental analyses, documented in environmental assessments (EAs) and EISs, will refer to the Plan, the accompanying EIS, and related documents wherever possible. Environmental site-specific assessments will be developed for project-level activities not specifically described in the Plan and will concentrate on issues unique to the project.

Clearcutting can be a valuable silvicultural option. Overall, the Revised Plan reduces clearcutting because of the reduced treatment of lodgepole pine species and includes additional direction that limits clearcutting in some areas. DS/LB

COMMENTS: Look beyond all even aged methods, including clearcuts, shelterwood and seed-tree cutting. Proposed plan perpetuates the application and abuse of clearcuts.

The use of even-aged management techniques is not acceptable. Harvesting techniques must be guided by a stringent set of standards. Standards are sorely lacking.

1365

Prohibit clearcutting. A forest should be a forest. TNF has had too many clearcuts in the past.

317

Initiate newer, more environmentally sound, methods of cutting timber than clearcutting.

1392

Eliminate clearcutting to ensure long-term health of the forest as a first priority.

F-K(4), 189, 318, 359, 399, 625, 656, 726, 1243, 1330, 1365

RESPONSE: Clearcutting remains as a silvicultural option. Overall the Revised Plan reduces the use of clearcutting because of the reduced treatment of lodgepole pine species and includes additional direction that limits clearcutting in some areas. LB

COMMENTS: Prohibit clearcutting to protect elk and grizzly bear.

244, 438, 519

RESPONSE: Management prescriptions in the Revised Plan are specific as to the extent clearcutting can or cannot be used in elk and grizzly bear habitat. LB

COMMENTS: Prohibit the use of logging to mimic natural processes and fire disturbances. Eliminate clearcuts in favor of select cut methods only. Contention that clearcuts mimic the effects of fire has been refuted. Support

TIMBER - SILVICULTURAL/HARVEST

with cited literature the statement on Page I-4 (EIS) that clearcutting can approximate the role of fire in the regeneration of lodgepole.

150, 489, 643, 1270, 1276, 1365, 1446

RESPONSE: Harvest methods will meet the objectives of the specific project with the least impact. All methods must meet forestwide standards and guidelines for resource protection. The Plan provides for significantly less clearcutting and more selection and shelterwood logging. The closest approximation to the extreme open situations created by clearcutting is a fire-killed stand (Daniel, Helms, and Baker 1979). Clearcut harvesting imperfectly mimics wildfire (Koch 1996). DS

COMMENTS: Discuss prescriptions to mimic fire disturbance (seed tree, shelterwood, select and clear cuts) and how they differ from the same kind of management that have previously failed on the Targhee National Forest where clearcuts of Douglas-fir have regenerated to only brush and lodgepole pine.

410

RESPONSE: Of the approximately 120,000 acres harvested on the Targhee, less than 7,500 acres remain unstocked as of September 1996. These remaining acres are expected to be stocked by 1998. The majority of these acres are in lodgepole pine stands. None of the Forest's Douglas-fir stands have been clearcut in the last decade, and no Douglas-fir clearcuts are planned. DS

Clearcutting - Continue To Allow

COMMENTS: Retain clearcutting silvicultural tool that may be needed in the case of fire or insect and disease. Continue to harvest in small clearcuts. Mature timber should be cut for wood products needed by American people.

5, 283

RESPONSE: Clearcutting remains a silvicultural tool. It will be used in small clearcuts (40 acres or less) in mainly mature stands. LB

Clearcutting - Regeneration

(CROSS REFERENCE: Timber, Regeneration)

COMMENTS: Replant clearcuts.

293, 377

RESPONSE: Of the approximately 120,000 acres harvested on the Targhee National Forest, less than 7,500 acres remain unstocked as of September 1996.

TIMBER - SILVICULTURAL/HARVEST

These remaining acres are scheduled to be stocked by 1998. Approximately 80% of all acres harvested regenerated naturally. The other 20% were planted. DS

Succession

COMMENTS: Studies show that clearcuts do not approximate the role of fire in the regeneration process in lodgepole pine. Stands include many seedlings in

TIMBER - SILVICULTURAL/HARVEST

the understory that provide succession and regeneration.

643

RESPONSE: The closest approximation to the extreme open situations created by clearcutting is a fire-killed stand (Daniel, Helms, and Baker 1979). Clearcut harvesting imperfectly mimics wildfire. Clearcuts with retention of 10 to 20 percent standing and down lodgepole pine biomass more closely approximate wildfire effects (Koch 1996). Clearcutting under the standards and guidelines of the Revised Plan (such as, snag retention, reserve trees, dead and down requirements, etc.) differs from clearcutting in the past. DS

COMMENTS: Consider that the presence of conifer in lodgepole pine does not mean stands will move to Douglas-fir or spruce. Lodgepole pine is a climax species on many infertile sites where conditions do not favor other species. Where spruce and fir have become established and canopy is more open, lodgepole pine regeneration is found in many forest gaps.

643

RESPONSE: Refer to the forestwide Ecological Unit Inventory which guides the Forest in the management of vegetative communities and identifies and maps Potential Natural Community. DM

COMMENTS: Correct statement that mountain pine beetle invasions in lodgepole pine stands allow more shade tolerant species to take over. Post-fire research shows that conifer species most likely to appear in lodgepole pine after canopy is opened is lodgepole pine.

643

RESPONSE: Your comment is acknowledged. This concern is best evaluated on a case-by-case basis at either the landscape- or project-level, rather than at a forestwide scale. DM

COMMENTS: Consider that post lodgepole pine seedling densities span four orders of magnitude, ranging from 80 to 1.9 million seedlings per hectare. Densities are dependent on the proportions of serotinous trees in the pre-fire stand and on fire severity.

489

RESPONSE: Your comment is acknowledged. This concern is best evaluated on a case-by-case basis at the project-level scale, since it is dependent on site-specific characteristics or factors. DM

COMMENTS: The Revised Plan does not elaborate what decision processes are to be used to ensure species complexes are maintained.

384

RESPONSE: Please refer to the Properly Functioning Condition section of the Revised Plan (Chapter III) where approximate project-specific NEPA analysis will yield the decision for management actions to maintain species. DM

COMMENTS: Consider the failure of lodgepole pine areas on infertile, subalpine sites to become adequately stocked as being within the RNV. Several

area studies suggest these sites will gradually fill in over relatively long periods of time as individual lodgepole pine are recruited from seeds from open-coned trees.

489

RESPONSE: National Forest Management Act, 1976, requires units to be fully stocked within five years after harvest. DS

COMMENTS: Do not break down successional stages into "mature" and "immature," rather follow Despain (1990) who uses five stages. To use only two stages is a poor scientific basis on which to manage biodiversity for Forest dependent species.

1273b

RESPONSE: The Forest used the six successional stages found throughout silvicultural literature, most recently in Characteristics of Old Growth Forests in the Intermountain Region, USDA Forest Service, 1993. Late seral and climax species may be present in young stands. This can occur in any habitat type. See table under "Late Successional Stages by Forest Type" in Final Revised Plan. The Forest is cooperating with Montana State University to develop succession modeling. DS

COMMENTS: Update plant succession discussion on Page III-5 of the DEIS to include ideas presented by Lyon and Stickney (1976). Description is archaic and research over the past several decades has shown this model seldom holds and it has been largely abandoned by plant ecologists.

489

RESPONSE: The description of the general pattern of succession is adequate. The Forest used the six successional stages found throughout silvicultural literature, most recently in Characteristics of Old Growth Forests in the Intermountain Region, USDA Forest Service, 1993. Late seral and climax species may be present in young stands. This can occur in any habitat type. See table under "Late Successional Stages by Forest Type" in Revised Plan. DS

COMMENTS: Reflect recent studies regarding succession that state idealized progression rarely happens and is more directly related to species present prior to disturbance and the mix of environmental conditions (slope, soil, aspect, elevation and other factors) that characterize the site.

643

RESPONSE: The Forest acknowledges that some inherent unpredictability exists in specific successional pathways, but the classic successional model is adequate for this analysis. RR

COMMENTS: Consider lodgepole pine as much of a climax species as subalpine fir or Engleman spruce, because as lodgepole canopy opens up, recruitment of new lodgepole pine occurs in many of the gaps or "leave strips".

Reconsider the assumption that the presence of subalpine fir or Douglas-fir in lodgepole pine stands will succeed to a Douglas-fir or spruce-fir forest. Environmental conditions may be such that two or more

TIMBER - SILVICULTURAL/HARVEST

species can co-exist. Suspect this is the case on the forested area on the west slope of Teton Range.

489

RESPONSE: A climatic climax is found on deep loamy soils of gently undulating relief; an edaphic climax develops on the other soils and types of relief; and a topographic climax reflects compensating effects of aspect or different microclimatic effect.

Lodgepole pine plays a minor seral role when in a component of stands with a mixed overstory composition, and is usually replaced by more tolerant associates in 50 to 100 years. It is dominant seral when it is the principal overstory component of stands with a vigorous understory of more tolerant associates that will ultimately replace lodgepole pine in 100 to 200 years. Where lodgepole pine stands are the result of catastrophic fires, it can be a persistent seral because there is no seed source for the normal replacement species. Even though most of the lodgepole stands on the Targhee developed as a result of catastrophic fire, few, if any, reflect the condition of not having seed sources of more tolerant species. Where lodgepole pine is the only available species capable of growing in a particular environment, such as in frost pockets, it is a self perpetuating climax.

Most of the lodgepole pine stands on the Targhee are considered serotinous, but approximately 70% of the cones are non serotinous which allows "gaps or leave strips" to become stocked. DS

COMMENTS: Clarify that for silvicultural purposes, stocking is achieved when trees are two feet tall, not seven feet tall. Requirements may be different for wildlife on visuals.

413

RESPONSE: A stand is certified stocked when 150-250+ trees are established, regardless of size, five years after a regeneration cut. Other objectives or guidelines, such as hiding cover (250 trees per acre, seven feet tall, capable of hiding 90% of an elk at 200 feet) are met for reasons other than stocking certification. DS

TIMBER - SITE-SPECIFIC

Lemhi/Medicine Lodge Subsection

COMMENTS: Explain the cause of the presumed lack of tree species diversity in the Lemhi/Medicine Lodge Subsection and whether the Forest Service expects an increase in diversity with more frequent fires or some sort of vegetation treatment. It's unlikely the area would support species that aren't there now.

489

RESPONSE: Douglas-fir commonly dominates many northern aspects of the drier mountain lands of southern Idaho and is typical of the situation in the Medicine Lodge area; the south slopes are sage/grasslands and the north slopes are Douglas-fir. In the Lemhi Mountains, Douglas-fir occupies a narrow elevational band that allows growing conditions for this species, but not

TIMBER - SITE-SPECIFIC

others. Farther north in the Lemhi Range the elevational band becomes wider. As moisture increases, the number of tree species becomes more diverse. Projects proposed in this subsection will focus on increasing the diversity of age classes rather than increasing species diversity. Forested systems in these areas have been dominated by successional pathways associated with dry Douglas-fir types and should remain dominated by these pathways. JC

Jackpine Loop and Leigh Creek

COMMENTS: Intensive timber harvests have occurred in the Jackpine Loop and Leigh Creek areas, creating unnatural openings that span many hundreds of acres. Shrub slopes at lower elevations that are critical ungulate range are no longer bordered by good hiding and thermal cover due to timber harvest. Shrub slopes are often in proximity to new houses, roads, and activities on adjacent private lands. Roads and trails are present in almost all of the drainages in the Tetons. Teton Pass Road and the Ashton-Flagg Ranch Road may have a major effect on landscape connectivity for large and small animals.

643

RESPONSE: The amount of timber harvest proposed in the Jackpine Loop area and Leigh Creek Watershed is 5.928 MMBF/decade, and considered an upper limit based on other constraints in the Revised Plan, such as the standard that more than 70 percent cover must be maintained in the Jackpine Loop area. In the Leigh Creek Watershed, maintaining forested blocks greater than 250 acres is a constraint that limits timber harvest. During site-specific analysis, the disturbance of adjacent lands becomes a factor as it relates to the landscape. Management prescriptions in the Teton Pass are not timber prescriptions. Harvest is unlikely, unless resource objectives for the area cannot be met otherwise. A site-specific analysis will be completed before any project is implemented. Management prescriptions for these two areas establish maximum road densities. In these two areas, road densities will be reduced from current levels. LD

Timber Harvest on the Palisades Ranger District

COMMENTS: Harvest on the Palisades Ranger District in Wyoming should only occur after development of a comprehensive cumulative impacts analysis that evaluates the impacts of old growth and wildlife and reviews public access to areas that winter big game species.

389

RESPONSE: Any harvest proposal requires site-specific analysis through the NEPA process. Site-specific analysis must address cumulative effects on all resources. LB

Boot Jack Pass to Red Rock Pass

COMMENTS: Eliminate further harvesting from this area and on the north side of Sawtell, Jefferson Peaks and adjoining mountains, because this is a major watershed to Henry's Lake that harbors big game. Harvest does not sustain

TIMBER - SITE-SPECIFIC

habitat or free movement of wildlife and our property is next to the Forest and we want peace and quiet.

1457

RESPONSE: The Revised Plan does not schedule any timber harvesting from Hope Creek to Red Rock Pass, the north side of Sawtell, and Jefferson Peaks. These areas are designated nonmotorized or semi-primitive motorized. This management prescription does not allow scheduled timber harvesting. The Revised Plan does allow a small amount of timber harvesting from Boot Jack Pass to Hope Creek. Timber harvesting must follow specific standards and guidelines to maintain grizzly bear habitat. MO

Big Holes

COMMENTS: If the Forest plans substantial management changes in Big Holes area, elaborate and disclose those plans and allow additional time for comment. The area in question is not labeled in regard to management prescription on page III-50. I would like to know the prescription number for the mile-wide area south and west of Driggs on the east slope of the Big Holes. Prohibit clearcutting in this area.

1186

RESPONSE: The management prescription for this area is 5.1.3 (b). Clearcutting is not allowed in this prescription. The intent of this prescription is to provide fuels management adjacent to an urban interface area. LD

COMMENTS: Fire risks in Big Holes area are the landowner's responsibility. This area is important for wildlife, and rich riparian areas need to be protected and rejuvenated from grazing. Creating new roads is expensive and provides more needless access to areas and could jeopardize wildlife security. Unsightly clearcuts would destroy the aesthetics and possibly devalue private property. Firewood gathering is fine as long as no new roads are built.

325

RESPONSE: Clearcuts are not allowed in the 5.1.3 (b) Prescription applied to the Big Holes area. New roads would not be permitted if road density exceeds 3 mi./sq.mi. The forestwide standard and guidelines covering grazing in

riparian areas and Prescription 2.8.3 guidance are designed for recovery of riparian areas. LD/RSM

Sheridan Creek - Table Mountain (Low Elevations)

COMMENTS: Prescribed Timber Management (Big Game Emphasis) is a concern in that harvest will reduce late seral conifer stands which are exceedingly rare throughout the US. Maintain representative examples of this habitat type wherever possible since old growth is important for wolverine and goshawk, both of which are indicator species as well as Category 2 candidate species

TIMBER - SITE-SPECIFIC

and sensitive species. It also provides unparalleled security cover for elk and grizzly bear.

1185

RESPONSE: Table Mountain is designated a special management area (Management Prescription 2.1.1) in the Revised Plan. This management prescription does not allow scheduled timber harvesting.

The lower elevation area of Sheridan Creek allows scheduled timber harvesting. Timber harvesting must follow standards and guidelines for Management Prescription 5.1.4, for goshawk territories, and for old growth and late successional forests. Targhee analyses shows 70% of forested acres will be unharvested and in a late succession or old growth condition at the end of the first decade. MO

Proposed Timber Sales

COMMENTS: The following proposed timber sales will have a direct impact on resource management on adjacent BLM land: (WA = WATERSHED)

WA 009A	Island Park/Centennials	WA 014	Big Bend Ridge
WA 016	Falls River	WA 019	Teton Creek
WA 020	Leigh Creek	WA 023/024	Canyon/Moddy Creek
WA 025	Camas Creek	WA 026A	Beaver Creek

Timber harvest may render BLM objectives useless due to individual or cumulative impacts adversely affecting resources such as water quality, riparian, big game habitat, raptor nesting, recreation. True ecosystem management analyzes the cumulative effects of timber harvest and OHV plans on BLM and Idaho Department of Public Lands. These areas have been identified by Idaho Fish and Game as crucial big game summer-fall habitat as well as secure migration areas. This proposed harvest would fragment this important habitat shared by the Forest Service and BLM.

1446

RESPONSE: Management activities adjacent to BLM administered lands will be coordinated with BLM. JR

Island Park and Madison Subsections

COMMENTS: Correct the statement that says no harvest is planned in Island Park and Madison Subsections over the next ten years. This is an error, specifically for Alternative 2.

413

RESPONSE: Your comment is acknowledged. Harvest activities are permitted in both of these subsections. The statement was corrected in the Revised Plan. LB

COMMENTS: Consider all forest types in percentages described on Page III-37, Paragraph five. This is 46% for lodgepole pine only. It is 35% for all forest types in this subsection. Seems to defeat the purpose. These percentages are from Page III-10 of the DEIS.

413

TIMBER - SITE-SPECIFIC

RESPONSE: The information was changed in the Revised Plan to show that 35.1% of the forested acres are in nonstocked, seedling sapling classes. LB

Sand Creek

COMMENTS: Changes in the demographics of the wintering Sand Creek elk population are directly related to past timber harvests. Forest cannot rely on the State of Idaho to modify hunting regulations to improve the herd. Reduced cover and high road densities are detrimental to a sustainable herd. Forest should strive to meet 100% of the state guidelines under any alternative selected. Timber harvest should still be achievable with an increase in permanent road closures and innovative cutting units. If not, then timber should be reduced to a level compatible with this objective.

625

RESPONSE: The Revised Plan supports the goals of the State Fish and Game departments. Motorized access and timber harvesting are reduced so that previously harvested areas can grow to meet cover objectives before additional timber harvesting is done. About 91% of the Forest meets State Fish and Game thresholds for elk vulnerability. The remaining 9% contain areas with high hunter densities. MO

Pack Saddle Creek

COMMENTS: Discuss the relationship between water yield and timber harvest (clearcut equivalency) for each watershed. Some watersheds such as Pack Saddle Creek have nearly all of their headwaters subjected to clearcutting. (CROSS REFERENCE: Riparian, AIZ - Timber)

643

RESPONSE: The headwater of Packsaddle Creek is assigned the 5.1.4 (b) Prescription. The proposed ASQ for this area is 1.365 MMBF/decade which is based on the amount of timber that can be harvested and not violate the other standard and guidelines that apply to this prescription. The most limiting is the standard that states no more than 20% of the acres will be in a created opening at any point in time. This area has almost reached that point and therefore any new proposed clearcuts will be carefully scrutinized by the Forest in site-specific analysis. However, harvesting that does not generate a created opening i.e., select, could be done. LD/CC

TIMBER - SNAG MANAGEMENT

Clarify Direction on Snags, Dead, and Down Material

(CROSS REFERENCE: Wildlife, Snags/Cavity Nesters)

COMMENTS: Clarify the direction for guidelines on dead and down material on Page III-4.

1369

RESPONSE: Habitat-type specific guidelines are designed to ensure adequate amounts of organic matter will be available to provide for the maintenance of long-term forest (site) productivity after vegetation manipulations. Woody

debris recommendations (R. Graham et al. 1994) were developed based on research of the Rocky Mountain Forests using ectomycorrhiza as a bioindicator of healthy productive forest soils. DM

COMMENTS: Describe the role that the structure of woody debris has on wildlife effectiveness and how wildlife effectiveness will be achieved in guidelines (III-6). If structure is not important, cite current science that this management assumption is based on.

1369

RESPONSE: The Targhee assumes this question refers to the woody residue (debris) guidelines on Pages III-4 and III-5 of the Draft Plan (no woody residue guidelines are found on Page III-6) regarding maintaining site productivity. The Targhee recognized guidelines in the Draft would not meet the needs for wildlife habitat. Additional guidelines were developed for dead and down material (debris) for wildlife habitat and are in the Revised Plan. The guidelines call for providing different decomposition classes and minimum sizes for the dead and down material to enhance forest structure. MO

COMMENTS: Cite references that indicate logs are the only limiting habitat factor for wildlife associated with woody debris.

1369

RESPONSE: Snags and logs, associated with woody debris, are an important factor in habitat requirements for wildlife. They may or may not be a limiting factor, depending on site-specific conditions. For example, numerous snags may exist in openings, but if a wildlife species needs snags on forested sites, availability of forested sites is the limiting factor and not the number of snags. References for the analysis on cavity nesting species are provided in Process Paper D. MO

COMMENTS: Explain how you derived the number of green trees needed for replacement of snags. Include estimated mortality rates per given basal area of lodgepole pine and Douglas-fir.

1369

RESPONSE: Mortality rates on green trees came from the prognosis model developed for the Revised Plan. Process Paper D discusses and displays the data for green tree replacement. MO

COMMENTS: Explain how a threshold value of 25 green trees per acre for snag recruitment was determined.

1369

RESPONSE: Mortality rates on green trees came from the prognosis model developed for the Revised Plan. Process Paper D discusses and displays the data for green tree replacement. MO

COMMENTS: Cite scientific reference regarding the statement that green tree replacement strategy will mitigate impacts on cavity nesters.

1369

TIMBER - SNAG MANAGEMENT

RESPONSE: This statement did not occur in the DEIS and does not occur in the FEIS. The statement that does occur is as follows: "As a result of the snag and green replacement tree requirements in the management prescriptions, there is no measurable difference in biological potential for primary cavity nesting species between the alternatives due to scheduled and unscheduled timber harvest activities." MO

COMMENTS: Discuss maximum snag potential and explain why snag recruitment does/does not increase along with the number of trees in the stand. Cite current research or monitoring for this assessment.
1369

RESPONSE: Process Paper D discusses and displays the analysis for primary cavity nesting species (snag) habitat. MO

COMMENTS: Discuss how snags have been measured or will be measured in the future.
1369

RESPONSE: Process Paper D discusses and displays the analysis for primary cavity nesting species (snag) habitat. The monitoring plan discusses how primary cavity nesting species (snag) habitat will be monitored. MO

COMMENTS: Explain how the Forest has determined future snag densities, since there are no standards and this information is needed to evaluate the impacts of each Alternative.
1369

RESPONSE: Specific direction for maintaining snag habitat is stated in each management prescription. Details of the analysis used to evaluate the alternatives is presented in Process Paper D. MO

COMMENTS: Explain how the Forest ascribed snags and replacement trees to the planned forest conditions since there are no actual standards for snags and tree replacement.
1369

RESPONSE: Specific direction for maintaining snag habitat is stated in each management prescription. MO

COMMENTS: Analyze the viability impacts of existing snag levels on the Forest. Explain why mitigation measures are not needed to correct the existing problems in past clearcuts without snags.
1369

RESPONSE: Process Paper D displays the complete analysis for primary cavity nesting species habitat. In areas where lodgepole salvage has occurred, no timber harvest is proposed for one to three decades. Management prescriptions that allow timber harvesting have guidelines for maintaining specific potential snag habitat. MO

COMMENTS: Cite scientific reference for the downed log guidelines. Explain the basis for 20 logs per acre and identify species for which these guidelines were developed.

1369

RESPONSE: Process Paper D discusses the dead and downed material guidelines, and references used in developing the guidelines. The species which use dead and downed material for habitat were identified in the Analysis of the Management Situation and are not repeated in the Revised Plan. MO

COMMENTS: Cite scientific references that are the basis for requiring only 60% of an area to meet the down and dead wood guidelines and how this requirement will ensure wildlife viability.

1369

RESPONSE: The dead and downed material requirements are applied to all activity areas. Even under natural conditions, dead and downed woody material is not evenly distributed, and distribution changes over time with natural disturbances. The 60% standard recognizes this fact. Process Paper D discusses the dead and downed material guidelines and references used in developing the guidelines. The species which use dead and downed material for habitat were identified in the Analysis of the Management Situation and are not repeated in the Revised Plan. MO

Reduce the Number of Trees Per Acre Requirement for Snag Recruitment

COMMENTS: Reduce the number of live trees per acre requirement for snags from 25 live trees per acre to ten per acre. Twenty-five trees is 250% of the biological need of ten dead snags per acre. Reduce the amount of woody debris by 50%.

413, 767, 1267

RESPONSE: The number of live trees requirement is retained in the Revised Plan because both snags and green trees decay or decompose over time. The need to retain more green trees is to maintain a consistent number of snags over time.

The dead and downed material requirements are based on a range of dead and downed material found in naturally occurring stands over time. MO

COMMENTS: Reduce to 20 logs per acre in each of the three decomposition classes. Sixty logs per acre is excessive. This density does not occur naturally, especially in lodgepole pine types.

413

RESPONSE: The standard sets a total of 20 logs per acre, distributed in decomposition classes 1, 2, and 3. MO

Increase the Amount of Trees Per Acre

COMMENTS: Forest stands dominated by 5" or 9" trees do not provide an adequate abundance of functional snags.

1365

TIMBER - SNAG MANAGEMENT

RESPONSE: This comment refers to the guideline for retaining live trees for future snag recruitment. In this guideline, some smaller live trees (5' to 9') are left, along with some larger live trees. As larger trees die and become snags, smaller live healthy trees continue to grow to replace larger, fallen trees. The intent is to manage for continual replacement over time by leaving a variety of tree sizes and ages. MO

COMMENTS: Leave more snags and deadfall for habitat.

359

RESPONSE: The Targhee's analysis indicates that the number of snags and deadfall established in the Revised Plan will provide habitat conditions within the range of natural conditions in unmanaged stands. MO

Use Snags as Indicator of Old Growth

COMMENTS: Use large snags associated with late successional forests and their relationship to biological potential for woodpeckers as an indicator of old growth.

643

RESPONSE: Old growth definitions include criteria for size and number of snags. However, woodpeckers on the Targhee are not restricted to old growth. Some species of woodpeckers use recently burned areas, and young forests, if suitable snag habitat is available. MO

TIMBER - STANDARDS AND GUIDELINES

Add Skidding Requirements

COMMENTS: Combine skidding constraint with a requirement to rip these skid trails if compaction occurs due to wet weather operations. Loosen skid constraints and require skid equipment to stay on designated skid trails during wet weather.

90

Use specific skid patterns. Felling trees toward a predetermined skid area (felling to the lead) may be appropriate in certain areas. In important fish habitat or where slopes are greater than 40% use winching logs directly out of sensitive areas (end-lining).

389

RESPONSE: Where appropriate, directional felling can be used to mitigate adverse impacts. Site-specific NEPA analysis addresses the needs of the land area involved in the individual project. Timber Sale Contracts contain specific requirements for the purchaser and provisions that may require ripping of skid trails and roads when required by the NEPA document. BR

Add Standards

COMMENTS: Soils - Set standard to keep soil disruption to a minimum as a result of logging.

697

TIMBER - STANDARDS AND GUIDELINES

RESPONSE: Timber sale contracts under section BT6.6, Erosion Prevention and Control, (FS-2400-6T Page 125) address this concern. LB

COMMENTS: Other Tree Species - Add a standard that all trees of other species (Douglas-fir, subalpine fir, spruce, limber and whitebark pine, etc.) be preserved when harvest occurs in lodgepole pine. Biodiversity - Add a standard that all trees under a certain size class be protected to hasten regeneration and preserve biodiversity in logged areas. The desired stand structure should be determined site-specifically based on management objectives.

643

RESPONSE: Such a standard may not meet the silvicultural need of site-specific stands or meet other resource objectives in the project area. Clearly defined management objectives determine applicable silviculture treatment. Each management objective influences the mixture of species and age classes present. Silvicultural applications are designed to meet the management objective and result in landscapes of various structure and composition that are responsive to the overall biodiversity needs of the Forest. DS

COMMENTS: Big Game - Delineate standards that assure that blocks of timber are a reasonable distance from open roads to protect big game.

1273b

RESPONSE: Management Prescriptions 5.1.4 and 5.4 require blocks of cover greater than 250 acres in size be left for big game. The distribution of these blocks, and whether they are always greater than 1/2 mile from an open road, will depend on site-specific analysis. MO

COMMENTS: Visuals - Page III-128 to III-129 - Develop Standards and Guidelines for silvicultural practices to assure that visual quality is maintained and improved.

1273b

RESPONSE: Based on the site-specific location, and visual quality objectives established for that area, silvicultural treatments are developed to meet the criteria. No additional standards are necessary. LB

COMMENTS: Establish a standard that no damaged or diseased trees will be removed, and specifically state exceptions to this standard. Let natural disturbance play its role in ecosystem dynamics.

695

RESPONSE: Requirements for dead and down woody material and snag retention are found in both Wildlife and Soils sections of the Revised Plan. Determination is site-specific based on the management prescription. DM

TIMBER - STANDARDS AND GUIDELINES

Develop Standards and Guidelines for Salvage Harvesting

COMMENTS: Develop standards and guidelines for salvage harvest methods to avoid detrimental impacts to other forest resources.

389

Develop standards and guidelines for salvage harvest methods, especially in old growth and crucial security areas, to avoid timber harvest levels that would have a detrimental impact on other forest resources.

643

RESPONSE: Standard and guidelines were developed for timber activities in general and apply to salvage logging. The Revised Plan serves as an umbrella for site-specific environmental analysis at the Forest or District level. Any timber harvest, whether salvage logging or removal of green volume, will be analyzed on a site-specific basis, and appropriate mitigation and monitoring will be implemented to address site-specific factors. Standards and guidelines serve as sideboards for all management activities. No additional standards and guidelines are needed. LB

COMMENTS: Use the standards and guidelines based on Beschta et. al. 1995: "Wildfire and Salvage Logging: Recommendations for Ecologically Sound Post-Fire Salvage Logging and Other Post-Fire Treatments on Federal Lands in the West."

1. Prohibit salvage logging in sensitive areas, which include, but are not limited to: Severely burned areas; on erosive sites, or any site where accelerated erosion is possible; on fragile soils; on roadless areas; in riparian areas; on steep slopes; and in watersheds with existing serious sedimentation problems.

2. Leave at least 50% standing dead trees in each diameter class; leave all trees greater than 20 inches dbh or older than 150 years; leave all live trees:

3. Prevent soil compaction and erosion in areas determined suitable for salvage logging by prohibiting conventional types of ground-based yarding systems (tractors and skidders) and using new equipment or techniques where it can be demonstrated that soil integrity will be protected.

1367a

RESPONSE: Recommendations 1 and 3 are found in forestwide standards and guidelines or in existing laws and regulations. All three items, and especially item two, are by definition "post-fire treatments". The Forest is not logging in a fire area at the present; however, these recommendations would be considered after this type of disturbance and would be based on the site-specific area at that time. Salvage is limited in the next decade. LB

Include Buffer Zones

COMMENTS: Buffer zones along side of each standing body of water or have water course. Consider factors such as slope, stream channel stability and fish habitat when determining appropriate buffer zone width.

389

TIMBER - STANDARDS AND GUIDELINES

RESPONSE: These items are covered in Chapter III of Final Revised Plan. Refer to the AIZ prescriptions. LB

Protect Steep Slopes

COMMENTS: Develop strict standards for harvest in the ASQ and non-ASQ prescriptions that protect soil, water, wildlife and other resources. For example, stricter standards are needed to regulate timber harvest on steep slopes.

1365

RESPONSE: The standards and guidelines are provided in the Revised Plan, along with existing laws and regulations, and establish constraints for management activities. The Revised Plan serves as an umbrella for site-specific environmental analysis for proposal at the Forest and District level. Any timber harvest proposals, whether for salvage or removal of green volume, will be analyzed on a site-specific basis, and appropriate mitigation and monitoring implemented to address site-specific factors. Standards and guidelines in the Revised Plan serve as sideboards for all management activities. No additional standards and guidelines are needed. LB

Add Standard for Coordination with Other Agencies

COMMENTS: Add a standard requiring analysis of land management practices on BLM lands adjacent to proposed sales and interagency coordination with BLM to ensure management of the total ecosystem. (CROSS REFERENCE: Soils, HD)

1446

RESPONSE: No additional standards and guidelines were added to the Revised Plan. Site-specific analysis requires disclosure of affected environment, including activities on adjacent land. LB

COMMENTS: On slopes greater than 40%, technical consideration should be given to protect soil stability and coordination with Wyoming Game and Fish personnel in Jackson for activities within Wyoming.

389

RESPONSE: See Chapter III of the Final Revised Plan. This is currently standard operating procedure on all projects. LB

Clarify Table on III-24

COMMENTS: Clarify the table on Page III-24 to show which treatments are standards or guidelines. Precommercial and commercial thinning treatments may cause an accumulation of slash that impairs movement of big game and other terrestrial species.

1446

RESPONSE: The entire table is designated as a guideline in the Revised Plan. The table title read "Guideline", but it is in a different format in the Revised Plan. LB

TIMBER - STANDARDS AND GUIDELINES

Change the Following from Guidelines (G) to Standards (S)

COMMENTS: 1) Change guidelines two on Page III-25; 2) Page III-124, (Timber) the final guideline should be a standard; 3) Page III-125, the first guidelines should be standards requiring the maximum use of non-chemical methods; 4) Page III-127, change this guideline to a standard; 5) Page III-128, change items two and three to standards; 6) Page III-130, change the regeneration systems guidelines to standards.

1365

RESPONSE: 1) Timber sale contracts have clauses that require logging operations be shut down any time the operation causes/could cause adverse resource damage. 2) The Forest will rely on natural regeneration when analysis indicates its probability. National Forest Management Act requires establishment of regenerated stands by the end of the fifth year after harvest. 3) This defeats the purpose of the prescribed silvicultural treatment for the area and does not allow consideration of other resource values. 4) See previous response. 5) Items two and three are standards. 6) Based on the wording in the guideline as written, it is meaningless to change to a standard. The Forest will rely on natural regeneration when analysis indicates its probability. National Forest Management Act requires establishment of regenerated stands by the end of the fifth year after harvest. LB

Change/Correct the Following Items

COMMENTS: Change Item E to a standard to be consistent with Item C.2.

1446

RESPONSE: The Revised Plan retains Item E as a guideline. Item E and C.2 are two separate items that can be implemented as proposed without being inconsistent. WG

COMMENTS: DFPR, Page III-99, eliminate the entire second item under timber so any changes to standards and guidelines would require an amendment.

1446

RESPONSE: Any project that recommends changes to standards and guidelines is analyzed in a separate NEPA process, including public review, and is approved by the Regional Forester and Forest Supervisor in a decision document. LB/CC

COMMENTS: DFPR, Page III-99, rewrite 4th item to read, "mechanized treatment of wood residue is eliminated."

1446

RESPONSE: The Revised Plan retains this statement. On a site-specific basis, this tool may be appropriate. JR

COMMENTS: Add the following words to the last sentence: "Only where salvage will improve AIZ."

1446

TIMBER - STANDARDS AND GUIDELINES

RESPONSE: Prescription 2.8.3 states, "Emphasis is directed at the application of ecological knowledge to restore and maintain the health of these areas in ways that also produce desired resource values, products, protection, restoration, enhancement, interpretation, and appreciation of these areas." Based on this direction, any activity in the AIZ is accomplished with the intention of maintaining or improving the condition. LB

COMMENTS: Remove the Standards and Guidelines section Logging System #2, since it is already part of Timber Sale Contracts and administered by a certified sale administrator.

283

RESPONSE: Although there is a contract clause about wet weather conditions, standards and guidelines provide the sale administrator with specific guidelines when resource damage occurs and when work should temporarily cease. LB

COMMENTS: Page III-122, 5.1 (b-c), change last paragraph to read, "By permit, from live and dead trees, designated . . ." There may be a need to harvest green trees, so why limit options?

283

RESPONSE: Your comment is acknowledged. The Revised Plan was changed to reflect this recommendation. LB

COMMENTS: Change Guideline 36 (sawtimber) from trees that are 9" in diameter dbh to trees that are 7" dbh.

283

RESPONSE: This comment refers to the definition of sawtimber in the glossary and is corrected in the Revised Plan. LB

TIMBER - UNSCHEDULED TIMBER HARVEST

Include ASQ From Unscheduled Harvest in 7.5 MMBF Per Year

COMMENTS: Include "unscheduled (EM) harvest" in 7.5 mmbf/yr. ASQ to remain within "sustainable" limits.

643, 658, 690, 693, 1194, 1381, 1401

Remove from the plan or include in the overall 3.7 mmbf/year ASQ allowed by the plan.

Include all EM harvest in the proposed ASQ of 3.7 MMBF.

337, 644, 658

RESPONSE: Unscheduled harvest is not counted in ASQ. Harvest volumes counted in ASQ come from suitable lands under a timber prescription. Unscheduled comes from forested lands in other than suitable-timber prescription lands. Unscheduled harvest is limited to a maximum of 2.0 MMBF per year in the Revised Plan. This amount is in addition to ASQ (8.0 MMBF) and firewood products (3.8 MMBF). The total of 13.8 MMBF potential is below the LTSY level of 22.0 MMBF. LB

TIMBER - UNSCHEDULED TIMBER HARVEST

Prohibit Unscheduled Harvests

COMMENTS: Prohibit unscheduled harvests for any experimental or ecosystem management purpose, especially on unsuitable lands, because it is the misapplication of ecosystem management; no rules or guidelines for its application are presented; focus should be to restore wildlife habitat, riparian areas and closing roads to protect wildlife, not on cutting trees and destroying wildlife habitat; logging does not mimic fire; logging should be sustainable; it's a "devious plan" to allow harvests, especially in areas generally unsuitable for timber production; you don't know the ramifications; you don't have an accurate Range of Natural Variation; and you haven't had a review by the scientific community or public.

F-G-1(475), F-H(8), F-J(3), F-K(4), 136, 161, 165, 167, 185, 196, 208, 212, 226, 280, 392, 396, 400, 405, 410, 438, 441, 496, 622, 631, 634, 636, 640, 643, 650, 652, 669, 690, 695, 766, 1194, 1197, 1203, 1241, 1258, 1270, 1277, 1313, 1327, 1330, 1368

RESPONSE: The Revised Plan allows unscheduled harvests and sets a cap of 2.0 MMBF/year. In order to meet ecosystem management principles for forest health, it may be necessary to treat forested lands that are not in the suitable base. ASQ provides the Forest with the means to treat suitable lands within a timber prescription. Unscheduled harvest covers the remaining forested lands, regardless of what prescription is applied. The Revised Plan does not mandate harvesting the unscheduled component. If unscheduled harvesting occurs, it is subject to the same laws, regulations, goals, objectives, standards and guides as ASQ harvest. Any proposal would use silvicultural prescriptions for identifying the need for harvest, and projects would be subject to site-specific NEPA analysis including disclosure of effects and public involvement. LB

Clarify/Limit Unscheduled Timber Harvest

COMMENTS: Clarify "experimental", "unscheduled", or "EM" harvests in regard to projected volume outside the ASQ; how it will improve wildlife and riparian conditions; impacts on MIS and other resources; and options for each prescription so that total impacts can be evaluated (Page III-70 and 72, Objectives 1 and 2).

161, 165, 167, 185, 228, 335, 669, 719, 766, 1257, 1258, 1276, 1364, 1365, 1368, 1369, 1371, 1446

Show how Em harvest fits into EM goals and establish rules or guidelines/criteria for unscheduled harvest.

280, 389, 644, 695, 1368

RESPONSE: The Revised Plan sets a maximum volume of 2.0 MMBF per year on other than ASQ lands. The number of acres depends on the treatment prescribed. Unscheduled harvest could be designed to meet specific ecological objectives, including wildlife habitat needs and would be subject to all laws, regulations, goals, objectives, standards and guides. The Revised Plan does not mandate the harvesting of the unscheduled component. Resource need must be shown, NEPA accomplished, and public review assured. Effects on wildlife will be addressed in a site-specific NEPA analysis. LB

TIMBER - UNSCHEDULED TIMBER HARVEST

COMMENTS: Set an upper limit/volume/acreage on unscheduled timber harvest and analyze environmental consequences of estimated level of unscheduled quantity to meet NEPA requirements.

Consider a cap of 1/2 to 1 MMBF as a maximum harvest for EM concerns.

143, 1273b

RESPONSE: An upper limit of 2.0 MMBF per year was set for unscheduled timber harvest in the Revised Plan. Unscheduled timber harvest is subject to NEPA. LB

COMMENTS: Eliminate stand maintenance logging, including sanitation and salvage, in habitat reserved for TES, in ceremonial areas sacred to Native Americans, wild and scenic viewsheds, and in designated back country areas.

1365

RESPONSE: All vegetation treatments in these areas will be analyzed through the NEPA process and include public participation. The goals and objectives and standards and guidelines in the Revised Plan address these concerns. LB

COMMENTS: Show how Forest will use unscheduled harvests in Douglas-fir stands where patch sizes exceed presumed historical patch size.

643

RESPONSE: Unscheduled harvest allows the Forest Service to treat forested areas outside of suitable acres. Each project would be site-specific and may be on a different scale (subsection, watershed, subwatershed, etc.) LB

Incorporate Public Review Process for Unscheduled Harvest

COMMENTS: Incorporate an adequate public review process for harvest outside the ASQ to ensure required public involvement.

644, 1273b, 1276

RESPONSE: All unscheduled harvest projects are subject to the same analysis and review as scheduled (ASQ) harvest, including disclosure of environmental effects and public involvement. LB

COMMENTS: Establish a working group of scientific advisors outside the Forest Service to assist in adaptive decision-making required of ecosystem management.

161, 1276

RESPONSE: The Targhee is currently involved in several cooperative efforts with various scientists and universities. On-going opportunities, such as the NEPA process, grants/agreements, and memorandums of understanding, allow the Targhee to benefit from collaboration with the scientific community.

LB/AM/JR

WILD AND SCENIC RIVERS

General Issues

COMMENTS: Support the 249 miles of eligible sections designated for wild and scenic status, including Henry's Fork and South Fork of the Snake River. These areas deserve protection because: they are unique and are some of the most famous rivers in North America; provide a basis for future protection; protect rivers for children/grandchildren; streams and rivers located in the Targhee deserve additional protection; protect damaged streams and waterways by designating as Wild and Scenic vital; for human health, historical significance, recreation, aesthetics and wildlife, specifically fish rearing and spawning; and the economic benefits received from fisherman who would use the Wild and Scenic Rivers. Support legislation for protection of our fish and wildlife that use our rivers. Do not support any dam proposal because of the environmental damage to fish and wildlife in river. Want more wild & scenic designation.

F-B(4), F-H(8), F-J(3), F-K(4), 60, 136, 157, 159, 162, 168, 174, 175, 178, 179, 180, 181, 185, 190, 195, 201, 203, 209, 212, 226, 244, 252, 271, 273, 318, 356, 360, 368, 377, 379, 382, 391, 396, 398, 400, 405, 408, 411, 424, 430, 433, 441, 443, 490, 491, 492, 494, 516, 518, 519, 609, 621, 622, 626, 629, 630, 640, 650, 651, 652, 653, 655, 659, 666, 690, 695, 697, 725, 726, 739, 1207, 1243, 1245, 1257, 1258, 1270, 1273, 1275, 1277, 1327, 1381, 1383, 1388, 1392, 1393, 1395, 1443

RESPONSE: The Forest agrees that many of the streams on the Targhee are unique and should be studied for additional protection. The Revised Forest Plan recommends streams for suitability studies. The designation of streams is determined by Congress based on recommendations of the suitability studies. The Wild and Scenic Rivers Act was established to preserve outstanding resource values in unique quality streams. Damaged streams will receive recognition and protection through the 2.8.1-3 aquatic influence zone prescriptions. The Wild and Scenic Rivers Act protects the existing resource value. In the Forest analysis, McCoy Creek's 3.5 miles were determined ineligible based on a joint analysis with the Caribou National Forest. The Forest ended up with 245.5 miles of eligible in Final Revised Plan. AS

COMMENTS: Oppose the 249 miles of eligible wild and scenic sections.
368, 391

RESPONSE: The Forest is required to study qualifying streams and rivers under the direction of the Wild and Scenic Act. Forest analysis indicates that the listed streams were eligible. Once eligible, the law requires protection of the streams until suitability studies and recommendations to Congress are completed. AS

Analysis Process

COMMENTS: Make eligibility studies a priority and support the completion of these studies by 2002.

1273a

WILD AND SCENIC RIVERS

RESPONSE: These suitability studies are a priority and funding requests to perform them have been made for several years. No funding has been received. Alternative approaches for completing the studies are being explored. AS

COMMENTS: Develop a single management prescription for all land, including rivers, in the South Fork corridor using the Snake River operations plan, incorporating BLM grazing criteria; adjust boundaries to restrict cattle; and address issue of trespass of cattle from the Targhee National Forest trespassing on BLM lands.

643, 766

RESPONSE: The two prescriptions for the South Fork address these concerns. Two prescriptions are necessary to cover the potential scenic and recreational segments of the river. Grazing issues are addressed in both prescription guidelines. AS

Prescriptions

COMMENTS: The prescription for the South Fork of the Snake should incorporate prescriptions for all scenic and recreational rivers on the forest, in addition to those addressed in 2.9.1 and 2.9.2.

1273a

RESPONSE: The scenic and recreational river prescriptions used elsewhere on the forest form the basic building blocks for prescription 2.9.1 and 2.9.2. The latter two prescriptions are specific to the South Fork; they can not reflect all of the language from the prescriptions used elsewhere on the forest. AS

COMMENTS: Recommend a prescription for candidate rivers that addresses prohibiting water supply dams, major diversions, flood control dams, levees and development of hydroelectric facilities; prohibit new trails or roads in the river corridors; close non system and existing system roads; prohibit timber harvest; allow salvage of insect-infested timber only if no adverse effects; and allow dispersed recreation only if no adverse effects are noted.

1273a

RESPONSE: The intent of the management direction and standards and guidelines of each of the five Wild and Scenic Rivers prescriptions is to provide interim protection such as that listed above. AS

COMMENTS: Present an evaluation of data on the impacts of jet skiing on nesting bald eagles.

1446

RESPONSE: The Forest considered the effects of jet skiing. The limited amount of use at the present time results in minor effects on bald eagles in comparison to the large number of jet boats and rafts. Restriction of use is generally the county's option, due to the amount of private land ownership in the area. AS

WILD AND SCENIC RIVERS

Other Agencies

COMMENTS: Reevaluate the eligibility of the Henry's Fork and South Fork Snake because of the results in the State of Idaho Comprehensive Basin Plans. Ensure the Idaho Water Resource Board designations are incorporated in the plan.

766, 1207, 1276

RESPONSE: The planning analysis and decisions for the various Basin Studies will be developed in future suitability studies. Current decisions on eligibility fully considered the Idaho Water Resource Board analysis and state legislative actions.

While there is some difference in analysis systems values, State interests are protected by eligibility and prescription designation. The Forest added this reference to chapter III - Wild & Scenic Rivers. Refer to the Wild & Scenic Rivers Process Paper for details on proposed segments and classifications. The Forest has also added a sentence to Chapter IV to show that the proposed eligibility classification and management prescriptions will protect the values identified in State designations. AS

COMMENTS: The Idaho Water Resource Board does not support federal wild and scenic designation currently designated or being recommended as State Natural or Recreational Rivers.

1207

RESPONSE: The Forest acknowledges your concern. The Wild and Scenic Rivers Act requires the Forest to provide an analysis and protection of the resource values found to be eligible. AS

Goals/Objectives

COMMENTS: The definition for goals for Wild and Scenic Rivers should be to maintain free flowing and outstanding values, and not only show a reflection of the amount of development. Provide objectives that have adequate direction to protect their outstanding values including the following: no mineral, oil or gas exploration should be allowed as directed by NEPA and Wild and Scenic Rivers Act; no new mining claims or mineral leases with 1/4 mile of wild rivers; and enforce the Wild and Scenic Act that prohibits management activities that threaten outstanding values, even when activities are conducted beyond 1/4 mile corridors especially as related to ORVs. Delete both objectives for recreational rivers because they protect off-road vehicles, not forest health.

1273a

RESPONSE: The prescription direction for each of these potential streams will maintain and protect the outstanding resource values. The prescription and manual and handbook policies provide direction in relation to all these concerns. Oil and gas leasing is allowed with conditions. The purpose of the objectives is to maintain the outstanding resource values. If those are maintained, forest health is maintained. AS

Standards & Guides

COMMENTS: Insert the objectives, standards and guidelines for wild, scenic, recreational rivers and visual quality after standards and guidelines for winter recreation.

1446

RESPONSE: Visual Quality Goal, Standards and Guidelines to follow Winter Recreation in the Forestwide Standards and Guidelines Chapter of the Revised Forest Plan (Chapter 111-Part I). Wild, Scenic and Recreational Rivers are handled with the Management Prescription (Chapter 111-Part 3). AS

DFPR

COMMENTS: Change or add the following to the Revised Plan: ensure that cross country motorized use is prohibited in Wild and Scenic River areas; include interim standards and guidelines to assure protection of wild, scenic and recreational rivers; change current wordage in dispersed recreation and timber salvage to avoid adverse effects to rivers to ensure protection of candidate river values until suitability studies are completed; address management direction used from the Snake River Activity/Operations Plan 1991 including domestic livestock grazing. (CROSS REFERENCE: Access, Timber, Recreation, Range)

494, 518, 626, 643, 766, 1203, 1273b

RESPONSE: Cross-country motorized use is prohibited in these prescriptions. The prescriptions for these rivers provide the interim direction needed to protect the resource values until suitability studies are completed and recommendations can be made on designation. The Snake River is addressed with two prescriptions that correspond to the Activity/Operations Plan direction.

COMMENTS: Recommend following revisions to DFPR in regard to Wild and Scenic Rivers: Page 3-75 through 3-86 - All eligible wild, scenic, and recreation rivers should be managed as though they had already obtained the appropriate designation; Pg. 3-75, Fire/Fuels - the guideline should be a standard; Pg. 3-76, Land - the guideline should be a standard; Pg. 3-76, Soil and Water - both guidelines should be a standard; Pg. 3-76, Lands - the guideline should be a standard; Pg. 3-76 and 3-77, Minerals/Geology - Guidelines 1,6,7 and 10 should be standards; Pg. 3-77, Fish and Other Aquatic Resources - the guideline should be a standard; Pg. 3-78, Recreation - the guidelines should be standards; Pg. 3-80, Fire/Fuels - the guideline should be a standard; Pg. 3-80, Insects and Disease - the guideline should be a standard; Pg. 3-80, Soil and Water - the two guidelines should be standards; Pg. 3-84, Soil and Water - the second and third guidelines should be standards. The standard regarding reestablishing vegetation should state "Whenever possible" instead of the phrase "consider the use of."; Pg. 3-82, Range - the first two guidelines should be standards; Pg. 3-85, the dispersed recreation guideline should be a standard. Cross-country snowmobile travel should not be allowed. The first Trails guideline should be a standard. The ROS guideline should be a standard mandating semi-primitive motorized; Pg. 3-86, The Outfitter Guide guideline should be a standard. The Timber guideline should be a standard.

1365

WILD AND SCENIC RIVERS

RESPONSE: These recommendations were considered, but no changes were made to the standards or guidelines. The direction as written is adequate to protect these streams until suitability studies are completed. Special changes can be made at the time suitability studies are completed, or when the individual river plans are written following designations. AS

COMMENT: Pg. 3-78, Access - No motorized activity should be allowed, regardless of historic use patterns.

1365

RESPONSE: Motorized use is usually allowed at historic levels until designation through legislation or individual river planning determines motorized use is inappropriate. This is not a decision appropriate for a comprehensive plan and is best addressed on a site-specific basis. AS

COMMENTS: Pg. 3-78, Timber - the second standard should include a provision requiring that the danger from fire or some other environmental phenomenon must be imminent in order to justify harvesting trees.

1365

RESPONSE: The guideline says, "will not be allowed except..." The conditions outlined and the specific circumstances at the time of a future decision will control the outcome; therefore, no additional clarification is warranted at this time. AS

COMMENTS: Pg. 3-81, Roads - Modify this standard to mandate the obliteration of roads that are likely to cause or are causing negative resource impacts. Pg. 3-82, Recreation - Modify the standard regarding the construction of trails to mandate the obliteration of roads that are likely to cause or are causing negative resource impacts. The ROS guideline should be a standard.

1365

RESPONSE: Changes to road use are determined by the suitability study and river management plan if the river is designated by Congress. This type of direction is not appropriate for a comprehensive revised plan and is best addressed in site specific analysis. AS

COMMENTS: Page 3-84, Biological Elements - stocking of non-native species should be prohibited.

RESPONSE: The Targhee allows it where it is pre-existing. AS

Site-Specific

COMMENTS: Recommend the following rivers and tributaries for wild and scenic designation: Targhee Creek; South Fork of Snake between Conant Valley and Burns Creek, including Palisades and Burns Creek; Teton Creek (North, South, Roaring Forks); Targhee Creek; Henry's Fork; Bitch Creek; Pine Creek; Darby Creek; Fall River; Trail Creek; Palisades Creek; Big Elk Creek; Bear Creek North Fork; Waterfall Canyon, including upper ends of Big Elk and Palisades; McCoy Creek, Warm River; Robinson Creek; Buffalo River; Little Dam River; Moose Creek; Deadman Creek; West/North Pine Creek; and Rainey Creek. The only

WILD AND SCENIC RIVERS

Wild, Scenic, or Recreational River identified by name in the DEIS is South Fork of the Snake. Clarify if 3M, or any alternative, would protect all other eligible segments.

F-K(4), 276, 282, 448, 631, 632, 643, 655, 662, 664, 695, 726

RESPONSE: The eligibility determination analysis is documented in the Wild and Scenic Rivers Process Papers. Most of these streams are listed as eligible for suitability study and are protected by prescriptions until the suitability studies are completed. All eligible stream segments were listed in the appropriate prescription descriptions in the Final Plan.

Targhee Creek is recommended for classification as wild. The section of the South Fork of the Snake between Conant Valley and Burns Creek is eligible and is recommended in two segments: the upper as scenic, the lower as recreational. No outstanding resource values are determined to exist for Rainey Creek, therefore, it was not included as eligible for study. Burns Creek is recommended for scenic classification. The Forest considered the entire stretch of upper Big Elk, Upper Palisades, and Waterfall Creek. Final suitability studies may adjust the length of these segments. All eligible segments will be protected by their prescription direction so that resource values will be maintained for potential designation if suitability studies so indicate. AS

Specific Comments

COMMENTS: Provide maximum protection to Henry's Fork and South Fork - Snake River, Fall River, Bitch Creek, Trail Creek, Palisades Creek, Big Elk Creek, Bear Creek because they are threatened by hydro electric projects.

664

RESPONSE: All of these streams except Trail Creek were listed as eligible for Wild and Scenic Rivers suitability study. Therefore, they would receive the protection allowed under their proposed classifications, until suitability studies are completed. AS

COMMENTS: Bear Creek and Burns should qualify as a Wild River 2.3 rather than a Scenic River 2.4.

695

RESPONSE: The final determination will be made during the suitability study. AS

COMMENTS: Restore and protection of Yellowstone Cutthroat in Robinson Creek and Fall River.

1258

RESPONSE: Additional standards and guidelines, goals and objectives for cutthroat trout are added to the Revised Plan in order to study and protect them. AS

WILD AND SCENIC RIVERS

Alternatives

COMMENTS: Do not treat all the Wild and Scenic segments the same in all alternatives because the Forest will not commit to the eligibility study. Targhee and Robinson Creeks should be deleted from eligibility classification in Alternative 2 because a decision by the National Marine Fisheries, Environmental Protection Agency, and United States Fish and Wildlife Service direct that not all alternatives need to have a single comprehensive conservation strategy.

413, 767

RESPONSE: If a stream segment is determined eligible, it must be eligible in all alternatives until suitability studies are completed. This is necessary to protect resource values required by the Wild and Scenic Rivers Act. AS

COMMENTS: Support proposal for Bitch Creek and recommend the Forest include Teton and Darby Creeks on Alternative 3M maps as in former DFC Alternative.

RESPONSE: These streams have always been included in the Forest's eligibility table. See the Wild and Scenic Rivers process paper. Some display maps have not shown all segments due to other prescriptions which pre-empted displaying the Wild and Scenic River prescriptions. All eligible streams are now shown on the roadless map in the Final Revised Plan. AS

Access General

COMMENTS: Restrict and regulate motorized use in and around wild and scenic and recreational rivers: prohibit helicopter landing in wild and scenic corridors; exclude jet skiing from South Fork of the Snake River; prohibit motorized use in wild and scenic rivers and but allow in recreational rivers; allow access to wild and scenic rivers as defined in South Fork of the Snake activity plan.

136, 159, 180, 203, 273, 356, 494, 518, 630, 650, 652, 1270, 1388,
1446

RESPONSE: Helicopter landings are rare and are usually allowed only for administration activities such as fire fighting. Cross-country motorized use is prohibited within these prescriptions. Decisions on jet-skiing are made in the legislation, in the river plan after designation, or by County legislation as was done for the Henry's Fork. AS

COMMENTS: Recommend interim management of Robinson Creek, Warm River and Pine Creek that would prohibit motorized boat use unless previously allowed.

477

RESPONSE: The Forest is unaware of any motorized use currently or historically occurring on these streams. The management direction in the various wild and scenic prescriptions should prevent any adverse effects on river values. AS

WILD *AND* SCENIC RIVERS

COMMENTS: Clarify motor bike restriction of OROMTRD 0.0 mi./sq.mile for eligible wild rivers.

1273b

RESPONSE: This means there will be no designated travel routes open to motorized use within the 2.3 prescription area. AS

WILDERNESS

Supports Wilderness Designation

COMMENTS: Support wilderness proposals because wilderness designation limits motorized access and resource extraction in those areas and such activities lead to degradation of riparian areas and wildlife habitat, negative visual impacts, noise and odor from motorized vehicles, water quality impacts, and general loss of ecosystem integrity. If allowed in roadless or wilderness study areas, motorized use becomes historic and sets a precedent for continued use. (CROSS REFERENCE: Access)

F-G-1(475), F-G-P(1), F-H(8), F-J(3), 34, 42, 150, 161, 162, 165, 168, 171, 179, 189, 206, 213, 242, 273, 280, 331, 359, 377, 382, 392, 396, 398, 400, 405, 424, 439, 444, 491, 516, 607, 609, 611, 613, 620, 622, 627, 636, 640, 643, 644, 650, 653, 656, 666, 690, 725, 727, 731, 1185, 1194, 1205, 1266, 1243, 1273b, 1275, 1276, 1327, 1365, 1382, 1395, 1443, 1458.

Support wilderness for wildlife, recreation, future, and economics. Keep options for future uses or future generations; preserve the habitat and opportunity for genetic exchange for various species including TES; keep opportunities for solitude, quiet, aesthetic and intrinsic values in pristine land. Preserve because humans cannot reconstruct the diversity of a land which took thousands of years to evolve in all its complex interrelationships. Politicians and industry have too much influence; revenues lost from resource extraction in wilderness areas will be offset by income from visitors; there are sufficient areas for sustainable logging even with more designated wilderness. (CROSS REFERENCE: Economics, Timber)

F-G-1(475), 73, 136, 137, 156, 157, 158, 168, 173, 174, 175, 176, 178, 180, 181, 189, 196, 201, 252, 276, 293, 318, 321, 328, 339, 340, 354, 356, 357, 359, 373, 379, 382, 405, 453, 491, 527, 610, 613, 620, 627b, 638, 640, 651, 668, 695, 730, 739, 1185, 1197, 1242, 1265, 1270, 1271, 1327, 1330, 1331, 1337, 1348, 1364, 1364, 1367b, 1371, 1381, 1393

RESPONSE: Support and rationale for wilderness recommendation and designation were noted and considered. These concerns were also identified and considered during the issue and desired future condition analysis for the EIS. AS

COMMENTS: Want more wilderness areas than are being proposed, or more than any of the alternatives because the amount of wilderness area proposed is not adequate for wildlife, biodiversity, or refuge. Make all of Targhee National Forest wilderness.

136, 276, 293, 620, 1273b, 1365

RESPONSE: Your comments were noted and considered. Additional analysis of recommended wilderness is documented in the FEIS to more clearly show the basis for recommendations. As a result, a portion of the Diamond Peak roadless area is recommended for wilderness designation in the Revised Plan. Other modifications of alternatives to recommend more wilderness are discussed under responses in the Alternatives comments Section of Appendix A in the FEIS. An additional Alternative 5M with considerably more recommended wilderness is documented in Chapter II of the FEIS. After consideration, it was dismissed from detailed analysis. AS

WILDERNESS

COMMENTS: Support wilderness designations.

F-B(4), F-G-1(475), F-G-P(1), F-G-P(3), F-G-P(4), F-G-P(5), F-H(8), F-J(3), F-K(4), 11, 32, 34, 39, 42, 45, 52, 62, 68, 73, 136, 143, 150, 156, 157, 158, 161, 162, 163, 165, 168, 171, 173, 174, 175, 176, 178, 179, 180, 181, 184, 185, 189, 192, 193, 196, 201, 203, 204, 206, 209, 210, 211, 212, 213, 219, 226, 227, 242, 252, 273, 276, 278, 280, 292, 293, 305, 317, 318, 321, 328, 331, 339, 340, 354, 356, 357, 359, 361, 362, 368, 370, 373, 376, 377, 379, 380, 382, 389, 392, 396, 398, 400, 405, 410, 411, 424, 430, 439, 441, 443, 444, 453, 491, 492, 496, 516, 519, 527, 607, 609, 610, 611, 613, 615, 620, 621, 622, 625a, 627b, 631, 632, 636, 638, 640, 643, 644, 650, 651, 652, 653, 656, 658, 659, 662, 664, 666, 668, 668, 687, 690, 695, 697, 725, 727, 730, 731, 736, 739, 1185, 1194, 1195, 1197, 1202, 1205, 1206, 1241, 1242, 1243, 1257, 1265, 1266, 1269, 1270, 1271, 1273b, 1275, 1276, 1312, 1313, 1314, 1325, 1327, 1328, 1330, 1331, 1337, 1348, 1360, 1361, 1364, 1365, 1367b, 1368, 1371, 1374, 1381, 1382, 1392, 1393, 1395, 1401, 1443, 1458

RESPONSE: These support letters were noted and considered. AS

Supports Wilderness - Alternatives 3M, 4, 5, 6

COMMENTS: Favor amounts of wilderness in Alternative 3M or 4 because it represents a good balance. Favor wilderness proposals in Alternatives 5 or 6 because more wilderness is recommended. Wants more wilderness than any of the alternatives. Support more wilderness because, once lost to development, wilderness can not be recreated; increasing populations place heavier demands on less and less wilderness; more wilderness is necessary to protect biodiversity, wildlife corridors, and habitat; and the American public consistently votes to preserve more wilderness. (CROSS REFERENCE: Alternatives)

F-G-P(4), F-K(4), 11, 32, 39, 52, 62, 143, 211, 227, 293, 305, 331, 354, 356, 359, 389, 496, 609, 610, 625, 664, 668, 695, 1185, 1325, 1348, 1365, 1374, 1395

RESPONSE: Your comments were noted and considered. Additional analysis of recommended wilderness is documented in the FEIS to more clearly show the basis for recommendations. As a result, a portion of the Diamond Peak roadless area is recommended for wilderness designation in the Revised Plan. An additional Alternative 5M with considerably more recommended wilderness is documented in Chapter II of the FEIS. After consideration, it was dismissed from detailed analysis. (For more discussion about modifying alternatives to add more wilderness, see Alternatives.) AS

Alternative 2 - Non Support

COMMENTS: The statement that Targhee National Forest Alternative 2 commodity emphasis on Targhee Creek does not match with the Gallatin National Forest proposal does not consider the opposition, by such as Senator Burns, to making that area of Gallatin into a wilderness designation.

WILDERNESS

RESPONSE: Both ASQ/non-wilderness and non-ASQ/wilderness options were considered in the various alternatives for Targhee Creek. The wilderness recommendation prescription was selected in the Preferred Alternative for reasons documented in the Roadless Process Paper and Appendix A of the FEIS. AS

COMMENTS: If the land use proposal in Alternative 2 is inconsistent with wilderness proposals of the Targhee National Forest and Gallatin National Forest, this indicates Alternative 2 is flawed and the Targhee National Forest is failing to coordinate with surrounding land management agencies.
1365

RESPONSE: Alternative 2 was an alternative considered. It was not selected as the Preferred Alternative. AS

Alternative 3M - Non Support

COMMENTS: Modifying Alternative 3M to further restrict timber harvest and place in "no ASQ" all roadless areas not placed in wilderness, in order to better protect and move ahead to place in wilderness.
643

RESPONSE: This was considered in other alternatives but was not selected. AS

Supports Wilderness - Specific Areas

COMMENTS: Recommend Diamond Peak as wilderness because it: meets the requirements of wilderness; is a scenic area, notable for limestone natural arches and exposed folds of sedimentary rock; provides great wildlife habitat; offers geological, ecological, scientific, educational, and historical interest; and retains its primeval character in spite of livestock grazing.

F-B(4), F-G-P(3), F-H(8), F-J(3), 157, 163, 165, 174, 175, 179, 180, 181, 185, 192, 193, 203, 209, 210, 226, 273, 278, 359, 368, 377, 379, 382, 392, 396, 398, 400, 405, 411, 424, 430, 441, 443, 444, 491, 492, 496, 516, 519, 621, 622, 640, 643, 651, 652, 653, 664, 690, 695, 717, 739, 1194, 1197, 1202, 1241, 1243, 1257, 1275, 1327, 1328, 1330, 1331, 1337, 1368, 1381, 1401, 1443

Recommend all the Centennials because it is a crucial wildlife corridor of the Greater Yellowstone Ecosystem and a scenic, pristine area.

F-G-1(475), F-G-P(1), 136, 165, 174, 178, 179, 180, 193, 204, 209, 212, 226, 362, 496, 613, 621, 644, 653, 695, 725, 1206, 1257, 1270, 1327, 1331, 1392, 1458

Recommend Mount Jefferson in the Centennials because of its beauty and grizzly bear habitat. It was considered for wilderness once before and should be again.

F-B(4), F-GP(2), F-H(8), F-J(13), 19, 136, 143, 157, 163, 165, 174, 179, 180, 181, 185, 192, 193, 209, 210, 226, 273, 278, 359, 368, 377, 379, 382, 396, 398, 400, 405, 411, 424, 430, 441, 443, 444, 491, 492, 496, 516, 621, 622, 640, 643, 651, 652, 653, 690, 695, 727, 739, 1194, 1197, 1206, 1241, 1243, 1275, 1327, 1328, 1330, 1331, 1337, 1368, 1381, 1382, 1395, 1401, 1443

WILDERNESS

Support Garn's Mountain as wilderness because it is a crucial wildlife habitat and represents the main watershed for the Snake River.

F-B(4), F-G-P(3), F-H(8), F-J(3), 136, 157, 163, 165, 174, 179, 180, 181, 185, 192, 193, 209, 210, 226, 273, 278, 359, 368, 377, 379, 382, 396, 398, 400, 405, 411, 424, 430, 441, 443, 444, 491, 492, 496, 516, 621, 622, 640, 643, 651, 652, 653, 690, 695, 722, 739, 1194, 1197, 1206, 1241, 1243, 1275, 1327, 1328, 1330, 1331, 1337, 1368, 1381, 1382, 1395, 1401, 1443

Other areas supported for wilderness designation are: Garfield Mountain, Bell Mountain, Lemhi Mountains, Lionhead, Winegar Hole, Caribou Mt. area, Poker Peak, Bear Creek, Snake River area, west slope of the Tetons, and Jackpine Creek because these areas have outstanding geological, ecological, scientific, educational, and/or historical characteristics; and are important to wildlife.

163, 204, 210, 212, 362, 376, 410, 643, 644, 658, 664, 687, 695, 725, 727, 736, 1185, 1194, 1206, 1270, 1276, 1312, 1330, 1331, 1337, 1361, 1365, 1368, 1395, 1401.

Support for wilderness: Italian Peaks (one of the locations proposed by Alternative 3M as wilderness); all of the Palisades (not just the two-thirds being recommended in alternative 3M); all the areas recommended in the 3M proposal, and the existing Jedediah Smith Wilderness area because these areas are crucial for wildlife and watershed, and the Forest must work to protect the outstanding values.

F-B(4), F-G-P(3), F-H(8), F-J(3), 68, 136, 157, 161, 165, 174, 179, 180, 185, 187, 193, 203, 204, 209, 210, 226, 273, 278, 331, 356, 359, 361, 362, 368, 370, 376, 377, 379, 382, 396, 398, 400, 405, 410, 411, 424, 430, 441, 443, 444, 491, 492, 496, 516, 519, 615, 621, 622, 632, 640, 643, 651, 653, 658, 659, 662, 664, 687, 690, 695, 725, 727, 739, 1185, 1194, 1197, 1202, 1206, 1241, 1243, 1257, 1275, 1312, 1314, 1327, 1328, 1330, 1331, 1337, 1360, 1368, 1381, 1382, 1392, 1395, 1401, 1443.

Support wilderness designation - specific areas.

F-B(4), F-G-1(475), F-G-P(1), F-G-P(2), F-G-P(3), F-G-P(5), F-H(8), F-J(3), 68, 136, 143, 157, 161, 163, 165, 174, 175, 179, 180, 181, 185, 192, 193, 203, 204, 209, 210, 212, 226, 273, 278, 292, 331, 356, 359, 361, 362, 368, 370, 376, 377, 379, 380, 382, 396, 398, 400, 405, 410, 411, 424, 430, 441, 443, 444, 491, 492, 496, 516, 519, 613, 615, 621, 622, 640, 632, 643, 644, 651, 652, 653, 658, 662, 664, 687, 690, 695, 725, 727, 736, 739, 1185, 1194, 1197, 1202, 1206, 1241, 1243, 1257, 1270, 1275, 1276, 1312, 1314, 1327, 1328, 1330, 1331, 1337, 1360, 1365, 1368, 1381, 1382, 1392, 1395, 1401, 1443, 1458

RESPONSE: The Forest considered your comments. After a review and update of the wilderness characteristics in the Roadless Process Paper, the Forest added a large portion of the Diamond Peak area as recommended wilderness in the Preferred Alternative (3M) because this area's high wilderness characteristics rating is similar to the other wilderness areas recommended in the Revised Plan. No other changes were made in recommended wilderness prescription areas. This is because no other areas rated high enough on the updated wilderness characteristics rating except for Garns Mountain which was dedicated to a motorized use prescription rather than to recommended wilderness. AS

WILDERNESS

Prohibit Recreation in Wilderness

COMMENTS: Eliminate/prohibit trailhead facilities from opportunity Class 1 areas (wilderness).

1312

RESPONSE: Trailhead facilities are not included within the Class I areas, and the reference to constructed trailhead facilities was removed from the three wilderness prescriptions since facilities are not allowed within the wilderness. Developed trailheads are in Prescription 4.1. AS

Oppose Wilderness Designation

COMMENTS: Oppose additional wilderness on the Targhee, or the entire concept of designated wilderness areas because: wilderness designation imposes restrictions on access; limits recreational use of motorized vehicles in wilderness (OHVs and snowmobiles); possibly restricts mountain bikes, horses, and numbers of hikers; and restricting access in some areas will increase the demand, impacts, and conflicts on those areas that are unrestricted.

F-C(13), F-I(4), F-O(4), 28, 29, 30, 34, 42, 50, 55, 63, 214, 270, 280, 285, 286, 300, 314, 323, 353, 358, 366, 367, 380, 381, 385, 386, 412, 413, 473, 474, 476, 495, 506, 521, 524, 529, 608, 614, 626, 627, 638, 645, 664, 665, 702, 704, 738, 1183, 1332, 1375, 1385, 1447, 1454

Restricting motorized access discriminates against those who are physically unable to hike or pack in. (CROSSREFERENCE: Access)

46, 488, 1332

RESPONSE: It is true that if the areas recommended for wilderness consideration are designated wilderness by Congress that motorized uses in those areas are displaced to adjacent areas or the users might stop participating. This situation is discussed in the Cumulative Effects Analysis for summer access in Chapter IV of the FEIS. AS

COMMENTS: Wilderness provides no management options.

665

RESPONSE: This is not correct. There are several options for management of range, wildlife, water, recreation, fire, and so forth. AS

Allow Recreation in Wilderness

COMMENTS: Oppose wilderness designations because wilderness imposes limits on recreationists and Forest management efforts. Manage wilderness as recreation areas; designate more land to accommodate recreation pressure in the back country; maintain roadless areas because they are vital to recreation.

643, 665, 1377, 704, 291

RESPONSE: It is true that wilderness designation results in the need for careful management of recreation use to prevent adverse effects on wilderness. However, these areas are sensitive to use impacts and must be managed regardless of the wilderness designation. Therefore there is little loss of recreation opportunity. AS

WILDERNESS

COMMENTS: Snowmobile use is not a major threat in wilderness areas and should be allowed. (CROSS REFERENCE: Snowmobiles)

280, 476

RESPONSE: This would be contrary to the Wilderness Act which prohibits any motorized use. AS

Economic Concerns

COMMENTS: Concerned about loss of economic opportunity due to potential wilderness designation including: limits on uses of timber, minerals, and other such forest resources; impacts on ranchers from grazing reductions; negative impacts on snowmobile and ATV sales and rentals; impacts on hut skiing and heliskiing operations; and revenues lost to local communities. (CROSS REFERENCE: Economics)

F-C(13), F-E(2), 12, 214, 281, 285, 405, 412, 521, 638, 665, 738

RESPONSE: The Forest considered these factors in the estimation of effects on local economies. Some motorized use is permitted in recommended wilderness where it will not impair wilderness character. The Forest acknowledges possible shifts in the types of recreation opportunities and expanded the consequences section of the EIS to reflect this. Overall, recreation on the Forest is expected to remain an important factor in the local economies. DP

COMMENTS: Provide information on how commercial/recreational use (hut skiing operation) fits into future plans for proposed wilderness. (CROSS REFERENCE: Recreation)

191

RESPONSE: Guided skiing operations would be allowed to continue. Facilities such as huts would not be allowed in the wilderness. AS

COMMENTS: Additional wilderness designation creates negative economic impact on heliskiing business already impacted by 1984 Wyoming Wilderness Bill. (CROSS REFERENCE: Recreation)

281

RESPONSE: The Forest has noted this potential in our documentation of consequences of recommended wilderness for the Palisades areas in Chapter IV of the FEIS. AS

Predator Control

COMMENTS: Concerned about predator control for livestock in wilderness.

1354

RESPONSE: According to the direction specified in the 1996 APHIS-ADC environmental assessment for predator damage in southern Idaho, predator control activities will be conducted on the Forest. The 1996 APHIS-ADC environmental assessment incorporates the existing Targhee National Forest direction. WG

WILDERNESS

COMMENTS: Reducing grazing due to wilderness would probably be illegal, according to 1980 "Colorado Grazing Guidelines".

643

RESPONSE: There is no proposal in the Revised Plan or FEIS to reduce grazing because of wilderness recommendations. AS

Already Enough Wilderness

COMMENTS: There is already enough or more than enough wilderness in Idaho or this area of the country; no one can use wilderness; local decisions should be made by and/or for local interests; environmentalists have too much influence.

F-C(13), F-F(6), F-G-2(2), 1, 12, 20, 26, 43, 45, 205, 229, 251, 258, 265, 270, 272, 287, 288, 291, 298, 300, 311, 346, 347, 348, 352, 358, 371, 388, 413, 423, 431, 468, 470, 488, 501, 520, 607, 614, 642, 646, 665, 661, 693, 720, 1200, 1239, 1317, 1332, 1335, 1448, 1454.

RESPONSE: The wilderness recommendations in the Revised Plan are based on a review of wilderness characteristics and public concerns for roadless areas as expressed in the Desired Future Condition (DFC). Final determination of whether these areas are designated is determined by the public through their elected delegations. In the interim, management and recreational opportunities or resource conditions will remain essentially unchanged from existing conditions. AS

Other/Better Management Plan

COMMENTS: Use other management options, such as educating people how not to negatively impact the land. Use local people because they will protect their interests in the land. Control impacts through regulation, not wilderness designation. Oppose preserving areas for grizzly bears. Designating wilderness is pointless because areas are too small for wildlife or ecosystem protection.

22, 32, 33, 34, 49, 51, 52, 53, 54, 55, 248, 272, 277, 285, 298, 315, 319, 324, 358, 363, 369, 375, 420, 432, 472, 512, 627a, 630, 638, 642 665, 1190, 1240, 1261, 1335, 1341, 1378.

RESPONSE: The wilderness recommendations in the Revised Plan are based on a review of wilderness characteristics and public concerns for roadless areas as expressed in the Desired Future Condition (DFC). Final determination of whether these areas are designated is determined by the public through their elected delegations. In the interim, management and recreational opportunities or resource conditions will remain essentially unchanged from existing conditions. AS

COMMENTS: Guarantee wilderness viability for the future, and do not leave a legacy of irreversible damage because we are fortunate, in the U.S., to still have wild lands.

252

RESPONSE: The wilderness plan proposed for the Jedediah Smith Wilderness will adequately protect the wilderness values. AS

COMMENTS: oppose wilderness designations.

F-C(13), F-E(2), F-F(6), F-G(2), F-I(4), F-O(4), 1, 2, 5, 6, 12, 20, 21, 22, 25, 26, 27, 28, 29, 30, 32, 33, 34, 35, 36, 37, 39, 40, 41, 42, 43, 45, 46, 49, 50, 51, 52, 53, 54, 55, 63, 165, 173, 182, 205, 214, 229, 243, 248, 251, 258, 265, 270, 272, 277, 280, 281, 285, 286, 287, 288, 291, 292, 293, 296, 298, 300, 307, 311, 314, 315, 319, 323, 324, 344, 346, 347, 348, 352, 353, 356, 358, 363, 366, 367, 369, 371, 373, 374, 375, 380, 381, 385, 386, 388, 391, 397, 405, 412, 413, 420, 423, 431, 432, 445, 466, 468, 470, 472, 473, 474, 476, 480, 482, 488, 495, 501, 506, 512, 513, 520, 521, 524, 528, 529, 607, 608, 610, 614, 625b, 626, 1183, 630, 638, 642, 643, 645, 646, 648, 652, 653, 661, 664, 665, 687, 693, 702, 704, 720, 738, 1182, 1187, 1190, 1198, 1200, 1239, 1240, 1259, 1260, 1261, 1265, 1316, 1317, 1319, 1321, 1329, 1332, 1335, 1341, 1354, 1363, 1375, 1376, 1377, 1378, 1385, 1447, 1448a, 1448b, 1454, 1456

RESPONSE: These comments were noted and considered. AS

Opposes Wilderness Alternatives 3M, or Supports 1, 2

COMMENTS: Support alternatives which recommend no additional wilderness, such as Alternatives 1 and 2. Favor Alternative 2 because this Alternative is supported, with some revisions, by Citizens for a User Friendly Forest (CUFF). Oppose Alternative 3M because it proposes too much wilderness. Recommend compromises between Alternatives 2 and 3M because such an alternative would allow more access, recommend no more wilderness, contribute more to economic development, and provide a better balance of uses. (CROSS REFERENCE: Alternatives)

1, 21, 22, 24, 25, 26, 27, 29, 30, 34, 35, 36, 37, 38, 40, 41, 42, 43, 46, 47, 48, 49, 51, 53, 54, 55, 165, 288, 292, 293, 296, 319, 352, 358, 373, 375, 413, 445, 506, 610, 638, 648, 652, 653, 687, 737, 1202, 1335

RESPONSE: The Forest reviewed and considered these comments. The Revised Plan reflects a recommendation of areas that display the highest Wilderness characteristics and have the highest potential for consideration by Congress. Garns Mountain, which received a high rating, was not recommended because it was designated to a motorized use prescription. AS

Opposes Wilderness Designation - Specific Areas

COMMENTS: Do not recommend for wilderness: Palisades, the Big Hole Mountains, and Lionhead.

28, 214, 307, 311, 482, 466, 470

RESPONSE: Your comments were noted and considered. No changes were made from the DEIS for any of these three areas. Rationale for wilderness recommendations is displayed in the Roadless Process Paper.

WILDERNESS

Enforcement and Monitorins

COMMENTS: Need monitoring and enforcement in wilderness; correct the lack of funding and personnel; keep motorized vehicles out of wilderness; and provide adequate signage. Use groups to monitor enforcement problems; change language in the Final Plan to ensure adequate enforcement and funding; provide heavy fines for offenders; divert funds from administration to enforcement. Educate people about wilderness use and issues of concern. Address conflicts where there is a shortage of areas for recreation. Revise page V-22 Jedediah Smith Wilderness Monitoring to include the Park. Indicate what level of monitoring should occur in the DEIS and how much TNF spent on monitoring in past 10 years, and how much will occur next 10 years. Give monitoring a higher priority than Group 3 in the Plan; provide a detailed list of monitoring indicators rather than just the six mentioned.

26, 137, 161, 170, 179, 191, 212, 377, 643, 699, 1277, 1312, 1330, 1371, 1395

RESPONSE: The Revised Plan proposes adequate monitoring, enforcement, and funding for those activities to minimize these types of concerns. There are no guarantees but the Limits of Acceptable Change (LAC) process established for the Jedediah Smith Wilderness allows adjustments in management if needed in the future. The detailed indicators in Chapter V - Monitoring are the items developed by the task force. Many of these indicators will be easily observed as routine wilderness patrol and administration occur. These actions are given a Priority 3 for Forest Plan monitoring funding, but may get higher priority based on wilderness management funding. AS

COMMENTS: One popular area for OHV use on the west slope of the Tetons is sandwiched between an area where motorized use is restricted on the Jedediah Smith Wilderness and crucial winter range.

1277

RESPONSE: You are correct. The prescription for this area was modified so that motorized use is restricted to designated routes from October 1 to December 30 and cross-country travel is allowed in the summer only. Although designated routes for snowmobiles will exist through the winter range, no significant adverse effects on wildlife are anticipated and the wilderness will be protected by boundary signing. AS

COMMENTS: Revise Page V-22 Monitoring Item - Jedediah Smith Wilderness Monitoring Item 3 - to include the Park.

699

RESPONSE: The Forest Service does not review National Park Service regulations for appropriateness as stated in this area. Therefore, no change was made. AS

COMMENTS: Explain in the DFPR monitoring plan whether the issues referred to by number are issues described in the environmental assessment.

1277

WILDERNESS

RESPONSE: Yes, they are the same, and we added a note to the Table to indicate this. AS

Recommended Revisions

COMMENTS: Clarify and explain the additions or deletions, or changes to the Revised Plan or the DEIS regarding wilderness. Explain the DEIS or DFPR's basis for recommending some areas and not others; wilderness recommendations appear to be made with no identifiable analysis.

196, 278, 392, 622, 643, 695, 1368

RESPONSE: The Forest added documentation to the Roadless Area Process Paper Update (Appendix B of the FEIS) to display the rationale for why each roadless areas was or was not recommended for wilderness consideration. This documentation includes a text and wilderness characteristics rating table. Not all qualifying roadless areas are recommended for wilderness because the Desired Future Condition (DFC) in the purpose and need section of the EIS does not call for such classifications and because of other desired multiple-use objectives. Only those roadless areas in the group having a rating equal to or higher than the group recommended in the Revised Plan were considered essential to meet the Desired Future Condition.

AS

COMMENTS: Clarify how wilderness can be designated if prior development or extractive uses have occurred; why it appears that managed lands are less likely to suffer forest health problems than unmanaged lands; what the direction is for wilderness ecological or physical elements; and what the Standards and Guidelines are for timber, ecological process, soil, water, etc., in wilderness areas, or designated wilderness areas.

388, 514, 643, 668

RESPONSE: It is possible for minor disturbances (roads, pipelines) to exist in designated wilderness if they are not noticeable, according to the Wilderness Act. Perceptions about managed lands depend on the definition of "forest health." Generally, managed lands (timber) are more resistant to insects, diseases, and fire loss. The standards and guidelines section explains the wilderness direction. AS

COMMENTS: Bar exotic pack animals (llamas) from wilderness. Consider summer residents when making wilderness proposals. Make some definitive decisions on wilderness **so** a book on hiking areas in Idaho will not require costly rewrites. Explain how hut skiing fits into wilderness designations. Explain how wilderness designations are not final because lands can be withdrawn from wilderness.

191, 293, 343, 392, 432

RESPONSE: Wilderness designations do not limit the type of pack animals or backcountry skiing. However, individual wilderness plans may require some restrictions on types of uses to protect the wilderness character. Structures such as huts are generally not allowed in Wilderness. Book writers are dependent on decisions about wilderness designations by Congress and not

WILDERNESS

decisions in forest plans. Wilderness designations are final, unless Congress reverses its decision. AS

COMMENTS: Explain why alternatives with increased recommended wilderness have an inverse correlation with ASQ, even though there is more than enough timber to meet the ASQ even with more wilderness recommended. Oppose the reduction in timber harvest to accommodate more wilderness because it is unnecessary to do so.

317, 643, 695

RESPONSE: The recommendation of wilderness in several alternatives results in some reduction in ASQ although there is not a direct, inverse relationship. The EIS does not intend to suggest such a relationship and the Alternative Continuum in Chapter II of the EIS is updated to clarify this. AS

COMMENTS: Give direction for any ecological or physical elements in this management area. Standards and guidelines should be given for timber, ecological processes, soil, water, etc.

1273b

RESPONSE: Wilderness management is conducted through the Limits of Acceptable Change (LAC) process. Standards and guidelines are generally not needed for these because the Wilderness Act controls allowed effects. The Revised Plan contains goals and objectives within each of the three management categories (See Wilderness Process Paper) or in the wilderness prescriptions. The categories shown in the Wilderness Process Paper contain goals for vegetation, soils, aquatics and other resources. These, along with the prescription standards and guidelines, provide the direction for achieving Desired Future Conditions for wilderness resources. AS

COMMENTS: Include buffers around all wilderness areas, all recommended or proposed for wilderness designation, around all Class I areas (Clean Air Act) on and off forest, and around other important habitat.

1365

RESPONSE: The concept of buffering wilderness or recommended wilderness is seldom discussed any longer. However, in most instances, we have tried not to put timber harvest or other significant development areas immediately adjacent to such areas. AS

COMMENTS: Balance the boundaries of alternatives between wilderness and multiple-use.

325, 1277

RESPONSE: The range of alternatives display a variety of "balanced" concepts for activity and resource allocations. The Revised Plan (Alternative 3M) best fits the balance indicated by the desired future conditions and public comments. AS

COMMENTS: Refer to the wilderness management EA or task force in the DFPR (as it is an important document); and provide buffers around all wilderness areas,

WILDERNESS

all recommended or proposed wilderness, all Class I (Clean Air Act) areas on and off forest, and around other important habitat.

325, 1277

RESPONSE: The task force is referred to in Chapter IV of the FEIS as the Jedediah Smith Project Team. The text makes it clear that the wilderness prescriptions and management direction in the Revised Plan is a result of this team's efforts. Buffers are not intentionally included in the Revised Plan, but in some places, other prescriptions have a buffer effect on wilderness, roadless and other areas. AS

COMMENTS: Recommend revisions.

FS-4, 191, 196, 293, 317, 325, 341, 343, 354, 388, 389, 392, 410, 432, 496, 514, 625, 632, 643, 695, 699, 727, 1202, 1273b, 1277, 1312, 1365, 1395, 1456

RESPONSE: Your comments are acknowledged. AS

COMMENTS: Close wilderness areas to all traffic including foot traffic; leave it completely alone.

219

RESPONSE: Such a restriction would be contrary to the Wilderness Act and intent of designation. We have not implemented this proposal. AS

COMMENTS: Add to Page 111-57, 1.1.6, Designated Wilderness Opportunity Class I, Goals: "Maintenance of a viable bighorn sheep population in the Jedediah Smith Wilderness area is given highest priority and is dominant over other uses as a wilderness resource and viable population of native vertebrates."

699

RESPONSE: Although bighorn sheep are recognized as an important value, the wilderness plan does not emphasize bighorn sheep over other uses. The Revised Plan provides a variety of uses and resource values while maintaining wilderness values. AS

COMMENTS: Page 111-58, 1.1.6, DREV: The word "great" in Goal 5 should be replaced with the word "significant".

1365

RESPONSE: No change is warranted. The wording was taken directly from the Draft Environmental Assessment for the Jedediah Smith Wilderness. AS.

COMMENTS: Page 111-62, Recreation, DREV 1.1.7: The standards and guidelines for recreation should be identical to those of prescription 1.1.6.

1365

RESPONSE: The differences are because this is a difficult Opportunity Class with different goals and activity levels than Prescription 1.1.6. AS

WILDERNESS

COMMENTS: Correct discrepancies between draft wilderness EA and DFPR in 1.1.6 prescriptions: 1) EA map, wilderness opportunity classes for Alternative 4B (sic) (Alternative 3M Preferred Alternative) shows special restriction zones for several areas for open fires and livestock, which do not appear in DFPR; 2) Overall goals for various ecological, public, and scientific use are in EA but not DFPR; 3) Several mitigations in relation to grizzly and sheep were in EA but not DFPR; 4) Several mitigation measures in relation to public use were in EA but not in DFPR. All constitute a step backward in describing and protecting Jedediah Smith.

1277

RESPONSE: These special restrictions are implemented by a legal order signed by the Forest Supervisor and do not need to be in the Revised Plan. All of the goals and direction contained in the Jedediah Smith EA (Process Paper) which is referred to in the FEIS were included in the three wilderness prescriptions. The riparian goals were not in the Draft Plan prescriptions, but were added to the Final Revised Plan. The mitigation measures were not brought forward into the Revised Plan because it contains mostly broad direction, and not how-to details. The LAC process is an adaptive process that will allow us to implement mitigation as needed on a case-by-case basis when conditions develop which significantly affect wilderness conditions. AS

Effects of Recreation in Wilderness

COMMENTS: Explain the Limits of Acceptable Change (LAC) system and whether it will allow additional recreational use and increase degradation in wilderness areas; include statistical data on the magnitude and trends of recreational activities on wilderness and non wilderness; address recreational impacts on wilderness and non wilderness; clarify how impacts will be mitigated.

325, 699, 1365

RESPONSE: The LAC system is described in the Jedediah Smith Wilderness process paper referred to in the EIS and is part of the Revised Plan. Acceptable change is determined by degree of change in the resource or social factor to be monitored as shown in the monitoring plan. As indicated in the wilderness consequences Section of the EIS, additional use expected to occur within the wilderness should result in, "Little cumulative impact or secondary effects." This is a result of the monitoring process that detects unwanted changes in biological, social or other factors. Mitigation occurs as a result of implementing corrective actions listed in the monitoring Plan in the EIS. AS

COMMENTS: Opportunity Class I, Biological Elements, Fish and Aquatic Resources, (Page III-59); The reference to "Fish stocking for recreational purposes is permitted with species native to wilderness," seems inappropriate because Fish Lake is the only water so managed and has been and will be stocked with brook trout as was "grand-fathered" in the Wyoming Wilderness Act: recommend a change of wording to reflect states' right to stock. (CROSS REFERENCE: Riparian, Fisheries)

389

WILDERNESS

RESPONSE: The Forest Service has the responsibility to coordinate with State fish managers to ensure that fish stocking does not compromise Federal interests (such as compliance with the Endangered Species Act and Wilderness Act). This direction is in accordance with Forest Service Manuals 2640 and 2323.3 and the agreement between Forest Service, Bureau of Land Management, and the International Association of Fish and Wildlife Agencies entitled "Policies and Guidelines for Fish and Wildlife Management in National Forests and Bureau of Land Management Wilderness". DD/AS/MO

COMMENTS: Page III-59, Biological Elements of Wilderness, DFPR 1.1.6; Page 111-64, Wildlife, DFPR 1.1.8: A standard should be included in the fish section prohibiting the stocking of any non-native fish species.

1365

RESPONSE: A standard is not necessary. This direction is contained in manual and handbook policies referenced in Appendix A of the Revised Plan. AS

COMMENTS: Change recommendations for guidelines to standards; be more definitive or use more prescriptive language within the DFPR section on wilderness.

1365

RESPONSE: Refer to Standards and Guidelines Section of the Revised Plan. Only minor clarification and wording adjustments are made to the wilderness standards and guidelines. AS

COMMENTS: Page 111-57, Opportunity Class I Designated Wilderness Goals: Explain how, "Maintenance of the natural diversity of wildlife species" and "No measurable downward trend in plant species composition and plant diversity" are determined. Support these objectives, though it may require more resources and time than Targhee National Forest has. Follow up with clearly stated and publicly known management actions that are realistic to achieve.

1249

RESPONSE: Monitoring management indicator species allows the forest to determine if Goal # 1 - "The maintenance of the natural diversity..." is being met. Goal # 3 - "There is no measurable downward trend in plant species composition..." can also be monitored. The direction in the Targhee National Forest Range Monitoring Protocol requires monitoring of grazing allotments located within and outside wilderness areas. Resources are adequate to accomplish the needed monitoring if continued funding is received from Congress. AS/WG/MO

COMMENTS: Reduce encroachment of ever present ORVs.

165

RESPONSE: This was done extensively with 93% of the Forest now closed to cross-country summer OHV travel.

WILDERNESS

COMMENTS: Management plans for wilderness should include desired conditions and standards for outfitter services, the standards should include outfitter compliance with Greater Yellowstone Area Outfitter Guide Policy,

1312

RESPONSE: The Jedediah Smith Wilderness Plan contains the desired conditions for all users. Operating Plans for outfitter and guides are designed to comply with the direction of the wilderness management plans. The GYAOP direction is applied during the development and administration of all operating plans. AS

Cooperation and Other Agencies

COMMENTS: Cooperate and coordinate with local, state, and other federal agencies, land managers, or political groups. Work with local, state, and federal agencies or leaders in developing adequate wilderness recommendations. Include a goal to restrict air space over Jedediah Smith Wilderness and Grand Teton National Park in cooperation with the park service.

314, 431, 627a, 1240, 1365, 1395

RESPONSE: It is Forest Service policy to cooperate in all planning recommendations. During the public scoping and analysis process, no other agencies indicated concerns about which areas were recommended for future wilderness consideration by Congress. Therefore, the Forest conducted an analysis of wilderness characteristics and included it in the the Roadless Process Paper in the FEIS. As a result of this analysis and the comments on the DEIS, a large portion of the Diamond Peak area is recommended wilderness in the Revised Plan. Other options for more or less recommended wilderness were considered in the various alternatives to reflect public interests. Air space restrictions are the responsibility of the Federal Aviation Administration. The forest may coordinate with local aviation groups to reduce potential impacts to falcon aeries and wilderness. AS

Wilderness Study Areas

COMMENTS: Object to emergency burned area rehabilitation in WSAs as unnecessary; and object to timber cutting for fire, insect, or disease problems.

1369

RESPONSE: Activities in Wilderness Study Areas (WSAs) must not, by regulation, degrade the wilderness character of the study area. All management actions must be planned to accommodate study designation. The Revised Plan does not provide any direction that would result in activities or conditions contrary to the regulations. AS

COMMENT: List all WSAs as actual wilderness.

179

Provide different designations that would protect WSAs from possible logging and mining.

179, 220, 280

WILDERNESS

RESPONSE: Listing all WSAs as wilderness is misleading and inappropriate. Such designation occurs through congressional legislation. AS

COMMENTS: Keep all motorized activity out of WSAs and roadless areas because allowing motorized use will make future wilderness designation difficult. Snowmobile use is a major threat in WSAs. Close all trails to OHV use in Italian Peaks WSA because they are degrading the wilderness characteristics. Close Indian Creek in Palisades to summer OHV use. Increase law enforcement. Provide a joint management strategy with the Beaverhead National Forest for enforcing ORV regulations. What does "already exist" mean in statement: "Roads allowed to the extent they already exist" -- does this mean these are open or closed roads or loop roads? If the roads are sources of sediment, are there plans to obliterate them?

150, 161, 220, 280, 314, 1361

RESPONSE: Motorized use is often allowed in WSAs and roadless areas nationwide. The Forest is directed to prohibit such activity where it would degrade wilderness character. When trails are sufficient to support motorized use without trail or resource damage in WSA and roadless areas, the use is usually allowed to continue. AS

COMMENTS: Change these guidelines to standards: allow no motorized activity; mandate all management for recreation in a primitive classification; allow only existing official and legal roads to remain, and obliterate the rest. Add a provision that requires a reduction in the number of camps if studies or other research/monitoring suggests that reduction would be desirable ecologically or biologically.

1365

RESPONSE: Minor wording changes to the standards and guidelines are made for clarification. Other changes as suggested are unwarranted. Motorized travel is allowed in the Palisades WSA by the 1984 Act. A primitive classification is not required, even in designated wilderness. Management of any roads in the WSA is also directly controlled by the Acts. The Wilderness Act and Forest Service policy (Appendix A) address concerns about possible reduction in number of camps in WSAs if adverse impacts are occurring to potential wilderness character. AS

COMMENTS: Add the entire Palisades WSA to wilderness proposals.

161

RESPONSE: The Roadless Process Paper Update (Appendix B) explains that this was not done because of a decision to allow motorized use to continue in the northwestern part of the area, and because of the difficulty to identify and manage a boundary in that area. AS

COMMENTS: Palisades Wilderness Study Area should be wilderness as habitat for grizzly bear and wolves.

1314

WILDERNESS

RESPONSE: Wilderness designation would not necessarily ignore the habitat for bear and wolf. Severe restrictions on recreation use in that area would be the only action that could improve habitat. AS

Roadless Areas Protect/Designate As Wilderness

COMMENTS: Recommend all roadless areas for wilderness. Protect all roadless areas. Do not manage roadless areas for extractive uses. Keep these areas unroaded for wildlife, watershed protection, social and aesthetic values, future generations, or future wilderness. Roadless areas are crucial for biodiversity as well as human uses. Analysis of roadless areas for wilderness designation was cursory and inadequate; described only four of 16 areas, stating only that others "did not exhibit sufficient wilderness qualities; and violated provisions of NEPA, NFMA (16 USC 1604 (e), 36 CFR 219.17, and 60 Fed. Reg 18931 S219.14(b)). Clarify the process or basis by which certain areas are recommended for wilderness while others are not. The alternative with the highest amount of wilderness recommended has only about 53% of roadless areas.

F-G-1(475), F-G-2(2), F-H(8), F-J(3), 61, 136, 150, 157, 162, 163, 174, 175, 176, 181, 184, 185, 189, 193, 204, 206, 210, 212, 213, 226, 280, 317, 341, 354, 356, 357, 377, 379, 396, 400, 405, 409, 411, 424, 441, 443, 610, 613, 621, 622, 643, 651, 690, 695, 697, 731, 739, 766, 1194, 1241, 1243, 1270, 1273b, 1275, 1327, 1328, 1330, 1365, 1367b, 1368, 1381, 1382, 1383, 1395, 1443

RESPONSE: The Forest considered your comments. Additional analysis of recommended wilderness is documented in the FEIS to show the basis for recommendations. The Forest added documentation to the Roadless Area Process Paper Update (Appendix B of the FEIS) to display the rationale for why each roadless areas was or was not recommended for wilderness consideration. This documentation includes text and a wilderness characteristics rating table. Not all qualifying roadless areas are recommended for wilderness because the Desired Future Condition in the purpose and need section of the EIS does not call for such classifications. Only those roadless areas in the group having a rating equal to or higher than the group recommended in the 1984 Plan are considered essential to meet the DFC. AS

Recommended changes/corrections to DEIS on Roadless Areas

COMMENTS: Move the AMS summary about roadless areas from the Social Component to an Ecological Component.

695

RESPONSE: Roadless and wilderness areas are listed under social component because much of the use in these areas is recreational and designation is often political. Although the Forest recognizes the importance of the ecological component, most management direction involves social activity. AS

COMMENTS: Adopt the language describing roadless characteristics in DFPR Page 11-2, which reads, "Roadless characteristics are preserved in existing roadless areas and proposed wilderness" and include this description in the

WILDERNESS

DEIS Page 1-12 and S-4. Change this description to Ecosystem Process/DFC rather than Forest Use and Occupation/DFC.

695

RESPONSE: The Forest adopted your wording suggestion and added a reference to the Roadless Process paper where the characteristics are listed for each roadless area. AS

COMMENTS: Need more discussion, analysis of fact that only Alt 6 in DEIS calls for reduction in groomed trails and OHV access; request additional analysis that wilderness designation reduces winter forage availability.

643, 1368

RESPONSE: The reduction in motorized access is fully analyzed and occurs in Alternatives 3, 3M, 4, 5 and 6. There is no indication in the EIS or Revised Plan that wilderness designation reduces winter forage availability. AS

COMMENTS: Discuss impacts of the DFPR on roadless areas proposed for inclusion in the Northern Rockies Ecosystem Protection Act. No ground disturbing activities should occur in these areas before designation.

1364

RESPONSE: The EIS addresses the potential for ground disturbing activities that impact roadless areas. The areas disturbed would be less than two-tenths of one percent of all roadless areas on the forest. AS

COMMENTS: Provide specific provision for achieving roadless area DFC. Adjust management prescriptions accordingly.

643

RESPONSE: The roadless characteristics will be preserved as suggested in the Desired Future Condition (DFC) of the Revised Plan and biodiversity attributes will not be affected. AS

Roadless - Specific Areas

COMMENTS: Analyze Diamond Peak and Mount Jefferson for wilderness characteristics as both would qualify; roadless character of the Lemhi subsection should be protected; revise Plan to reduce motorized use.

392, 643, 1184, 1185

RESPONSE: The Forest considered your comments. After a review and update of the wilderness characteristics in additional analysis the Forest added a large portion of the Diamond Peak area as recommended wilderness in the Revised Plan because this area's high wilderness characteristics rating is similar to the other wilderness areas recommended in the Revised Plan. No other changes were made in recommended wilderness prescription areas. This is because no other areas rated high enough on the updated wilderness characteristics rating except for Garns Mountain which was dedicated to a motorized use prescription rather than recommended wilderness. AS

WILDERNESS

COMMENTS: Map for Alternative 5 shows Garn's Mountain roadless area as part of recommended wilderness, but discussion does not mention it; and the map for Alternative 6 shows Garn's Mountain, Bear Creek, and Poker Peak as recommended wilderness but discussion doesn't mention them.

695

RESPONSE: The EIS text is corrected to match the map displays by adding reference to all areas mapped as recommended wilderness. AS

Roadless - Numerical Inconsistencies

COMMENTS: Correct inconsistencies in the amount of roadless area listed by different documents. The 1993 inventory shows 873,000 acres, while the DEIS and Executive Summary give 841,000; the Process Paper for roadless areas suggests that 53,700 acres have been lost to road construction since 1983 and four roadless areas have been deleted from inventory; there are 872,000 acres of roadless, not 841,000; the preliminary DEIS reports 879,000 acres, the process paper reports 871,000 acres, the DEIS reports 841,000 acres, and 3M reports protecting 772,000 as roadless.

643, 695, 766, 1368

RESPONSE: The final inventory acreages are added to the rating of the Wilderness Characteristic Factors Table in the Roadless Process Paper. There are fewer acres (841,000) in this table than in the original inventory table of 872,676. This reduction is due to improved accuracy from computer digitizing and represents a 3.5% correction. 3M Alternative roadless acres are less than 841,000 acres total inventoried because management prescriptions in the alternative will not necessarily protect all roadless characteristics. The Forest added text to the FEIS under the roadless heading in Chapters III and IV to address this. AS

COMMENTS: Inventory figure of 93 thousand acres in Bear Creek R.A. is incorrect.

695

RESPONSE: The final computer calculation shows the area to be 97,775 acres. AS

Roadless Area Management

COMMENTS: The Forest proposals seem contradictory to DFC as stated in DEIS, "Roadless characteristics are preserved in existing roadless and those proposed; and that a comprehensive analysis of key indicators of biodiversity would clearly demonstrate critical importance of roadless areas for species sensitive to human disturbance." Do not focus discussion of roadless area management to maintaining roadlessness in opposition to opening them up to motorized and resource extraction; rather focus on values public receives from roadless areas at little or no cost, e.g., clean air, water.

643, 766

WILDERNESS

RESPONSE: Less than two-tenths of one percent of the roadless areas are potentially impacted by ground disturbing activities. Therefore the roadless characteristics are preserved as suggested in the Desired Future Condition of the Revised Plan and biodiversity attributes are not affected. AS

COMMENTS: Since most summer motorized trail recreation occurs in roadless areas, manage recreation facilities as such. The DEIS equates trails with roads (Island Park Plateau), which is wrong.

1202

RESPONSE: Most of the motorized trail opportunities within roadless areas are maintained. AS

COMMENTS: Manage roadless areas as roadless and control usage through regulation, not by designation as wilderness, because multiple use should include areas maintained for all uses; no roadless areas.

285, 627a, 1277

RESPONSE: The Forest acknowledges your comments. AS

COMMENTS: Explain how the Forest can protect/mitigate against fires to maintain DFC, even though DEIS acknowledges that "these ecosystems are susceptible to fires of higher intensity/severity" and such fires result in soil damage.

228

RESPONSE: Ongoing studies mentioned in the Revised Plan will provide additional insight as to how to manage fire and use harvest methods that closely simulate ecosystem patterns of patch size and other natural processes. AS

COMMENTS: Nothing in NFMA, Section 219.17 requires that roadless areas be in a non-interchangeable component (NIC); therefore, in Alternative 2, allow all roadless areas that have a timber harvest prescription to be a part of the suitable timber base. (CROSS REFERENCE: Timber)

413

RESPONSE: The 1995 Draft RPA Assessment requires that the Forest quantify the contribution of Rare II areas to the maximum amount of timber that can be sold in a decade. This amount is identified as a non-interchangeable component (NIC) of the ASQ in the Revised Plan to prevent over harvesting in roaded areas in the event roadless areas cannot be harvested. Site-specific analysis is necessary for entry into roadless areas. In the first round of the Forest Plan, much of the volume in roadless areas could not be harvested. AS/LB/JR

COMMENTS: Provide specific provisions for achieving Roadless Area DFC. Adjust management prescriptions accordingly.

643

RESPONSE: The roadless characteristics will be preserved as suggested in the Desired Future Condition (DFC) of the Revised Plan and biodiversity attributes will not be affected. AS

WILDERNESS

COMMENTS: Comply with RPA program that requires the ASQ for roaded and **RARE** II roadless areas tracked and reported separately in the Forest Plan. (CROSS REFERENCE: Timber)

1368

RESPONSE: It will be tracked in the NIC component. LB/AS

COMMENTS: The number of acres retained as roadless are a better indicator than the number of acres recommended for wilderness in Issue #6.

No Letter Number

RESPONSE: Acres retained as roadless were not used as a key indicator because there is little change between alternatives for this indicator as shown on Table II-1 of the FEIS. The most significant difference in alternative comparison indicators that effect roadless areas is the number of acres recommended as wilderness. This was selected for the comparison, because it provides a significant difference in the level of protection of roadless values.

WILDLIFE - AMPHIBIANS

Spotted Frog Habitat

COMMENTS: The forestwide objective (DFPR 111-15) for spotted frog habitat (maintain riparian vegetation in desired vegetation condition) does not provide clear direction for maintaining habitat for amphibians because DVC is not rigorously defined. Please clarify.

643, 1277, 1369

RESPONSE: The definition for DVC is found in the Glossary of the Revised Plan. Site-specific determination of DVC will be made at the time of specific project proposals. RR

COMMENTS: It is not clear that Alternative 3M will protect the spotted frogs' habitat's key components. Human modifications negatively affect habitat quality for spotted frogs.

1277

RESPONSE: Forestwide Standards and Guidelines--such as, Properly Functioning Condition and Fisheries, Water and Riparian Resources sections, including a spotted frog goal; Aquatic Influence Zone management prescription--provide direction which will protect frog habitat. The effects confirming adequate protection and maintenance of spotted frog habitat are disclosed in Chapter IV of the FEIS. RR

Boreal/Western Toad Habitat

COMMENTS: Support leaving more forest debris to benefit boreal toads because radiotelemetry studies show that some toads use slash piles extensively.

1343

Maintain or protect shrub cover in forested habitat for western toads. Shrub cover is a significant component of toad habitat, especially in dry to normal weather conditions.

1204

RESPONSE: The Revision includes direction to manage for natural levels of shrub cover. This will increase shrub cover in many areas which will benefit a variety of plant and animal species. DD

Protect Amphibian Breeding Sites

COMMENTS: Protect all known amphibian breeding sites from direct or indirect negative impacts of timber, grazing, road-building, mining or recreation.

1277

RESPONSE: While specific breeding sites are not identified in this programmatic analysis, Forestwide Standards and Guidelines--such as, Properly Functioning Condition and Fisheries, Water and Riparian Resources sections, including a spotted frog goal; Aquatic Influence Zone management prescription--provide direction which will protect amphibian habitat. The effects confirming adequate protection and maintenance of habitat are disclosed in Chapter IV of the FEIS. RR

COMMENTS: Do not permit fish kills or pesticides or herbicides at possible amphibian breeding areas and other aquatic habitat that may be used for wintering or foraging.

1277

RESPONSE: State wildlife agencies may make proposals for using pesticides in preparation for restocking watercourses with desirable fish species. These will be evaluated on a case-by-case basis, with coordination between the Forest Service and the agency. All pesticide or herbicide use is subject to compliance with EPA safety, use and disposal requirements, particularly near water bodies. RR

Amphibian Buffer Zones

COMMENTS: Requirements for buffers on all streams and water types will improve riparian area conditions for most amphibians species.

643, 1343

RESPONSE: This is one of the intents of the aquatic influence zone management prescription. DD

COMMENTS: Do not believe this statement on Page IV-91 of DEIS is justifiable: "We doubt there is much of a measurable difference in effect due to different buffer widths."

1277

RESPONSE: At this time we do not know of any scientific study that would change our effects analysis on spotted frogs. MO

Reduce Access to Protect Amuhibians

COMMENTS: Reduce motorized access to decrease anuran (lacking a tail) mortality caused by motorized vehicles; seasonally wet seeps and marshes should not be crossed by roads or trails if alternate routes are possible.

643, 1277, 1343

RESPONSE: The access and aquatic influence zone direction provides adequate protection. RR

COMMENTS: Do not allow stocking of fish in previously fishless waters that are occupied by amphibians.

1277

RESPONSE: The States of Idaho and Wyoming have the legal authority to stock fish in the waters of their state. They consider the protection of native species in their stocking policies. DD

Grazing Imuacts on Amphibians

COMMENTS: DEIS implies grazing is of no concern, but in frog/toad breeding areas, trampled stream banks, degraded riparian vegetation and livestock

WILDLIFE - AMPHIBIANS

congregations in seasonal wetlands and pond edges all have negative effects on frogs or their ability to reproduce and persist in an area.

1277

Prevent sheep grazing in or near critical breeding sites of boreal toads during and soon after the period of metamorphosis.

1343

RESPONSE: Forestwide Standards and Guidelines--such as, Production of Commodity Resources, Properly Functioning Condition, and Fisheries, Water and Riparian Resources sections; and Aquatic Influence Zone management prescription--provide direction which will protect frog and toad habitat. The effects confirming adequate protection and maintenance of frog habitat are disclosed in Chapter IV of the FEIS. RR

COMMENTS: Explain changes in the grazing program that will restore and recover the western boreal toad on the Forest.

1365

Management recommendations for western toads should include the following: Protect riparian habitat, create buffers around riparian areas, keep livestock away from riparian areas and amphibian breeding sites.

1204, 1277

RESPONSE: Changes in specific grazing systems is a site-specific determination during allotment management planning or administration. Forestwide and management prescription direction protecting riparian and aquatic resources is adequate to maintain effective habitat for the boreal toad. RR

Timber Harvest Impacts on Amphibians

COMMENTS: Disagree with claims that timber harvest within AIZs will have, "site-specific, short term impacts on spotted frog populations and habitat" because timber harvesting that alters hydro character, temperature, moisture, and connectivity results in loss of breed sites, winter areas, moist summer forage areas and movement corridors. Do not allow any timber harvesting in riparian influence zones which are spotted frog habitat.

643, 1277, 1365

RESPONSE: The Revised Plan does not permit scheduled timber harvest within the aquatic influence zone. However, small scale timber harvest is permitted only if specifically needed and designed to maintain or improve aquatic or riparian ecosystems. No such timber sales are planned or anticipated. DD

COMMENTS: Expand habitat features beyond the needs of birds and mammals. Address needs of smaller, more sensitive species such as amphibians, for example, how timber harvest affects amphibians (Chen et. al 1993).

1204

RESPONSE: Forestwide Standards and Guidelines--such as, Properly Functioning Condition and Fisheries, Water and Riparian Resources sections, including a spotted frog goal; Aquatic Influence Zone management prescription--provide direction which will protect amphibian habitat. The effects confirming

adequate protection and maintenance of spotted frog habitat are disclosed in Chapter IV of the FEIS. RR

COMMENTS: Logging does not mimic fire as a process and creates a very different ecological situation for amphibians.

643, 1343

RESPONSE: We acknowledge that logging does not replicate all of the ecological effects of natural fire. The Revised Plan includes direction to increase the use of prescribed and natural fire where desirable effects are expected. DD

COMMENTS: Consider that landscape pattern of logging activities has a considerable impact on toad movements and habitat. A clearcut area with no regrowth of trees or shrubs seriously decreases the quality of habitat.

643, 1204, 1343

RESPONSE: Under ecosystem management and properly functioning condition, most harvest activities will be considered in a landscape context, with evaluation of effects on wildlife species. Depending on the objectives, the effects of clearcutting without adequate restocking can create undesirable habitat condition. RR

COMMENTS: Address the findings of researcher Paul Bartelt (1995) that amphibian decline is related to habitat alteration at historic sites through evaporation loss in clearcuts, the movement of sheep through toadlet nursery areas and the destruction of overhead covering where toads locate.

1365

RESPONSE: The Forest's management approach is to maintain, on a landscape basis, quality riparian/wetland and upland habitats that will provide for a variety of species over time. There will be natural and management disturbances but the overall intent is to maintain habitat conditions for all other species. MO

Amphibian Management

COMMENTS: Provide more substantive changes in the management of potential toad habitat in riparian/wetland areas so that the species does not completely disappear from the Forest: write an accountable and enforceable conservation management plan for boreal toad and other amphibians that are in decline.

1343, 1365

RESPONSE: The Revision includes substantive changes in the management of Forest riparian/wetland areas. This will benefit a variety of plant and animal species which use these areas. A conservation management plan is not considered necessary. The Revised Plan allows further action, should new information or changed conditions occur. DD/RR

WILDLIFE - AMPHIBIANS

COMMENTS: Manage for the fact that toad populations decline sharply if a metapopulation structure is lost or fragmented by either natural or man-caused events.

1277

RESPONSE: Forestwide Standards and Guidelines—such as, Properly Functioning Condition and Fisheries, Water and Riparian Resources sections, including a spotted frog goal; and Aquatic Influence Zone management prescription--provide direction which will protect frog habitat. The effects confirming adequate protection and maintenance of frog habitat are disclosed in Chapter IV of the FEIS. RR

COMMENTS: Justify statement: "all alternatives are expected to maintain the current spotted frog distribution on the Forest."

1277

RESPONSE: No data in literature suggests spotted frogs are dependent upon a particular forested condition. The AIZ Management Prescription is used as a coarse filter to maintain aquatic and riparian habitats in properly functioning conditions. This prescription will benefit spotted frogs. MO/AM

Use Scientific Studies

COMMENTS: Forest needs to use the herpetological research already done to assess trends, develop management guidelines and monitoring (Peterson et al. 1992; Groves and Peterson 1993; Clark et al. 1993; Clark and Peterson 1994; Patla and Peterson 1994; Bartelt and Peterson 1994, and in prep; Koch and Peterson 1995). Include the information and analyses from the Upper Columbia River Basin Assessment for amphibians so that you do not neglect an appropriate ecosystem management.

643

The Plan needs to deal with research showing declines on the Forest of the northern leopard frog and the boreal or western toads, especially since the Forest has a few of the remaining known breeding sites for the boreal.

643, 1343

RESPONSE: The Forest used the above cited research in the development of forestwide standards, guidelines and management prescriptions for riparian and wetland habitats. The Forest's approach is to maintain, on a landscape basis, quality riparian wetland and upland habitats that will provide for a variety of species over time. MO

Survey/Monitor Amphibian Sites

COMMENTS: Establish a schedule of amphibian surveys and monitoring of spotted frog breeding sites. Cover representative areas in all subsections across the Forest and extend each year.

1277

RESPONSE: Monitoring of spotted frog habitat is included in Chapter V of the Revised Plan. RR

COMMENTS: The amphibian surveying/monitoring effort is inadequate to determine the status of populations and how they are reacting to management decisions. Resurvey (every 5 years) historical sites for the northern leopard frog and the leopard frog to help understand their declines; survey data does not suggest declines of tiger salamanders or boreal chorus frogs.

1343

Provide needed, critical, long-term monitoring for all amphibians based on available scientific information. ~~Emphasize~~ inventory and monitoring of breeding sites of all amphibians and protection of the few known breeding sites of the rare western boreal toad; use the results of ISU research as a starting point.

643, 1277

Site-specific project analysis should consider the possibility that breeding pools may be isolated or fragmented from other suitable habitat. Analysis projects should include searches for ephemeral pools and intermittent or ephemeral drainages that may not show up on aerial photos or maps. These sites should be protected if suspected of being occupied or used by spotted frogs or western toads.

1277

RESPONSE: Forestwide Standards and Guidelines--such as, Properly Functioning Condition and Fisheries, Water and Riparian Resources sections, including a spotted frog goal; Aquatic Influence Zone management prescription--provide direction which will protect frog habitat. The effects confirming adequate protection and maintenance of Management Indicator Species spotted frog habitat are disclosed in Chapter IV of the FEIS. KR

Amphibians as Management Indicator Species

COMMENTS: The spotted frog is the most common amphibian on the forest and should not be the only species of concern used as a management indicator, because amphibians are especially sensitive to environmental change in aquatic and riparian systems (DEIS 111-31).

643

Incorporate western boreal toads as indicator species. They are more vulnerable to impacts of land management activities because they are affected in both riparian and upland habitats.

206

RESPONSE: The Forest used the spotted frog because it was listed as a regional sensitive species and therefore became a Management Indicator Species. Boreal toads were not listed. As we learn more information about boreal toads, we will include this in site-specific planning. MO

Standards and Guidelines

COMMENTS: Explain why there are no standards and guidelines for the spotted frog.

1369

WILDLIFE - AMPHIBIANS

Page III-15 - Standards and Guidelines - Spotted Frog Habitat.

Objective should read: "Maintain riparian vegetation in late seral or potential natural community condition."

1446

Develop objectives for amphibian habitat protection including the following: pesticides, herbicides, placement of trails and roads, stocking of fish, recreational base, livestock use and timber harvest.

643

RESPONSE: Forestwide Standards and Guidelines--such as, Properly Functioning Condition and Fisheries, Water and Riparian Resources sections, including a spotted frog goal; Aquatic Influence Zone management prescription--provide direction which will protect frog habitat. The effects confirming adequate protection and maintenance of MIS spotted frog habitat are disclosed in Chapter IV of the FEIS. RR

Site specific

COMMENTS: The Lodge Creek spotted frogs' breeding sites are two small pools in Island Park that are spatially separated from permanent streams and are vitally important. The first area is located in lodgepole forest 200 meters from the headwater springs of Lodge Creek. The second has been separated from Lodge Creek by highway construction which has caused negative impacts on this population. The frogs do not migrate in mass, but individually.

1277

Recent surveys show spotted frogs are common/abundant in Island Park but rare/non-existent in Big Holes/Palmsades district.

1277, 1343

RESPONSE: Thank you for this information. These are site-specific concerns and should be addressed during analysis of project proposals. RR

WILDLIFE - ANALYSIS

Environmental Analysis of Wildlife
Impacts is Inadequate

COMMENTS: Environmental analysis of wildlife impacts are grossly inadequate; analysis fails to meet the legal requirements of NEPA or APA, and fails to ensure the viability requirements of NFMA. Analysis of wildlife impacts should include: current science; effects of past impacts of logging/roading on habitat potentials for wildlife; cumulative effects; wildlife standards so the Forest can predict habitat conditions for the next ten years; professionalism and science quality.

1369

RESPONSE: The Analysis of the Management Situation (1992) and Process Paper D contain much of what you request. The DEIS contained a summary of this information and referred to these other documents for more information. The FEIS will contain more information about each management indicator species, but it will still be a summary, and the Analysis of the Management Situation and Process Paper D will still be referenced in the FEIS. The analysis is

based on the best information available, sound science, and fully complies with all laws and regulations. MO

COMMENTS: The Plan should include the following: monitoring and evaluating program, recreational impacts on wildlife, OHV impacts on wildlife, access habitats and populations of indicator species, reasonable frequency of measurements, predetermined degree of change, and interrelated set of impact indicators.

1365

RESPONSE: The Revised Plan has a monitoring item for each management indicator species (MIS). Each monitoring item includes the following parameters: type of monitoring, priority, where applied, the indicator being monitored, the method, expected precision and reliability, tolerance or variability indicating action, frequency of monitoring, lead responsibility and estimated annual cost.

Recreational impacts on wildlife MIS are analyzed as appropriate for each individual MIS. The analysis includes measuring recreational activity in a variety of ways, including motorized use on roads and trails, cross-country OHV use, dispersed recreation activity, campsites, and so forth.

The FEIS provides a summary of known information about the populations of each MIS. MO

COMMENTS: The Plan needs to address public issues: evaluation of habitat fragmentation created by roads and harvest units; no plans to manage wildlife for the above reason; old growth and the species dependent on it; firewood harvest in potential wildlife habitat; management of sensitive species beyond goshawk and owls; forest songbirds, especially those dependent on denser, old forest habitat, at lower elevations.

1369

RESPONSE: The FEIS and Process Paper D contain additional information about fragmentation. Process Paper D contains a review of the effects of timber harvesting on neotropical migratory birds. The Revised Plan contains new management direction for old growth and late successional forests. All sensitive species which occur on the Forest are analyzed in the FEIS. There are numerous forestwide standards and guidelines and management prescriptions which provide for the habitat requirements of wildlife species, but they are not necessarily identified by species name. For example, the forestwide standards and guidelines for old growth and late successional forest, combined with the management prescription standards and guidelines for limiting the amount of forested acres that can be in a nonstocked or seedling stage at point in time provide for the maintenance of late successional and old growth forest for numerous wildlife species. MO

DFPR Fails to Analyze Existina Conditions

COMMENTS: The DFPR is seriously flawed due to the lack of a thorough analysis of Forest conditions (all resources). A principle area lacking in analysis is for wildlife, relating existing conditions and habitat effectiveness to implementation of the DFPR. All appeals over the past decade have been wildlife related. To avoid perpetuating the cycle of

WILDLIFE - ANALYSIS

"planning/appealing/revising" the DFPR should 1) make clear, existing conditions forestwide, 2) identifying causative factors to explain these conditions, (for example, number of roads and degree of fragmentation which resulted from the Forest's departure from sustained yield logging), 3) address habitat needs for a wide variety of species, and 4) make clear that standards, guidelines and prescriptions will accommodate those resources into the future.

643

RESPONSE: 1) The FEIS and Process Paper D describe the existing condition for each MIS, 2) The FEIS and Process Paper D describe the habitat components which are most important and influenced by Forest Service management activities, 3) The Revised Plan and FEIS specifically address the habitat needs of the MIS and the AMS and Process Paper D provide additional information about other wildlife species on the Forest; and 4) Analysis in the FEIS includes the effects of incorporating and implementing all of the forestwide standards and guidelines and the management prescriptions. MO

Surveys/Inventories

COMMENTS: Recommend mandatory surveys for important wildlife and habitats prior to any project or activity; suggest standards and guidelines requiring surveys.

389, 766

RESPONSE: Each project or activity is unique, and the necessary surveys required for each project or activity is unique. Therefore, it is not possible to establish mandatory surveys for projects or activities in the Revised Plan. The necessary surveys will be identified when projects or activities are proposed. MO

COMMENTS: Need a terrestrial biological assessment and a species inventory.

1368

RESPONSE: A list of all wildlife species which potentially occur on or adjacent to the Forest was provided in the Analysis of the Management Situation (completed in 1992) and in Process Paper D. The FEIS provides an assessment of populations and habitat conditions for the terrestrial wildlife species selected as MIS. MO

Standards and Guidelines

COMMENTS: Plan has too many arbitrary standards that have little biological or scientific merit for wildlife.

1369

RESPONSE: Every Standard and Guideline in the Revised Plan was reviewed again. They are based on the best available science and management information. MO

Language

COMMENTS: Define "limited" access, because the word is too ambiguous.

389

RESPONSE: We agree that words like "limited" are ambiguous. That is why access information is displayed in tables and figures in quantitative terms, like miles of roads and trails and density of roads and trails. MO

COMMENTS: Require the Plan to more strongly guarantee the integrity of wildlife.

252

RESPONSE: Compared to the existing condition, the Revised Plan reduces motorized access, reduces the amount of timber harvesting, maintains or improves riparian habitats, provides for more late successional and old growth forests in every watershed, provides better direction for important habitat components such as snags and downed woody debris, provides improved winter range conditions for deer and elk, and provides more protection for important site-specific areas, such as nest sites for all of the endangered and threatened and sensitive bird species. Analysis in the FEIS for the MIS demonstrates that suitable habitat will be maintained for viable populations of wildlife, and this habitat will be well-distributed across the Forest. MO

Monitoring

COMMENTS: Monitor biodiversity before treatments, not just after treatments, so that you can have proactive planning.

1368

RESPONSE: Biological diversity can be defined as the diversity of genes, species, communities, ecosystems, and the interactions of all of these. It is not possible to monitor everything that fits under the term biodiversity. Therefore, the Revised Plan identifies the important monitoring items which are to be done when the Forest Plan is implemented. Each monitoring item includes the following parameters: type of monitoring, priority, where applied, the indicator being monitored, the method, expected precision and reliability, tolerance or variability indicating action, frequency of monitoring, lead responsibility, and estimated annual cost. MO

COMMENTS: Add this statement to the plan: Develop monitoring partnerships with state wildlife agencies, state recreation agencies, possibly recreation user-groups, and Grand Teton National Park.

699

RESPONSE: Cooperating with other agencies and user groups has become a standard way of doing business for the Targhee and the other agencies and user groups. The Forest Service has numerous Memorandum of Understanding with other agencies and user groups to facilitate partnerships and cooperative relations. Therefore, it is not necessary to add such a statement to the Revised Plan. MO

WILDLIFE - ANALYSIS

COMMENTS: Revise the Jedediah Smith Monitoring Plan to include monitoring of winter survival of yearlings of bighorn sheep populations in the Teton Mountain Range and include the Grand Teton National Park.

699

RESPONSE: Monitoring wildlife populations, especially those that are hunted, is the primary responsibility of the State Fish and Game Departments. In this case, that is the Wyoming Game and Fish Department. In the past, the Targhee cooperated with the Wyoming Game and Fish Department and Grand Teton National Park on research and monitoring of the bighorn sheep population in the Teton Mountain Range. We will continue to work with these agencies. MO

COMMENTS: "Important habitat or ecological values" are broad terms, and the commenter does not define them. For monitoring to be effective, items need to be well defined. Therefore, these recommended changes were not made in the Revised Plan.

1365

RESPONSE: Add the words "and in areas with important habitat or ecological values" to the monitoring item for conflicts between all forms of recreation and wildlife. MO

Education

COMMENTS: Regain public support for Fish and Game, hunting, fishing and outdoor recreation activities.

250

RESPONSE: Your comments are acknowledged. We continually seek to involve the public in project planning and foster support for management activities.

MO/RR

COMMENTS: Regarding Developed Recreation Sites: Support watchable wildlife provisions in objectives because informing public of areas to enjoy wildlife

in native habitats encourages public support for habitat needs.

(CROSS REFERENCE: Recreation)

1446

RESPONSE: One of several national wildlife program emphasis areas is "watchable wildlife." It is not necessary to restate the goals and objectives of these national programs in the Revised Plan. MO

WILDLIFE - BIGHORN SHEEP

Needs More Protection

COMMENTS: The few management guidelines the Forest has for bighorn sheep are untimely and madequate to ensure future populations. The Forest needs to follow agencies like Wyoming Game and Fish, and the Grand Teton National Park and give bighorn sheep more consideration.

699, 1247

Protection efforts are needed, because bighorn populations lost lower elevation and winter range due to development, poaching, plant successional and fire suppression, and recreation; there is genetic isolation and inbreeding (especially in the Teton Range).

25, 389, 699, 1247, 1381

The Forest Plan does not meet NFMA/FS regulations for maintaining populations of native vertebrate species, especially bighorn sheep, which is required by NSP (1988, 5.5) and is a goal of Wyoming Game and Fish with their objectives of 125 animals.

699

RESPONSE: The public raised four main issues related to bighorn sheep. These four issues and the response are:

1. Loss or abandonment of former low-elevation winter range due to human disturbance (e.g., developments, poaching, recreational activities) and vegetation succession from alteration of the natural fire regime.

There is no argument that former low elevation winter ranges are not being used for a variety of factors. However, The Forest knows of no analysis/evaluation about the feasibility of restoring use to former low elevation winter ranges.

Some of the winter ranges are probably permanently lost due to permanent developments.

Historical bighorn range in the Palisades and Big Hole Mountains areas is now occupied by mountain goats (the result of transplants conducted by the Idaho Department of Fish and Game). It is our understanding that mountain goats use the same habitats, are more aggressive, and will out compete bighorn sheep.

The Forest knows of no analysis or evaluation of the burning conditions which would be necessary to restore appropriate vegetation conditions. The Teton bighorn sheep working group documented that "natural fire regimes" were often the result of native Americans and early trappers. It is unlikely these fire regimes can be restored today. The Teton Basin Ranger District has tried since the mid-1980s to do a spring prescribed burn in Darby Creek. They have tried slashing the brush to create more dry fuel; they have put a cat line around it to allow for more severe burning conditions; and they have used both diesel fuel and a helitorch to burn the area, but with no success.

In the Revised Plan, the Targhee added an objective as follows: By the year 2007, complete a fire management plan for the entire west slope of the Tetons which would include opportunities for improving bighorn sheep habitat.

Bighorn sheep occupy traditional use areas, and often do not disperse into suitable unused habitat. Even to get bighorns to use new areas that are in proximity to each other usually requires transplanting them.

2. Potential disease transmission from, and competition with, domestic sheep.

The Forest has already implemented protection measures to reduce the transmission of disease between domestic sheep and bighorn sheep. In addition, the Revised Plan provides some new management direction. The following summarizes what the Forest has already done, plus the new management direction in the Revised Plan.

What the Forest has already done:

WILDLIFE - BIGHORN SHEEP

On the west slope of the Tetons, 45,700 acres of bighorn sheep habitat do not have domestic sheep grazing at this time. These 45,700 acres include all of the areas currently used by bighorn sheep. Domestic sheep are not grazed on the west slope during the seasons when "nose-to-nose" contact with bighorn sheep is likely to occur. Therefore, the potential for disease transfer is very low, there is no forage competition, and there is no displacement.

In the Lionhead area, there is no domestic sheep grazing. Therefore, the potential for disease transfer is zero, there is no forage competition, and there is no displacement.

In the Medicine Lodge area, there is no domestic sheep grazing in the area currently occupied by bighorn sheep. There are some winter and summer domestic sheep allotments currently in use in areas adjacent to the currently occupied bighorn sheep areas. Therefore, the potential for disease transfer is very low, there is no forage competition, and there is no displacement.

New management direction contained in the Revised Plan is: Phase out domestic sheep grazing on the west slope of the Tetons on an opportunity basis; phase out winter domestic sheep grazing in the Medicine Lodge Subsection; evaluate additional opportunities for adjusting domestic sheep grazing while the phase out program is in progress; and allow no conversions from cattle allotments to domestic sheep allotments within bighorn sheep habitat.

3. Likely genetic isolation and related consequences of inbreeding.

This issue was raised primarily for the bighorn sheep population on the west slope of the Tetons. The Teton Range bighorn sheep population is among a small number of bighorn sheep populations that are endemic and have not been augmented with animals from other bighorn sheep populations. However, genetic research on this population indicates the Teton Range bighorn sheep had the lowest heterozygosity of 12 herds in Wyoming which were analyzed for genetic variability. Additional genetic analysis is currently being done.

The concern for genetic isolation and related consequences of inbreeding appears to be diametrically opposed to the scientific value of an endemic population. At this time, the Forest does not know what will be needed to resolve this dilemma.

4. Displacement from seasonal ranges due to recreational activities.

Bighorn sheep habitat on the Forest is within designated wilderness, proposed wilderness and semi-primitive backcountry areas. These areas already have limited access. There are some concerns about potential adverse effects of recreation activity, but none of the concerns have substantive documentation to support the claim that recreation activity is adversely affecting bighorn sheep populations. The Revised Plan has an added objective to work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons.

Recreational activities are evaluated and coordinated between all agencies. This includes the permitting of hunting by the Wyoming Game and Fish Department. MO

COMMENTS: Plan does not describe the environmental consequences of any of the alternatives relative to bighorn sheep which is required by NEPA, Forest Service Handbook, Forest Service Manual 1950 and 2602 plus NFMA and USFS regulations (36 CFR 219),

699

RESPONSE: Laws and regulations and policy for Forest planning require the selection of management indicator species (MIS). It is neither required, nor is it possible to select every wildlife species as a MIS. The Forest conducted several workshops to identify and select the MIS for the Revised Plan. Bighorn sheep were not selected as a MIS because they have not responded to management efforts in the past and populations and habitat conditions would be the same in all alternatives. The Forest is not violating any laws, regulations or policy by not selecting bighorn sheep as a MIS. MO

Protection Measures

COMMENTS: Limit access to bighorn sheep habitat by restricting recreation and prohibiting new trails and campsites in bighorn sheep habitat; develop standards for travel constraints in bighorn sheep habitat; develop goals and objectives for maintaining a viable sheep population.

389, 699, 1247, 1347

RESPONSE: Bighorn sheep habitat on the Forest is within designated wilderness, proposed wilderness and semi-primitive backcountry areas. These areas already have limited access. Concerns about possible or potential adverse effects of recreation activity have not provided substantive documentation to support the claim that recreation activity is adversely affecting bighorn sheep populations. The Revised Plan has an added objective to work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons.

Habitat currently exists and will continue to exist in the future to sustain a viable population of bighorn sheep. However, there are other factors outside the management authority of the Forest Service which may affect population viability, such as traditional bighorn sheep behavioral traits which have some populations wintering on high elevation winter ranges with limited carrying capacity and severe wintering conditions. There are also concerns about genetic inbreeding, which may require some population manipulation which is outside the authority of the Forest Service. MO

COMMENTS: Support management strategies outlined by Suminski (1991). Emphasize implementation of management strategies 1, 2, 3, 4, 5, 7, 8, 10.

389

RESPONSE: These management strategies deal with concerns about grazing domestic sheep within or close to bighorn sheep habitat. The concerns include potential for disease transfer, competition for forage and displacement. What the Forest has already done:

On the west slope of the Tetons, 45,700 acres of bighorn sheep habitat do not have domestic sheep grazing at this time. These 45,700 acres include all of the areas currently used by bighorn sheep. Domestic sheep are

WILDLIFE - BIGHORN SHEEP

not grazed on the west slope during the seasons when "nose-to-nose" contact with bighorn sheep is likely to occur. Therefore, the potential for disease transfer is low, there is no forage competition and there is no displacement.

In the Lionhead area, there is no domestic sheep grazing. Therefore, the potential for disease transfer is zero, there is no forage competition and there is no displacement.

In the Medicine Lodge area, there is no domestic sheep grazing in the area currently occupied by bighorn sheep. There are some winter and summer domestic sheep allotments currently in use in areas adjacent to the currently occupied bighorn sheep areas. Therefore, the potential for disease transfer is very low, there is no forage competition and there is no displacement.

New management direction contained in the Revised Plan is: Phase out domestic sheep grazing on the west slope of the Tetons; Phase out winter domestic sheep grazing in the Medicine Lodge Subsection; evaluate additional opportunities for adjusting domestic sheep grazing while the phase out program is in progress; and allow no conversions from cattle allotments to domestic sheep allotments within bighorn sheep habitat. MO

COMMENTS: Consider bighorn sheep as an indicator species.

389

RESPONSE: Laws and regulations and policy for Forest planning require the selection of management indicator species (MIS). It is neither required, nor is it possible to have every wildlife species selected as a MIS. The Forest conducted several workshops to identify and select the MIS for the Revised Plan. Bighorn sheep were not selected as a MIS for the Revised Plan because they have not responded to management efforts in the past and populations and habitat conditions would be the same in all alternatives. The Forest did not violate any laws or regulations or policy by not selecting bighorn sheep as a MIS. MO

COMMENTS: Include bighorn sheep during scoping or grazing allotment reviews.

1247

RESPONSE: This was done in the past, and will be done in the future, on grazing allotments that have bighorn sheep concerns. The Revised Plan provides the following management direction related to domestic sheep grazing and bighorn sheep habitat: Phase out domestic sheep grazing on the west slope of the Tetons; phase out winter sheep grazing in the Medicine Lodge Subsection; evaluate additional opportunities for adjusting domestic sheep grazing while the phase out program is in progress; and allow no conversions from cattle to domestic sheep within bighorn sheep habitat. MO

Protection Measure - Winter

COMMENTS: Add management goals to protect bighorn sheep habitat in winter. Restrict recreation (including travel, new campsites and outfitter and guide special use permits) in bighorn sheep winter range and other key habitat; make a forestwide standard protecting crucial bighorn sheep winter range that includes recreation and travel restraints.

FS-9, F-G-1(475), 389, 1247, 1249, 1312

RESPONSE: Bighorn sheep habitat on the Forest is within designated wilderness, proposed wilderness, and semi-primitive backcountry areas. These areas already have limited access. There are concerns about possible adverse effects of recreation activity, but none of the concerns have substantive documentation to support the claim that recreation activity is adversely affecting bighorn sheep populations. The Revised Plan has an added objective to work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons. MO

COMMENTS: Reference Wyoming Game and Fish license approach to bighorn sheep as premier big game animals, recognize their bighorn sheep plans, and coordinate with them to include all winter range.

1247

RESPONSE: The Targhee has, and will continue in the future, to coordinate with the Wyoming Game and Fish Department in the management of bighorn sheep. MO

COMMENTS: Provide a guideline to assist State agencies for transplant into historic winter ranges, especially after domestic sheep are removed from an area.

1247

RESPONSE: It is Forest Service policy to coordinate with the State Fish and Game Departments on proposed transplants for all wildlife species. Since this is policy, the Targhee will not create a guideline specific for bighorn sheep transplants for the Revised Plan. MO

Non-Support Protection Measures

COMMENTS: "Bighorn sheep winter range should be closed to all human activities between December 1 and April 30" as should elk and deer winter range and also apply to MP 2,7(a-b). This should be added and made a Standard.

699

RESPONSE: Bighorn sheep winter ranges are distributed in several areas of the Forest, including the Jedediah Smith Wilderness Area, the Lionhead Proposed Wilderness Area, in the Medicine Lodge area and the Lemhi Mountains, a portion of which is proposed wilderness. At the present time, human use in these areas is limited or non-existent. However, because of concerns about recreation impacts on bighorn sheep, an objective is added to the Revised Plan to work with the Intermountain Research Station on a research project to assess the existing and potential impacts from recreation use on bighorn sheep. MO

COMMENTS: Bighorn sheep is not a threatened and endangered species. It is a big game animal whose numbers are on the increase across the west.

1363

WILDLIFE - BIGHORN SHEEP

RESPONSE: You are correct that bighorn sheep are not a threatened or endangered species. The Targhee is unfamiliar with the population numbers throughout the west, but the bighorn sheep population on the Forest is estimated to be 225 animals, and there has been no population increase for the past 15 years. MO

Interaction with Domestic Sheep

COMMENTS: Separate domestic sheep from bighorn sheep. Specific sites of conflict include the headwaters of Game and Moose Creeks, Mail Cabin Creek, Fox Creek Divide, Fred's Mountain, Rendezvous Mountain, Jedediah Smith Wilderness, and the Teton Range. Domestic sheep transmit disease to bighorn sheep which is the most serious threat to bighorn sheep survival. The two species compete for forage. Develop buffer strips between domestic and bighorn sheep populations with suggested widths ranging from 2 to 3 to 9 miles; and separate domestic from bighorn sheep in a standard.

FS-9, 212, 293, 389, 690, 699, 1247, 1277, 1312, 1331, 1381, 1387

Reflect ecosystem management emphasis with regards to the impacts of domestic sheep grazing on bighorn sheep populations (especially in the Teton Range) because numerous studies cite this is a concern (cites Citizens Task Force Work Group and memorandum from Wyoming Game and Fish to the Targhee National Forest, 1989, 1994, 1995).

699

Research has established that bighorn sheep carry their own strain of pasteurilla and are capable of die-offs without contact with domestic sheep (e.g. bighorn sheep die-off in Hells Canyon past winter); oppose Targhee's radical proposal to reduce sheep grazing by 20% AUMs (especially in Districts 2 and 3) in order to "improve" grizzly bear and bighorn sheep habitat.

1363

RESPONSE: These comments deal with concerns about grazing domestic sheep within or close to bighorn sheep habitat. The following documents what the Forest has already done about these concerns and new management direction contained in the Revised Plan. What the Forest has already done:

On the west slope of the Tetons, 45,700 acres of bighorn sheep habitat do not have domestic sheep grazing at this time. These 45,700 acres include all of the areas currently used by bighorn sheep. Domestic sheep are not grazed on the west slope during the seasons when "nose-to-nose" contact with bighorn sheep is likely to occur. Therefore, the potential for disease transfer is low, there is no forage competition and there is no displacement.

In the Lionhead area, there is no domestic sheep grazing. Therefore, the potential for disease transfer is zero, there is no forage competition and there is no displacement.

In the Medicine Lodge area, there is no domestic sheep grazing in the area currently occupied by bighorn sheep. There are some winter and summer domestic sheep allotments currently in use in areas adjacent to the currently occupied bighorn sheep areas. Therefore, the potential for disease transfer is very low, there is no forage competition and there is no displacement. There is no need for a 3 to 9 mile buffer between domestic and bighorn sheep at this time.

New management direction contained in the Forest Plan is: Phase out domestic sheep grazing on the west slope of the Tetons; phase out winter

domestic sheep grazing in the Medicine Lodge Subsection; evaluate additional opportunities for adjusting domestic sheep grazing while the phase out program is in progress; and allow no conversions from cattle allotments to domestic sheep allotments within bighorn sheep habitat. MO

Standards and Guidelines

COMMENTS: Incorporate bighorn sheep management into forestwide goals, objectives, standards and guidelines. Recommend the following changes to DFPR, Chapter 3, Standards and Guidelines:

Introduction, 6th paragraph If an effort is being made to make standards and guidelines specific to the Targhee, recognize bighorn sheep as a species of special concern that requires special management attention on the Targhee.

New Information Mention the new information regarding the precarious status of bighorn sheep in the Teton Range which is summarized in the Strategic Plan.

Wildlife Goals Maintain viable populations of native wildlife species, as is required by the National Forest Management Act of 1976 (16 USC 1600) and USFS regulations for implementing this act (36 CFR 219).

Wildlife Section Include forestwide standards for protecting crucial bighorn sheep winter habitat from use by domestic sheep and cattle and include constraints on human activities on bighorn sheep winter range between December 1 and April 30.

Standards and Guidelines - Winter Recreation Include a forestwide standard that seasonally prohibits all human activities on crucial bighorn sheep between December 1 and April 30.

Production of Natural Resources. Ranse, Goal 2 Expand this goal to include eliminating potential disease transmission between domestic sheep and bighorn sheep populations on the Targhee.

Teton Ranse Subsection, Standards and Guidelines Add a specific section for wildlife which includes a standard to implement the Teton Range Bighorn Sheep Working Group's Strategic Plan.

699

RESPONSE: For the Revised Plan, the Targhee added the following management direction for bighorn sheep habitat: 1) phase out domestic sheep grazing on the west slope of the Tetons; 2) phase out winter sheep grazing in the Medicine Lodge Subsection; 3) work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons; 4) evaluate additional opportunities for adjusting domestic sheep grazing while the phase out program is in progress; 5) complete a fire management plan by the year 2007 for the entire west slope of the Tetons which would include opportunities for improving bighorn sheep habitat; 6) and allow no conversions from cattle allotments to domestic sheep allotments within bighorn sheep habitat. MO

Monitoring

COMMENTS: Chapter IV Implementation Schedule for the Jedediah Smith

WILDLIFE - BIGHORN SHEEP

Wilderness Area Revise monitoring item to: Develop (or continue) monitoring plan with the Wyoming Game and Fish Department and Grand Teton National Park.
699

RESPONSE: A monitoring item is added for bighorn sheep to the Revised Plan.
MO

COMMENTS: Chapter V Monitorins Item - Amount of authorized motorized use includingo uermitted same retrieval on closed roads and trails. to determine if a route or area is effectively open Under "Where Applies", here and on pages V-23 and V-25, "elk and deer habitat values" should be changed to "big game habitat values"

No Letter #

RESPONSE: Thank you. The wording is changed as you suggested. MO

Changes to DEIS

COMMENTS: Address bighorn sheep protection more strongly in the DEIS.
Chapter 2 - Alternative: Add Issue Indicators That Are The Same Or That Vary Slightly In All Alternatives Add bighorn sheep as a species of special concern, since sustaining the viability of the population should be management direction under all the alternatives proposed and analyzed in the DEIS.

Chapter 3 - Affected Environment Fire - Scale: Veaetative Community and Subsection, 2nd Paragraph Mention here that changes in vegetation due to alteration of the natural fire regime may have reduced the amount of winter habitat for bighorn sheep in the Teton Range sufficiently to adversely effect the population.

Wildlife Associated with Terrestrial Habitats Include Bighorn sheep in the Teton Range in the species discussed here and list them in Table 111-12 under either "General Forested and Non-forested Habitats" or "Special and Unique Habitats," with inclusion of a footnote that specifies the bighorn sheep population in the Teton Range. Discuss this population at the same level of detail for the other species and briefly summarize the precarious status of the population and the probable reasons for this; describe the environmental consequences of bighorn sheep in the Teton Range in this section.

699

RESPONSE: Due to requests for more information on bighorn sheep, the Targhee added a summary about bighorn sheep to the FEIS. However, bighorn sheep are not designated a Management Indicator Species. MO

COMMENTS: Elk and Deer Winter Range - Scale: Forestwide Refer to "Big Game Winter Range", use "elk and deer" only when these species are specifically referred to.

699

RESPONSE: The analysis in both the DEIS and the FEIS is specific to elk and deer winter, not all big game winter range. Therefore, making the change to big game winter range would not be correct. MO

COMMENTS: Livestock Grazing: The DEIS should have pointed out that historic and continuing use of bighorn sheep habitats in the Teton Range by domestic sheep may adversely impact the bighorn sheep population due to transmission of diseases and parasites and competition for forage.

699

RESPONSE: On the west slope of the Tetons, 45,700 acres of bighorn sheep habitat do not have domestic sheep grazing at this time. These 45,700 acres include all of the areas currently used by bighorn sheep. Domestic sheep are not grazed on the west slope during the seasons when "nose-to-nose" contact with bighorn sheep is likely to occur. Therefore, the potential for disease transfer is low, there is no forage competition and there is no displacement.
MO

COMMENTS: Chapter 4 - Environmental Consequences Fire Discuss in this section the environmental consequences of the effect on vegetation patterns and bighorn sheep habitat in the Teton Range due to the differences among the alternatives in the proposed use of prescribed fire. One goal of fire management in the Teton Range Subsection should be to restore bighorn sheep habitat, particularly winter habitat, that has been degraded due to alteration of the natural fire regime.

699

RESPONSE: There is virtually no difference between the alternatives in the proposed use of prescribed fire in the Teton Range. The Targhee added an objective to, by the year 2007, complete a fire management plan for the entire west slope of the Tetons which would include opportunities for improving bighorn sheep habitat. MO

COMMENTS: Elk and Deer Winter Range: Address the consequences for bighorn sheep winter range in the Teton Range.

699

RESPONSE: The Targhee added a brief summary of bighorn sheep information to the FEIS. MO

Designated Wilderness Prescription 1.1.6, 1.1.7, 1.1.8

COMMENTS: Bighorn sheep require more emphasis in the Designated Wilderness Management Prescriptions. Include bighorn sheep as one of the species in all opportunity classes and give them priority over all other wilderness uses.

FS-9, 389

Include a goal and expand upon the objective to maintain habitat for a viable bighorn sheep population; and allow no displacement of bighorn sheep.

FS-9, 389, 1247

Management Prescriptions for Designated Wilderness The 1985 Plan states, "Regulate recreation use in key bighorn sheep areas. Close key areas to camping" in the management direction for the Jedediah Smith Wilderness Area (1985 Plan, Page 415, item E, under Element C - Wildlife and Fish). This direction is not included in the Draft Plan Revision. In all likelihood, the potential conflict between recreational users and bighorn sheep has not

WILDLIFE - BIGHORN SHEEP

lessened and may have increased. In addition, if key bighorn sheep areas were to be closed to camping to counter impacts from recreationists, as directed in the 1985 Plan, these key areas should be closed to domestic sheep grazing, which has a greater potential for adversely affecting the size and viability of the bighorn sheep population than does recreational use.

1.1.6 Designated Wilderness - Opportunity Class I, Goals Add the following goal: Maintenance of a viable bighorn sheep population in the Jedediah Smith Wilderness Area is given highest priority and is dominant over other uses. The rationale is that the bighorn sheep population is a wilderness resource which the Targhee is mandated to maintain according to the Wilderness Act of 1964 (PL 88-577) (FSM 2323.31) and further, the Targhee is required to maintain viable populations of native vertebrate species according to the National Forest Management Act (16 USC 1600) and USFS regulation for implementing the Act (36 CFR 219).

1.1.7 Designated Wilderness - Opportunity Class II, Goals Add the following goals to your Plan: In the Jedediah Smith Wilderness Area, maintenance of a viable bighorn sheep population is given highest priority and is dominant over other uses. The rationale is as described for MP 1.1.6.

1.1.8 Designated Wilderness - Opportunity Class III, Goals, 1st Sentence This needs to be revised to state: The maintenance of the natural diversity of wildlife species is given high priority but does not dominate other uses except where measures are needed to recover Threatened and Endangered species and to sustain a viable population of bighorn sheep.

1.1.8 Designated Wilderness - Opportunity Class III, Goals In the Jedediah Smith Wilderness Area, maintenance of a viable bighorn sheep population is given highest priority and is dominant over other uses. This should be made a goal and the rationale is as described above for MP 1.1.6.

699

RESPONSE: All of the above comments refer to the wilderness management prescriptions used in the Jedediah Smith Wilderness in Alternative 3M. The following summarizes what the Forest has already done for bighorn sheep in the Jedediah Smith Wilderness, and new management direction contained in the Revised Plan for bighorn sheep in the Jedediah Smith Wilderness.

What the Forest has already done in the Jedediah Smith Wilderness: Forty-five thousand, seven hundred acres of bighorn sheep habitat do not have domestic sheep grazing at this time. These 45,700 acres include all of the areas currently used by bighorn sheep. Domestic sheep are not grazed in the Wilderness during the seasons when "nose-to-nose" contact with bighorn sheep is likely to occur (the bighorn sheep breeding season and the spring green up season). Therefore, the potential for disease transfer is low, there is no forage competition and there is no displacement.

New management direction contained in the Revised Plan for the Jedediah Smith Wilderness: Phase out domestic sheep grazing on the entire west slope of the Tetons, which includes all of the Jedediah Smith Wilderness; evaluate additional opportunities for adjusting domestic sheep grazing while the phase out program is in progress; and allow no conversions from cattle allotments to domestic sheep allotments within bighorn sheep habitat.

By the year 2007, complete a fire management plan for the entire west slope of the Tetons which would include opportunities for improving bighorn sheep habitat.

WILDLIFE - BIGHORN SHEEP

An objective is added to the Revised Plan to work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons.

A goal for Prescription 1.1.6 is added to the Revised Plan and states: "The maintenance of the natural diversity of wildlife species is given the highest priority and is dominant over other uses. There is no great alteration of wildlife behavior or use of crucial habitat by wildlife as a result of human activities." (This goal includes bighorn sheep and all other wildlife species.)

An objective for Prescription 1.1.6 is added to the Revised Plan and states: "Coordinate with Grand Teton National Park and Wyoming Game and Fish Department in the management of the bighorn sheep population and habitat."

A goal for Prescription 1.1.7 is added to the Revised Plan and states: "The maintenance of the natural diversity of wildlife species is given high priority. There is no displacement of wildlife during critical periods (winter and birthing), and only temporary displacement during noncritical periods." (This goal includes bighorn sheep and all other wildlife species.)

An objective for Prescription 1.1.7 is added to the Revised Plan and states: "Coordinate with Grand Teton National Park and Wyoming Game and Fish Department in the management of the bighorn sheep population and habitat."

A goal for Prescription 1.1.8 is added to the Revised Plan and states: "The maintenance of the natural diversity of wildlife species is given high priority but does not dominate other uses except where measures are needed to recover threatened and endangered (T&E) species. Temporary displacement of non-T&E species may occur except on crucial ranges but there is no permanent displacement. Some habituation of species may be evident." (This goal includes bighorn sheep and all other wildlife species).

An objective for Prescription 1.1.8 is added to the Revised Plan and states: "Coordinate with Grand Teton National Park and Wyoming Game and Fish Department in the management of the bighorn sheep population and habitat."

This management direction provides habitat conditions necessary to sustain a viable population of bighorn sheep. There are many other factors affecting the viability of bighorn sheep in the Jedediah Smith Wilderness, such as genetic inbreeding and behavioral traits of using traditional limited wintering areas and not pioneering to other suitable areas. The Forest will continue to work with other agencies to solve these problems for this bighorn sheep population. MO

COMMENTS: Give bighorn sheep their own management prescription; show historical range.

FS-9, 389, 1247

RESPONSE: Suitable bighorn sheep habitat is provided by numerous management prescriptions; therefore they do not need their own management prescription.

Information on historical range is provided in Process Paper D. MO

COMMENTS: 1.1.6 Designated Wilderness - Opportunity Class I - Objective 3
Monitor lamb survival by surveying for yearlings (indicating lamb survival

after first winter). Objective 5 in the DFPR contradicts Page 111-47 which is described as an opportunity; Page 58 is stated more definitely.

1249

RESPONSE: Population management and monitoring are primarily responsibilities of the State Fish and Game departments. Therefore, the Forest did not incorporate details of population monitoring in the Revised Plan. The Forest will continue to cooperate with the State Fish and Game agencies in their management and monitoring of populations.

Thank you for showing us the discrepancy between Objective 5 and Page 111-47 of the Draft Plan. This discrepancy is corrected. MO

Elk and Deer Range Prescriptions

COMMENTS: 2.7(a-b) Elk and Deer Winter Range. Description Revise the title for this management prescription to "Big Game Winter Range", or "ungulate winter range" and bighorn sheep as well as elk, deer, moose, and antelope should be referred to in the description.

2.7(a-b) Elk and Deer Winter Range, Goal Change this to "Provide quality big game winter range." Throughout this management prescription, "big game" should be used instead of "elk and deer." Critical bighorn sheep winter range is in Teton, Darby, Fox, and Phillips Canyons, on Rendezvous Mountain, in the Bitch Creek drainage, and along the Targhee/Park divide north to Survey Peak.

699

RESPONSE: This prescription is specific to elk and deer winter ranges on the Forest. Moose winter almost everywhere on the Forest, from sagebrush desert to alpine forest and everything in between. Suitable winter habitat conditions for moose are provided in all management prescriptions. Bighorn sheep winter on high elevation ridges in the Jedediah Smith Wilderness, and therefore these areas are within the wilderness management prescriptions. Antelope winter ranges are almost entirely off the Targhee National Forest. MO

COMMENTS: 5.4(a,b,c,) Elk and Deer Summer Range Change the title to "Big Game Summer Range", especially since the term "big game" is used elsewhere throughout the management prescription.

699

RESPONSE: This management prescription is developed primarily for elk security while also allowing for other multiple uses. The habitat conditions provided by this prescription are suitable for a variety of other wildlife species, including other big game animals like moose and deer. MO

Site Specific

D-1 Copper Mountain

COMMENTS: Address bighorn sheep population in the DFPR and EIS; include an objective to sustain the viability of this population.

699

RESPONSE: Copper Mountain is in the Medicine Lodge Subsection. The Targhee added information about bighorn sheep in the Medicine Lodge Subsection to the FEIS. The Revised Plan also contains goals and objectives for bighorn sheep habitat. The goals and objectives in the Revised Plan provide suitable habitat to sustain a viable population of bighorn sheep. MO

D-2 Lionhead

COMMENTS: Address bighorn sheep population in the DFPR.

699

RESPONSE: Information is added about bighorn sheep in the Lionhead area to the FEIS. The Revised Plan also contains goals and objectives for bighorn sheep habitat. MO

D-5

COMMENTS: Do not allow domestic sheep and protect the bighorn sheep habitat in Fox Creek Divide, Game Creek, Moose Creek, Mail Cabin Creek, Fred's Mountain, Jedediah Smith Wilderness, and Teton Range.

293, 699, 1331, 1381, 1387

Do not allow domestic sheep on the Teton Range because of the potential threat of disease to the Teton Range population.

699, 1381

Develop a standard which eliminates the potential for overlap between domestic and bighorn sheep on the Teton Range.

699

Cooperate and coordinate with the USFS, the Grand Teton National Park and Wyoming Game and Fish to manage the problem of domestic sheep grazing on bighorn sheep population in the Teton Range.

699

Establish a 3 mile buffer zone in the Teton Range because it would eliminate all domestic sheep allotments from the entire Subsection (other areas may require anywhere from 3-20 mile buffers).

699

Regarding Chapter 3, Standards and Guidelines, Range The Draft Plan as originally distributed included #2 Guidelines which required elimination of domestic sheep grazing in the entire Teton Range Subsection. This was appropriate. However, in a memorandum of March 20, 1996, the Targhee deleted both of these guidelines as subsectionwide guidelines and transferred and weakened management direction for dealing with the issue of domestic sheep grazing in the Teton Range Subsection to only some of the specific MP's (1.1.6, 1.1.7, 1.1.8, 2.6.5, and 5.3.5), which cover about 73% of the Teton Range Subsection.

699

The Final Plan should include an aggressive strategy to eliminate domestic sheep use of these areas and should include the following strengthened standards--not just guidelines--as a Teton Range Subsection-wide standard. An alternative is to include the standard in each of the MP's that occur in the Teton Range Subsection and specify that the standard applies only to the Teton Range Subsection: By the end of 1998 eliminate sheep use and trailing on currently occupied, historic, and potential bighorn sheep habitat

WILDLIFE - BIGHORN SHEEP

and within a buffer zone of these habitats which is at least 3 miles wide and, depending on local conditions and management options, up to 20 miles wide. (S)

699

Develop protocol for monitoring and evaluating the elimination of domestic sheep grazing on currently occupied, historic, and potential bighorn sheep habitats in the Teton Range Subsection. Should be added to section Monitoring and Evaluating Strategy for Range.

699

RESPONSE: The above comments deal with the concern about domestic sheep grazing in the Teton Range Subsection. The Forest has already implemented protection measures to reduce the transmission of disease between domestic sheep and bighorn sheep in the Teton Range Subsection. In addition, the Revised Plan provides some new management direction. The following summarizes what the Forest has already done, plus the new management direction in the Revised Plan.

What the Forest has already done: On the west slope of the Tetons, 45,700 acres of bighorn sheep habitat do not have domestic sheep grazing at this time. These 45,700 acres include all of the areas currently used by bighorn sheep. Domestic sheep are not grazed on the west slope during the seasons when "nose-to-nose" contact with bighorn sheep is likely to occur (the breeding season and the spring green up season). Therefore, the potential for disease transfer is very low, there is no forage competition and there is no displacement.

New management direction contained in the Forest Plan for the west slope of the Tetons is as follows: Phase out domestic sheep grazing on the entire west slope of the Tetons; evaluate additional opportunities for adjusting domestic sheep grazing while the phase out program is in progress; and allow no conversions from cattle allotments to domestic sheep allotments within bighorn sheep habitat. By the year 2007, complete a fire management plan for the entire west slope of the Tetons which would include opportunities for improving bighorn sheep habitat.

The Revised Plan has an added objective to work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons.

A goal for Prescription 1.1.6 in the Revised Plan states: "The maintenance of the natural diversity of wildlife species is given the highest priority and is dominant over other uses. There is no great alteration of wildlife behavior or use of crucial habitat by wildlife as a result of human activities." (This goal includes bighorn sheep and all other wildlife species.)

An objective for Prescription 1.1.6 in the Revised Plan states: "Coordinate with Grand Teton National Park and Wyoming Game and Fish Department in the management of the bighorn sheep population and habitat."

A goal for Prescription 1.1.7 in the Revised Plan states: "The maintenance of the natural diversity of wildlife species is given high priority. There is no displacement of wildlife during critical periods (winter and birthing), and only temporary displacement during noncritical periods." (This goal includes bighorn sheep and all other wildlife species.)

An objective for Prescription 1.1.7 in the Revised Plan states: "Coordinate with Grand Teton National Park and Wyoming Game and Fish Department in the management of the bighorn sheep population and habitat."

WILDLIFE - BIGHORN SHEEP

A goal for Prescription 1.1.8 in the Revised Plan states: "The maintenance of the natural diversity of wildlife species is given high priority but does not dominate other uses except where measures are needed to recover threatened and endangered species. Temporary displacement of non-threatened and endangered species may occur except on crucial ranges but there is no permanent displacement. Some habituation of species may be evident." (This goal includes bighorn sheep and all other wildlife species).

An objective for Prescription 1.1.8 in the Revised Plan states: "Coordinate with Grand Teton National Park and Wyoming Game and Fish Department in the management of the bighorn sheep population and habitat."

This management direction provides habitat conditions necessary to sustain a viable population of bighorn sheep. There are many other factors affecting the viability of bighorn sheep on the west slope of the Tetons, such as genetic inbreeding and behavioral traits of using traditional limited wintering areas and not pioneering to other suitable areas. The Forest will continue to work with other agencies to solve these problems for this bighorn sheep population. MO

Teton Canyon

COMMENTS: Address historic bighorn sheep winter range recreation, and travel constraints in Fox Canyon, Darby Canyon, Phillips Canyon, Bitch Creek and Rendezvous Mountain.

389, 699, 1247

RESPONSE: There is no argument that former low elevation winter ranges are not being used for a variety of factors. However, the Forest knows of no analysis/evaluation about the feasibility of restoring use to these former low elevation winter ranges. Some of the winter ranges are probably permanently lost due to permanent developments. Bighorn sheep use traditional use areas, and often do not disperse into suitable unused habitat. Even to get bighorns to use new areas that are in proximity to each other usually requires transplanting them.

Most of the currently occupied bighorn sheep habitat on the west slope of the Tetons is within designated wilderness. There is no motorized access allowed in designated wilderness. Some historical bighorn sheep habitat occurs at lower elevations outside of the wilderness. There are seven principal watersheds on the west slope of the Tetons, and the Revised Plan reduces the OROMTRD in six of these watersheds. The OROMTRD in all watersheds is less than .5 miles per square mile with the Revised Plan. None of the concerns about possible or potential adverse effects of recreation activity, have substantive documentation to support the claim that recreation activity is adversely affecting bighorn sheep populations. The Revised Plan has an objective to work with the Intermountain Research Station to establish a credible research project on the effects of recreation on bighorn sheep on the west slope of the Tetons. Recreational activities are evaluated and coordinated between all of the agencies. This includes the current permitting of hunting by the Wyoming Game and Fish Department. MO

WILDLIFE - BIGHORN SHEEP

Teton Range Population - Protect

COMMENTS: The population group of bighorn sheep on the Teton Range Subsection deserves attention because of its scientific value; it has not been augmented with animals from other bighorn sheep populations.

699

RESPONSE: The Teton Range bighorn sheep population is among a small number of bighorn sheep populations that are endemic and have not been augmented with animals from other bighorn sheep populations. If their genetics are unique from other bighorn populations, then there may be some scientific value.

However, genetic research on this population indicates the Teton Range bighorn sheep had the lowest heterozygosity of 12 herds in Wyoming which were analyzed for genetic variability. Additional genetic analysis is currently being done. This low genetic heterozygosity may be the result of or result in inbreeding problems within the population.

The scientific value of an endemic population appears to be diametrically opposed to the potential problems associated with inbreeding. At this time, the Forest does not know what is needed to resolve this dilemma.

Teton Range Population - Interaction with Mountain Goats

COMMENTS: Monitor the status of mountain goats in Teton Range.

699

RESPONSE: Monitoring animal populations is primarily the responsibility of the State Fish and Game departments. In the past, the Targhee cooperated with the State agencies on reporting mountain goats in the Teton Range, and we will continue to do this. Since this is not one of the Forest's primary responsibilities, it is not added as a monitoring item in the Revised Plan.
MO

COMMENTS: Synthesize and evaluate information on the interrelationships between bighorn sheep and mountain goats as they pertain to ecological conditions on the Teton Range. Based on this information, determine alternative actions and a preferred course of action for dealing with the possibility that mountain goats may be established in the Teton Range.

699

RESPONSE: Mountain goats are not native to the Teton Range and the adjacent Big Hole and Palisades mountains. Mountain goats were introduced into the Big Hole and Palisades areas of the Forest by the Idaho Department of Fish and Game. The introductions have been successful, and the mountain goats have been expanding from their original release sites. A few years ago, several mountain goats were reported in the Teton Range, but the Targhee knows of no recent sightings. Mountain goats use the same habitats, are more aggressive, and out compete bighorn sheep. State Fish and Game departments are responsible for managing wildlife populations. Therefore, any course of action for dealing with mountain goats on National Forest in the Teton Range would be the responsibility of the State agencies. MO

Teton Range Population - Monitor

COMMENTS: Increase monitoring of the sex and age structure and trend of the population; its seasonal distribution; and the availability, condition, and use of its currently occupied, historic and potential habitat. Determine the population's seasonal distribution, movements and causes of mortality by means of coordinated ground and aerial surveys and radio-telemetry monitoring.

699

RESPONSE: Monitoring animal populations is primarily the responsibility of the State Fish and Game departments. In the past, the Targhee cooperated with the State agencies on population monitoring in the Teton Range and will continue to do so. Since this is not one of the Forest's primary responsibilities, it is not added as a monitoring item in the Revised Plan. The Revised Plan does contain goals and objectives for managing bighorn sheep habitat. MO

WILDLIFE - CORRIDORS

General

COMMENTS: Secure and protect wildlife migration corridors to give wildlife including grizzly bear, moose, elk and riparian species a chance for survival. (CROSS REFERENCE: Grizzly Bear; Centennials)

F-G1(475), 150, 162, 174, 175, 189, 203, 206, 280, 325, 622, 690, 1348

Delineate wildlife corridors to link the Greater Yellowstone Ecosystem and other large ecosystems in central Idaho and northern Montana to prevent loss and fragmentation of habitat which is important to many species, especially grizzly bear. (CROSS REFERENCE: Grizzly Bear; Centennials)

175, 278, 280, 622, 1273b, 1348

Clarify how core areas and buffers will remain connected to the Park and to areas west along the Continental Divide.

1273b

Include the Targhee as an important linkage area in the Greater Yellowstone Ecosystem to ensure that Yellowstone is not an "island" geographically isolated from other areas in the Northern Rockies; make the Targhee a buffer in order to protect Grand Teton ecosystems.

167, 1273b, 1396

Develop standards and guidelines and objectives for wildlife corridor management areas; develop standards and guidelines for wildlife protection.

1273b

Reconsider references to "connectivity" because this "connectivity habitat block" management scenario is a popularized notion designed to establish millions of acres of wilderness and is not reputable.

1202

Provide corridors for secure travel within the Forest and for genetic interchange.

175, 1273b, 1348

RESPONSE: Our response to these comments will address each species mentioned, and a broad overview of wildlife corridors in general.

WILDLIFE - CORRIDORS

Grizzly Bear: The 1993 Grizzly Bear Recovery Plan identified the need to assess the potential of linkage zones (corridors) between the different grizzly bear recovery areas. At this time, little is known about the potential for linkage zones. For the Targhee, the linkage zone assessment for the Centennial Mountains has not been done. While the assessments are being done, the Recovery Plan suggests the following management considerations:

"Future land management activities within these areas may be critical to maintaining their utility as linkage zones. It is essential that existing options for carnivore movement between existing ecosystems be maintained while the evaluation of linkage zones is underway. Management strategies that limit human-induced mortality and address access management will facilitate the maintenance of the potential of these zones during the five-year evaluation period. On public lands, management prescriptions similar to big game summer range prescriptions that address access management would likely conserve any existing potential of these areas for linkage until completion of the 5-year evaluation process."

Connectivity between the Yellowstone Grizzly Bear Ecosystem and other grizzly ecosystems is not likely to be realized in the near future because of the distance to other ecosystems and the intervening human development and alteration of landscape. Therefore, the recovery plan recommends that one grizzly be placed into the ecosystem from an outside population every 10 years as an effort to maintain the genetic health of the population."

The Revised Plan incorporates these management considerations by reducing motorized access throughout the Centennial Mountains, and using management prescriptions which improve or maintain big game habitat.

Moose and Elk: These two big game species are "habitat generalists," which means they use a wide variety of habitats throughout the year. They migrate from summer ranges to winter ranges, crossing a wide variety of vegetation types from mature forest to sagebrush desert. They cross a variety of roads, from backcountry gravel roads to state and federal highways. Therefore specific corridor requirements are not needed for these species. The Revised Plan improves habitat conditions throughout the Forest for these species by: reducing the number of miles of open roads and open motorized trails; closing 93% of the forest to summer cross-country motorized travel; reducing timber harvesting from what has occurred in the past which results in more hiding cover in the future. These improved habitat conditions will continue to allow for the distribution and migration of these species throughout the Forest.

Riparian Species: The Aquatic Influence Zone Management Prescription (2.8.3) provides a high level of aquatic protection and maintains ecological functions and processes necessary for the restoration and maintenance of habitat for aquatic and riparian dependent organisms. This management prescription provides continuous suitable riparian habitat for the distribution and movement of riparian dependent species.

Wildlife Corridors in General: Generally corridors are used to maintain connectivity among formerly contiguous wildlands, not to connect naturally isolated units. On the Targhee, all of the ecological subsections are still contiguous with adjacent areas. Therefore, the intent of the Revised Plan is to maintain or improve the existing connectivity between contiguous ecological subsections by management actions such as: reducing

motorized access on roads and trails and cross-country; maintaining old growth and late successional forests distributed throughout the Forest; limiting the amount of nonstocked and seedling forest successional stages which can exist at any point in time; providing for snags and downed woody debris distributed throughout the Forest; maintaining nonforested habitats (such as sagebrush/grasslands) in properly functioning conditions; maintaining riparian habitats with the aquatic influence zone management prescription; maintaining or restoring fire dependent habitats by allowing prescribed fire; and disallowing timber harvest for one to three decades in areas of the forest where the previous lodgepole pine salvage program occurred, thereby allowing cover to increase as trees in previously harvested areas grow to sapling and pole successional stages. MO

Effects of Timber Harvest on Corridors

COMMENTS: Make roadless wildlife corridors free from logging.

212, 280, 325, 396, 398, 400, 405, 409, 411, 424, 441, 489, 519, 621, 650, 697, 1348, 1382

Show how timber harvest disrupts species ability to move between habitat blocks and how this affects populations.

228

RESPONSE: Different wildlife species respond differently to timber harvesting activities. Therefore, effects of timber harvesting on corridors needs to be species specific. For many wildlife species, corridors do not always need to be free from logging or other vegetation changes (due to natural disturbances such as fire). What is important is that the overall habitat conditions are suitable for specific wildlife species to reside in or move through. Corridors should have limited motorized access, and the amount and distribution of forest successional stages that provide suitable habitat for wildlife species. MO

Site Specific - D-3

Ashton - Flagg Ranch Road

COMMENTS: Ashton - Flagg Ranch Road may have a major effect on landscape connectivity for large and small animals.

643

RESPONSE: This is a gravel surface road which has been in existence for several decades. All big game animals easily cross the road. Grizzly bear research shows that grizzly bears have crossed the road. Small mammals are often seen running across the road, particularly at night. Bird species easily fly across the road. The Forest is unaware of this road creating any landscape connectivity problems. MO

Site Specific - D-5

Teton Pass

WILDLIFE - CORRIDORS

COMMENTS: Teton Pass road may have a major effect on landscape connectivity for large and small animals.

643

RESPONSE: This road is a State Highway. The Forest has no data about the effects of this highway on landscape connectivity for large and small animals, and the Forest does not have management authority for this highway. MO

Jackpine LOOP and Leigh Creek

COMMENTS: It is unlikely connectivity exists at levels greater than historical levels at lower elevations because of intensive timber harvest in the Jackpine Loop and Leigh Creek area; shrub slopes adjacent to houses, road and activities; and roads/trails in almost all of the drainages in the Tetons.

643

RESPONSE: We agree that connectivity levels are not greater than historical levels. The Revised Plan will improve connectivity in this area by reducing open road and open trail route densities along the entire west slope of the Tetons. Also, previously harvested areas will continue to improve in cover as trees grow to sapling and pole sizes. MO

WILDLIFE - ECOSYSTEM MANAGEMENT

support

This subcategory addresses Ecosystem Management issues from a wildlife perspective. For more information cross-reference the Ecosystem Management category.

COMMENTS: Pases 111-123 and 131, Objectives: Add the following as Objective 5 on Page 123 and Objective 7 on Page 131: "Maintain or enhance inherent habitat values associated with fish, wildlife and vegetation of the area." This will assist the Forest Service in obtaining the goals and desired future conditions proffered in ecosystem management objectives being implemented on the Forest.

1446

RESPONSE: This recommendation is for the following two Management Prescriptions: 5.1 - Timber Management and 5.2.2 - Visual Quality Maintenance. Forestwide goals, objectives, standards and guidelines apply to these management prescriptions, and these include ecosystem management goals, objectives and standards and guidelines. Also, the Aquatic Influence Zone Management Prescription (2.8.3) applies within these two management prescriptions. Therefore, the Forest did not use this recommendation. MO

Non Support

COMMENTS: Your Alternative 3M has some scary long-term surprises for biodiversity such as smaller patches, reduced seral stages, older age classes

and those impacts on wildlife such as the great gray owl that feed on gophers in clearcuts.

413

RESPONSE: The limits on patch sizes for vegetation treatments is based on the guidelines developed for specific wildlife species based on current knowledge. Patch size limitations are purposefully made "guidelines" to accommodate future analysis which will occur when specific projects are proposed. Any deviation from the guidelines must be fully justified and documented.

The amount of future seral stages and older age classes is based on the standards and guidelines developed for specific wildlife species based on current knowledge. Future analysis will occur when specific projects are proposed. **Any** deviation from a standard will require a Forest Plan amendment. **Any** deviation from a guideline must be fully justified and documented.

We agree that great gray owls feed on gophers in clearcuts. However, they are also present in forested areas which have no clearcuts. MO

Toxicants

COMMENTS: Using toxicants to kill wildlife contradicts ecosystem approach of land management. Restrict the use of toxicants (including M-44s).

389

RESPONSE: M-44s and other toxicants to kill wildlife are not allowed on the Targhee. MO

Monitoring

COMMENTS: Move the biodiversity item (DFPR V-13) concerning biodiversity assessment to Priority Group 1 with a time line included in the Implementation Schedule of Chapter IV. **Also** provide additional descriptions of components, methodologies, and where and when monitoring will occur.

643

RESPONSE: Many monitoring items in Chapter V of the Revised Plan are components of biodiversity. The monitoring items identified as priority 1 will have the greatest effect on maintaining or improving biodiversity on the Forest. The above biodiversity monitoring item deals more with mathematical modeling and theory and therefore is not given a priority 1 rating. MO

Use Better Science

COMMENTS: Recommend ecosystem management either be fully disclosed and justified by scientific evidence or delete it from the Plan until sufficient information is provided for wildlife needs.

766

RESPONSE: It is impossible to fully disclose everything about ecosystem management because not everything is known about ecosystem management. However, ecosystem management is Forest Service Policy, as quoted from Chief

WILDLIFE " ECOSYSTEM MANAGEMENT

F. Dale Robertson (1992): "The Forest Service is committed to using an ecological approach in the future management of the National Forests and Grasslands.....By ecosystem management, we mean an ecological approach will be used to achieve the multiple use management of our National Forests and Grasslands. It means that we must blend the needs of people and environmental values in such a way that the National Forest and Grasslands represent diverse, healthy, productive and sustainable ecosystems." MO

COMMENTS: The reference to "unscheduled" timber harvests to achieve ecosystem management goals is alarming. No habitat manipulations (such as logging in riparian areas or aspen stands, or sagebrush burning) under the rubric of ecosystem management should be carried out unless or until reliable data is available to predict results; acquire more information pertaining to historical landscape level patterns.

643

RESPONSE: The FEIS and Revised Plan specify how much unscheduled timber harvests will be permitted. Forestwide goals, objectives, standards and guidelines provide the management direction for future unscheduled timber harvests and any other habitat manipulations. Additional site-specific analysis will occur prior to implementing any timber harvesting or other habitat manipulations. MO

COMMENTS: The Revised Plan should provide detailed strategies for collecting and analyzing a broader range of species and communities because the Forest should complete biodiversity assessments at all hierarchical levels. The Forest mistakenly assumes that by attending to ungulates, TES species, and management indicators other species will be "captured" as well.

643

RESPONSE: The forestwide, subsection, and management prescription goals, objectives, standards and guidelines include management direction for many habitats not specifically covered by the MIS. The following are a few examples: sagebrush/grassland, dead and downed woody habitat, old growth and late forested successional stages, and plant species diversity.

Selection of MIS followed National Forest Management Act Regulations. MIS may or may not represent other species, but were never intended to represent all species.

Assessments being done for the Upper Columbia River Basin Assessment will provide additional information at larger landscape scales than covered by the analysis in the Targhee Forest Plan. MO

COMMENTS: Wildlife analysis work paper was flawed because it had no evaluation of habitat conditions for the vast majority of species endemic to TNF and creates problems for rare, sensitive and locally endemic species not listed under ESA but which might be adversely affected by management activities. Add some species management guides or other coarse filter approaches such as patch size thresholds for assessing likelihood of maintaining viable, well distributed populations of native species. (CROSS REFERENCE: Wildlife, Analysis Process)

1368

RESPONSE: Selection of MIS followed National Forest Management Act Regulations. All of the MIS are endemic species to the Targhee National Forest. MIS may or may not represent other species, but were never intended to represent all species.

The forestwide, subsection, and management prescription goals, objectives, standards and guidelines include management direction for many habitats not specifically covered by the MIS. The following are a few examples: sagebrush/grassland, dead and downed woody habitat, old growth and late forested successional stages, and plant species diversity.

Due to public comments, the FEIS contains additional information about bighorn sheep and neotropical migratory birds.

Assessments for the Upper Columbia River Basin Assessment will provide additional information at larger landscape scales than covered by the analysis in the Targhee Forest Plan. MO

Patch Size

COMMENTS: Note that animal species and populations evolved, like vegetation, as a result of very large vegetation patches.

228

RESPONSE: The limits on patch sizes for vegetation treatments is based on the guidelines developed for specific wildlife species based on current knowledge. Patch size limitations are purposefully made "guidelines" to accommodate future analysis which will occur when specific projects are proposed. Any deviation from the guidelines must be fully justified and documented. MO

COMMENTS: Patch size as an indicator is not sufficient to ensure representation of all habitat types in ages and distributions that approximate the range of natural variability and fails to address population declines of some species (Indicator for Key Issue 1 in **DEIS**).

643

RESPONSE: We agree that patch size is not the only indicator that should be evaluated. The FEIS is changed to clarify that patch size is not the only indicator that will be evaluated for future vegetation management projects. MO

COMMENTS: Specify the desired mosaic of age classes, including what constitutes an age class (dbh & age), canopy closure needs, desired combination, how desired condition is based on wildlife needs and current science and the desired patch size of each age class within the mosaic.

1369

RESPONSE: The desired mosaic of age classes is specified in different management prescriptions (such as 5.1.4 and 5.4), and also specific forestwide standards and guidelines, such as for the goshawk.

What constitutes an age class is defined in the vegetation database developed for the Revised Plan, and in the forestwide standards and guidelines for old growth and late successional forest.

Canopy closure needs are met by achieving the minimum stocking requirements established in the forestwide standards and guidelines.

Desired patch sizes are specified in different management prescriptions and also specific forestwide standards and guidelines.

The FEIS and Process Paper D provide a listing of the scientific literature used to develop the Revised Plan. MO

Predators of Insect Pests

COMMENTS: Management techniques intended to control fire (salvage, thinning, and logging) which removes dead wood may exacerbate insect problems by removing predators or habitat for predators (insect-eating birds and predatory or parasitic insect species). Sources: (Torgerson 1994; Bull 1994; Perry 1988). (CROSS REFERENCE: Timber; Insects and Disease)

643

RESPONSE: Forestwide standards and guidelines and management prescription standards and guidelines provide direction for maintaining snag habitat capability and downed and dead woody habitat for insect-eating birds and other predatory or parasitic insect species. MO

Sustainability

COMMENTS: Sustain habitat and conditions necessary for free movement of wildlife because it is vital to the survival of all.

173

RESPONSE: The Revised Plan reduces the amount of motorized access, reduces the amount of timber harvesting from what occurred in the past, allows hiding cover to increase in previously harvested areas, maintains and improves riparian habitats, maintains old growth and late successional forests well-distributed throughout the Forest, all of which maintains or improves wildlife habitat and allows free movement of wildlife. MO

COMMENTS: Concentrate on ensuring sustainable levels of wildlife, fish, recreation, and forest products.

174

RESPONSE: The DEIS and FEIS analysis documents that suitable habitat will sustain wildlife and fish populations. Recreation use is expected to continue to increase. The level of forest products to be harvested in the future is calculated as a long-term sustained yield. MO

Viable Populations

COMMENTS: Add information about the current status of wildlife and demonstrate how you currently, or in the future, maintain viable populations of native species; support a healthy wildlife population.

1369, 1459

WILDLIFE - ECOSYSTEM MANAGEMENT

RESPONSE: The FEIS provides additional information about populations of the MIS. The FEIS analysis displays a sustainable habitat across the Forest that maintains well-distributed, viable populations. **MO**

COMMENTS: Since wildlife viability is ensured by maintaining the RNV - but currently we cannot define RNV - explain how you will ensure viability of all native species.

1369

RESPONSE: The concept of the Range of Natural Variability (RNV) includes the fact that there was a range in the quantity, quality and distribution of habitats over time. Although the Targhee does not have the information (and may never have the information) to know the full RNV across the Forest, the Targhee has the ability to maintain all of the habitat components well distributed across the Forest, and to avoid going to extremes in any one direction. The FEIS provides additional information about populations of the MIS. The analysis in the FEIS displays a sustainable habitat across the Forest that maintains well-distributed viable populations. **MO**

COMMENTS: Population objectives for wildlife for the respective states should become forestwide goals.

389

RESPONSE: The Revised Plan has a goal which states: "Provide habitat to support the wildlife and hunting goals of the States of Idaho and Wyoming." The Forest Service has the primary responsibility to provide suitable habitat conditions for wildlife species. The States have the primary responsibility to manage wildlife populations. The goal as written in the Revised Plan accurately states the Forest's responsibilities. **MO**

WILDLIFE - GAME RETRIEVAL

All substantive comments received on this issue receive the same response, so the comments are lumped together.

COMMENTS: Support proposal to allow hunters to retrieve their game using a motorized vehicle. Allow hunters to retrieve game at any time, any season, to use any existing roads and not have to wait for a ranger or leave guns behind. Allow motorized game retrieval between the hours on noon - 5:00 p.m.

272, 646, 1202, 1239, 1247

Oppose motorized game retrieval for reasons of economics, fairness and access. The Forest defeats the purpose and success of closures and restrictions when it allows motorized game retrieval in areas where roads are closed and cross-country travel is prohibited the rest of the year. Motorized game retrieval encourages the creation of non system roads and off-road vehicles in roadless areas. It is neither reasonable to permit individual access behind closures that effectively restrict the general public, nor is it reasonable to distribute keys to everyone.

F-H(8), F-K(4), FS-4, FS-5, FS-9, FS-10, 143, 153, 157, 167, 170, 174, 178, 181, 209, 215, 226, 250, 252, 274, 278, 280, 293, 314, 356, 376, 377, 379, 389, 392, 396, 400, 438, 441, 444, 491, 621, 622, 632, 634, 637, 643, 644, 651, 652, 655, 656, 658, 666, 667, 669, 680, 690, 695,

WILDLIFE - GAME RETRIEVAL

719, 731, 766, 1194, 1243, 1247, 1273b, 1275, 1333, 1365, 1381, 1387, 1388, 1392, 1393, 1395, 1401, 1446

Encountering motorized vehicles off-road destroys the hunting experience and creates conflicts with those hunters who prefer the "old fashioned way" eighty-five percent of the 3,300 Idaho elk and deer hunters surveyed agree that off-road vehicles are the main factor affecting hunting quality (McLaughlin 1989). (CROSS REFERENCE: Wildlife, Elk; Hunting)

FS-9, FS-10, 143, 179, 215, 356, 392, 396, 645a, 669, 690, 731, 766, 333, 1387, 1393

Object to motorized game retrieval because of the difficulty imposed on the Forest Service and Idaho Fish and Game personnel to enforce, administer, monitor and fund the program; causes public relations problems.

FS-9, FS-10, 143, 167, 174, 176, 280, 376, 392, 438, 444, 622, 634, 637, 645a, 669, 680, 690, 695, 719, 731, 766, 1312, 1333, 1337, 1387, 1393, 1395, 1446

Object to motorized game retrieval because of impacts to big game, elk security and to habitat including winter range; prohibit motorized game retrieval in Management Prescriptions 2.7(a-b) and 5.4(a-c).

170, 215, 280, 389, 444, 643, 645a, 658, 669, 690, 695, 731, 1247, 1273b, 1333, 1337, 1365, 1393, 1427, 1446

Explain if there is any way to track unauthorized use, how elk effectiveness lost by game retrieval will be monitored and what monitoring will indicate.

1273b

Oppose this issue because it causes undesirable impacts to the resource (especially in or near riparian areas) such as damaging vegetation, **soils** and water through erosion and litter.

FS-4, 293, 1395

Game retrieval is a significant variable in predicting elk vulnerability and this provision is not included in the study that formed the foundation of the elk vulnerability model.

643, 766

Game retrieval was not developed by the interagency/tribal elk work group during the past 4 years which violates the Targhee National Forest agreement that analysis and proposals for elk habitat management would be jointly developed.

766

The Plan may need to be amended because game retrieval is included in it.

FS-5

If game retrieval is allowed, it is imperative to allow for an equivalent amount of road closure in areas not open to retrieval to keep the OROMTRD/TWARD within management Standards; authorized use should be put into a formula for use on "temporarily" open roads.

1273b, 1361

Try motorized game retrieval on a trial basis, possibly for 2 years, and monitor damage to the resource, vegetation loss from new routes and the effect on elk vulnerability and security; discontinue motorized game retrieval if negative impacts are discovered.

FS-3, FS-5, FS-9, 643, 766, 1312

WILDLIFE " GAME RETRIEVAL.

If game retrieval is allowed, reduce the amount of open area, restrict it to designated routes, and do not allow hill climbing over 40-50% slopes.

FS-3, 644, 645a

Require hunters to get advance passes with retrieval rules before hunting season.

FS-3

RESPONSE: The Final Revised Plan no longer includes the game retrieval provision. Game retrieval was dropped after considering the above comments and for reasons such as difficulties in enforcement, administration and monitoring; potential decrease in elk security; the appearance of special treatment for hunters with All Terrain Vehicles; and potential damage to resources such as soil, water and fisheries. CC

WILDLIFE " GOSHAWK

General

COMMENTS: Plan properly reflects the needs of the big four ESA species as well as the more sensitive, non-listed species: cutthroat trout and goshawks.

314

RESPONSE: Thank you for your support. DD

COMMENTS: Provide greater habitat protection for northern goshawks.

697

RESPONSE: The Revision provides adequate protection for this species. If new information gathered through monitoring or research suggests greater protection is necessary, a change in management will be initiated. Monitoring and research will continue to assess this changed management. DD

COMMENTS: The Forest has got to pull its weight and not become a sanctuary for grizzlies and goshawks. (CROSS REFERENCE: Grizzly Bear)

1202

RESPONSE: The Revision provides for sustainable ecosystems and a reasonable level of use while protecting threatened, endangered, and sensitive species. DD

Improve Analysis

COMMENTS: Include goshawk as a key issue since Standard and Guidelines and change in patch size are a major factor in the significant change from the historic range of variability.

228

RESPONSE: There were over 70 issues and concerns identified during the planning process. These were grouped into seven key issues to simplify analysis. Generally, concerns over goshawk habitat, patterns (patch size is a measure of pattern), and historic range of variability are addressed in Key

Issue 1: Sustainability, Fire and Natural Disturbances and Key Issue 7: Timber Management. In addition, goshawks were selected as a management indicator species during development of the Revision, and Forestwide standards and guidelines for all goshawk territories are included in the Revised Plan. DD

COMMENTS: Consider neighboring goshawk populations in Yellowstone National Park and discuss effects of massive fires in 1988 on goshawks and their nest sites.

275

RESPONSE: During this analysis, the Forest contacted all adjacent Parks and National Forests to see if they had territories adjacent to the Targhee. These are documented in Process Paper D. The FEIS discusses territories on adjacent lands. Personal communication with Yellowstone National Park biologists indicated that they are not monitoring goshawks and no reports or accounts have been published. There are no published accounts of effects of the 1988 fires on goshawks and their nests. This information is not essential for analysis of effects nor to a reasoned choice among the alternatives. Our intent is to maintain goshawk territories on the Targhee to allow interchange by goshawks with habitat on adjacent lands. RR/MO

COMMENTS: Explain why you incorporated only a few specifics from the SW Guidelines and not others. It appears the Forest has been arbitrary, opportunistic and without scientific merit.

643, 1369, 1370

RESPONSE: We incorporated those portions of the SW Guidelines that are relevant to habitat conditions on the Targhee. Some portions were derived from research conducted on the Forest or in areas with similar ecosystems. DD

COMMENTS: Discuss current status of goshawks on the Forest. Disclose the number of historic goshawk territories still occupied and their nesting status and reproductive success; discuss how proposed standards and guidelines will address goshawk trends and define the various age classes and habitat types the Forest plans to maintain.

1369

RESPONSE: Goshawk habitat requirements and productivity are discussed in Chapter III of the FEIS. The effects of implementing the standards and guidelines are discussed in Chapter IV of the FEIS. DD

COMMENTS: Cite scientific basis for the assumption that goshawk habitat will remain at existing levels with the implementation of guidelines. Guidelines are not enforceable, there is no evidence they are adequate, and current population numbers are unknown; disclose if current goshawk population has been severely reduced by harvest activities, in that populations may only be marginally viable or remain viable with recruitment from other habitats.

1369

RESPONSE: The literature and analysis used in developing the forestwide goshawk standards and guidelines are presented in Process Paper D. Some of the goshawk management direction are standards, and some are guidelines.

Guidelines are preferred or advisable courses of action that are generally expected to be carried out. Any deviation in guidelines must be documented. Guidelines allow some flexibility to respond to changing site conditions or changed management circumstances. We agree that total goshawk population numbers are unknown, and we would add that they will never be known. What we need to know over time is the trend in goshawk populations. In a recent review of northern goshawk and forest management, the Wildlife Society stated there was no evidence to indicate that northern goshawk populations are declining, threatened or endangered anywhere within its range, and there was no evidence of a long-term decline in goshawk breeding populations. The management direction in the Revised Plan is to maintain suitable habitat conditions in all documented historic territories, existing territories, and any new territories found in the future. MO

COMMENTS: Use science acquired from the Targhee or similar lodgepole forests when making decisions on goshawks.

1267

RESPONSE: All available scientific information from the Targhee and similar ecosystems were considered. The Forest will continue to monitor and sponsor research on the effects of forest management activities on goshawks and make adjustments, if necessary. DD

COMMENTS: Conduct goshawk surveys for any activity which may disturb species to better protect goshawks and their nesting areas.

389

RESPONSE: This is standard procedure. The potential effects to goshawks, and other sensitive species present in the area, are then documented in a Biological Evaluation. DD

Improve Monitorins for Goshawk

COMMENTS: Make goshawk, bald eagle, and peregrine falcon a high priority for monitoring.

58

RESPONSE: These species are a high priority for monitoring in the Revision. DD

COMMENTS: Include data and observations on nest abandonment during timber harvest activities and return rate to next area after timber harvest. Monitor productivity of goshawks and productivity variations between managed and unmanaged lands.

No Letter #

RESPONSE: This type of information is lacking on the Forest. We currently sponsor research aimed at documenting this and other relationships to timber harvest activities. DD

Specifically Define Goshawk Habitat

COMMENTS: Specifically identify (using appropriate data on cover type, canopy cover, elevation and aspect from unknown nesting areas [AGNH]) what portion of non-suitable forest land contains suitable nesting habitat for goshawk and calculate a potential population based on these calculations.

1370

RESPONSE: Goshawks are a habitat generalist; they occupy most forest types in North America; and they use a variety of stand and landscape conditions. Analysis as you suggest would simply indicate that most of the forested landscapes on the Forest contain suitable nesting habitat. A calculation of potential population does not provide any useful information for management. What we need to know over time is the trend in goshawk populations. In a recent review of northern goshawk and forest management, the Wildlife Society stated there was no evidence to indicate that northern goshawk populations are declining, threatened or endangered anywhere within its range, and there was no evidence of a long-term decline in goshawk breeding populations. The management direction in the Revised Plan is to maintain suitable habitat conditions in all documented historic territories, existing territories, and any new territories found in the future. MO

COMMENTS: Discuss long-term changes to goshawk habitat if dead lodgepole pine stands are not managed. Short-term habitat may be okay, but long-term habitat changes will continue to occur naturally.

283

RESPONSE: We acknowledge that goshawk use within the lodgepole pine ecosystem varies over time as the character of the stands change in response to tree age, insect attack, and fire. See Chapter IV of the FEIS for a discussion of the effects of implementing various alternatives, including the selected alternative. DD

COMMENTS: Include canopy closure criteria for FA categories.

1369

RESPONSE: The foraging area (FA) is about 5,400 acres in size, and will contain a variety of forested successional stages with a wide range of canopy closures. The mature to old growth component will consist of natural stands within the range or natural stocking levels and associated canopy closure. The natural stocking levels and associated canopy closure is suitable for the goshawk within the foraging area. MO

COMMENTS: Identify and define existing goshawk territories clearly and unequivocally so public can monitor forest management.

1369

RESPONSE: Site-specific information for threatened, endangered and sensitive species is considered sensitive information and is not made available to the general public. MO

Address the Impacts of Habitat Constraints on Other Resources

COMMENTS: Re-examine the prominence you have given to habitat constraints. All alternatives include an extensive network of goshawk habitat that constrains other activities; analyze the effects of restraints on social and economic conditions.

393, 432, 1389

RESPONSE: The effects of managing for a specified amount of goshawk habitat is described in Chapter IV of the FEIS. The goshawk standards and guidelines in Chapter 111-Part 1 of the Revision will be monitored over time and adjusted as necessary. DD

COMMENTS: Re-evaluate habitat constraints related to sensitive species. Only four Idaho species remain on the ESA Candidate List and the goshawk is not one of them; this species has never been listed as a threatened and endangered species. Goshawks are doing quite well on the Targhee National Forest.

432, 1339, 1389

RESPONSE: The goshawk standards and guidelines in Chapter 111-Part 1 of the Revision will be monitored over time and adjusted as necessary. The intent of protecting sensitive species is to prevent the need for Federal listing. DD

COMMENTS: Reconsider objective to manage for all active historic nesting territories. Standards and guidelines to meet this objective restrict timber management and there is no evidence that conditions described in the standards and guidelines existed historically or that these conditions are necessary to maintain this sensitive species.

393

RESPONSE: This objective reflects agency policy for goshawk management. The goshawk standards and guidelines in Chapter 111-Part 1 of the Revision will be monitored over time and adjusted as necessary. DD

Protect New Goshawk Territories

COMMENTS: Discuss how new territories will be protected under the proposed standards and guidelines, specifically how the forest will complete adequate surveys within proposed Timber Sale Areas and how prime nesting habitat will be protected even if no surveys can be completed.

643

RESPONSE: The Revision sets management direction to protect all active and historic nesting territories. The details of how this will be implemented on the ground will be determined at a later date. DD

COMMENTS: Manage current and new territories using SW Guidelines until at least 50-60 consistently used territories have been identified.

643

WILDLIFE - GOSHAWK

RESPONSE: The selected method is to protect all active and historic nesting habitats. The goshawk standards and guidelines in Chapter 111-Part 1 of the Revision will be monitored over time and adjusted as necessary. DD

COMMENTS: Incorporate contingency plans which allow for modification of a sale area if a raptor nest is located during or after harvest.

No Letter #

RESPONSE: We will follow our policy and regulations pertaining to modifying timber sale contracts and other types of contracts when necessary to protect threatened, endangered, or sensitive species. MO

COMMENTS: Consider innovative timber sale layout to provide better protection for goshawk.

No Letter #

RESPONSE: We are doing **so**. We are also considering ways to adjust the timing of timber sale activities to reduce disturbance to nesting goshawks. DD

COMMENTS: Apply standards and guidelines to all new territories that are found during the next planning period. Please state this clearly.

1370

RESPONSE: The Revision states "manage for all active and historic nesting territories". DD

COMMENTS: Re-examine plans to limit goshawk management to identified historic and existing nests. This represents only 16% of the Forest. Explain rationale for why the Forest only needs to manage 16% of the Forest to maintain this species.

1369

RESPONSE: It is Region 4 policy to conduct goshawk surveys prior to timber harvesting activities. Therefore, as new territories are found, they will be added to the area of the Forest where goshawk standards and guidelines apply. In addition, all of the forested acres within the following management prescriptions will contribute to suitable habitat for goshawks: 1.1.6, 1.1.7, 1.1.8, 1.2, 1.3, 2.2, 2.3, 2.4, 2.5, 2.6.1a, 2.6.2, 2.6.5, 2.8.3, 3.1.1, 3.1.2, 3.2. MO

Reserve Patches of Mature Trees

COMMENTS: Reserve remaining large patches of mature trees (200-600 acres) in post harvest areas with more than 50% mature trees already harvested. Locate these reserves in Island Park, Jackpine Loop and west side of Big Hole Mountains.

643

RESPONSE: The Revision calls for "reserving" at least 20% of the forested acres within each principle watershed as old growth and late seral stages. Patch size should be at least 300 acres. DD

COMMENTS: Drop the following Territories listed in Table 9.1 from managed territories: D03-02, D03-03, D03-04, D03-05, D04-03, D05-01, D05-02, D05-05, 005-06, D05-08. Instead create reserves in the Island Park, Jackpine Loop and Big Hole Mountains in the remaining larger, unfragmented, high canopy cover, intact stands of timber.

1370

RESPONSE: These are historic territories that once supported goshawks, and we desire to return them to habitat conditions to again support goshawks. If the reserve areas that you request contain goshawk territories, then the goshawk standards and guidelines in the Revised Plan will apply to them to maintain suitable goshawk habitat. MO

COMMENTS: Incorporate reserves across unsurveyed areas of the forest where no nests have been identified, but where new timber harvests have been proposed. Base these reserves on SW guidelines in potential habitat in lower elevation mature forests in a systematic way across the landscape.

643

RESPONSE: It is Region 4 policy to conduct goshawk surveys prior to timber harvesting activities. Therefore, as new territories are found, they will be added to the area of the Forest where goshawk standards and guidelines apply. In addition, all of the forested acres within the following management prescriptions will contribute to suitable habitat for goshawks: 1.1.6, 1.1.7, 1.1.8, 1.2, 1.3, 2.2, 2.3, 2.4, 2.5, 2.6.1a, 2.6.2, 2.6.5, 2.8.3, 3.1.1, 3.1.2, 3.2. MO

COMMENTS: Leave large secure patches of good nesting habitat at known sites and plan for such patches throughout the forest to ensure long-term viability and reduce potential nest abandonment.

1370

RESPONSE: The goshawk standards and guidelines in Chapter 111-Part 1 of the Revision adequately protect known nesting habitat. Other management direction involving non-timber emphasis areas; guidelines for snags, dead and down trees; livestock grazing; and vegetation in the Revised Plan allow for suitable habitat conditions for goshawk across the Forest. DD

COMMENTS: Various studies (Patla & Trost 1996) have shown that the goshawk is highly dependent upon older forest stands with high basal area. Logging will impact goshawks through loss of nesting and foraging habitat, and increase habitat fragmentation, which will cause the goshawk to quit breeding in areas. The DEIS failed to analyze cumulative effects of logging of mature forests within foraging areas of goshawks.

1273b

RESPONSE: We are sponsoring research on the Forest by Patla and Trost to determine the effects (positive and negative) of logging within nesting and foraging habitat. This and similar research can provide the basis for monitoring and amending, if necessary, Forestwide goshawk standards and guidelines in the future. DD

Manage for Older Age Class Stands

COMMENTS: Manage for older age class stands if you are sincere about conserving goshawk habitat. Data indicate goshawk select for taller, denser stands of mature trees set farther back from the forest's edge. The goshawk is a "mature" forest "specialist" in terms of nesting habitat preference.

643

RESPONSE: The Revised Plan requires that 200 acres of mature to old growth forest be maintained for goshawk nesting areas in every identified goshawk territory. Around these 200 acres, there is to be an additional 400 acre post-fledging family area managed for specific habitat conditions suitable for the goshawk. Around the post-fledging family area, there is a 5,400 acre foraging area managed for specific habitat conditions suitable for the goshawk. This management direction will maintain suitable goshawk habitat.
MO

COMMENTS: Consider a moratorium on cutting any old-growth trees greater than 30" dbh within PFAs. These trees provide lookout/communication perches and replacement may take generations.

1370

RESPONSE: The goshawk standards and guidelines require that 40 percent of the PFA be maintained in mature to old growth status. This 40 percent is adequate to provide lookout/communication perches. MO

COMMENTS: Strengthen goshawk guidelines so that goshawk habitat is protected in such a way to maintain well functioning mature forest ecosystems. Data collected and analyzed on the Forest make it appear that certain age classes are over represented and the Forest lacks biodiversity. Extending rotation ages and making much smaller openings is the only way timber management could possibly increase diversity in a way that would benefit native forest species and keep ecosystem processes intact.

1370

RESPONSE: This is a broad comment that does not define biodiversity, rotation ages, and opening sizes; therefore, it is difficult to know exactly what is being suggested. The natural biodiversity of the lodgepole pine forests includes large natural disturbances (large patch sizes) from a combination of insects and fires. These large natural disturbances in lodgepole pine also resulted in large fluctuations in the abundance and distribution of some species over time. Aspen has significantly declined in many portions of the Forest because conifers are replacing aspen. If aspen is an important component of biodiversity, then there needs to be more frequent fire and/or shorter rotation ages. The natural biodiversity of Douglas-fir forests may have included more frequent understory fires and smaller openings. At the present time, 79 percent of the forested acres are classified as being mature to old growth. There are more mature and old growth acres than existed 100 years ago. The Revised Plan proposes to harvest only 2.5 percent of the existing mature to old growth acres during the next 10 years. Timber harvesting will meet all of the standards and guidelines in the Revised Plan, including standards and guidelines for goshawks. Mature to old growth forests

WILDLIFE - GOSHAWK

are going to exist in all watersheds under the Revised Plan. This will provide suitable goshawk habitat. MO

Increase Nest Areas

COMMENTS: Manage for nest areas of 180 acres minimum as well as equally sized replacement nest areas, since the goshawk nests on the Forest are found within large contiguous stands of maturring forests, not isolated small patches of trees. Consider established goshawk territories with highest occupancy rates as nest clusters, not just a single nest.

643

RESPONSE: The Forestwide goshawk standards and guidelines require maintaining nest areas that are at least 200 acres in size in all goshawk territories. These 200 acres include suitable alternate nest sites. MO

COMMENTS: Strengthen guideline language for managing nesting areas as contiguous areas. Studies show traditional goshawk nest areas contain a number of alternate host trees within a large patch of mature forest.

1370

Conduct studies on whether 30-acre nest area is adequate.

No Letter #

RESPONSE: We are sponsoring research on the Forest by Patla and Trost to determine the effects (positive and negative) of logging within nesting and foraging habitat. This and similar research can provide the basis for monitoring and amending, if necessary, Forestwide goshawk standards and guidelines in the future. DD

COMMENTS: Provide a 300-foot buffer as a minimum along first and second order streams to allow for adequate goshawk foraging and nesting opportunities in riparian areas.

1370

RESPONSE: The Forestwide goshawk standards and guidelines, combined with the aquatic influence zone prescription, should provide adequate foraging and nesting opportunities for goshawks in riparian areas. DD

Reduce Nest Areas

COMMENTS: Consider reducing the size of nest acres from 30 to 20 acres. Studies indicate 20 acres is sufficient.

283

RESPONSE: Goshawk monitoring on the Forest shows that highest occupancy rates occur in large mature to late successional forest stands. Therefore, the goshawk standards and guidelines require at least a 200 acre nest area to be maintained in goshawk territories. MO

COMMENTS: Reduce buffer size to 30 acres around nest sites until evidence indicates goshawk habitat is being destroyed in Idaho.

275

WILDLIFE - GOSHAWK

RESPONSE: We have used the results of goshawk monitoring on the Forest, plus a review of scientific literature on the goshawk, to develop goshawk standards and guidelines which will maintain suitable goshawk habitat. A 30 acre buffer around nest sites is inadequate. MO

Increase Maximum Created Openings

COMMENTS: Discuss the effects of limiting patch size to less than 40 acres to meet goshawk needs on other planned resources activities like prescribed fire.

283

RESPONSE: The 40 acre limit only applies to prescribed fire within goshawk territories. If prescribed fire in a goshawk territory is a stand replacing fire which creates an opening, it should be less than 40 acres in size. If the prescribed fire in a goshawk territory is an understory burn that does not create an opening, it can be larger. MO

COMMENTS: Consider patches larger than 1/2 to 40 acres for standard. Proposed standard flies in the face of historic patterns. Goshawk guidelines should not be more important than overall ecosystem condition.

283, 413

RESPONSE: We acknowledge that in some forest types, especially lodgepole pine forests, historic natural disturbances resulted in larger patch sizes than 40 acres. We do not know of any scientific documentation of how goshawk populations responded to those large natural disturbances. Since the goshawk is currently listed as a sensitive species, we have selected smaller patch sizes to maintain suitable goshawk habitat until more credible information is obtained. MO

Reduce Maximum Created Opening Acres

COMMENTS: Reduce 40-acre openings to 1-2 acres in size. 40-acre PFAs decrease prey abundance and allow for open country raptors to move closer to nest sites.

1370

RESPONSE: There is currently a lot of debate about what size of created openings are acceptable for maintaining suitable goshawk habitat. We know that in some forest types, especially lodgepole pine forests, historic natural disturbances resulted in larger patch sizes than 40 acres. We do not know of any scientific documentation of how goshawk populations responded to those large natural disturbances. There is scientific literature which documents goshawks using forested landscapes with larger created openings than just 1-2 acres in size. For the Revised Plan, we selected a guideline that creates openings less than or equal to 40 acres. Monitoring and new research may help us refine this management direction in the future. MO

Increase Size Class Distribution Percentage

COMMENTS: Increase PFA and FA forested acres to 60-80% mature/overmature cover with 80% considered highest quality for goshawk breeding pairs. SW

guidelines call for 60% mature with specified canopy cover minimums. Minimum standard of 40% is below the minimum needed to maintain goshawk breeding pairs.

643

RESPONSE: The Southwest Guidelines call for 20% mature and 20% old forest, for a total of 40%. We have reviewed the ages of different forest types on the Forest, and we have looked at some historical vegetation patterns in several watersheds. Eased on this analysis the Revised Plan standards and guidelines provide suitable goshawk habitat. MO

COMMENTS: Cite reference to justify patch sizes in Table on Page 111-14. A 40-acre opening makes no sense and contradicts research that indicates canopy cover should range from 50-90% in the PFA. The PFA should remain unmanaged and undisturbed.

643, 1369

RESPONSE: Responses to comments on patch sizes are given in previous responses. Review of scientific literature does not suggest that the PFA needs to be undisturbed. Canopy cover in the mature to old growth portions of the PFA will be the natural levels that exist in mature and old growth forests, which should be what the goshawk has been using. MO

COMMENTS: Increase minimum mature cover to 60% for FAs and 70% for PFAs. The 40% minimum cover left in a post-harvest area would most often be of lower quality. The best nesting foraging habitat is usually harvested forest (stands with high basal area and canopy cover on moderate slopes.)

1370

RESPONSE: Review of scientific literature does not support the need to have 60% mature forest for FA's and 70% for PFA's. If we increased mature cover to 60% and 70% as you suggest, we would be striving to maintain older aged forests which, according to our data, have not existed naturally on the Targhee for the last 100+ years. Our data does not suggest that this is needed to maintain suitable goshawk habitat on the Forest. MO

Decrease Size Class Distribution Percentase

COMMENTS: Change goshawk constraint to the total of non-stocked seedling and saplings shall be less than 45% of the forested area; the area of mature/overmature shall be no more than 30%. SW guidelines do not indicate that goshawk are dependent upon non-stocked seedling and saplings for survival. If 30% or more of a forested area is always in a mature or overmature condition, the species should be provided for. This will also give allocation model more flexibility.

413

Consider no more than 45% of analysis area may be in a non-stocked seedling/sapling condition; at least 30% must be in a mature/old growth class.

767

RESPONSE: Our review of literature suggests that goshawks will use non-stocked, seedling and sapling areas for foraging habitat. The important

WILDLIFE - GOSHAWK

management consideration over time is to maintain a constant supply of forest successional stages. Our analysis shows that the percent distribution of successional stages in the goshawk standards and guidelines will provide for the constant supply of successional stages for suitable goshawk habitat. MO

RESPONSE: Same as previous comment and response. MO

Increase FA Acres

COMMENTS: Consider increasing buffer zone patches to 3,000 to 10,000 acres over 20/30 years. Historically fires created patches this size and larger and the goshawk survived. Larger patches will reduce "cookie cutter" effect on the rest of the Forest.

413

RESPONSE: In the lodgepole pine forests, natural disturbances created larger patch sizes. We do not know of any scientific literature that documents how goshawk populations responded to these large disturbances. Until monitoring or research provides us with more information, we are using the best available information for the sizes of goshawk territories. MO

Reduce FA Acres

COMMENTS: Protect goshawks where they are known to be in trouble. Setting aside 6,000 acres per nest in Idaho cannot be justified until it is shown their population is declining here; consider negative effects of 6,000 acre buffer on biodiversity, food sources for goshawks when you eliminate small clearcuts that maximize biodiversity.

275

RESPONSE: Until monitoring or research provides us with more information, we are using what we consider is the best available information for the sizes of goshawk territories. MO

Address Rotation Ages

COMMENTS: Change suggested rotation ages in PFAs and FAs from 60 to 240 years to 140 years for lodgepole pine, and 240 years for Douglas-fir.

643

Consider minimum rotation ages within PFAs of 120 years for lodgepole pine and 180 years for Douglas-fir to insure adequate number of mature nesting and roosting trees.

1370

RESPONSE: Aspen is an important component of many goshawk territories. To maintain aspen forests so they are not replaced with conifers, rotation ages of 60 years are needed. Data from permanent forest inventory plots shows that lodgepole pine forests seldom reach 140 years of age on the Targhee, and most of the Douglas-fir forests are less than 240 years of age. The goshawk standards and guidelines are applicable to the forest conditions on the Targhee. MO

WILDLIFE - GOSHAWK

COMMENTS: Adopt forestwide rotation ages so that at least two thirds of the lower elevations forest (below 8000 feet) remains in a mature/old growth condition over time. This would be easier to manage than numerous individual nests and ensure viability of other species. Individual nests should be protected until such a system is well established.

1370

RESPONSE: It is Region 4 policy to conduct goshawk surveys prior to timber harvesting activities. Therefore, as new territories are found, they will be added to the area of the Forest where goshawk standards and guidelines apply. In addition, all of the forested acres within the following management prescriptions contribute to suitable habitat for goshawks: 1.1.6, 1.1.7, 1.1.8, 1.2, 1.3, 2.2, 2.3, 2.4, 2.5, 2.6.1a, 2.6.2, 2.6.5, 2.8.3, 3.1.1, 3.1.2, 3.2. Also, the total amount of timber harvesting proposed in the Revised Plan amounts to 2.5% of the total forested acres for the 1st decade; therefore, about 77% of the total forested acres will still be in mature to old growth age classes at the end of the 1st decade. MO

Address Management Activity/Management Season

COMMENTS: Prohibit management activities within the nest areas without a thorough review by a District biologist.

643

RESPONSE: Management activities in the 200 acre nest area will require site specific analysis and will include the involvement of appropriate professional Staff. MO

COMMENTS: Restrict thinning activities in PFAs and FAS unless objectives are clearly stated.

1370

RESPONSE: Thinning activities will be evaluated on a site specific basis, and must occur during the season allowed in the goshawk S&G's. MO

COMMENTS: Consider time of year of management activities, especially during nesting periods.

No Letter #

RESPONSE: The goshawk Standards and Guidelines state the time of year when management activities can occur. MO

COMMENTS: Define what you mean by a management season from October to February.

9

RESPONSE: This is the time of year when management activities, such as timber harvesting or thinning can occur. MO

COMMENTS: Consider no management season within goshawk areas and change Standards and Guidelines that allow "non-uniform" thinning. High canopy cover is one of the most important features of goshawk habitat, and there is no data

to indicate thinning or other types of management improve the quality of nest area habitat.

643

RESPONSE: Scientific literature shows that management activities can occur within goshawk territories. Management activities, including thinning, will require site-specific analysis and will involve appropriate professional staff. MO

Open Road Density Should Be Zero in PFAs

COMMENTS: Maintain open road density at zero, except for clearly defined situations, i.e., road existed prior to discovery of goshawk territory; allow no new roads in PFAs unless a thorough review is made by a biologist.

1370

Change prescription in DFPR Chapter 3 from: "Where possible, open road density should be zero in the nest areas and post-fledging family areas" to following wording: "Will be zero in the nest areas and post-fledging family areas."

1273b

Prohibit construction of new roads and obliterate roads that cause detrimental impacts to goshawks and other sensitive, threatened and endangered, and management indicator species.

1365

RESPONSE: There is no scientific literature documenting adverse effects of roads on goshawk populations. Active goshawk territories contain roads. The road guidelines for goshawks are based on this information. MO

Standards and Guidelines

COMMENTS: Explain why the number of goshawk territories and the management season are listed as standards in Table 9.4 and all other categories are defined as guidelines. All guidelines should be changed to standards for consistent management.

1370

RESPONSE: Guidelines are preferred or advisable courses of action that are generally expected to be carried out. Any deviation in guidelines must be documented. Guidelines allow some flexibility to respond to changing site conditions or changed management circumstances. MO

COMMENTS: Change goshawk open road density guidelines to standards.

695

RESPONSE: There is no scientific literature documenting adverse effects of roads on goshawk populations. Active goshawk territories contain roads. We developed the road guidelines for goshawks based on this information. Guidelines are preferred or advisable courses of action that are generally expected to be carried out. Any deviation in guidelines must be documented. Guidelines allow some flexibility to respond to changing site conditions or changed management circumstances. MO

WILDLIFE - GOSHAWK

COMMENTS: Apply guidelines to intact areas where mature forested stands have not yet been fragmented even if goshawk nests are not found. The intent is to prevent excessive habitat loss and fragmentation that occurred in the past in mature forests. This will not only protect goshawks but also most other forest dependent species.

1370

RESPONSE: The scientific literature shows that suitable goshawk habitat can be provided in managed forests when consideration is given to maintaining the necessary amounts of forest successional stages and other habitat conditions necessary for goshawks. The goshawk standards and guidelines in the Revised Plan will provide suitable habitat in all goshawk territories. MO

WILDLIFE - HABITAT

Protect Habitat

COMMENTS: Protect/preserve wildlife habitat; protecting wildlife and habitat will help the economy because many visitors come here for wildlife viewing or hunting. Protect wildlife from hunting and from machines and poachers. Protecting wildlife habitat will also protect wilderness and riparian areas or will provide a healthy ecosystem. Concerned about fragmentation of wildlife habitat and biological or migration corridors.

F-G2(2), 21, 37, 136, 157, 158, 165, 168, 173, 178, 180, 192, 195, 203, 206, 215, 226, **252**, 271, 280, 318, 325, 328, 360, 379, 438, 519, 527, 621, 631, 638, 640, 643, 650, 662, 667, 730, 1273b, 1328, 1383, 1393

RESPONSE: The Revised Plan places special emphasis on managing ecosystems in properly functioning condition, conserving biodiversity, and protecting threatened, endangered, and sensitive species and their habitats. Standards and guidelines provide the basis for accomplishing this direction. The Revised Plan provides for a reasonable level of resource use while sustaining healthy ecosystems. DD

COMMENTS: Make the Targhee a reserve for fish, wildlife, and plant species; restrict hunting, logging, roads, OHVs and/or snowmobiles to protect habitat and use controlled burning to improve habitat. Conduct adequate research and monitoring of current management activities to establish baseline information, then develop appropriate objectives, standards and guidelines. Proposed management activities must be fully discussed, monitored for effectiveness, based in sound science, and science must be adequately cited.

F-G-1(475), F-H(8), 179, 280, 328, 357, 396, 620, 640, 643, 651, 652, 665, 697, 1369, 1383, 1446

RESPONSE: The Revised Plan provides for a reasonable level of resource use while sustaining healthy ecosystems. It places special emphasis on increasing the amount of prescribed and natural fire allowed in managing ecosystems. It contains an extensive monitoring plan which allows management activities to be rapidly adjusted to achieve desired results. The Forest will continue to collaborate with research scientists to improve management of ecosystems. DD

WILDLIFE - HABITAT

COMMENTS: Support Idaho Department of Fish and Game's proposals for wildlife protection. Certain guidelines for wildlife security should be standards. Support ecosystem management to protect habitat. Security areas should be at least 250 acres, retained for no less than 10 years and distributed so they function as a network rather than isolated islands.

FS-9, 157, 168, 179, 201, 209, 280, 360, 659, 690, 766, 1195, 1365, 1388, 1392, 1401, 1446

RESPONSE: The Revised Plan places special emphasis on managing ecosystems in properly functioning condition, conserving biodiversity, and protecting threatened, endangered, and sensitive species and their habitats. It includes goals to reduce elk vulnerability and increase grizzly bear security. Direction also includes provision for big game security areas. Historic patch sizes and vegetation patterns are considered in all vegetation management activities to address the effects of fragmentation. The Forest added a section to the FEIS on neotropical birds. This section summarizes what is known about fragmentation in the Rocky Mountains. RR/DD/MO.

Access

COMMENTS: Roads and access are critical concerns for wildlife. Recommend providing more cover near roads and trails, developing noise buffers and designing and controlling road and trail systems to make noise sources predictable. The road density of <3.0 ml/sq.ml. in timber management areas is too high for wildlife needs. Do not present road management as a wildlife issue because this strategy creates public animosity toward those species you want to protect. Clarify why road density is the basis for nearly all wildlife management, and present rationale and references to show how guidelines will provide optimum management for wildlife and habitat. Address habitat fragmentation.

1249, 1273b, 1361, 1365, 1368, 1369

RESPONSE: Your recommendations for increasing cover near roads can best be evaluated on a site-specific basis. For example, in some cases, increased cover near roads has increased vehicle/wildlife collisions. Road density standards were established to reduce disturbance and mortality to wildlife; to protect fisheries, water quality, and soils while allowing for timber management, livestock management, access to private lands, and recreational use. The Revised Plan contains direction to manage ecosystems in properly functioning condition. This includes striving to maintain natural landscape patterns of connectivity. Management activities which fragment the natural connectivity of the landscape would be used sparingly and only to create specific conditions, such as a fire break. DD

COMMENTS: Support road closures and restrictions for sensitive areas, big game summer and winter range and on cross-country and/or OHV travel for wildlife protection. Restore habitat degraded by logging and roading. Restrict ORVs during hunting season or year-round because restricting access will help other hunters as well as wildlife security. ORV use should be banned in sensitive habitats, wetland and riparian areas, old growth, alpine areas above timberline, and degraded rangeland, and remote areas because these areas are important for wildlife and our own peace of mind.

WILDLIFE - HABITAT

F-F(6), F-G1(475), F-H(8), F-J(3), 37, 150, 157, 162, 165, 168, 174, 179, 180, 181, 187, 190, 201, 203, 206, 215, 226, 252, 277, 278, 280, 305, 325, 328, 357, 360, 389, 396, 400, 405, 611, 620, 621, 622, 640, 643, 644, 650, 651, 652, 656, 665, 666, 690, 739, 1183, 1195, 1247, 1275, 1313, 1327, 1388, 1448, 1458

RESPONSE: The Revised Plan substantially reduces road densities to: protect threatened, endangered, and sensitive species and their habitats; reduce elk vulnerability; increase grizzly bear security; protect and restore degraded soils and habitats; protect ecologically unique habitats; and allow for a non-motorized recreational experience. Summer cross-country motorized access is reduced from 93% to 7% of the Forest. Each management prescription includes access standards designed to meet goals. DD/MO

COMMENTS: ORVs impact wildlife: they destroy vegetation which negatively affect food and cover, resulting in decreased populations; destroy structural variability and reduce small mammal populations; reduce reptile numbers, diversity, biodiversity and species richness; destroys migratory bird and game populations through loss of food and cover, nesting and bedding areas and harassment; causes noise impacts to rodents; increases air pollution; creates haze and emission effects on insects and birds; negatively impacts feeding, spatial use patterns and leads to decreased reproduction.

1365

RESPONSE: These impacts, and others, were considered in the development of the travel and access management portion of the Revised Plan. The Revised Plan allows for a reasonable level of access while minimizing adverse impacts to wildlife and other resources. DD

COMMENTS: Provide a specific definition for "limited access" in big game security areas.

389

RESPONSE: Specific access standards are defined in each individual management prescription and displayed on detailed access tables. MO

COMMENTS: Make a comprehensive scientific review of environmental and user impacts over the past 10 years, and based on the findings, develop monitoring and evaluation for OHVs. Defer any management decision that could negatively impact wildlife until such a study is completed. Provide funding for flora and fauna inventory and assessment of OHV impacts. Establish baseline data. Prohibit OHVs in the following areas: roadless areas; wilderness study areas; wilderness; crucial seasonal habitat; areas noted as important habitat by any state Natural Heritage Program, areas for threatened, endangered, or sensitive species; riparian areas except where designated; and areas where noise impacts are likely to be significant. Expand objective on page III-13 to minimize OHV impacts on riparian, aquatic, critical and crucial habitat. Impose and enforce speed limits, party size, length of stay and minimum distances for approaching wildlife. (CROSS REFERENCE: Access)

1365

WILDLIFE - HABITAT

RESPONSE: The Revised Plan addresses all of your concerns. The Revised Plan analysis identified much of this during the Analysis of the Management situation and Affected Environment. Deferring management actions is not necessary. Enough information exists to make prudent decisions about suitable management practices and environmental protection and a reasoned choice among alternatives, in compliance with all laws, regulations, Executive Orders, and agency policy and guidance. The Access Standards and Guidelines of the Revised Plan provide for effective protection of wildlife habitat, riparian areas, TES habitat, and roadless areas. As to some of the particulars in your comments, the Forest Service doesn't enforce speed limits; the Plan does not repeat manual directions about group sizes (other than the limits placed in the Jedediah Smith Wilderness) or length of stay requirements. The Revised Plan did not add minimal distances for approaching wildlife or noise impacts. Additional restrictions may be appropriate if identified during site-specific analysis of project proposals. RR

Oppose Access Restrictions

COMMENTS: Oppose access restrictions for wildlife protection. Allow Prescription road densities in bird post-fledging areas because once birds are able to fly, they can avoid road activity. Prove that road density is a significant factor in carnivore habitat management. There is no scientific evidence to equate the impact of single-track trails on wildlife with roads; it is extrapolation only. The notion that motorized use negatively affects wildlife is merely an excuse to deprive the public of legitimate use of their lands. Trail bikers care for the land and wildlife. With the exception of grizzly bears, open road densities have little or no effect on wildlife.

(CROSS REFERENCE: Access)

270, 288, 291, 306, 313, 344, 367, 371, 381, 386, 389, 413, 528, 1179, 1375, 1369, 1449

RESPONSE: The negative impacts of motorized use on wildlife are well established in the scientific research. The Revised Plan is a balanced attempt at protecting critical wildlife habitat, reducing elk vulnerability, and still providing public access to the Forest. RR

Specific Species

COMMENTS: Provide greater protection of grizzly and elk habitat, elk migration corridors and calving areas, and all wildlife species including mule deer, wolves, goshawk, eagles, moose, mountain goats, bighorn sheep and mountain lions. Road density impacts should be evaluated for all wildlife including neotropical migrants/songbirds, wolverine, marten and lynx. (CROSS REFERENCE: Wildlife, Specific Species)

25, 203, 206, 280, 387, 643, 697, 698, 766, 1367, 1368, 1369

RESPONSE: The Revised Plan greatly improves protection of grizzly bear and elk habitat, elk migration corridors and calving areas, and other wildlife habitats. Impacts to all wildlife species, soils, water quality, fisheries, and other resources were considered along with public demand for a reasonable level of access during development of the Revision. DD

WILDLIFE - HABITAT

Recreation Impacts

COMMENTS: Expand OHV recreation objectives to minimize impacts on riparian, aquatic, critical, crucial and important seasonal wildlife habitat. Complete the following management activities: establish minimum approach distances to wildlife for recreational users; maintain natural vegetation and habitat structure in campgrounds; rehabilitate and revegetate abandoned campgrounds; maintain a buffer around developed recreation sites; close areas, seasonally or permanently, to small aircraft, glider planes and hang gliders; do not promote recreational use of caves and protect cave ecosystems; and restrict boating because boating can cause displacement, nest failures and feeding disruptions. (CROSS REFERENCE: Recreation)

1365, 1446

RESPONSE: Your comments were considered but not all were adopted. Some of these items are already part of the Revised Plan direction. The Revised Plan "Access" and wildlife, Properly Functioning Condition, and Aquatic Influence Zone (AIZ) standards and guidelines provide for effective protection of wildlife habitat, riparian areas, cave ecosystems, and TES habitat. Restricting non-agency aircraft is outside the scope and authority of the Forest Service. The Forest Service manages campgrounds for public safety and visitor use and other resources and considerations are secondary to this management emphasis. The Forest has no abandoned developed campgrounds and dispersed campgrounds will be rehabilitated where resource needs dictate. Additional restrictions may be considered if identified during site-specific analysis of project proposals. RR/MO

Request Explanation/Clarification

COMMENTS: Request scientific evidence to support this statement in the DEIS: "optimum habitat exists when 50-60% of a watershed is in hiding cover." Classify all habitat structures per cover and forage. Explain which cover category pertains to open stands. Clarify which scientific reference defines thermal cover as 45% canopy cover. In order to comply with IGBC standards, road density standards must be implemented within 1 year and completed within 3 years. Waiting 10 years would throw project into next plan revision.

228, 1369, 1446

RESPONSE: Process Paper D provides detailed analysis and scientific references for hiding and thermal cover. The Revised Plan has an objective to achieve all the road density standards in the **BMUs** within 3 years. MO

COMMENTS: Provide more direct and scientific supported measurement of species diversity in sagebrush/grasslands, on management standards for willow in riparian areas, and for birds and mammals dependent on sagebrush.

643, 1369

RESPONSE: The Revised Plan has Forestwide standards and guidelines for sagebrush/grassland ecosystems. Process Paper D provides the scientific support for the Forestwide standards and guidelines. Riparian standards and guidelines and Prescription 2.8.3 provide for sustaining healthy willow habitats. MO

WILDLIFE - HABITAT

COMMENTS: Question management to preserve "open" areas for species requiring early successional habitats. (CROSS REFERENCE: EM, General; EM, RNV; Timber, Old Growth)

643

RESPONSE: The overall intent of the Revised Plan is to manage landscapes for Properly Functioning Condition, including maintenance of open areas. MO

WILDLIFE - MISCELLANEOUS

Protect Wildlife

COMMENTS: Protect wildlife for future generations and restore degraded fish and wildlife habitats.

201, 391, 424, 615

RESPONSE: The Revision is intended to achieve these goals, as well as goals involving resource use. DD

Management Decision

COMMENTS: Use science to guide management and support biologists to manage our resources since they know better than John Q. Public; stick to science and carry out mandated projects to protect wildlife, even if it reduces access.

250, 643

RESPONSE: We used the best science available to us in development of the Revision. Overall, access was greatly reduced across the forest to improve conditions for wildlife, water quality, fisheries, soils, and scenic beauty. DD

COMMENTS: Use "common sense" and listen to the public when managing wildlife because Fish and Wildlife poisoned 3,000 seagulls to save nests for plovers, but allowed beach to be open to ORV users who destroyed nests anyway.

640

RESPONSE: Public input played a vital role in development of the Revised Plan. We feel it represents a balanced approach to resource management. DD

COMMENTS: Consider impacts of wildlife management decisions upon summer home residents because these people help ensure that wildlife are not molested.

343

RESPONSE: We listened to summer home residents, as well as residents along the urban interface, and accommodated their needs (such as for maintenance of visual quality, protection from wildfire, access, and so on) where practical. DD

COMMENTS: Disagree that human use negatively impacts wildlife because we have more elk, moose, deer and bear than we did 30-40 years ago and grizzly bear are not afraid of humans.

1200

WILDLIFE - MISCELLANEOUS

RESPONSE: Some types of human activities may be harmful to some species of wildlife, while other types of use may benefit other species of wildlife. Many of these relationships are described in the FEIS. The number of elk, moose, deer, and bear are greatly controlled by habitat motorized access, and the amount of and type of hunting mortality. DD

Economics

COMMENTS: Maintain a rich variety of habitat for wildlife and birds to help support Idaho tourism, largest industries and the economy.
185, 318, 527

RESPONSE: A primary wildlife goal of the Revised Plan, as stated in Chapter 111-Part 1, is to maintain or enhance wildlife biodiversity by managing for a diverse array of habitats and distribution of plant communities. DD

COMMENTS: Develop management for environmental assessments and analyze the effect on people and the economy.

314

RESPONSE: Forest activities are subject to the National Environmental Policy Act when the Forest analyzes the possible effects of management actions on the resource. Normally these analyses include social and economic effects. DP

COMMENTS: Big game hunting is a valuable resource.
766

RESPONSE: Big game hunting is valuable on a social and economic level. People look forward to hunting with family and friends on an annual basis. For many it is their single defining social event, or even a reason for locating into a certain area. It also brings money into the local economies, not just through the recreational activity itself, but by serving as a means to attract people to the area, which in turn can lead to the purchase of property. DP

WILDLIFE - STANDARDS & GUIDELINES/LAWS/REGULATIONS

Should Address More Issues

COMMENTS: Include and enforce all the standards that address the concerns of ours regarding wildlife.
1365

RESPONSE: We reviewed all the concerns stated in your comments, in the context of all public comments received. Some recommendations were adopted. Others are adequately addressed by the standards which were initially proposed in the Draft Revised Plan. Still others were not adopted because the direction in the Plan was adequate, or the concern expressed was not sufficient to warrant specific Plan direction. RR

COMMENTS: Change 5.4 a-c guidelmes to standards.
1365

WILDLIFE - STANDARDS & GUIDELINES/LAWS/REGULATIONS

RESPONSE: Standards were identified and adopted where a specific practice or condition was viewed as necessary to fully meet the intent of environmental protection and cannot be effective except by the specified course of action. Other direction was established as guidelines where a certain course is advisable but where alternative courses of action may be permissible and still meet the intent of the prescription emphasis. Establishing all direction as standards is not necessary and could actually be detrimental to achieving desired outcomes because broad programmatic direction at the Plan level often is not sensitive to the inevitable variations, nuances, and complexity at the site-specific project level. RR

COMMENTS: Include standards and guidelines for thermal cover, corridors, opening sizes and elk habitat effectiveness (EHE) parameters to ensure adequate protection.

1273b

RESPONSE: Standards and guidelines were incorporated into the Revised Plan for opening size and open road density. These parameters are part of EHE determination. Research does not indicate that thermal cover is critical for winter range because elk winter in various cover conditions--in areas with dense thermal cover--such as timber, and with virtually no thermal cover, such as sagebrush. Research has not shown that travel corridors for elk are essential because elk migrate across a broad range of cover conditions. RR

COMMENTS: Develop more specific, measurable objectives for species selected in forestwide standards and guidelines test, and monitor some of the numerous management practices even from other regions.

1249

RESPONSE: The objectives and the methods identified in the Revised Plan are sufficient to meet resource management needs. Management practices from this and other regions are reviewed which may have value to improving management on the Targhee. RR

COMMENTS: Regarding standards and guidelines about wildlife goals (DFPR, Chapter 111): explain how the "natural occurrence and distribution of plant communities" is determined.

1249

RESPONSE: Historical maps and inventory data are used to identify natural ranges of plant community occurrence. Current inventory, habitat type, land type association, ecological unit inventory data may be used. State and other agency, research and academic sources or records, and scientific literature provide information. Professional judgement and understanding of ecological and successional processes provide insight into occurrence and distribution. Personal anecdotal and field observation, and occurrence of relic individuals of seral species play a role. Other sources are used as available. RR

All Species

COMMENTS: Establish comprehensive wildlife standards and guidelines for all species including carnivores and their habitat. Explain why some species were presented in forestwide standards and guidelines and others were not.

1249, 1361, 1365, 1446

RESPONSE: Establishing comprehensive standards and guidelines (S&Gs) for all species is not necessary to maintain viable populations or effective habitat. The Revised Plan uses an ecological approach to managing forest landscapes which can capture most requirements for habitat generalists. Some species are listed as threatened or endangered and require more specific protection and maintenance of individuals or habitat. The grizzly bear, peregrine falcon, and bald eagle have very specific and extensive standards and guidelines to ensure the Targhee management practices support recovery objectives. Other unlisted species may be classified as sensitive within Region 4 and have specific standards and guidelines that will foster their stabilization and recovery. Still others are identified as Management Indicator Species (MIS) which represents other species which depend on the same habitat type. RR

COMMENTS: Retain standards to use indicator species to assess habitat and species diversity because without standards, habitat management will become inconsistent.

389

RESPONSE: These were retained. RR

Strengthen Standards and Guidelines

COMMENTS: Make changes in wording to make the protection language stronger or more precise.

1365

RESPONSE: Some parts of the Revised Plan were modified to provide more explicit protection, such as for native trout. Overall, the language adopted in the Revised Plan is sufficient to meet needs for protection or mitigation.

RR

COMMENTS: In many cases the Plan erroneously lists as "guidelines" those binding, measurable guides; and lists as "standards" general, non-binding directions. Measuring and monitoring of fish and wildlife resources depends on detailed, accurate standards.

1446

RESPONSE: We tried to clean up any ambiguity which may lead to confusion. The key is - if the language, however broad, is a standard (S), then the direction must be followed. Deviations require a Plan amendment. Guidelines (G) may permit deviation and the rationale must be documented. Some direction for certain practices does not lend itself to simple, explicit descriptions with no nuance. RR

Compliance with Laws

COMMENTS: Targhee National Forest must comply with the National Forest Management Act and guidance supplied by the Forest Service Manual as well as the Endangered Species Act, in protecting fish and wildlife, and should be included in reasons for revising the Plan.

1446

RESPONSE: We agree. RR

COMMENTS: Both the ESA and NFMA are flexible as long as concern and appropriate management of endangered species are included in the Plan, thus the word "stringent" should be deleted from DEIS Page I-9, Issue 4, and after the words "Endangered Species Act" add "and NFMA."

1446

RESPONSE: This change was adopted. RR

Re-Write Management Prescription 5.1.3(a-b)

COMMENTS: Revise Management Prescription 5.1.3(a-b): Timber Management (no clearcutting, urban interface, wildlife and recreation protection, limited fuels management) as follows:

Description: The purpose of this prescription is to: Protect wildlife habitat especially habitat for threatened and endangered listed species, forestwide sensitive species and big game species including moose and mountain goats: Protect valuable recreation resources: Provide limited timber management with no clearcutting and to: Educate the public on the danger of wildfire and its consequences when choosing to live in or adjacent to wildlands. Fuels management is allowed if it does not impact the above mentioned wildlife values.

Goal: Protect valuable wildlife and recreation values while allowing some timber harvest that may help minimize fuel risks.

Standards and Guidelines: Forestwide Standards and Guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes: Fire/Fuels Same as 5.1(a-b) except prescribed fire may not be used for any purpose. **(S)** Insects and Disease Insects and disease are allowed to play their natural role in ecosystem processes. (S)

Biological Elements: Wildlife Wildlife habitat, especially habitat for T&E listed species, forestwide sensitive species and big game species including moose and mountain goats will be protected. Wildlife habitat will exist/evolve with natural ecological processes. No wildlife habitat improvements will be allowed. **(S)** Maintain snag habitat at 260% of the biological potential for all cavity nesters. (S)

Forest Use and Occupation: Access **(S)** The same as 5.1 except no cross-country snowmachine travel is permitted.

Recreation: Trails - No new motorized trails will be allowed. (S)
ROS - Recreation is managed to provide a combination of semi-primitive nonmotorized to roaded natural opportunities. (G) VQO - Retention **(S)**.

WILDLIFE - STANDARDS & GUIDELINES/LAWS/REGULATIONS

Production of Natural Resources: Timber No clearcutting, snag retention, protection of trees for wildlife and scenic purposes.

643

RESPONSE: This proposal was not adopted. The Forestwide Standards and Guidelines apply to this prescription and provide adequate protection of Threatened, Endangered and Sensitive species. The emphasis is to provide fuels hazard reduction in areas of human development and activity within and adjacent to the Forest, principally around Island Park and along the South Fork Snake River and Palisades Reservoir. Harvest would be done with consideration of visual effects and human activity in the area, therefore there would be no clearcutting. Your proposed alternative wording does not meet this intent nor does it recognize the amount of current human development already affecting wildlife resources or natural ecological processes. RR

WILDLIFE - SITE-SPECIFIC

Italian Peaks

COMMENTS: Use the elk and deer prescription wherever there is winter range. Italian Peaks, Bear Creek and the central part of Garfield Mountain have the wrong prescription; it is a range prescription rather than elk and deer and is detrimental to wildlife.

695

RESPONSE: The winter range prescription was applied to all areas identified by the Idaho Fish and Game as "crucial". Because these areas are most important during the winter, the winter range prescription was applied instead of the elk summer range prescription. The goal of the elk summer range prescription 5.4 is to "provide elk security areas" and to "use silvicultural techniques which prevent...insect and disease epidemics..." This is not the best approach to an area used by animals for winter range.

The Italian Peaks proposed wilderness is in the 1.3 prescription for "Recommended/Proposed Wilderness". The area east and south of Italian Peaks is in the range prescription because management of the rangeland vegetation is the primary concern, not providing elk security areas. A part of the Medicine Lodge area is in the elk and deer winter range prescription. CP

COMMENTS: Do not allow cross-country motorized travel or game retrieval in 5.4 a-c.

1365

RESPONSE: The game retrieval proposal was dropped for all areas. Cross-country motorized travel is not allowed on the Dubois Ranger District in the Revised Plan. CP

Mount Jefferson

COMMENTS: Protect Mount Jefferson as wilderness so that in the future, great grandchildren can enjoy wildlife in the area.

613

WILDLIFE - SITE-SPECIFIC

RESPONSE: Mount Jefferson was not recommended for wilderness. This area was analyzed for wilderness potential in the FEIS along with all the roadless areas. The area did not score high enough to be recommended for wilderness. Furthermore, the area was not recommended by the 1990 BLM EIS. This analysis is documented in the Roadless Areas Appendix. In the Revised Plan, the management prescription for the Mount Jefferson area is nonmotorized with an emphasis on semi-primitive nonmotorized recreation use. This prescription provides protection to wildlife habitat. AS/Ak

Henry's Lake Mountains

COMMENTS: Upgrade to a prescription that provides better habitat security for grizzly bear and other wildlife. Suggest non-motorized, grizzly bear habitat (Sit.2) or grizzly bear habitat (no ASQ, cross-country, or sheep). (CROSS REFERENCE: Grizzly Bear)

1185, 1348

RESPONSE: Henry's Lake Mountains are geographically located between Targhee Creek basin and the Moose Creek Plateau on the Targhee National Forest. In the Revised Plan, the prescriptions for this area are 1.3 Recommended/Proposed Wilderness in the Targhee Creek Basin, 2.6.1 (a) Grizzly Bear Habitat (No ASQ, No Cross-country, No Sheep) in the vicinity of Mt. Two Top and 5.3.5 Grizzly Bear Habitat (NIC for ASQ, No Cross-country, Phase Out Sheep) between Mt. Two Top and the Moose Creek Plateau. AK

COMMENTS: Prescription needs to address winter use by non-motorized and motorized recreation in high elevation areas like this because of impacts on wolverine ecology and natal dens (see Copeland's research).

1348

RESPONSE: The Revised Plan has an objective to analyze the potential wolverine sites and field check for actual wolverine use. Idaho Fish and Game wants identified boulder sites closed. This concern would be addressed in a site-specific analysis. AK

Bootjack Pass/Sawtall/Jefferson

COMMENTS: Do not allow timber cutting in Bootjack Pass to Red Rock Pass and on north side of Sawtall, Jefferson Peaks, and adjoining mountains because this area is a narrow strip that harbors Idaho's small elk herd as well as other big game animals and such activities do not sustain habitat or free movement for wildlife on a narrow strip; these and other activities in the summer cabin area are disruptive to the environment.

1457

RESPONSE: In the Revised Plan, one prescription for this area is 3.1.2, nonmotorized, which is not in the suitable timber base and does not contribute toward the ASQ. The other prescription is 5.3.5 Grizzly Bear Habitat and is included in the suitable timber base, but these lands are considered a Non-Interchangeable Component (NIC). Timber harvest proposals would have to meet standards and guidelines that promote the enhancement of grizzly bear and other wildlife habitat in the area. AX

Jackpine Creek - Bitch Creek

COMMENTS: Support the roadless area east of Jackpine Creek and south of Bitch Creek. Keep the 2.6.5 Prescription to protect its high quality habitat for bears, elk, and mature forest species (marten, forest accipiters).

1277

RESPONSE: The management for this area in the Revised Plan satisfies your concern. AK

Snake River and Palisades

COMMENTS: Protect the South Fork Snake River/Palisades Reservoir from timber harvest and any road construction to protect valuable wildlife habitat.

766

Keep the same prescriptions as in the current plan in Palisades Reservoir. Limit timber harvest to 100 acres and only allow temporary roads. Keep wording, "treated acres must either be beneficial or neutral to wildlife habitat." Give priority to wildlife in these areas.

FS-11

RESPONSE: Wildlife is a priority in most of the area. The Revised Plan identifies lands which are suitable for timber harvest and these lands are placed in a timber prescription. Harvesting timber outside of the timber prescriptions can only be done to benefit other resources values including wildlife habitat. The South Fork of the Snake River (within at least one-fourth mile) and the Palisades Backcountry are not within a timber prescription. Forestwide and individual prescription standards and guidelines for the South Fork and Palisades Backcountry protect wildlife values. Values for the river corridor are maintained so that it remains eligible for wild and scenic river status.

Timber harvest is planned in the urban interface prescriptions along the east and southwest shores of Palisades Reservoir to reduce fuel loading near homes on private lands, which are increasing in the area, as well as near summer homes permitted on National Forest land at Calamity, Alpine and Hoffman.

Because these areas also have important tree habitat for eagles and other wildlife, a new guideline was added to emphasize management of old growth Douglas-fir, spruce and cottonwood within one mile of the reservoir or river.

Road construction of permanent roads for timber harvest or any purpose would only be allowed up to a limit of 3 miles per square mile in the urban interface prescription areas (5.1.3.b), up to 2 miles per square mile in the big game winter range prescription (2.7.a), and up to 1 mile per square mile in the semi-primitive motorized (3.2.d) along the river and reservoir.

BP/BA

COMMENTS: Protect winter moose habitat along the South Fork Snake River and adjacent to Palisades Reservoir.

766

=

WILDLIFE - SITE-SPECIFIC

RESPONSE: No specific standards, guidelines or prescriptions were identified for protecting winter moose habitat only because moose do not congregate in one area and are spread out throughout the Forest. However, many moose winter within identified big game winter range of elk and deer. The Revised Plan now includes winter range protection along Palisades Reservoir and the South Fork of the Snake River below the dam, providing the same protections for wintering moose. The changes that expanded big game winter range protections were done in cooperation with the Idaho and Wyoming Game and Fish Departments. These protections are shown on the Forest Travel map. BA

COMMENTS: Protect crucial deer habitat along the South Fork Snake River and adjacent to Palisades Reservoir.

766

Snake River Canyon to the state line needs to be recognized as big game winter range.

389

RESPONSE: The area along the South Fork of the Snake River is in the big game winter range prescription (2.7.a) downstream from Swan Valley, providing a great amount of protection during the snow season from human activity except on designated routes. For Palisades Reservoir and the river below the dam in Swan Valley, additional protections were added to the winter range, in cooperation with the Idaho and Wyoming Game and Fish Departments. These protections are shown on the Forest Travel map. BA

COMMENTS: Support your biodiversity effort to regenerate cottonwood along the South Fork Snake River.

695

RESPONSE: Thank you for your support recognizing the importance of the cottonwoods along the South Fork. The plan has standards and goals for cottonwood regeneration. We are continuing to use the BLM/FS South Fork Activities and Operation Plan of 1991 as the management direction for the South Fork of the Snake River in the Revised Plan. BA

COMMENTS: Recognize the area from the Snake River Canyon to the state line as big game winter range.

389

Alternative 3M does not adequately protect "crucial" elk winter range areas along the South Fork Snake River and adjacent to Palisades Reservoir.

766

RESPONSE: Working with the Wyoming Game and Fish Department, the Forest added this area as winter range in the Revised Plan. The area has designated routes for over-the-snow vehicles and other human activities. BA

Alpine

COMMENTS: Recognize elk winter range from Alpine northward to Swan Valley per Wyoming Game and Fish. The area needs winter range protection.

FS-10

WILDLIFE - SITE-SPECIFIC

RESPONSE: The Revised Plan added big game winter range protection during the snow season from human activity to the area in Idaho and Wyoming from Alpine to Swan Valley, in cooperation with the Idaho and Wyoming Game and Fish Departments. These protections are shown on the Forest travel map. BP/BA

COMMENTS: Antelope drainage is not winter range and was shown as one whereas Alpine is winter range (and is not shown as one).

FS-1

RESPONSE: The Antelope drainage was removed from the winter range prescription and replaced with a range management prescription (6.1.b). In cooperation with the Wyoming Game and Fish Department, protection to the Alpine big game winter range was added. Designated routes for human activity are allowed. These routes and protections are shown on the Forest travel map. BA

COMMENTS: The area in Wyoming needs a comprehensive cumulative impacts analysis that evaluates impacts to old growth and wildlife, and especially to winter big game species (with emphasis on crucial areas). Palisades standards and guidelines need to protect crucial mule deer and elk winter ranges.

389

RESPONSE: In cooperation with the Wyoming Game and Fish Department, the Forest added protections to the winter range here. These protections are shown on the Forest travel map. Some designated routes are identified for human activity. A comprehensive cumulative impacts analysis is not needed for travel in this winter range.

The future impacts that might occur to old growth and wildlife in the Wyoming prescription areas are small or localized. The prescriptions are: Wilderness Study Area (1.2), Eligible Wild River (2.3), Semi-primitive Motorized (3.2.d, 3.2.g), Timber Management/Urban Interface Fuels (5.1.3.b), and Visual Quality Maintenance (5.2.2).

Of these, the 3.2 and 5.1.3 prescriptions have the most potential to change habitat and they represent a localized acreage near Alpine. In the Final Revised Plan, a new guideline was added to emphasize old growth Douglas-fir, spruce and cottonwood trees within one mile of the Palisades Reservoir or the Snake River. This protection overlaps two prescription areas. The summer time motorized trail density standards for these areas are: 3 miles per square mile in 5.1.3.b and 1 mile per square mile in area 3.2.d. Additional roads or motorized trails in road construction of permanent roads for timber harvest or any purpose would only be allowed up to a limit of 3 miles per square mile in the urban interface prescription areas (5.1.3.b), up to 2 miles per square miles in the big game winter range prescription (2.7.a), up to 1 mile per square mile in the semi-primitive motorized (3.2.d), and 1.25 miles per square miles in the elk summer range ASQ prescription standard would be on a temporary basis. Any cumulative effects from logging, vegetation manipulation or roading activity would be analyzed in a site-specific environmental assessment. BA/BP

WILDLIFE - SITE-SPECIFIC

Bald Mountain Roadless Area (near Bear Mountain in Caribou Section)

COMMENTS: Support the area for elk and deer winter range.
695

RESPONSE: The Bald Mountain roadless area is administered by the Soda springs Ranger District on the Caribou National Forest and is not covered by the Targhee's Revised Plan. All winter range for deer and elk is protected on the Targhee. BP

Big Holes

COMMENTS: Deer are not bothered in Big Holes by motorcycle use; deer do not stop grazing and look when bikes stop unless we leave the bikes.
97

RESPONSE: Research has shown that wildlife can be disturbed by motorized travel. Semi-primitive motorized access prescription 3.2 (g) assigns a portion of the Big Holes to provide motorized use on designated roads and trails. This provides wildlife with large areas free from disturbance by summer cross-country motorized human activities. M05

COMMENTS: Temporarily close some trails in the area where heavy use is causing erosion, let it rejuvenate and then reopen the area. There is no need for permanent closures.
97

RESPONSE: The Forest is closing some trails permanently where resource damage is due to poor trail design and location. Trails that have erosion or resource problems but are being kept in the trail system will be rehabilitated or have sections rerouted to eliminate resource damage or potential damage.
RS

COMMENTS: Regulate OHV travel in the Big Holes so that elk populations might increase.
215

RESPONSE: Semi-primitive motorized access prescription 3.2 (g) provides motorized use on designated roads and trails. This provides wildlife with large areas free from disturbance by cross-country motorized human activities.
M05

COMMENTS: Close roads in the Big Holes for elk security.
356

Do not close roads in Big Hole Mountains to provide elk security.
311

Big Holes look to be an ideal elk natural habitat area.
215

RESPONSE: The Big Holes do contain ideal elk habitat. Roads in the Big Holes were designated open or restricted in the Revised Plan to provide access opportunities for the public, allow resource management planning, and provide

security areas for wildlife, including elk. Travel routes and restrictions are reflected on the Travel Plan Map in the Record of Decision. M05

COMMENTS: Do not harvest timber along Big Hole Mountains corridor because it would affect moose and elk.

325

RESPONSE: The eastern edge of the Big Holes in the FEIS was changed from prescription 7.1 to prescription 5.1.3. The emphasis of prescription 5.1.3 is management of fuels to minimize fire hazard to urban facilities by thinning forested stands and removal of deadwood. No clearcutting is allowed. Impacts to big game from future project proposals will be evaluated through a site-specific analysis during the NEPA process. Identified big game winter ranges are managed to provide quality habitat for elk and deer. Prescribed fire may be used to improve and increase wildlife habitat. M05

COMMENTS: Grizzlies are doing quite well here; there are too many grizzly bears and mountain lions.

307, 311

RESPONSE: Grizzly bears are expanding their range in the Greater Yellowstone Ecosystem. No grizzly bears are known to exist in the Big Holes. Mountain lion sightings occur on the Forest. Mountain Lion populations are managed by the States of Idaho and Wyoming. M05

COMMENTS: Address the possibility of fire in residential areas adjacent or within forested areas, especially Big Holes.

325

RESPONSE: The Revised Plan allows fuels management along the east face of the Big Holes, under Timber Management prescription 5.1.3 (b). This prescription does not allow clearcutting. Vegetation will be managed to minimize fire risk around urban facilities by thinning forested stands and deadwood removal. RS

Teton Range Subsection

COMMENTS: Include and protect moose winter range in the following areas: From Wyoming State Highway **22** north to Teton Canyon in Management Prescription 3.2; from north and south Leigh Creek to Badger Creek in Management Prescription 5.4, and north of Badger Creek in Management Prescription 5.3.5. Include a wildlife objective, standards and guidelines to improve moose winter range in the Teton Range Subsection. Moose winter ranges have been overlooked in Teton Subsection (Page, 111-47); include standards and guidelines.

389

RESPONSE: Unlike deer and elk, moose are less restricted elevationally by snow depth and are widely scattered over the winter landscape. Prescriptions, standards and guidelines were not developed specifically for wintering moose. The Forest will adaptively manage moose across its range by adhering to upland and riparian browse utilization standards, prescribed fire and selective vegetative management techniques. M05

WILDLIFE - SITE-SPECIFIC

Jedediah Smith Wilderness

COMMENTS: Restore degraded fish and wildlife habitats.

195

RESPONSE: Forestwide Goals for Fisheries, Water and Riparian Resources, Wildlife and Vegetation emphasize maintaining diverse ecosystems and habitats, and restoration of degraded areas to a properly functioning condition. These goals are supported by an array of standards and guidelines. In addition, standards and guidelines for the Jedediah Smith Wilderness under prescriptions 1.16, 1.17 and 1.18 identify the amount of degradation allowed from no measurable (1.1.6) to no measurable degradation cumulatively over 3 years (1.1.8). If these thresholds are reached within each prescription area, restoration and area management will change. RS

Mill Creek Area

COMMENTS: Avoid any activity which might degrade the vegetation, soils and critical winter range habitat for deer and elk in Mill Creek Area (near Targhee Ski Hill).

329

RESPONSE: The Mill Creek area is within Prescription 2.7 that emphasizes resource conditions that provide quality elk and deer winter habitat. Management activities are at levels that are compatible with maintaining or improving winter range and do not contribute to degradation of the prescription area. Recreation, cattle grazing, vegetation management (Non-ASQ timber and fire) and wildlife habitat improvement are planned activities within the Prescription. Activities are subject to Prescription 2.7 standards and guidelines, and Forestwide standards and guidelines for: Biological Elements (Fisheries, Water, Riparian Resources, Vegetation, Wildlife), Physical Elements (Soils), Forest Use and Occupation (Recreation), Production of Commodity Resources (Range upland and riparian forage utilization), and Timber Management. RS

WILDLIFE - SMALL MAMMALS

Manage Non-Game Species

COMMENTS: Need to include management for non-game species such as bats (especially as they relate to insects, snag and cave management -- some bats were recently added to the Fish and Wildlife sensitive species list); flying squirrels; bird habitat; fisher and wolverine; rodentia in general, since they are important parts of the food pyramids of medium sized birds and mammals.

384, 389, 643, 731

RESPONSE: The Revision includes direction to maintain or enhance biodiversity and to manage ecosystems in properly functioning condition. This requires managing for an array of habitat conditions across the Forest. Many standards and guidelines were developed which provide for the habitat needs of all non-game species. Specifically, the Revision has direction to develop management plans for any caves, mine shafts, or other suitable habitats where

spotted and Western big-eared bats are found. It also stipulates the amount of snags and logs needed to provide wildlife habitat and for site productivity. DD

COMMENTS: Determine population data for non-game species including the types of species, their location and health. Without this data it's difficult, if not impossible, to assess potential impacts, biodiversity, gradient diversity and variability across the landscape.

1368

RESPONSE: It is not possible to determine population levels, location, and health of all non-game species inhabiting the Forest. However, we do collaborate with researchers and other interested publics to monitor the population trend and distribution of many species of non-game wildlife. Most of our effort is focussed on those species which are threatened, endangered, or sensitive to management activities. DD

COMMENTS: Targhee National Forest does not meet NFMA, Forest Service regulations (36 CFR 219) requirement to maintain viable populations of native vertebrate species.

645, 699

RESPONSE: Various analyses, literature reviews, and consultations with other agencies has led us to the conclusion that the Revision will maintain and promote viable populations of these species. Summaries of those findings are contained in the various wildlife segments of the FEIS. DP

COMMENTS: Analyze existing/planned habitat conditions for small mammals, especially where associated with range or old growth; create standards for small mammal habitat on grazing allotments.

384, 389, 1369

RESPONSE: Habitat conditions for small mammals were analyzed during the planning process. Many standards and guidelines were developed which provide for the habitat needs of small mammals inhabiting all areas of the Forest, including grazing allotments and areas of old growth forest. DD

COMMENTS: Consult with coordinating agencies and reintroduce extirpated species. Make this a guideline.

1365

RESPONSE: The Forest often coordinates with other agencies to recover dwindling or extirpated species. The policy direction and legal authority to enter into these conservation efforts is already in place. Therefore, a guideline is not necessary. DD

COMMENTS: DEIS must address habitat needs and conditions for old growth dependent species so that it can assess habitat conditions for carnivores; need to consider roads, elevation and vegetation that also define carnivore habitat.

1361

WILDLIFE - SMALL MAMMALS

RESPONSE: The Forest added new analysis, information and management direction for old growth in the Revised Plan and FEIS. Forest carnivores are a management indicator species and we analyzed habitat components deemed important for their consideration. MO

COMMENTS: Explain if Process Paper D's list of mature and older forest acres by watershed are all available for carnivores and explain when the acreage data was collected.

1361

RESPONSE: Process Paper D's list of mature and older forested acres by watershed is available for carnivores. The vegetation acreage data is collected from the ranger districts from September, 1991. MO

COMMENTS: In working to protect certain "charismatic" large mammals and birds, we trust that you will also protect less entertaining, but probably more important species.

1393

RESPONSE: The Revision contains a goal to maintain or enhance wildlife biodiversity by managing for a diverse array of habitats and distribution of plant communities. This goal will be achieved through the application of several standards and guidelines which protect species and habitats. DD

Protect Management Indicator species

COMMENTS: Evaluate the effects of pest and fire management practices on MIS and discuss access and human dispersal effects on MIS species.

1365

Provide data on MIS so you can estimate the existing conditions of populations.

1369

RESPONSE: A description of all MIS is presented in Chapter III of the FEIS. The effects of all proposed activities on MIS are described in Chapter IV of the FEIS. DD

COMMENTS: Prohibit construction of new roads and obliterate any roads that are causing detrimental impacts to goshawks, sensitive species, threatened and endangered species or any species used as a management indicator.

1365

RESPONSE: The Forest completed an assessment of all roads and trails to consider: value to the public, damage to soils and other resources, disturbance to wildlife, threat of mortality to certain species, and administrative needs of the agency. This assessment provided the basis for deciding which roads will be left open, closed, obliterated, or restricted. Construction of new roads will be evaluated on a site-specific basis. DD

Make Management Indicator Species Standards and Guidelines

COMMENTS: Develop management standards for management indicator species even though this is not a major public issue. Management standards are needed when the level of timber harvest is so high; without standards, habitat management will become inconsistent.

389, 1365, 1369

RESPONSE: The Revision contains standards and guidelines for several management indicator species. DD

COMMENTS: Evaluate the amount, quality and quantity of MIS habitat and animal population trends in each alternative and make this a guideline.

1365

RESPONSE: MIS habitat and population trend is described in Chapter III of the FEIS. MIS habitat will be conserved through the application of the standards and guidelines described in the selected alternative. DD

Consider Additional Management Indicator Species

COMMENTS: Consider mammals as wildlife management indicators for aquatic and riparian habitats. Beaver, mink and otter are important indicators of aquatic and riparian habitat conditions and provide different information than the birds and amphibians currently proposed as indicators. Consider at least two small mammals (e.g., water vole, snowshoe hare, western jumping mouse; or vagrant shrew) as indicators of riparian health.

282, 389, 643

RESPONSE: We did consider selecting mammals as MIS for aquatic and riparian habitats but found bald eagle, trumpeter swan, spotted frog, common loon, harlequin duck, and cutthroat trout to be suitable. DD

COMMENTS: Your list of wildlife management indicator species (DEIS, Chapters 3 & 4) is incomplete until you include any small mammal species. Include the snowshoe hare as indicator of forest successional stages since its presence or absence is also an indicator of the potential for the existence of lynx and fisher. The red-backed vole and northern flying squirrel are indicators of the condition of conifer habitats.

389

RESPONSE: The 16 management indicator species selected to represent other species within forested habitats are adequate. The Forest uses other techniques, such as aerial photography and habitat measurements, to determine forest successional stages and condition of conifer habitats. DD

COMMENTS: Incorporate the notion of representativeness for Management Indicator Species. There is growing criticism of exclusively relying on indicator species.

1365

WILDLIFE - SMALL MAMMALS

RESPONSE: We acknowledge the debate about the use of the Management Indicator Species, however, our planning regulations require their use and we followed those regulations. MO

WILDLIFE - SNAGS, CAVITY NESTERS

Snag/Cavity Nesting Habitat Standards and Guidelines

COMMENTS: Change the guidelines for snags for cavity nesting habitat to standards.

695

RESPONSE: Guidelines are used because they increase our ability to match snag levels to the natural potential of each unique site. Standards do not allow the flexibility needed to account for site variability. DD

COMMENTS: Need a second guideline for the snag/cavity nesting habitat. It should read: "consider cavity nest species and protection measures for retained wildlife trees in cutting units when designating fuelwood areas and sales, both commercial and personal use charge areas."

FS-9, FS-10

RESPONSE: The guidelines for cavity nesting habitat apply to specific management prescriptions. Any vegetation management activities, including commercial and personal use fuelwood, within a management prescription must take into account the specific guidelines in that management prescription area for maintaining cavity nesting habitat. MO

COMMENTS: Include other factors besides dead trees when determining the habitat needs of cavity nesters; include structure of forest stand, including basal area, dead and downed material, patch size and connectivity; consider the effects that future natural disturbances may have on cavity nesting species.

1365, 1369

RESPONSE: All of these factors were considered. The Revision includes direction to manage forests in properly functioning condition. This includes assessing stand structure (which includes basal area), composition, disturbance regime, and patterns (which includes patch size and connectivity). Chapter III of the Revision describes the Forestwide guidelines for the management of dead and down material which are aimed at providing for both site productivity and wildlife habitat needs. DD

COMMENTS: Snags/cavity nesting should be done on a subsection basis, not watershed basis.

413

RESPONSE: Most snag/cavity nesting habitat needs assessments are conducted on a watershed basis or management prescription area basis. This scale was chosen because it helps maintain snag habitat well distributed across the Forest. MO

Create Snag Standards

COMMENTS: Create snag standards so that the Forest can determine future snag densities in order to evaluate impacts of each alternative; include minimum height and dbh. Do not call any dead tree a snag.

1369

RESPONSE: We have done so. The definitions of the various types of snags are found in the Revision glossary. DD

General Habitat Standards and Guidelines

COMMENTS: Leave more snags and dead fall for wildlife to use.

359

RESPONSE: The direction in Chapter III of the Revision increases the amount of snags and dead fall which will be retained in timber harvest areas. DD

COMMENTS: Cite the science and basis for requiring only 60% of an area (20 logs per acre) to meet dead and down wood guidelines and how this ensures wildlife viability; explain why logs are considered for a guideline and other woody debris are not.

1369

RESPONSE: Dead and downed wood (logs) are not evenly distributed, even under natural conditions. We need to take into account uneven distributions, without having to haul logs into an area that does not have any. The science and literature on which we based the dead and down wood guidelines are presented in Process Paper D. MO

COMMENTS: Change the following from a guideline to a standard: Maintain snag habitat at >60% of the biological potential for woodpeckers.

643

RESPONSE: This recommendation was considered but not adopted. A guideline is an appropriate measure. Guidelines are appropriate where variability occurs at the implementation level or desired goals or conditions can be achieved by more than one approach. A guideline provides for some site-specific flexibility while still meeting the essential intent. RR

COMMENTS: Page 111-134, Wildlife (5.3.5) - Create a standard requiring the maintenance of snag potential at >40% of the biological potential for woodpeckers.

1365

RESPONSE: This recommendation was considered but not adopted. Management prescription 5.3.5 (grizzly bear habitat) has a guideline for maintaining snag habitat at 260 percent of biological potential. We chose the higher level because snags eventually become dead and downed logs, and dead and downed logs are important grizzly bear habitat components. MO

WILDLIFE - SNAQS, CAVITY NESTERS

COMMENTS: Determine the viability impacts of existing snag levels in order to come up with mitigation measures to correct existing problems.
1369

RESPONSE: The analysis of snag habitat included a detailed analysis of more than 400 permanent forest inventory plots distributed across the Forest. This analysis is presented in detail in Process Paper D. Species viability analysis included information from the Upper Columbia River Basin Project and the detailed analysis done on the Forest. This is presented in Process Paper D. **MO**

Explain science

COMMENTS: Explain the science and basis for how the structure of woody debris plays a role in wildlife effectiveness and how this will be achieved in the Guideline for Wildlife, General Habitat, Chapter **III**.
1369

RESPONSE: The science and literature on which we based the dead and down wood guidelines are presented in Process Paper D. **MO**

COMMENTS: Cite all references used to incorporate snag guidelines and demonstrate what research validates them as a useful tool in your wildlife management strategy.
1369

RESPONSE: The references used in development of the Revision are listed in the references section at the end of the document and in Process Paper D. **DD**

COMMENTS: Explain how the biological potential of your analysis has been validated in order to use it as a guideline for management; explain how/if this approach worked in the past, if it maintained historical densities of cavity nesters and the reasoning for continuing this approach. Explain, with scientific reference, how the green tree replacement strategy will fully mitigate impacts on cavity nesters, especially the adequacy of 25 trees per acre; evaluate the implication of 41% biological potential for cavity nesters and what this means for viability.
1369

RESPONSE: The science, literature and analysis on which we based the primary cavity nesting species guidelines are presented in Process Paper D. Documentation on historical densities of cavity nesting species does not exist. Validation of the guidelines proposed in the Revised Plan will occur through monitoring of population trends of primary cavity nesting species and monitoring snag densities. **MO**

COMMENTS: Reference the Live Trees Chart in chapter **111**: Use the **40-60%** biological potential for snags in foraging areas because the emphasis in foraging areas is food, not nesting potential. Snags are more important for nesting, not foraging.
413

WILDLIFE - SNAGS, CAVITY NESTERS

RESPONSE: The application of the biological potential and snag recruitment will be made during site-specific analysis of project proposals. RR

COMMENTS: Only need 10 trees per acre recruitment snags for 100% biological potential. Twenty-five live trees per acre is excessive.

413

RESPONSE: This recommendation was not adopted. To maintain snag levels over time, 25 live trees per acre, with a range of ages and sizes, are needed as replacement trees for future snags. MO

COMMENTS: Establish snag and green tree replacement requirements within prescriptions that emphasize public safety and protection of facilities.

1365

RESPONSE: A standard was added to ensure public, contractor, and employee safety in selecting trees for snag recruitment. Snag and green tree replacement requirements can be achieved while protecting public safety and protecting facilities. The "requirements" are Forestwide "guidelines", which allow for deviation if necessary on a site-specific basis. Deviations will be documented with a clear rationale as to the intent of the deviation. DD/RR

COMMENTS: Develop standards for snags or replacement trees so that the Forest can know what to ascribe the planned Forest condition.

1369

RESPONSE: Guidelines for snags and replacement trees are presented in Chapter 111-Part 1 of the Revision. DD

WILDLIFE - SPECIFIC SPECIES

Antelope

COMMENTS: Create forestwide standards and guidelines for antelope winter range.

1249

RESPONSE: This recommendation was considered but not adopted. Very little antelope winter range occurs on the Forest. Most is off-Forest and not meaningfully affected by Forest activities. RR

Bald Eagle - General

COMMENTS: Protect bald eagles and their habitat from human activity.

265, 697

RESPONSE: It is our policy to protect bald eagles and their habitat from human activity. This is accomplished through development and implementation of bald eagle management plans, standard operating procedures, standards and guidelines in the Revision, and monitoring. DD

WILDLIFE - SPECIFIC SPECIES

COMMENTS: Although the bald eagle has been re-classified as threatened, continue recovery.

1446

RESPONSE: We will continue recovery efforts until delisting. Then our management emphasis will shift toward maintenance of healthy habitats and monitoring. DD

Bald Eagle - Roads

COMMENTS: Clarify in EIS that the construction of temporary roads, especially in bald eagle habitat, is not included in new road construction.

1446

RESPONSE: This will be a site-specific consideration when site-specific projects are proposed in bald eagle habitat. MO

COMMENTS: Standard B should be changed to, "no new roads in zone 1 or zone 2."

1365

Standards and guidelines item 1A for bald eagles should read: "Road closures will be located and designed to effectively control human use."

1446

RESPONSE: These recommendations were considered but not adopted. The Revised Plan direction is based on the recovery goals for the eagle. The Forest is meeting or exceeding goals for recovery. Additional direction is not necessary to provide for effective protection of bald eagles. RR

Bald Eagle - Old Growth

COMMENTS: Explain how you can have bald eagle old growth habitat without insect and disease.

1369

RESPONSE: All healthy old growth habitats have endemic levels of insects and disease. This is normal and is usually sustained over relatively long periods of time. Lodgepole pine ecosystems are the exception in that the old growth stage is not sustainable for relatively long periods. The Revised Plan provides for this and prescribes no extraordinary measure to eliminate pathological activity, except some limited actions in developed campgrounds, for example. DD/RR

Bald Eagle - Management Plan

COMMENTS: Include as a standard for bald eagle habitat: "Nest management plans for all existing bald eagle nests will be completed as soon as possible. Future nest sites will have management plans completed within two years of discovery."

1446

RESPONSE: This recommendation was considered but not adopted. The Revised Plan direction provides for effective protection of bald eagles. RR

COMMENTS: Acknowledge the recovery goals and objectives outlined in Pacific Northwest Recovery Plan as the guiding bald eagle management protocol. Chapter V, Monitoring Item summary, Bio Elements, Wildlife: include the completion of bald eagle nest site management plans and give priority 1 status.

RESPONSE: The FEIS and Process Paper D discuss the goals and objectives of the Pacific Bald Eagle Recovery Plan. The Forest developed forestwide standards and guidelines that are responsive to the bald eagle recovery plan. Currently bald eagles in the Greater Yellowstone Area exceed the goals and objectives of the recovery plan. MO

COMMENTS: Incorporate reference to activity plan in South Fork Snake River Activity/Operations Plan prepared by BLM and Forest Service.

1446

RESPONSE: This is referenced in Chapter IV of the FEIS. RR

Bald Eagle - Correction/Definitions

COMMENTS: Correct paragraph 2 in bald eagle nesting habitat, where it lists 1992 Forest Service report with 1995 data.

1446

RESPONSE: This was corrected in the FEIS. RR

COMMENTS: Define "adverse impacts" by livestock use near bald eagle nests.

389

RESPONSE: This would include activity near the nest site which risks disturbing nesting eagles. Some examples include livestock persistently congregating near the nest or human activity necessary to manage livestock or an allotment which occurs near an active nest. RR

COMMENTS: Chapter 3, Bald Eagle Habitat: For consistency with NFMA, ESA and other bald eagle management standards: #A should be a standard to be consistent with #I; #B (second part) should be changed to a standard; #C and #J were listed as standards in the preliminary draft biological assessment (BA pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and #L should be a standard to be consistent with #M, wildlife management actions on the Forest.

1446

RESPONSE: For the Greater Yellowstone area, the bald eagle has exceeded all the goals and objectives of the Pacific Bald Eagle Recovery Plan. Forestwide standards and guidelines are the same that we have operated under for the past 12 years which has led to success. Therefore, no changes were warranted.

WILDLIFE - SPECIFIC SPECIES

Bald Eagle - Establish Stronger Protection

COMMENTS: Human activity should be prohibited, not just minimized in bald eagle nesting zones and use areas.

389

Need a more protective measure than "avoid" in bald eagle standards and guidelines. Use the same protective measure in Zone II relative to recreation site development because that is within the Forest Service's control.

1249

RESPONSE: Prohibiting human activity within bald eagle nesting zones is not practical and may not be necessary in most cases. Controlling the type, duration, timing, and distance of the activity is more practical and effective in protecting bald eagle nesting success. DD

COMMENTS: Chapter 3, Bald Eagle Habitat: Add standards restricting human entry and development within bald eagle zones 1 and 2 and within at least 1/4 mile radius of existing/new nests.

1446

RESPONSE: If this was done, fishing, boating and other recreation activities would be nearly eliminated on the South Fork and Henry's Fork of the Snake River. In the Greater Yellowstone area, the bald eagle population has exceeded all the goals and objectives of the Pacific Bald Eagle Recovery Plan. Forestwide standards and guidelines are the same that we have operated under for the past 12 years, with great success. Therefore the Forest did not elect to proceed with any serious, drastic measures. MO

COMMENTS: Develop a guideline to educate recreationists (e.g., floaters, hikers, campers, ATV users, etc.) about Zone 1 areas.

1446

RESPONSE: A guideline was not added as suggested. The Forest recognizes that public education is important to continued success of the bald eagle and we will take opportunities to do so in the future. MO

COMMENTS: Chapter 3, Bald Eagle Habitat, Standards and Guidelines: Add a guideline to protect alternate and potential nest sites from timber harvest, roads and permanent recreation developments.

1446

RESPONSE: The Forestwide standards and guidelines apply to all existing and newly occupied nest zones in primary use areas. MO

COMMENTS: Standards and Guidelines, #G: Bald eagle populations are doing well in the Greater Yellowstone Ecosystem (GYE), but in the rest of the Pacific Northwest they are not meeting recovery standards. Concern for nesting success should be reflected in all forestwide standards.

1446

WILDLIFE - SPECIFIC SPECIES

RESPONSE: The standards and guidelines in the Revised Plan will continue the success achieved so far on the Targhee and this is reflected in the Revised Plan direction. RR

COMMENTS: Because the bald eagle is threatened, use standards rather than guidelines in this portion of the document.

1446

Change guidelines to standards and the word "discouraged" to "prohibited".

1365

RESPONSE: Standards are used where total (unconditional) compliance is necessary to achieve a desired condition or goal and where we have absolute control over the outcome. There are many instances where standards would not be practical but guidelines would achieve the desired condition or goal. DD

COMMENTS: Explain that potential impacts to eagles and other threatened and endangered species (T&E) require ESA section 7 consultation with Fish and Wildlife Service.

1446

RESPONSE: Since this is a standard operating procedure, it is not reiterated in the Revision. National direction and established policy which exists in other official documents, such as Manuals, Handbooks, Executive Orders, and so forth, are not repeated in the Revised Plan but still will be adhered to. This official direction is referenced in Appendix A, National Goals Relevant to Land and Resource Management, Wildlife and Fish (FSM 2600), of the Revised Plan. DD/RR

COMMENTS: Guideline A and C should be a standard. State how activities will be restricted to protect bald eagle habitat.

1365

RESPONSE: This was not changed. The language, "minimize", connotes a guideline. The practical effect of implementing this direction would be the same if it were established as a Standard. RR

COMMENTS: Add a standard to monitor the effectiveness of bald eagle standards and guidelines.

1365

RESPONSE: The Forest monitors bald eagle habitat and compliance with standards and guidelines in the normal course of duties. A standard is not necessary. Monitoring bald eagle nesting population and the relationship to habitat changes is a Priority 1 monitoring item in Chapter V of the Revised Plan. This is sufficient to determine the effectiveness on the Plan direction for Bald eagles. DD/RR

COMMENTS: Change D to a standard and add, "prohibit new developed recreation sites or facilities in Zones 1 and 2 and to obliterate developed sites or facilities should they have a negative impact on bald eagles." Change L to a standard and include provisions for monitoring and evaluation.

1365

WILDLIFE - SPECIFIC SPECIES

RESPONSE: These recommendations were considered but not adopted. The direction as stated provides adequate protection for bald eagles. If monitoring determines that these actions are not effective or if recovery objectives are not being met then further action could be taken in the future with a Plan amendment. RR

Bald Eagle - Do Not Establish Stronger Protection

COMMENTS: If eagles establish new nest sites in areas already receiving human use, do not restrict the use since it is unnecessarily restrictive and lacks common sense.

413

RESPONSE: The Revised Plan has a bald eagle guideline 1 (g) that addresses your comment. MO

COMMENTS: Do not over-restrict human activities in bald eagle habitat. Remove direction to minimize all human activity from February 1 to August 1 in Zones I and II because they are unnecessary. Bald eagles *nest* quite happily in areas occupied by humans (e.g., NASA's space shuttle launch site is next to eagle nests). Provide education to ensure compatibility between humans and eagles.

734

RESPONSE: The direction as stated meets adequate protection needs of bald eagles yet still provides for human activity. The Forest will comply with the Endangered Species Act and the Revised Plan when managing bald eagle habitat. Research has found that individual eagles have individual tolerances to human activity. This is taken into account when managing human disturbance within bald eagle habitat. We agree that increased education would improve compatibility of humans and bald eagles. DD/RR

Bats

COMMENTS: Include bat habitat prescriptions and management, particularly as they relate to caves, abandoned mines and human activities (especially timber) in or near known bat habitats.

384, 389, 766

Do not mark caves or encourage this type of recreation because it causes a decline in the number of sensitive wildlife populations. Protect caves by making the guidelines standards. Restrict heavy equipment in or near thin-roofed caves if there is a potential for damage; retain vegetation in or near caves to protect the microenvironment; fell trees away from caves in areas where harvest is permitted.

1365

Standard for bat management should prohibit heavy equipment above any cave or abandoned mine known or suspected to be bat habitat; identify season of bat use and apply seasonal restrictions; provide a buffer zone of 500-foot radius around all bat roosts; and minimize human disturbances.

766

WILDLIFE " SPECIFIC SPECIES

Chapter 111, Objective, spotted bat and Western big-eared bat habitat: Recommend consideration of other aspects of bat ecology and emphasize roosting and foraging areas in the final plan.

1446

RESPONSE: The Revised Plan has standards and guidelines to protect bat habitat associated with caves and Forestwide standards and guidelines that maintain late successional forested habitat that will provide suitable bat habitat across the Forest. Site-specific analysis will be done when any activity occurs near caves or mines. Refer to the Standards and Guidelines for caves in the Revised Plan (Chapter 111, Part 1). Guidelines (see the glossary for a complete definition) are generally expected to be carried out. Deviation from a guideline requires documented rationale. MO/AS

COMMENTS: Targhee National Forest should work cooperatively with State wildlife agencies for surveys, long term monitoring and developing prescriptions for bats.

389

RESPONSE: The Targhee works cooperatively with State agencies in areas of common interest. RR

Beavers

COMMENTS: Reintroduce beavers to Yellowstone (ecosystem) because their dams would keep more water in the Forest, which would provide more fish for bears and fisherman, and water runoff would be more gradual instead of causing erosion.

468

Attach a time line to the implementation schedule for AIZs in Chapter IV for beaver reintroduction as well and provide more detailed plans in Chapter 3, 2.8.3 Aquatic Influence Zone, objectives.

643

RESPONSE: This is a Plan implementation concern. The reintroduction of wildlife species is the responsibility of the States of Idaho and Wyoming and the Forest cannot schedule it as one of its activities. Reintroductions are evaluated by the States on a case-by-case basis to ensure that private property and public interests are protected. We support reintroductions under these conditions. DD/RR

COMMENTS: The Forest needs more than just one reference (Objective 4) to beaver.

282

RESPONSE: The objective cited was changed to a goal since it was not time specific. The direction for aquatic resources in prescription 2.8.3 provides for beaver habitat, where they are present, or where the State may want to reintroduce them. RR

WILDLIFE - SPECIFIC SPECIES

Birds

COMMENTS: Protect birds, including songbirds, by protecting older forest habitat from fragmentation and develop management prescriptions for the following avian species dependent on the forest: northern goshawk, boreal owl, great gray owl, northern pygmy owl, northern saw-whet owl, Lewis' woodpecker, three-toed woodpecker, Williamson's sapsucker, and black-backed woodpecker.

318, 389, 1369

RESPONSE: The direction in the Revised Plan provides for maintaining effective habitat for these species through its wildlife [general habitat, goshawk, boreal owl, great grey owl, etc.), snag/cavity nesting habitat, properly functioning condition, and vegetation goals, objectives, standards and guidelines. This means that fragmentation will be avoided. RR/DD

Black Bear

COMMENTS: Oppose management for black bear security because it closes access for hunters and others; oppose bear habitat issue because it is misleading to the public.

46, 311

RESPONSE: Access considerations in the Revised Plan are related to a wide variety of wildlife species, such as elk, grizzly bears, wolves, deer and other fur bearers, not just black bears. The grizzly bear habitat issue is of national concern because the grizzly bear is listed as an endangered species under the Threatened and Endangered Species Act. MO

COMMENTS: Need black bear education program guidelines.

FS-9

RESPONSE: This is an implementation concern. The Revised Plan allows for Forest efforts to educate the public on bears. RR

COMMENTS: Require bear-proof dumpsters in developed campgrounds.

FS-9

RESPONSE: These are required in grizzly bear habitat. RR

COMMENTS: Change guideline prohibiting black bear baiting in grizzly bear habitat to a standard.

695

RESPONSE: Prohibition of black bear baiting in grizzly bear habitat is a separate special order which is separate from the Revised Plan. MO

Deer

COMMENTS: Clarify why the amount of winter range for deer is less than the present amount.

389

WILDLIFE - SPECIFIC SPECIES

RESPONSE: The Forest incorporated all the Idaho Fish and Game identification of winter range into the Revised Plan. RR

COMMENTS: Incorporate crucial deer winter range prescriptions into the Plan.
389

Create forestwide standards and guidelines for mule deer winter range.

1249

RESPONSE: Crucial winter range for elk and deer is included as a specific management prescription or is included in other prescriptions such as wilderness which provide adequate protection. The Forest added Forestwide standards that close all crucial winter range to cross-country snowmachine use. MO

COMMENTS: Include goals and objectives in the allotment management plan for the number of AUMs needed to sustain deer on their summer and winter range.

1206

RESPONSE: This recommendation was considered but not adopted. Direction in allotment management plans are plan implementation concerns and would be addressed in site-specific allotment analysis. The direction for livestock forage utilization includes use by wildlife. RR

COMMENTS: Secure deer habitat.

25, 766

RESPONSE: The Revised Plan maintains and restores deer habitat. DD

COMMENTS: Secure goat habitat.

25

Provide management direction for mountain goats. Include the Idaho and Wyoming State wildlife management agencies' goals, objectives and implementation process for mountain goats in Idaho and Wyoming.

389

RESPONSE: All mountain goat habitat is within Wilderness, proposed wilderness, or backcountry management prescriptions. There is no difference between the prescriptions between the alternatives. Those prescriptions provide adequate protection for mountain goat habitat. MO

COMMENTS: Address conflicts between mountain goat and domestic sheep such as displacement and potential for disease transmission from sheep to goats. Address specific conflict between domestic sheep and mountain goats in Neely Cove, head of Canyon Creek, Waterfall Canyon, Little Horn, Hell's Hole and the ridge between the headwaters of Waterfall Canyon and Little Elk Creek.

766

RESPONSE: There is no documentation of disease problems between domestic sheep and mountain goats. Our data indicates that displacement by domestic

WILDLIFE - SPECIFIC SPECIES

sheep is not a problem. The Palisades Ranger District is working with state fish and game departments to address site-specific conflicts. More information is in Process Paper D. MO

Harlequin Duck

COMMENTS: Change the guideline for Harlequin duck habitat back to a standard as written in the preliminary draft BA. Standards are more consistent with Forest Service commitment to manage for viable populations under NFMA and 36 CFR 219.19.

695, 1446

RESPONSE: A guideline is the appropriate measure. A standard would "prevent" establishing new trails, new roads, or new recreation facilities within 300 feet of any stream reach... regardless of the potential to negatively affect harlequin duck breeding activity. A standard would also prevent relocating an existing trail, road, or facility, even if the new location would reduce disturbance. DD

COMMENTS: Expand Harlequin duck habitat guideline to include all riparian zones and habitat, and tie it to more than a single species because this modification will benefit watershed and water quality, as well as the species.

1446

RESPONSE: This recommendation was considered but not adopted. See preceding response. The Revised Plan direction for Harlequin ducks is sufficient to provide effective habitat. This would be redundant to the Forestwide S&Gs for fisheries, water, and aquatic resources, and Management Prescription 2.8.3 for Aquatic Influence Zone which provide adequate direction beneficial to the duck and for maintaining and improving watershed integrity and water quality. RR

Hawks

COMMENTS: Enforce access restrictions to protect hawks.

(CROSS REFERENCE: Goshawk)

265

RESPONSE: Access restrictions will be enforced to protect a variety of resources. DD

Common Loon

COMMENTS: Develop a management prescription for the common loon because the existing breeding habitat on the Targhee National Forest is important to the continued nesting success of this small population.

389

RESPONSE: This recommendation was considered but not adopted. The Revised Plan direction for common loon is sufficient to provide effective habitat. RR

COMMENTS: Coordinate all management decisions, including the development of a management prescription, about the Fish Creek common loon habitat with Wyoming wildlife and fisheries personnel. Continue to allow angler access because Wyoming wildlife biologists report current public use in this area does not appear to have impacted loons.

389

RESPONSE: This is an implementation concern. Any proposals for management activities which involve common loon or other wildlife habitat will be coordinated with the respective State wildlife agency. Decisions about angler access are outside the scope of this analysis. RR

Moose

COMMENTS: Protect moose habitat by restricting ORVs and prohibiting new roads. (CROSS REFERENCE: Wildlife, Site Specific)

FS-9, 25, 62, 697, 766, 1331

Address moose winter range; create forestwide standards and guides for moose winter range and habitat and add language for moose to the winter range prescriptions.

F-G-1-P, FS-9, 389, 1247, 1249

Coordinate with Wyoming Game and Fish to manage moose winter range.

1249

RESPONSE: It is standard procedure to coordinate with the respective State wildlife agency on any proposals that may affect wildlife. The other recommendations were considered but not adopted. The Revised Plan direction is sufficient to provide effective moose habitat. Moose are generally not displaced by human activity. The Forestwide Standards and Guidelines for fisheries, water, and aquatic resources; access management; properly functioning condition; vegetation; and Management Prescription 2.8.3 for Aquatic Influence Zone provide adequate direction beneficial to the moose. RR

COMMENTS: Provide more moose hunting permits.

285

RESPONSE: The number, type, and location of available moose permits is controlled by the States of Idaho and Wyoming and is not within the authority of the Forest Service. DD/RR

Owl - Buffers

COMMENTS: Cite the science and basis for requiring a 20-acre buffer, greater than 40 percent forested and 1/2 mile strychnine buffer to protect habitat and existing owls; explain how this ensures protection. Cite the science and basis for requiring a 30-acre buffer to protect habitat and existing flammulated and boreal owls; explain how this ensures their protection.

1365

RESPONSE: The FEIS and Process Paper D cite the scientific references used and discuss the rationale for management for Forest owls.

WILDLIFE - SPECIFIC SPECIES

COMMENTS: Change the standard to "not manipulate vegetation within 20-30 acre areas around all active and historic nest sites," since it is not clear whether or not it forbids prescribed fire and grazing. Need a standard or guide to specify what management activities are allowed.

FS-9

RESPONSE: The standard refers to mechanical removal or manipulation of vegetation within the nest area, not grazing or prescribed fire. RR

COMMENTS: Standards and guidelines, Great Gray Owl Habitat: Increase the radius for use of strychnine poison for gopher control to 1 mile around all the great gray owl nest sites.

1446

Expand Standard 3 which says, "Don't allow use of strychnine poison to control pocket gophers within buffer around all active great gray owl nests," to include the 10 guidelines for gopher treatment within great gray owl activity areas.

FS-9

RESPONSE: These recommendations were considered but not adopted. The Revised Plan direction is sufficient to provide effective habitat for great gray owls. The Plan permits application of these guidelines if site-specific analysis at the project level determines that it is necessary. RR

Owl - Habitat

COMMENTS: Provide management prescriptions for boreal, great gray, Northern pygmy, and Northern saw-whet owls since these species are dependent on forested habitat for population viability.

389

RESPONSE: Forestwide standards and guidelines provide the appropriate method to manage these habitats. DD

COMMENTS: Provide an analysis on existing/planned owl habitat.

1369

RESPONSE: This information is found in Process Paper D. It is also discussed in the FEIS, Chapter 111, Affected Environment. "Planned" owl habitat is not part of the Revised Plan, however, maintenance of existing habitat is provided in the Revised Plan direction. RR

COMMENTS: Explain the analysis used and conclusion to, "only protect nest sites if located." Analyze existing and potential impacts on owls.

1369

RESPONSE: The existing situation is discussed in FEIS, Chapter 111, Affected Environment. Impacts are disclosed in Chapter IV, Environmental Consequences, of the FEIS. Analysis documentation is found in PROCESS Paper D. RR

WILDLIFE - SPECIFIC SPECIES

COMMENTS: Explain the term "late age classes" in the owl habitat guidelines as it relates to forest age, basal area, canopy closure, tree species and elevation.

1369

RESPONSE: "Late age classes" is synonymous with "late successional stages" found in the Glossary. Basal area, canopy closure, tree species or elevation are specific details that would be addressed at the site-specific level during project environmental analysis. RR

COMMENTS: Explain the reason for only protecting flammulated owl nest sites and not the surrounding habitat (since it all affects the owl).

1369

RESPONSE: The 30-acres encompass the entire home range for flammulated owls. The limited extent of manipulation of forest vegetation in the Revised Plan's decade is not expected to cause unacceptable impacts to owls. MO

COMMENTS: Explain/calculate the probability that owl nests will be located since this is the key factor in managing boreal and flammulated owls.

1369

RESPONSE: There is no calculated probability that owl nests will be located during project level planning, other than there is no certainty nor any expectation that all nests, without exception, will be discovered. This information is not essential to evaluating the effects of the proposed action or a reasoned choice among alternatives. Application of the standards are expected to maintain or restore existing owl habitat. RR

COMMENTS: Provide vegetation management after owls (flammulated, boreal and great gray) leave the nest in the fall the same as for goshawk.

413

RESPONSE: The Revised Plan's management direction for nest sites and territories applies year round. MO

Peregrine Falcons

COMMENTS: Protect all known peregrine falcons nest sites/cliffs from human activity.

389

RESPONSE: This is standard procedure under ESA. RR

COMMENTS: Protect timber sales and mineral extraction within defined buffers for known peregrine falcon nest sites. This should be a standard, not a guideline.

389

For peregrine guidelines #1: Add shooting ranges due to the disturbance

WILDLIFE - SPECIFIC SPECIES

caused by the Treasure Mountain Boy Scout Camp shooting range in Teton Canyon. Delete aircraft since the Forest Service has no jurisdiction over these.

FS-4

RESPONSE: This recommendation was considered but not adopted. We have no data suggesting that the shooting range is adversely affecting peregrine falcons. The Revised Plan direction is sufficient to protect peregrine falcons. Actions noted refer to agency actions--such as agency aircraft, equipment, or facilities--or third parties operating under a Forest Service authorized permit or contract. RR

COMMENTS: Peregrine standard: Replace herbicides and insecticides with pesticides and develop dates on restrictions.

FS-4

RESPONSE: This is not necessary to provide adequate protection for the falcon. Dates and other restrictions can be specified during project level analysis decision making. RR

COMMENTS: Peregrine guideline 1 should be a standard and it should clearly specify a review process for proposed projects.

1365

RESPONSE: A guideline is adequate and any review process is an implementation issue determined through project level analysis. RR

COMMENTS: First item related to peregrine falcon habitat in Chapter 3 was a standard in the preliminary draft BA but was changed to a guideline here and in the current draft BA which is inconsistent with Forest Service responsibilities under Section 7(a)(2) of ESA.

1446

RESPONSE: Peregrine falcons use a wide variety of habitats for foraging. Since the use of DDT has been stopped, falcon populations have increased in a wide variety of habitats. The guideline is appropriate given the wide variety of habitats and conditions which can be and are being used by peregrine falcons. MO

COMMENTS: Regarding Designated Wilderness Prescriptions 1.1.7 and 1.1.8: Items affecting listed peregrine falcon should be standards. Forest Service control over location of campsites and trails is consistent with responsibilities under Section 7(2)(2) FSM 2670 and NFMA 36 CFR to protect species and habitat without adverse effects by public forest uses.

1446

RESPONSE: A guideline is the appropriate measure. Guidelines are appropriate where variability occurs at the implementation level or desired goals or conditions can be achieved by more than one approach. Guidelines do not mean that compliance with them is discretionary and can be ignored. Variance from a Plan guideline requires documentation in the decision authorizing it. A

guideline provides for some site specific flexibility while still meeting the practical intent. RR

Raptors - Standards and Guidelines

COMMENTS: Raptor Nest Sites: Action should be listed as a standard for consistency with Forest Service policy and sensitive species protection; add a guideline to protect potential raptor nest sites for sensitive/listed species.

1446

Change the guidelines for raptor nest sites to standards.

695

The raptor nest site protection should be a minimum distance; this should be a standard, not a goal.

1273b

RESPONSE: The Revised Plan provides for nest site protection of sensitive species in Forestwide standards and guidelines. The broader guideline for Raptor Nest Sites (other than Threatened, Endangered and Sensitive Species) was dropped from the Revised Plan because the intent is to manage landscapes in their properly functioning ecological condition, which would provide adequate habitat for all species. RR

COMMENTS: General Habitat: Include protective measures for more than the nests of raptors. Provide management guidelines that protect foraging and post-fledgling habitat. Suggest what silviculture practices would or would not be allowed.

1249

RESPONSE: This recommendation was considered but not adopted. Threatened, Endangered and Sensitive Species raptors receive specific direction for habitat management which meets their recovery needs. For other species, the overall Revised Plan direction to manage for properly functioning condition, in ecological context, with emphasis on forest health, biological diversity, vegetation structure and composition which maintains plant and animal communities is expected to adequately meet general habitat needs. RR

Raptors - General Protection

COMMENTS: Cite the science and basis for the 2-tree-height buffer to protect nesting raptors, and explain how this ensures protection.

1365

RESPONSE: This guideline for Raptor Nest Sites (other than Threatened, Endangered and Sensitive Species) was dropped from the Revised Plan because the intent is to manage landscapes in their properly functioning ecological condition, which would provide adequate habitat for all species. RR

Red Squirrel

COMMENTS: Consider the red squirrel's sensitivity to fragmentation and identify existing and planned habitat conditions.

1369

WILDLIFE - SPECIFIC SPECIES

RESPONSE: Existing habitat is described in Chapter III of the FEIS, Affected Environment. "Planned" habitat is not proposed in the Revised Plan, other than that which will be maintained by implementation of the Revised Plan direction for wildlife, ecosystem management, forest health and properly functioning condition. RR

Sage Grouse - Treatments to Sagebrush Habitat

COMMENTS: To reverse declining trend of sage grouse, follow habitat treatment standards (Draft ID Sage Grouse Management Plan 1996-2000) which includes vegetation manipulation, grazing management, fire management and rehabilitation. Use caution for any treatments to sagebrush habitat until the causes for the significant decline in sage grouse can be determined. Any treatment needs to consider significant habitat reductions and fragmentation.

766

RESPONSE: Forestwide standards and guidelines were developed for sagebrush/grassland ecosystems on the Forest. These are based on the ecology and properly functioning conditions for sagebrush/grassland ecosystems. They will provide for suitable sage grouse habitat with conditions that historically existed within the sagebrush/grassland ecosystem. MO

COMMENTS: In low precipitation areas less than 11 inches, prohibit habitat treatment for 5 years. In high precipitation areas more than 11 inches, allow treatments only if sagebrush canopy cover is greater than 25%. Allow treatment only if area is less than 500 acres and more than 1.6 miles from existing treatments with less than 15% sagebrush canopy cover.

766

RESPONSE: These are site-specific implementation concern, to be conducted in the context of a Revised Plan guideline for sagebrush/grassland habitats. RR

COMMENTS: Prevent a reduction in average sagebrush canopy in herbicide or mechanically treated areas to less than 15% canopy cover in winter, brooding, or nesting habitat.

766

RESPONSE: This recommendation was considered but not adopted. The Revised Plan direction is adequate to provide effective habitat for sage grouse. More detailed specifications will be provided during project level analysis. RR

Sage Grouse - Manage Livestock

COMMENTS: Manage livestock for a healthy understory of perennial grasses and forbs and for a fall stubble height of greater than or equal to 7 inches. Manage livestock to produce a fall stubble height of greater than or equal to 4 inches in brood rearing areas.

766

RESPONSE: The Revised Plan provides for managing for a healthy understory of grasses and forbs. The upland and riparian utilization standards provide for adequate stubble height, respectively, to provide for healthy range

WILDLIFE - SPECIFIC SPECIES

ecosystems. If project level analysis identifies a need for more stubble height to meet sage grouse habitat needs, this specification can be implemented in the project decision. RR

Sage Grouse - General

COMMENTS: Use sage grouse as indicator species for other wildlife species dependent on sagebrush-grasslands.

766

RESPONSE: This recommendation was considered but not adopted. Management Indicator Species (MIS) were established in a series of three workshops in 1991-92, with Idaho and Wyoming fish and game departments, and in coordination with adjacent Forests' Management Indicator Species lists. Some additions were made throughout the revision process. Sage grouse was not selected as an MIS. More detailed information is provided in Process Paper D. The sagebrush/grassland community type will be managed to maintain a healthy ecological condition which would provide for adequate habitat for dependent species. RR

COMMENTS: Include in FEIS and FPR some objectives, standards and guidelines to maintain/enhance sage grouse habitat because sage grouse populations have declined in the Lemhi-Medicine Lodge and Centennial subsections.

1446

RESPONSE: Forestwide standards and guidelines apply and are sufficient to provide adequate habitat for sage grouse at the subsection scale. RR

Trumpeter Swan - Habitat

COMMENTS: Evaluate each trumpeter swan territory individually; summarize its production history over past decades, identify specific factors interfering with cygnet production, and correct those factors where possible. Develop swan habitat plans that are not elaborate, about five pages per site, and address past history of occupation and cygnet production, physical/chemical data, potentials and vulnerabilities, and actions to enhance and ensure long-term value to the population.

669

RESPONSE: This recommendation was considered but not adopted. The Revised Plan direction is adequate to provide effective habitat for trumpeter swan. Additional specifications may be made during a site-specific analysis, if it is determined that it is necessary for swan habitat needs. The Revised Plan permits these types of management actions if warranted to provide for swan habitat. RR

COMMENTS: Explain the biological basis for recommending habitat for 10 pairs of trumpeter swans and not 20-30.

1369

RESPONSE: This is described in Process Paper D. RR

WILDLIFE - SPECIFIC SPECIES

COMMENTS: Make Objective 2 (protect emergent vegetation) a standard and guideline.

669

RESPONSE: This recommendation was considered but not adopted. The Revised Plan direction is adequate to provide effective habitat for trumpeter swans. RR

Trumpeter Swan - Nesting sites

COMMENTS: Trumpeter Swans, Standards and Guidelines: Develop individual nest site plans for all active and historic territories. Plans should ensure proper guidelines are applied.

1249

RESPONSE: This recommendation was considered but not adopted. The Revised Plan permits this type of activity if site-specific analysis determines it is necessary for maintaining or improving swan habitat. RR

COMMENTS: Explain why there are no grazing standards for swan nesting areas; nesting cannot be managed without considering grazing.

1369

RESPONSE: Guideline A provides direction for controlling grazing which may affect swan productivity. RR

COMMENTS: Explain why there are no standards for disturbance of swan nesting.

1369

RESPONSE: There are standards and guidelines to limit this type of impact. These are adequate for protecting swans during the nesting period. RR

Human Access to Trumpeter Swan Habitat

COMMENTS: Prohibit ORV and human access in swan and waterfowl winter range wetland areas from December 1 to March 31 and provide an additional restriction to prohibit motorized access from November 1 - August 31 in trumpeter swan and waterfowl habitat to include protecting their nesting and brooding periods. Need education/signs about impacts of humans/motorized access in swan wetlands.

389

RESPONSE: These recommendations were considered but not adopted. The Revised Plan direction provides for mitigating human disturbance. The specific means to do so are highly variable, but can be equally effective. This detail is more appropriate for site-specific analysis and determination. RR

Trumpeter Swan - Management Plans

COMMENTS: Develop new objectives similar to plan for loons. Specific plans are needed to ensure that each territory remains suitable in the decade ahead.

669

WILDLIFE - SPECIFIC SPECIES

Define "active management" and what actions are necessary to maintain suitable water depths for swans in lakes and ponds (e.g., dredging).

1365

RESPONSE: These recommendations were considered but not adopted. New objectives are not necessary to adequately provide for swan habitat. Specific plans and 'necessary' actions are site-specific determinations to be identified at the project level. Generally, 'active management' means any agency proposed action in response to a need for manipulating conditions influencing swan habitat. RR

COMMENTS: Ensure that activities do not increase sediment loads in the streams; reduce sediment loads to protect trumpeter swan nesting habitat (which also produces numerous other environmental benefits to the Forest).

1365

RESPONSE: These are site-specific considerations for specific proposed actions. Forestwide aquatic resources Standards and Guidelines apply. For areas within the aquatic influence zone--management prescription 2.8.3--that direction applies. The Revised Plan is designed to minimize or prevent sediment delivery to any water body/delivery

Palisades Wetland Area

COMMENTS: Provide management direction for ORV travel and human access in trumpeter swan and waterfowl winter areas of the Palisades wetland area. Currently there is no analysis or consideration.

389

RESPONSE: This recommendation was considered but not adopted. The Revised Plan direction is adequate to provide effective habitat for trumpeter swans. RR

Wolves

COMMENTS: Oppose wolf protection efforts because tax dollars are used for wolf habitat; wolves feed on elk and disrupt their populations; and fear that wolves attack backpackers and cross-country skiers.

6, 285, 397, 468

Support wolf protection measures and protect wolf habitat.

697

RESPONSE: The Forest will comply with the Endangered species Act (ESA) and consult with the Fish and Wildlife Service on matters relating to gray wolf and all listed species. The Revised Plan provides for multiple use opportunity while meeting objectives for wolf recovery in the Greater Yellowstone area. This includes coordination with permittees, the recreating public, and others to avoid or minimize conflicts with wolves. RR

COMMENTS: Establish travel corridors and linkage zones for wolves.

1365

WILDLIFE - SPECIFIC SPECIES

RESPONSE: This recommendation was considered but not adopted. The wolf is a nonessential experimental population. The wolf reintroduction FEIS did not consider establishment of corridors or linkage zones essential for wolf recovery. RR

COMMENTS: Change wording in the EIS - Environmental Consequences and Affected Environment chapters-to allow full protection for naturally migrated wolves on the Targhee.

1273b

RESPONSE: This recommendation was considered but not adopted. The FEIS discloses the documentation of the environmental analysis of the proposed programmatic action and its alternatives, and their environmental effects, but does not establish direction for the Forest. This is only done in the Revised Plan upon signature of the Record of Decision. Revised Plan direction is consistent with direction under ESA for management of wolves on the Targhee. RR

Human Impacts on Wolves

COMMENTS: Impose land use restrictions for any area in which human activity might negatively impact wolves, including all active den sites regardless of how many breeding pairs are present in a recovery area. Consider wolf road densities. Roads used by recreationists have numerous wildlife impacts (Rost & Bailey 1974). Road densities greater than 0.61 km/square km adversely affect the suitability of potential wolf habitat because roads provide access to humans who hunt or accidentally kill them (Thiel 1985, Jensen et al. 1986, Mech et al. 1988, DeVos 1949).

1365

RESPONSE: These recommendations were considered but not adopted. The Revised Plan direction provides adequate direction for wolf management. RR

Wolves - Population Control

COMMENTS: "Experimental population" means any population (including any offspring arising solely therefrom) authorized by the Secretary for release..." and you need an objective to protect wolves not included in "experimental" population under the ESA.

1273b

Explain why there will be no standards and guidelines for wolves once their populations are maintained.

1369

RESPONSE: The FEIS for the Reintroduction of Gray Wolves stated that all wolves found in the wild at the time of the first release of wolves would be designated a nonessential experimental population. therefore, all wolves are now included in the rules and management direction developed by the US Fish and Wildlife Service for the wolf reintroduction. The Revised Plan incorporates the rules and management direction developed by the USFWS. In the final rule published in the Federal Register, November 22, 1994, the USFWS stated that the gray wolf reintroduction does not conflict with existing or

WILDLIFE - SPECIFIC SPECIES

anticipated Federal agency actions or traditional public uses of park lands, wilderness areas, or surrounding lands. The USFWS also stated that there are no conflicts envisioned with any current or anticipated management actions of the Forest Service. MO

COMMENTS: Define how conflicts between wolves and livestock will be solved while still maintaining a viable wolf population.

1369

RESPONSE The direction in the Revised Plan for gray wolf management defines this. Additional detail is a site-specific consideration and will be determined at the appropriate time to resolve conflicts. RR

COMMENTS: Gray Wolf Habitat - Standard 3: Indicate that the removal or resolution of attractants must precede any control action.

1365

RESPONSE: Determination of the problem status of wolves includes identification of any attractant that may be drawing wolves to livestock. No change was made to this direction. RR

COMMENTS: Gray Wolf Habitat - Standard 2: Identify more clearly what can occur (when grazing permit holders are allowed to harass adult wolves).

1365

RESPONSE: This is a site-specific determination that will be made at the time a permit is issued or modified, and incorporated into the terms and conditions of the permit. RR

COMMENTS: Gray Wolf Habitat, Standard 4: Last sentence about livestock depredation by female with pups is out of context (page 60257 Federal Register, V 59 N.224). Should read: "prior to the establishment of six breeding pairs, depredating females and their pups will be captured and released at or near the site of capture, one time prior to October 1. If depredations continue, or if six packs are present, females and their pups will be removed."

1446

RESPONSE: This was corrected in the Final Revised Plan. RR

WILDLIFE - THREATENED **AND** ENDANGERED SPECIES

COMMENTS: With only four species remaining on the sensitive species list for Idaho, there should be substantial relief from constraints in the Final Plan. Reevaluate the role of sensitive species and reduce restrictions because there are fewer candidate species. Sixty-one percent of people in the United States agree that threatened and endangered species should be protected, even if such protection results in negative impacts on humans. The Plan reflects the needs of four ESA species: bald eagle, grizzly, gray wolf and peregrine falcon; as well as non-listed native cutthroat trout and goshawk. Clarify the fourth paragraph, page 111-63, 1.1.8, how campsites will facilitate recovery of

threatened and endangered species, because there seems to be no connection between these points.

314, 1364, 1389, 1446

RESPONSE: The Revised Plan must meet the Threatened and Endangered Species Act and the Forest Service Sensitive Species Policy. we consulted with the Fish and Wildlife Service on these aspects of the Revised Plan. There are presently 24 species (12 animal and 12 plant) on the Forest that are Forest Service Region 4 Sensitive. There are presently 5 species (4 animal and 1 plant) listed as threatened or endangered. The Revised Plan provides effective protection for species of concern, while still providing for multiple use opportunities. Developed campsite facilities can concentrate use away from threatened or endangered species habitat or facilities such as bear-proof food boxes can reduce conflict possibilities. MO/AS/RR

Recommendations/Suggestions

COMMENTS: Add the statement, "preventing new listing of threatened or endangered species" to the sentence on Ecological Component on Page 11-2 Clarify that designation of species demanding special management is not optional. Change definition to include all species of plants and animals that require special consideration, this should not be a Forest or Regional decision. Restrict logging, snowmobiles, and open roads/trails to better protect threatened and endangered species habitat.

179, 325, 389, 1365

RESPONSE: Since the prevention of new listings of threatened or endangered species is agency policy, it need not be restated in the Revision. The Revision includes several broad-scale conservation measures designed to protect threatened, endangered, and sensitive species. In addition, further analysis of threatened, endangered, and sensitive species is conducted during the planning of on-the-ground activities. These analyses identify specific measures which can be used to best protect species and their habitats. DD

COMMENTS: Define the term "viability" as a population essentially certain to persist (99% chance of persistence for at least 1000 years), and is well-distributed in current range. If population viability is in doubt, extend range as necessary. Give priority to habitat needs of all threatened and endangered species, including in Aquatic Influence Zones. Map or determine distribution, status and trend of all threatened and endangered species specific prescriptions, standards, guidelines and recovery objectives. Meet all legal and biological requirements. Gather and evaluate data on effects of past management plan; research current status, distribution and threats.

389, 1273b, 1365, 1368, 1369

RESPONSE: A "viable population" is defined in the Revision as the number of individuals of a species sufficient to ensure the long-term existence of the species in natural, self-sustaining populations adequately distributed throughout their range. The Revised Plan places special management emphasis on the recovery of threatened, endangered, and sensitive species as well as the maintenance and restoration of aquatic influence zones. Chapter III of

the FEIS describes the current status, distribution, and threats of all threatened, endangered, and sensitive species while Chapter IV evaluates the past and possible future effects on these species. DD

COMMENTS: The Endangered Species Act may be violated if toxicants are used in areas that are or may be inhabited by threatened or endangered species. Develop a method for monitoring sensitive species and their habitat in order to meet statutory requirements of NFMA. Develop management practices to ensure sensitive species do not become threatened or endangered. Guidelines are provided for only two owl species and the goshawk; monitoring proposals are provided for only grizzly and goshawk.

389, 1273b, 1365, 1369

RESPONSE: The use of toxicants is largely controlled through the application of best management practices (BMP's) and Manual and Handbook guidance and is, therefore, not reiterated in the Revised Plan. A thorough on-site evaluation of threatened, endangered, and sensitive species is always conducted prior to the use of toxicants. It is agency policy to monitor all management indicator and sensitive species. Your concerns are covered in the Revised Plan and FEIS and Process Paper D. Monitoring plans were developed for all the Management Indicator Species. See species specific responses in Appendix A. DD/MO

COMMENTS: Produce better science, more standards and guidelines, or quantifiable objectives for indicator or sensitive species. Monitor and evaluate impacts of the past 10 years; monitor old growth habitat. Require wildlife surveys for sensitive species. Make a goal to support existing populations and distribution of non-game birds and mammals listed as species of special concern. Meet legal and biological requirements of forest carnivores. Provide standards and procedures for selection of sensitive species.

389. 1273b, 1365, 1369

RESPONSE: The FEIS includes more scientific findings and analysis of management indicator and sensitive species than did the draft. The Revision includes new goals, objectives, standards, guidelines, and monitoring requirements directed at improving management indicator and sensitive species. Impacts of the past 10 years are documented in the Analysis of the Management Situation (AMS) and in Chapter IV of the FEIS. Sensitive species are selected by the Regional Forester through a process unrelated to the Revision. The selection process is being reviewed by the Regional Forester and may be revised in the future. DD

Specific species

COMMENTS: Protect wolverines, wolverine natal dens, and reproduction areas from skiers, snowmobiles and snowshoers, particularly in higher elevations (above 8000 feet). Little is known about wolverine habitat and habits, which has resulted in little management attention. The Targhee may provide a critical link between Montana, Central Idaho and Wyoming wolverine populations, and this link should be protected. Provide an 8km buffer around predicted wolverine habitat from January 1 to May 31.

FS-3, 766, 1185, **1348**

WILDLIFE - THREATENED AND ENDANGERED SPECIES

RESPONSE: Chapter V of the Revised Plan contains a priority 1 monitoring item to monitor population trends of marten, fisher, and wolverine and their relationships to habitat changes. We added two new Objectives for wolverines to the Revised Plan: within two years, a GIS inventory will be completed to identify potential wolverine natal den sites, and within four years, the Forest will survey these potential den sites to document wolverine presence. The Revision does not require buffers around predicted habitat. DD

COMMENTS: Provide recovery objectives and strategies; determination of distribution, status and trend; management priorities; and monitoring plans for lynx, fisher, and wolverine as is required by Forest Service management plan. Consult lynx and wolverine Draft Conservation Strategies. Develop road density thresholds relative to habitat segments of wolverine, martin, lynx and neotropical migrant songbirds. Discuss management objectives for fisher, marten and wolverine rather than just grizzly bear, wolf and goshawk.

389, 410, 643, 1273b, 1361, 1365, 1368

RESPONSE: Process Paper D and the FEIS discuss the habitat needs for lynx, fisher, and wolverine and neotropical migratory songbirds. Two wolverine objectives were added the Revised Plan. MO

COMMENTS: Provide prescriptions, standards and guidelines, research, evaluation and protection of pine martens, trumpeter swans, great gray owls, cavity nest birds, bald eagles, peregrine falcons, spotted frog, Harlequin duck, goshawk, lynx, marten, fisher and wolverine. Although some of these species have been removed from federal candidate lists, they should be maintained on forest lists as indicators of forestwide health and habitat. Protect and monitor old growth habitat. Restrict winter recreational activities in crucial breeding or denning areas.

389, 643, 1273b, 1365, 1368, 1446

RESPONSE: Chapter III of the Revision includes specific management direction for trumpeter swan, great gray owl, cavity nesting species, bald eagle, peregrine falcon, spotted frog, harlequin duck, goshawk, wolverine, and other sensitive or management indicator species. Chapter V includes a priority 1 monitoring item to monitor population trends of marten, fisher, and wolverine and to determine their relationships to habitat changes. Chapter III of the Revision contains standards and guidelines to direct the management of old growth and late seral forest stages. The Revision does not restrict winter recreational activities within breeding or denning areas. DD

WILDLIFE - TIMBER

Manase for Wildlife not Timber Harvests

COMMENTS: Use Forest Service Survey (issued by Jack W. Thomas) that shows most Americans want forests managed for recreation and wildlife protection, not lumber and commercial products. (CROSS REFERENCE: Recreation; Miscellaneous)

1364

RESPONSE: The Forest Service operates within the direction of various laws, regulations, executive orders, and other policy instruments. "Multiple Use" is an established maxim in these policy shaping authorities. The Revised Plan provides for recreation opportunity, effective wildlife habitat, and production of forest resources, including wood products, in a balanced manner.
RR.

COMMENTS: Explain the reasons for determining how many and what acres can be harvested while still maintaining native species of wildlife. (CROSS REFERENCE: Timber; Wildlife)

1369

RESPONSE: Some of the standards and guidelines in the Revised Plan are used to determine how much harvest can occur and where. Examples are guidelines for primary cavity nesting species and goshawk management. A goal of the Revised Plan is to maintain or enhance wildlife biodiversity.

This is a site-specific implementation question when individual projects are proposed. For the Revised Plan, the process used to identify suitable acres and sustainable harvest levels is described in detail in Process Papers B, "FORPLAN Analysis", and C, "Tentatively Suitable Timber Analysis." The effects of the selected level of harvest by alternative are described in Chapter IV, Environmental Consequences, of the FEIS. The rationale for selecting the harvest level in the preferred alternative 3M is described in the Record of Decision. RR/CC

Curtail Timber Harvests when Negative Impacts to Wildlife are the Result

COMMENTS: Assess existing native wildlife populations, source habitats, suitability of habitats and allow timber harvest only if further timber reductions are deemed appropriate in light of this information.

1369

RESPONSE: In the FEIS, chapter III populations data are stated for grizzly bear, gray wolf, primary cavity nesters, boreal owl, great gray owl and flammulated owl. Goshawks have been monitored on the Forest for a number of years. During site-specific analysis, surveys are typically completed for various wildlife species which may occur in the specific analysis area. .

This is an implementation issue for specific project proposals. Analysis of the affected environment is conducted when these types of proposed actions are made and may involve some or all of these items. The Forestwide and specific Management Prescription Standards and Guidelines provide direction for mitigating adverse impacts to wildlife in site-specific project proposals. RR/CC

COMMENTS: Restrict timber harvesting in areas where it would have the most negative impact on fish and wildlife.

239

RESPONSE: Many areas in the Revised Plan are not included in the suitable timber bases. Some of these include the aquatic influence zones, grizzly bear core areas, and recommended Wilderness.

WILDLIFE - TIMBER

Limitations on timber harvest are provided where unacceptable adverse impacts to wildlife resources would occur. The forestwide and specific Management Prescription Standards and Guidelines provide direction for mitigating adverse impacts to wildlife in site-specific project proposals.
RR/CC

COMMENTS: Individual or cumulative impacts from some timber harvests may adversely affect BLM management objectives for water quality, riparian, big game habitat, raptor nesting and recreation activities. Analyze these possible effects. Areas identified by Department of Fish and Game as summer and fall crucial habitat and migration habitat may be fragmented by timber harvest schedule.

1446

RESPONSE: The Forest analyzed and realized the past, present and future cumulative effects of timber harvesting. We considered other agencies' objectives. The Revised Plan meets water quality, riparian, big game habitat raptor nesting and recreation activities needs through forestwide standards, guidelines, goals, objectives and prescriptions. The Forest added standards and guides for sensitive raptor species and new prescriptions which will result in more cover being retained over time.

During a site-specific analysis, adjacent land ownerships, including BLM, are considered during assessments. Where anticipated impacts are identified, coordination with BLM may occur to minimize adverse cumulative effects. RR/CC

Address Harvests Designed to Improve Wildlife Habitat

COMMENTS: oppose cutting more trees to improve elk and grizzly habitat because it is ridiculous, in lieu of safe corridors between ecosystems.

51

RESPONSE: Your comment is noted. RR

COMMENTS: Provide information about how past "heavy" timber harvest has impacted native wildlife species, especially in the lodgepole pine salvage areas, and how it has not/will not significantly impact wildlife viability. (CROSS REFERENCE: Timber)

1369

RESPONSE: The Revised Plan estimates less than three percent of the forested acres will have vegetation management in the next decade. As discussed in the FEIS, the proposed treatments are expected to provide for viable populations of wildlife species.

Discussion of past timber harvest can be found in the Analysis of Management Situation and the FEIS, chapter 111, Affected Environment. The cumulative effects of past timber harvest in the lodgepole can be found in the FEIS, Chapter IV. RR/CC

COMMENTS: Define which range timber harvests constitute wildlife improvements and show how you will determine when optimum conditions require timber harvest

on these rangelands. Define your criteria for initiating timber harvests.

1369

RESPONSE: Specific types of timber harvest will be analyzed during implementation of the Revised Plan. Timber harvest could be initiated after an assessment is done which determines ecosystems are not functioning properly or that the existing condition of an ecosystems is not in a desired condition based on goals and objectives outlined in the Revised Plan.

These considerations are more related to a site-specific proposal which may involve different variables that cannot be enumerated in a Forest Plan's programmatic analysis. The Properly Functioning Condition section of Chapter III, Revised Forest Plan, describes the broad goals and objectives where these types of proposals may be appropriate. The Vegetation section of the same chapter describes objectives for treating landscapes to achieve a variety of desirable conditions. RR/CC

COMMENTS: Standards and Guidelines - Size of Harvest Units and Leave Blocks/Strips: To benefit wildlife, adopt an ecological approach to silviculture standards and guidelines. Cite scientific data to demonstrate light, wind and moisture regime. Vertical stratification of vegetation may be such that an area is no longer a "created opening". Standardize maximum clearcut size.

1446

RESPONSE: Chapter III of the Revised Forest Plan Ecological Processes and Patterns, describes the direction for managing Forest resources in an ecological context. Local environmental variables such as light, wind, and moisture are site-specific in nature and outside the scope of this programmatic analysis. Clearcut size is stipulated by Forestwide standards and guidelines and, where noted, in specific Management Prescriptions. RR

Leave Timber for Wildlife Habitat

COMMENTS: Prohibit burning of slash after logging. Slash is an important habitat for toads, chipmunks, martens and other wildlife species.

1204

RESPONSE: The Revised Plan's goal is to have appropriate fuel loading which will meet wildlife needs and fire objectives. Post logging treatments are determined in a site-specific analysis and different alternatives to burning may be considered, depending on what the objective is.

The Revised Plan provides down-woody debris requirements for wildlife habitat and long-term soil productivity, within reasonable fuel loading risk. Burning of activity fuels is permitted within these guidelines. RR/CC

COMMENTS: Do not cut 7.5 MMBF of unsuitable timber over the next 10 years because "unsuitable" timber is necessary to preserve wildlife habitat/species and it is destructive to the environment.

167

RESPONSE: The Revised Plan limits the amount of volume that would be removed from lands not included in the suitable timber base to twenty million board

feet per decade. The Revised Plan allows up to a maximum of 20 MMBF harvest from unsuitable lands. This is not an objective, however, but a ceiling to disclose a maximum level, which was not identified in the Draft Plan and DEIS. There are no plans presently to harvest to that level. The purpose of such harvests would be to enhance or maintain a desired ecological condition, such as aspen regeneration where aspen is being eliminated by conifer succession, not wood production. In most cases, the intended effect would be to improve biodiversity and wildlife habitat. RR/CC

Protect Wildlife in Timber Management Prescriptions

COMMENTS: Either provide habitat for all wildlife, including old growth, or call it timber management; it is misleading to call these areas big game summer habitat/wildlife areas when they could be completely harvested within 30-40 years.

1369

RESPONSE: Many standards and guidelines in the Revised Plan restrict areas from being completely harvested. Included are guidelines for old growth habitat, hydrologic disturbance, and percent of an analysis area in a mature age class.

When done appropriately, timber harvest is not inconsistent with providing effective wildlife habitat. Where management prescriptions, such as 5.4 or 5.3.5, emphasize wildlife habitat, harvest must be consistent with maintaining or enhancing wildlife habitat. The Targhee is moving from an emphasis on timber management to vegetation management for a broader array of objectives. Chapter III, Forestwide Standards and Guidelines, Vegetation, describes the goals and objectives of vegetation management through timber harvest. RR/CC

COMMENTS: Include wildlife standards in all timber emphasis areas or explain the reason for creating these "wildlife sacrifice areas." Significant impacts are inevitable on big game security, old growth species and species affected by habitat fragmentation.

1365, 1369

RESPONSE: The Revised Plan has wildlife standards and guidelines in the Forestwide section and in the management prescription section. If a specific prescription area does not have wildlife standards and guidelines, then the Forestwide standards and guidelines apply.

There are no "wildlife sacrifice" areas proposed in the Revised Plan. Wildlife standards and guidelines are provided in Forestwide and Management Prescription direction which permit or emphasize timber harvest. Chapter IV, Environmental Consequences, describes the effects of implementing the selected Alternative 3M. The Revised Plan meets the goals of the Recovery Plans for threatened and endangered species, such as grizzly bear, bald eagle, and peregrine falcon, meets ninety-one percent of the State goals for elk vulnerability, and provides for maintenance of old growth and late successional forest. Habitat fragmentation from past harvest practices will be a consideration in any future proposals to manipulate vegetation. RR/CC

COMMENTS: The Plan needs a wildlife standard in timber management areas that will protect habitat for wildlife dependent upon older forest habitat in large, unfragmented blocks.

1369

RESPONSE: A set of forestwide guidelines was added to the Revised Plan for maintenance of old growth and late seral forest stages in Chapter III of the Revised Plan. CC

COMMENTS: Evaluate the impacts of big game security in timber management areas and show minimum acceptable levels for big game security. Show all significant impacts.

1369

RESPONSE: Chapter IV, Environmental Consequences, describes the effects of implementing the selected alternative 3M on elk vulnerability. RR

COMMENTS: Raise the minimum security standard needed to hold big game in a big game emphasis area above 30%. because one 250 acre security patch for an entire management area of thousands of acres is not enough.

1369

RESPONSE: This change was not made. The proposed standard actually provides for more than one **250** acre block and is sufficient to provide security for big game. CC

COMMENTS: Evaluate the impact of roads on wildlife in timber management areas. Add standards. Show expected wildlife use and population impacts.

1369

RESPONSE: Viability of various wildlife species is discussed in the FEIS. Open motorized roads and trails are used to evaluate impacts to wildlife using the elk habitat effectiveness model and the elk vulnerability model. These effects are displayed in Chapter IV of the FEIS.

The Revised Plan includes standards for motorized open road density limits to maintain elk security and reduce grizzly bear vulnerability. Chapter IV, Environmental Consequences, describes the effects of implementing the selected alternative 3M on wildlife. RR/CC

COMMENTS: The last item under the standards and guidelines for the Management Prescription Timber Management (Big Game Security Emphasis) should be changed to read as follows: No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated as a security area. Security area designations will be at least 10 years in duration. New security areas will be designated and protected at least 18 months prior to entry into a currently designated security areas.

(S)

643

RESPONSE: This change was not adopted. The standard as presently worded is sufficient to meet the intent of providing adequate security for big game. RR/CC

Address Habitat Fragmentation Caused by Timber Harvests

COMMENTS: Evaluate the impacts of existing fragmentation caused by timber harvest and road-building and explain how the Preferred Alternative will change fragmentation patterns.

1365

RESPONSE: Impacts of road building and timber harvesting are discussed in the FEIS. All alternatives that were considered in detail discuss impacts on connectivity (inverse of fragmentation), wildlife habitat, old growth and late seral stages etc. **CC**

COMMENTS: Address edge effects in regards to quality of remaining habitat and include changes in forest microclimate, reduced reproduction success of forest songbirds, and the proliferation of shade-tolerant weedy plant species. Fragmentation leads to the decline of remaining habitat due to edge effects.

1365

RESPONSE: Due to your comments, the Forest added a section on neotropical migratory birds and the effects of timber harvesting in the FEIS. This section discusses what is currently known about effects of Forest fragmentation and edge on songbirds in the Rocky Mountains. The Revised Plan recognizes the need to consider natural patch sizes and historic vegetation patterns when we do vegetation management. Refer to Process Paper D for more information. See the section on Noxious weeds in Appendix A for a response to your concern about weedy plant species. MO

Age Class Diversity

COMMENTS: Define why a variety of successional stages is a management objective and why it is needed to maintain species of all native wildlife and connectivity.

1369

RESPONSE: The objective of managing for an array of successional stages is to improve the overall biodiversity in sections of the Targhee. Mixes of successional stages and the maintenance of key species (such as aspen) makes the ecosystem more resistant to perturbations and more resilient when perturbations occur (keeps the systems from becoming simplified). Refer to the Properly Functioning Condition section of the Revised Plan under "Ecological Processes and Patterns", Chapter 111. An array of ecological indices (such as patch size, patch shape, connectivity, diversity) are being considered at the Forest's landscape level analysis and are being evaluated when considering management options. The intent of the Revised Plan is to introduce some of these key concepts and to lay the foundation for finer levels of analysis that are or will be occurring on the Forest. DM

COMMENTS: Old growth for virtually all forest types is, on a regional scale, far below historic levels, thus the appropriate application of RNW is dependent on scale.

643

RESPONSE: Your comment is noted. Scale is an important consideration in any analysis, including RNV. A set of forestwide guidelines was added to the Revised Plan for maintenance of old growth and late seral forest stages in Chapter III of the Revised Plan. RR

COMMENTS: Conservation should focus on older forests rather than increasing age class diversity across the Targhee National Forest and providing open habitats (e.g., DFPR, Page 111-129; DFPR, Page 111-33; DFPR, Page 111-41) because over the past century logging has replaced old growth with early habitat over vast areas throughout the Interior Columbia River Basin.

643

RESPONSE: The Targhee has a large proportion of forest age classes in late successional, mature condition. The proposed level of vegetation manipulation in these age classes is still quite small and will not substantially reduce this amount of late successional forest. A set of forestwide guidelines was added to the Revised Plan for maintenance of old growth and late seral forest stages in Chapter III of the Revised Plan. RR

Old Growth Habitat

COMMENTS: Measure viability of late successional forest by distribution, patch size and connectivity for wildlife habitats.

1369

RESPONSE: Discussion of these variables can be found in Chapter IV, Environmental Consequences, of the FEIS. RR

COMMENTS: Demonstrate that the guidelines for sensitive species in older forest habitat are not arbitrary; describe your sources and explain why the new guidelines are so different from current recommendations.

1369

RESPONSE: The FEIS and Process Paper D document literature sources and the analysis used for sensitive species and older Forest habitats. MO

COMMENTS: For species dependent on older forest habitat, consider a long-range habitat strategy that is not dependent upon the Forest's ability to locate nests.

1369

RESPONSE: A set of forestwide guidelines was added to the Revised Plan for maintenance of old growth and late seral forest stages in Chapter III of the Revised Plan. These will provide adequate habitat for old growth dependent species. The Forest Plan represents a programmatic long-term strategy to provide for these resources. RR

COMMENTS: Standards, guidelines and prescriptions do not adequately deal with objectives for managing old growth habitat for pine martens, great gray owls, or cavity nesting birds. (CROSS REFERENCE: Wildlife, Snags/Cavity Nesters)

389

WILDLIFE - TIMBER

RESPONSE: A set of forestwide guidelines was added to the Revised Plan for maintenance of old growth and late seral forest stages in Chapter III of the Revised Plan. The Plan also provides standards and guidelines for habitat maintenance for these species. RR

COMMENTS: Monitor the golden-crowned kinglet, pine marten, boreal owl, brown creeper, red crossbill and northern three-toed woodpecker. They could be affected by the harvest of old growth.

1365

RESPONSE: The Revised Plan provides for monitoring the boreal owl, pine marten and northern three-toed woodpecker: all are Management Indicator Species (MIS). The boreal owl and northern three-toed woodpecker are also R-4 Sensitive species. The others are not proposed to be monitored presently. Should the need arise to conduct monitoring of one or more of these species, the Revised Plan provides for doing so. It is not necessary to monitor all species to provide adequate habitat. RR

COMMENTS: The Revised Plan makes no provisions to increase old growth habitat without undergoing a forest plan amendment. This seems inconsistent with the flexibility that the timber and range programs have to enlarge a timber sale area or increase the stocking levels of livestock with only minor National Environmental Policy Act documentation. The same guidelines should also apply to increasing old growth acreage.

389

RESPONSE: The Forest presents additional information in the FEIS about the amounts and distribution of old growth and late successional Forest habitat. The Revised Plan would only alter the amount of late successional forested acres by 2.5%. Therefore, almost all the forested late successional acres will move into the old growth in the first decade. MO

COMMENTS: No objectives are specifically tied to maintaining old growth vegetative diversity.

389

RESPONSE: A set of forestwide guidelines was added to the Revised Plan for maintenance of old growth and late seral forest stages in Chapter III. Forestwide goal statements provide for biodiversity of habitats and plant communities, which include old growth; vegetation goals include biological diversity of plant communities and maintenance of vegetation structure, composition and distribution across landscapes, again, including old growth. RR

COMMENTS: The Forest would lose far more than it would gain from harvesting timber on the corridor in the Big Holes because this area is important for wildlife; timber cutting would increase chances of fire; unsightly clearcuts will destroy the aesthetics of this area and devalue home owners' property.

325

RESPONSE: The level of potential harvest in this area is limited and can only be done consistent with protection and maintenance of other valuable

resources, such as wildlife, recreation, visual quality or wilderness character. Most of the Big Holes are in a semi-primitive motorized or recommended wilderness category. A small proportion is timber management for big game security emphasis. Any proposed harvest in the vicinity of private lands, should it occur, would include mitigating visual impacts and would be primarily focused on fuels hazard reduction in the urban-wildland interface or on wildlife habitat improvement. RR

WILDLIFE - WINTER RANGE

Protect Winter Range

COMMENTS: Protect, maintain, and enhance wildlife (big game) winter range including "crucial", "critical", "lower", "winter feeding", and "potential" winter range. Protect winter range protected to improve the quality of hunting and to carry out proposals of Idaho Fish and Game and Wyoming Game & Fish.

FS-1, F-G-1-P, **F-G-1(475)**, 136, 150, 157, 161, 162, 174, 175, 179, 180, 185, 189, 193, 203, 206, 209, 226, 252, 278, 280, 387, 645, 659, 669, 690, 695, 697, 766, 1245, 1247, 1270, 1388

RESPONSE: The Forest worked with Idaho and Wyoming Fish and Game Departments to identify the critical or crucial elk and deer winter range areas on the Forest. By protecting elk and deer winter range, many other wildlife critical winter range areas are also protected. In the Revised Plan, all elk and deer winter range areas are closed to cross-country snowmachine use. In some places, the elk and deer winter range areas fall within other management prescriptions, such as wilderness, proposed wilderness, wild and scenic and recreational rivers, and grizzly bear habitat. Even though they are within other management prescriptions, the habitat components that make them winter range areas are protected. **MO**

Manase Access to Winter Range

COMMENTS: Limit access for cross-country skiing, downhill skiing, and dog sledding to corridors where impacts to wintering big game are minimized.

(CROSS REFERENCE: Snowmobiles)

F-G-1-P, 150, 161, 162, 174, 227, 293, 389, 645, 669, 695, 697, 1247

Close winter range to any motorized vehicles, except on designated routes, from late fall until spring.

219, 293, 1312, 1395

Keep motor vehicles out of certain areas to protect the animals when their energy reserves are low in the winter.

179, 185, 697

Close access to winter areas, but do not institute complete closures.

66

By December 15 the hunting seasons are over and people are far from game winter areas.

289

WILDLIFE - WINTER RANGE

Science clearly shows that protection from disturbance in winter is a crucial factor to individual survival and recruitment rates.

766

RESPONSE: In the Revised Plan, all elk and deer winter ranges are closed to cross-country snowmachine travel to protect wintering big game animals during a time of the year when they need to conserve as much energy as possible. Working with the Idaho and Wyoming Fish and Game agencies, the Forest identified the crucial mid-to-late natural elk and deer winter ranges on the Forest. Crucial winter ranges are those areas which determine a population's ability to maintain itself at a certain level over the long term. MO/AM

COMMENTS: Address horn hunting in big game winter range.

293, 697

RESPONSE: We have no data which indicates that horn hunting on big game winter ranges on the Forest is at a level that is causing detrimental impacts to big game populations. Even though horn hunting is at a very low level on the Forest, horn hunters will have to abide by the Revised Plan standards which close all elk and deer winter ranges to cross-country snowmachine travel during the winter season. Also, horn hunters will not be able to travel on foot or horseback on winter ranges with the 2.7 (a) management prescription during the winter season. MO

COMMENTS: Regarding the topic of Recreation/Goal-Winter Recreation, minimize winter recreation use in habitats for all threatened & endangered species, candidate, and sensitive species in addition to big game; reference & incorporate Teton Basin Ranser District Teton Front Winter Recreation Plan into big game winter habitat objectives.

1446

RESPONSE: The Revised Plan provides direction for protection of winter range through access management in 2.7 management prescription standards and guidelines and Forestwide Standards and Guidelines for Threatened, Endangered and Sensitive species. RR

Monitor Access to Winter Range

COMMENTS: Worthwhile to establish a standard and a monitoring plan for total use (both wildlife and livestock) in many areas.

643

RESPONSE: The forage utilization guidelines in the Revised Plan include both livestock and wildlife utilization. MO

COMMENTS: Change monitoring frequency for the wildlife/recreation conflicts to weekly in 20% of winter range.

1365

RESPONSE: This recommendation was considered but not adopted. The Revised Plan monitoring item is adequate to identify trends and effectiveness of Plan direction for mitigating recreation and wildlife conflicts; precision and

reliability are 50-75%. The intent is to provide a realistic monitoring program that reflects priorities. RR

Maps/Prescriptions

COMMENTS: Map winter range using scientific data.

FS-4

Map the entire Idaho Fish and Game proposal in Prescription 2.7 (a and b).

161, 617, 690, 766, 1194

Protect all big game range defined by Wyoming Game & Fish.

FS-1, FG-1-P, 161, 1247

Clarify on travel maps that closures apply to all roads/trails - not just system roads.

643

Consider increasing winter range because wildlife numbers are increasing and there is not adequate predator pressure or winter range to support the increase.

432

Include deer, elk, and moose winter range and to a higher level that was indicated in Forest Service memo 2/18/92.

389

Since the Forest agrees that winter range is the determining factor in populations' ability to maintain itself over the long term, explain why the proposed prescription winter range 2.7 is even smaller than the areas mapped under current LMP.

766

Incorporate crucial elk, moose, & deer winter range prescriptions into the Plans (areas managed under a winter range prescription in the previous plan).

389

Use the elk and deer prescription wherever there is winter range. Since you say winter range is so important. Italian Peaks and Bear Creek have a range prescription rather than an elk and deer prescription.

643

Include all crucial deer and elk winter range on Map 24 within Management Prescription 2.7 (a-c).

643, 1401

RESPONSE: We worked with the Idaho Department of Fish and Game, and the Wyoming Game and Fish Department to identify the crucial elk and deer winter range areas on the Forest. This was not an easy task because winters are highly variable, and animals are distributed differently in different years depending on winter severity.

Not all of the crucial elk and deer winter ranges were given the winter range management prescriptions (2.7 a or 2.7 b) because some of these winter range areas are in management prescriptions such as wilderness, proposed wilderness, or grizzly bear habitat, and these other management prescriptions provide protection and management direction which is compatible with the needs of winter range. All of the crucial elk and deer winter ranges

are closed to cross-country snowmachine use during the winter period, regardless of which management prescription they are within.

At this time, moose winter range prescriptions are not considered necessary because of the wide range of habitats used by wintering moose and their adaptability to human disturbance. MO

Quality of Winter Range Vegetation

COMMENTS: Improve the condition of big game winter range and protect from degradation from overgrazing by sheep and other domestic livestock, conversion of agricultural land, growing communities and traffic.

293, 389, 643, 1365

RESPONSE: The forage utilization standards in the Revised Plan include the needs of wildlife. If forage utilization standards are exceeded, domestic livestock grazing is adjusted to meet the needs of wildlife. Conversion of agricultural land and growing communities are outside the control of the Forest Service. The Revised Plan prohibits cross-country use and restricts traffic in winter range areas to designated routes only. MO

COMMENTS: Disclose the needs of wintering big game and the proposals to improve winter habitat quality; clarify what is meant by "vegetation management."

643, 766

RESPONSE: The Revised Plan closes all elk and deer winter ranges to cross-country travel to protect wintering big game animals during a time of the year when they need to conserve as much energy as possible. Crucial winter range areas determine a population's ability to maintain itself at a certain level over the long term.

The glossary defines vegetation management as activities designed primarily to promote the health of forest vegetation for multiple-use purposes. For winter range, vegetation management would promote the health of vegetation that provides shelter and food. MO/AM

COMMENTS: The objective to manage for RNV can be misapplied because the Forest only has a very preliminary understanding of what the RNV is (DFPR III-92 third paragraph under the Winter Range description).

643

RESPONSE: The Revised Plan describes the principles and objectives of Properly Functioning Condition which incorporates RNV but uses other criteria for identifying ecological systems at **risk** or in PFC. The concept of RNV originates in the scientific record and, although a relatively new concept, shows merit as one tool for implementing ecosystem based management. The specifics of identifying and applying RNV will be determined after adoption of the Revised Plan. RR/AM

COMMENTS: We recommend the Forest abide by its earlier acknowledgement of ecosystem processes (e.g. insects, fire, disease) so that artificial "vegetation management" projects will not be required (DFPR III-92 to 111-93)

643

RESPONSE: The Final Revised Plan continues to acknowledge the role of natural ecosystem processes. Human demands on ecosystem also introduces a complex set of effects that interferes with the natural processes. Human induced disturbance does not perfectly replicate natural disturbance processes and we do not contend that it does. However, artificially designed disturbance can achieve desired social, ecological, and economic effects while ecologically approximating natural disturbance, with mitigation for risk to undesirable adverse effects. Humans will continue to affect ecosystems. The Revised Plan provides for this in a manner consistent with maintaining sustainable ecosystems. RR/AM

Analysis Flaw

COMMENTS: Condition of shrubs on winter range needs better data in percent utilization of browse species, effects of fire suppression, and effects of livestock grazing in the DEIS because State and Federal biologists have documented poor shrub conditions on winter range.

643

RESPONSE: Current and continued monitoring and data collection about the condition of shrubs on winter range will determine if they are at-risk or meeting the Properly Functioning Condition. At-risk areas will receive priority for restoration within the framework of a site-specific project level or landscape level environmental analysis. The Targhee has other data showing condition and trends, utilization, and actual use utilization for domestic livestock. The grazing utilization standard in the Revised Plan applies to all utilization on plants, regardless of animal species and speaks to maximum allowable use. Regardless of what animal species utilized the plants as forage, livestock will be removed once the desired utilization level is achieved. RR

COMMENTS: Data that are not current and not generated by statistically reliable methods should have its limitation noted in the narrative. DEIS 111-42 gives statistics for winter range meeting DVC with no reference to source.

643

RESPONSE: We used the most current and reliable data available. RR

Road Density

COMMENTS: Explain why you selected two (2) miles per section of open road in big game winter range and why that will promote wildlife habitat.

1369

The OROMTRD of less than or equal to **2.0** mile per square mile is too high for the elk and deer winter range prescription. The density standard should be set no higher than 1.0 mile per square mile. (DFPR 111-93).

643

RESPONSE: The OROMTRD standard applies to the nonwinter period, and therefore does not affect wintering big game animals. During the winter period,

WILDLIFE " WINTER RANGE

snowmachine use is restricted to designated routes to protect wintering wildlife. MO

Standards & Guidelines

COMMENTS: Need Standards and Guidelines and change Prescription 2.7 for big game winter range that includes moose & bighorn sheep in addition to elk & deer.

1247

Change the name "Elk and Deer Winter Range" to "Big Game Winter Range" unless the designation refers only to elk and deer.

699

Provide guidelines for management and mitigation for timber harvest on crucial big game winter range.

389

Develop standards and guidelines to enforce minimizing winter recreation impacts on wintering wildlife, especially by outfitters and guides.

389

Add a standard to prohibit human presence in critical big game winter range that prohibits human presence from Dec. 1 to April 30.

1247

April 1 is far too early to open winter range because spring is the period of greatest stress. Timing should depend on winter conditions and established through consultation with state game biologists (DFPR 111-93).

643

RESPONSE: Moose and bighorn sheep are not included in the 2.7 prescription. Moose do not winter in any particular spot nor in herds like the deer and elk and their "winter range" is the entire Forest. Bighorn sheep have winter range in roadless or designated Wilderness areas where motorized use is prohibited and/or inaccessible.

The Forest worked with the State Fish and Game agencies to identify the important elk and deer wintering areas on the forest. The Targhee developed a winter range management prescription to provide the habitat conditions needed by wintering big game animals. The Revised Plan allows timber harvesting only when site-specific analysis indicates it will maintain or improve winter habitat conditions. Any timber harvesting which may occur in the elk and deer winter range prescription is not part of the ASQ. One example of how timber harvesting can improve winter range is when trees have shaded out important forage plants and reduced the amount of winter forage available for big game.

Outfitters and guides must meet the same restrictions that the general public must meet in winter range. Winter range is closed to cross-country use and may be entered and exited only on designated trails. Designated trails are placed, with the assistance of fish and game agencies, in locations where impacts are minimal, such as on the periphery.

The winter travel plan remains in effect until June 1 (except for prescription area 5.1.4(c), Big Bend Ridge, which ends April 30). This means there is no cross-country travel allowed in winter range areas until June 1. After June 1, the summer travel plan goes into effect. MO/AM

Site Specific D-3

Palisades District

COMMENTS: EIS and Standards and Guidelines should identify and protect crucial winter ranges, specifically on the Palisades District because absence of protection for mule deer and elk crucial winter ranges is of great concern here.

389

RESPONSE: The District staff met with the Idaho and Wyoming fish and game agencies to determine the crucial winter ranges of elk and deer in the Palisades. Additional areas were added to the Final Revised Plan. These areas are protected by the winter range prescription or by another prescription that includes winter range restrictions, such as wild and scenic rivers or recommended wilderness prescriptions. AM

COMMENTS: Evaluate public access to big game winter range in the Palisades District as part of an impact analysis for timber harvest.

389

RESPONSE: Such an analysis would occur on a site-specific, NEPA project basis and is not included in a programmatic Forest Plan. The Revised Plan allows timber harvest in big game winter range after site-specific analysis shows it would benefit big game habitat; such a harvest is not part of the ASQ. AM

Re Targhee National Forest, Draft Environmental Impact
 Statement and Forest Plan Revision

Dear Ms. Cushing:

The U.S. Environmental Protection Agency (EPA) has received the Targhee National Forest Draft: Environmental Impact Statement (EIS) and Forest Plan Revision for review in accordance with our responsibilities under the National Environmental Policy Act and under Section 309 of the Clean Air Act.

EPA Region 10 has used a screening tool to conduct a limited review of the draft supplemental EIS Evaluating management strategies for the Targhee National Forest. Based upon the screen, we do not foresee having any environmental objections to the proposed project. Therefore, we will not be conducting a detailed review of the draft EIS.

If you have any questions, please contact me in Seattle at 206/553-1984

Sincerely,

Richard B. Parkin, Manager
 Geographic Implementation Unit

#1277- Beraud, Robert

Dear Mr Reese:

Thank you for providing Bonneville Power Administration (BPA) the opportunity to comment on the Draft Environmental Impact Statement (DEIS) for the Targhee National Forest, Forest Plan Revision (Forest Plan). Staff specialists have reviewed the Preferred Alternative, Alternative 3-M, and determined that potential conflicts could exist between the Forest management prescriptions and the needs and objectives of BPA's various transmission line corridors. Table 1 lists BPA's transmission lines and the associated Forest Management Prescriptions.

To fulfill its obligations, BPA needs to serve its customers. To meet this need, BPA must provide a transmission system that is safe and reliable. A safe and reliable transmission system requires that certain construction, operation, and maintenance activities occur that may conflict with the goals, standards, and guidelines of the management prescriptions proposed in the Forest Plan and DEIS. Objectives to consider in the management of utility corridors include the following:

1. Ensure that reliable and buildable utility corridors are available to serve existing and future regional and local energy needs. It is expected that road closures would be designated and located so there would be no effect on access to corridors for maintenance and emergency activities.
2. As endorsed in the attached July 23, 1993 memo from the Chief of the Forest Service and Director of the Bureau of Land Management, the 1993 Western Regional Corridor Study¹ is to be used as a reference document when considering land use decisions that may affect existing and/or proposed major utility corridors.
3. Ensure that access essential for transmission line infrastructure repairs and maintenance is available.
4. Continue to provide access to and maintenance of existing utility rights-of-way (ROW) for infrastructure repairs and maintenance activities in accordance with special use permits, land use grant instruments, and easement agreements.

¹ Michael Clayton & Associates for the Western Utility Group 1992 Western Regional Corridor Study Copyright 1992 Sierra Pacific Power Company

Printed on Recycled Paper

- 5 Encourage integrated ROW vegetation management which minimizes impacts and reduces maintenance activities while enhancing ecosystem values.

Although BPA strives to balance the need for a safe and reliable transmission system with the goal of restoring and enhancing environmental quality and avoiding or minimizing possible environmental effects, this may not prevent conflicts with the proposed Forest Plan

To help you identify appropriate changes to include in the Forest Plan Final EIS that consider the management objectives of utility corridors, BPA suggests the three alternative solutions listed below in order of preference:

- 1 Create a new management prescription with standards and guidelines for transmission corridors that applies to all existing transmission line and potential transmission corridors identified by the Western Utility Group (WUG). This would allow the Forest to implement the practice of designating utility corridor management areas which provide for a safe and reliable transmission system. Reducing the proliferation of corridors would have environmental benefits. Additionally, the utility industry would benefit by simplified Forest siting and mitigation requirements.
- 2 Reclassify all existing transmission line corridors and potential transmission line corridors identified in the Western Regional Corridor Study under management prescription 8.1 Concentrated Development Area. As described in *Chapter III - Forestwide Standards and Guidelines, Subsection Direction, and Prescriptions for Implementing the Preferred Alternative of the Draft Forest Plan Revision*, the Concentrated Development Area prescription applies to all existing concentrated developments including utility and transportation corridors. Utility and transportation corridors are defined in the Forest Plan as "a strip of land, up to approximately 600 feet in width, designated for the transportation of energy, commodities, and communications by railroad, State highway, electrical power transmission (66-kV and above), oil and gas and coal slurry pipelines 10 inches in diameter or larger, and telecommunication cable and electronic sites for interstate use"². This management prescription may actually allow more intensive development than is necessary for transmission line corridors.
- 3 Clarify in the Forest Plan and the Final EIS how transmission line corridors will be managed given the current management prescriptions in the Forest Plan DEIS. Include standards and guidelines within the management prescriptions that allow utilities to adequately construct, operate, and maintain transmission lines and corridors.

As you are aware, BPA and Lower Valley Power & Light (LVPL) are proposing to construct a single-circuit 115-kV line from BPA's Swan Valley Substation, west of Swan Valley, Idaho, east approximately 57.9 km (36 miles) to BPA's Teton Substation, northwest of Jackson, Wyoming. The line would parallel the existing ROW when possible. This existing transmission line was constructed in 1968 and was located to make use of the existing State, County, and Forest road systems. The transmission line transportation plan used State Highways 31 and 22 as the main arterioles with secondary roads on the County and Forest road system. A system of on- and off-ROW access roads was constructed during the clearing and power line construction, but some

² Targhee National Forest, Draft Forest Plan Revision, January 1996, pg. G-45

sections of the line remain inaccessible by vehicle. These sections of line are nearly impossible to maintain by conventional methods and, given the level of difficulty of access throughout the snow season, wheeled vehicle access to the remainder of the ROW during the summer season is limited until the ground is firm enough to cross.

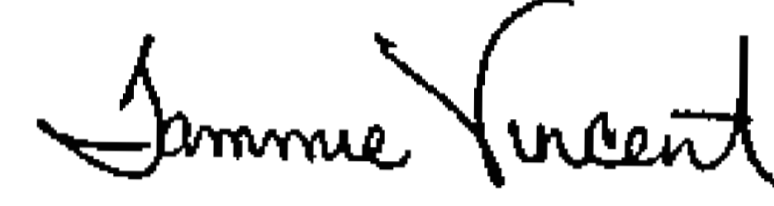

Although the Forest Access Plan restricts access to currently accessible areas of the Forest, it would have limited impacts to the Swan Valley-Teton line access road system. We have included as Attachment 1 to this letter a listing of our proposed changes to the existing access of the Swan Valley-Teton transmission. We request that these changes be included in the final Forest Access Plan. Please understand that BPA staff has not field verified the condition of some on-ROW access roads or the usefulness of several roads that ford streams. BPA may have to propose adjustments based on site specific resource considerations after a comprehensive field review is completed.

Additionally, we have listed the Targhee to Drummond line in Table 1. This line is leased by BPA from Fall River Electric. The same is true for that portion of the Drummond to Madison line located between Macks Inn and Madison. These lines should be added to the Forest Geographic Information System if they are not already included. Attached is a BPA map showing the location of these lines. The Management Prescriptions for the Targhee to Drummond line shown in Table 1 were determined using Map #10, Alternative 3-M Prescriptions, in the Forest Plan DEIS and may be misidentified in Table 1.

Although the management needs for utility corridors were inadvertently neglected in the Forest Plan DEIS, we believe that with some minor modifications the Final EIS will be extremely helpful as a planning tool. Forest staff as well as Forest users should be better able to consistently apply and comprehend the goals and objectives of the Targhee National Forest lands. We commend your staff for the results of their efforts.

We would be happy to work closely with your staff to assure that an adequate consideration of BPA needs and objectives are addressed in the Forest Plan Final EIS. Please feel free to contact Kathy Fisher of my staff at (503) 230-4375 if you would like to discuss these comments further.

Sincerely,

for Robert W. Beraud

Jerry B. Reese, Forest Supervisor
Targhee National Forest
P.O. BOX 208
St. Anthony, Idaho 83445

Dear Mr. Reese:

The Department of the Interior (Department) has reviewed the Draft Environmental Impact Statement (DEIS) for the Revised Plan (Plan) for the Targhee National Forest (Forest), Bonneville, Butte, Clark, Fremont, Jefferson, Lemhi, Madison, and Teton counties, Idaho and Lincoln and Teton Counties, Wyoming. The Fish and Wildlife service (Service) previously commented on the preliminary draft Of the DEIS and the Draft Forest Plan Revision (Plan) on November 14, 1995. Because the DEIS and the Plan addresses only two of the Service's concerns, many of the Service's previous comments are repeated in these comments. The following comments are provided for your use and information when preparing the Final Environmental Impact Statement (FEIS) and Final Forest Plan Revision.

GENERAL COMMENTS

The efforts Of the Targhee National Forest to address the needs Of fish and wildlife resources, particularly with respect to species listed as threatened and endangered under the Endangered species Act of 1973 (ESA), is commendable. Compliance with the ESA is essential; nevertheless, other environmental laws, such as the National Forest Management Act (NFMA) and the guidance provided in the Forest Service Manual (FSM), are equally important for protecting fish and wildlife species on the Forest and should be included as central reasons for revising the Plan. Further, the ESA should be used as a planning tool to accomplish the planning needs and purposes of the NFMA and the FSH.

The Department is concerned about language in the Plan regarding species protection under the ESA and domestic animal grazing. The summary sections Of the DEIS and the Plan should be carefully evaluated and modified in the FEIS to address this concern. For

³ Indicated print denotes Forest GIS name classification.

example, the preferred alternative in the DEIS states sheep grazing will be phased out on an opportunity basis over much of the Forest for grizzly bear protection. This language could influence the public to become polarized against protection for the grizzly bear. Forest Service regulations, such as the NFMA and the FSM, should be referenced when justifying recommendations for the Forest planning decisions involving species protection and changes in domestic animal grazing allotments.

The DEIS and the Plan do not include "core" and "security" area designations for the Henry's Lake Bear Management Unit (BMU) or a "security" area for the Bechler-Teton BMU. In order to comply with previous biological opinions and the existing Interagency Grizzly Bear Committee (IGBC) Management Guidelines (Guidelines), the Service recommended in previous letters the Forest include these types of designations in the final Plan. These designations should also be included in the FEIS.

Fish and wildlife resources seem to be appropriately treated in the standards and guidelines section of the Plan. However, in many cases "guidelines" known as general, non-binding directions, are designated for an action when a "standard", which is a binding, measurable guide for management on the Forest, may be more appropriate. Management and monitoring of these resources for the next 10 to 15 years on the Forest are closely tied to the standards and guidelines. Thus, the FEIS should include detailed, accurate standards for fish and wildlife resources.

The Forest's detailed treatment of standards and guidelines for the aquatic and riparian resources is commendable. We have seen significant progress by the Forest since 1985 in addressing the needs of these essential habitat areas for fish and wildlife. Many of the guidelines for aquatic resources should be changed to standards so the protection of these resources can be insured (see specific comments).

The section on Standards and Guidelines for Wildlife does not clearly state general goals apply to all of the species. Listing of additional goals in subsequent sections enables the reader to come to understand there are additional concerns for a species. A similar observation was made with respect to the section on Goals and Objectives. Goals and Objectives should be formulated for each species and for each of the other items listed in the Standards and Guidelines section that do not have specific Goals and Objectives statements. The FEIS should clarify this issue in the introduction.

DRAFT EIS - SPECIFIC COMMENTS

Page I-4, Background It would be helpful to include a summary breakdown (%) of the various vegetation types on the Forest beyond the 60 percent lodgepole pine component.

Background - third paragraph In terms of energy and nutrient movement in an ecosystem, clearcutting of a lodgepole pine forest, or other forest types does not duplicate the role of fire. This statement should either be removed or clarified.

Page I-9, Key Issue 4 The ESA does not necessarily contain "stringent" guidelines. As long as listed species are included in the planning process and managed accordingly, in cooperation with other activities, the ESA can be flexible. NFMA has just as stringent requirements for maintaining wildlife populations as the ESA. The ESA aims for the recovery of listed species and the ecosystems upon which they depend. These points should be made in this paragraph by deleting the word "stringent" and, after the words Endangered Species Act, adding "and NFMA."

Pages II-3 and II-15 Description of Alternatives The statements, "All the alternatives comply with State and Federal law" (page II-3) and "All alternatives meet baseline State and Federal Standards..." (page II-15) are misleading and should be removed. All of the alternatives do not comply with all State and Federal laws. For example, there are no designated "core" or "security" areas for the Henry's Lake BMU; there is no "security" area designated for the Bechler-Teton BMU. The prescriptions for these areas provide a moderate amount of protection but do not afford the area the same degree of security as do the "core" and "security" areas for the Plateau BMU. On page II-9, 4. Grizzly Bear Management, the DEIS says, "No timber harvest would be scheduled in the 'core' or 'secure' areas." Therefore, if "core" and "security" areas are not designated, timber harvest can take place in a BMU under various scenarios including ecosystem management. The IGBC Guidelines were in effect during the early 1980's. The Guidelines were not adhered to then and quoting them as the standard now likely will not provide a level of security for the grizzly bear beyond that of the 1980's. Vehicle access is only one of the IGBC Guidelines that need to be met in the Plan.

Page II-9, Grizzly Bear Management There are no "core" or "secure" areas, as defined in the January 27, 1994, Grizzly Bear Management Direction for the Plateau Bear Management Unit (Strategy) and the February 22, 1994, Biological Opinion on the Strategy, in the Henry's Lake BMU, and no "secure" area in the Bechler-Teton BMU. Timber harvest and other activities can take place in these BMUs since there are no "core" or "secure" areas.

These components should be addressed in the FEIS

Page II-15. Second paragraph See comments for page II-3 above.

Page II-17. Second paragraph The Service suggests additional examples be articulated in the discussion, not just grizzly bears and open roads. This would better emphasize the ecosystem management approach being proposed

Page II-19. Table II-1 BIOLOGICAL/Other Riparian and Water Indicators The category, "Mi cutthroat stream with/min. 6" stubble height at HGL", shows the second worse mileage. We assume there is a mistake here. The preferred alternative likely can not reach all of the stated riparian and water quality goals if it results in fewer stream miles with 6" stubble than the existing level of management,

Page III-4. Range of Variability This section says the Forest Service is in the "process" of compiling data to better understand the range of variability. Lacking complete and quantifiable information upon which to base decisions, the Forest Service should withhold implementing decisions until all of the information and proposed process methodology have been reviewed by the scientific and public communities. Until all of the information is available, the Forest Service has developed the appropriate management strategies, and the process has been through public comment, this management methodology should not be included as a part of the Plan.

Page III-5. Succession The discussion of succession is oversimplified. Current theories on the state and transition model of community change have not been incorporated. The model suggests there are forces that, if applied as presented, may change the existing state of a community. This is known as transition. Therefore, re-applying similar forces on a community type may not necessarily yield the previous state. This section should be expanded to include current thinking and knowledge of community ecology and dynamics.

Page III-8. Insects and Disease Insects and disease are viewed primarily from a detrimental perspective. A number of Insects are regarded as pests, however, a greater number are important to healthy ecosystems. The discussion should provide a more complete presentation of these types of organisms.

Page III-19. Riparian In the first paragraph, the Service agrees with the statement that riparian areas visibly reflect the quality and success of management activities in tributary watersheds. We recommend the Forest review the document to ensure this thinking is carried through to other issues related to the needs of fish and wildlife species.

Page III-21. Water In both the DEIS and the Plan revision water is included as a biological element, when it is really a physical element (hydrology is a physical science). Correct or explain to the reader the reason(s) for the characterization,

Page III-21. Lemhi/Medicine Lodge The third paragraph indicates no standards for nutrients, nor any clear direction as to what farms of nitrogen and phosphorus are to be monitored, so recommendations from researchers were used. The Service suggests specific studies be referenced in the document to allow the reader to further understand why these criteria were chosen,

Page III-26. Second paragraph from the bottom The discussion about influence zones should be expanded to include how the influences of topography, geology, location, and season can also modify the area. Standards are, therefore, developed from site specific information. The entire watershed and climate also have influence and control over lakes, reservoirs, ponds, perennial and intermittent streams and wetlands (as defined in the glossary). The second sentence should be rewritten to read, "The entire watershed and climate influence the . ." The third sentence should read, "Lakes, reservoirs, ponds, perennial, and intermittent streams, and wetlands provide unique...."

Pages III-30 and 39. Table III-8 and 12 The Service recently removed the trumpeter swan, spotted frog (in eastern Idaho), Harlequin duck, wolverine, North American lynx, and Northern goshawk from the Federal candidate species list. We suggest the Forest Service maintain these species as sensitive forest species. They are important indicators of forest wide habitat conditions.

Even though the bald eagle has been reclassified as threatened, recovery efforts still need to be implemented and carried out. The Forest Service should ensure that its activities do not directly, indirectly, or cumulatively contribute to a downward trend in the status of this species. All data and references included in the Plan should be the most up to date available. The second paragraph under Bald Eagle Nesting Habitat lists a 1992 Forest Service report and data from 1995. This should be corrected in the FEIS.

Page III-36. Second paragraph It is unclear what is meant by an ecological condition. The phrase should be quantitatively or qualitatively defined in the attached glossary.

Page III-37. Characteristics of noxious weeds In terms of ecosystem-based management, unless the plant species is non-native to the area, all plants are part of a fully functioning ecosystem. If, however, the Forest is referring to specific

grouping of plants listed by Animal and Plant Health Inspection Service (APHIS), for example, this should be referenced as such, thus clarifying the issue.

Page III-49. Last paragraph The last sentence referring to livestock depredation by a female wolf with pups, is taken out of context from the referenced document. The sentence should be rewritten to read, "Prior to the establishment of six breeding pairs, depredating females and their pups will be captured and released at or near the site of capture, one time prior to October 1. If depredations continue, or if six packs are present, females and their pups will be removed."

Page IV-15. First paragraph Timber harvest is another impact to the riparian area that should be included as a reason for riparian acres not meeting the DVC (desired vegetative condition).

Page IV-16. Water Indicators Although stubble height measurements when applied properly are an excellent tool, there can be problems inherent to using stubble height as a monitoring method. Some problems are: 1) which plant species are being measured for stubble height and 2) is this criterion allowing for perpetuation of undesirable plant species - especially Kentucky bluegrass. Especially as it pertains to fisheries habitat, two other key factors provide better information and more channel stability and habitat. These factors are: 1) percent of bank covered with a deep, binding root mass and 2) percent of tree and shrub regeneration along the stream bank,

Page IV-32. Forest Acres Within Core Areas, third paragraph Strictly speaking the existing core areas do not meet all of the core area standards because of past management activities. However, the Forest Service is working to meet those standards and this section should reflect this goal,

DRAFT FOREST PLAN - SPECIFIC COMMENTS

Page II-1 The Service concurs with the statement that habitat effectiveness for big game and particularly grizzly bear has been reduced through increases in road density and reduction of cover. In the context of true ecosystem management, road management applies to many other resources, not just the grizzly bear or big game. This discussion should be expanded in the FEIS,

Page II-3 & 4. Needs for Change Page 5 of the IGBC Guidelines specifically states the "GUIDELINES ARE SUBJECT TO CHANGE AS RESEARCH PROVIDES ADDITIONAL DATA AND/OR MANAGEMENT DIRECTIVES CHANGE." The Service recommends the last paragraph be deleted and replaced with the following statement: "The provisions of the

ESA have not changed since the Plan was put into effect in 1985. However, the understanding of the habitat needs of the species has changed substantially. Meeting the needs of the listed species, in particular the grizzly bear, has substantially changed management on a large portion of the Forest. New information, accumulated over the last ten years, provides new insight and direction regarding effective management of access, vegetation manipulation, and human activities in grizzly bear habitat." Including the above wording will alleviate the need for a detailed discussion of why alternative 1 does not fully comply with the 1985 Forest Plan or the Guidelines direction for timber management in Situation 1 and 2 grizzly bear habitat,

Region 4 of the Forest Service did not have a sensitive species list or direction for dealing with sensitive species in 1985 when the current Plan was signed. The Service is of the opinion that since signing of the Plan in 1985, significant additional information has led to refinement of forest management techniques, including sensitive species life history and habitat needs. It is our understanding that the Plan is to be flexible and where and when appropriate, as new information becomes available, such information will be incorporated, thus leading to continued improvement of natural resource management on the Forest

Page III-2. Definitions of Standards and Guidelines The standards should contain sufficient information to allow for adequate management. The Forest Plan Standards and Guidelines should be developed to reflect a conservative approach until information is available that would allow for changes in management. The majority of the Guidelines have not been standardized, they are non-committal, optional, and may not fulfill Forest Service responsibilities as defined in the FSM section 2670 on Biological Diversity and Threatened and Endangered Species, 36 CFR §219.19 guidelines for viable populations, or sections 7(a)(1) and (2) of the ESA. The Service recommends many of the Guidelines listed in Chapter III be changed to Standards. This would be essential when discussing endangered and threatened species consultations. Additionally, such standards would be important to achieving the ecosystem-based management alternative 3-M is seeking to meet.

Introduction, last paragraph relating to emergency events A list of all potential events should be presented to give the reader a better perspective of what constitutes an emergency. As stated, the list appears to only include events related to law enforcement, search and rescue, and fire,

Page III-6. Last paragraph Other "natural causes" such as high water runoff and floods would be more likely to cause changes in

stream channel stability than avalanches in this area. This point should be expanded in the FEIS.

Page III-7. Goals, Objectives, and Forestwide Standards and Guidelines for wetland types are available, but have not been fully developed in the Plan. These need to be included in the FEIS because of existing Executive Orders that pertain to wetland protection.

Page III-7. Standards and Guidelines - Aquatic Resources The Service suggests item number 2 be a Standard to be consistent with Forest Service direction for new special use permits guidelines.

Page III-7. Standards and Guideline - Watershed General Allowing as much as 30 percent hydrologic disturbance in watersheds at any one time seems inconsistent with many of the revision's goals regarding biodiversity, soils, aquatic, riparian, watershed, municipal watershed, vegetation, wildlife and threatened and endangered species. Furthermore, this quantity of disturbance would likely adversely affect Bureau of Land Management's (BLM) management efforts to improve and enhance important natural resources on that land.

Page III-7. Standards and Guidelines - Municipal Watershed Add standards and guidelines having livestock grazing, timber harvest, camping, and all terrain vehicle (ATV) restrictions to ensure adequate protection of municipal watersheds.

Page III-8. Vegetation Guidelines related to plant species diversity should be reconsidered in the FEIS. Non-native plant species may inhibit efforts to implement ecosystem management. Projects should be designed so they would require use of native plant species.

Page III-9. Raptor Nest Sites This action should be listed as a Standard to be consistent with the Forest Service policy and efforts to protect sensitive species.

Page III-9. Standards and Guidelines - Raptor Nest Sites Add a guideline to protect potential raptor nest sites for sensitive and listed species.

Page III-11. Goals-Grizzly Bear Habitat Goal number 1 should be rewritten to reflect the commitment of the Forest Service to fulfill section 7(a)(2) and comply with 36 CFR § 219.19 of the NFMA. The Goal should read, "Habitat conditions will conserve and sustain a recovered population of grizzly bear in the Greater Yellowstone Ecosystem (GYE) and on the Forest." This wording is consistent with the Forest Service resolve to manage resources on

an ecosystem basis.

Objectives for Grizzly Bear Habitat The objectives of all actions for listed species should be to meet or exceed recovery criteria based on guidelines from the FSM section 2670. Therefore, objective number 1 should be rewritten to read, "Meet or exceed recovery criteria in the Grizzly Bear Recovery Plan."

Objective 3 should be clarified as to what is meant by "bears in trouble." Following IGBC Guidelines, page 51, this objective should be rewritten to read, "Provide safe, secure release sites for relocation of nuisance bears."

Objective 4 should be rewritten as follows, "Implement the road density standards in the BMU's within 1 year of the signing of the ROD in coordination with USFWS and State Wildlife agencies." Compliance with these standards is already in progress and should be completed as expeditiously as possible.

The Service also recommends methods for calculating road densities be included in the final Plan and FEIS.

The following should be included as Standards, in addition to the education program, for Grizzly Bear Habitat. "1. Sanitation standards will be set for human habitation and use on portions of the forest within the recovery zones; and 2. Core area maps for each BMU are enclosed in the appendix." Standards for core areas shall be consistent for all alternatives. The draft Forest Plan does not describe the location of the security or core areas for all of the BMU's. According to the IGBC task force and previous biological opinions, core and security areas are to be designated and are required in each BMU.

Page III-11. Goals - Grizzly Bear Habitat Provide each of these goals with a standard stating that pursuant to the Grizzly Bear Recovery Plan, no timber cutting activities will be allowed within situation I&II Habitat.

Page III-11. Standards and Guidelines - Bald Eagle Habitat Add standards to restrict human entry and development within Bald Eagle Zones 172 and within at least a quarter miles radius around existing and new nests.

No reference has been made to Bald Eagle habitat management and guidelines along the South Fork Snake River - especially relating to the South Fork Snake River Activity/Operations Plan prepared jointly by the BLM and the U.S. Forest Service. Incorporate by reference this activity plan in this section of the document.

Explain that potential impacts to eagles and other threatened and

should read, "Prior to the establishment of six breeding pairs, depredated females and their pups will be captured and released at or near the site of capture, one time prior to October 1. If depredated females are present, or if six packs are present, females and their pups will be removed."

Page III-13. Standards and guidelines - Peregrine Falcon Habitat BA (see page 224) but has been changed to a guideline here and in the preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-15. Standards and guidelines - Great Owl Habitat Increase to 1 mile the radius of use for strychnine poison to control pocket gophers around all active Great Owl nest sites.

Page III-15. Standards and guidelines - Trumpeter Swan Habitat Items A, C, and E were listed as standards in the preliminary draft BA but have been changed to guidelines in the Plan. Use of Standards rather than guidelines would be consistent with the Forest Service commitment to manage for viable populations under NFWA (36 CFR § 219.19.)

Page III-16. Objective - Spotted Bat and Western Big-eared Bat Habitat It is important to consider other aspects of bat ecology. The Service recommends that areas necessary for roosting and foraging also be emphasized in the final Forest Use and Occupation in order to comply with IGBC standards, road density standards should be implemented within one year of signing the Forest Plan and completed within 3 years from implementation. All other areas should be completed within 5 years. To wait a full 10 years to complete the road density standards will put the completion date into the next Forest Plan revision cycle.

Page III-12. Standards and guidelines - Bald Eagle Habitat Add a guideline to protect alternate nest sites and potential nest sites from timber harvest, roads, and permanent recreation developments.

Page III-12. Standards and guidelines - Bald Eagle Habitat Add a guideline to educate recreationists (e.g. hikers, bikers, campers, ATV users etc.) about zone 1 areas.

Page III-13. Standards and guidelines - Gray Wolf Habitat The last sentence referring to livestock depredation by a female wolf with pups, is taken out of context from the referenced document. (See page 60257 of the Federal Register, Vol. 59, No. 224 for the gray wolf reintroduction.) The sentence

developed for all bald eagle nesting territories on the forest. Add a standard requiring that site-specific management plans be developed for all bald eagle nesting territories on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

endangered species require the ESA section 7 consultation with the Fish and Wildlife Service.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-15. Standards and guidelines - Great Owl Habitat Increase to 1 mile the radius of use for strychnine poison to control pocket gophers around all active Great Owl nest sites.

Page III-15. Standards and guidelines - Trumpeter Swan Habitat Items A, C, and E were listed as standards in the preliminary draft BA but have been changed to guidelines in the Plan. Use of Standards rather than guidelines would be consistent with the Forest Service commitment to manage for viable populations under NFWA (36 CFR § 219.19.)

Page III-16. Objective - Spotted Bat and Western Big-eared Bat Habitat It is important to consider other aspects of bat ecology. The Service recommends that areas necessary for roosting and foraging also be emphasized in the final Forest Use and Occupation in order to comply with IGBC standards, road density standards should be implemented within one year of signing the Forest Plan and completed within 3 years from implementation. All other areas should be completed within 5 years. To wait a full 10 years to complete the road density standards will put the completion date into the next Forest Plan revision cycle.

Page III-12. Standards and guidelines - Bald Eagle Habitat Add a guideline to educate recreationists (e.g. hikers, bikers, campers, ATV users etc.) about zone 1 areas.

Page III-12. Standards and guidelines - Bald Eagle Habitat Add a guideline to protect alternate nest sites and potential nest sites from timber harvest, roads, and permanent recreation developments.

Page III-13. Standards and guidelines - Gray Wolf Habitat The last sentence referring to livestock depredation by a female wolf with pups, is taken out of context from the referenced document. (See page 60257 of the Federal Register, Vol. 59, No. 224 for the gray wolf reintroduction.) The sentence

developed for all bald eagle nesting territories on the forest. Add a standard requiring that site-specific management plans be developed for all bald eagle nesting territories on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Page III-11 and 12. Standards and guidelines Change the following guidelines to standards to be consistent with recovery guidelines, NFWA, ESA, and other warranted management standards for protection of the bald eagle: 1) #A should be a standard to a preliminary draft biological assessment (BA) (pages 15 and 18) Standard; 3) #C and #D listed as standards in the preliminary draft biological assessment (BA) (pages 15 and 18) but have been changed to guidelines here and in the current draft BA. Both items are under the control of the Forest Service and should be listed as standards to protect the species and its habitat; and 4) #E should be a standard to be consistent with #M, wildlife management actions on the forest.

Standards and Guidelines, item 1A should be changed to read, "Road closures will be located and designed to effectively control human use." Standards and Guidelines for temporary roads are not designated in this section. It is our understanding that the DEIS does not include the construction of temporary roads as new road construction. This should be clarified in the FEIS.

Page III-16. Standards and Guidelines - Harlequin Duck Habitat
Expand the guideline to include all riparian zones and habitat, and tie it to more than a single wildlife species. Modifying this guideline will benefit watershed and water quality objectives as well as protect the species.

Page III-16. Forest Use and Occupation/Access/Goal Modify this goal (or create another) to also emphasize threatened and endangered species, candidate species, sensitive species and big game habitat.

Page III-17. Recreation/Goal-Winter Recreation Minimize winter recreation use in habitats for all threatened and endangered species, candidate, and sensitive species as well as big game.

Pages III-17-18. Information, education, and sanitation
standards have been set for areas within the recovery zone for grizzly bears by the Forest Service, based on IGBC Guidelines. These should be presented in this section as an overall goal or in the Dispersed Recreation or Developed Facilities section. Similar information was requested to be included in the Forestwide Standards and Guidelines beginning on page III-118. The Objectives and standard and Guideline for Wild, Scenic, and Recreation Rivers and Visual Quality are out of order. They should be inserted after the Standards and Guidelines for Winter Recreation.

Page III-18. recreation/Objective - OHV (Off Highway Vehicle)
Expand this objective to minimize also the effects of OHV use on riparian, aquatic, critical and crucial wildlife habitat. Develop motorized recreation management standards and guidelines to exclude use within crucial seasonal wildlife habitat.

Page III-20. Objectives Under Objective 3, change the Roman numerals to ordinal numbers for consistent format.

Page III-20. Range, Goals Explain how these goals protect the social and economic values of the local communities and of the livestock industry. Explain how these objectives can be achieved while maintaining the grazing opportunities on the forest.

Page III-20. Range, Goals/Objectives List criteria that will be used to determine desired vegetative conditions for site-specific

areas. Desired vegetation conditions could be established at an unhealthy level without key native species being identified as indicators of healthy systems.

Under Objective #1, it may be inherently difficult to manage for mid- or late-seral riparian communities, since these dynamic, shifting channel systems are continually undergoing changes. Natural flooding, meandering and erosive processes will annually provide for early-seral vegetation establishment. The ecological status of riparian habitat may be more beneficial to the ecosystem by remaining in an early seral stage rather than moving to a mid- or late-seral stage.

Add an objective to recruit and re-establish riparian-wetland vegetative communities back into these riparian zones.

Page III-21. Riparian Forage Utilization/E Riparian Vegetation Stubble Height If the 4-inch stubble height standards applied only to native and desirable non-native, hydric vegetation-grazing undesirable species without such standards may perpetuate unhealthy, unstable riparian zones.

The 4-inch stubble height can certainly be a good management tool within the "greenline" portion of riparian areas, but this tool should be used throughout the entire riparian zone.

Page III-22. Range/Standards and Guidelines/3 E Reword this guideline so that it does not suggest that projects can only be done if the Forest Service provides 50 percent of the necessary funding.

Page III-22. Range/Standards and Guidelines/3 G Summarize or otherwise elaborate on the process outlined in the National Programmatic Agreement, Option 2 referred to here.

Page III-22. (General) Timber cut under "ecosystem management" does not appear to be part of the allowable sale quantity (ASQ) as it should. Clarify here so one does not conclude that the real sustainable cut is described as part of "ecosystem management". Identify estimates of cuts outside the ASQ to explain to the reader the general magnitude of ecosystem management cut as it relates to the allowable cut.

Page III-22. C.3 This should be rewritten to read, "Do not convert from a cattle allotment to a sheep allotment within bighorn sheep habitat or in a grizzly bear BMU." This will be consistent with Forest Service direction for management of BMUs on the forest.

Page III-22. C.4 The Service recommends a botanist be included

as a member of the ID Team,

Item E should be changed to a Standard, This will be consistent with item C.2.

Page III-23-25 The table shown on page III-24 does not indicate which treatments are standards and which are Guidelines; this should be clarified since the table is presented under the Standards and Guidelines heading. In pre-commercial and commercial thinning, slash may accumulate to the extent that movement of big game and other terrestrial species is impaired.

Standards and Guidelines-Size of Harvest Units and Leave Blocks/Strips The Service has concerns about this Standard because of the far reaching effects timber harvest has had on fish and wildlife species on the Forest prior to 1994. An ecological approach to silvicultural Standards and Guidelines in the Plan is necessary to meet fish and wildlife needs on the Forest. Scientific data to support the adoption of this Standard should be cited in the Plan. The scientific data will assist in demonstrating that light, wind, moisture regime, and vertical stratification of vegetation in an area may be such that the area is no longer a "created opening". Maximum clearcut size and dimensions must be standardized under the preferred alternative to adequately protect fish and wildlife resources.

Page III-29 This section lacks objectives, standards, and guidelines with which to maintain or enhance big game habitat and sage grouse habitat. Since the EIS designates winter range for this area, and sage grouse populations have drastically declined, management guidelines for sage grouse habitat are obviously needed.

Add specific goals and objectives for maintenance of existing suitable wildlife habitat conditions and improvement of presently poor wildlife habitat areas. For objectives to be achievable, it is critical to know current area specific habitat conditions against which future accomplishments can be measured,

Describe for each geographic subsection a clear and definite time frame within which to attain its "desired future condition".

Page III-29. Goals and Objectives/Aquatic and Riparian Ecosystem Add the following streams to this objective: Pass Creek; Warm Springs Creek; Divide Creek; and West Fork Irving Creek.

BLM riparian inventories on these streams show riparian health and/or channel stability problems. Unless riparian conditions are improved throughout the landscape, the Targhee National Forest will not be able to meet many of its overall goals related

to biodiversity, threatened and endangered species, wildlife, soils, aquatic, and riparian protection.

Pages III-26 - 55 There are numerous inconsistencies throughout this section. The Figures list prescriptions (Rx) and the attendant acres for prescriptions in a Table but many of the prescriptions are not listed on the map or are listed on the map but not in the Table. The Desired Future Conditions do not list similar statements in the standards and Guidelines section for Goals and Objectives. These two sections should support each other. There are no "core" or "security" areas shown for the Henry's Lake BMU or "security" area for the Bechler-Teton BMU. Page III-42 lists a prescription 1.1.1 for 10,664 acres, but there is no prescription 1.1.1 shown. Where do these 10,664 acres belong? This entire section should be reviewed and the information adjusted to reflect consistency with the maps, tables and narrative that will be presented in the FEIS.

Page III-35 Goals and Objectives This section lacks objectives, standards, and guidelines with which to maintain or enhance big game habitat and sage grouse habitat. Since the EIS designates winter range for this area and sage grouse populations have drastically declined, management guidelines for sage grouse habitat should be developed and included in the FEIS.

Page III-35 Goals and Objectives/Aquatic and Riparian Ecosystem Add the following streams to this objective: East Fork Irving Creek; Dry Creek; Middle creek; West Fork Indian Creek; East Fork Indian Creek; and Middle and East Forks Dry Creeks

BLM riparian inventories on these streams show riparian health and/or channel stability problems. Unless riparian conditions are improved throughout the landscape, the Targhee National Forest will not be able to meet their overall goals related to biodiversity, threatened and endangered species, wildlife, soils, aquatic, and riparian protection.

Page III-49 through III-55 Big Hole/Palisades Subsection (M331D-1) and Caribou Subsection (M331D-19) Modify write-ups for these subsections to include standards requiring management of forest lands along the South Fork Snake River to be in accordance with the Guidelines in the Snake River/Activity and Operations Plan prepared jointly by ELM and Forest Service. Incorporate by reference this activity plan into this section of the document,

Discuss and incorporate by reference the Teton Basin ranger District's (Driggs) Teton Front Winter Recreation Plan and it crucial big game winter habitat objectives or ORV restrictions

III-51 Goals and Objectives/Aquatic and Riparian Ecosystems Add

Wolverine Creek, tributary to the South Fork of the Snake River to this list. The condition of this stream upstream of the road has been highly impacted by grazing as well as day use and camping taking place at the mouth.

Pages III-61 - 62, last paragraph on page 61 and first paragraph on page 62 The Forest Service has control over the location of future campsite and trail development and activities that may impact the listed peregrine falcon. (Also applies to page III-64, Wildlife.) Listing these items as Standards would be consistent with stated responsibilities under section 7(a)(2), FSM 2670, and NFMA 36 CFR § 219.19 and will provide the protection for the species and their habitat without adversely impacting use of the forest by the public.

Page III-63, 1.1.8, fourth paragraph Clarify how the statement, "campsite facilities may be present for recovery of T&E species" will facilitate recovery of a species. There appears to be no connection between these two points.

Pages III-66, 75, and 97 Pages 66 and 97 use the heading "Ecological Processes", page 75 lists the same heading as "Ecological Elements." Is there a difference in definition for these two terms? If so, please explain. Constant use of terms will assist in understanding the proposals in the Plan.

Pages III-70 and 72, Objectives 2 and 1 respectively These two goals appear to provide the Forest Service the option of cutting timber in areas that otherwise are not scheduled or considered for such management treatments. If this is the case then the options should be specified for each prescription so the total impacts can be evaluated for the entire plan.

Pages III-73, 76, 80, 84, 103, and 105 Under Physical Elements, the use of indigenous species to reestablish vegetation is commendable. Clarify what a "naturalized" species is. "Reasonable time" should be quantified for the specific project or activity and so stated in this section. On page 84 the word "consider" should be changed to "use" to be consistent with the other areas.

Pages III-87 and 89 Standards and Guidelines state that Interagency Guidelines for Management Situation I (MS-1) habitat apply to the Core area. This statement should be deleted from the document. MS-1 and Management Situation 2 divisions on the Targhee Forest were a part of the original Forest Plan. New scientific information regarding grizzly bears has been acquired since the completion of this original plan in 1985 that contradicts the use of MS-1 as a biological standard for grizzly bears. Omitting MS-1 designation is supported by the IGBC Roads

Task Force report and recent formal section 7 consultations with the Service.

Page III-87, Physical and Biological Elements: Lands The Rule Set developed for grizzly bear management in the Grizzly Bear Management Strategy for the Plateau BMU should be incorporated as a table in this section.

Page III-88, Forest Use and Occupation For the most part, mountain biking and other means of mechanized travel should be discouraged in core areas. Additionally, beginning the reclamation of all roads within 1 year of signing of the ROD should be considered a Standard to be consistent with objective 4, page III-11, Forest Wide Standards and Guidelines. Further, it should also be a Standard there will no construction of temporary roads in the core areas.

Outfitter/Guide Outfitter and guide permits should be allowed if the activities are compatible with the objectives for the core area. For example, sleigh rides in November after bear hibernation has been initiated would be allowed.

Page III-89, 2.6 5 Grizzly Bear Security Area The above comments concerning the core area (Page III-86 to 88, management prescription 2.6.2) related to grizzly bear also apply to this section.

Page III-90, Biological Elements Scheduling of activities should follow the Rule Set standards set forth in the Grizzly Bear Management Strategy for the Plateau BMU and the draft Grizzly Bear management direction for the Bechler-Teton BMU.

Page III-91, Range The Targhee Forest should consult with the Service on all of the allotments within the grizzly bear Recovery Zone. The Forest has done a thorough job of addressing Service concerns in this section. Standards for permittees stated in this section should also be included in the Recreation section of the document for Outfitter and Guide permits in security and core areas.

Page III-94, Aquatic Influence Zone, Description The entire watershed and climate also have influence and control over lakes, reservoirs, ponds, perennial and intermittent streams and wetlands (as defined in the glossary). To address this, the second sentence should be rewritten to read, "The entire watershed and climate influence the..." The third sentence should read, "Lakes, reservoirs, ponds, perennial, and intermittent streams, and wetlands provide unique..."

III-94 2.7 (a-b) Elk and Deer Winter Range/Standards and

Guidelines/Game Retrieval] Allowing game retrieval using ATVs is inconsistent with the original strategy of maintaining security areas for big game during harvest seasons in order to prevent early migration to big game winter ranges on BLM lands. Also, the game retrieval allowance in deer and elk winter range generally contradicts the goal of minimizing intrusion. Enforcement would be a nightmare as the Forest does not have adequate personnel to do the job. Early arrival of big game herds on BLM winter range clearly results in conflicts with livestock, winter range over utilization, increased vulnerability to poaching, and increased agricultural depredations.

Page III-95, second paragraph change "ecology" to "ecology." The service recommends certain geomorphic types should always be included in the boundary width. These include but are not all inclusive: 100-year floodplain; areas with unstable soils; landslides; and landslide-prone areas. Under goals, number 1, delete the last two words so the sentence ends after the word "variation."

Page III-96, Boundary Widths of Water Types, by subsections fish bearing stream reaches and non-fish bearing stream reaches should have identical standards because of their importance for watershed cumulative effects analysis. Non-fish bearing streams are especially important in an ecosystem approach to watershed analysis and aquatic/riparian dependent species. This is vitally important for waters in the Central, Island Park, Madison Plateau, and Teton Range subsections where timber harvest has taken place or is scheduled to take place.

Watershed areas in the Island Park and Madison Plateau subsections have already been heavily impacted by resource extraction activities. We suggest the boundary widths in these areas be extended to 300 feet unless site specific scientific data indicates otherwise. This in turn would be consistent with other amended forest plans in the Pacific Northwest in dealing with fisheries and watershed resources.

Page III-97, Insects and Disease This section should be expanded so the goals of ecosystem-based management and aquatic habitat protection are projected and maintained throughout the plan

Pages III-98, 99, and 120, Roads and Trails The first line should start, "No new roads, including temporary roads,..." To habitat, all of the guidelines in this section should be made

Page III-99, Paragraph 4 Additional standards on instream sediment generated by temporary stream crossings should be

Page III-118, Dispersed Camping Management Information, education, and sanitation standards have been set for areas

Page III-114, Special Use Permit Recreation Sites Goals, Objectives, and Standards should be included that require proper sanitation practices for human refuse and pet food in grizzly bear recovery zones on the forest. This is consistent with reasonable and prudent measures agreed to in past consultation on the forest and should be included in the revised Forest Plan.

Page III-118, Dispersed Camping Management Information, education, and sanitation standards have been set for areas

Page III-114, Special Use Permit Recreation Sites Goals, Objectives, and Standards should be included that require proper sanitation practices for human refuse and pet food in grizzly bear recovery zones on the forest. This is consistent with reasonable and prudent measures agreed to in past consultation on the forest and should be included in the revised Forest Plan.

Page III-114, Special Use Permit Recreation Sites Goals, Objectives, and Standards should be included that require proper sanitation practices for human refuse and pet food in grizzly bear recovery zones on the forest. This is consistent with reasonable and prudent measures agreed to in past consultation on the forest and should be included in the revised Forest Plan.

Under timber, the entire second item should be eliminated so any changes to the standards and guidelines would have to be addressed in a forest plan amendment. As written, this item permits changes without appropriate public review and comment. The fourth item should be rewritten to read, "Mechanized treatment of wood residue is eliminated."

The last line on the page should have the following words added at the end of the sentence, "...only where salvage will improve the aquatic influence zone." The aquatic influence zone and III-100 2.8.3 Aquatic Influence Zone/Standards and cooperative livestock management strategy between the Forest Service and the BLM where feasible when a stream reach crosses both ownerships of adjacent Forest Service and BLM land

Page III-100, South Fork Big Lost River, Scented River River uses such as jet skiing should be excluded from the South Fork Snake River. The Forest Service has not presented any data to show there has been an evaluation of noise impacts to nesting bald eagles from this type of recreation.

Pages III-104 and III-111, Range Management of allotments at levels below the "C" level is not consistent with the desired future conditions and allotment management plan objectives; therefore level "D" should not be considered as part of the management "goal" for this or any other management prescription.

Page III-112, Developed Recreation Sites The Service supports the watchable wildlife provisions in the objectives for this section and other sections of the forest plan. By informing the public of areas to enjoy wildlife in native habitats, possibly more support for fish and wildlife habitat needs can be encouraged in the local community. Outreach is an important mission of the Service, we would be available to assist in your watchable wildlife efforts.

Page III-114, Special Use Permit Recreation Sites Goals, Objectives, and Standards should be included that require proper sanitation practices for human refuse and pet food in grizzly bear recovery zones on the forest. This is consistent with reasonable and prudent measures agreed to in past consultation on the forest and should be included in the revised Forest Plan.

Page III-118, Dispersed Camping Management Information, education, and sanitation standards have been set for areas

Page III-114, Special Use Permit Recreation Sites Goals, Objectives, and Standards should be included that require proper sanitation practices for human refuse and pet food in grizzly bear recovery zones on the forest. This is consistent with reasonable and prudent measures agreed to in past consultation on the forest and should be included in the revised Forest Plan.

Page III-114, Special Use Permit Recreation Sites Goals, Objectives, and Standards should be included that require proper sanitation practices for human refuse and pet food in grizzly bear recovery zones on the forest. This is consistent with reasonable and prudent measures agreed to in past consultation on the forest and should be included in the revised Forest Plan.

within the recovery zone for grizzly bears. These should be presented in this section under the Description or a section entitled "Wildlife" under Standards and Guidelines. Similar information was requested to be included in the Forestwide Standards and Guidelines beginning on page III-17.

Page III-122, Range, last paragraph This item should be replaced with the statement shown under 3.A, on page III-21. This will provide consistency for the prescriptions and the Forestwide Standards and Guidelines.

Pages III-123 and 131, Objectives Add the following as Objective number 5 on page 123 and Objective 7 on page 131, "Maintain or enhance inherent habitat values associated with fish, wildlife, and vegetation of the area." This will assist the Forest Service in obtaining the goals and desired future conditions proffered in ecosystem management objectives being implemented on the Forest.

Page III-133 Grizzly Bear habitat within the recovery zone but outside the security area and core area - Biological Elements - Wildlife. The prescriptions for activity areas are appropriately stated, however, the analysis area for EA purposes should be stated as a Standard instead of a Guideline.

Page III-134, Forest Use and Occupation, Access The Service supports the Standards set in the Table on page III-134 for cross Country and Road and Trail use. Temporary roads should be included as a part of TMARD (Total Motorized Access Route Density) and OROMTRD (Open Road and Open Motorized Trail Route Density). Road density standards should be met and calculated on an activity area basis.

Page IV-2, Implementation Schedules Implementation of road closures should be included as an objective to be consistent with the recommended changes on pages III-11 and 16.

Page V-3, Monitoring Item Summary Biological Elements, Wildlife Completion of bald eagle nest site management plans should be included and given priority 1 status,

Aquatic/Riparian Riparian and aquatic monitoring should receive as high a priority as Hydrologic Disturbance in Watersheds. All species of wildlife benefit from aquatic habitat types during some portion of their life history. The Service recommends the monitoring program emulate a pulsed monitoring format for watershed and stream restoration.

Roads and Trail Access Road Closure effectiveness should receive as high a priority as Grizzly Bear Habitat Improvement, since these two activities are interrelated and will be mutually

beneficial.

IV-17 Forest Timber Schedule The following proposed timber sales will have direct impacts on resource management on adjacent BLM lands: Watershed 009A - Island Park/Centennials; Watershed 014 - Big Bend Ridge; Watershed 016 - Falls River; Watershed 019 - Teton Creek; Watershed 020 - Leigh Creek; Watershed 023/024 - Canyon and Moody Creek; Watershed 025 - Camas Creek; and Watershed 026A - Beaver Creek.

In some cases timber harvest may render BLM management objectives useless due to individual or cumulative impacts adversely affecting resources such as water quality, riparian, big game habitat, raptor nesting, recreation (e.g. hunting, fishing, camping, hiking, snowmobiling). True ecosystem management would involve analyzing the cumulative effects of timber harvest and OHV plans on BLM land and that administered by the Idaho Department of Public Lands. The areas in which the above-mentioned harvests would occur have been identified by the Idaho Department of Fish and Game as crucial habitat for big game summer-fall habitat as well as secure migration areas. These areas are crucial today because there has been minimal harvest in the past. This proposed timber harvest schedule would fragment crucial big game habitat, raptor nesting habitat, riparian areas, and recreation activities shared by the Forest Service and BLM.

Add a standard requiring: 1) analysis of the land management practices on BLM Lands adjacent to the proposed sales; and 2) interagency coordination with BLM to ensure management of the total ecosystem.

V-2 Monitoring and Evaluation/Monitoring and the Budget Clarify how under shrinking budgets and staff the Forest is proposing to monitor and enforce these extensive standards and guidelines. All monitoring and enforcement plans should include a Forest Service manpower work load analysis.

A-1 (Appendix A) National Goals Relevant to Land and Resource Management Include reference to the following resource programs both of which greatly impact land management:

1. Hazardous Materials laws, rules and regulations as they affect discovery of illegal dump sites, transportation across Forest roads, and incidents, spills and accidents; and
2. Idaho Abandoned Mine Inventory Program as it addresses abandoned mine inventories and assessment for hazards.

Grand Teton Natl Park
Nichols, Jack

Mr Jerry B Reese
Forest Supervisor
Targhee National Forest
P O Box 208
St. Anthony, ID 83445

Dear Jerry:

I wanted to thank you for the time your staff spent meeting with my staff at the Driggs office. That meeting helped clear up many of the questions and concerns we had related to the forest plan update. We do, however, still have some comments related to the plan, most of which refer to bighorn sheep.

The Park's greatest concern regarding the Draft Forest Plan Revision and Draft Environmental Impact Statement is management of an important shared resource, the Teton range bighorn sheep population. The Park's Senior Wildlife Biologist, Steve Cain, has been a key member of the Teton Range Bighorn Sheep Working Group (hereafter Working Group) since it beginning in 1990. Recognizing the importance and potential implications of revising the Targhee Forest Plan on the welfare of the Teton range bighorn sheep, the Working Group has met several times over the last several weeks to finalize an interagency strategic plan for management of the herd. Based on this strategic plan, the Working Group has submitted comments on the Forest Plan and EIS under separate cover. Grand Teton National Park fully endorses and echoes these comments. Accordingly, please consider the comments submitted by the interagency Working Group to reflect the Park's position, a copy of the comments and supporting documents are enclosed for your convenience.

Among the concerns raised by the Working Group, we feel that those related to 1) domestic sheep grazing and the potential for disease transmission to bighorn sheep, 2) the loss of former low elevation winter ranges on the west side of the Tetons, and 3) the need for protection of winter ranges from human disturbance and from forage utilization by domestic sheep during summer are most important. As we indicated in our November 6, 1995 letter to you regarding renewal of the Moose Creek Sheep and Goat Allotment, the potential for complete bighorn sheep herd die-offs resulting from contact with domestic sheep is well documented. Current domestic sheep grazing practices on the Targhee pose an unacceptable risk to Teton bighorn sheep. In addition, the ability to reintroduce fire to, protect from human disturbance, and reestablish use of former low elevation winter ranges on the Targhee are critical components of maintaining or enhancing the viability of the herd. These issues should be taken seriously, and, as the Working Group's comments suggest, the Draft Plan should be modified appropriately to specifically address them.

Thank you far the opportunity to comment on the draft Forest Plan Revision and DEIS. We look forward to reviewing the next series of environmental documents for the Forest Plan revision. For questions on land and natural resource comments, please refer them to Mr. Joe Kraayenbrink, Acting Manager of the BLM's Idaho Falls District Office at (208) 254-7525. Mr. Dennis Hoyem is the project contact at the above number. If you have any questions concerning fish and wildlife resources, please contact Mr. Hike Donahoo of the Service's Eastern Idaho Field Office at (208) 233-8550.

sincerely,

Preston Sleeper
Acting Regional Environmental Officer

I believe that successful management and conservation of this valuable resource will require an increased level of cooperation among the Targhee and Bridger-Teton National Forests, Wyoming Game and Fish Department, and Grand Teton National Park in the future. Myself and my staff appreciate the opportunity for input on this planning process as it affects bighorn sheep, and encourage your continued involvement with the Interagency Working Group.

Other specific comments related to the plan include:

Page 3-59 Under access. Will there be any provision to develop more handicapped accessible access?

Page 3-63 Goal #4 Define what "moderate" means.

We would like to continue to work with the forest on operational issues such as permits, visitor information and law enforcement. Please contact Steve Cain (307-739-3485) for bighorn sheep or Nancy Arkin, Park Planner (307-739-3486) for other topics if you would like to discuss these issues further.

Thanks again for the opportunity to comment on your forest plan revision. We look forward to continuing to work with you in the future.

Sincerely,

Jack Neckels
Superintendent

JUN 27 1996

Mr. Jerry Reese
Targhee National Forest
P.O. Box 208
St. Anthony, Idaho 83445

#1351 - Finley, Michael

Dear Mr. Reese:

Thank you for providing Yellowstone National Park the opportunity to review the Targhee National Forest, Draft Forest Plan Revision and accompanying Draft Environmental Impact Statement (EIS). We offer the following comments.

The draft Forest Plan Revision calls for additional marked or groomed trails that lead snowmobilers near the boundary of Yellowstone National Park. We believe that two of these trails will encourage trespass activity into the park by snowmobilers. One trail is a loop trail that brings snowmobilers close to the park boundary; the other trail dead ends at the park boundary. We strongly urge that both of these trails be deleted from the final plan. We have enclosed a copy of a portion of Map 12, Winter Motorized Access, Alternative 3-M, indicating the trails we are referring to. Furthermore, we urge that cross-country motorized use be prohibited on the forest lands adjacent to the park in the area shown on another enclosed map (also a portion of Map 12, Winter Motorized Access, Alternative 3-M). Such a buffer would further reduce trespass snowmobiling in the park.

The draft Forest Plan Revision and EIS do not discuss the Targhee National Forest's participation (since 1994) in the Greater Yellowstone Coordinating Committee's Interagency winter Visitor Use Management Planning effort. We recognize that the team's recommendations will not be ready before the completion of the Forest Plan Revision, but we recommend that you include a discussion indicating how the winter visitor use planning effort may be integrated with the revised plan.

We support the proposal to restrict cross-country oversnow motorized travel after April 15. We believe this proposal will provide added protection for grizzly bears emerging from their dens in the spring.

The plan calls for a significant increase in the number of miles of marked and groomed snowmobile routes on the forest. However,

the EIS does not discuss how this increase will affect winter recreation users.

We support your recommendations for wilderness designations. Wilderness designation for areas adjacent to Yellowstone would benefit wildlife that move between the park and forest by minimizing the loss of habitat resulting from motorized access.

The statement that geothermal development is prohibited in the Island Park Geothermal Area (draft EIS, page III-18) was hard to find. In view of the controversy and continued public interest in geothermal protection, we suggest that "Geothermal Development, III-18" be added to the Index to aid the reader. We also suggest that you cite the 1990 regulations, 43 CFR 3201.1-6(f), which implement Public Law 98-473, the Geothermal Steam Act Amendments of 1988. A similar discussion in the draft Forest Plan Revision may also help.

Noxious weeds are listed in the draft EIS (page II-2) among "issue indicators that are the same or vary slightly in all alternatives." We are extremely interested in this issue as noxious weeds have the potential to significantly adversely affect park resources. Our thoughts on this issue are contained in a letter dated February 7, 1994, commenting on the Targhee National Forest's Noxious Weed and Poisonous Plant Control Program (copy enclosed).

If the draft Forest Plan Revision is implemented as described, the steps you propose to reduce timber harvest to sustainable levels, to reduce open road mileage, to improve the condition of riparian areas, and to manage motorized access in order to provide secure habitat for wildlife, especially grizzly bears, will benefit the Greater Yellowstone Ecosystem. Thank you again for the opportunity to comment on the document.

Sincerely,

Michael V. Finley

RE DRAFT FOREST PLAN REVISION AND ENVIRONMENTAL IMPACT STATEMENT FOR THE TARGHEE NATIONAL FOREST

Dear Mr Reese

Staff for the Shoshone-Bannock Tribes (Tribe) has reviewed the above-referenced documents forwarded to my office. Enclosed, please find one (1) copy of our comments for your staff's consideration. We appreciate the Forest's attempts to keep Tribal staff informed of their management activities. If you have any questions concerning our comments, feel free to contact me at the above address or at (208) 238-3758.

Sincerely,

JUL 15 '96

ACT	DATE	BY	REMARKS

I. INTRODUCTION

The Shoshone-Bannock Tribes (Tribes) collectively comprise a single, federally recognized Indian Tribe with a governing body, the Fort Hall Business Council, which is duly recognized by the Secretary of the Interior¹. Tribal members are successors-in-interest of Indian signatories to the Fort Bridger Treaty² (Treaty). In part, that Treaty secured the Fort Hall Indian Reservation in Idaho Territory as a permanent tribal homeland.

Article 4 of that Treaty secured for the Tribes--and guaranteed in perpetuity--the continuation of a wide variety of 'use rights' to off-Reservation lands. More specifically, by virtue of Article 4 of the Treaty, the Tribes expressly reserved rights to hunt, fish, and gather natural resources for subsistence and ceremonial purposes "on the unoccupied lands of the United States", including such lands owned by the federal government outside the boundaries of the Reservation⁴.

Tribal members have legal rights to hunt, fish, gather and otherwise use the unoccupied lands of the United States. Thus, the application of any land management action has the potential for impermissible interference with the exercise of such Treaty rights. As such, the Tribes are very concerned about potential impacts to fish and wildlife, habitat, and other natural and cultural resources from various land uses and activities.

The proposed Forest Plan revision represents a significant opportunity to address Tribal concerns regarding resource use and protection on the Targhee National Forest. The Tribes provide the following comments to be included within the public record related to the proposed Project and to be used within the evaluation process.

II. COMMENTS

In written and verbal input to the Forest, the Tribes have submitted comments requesting the Forest to consider specific issues identified by the Tribes to be crucial in protecting Tribal interests. Each of the comments outlined below have been previously submitted to the Forest and are being resubmitted due to the Forest's inadequate consideration of them within the proposed Plan.

A. The Forest has failed to appropriately consider alternatives which maintain Tribal member harvesting of firewood, posts, and poles for personal use under

¹See Swim v. Bergland, Civil No. 78-4021 (D. Idaho 1981), 696 F.2d 712 (9th Cir. 1983).

²15 Stat. 673, July 3, 1868.

³15 Stat. 674-75

⁴State v. Tinno, 497 P.2d 1386 (1972) (1868 Treaty rights extended to "unoccupied" federal lands off-Reservation).

established Treaty rights.

The Targhee National Forest is one of the most important forests in the region for Tribal members to acquire forest wood products--in particular posts, poles, and firewood. It is also one of the few forests which has an abundant supply of these products (primarily lodgepole pine) in a readily available and accessible manner. Since time immemorial, Tribal members have continuously used the Forest lands in procuring these resources for both on- and off-Reservation uses. In numerous coordination and public meetings with Forest representatives, the Tribal government, as well as its members individually, expressed a compelling need to maintain continued access to these products. We also requested that the Forest consider, within the Forest Plan, alternatives which serve to maintain Tribal uses of these products in a manner which meets the members identified needs. However, the Forest Plan lacks any discussion of this issue and fails to recognize the Tribal Treaty right to harvest wood products and the importance of continuing this right with minimal interference from other Forest activities or administrative efforts (such as fee permit harvesting).

Based on our unproductive discussions with Forest employees, we assert that the Forest inappropriately relies upon invalid assumptions when they fail to recognize Tribal gathering as an established right covered by Treaty. Forest staff have stated that in their opinion, the Treaty only covers Tribal hunting and fishing. The Tribes dispute this contention and offer the following information for the Forest's consideration.

The U.S. Supreme Court has established principles, termed canons of construction, for interpreting Indian treaties, which the Forest--as a federal agency--must recognize and uphold. An important principle is that Indian tribes reserve all rights not expressly extinguished by treaty or statute, regardless of whether those rights are specifically described in the Treaty ("reserved rights doctrine", see Swim v. Bergland). While the Fort Bridger Treaty only refers to the reserved right to "hunt" on unoccupied lands, this language has been interpreted as the right to fish and otherwise gather (State v. Tinno). In addition, subsequent agreements between the Tribes and the federal government have upheld the gathering rights reserved under the original Treaty and specifically reference harvesting of timber for personal use (Swim v. Bergland). The Forest has not shown evidence that Tribal rights for gathering of personal use forest products have been extinguished.

The Forest as a trust steward of Indian assets and Tribal rights must ensure consistent analysis with court established legal doctrine, in addition to meeting the expressed needs of American Indians. Quite to the contrary, the Forest has responded to our many requests simply by stating that this issue requires additional clarification of the Treaty right by the Tribal attorney's office and the Office of General Counsel. This request is unnecessary provided that the Forest follows established principles of the government-to-government relationship and ensures consistency with federal statute.

Furthermore, the Forest has failed to provide any justification for not assessing Tribal harvesting needs in the Forest Plan or the reasons for applying a strict prohibition on wood products gathering by Indians. Not only is this approach inconsistent with basic NEPA and trust responsibility principles, but is inconsistent with the analysis in other parts of the

proposed Forest Plan'

Given that the Forest must consider Tribal rights activities including wood gathering within the Forest Plan we also request that the Forest consider the established Tribal need to use these resources in support of other rights activities. This rights activity occurs when gathered wood products effectuate other terms of the Treaty. For example, corral poles are used for promoting an agrarian livelihood on the Reservation and firewood/poles are utilized when hunting or conducting ceremonies. Following other standards of construing Indian treaties it is clear that Indian tribes reserve all rights necessary for effectuation of treaty purposes⁶. Through historical and ethnographic research, it is well established that the Tribes have a long history of use of the Targhee Forest for Treaty purposes and that the gathering of wood products supports those Treaty purposes.

The Tribes again request that the Forest analyze the effects of prohibiting future gathering efforts of the members and provide reasonable accommodations to continue the gathering of wood products under Treaty. Further, within this analysis, the Forest must clearly recognize that Tribal rights, including gathering rights are a protected interest and not a privilege afforded the Tribes by the Forest Service.

B The Forest has failed to assess the direct, indirect, and cumulative effects of existing and proposed road closures on Tribal rights activities.

In addition to providing wood products to the Tribes, the Targhee Forest is also important for providing habitat for big game species hunted by Tribal members. The Forest must recognize that Tribal hunting is maintained by the Tribal government, through the assurance of a harvest opportunity as well as implementing habitat/species protection and management programs as an important contemporary ceremonial and subsistence activity of the Tribes. The Forest Plan implies that these activities are important from a historical perspective but neglects to emphasize the contemporary importance.

Under recent management, the Forest has effectively closed (through road closures) many areas of the Forest that were extensively used by the Tribes, especially for hunting and gathering. The Tribes understand that many of these closures were implemented as mitigation for an extensive timber harvesting program, however, this harvesting program has been effectuated at the expense of Tribal hunting. As expressed to the Forest previously, Tribal hunting is a crucial lifeway and a direct link exists between the harvest opportunities on the Forest and the Reservation socio-economic condition.

We acknowledge that road closures will assist with maintaining a resident big game herd on

⁶The Forest has recognized other gathering rights of the Tribes (e.g. medicinal plants) but not other forest resources.

⁶Winters v. U.S., 207 U.S. 564 (1908) *citation not seen*, and Swim v. Bergland

the Forest which has been supplanted due to harvest activities. However, based upon the extensive road closures to-date, the Tribes request that the Forest describe in detail the nature and extent of previous closures in order to assess the specific cumulative effects to Tribal access.

Specifically, the Antelope Flats area forest road 771, and the Keg Spring locale (road 042) are of special interest to the Tribes for purposes of hunting. We request that the Forest revise the access management strategy to provide reasonable access to these areas prior to and following the general rifle season.

In addition, the Forest has also proposed the seasonal closure of roads beginning prior to the general archery season. The Tribes specifically identified the time from August 1 to the opening of the general rifle season as a critical time for Tribal resource use. However, this was not considered or discussed in the Forest plan. Further, the Forest has not described a compelling conservation necessity for closing roads this early in the summer/fall season. The Tribes request that the Forest assess the potential for leaving roads open during this time period for mitigation of detrimental effects on Tribal rights activities from cumulative road closures.

C Monitor cultural resource sites on grazing allotments consistent with the national programmatic agreement.

The Tribes were a principle party in the Southeastern Idaho efforts to integrate grazing management with cultural resource protection efforts. We appreciate the Forest's attention to these efforts by proposing activity compliance with the pending State/R-4 agreement and the national programmatic agreement. However, we call to the Forest's attention, the agreement standards for monitoring cultural sites on grazing allotments.

In order to assess the potential mitigative benefits of the Forest's selected alternative we request that the Forest identify which sites will be selected for monitoring, the monitoring procedure that will be used, and the schedule for monitoring.

D Establish a consultation procedure and intergovernmental agreement with the Tribes to guide future cooperative efforts.

As an outgrowth of the Forest Plan revision, accompanied with other regional efforts, the Tribes and Forest Service have fostered new principles for cooperative management and consultation efforts. The President (through Memorandum April 29, 1994), and the Forest Service (through recent policy direction) have provided a foundation, in addition to existing law and policy, which reinforces the need to develop future partnerships and relationships.

A crucial component of an effective working relationship is an efficient consultation procedure that meets the needs of both parties. Further, many site specific issues regarding Treaty rights and Tribal issues can only be identified and considered under the project level analysis performed by the Forest staff. Since the Intermountain Region lacks such a detailed procedure in the Forest Service Manual, the Tribes request that the Forest include provisions

in the Forest Plan for developing such a procedure specific to activities on the Targhee. The Tribes also request that the development of this process be included as a mitigation proposal for effects on Tribal activities and be included in the schedule of activity completion in the Forest Plan.

E Recognize Tribes as comanagers along with other agencies including the IDF&G.

By virtue of Treaty and well established legal principles, the Tribes are recognized comanagers of natural resources along with the other federal and state agencies with jurisdiction or authority on the Forest. Tribal agencies, such as the Natural Resources Division and Fish and Game Department, have been institutionalized by the Tribal government with authorities and responsibilities similar to our cooperating agencies. As such, the Forest must recognize Tribal agencies similar to their recognition of other agencies (i.e. the Idaho Department of Fish and Game). Consequently, the Forest should reference the Tribes as a party to future coordination efforts where they have recognized the IDF&G, in particular where it effects resources of special concern to the Tribes.

In addition, based upon our comanagement status the Forest must ensure consistency of the proposed Plan, and management actions, with established Tribal policies and objectives (40 CFR §1502.16(c), 40 CFR §1506.2(d)). This was recommended to the Forest previously, however, no copies of Tribal policies were solicited by Forest representatives.

F Socio-economic analysis.

The Tribes specifically requested a socio-economic analysis which describes the Reservation as a discrete economic unit. While the justification for this request was described to the Forest in previous correspondence, the Tribes again call to the Forest's attention Northern Cheyenne Tribe v. Hodel, et al.⁷ in support of our recommendation. In addition, we encourage the Forest to contact the Challis Resource Area of the Bureau of Land Management which is in the process of conducting a similar analysis, for reference materials if needed.

G Minimum level of analysis for treaty rights in future project EA's/EIS's

The Tribes appreciate the Forest's recognition of Tribal reserved rights within the Forest Plan. The above comments detail additional analysts that we contend is necessary to appropriately assess the potential effects of proposed Plan commitments on rights and trust assets. Since Treaty rights are a protected property interest⁸ and are of particularly high value to the Tribal members and government, we request that the Forest provide additional emphasis toward the

⁷No. CV 82-116BLG (D. Mont., May 28, 1985).

⁸Menominee Tribe v. U.S. 391 U.S. 404 (1968) citation not seen in The Rights of Indians and Tribes S. L. Pevar 1992 Southern Illinois University Press.

future need to consider Treaty rights and Tribal interests during all Forest undertakings and activities.

As previously expressed to the Forest in written comments, effects to Treaty rights from Forest activities can be continually eroded as individual projects are implemented. Since the effects are often also site specific, not all of the potential effects can be identified or addressed in this Plan. Consequently, we are requesting that the Forest commit, within the Forest Plan to developing a minimum baseline level analysis that would be incorporated into each NEPA document prepared under the Plan in the future. In addition, we request that the Forest discuss this commitment in the mitigation proposals and propose a schedule to work towards developing this procedure.

Tribal staff are committed to working with the Forest in developing an appropriate procedure that meets both parties management needs. As discussed above, this item could be included within the outlined consultation procedure and/or an intergovernmental agreement.

III CONCLUSION

We appreciate the Forest's attention to certain Tribal comments within the Forest Plan. However, we recognize serious deficiencies in the analysis that can only be rectified with additional consideration and assessment as we have requested. Integral to the Forest's efforts to complete the final plan, we encourage the Forest to provide for meaningful consultation opportunities with Tribal representatives in order to arrive at a final Plan which meets the needs of both parties.

Dear Mr Reese

I and several members of my research team have reviewed with great interest the Forest Revision Plan you are presenting. Clearly significant time and resources have been invested in developing the alternative approaches presented in the plan.

Two factors are the underlying basis for our response. The concept of multiple use and the fact that the U S Sheep Experiment Station has collected and analyzed data from our Centennial Mountain summer ranges for a considerable period of time. This data base provides an excellent resource for determining long term ecological trends for this forest

Our research has demonstrated that sheep have very marginal if any impact on riparian areas. In fact in a forth coming article we demonstrate that for willow and wildlife species our grazing areas are in better condition than those found in Yellowstone National Park. Given this type of information we believe any reduction in AUMs especially for sheep is unjustified. Furthermore, and in general to the entire forest, by the proposed reduction in sheep AUMs the Forest Service is losing a valuable means of managing and manipulating native vegetation towards a desired condition.

Specific to the Sheep Station grazing in the Centennials, our long term range and ecological research represent a significant data base from which ecological trends can be evaluated. In fact it is impossible for us to relocate and keep our long term data collect effort in place.

From the Sheep Station perspective we find Alternatives 1, 2 and 3 a more beneficial alternative than Alternative 3-M and would prefer the adoption of Alternative 3.

We would like to thank the Forest Service for providing us an opportunity to comment on this important document.

On behalf of the State of Wyoming, please be advised that we have reviewed the Draft Environmental Impact Statement and the Draft Forest Plan Revision for the Targhee National Forest. In accordance with our own comment period given to all affected state agencies, I have attached comments from the Game and Fish Department, the State Historical Preservation Office and the State Geological Survey for your review. I trust you will give them due consideration as they raise significant issues which should be addressed.

Thank you for the opportunity to comment and I look forward to your response as well as the progress of these studies.

Sincerely,

Jim Magagna
Director of Federal Land Policy

MEMORANDUM

TO Julie Hamilton, Wyoming State Clearing House

FROM Gary B. Glass, P.G., State Geologist

SUBJECT Draft Environmental Impact Statement and Draft Revised Forest Plan for Targhee National Forest (State Identifier # 96-015)

We have reviewed these two documents and have the following comments.

There is no indication that the preparers of either document considered the earthquake (seismic) potential in the area. The maximum credible earthquake in this region could cause loss of life as well as considerable property damage. Seismicity should be considered in the design, construction, and siting of facilities throughout the area.

We have prepared preliminary landslide maps of the Wyoming portion of the Targhee National Forest. These maps are available if the Forest does not have them.

There is no discussion of groundwater concerns. The Madison Limestone in this area is a significant aquifer.

In addition to gold in the Wyoming portions of the Targhee National Forest, there is a potential for copper-silver-zinc-lead mineralization in red beds, especially in the Caribou area. In the past, gold was mined near Alpine.

There are other mineral resources of potential economic importance in the Teton Range. There has been production of granite for dimension stone in T44N, R117W and there is still a possible quarry site at that location. There was a very large chemical-grade limestone quarry in T42N, R118W, which was used to refine sugar beets. There are large resources of chemical-grade limestone in the area. There are some minable phosphate occurrences in T43N, R118W. Sand, gravel, and crushed stone resources also occur throughout the forest including the Teton Range. And at least one diamond has reportedly been found in the Teton Range.

If there are questions regarding our comments, the following members of my staff are available (their specialties are in parentheses)

Jim Case (Geologic hazards- landslides and earthquakes, aquifers)
 Dan Hausel (Metals and precious stones)
 Ray Harris (Industrial minerals and construction materials)

RE: Targhee National Forest, Draft Environmental Impact Statement and Draft Revised Forest Plan (State Identifier Number: 96-015); SHPO #0396RLC006

Dear Sir

Richard Currit of our staff has received information concerning the aforementioned statement and plan. Thank you for allowing us the opportunity to comment.

Management of cultural resources on impact and plan projects is conducted in accordance with Section 106 of the National Historic Preservation Act and Advisory Council regulations 36 CFR Part 800. These regulations call for survey, evaluation and protection of significant historic and archeological sites prior to any disturbance. Provided the U.S. Forest Service (USFS) follows the procedures established in the regulations, we have no objections to the project. Specific comments on the project's effect on cultural resource sites will be provided to the USFS when we review the cultural resource documentation called for in 36 CFR Part 800.

Please refer to SHPO project control number #0396RLC006 on any future correspondence dealing with this project. If you have any questions contact Richard Currit at 307-777-5497 or Judy Wolf, Deputy SHPO, at 307-777-6311.

Sincerely,

Judy Wolf

Dear Ms. Hamilton

The staff of the Wyoming Game and Fish Department has reviewed the draft environmental impact statement and draft revised forest plan for the Targhee National Forest. We offer the following comments:

Terrestrial Considerations

Wyoming Game & Fish Department personnel have previously commented on the Targhee National Forest plan revision and draft environmental impact statement in a letter dated November 15, 1995. However, the Forest Service did not address any of our terrestrial wildlife concerns described in that letter. Since our previous comments reflect our concerns about significant omissions in the documents relative to wildlife and wildlife habitat, we have repeated them below and have provided additional comments:

DRAFT FOREST PLAN REVISION

1 Harvest Techniques Standards and guidelines for when and how clearcutting will be used are unclear. We request the Forest Service identify goals for this management method and clarify why clearcutting is the most appropriate technique for these goals. Application of the salvage cut or catastrophic event clause in almost all the proposed prescriptions is also of concern. Our interpretation of the draft revision is that salvage cut principles could occur in any area including old growth and crucial security areas which would normally not be considered for timber harvest. Standards and guidelines should be

developed for this timber harvest method to avoid timber harvest levels that would have a detrimental impact to other forest resources.

2. Additional Cutting The identified management prescriptions and standards and guidelines are lacking the unscheduled timber harvest clause in prescription areas that are not included in the allowable sale quotient. In the past, some commercial timber has been removed from these areas. The plan revision should provide guidelines as to when, how, or where this can occur. If such activities are considered for crucial big game winter range, the plan revision should provide guidelines on management and mitigation for these areas, or if the cut will be permitted at all.

3. Road Density The draft management prescriptions establish standards and guidelines which limit the density of open roads and trails. Road densities vary by prescription and to some degree are based on security habitat needs for wildlife, especially elk. However, many areas in Wyoming on the Ashton Ranger District and the northern portion of the Teton Basin Ranger District already exceed the standards for open road density. We believe two miles or less of roads per square mile, with more restrictive standards dependent on specific prescriptions, should be adequate to accomplish Forest Service objectives. Wildlife security areas adjacent to timber harvest activities should be at least 3-4 times larger than the timber sale area.

The existing and proposed plan revision allow road density to be achieved by closing or reclaiming existing roads. However, the Forest Service often prefers to install gates to control road use and access rather than obliterating portions of, or reclaiming a road. The gate closure technique allows access by all-terrain vehicles, snowmachines, and other motorized vehicles, (even if prohibited by Forest Service policy) and for administrative purposes. From a wildlife perspective, an open road should be defined as any road that can be traveled on by motorized vehicle even if the road is designated as closed. A comprehensive road management and transportation plan should evaluate the need for roads on the Forest, how those needs are achieved by the existing road system and what impacts these roads have on other forest resources. The forest plan should also include a forest-wide direction to limit cross country motorized travel to protect big game habitat.

Recent research indicates road density is significant in habitat management for forest carnivores such as lynx and wolverine. Both species are on the Forest Service Region 4 sensitive species list. The forest plan should acknowledge this association.

4. Standards There is a lack of specific, quantifiable standards throughout both documents for all resources. Standards govern management of Targhee National Forest resources. Many objectives are listed as guidelines or optional management. A forest plan that is heavily reliant on guidelines and de-emphasizes standards will not provide managers the needed direction to address problems as they arise, or implement sound resource management decisions.

5 Indicator Species According to a Forest Service memo dated Feb 18, 1992, deer elk and moose winter range habitats were recommended as management indicators for the forest plan revision. However, the revision does not include moose crucial winter range, and the amount of winter range for deer and elk is less than that currently present. Please clarify this discrepancy.

6 Trumpeter Swan and Waterfowl Wintering Areas No analysis or consideration is indicated for off road vehicle travel and human access in trumpeter swan and waterfowl wintering areas associated with the Palisades Wetland Area (Palisades Ranger District). We recommend off-road vehicles and human access be prohibited in the wetland area from December 1 - March 31 in order to provide a secure area for waterfowl and trumpeter swans to winter. All corridors for winter motorized travel in the immediate area of this wetland should be located on/or south of the McCoy Creek Road. An additional restriction to prohibit motorized access from November 1 - August 31 should be considered to protect the nesting and brood rearing period. In addition, we recommend posting of signs around the wetland educating the public about negative impacts of human and motorized access in this area.

7 Winter Range The preferred alternative does not recognize big game winter range from the Snake River Canyon to the state line. Areas managed under a winter range prescription in the previous forest plan are now proposed to be managed under a timber prescription that emphasizes timber management in an urban/interface situation, a semi-primitive motorized recreation prescription or a visual quality prescription. We recommend the Forest Service correct this oversight and incorporate crucial elk, moose and deer winter range prescriptions into the forest plan.

Moose winter ranges in the following areas need to be included and protected in the forest plan: from Wyoming State Highway 22, north to Teton Canyon in Management Prescription 3 2, from North and South Leigh Creek to Badger Creek in Management Prescription 5 4, and north of Badger Creek in Management Prescription 5 3 5.

8 Targhee Bighorn Sheep Teton Range bighorn sheep exhibit many characteristics of a low quality population (Whitfield and Keller 1984). Low quality populations result from poor forage availability and habitat conditions (Geist 1971). The continued existence of this genetically isolated bighorn sheep herd is uncertain, and we support management strategies (Suminski 1991) directed at maintenance and perpetuation of this population.

This bighorn sheep herd is threatened by a number of factors, including a) potential competition with and disease transmission from, domestic sheep grazing on national forest lands, b) loss or abandonment of former low-elevation winter ranges due to development, fire suppression, poaching and other human disturbances, c) likely genetic isolation and related consequences of inbreeding, and d) habitat displacement due to recreationist activities.
